Understanding and Configuring Junos Routing Policies

Overview | 3

Policy Framework Overview | 3

Routing Policy and Firewall Filters | 4

Reasons to Create a Routing Policy | 4

Router Flows Affected by Policies | 5

Control Points | 8

Policy Components | 9

Comparison of Routing Policies and Firewall Filters | 10

Prefix Prioritization Overview | 15

Accounting of the Policer Overhead Attribute at the Interface Level | 15

Need for Policer Overhead adjustment | 16

Policer Overhead Adjustment Applicability for Policers | 16

Configuring the Accounting of Policer Overhead in Interface Statistics | 18

Understanding Routing Policies | 21

Importing and Exporting Routes | 21

Active and Inactive Routes | 23

Explicitly Configured Routes | 23

Dynamic Database | 23

Protocol Support for Import and Export Policies | 24

Example: Applying Routing Policies at Different Levels of the BGP Hierarchy | 25

Default Routing Policies | 37

OSPF and IS-IS Import Policies | 39

Automatic Export | 39

Example: Configuring a Conditional Default Route Policy | 40

Evaluating Routing Policies Using Match Conditions, Actions, Terms, and Expressions | 50

How a Routing Policy Is Evaluated | 50

Categories of Routing Policy Match Conditions | 51

Routing Policy Match Conditions | 54

Route Filter Match Conditions | 65

Actions in Routing Policy Terms | 67

Configuring Flow Control Actions | 69

Configuring Actions That Manipulate Route Characteristics | 70

Configuring the Default Action in Routing Policies | 80

Example: Configuring the Default Action in a Routing Policy | 81

Configuring a Final Action in Routing Policies | 82

Logging Matches to a Routing Policy Term | 83

Configuring Separate Actions for Routes in Route Lists | 83

Summary of Routing Policy Actions | 83

Example: Configuring a Routing Policy to Advertise the Best External Route to Internal Peers | 86

Example: Configuring BGP to Advertise Inactive Routes | 97

Example: Using Routing Policy to Set a Preference Value for BGP Routes | 106

Example: Enabling BGP Route Advertisements | 113

Example: Rejecting Known Invalid Routes | 123

Example: Using Routing Policy in an ISP Network | 126

Understanding Policy Expressions | 184

Policy Expression Examples | 185

Policy Expression Evaluation | 187

Evaluating Policy Expressions | 188

Understanding Backup Selection Policy for OSPF Protocol | 190

Configuring Backup Selection Policy for the OSPF Protocol | 192

Configuring Backup Selection Policy for IS-IS Protocol | 198

Understanding Backup Selection Policy for IS-IS Protocol | 198

Example: Configuring Backup Selection Policy for the OSPF or OSPF3 Protocol | 200

Evaluating Complex Cases Using Policy Chains and Subroutines | 233

Understanding How a Routing Policy Chain Is Evaluated | 233

Example: Configuring Policy Chains and Route Filters | 235

Example: Using Firewall Filter Chains | 250

Understanding Policy Subroutines in Routing Policy Match Conditions | 257

Configuring Subroutines | 258

Possible Consequences of Termination Actions in Subroutines | 258

How a Routing Policy Subroutine Is Evaluated | 261

Example: Configuring a Policy Subroutine | 263

Configuring Route Filters and Prefix Lists as Match Conditions | 276

Understanding Route Filters for Use in Routing Policy Match Conditions | 276

Radix Trees | 277

Configuring Route Filters | 279

How Route Filters Are Evaluated in Routing Policy Match Conditions | 285

How Prefix Order Affects Route Filter Evaluation | 287

How an Address Mask Match Type Is Evaluated | 287

Common Configuration Problem with the Longest-Match Lookup | 288

Route Filter Examples | 288

Rejecting Routes with Specific Destination Prefixes and Mask Lengths | 289

Rejecting Routes with a Mask Length Greater than Eight | 289

Rejecting Routes with Mask Length Between 26 and 29 | 290

Rejecting Routes from Specific Hosts | 290

Accepting Routes with a Defined Set of Prefixes | 291

Rejecting Routes with a Defined Set of Prefixes | 291

Rejecting Routes with Prefixes Longer than 24 Bits | 292

Rejecting PIM Multicast Traffic Joins | 292

Rejecting PIM Traffic | 293

Accepting Incoming IPv4 Routes by Applying an Address Mask to the Route Address and the Destination Match Prefix	293
Accepting Incoming IPv4 Routes with Similar Patterns But Different Prefix Lengths	295
Evaluation of an Address Mask Match Type with Longest-Match Lookup	296
Understanding Route Filter and Source Address Filter Lists for Use in Routing Policy Match Conditions	297
Understanding Load Balancing Using Source or Destination IP Only	298
Configuring Load Balancing Using Source or Destination IP Only	299
Walkup for Route Filters Overview	301
Configuring Walkup for Route Filters to Improve Operational Efficiency	305
Example: Configuring Route Filter Lists	310
Example: Configuring Walkup for Route Filters Globally to Improve Operational Efficiency	316
Example: Configuring Walkup for Route Filters Locally to Improve Operational Efficiency	323
Example: Configuring a Route Filter Policy to Specify Priority for Prefixes Learned Through OSPF	330
Example: Configuring the MED Using Route Filters	335
Example: Configuring Layer 3 VPN Protocol Family Qualifiers for Route Filters	353
Understanding Prefix Lists for Use in Routing Policy Match Conditions	357
Configuring Prefix Lists	358
How Prefix Lists Are Evaluated in Routing Policy Match Conditions	359
Configuring Prefix List Filters	360
Example: Configuring Routing Policy Prefix Lists	361
Example: Configuring the Priority for Route Prefixes in the RPD Infrastructure	374
Configuring Priority for Route Prefixes in RPD Infrastructure	387
Configuring AS Paths as Match Conditions 	395
Understanding AS Path Regular Expressions for Use as Routing Policy Match Conditions	395
Configuration of AS Path Regular Expressions	396
Configuring a Null AS Path	400
How AS Path Regular Expressions Are Evaluated	401
Examples: Configuring AS Path Regular Expressions	402
Example: Using AS Path Regular Expressions	403
Understanding Prepending AS Numbers to BGP AS Paths	416
Example: Configuring a Routing Policy to Prepend the AS Path	417
Understanding Adding AS Numbers to BGP AS Paths	421

Example: Advertising Multiple Paths in BGP | 422

Configuring Communities as Match Conditions | 457

Understanding BGP Communities, Extended Communities, and Large Communities as Routing Policy Match Conditions | 457

Understanding How to Define BGP Communities and Extended Communities | 459

Defining BGP Communities for Use in Routing Policy Match Conditions | 459

Using UNIX Regular Expressions in Community Names | 460

Defining BGP Extended Communities for Use in Routing Policy Match Conditions | 463

Examples: Defining BGP Extended Communities | 464

How BGP Communities and Extended Communities Are Evaluated in Routing Policy Match Conditions | 465

Multiple Matches | 466

Inverting Community Matches | 468

Extended Community Type | 469

Multiple Communities Are Matched with Ex-OR Logic | 470

Including BGP Communities and Extended Communities in Routing Policy Match Conditions | 471

Example: Configuring Communities in a Routing Policy | 472

Example: Configuring Extended Communities in a Routing Policy | 490

Example: Configuring BGP Large Communities | 501

Example: Configuring a Routing Policy Based on the Number of BGP Communities | 512

Example: Configuring a Routing Policy That Removes BGP Communities | 522

Increasing Network Stability with BGP Route Flapping Actions | 534

Understanding Damping Parameters | 534

Using Routing Policies to Damp BGP Route Flapping | 535

Configuring BGP Flap Damping Parameters | 536

Specifying BGP Flap Damping as the Action in Routing Policy Terms | 539

Disabling Damping for Specific Address Prefixes | 539

Disabling Damping for a Specific Address Prefix | 539

Configuring BGP Flap Damping | 540

Example: Configuring BGP Route Flap Damping Parameters | 542

Example: Configuring BGP Route Flap Damping Based on the MBGP MVPN Address Family | 555

Tracking Traffic Usage with Source Class Usage and Destination Class Usage Actions | 570

Understanding Source Class Usage and Destination Class Usage Options | 570

Source Class Usage Overview | 572

Guidelines for Configuring SCU | 573

System Requirements for SCU | 574

Terms and Acronyms for SCU | 575

Roadmap for Configuring SCU | 576

Roadmap for Configuring SCU with Layer 3 VPNs | 576

Configuring Route Filters and Source Classes in a Routing Policy | 577

Applying the Policy to the Forwarding Table | 578

Enabling Accounting on Inbound and Outbound Interfaces | 579

Configuring Input SCU on the vt Interface of the Egress PE Router | 580

Mapping the SCU-Enabled vt Interface to the VRF Instance | 580

Configuring SCU on the Output Interface | 581

Associating an Accounting Profile with SCU Classes | 582

Verifying Your SCU Accounting Profile | 583

SCU Configuration | 584

Configuring SCU | 584

Verifying Your Work | 588

SCU with Layer 3 VPNs Configuration | 595

Configuring SCU in a Layer 3 VPN | 596

Verifying Your Work | 604

Example: Grouping Source and Destination Prefixes into a Forwarding Class | 606

Avoiding Traffic Routing Threats with Conditional Routing Policies | 619

Conditional Advertisement and Import Policy (Routing Table) with certain match conditions | 620

Conditional Advertisement Enabling Conditional Installation of Prefixes Use Cases | 623

Example: Configuring a Routing Policy for Conditional Advertisement Enabling Conditional Installation of Prefixes in a Routing Table | 625

Protecting Against DoS Attacks by Forwarding Traffic to the Discard Interface | 646

Assigning Forwarding Classes and Loss Priority | 647

Understanding Forwarding Packets to the Discard Interface | 648

Example: Forwarding Packets to the Discard Interface | 650

Improving Commit Times with Dynamic Routing Policies | 663

Understanding Dynamic Routing Policies | 663

Configuring Routing Policies and Policy Objects in the Dynamic Database | 664

Configuring Routing Policies Based on Dynamic Database Configuration | 665

Applying Dynamic Routing Policies to BGP | 666

Preventing Reestablishment of BGP Peering Sessions After NSR Routing Engine Switchover | 667

Example: Configuring Dynamic Routing Policies | 668

Testing Before Applying Routing Policies | 688

Understanding Routing Policy Tests | 688

Example: Testing a Routing Policy | 688

Example: Testing a Routing Policy with Complex Regular Expressions | 689

Configuring Firewall Filters

Understanding How Firewall Filters Protect Your Network | 701

Firewall Filters Overview | 701

Router Data Flow Overview | 702

Flow of Routing Information | 702

Flow of Data Packets | 703

Flow of Local Packets | 703

Interdependent Flows of Routing Information and Packets | 704

Stateless and Stateful Firewall Filters | 704

Stateless Firewall Filter Application Points | 705

Understanding How Firewall Filters Control Packet Flows | 710

Stateless Firewall Filter Overview | 712

Packet Flow Control | 712

Data Packet Flow Control | 712

Local Packet Flow Control | 712

Junos OS Evolved Local Packet Flow Control | 712

Stateless and Stateful Firewall Filters | 713

Purpose of Stateless Firewall Filters | 713

Understanding How to Use Standard Firewall Filters | 713

Using Standard Firewall Filters to Affect Local Packets | 714

- Trusted Sources | 714

- Flood Prevention | 714

Using Standard Firewall Filters to Affect Data Packets | 714

Understanding How Firewall Filters Control Packet Flows | 715

Stateless Firewall Filter Components | 716

- Protocol Family | 716

- Filter Type | 717

- Terms | 719

- Match Conditions | 719

- Actions | 720

- Filter-Terminating Actions | 721

- Nonterminating Actions | 721

- Flow Control Action | 722

Stateless Firewall Filter Application Points | 723

How Standard Firewall Filters Evaluate Packets | 728

- Firewall Filter Packet Evaluation Overview | 729

- Packet Evaluation at a Single Firewall Filter | 730

- Best Practice: Explicitly Accept Any Traffic That Is Not Specifically Discarded | 731

- Best Practice: Explicitly Reject Any Traffic That Is Not Specifically Accepted | 732

- Multiple Firewall Filters Attached to a Single Interface | 732

- Single Firewall Filter Attached to Multiple Interfaces | 732

Understanding Firewall Filter Fast Lookup Filter | 733

Understanding Egress Firewall Filters with PVLANS | 734

Multifield Classifier for Ingress Queuing on MX Series Routers with MPC | 735

Guidelines for Configuring Firewall Filters | 736

- Statement Hierarchy for Configuring Firewall Filters | 737

- Firewall Filter Protocol Families | 738

- Firewall Filter Names and Options | 738

- Firewall Filter Terms | 739

- Firewall Filter Match Conditions | 739

- Firewall Filter Actions | 741

Guidelines for Applying Standard Firewall Filters | 743

Applying Firewall Filters Overview | 743

Statement Hierarchy for Applying Firewall Filters | 744

- Protocol-Independent Firewall Filters on MX Series Routers | 745

- All Other Firewall Filters on Logical Interfaces | 745

Restrictions on Applying Firewall Filters | 746

- Number of Input and Output Filters Per Logical Interface | 746

- MPLS and Layer 2 CCC Firewall Filters in Lists | 746

- Layer 2 CCC Firewall Filters on MX Series Routers and EX Series Switches | 746

- IPv6 Firewall Filters on PTX Series Packet Transport Routers | 747

Supported Standards for Filtering | 747

Verifying That Firewall Filters Are Operational | 748

Monitoring Firewall Filter Traffic | 749

- Monitoring Traffic for All Firewall Filters and Policers That Are Configured | 749

- Monitoring Traffic for a Specific Firewall Filter | 750

- Monitoring Traffic for a Specific Policer | 750

Troubleshooting Firewall Filters | 751

Troubleshooting QFX10000 Switches | 752

- Do Not Combine Match Conditions for Different Layers | 752

- Layer 2 Packets Cannot be Discarded with Firewall Filters | 752

- Protect-RE (loopback) Firewall Filter Does Not Filter Packets Applied to EMO Interfaces | 752

Troubleshooting Other Switches | 753

- Firewall Filter Configuration Returns a No Space Available in TCAM Message | 753

- Filter Counts Previously Dropped Packet | 755

- Matching Packets Not Counted | 756

- Counter Reset When Editing Filter | 756

- Cannot Include loss-priority and policer Actions in Same Term | 757

- Cannot Egress Filter Certain Traffic Originating on QFX Switch | 757

- Firewall Filter Match Condition Not Working with Q-in-Q Tunneling | 757

- Egress Firewall Filters with Private VLANs | 757

- Egress Filtering of L2PT Traffic Not Supported | 758

- Cannot Drop BGP Packets in Certain Circumstances | 759

- Invalid Statistics for Policer | 759

Policers can Limit Egress Filters | 759

Firewall Filter Match Conditions and Actions | 761

Overview of Firewall Filters | 762

Where You Can Apply Filters | 762

Firewall Filter Components | 763

Firewall Filter Processing | 764

Understanding Firewall Filter Match Conditions | 764

Filter Match Conditions | 765

Numeric Filter Match Conditions | 765

Interface Filter Match Conditions | 766

IP Address Filter Match Conditions | 766

Bit-Field Filter Match Conditions | 767

Understanding Firewall Filter Planning | 769

Understanding How Firewall Filters Are Evaluated | 770

Understanding Firewall Filter Match Conditions | 772

Filter Match Conditions | 772

Numeric Filter Match Conditions | 773

Interface Filter Match Conditions | 774

IP Address Filter Match Conditions | 774

MAC Address Filter Match Conditions | 775

Bit-Field Filter Match Conditions | 775

Firewall Filter Flexible Match Conditions | 777

Statement Hierarchy | 778

Flexible Filter Match Types | 779

Flexible Filter Match Start Locations | 780

Flexible Filter Match Examples | 781

Firewall Filter Nonterminating Actions | 785

Firewall Filter Terminating Actions | 794

Firewall Filter Match Conditions and Actions (ACX Series Routers) | 812

Overview of Firewall Filter Match Conditions and Actions on ACX Series Routers | 812

Match Conditions for Bridge Family Firewall Filters (ACX Series Routers) | 814

Bridge Family Firewall Filters on ACX Series Routers | 814

Match Conditions for CCC Firewall Family Filters (ACX Series Routers)	816
Match Conditions for CCC Family Firewall Filters	816
Match Conditions for IPv4 Traffic (ACX Series Routers)	817
Match Conditions for IPv6 Traffic (ACX Series Routers)	821
Match Conditions for MPLS Traffic (ACX Series Routers)	827
Nonterminating Actions (ACX Series Routers)	828
Terminating Actions (ACX Series Routers)	832
Firewall Filter Match Conditions for Protocol-Independent Traffic	833
Firewall Filter Match Conditions for IPv4 Traffic	835
Firewall Filter Match Conditions for IPv6 Traffic	851
Firewall Filter Match Conditions Based on Numbers or Text Aliases	864
Matching on a Single Numeric Value	864
Matching on a Range of Numeric Values	864
Matching on a Text Alias for a Numeric Value	865
Matching on a List of Numeric Values or Text Aliases	865
Firewall Filter Match Conditions Based on Bit-Field Values	865
Match Conditions for Bit-Field Values	866
Match Conditions for Common Bit-Field Values or Combinations	867
Logical Operators for Bit-Field Values	868
Matching on a Single Bit-Field Value or Text Alias	869
Matching on Multiple Bit-Field Values or Text Aliases	869
Matching on a Negated Bit-Field Value	870
Matching on the Logical OR of Two Bit-Field Values	870
Matching on the Logical AND of Two Bit-Field Values	870
Grouping Bit-Field Match Conditions	871
Firewall Filter Match Conditions Based on Address Fields	871
Implied Match on the '0/0 except' Address for Firewall Filter Match Conditions Based on Address Fields	872
Matching an Address Field to a Subnet Mask or Prefix	872
IPv4 Subnet Mask Notation	872
Prefix Notation	872
Default Prefix Length for IPv4 Addresses	872
Default Prefix Length for IPv6 Addresses	873
Default Prefix Length for MAC Addresses	873

Matching an Address Field to an Excluded Value | 873**Excluding IP Addresses in IPv4 or IPv6 Traffic | 873****Excluding IP Addresses in VPLS or Layer 2 Bridging Traffic | 874****Excluding MAC Addresses in VPLS or Layer 2 Bridging Traffic | 875****Excluding All Addresses Requires an Explicit Match on the '0/0' Address | 875****Matching Either IP Address Field to a Single Value | 877****Matching Either IP Address Field in IPv4 or IPv6 Traffic | 877****Matching Either IP Address Field in VPLS or Layer 2 Bridging Traffic | 878****Matching an Address Field to Noncontiguous Prefixes | 878****Matching an Address Field to a Prefix List | 880****Firewall Filter Match Conditions Based on Address Classes | 881****Source-Class Usage | 881****Destination-Class Usage | 881****Guidelines for Applying SCU or DCU Firewall Filters to Output Interfaces | 882****Understanding IP-Based Filtering and Selective Port Mirroring of MPLS Traffic | 882****IP-Based Filtering of MPLS Traffic | 883****Selective Port Mirroring of MPLS Traffic | 884****Sample Configurations | 885****IP-Based Filtering Configuration | 885****Selective Port Mirroring Configuration | 887****Mirrored Destination Configuration | 888****Firewall Filter Match Conditions for MPLS Traffic | 888****Firewall Filter Match Conditions for MPLS-Tagged IPv4 or IPv6 Traffic | 892****Matching on IPv4 or IPv6 Packet Header Address or Port Fields in MPLS Flows | 893****IP Address Match Conditions for MPLS Traffic | 893****IP Port Match Conditions for MPLS Traffic | 894****Firewall Filter Match Conditions for VPLS Traffic | 895****Firewall Filter Match Conditions for Layer 2 CCC Traffic | 909****Firewall Filter Match Conditions for Layer 2 Bridging Traffic | 914****Firewall Filter Support on Loopback Interface | 926**

Applying Firewall Filters to Routing Engine Traffic | 929

Configuring Logical Units on the Loopback Interface for Routing Instances in Layer 3 VPNs | 929

Example: Configuring a Filter to Limit TCP Access to a Port Based On a Prefix List | 931

Example: Configuring a Stateless Firewall Filter to Accept Traffic from Trusted Sources | 935

Example: Configuring a Filter to Block Telnet and SSH Access | 942

Example: Configuring a Filter to Block TFTP Access | 949

Example: Configuring a Filter to Accept Packets Based on IPv6 TCP Flags | 953

Example: Configuring a Filter to Block TCP Access to a Port Except from Specified BGP Peers | 956

Example: Configuring a Stateless Firewall Filter to Protect Against TCP and ICMP Floods | 964

Example: Protecting the Routing Engine with a Packets-Per-Second Rate Limiting Filter | 979

Example: Configuring a Filter to Exclude DHCPv6 and ICMPv6 Control Traffic for LAC Subscriber | 983

Port Number Requirements for DHCP Firewall Filters | 989

Example: Configuring a DHCP Firewall Filter to Protect the Routing Engine | 990

Applying Firewall Filters to Transit Traffic | 996

Example: Configuring a Filter for Use as an Ingress Queuing Filter | 996

Example: Configuring a Filter to Match on IPv6 Flags | 999

Example: Configuring a Filter to Match on Port and Protocol Fields | 1001

Example: Configuring a Filter to Count Accepted and Rejected Packets | 1006

Example: Configuring a Filter to Count and Discard IP Options Packets | 1010

Example: Configuring a Filter to Count IP Options Packets | 1015

Example: Configuring a Filter to Count and Sample Accepted Packets | 1021

Example: Configuring a Filter to Set the DSCP Bit to Zero | 1028

Example: Configuring a Filter to Set the DSCP Bit to Zero | 1032

Example: Configuring a Filter to Match on Two Unrelated Criteria | 1036

Example: Configuring a Filter to Accept DHCP Packets Based on Address | 1039

Example: Configuring a Filter to Accept OSPF Packets from a Prefix | 1043

Example: Configuring a Stateless Firewall Filter to Handle Fragments | 1047

Configuring a Firewall Filter to Prevent or Allow IPv4 Packet Fragmentation | 1053

Configuring a Firewall Filter to Discard Ingress IPv6 Packets with a Mobility Extension Header | 1055

Example: Configuring an Egress Filter Based on IPv6 Source or Destination IP Addresses | 1056

Example: Configuring a Rate-Limiting Filter Based on Destination Class | 1060

Configuring Firewall Filters in Logical Systems | 1065

Firewall Filters in Logical Systems Overview | 1065

- Logical Systems | **1066**
- Firewall Filters in Logical Systems | **1066**
- Identifiers for Firewall Objects in Logical Systems | **1066**

Guidelines for Configuring and Applying Firewall Filters in Logical Systems | 1066

- Statement Hierarchy for Configuring Firewall Filters in Logical Systems | **1067**
- Filter Types in Logical Systems | **1068**
- Firewall Filter Protocol Families in Logical Systems | **1068**
- Firewall Filter Match Conditions in Logical Systems | **1069**
- Firewall Filter Actions in Logical Systems | **1069**
- Statement Hierarchy for Applying Firewall Filters in Logical Systems | **1069**

References from a Firewall Filter in a Logical System to Subordinate Objects | 1070

- Resolution of References from a Firewall Filter to Subordinate Objects | **1070**
- Valid Reference from a Firewall Filter to a Subordinate Object | **1071**

References from a Firewall Filter in a Logical System to Nonfirewall Objects | 1072

- Resolution of References from a Firewall Filter to Nonfirewall Objects | **1072**
- Valid Reference to a Nonfirewall Object Outside of the Logical System | **1072**

References from a Nonfirewall Object in a Logical System to a Firewall Filter | 1075

- Resolution of References from a Nonfirewall Object to a Firewall Filter | **1075**
- Invalid Reference to a Firewall Filter Outside of the Logical System | **1076**
- Valid Reference to a Firewall Filter Within the Logical System | **1078**
- Valid Reference to a Firewall Filter Outside of the Logical System | **1080**

Example: Configuring Filter-Based Forwarding | 1082

Example: Configuring Filter-Based Forwarding on Logical Systems | 1087

Example: Configuring a Stateless Firewall Filter to Protect a Logical System Against ICMP Floods | 1100

Example: Configuring a Stateless Firewall Filter to Protect a Logical System Against ICMP Floods | 1104

Unsupported Firewall Filter Statements for Logical Systems | 1109

Unsupported Actions for Firewall Filters in Logical Systems | 1111

Filter-Based Forwarding for Routing Instances | 1115

Forwarding Table Filters for Routing Instances on ACX Series Routers | 1116

Configuring Forwarding Table Filters | 1117

Configuring Firewall Filter Accounting and Logging | 1120

Accounting for Firewall Filters Overview | 1120

System Logging Overview | 1121

System Logging of Events Generated for the Firewall Facility | 1121

Firewall Filter Logging Actions | 1124

Example: Configuring Statistics Collection for a Firewall Filter | 1127

Example: Configuring Logging for a Firewall Filter Term | 1134

Attaching Multiple Firewall Filters to a Single Interface | 1141

Applying Firewall Filters to Interfaces | 1141

Configuring Firewall Filters | 1142

Configuring a Firewall Filter | 1142

Applying a Firewall Filter to a Layer 3 (Routed) Interface | 1144

Understanding Multiple Firewall Filters in a Nested Configuration | 1145

The Challenge: Simplify Large-Scale Firewall Filter Administration | 1145

A Solution: Configure Nested References to Firewall Filters | 1145

Configuration of Nested Firewall Filters | 1146

Application of Nested Firewall Filters to a Router or Switch Interface | 1146

Guidelines for Nesting References to Multiple Firewall Filters | 1147

Statement Hierarchy for Configuring Nested Firewall Filters | 1147

Filter-Defining Terms and Filter-Referencing Terms | 1147

Types of Filters Supported in Nested Configurations | 1148

Number of Filter References in a Single Filter | 1148

Depth of Filter Nesting | 1148

Understanding Multiple Firewall Filters Applied as a List | 1149

The Challenge: Simplify Large-Scale Firewall Filter Administration | 1149

A Solution: Apply Lists of Firewall Filters | 1149

Configuration of Multiple Filters for Filter Lists | 1150

Application of Filter Lists to a Router Interface | 1150

Interface-Specific Names for Filter Lists | 1151

How Filter Lists Evaluate Packets When the Matched Term Includes Terminating or Next Term Actions | 1151

How Filter Lists Evaluate Packets When the List Includes Protocol-Independent and IP Firewall Filters | 1152

Guidelines for Applying Multiple Firewall Filters as a List | 1153

Statement Hierarchy for Applying Lists of Multiple Firewall Filters | 1153

Filter Input Lists and Output Lists for Router or Switch Interfaces | 1154

Types of Filters Supported in Lists | 1154

Restrictions on Applying Filter Lists for MPLS or Layer 2 CCC Traffic | 1154

Example: Applying Lists of Multiple Firewall Filters | 1155

Example: Nesting References to Multiple Firewall Filters | 1162

Example: Filtering Packets Received on an Interface Set | 1167

Attaching a Single Firewall Filter to Multiple Interfaces | 1176

Interface-Specific Firewall Filter Instances Overview | 1176

Instantiation of Interface-Specific Firewall Filters | 1176

Interface-Specific Names for Firewall Filter Instances | 1177

Interface-Specific Firewall Filter Counters | 1178

Interface-Specific Firewall Filter Policers | 1178

Interface-Specific Firewall Filter Instances Overview | 1179

Instantiation of Interface-Specific Firewall Filters | 1179

Interface-Specific Names for Firewall Filter Instances | 1180

Interface-Specific Firewall Filter Counters | 1180

Interface-Specific Firewall Filter Policers | 1181

Filtering Packets Received on a Set of Interface Groups Overview | 1181

Filtering Packets Received on an Interface Set Overview | 1182

Example: Configuring Interface-Specific Firewall Filter Counters | 1183

Example: Configuring a Stateless Firewall Filter on an Interface Group | 1189

Configuring Filter-Based Tunneling Across IP Networks | 1201

Understanding Filter-Based Tunneling Across IPv4 Networks | 1201

Understanding Filter-Based Tunneling Across IPv4 Networks | 1201

Ingress Firewall Filter on the Ingress PE Router | 1202

Ingress Firewall Filter on the Egress PE Router | 1202

Characteristics of Filter-Based Tunneling Across IPv4 Networks | 1202

Unidirectional Tunneling | 1202

Bidirectional Tunneling | 1202

Transit Traffic Payloads | 1202

- Compact Configuration for Multiple GRE Tunnels | 1203

- Tunneling with Firewall Filters and Tunneling with Tunnel Interfaces | 1203

- Forwarding Performance | 1203

- Firewall Filter-Based L2TP Tunneling in IPv4 Networks Overview | 1204

- Unidirectional Tunneling | 1206

- Tunnel Security | 1206

- Forwarding Performance | 1206

- Forwarding Scalability | 1206

- Interfaces That Support Filter-Based Tunneling Across IPv4 Networks | 1207

- Interfaces on MX240, MX480, MX960, MX2010, and MX2020 Routers | 1208

- Interfaces on MX5, MX10, MX40, and MX80 Routers | 1208

- CLI Commit Check for Filter-Based Tunneling Across IPv4 Networks | 1209

- Components of Filter-Based Tunneling Across IPv4 Networks | 1209

- Topology of Filter-Based Tunneling Across IPv4 Networks | 1209

- Routing of GRE Packets Across the Tunnel | 1210

- Routing of Passenger Protocol Packets from PE2 to C2 | 1210

- Terminology at the Network Layer Protocols Level | 1211

- Terminology at the Ingress PE Router | 1211

- Terminology at the Egress PE Router | 1212

- GRE Protocol Format for Filter-Based Tunneling Across IPv4 Networks | 1212

- Packet Encapsulation Structure | 1212

- GRE Header Format | 1213

- Example: Transporting IPv6 Traffic Across IPv4 Using Filter-Based Tunneling | 1214

Configuring Service Filters | 1236

- Service Filter Overview | 1236

- Services | 1236

- Service Rules | 1237

- Service Rule Refinement | 1237

- Service Filter Counters | 1237

- How Service Filters Evaluate Packets | 1238

- Service Filters That Contain a Single Term | 1238

- Service Filters That Contain Multiple Terms | 1239

- Service Filter Terms That Do Not Contain Any Match Conditions | 1239

Service Filter Terms That Do Not Contain Any Actions | 1239

Service Filter Default Action | 1239

Guidelines for Configuring Service Filters | 1240

Statement Hierarchy for Configuring Service Filters | 1240

Service Filter Protocol Families | 1241

Service Filter Names | 1241

Service Filter Terms | 1241

Service Filter Match Conditions | 1241

Service Filter Terminating Actions | 1241

Guidelines for Applying Service Filters | 1242

Restrictions for Adaptive Services Interfaces | 1243

Adaptive Services Interfaces | 1243

System Logging to a Remote Host from M Series Routers | 1243

Statement Hierarchy for Applying Service Filters | 1243

Associating Service Rules with Adaptive Services Interfaces | 1244

Filtering Traffic Before Accepting Packets for Service Processing | 1244

Postservice Filtering of Returning Service Traffic | 1245

Example: Configuring and Applying Service Filters | 1246

Service Filter Match Conditions for IPv4 or IPv6 Traffic | 1252

Service Filter Nonterminating Actions | 1263

Service Filter Terminating Actions | 1264

Configuring Simple Filters | 1265

Simple Filter Overview | 1265

How Simple Filters Evaluate Packets | 1266

Simple Filters That Contain a Single Term | 1266

Simple Filters That Contain Multiple Terms | 1266

Simple Filter Terms That Do Not Contain Any Match Conditions | 1266

Simple Filter Terms That Do Not Contain Any Actions | 1267

Simple Filter Default Action | 1267

Guidelines for Configuring Simple Filters | 1267

Statement Hierarchy for Configuring Simple Filters | 1268

Simple Filter Protocol Families | 1268

Simple Filter Names | 1268

- Simple Filter Terms | 1268
- Simple Filter Match Conditions | 1269
- Simple Filter Terminating Actions | 1271
- Simple Filter Nonterminating Actions | 1271

Guidelines for Applying Simple Filters | 1271

- Statement Hierarchy for Applying Simple Filters | 1272
- Restrictions for Applying Simple Filters | 1272

Example: Configuring and Applying a Simple Filter | 1273

Configuring Layer 2 Firewall Filters | 1280

Understanding Firewall Filters Used to Control Traffic Within Bridge Domains and VPLS Instances | 1280

Example: Configuring Filtering of Frames by MAC Address | 1281

Example: Configuring Filtering of Frames by IEEE 802.1p Bits | 1283

Example: Configuring Filtering of Frames by Packet Loss Priority | 1284

Example: Configuring Policing and Marking of Traffic Entering a VPLS Core | 1286

Understanding Firewall Filters on OVSDb-Managed Interfaces | 1289

Example: Applying a Firewall Filter to OVSDb-Managed Interfaces | 1290

Configuring Firewall Filters for Forwarding, Fragments, and Policing | 1293

Filter-Based Forwarding Overview | 1293

- Filters That Classify Packets or Direct Them to Routing Instances | 1293
- Input Filtering to Classify and Forward Packets Within the Router or Switch | 1294
- Output Filtering to Forward Packets to Another Routing Table | 1295
- Restrictions for Applying Filter-Based Forwarding | 1295

Firewall Filters That Handle Fragmented Packets Overview | 1295

Stateless Firewall Filters That Reference Policers Overview | 1296

Example: Configuring Filter-Based Forwarding on the Source Address | 1297

Example: Configuring Filter-Based Forwarding to a Specific Outgoing Interface or Destination IP Address | 1309

- Understanding Filter-Based Forwarding to a Specific Outgoing Interface or Destination IP Address | 1310

Example: Configuring Filter-Based Forwarding to a Specific Outgoing Interface | 1312

Example: Configuring Filter-Based Forwarding to a Specific Destination IP Address | 1317

Configuring Firewall Filters (EX2300, EX3400, EX4300 Series Switches) | 1330

Firewall Filters for EX Series Switches Overview | 1331

Firewall Filter Types | **1331**

Firewall Filter Components | **1332**

Firewall Filter Processing | **1334**

Understanding Planning of Firewall Filters | 1334

Understanding Firewall Filter Match Conditions | 1338

Filter Match Conditions | **1338**

Numeric Filter Match Conditions | **1338**

Interface Filter Match Conditions | **1339**

IP Address Filter Match Conditions | **1340**

MAC Address Filter Match Conditions | **1341**

Bit-Field Filter Match Conditions | **1341**

Understanding How Firewall Filters Control Packet Flows | 1343

Understanding How Firewall Filters Are Evaluated | 1345

Understanding Firewall Filter Processing Points for Bridged and Routed Packets on EX Series Switches | 1347

Firewall Filter Match Conditions, Actions, and Action Modifiers for EX Series Switches | 1348

Firewall Filter Elements | **1349**

Match Conditions Supported on Switches | **1349**

Actions for Firewall Filters | **1357**

Action Modifiers for Firewall Filters | **1358**

Platform Support for Firewall Filter Match Conditions, Actions, and Action Modifiers on EX Series Switches | 1361

Firewall Filter Types and Their Bind Points | **1362**

Support for IPv4 and IPv6 Firewall Filters on Switches | **1362**

Platform Support for Match Conditions for IPv4 Traffic | **1363**

Platform Support for Match Conditions for IPv6 Traffic | **1386**

Platform Support for Match Conditions for Non-IP Traffic | **1401**

Platform Support for Actions for IPv4 Traffic | **1402**

Platform Support for Actions for IPv6 Traffic | **1406**

Platform Support for Action Modifiers for IPv4 Traffic | **1409**

Platform Support for Action Modifiers for IPv6 Traffic | **1419**

Support for Match Conditions and Actions for Loopback Firewall Filters on Switches | **1429**

Configuring Firewall Filters (CLI Procedure) | **1433**

Configuring a Firewall Filter | **1433**

Configuring a Term Specifically for IPv4 or IPv6 Traffic | **1439**

Applying a Firewall Filter to a Port on a Switch | **1441**

Applying a Firewall Filter to a Management Interface on a Switch | **1442**

Applying a Firewall Filter to a VLAN on a Network | **1443**

Applying a Firewall Filter to a Layer 3 (Routed) Interface | **1444**

Understanding How Firewall Filters Test a Packet's Protocol | **1446**

Understanding Filter-Based Forwarding for EX Series Switches | **1446**

Example: Configuring Firewall Filters for Port, VLAN, and Router Traffic on EX Series Switches | **1447**

Example: Configuring a Firewall Filter on a Management Interface on an EX Series Switch | **1473**

Example: Using Filter-Based Forwarding to Route Application Traffic to a Security Device | **1477**

Example: Applying Firewall Filters to Multiple Supplicants on Interfaces Enabled for 802.1X or
MAC RADIUS Authentication | **1483**

Verifying That Policers Are Operational | **1489**

Troubleshooting Firewall Filters | **1490**

A Firewall Filter Configuration Returns a "No Space Available in TCAM" Message | **1490**

**Configuring Firewall Filters (QFX Series Switches, EX4600 Switches, PTX Series
Routers) | 1493**

Overview of Firewall Filters | **1494**

Where You Can Apply Filters | **1494**

What Makes up a Firewall Filter | **1495**

How Firewall Filters are Processed | **1495**

Understanding Firewall Filter Planning | **1497**

Planning the Number of Firewall Filters to Create | **1498**

Maximum Number of Supported Firewall Filters | **1499**

How to Increase the Number of Firewall Filters | **1499**

TCAM | **1500**

Avoid Configuring too Many Filters | **1501**

Configuring TCAM Error Messages | **1501**

How Policers can Limit Egress Filters | **1502**

Planning for Filter-Specific Policers | **1503**

Planning for Filter-Based Forwarding	1503
Firewall Filter Match Conditions and Actions (QFX and EX Series Switches)	1504
Firewall Filter Match Conditions and Actions (QFX5100, QFX5110, QFX5120, QFX5200, EX4600, EX4650)	1504
Firewall Filter Match Conditions and Actions (QFX5220)	1527
Firewall Filter Match Conditions and Actions (QFX10000 Switches)	1539
Firewall Filter Match Conditions and Actions (PTX Series Routers)	1555
Firewall Filter Match Conditions and Actions (PTX10003 and PTX10008)	1556
IPv6 Firewall Filter Match Conditions and Actions (PTX10001-20C)	1570
Firewall and Policing Differences Between PTX Series Packet Transport Routers and T Series Matrix Routers	1577
Configuring Firewall Filters	1579
Configuring a Firewall Filter	1580
Configuring Enhanced Egress Firewall Filters (QFX5110 and QFX5220 Switches)	1582
Applying a Firewall Filter to a Port	1583
Applying a Firewall Filter to a VLAN	1584
Applying a Firewall Filter to a Layer 3 (Routed) Interface	1585
Applying a Firewall Filter to a Layer 2 CCC (QFX10000 Switches)	1586
Applying Firewall Filters to Interfaces	1586
Overview of MPLS Firewall Filters on Loopback Interface	1587
Benefits of Adding MPLS Firewall Filters on the Loopback Interface	1587
Guidelines and Limitations	1588
Configuring MPLS Firewall Filters and Policers on Switches	1588
Configuring an MPLS Firewall Filter	1589
Applying an MPLS Firewall Filter to an MPLS Interface	1590
Applying an MPLS Firewall Filter to a Loopback Interface	1590
Configuring Policers for LSPs	1591
Configuring MPLS Firewall Filters and Policers on Routers	1592
Configuring MPLS Firewall Filters	1592
Examples: Configuring MPLS Firewall Filters	1593
Configuring Policers for LSPs	1594
LSP Policer Limitations	1595
Example: Configuring an LSP Policer	1596

Configuring Automatic Policers | 1597

- Configuring Automatic Policers for LSPs | 1598

- Configuring Automatic Policers for DiffServ-Aware Traffic Engineering LSPs | 1598

- Configuring Automatic Policers for Point-to-Multipoint LSPs | 1599

- Disabling Automatic Policing on an LSP | 1599

- Example: Configuring Automatic Policing for an LSP | 1600

Writing Different DSCP and EXP Values in MPLS-Tagged IP Packets | 1600

Configuring MPLS Firewall Filters and Policers | 1601

- Configuring MPLS Firewall Filters | 1601

- Examples: Configuring MPLS Firewall Filters | 1602

- Configuring Policers for LSPs | 1602

- LSP Policer Limitations | 1603

Understanding How a Firewall Filter Tests a Protocol | 1603

Understanding Firewall Filter Processing Points for Bridged and Routed Packets | 1604

Understanding Filter-Based Forwarding | 1605

- Benefits of Filter-Based Forwarding | 1606

Example: Using Filter-Based Forwarding to Route Application Traffic to a Security Device | 1606

Configuring a Firewall Filter to De-Encapsulate GRE Traffic | 1612

- Configuring a Filter to De-Encapsulate GRE Traffic | 1612

- Applying the Filter to an Interface | 1614

Verifying That Firewall Filters Are Operational | 1614

Monitoring Firewall Filter Traffic | 1616

- Monitoring Traffic for All Firewall Filters and Policers That Are Configured on the Switch | 1616

- Monitoring Traffic for a Specific Firewall Filter | 1617

- Monitoring Traffic for a Specific Policer | 1617

Troubleshooting Firewall Filter Configuration | 1618

- Firewall Filter Configuration Returns a No Space Available in TCAM Message | 1618

- Filter Counts Previously Dropped Packet | 1620

- Matching Packets Not Counted | 1621

- Counter Reset When Editing Filter | 1621

- Cannot Include loss-priority and policer Actions in Same Term | 1622

- Cannot Egress Filter Certain Traffic Originating on QFX Switch | 1622

- Firewall Filter Match Condition Not Working with Q-in-Q Tunneling | 1622

- Egress Firewall Filters with Private VLANs | 1623

Egress Filtering of L2PT Traffic Not Supported | 1624

Cannot Drop BGP Packets in Certain Circumstances | 1624

Invalid Statistics for Policer | 1624

Policers can Limit Egress Filters | 1624

Configuring Firewall Filter Accounting and Logging (EX9200 Switches) | 1626

Example: Configuring Logging for a Stateless Firewall Filter Term | 1626

Using the CLI Editor in Configuration Mode | 1632

Configuring Traffic Policers

Understanding Traffic Policers | 1636

Policer Implementation Overview | 1637

ARP Policer Overview | 1640

Benefits of the ARP Policer | 1641

Example: Configuring ARP Policer | 1642

Understanding the Benefits of Policers and Token Bucket Algorithms | 1646

Scenario 1: Single TCP Connection | 1646

Scenario 2: Multiple TCP Connections | 1646

Determining Proper Burst Size for Traffic Policers | 1647

Policer Burst Size Limit Overview | 1647

Effect of Burst-Size Limit | 1648

Bursty Traffic Policed Without a Burst-Size Limit | 1648

Burst-Size Limit Configured to Match Bandwidth Limit and Flow Burstiness | 1649

Burst-Size Limit That Depletes All Accumulated Tokens | 1649

Two Methods for Calculating Burst-Size Limit | 1650

Calculation Based on Interface Bandwidth and Allowable Burst Time | 1650

Calculation Based on Interface Traffic MTU | 1650

Comparison of the Two Methods | 1650

10 x MTU Method for Selecting Initial Burst Size for Gigabit Ethernet with 100 Kbps Bandwidth | 1651

5 ms Method for Selecting Initial Burst Size for Gigabit Ethernet Interface with 200 Mbps Bandwidth | 1652

200 Mbps Bandwidth Limit, 5 ms Burst Duration | 1653

200 Mbps Bandwidth Limit, 600 ms Burst Duration | 1653

Controlling Network Access Using Traffic Policing Overview | 1654**Congestion Management for IP Traffic Flows | 1654****Traffic Limits | 1655****Traffic Color Marking | 1656****Forwarding Classes and PLP Levels | 1657****Policer Application to Traffic | 1658****Traffic Policer Types | 1659****Single-Rate Two-Color Policers | 1659****Basic Single-Rate Two-Color Policer | 1659****Bandwidth Policer | 1659****Logical Bandwidth Policer | 1659****Three-Color Policers | 1660****Single-Rate Three-Color Policers | 1660****Two-Rate Three-Color Policers | 1660****Hierarchical Policers | 1660****Two-Color and Three-Color Policer Options | 1661****Logical Interface (Aggregate) Policers | 1661****Physical Interface Policers | 1661****Policers Applied to Layer 2 Traffic | 1662****Multifield Classification | 1662****Order of Policer and Firewall Filter Operations | 1663****Understanding the Frame Length for Policing Packets | 1663****Supported Standards for Policing | 1664****Hierarchical Policer Configuration Overview | 1665****Packets-Per-Second (pps)-Based Policer Overview | 1667****Guidelines for Applying Traffic Policers | 1668****Policer Support for Aggregated Ethernet Interfaces Overview | 1669****Example: Configuring a Physical Interface Policer for Aggregate Traffic at a Physical Interface | 1670****Firewall and Policing Differences Between PTX Series Packet Transport Routers and T Series Matrix Routers | 1678****Hierarchical Policers on ACX Series Routers Overview | 1681****Guidelines for Configuring Hierarchical Policers on ACX Series Routers | 1683**

Hierarchical Policer Modes on ACX Series Routers | 1685**Guarantee Mode | 1685****Peak Mode | 1686****Hybrid Mode | 1688****Processing of Hierarchical Policers on ACX Series Routers | 1690****Actions Performed for Hierarchical Policers on ACX Series Routers | 1691****Instantiation Methods for Child and Aggregate Policers | 1691****Instantiation Methods for Child Policers or Normal Policers | 1691****Instantiation Methods for Aggregate Policers | 1692****Configuring Aggregate Parent and Child Policers on ACX Series Routers | 1693****Configuring Policer Rate Limits and Actions | 1697****Policer Bandwidth and Burst-Size Limits | 1697****Policer Color-Marking and Actions | 1699****Single Token Bucket Algorithm | 1701****Token Bucket Concepts | 1701****Single Token Bucket Algorithm | 1702****Conformance Measurement for Two-Color Marking | 1702****Dual Token Bucket Algorithms | 1703****Token Bucket Concepts | 1704****Guaranteed Bandwidth for Three-Color Marking | 1704****Nonconformance Measurement for Single-Rate Three-Color Marking | 1704****Nonconformance Measurement for Two-Rate Three-Color Marking | 1704****Configuring Layer 2 Policers | 1706****Hierarchical Policers | 1706****Hierarchical Policer Overview | 1707****Example: Configuring a Hierarchical Policer | 1708****Configuring a Policer Overhead | 1716****Two-Color and Three-Color Policers at Layer 2 | 1717****Two-Color Policing at Layer 2 Overview | 1718****Guidelines for Configuring Two-Color Policing of Layer 2 Traffic | 1718****Statement Hierarchy for Configuring a Two-Color Policer for Layer 2 Traffic | 1718**

Statement Hierarchy for Applying a Two-Color Policer to Layer 2 Traffic | 1719

Three-Color Policing at Layer 2 Overview | 1720

Guidelines for Configuring Three-Color Policing of Layer 2 Traffic | 1720

Statement Hierarchy for Configuring a Three-Color Policer for Layer 2 Traffic | 1720

Statement Hierarchy for Applying a Three-Color Policer to Layer 2 Traffic | 1721

Example: Configuring a Three-Color Logical Interface (Aggregate) Policer | 1722

Layer 2 Traffic Policing at the Pseudowire Overview | 1730

Configuring a Two-Color Layer 2 Policer for the Pseudowire | 1731

Configuring a Three-Color Layer 2 Policer for the Pseudowire | 1732

Applying the Policers to Dynamic Profile Interfaces | 1733

Attaching Dynamic Profiles to Routing Instances | 1735

Using Variables for Layer 2 Traffic Policing at the Pseudowire Overview | 1736

Configuring a Policer for the Complex Configuration | 1736

Creating a Dynamic Profile for the Complex Configuration | 1738

Attaching Dynamic Profiles to Routing Instances for the Complex Configuration | 1739

Verifying Layer 2 Traffic Policers on VPLS Connections | 1740

Understanding Policers on OVSDb-Managed Interfaces | 1741

Example: Applying a Policer to OVSDb-Managed Interfaces | 1742

Configuring Two-Color and Three-Color Traffic Policers at Layer 3 | 1746

Two-Color Policer Configuration Overview | 1746

Basic Single-Rate Two-Color Policers | 1753

Single-Rate Two-Color Policer Overview | 1753

Example: Limiting Inbound Traffic at Your Network Border by Configuring an Ingress Single-Rate Two-Color Policer | 1754

Example: Configuring Interface and Firewall Filter Policers at the Same Interface | 1765

Bandwidth Policers | 1778

Bandwidth Policer Overview | 1778

Guidelines for Configuring a Bandwidth Policer | 1778

Guidelines for Applying a Bandwidth Policer | 1779

Example: Configuring a Logical Bandwidth Policer | 1780

Filter-Specific Counters and Policers | 1790

Filter-Specific Policer Overview | 1790

Example: Configuring a Stateless Firewall Filter to Protect Against TCP and ICMP Floods | 1791

Prefix-Specific Counting and Policing Actions | 1805

Prefix-Specific Counting and Policing Overview | 1805

Separate Counting and Policing for Each IPv4 Address Range | 1805

Prefix-Specific Action Configuration | 1806

Counter and Policer Set Size and Indexing | 1807

Filter-Specific Counter and Policer Set Overview | 1808

Example: Configuring Prefix-Specific Counting and Policing | 1809

Prefix-Specific Counting and Policing Configuration Scenarios | 1818

Prefix Length of the Action and Prefix Length of Addresses in Filtered Packets | 1818

Scenario 1: Firewall Filter Term Matches on Multiple Addresses | 1820

Scenario 2: Subnet Prefix Is Longer Than the Prefix in the Filter Match Condition | 1822

Scenario 3: Subnet Prefix Is Shorter Than the Prefix in the Firewall Filter Match Condition | 1823

Multifield Classification | 1825

Multifield Classification Overview | 1826

Forwarding Classes and PLP Levels | 1826

Multifield Classification and BA Classification | 1826

Multifield Classification Used In Conjunction with Policers | 1827

Multifield Classification Requirements and Restrictions | 1829

Supported Platforms | 1829

CoS Tricolor Marking Requirement | 1829

Restrictions | 1829

Multifield Classification Limitations on M Series Routers | 1830

Problem: Output-Filter Matching on Input-Filter Classification | 1830

Workaround: Configure All Actions in the Ingress Filter | 1831

Example: Configuring Multifield Classification | 1832

Example: Configuring and Applying a Firewall Filter for a Multifield Classifier | 1841

Policer Overhead to Account for Rate Shaping in the Traffic Manager | 1849

Policer Overhead to Account for Rate Shaping Overview | 1849

Example: Configuring Policer Overhead to Account for Rate Shaping | 1850

Three-Color Policer Configuration Overview | 1860

Applying Policers | 1864

- Overview of Applying Policers | 1864

- Applying Aggregate Policers | 1865

 - Applying Aggregate Policers | 1866

- Applying Hierarchical Policers on Enhanced Intelligent Queuing PICs | 1868

 - Applying Hierarchical Policers on Enhanced Intelligent Queuing PICs | 1868

- Configuring Hierarchical Policers | 1870

- Configuring a Single-Rate Two-Color Policer | 1872

- Configuring a Single-Rate Color-Blind Policer | 1872

- Configuring a Two-Rate Tricolor Marker Policer | 1873

Three-Color Policer Configuration Guidelines | 1876

- Platforms Supported for Three-Color Policers | 1876

- Color Modes for Three-Color Policers | 1877

 - Color-Blind Mode | 1877

 - Color-Aware Mode | 1877

- Naming Conventions for Three-Color Policers | 1878

Basic Single-Rate Three-Color Policers | 1880

- Single-Rate Three-Color Policer Overview | 1880

- Example: Configuring a Single-Rate Three-Color Policer | 1881

Basic Two-Rate Three-Color Policers | 1888

- Two-Rate Three-Color Policer Overview | 1888

- Example: Configuring a Two-Rate Three-Color Policer | 1889

- Example: Configuring a Two-Rate Three-Color Policer | 1897

Configuring Logical and Physical Interface Traffic Policers at Layer 3 | 1905

Two-Color and Three-Color Logical Interface Policers | 1905

- Logical Interface (Aggregate) Policer Overview | 1905

- Example: Configuring a Two-Color Logical Interface (Aggregate) Policer | 1906

- Example: Configuring a Three-Color Logical Interface (Aggregate) Policer | 1914

Two-Color and Three-Color Physical Interface Policers | 1922

- Physical Interface Policer Overview | 1922

- Example: Configuring a Physical Interface Policer for Aggregate Traffic at a Physical Interface | 1923

Configuring Policers on Switches | 1933

Overview of Policers | 1934

- Policer Overview | 1934**
- Policer Types | 1935**
- Policer Actions | 1936**
- Policer Colors | 1937**
- Filter-Specific Policers | 1937**
- Suggested Naming Convention for Policers | 1937**

About the Documentation

IN THIS SECTION

- Documentation and Release Notes | xliii
- Using the Examples in This Manual | xliv
- Documentation Conventions | xlv
- Documentation Feedback | xlviii
- Requesting Technical Support | xlviii

Routing policies allow you to control the routing information between the routing protocols and the routing tables and between the routing tables and the forwarding table. All routing protocols use the Junos OS routing tables to store the routes that they learn and to determine which routes they should advertise in their protocol packets. Routing policies also allow you to control which routes the routing protocols store in and retrieve from the routing table.

Firewall filter policies allow you to control packets transiting the router to a network destination and packets destined for and sent by the router. They provide a means of protecting your router from excessive traffic transiting the router to a network destination or destined for the Routing Engine. Firewall filters that control local packets can also protect your router from external incidents such as denial-of-service attacks.

Documentation and Release Notes

To obtain the most current version of all Juniper Networks® technical documentation, see the product documentation page on the Juniper Networks website at <https://www.juniper.net/documentation/>.

If the information in the latest release notes differs from the information in the documentation, follow the product Release Notes.

Juniper Networks Books publishes books by Juniper Networks engineers and subject matter experts. These books go beyond the technical documentation to explore the nuances of network architecture, deployment, and administration. The current list can be viewed at <https://www.juniper.net/books>.

Using the Examples in This Manual

If you want to use the examples in this manual, you can use the **load merge** or the **load merge relative** command. These commands cause the software to merge the incoming configuration into the current candidate configuration. The example does not become active until you commit the candidate configuration.

If the example configuration contains the top level of the hierarchy (or multiple hierarchies), the example is a *full example*. In this case, use the **load merge** command.

If the example configuration does not start at the top level of the hierarchy, the example is a *snippet*. In this case, use the **load merge relative** command. These procedures are described in the following sections.

Merging a Full Example

To merge a full example, follow these steps:

1. From the HTML or PDF version of the manual, copy a configuration example into a text file, save the file with a name, and copy the file to a directory on your routing platform.

For example, copy the following configuration to a file and name the file **ex-script.conf**. Copy the **ex-script.conf** file to the **/var/tmp** directory on your routing platform.

```
system {
  scripts {
    commit {
      file ex-script.xsl;
    }
  }
}
interfaces {
  fxp0 {
    disable;
    unit 0 {
      family inet {
        address 10.0.0.1/24;
      }
    }
  }
}
```

2. Merge the contents of the file into your routing platform configuration by issuing the **load merge** configuration mode command:

```
[edit]
user@host# load merge /var/tmp/ex-script.conf
load complete
```

Merging a Snippet

To merge a snippet, follow these steps:

1. From the HTML or PDF version of the manual, copy a configuration snippet into a text file, save the file with a name, and copy the file to a directory on your routing platform.

For example, copy the following snippet to a file and name the file **ex-script-snippet.conf**. Copy the **ex-script-snippet.conf** file to the **/var/tmp** directory on your routing platform.

```
commit {
  file ex-script-snippet.xml; }
```

2. Move to the hierarchy level that is relevant for this snippet by issuing the following configuration mode command:

```
[edit]
user@host# edit system scripts
[edit system scripts]
```

3. Merge the contents of the file into your routing platform configuration by issuing the **load merge relative** configuration mode command:

```
[edit system scripts]
user@host# load merge relative /var/tmp/ex-script-snippet.conf
load complete
```

For more information about the **load** command, see [CLI Explorer](#).

Documentation Conventions

[Table 1 on page xlv](#) defines notice icons used in this guide.

Table 1: Notice Icons

Icon	Meaning	Description
	Informational note	Indicates important features or instructions.
	Caution	Indicates a situation that might result in loss of data or hardware damage.
	Warning	Alerts you to the risk of personal injury or death.
	Laser warning	Alerts you to the risk of personal injury from a laser.
	Tip	Indicates helpful information.
	Best practice	Alerts you to a recommended use or implementation.

Table 2 on page [xlvi](#) defines the text and syntax conventions used in this guide.

Table 2: Text and Syntax Conventions

Convention	Description	Examples
Bold text like this	Represents text that you type.	To enter configuration mode, type the configure command: user@host> configure
Fixed-width text like this	Represents output that appears on the terminal screen.	user@host> show chassis alarms No alarms currently active
<i>Italic text like this</i>	<ul style="list-style-type: none"> Introduces or emphasizes important new terms. Identifies guide names. Identifies RFC and Internet draft titles. 	<ul style="list-style-type: none"> A policy <i>term</i> is a named structure that defines match conditions and actions. <i>Junos OS CLI User Guide</i> RFC 1997, <i>BGP Communities Attribute</i>

Table 2: Text and Syntax Conventions (*continued*)

Convention	Description	Examples
<i>Italic text like this</i>	Represents variables (options for which you substitute a value) in commands or configuration statements.	Configure the machine's domain name: [edit] root@# set system domain-name <i>domain-name</i>
Text like this	Represents names of configuration statements, commands, files, and directories; configuration hierarchy levels; or labels on routing platform components.	<ul style="list-style-type: none"> To configure a stub area, include the stub statement at the [edit protocols ospf area area-id] hierarchy level. The console port is labeled CONSOLE.
< > (angle brackets)	Encloses optional keywords or variables.	stub <default-metric <i>metric</i> >;
(pipe symbol)	Indicates a choice between the mutually exclusive keywords or variables on either side of the symbol. The set of choices is often enclosed in parentheses for clarity.	broadcast multicast (<i>string1</i> <i>string2</i> <i>string3</i>)
# (pound sign)	Indicates a comment specified on the same line as the configuration statement to which it applies.	rsvp { # Required for dynamic MPLS only
[] (square brackets)	Encloses a variable for which you can substitute one or more values.	community name members [<i>community-ids</i>]
Indentation and braces ({ })	Identifies a level in the configuration hierarchy.	[edit] routing-options { static { route default { nexthop <i>address</i> ; retain; } } }
; (semicolon)	Identifies a leaf statement at a configuration hierarchy level.	

GUI Conventions

Table 2: Text and Syntax Conventions (*continued*)

Convention	Description	Examples
Bold text like this	Represents graphical user interface (GUI) items you click or select.	<ul style="list-style-type: none"> In the Logical Interfaces box, select All Interfaces. To cancel the configuration, click Cancel.
> (bold right angle bracket)	Separates levels in a hierarchy of menu selections.	In the configuration editor hierarchy, select Protocols>Ospf .

Documentation Feedback

We encourage you to provide feedback so that we can improve our documentation. You can use either of the following methods:

- Online feedback system—Click TechLibrary Feedback, on the lower right of any page on the [Juniper Networks TechLibrary](#) site, and do one of the following:

- Click the thumbs-up icon if the information on the page was helpful to you.
- Click the thumbs-down icon if the information on the page was not helpful to you or if you have suggestions for improvement, and use the pop-up form to provide feedback.
- E-mail—Send your comments to techpubs-comments@juniper.net. Include the document or topic name, URL or page number, and software version (if applicable).

Requesting Technical Support

Technical product support is available through the Juniper Networks Technical Assistance Center (JTAC). If you are a customer with an active Juniper Care or Partner Support Services support contract, or are

covered under warranty, and need post-sales technical support, you can access our tools and resources online or open a case with JTAC.

- JTAC policies—For a complete understanding of our JTAC procedures and policies, review the *JTAC User Guide* located at <https://www.juniper.net/us/en/local/pdf/resource-guides/7100059-en.pdf>.
- Product warranties—For product warranty information, visit <https://www.juniper.net/support/warranty/>.
- JTAC hours of operation—The JTAC centers have resources available 24 hours a day, 7 days a week, 365 days a year.

Self-Help Online Tools and Resources

For quick and easy problem resolution, Juniper Networks has designed an online self-service portal called the Customer Support Center (CSC) that provides you with the following features:

- Find CSC offerings: <https://www.juniper.net/customers/support/>
- Search for known bugs: <https://prsearch.juniper.net/>
- Find product documentation: <https://www.juniper.net/documentation/>
- Find solutions and answer questions using our Knowledge Base: <https://kb.juniper.net/>
- Download the latest versions of software and review release notes: <https://www.juniper.net/customers/csc/software/>
- Search technical bulletins for relevant hardware and software notifications: <https://kb.juniper.net/InfoCenter/>
- Join and participate in the Juniper Networks Community Forum: <https://www.juniper.net/company/communities/>
- Create a service request online: <https://myjuniper.juniper.net>

To verify service entitlement by product serial number, use our Serial Number Entitlement (SNE) Tool: <https://entitlementsearch.juniper.net/entitlementsearch/>

Creating a Service Request with JTAC

You can create a service request with JTAC on the Web or by telephone.

- Visit <https://myjuniper.juniper.net>.
- Call 1-888-314-JTAC (1-888-314-5822 toll-free in the USA, Canada, and Mexico).

For international or direct-dial options in countries without toll-free numbers, see <https://support.juniper.net/support/requesting-support/>.

Policy Framework Overview

IN THIS SECTION

- Routing Policy and Firewall Filters | 4
- Reasons to Create a Routing Policy | 4
- Router Flows Affected by Policies | 5
- Control Points | 8
- Policy Components | 9

The Junos[®] operating system (Junos OS) provides a *policy framework*, which is a collection of Junos OS policies that allows you to control flows of routing information and packets.

The Junos OS policy architecture is simple and straightforward. However, the actual implementation of each policy adds layers of complexity to the policy as well as adding power and flexibility to your router's capabilities. Configuring a policy has a major impact on the flow of routing information or packets within and through the router. For example, you can configure a routing policy that does not allow routes associated with a particular customer to be placed in the routing table. As a result of this routing policy, the customer routes are not used to forward data packets to various destinations and the routes are not advertised by the routing protocol to neighbors.

Before configuring a policy, determine what you want to accomplish with it and thoroughly understand how to achieve your goal using the various match conditions and actions. Also, make certain that you understand the default policies and actions for the policy you are configuring.

Routing Policy and Firewall Filters

The policy framework is composed of the following policies:

- Routing policy—Allows you to control the routing information between the routing protocols and the routing tables and between the routing tables and the forwarding table. All routing protocols use the Junos OS routing tables to store the routes that they learn and to determine which routes they should advertise in their protocol packets. Routing policy allows you to control which routes the routing protocols store in and retrieve from the routing table.
- Firewall filter policy—Allows you to control packets transiting the router to a network destination and packets destined for and sent by the router.

NOTE: The term *firewall filter policy* is used here to emphasize that a firewall filter is a policy and shares some fundamental similarities with a routing policy. However, when referring to a firewall filter policy in the rest of this manual, the term *firewall filter* is used.

Reasons to Create a Routing Policy

The following are typical circumstances under which you might want to preempt the default routing policies in the routing policy framework by creating your own routing policies:

- You do not want a protocol to import all routes into the routing table. If the routing table does not learn about certain routes, they can never be used to forward packets and they can never be redistributed into other routing protocols.
- You do not want a routing protocol to export all the active routes it learns.

- You want a routing protocol to announce active routes learned from another routing protocol, which is sometimes called *route redistribution*.
- You want to manipulate route characteristics, such as the preference value, AS path, or community. You can manipulate the route characteristics to control which route is selected as the active route to reach a destination. In general, the active route is also advertised to a router's neighbors.
- You want to change the default BGP route flap-damping parameters.
- You want to perform per-packet load balancing.
- You want to enable class of service (CoS).

Router Flows Affected by Policies

The Junos OS policies affect the following router flows:

- Flow of routing information between the routing protocols and the routing tables and between the routing tables and the forwarding table. The Routing Engine handles this flow. *Routing information* is the information about routes learned by the routing protocols from a router's neighbors. This information is stored in routing tables and is subsequently advertised by the routing protocols to the router's neighbors. Routing policies allow you to control the flow of this information.
- Flow of data packets in and out of the router's physical interfaces. The Packet Forwarding Engine handles this flow. *Data packets* are chunks of data that transit the router as they are being forwarded from a source to a destination. When a router receives a data packet on an interface, it determines where to forward the packet by looking in the forwarding table for the best route to a destination. The router then forwards the data packet toward its destination through the appropriate interface. Firewall filters allow you to control the flow of these data packets.
- Flow of local packets from the router's physical interfaces and to the Routing Engine. The Routing Engine handles this flow. *Local packets* are chunks of data that are destined for or sent by the router. Local packets usually contain routing protocol data, data for IP services such as Telnet or SSH, and data for administrative protocols such as the Internet Control Message Protocol (ICMP). When the Routing Engine receives a local packet, it forwards the packet to the appropriate process or to the kernel, which are both part of the Routing Engine, or to the Packet Forwarding Engine. Firewall filters allow you to control the flow of these local packets.

NOTE: In the rest of this chapter, the term *packets* refers to both data and local packets unless explicitly stated otherwise.

Figure 1 on page 6 illustrates the flows through the router. Although the flows are very different from each other, they are also interdependent. Routing policies determine which routes are placed in the

forwarding table. The forwarding table, in turn, has an integral role in determining the appropriate physical interface through which to forward a packet.

Figure 1: Flows of Routing Information and Packets

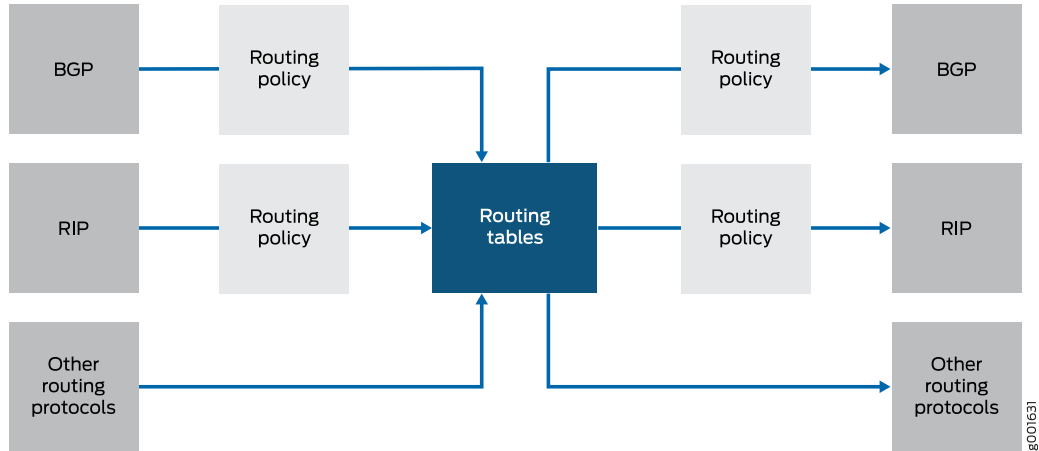

You can configure routing policies to control which routes the routing protocols place in the routing tables and to control which routes the routing protocols advertise from the routing tables (see [Figure 2 on page 7](#)). The routing protocols advertise active routes only from the routing tables. (An *active route* is a route that is chosen from all routes in the routing table to reach a destination.)

You can also use routing policies to do the following:

- Change specific route characteristics, which allow you to control which route is selected as the active route to reach a destination. In general, the active route is also advertised to a router's neighbors.
- Change to the default BGP route flap-damping values.
- Perform per-packet load balancing.
- Enable class of service (CoS).

Figure 2: Routing Policies to Control Routing Information Flow

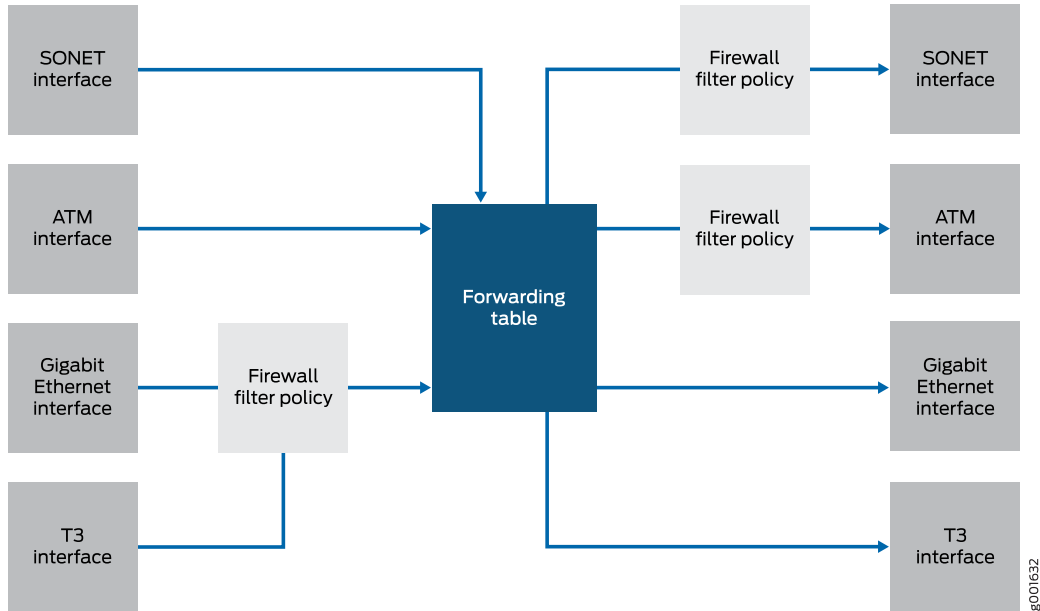

You can configure firewall filters to control the following aspects of packet flow (see [Figure 3 on page 8](#)):

- Which data packets are accepted on and transmitted from the physical interfaces. To control the flow of data packets, you apply firewall filters to the physical interfaces.
- Which local packets are transmitted from the physical interfaces and to the Routing Engine. To control local packets, you apply firewall filters on the loopback interface, which is the interface to the Routing Engine.

Firewall filters provide a means of protecting your router from excessive traffic transiting the router to a network destination or destined for the Routing Engine. Firewall filters that control local packets can also protect your router from external incidents such as denial-of-service attacks.

Figure 3: Firewall Filters to Control Packet Flow

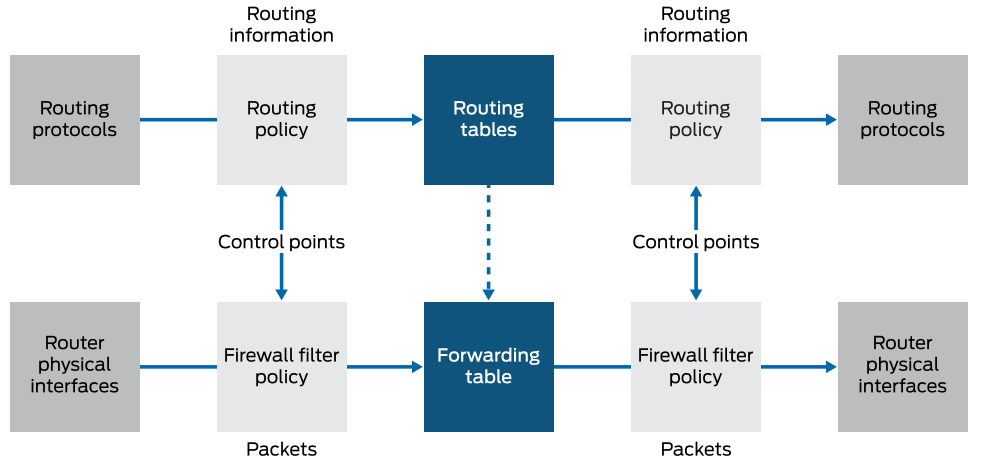

Control Points

All policies provide two points at which you can control routing information or packets through the router (see [Figure 4 on page 9](#)). These control points allow you to control the following:

- Routing information before and after it is placed in the routing table.
- Data packets before and after a forwarding table lookup.
- Local packets before and after they are received by the Routing Engine. ([Figure 4 on page 9](#) appears to depict only one control point but because of the bidirectional flow of the local packets, two control points actually exist.)

Figure 4: Policy Control Points

Because there are two control points, you can configure policies that control the routing information or data packets before and after their interaction with their respective tables, and policies that control local packets before and after their interaction with the Routing Engine. *Import routing policies* control the routing information that is placed in the routing tables, whereas *export routing policies* control the routing information that is advertised from the routing tables. *Input firewall filters* control packets that are received on a router interface, whereas *output firewall filters* control packets that are transmitted from a router interface.

Policy Components

All policies are composed of the following components that you configure:

- **Match conditions**—Criteria against which a route or packets are compared. You can configure one or more criteria. If all criteria match, one or more actions are applied.
- **Actions**—What happens if all criteria match. You can configure one or more actions.
- **Terms**—Named structures in which match conditions and actions are defined. You can define one or more terms.

The policy framework software evaluates each incoming and outgoing route or packet against the match conditions in a term. If the criteria in the match conditions are met, the defined action is taken.

In general, the policy framework software compares the route or packet against the match conditions in the first term in the policy, then goes on to the next term, and so on. Therefore, the order in which you arrange terms in a policy is relevant.

The order of match conditions within a term is not relevant because a route or packet must match all match conditions in a term for an action to be taken.

Comparison of Routing Policies and Firewall Filters

Although routing policies and firewall filters share an architecture, their purposes, implementation, and configuration are different. [Table 3 on page 10](#) describes their purposes. [Table 4 on page 10](#) compares the implementation details for routing policies and firewall filters, highlighting the similarities and differences in their configuration.

Table 3: Purpose of Routing Policies and Firewall Filters

Policies	Source	Policy Purpose
Routing policies	Routing information is generated by internal networking peers.	To control the size and content of the routing tables, which routes are advertised, and which routes are considered the best to reach various destinations.
Firewall filters	Packets are generated by internal and external devices through which hostile attacks can be perpetrated.	To protect your router and network from excessive incoming traffic or hostile attacks that can disrupt network service, and to control which packets are forwarded from which router interfaces.

Table 4: Implementation Differences Between Routing Policies and Firewall Filters

Policy Architecture	Routing Policy Implementation	Firewall Filter Implementation
Control points	Control routing information that is placed in the routing table with an import routing policy and advertised from the routing table with an export routing policy.	Control packets that are accepted on a router interface with an input firewall filter and that are forwarded from an interface with an output firewall filter.

Table 4: Implementation Differences Between Routing Policies and Firewall Filters (*continued*)

Policy Architecture	Routing Policy Implementation	Firewall Filter Implementation
<p>Configuration tasks:</p> <ul style="list-style-type: none"> • Define policy • Apply policy 	<p>Define a policy that contains terms, match conditions, and actions.</p> <p>Apply one or more export or import policies to a routing protocol. You can also apply a <i>policy expression</i>, which uses Boolean logical operators with multiple import or export policies.</p> <p>You can also apply one or more export policies to the forwarding table.</p>	<p>Define a policy that contains terms, match conditions, and actions.</p> <p>Apply one input or output firewall filter to a physical interface or physical interface group to filter data packets received by or forwarded to a physical interface (on routing platforms with an Internet Processor II application-specific integrated circuit [ASIC] only).</p> <p>You can also apply one input or output firewall filter to the routing platform's loopback interface, which is the interface to the Routing Engine (on all routing platforms). This allows you to filter local packets received by or forwarded from the Routing Engine.</p>
Terms	<p>Configure as many terms as desired. Define a name for each term.</p> <p>Terms are evaluated in the order in which you specify them.</p> <p>Evaluation of a policy ends after a packet matches the criteria in a term and the defined or default policy action of accept or reject is taken. The route is not evaluated against subsequent terms in the same policy or subsequent policies.</p>	<p>Configure as many terms as desired. Define a name for each term.</p> <p>Terms are evaluated in the order in which you specify them.</p> <p>Evaluation of a firewall filter ends after a packet matches the criteria in a term and the defined or default action is taken. The packet is not evaluated against subsequent terms in the firewall filter.</p>

Table 4: Implementation Differences Between Routing Policies and Firewall Filters (*continued*)

Policy Architecture	Routing Policy Implementation	Firewall Filter Implementation
Match conditions	<p>Specify zero or more criteria that a route must match. You can specify criteria based on source, destination, or properties of a route. You can also specify the following match conditions, which require more configuration:</p> <ul style="list-style-type: none"> • Autonomous system (AS) path expression—A combination of AS numbers and regular expression operators. • Community—A group of destinations that share a common property. • Prefix list—A named list of prefixes. • Route list—A list of destination prefixes. • Subroutine—A routing policy that is called repeatedly from other routing policies. 	<p>Specify zero or more criteria that a packet must match. You must match various fields in the packet's header. The fields are grouped into the following categories:</p> <ul style="list-style-type: none"> • Numeric values, such as port and protocol numbers. • Prefix values, such as IP source and destination prefixes. • Bit-field values—Whether particular bits in the fields are set, such as IP options, Transmission Control Protocol (TCP) flags, and IP fragmentation fields. You can specify the fields using Boolean logical operators.

Table 4: Implementation Differences Between Routing Policies and Firewall Filters (*continued*)

Policy Architecture	Routing Policy Implementation	Firewall Filter Implementation
Actions	<p>Specify zero or one action to take if a route matches all criteria. You can specify the following actions:</p> <ul style="list-style-type: none"> • Accept—Accept the route into the routing table, and propagate it. After this action is taken, the evaluation of subsequent terms and policies ends. • Reject—Do not accept the route into the routing table, and do not propagate it. After this action is taken, the evaluation of subsequent terms and policies ends. <p>In addition to the preceding actions, you can also specify zero or more of the following types of actions:</p> <ul style="list-style-type: none"> • Next term—Evaluate the next term in the routing policy. • Next policy—Evaluate the next routing policy. • Actions that manipulate characteristics associated with a route as the routing protocol places it in the routing table or advertises it from the routing table. • Trace action, which logs route matches. 	<p>Specify zero or one action to take if a packet matches all criteria. (We recommend that you always explicitly configure an action.) You can specify the following actions:</p> <ul style="list-style-type: none"> • Accept—Accept a packet. • Discard—Discard a packet silently, without sending an ICMP message. • Reject—Discard a packet, and send an ICMP destination unreachable message. • Routing instance—Specify a routing table to which packets are forwarded. • Next term—Evaluate the next term in the firewall filter. <p>NOTE: On Junos OS Evolved, next term cannot appear as the last term of the action. A filter term where next term is specified as an action but without any match conditions configured is not supported.</p> <p>In addition to zero or the preceding actions, you can also specify zero or more action modifiers. You can specify the following action modifiers:</p> <ul style="list-style-type: none"> • Count—Add packet to a count total. • Forwarding class—Set the packet forwarding class to a specified value from 0 through 3. • IPsec security association—Used with the source and destination address match conditions, specify an IP Security (IPsec) security association (SA) for the packet. • Log—Store the header information of a packet on the Routing Engine. • Loss priority—Set the packet loss priority (PLP) bit to a specified value, 0 or 1. • Policer—Apply rate-limiting procedures to the traffic. • Sample—Sample the packet traffic. • Syslog—Log an alert for the packet.

Table 4: Implementation Differences Between Routing Policies and Firewall Filters (*continued*)

Policy Architecture	Routing Policy Implementation	Firewall Filter Implementation
Default policies and actions	<p>If an incoming or outgoing route arrives and a policy related to the route is not explicitly configured, the action specified by the default policy for the associated routing protocol is taken.</p> <p>The following default actions exist for routing policies:</p> <ul style="list-style-type: none"> • If a policy does not specify a match condition, all routes evaluated against the policy match. • If a match occurs but the policy does not specify an accept, reject, next term, or next policy action, one of the following occurs: <ul style="list-style-type: none"> • The next term, if present, is evaluated. • If no other terms are present, the next policy is evaluated. • If no other policies are present, the action specified by the default policy is taken. • If a match does not occur with a term in a policy and subsequent terms in the same policy exist, the next term is evaluated. • If a match does not occur with any terms in a policy and subsequent policies exist, the next policy is evaluated. • If a match does not occur by the end of a policy and no other policies exist, the accept or reject action specified by the default policy is taken. 	<p>If an incoming or outgoing packet arrives on an interface and a firewall filter is not configured for the interface, the default policy is taken (the packet is accepted).</p> <p>The following default actions exist for firewall filters:</p> <ul style="list-style-type: none"> • If a firewall filter does not specify a match condition, all packets are considered to match. • If a match occurs but the firewall filter does not specify an action, the packet is accepted. • If a match occurs, the defined or default action is taken and the evaluation ends. Subsequent terms in the firewall filter are not evaluated, unless the next term action is specified. <p>NOTE: On Junos OS Evolved, next term cannot appear as the last term of the action. A filter term where next term is specified as an action but without any match conditions configured is not supported.</p> <ul style="list-style-type: none"> • If a match does not occur with a term in a firewall filter and subsequent terms in the same filter exist, the next term is evaluated. • If a match does not occur by the end of a firewall filter, the packet is discarded.

Routing Policies, Firewall Filters, and Traffic Policers User Guide

Understanding the Algorithm Used to Load Balance Traffic on MX Series Routers

Prefix Prioritization Overview

Junos OS routes have a predetermined order for route installation. This is no longer sufficient as it is sometimes required to prioritize certain routes or prefixes over others for better convergence or to provide differentiated services. In a network with a large number of routes, it is sometimes important to control the order in which routes get updated due to a change in the network topology. For example, it would be useful to first update OSPF routes that correspond to an IBGP neighbor, and only then update the rest of the OSPF routes. At a system level, Junos OS implements reasonable defaults based on heuristics to determine the order in which routes get updated. However, the default behavior is not always optimal. Prefix prioritization allows the user to control the order in which the routes get updated from LDP or OSPF to rpd, and from rpd to kernel. In Junos OS Release 16.1 and later, you can control the order in which the routes get updated from LDP or OSPF to rpd, and from rpd to kernel.

In Junos OS Release 16.1 and later, the Junos OS policy language is extended to let the user set the relative priority **high** and **low** for prefixes via the existing protocol import policy. Based on the tagged priority, the routes are placed in different priority queues. Routes that are not explicitly assigned a priority are treated as medium priority. Within the same priority level, routes will continue to be updated in lexicographic order. Prefix prioritization would need each supporting protocol to prioritize its routes internally. Prefix prioritization ensures that high priority IGP and LDP routes get updated to the FIB (forwarding table) before medium and low priority routes.

NOTE: There is an upper limit on how many high priority prefixes are allowed in the kernel. Not more than 10,000 high priority prefixes can coexist in the kernel. If this threshold is crossed in the kernel, then any new high priority prefix addition request will be considered as normal priority. This is a “best effort” prioritization scheme and will not be handled if the kernel is highly loaded.

Accounting of the Policer Overhead Attribute at the Interface Level

A bandwidth profile (BWP) enforces limits on bandwidth utilization according to the service level specification (SLS) that has been agreed upon by the subscriber and the service provider as part of the service level agreement (SLA). There are two types of bandwidth profiles:

- Ingress Bandwidth Profile
- Egress Bandwidth Profile

Need for Policer Overhead adjustment

The Metro Ethernet Forum (MEF) Carrier Ethernet (CE) 2.0 set of standards has stringent requirements for the bandwidth profile enforcement at the user network interface (UNI). MEF CE 2.0 certification compliance allows only a 2 percent deviation from UNI committed or peak rate across all frame sizes. This means that the policers should take into account the frame size at the UNI interface, including frame checksum and excluding all additional overheads that might be added inside the service provider network (such as S-VLANs). Therefore, this translates into two customer requirements:

- Junos OS egress policers use frame length before output VLAN manipulation. If VLANs are added on output, those extra bytes will not be counted. In order to address MEF CE 2.0 requirements, adjust the length of the packet that is used for policing purposes for Junos egress policers that use frame length before output VLAN manipulation. Therefore, if VLANs are added on output, the extra bytes will not be counted.
- In some network designs, bandwidth profile enforcement is implemented at the Layer 2 (L2) VPN Provider Edge Router and not at the Ethernet access device (EAD) terminating the physical UNI interface. The EAD typically adds an S-VLAN that identifies the port in the access network. The S-VLAN that is added is considered internal to the service provider network and typically should not be taken into account for bandwidth profile enforcement purposes at the Provider Edge device in both ingress and egress directions. This also translates into a requirement to allow adjusting the packet length used for policing purposes on ingress and egress.

In order to address these requirements, **policer-overhead** adjustment is defined on a per logical interface (IFL)/direction granularity, which is the range of -16 bytes to +16 bytes. The **policer-overhead** adjustment is applied for all the policers that take into account Layer 1 (L1) or L2 packet length that are exercised in the specified IFL/direction, including corresponding logical interface family (IFF) feature policers, and is applied only to interface or filter-based policers.

Policer Overhead Adjustment Applicability for Policers

The ingress or egress **policer overhead** adjustment configuration is applicable for the following types of policers on ingress or egress IFL and IFF, respectively:

- L2 two-color and three-color policers.
- IFL-level policers (configured at the IFL or in a filter attached to IFL).
- Family-level policers that use L2 packet length, or policers in filters attached to L2 IFF (family bridge, vpls, ccc).

NOTE: The list is applicable for all types of policers, including regular two-color policers, three-color policers, and hierarchical policers, provided that the policer operates on an L1 or L2 packet length.

Ingress policer overhead adjustment configuration is applied to any policers attached to ingress L2 routing instances.

NOTE: Note that any IFF policer on the L3 family (inet inet6), which considers only L3 packet length, will not consider this adjustment. The **policer overhead** adjustment value (+ve or -ve) is added to the actual L2 packet length to obtain the number of bytes to charge the policer. Therefore, this is used only as an intermediate value, and does not affect actual L2 packet length. This feature is applied before VLAN normalization, and is independent of the **egress-shaping-overhead** or **ingress-shaping-overhead** configuration under class of service.

[Configuring the Accounting of Policer Overhead in Interface Statistics | 18](#)

Configuring the Accounting of Policer Overhead in Interface Statistics

The Metro Ethernet Forum (MEF) Carrier Ethernet (CE) 2.0 set of standards has stringent requirements to the bandwidth profile enforcement at the user-to-network interfaces (UNI). MEF CE 2.0 certification compliance allows only a 2 percent deviation from UNI committed or peak rate across all frame sizes. This means that the policers should take into account the frame size at the UNI interface, including frame checksum and excluding all additional overheads that might be added inside the service provider network (such as S-VLANs).

In order to address the MEF CE 2.0 stringent requirements to the bandwidth profile, **policer-overhead** adjustment is defined on a per IFL or direction granularity. The **policer-overhead** adjustment is in the range of -16 bytes to +16 bytes and is applied for all the policers that take into account Layer 1/ Layer 2 (L1/L2) packet length in the specified IFL or direction, including corresponding logical interface family (IFF) feature policers.

To configure the policer-overhead:

1. At the [edit interfaces] hierarchy level in configuration mode, create the interface on which to add the policer-overhead to input or output traffic.

```
[edit interfaces]
user@host# edit interfaces interface name
```

For example:

```
[edit interfaces interface name]
user@host# edit xe-0/1/6
```

2. Create the unit on which to add the policer overhead.

```
[edit interfaces unit]
[edit interfaces interface name unit unit-number]
```

For example:

```
[edit interfaces unit]
user@host# edit xe-0/1/6 unit 0
```

3. Configure the policer-overhead for the ingress policer.

```
[edit interfaces interface name unit unit-number ]
user@host# set policer-overhead ingress value in bytes (-16..+16 bytes)
```

For example:

```
[edit xe-0/1/6 unit 0]
user@host# set policer-overhead ingress 10;
```

4. Configure the policer-overhead for the egress policer.

```
user@host# set policer-overhead egress value in bytes (-16..+16 bytes)
```

```
[edit xe-0/1/6 unit 0]
user@host# set policer-overhead egress 10;
```

5. Verify the configuration.

```
[edit interfaces]
user@host# show interfaces xe-0/1/6
xe-0/1/6 {
    unit 0 {
        policer-overhead {
            ingress 10;
            egress 10;
        }
    }
}
```

```
user@host>show interfaces xe-0/1/6

Understanding Routing Policies

IN THIS SECTION

- [Importing and Exporting Routes | 21](#)
- [Active and Inactive Routes | 23](#)
- [Explicitly Configured Routes | 23](#)
- [Dynamic Database | 23](#)

For some routing platform vendors, the flow of routes occurs between various protocols. If, for example, you want to configure redistribution from RIP to OSPF, the RIP process tells the OSPF process that it has routes that might be included for redistribution. In Junos OS, there is not much direct interaction between the routing protocols. Instead, there are central gathering points where all protocols install their routing information. These are the main unicast routing tables `inet.0` and `inet6.0`.

From these tables, the routing protocols calculate the best route to each destination and place these routes in a forwarding table. These routes are then used to forward routing protocol traffic toward a destination, and they can be advertised to neighbors.

Importing and Exporting Routes

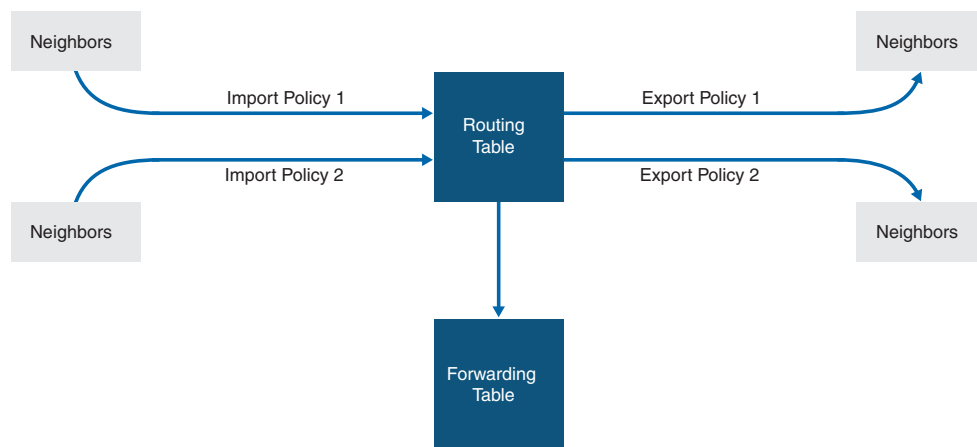

Two terms—*import* and *export*—explain how routes move between the routing protocols and the routing table.

- When the Routing Engine places the routes of a routing protocol into the routing table, it is *importing* routes into the routing table.
- When the Routing Engine uses active routes from the routing table to send a protocol advertisement, it is *exporting* routes from the routing table.

NOTE: The process of moving routes between a routing protocol and the routing table is described always *from the point of view of the routing table*. That is, routes are *imported into* a routing table from a routing protocol and they are *exported from* a routing table to a routing protocol. Remember this distinction when working with routing policies.

As shown in [Figure 5 on page 22](#), you use import routing policies to control which routes are placed in the routing table, and export routing policies to control which routes are advertised from the routing table to neighbors.

Figure 5: Importing and Exporting Routes

In general, the routing protocols place all their routes in the routing table and advertise a limited set of routes from the routing table. The general rules for handling the routing information between the routing protocols and the routing table are known as the *routing policy framework*.

The routing policy framework is composed of default rules for each routing protocol that determine which routes the protocol places in the routing table and advertises from the routing table. The default rules for each routing protocol are known as *default routing policies*.

You can create routing policies to preempt the default policies, which are always present. A *routing policy* allows you to modify the routing policy framework to suit your needs. You can create and implement your own routing policies to do the following:

- Control which routes a routing protocol places in the routing table.
- Control which active routes a routing protocol advertises from the routing table. An *active route* is a route that is chosen from all routes in the routing table to reach a destination.
- Manipulate the route characteristics as a routing protocol places the route in the routing table or advertises the route from the routing table.

You can manipulate the route characteristics to control which route is selected as the active route to reach a destination. The active route is placed in the forwarding table and is used to forward traffic toward the route's destination. In general, the active route is also advertised to a router's neighbors.

Active and Inactive Routes

When multiple routes for a destination exist in the routing table, the protocol selects an active route and that route is placed in the appropriate routing table. For equal-cost routes, the Junos OS places multiple next hops in the appropriate routing table.

When a protocol is exporting routes from the routing table, it exports active routes only. This applies to actions specified by both default and user-defined export policies.

When evaluating routes for export, the Routing Engine uses only active routes from the routing table. For example, if a routing table contains multiple routes to the same destination and one route has a preferable metric, only that route is evaluated. In other words, an export policy does not evaluate all routes; it evaluates only those routes that a routing protocol is allowed to advertise to a neighbor.

NOTE: By default, BGP advertises active routes. However, you can configure BGP to advertise *inactive routes*, which go to the same destination as other routes but have less preferable metrics.

Explicitly Configured Routes

An *explicitly configured route* is a route that you have configured. *Direct routes* are not explicitly configured. They are created as a result of IP addresses being configured on an interface. Explicitly configured routes include aggregate, generated, local, and static routes. (An *aggregate route* is a route that distills groups of routes with common addresses into one route. A *generated route* is a route used when the routing table has no information about how to reach a particular destination. A *local route* is an IP address assigned to a router interface. A *static route* is an unchanging route to a destination.)

The policy framework software treats direct and explicitly configured routes as if they are learned through routing protocols; therefore, they can be imported into the routing table. Routes cannot be exported from the routing table to the pseudoprotocol, because this protocol is not a real routing protocol. However, aggregate, direct, generated, and static routes can be exported from the routing table to routing protocols, whereas local routes cannot.

Dynamic Database

In Junos OS Release 9.5 and later, you can configure routing policies and certain routing policy objects in a dynamic database that is not subject to the same verification required by the standard configuration database. As a result, you can quickly commit these routing policies and policy objects, which can be

referenced and applied in the standard configuration as needed. BGP is the only protocol to which you can apply routing policies that reference policies configured in the dynamic database. After a routing policy based on the dynamic database is configured and committed in the standard configuration, you can quickly make changes to existing routing policies by modifying policy objects in the dynamic database. Because Junos OS does not validate configuration changes to the dynamic database, when you use this feature, you should test and verify all configuration changes before committing them.

RIP and RIPv6	Yes	Yes	Import: global, neighbor Export: group

Example: Applying Routing Policies at Different Levels of the BGP Hierarchy

IN THIS SECTION

- [Requirements | 25](#)
- [Overview | 26](#)
- [Configuration | 27](#)
- [Verification | 33](#)

This example shows BGP configured in a simple network topology and explains how routing policies take effect when they are applied at different levels of the BGP configuration.

Requirements

No special configuration beyond device initialization is required before configuring this example.

Overview

For BGP, you can apply policies as follows:

- BGP global **import** and **export** statements—Include these statements at the **[edit protocols bgp]** hierarchy level (for routing instances, include these statements at the **[edit routing-instances routing-instance-name protocols bgp]** hierarchy level).
- Group **import** and **export** statements—Include these statements at the **[edit protocols bgp group group-name]** hierarchy level (for routing instances, include these statements at the **[edit routing-instances routing-instance-name protocols bgp group group-name]** hierarchy level).
- Peer **import** and **export** statements—Include these statements at the **[edit protocols bgp group group-name neighbor address]** hierarchy level (for routing instances, include these statements at the **[edit routing-instances routing-instance-name protocols bgp group group-name neighbor address]** hierarchy level).

A peer-level **import** or **export** statement overrides a group **import** or **export** statement. A group-level **import** or **export** statement overrides a global BGP **import** or **export** statement.

In this example, a policy named **send-direct** is applied at the global level, another policy named **send-192.168.0.1** is applied at the group level, and a third policy named **send-192.168.20.1** is applied at the neighbor level.

```
user@host# show protocols
bgp {
  local-address 172.16.1.1;
  export send-direct;
  group internal-peers {
    type internal;
    export send-192.168.0.1;
    neighbor 172.16.2.2 {
      export send-192.168.20.1;
    }
    neighbor 172.16.3.3;
  }
  group other-group {
    type internal;
    neighbor 172.16.4.4;
  }
}
```

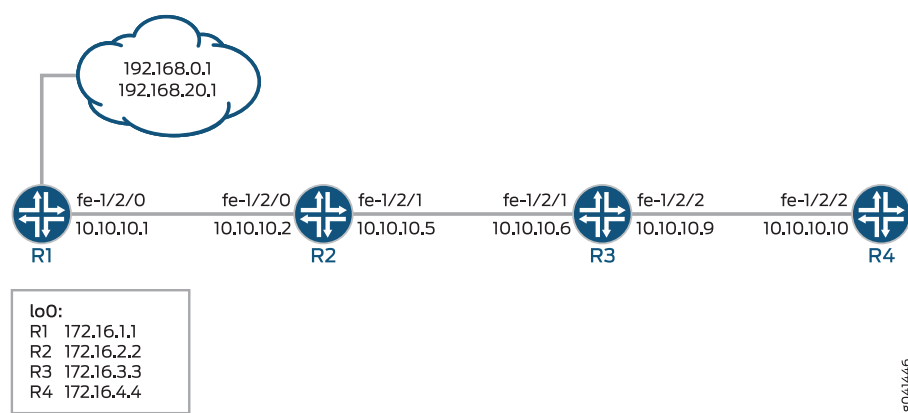

A key point, and one that is often misunderstood and that can lead to problems, is that in such a configuration, only the most explicit policy is applied. A neighbor-level policy is more explicit than a group-level policy, which in turn is more explicit than a global policy.

The neighbor 172.16.2.2 is subjected only to the send-192.168.20.1 policy. The neighbor 172.16.3.3, lacking anything more specific, is subjected only to the send-192.168.0.1 policy. Meanwhile, neighbor 172.16.4.4 in group other-group has no group or neighbor-level policy, so it uses the send-direct policy.

If you need to have neighbor 172.16.2.2 perform the function of all three policies, you can write and apply a new neighbor-level policy that encompasses the functions of the other three, or you can apply all three existing policies, as a chain, to neighbor 172.16.2.2.

Figure 6 on page 27 shows the sample network.

Figure 6: Applying Routing Policies to BGP

“CLI Quick Configuration” on page 27 shows the configuration for all of the devices in Figure 6 on page 27.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

Device R1

```
set interfaces fe-1/2/0 unit 0 description to-R2
set interfaces fe-1/2/0 unit 0 family inet address 10.10.10.1/30
set interfaces lo0 unit 0 family inet address 172.16.1.1/32
set protocols bgp local-address 172.16.1.1
set protocols bgp export send-direct
```

```

set protocols bgp group internal-peers type internal
set protocols bgp group internal-peers export send-static-192.168.0
set protocols bgp group internal-peers neighbor 172.16.2.2 export send-static-192.168.20
set protocols bgp group internal-peers neighbor 172.16.3.3
set protocols bgp group other-group type internal
set protocols bgp group other-group neighbor 172.16.4.4
set protocols ospf area 0.0.0.0 interface lo0.0 passive
set protocols ospf area 0.0.0.0 interface fe-1/2/0.0
set policy-options policy-statement send-direct term 1 from protocol direct
set policy-options policy-statement send-direct term 1 then accept
set policy-options policy-statement send-static-192.168.0 term 1 from protocol static
set policy-options policy-statement send-static-192.168.0 term 1 from route-filter 192.168.0.0/24
  orlonger
set policy-options policy-statement send-static-192.168.0 term 1 then accept
set policy-options policy-statement send-static-192.168.20 term 1 from protocol static
set policy-options policy-statement send-static-192.168.20 term 1 from route-filter 192.168.20.0/24
  orlonger
set policy-options policy-statement send-static-192.168.20 term 1 then accept
set routing-options static route 192.168.0.1/32 discard
set routing-options static route 192.168.20.1/32 discard
set routing-options router-id 172.16.1.1
set routing-options autonomous-system 17

```

Device R2

```

set interfaces fe-1/2/0 unit 0 description to-R1
set interfaces fe-1/2/0 unit 0 family inet address 10.10.10.2/30
set interfaces fe-1/2/1 unit 0 description to-R3
set interfaces fe-1/2/1 unit 0 family inet address 10.10.10.5/30
set interfaces lo0 unit 0 family inet address 172.16.2.2/32
set protocols bgp group internal-peers type internal
set protocols bgp group internal-peers local-address 172.16.2.2
set protocols bgp group internal-peers neighbor 172.16.3.3
set protocols bgp group internal-peers neighbor 172.16.1.1
set protocols bgp group internal-peers neighbor 172.16.4.4
set protocols ospf area 0.0.0.0 interface lo0.0 passive
set protocols ospf area 0.0.0.0 interface fe-1/2/0.0
set protocols ospf area 0.0.0.0 interface fe-1/2/1.0
set routing-options router-id 172.16.2.2
set routing-options autonomous-system 17

```

Device R3

```
set interfaces fe-1/2/1 unit 0 description to-R2
set interfaces fe-1/2/1 unit 0 family inet address 10.10.10.6/30
set interfaces fe-1/2/2 unit 0 description to-R4
set interfaces fe-1/2/2 unit 0 family inet address 10.10.10.9/30
set interfaces lo0 unit 0 family inet address 172.16.3.3/32
set protocols bgp group internal-peers type internal
set protocols bgp group internal-peers local-address 172.16.3.3
set protocols bgp group internal-peers neighbor 172.16.2.2
set protocols bgp group internal-peers neighbor 172.16.1.1
set protocols bgp group internal-peers neighbor 172.16.4.4
set protocols ospf area 0.0.0.0 interface lo0.0 passive
set protocols ospf area 0.0.0.0 interface fe-1/2/1.0
set protocols ospf area 0.0.0.0 interface fe-1/2/2.0
set routing-options router-id 172.16.3.3
set routing-options autonomous-system 17
```

Device R4

```
set interfaces fe-1/2/2 unit 0 description to-R3
set interfaces fe-1/2/2 unit 0 family inet address 10.10.10.10/30
set interfaces lo0 unit 0 family inet address 172.16.4.4/32
set protocols bgp group internal-peers type internal
set protocols bgp group internal-peers local-address 172.16.4.4
set protocols bgp group internal-peers neighbor 172.16.2.2
set protocols bgp group internal-peers neighbor 172.16.1.1
set protocols bgp group internal-peers neighbor 172.16.3.3
set protocols ospf area 0.0.0.0 interface lo0.0 passive
set protocols ospf area 0.0.0.0 interface fe-1/2/2.0
set routing-options router-id 172.16.4.4
set routing-options autonomous-system 17
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure an IS-IS default route policy:

1. Configure the device interfaces.

```
[edit interfaces]
user@R1# set fe-1/2/0 unit 0 description to-R2
user@R1# set fe-1/2/0 unit 0 family inet address 10.10.10.1/30
user@R1# set lo0 unit 0 family inet address 172.16.1.1/32
```

2. Enable OSPF, or another interior gateway protocols (IGP), on the interfaces.

```
[edit protocols OSPF area 0.0.0.0]
user@R1# set interface lo0.0 passive
user@R1# set interface fe-1/2/0.0
```

3. Configure static routes.

```
[edit routing-options]
user@R1# set static route 192.168.0.1/32 discard
user@R1# set static route 192.168.20.1/32 discard
```

4. Enable the routing policies.

```
[edit protocols policy-options]
user@R1# set policy-statement send-direct term 1 from protocol direct
user@R1# set policy-statement send-direct term 1 then accept
user@R1# set policy-statement send-static-192.168.0 term 1 from protocol static
user@R1# set policy-statement send-static-192.168.0 term 1 from route-filter 192.168.0.0/24 orlonger
user@R1# set policy-statement send-static-192.168.0 term 1 then accept
user@R1# set policy-statement send-static-192.168.20 term 1 from protocol static
user@R1# set policy-statement send-static-192.168.20 term 1 from route-filter 192.168.20.0/24 orlonger
user@R1# set policy-statement send-static-192.168.20 term 1 then accept
```

5. Configure BGP and apply the export policies.

```
[edit protocols bgp]
```

```

user@R1# set local-address 172.16.1.1
user@R1# set group internal-peers type internal
user@R1# set group internal-peers export send-static-192.168.0
user@R1# set group internal-peers neighbor 172.16.2.2 export send-static-192.168.20
user@R1# set group internal-peers neighbor 172.16.3.3
user@R1# set group other-group type internal
user@R1# set group other-group neighbor 172.16.4.4

```

6. Configure the router ID and autonomous system (AS) number.

```

[edit routing-options]
user@R1# set router-id 172.16.1.1
user@R1# set autonomous-system 17

```

7. If you are done configuring the device, commit the configuration.

```

[edit]
user@R1# commit

```

Results

From configuration mode, confirm your configuration by issuing the **show interfaces**, **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

user@R1# show interfaces
fe-1/2/0 {
  unit 0 {
    description to-R2;
    family inet {
      address 10.10.10.1/30;
    }
  }
}
lo0 {
  unit 0 {
    family inet {
      address 172.16.1.1/32;
    }
  }
}

```

```

user@R1# show protocols
bgp {
  local-address 172.16.1.1;
  export send-direct;
  group internal-peers {
    type internal;
    export send-static-192.168.0;
    neighbor 172.16.2.2 {
      export send-static-192.168.20;
    }
    neighbor 172.16.3.3;
  }
  group other-group {
    type internal;
    neighbor 172.16.4.4;
  }
}
ospf {
  area 0.0.0.0 {
    interface lo0.0 {
      passive;
    }
    interface fe-1/2/0.0;
  }
}

```

```

user@R1# show policy-options
policy-statement send-direct {
  term 1 {
    from protocol direct;
    then accept;
  }
}
policy-statement send-static-192.168.0 {
  term 1 {
    from {
      protocol static;
      route-filter 192.168.0.0/24 orlonger;
    }
    then accept;
  }
}
policy-statement send-static-192.168.20 {
  term 1 {

```

```

    from {
        protocol static;
        route-filter 192.168.20.0/24 orlonger;
    }
    then accept;
}
}

```

```

user@R1# show routing-options
static {
    route 192.168.0.1/32 discard;
    route 192.168.20.1/32 discard;
}
router-id 172.16.1.1;
autonomous-system 17;

```

Verification

IN THIS SECTION

- [Verifying BGP Route Learning | 33](#)
- [Verifying BGP Route Receiving | 35](#)

Confirm that the configuration is working properly.

Verifying BGP Route Learning

Purpose

Make sure that the BGP export policies are working as expected by checking the routing tables.

Action

```
user@R1> show route protocol direct
```

```

inet.0: 11 destinations, 11 routes (11 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

172.16.1.1/32          *[Direct/0] 1d 22:19:47

```

```

10.10.10.0/30      > via lo0.0
                  *[Direct/0] 1d 22:19:47
                  > via fe-1/2/0.0

```

user@R1> **show route protocol static**

```

inet.0: 11 destinations, 11 routes (11 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192.168.0.1/32      *[Static/5] 02:20:03
                   Discard
192.168.20.1/32     *[Static/5] 02:20:03
                   Discard

```

user@R2> **show route protocol bgp**

```

inet.0: 11 destinations, 11 routes (11 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192.168.20.1/32     *[BGP/170] 02:02:40, localpref 100, from 172.16.1.1
                   AS path: I, validation-state: unverified
                   > to 10.10.10.1 via fe-1/2/0.0

```

user@R3> **show route protocol bgp**

```

inet.0: 11 destinations, 11 routes (11 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192.168.0.1/32      *[BGP/170] 02:02:51, localpref 100, from 172.16.1.1
                   AS path: I, validation-state: unverified
                   > to 10.10.10.5 via fe-1/2/1.0

```

user@R4> **show route protocol bgp**

```

inet.0: 9 destinations, 11 routes (9 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

```

```

172.16.1.1/32      [BGP/170] 1d 20:38:54, localpref 100, from 172.16.1.1
                  AS path: I, validation-state: unverified
> to 10.10.10.9 via fe-1/2/2.0
10.10.10.0/30     [BGP/170] 1d 20:38:54, localpref 100, from 172.16.1.1
                  AS path: I, validation-state: unverified
> to 10.10.10.9 via fe-1/2/2.0

```

Meaning

On Device R1, the **show route protocol direct** command displays two direct routes: 172.16.1.1/32 and 10.10.10.0/30. The **show route protocol static** command displays two static routes: 192.168.0.1/32 and 192.168.20.1/32.

On Device R2, the **show route protocol bgp** command shows that the only route that Device R2 has learned through BGP is the 192.168.20.1/32 route.

On Device R3, the **show route protocol bgp** command shows that the only route that Device R3 has learned through BGP is the 192.168.0.1/32 route.

On Device R4, the **show route protocol bgp** command shows that the only routes that Device R4 has learned through BGP are the 172.16.1.1/32 and 10.10.10.0/30 routes.

Verifying BGP Route Receiving

Purpose

Make sure that the BGP export policies are working as expected by checking the BGP routes received from Device R1.

Action

```
user@R2> show route receive-protocol bgp 172.16.1.1
```

```

inet.0: 11 destinations, 11 routes (11 active, 0 holddown, 0 hidden)
  Prefix                Nexthop                MED      Lclpref    AS path
* 192.168.20.1/32      172.16.1.1              100         100         I

```

```
user@R3> show route receive-protocol bgp 172.16.1.1
```

```

inet.0: 11 destinations, 11 routes (11 active, 0 holddown, 0 hidden)

```

Prefix	Nexthop	MED	Lclpref	AS path
* 192.168.0.1/32	172.16.1.1		100	I

user@R4> **show route receive-protocol bgp 172.16.1.1**

```
inet.0: 9 destinations, 11 routes (9 active, 0 holddown, 0 hidden)
```

Prefix	Nexthop	MED	Lclpref	AS path
172.16.1.1/32	172.16.1.1		100	I
10.10.10.0/30	172.16.1.1		100	I

Meaning

On Device R2, the **route receive-protocol bgp 172.16.1.1** command shows that Device R2 received only one BGP route, 192.168.20.1/32, from Device R1.

On Device R3, the **route receive-protocol bgp 172.16.1.1** command shows that Device R3 received only one BGP route, 192.168.0.1/32, from Device R1.

On Device R4, the **route receive-protocol bgp 172.16.1.1** command shows that Device R4 received two BGP routes, 172.16.1.1/32 and 10.10.10.0/30, from Device R1.

In summary, when multiple policies are applied at different CLI hierarchies in BGP, only the most specific application is evaluated, to the exclusion of other, less specific policy applications. Although this point might seem to make sense, it is easily forgotten during router configuration, when you mistakenly believe that a neighbor-level policy is combined with a global or group-level policy, only to find that your policy behavior is not as anticipated.

Default Routing Policies

If an incoming or outgoing route or packet arrives and there is no explicitly configured policy related to the route or to the interface upon which the packet arrives, the action specified by the default policy is taken. A *default policy* is a rule or a set of rules that determine whether the route is placed in or advertised from the routing table, or whether the packet is accepted into or transmitted from the router interface.

You must be familiar with the default routing policies to know when you need to modify them to suit your needs. [Table 6 on page 37](#) summarizes the default routing policies for each routing protocol that imports and exports routes. The actions in the default routing policies are taken if you have not explicitly configured a routing policy. This table also shows direct and explicitly configured routes, which for the purposes of this table are considered a pseudoprotocol. Explicitly configured routes include aggregate, generated, and static routes.

Table 6: Default Import and Export Policies for Protocols

Importing or Exporting Protocol	Default Import Policy	Default Export Policy
BGP	Accept all received BGP IPv4 routes learned from configured neighbors and import into the inet.0 routing table. Accept all received BGP IPv6 routes learned from configured neighbors and import into the inet6.0 routing table.	Readvertise all active BGP routes to all BGP speakers, while following protocol-specific rules that prohibit one IBGP speaker from readvertising routes learned from another IBGP speaker, unless it is functioning as a route reflector.
DVMRP	Accept all DVMRP routes and import into the inet.1 routing table.	Accept and export active DVMRP routes.
IS-IS	Accept all IS-IS routes and import into the inet.0 and inet6.0 routing tables. More information is available here: <i>import (Protocols IS-IS)</i>	Reject everything. (The protocol uses flooding to announce local routes and any learned routes.)
LDP	Accept all LDP routes and import into the inet.3 routing table.	Reject everything.

Table 6: Default Import and Export Policies for Protocols (*continued*)

Importing or Exporting Protocol	Default Import Policy	Default Export Policy
MPLS	Accept all MPLS routes and import into the inet.3 routing table.	Accept and export active MPLS routes.
OSPF	Accept all OSPF routes and import into the inet.0 routing table. (You cannot override or change this default policy.)	Reject everything. (The protocol uses flooding to announce local routes and any learned routes.)
PIM dense mode	Accept all PIM dense mode routes and import into the inet.1 routing table.	Accept active PIM dense mode routes.
PIM sparse mode	Accept all PIM sparse mode routes and import into the inet.1 routing table.	Accept and export active PIM sparse mode routes.
Pseudoprotocol: <ul style="list-style-type: none"> • Direct routes • Explicitly configured routes: <ul style="list-style-type: none"> • Aggregate routes • Generated routes • Static routes 	Accept all direct and explicitly configured routes and import into the inet.0 routing table.	The pseudoprotocol cannot export any routes from the routing table because it is not a routing protocol. Routing protocols can export these or any routes from the routing table.
RIP	Accept all RIP routes learned from configured neighbors and import into the inet.0 routing table.	Reject everything. To export RIP routes, you must configure an export policy for RIP.
RIPng	Accept all RIPng routes learned from configured neighbors and import into the inet6.0 routing table.	Reject everything. To export RIPng routes, you must configure an export policy for RIPng.

Table 6: Default Import and Export Policies for Protocols (*continued*)

Importing or Exporting Protocol	Default Import Policy	Default Export Policy
Test policy	Accept all routes. For additional information about test policy, see “Example: Testing a Routing Policy with Complex Regular Expressions” on page 689.	

OSPF and IS-IS Import Policies

For OSPF, import policies apply to external routes only. An external route is a route that is outside the OSPF autonomous system (AS). For internal routes (routes learned from OSPF), you cannot change the default import policy for OSPF. As link-state protocols, IS-IS and OSPF exchange routes between systems within an autonomous system (AS). All routers and systems within an AS must share the same link-state database, which includes routes to reachable prefixes and the metrics associated with the prefixes. If an import policy is configured and applied to IS-IS or OSPF, some routes might not be learned or advertised or the metrics for learned routes might be altered, which would make a consistent link-state database impossible.

The default export policy for IS-IS and OSPF protocols is to reject everything. These protocols do not actually export their internally learned routes (the directly connected routes on interfaces that are running the protocol). Both IS-IS and OSPF protocols use a procedure called flooding to announce local routes and any routes learned by the protocol. The flooding procedure is internal to the protocol, and is unaffected by the policy framework. Exporting can be used only to announce information from other protocols, and the default is not to do so.

Automatic Export

For Layer 3 VPNs, the automatic export feature can be configured to overcome the limitation of local prefix leaking and automatically export routes between local VPN routing and forwarding (VRF) routing instances.

In Layer 3 VPNs, multiple CE routers can belong to a single VRF routing instance on a PE router. A PE router can have multiple VRF routing instances. In some cases, shared services might require routes to be written to multiple VRF routing tables, both at the local and remote PE router. This requires the PE router to share route information among each configured VRF routing instance. This exchange of route information is accomplished with custom **vrf-export** and **vrf-import** policies that utilize BGP extended community attributes to create hub-and-spoke topologies. This exchange of routing information, such as route prefixes, is known as prefix leaking.

The automatic export feature leaks prefixes between VRF routing instances that are locally configured on a given PE router. The automatic export feature is enabled by using the **auto-export** statement.

Automatic export is always applied on the local PE router, because it takes care of only local prefix leaking by evaluating the export policy of each VRF and determining which route targets can be leaked locally. The standard VRF import and export policies still affect only the remote PE prefix leaking.

If the **vrf-export** policy examined by the automatic export does not have an explicit **then accept** action, the automatic export essentially ignores the policy and, therefore, does not leak the route targets specified within it.

Example: Configuring a Conditional Default Route Policy

IN THIS SECTION

- [Requirements | 40](#)
- [Overview | 40](#)
- [Configuration | 41](#)
- [Verification | 46](#)

This example shows how to configure a conditional default route on one routing device and redistribute the default route into OSPF.

Requirements

No special configuration beyond device initialization is required before configuring this example.

Overview

In this example, OSPF area 0 contains three routing devices. Device R3 has a BGP session with an external peer, for example, an Internet Service Provider (ISP).

To propagate a static route into BGP, this example includes the **discard** statement when defining the route. The ISP injects a default static route into BGP, which provides the customer network with a default static

route to reach external networks. The static route has a discard next hop. This means that if a packet does not match a more specific route, the packet is rejected and a reject route for this destination is installed in the routing table, but Internet Control Message Protocol (ICMP) unreachable messages are not sent. The discard next hop allows you to originate a summary route, which can be advertised through dynamic routing protocols.

Device R3 exports the default route into OSPF. The route policy on Device R3 is conditional such that if the connection to the ISP goes down, the default route is no longer exported into OSPF because it is no longer active in the routing table. This policy prevents packets from being silently dropped without notification (also known as blackholing).

This example shows the configuration for all of the devices and the step-by-step configuration on Device R3.

Figure 7 on page 41 shows the sample network.

Figure 7: OSPF with a Conditional Default Route to an ISP

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level.

Device R1

```
set interfaces fe-1/2/0 unit 0 description R1->R3
set interfaces fe-1/2/0 unit 0 family inet address 10.0.1.2/30
set interfaces fe-1/2/1 unit 2 description R1->R2
```

```

set interfaces fe-1/2/1 unit 2 family inet address 10.0.0.1/30
set protocols ospf area 0.0.0.0 interface fe-1/2/0.0
set protocols ospf area 0.0.0.0 interface fe-1/2/1.2

```

Device R2

```

set interfaces fe-1/2/0 unit 1 description R2->R1
set interfaces fe-1/2/0 unit 1 family inet address 10.0.0.2/30
set interfaces fe-1/2/1 unit 4 description R2->R3
set interfaces fe-1/2/1 unit 4 family inet address 10.0.2.2/30
set protocols ospf area 0.0.0.0 interface fe-1/2/0.1
set protocols ospf area 0.0.0.0 interface fe-1/2/1.4

```

Device R3

```

set interfaces fe-1/2/0 unit 3 description R3->R2
set interfaces fe-1/2/0 unit 3 family inet address 10.0.2.1/30
set interfaces fe-1/2/1 unit 5 description R3->R1
set interfaces fe-1/2/1 unit 5 family inet address 10.0.1.1/30
set interfaces ge-0/0/2 unit 0 description R3->ISP
set interfaces ge-0/0/2 unit 0 family inet address 10.0.45.2/30
set protocols bgp group ext type external
set protocols bgp group ext peer-as 64500
set protocols bgp group ext neighbor 10.0.45.1
set protocols ospf export gendefault
set protocols ospf area 0.0.0.0 interface fe-1/2/1.4
set protocols ospf area 0.0.0.0 interface fe-1/2/0.3
set policy-options policy-statement gendefault term upstreamroutes from protocol bgp
set policy-options policy-statement gendefault term upstreamroutes from as-path upstream
set policy-options policy-statement gendefault term upstreamroutes from route-filter 0.0.0.0/0 upto
  /16

set policy-options policy-statement gendefault term end then reject
set policy-options as-path upstream "^64500 "
set routing-options autonomous-system 64501

```

Device ISP

```

set interfaces ge-0/0/2 unit 0 family inet address 10.0.45.1/30
set protocols bgp group ext type external
set protocols bgp group ext export advertise-default
set protocols bgp group ext peer-as 64501
set protocols bgp group ext neighbor 10.0.45.2
set policy-options policy-statement advertise-default term 1 from route-filter 0.0.0.0/0 exact
set policy-options policy-statement advertise-default term 1 then accept
set routing-options static route 0.0.0.0/0 discard
set routing-options autonomous-system 64500

```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure Device R3:

1. Configure the interfaces.

```

[edit interfaces]
user@R3# set fe-1/2/0 unit 3 description R3->R2
user@R3# set fe-1/2/0 unit 3 family inet address 10.0.2.1/30
user@R3# set fe-1/2/1 unit 5 description R3->R1
user@R3# set fe-1/2/1 unit 5 family inet address 10.0.1.1/30
user@R3# set ge-0/0/2 unit 0 description R3->ISP
user@R3# set ge-0/0/2 unit 0 family inet address 10.0.45.2/30

```

2. Configure the autonomous system (AS) number.

```

[edit routing-options]
user@R3# set autonomous-system 64501

```

3. Configure the BGP session with the ISP device.

```

[edit protocols bgp group ext]
user@R3# set type external
user@R3# set peer-as 64500

```

```
user@R3# set neighbor 10.0.45.1
```

4. Configure OSPF.

```
[edit protocols ospf area 0.0.0.0]
user@R3# set interface fe-1/2/1.4
user@R3# set interface fe-1/2/0.3
```

5. Configure the routing policy.

```
[edit policy-options policy-statement gendefault]
user@R3# set term upstreamroutes from protocol bgp
user@R3# set term upstreamroutes from as-path upstream
user@R3# set term upstreamroutes from route-filter 0.0.0.0/0 upto /16
user@R3# set term upstreamroutes then next-hop 10.0.45.1
user@R3# set term upstreamroutes then accept
user@R3# set term end then reject
[edit policy-options]
user@R3# set as-path upstream "^64500 "
```

6. Apply the export policy to OSPF.

```
[edit protocols ospf]
user@R3# set export gendefault
```

7. If you are done configuring the device, commit the configuration.

```
[edit]
user@R3# commit
```

Results

Confirm your configuration by issuing the **show** command. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R3# show
interfaces {
```

```

fe-1/2/0 {
  unit 3 {
    description R3->R2;
    family inet {
      address 10.0.2.1/30;
    }
  }
}
fe-1/2/1 {
  unit 5 {
    description R3->R1;
    family inet {
      address 10.0.1.1/30;
    }
  }
}
ge-1/2/0 {
  unit 0 {
    description R3->ISP;
    family inet {
      address 10.0.45.2/30;
    }
  }
}
}
protocols {
  bgp {
    group ext {
      type external;
      peer-as 64500;
      neighbor 10.0.45.1;
    }
  }
  ospf {
    export gendefault;
    area 0.0.0.0 {
      interface fe-1/2/1.4;
      interface fe-1/2/0.3;
    }
  }
}
policy-options {
  policy-statement gendefault {
    term upstreamroutes {

```

```
    from {
        protocol bgp;
        as-path upstream;
        route-filter 0.0.0.0/0 upto /16;
    }
    then {
        next-hop 10.0.45.1;
        accept;
    }
}
term end {
    then reject;
}
}
as-path upstream "^64500 ";
}
routing-options {
    autonomous-system 64501;
}
```

Verification

IN THIS SECTION

- [Verifying That the Route to the ISP Is Working | 46](#)
- [Verifying That the Static Route Is Redistributed | 47](#)
- [Testing the Policy Condition | 48](#)

Confirm that the configuration is working properly.

Verifying That the Route to the ISP Is Working

Purpose

Make sure connectivity is established between Device R3 and the ISP's router.

Action

```
user@R3> ping 10.0.45.1
```

```
PING 10.0.45.1 (10.0.45.1): 56 data bytes
64 bytes from 10.0.45.1: icmp_seq=0 ttl=64 time=1.185 ms
64 bytes from 10.0.45.1: icmp_seq=1 ttl=64 time=1.199 ms
64 bytes from 10.0.45.1: icmp_seq=2 ttl=64 time=1.186 ms
```

Meaning

The **ping** command confirms reachability.

Verifying That the Static Route Is Redistributed

Purpose

Make sure that the BGP policy is redistributing the static route into Device R3's routing table. Also make sure that the OSPF policy is redistributing the static route into the routing tables of Device R1 and Device R2.

Action

user@R3> **show route protocol bgp**

```
inet.0: 9 destinations, 10 routes (9 active, 0 holddown, 1 hidden)
+ = Active Route, - = Last Active, * = Both

0.0.0.0/0          *[BGP/170] 00:00:25, localpref 100
                   AS path: 64500 I
                   > to 10.0.45.1 via ge-0/0/2.6
```

user@R1> **show route protocol ospf**

```
inet.0: 7 destinations, 7 routes (7 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

0.0.0.0/0          *[OSPF/150] 00:03:58, metric 0, tag 0
                   > to 10.0.1.1 via fe-1/2/0.0
10.0.2.0/30        *[OSPF/10] 03:37:45, metric 2
                   to 10.0.1.1 via fe-1/2/0.0
                   > to 10.0.0.2 via fe-1/2/1.2
```

```
172.16.233.5/32      *[OSPF/10] 03:38:41, metric 1
MultiRecv
```

user@R2> **show route protocol ospf**

```
inet.0: 7 destinations, 7 routes (7 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

0.0.0.0/0           *[OSPF/150] 00:04:04, metric 0, tag 0
> to 10.0.2.1 via fe-1/2/1.4
10.0.1.0/30         *[OSPF/10] 03:37:46, metric 2
to 10.0.0.1 via fe-1/2/0.1
> to 10.0.2.1 via fe-1/2/1.4
172.16.233.5/32     *[OSPF/10] 03:38:47, metric 1
MultiRecv
```

Meaning

The routing tables contain the default 0.0.0.0/0 route. If Device R1 and Device R2 receive packets destined for networks not specified in their routing tables, those packets will be sent to Device R3 for further processing. If Device R3 receives packets destined for networks not specified in its routing table, those packets will be sent to the ISP for further processing.

Testing the Policy Condition

Purpose

Deactivate the interface to make sure that the route is removed from the routing tables if the external network becomes unreachable.

Action

user@R3> **deactivate interfaces ge-0/0/2 unit 0 family inet address 10.0.45.2/30**

user@R3> **commit**

user@R1> **show route protocol ospf**

```
inet.0: 6 destinations, 6 routes (6 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.0.2.0/30         *[OSPF/10] 03:41:48, metric 2
```

```

to 10.0.1.1 via fe-1/2/0.0
> to 10.0.0.2 via fe-1/2/1.2
172.16.233.5/32      *[OSPF/10] 03:42:44, metric 1
MultiRecv

```

user@R2> **show route protocol ospf**

```

inet.0: 6 destinations, 6 routes (6 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.0.1.0/30          *[OSPF/10] 03:42:10, metric 2
to 10.0.0.1 via fe-1/2/0.1
> to 10.0.2.1 via fe-1/2/1.4
172.16.233.5/32      *[OSPF/10] 03:43:11, metric 1
MultiRecv

```

Meaning

The routing tables on Device R1 and Device R2 do not contain the default 0.0.0.0/0 route. This verifies that the default route is no longer present in the OSPF domain. To reactivate the ge-0/0/2.6 interface, issue the **activate interfaces ge-0/0/2 unit 0 family inet address 10.0.45.2/30** configuration mode command.

Evaluating Routing Policies Using Match Conditions, Actions, Terms, and Expressions

How a Routing Policy Is Evaluated

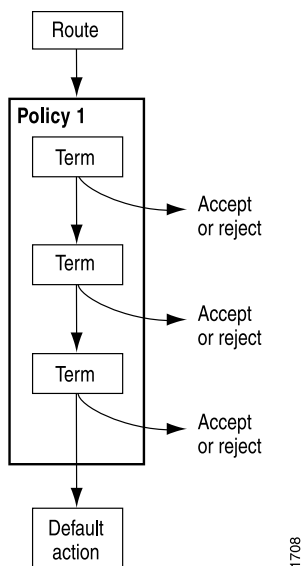

[Figure 8 on page 51](#) shows how a single routing policy is evaluated. This routing policy consists of multiple terms. Each term consists of match conditions and actions to apply to matching routes. Each route is evaluated against the policy as follows:

1. The route is evaluated against the first term. If it matches, the specified action is taken. If the action is to accept or reject the route, that action is taken and the evaluation of the route ends. If the next term

action is specified, if no action is specified, or if the route does not match, the evaluation continues as described in Step 2. If the next policy action is specified, any accept or reject action specified in this term is skipped, all remaining terms in this policy are skipped, all other actions are taken, and the evaluation continues as described in Step 3.

2. The route is evaluated against the second term. If it matches, the specified action is taken. If the action is to accept or reject the route, that action is taken and the evaluation of the route ends. If the next term action is specified, if no action is specified, or if the route does not match, the evaluation continues in a similar manner against the last term. If the next policy action is specified, any accept or reject action specified in this term is skipped, all remaining terms in this policy are skipped, all other actions are taken, and the evaluation continues as described in Step 3.
3. If the route matches no terms in the routing policy or the next policy action is specified, the accept or reject action specified by the default policy is taken. For more information about the default routing policies, see [“Default Routing Policies” on page 37](#).

Figure 8: Routing Policy Evaluation

Categories of Routing Policy Match Conditions

A *match condition* defines the criteria that a route must match. You can define one or more match conditions. If a route matches all match conditions, one or more actions are applied to the route.

Match conditions fall into two categories: standard and extended. In general, the extended match conditions are more complex than standard match conditions. The extended match conditions provide many powerful

capabilities. The standard match conditions include criteria that are defined within a routing policy and are less complex than the extended match conditions, also called named match conditions.

Extended match conditions are defined separately from the routing policy and are given names. You then reference the name of the match condition in the definition of the routing policy itself.

Named match conditions allow you to do the following:

- Reuse match conditions in other routing policies.
- Read configurations that include complex match conditions more easily.

Named match conditions include communities, prefix lists, and AS path regular expressions.

[Table 7 on page 52](#) describes each match condition, including its category, when you typically use it, and any relevant notes about it. For more information about match conditions, see [“Routing Policy Match Conditions” on page 54](#).

Table 7: Match Condition Concepts

Match Condition	Category	When to Use	Notes
AS path regular expression—A combination of AS numbers and regular expression operators.	Extended	(BGP only) Match a route based on its AS path. (An AS path consists of the AS numbers of all routers a packet must go through to reach a destination.) You can specify an exact match with a particular AS path or a less precise match.	You use regular expressions to match the AS path.
Community—A group of destinations that share a property. (Community information is included as a path attribute in BGP update messages.)	Extended	Match a group of destinations that share a property. Use a routing policy to define a community that specifies a group of destinations you want to match and one or more actions that you want taken on this community.	<p>Actions can be performed on the entire group.</p> <p>You can create multiple communities associated with a particular destination.</p> <p>You can create match conditions using regular expressions.</p>
Prefix list—A named list of IP addresses.	Extended	Match a route based on prefix information. You can specify an exact match of a particular route only.	You can specify a common action only for all prefixes in the list.

Table 7: Match Condition Concepts (*continued*)

Match Condition	Category	When to Use	Notes
Route list—A list of destination prefixes.	Extended	Match a route based on prefix information. You can specify an exact match of a particular route or a less precise match.	You can specify an action for each prefix in the route list or a common action for all prefixes in the route list.
Standard—A collection of criteria that can match a route.	Standard	Match a route based on one of the following criteria: area ID, color, external route, family, instance (routing), interface name, level number, local preference, metric, neighbor address, next-hop address, origin, preference, protocol, routing table name, or tag. You can specify a match condition for policies based on protocols by naming a protocol from which the route is learned or to which the route is being advertised.	None.
Subroutine—A routing policy that is called repeatedly from another routing policy.	Extended	Use an effective routing policy in other routing policies. You can create a subroutine that you can call over and over from other routing policies.	The subroutine action influences but does not necessarily determine the final action. For more information, see “How a Routing Policy Subroutine Is Evaluated” on page 261 .

Each term can consist of two statements, **from** and **to**, that define match conditions:

- In the **from** statement, you define the criteria that an *incoming* route must match. You can specify one or more match conditions. If you specify more than one, all conditions must match the route for a match to occur.
- In the **to** statement, you define the criteria that an *outgoing* route must match. You can specify one or more match conditions. If you specify more than one, all conditions must match the route for a match to occur.

The order of match conditions in a term is not important, because a route must match all match conditions in a term for an action to be taken.

RELATED DOCUMENTATION

[Routing Policy Match Conditions](#) | 54

Routing Policy Match Conditions

Each term in a routing policy can include two statements, **from** and **to**, to define the conditions that a route must match for the policy to apply:

```
from {  
    family family-name;  
    match-conditions;  
    policy subroutine-policy-name;  
    prefix-list name;  
    route-filter destination-prefix match-type <actions>;  
    source-address-filter source-prefix match-type <actions>;  
}  
to {  
    match-conditions;  
    policy subroutine-policy-name;  
}
```

In the **from** statement, you define the criteria that an incoming route must match. You can specify one or more match conditions. If you specify more than one, they all must match the route for a match to occur.

The **from** statement is optional. If you omit the **from**, all routes are considered to match. All routes then take the configured actions of the policy term.

In the **to** statement, you define the criteria that an outgoing route must match. You can specify one or more match conditions. If you specify more than one, they all must match the route for a match to occur. You can specify most of the same match conditions in the **to** statement that you can in the **from** statement. In most cases, specifying a match condition in the **to** statement produces the same result as specifying the same match condition in the **from** statement.

The **to** statement is optional. If you omit both the **to** and the **from** statements, all routes are considered to match.

[Table 8 on page 55](#) summarizes key routing policy match conditions.

Table 8: Summary of Key Routing Policy Match Conditions

Match Condition	Description
aggregate-contributor	Matches routes that are contributing to a configured aggregate. This match condition can be used to suppress a contributor in an aggregate route.
area <i>area-id</i>	Matches a route learned from the specified OSPF area during the exporting of OSPF routes into other protocols.
as-path <i>name</i>	Matches the name of the path regular expression of an autonomous systems (AS). BGP routes whose AS path matches the regular expression are processed.
color <i>preference</i>	Matches a color value. You can specify preference values that are finer-grained than those specified in the preference match conditions. The color value can be a number from 0 through 4,294,967,295 ($2^{32} - 1$). A lower number indicates a more preferred route.
community	Matches the name of one or more communities. If you list more than one name, only one name needs to match for a match to occur. (The matching is effectively a logical OR operation.)
external [<i>type metric-type</i>]	Matches external OSPF routes, including routes exported from one level to another. In this match condition, type is an optional keyword. The metric-type value can be either 1 or 2. When you do not specify type , this condition matches all external routes.
interface <i>interface-name</i>	<p>Matches the name or IP address of one or more router interfaces. Use this condition with protocols that are interface-specific. For example, do not use this condition with internal BGP (IBGP).</p> <p>Depending on where the policy is applied, this match condition matches routes learned from or advertised through the specified interface.</p>
internal	Matches a routing policy against the internal flag for simplified next-hop self policies.
level <i>level</i>	Matches the IS-IS level. Routes that are from the specified level or are being advertised to the specified level are processed.
local-preference <i>value</i>	Matches a BGP local preference attribute. The preference value can be from 0 through 4,294,967,295 ($2^{32} - 1$).

Table 8: Summary of Key Routing Policy Match Conditions (*continued*)

Match Condition	Description
lsp lsp-regex	<p>Match the LSP name or LSP name regular expression. These match conditions are mutually exclusive and only one of them can be configured at a given point in time.</p> <p>The LSP type supported is PCE-initiated segment routing LSPs only.</p>
metric <i>metric</i> metric2 <i>metric</i>	Matches a metric value. The metric value corresponds to the multiple exit discriminator (MED), and metric2 corresponds to the IGP metric if the BGP next hop runs back through another route.
neighbor <i>address</i>	<p>Matches the address of one or more neighbors (peers).</p> <p>For BGP export policies, the address can be for a directly connected or indirectly connected peer. For all other protocols, the address is for the neighbor from which the advertisement is received.</p>
next-hop <i>address</i>	Matches the next-hop address or addresses specified in the routing information for a particular route. For BGP routes, matches are performed against each protocol next hop.
origin <i>value</i>	<p>Matches the BGP origin attribute, which is the origin of the AS path information. The value can be one of the following:</p> <ul style="list-style-type: none"> • egp—Path information originated from another AS. • igp—Path information originated from within the local AS. • incomplete—Path information was learned by some other means.
preference <i>preference</i> preference2 <i>preference</i>	<p>Matches the preference value. You can specify a primary preference value (preference) and a secondary preference value (preference2). The preference value can be a number from 0 through 4,294,967,295 ($2^{32} - 1$). A lower number indicates a more preferred route.</p> <p>NOTE: Do not set preference2 for BGP route-policy.</p>
protocol <i>protocol</i>	Matches the name of the protocol from which the route was learned or to which the route is being advertised. It can be one of the following: aggregate , bgp , direct , dvmrp , isis , local , ospf , pim-dense , pim-sparse , rip , ripng , or static .
route-type <i>value</i>	Matches the type of route. The value can be either external or internal .

All conditions in the **from** and **to** statements must match for the action to be taken. The match conditions defined in [Table 9 on page 57](#) are effectively a logical AND operation. Matching in prefix lists and route lists is handled differently. They are effectively a logical OR operation. If you configure a policy that includes

some combination of route filters, prefix lists, and source address filters, they are evaluated according to a logical OR operation or a longest-route match lookup.

Table 9 on page 57 describes the match conditions available for matching an incoming or outgoing route. The table indicates whether you can use the match condition in both **from** and **to** statements and whether the match condition functions the same or differently when used with both statements. If a match condition functions differently in a **from** statement than in a **to** statement, or if the condition cannot be used in one type of statement, there is a separate description for each type of statement. Otherwise, the same description applies to both types of statements.

Table 9 on page 57 also indicates whether the match condition is standard or extended. In general, the extended match conditions include criteria that are defined separately from the routing policy (autonomous system [AS] path regular expressions, communities, and prefix lists) and are more complex than standard match conditions. The extended match conditions provide many powerful capabilities. The standard match conditions include criteria that are defined within a routing policy and are less complex than the extended match conditions.

Table 9: Complete List of Routing Policy Match Conditions

Match Condition	Match Condition Category	Statement Description
aggregate-contributor	Standard	Match routes that are contributing to a configured aggregate. This match condition can be used to suppress a contributor in an aggregate route.
area <i>area-id</i>	Standard	(Open Shortest Path First [OSPF] only) Area identifier. In a from statement used with an export policy, match a route learned from the specified OSPF area when exporting OSPF routes into other protocols.
as-path <i>name</i>	Extended	(Border Gateway Protocol [BGP] only) Name of an AS path regular expression. For more information, see “Understanding AS Path Regular Expressions for Use as Routing Policy Match Conditions” on page 395 .
as-path-group <i>group-name</i>	Extended	(BGP only) Name of an AS path group regular expression. For more information, see “Understanding AS Path Regular Expressions for Use as Routing Policy Match Conditions” on page 395 .
color <i>preference</i> color2 <i>preference</i>	Standard	Color value. You can specify preference values (color and color2) that are finer-grained than those specified in the preference and preference2 match conditions. The color value can be a number in the range from 0 through 4,294,967,295 ($2^{32} - 1$). A lower number indicates a more preferred route.

Table 9: Complete List of Routing Policy Match Conditions (*continued*)

Match Condition	Match Condition Category	Statement Description
community-count <i>value</i> (equal orhigher orlower)	Standard	<p>(BGP only) Number of community entries required for a route to match. The count value can be a number in the range of 0 through 1,024. Specify one of the following options:</p> <ul style="list-style-type: none"> • equal—The number of communities must equal this value to be considered a match. • orhigher —The number of communities must be greater than or equal to this value to be considered a match. • orlower—The number of communities must be less than or equal to this value to be considered a match. <p>NOTE: If you configure multiple community-count statements, the matching is effectively a logical AND operation.</p> <p>NOTE: The community-count attribute only works with standard communities. It does not work with extended communities.</p> <p>This match condition is not supported for use with the To statement.</p>
community [<i>names</i>]	Extended	<p>Name of one or more communities. If you list more than one name, only one name needs to match for a match to occur (the matching is effectively a logical OR operation). For more information, see “Understanding BGP Communities, Extended Communities, and Large Communities as Routing Policy Match Conditions” on page 457.</p> <p>BGP EVPN routes have a set of EVPN extended communities (Type 6) carried in the BGP update message path attribute, and as such, you can use these EVPN extended communities for filtering BGP EVPN routes. The information available includes, for example, encapsulation type, mac-mobility information, EVPN split-horizon label information, ESI mode, Etree leaf label, and more.</p> <p>Use the following syntax to specify BGP EVPN extended communities:</p> <ul style="list-style-type: none"> • community (sub-type) val1:val2 <p>All values (including sub-type) are in decimal; type is 2 octets, where val1 and val2 can be specified as [2 + 4] octets, or as [4 + 2] octets. See EVPN Extended Community Sub-Types for the full list of EVPN extended community sub-type values.</p>

Table 9: Complete List of Routing Policy Match Conditions (*continued*)

Match Condition	Match Condition Category	Statement Description
external [type metric-type]	Standard	<p>(OSPF and IS-IS only) Match IGP external routes. For IS-IS routes, the external condition also matches routes that are exported from one IS-IS level to another. The type keyword is optional and is applicable only to OSPF external routes. When you do not specify type, the external condition matches all IGP external (OSPF and IS-IS) routes. When you specify type, the external condition matches only OSPF external routes with the specified OSPF metric type. The metric type can either be 1 or 2.</p> <p>To match BGP external routes, use the route-type match condition.</p>
evpn-esi	Standard	You can filter BGP EVPN routes on the basis of Ethernet Segment Identifiers (ESIs) information for routes types 1, 2, 4, 7, and 8, which are the only types to include the ESI attribute in their prefix. (ESI values are encoded as 10-byte integers and are used to identify a multihomed segment.) Note that the evpn-esi matching statement is valid only together with “family evpn” matching statement
evpn-etag	Standard	You can filter BGP EVPN routes on the basis of EVPN tag information, which is available from the prefix of the EVPN route. Requires EVPN be set in the following CLI hierarchy:
evpn-mac-route	Standard	<p>Filtering BGP EVPN Type 2 routes based on if it has any IP address.</p> <p>EVPN Type 2 MAC/IP Advertisement routes can have IP address in the prefix along with MAC address. The IP address carried in the MAC-IP Advertisement route can be either IPv4 or IPv6 address. It is possible to filter out Type 2 routes based on MAC address only, MAC+IPv4 address, or MAC+IPv6 address. To do so requires the following CLI statement be set:</p> <ul style="list-style-type: none"> • from evpn-mac-route [mac-ipv4 mac-ipv6 mac-only] <p>Note that this match statement is valid only together with the family evpn match statement.</p>
interface interface-name	Standard	<p>Name or IP address of one or more routing device interfaces. Do not use this qualifier with protocols that are not interface-specific, such as IBGP.</p> <p>Match a route learned from, or to be advertised to, one of the specified interfaces. Direct routes match routes configured on the specified interface.</p>
level level	Standard	<p>(Intermediate System-to-Intermediate System [IS-IS] only) IS-IS level.</p> <p>Match a route learned from, or to be advertised to, a specified level.</p>

Table 9: Complete List of Routing Policy Match Conditions (*continued*)

Match Condition	Match Condition Category	Statement Description
local-preference value	Standard	(BGP only) BGP local preference (LOCAL_PREF local-preference (add subtract) number) attribute. The preference value can be a number in the range 0 through 4,294,967,295 ($2^{32} - 1$).
mac-filter-list	Standard	(BGP only) Named MAC filter list. EVPN Type 2 routes have MAC address as part of the prefix, which you can use to create a list of MAC addresses.
multicast-scoping (scoping-name number) < (orhigher orlower) >	Standard	<p>Multicast scope value of IPv4 or IPv6 multicast group address. The multicast-scoping name corresponds to an IPv4 prefix. You can match on a specific multicast-scoping prefix or on a range of prefixes. Specify orhigher to match on a scope and numerically higher scopes, or orlower to match on a scope and numerically lower scopes. For more information, see the <i>Multicast Protocols User Guide</i> .</p> <p>You can apply this scoping policy to the routing table by including the scope-policy statement at the [edit routing-options] hierarchy level.</p> <p>The number value can be any hexadecimal number from 0 through F. The multicast-scope value is a number from 0 through 15, or one of the following keywords with the associated meanings:</p> <ul style="list-style-type: none"> • node-local (value=1)—No corresponding prefix • link-local (value=2)—Corresponding prefix 224.0.0.0/24 • site-local (value=5)—No corresponding prefix • global (value=14)—Corresponding prefix 224.0.1.0 through 238.255.255.255 • organization-local (value=8)—Corresponding prefix 239.192.0.0/14

Table 9: Complete List of Routing Policy Match Conditions (*continued*)

Match Condition	Match Condition Category	Statement Description
neighbor address	Standard	<p>Address of one or more neighbors (peers).</p> <p>For BGP, the address can be a directly connected or indirectly connected peer.</p> <p>For BGP <i>import</i> policies, specifying to neighbor produces the same result as specifying from neighbor.</p> <p>For BGP <i>export</i> policies, specifying the neighbor match condition has no effect and is ignored.</p> <p>For all other protocols, the address is the neighbor from which the advertisement is received, or for to statements, it matches the neighbor to which the advertisement is sent.</p> <p>NOTE: The neighbor address match condition is not valid for the Routing Information Protocol (RIP).</p>
next-hop [<i>addresses</i>]	Standard	One or more next-hop addresses specified in the routing information for a particular route. A next-hop address cannot include a netmask. For BGP routes, matches are performed against each protocol next hop.
next-hop-type merged	Standard	<p>LDP generates a next hop based on RSVP and IP next hops available to use, combined with forwarding-class mapping.</p> <p>This match condition is not supported for use with the To statement.</p>
nlri-route-type	Standard	<p>Route type from NLRI 1 through NLRI 10. Multiple route types can be specified in a single policy.</p> <p>For EVPN, NLRI route types range from 1 to 8 (the first octet of the route prefix in the BGP update message is the EVPN route type).</p>
origin value	Standard	<p>(BGP only) BGP origin attribute, which is the origin of the AS path information. The value can be one of the following:</p> <ul style="list-style-type: none"> • egp—Path information originated in another AS. • igp—Path information originated within the local AS. • incomplete—Path information was learned by some other means.
policy [<i>policy-name</i>]	Extended	<p>Name of a policy to evaluate as a subroutine.</p> <p>For information about this extended match condition, see “Understanding Policy Subroutines in Routing Policy Match Conditions” on page 257.</p>

Table 9: Complete List of Routing Policy Match Conditions (*continued*)

Match Condition	Match Condition Category	Statement Description
preference preference preference2 preference	Standard	<p>Preference value. You can specify a primary preference value (preference) and a secondary preference value (preference2). The preference value can be a number from 0 through 4,294,967,295 ($2^{32} - 1$). A lower number indicates a more preferred route.</p> <p>To specify even finer-grained preference values, see the color and color2 match conditions in this table.</p>
prefix-list prefix-list-name ip-addresses	Extended	<p>Named list of IP addresses. You can specify an exact match with incoming routes.</p> <p>For information about this extended match condition, see “Understanding Prefix Lists for Use in Routing Policy Match Conditions” on page 357.</p> <p>This match condition is not supported for use with the To statement.</p> <p>This match condition is not supported for use with the To statement.</p>
prefix-list-filter prefix-list-name match-type	Extended	<p>Both prefix-list and prefix-list-filter match conditions are supported. prefix-list is similar to prefix-list-filter, with the exception that a match-type can be specified only with prefix-list-filter. You can specify prefix length qualifiers for the list of prefixes in the prefix list.</p> <p>When used with EVPN NRLI route types 2 and 5, the following are supported:</p> <ul style="list-style-type: none"> • from prefix-list-filter [exact longer orlonger] <p>For information about this extended match condition, see “Understanding Prefix Lists for Use in Routing Policy Match Conditions” on page 357.</p> <p>This match condition is not supported for use with the To statement.</p>
protocol protocol	Standard	<p>Name of the protocol from which the route was learned or to which the route is being advertised. It can be one of the following: access, access-internal, aggregate, anchor, arp, bgp, bgp-ls-epe, bgp-static, direct, dvmrp, esis, evpn, frr, isis, l-isis, isis, l2-learned-host-routing, l2circuit, l2vpn, ldp, local, mpls, msdp, ospf (matches both OSPFv2 and OSPFv3 routes), ospf2 (matches OSPFv2 routes only), ospf3 (matches OSPFv3 routes only), pim, rift, rip, ripng, route-target, rsvp, spring-te, static, or vpls.</p>

Table 9: Complete List of Routing Policy Match Conditions (*continued*)

Match Condition	Match Condition Category	Statement Description
rib <i>routing-table</i>	Standard	<p>Name of a routing table. The value of <i>routing-table</i> can be one of the following:</p> <ul style="list-style-type: none"> • inet.0—Unicast IPv4 routes • <i>instance-name</i> inet.0—Unicast IPv4 routes for a particular routing instance • inet.1—Multicast IPv4 routes • inet.2—Unicast IPv4 routes for multicast reverse-path forwarding (RPF) lookup • inet.3—MPLS routes • mpls.0—MPLS routes for label-switched path (LSP) next hops • inet6.0—Unicast IPv6 routes
route-distinguisher	Standard	<p>Value of the route-distinguisher (RD).</p> <p>Filtering BGP EVPN routes based on RD is supported. The RD information is carried in the prefix of the EVPN route.</p>
route-filter route-filter-list	Standard	<p>Named route filter or route filter list. You can specify prefix length qualifiers for the list of routes in the route filter list.</p> <p>When used with EVPN NRLI route types 2 and 5, the following are supported:</p> <ul style="list-style-type: none"> • from route-filter [address-mask exact longer orlonger prefix-length-range through upto] <p>This match condition is not supported for use with the To statement.</p>
rtf-prefix-list name route-targets	Extended	<p>(BGP only) Named list of route target prefixes for BGP route target filtering and proxy BGP route target filtering.</p> <p>For information about this extended match condition, see <i>Example: Configuring an Export Policy for BGP Route Target Filtering for VPNs</i>.</p> <p>This match condition is not supported for use with the To statement.</p>
source-address-filter destination-prefix match-type <actions>	Extended	<p>List of multicast source addresses. When specifying a source address, you can specify an exact match with a specific route or a less precise match using match types. You can configure either a common action that applies to the entire list or an action associated with each prefix. For more information, see “Understanding Route Filters for Use in Routing Policy Match Conditions” on page 276.</p> <p>This match condition is not supported for use with the To statement.</p>

Table 9: Complete List of Routing Policy Match Conditions (*continued*)

Match Condition	Match Condition Category	Statement Description
state (active inactive)	Standard	<p>(BGP export only) Match on the following types of advertised routes:</p> <ul style="list-style-type: none"> • active—An active BGP route • inactive—A route advertised to internal BGP peers as the best external path even if the best path is an internal route • inactive—A route advertised by BGP as the best route even if the routing table did not select it to be an active route
tag string tag2 string	Standard	<p>Tag value. You can specify two tag strings: tag (for the first string) and tag2. These values are local to the router and can be set on configured routes or by using an import routing policy.</p> <p>You can specify multiple tags under one match condition by including the tags within a bracketed list. For example: from tag [tag1 tag2 tag3];</p> <p>For OSPF routes, the tag action sets the 32-bit tag field in OSPF external link-state advertisement (LSA) packets.</p> <p>For IS-IS routes, the tag action sets the 32-bit flag in the IS-IS IP prefix type length values. (TLV).</p> <p>OSPF stores the INTERNAL route's OSPF area ID in the tag2 attribute. However, for EXTERNAL routes, OSPF does not store anything in the tag2 attribute.</p> <p>You can configure a policy term to set the tag2 value for a route. If the route, already has a tag2 value (for example, an OSPF route that stores area id in tag2), then the original tag2 value is overwritten by the new value.</p> <p>When the policy contains the "from area" match condition, for internal OSPF routes, where tag2 is set, based on the OSPF area- ID, the evaluation is conducted to compare the tag2 attribute with the area ID. For external OSPF routes that do not have the tag2 attribute set, the match condition fails.</p>
validation-database	Standard	<p>When BGP origin validation is configured, triggers a lookup in the route validation database to determine if the route prefix is valid, invalid, or unknown. The route validation database contains route origin authorization (ROA) records that map route prefixes to expected originating autonomous systems (ASs). This prevents the accidental advertisement of invalid routes.</p> <p>See <i>Configuring Origin Validation for BGP</i>.</p>

Understanding Route Filters for Use in Routing Policy Match Conditions	276

Route Filter Match Conditions

When specifying a destination prefix, you can specify an exact match with a specific route, or a less precise match by using match types. You can configure either a common reject action that applies to the entire list, or an action associated with each prefix.

You can specify known invalid (“bad”) routes to ignore by specifying matches on destination prefixes. Additionally, you can specify that “good” routes be processed in a particular way. For instance, you can group traffic from specific source or destination addresses into forwarding classes to be processed using the class of service (CoS) feature.

[Table 10 on page 66](#) lists route list match types.

Table 10: Route List Match Types

Match Type	Match Conditions
address-mask <i>netmask-value</i>	<p>All of the following are true:</p> <ul style="list-style-type: none"> • The bit-wise logical AND of the netmask-value pattern and the incoming IPv4 or IPv6 route address and the bit-wise logical AND of the netmask-value pattern and the destination-prefix address are the same. The bits set in the netmask-value pattern do not need to be contiguous. • The prefix-length component of the incoming IPv4 or IPv6 route address and the prefix-length component of the destination-prefix address are the same. <p>NOTE: The address-mask routing policy match type is valid only for matching an incoming IPv4 (family inet) or IPv6 (family inet6) route address to a list of destination match prefixes specified in a route-filter statement.</p> <p>The address-mask routing policy match type enables you to match an incoming IPv4 or IPv6 route address on a configured netmask address in addition to the length of a configured destination match prefix. The length of the route address must match exactly with the length of the configured destination match prefix, as the address-mask match type does not support prefix length variations for a range of prefix lengths.</p> <p>When the longest-match lookup is performed on a route filter, the lookup evaluates an address-mask match type differently from other routing policy match types. The lookup does not consider the length of the destination match prefix. Instead, the lookup considers the number of contiguous high-order bits set in the netmask value.</p>
exact	The route shares the same most-significant bits (described by prefix-length), and prefix-length is equal to the route's prefix length.
longer	The route shares the same most-significant bits (described by prefix-length), and prefix-length is greater than the route's prefix length.
orlonger	The route shares the same most-significant bits (described by prefix-length), and prefix-length is equal to or greater than the route's prefix length.

Table 10: Route List Match Types (*continued*)

Match Type	Match Conditions
prefix-length-range <i>prefix-length2-prefix-length3</i>	The route shares the same most-significant bits (described by prefix-length), and the route's prefix length falls between prefix-length2 and prefix-length3 , inclusive.
through <i>destination-prefix</i>	<p>All the following are true:</p> <ul style="list-style-type: none"> • The route shares the same most-significant bits (described by prefix-length) of the first destination prefix. • The route shares the same most-significant bits (described by prefix-length) of the second destination prefix for the number of bits in the prefix length. • The number of bits in the route's prefix length is less than or equal to the number of bits in the second prefix. <p>You do not use the through match type in most routing policy configurations.</p>
upto <i>prefix-length2</i>	The route shares the same most-significant bits (described by prefix-length) and the route's prefix length falls between prefix-length and prefix-length2 .

Actions in Routing Policy Terms

IN THIS SECTION

- [Configuring Flow Control Actions | 69](#)
- [Configuring Actions That Manipulate Route Characteristics | 70](#)
- [Configuring the Default Action in Routing Policies | 80](#)

- [Configuring a Final Action in Routing Policies | 82](#)
- [Logging Matches to a Routing Policy Term | 83](#)
- [Configuring Separate Actions for Routes in Route Lists | 83](#)

Each term in a routing policy can include a **then** statement, which defines the actions to take if a route matches all the conditions in the **from** and **to** statements in the term:

```
then {
    actions;
}
```

You can include this statement at the following hierarchy levels:

- **[edit policy-options [policy-statement](#) *policy-name* term *term-name*]**
- **[edit logical-systems *logical-system-name* policy-options [policy-statement](#) *policy-name* term *term-name*]**

If a term does not have **from** and **to** statements, all routes are considered to match, and the actions apply to them all. For information about the **from** and **to** statements, see [“Routing Policy Match Conditions” on page 54](#).

You can specify one or more actions in the **then** statement. There are three types of actions:

- Flow control actions, which affect whether to accept or reject the route and whether to evaluate the next term or routing policy.
- Actions that manipulate route characteristics.
- Trace action, which logs route matches.

NOTE: When you specify an action that manipulates the route characteristics, the changes occur in a copy of the source route. The source route itself does not change. The effect of the action is visible only after the route is imported into or exported from the routing table. To view the source route before the routing policy has been applied, use the **show route receive-protocol** command. To view a route after an export policy has been applied, use the **show route advertised-protocol** command.

During policy evaluation, the characteristics in the copy of the source route always change immediately after the action is evaluated. However, the route is not copied to the routing table or a routing protocol until the policy evaluation is complete.

The **then** statement is optional. If you omit it, one of the following occurs:

- The next term in the routing policy, if one is present, is evaluated.
- If there are no more terms in the routing policy, the next routing policy, if one is present, is evaluated.
- If there are no more terms or routing policies, the accept or reject action specified by the default policy is taken. For more information, see [“Default Routing Policies” on page 37](#).

The following sections discuss these actions:

Configuring Flow Control Actions

[Table 11 on page 69](#) lists the flow control actions. You can specify one of these actions along with the trace action or one or more of the actions that manipulate route characteristics (see [“Configuring Actions That Manipulate Route Characteristics” on page 70](#)).

Table 11: Flow Control Actions

Flow Control Action	Description
accept	Accept the route and propagate it. After a route is accepted, no other terms in the routing policy and no other routing policies are evaluated.
default-action accept	Accept and override any action intrinsic to the protocol. This is a nonterminating policy action.
reject	Reject the route and do not propagate it. After a route is rejected, no other terms in the routing policy and no other routing policies are evaluated.
default-action reject	Reject and override any action intrinsic to the protocol. This is a nonterminating policy action.
next term	<p>Skip to and evaluate the next term in the same routing policy. Any accept or reject action specified in the then statement is skipped. Any actions in the then statement that manipulate route characteristics are applied to the route.</p> <p>next term is the default control action if a match occurs and you do not specify a flow control action.</p> <p>NOTE: On Junos OS Evolved, next term cannot appear as the last term of the action. A filter term where next term is specified as an action but without any match conditions configured is not supported.</p>

Table 11: Flow Control Actions (*continued*)

Flow Control Action	Description
next policy	<p>Skip to and evaluate the next routing policy. Any accept or reject action specified in the then statement is skipped. Any actions in the then statement that manipulate route characteristics are applied to the route.</p> <p>next policy is the default control action if a match occurs, you do not specify a flow control action, and there are no further terms in the current routing policy.</p>
sr-te-template	Segment routing-traffic engineered (SR-TE) template to apply for PCE-initiated LSPs.

Configuring Actions That Manipulate Route Characteristics

You can specify one or more of the actions listed in [Table 12 on page 70](#) to manipulate route characteristics.

Table 12: Actions That Manipulate Route Characteristics

Action	Description
add-path send-count path-count	(BGP only) Enable sending up to 20 BGP paths to a destination for a subset of add-path advertised prefixes.
as-path-prepend as-path	<p>(BGP only) Affix one or more AS numbers at the beginning of the AS path. If specifying more than one AS number, enclose the numbers in quotation marks (" "). The AS numbers are added after the local AS number has been added to the path. This action adds AS numbers to AS sequences only, not to AS sets. If the existing AS path begins with a confederation sequence or set, the affixed AS numbers are placed within a confederation sequence. Otherwise, the affixed AS numbers are placed within a nonconfederation sequence. For more information, see "Understanding Prepending AS Numbers to BGP AS Paths" on page 416.</p> <p>In Junos OS Release 9.1 and later, you can specify 4-byte AS numbers as defined in RFC 4893, <i>BGP Support for Four-octet AS Number Space</i>, as well as the 2-byte AS numbers that are supported in earlier releases of the Junos OS.</p>

Table 12: Actions That Manipulate Route Characteristics (*continued*)

Action	Description
as-path-expand last-as count <i>n</i>	<p>(BGP only) Extract the last AS number in the existing AS path and affix that AS number to the beginning of the AS path <i>n</i> times, where <i>n</i> is a number from 1 through 32.</p> <p>The AS number is added before the local AS number has been added to the path. This action adds AS numbers to AS sequences only, not to AS sets. If the existing AS path begins with a confederation sequence or set, the affixed AS numbers are placed within a confederation sequence. Otherwise, the affixed AS numbers are placed within a non-confederation sequence. This option is typically used in non-IBGP export policies.</p> <p>NOTE: Starting in Junos OS Release 17.3, it is possible to commit a null configuration for the count value, and if so, Junos will convert the null to a 1 count rather than a 0 count, or disallowing the commit. The effect of having your as-path-expand count equal one is that such an <i>as-path</i> is longer, and therefore less preferable. We recommend that you either explicitly set the as-path-expand count, or delete the unused setting to avoid any unexpected behavior.</p>
bgp-output-queue-priority	(BGP only) Set the output priority queue used for this route. There are 17 prioritized output queues: an expedited queue that is the highest priority, and 16 numbered queues where 1 is the lowest priority and 16 is the highest.
class <i>class-name</i>	(Class of service [CoS] only) Apply the specified class-of-service parameters to routes installed into the routing table. For more information, see the <i>Class of Service User Guide (Routers and EX9200 Switches)</i> .
color preference color2 preference	<p>Set the preference value to the specified value. The color and color2 preference values are even more fine-grained than those specified in the preference and preference2 actions. The color value can be a number in the range from 0 through 4,294,967,295 ($2^{32} - 1$). A lower number indicates a more preferred route.</p> <p>If you set the preference with the color action, the value is internal to Junos OS and is not transitive.</p>
color (add subtract) <i>number</i> color2 (add subtract) <i>number</i>	Change the color preference value by the specified amount. If an addition operation results in a value that is greater than 4,294,967,295 ($2^{32} - 1$), the value is set to $2^{32} - 1$. If a subtraction operation results in a value less than 0, the value is set to 0. If an attribute value is not already set at the time of the addition or subtraction operation, the attribute value defaults to a value of 0 regardless of the amount specified. If you perform an addition to an attribute with a value of 0, the number you add becomes the resulting attribute value.

Table 12: Actions That Manipulate Route Characteristics (*continued*)

Action	Description
community (+ add) [<i>names</i>]	(BGP only) Add the specified communities to the set of communities in the route. For more information, see “Understanding BGP Communities, Extended Communities, and Large Communities as Routing Policy Match Conditions” on page 457.
community (– delete) [<i>names</i>]	(BGP only) Delete the specified communities from the set of communities in the route. For more information, see “Understanding BGP Communities, Extended Communities, and Large Communities as Routing Policy Match Conditions” on page 457.
community (= set) [<i>names</i>]	(BGP only) Replace any communities that were in the route in with the specified communities. For more information, see “Understanding BGP Communities, Extended Communities, and Large Communities as Routing Policy Match Conditions” on page 457.
cos-next-hop-map <i>map-name</i>	Set CoS-based next-hop map in forwarding table.
damping <i>name</i>	<p>(BGP only) Apply the specified route-damping parameters to the route. These parameters override the default damping parameters. This action is useful only in an import policy, because the damping parameters affect the state of routes in the routing table.</p> <p>To apply damping parameters, you must enable BGP flap damping as described in the <i>Junos OS Routing Protocols Library</i>, and you must create a named list of parameters as described in “Using Routing Policies to Damp BGP Route Flapping” on page 535.</p>
destination-class <i>destination-class-name</i>	<p>Maintain packet counts for a route passing through your network, based on the destination address in the packet. You can do the following:</p> <ul style="list-style-type: none"> • Configure group destination prefixes by configuring a routing policy. • Apply that routing policy to the forwarding table with the corresponding destination class. • Enable packet counting on one or more interfaces by including the destination-class-usage statement at the [edit interfaces <i>interface-name</i> unit <i>logical-unit-number</i> family inet accounting] hierarchy level (see the <i>Class of Service User Guide (Routers and EX9200 Switches)</i>). • View the output by using one of the following commands: show interfaces destination-class (all <i>destination-class-name</i> <i>logical-interface-name</i>), show interfaces <i>interface-name</i> extensive, or show interfaces <i>interface-name</i> statistics (see the CLI Explorer). • To configure a packet count based on the source address, use the source-class statement described in this table.

Table 12: Actions That Manipulate Route Characteristics (*continued*)

Action	Description
external type metric	Set the external metric type for routes exported by OSPF. You must specify the keyword type .
forwarding-class forwarding-class-name	<p>Create the forwarding class that includes packets based on both the destination address and the source address in the packet. You can do the following:</p> <ul style="list-style-type: none"> • Configure group prefixes by configuring a routing policy. • Apply that routing policy to the forwarding table with the corresponding forwarding class. • Enable packet counting on one or more interfaces by using the procedure described in either the destination-class or source-class actions defined in this table.
install-nexthop <strict> lsp lsp-name	Choose which next hops, among a set of equal LSP next hops, are installed in the forwarding table. Use the export policy for the forwarding table to specify the LSP next hop to be used for the desired routes. Specify the strict option to enable strict mode, which checks to see if any of the LSP next hops specified in the policy are up. If none of the specified LSP next hops are up, the policy installs the discard next hop.
install-to-fib	For PTX Series routers only, override the default BGP routing policy. For more information, see <i>Example: Overriding the Default BGP Routing Policy on PTX Series Packet Transport Routers</i> .
load-balance consistent-hash	(BGP only) For MX Series routers with modular port concentrators (MPCs) and for QFX10000 switches only, specify consistent load balancing for one or more IP addresses. This feature preserves the affinity of a flow to a path in an equal-cost multipath (ECMP) group when one or more next-hop paths fail. Only flows for paths that are inactive are redirected. Flows mapped to servers that remain active are maintained.
load-balance destination-ip-only	Calculate load balancing hash based solely on destination IP address. This allows a service provider to direct traffic toward a specific content server in per-subscriber aware environments.
load-balance per-packet	(For export to the forwarding table only) Install all next-hop addresses in the forwarding table and have the forwarding table perform per-packet load balancing. This policy action allows you to optimize VPLS traffic flows across multiple paths. For more information, see <i>Configuring Per-Packet Load Balancing</i> .
load-balance per-prefix	For PTX Series routers only, override the default per-packet load balancing routing policy for BGP. For more information, see <i>Example: Overriding the Default BGP Routing Policy on PTX Series Packet Transport Routers</i> .

Table 12: Actions That Manipulate Route Characteristics (*continued*)

Action	Description
load-balance source-ip-only	Calculate load balancing hash based solely on source IP address. This allows a service provider to direct traffic toward a specific content server in per-subscriber aware environments.
local-preference <i>value</i>	(BGP only) Set the BGP local preference (LOCAL_PREF) attribute. The preference value can be a number in the range from 0 through 4,294,967,295 ($2^{32} - 1$).
local-preference (add subtract) <i>number</i>	<p>Change the local preference value by the specified amount. If an addition operation results in a value that is greater than 4,294,967,295 ($2^{32} - 1$), the value is set to $2^{32} - 1$. If a subtraction operation results in a value less than 0, the value is set to 0. If an attribute value is not already set at the time of the addition or subtraction operation, the attribute value defaults to a value of 0 regardless of the amount specified. If you perform an addition to an attribute with a value of 0, the number you add becomes the resulting attribute value.</p> <p>For BGP, if the attribute value is not known, it is initialized to 100 before the routing policy is applied.</p>
map-to-interface (<i>interface-name</i> self)	<p>Sets the map-to-interface value which is similar to existing metric or tag actions. The map-to-interface action requires you to specify one of the following:</p> <ul style="list-style-type: none"> • A logical interface (for example, ge-0/0/0.0). The logical interface can be any interface that multicast currently supports, including VLAN and aggregated Ethernet interfaces. <p>NOTE: If you specify a physical interface as the map-to-interface (for example, ge-0/0/0), a value of .0 is appended to physical interface to create a logical interface.</p> <ul style="list-style-type: none"> • The keyword self. The self keyword specifies that multicast data packets are sent on the same interface as the control packets and no mapping occurs. <p>If no term matches, then no multicast data packets are sent.</p>
metric <i>metric</i> metric2 <i>metric</i> metric3 <i>metric</i> metric4 <i>metric</i>	<p>Set the metric. You can specify up to four metric values, starting with metric (for the first metric value) and continuing with metric2, metric3, and metric4.</p> <p>(BGP only) metric corresponds to the MED, and metric2 corresponds to the IGP metric if the BGP next hop loops through another router.</p>

Table 12: Actions That Manipulate Route Characteristics (*continued*)

Action	Description
metric (add subtract) <i>number</i> metric2 (add subtract) <i>number</i> metric3 (add subtract) <i>number</i> metric4 (add subtract) <i>number</i>	Change the metric value by the specified amount. If an addition operation results in a value that is greater than 4,294,967,295 ($2^{32} - 1$), the value is set to $2^{32} - 1$. If a subtraction operation results in a value less than 0, the value is set to 0. If an attribute value is not already set at the time of the addition or subtraction operation, the attribute value defaults to a value of 0 regardless of the amount specified. If you perform an addition to an attribute with a value of 0, the number you add becomes the resulting attribute value.
metric expression (metric multiplier <i>x</i> offset <i>a</i> metric2 multiplier <i>y</i> offset <i>b</i>)	<p>Calculate a metric based on the current values of metric and metric2.</p> <p>This policy action overrides the current value of the metric attribute with the result of the expression</p> $((x * \text{metric}) + a) + ((y * \text{metric2}) + b)$ <p>where metric and metric2 are the current input values. Metric multipliers are limited in range to eight significant digits.</p>
metric (igp minimum-igp) <i>site-offset</i>	(BGP only) Change the metric (MED) value by the specified negative or positive offset. This action is useful only in an external BGP (EBGP) export policy.

Table 12: Actions That Manipulate Route Characteristics (*continued*)

Action	Description
<code>next-hop</code> (<i>address</i> <code>discard</code> <code>next-table</code> <i>table-name</i> <code>peer-address</code> <code>reject</code> <code>self</code>)	

Table 12: Actions That Manipulate Route Characteristics (*continued*)

Action	Description
	<p>Set the next-hop address. When the advertising protocol is BGP, you can set the next hop only when any third-party next hop can be advertised; that is, when you are using IBGP or EBGP confederations.</p> <p>If you specify self, the next-hop address is replaced by one of the local routing device's addresses. The advertising protocol determines which address to use. When the advertising protocol is BGP, this address is set to the local IP address used for the BGP adjacency. A routing device cannot install routes with itself as the next hop.</p> <p>If you specify peer-address, the next-hop address is replaced by the peer's IP address. This option is valid only in import policies. Primarily used by BGP to enforce using the peer's IP address for advertised routes, this option is meaningful only when the next hop is the advertising routing device or another directly connected routing device.</p> <p>If you specify discard, the next-hop address is replaced by a discard next hop.</p> <p>If you specify next-table, the routing device performs a forwarding lookup in the specified table.</p> <p>If you use the next-table action, the configuration must include a term qualifier that specifies a different table than the one specified in the next-table action. In other words, the term qualifier in the from statement must exclude the table in the next-table action. In the following example, the first term contains rib vrf-customer2.inet.0 as a matching condition. The action specifies a next-hop in a different routing table, vrf-customer1.inet.0. The second term does the opposite by using rib vrf-customer1.inet.0 in the match condition and vrf-customer2.inet.0 in the next-table action.</p> <pre> term 1 { from { protocol bgp; rib vrf-customer2.inet.0; community customer; } then { next-hop next-table vrf-customer1.inet.0; } } term 2 { from { protocol bgp; rib vrf-customer1.inet.0; </pre>

Table 12: Actions That Manipulate Route Characteristics (*continued*)

Action	Description
	<pre> community customer; } then { next-hop next-table vrf-customer2.inet.0; } } </pre> <p>If you specify reject, the next-hop address is replaced by a reject next hop.</p>
origin value	<p>(BGP only) Set the BGP origin attribute to one of the following values:</p> <ul style="list-style-type: none"> • igp—Path information originated within the local AS. • egp—Path information originated in another AS. • incomplete—Path information learned by some other means.
p2mp-lsp-root	<p>Set the ingress root node for a multipoint LDP (M-LDP)-based point-to-multipoint label-switched path (LSP). For more information, see <i>Example: Configuring Multipoint LDP In-Band Signaling for Point-to-Multipoint LSPs</i>.</p>
preference preference preference2 preference	<p>Set the preference value. You can specify a primary preference value (preference) and a secondary preference value (preference2). The preference value can be a number in the range from 0 through 4,294,967,295 ($2^{32} - 1$). A lower number indicates a more preferred route. When you use an import policy to set the value of preference2 to the highest allowed value of 4,294,967,295, Junos OS resets this value to -1. If you set preference2 to a number greater than ($2^{31} - 1$), it is reset to a negative value.</p> <p>To specify even finer-grained preference values, see the color and color2 actions in this table.</p> <p>If you set the preference with the preference action, the new preference remains associated with the route. The new preference is internal to the Junos OS and is not transitive.</p>
preference (add subtract) number preference2 (add subtract) number	<p>Change the preference value by the specified amount. If an addition operation results in a value that is greater than 4,294,967,295 ($2^{32} - 1$), the value is set to $2^{32} - 1$. If a subtraction operation results in a value less than 0, the value is set to 0. If an attribute value is not already set at the time of the addition or subtraction operation, the attribute value defaults to a value of 0 regardless of the amount specified. If you perform an addition to an attribute with a value of 0, the number you add becomes the resulting attribute value.</p>

Table 12: Actions That Manipulate Route Characteristics (*continued*)

Action	Description
priority (low medium high)	<p>(OSPF import only) Specify a priority for prefixes included in an OSPF import policy. Prefixes learned through OSPF are installed in the routing table based on the priority assigned to the prefixes. Prefixes assigned a priority of high are installed first, while prefixes assigned a priority of low are installed last.</p> <p>NOTE: An OSPF import policy can only be used to set priority or to filter OSPF external routes. If an OSPF import policy is applied that results in a reject terminating action for a nonexternal route, then the reject action is ignored and the route is accepted anyway.</p>
source-class <i>source-class-name</i>	<p>Maintain packet counts for a route passing through your network, based on the source address. You can do the following:</p> <ul style="list-style-type: none"> • Configure group source prefixes by configuring a routing policy. • Apply that routing policy to the forwarding table with the corresponding source class. • Enable packet counting on one or more interfaces by including the source-class-usage <i>interface-name</i> statement at the [edit interfaces <i>logical-unit-number</i> unit family inet accounting] hierarchy level. Also, follow the source-class-usage statement with the input or output statement to define the inbound and outbound interfaces on which traffic monitored for source-class usage (SCU) is arriving and departing (or define one interface for both). The complete syntax is [edit interfaces <i>interface-name</i> unit family inet accounting source-class-usage (input output input output) <i>unit-number</i>]. • View the output by using one of the following commands: show interfaces <i>interface-name</i> source-class <i>source-class-name</i>, show interfaces <i>interface-name</i> extensive, or show interfaces <i>interface-name</i> statistics (see the CLI Explorer). • To configure a packet count based on the destination address, use the destination-class statement described in this table. • For a detailed source-class usage example configuration, see the “Example: Grouping Source and Destination Prefixes into a Forwarding Class” on page 606. <p>NOTE: When configuring policy action statements, you can configure only one source class for each matching route. In other words, more than one source class cannot be applied to the same route.</p>
ssm-source [<i>addresses</i>];	Specify one or more IPv4 or IPv6 source addresses for the source-specific multicast (SSM) policy
ssm-source [<i>addresses</i>];	Specify one or more IPv4 or IPv6 source addresses for the source-specific multicast (SSM) policy.

Table 12: Actions That Manipulate Route Characteristics (*continued*)

Action	Description
tag tag tag2 tag	<p>Set the tag value. You can specify two tag strings: tag (for the first string) and tag2 (a second string). These values are local to the router.</p> <ul style="list-style-type: none"> For OSPF routes the tag action sets the 32-bit tag field in OSPF external link-state advertisement (LSA) packets. For IS-IS routes, the tag action sets the 32-bit flag in the IS-IS IP prefix type length values (TLV). For RIPv2 routes, the tag action sets the route-tag community. The tag2 option is not supported.
tag (add subtract) number tag2 (add subtract) number	<p>Change the tag value by the specified amount. If an addition operation results in a value that is greater than 4,294,967,295 ($2^{32} - 1$), the value is set to $2^{32} - 1$. If a subtraction operation results in a value less than 0, the value is set to 0. If an attribute value is not already set at the time of the addition or subtraction operation, the attribute value defaults to a value of 0 regardless of the amount specified. If you perform an addition to an attribute with a value of 0, the number you add becomes the resulting attribute value.</p>
validation-state	<p>When BGP origin validation is configured, set the validation state of a route prefix to valid, invalid, or unknown.</p> <p>The route validation database contains route origin authorization (ROA) records that map route prefixes to expected originating autonomous systems (ASs). This prevents the accidental advertisement of invalid routes.</p> <p>See <i>Understanding Origin Validation for BGP</i>.</p>

Configuring the Default Action in Routing Policies

The **default-action** statement overrides any action intrinsic to the protocol. This action is also nonterminating, so that various policy terms can be evaluated before the policy is terminated. You can specify a default action, either **accept** or **reject**, as follows:

```
[edit]
policy-options {
  policy-statement policy-name {
    term term-name {
      from {
        family family-name;
        match-conditions;
        policy subroutine-policy-name;
```

```

    prefix-list name;
    route-filter destination-prefix match-type <actions>;
    source-address-filter source-prefix match-type <actions>;
  }
  to {
    match-conditions;
    policy subroutine-policy-name;
  }
  then {
    actions;
    default-action (accept | reject);
  }
}
}
}

```

The resulting action is set either by the protocol or by the last policy term that is matched.

Example: Configuring the Default Action in a Routing Policy

Configure a routing policy that matches routes based on three policy terms. If the route matches the first term, a certain community tag is attached. If the route matches two separate terms, then both community tags are attached. If the route does not match any terms, it is rejected (protocol's default action). Note that the terms **hub** and **spoke** are mutually exclusive.

```

[edit]
policy-options {
  policy-statement test {
    term set-default {
      then default-action reject;
    }
    term hub {
      from interface ge-2/1/0.5;
      then {
        community add test-01-hub;
        default-action accept;
      }
    }
    term spoke {
      from interface [ ge-2/1/0.1 ge-2/1/0.2 ];
      then {
        community add test-01-spoke;
        default-action accept;
      }
    }
  }
}

```

```

term management {
    from protocol direct;
    then {
        community add management;
        default-action accept;
    }
}
}
}
}

```

Configuring a Final Action in Routing Policies

In addition to specifying an action using the **then** statement in a named term, you can also specify an action using the **then** statement in an unnamed term, as follows:

```

[edit]
policy-options {
  policy-statement policy-name {
    term term-name {
      from {
        family family-name;
        match-conditions;
        policy subroutine-policy-name;
        prefix-list name;
        route-filter destination-prefix match-type <actions>;
        source-address-filter source-prefix match-type <actions>;
      }
      to {
        match-conditions;
        policy subroutine-policy-name;
      }
      then {
        actions;
      }
    }
    then action;
  }
}

```

Logging Matches to a Routing Policy Term

If you specify the trace action, the match is logged to a trace file. To set up a trace file, you must specify the following elements in the global **traceoptions** statement:

- Trace filename
- **policy** option in the **flag** statement

The following example uses the trace filename of **policy-log**:

```
[edit]
routing-options {
  traceoptions {
    file "policy-log";
    flag policy;
  }
}
```

This action does not affect the flow control during routing policy evaluation.

If a term that specifies a trace action also specifies a flow control action, the name of the term is logged in the trace file. If a term specifies a trace action only, the word **<default>** is logged.

Configuring Separate Actions for Routes in Route Lists

If you specify route lists in the **from** statement, for each route in the list, you can specify an action to take on that individual route directly, without including a **then** statement. For more information, see [“Understanding Route Filters for Use in Routing Policy Match Conditions” on page 276](#).

[Routing Policy Match Conditions | 54](#)

Summary of Routing Policy Actions

An *action* is what the policy framework software does if a route matches all criteria defined in a match condition. You can configure one or more actions in a term.

The policy framework software supports the following types of actions:

- Flow control actions, which affect whether to accept or reject the route or whether to evaluate the next term or routing policy
- Actions that manipulate route characteristics
- Trace action, which logs route matches

Manipulating the route characteristics allows you to control which route is selected as the active route to reach a destination. In general, the active route is also advertised to a routing platform's neighbors. You can manipulate the following route characteristics: AS path, class, color, community, damping parameters, destination class, external type, next hop, load balance, local preference, metric, origin, preference, and tag.

For the numeric information (color, local preference, metric, preference, and tag), you can set a specific value or change the value by adding or subtracting a specified amount. The addition and subtraction operations do not allow the value to exceed a maximum value and drop below a minimum value.

All policies have default actions in case one of the following situations arises during policy evaluation:

- A policy does not specify a match condition.
- A match occurs, but a policy does not specify an action.
- A match does not occur with a term in a policy and subsequent terms in the same policy exist.
- A match does not occur by the end of a policy.

An action defines what the router does with the route when the route matches all the match conditions in the **from** and **to** statements for a particular term. If a term does not have **from** and **to** statements, all routes are considered to match and the actions apply to all routes.

Each term can have one or more of the following types of actions. The actions are configured under the **then** statement.

- Flow control actions, which affect whether to accept or reject the route and whether to evaluate the next term or routing policy
- Actions that manipulate route characteristics
- Trace action, which logs route matches

If you do not specify an action, one of the following results occurs:

- The next term in the routing policy, if one exists, is evaluated.
- If the routing policy has no more terms, the next routing policy, if one exists, is evaluated.
- If there are no more terms or routing policies, the accept or reject action specified by the default policy is executed.

[Table 13 on page 85](#) summarizes the routing policy actions.

Table 13: Summary of Key Routing Policy Actions

Action	Description
Flow Control Actions	These actions control the flow of routing information into and out of the routing table.
accept	Accepts the route and propagates it. After a route is accepted, no other terms in the routing policy and no other routing policies are evaluated.
reject	Rejects the route and does not propagate it. After a route is rejected, no other terms in the routing policy and no other routing policies are evaluated.
next term	Skips to and evaluates the next term in the same routing policy. Any accept or reject action specified in the then statement is ignored. Any actions specified in the then statement that manipulate route characteristics are applied to the route.
next policy	Skips to and evaluates the next routing policy. Any accept or reject action specified in the then statement is ignored. Any actions specified in the then statement that manipulate route characteristics are applied to the route.
Route Manipulation Actions	These actions manipulate the route characteristics.
as-path-prepend <i>as-path</i>	<p>Appends one or more AS numbers at the beginning of the AS path. If you are specifying more than one AS number, include the numbers in quotation marks.</p> <p>The AS numbers are added after the local AS number has been added to the path. This action adds AS numbers to AS sequences only, not to AS sets. If the existing AS path begins with a confederation sequence or set, the appended AS numbers are placed within a confederation sequence. Otherwise, the appended AS numbers are placed with a nonconfederation sequence.</p>
as-path-expand last-as count <i>n</i>	<p>Extracts the last AS number in the existing AS path and appends that AS number to the beginning of the AS path <i>n</i> times. Replace <i>n</i> with a number from 1 through 32.</p> <p>The AS numbers are added after the local AS number has been added to the path. This action adds AS numbers to AS sequences only, not to AS sets. If the existing AS path begins with a confederation sequence or set, the appended AS numbers are placed within a confederation sequence. Otherwise, the appended AS numbers are placed with a nonconfederation sequence.</p>
class <i>class-name</i>	Applies the specified class-of-service (CoS) parameters to routes installed into the routing table.

Table 13: Summary of Key Routing Policy Actions (*continued*)

Action	Description
color preference color2 preference	Sets the preference value to the specified value. The color and color2 preference values can be a number from 0 through 4,294,967,295 ($2^{32} - 1$). A lower number indicates a more preferred route.
damping name	<p>Applies the specified route-damping parameters to the route. These parameters override BGP's default damping parameters.</p> <p>This action is useful only in import policies.</p>
local-preference value	Sets the BGP local preference attribute. The preference can be a number from 0 through 4,294,967,295 ($2^{32} - 1$).
metric metric metric2 metric metric3 metric metric4 metric	<p>Sets the metric. You can specify up to four metric values, starting with metric (for the first metric value) and continuing with metric2, metric3, and metric4.</p> <p>For BGP routes, metric corresponds to the MED, and metric2 corresponds to the IGP metric if the BGP next hop loops through another router.</p>
next-hop address	<p>Sets the next hop.</p> <p>If you specify address as self, the next-hop address is replaced by one of the local router's addresses. The advertising protocol determines which address to use.</p>

Example: Configuring a Routing Policy to Advertise the Best External Route to Internal Peers

IN THIS SECTION

- Requirements | 88
- Overview | 88

The BGP protocol specification, as defined in RFC 1771, specifies that a BGP peer shall advertise to its internal peers the higher preference external path, even if this path is not the overall best (in other words, even if the best path is an internal path). In practice, deployed BGP implementations do not follow this rule. The reasons for deviating from the specification are as follows:

- Minimizing the amount of advertised information. BGP scales according to the number of available paths.
- Avoiding routing and forwarding loops.

There are, however, several scenarios in which the behavior, specified in RFC 1771, of advertising the best external route might be beneficial. Limiting path information is not always desirable as path diversity might help reduce restoration times. Advertising the best external path can also address internal BGP (IBGP) route oscillation issues as described in RFC 3345, *Border Gateway Protocol (BGP) Persistent Route Oscillation Condition*.

The **advertise-external** statement modifies the behavior of a BGP speaker to advertise the best external path to IBGP peers, even when the best overall path is an internal path.

NOTE: The **advertise-external** statement is supported at both the group and neighbor level. If you configure the statement at the neighbor level, you must configure it for all neighbors in a group. Otherwise, the group is automatically split into different groups.

The **conditional** option limits the behavior of the **advertise-external** setting, such that the external route is advertised only if the route selection process reaches the point where the multiple exit discriminator (MED) metric is evaluated. Thus, an external route is not advertised if it has, for instance, an AS path that is worse (longer) than that of the active path. The **conditional** option restricts external path advertisement to when the best external path and the active path are equal until the MED step of the route selection process. Note that the criteria used for selecting the best external path is the same whether or not the **conditional** option is configured.

Junos OS also provides support for configuring a BGP export policy that matches the state of an advertised route. You can match either active or inactive routes, as follows:

```
policy-options {  
  policy-statement name{  
    from state (active|inactive);
```

```

    }
}

```

This qualifier only matches when used in the context of an export policy. When a route is being advertised by a protocol that can advertise inactive routes (such as BGP), **state inactive** matches routes advertised as a result of the **advertise-inactive** and **advertise-external** statements.

For example, the following configuration can be used as a BGP export policy toward internal peers to mark routes advertised due to the **advertise-external** setting with a user-defined community. That community can be later used by the receiving routers to filter out such routes from the forwarding table. Such a mechanism can be used to address concerns that advertising paths not used for forwarding by the sender might lead to forwarding loops.

```

user@host# show policy-options
policy-statement mark-inactive {
  term inactive {
    from state inactive;
    then {
      community set comm-inactive;
    }
  }
  term default {
    from protocol bgp;
    then accept;
  }
  then reject;
}
community comm-inactive members 65536:65284;

```

Requirements

Junos OS 9.3 or later is required.

Overview

This example shows three routing devices. Device R2 has an external BGP (EBGP) connection to Device R1. Device R2 has an IBGP connection to Device R3.

Device R1 advertises 172.16.6.0/24. Device R2 does not set the local preference in an import policy for Device R1's routes, and thus 172.16.6.0/24 has the default local preference of 100.

Device R3 advertises 172.16.6.0/24 with a local preference of 200.

When the **advertise-external** statement is not configured on Device R2, 172.16.6.0/24 is not advertised by Device R2 toward Device R3.

When the **advertise-external** statement is configured on Device R2 on the session toward Device R3, 172.16.6.0/24 is advertised by Device R2 toward Device R3.

When **advertise-external conditional** is configured on Device R2 on the session toward Device R3, 172.16.6.0/24 is not advertised by Device R2 toward Device R3. If you remove the **then local-preference 200** setting on Device R3 and add the **path-selection as-path-ignore** setting on Device R2 (thus making the path selection criteria equal until the MED step of the route selection process), 172.16.6.0/24 is advertised by Device R2 toward Device R3.

NOTE: To configure the **advertise-external** statement on a route reflector, you must disable intracluster reflection with the **no-client-reflect** statement, and the client cluster must be fully meshed to prevent the sending of redundant route advertisements.

When a routing device is configured as a route reflector for a cluster, a route advertised by the route reflector is considered internal if it is received from an internal peer with the same cluster identifier or if both peers have no cluster identifier configured. A route received from an internal peer that belongs to another cluster, that is, with a different cluster identifier, is considered external.

Topology

Figure 9 on page 89 shows the sample network.

Figure 9: BGP Topology for advertise-external

"CLI Quick Configuration" on page 89 shows the configuration for all of the devices in Figure 9 on page 89.

The section "Step-by-Step Procedure" on page 91 describes the steps on Device R2.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

Device R1

```
set interfaces fe-1/2/0 unit 0 description to-R2
set interfaces fe-1/2/0 unit 0 family inet address 10.0.0.1/30
set interfaces lo0 unit 0 family inet address 192.168.0.1/32
set protocols bgp group ext type external
set protocols bgp group ext export send-static
set protocols bgp group ext peer-as 200
set protocols bgp group ext neighbor 10.0.0.2
set policy-options policy-statement send-static term 1 from protocol static
set policy-options policy-statement send-static term 1 from route-filter 172.16.6.0/24 exact
set policy-options policy-statement send-static term 1 then accept
set policy-options policy-statement send-static term 2 then reject
set routing-options static route 172.16.6.0/24 reject
set routing-options router-id 192.168.0.1
set routing-options autonomous-system 100
```

Device R2

```
set interfaces fe-1/2/0 unit 0 description to-R1
set interfaces fe-1/2/0 unit 0 family inet address 10.0.0.2/30
set interfaces fe-1/2/1 unit 0 description to-R3
set interfaces fe-1/2/1 unit 0 family inet address 10.0.0.5/30
set interfaces lo0 unit 0 family inet address 192.168.0.2/32
set protocols bgp group ext type external
set protocols bgp group ext peer-as 100
set protocols bgp group ext neighbor 10.0.0.1
set protocols bgp group int type internal
set protocols bgp group int local-address 192.168.0.2
set protocols bgp group int advertise-external
set protocols bgp group int neighbor 192.168.0.3
set protocols ospf area 0.0.0.0 interface fe-1/2/1.0
set protocols ospf area 0.0.0.0 interface lo0.0 passive
set routing-options router-id 192.168.0.2
set routing-options autonomous-system 200
```

Device R3

```

set interfaces fe-1/2/0 unit 6 family inet address 10.0.0.6/30
set interfaces lo0 unit 0 family inet address 192.168.0.3/32
set protocols bgp group int type internal
set protocols bgp group int local-address 192.168.0.3
set protocols bgp group int export send-static
set protocols bgp group int neighbor 192.168.0.2
set protocols ospf area 0.0.0.0 interface fe-1/2/0.6
set protocols ospf area 0.0.0.0 interface lo0.0 passive
set policy-options policy-statement send-static term 1 from protocol static
set policy-options policy-statement send-static term 1 then local-preference 200
set policy-options policy-statement send-static term 1 then accept
set routing-options static route 172.16.6.0/24 reject
set routing-options static route 0.0.0.0/0 next-hop 10.0.0.5
set routing-options autonomous-system 200

```

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure Device R2:

1. Configure the device interfaces.

```

[edit interfaces]
user@R2# set fe-1/2/0 unit 0 description to-R1
user@R2# set fe-1/2/0 unit 0 family inet address 10.0.0.2/30
user@R2# set fe-1/2/1 unit 0 description to-R3
user@R2# set fe-1/2/1 unit 0 family inet address 10.0.0.5/30
user@R2# set lo0 unit 0 family inet address 192.168.0.2/32

```

2. Configure OSPF or another interior gateway protocol (IGP).

```

[edit protocols ospf area 0.0.0.0]
user@R2# set interface fe-1/2/1.0
user@R2# set interface lo0.0 passive

```

3. Configure the EBGP connection to Device R1.

```
[edit protocols bgp group ext]
user@R2# set type external
user@R2# set peer-as 100
user@R2# set neighbor 10.0.0.1
```

4. Configure the IBGP connection to Device R3.

```
[edit protocols bgp group int]
user@R2# set type internal
user@R2# set local-address 192.168.0.2
user@R2# set neighbor 192.168.0.3
```

5. Add the **advertise-external** statement to the IBGP group peering session.

```
[edit protocols bgp group int]
user@R2# set advertise-external
```

6. Configure the autonomous system (AS) number and the router ID.

```
[edit routing-options ]
user@R2# set router-id 192.168.0.2
user@R2# set autonomous-system 200
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R2# show interfaces
fe-1/2/0 {
  unit 0 {
    description to-R1;
    family inet {
      address 10.0.0.2/30;
    }
  }
}
fe-1/2/1 {
  unit 0 {
```

```

        description to-R3;
        family inet {
            address 10.0.0.5/30;
        }
    }
}
lo0 {
    unit 0 {
        family inet {
            address 192.168.0.2/32;
        }
    }
}

```

```

user@R2# show protocols
bgp {
    group ext {
        type external;
        peer-as 100;
        neighbor 10.0.0.1;
    }
    group int {
        type internal;
        local-address 192.168.0.2;
        advertise-external;
        neighbor 192.168.0.3;
    }
}
ospf {
    area 0.0.0.0 {
        interface fe-1/2/1.0;
        interface lo0.0 {
            passive;
        }
    }
}

```

```

user@R2# show routing-options
router-id 192.168.0.2;
autonomous-system 200;

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

IN THIS SECTION

- [Verifying the BGP Active Path | 94](#)
- [Verifying the External Route Advertisement | 95](#)
- [Verifying the Route on Device R3 | 95](#)
- [Experimenting with the conditional Option | 96](#)

Confirm that the configuration is working properly.

Verifying the BGP Active Path

Purpose

On Device R2, make sure that the 172.16.6.0/24 prefix is in the routing table and has the expected active path.

Action

user@R2> **show route 172.16.6**

```
inet.0: 8 destinations, 9 routes (8 active, 1 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

172.16.6.0/24      *[BGP/170] 00:00:07, localpref 200, from 192.168.0.3
                   AS path: I, validation-state: unverified
                   > to 10.0.0.6 via fe-1/2/1.0
                   [BGP/170] 03:23:03, localpref 100
                   AS path: 100 I, validation-state: unverified
                   > to 10.0.0.1 via fe-1/2/0.0
```

Meaning

Device R2 receives the 172.16.6.0/24 route from both Device R1 and Device R3. The route from Device R3 is the active path, as designated by the asterisk (*). The active path has the highest local preference. Even if the local preferences of the two routes were equal, the route from Device R3 would remain active because it has the shortest AS path.

Verifying the External Route Advertisement

Purpose

On Device R2, make sure that the 172.16.6.0/24 route is advertised toward Device R3.

Action

```
user@R2> show route advertising-protocol bgp 192.168.0.3
```

```
inet.0: 8 destinations, 9 routes (8 active, 1 holddown, 0 hidden)
  Prefix            Nexthop          MED      Lclpref    AS path
  172.16.6.0/24      10.0.0.1          100       100        100 I
```

Meaning

Device R2 is advertising the 172.16.6.0/24 route toward Device R3.

Verifying the Route on Device R3

Purpose

Make sure that the 172.16.6.0/24 prefix is in Device R3's routing table.

Action

```
user@R3> show route 172.16.6.0/24
```

```
inet.0: 7 destinations, 8 routes (7 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

172.16.6.0/24      *[Static/5] 03:34:14
                   Reject
                   [BGP/170] 06:34:43, localpref 100, from 192.168.0.2
                   AS path: 100 I, validation-state: unverified
                   > to 10.0.0.5 via fe-1/2/0.6
```

Meaning

Device R3 has the static route and the BGP route for 172.16.6.0/24.

Note that the BGP route is hidden on Device R3 if the route is not reachable or if the next hop cannot be resolved. To fulfill this requirement, this example includes a static default route on Device R3 (**static route 0.0.0.0/0 next-hop 10.0.0.5**).

Experimenting with the conditional Option

Purpose

See how the **conditional** option works in the context of the BGP path selection algorithm.

Action

1. On Device R2, add the **conditional** option.

```
[edit protocols bgp group int]
user@R2# set advertise-external conditional
user@R2# commit
```

2. On Device R2, check to see if the 172.16.6.0/24 route is advertised toward Device R3.

```
user@R2> show route advertising-protocol bgp 192.168.0.3
```

As expected, the route is no longer advertised. You might need to wait a few seconds to see this result.

3. On Device R3, deactivate the **then local-preference** policy action.

```
[edit policy-options policy-statement send-static term 1]
user@R3# deactivate logical-systems R3 then local-preference
user@R3# commit
```

4. On Device R2, ensure that the local preferences of the two paths are equal.

```
user@R2> show route 172.16.6.0/24
```

```
inet.0: 8 destinations, 9 routes (8 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

172.16.6.0/24      *[BGP/170] 08:02:59, localpref 100
                   AS path: 100 I, validation-state: unverified
                   > to 10.0.0.1 via fe-1/2/0.0
                   [BGP/170] 00:07:51, localpref 100, from 192.168.0.3
                   AS path: I, validation-state: unverified
                   > to 10.0.0.6 via fe-1/2/1.0
```

5. On Device R2, add the **as-path-ignore** statement.

```
[edit protocols bgp]
```

```
user@R2# set path-selection as-path-ignore
user@R2# commit
```

6. On Device R2, check to see if the 172.16.6.0/24 route is advertised toward Device R3.

```
user@R2> show route advertising-protocol bgp 192.168.0.3
```

```
inet.0: 8 destinations, 9 routes (8 active, 0 holddown, 0 hidden)
  Prefix                Nexthop          MED      Lclpref   AS path
* 172.16.6.0/24         10.0.0.1         100      100      100 I
```

As expected, the route is now advertised because the AS path length is ignored and because the local preferences are equal.

[Example: Configuring BGP to Advertise Inactive Routes | 97](#)

Understanding BGP Path Selection

Example: Configuring BGP to Advertise Inactive Routes

IN THIS SECTION

- [Requirements | 99](#)
- [Overview | 99](#)
- [Configuration | 99](#)
- [Verification | 103](#)

By default, BGP readvertises only active routes. To have the routing table export to BGP the best route learned by BGP even if Junos OS did not select it to be an active route, include the **advertise-inactive** statement:

```
advertise-inactive;
```

In Junos OS, BGP advertises BGP routes that are installed or active, which are routes selected as the best based on the BGP path selection rules. The **advertise-inactive** statement allows nonactive BGP routes to be advertised to other peers.

NOTE: If the routing table has two BGP routes where one is active and the other is inactive, the **advertise-inactive** statement does not advertise the inactive BGP prefix. This statement does not advertise an inactive BGP route in the presence of another active BGP route. However, if the active route is a static route, the **advertise-inactive** statement advertises the inactive BGP route.

Junos OS also provides support for configuring a BGP export policy that matches the state of an advertised route. You can match either active or inactive routes, as follows:

```
policy-options {
  policy-statement name{
    from state (active|inactive);
  }
}
```

This qualifier only matches when used in the context of an export policy. When a route is being advertised by a protocol that can advertise inactive routes (such as BGP), **state inactive** matches routes advertised as a result of the **advertise-inactive** (or **advertise-external**) statement.

For example, the following configuration can be used as a BGP export policy to mark routes advertised due to the **advertise-inactive** setting with a user-defined community. That community can be later used by the receiving routers to filter out such routes from the forwarding table. Such a mechanism can be used to address concerns that advertising paths not used for forwarding by the sender might lead to forwarding loops.

```
user@host# show policy-options
policy-statement mark-inactive {
  term inactive {
    from state inactive;
    then {
      community set comm-inactive;
    }
  }
  term default {
    from protocol bgp;
    then accept;
  }
}
```

```

    then reject;
}
community comm-inactive members 65536:65284;

```

Requirements

No special configuration beyond device initialization is required before configuring this example.

Overview

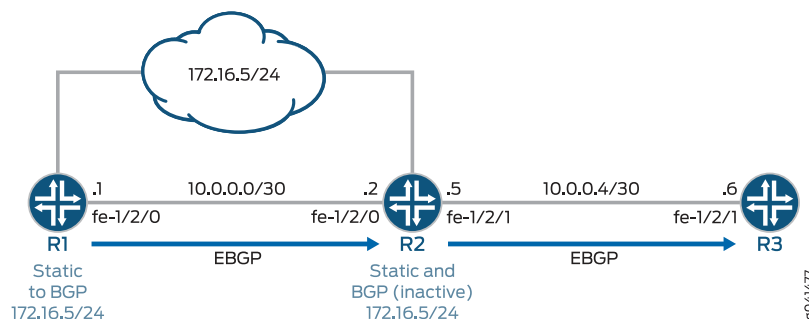

In this example, Device R2 has two external BGP (EBGP) peers, Device R1 and Device R3.

Device R1 has a static route to 172.16.5/24. Likewise, Device R2 also has a static route to 172.16.5/24. Through BGP, Device R1 sends information about its static route to Device R2. Device R2 now has information about 172.16.5/24 from two sources—its own static route and the BGP-learned route received from Device R1. Static routes are preferred over BGP-learned routes, so the BGP route is inactive on Device R2. Normally Device R2 would send the BGP-learned information to Device R3, but Device R2 does not do this because the BGP route is inactive. Device R3, therefore, has no information about 172.16.5/24 unless you enable the **advertise-inactive** command on Device R2, which causes Device R2 to send the BGP-learned to Device R3.

Topology

Figure 10 on page 99 shows the sample network.

Figure 10: BGP Topology for advertise-inactive

“CLI Quick Configuration” on page 99 shows the configuration for all of the devices in Figure 10 on page 99.

The section “Step-by-Step Procedure” on page 101 describes the steps on Device R2.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

Device R1

```
set interfaces fe-1/2/0 unit 0 family inet address 10.0.0.1/30
set interfaces lo0 unit 0 family inet address 192.168.0.1/32
set protocols bgp group to_R2 type external
set protocols bgp group to_R2 export send-static
set protocols bgp group to_R2 neighbor 10.0.0.2 peer-as 200
set policy-options policy-statement send-static term 1 from protocol static
set policy-options policy-statement send-static term 1 then accept
set routing-options static route 172.16.5.0/24 discard
set routing-options static route 172.16.5.0/24 install
set routing-options autonomous-system 100
```

Device R2

```
set interfaces fe-1/2/0 unit 0 family inet address 10.0.0.2/30
set interfaces fe-1/2/1 unit 0 family inet address 10.0.0.5/30
set interfaces lo0 unit 0 family inet address 192.168.0.2/32
set protocols bgp group to_R1 type external
set protocols bgp group to_R1 neighbor 10.0.0.1 peer-as 100
set protocols bgp group to_R3 type external
set protocols bgp group to_R3 advertise-inactive
set protocols bgp group to_R3 neighbor 10.0.0.6 peer-as 300
set routing-options static route 172.16.5.0/24 discard
set routing-options static route 172.16.5.0/24 install
set routing-options autonomous-system 200
```

Device R3

```
set interfaces fe-1/2/1 unit 0 family inet address 10.0.0.6/30
set interfaces fe-1/2/0 unit 9 family inet address 10.0.0.9/30
set interfaces lo0 unit 0 family inet address 192.168.0.3/32
set protocols bgp group ext type external
```

```

set protocols bgp group ext peer-as 200
set protocols bgp group ext neighbor 10.0.0.5
set routing-options autonomous-system 300

```

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure Device R2:

1. Configure the device interfaces.

```

[edit interfaces]
user@R2# set fe-1/2/0 unit 0 family inet address 10.0.0.2/30
user@R2# set fe-1/2/1 unit 0 family inet address 10.0.0.5/30
user@R2# set lo0 unit 0 family inet address 192.168.0.2/32

```

2. Configure the EBGp connection to Device R1.

```

[edit protocols bgp group to_R1]
user@R2# set type external
user@R2# set neighbor 10.0.0.1 peer-as 100

```

3. Configure the EBGp connection to Device R3.

```

[edit protocols bgp group to_R3]
user@R2# set type external
user@R2# set neighbor 10.0.0.6 peer-as 300

```

4. Add the **advertise-inactive** statement to the EBGp group peering session with Device R3.

```

[edit protocols bgp group to_R3]
user@R2# set advertise-inactive

```

5. Configure the static route to the 172.16.5.0/24 network.

```
[edit routing-options static]
user@R2# set route 172.16.5.0/24 discard
user@R2# set route 172.16.5.0/24 install
```

6. Configure the autonomous system (AS) number.

```
[edit routing-options]
user@R2# set autonomous-system 200
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R2# show interfaces
fe-1/2/0 {
  unit 0 {
    family inet {
      address 10.0.0.2/30;
    }
  }
}
fe-1/2/1 {
  unit 0 {
    family inet {
      address 10.0.0.5/30;
    }
  }
}
lo0 {
  unit 0 {
    family inet {
      address 192.168.0.2/32;
    }
  }
}
```

```
user@R2# show protocols
bgp {
  group to_R1 {
    type external;
```

```
    neighbor 10.0.0.1 {  
        peer-as 100;  
    }  
}  
group to_R3 {  
    type external;  
    advertise-inactive;  
    neighbor 10.0.0.6 {  
        peer-as 300;  
    }  
}  
}
```

```
user@R2# show routing-options  
static {  
    route 172.16.5.0/24 {  
        discard;  
        install;  
    }  
}  
autonomous-system 200;
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

IN THIS SECTION

- [Verifying the BGP Active Path | 103](#)
- [Verifying the External Route Advertisement | 104](#)
- [Verifying the Route on Device R3 | 104](#)
- [Experimenting with the advertise-inactive Statement | 105](#)

Confirm that the configuration is working properly.

Verifying the BGP Active Path

Purpose

On Device R2, make sure that the 172.16.5.0/24 prefix is in the routing table and has the expected active path.

Action

user@R2> **show route 172.16.5**

```
inet.0: 7 destinations, 8 routes (7 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

172.16.5.0/24      *[Static/5] 21:24:38
                   Discard
                   [BGP/170] 21:21:41, localpref 100
                   AS path: 100 I, validation-state: unverified
                   > to 10.0.0.1 via fe-1/2/0.0
```

Meaning

Device R2 receives the 172.16.5.0/24 route from both Device R1 and from its own statically configured route. The static route is the active path, as designated by the asterisk (*). The static route path has the lowest route preference (5) as compared to the BGP preference (170). Therefore, the static route becomes active.

Verifying the External Route Advertisement

Purpose

On Device R2, make sure that the 172.16.5.0/24 route is advertised toward Device R3.

Action

user@R2> **show route advertising-protocol bgp 10.0.0.6**

```
inet.0: 6 destinations, 7 routes (6 active, 0 holddown, 0 hidden)
  Prefix                Nexthop          MED      Lclpref   AS path
  172.16.5.0/24         Self              0         100      I
```

Meaning

Device R2 is advertising the 172.16.5.0/24 route toward Device R3

Verifying the Route on Device R3

Purpose

Make sure that the 172.16.6.0/24 prefix is in Device R3's routing table.

Action

user@R3> **show route 172.16.5.0/24**

```
inet.0: 5 destinations, 5 routes (5 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

172.16.5.0/24      *[BGP/170] 00:01:19, localpref 100
                   AS path: 200 100 I, validation-state: unverified
                   > to 10.0.0.5 via fe-1/2/1.0
```

Meaning

Device R3 has the BGP-learned route for 172.16.5.0/24.

Experimenting with the advertise-inactive Statement

Purpose

See what happens when the **advertise-inactive** statement is removed from the BGP configuration on Device R2.

Action

1. On Device R2, deactivate the **advertise-inactive** statement.

```
[edit protocols bgp group to_R3]
user@R2# deactivate advertise-inactive
user@R2# commit
```

2. On Device R2, check to see if the 172.16.5.0/24 route is advertised toward Device R3.

user@R2> **show route advertising-protocol bgp 10.0.0.6**

As expected, the route is no longer advertised.

3. On Device R3, ensure that the 172.16.5.0/24 route is absent from the routing table.

user@R3> **show route 172.16.5.0/24**

Meaning

Device R1 advertises route 172.16.5/24 to Device R2, but Device R2 has a manually configured static route for this prefix. Static routes are preferred over BGP routes, so Device R2 installs the BGP route as an inactive route. Because the BGP route is not active, Device R2 does not readvertise the BGP route to Device R3. This is the default behavior in Junos OS. If you add the **advertise-inactive** statement to the BGP configuration on Device R2, Device R2 readvertises nonactive routes.

RELATED DOCUMENTATION

[Example: Configuring a Routing Policy to Advertise the Best External Route to Internal Peers | 86](#)
[Understanding BGP Path Selection](#)

Example: Using Routing Policy to Set a Preference Value for BGP Routes

IN THIS SECTION

- [Requirements | 106](#)
- [Overview | 106](#)
- [Configuration | 107](#)
- [Verification | 112](#)

This example shows how to use routing policy to set the preference for routes learned from BGP. Routing information can be learned from multiple sources. To break ties among equally specific routes learned from multiple sources, each source has a preference value. Routes that are learned through explicit administrative action, such as static routes, are preferred over routes learned from a routing protocol, such as BGP or OSPF. This concept is called *administrative distance* by some vendors.

Requirements

No special configuration beyond device initialization is required before you configure this example.

Overview

Routing information can be learned from multiple sources, such as through static configuration, BGP, or an interior gateway protocol (IGP). When Junos OS determines a route's preference to become the active

route, it selects the route with the lowest preference as the active route and installs this route into the forwarding table. By default, the routing software assigns a preference of 170 to routes that originated from BGP. Of all the routing protocols, BGP has the highest default preference value, which means that routes learned by BGP are the least likely to become the active route.

Some vendors have a preference (distance) of 20 for external BGP (EBGP) and a distance of 200 for internal BGP (IGBP). Junos OS uses the same value (170) for both EBGP and IGBP. However, this difference between vendors has no operational impact because Junos OS always prefers EBGP routes over IGBP routes.

Another area in which vendors differ is in regard to IGP distance compared to BGP distance. For example, some vendors assign a distance of 110 to OSPF routes. This is higher than the EBGP distance of 20, and results in the selection of an EBGP route over an equivalent OSPF route. In the same scenario, Junos OS chooses the OSPF route, because of the default preference 10 for an internal OSPF route and 150 for an external OSPF route, which are both lower than the 170 preference assigned to all BGP routes.

This example shows a routing policy that matches routes from specific next hops and sets a preference. If a route does not match the first term, it is evaluated by the second term.

Topology

In the sample network, Device R1 and Device R3 have EBGP sessions with Device R2.

On Device R2, an import policy takes the following actions:

- For routes received through BGP from next-hop 10.0.0.1 (Device R1), set the route preference to 10.
- For routes received through BGP from next-hop 10.1.0.2 (Device R3), set the route preference to 15.

Figure 11 on page 107 shows the sample network.

Figure 11: BGP Preference Value Topology

"CLI Quick Configuration" on page 107 shows the configuration for all of the devices in Figure 11 on page 107.

The section "Step-by-Step Procedure" on page 109 describes the steps on Device R2.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

Device R1

```
set interfaces fe-1/2/0 unit 0 family inet address 10.0.0.1/30
set interfaces lo0 unit 0 family inet address 192.168.0.1/32
set protocols bgp group ext type external
set protocols bgp group ext export send-direct
set protocols bgp group ext peer-as 200
set protocols bgp group ext neighbor 10.0.0.2
set policy-options policy-statement send-direct term 1 from protocol direct
set policy-options policy-statement send-direct term 1 then accept
set routing-options autonomous-system 100
```

Device R2

```
set interfaces fe-1/2/0 unit 0 family inet address 10.0.0.2/30
set interfaces fe-1/2/1 unit 0 family inet address 10.1.0.1/30
set interfaces lo0 unit 0 family inet address 192.168.0.2/32
set protocols bgp group ext type external
set protocols bgp group ext import set-preference
set protocols bgp group ext export send-direct
set protocols bgp group ext neighbor 10.0.0.1 peer-as 100
set protocols bgp group ext neighbor 10.1.0.2 peer-as 300
set policy-options policy-statement send-direct term 1 from protocol direct
set policy-options policy-statement send-direct term 1 then accept
set policy-options policy-statement set-preference term term1 from protocol bgp
set policy-options policy-statement set-preference term term1 from next-hop 10.0.0.1
set policy-options policy-statement set-preference term term1 then preference 10
set policy-options policy-statement set-preference term term2 from protocol bgp
set policy-options policy-statement set-preference term term2 from next-hop 10.1.0.2
set policy-options policy-statement set-preference term term2 then preference 15
set routing-options autonomous-system 200
```

Device R3

```

set interfaces fe-1/2/1 unit 0 family inet address 10.1.0.2/30
set interfaces lo0 unit 0 family inet address 192.168.0.3/32
set protocols bgp group ext type external
set protocols bgp group ext export send-direct
set protocols bgp group ext peer-as 200
set protocols bgp group ext neighbor 10.1.0.1
set policy-options policy-statement send-direct term 1 from protocol direct
set policy-options policy-statement send-direct term 1 then accept
set routing-options autonomous-system 300

```

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure Device R2:

1. Configure the device interfaces.

```

[edit interfaces]
user@R2# set fe-1/2/0 unit 0 family inet address 10.0.0.2/30
user@R2# set fe-1/2/1 unit 0 family inet address 10.1.0.1/30
user@R2# set lo0 unit 0 family inet address 192.168.0.2/32

```

2. Configure the local autonomous system.

```

[edit routing-options]
user@R2# set autonomous-system 200

```

3. Configure the routing policy that sends direct routes.

```

[edit policy-options policy-statement send-direct term 1]
user@R2# set from protocol direct
user@R2# set then accept

```

4. Configure the routing policy that changes the preference of received routes.

```

[edit policy-options policy-statement set-preference]

```

```

user@R2# set term term1 from protocol bgp
user@R2# set term term1 from next-hop 10.0.0.1
user@R2# set term term1 then preference 10
user@R2# set term term2 from protocol bgp
user@R2# set term term2 from next-hop 10.1.0.2
user@R2# set term term2 then preference 15

```

5. Configure the external peering with Device R2.

```

[edit protocols bgp group ext]
user@R2# set type external
user@R2# set export send-direct
user@R2# set neighbor 10.0.0.1 peer-as 100
user@R2# set neighbor 10.1.0.2 peer-as 300

```

6. Apply the **set-preference** policy as an import policy.

This affects Device R2's routing table and has no impact on Device R1 and Device R3.

```

[edit protocols bgp group ext]
user@R2# set import set-preference

```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

user@R2# show interfaces
fe-1/2/0 {
  unit 0 {
    family inet {
      address 10.0.0.2/30;
    }
  }
}
fe-1/2/1 {
  unit 0 {
    family inet {
      address 10.1.0.1/30;
    }
  }
}

```

```

}
lo0 {
  unit 0 {
    family inet {
      address 192.168.0.2/32;
    }
  }
}
}

```

user@R2# **show protocols**

```

bgp {
  group ext {
    type external;
    import set-preference;
    export send-direct;
    neighbor 10.0.0.1 {
      peer-as 100;
    }
    neighbor 10.1.0.2 {
      peer-as 300;
    }
  }
}
}

```

user@R2# **show policy-options**

```

policy-statement send-direct {
  term 1 {
    from protocol direct;
    then accept;
  }
}
policy-statement set-preference {
  term term1 {
    from {
      protocol bgp;
      next-hop 10.0.0.1;
    }
    then {
      preference 10;
    }
  }
  term term2 {
    from {

```

```

        protocol bgp;
        next-hop 10.1.0.2;
    }
    then {
        preference 15;
    }
}
}

```

```

user@R2# show routing-options
autonomous-system 200;

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

Verifying the Preference

Purpose

Make sure that the routing tables on Device R1 and Device R2 reflect the fact that Device R1 is using the configured EBGp preference of 8, and Device R2 is using the default EBGp preference of 170.

Action

From operational mode, enter the **show route protocols bgp** command.

```

user@R2> show route protocols bgp

```

```

inet.0: 7 destinations, 9 routes (7 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.0.0.0/30      [BGP/10] 04:42:23, localpref 100
                 AS path: 100 I, validation-state: unverified
                 > to 10.0.0.1 via fe-1/2/0.0
10.1.0.0/30      [BGP/15] 04:42:23, localpref 100
                 AS path: 300 I, validation-state: unverified
                 > to 10.1.0.2 via fe-1/2/1.0
192.168.0.1/32   *[BGP/10] 04:42:23, localpref 100
                 AS path: 100 I, validation-state: unverified
                 > to 10.0.0.1 via fe-1/2/0.0
192.168.0.3/32   *[BGP/15] 04:42:23, localpref 100

```

```
AS path: 300 I, validation-state: unverified
> to 10.1.0.2 via fe-1/2/1.0
```

Meaning

The output shows that on Device R2, the preference values have been changed to 15 for routes learned from Device R3, and the preference values have been changed to 10 for routes learned from Device R1.

RELATED DOCUMENTATION

Route Preferences Overview

Understanding External BGP Peering Sessions

Example: Enabling BGP Route Advertisements

IN THIS SECTION

- [Requirements | 114](#)
- [Overview | 114](#)
- [Configuration | 114](#)
- [Verification | 121](#)

Junos OS does not advertise the routes learned from one EBGP peer back to the same external BGP (EBGP) peer. In addition, the software does not advertise those routes back to any EBGP peers that are in the same autonomous system (AS) as the originating peer, regardless of the routing instance. You can modify this behavior by including the **advertise-peer-as** statement in the configuration.

If you include the **advertise-peer-as** statement in the configuration, BGP advertises the route regardless of this check.

To restore the default behavior, include the **no-advertise-peer-as** statement in the configuration:

```
no-advertise-peer-as;
```

The route suppression default behavior is disabled if the **as-override** statement is included in the configuration. If you include both the **as-override** and **no-advertise-peer-as** statements in the configuration, the **no-advertise-peer-as** statement is ignored.

Requirements

No special configuration beyond device initialization is required before you configure this example.

Overview

This example shows three routing devices with external BGP (EBGP) connections. Device R2 has an EBGP connection to Device R1 and another EBGP connection to Device R3. Although separated by Device R2 which is in AS 64511, Device R1 and Device R3 are in the same AS (AS 64512). Device R1 and Device R3 advertise into BGP direct routes to their own loopback interface addresses.

Device R2 receives these loopback interface routes, and the **advertise peer-as** statement allows Device R2 to advertise them. Specifically, Device R1 sends the 192.168.0.1 route to Device R2, and because Device R2 has the **advertise peer-as** configured, Device R2 can send the 192.168.0.1 route to Device R3. Likewise, Device R3 sends the 192.168.0.3 route to Device R2, and **advertise peer-as** enables Device R2 to forward the route to Device R1.

To enable Device R1 and Device R3 to accept routes that contain their own AS number in the AS path, the **loops 2** statement is required on Device R1 and Device R3.

Topology

Figure 12: BGP Topology for advertise-peer-as

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

Device R1

```
set interfaces fe-1/2/0 unit 0 family inet address 10.0.0.1/30
set interfaces lo0 unit 0 family inet address 192.168.0.1/32
set protocols bgp family inet unicast loops 2
set protocols bgp group ext type external
set protocols bgp group ext export send-direct
set protocols bgp group ext peer-as 64511
set protocols bgp group ext neighbor 10.0.0.2
set policy-options policy-statement send-direct term 1 from protocol direct
set policy-options policy-statement send-direct term 1 then accept
set routing-options autonomous-system 64512
```

Device R2

```
set interfaces fe-1/2/0 unit 0 family inet address 10.0.0.2/30
set interfaces fe-1/2/1 unit 0 family inet address 10.1.0.1/30
set interfaces lo0 unit 0 family inet address 192.168.0.2/32
set protocols bgp group ext type external
set protocols bgp group ext advertise-peer-as
set protocols bgp group ext export send-direct
set protocols bgp group ext neighbor 10.0.0.1 peer-as 64512
set protocols bgp group ext neighbor 10.1.0.2 peer-as 64512
set policy-options policy-statement send-direct term 1 from protocol direct
set policy-options policy-statement send-direct term 1 then accept
set routing-options autonomous-system 64511
```

Device R3

```
set interfaces fe-1/2/1 unit 0 family inet address 10.1.0.2/30
set interfaces lo0 unit 0 family inet address 192.168.0.3/32
set protocols bgp family inet unicast loops 2
set protocols bgp group ext type external
set protocols bgp group ext export send-direct
set protocols bgp group ext peer-as 64511
set protocols bgp group ext neighbor 10.1.0.1
set policy-options policy-statement send-direct term 1 from protocol direct
```

```
set policy-options policy-statement send-direct term 1 then accept
set routing-options autonomous-system 64512
```

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure Device R1:

1. Configure the device interfaces.

```
[edit interfaces]
user@R1# set fe-1/2/0 unit 0 family inet address 10.0.0.1/30
user@R1# set lo0 unit 0 family inet address 192.168.0.1/32
```

2. Configure BGP.

```
[edit protocols bgp group ext]
user@R1# set type external
user@R1# set peer-as 64511
user@R1# set neighbor 10.0.0.2
```

3. Prevent routes from Device R3 from being hidden on Device R1 by including the **loops 2** statement.

The **loops 2** statement means that the local device's own AS number can appear in the AS path up to one time without causing the route to be hidden. The route is hidden if the local device's AS number is detected in the path two or more times.

```
[edit protocols bgp family inet unicast]
user@R1# set loops 2
```

4. Configure the routing policy that sends direct routes.

```
[edit policy-options policy-statement send-direct term 1]
user@R1# set from protocol direct
user@R1# set then accept
```

5. Apply the export policy to the BGP peering session with Device R2.

```
[edit protocols bgp group ext]
user@R1# set export send-direct
```

6. Configure the autonomous system (AS) number.

```
[edit routing-options ]
user@R1# set autonomous-system 64512
```

Step-by-Step Procedure

To configure Device R2:

1. Configure the device interfaces.

```
[edit interfaces]
user@R2# set fe-1/2/0 unit 0 family inet address 10.0.0.2/30
user@R2# set fe-1/2/1 unit 0 family inet address 10.1.0.1/30
user@R2# set lo0 unit 0 family inet address 192.168.0.2/32
```

2. Configure BGP.

```
[edit protocols bgp group ext]
user@R2# set type external
user@R2# set neighbor 10.0.0.1 peer-as 64512
user@R2# set neighbor 10.1.0.2 peer-as 64512
```

3. Configure Device R2 to advertise routes learned from one EBGp peer to another EBGp peer in the same AS.

In other words, advertise to Device R1 routes learned from Device R3 (and the reverse), even though Device R1 and Device R3 are in the same AS.

```
[edit protocols bgp group ext]
user@R2# set advertise-peer-as
```

4. Configure a routing policy that sends direct routes.

```
[edit policy-options policy-statement send-direct term 1]
user@R2# set from protocol direct
```

```
user@R2# set then accept
```

5. Apply the export policy.

```
[edit protocols bgp group ext]
user@R2# set export send-direct
```

6. Configure the AS number.

```
[edit routing-options]
user@R2# set autonomous-system 64511
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

Device R1

```
user@R1# show interfaces
fe-1/2/0 {
  unit 0 {
    family inet {
      address 10.0.0.1/30;
    }
  }
}
lo0 {
  unit 0 {
    family inet {
      address 192.168.0.1/32;
    }
  }
}
```

```
user@R1# show protocols
bgp {
```

```

family inet {
    unicast {
        loops 2;
    }
}
group ext {
    type external;
    export send-direct;
    peer-as 64511;
    neighbor 10.0.0.2;
}
}

```

```

user@R1# show policy-options
policy-statement send-direct {
    term 1 {
        from protocol direct;
        then accept;
    }
}

```

```

user@R1# show routing-options
autonomous-system 64512;

```

Device R2

```

user@R2# show interfaces
fe-1/2/0 {
    unit 0 {
        family inet {
            address 10.0.0.2/30;
        }
    }
}
fe-1/2/1 {
    unit 0 {
        family inet {
            address 10.1.0.1/30;
        }
    }
}

```

```

    }
    lo0 {
        unit 0 {
            family inet {
                address 192.168.0.2/32;
            }
        }
    }
}

```

user@R2# **show protocols**

```

bgp {
    group ext {
        type external;
        advertise-peer-as;
        export send-direct;
        neighbor 10.0.0.1 {
            peer-as 64512;
        }
        neighbor 10.1.0.2 {
            peer-as 64512;
        }
    }
}

```

user@R2# **show policy-options**

```

policy-statement send-direct {
    term 1 {
        from protocol direct;
        then accept;
    }
}

```

user@R2# **show routing-options**

```

autonomous-system 64511;

```

If you are done configuring the devices, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

Verifying the BGP Routes

Purpose

Make sure that the routing tables on Device R1 and Device R3 contain the expected routes.

Action

1. On Device R2, deactivate the **advertise-peer-as** statement in the BGP configuration.

```
[edit protocols bgp group ext]
user@R2# deactivate advertise-peer-as
user@R2# commit
```

2. On Device R3, deactivate the **loops** statement in the BGP configuration.

```
[edit protocols bgp family inet unicast ]
user@R3# deactivate unicast loops
user@R3# commit
```

3. On Device R1, check to see what routes are advertised to Device R2.

```
user@R1> show route advertising-protocol bgp 10.0.0.2
```

```
inet.0: 5 destinations, 6 routes (5 active, 0 holddown, 0 hidden)
  Prefix                Nexthop              MED      Lclpref    AS path
* 10.0.0.0/30           Self                  0
* 192.168.0.1/32        Self                  0
```

4. On Device R2, check to see what routes are received from Device R1.

```
user@R2> show route receive-protocol bgp 10.0.0.1
```

```
inet.0: 7 destinations, 9 routes (7 active, 0 holddown, 0 hidden)
  Prefix                Nexthop              MED      Lclpref    AS path
10.0.0.0/30            10.0.0.1              0
* 192.168.0.1/32        10.0.0.1              0
```

5. On Device R2, check to see what routes are advertised to Device R3.

```
user@R2> show route advertising-protocol bgp 10.1.0.2
```

```
inet.0: 7 destinations, 9 routes (7 active, 0 holddown, 0 hidden)
  Prefix                Nexthop                MED      Lclpref    AS path
* 10.0.0.0/30           Self                                I
* 10.1.0.0/30           Self                                I
* 192.168.0.2/32        Self                                I
```

6. On Device R2, activate the **advertise-peer-as** statement in the BGP configuration.

```
[edit protocols bgp group ext]
user@R2# activate advertise-peer-as
user@R2# commit
```

7. On Device R2, recheck the routes that are advertised to Device R3.

```
user@R2> show route advertising-protocol bgp 10.1.0.2
```

```
inet.0: 7 destinations, 9 routes (7 active, 0 holddown, 0 hidden)
  Prefix                Nexthop                MED      Lclpref    AS path
* 10.0.0.0/30           Self                                I
* 10.1.0.0/30           Self                                I
* 192.168.0.1/32        Self                64512 I
* 192.168.0.2/32        Self                                I
* 192.168.0.3/32        10.1.0.2            64512 I
```

8. On Device R3, check the routes that are received from Device R2.

```
user@R3> show route receive-protocol bgp 10.1.0.1
```

```
inet.0: 5 destinations, 6 routes (5 active, 0 holddown, 0 hidden)
  Prefix                Nexthop                MED      Lclpref    AS path
* 10.0.0.0/30           10.1.0.1              64511 I
  10.1.0.0/30           10.1.0.1              64511 I
* 192.168.0.2/32        10.1.0.1              64511 I
```

9. On Device R3, activate the **loops** statement in the BGP configuration.

```
[edit protocols bgp family inet unicast ]
user@R3# activate unicast loops
user@R3# commit
```

10. On Device R3, recheck the routes that are received from Device R2.

```
user@R3> show route receive-protocol bgp 10.1.0.1
```

```

inet.0: 6 destinations, 8 routes (6 active, 0 holddown, 1 hidden)
  Prefix                Nexthop          MED      Lclpref    AS path
* 10.0.0.0/30           10.1.0.1                64511 I

I
* 192.168.0.2/32        10.1.0.1                64511 I

```

Meaning

First the **advertise-peer-as** statement and the **loops** statement are deactivated so that the default behavior can be examined. Device R1 sends to Device R2 a route to Device R1's loopback interface address, 192.168.0.1/32. Device R2 does not advertise this route to Device R3. After activating the **advertise-peer-as** statement, Device R2 does advertise the 192.168.0.1/32 route to Device R3. Device R3 does not accept this route until after the **loops** statement is activated.

Example: Rejecting Known Invalid Routes

IN THIS SECTION

- Requirements | 123
- Overview | 124
- Configuration | 124
- Verification | 125

This example shows how to create route-based match conditions for a routing policy.

Requirements

Before you begin, be sure your router interfaces and protocols are correctly configured.

Overview

In this example, you create a policy called `rejectpolicy1` that rejects routes with a mask of /8 and greater (/8, /9, /10, and so on) that have the first 8 bits set to 0. This policy also accepts routes less than 8 bits in length by creating a mask of 0/0 up to /7.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
set policy-options policy-statement rejectpolicy1 term rejectterm1 from route-filter 0.0.0.0/0 upto /7 accept
set policy-options policy-statement rejectpolicy1 term rejectterm1 from route-filter 0.0.0.0/8 orlonger reject
set policy-options policy-statement test term 1 from protocol direct
```

Step-by-Step Procedure

To create a policy that rejects known invalid routes:

1. Create the routing policy.

```
[edit]
user@host# edit policy-options policy-statement rejectpolicy1
```

2. Create the policy term.

```
[edit policy-options policy-statement rejectpolicy1]
user@host# edit term rejectterm1
```

3. Create a mask that specifies which routes to accept.

```
[edit policy-options policy-statement rejectpolicy1 term rejectterm1]
user@host# set from route-filter 0/0 upto /7 accept
```

4. Create a mask that specifies which routes to reject.

```
[edit policy-options policy-statement rejectpolicy1 term rejectterm1]
user@host# set from route-filter 0/8 orlonger reject
```

Results

Confirm your configuration by entering the **show policy-options** command from configuration mode. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
user@host# show policy-options
policy-statement rejectpolicy1 {
  term rejectterm1 {
    from {
      route-filter 0.0.0.0/0 upto /7 accept;
      route-filter 0.0.0.0/8 orlonger reject;
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

IN THIS SECTION

- [Verifying the Route-Based Match Conditions | 125](#)

To confirm that the configuration is working properly, perform these tasks:

Verifying the Route-Based Match Conditions

Purpose

Verify that the policy and term are configured on the device with the appropriate route-based match conditions.

Action

From operational mode, enter the **show policy-options** command.

This example is a case study in how routing policies might be used in a typical Internet service provider (ISP) network.

Requirements

No special configuration beyond device initialization is required before configuring this example.

Overview

In this network example, the ISP's AS number is 64510. The ISP has two transit peers (AS 64514 and AS 64515) to which it connects at an exchange point. The ISP is also connected to two private peers (AS 64513 and AS 64516) with which it exchanges specific customer routes. The ISP has two customers (AS 64511 and AS 64512).

The ISP policies are configured in an outbound direction. That is, the example focuses on the routes that the ISP announces to its peers and customers, and includes the following:

1. The ISP has been assigned AS 64510 and the routing space of 172.16.32.0/21. With the exception of the two customer networks, all other customer routes are simulated with static routes.
2. The exchange peers are used for transit service to other portions of the Internet. This means that the ISP is accepting all routes (the full Internet routing table) from those BGP peers. To help maintain an

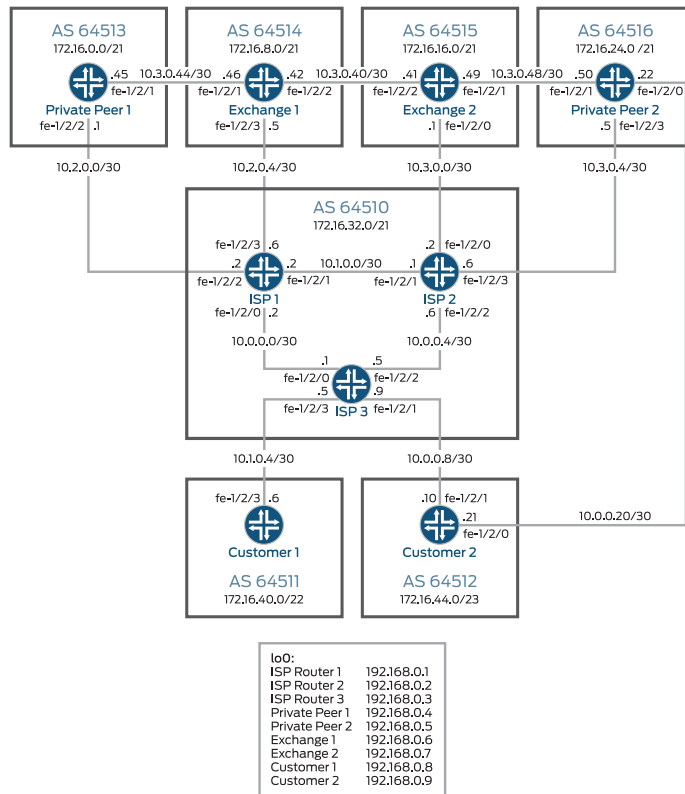

optimized Internet routing table, the ISP is configured to advertise only two aggregate routes to the transit peers.

3. The ISP administrators want all data to the private peers to use the direct links. As a result, all the customer routes from the ISP are advertised to those private peers. These peers then advertise all their customer routes to the ISP.
4. Finally, each customer has a different set of requirements. Customer-1 requires a single default route. Customer-2 requires specific routes.

Topology

Figure 13 on page 127 shows the sample network.

Configuring Device Customer-1

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

Device Customer-1 has multiple static routes configured to simulate customer routes. These routes are sent to the ISP.

To configure Device Customer-1:

1. Configure the device interfaces.

```
[edit interfaces]
user@Customer-1# set fe-1/2/3 unit 0 description to_ISP-3
user@Customer-1# set fe-1/2/3 unit 0 family inet address 10.1.0.6/30
user@Customer-1# set lo0 unit 0 family inet address 192.168.0.8/32
```

2. Configure the static routes.

```
[edit routing-options static]
user@Customer-1# set route 172.16.40.0/25 reject
user@Customer-1# set route 172.16.40.128/25 reject
user@Customer-1# set route 172.16.41.0/25 reject
user@Customer-1# set route 172.16.41.128/25 reject
```

3. Configure the policy to send static routes.

```
[edit policy-options policy-statement send-statics term static-routes]
user@Customer-1# set from protocol static
user@Customer-1# set then accept
```

4. Configure the external BGP (EBGP) connection to the ISP.

```
[edit protocols bgp group ext]
user@Customer-1# set type external
user@Customer-1# set export send-statics
user@Customer-1# set peer-as 64510
user@Customer-1# set neighbor 10.1.0.5
```

5. Configure the autonomous system (AS) number.

```
[edit routing-options]
```

```
user@Customer-1# set autonomous-system 64511
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@Customer-1# show interfaces
fe-1/2/1 {
  unit 0 {
    description to_ISP-3;
    family inet {
      address 10.1.0.6/30;
    }
  }
}
lo0 {
  unit 0 {
    family inet {
      address 192.168.0.8/32;
    }
  }
}
```

```
user@Customer-1# show protocols
bgp {
  group ext {
    type external;
    export send-statics;
    peer-as 64510;
    neighbor 10.1.0.5;
  }
}
```

```
user@Customer-1# show policy-options
policy-statement send-statics {
  term static-routes {
    from protocol static;
    then accept;
  }
}
```

```

user@Customer-1# show routing-options
static {
    route 172.16.40.0/25 reject;
    route 172.16.40.128/25 reject;
    route 172.16.41.0/25 reject;
    route 172.16.41.128/25 reject;
}
autonomous-system 64511;

```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring Device Customer-2

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

Device Customer-2 has two static routes configured to simulate customer routes. These routes are sent to the ISP. Customer-2 has a link to the ISP, as well as a link to AS 8000. This customer has requested specific customer routes from the ISP, as well as from AS 64516. Customer-2 wants to use the ISP for transit service to the Internet, and has requested a default route from the ISP.

To configure Device Customer-2:

1. Configure the device interfaces.

```

[edit interfaces]
user@Customer-2# set fe-1/2/1 unit 0 description to_ISP-3
user@Customer-2# set fe-1/2/1 unit 0 family inet address 10.0.0.10/30
user@Customer-2# set fe-1/2/0 unit 0 description to-Private-Peer-2
user@Customer-2# set fe-1/2/0 unit 0 family inet address 10.0.0.21/30
user@Customer-2# set lo0 unit 0 family inet address 192.168.0.9/32

```

2. Configure the static routes.

```

[edit routing-options static]
user@Customer-2# set route 172.16.44.0/26 reject
user@Customer-2# set route 172.16.44.64/26 reject
user@Customer-2# set route 172.16.44.128/26 reject
user@Customer-2# set route 172.16.44.192/26 reject

```

3. Configure the import routing policy.

The route with the highest local preference value is preferred. Routes from the ISP are preferred over the same routes from Device Private-Peer-2

```
[edit policy-options policy-statement inbound-routes]
user@Customer-2# set term AS64510-primary from protocol bgp
user@Customer-2# set term AS64510-primary from as-path AS64510-routes
user@Customer-2# set term AS64510-primary then local-preference 200
user@Customer-2# set term AS64510-primary then accept
[edit policy-options policy-statement inbound-routes]
user@Customer-2# set term AS64516-backup from protocol bgp
user@Customer-2# set term AS64516-backup from as-path AS64516-routes
user@Customer-2# set term AS64516-backup then local-preference 50
user@Customer-2# set term AS64516-backup then accept
[edit policy-options]
user@Customer-2# set as-path AS64510-routes "64510 .*"
user@Customer-2# set as-path AS64516-routes "64516 .*"
```

4. Configure the export routing policy.

```
[edit policy-options policy-statement outbound-routes]
user@Customer-2# set term statics from protocol static
user@Customer-2# set term statics then accept
user@Customer-2# set term internal-bgp-routes from protocol bgp
user@Customer-2# set term internal-bgp-routes from as-path my-own-routes
user@Customer-2# set term internal-bgp-routes then accept
user@Customer-2# set term no-transit then reject
[edit policy-options]
user@Customer-2# set as-path my-own-routes "()"
```

5. Configure the external BGP (EBGP) connection to the ISP and to Device Private-Peer-2.

```
[edit protocols bgp group ext]
user@Customer-2# set type external
user@Customer-2# set import inbound-routes
user@Customer-2# set export outbound-routes
user@Customer-2# set neighbor 10.0.0.9 peer-as 64510
user@Customer-2# set neighbor 10.0.0.22 peer-as 64516
```

6. Configure the autonomous system (AS) number.

```
[edit routing-options]
```

```
user@Customer-2# set autonomous-system 64512
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@Customer-2# show interfaces
fe-1/2/1 {
  unit 0 {
    description to_ISP-3;
    family inet {
      address 10.0.0.10/30;
    }
  }
}
fe-1/2/0 {
  unit 0 {
    description to-Private-Peer-2;
    family inet {
      address 10.0.0.21/30;
    }
  }
}
lo0 {
  unit 0 {
    family inet {
      address 192.168.0.9/32;
    }
  }
}
```

```
user@Customer-2# show protocols
bgp {
  group ext {
    type external;
    import inbound-routes;
    export outbound-routes;
    neighbor 10.0.0.9 {
      peer-as 64510;
    }
    neighbor 10.0.0.22 {
```

```

        peer-as 64516;
    }
}
}

```

user@Customer-2# **show policy-options**

```

policy-statement inbound-routes {
  term AS64510-primary {
    from {
      protocol bgp;
      as-path AS64510-routes;
    }
    then {
      local-preference 200;
      accept;
    }
  }
  term AS64516-backup {
    from {
      protocol bgp;
      as-path AS64516-routes;
    }
    then {
      local-preference 50;
      accept;
    }
  }
}
policy-statement outbound-routes {
  term statics {
    from protocol static;
    then accept;
  }
  term internal-bgp-routes {
    from {
      protocol bgp;
      as-path my-own-routes;
    }
    then accept;
  }
  term no-transit {
    then reject;
  }
}

```

```
as-path my-own-routes "();  
as-path AS64510-routes "64510 .*";  
as-path AS64516-routes "64516 .*";
```

```
user@Customer-2# show routing-options  
static {  
    route 172.16.44.0/26 reject;  
    route 172.16.44.64/26 reject;  
    route 172.16.44.128/26 reject;  
    route 172.16.44.192/26 reject;  
}  
autonomous-system 64512;
```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring Devices ISP-1 and ISP-2

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

Device ISP-1 and Device ISP-2 each have two policies configured: The **private-peer** policy and the **exchange-peer** policy. Because of their similar configurations, this example shows the step-by-step configuration only for Device ISP-2.

On Device ISP-2, the private-peer policy sends the ISP customer routes to Device Private-Peer-2. The policy accepts all local static routes (local Device ISP-2 customers) and all BGP routes in the 172.16.32.0/21 range (advertised by other ISP routers). These two policy terms represent the ISP customer routes. The final policy term rejects all other routes, which includes the entire Internet routing table sent by the exchange peers. These routes do not need to be sent to Device Private-Peer-2 for two reasons:

- The peer already maintains a connection to Device Exchange-2 in our example, so the routes are redundant.
- The private peer wants customer routes only. The **private-peer** policy accomplishes this goal. The **exchange-peer** policy sends routes to Device Exchange-2.

In the example, only two routes need to be sent to Device Exchange-2:

- The aggregate route that represents the AS 64510 routing space of 172.16.32.0/21. This route is configured as an aggregate route locally and is advertised by the **exchange-peer** policy.
- The address space assigned to Customer-2, 172.16.44.0/23. This smaller aggregate route needs to be sent to Device Exchange-2 because the customer is also attached to the AS 64516 peer (Device Private-Peer-2).

Sending these two routes to Device Exchange-2 allows other networks in the Internet to reach the customer through either the ISP or the private peer. If just the private peer were to advertise the /23 network while the ISP maintained only its /21 aggregate, all traffic destined for the customer would transit AS 64516 only. Because the customer also wants routes from the ISP, the 172.16.44.0/23 route is announced by Device ISP-2. Like the larger aggregate route, the 172.16.44.0/23 route is configured locally and is advertised by the exchange-peer policy. The final term in that policy rejects all routes, including the specific customer networks of the ISP, the customer routes from Device Private-Peer-1, the customer routes from Device Private-Peer-2, and the routing table from Device Exchange-1. In essence, this final term prevents the ISP from performing transit services for the Internet at large.

To configure Device ISP-2:

1. Configure the device interfaces.

```
[edit interfaces]
user@ISP-2# set fe-1/2/1 unit 0 description to_ISP-1
user@ISP-2# set fe-1/2/1 unit 0 family inet address 10.1.0.1/30
user@ISP-2# set fe-1/2/2 unit 0 description to_ISP-3
```

```

user@ISP-2# set fe-1/2/2 unit 0 family inet address 10.0.0.6/30
user@ISP-2# set fe-1/2/3 unit 0 description to_Private-Peer-2
user@ISP-2# set fe-1/2/3 unit 0 family inet address 10.3.0.6/30
user@ISP-2# set fe-1/2/0 unit 0 description to_Exchange-2
user@ISP-2# set fe-1/2/0 unit 0 family inet address 10.3.0.2/30
user@ISP-2# set lo0 unit 0 family inet address 192.168.0.2/32

```

2. Configure the interior gateway protocol (IGP).

```

[edit protocols ospf area 0.0.0.0]
user@ISP-2# set interface fe-1/2/2.0
user@ISP-2# set interface fe-1/2/1.0
user@ISP-2# set interface lo0.0 passive

```

3. Configure the static and aggregate routes.

```

[edit routing-options static]
user@ISP-2# set route 172.16.34.0/24 reject
user@ISP-2# set route 172.16.35.0/24 reject
[edit routing-options aggregate]
user@ISP-2# set route 172.16.44.0/23
user@ISP-2# set route 172.16.32.0/21

```

4. Configure the routing policies for the exchange peers.

```

[edit policy-options policy-statement exchange-peer]
user@ISP-2# set term AS64510-Aggregate from protocol aggregate
user@ISP-2# set term AS64510-Aggregate from route-filter 172.16.32.0/21 exact
user@ISP-2# set term AS64510-Aggregate then accept
user@ISP-2# set term Customer-2-Aggregate from protocol aggregate
user@ISP-2# set term Customer-2-Aggregate from route-filter 172.16.44.0/23 exact
user@ISP-2# set term Customer-2-Aggregate then accept
user@ISP-2# set term reject-all-other-routes then reject

```

5. Configure the routing policies for the internal peers.

```

[edit policy-options policy-statement internal-peers]
user@ISP-2# set term statics from protocol static
user@ISP-2# set term statics then accept
user@ISP-2# set term next-hop-self then next-hop self

```

6. Configure the routing policies for the private peer.

```
[edit policy-options policy-statement private-peer]
user@ISP-2# set term statics from protocol static
user@ISP-2# set term statics then accept
user@ISP-2# set term isp-and-customer-routes from protocol bgp
user@ISP-2# set term isp-and-customer-routes from route-filter 172.16.32.0/21 orlonger
user@ISP-2# set term isp-and-customer-routes then accept
user@ISP-2# set term reject-all then reject
```

7. Configure the internal BGP (IBGP) connections to the other ISP devices.

```
[edit protocols bgp group int]
user@ISP-2# set type internal
user@ISP-2# set local-address 192.168.0.2
user@ISP-2# set export internal-peers
user@ISP-2# set neighbor 192.168.0.1
user@ISP-2# set neighbor 192.168.0.3
```

8. Configure the EBGP connections to the exchange peer and the private peer.

```
[edit protocols bgp group AS-64516]
user@ISP-2# set type external
user@ISP-2# set export private-peer
user@ISP-2# set peer-as 64516
user@ISP-2# set neighbor 10.3.0.5
[edit protocols bgp group AS-64515]
user@ISP-2# set type external
user@ISP-2# set export exchange-peer
user@ISP-2# set peer-as 64515
user@ISP-2# set neighbor 10.3.0.1
```

9. Configure the autonomous system (AS) number and the router ID.

```
[edit routing-options]
user@ISP-2# set router-id 192.168.0.2
user@ISP-2# set autonomous-system 64510
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@ISP-2# show interfaces
fe-1/2/0 {
  unit 0{
    description to_Exchange-2;
    family inet {
      address 10.3.0.2/30;
    }
  }
}
fe-1/2/1 {

If you are done configuring the device, enter **commit** from configuration mode.

Configuring Device ISP-3

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

On Device ISP-3, a separate policy is in place for each customer. The default route for Customer-1 is being sent by the **customer-1-peer** policy. This policy finds the 0.0.0.0/0 default route in inet.0 and accepts it. The policy also rejects all other routes, thereby not sending all BGP routes on the ISP router. The **customer-2-peer** policy is for Customer-2 and contains the same policy terms, which also send the default route and no other transit BGP routes. The additional terms in the **customer-2-peer** policy send the ISP customer routes to Customer-2. Because there are local static routes on Device ISP-3 that represent local customers, these routes are sent as well as all other internal routes announced to the local router by the other ISP routers.

If the upstream route from Device Exchange-1 (172.16.8.0/21) is present, Device ISP-3 generates a default route.

To configure Device ISP-3:

1. Configure the device interfaces.

```

[edit interfaces]
user@ISP-3# set fe-1/2/0 unit 0 description to_ISP-1
user@ISP-3# set fe-1/2/0 unit 0 family inet address 10.0.0.1/30
user@ISP-3# set fe-1/2/2 unit 0 description to_ISP-2
user@ISP-3# set fe-1/2/2 unit 0 family inet address 10.0.0.5/30
user@ISP-3# set fe-1/2/3 unit 0 description to_Customer-1
user@ISP-3# set fe-1/2/3 unit 0 family inet address 10.1.0.5/30
user@ISP-3# set fe-1/2/1 unit 0 description to_Customer-2
user@ISP-3# set fe-1/2/1 unit 0 family inet address 10.0.0.9/30
user@ISP-3# set lo0 unit 0 family inet address 192.168.0.3/32

```

2. Configure the interior gateway protocol (IGP).

```

[edit protocols ospf area 0.0.0.0]

```

```

user@ISP-3# set interface fe-1/2/0.0
user@ISP-3# set interface fe-1/2/2.0
user@ISP-3# set interface lo0.0 passive

```

3. Configure the static routes.

```

[edit routing-options static]
user@ISP-3# set route 172.16.36.0/24 reject
user@ISP-3# set route 172.16.37.0/24 reject
user@ISP-3# set route 172.16.38.0/24 reject
user@ISP-3# set route 172.16.39.0/24 reject

```

4. Configure a routing policy that generates a default static route only if a certain upstream route exists.

```

[edit policy-options policy-statement if-upstream-routes-exist term only-certain-contributing-routes]
user@ISP-3# set from route-filter 172.16.8.0/21 exact
user@ISP-3# set then accept
[edit policy-options policy-statement if-upstream-routes-exist]
user@ISP-3# set term reject-all-other-routes then reject
[edit routing-options generate route 0.0.0.0/0]
user@ISP-3# set policy if-upstream-routes-exist

```

5. Configure the routing policy for Customer-1.

```

[edit policy-options policy-statement customer-1-peer]
user@ISP-3# set term default-route from route-filter 0.0.0.0/0 exact
user@ISP-3# set term default-route then accept
user@ISP-3# set term reject-all-other-routes then reject

```

6. Configure the routing policy for Customer-2.

```

[edit policy-options policy-statement customer-2-peer]
user@ISP-3# set term statics from protocol static
user@ISP-3# set term statics then accept
user@ISP-3# set term isp-and-customer-routes from protocol bgp
user@ISP-3# set term isp-and-customer-routes from route-filter 172.16.32.0/21 orlonger
user@ISP-3# set term isp-and-customer-routes then accept
user@ISP-3# set term default-route from route-filter 0.0.0.0/0 exact
user@ISP-3# set term default-route then accept
user@ISP-3# set term reject-all-other-routes then reject

```

7. Configure the routing policies for the internal peers.

```
[edit policy-options policy-statement internal-peers]
user@ISP-3# set term statics from protocol static
user@ISP-3# set term statics then accept
user@ISP-3# set term next then next-hop self
```

8. Configure the internal BGP (IBGP) connections to the other ISP devices.

```
[edit protocols bgp group int]
user@ISP-3# set type internal
user@ISP-3# set local-address 192.168.0.3
user@ISP-3# set export internal-peers
user@ISP-3# set neighbor 192.168.0.1
user@ISP-3# set neighbor 192.168.0.2
```

9. Configure the EBGP connections to the customer peers.

```
[edit protocols bgp group to_64511]
user@ISP-3# set type external
user@ISP-3# set export customer-1-peer
user@ISP-3# set neighbor 10.1.0.6 peer-as 64511
[edit protocols bgp group to_64512]
user@ISP-3# set type external
user@ISP-3# set export customer-2-peer
user@ISP-3# set neighbor 10.0.0.10 peer-as 64512
```

10. Configure the autonomous system (AS) number and the router ID.

```
[edit routing-options]
user@ISP-3# set router-id 192.168.0.3
user@ISP-3# set autonomous-system 64510
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@ISP-3# show interfaces
```

```

Configuring Device Exchange-2

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

Device Exchange-2 exchanges all BGP routes with all BGP peers. The outbound-routes policy for Device Exchange-2 advertises locally defined static routes using BGP. The exclusion of a final **then reject** term causes the default BGP export policy to take effect, which is to send all BGP routes to all external BGP peers.

To configure Device Exchange-2:

1. Configure the device interfaces.

```
[edit interfaces]
user@Exchange-2# set fe-1/2/0 unit 0 description to_ISP-2
user@Exchange-2# set fe-1/2/0 unit 0 family inet address 10.3.0.1/30
user@Exchange-2# set fe-1/2/2 unit 0 description to_Exchange-1
user@Exchange-2# set fe-1/2/2 unit 0 family inet address 10.3.0.41/30
user@Exchange-2# set fe-1/2/1 unit 0 description to_Private-Peer-2
user@Exchange-2# set fe-1/2/1 unit 0 family inet address 10.3.0.49/30
user@Exchange-2# set lo0 unit 0 family inet address 192.168.0.7/32
```

2. Configure the static routes.

```
[edit routing-options static]
set route 172.16.16.0/21 reject
```

3. Configure a routing policy that generates a default static route only if certain internal routes exist.

```
[edit policy-options policy-statement outbound-routes term statics]
user@Exchange-2# set from protocol static
user@Exchange-2# set then accept
```

4. Configure the EBGp connections to the customer peers.

```
[edit protocols bgp group ext]
user@Exchange-2# set type external
user@Exchange-2# set export outbound-routes
user@Exchange-2# set neighbor 10.3.0.2 peer-as 64510
user@Exchange-2# set neighbor 10.3.0.50 peer-as 64516
user@Exchange-2# set neighbor 10.3.0.42 peer-as 64514
```

5. Configure the autonomous system (AS) number.

```
[edit routing-options]
user@Exchange-2# set autonomous-system 64515
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@Exchange-2 show interfaces
fe-1/2/0 {
  unit 0 {
    description to_ISP-2;
    family inet {
      address 10.3.0.1/30;
    }
  }
}
fe-1/2/1 {
  unit 0 {
    description to_Private-Peer-2;
    family inet {
      address 10.3.0.49/30;
    }
  }
}
```

```

}

    route 172.16.16.0/21 reject;
}
autonomous-system 64515;

```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring Device Private-Peer-2

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

Device Private-Peer-2 performs two main functions:

- Advertises routes local to AS 64516 to both the exchange peers and the ISP routers. The **outbound-routes** policy advertises the local static routes (that is, customers) on the router, and also advertises all routes learned by BGP that originated in either AS 64516 or AS 64512. These routes include other AS 64516 customer routes in addition to the AS 64512 customer. The AS routes are identified by an AS path regular expression match criteria in the policy.
- Advertises the 0.0.0.0/0 default route to the AS 64512 customer router. To accomplish this, the private peer creates a generated route for 0.0.0.0/0 locally on the router. This generated route is further assigned a policy called **if-upstream-routes-exist**, which allows only certain routes to contribute to the generated route, making it an active route in the routing table. Once the route is active, it can be sent to the AS 64512 router using BGP and the configured policies. The **if-upstream-routes-exist** policy accepts only the 172.16.32.0/21 route from Device Exchange-2, and rejects all other routes. If the 172.16.32.0/21 route is withdrawn by the exchange peer, the private peer loses the 0.0.0.0/0 default route and withdraws the default route from the AS 64512 customer router.

To configure Device Private-Peer-2:

1. Configure the device interfaces.

```

[edit interfaces]
user@Private-Peer-2# set fe-1/2/3 unit 0 description to_ISP-2
user@Private-Peer-2# set fe-1/2/3 unit 0 family inet address 10.3.0.5/30
user@Private-Peer-2# set fe-1/2/0 unit 0 description to_Customer-1
user@Private-Peer-2# set fe-1/2/0 unit 0 family inet address 10.0.0.22/30
user@Private-Peer-2# set fe-1/2/1 unit 0 description to_Exchange-2
user@Private-Peer-2# set fe-1/2/1 unit 0 family inet address 10.3.0.50/30
user@Private-Peer-2# set lo0 unit 0 family inet address 192.168.0.5/32

```

2. Configure the static routes.

```
[edit routing-options static]
user@Private-Peer-2# set route 172.16.24.0/25 reject
user@Private-Peer-2# set route 172.16.24.128/25 reject
user@Private-Peer-2# set route 172.16.25.0/26 reject
user@Private-Peer-2# set route 172.16.25.64/26 reject
```

3. Configure a routing policy that generates a default static route only if certain internal routes exist.

```
[edit policy-options policy-statement if-upstream-routes-exist]
user@Private-Peer-2# set term as-64515-routes from route-filter 172.16.16.0/21 exact
user@Private-Peer-2# set term as-64515-routes then accept
user@Private-Peer-2# set term reject-all-other-routes then reject
[edit routing-options generate route 0.0.0.0/0]
user@Private-Peer-2# set policy if-upstream-routes-exist
```

4. Configure the routing policy that advertises local static routes and the default route.

```
[edit policy-options policy-statement internal-routes]
user@Private-Peer-2# set term statics from protocol static
user@Private-Peer-2# set term statics then accept
user@Private-Peer-2# set term default-route from route-filter 0.0.0.0/0 exact
user@Private-Peer-2# set term default-route then accept
user@Private-Peer-2# set term reject-all-other-routes then reject
```

5. Configure the routing policy that advertises local customer routes.

```
[edit policy-options policy-statement outbound-routes]
user@Private-Peer-2# set term statics from protocol static
user@Private-Peer-2# set term statics then accept
user@Private-Peer-2# set term allowed-bgp-routes from as-path my-own-routes
user@Private-Peer-2# set term allowed-bgp-routes from as-path AS64512-routes
user@Private-Peer-2# set term allowed-bgp-routes then accept
user@Private-Peer-2# set term no-transit then reject
[edit policy-options]
user@Private-Peer-2# set as-path my-own-routes "()"
user@Private-Peer-2# set as-path AS64512-routes 64512
```

6. Configure the EBGp connection to Customer-2.

```
[edit protocols bgp group to-64512]
user@Private-Peer-2# set type external
user@Private-Peer-2# set export internal-routes
user@Private-Peer-2# set peer-as 64512
user@Private-Peer-2# set neighbor 10.0.0.21
```

7. Configure the EBGp connection to Device Exchange-2.

```
[edit protocols bgp group to-64515]
user@Private-Peer-2# set type external
user@Private-Peer-2# set export outbound-routes
user@Private-Peer-2# set peer-as 64515
user@Private-Peer-2# set neighbor 10.3.0.49
```

8. Configure the EBGp connections to the ISP.

```
[edit protocols bgp group ext]
user@Private-Peer-2# set type external
user@Private-Peer-2# set export outbound-routes
user@Private-Peer-2# set peer-as 64510
user@Private-Peer-2# set neighbor 10.3.0.6
```

9. Configure the autonomous system (AS) number.

```
[edit routing-options]
user@Private-Peer-2# set autonomous-system 64516
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@Private-Peer-2# show interfaces
fe-1/2/0 {
  unit 0 {
    description to_Customer-1;

- [Verifying the Routes on Device Private-Peer-1 | 180](#)
- [Verifying the Routes on Device Private-Peer-2 | 181](#)

Confirm that the configuration is working properly.

Verifying the Routes on Device Customer-1

Purpose

On Device Customer-1, check the routes in the routing table.

Action

user@Customer-1> **show route**

```
inet.0: 8 destinations, 8 routes (8 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

0.0.0.0/0          *[BGP/170] 00:09:25, localpref 100
                   AS path: 64510 I, validation-state: unverified
                   > to 10.1.0.5 via fe-1/2/3.0
10.1.0.4/30        *[Direct/0] 23:50:20
                   > via fe-1/2/3.0
10.1.0.6/32        *[Local/0] 5d 21:56:47
                   Local via fe-1/2/3.0
172.16.40.0/25     *[Static/5] 22:59:04
                   Reject
172.16.40.128/25   *[Static/5] 22:59:04
                   Reject
172.16.41.0/25     *[Static/5] 22:59:04
                   Reject
172.16.41.128/25   *[Static/5] 22:59:04
                   Reject
192.168.0.8/32     *[Direct/0] 5d 21:25:45
                   > via lo0.0
```

Meaning

Device Customer-1 has its four static routes, and it has learned the default route through BGP.

Verifying the Routes on Device Customer-2

Purpose

On Device Customer-2, check the routes in the routing table.

Action

user@Customer-2> **show route**

```
inet.0: 22 destinations, 23 routes (22 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

```

Meaning

Device Customer-2 has learned the default route through its session with the ISP and also through its session with the private peer. The route learned from the ISP is preferred because it has a higher local preference.

Verifying the Routes on Device ISP-1

Purpose

On Device ISP-1, check the routes in the routing table.

Action

user@ISP-1> **show route**

```

                   > via lo0.0

```

Meaning

On Device Exchange-2, the default route 0/0 is hidden because the next hop for the route is its own interface to Device Private-Peer-2, from which the route was received. The route is hidden to avoid a loop.

Verifying the Routes on Device Private-Peer-1

Purpose

On Device Private-Peer-1, check the routes in the routing table.

Action

```
user@Private-Peer-1> show route
```

```

inet.0: 13 destinations, 13 routes (13 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

Understanding Policy Expressions

IN THIS SECTION

- Policy Expression Examples | 185
- Policy Expression Evaluation | 187
- Evaluating Policy Expressions | 188

Policy expressions give the policy framework software a different way to evaluate routing policies. A *policy expression* uses Boolean logical operators with policies. The logical operators establish rules by which the policies are evaluated.

During evaluation of a routing policy in a policy expression, the policy action of accept, reject, or next policy is converted to the value of TRUE or FALSE. This value is then evaluated against the specified logical operator to produce output of either TRUE or FALSE. The output is then converted back to a flow control action of accept, reject, or next policy. The result of the policy expression is applied as it would be applied to a single policy; the route is accepted or rejected and the evaluation ends, or the next policy is evaluated.

[Table 14 on page 184](#) summarizes the policy actions and their corresponding TRUE and FALSE values and flow control action values. [Table 15 on page 185](#) describes the logical operators. For complete information about policy expression evaluation, see [“Policy Expression Evaluation” on page 187](#).

You must enclose a policy expression in parentheses. You can place a policy expression anywhere in the **import** or **export** statements and in the **from policy** statement.

Table 14: Policy Action Conversion Values

Policy Action	Conversion Value	Flow Control Action Conversion Value
Accept	TRUE	Accept
Reject	FALSE	Reject
Next policy	TRUE	Next policy

Table 15: Policy Expression Logical Operators

Logical Operator	Policy Expression Logic	How Logical Operator Affects Policy Expression Evaluation
&& (Logical AND)	<p>Logical AND requires that all values must be TRUE to produce output of TRUE.</p> <p>Routing policy value of TRUE and TRUE produces output of TRUE. Value of TRUE and FALSE produces output of FALSE. Value of FALSE and FALSE produces output of FALSE.</p>	<p>If the first routing policy returns the value of TRUE, the next policy is evaluated. If the first policy returns the value of FALSE, the evaluation of the expression ends and subsequent policies in the expression are not evaluated.</p>
(Logical OR)	<p>Logical OR requires that at least one value must be TRUE to produce output of TRUE.</p> <p>Routing policy value of TRUE and FALSE produces output of TRUE. Value of TRUE and TRUE produces output of TRUE. Value of FALSE and FALSE produces output of FALSE.</p>	<p>If the first routing policy returns the value of TRUE, the evaluation of the expression ends and subsequent policies in the expression are not evaluated. If the first policy returns the value of FALSE, the next policy is evaluated.</p>
! (Logical NOT)	<p>Logical NOT reverses value of TRUE to FALSE and of FALSE to TRUE. It also reverses the actions of accept and next policy to reject, and reject to accept.</p>	<p>If used with the logical AND operator and the first routing policy value of FALSE is reversed to TRUE, the next policy is evaluated. If the value of TRUE is reversed to FALSE, the evaluation of the expression ends and subsequent policies in the expression are not evaluated.</p> <p>If used with the logical OR operator and the first routing policy value of FALSE is reversed to TRUE, the evaluation of the expression ends and subsequent policies in the expression are not evaluated. If the value of TRUE is reversed to FALSE, the next policy is evaluated.</p> <p>If used with a policy and the flow control action is accept or next policy, these actions are reversed to reject. If the flow control action is reject, this action is reversed to accept.</p>

For more information, see the following sections:

Policy Expression Examples

The following examples show how to use the logical operators to create policy expressions:

- Logical AND—In the following example, **policy1** is evaluated first. If after **policy1** is evaluated, a value of TRUE is returned, **policy2** is evaluated. If a value of FALSE is returned, **policy2** is not evaluated.

```
export (policy1 && policy2)
```

- Logical OR—In the following example, **policy1** is evaluated first. If after **policy1** is evaluated, a value of TRUE is returned, **policy2** is not evaluated. If a value of FALSE is returned, **policy2** is evaluated.

```
export (policy1 || policy2)
```

- Logical OR and logical AND—In the following example, **policy1** is evaluated first. If after **policy1** is evaluated, a value of TRUE is returned, **policy2** is skipped and **policy3** is evaluated. If after **policy1** is evaluated, a value of FALSE is returned, **policy2** is evaluated. If **policy2** returns a value of TRUE, **policy3** is evaluated. If **policy2** returns a value of FALSE, **policy3** is not evaluated.

```
export [(policy1 || policy2) && policy3]
```

- Logical NOT—In the following example, **policy1** is evaluated first. If after **policy1** is evaluated, a value of TRUE is returned, the value is reversed to FALSE and **policy2** is not evaluated. If a value of FALSE is returned, the value is reversed to TRUE and **policy2** is evaluated.

```
export (!policy1 && policy2)
```

The sequential list [**policy1 policy2 policy3**] is not the same as the policy expression (**policy1 && policy2 && policy3**).

The sequential list is evaluated on the basis of a route matching a routing policy. For example, if **policy1** matches and the action is **accept** or **reject**, **policy2** and **policy3** are not evaluated. If **policy1** does not match, **policy2** is evaluated and so on until a match occurs and the action is **accept** or **reject**.

The policy expressions are evaluated on the basis of the action in a routing policy that is converted to the value of TRUE or FALSE and the logic of the specified logical operator. (For complete information about policy expression evaluation, see [“Policy Expression Evaluation” on page 187](#).) For example, if **policy1** returns a value of FALSE, **policy2** and **policy3** are not evaluated. If **policy1** returns a value of TRUE, **policy2** is evaluated. If **policy2** returns a value of FALSE, **policy3** is not evaluated. If **policy2** returns a value of TRUE, **policy3** is evaluated.

You can also combine policy expressions and sequential lists. In the following example, if **policy1** returns a value of FALSE, **policy2** is evaluated. If **policy2** returns a value of TRUE and contains a **next policy** action, **policy3** is evaluated. If **policy2** returns a value of TRUE but does not contain an action, including a **next policy** action, **policy3** is still evaluated (because if you do not specify an action, next term or next policy are the default actions). If **policy2** returns a value of TRUE and contains an **accept** action, **policy3** is not evaluated.

```
export [(policy1 || policy2) policy3]
```

Policy Expression Evaluation

During evaluation, the policy framework software converts policy actions to values of TRUE or FALSE, which are factors in determining the flow control action that is performed upon a route. However, the software does not actually perform a flow control action on a route until it evaluates an entire policy expression.

The policy framework software evaluates a policy expression as follows:

1. The software evaluates a route against the first routing policy in a policy expression and converts the specified or default action to a value of TRUE or FALSE. (For information about the policy action conversion values, see [Table 14 on page 184](#).)
2. The software takes the value of TRUE or FALSE and evaluates it against the logical operator used in the policy expression (see [Table 15 on page 185](#)). Based upon the logical operator used, the software determines whether or not to evaluate the next policy, if one is present.

The policy framework software uses a shortcut method of evaluation: if the result of evaluating a policy predetermines the value of the entire policy expression, the software does not evaluate the subsequent policies in the expression. For example, if the policy expression uses the logical AND operator and the evaluation of a policy returns the value of FALSE, the software does not evaluate subsequent policies in the expression because the final value of the expression is guaranteed to be FALSE no matter what the values of the unevaluated policies.

3. The software performs Step 1 and Step 2 for each subsequent routing policy in the policy expression, if they are present and it is necessary to evaluate them.
4. After evaluating the last routing policy, if it is appropriate, the software evaluates the value of TRUE or FALSE obtained from each routing policy evaluation. Based upon the logical operator used, it calculates an output of TRUE or FALSE.
5. The software converts the output of TRUE or FALSE back to an action. (For information about the policy action conversion values, see [Table 14 on page 184](#).) The action is performed.

If each policy in the expression returned a value of TRUE, the software converts the output of TRUE back to the flow control action specified in the last policy. For example, if the policy expression (**policy1 && policy2**) is specified and **policy1** specifies **accept** and **policy2** specifies **next term**, the **next term** action is performed.

If an action specified in one of the policies manipulates a route characteristic, the policy framework software carries the new route characteristic forward during the evaluation of the remaining policies.

For example, if the action specified in the first policy of a policy expression sets a route's metric to 500, this route matches the criteria of **metric 500** defined in the next policy. However, if a route characteristic manipulation action is specified in a policy located in the middle or the end of a policy expression, it is possible, because of the shortcut evaluation, that the policy is never evaluated and the manipulation of the route characteristic never occurs.

Evaluating Policy Expressions

The following sample routing policy uses three policy expressions:

```
[edit]
policy-options {
  policy-statement policy-A {
    from {
      route-filter 10.10.0.0/16 orlonger;
    }
    then reject;
  }
}
policy-options {
  policy-statement policy-B {
    from {
      route-filter 10.20.0.0/16 orlonger;
    }
    then accept;
  }
}
protocols {
  bgp {
    neighbor 192.168.1.1 {
      export (policy-A && policy-B);
    }
    neighbor 192.168.2.1 {
      export (policy-A || policy-B);
    }
    neighbor 192.168.3.1 {
      export (!policy-A);
    }
  }
}
```

The policy framework software evaluates the transit BGP route 10.10.1.0/24 against the three policy expressions specified in the sample routing policy as follows:

- (policy-A && policy-B)—10.10.1.0/24 is evaluated against **policy-A**. 10.10.1.0/24 matches the route list specified in **policy-A**, so the specified action of **reject** is returned. **reject** is converted to a value of FALSE, and FALSE is evaluated against the specified logical AND. Because the result of FALSE is certain no matter what the results of the evaluation of **policy-B** are (in policy expression logic, any result AND a value of FALSE produces the output of FALSE), **policy-B** is not evaluated and the output of FALSE is produced. The FALSE output is converted to **reject**, and 10.10.1.0/24 is rejected.
- (policy-A || policy-B)—10.10.1.0/24 is evaluated against **policy-A**. 10.10.1.0/24 matches the route list specified in **policy-A**, so the specified action of **reject** is returned. **reject** is converted to a value of FALSE, then FALSE is evaluated against the specified logical OR. Because logical OR requires at least one value of TRUE to produce an output of TRUE, 10.10.1.0/24 is evaluated against **policy-B**. 10.10.1.0/24 does not match **policy-B**, so the default action of **next-policy** is returned. The **next-policy** is converted to a value of TRUE, then the value of FALSE (for **policy-A** evaluation) and TRUE (for **policy-B** evaluation) are evaluated against the specified logical OR. In policy expression logic, FALSE OR TRUE produce an output of TRUE. The output of TRUE is converted to **next-policy**. (TRUE is converted to **next-policy** because **next-policy** was the last action retained by the policy framework software.) **policy-B** is the last routing policy in the policy expression, so the action specified by the default export policy for BGP is taken.
- (!policy-A)—10.10.1.0/24 is evaluated against **policy-A**. 10.10.1.0/24 matches the route list specified in **policy-A**, so the specified action of **reject** is returned. **reject** is converted to a value of FALSE, and FALSE is evaluated against the specified logical NOT. The value of FALSE is reversed to an output of TRUE based on the rules of logical NOT. The output of TRUE is converted to **accept**, and route 10.10.1.0/24 is accepted.

Understanding Backup Selection Policy for OSPF Protocol

Support for OSPF loop-free alternate (LFA) routes essentially adds IP fast-reroute capability for OSPF. Junos OS precomputes multiple loop-free backup routes for all OSPF routes. These backup routes are pre-installed in the Packet Forwarding Engine, which performs a local repair and implements the backup path when the link for a primary next hop for a particular route is no longer available. The selection of LFA is done randomly by selecting any matching LFA to progress to the given destination. This does not ensure best backup coverage available for the network. In order to choose the best LFA, Junos OS allows you to configure network-wide backup selection policies for each destination (IPv4 and IPv6) and a primary next-hop interface. These policies are evaluated based on admin-group, srlg, bandwidth, protection-type, metric, and node information.

During backup shortest-path-first (SPF) computation, each node and link attribute of the backup path is accumulated by IGP and is associated with every node (router) in the topology. The next hop in the best backup path is selected as the backup next hop in the routing table. In general, backup evaluation policy rules are categorized into the following types:

- Pruning — Rules configured to select the eligible backup path.
- Ordering — Rules configured to select the best among the eligible backup paths.

The backup selection policies can be configured with both pruning and ordering rules. While evaluating the backup policies, each backup path is assigned a score, an integer value that signifies the total weight of the evaluated criteria. The backup path with the highest score is selected.

To enforce LFA selection, configure various rules for the following attributes:

- admin-group— Administrative groups, also known as link coloring or resource class, are manually assigned attributes that describe the “color” of links, such that links with the same color conceptually belong to the same class. These configured administrative groups are defined under protocol MPLS. You can use administrative groups to implement a variety of backup selection policies using exclude, include-all, include-any, or preference.
- srlg— A shared risk link group (SRLG) is a set of links sharing a common resource, which affects all links in the set if the common resource fails. These links share the same risk of failure and are therefore considered to belong to the same SRLG. For example, links sharing a common fiber are said to be in the same SRLG because a fault with the fiber might cause all links in the group to fail. An SRLG is represented by a 32-bit number unique within an IGP (OSPF) domain. A link might belong to multiple SRLGs. You can define the backup selection to either allow or reject the common SRLGs between the primary and the backup path. This rejection of common SRLGs are based on the non-existence of link having common SRLGs in the primary next-hop and the backup SPF.

NOTE: Administrative groups and SRLGs can be created only for default topologies.

- **bandwidth**—The bandwidth specifies the bandwidth constraints between the primary and the backup path. The backup next-hop link can be used only if the bandwidth of the backup next-hop interface is greater than or equal to the bandwidth of the primary next hop.
- **protection-type**— The protection-type protects the destination from node failure of the primary node or link failure of the primary link. You can configure node, link, or node-link to protect the destination. If link-node is configured , then the node-protecting LFA is preferred over link-protection LFA.
- **node**- The node is per-node policy information. Here, node can be a directly connected router, remote router like RSVP backup LSP tail-end, or any other router in the backup SPF path. The nodes are identified through the route-id advertised by a node in the LSP. You can list the nodes to either prefer or exclude them in the backup path.
- **metric**— Metric decides how the LFAs should be preferred. In backup selection path, root metric and dest-metric are the two types of metrics. root-metric indicates the metric to the one-hop neighbor or a remote router such as an RSVP backup LSP tail-end router. The dest-metric indicates the metric from a one-hop neighbor or remote router such as an RSVP backup LSP tail-end router to the final destination. The metric evaluation is done either in ascending or descending order. By default, the first preference is given to backup paths with lowest destination evaluation and then to backup paths with lowest root metrics.

The evaluation-order allows you to control the order and criteria of evaluating these attributes in the backup path. You can explicitly configure the evaluation order. Only the configured attributes influence the backup path selection. The default order of evaluation of these attributes for the LFA is [admin-group srlg bandwidth protection-type node metric] .

NOTE: TE attributes are not supported in OSPFv3 and cannot be used for backup selection policy evaluation for IPv6 prefixes.

Configuring Backup Selection Policy for the OSPF Protocol

Support for OSPF loop-free alternate (LFA) routes essentially adds IP fast-reroute capability for OSPF. Junos OS precomputes multiple loop-free backup routes for all OSPF routes. These backup routes are pre-installed in the Packet Forwarding Engine, which performs a local repair and implements the backup path when the link for a primary next hop for a particular route is no longer available. The selection of LFA is done randomly by selecting any matching LFA to progress to the given destination. This does not ensure best backup coverage available for the network. In order to choose the best LFA, Junos OS allows you to configure network-wide backup selection policies for each destination (IPv4 and IPv6) and a primary next-hop interface. These policies are evaluated based on admin-group, srlg, bandwidth, protection-type, metric, and node information.

Before you begin to configure the backup selection policy for the OSPF protocol:

- Configure the router interfaces. See the *Junos OS Network Management Administration Guide for Routing Devices*.
- Configure an interior gateway protocol or static routing. See the *Junos OS Routing Protocols Library for Routing Devices*.

To configure the backup selection policy for the OSPF protocol:

1. Configure per-packet load balancing.

```
[edit policy-options]  
user@host# set policy-statement ecmp term 1 then load-balance per-packet
```

2. Enable RSVP on all the interfaces.

```
[edit protocols]  
user@host# set rsvp interface all
```

3. Configure administrative groups.

```
[edit protocols mpls]  
user@host# set admin-groups group-name
```

4. Configure srlg values.

```
[edit routing-options]  
user@host# set srlg srlg-name srlg-value srlg-value
```

5. Enable MPLS on all the interfaces.

```
[edit protocols mpls]
user@host# set interface all
```

6. Apply MPLS to an interface configured with an administrative group.

```
[edit protocols mpls]
user@host# set interface interface-name admin-group group-name
```

7. Configure the ID of the router.

```
[edit routing-options]
user@host# set router-id router-id
```

8. Apply the routing policy to all equal cost multipaths exported from the routing table to the forwarding table.

```
[edit routing-options]
user@host# set forwarding-table export ecmp
```

9. Enable link protection and configure metric values on all the interfaces for an area.

```
[edit protocols ospf]
user@host# set area area-id interface interface-name link-protection
user@host# set area area-id interface interface-name metric metric
```

10. Configure the administrative group of the backup selection policy for an IP address.

You can choose to exclude, include all, include any, or prefer the administrative groups from the backup path.

```
[edit routing-options]
user@host# set backup-selection destination ip-address interface interface-name admin-group
```

- Specify the administrative group to be excluded.

```
[edit routing-options backup-selection destination ip-address interface interface-name admin-group]
user@host# set exclude group-name
```

The backup path is not selected as the loop-free alternate (LFA) or backup nexthop if any of the links in the path have any one of the listed administrative groups.

For example, to exclude the group c1 from the administrative group:

```
[edit routing-options backup-selection destination 0.0.0.0/0 interface all admin-group]
user@host# set exclude c1
```

- Configure all the administrative groups if each link in the backup path requires all the listed administrative groups in order to accept the path.

```
[edit routing-options backup-selection destination ip-address interface interface-name admin-group]
user@host# set include-all group-name
```

For example, to set all the administrative groups if each link requires all the listed administrative groups in order to accept the path:

```
[edit routing-options backup-selection destination 0.0.0.0/0 interface all admin-group]
user@host# set include-all c2
```

- Configure any administrative group if each link in the backup path requires at least one of the listed administrative groups in order to select the path.

```
[edit routing-options backup-selection destination ip-address interface interface-name admin-group]
user@host# set include-any group-name
```

For example, to set any administrative group if each link in the backup path requires at least one of the listed administrative groups in order to select the path:

```
[edit routing-options backup-selection destination 0.0.0.0/0 interface all admin-group]
user@host# set include-any c3
```

- Define an ordered set of an administrative group that specifies the preference of the backup path. The leftmost element in the set is given the highest preference.

```
[edit routing-options backup-selection destination ip-address interface interface-name admin-group]
user@host# set preference group-name
```

For example, to set an ordered set of an administrative group that specifies the preference of the backup path:

```
[edit routing-options backup-selection destination 0.0.0.0/0 interface all admin-group]
```

```
user@host# set preference c4
```

11. Configure the backup path to allow the selection of the backup next hop only if the bandwidth is greater than or equal to the bandwidth of the primary next hop.

```
[edit routing-options]
user@host# set backup-selection destination ip-address interface interface-name
bandwidth-greater-equal-primary
```

12. Configure the backup path to specify the metric from the one-hop neighbor or from the remote router such as an RSVP backup label-switched-path (LSP) tail-end router to the final destination.

The destination metric can be either highest or lowest.

- Configure the backup path that has the highest destination metric.

```
[edit routing-options]
user@host# set backup-selection destination ip-address interface interface-name dest-metric highest
```

- Configure the backup path that has the lowest destination metric.

```
[edit routing-options]
user@host# set backup-selection destination ip-address interface interface-name dest-metric lowest
```

13. Configure the backup path that is a downstream path to the destination.

```
[edit routing-options]
user@host# set backup-selection destination ip-address interface interface-name downstream-paths-only
```

14. Set the order of preference of the root and the destination metric during backup path selection.

The preference order can be :

- [root dest] — Backup path selection or preference is first based on the root-metric criteria. If the criteria of all the root-metric is the same, then the selection or preference is based on the dest-metric.
- [dest root] — Backup path selection or preference is first based on the dest-metric criteria. If the criteria of all the dest-metric is the same, then the selection is based on the root-metric.

```
[edit routing-options]
user@host# set backup-selection destination ip-address interface interface-name metric-order dest
user@host# set backup-selection destination ip-address interface interface-name metric-order root
```

15. Configure the backup path to define a list of loop-back IP addresses of the adjacent neighbors to either exclude or prefer in the backup path selection.

The neighbor can be a local (adjacent router) neighbor, remote neighbor, or any other router in the backup path.

```
[edit routing-options]
user@host# set backup-selection destination ip-address interface interface-name node
```

- Configure the list of neighbors to be excluded.

```
[edit routing-options backup-selection destination ip-address interface interface-name node]
user@host# set exclude node-address
```

The backup path that has a router from the list is not selected as the loop-free alternative or backup next hop.

- Configure an ordered set of neighbors to be preferred.

```
[edit routing-options backup-selection destination ip-address interface interface-name node]
user@host# set preference node-address
```

The backup path having the leftmost neighbor is selected.

16. Configure the backup path to specify the required protection type of the backup path to be link, node, or node-link.

- Select the backup path that provides link protection.

```
[edit routing-options]
user@host# set backup-selection destination ip-address interface interface-name protection-type link
```

- Select the backup path that provides node protection.

```
[edit routing-options]
user@host# set backup-selection destination ip-address interface interface-name protection-type node
```

- Select the backup path that allows either node or link protection LFA where node-protection LFA is preferred over link-protection LFA.

```
[edit routing-options]
user@host# set backup-selection destination ip-address interface interface-name protection-type node-link
```

17. Specify the metric to the one-hop neighbor or to the remote router such as an RSVP backup label-switched-path (LSP) tail-end router.

- Select the path with highest root metric.

```
[edit routing-options]
user@host# set backup-selection destination ip-address interface all root-metric highest
```

- Select the path with lowest root metric.

```
[edit routing-options]
user@host# set backup-selection destination ip-address interface all root-metric lowest
```

18. Configure the backup selection path to either allow or reject the common shared risk link groups (SRLGs) between the primary link and each link in the backup path.

- Configure the backup path to allow common srlgs between the primary link and each link in the backup path.

```
[edit routing-options]
user@host# set backup-selection destination ip-address interface all srlg loose
```

A backup path with a fewer number of srlg collisions is preferred.

- Configure the backup path to reject the backup path that has common srlgs between the primary next-hop link and each link in the backup path.

```
[edit routing-options]
user@host# set backup-selection destination ip-address interface all srlg strict
```

19. Configure the backup path to control the order and the criteria of evaluating the backup path based on the administrative group, srlg, bandwidth, protection type, node, and metric.

The default order of evaluation is admin-group, srlg, bandwidth, protection-type, node, and metric.

```
[edit routing-options]
user@host# set backup-selection destination ip-address interface all evaluation-order admin-group
user@host# set backup-selection destination ip-address interface all evaluation-order srlg
user@host# set backup-selection destination ip-address interface all evaluation-order bandwidth
```

Understanding Backup Selection Policy for IS-IS Protocol

Support for IS-IS loop-free alternate (LFA) routes essentially adds IP fast-reroute capability for IS-IS. Junos OS precomputes multiple loop-free backup routes for all IS-IS routes. These backup routes are pre-installed in the Packet Forwarding Engine, which performs a local repair and implements the backup path when the link for a primary next hop for a particular route is no longer available. The selection of LFA is done randomly by selecting any matching LFA to progress to the given destination. This does not ensure best backup coverage available for the network. In order to choose the best LFA, Junos OS allows you to configure network-wide backup selection policies for each destination (IPv4 and IPv6) and a primary next-hop interface. These policies are evaluated based on admin-group, srlg, bandwidth, protection-type, metric, and neighbor information.

During backup shortest-path-first (SPF) computation, each node and link attribute of the backup path is accumulated by IGP and is associated with every node (router) in the topology. The next hop in the best backup path is selected as the backup next hop in the routing table. In general, backup evaluation policy rules are categorized into the following types:

- Pruning — Rules configured to select the eligible backup path.
- Ordering — Rules configured to select the best among the eligible backup paths.

The backup selection policies can be configured with both pruning and ordering rules. While evaluating the backup policies, each backup path is assigned a score, an integer value that signifies the total weight of the evaluated criteria. The backup path with the highest score is selected.

To enforce LFA selection, configure various rules for the following attributes:

- admin-group— Administrative groups, also known as link coloring or resource class, are manually assigned attributes that describe the “color” of links, such that links with the same color conceptually belong to the same class. These configured administrative groups are defined under protocol MPLS. You can use administrative groups to implement a variety of backup selection policies using exclude, include-all, include-any, or preference.
- backup-neighbor— A neighbor ID to either prefer or exclude in the backup path selection.

- **node**— A list of loop-back IP addresses of the adjacent nodes to either prefer or exclude in the backup path selection. The node can be a local (adjacent router) node, remote node, or any other router in the backup path. The nodes are identified through the TE-router-ID TLV advertised by a node in the LSP.
- **node-tag**— A node tag identifies a group of nodes in the network based on criteria such as the same neighbor tag values for all PE nodes to either prefer or exclude in the a backup path selection. This is implemented using IS-IS admin-tags. The routers are not identified with the explicit router-id but with an admin-tag prefix to their lo0 address prefix. These tags are advertised as part of extended IP reachability with a /32 prefix length that represents the TE-router _ID or node-ID of a router.
- **srlg**— A shared risk link group (SRLG) is a set of links sharing a common resource, which affects all links in the set if the common resource fails. These links share the same risk of failure and are therefore considered to belong to the same SRLG. For example, links sharing a common fiber are said to be in the same SRLG because a fault with the fiber might cause all links in the group to fail. An SRLG is represented by a 32-bit number unique within an IGP (IS-IS) domain. A link might belong to multiple SRLGs. You can define the backup selection to either allow or reject the common SRLGs between the primary and the backup path.
- **bandwidth**—The bandwidth specifies the bandwidth constraints between the primary and the backup path. The backup next-hop link can be used only if the bandwidth of the backup next-hop interface is greater than or equal to the bandwidth of the primary next hop.
- **protection-type**— The protection-type protects the destination from node failure of the primary node or link failure of the primary link. You can configure node, link, or node-link to protect the destination.. If link-node is configured , then the node-protecting LFA is preferred over link-protection LFA.
- **metric**— Metric decides how the LFAs should be preferred. In backup selection path, root metric and dest-metric are the two types of metrics. root-metric indicates the metric to the one-hop neighbor or a remote router such as an RSVP backup LSP tail-end router. The dest-metric indicates the metric from a one-hop neighbor or remote router such as an RSVP backup LSP tail-end router to the final destination. The metric evaluation is done either in ascending or descending order. By default, the first preference is given to backup paths with lowest destination evaluation and then to backup paths with lowest root metrics.

The evaluation-order allows you to control the order and criteria of evaluating these attributes in the backup path. You can explicitly configure the evaluation order. Only the configured attributes influence the backup path selection. The default order of evaluation of these attributes for the LFA is [admin-group srlg bandwidth protection-type neighbor neighbor-tag metric] .

IN THIS SECTION

- [Requirements | 200](#)
- [Overview | 200](#)
- [Configuration | 201](#)
- [Verification | 226](#)

This example shows how to configure the backup selection policy for the OSPF or OSPF3 protocol, which enables you to select a loop-free alternate (LFA) in the network.

When you enable backup selection policies, Junos OS allows selection of LFA based on the policy rules and attributes of the links and nodes in the network. These attributes are admin-group, srlg, bandwidth, protection-type, metric, and node.

Requirements

This example uses the following hardware and software components:

- Eight routers that can be a combination of M Series Multiservice Edge Routers, MX Series 5G Universal Routing Platforms, PTX Series Packet Transport Routers, and T Series Core Routers
- Junos OS Release 15.1 or later running on all devices

Before you begin:

1. Configure the device interfaces.
2. Configure OSPF.

Overview

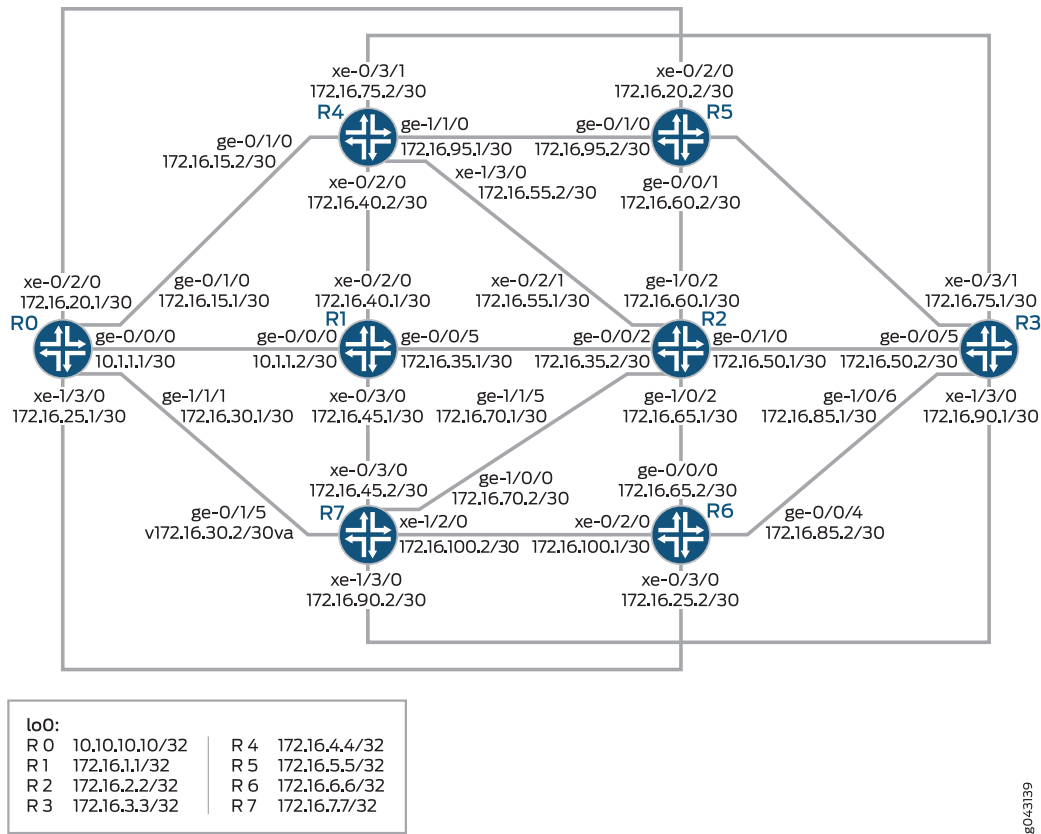

In Junos OS, the default loop-free alternative (LFA) selection algorithm or criteria can be overridden with an LFA policy. These policies are configured for each destination (IPv4 and IPv6) and a primary next-hop interface. These backup policies enforce LFA selection based on admin-group, srlg, bandwidth, protection-type, metric, and node attributes of the backup path. During backup shortest-path-first (SPF) computation, each attribute (both node and link) of the backup path, stored per backup next-hop, is accumulated by IGP. For the routes created internally by IGP, the attribute set of every backup path is

evaluated against the policy configured for each destination (IPv4 and IPv6) and a primary next-hop interface. The first or the best backup path is selected and installed as the backup next hop in the routing table. To configure the backup selection policy, include the **backup-selection** configuration statement at the **[edit routing-options]** hierarchy level. The **show backup-selection** command displays the configured policies for a given interface and destination. The display can be filtered against a particular destination, prefix, interface, or logical systems.

Topology

In this topology shown in [Figure 14 on page 201](#), the backup selection policy is configured on Device R3.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

Configuring Device R3

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure Device R3:

1. Configure the interfaces.

```

[edit interfaces]
user@R3# set ge-0/0/5 unit 0 family inet address 172.16.50.2/30
user@R3# set ge-0/0/5 unit 0 family inet6 address 2001:db8:50:1:1::2/64
user@R3# set ge-0/0/5 unit 0 family mpls

user@R3# set xe-0/3/1 unit 0 family inet address 172.16.75.1/30
user@R3# set xe-0/3/1 unit 0 family inet6 address 2001:db8:75:1:1::1/64
user@R3# set xe-0/3/1 unit 0 family mpls

```

```

user@R3# set ge-1/0/0 unit 0 family inet address 172.16.80.1/30
user@R3# set ge-1/0/0 unit 0 family inet6 address 2001:db8:80:1:1::1/64
user@R3# set ge-1/0/0 unit 0 family mpls

user@R3# set ge-1/0/5 unit 0 family inet address 172.16.200.1/24
user@R3# set ge-1/0/5 unit 0 family inet6 address 2001:db8:200:1:1::1/64

user@R3# set ge-1/0/6 unit 0 family inet address 172.16.85.1/30
user@R3# set ge-1/0/6 unit 0 family inet6 address 2001:db8:85:1:1::1/64
user@R3# set ge-1/0/6 unit 0 family mpls

user@R3# set xe-1/3/0 unit 0 family inet address 172.16.90.1/30
user@R3# set xe-1/3/0 unit 0 family inet6 address 2001:db8:90:1:1::1/64
user@R3# set xe-1/3/0 unit 0 family mpls

user@R3# set lo0 unit 0 family inet address 172.16.3.3/32 primary
user@R3# set lo0 unit 0 family inet6 address 2001:db8::3:3:3/128 primary
user@R3# set lo0 unit 0 family mpls

```

2. Configure srlg values.

```

[edit routing-options]
user@R3# set srlg srlg1 srlg-value 1001
user@R3# set srlg srlg2 srlg-value 1002
user@R3# set srlg srlg3 srlg-value 1003
user@R3# set srlg srlg4 srlg-value 1004
user@R3# set srlg srlg5 srlg-value 1005
user@R3# set srlg srlg6 srlg-value 1006
user@R3# set srlg srlg7 srlg-value 1007
user@R3# set srlg srlg8 srlg-value 1008
user@R3# set srlg srlg9 srlg-value 1009
user@R3# set srlg srlg10 srlg-value 10010
user@R3# set srlg srlg11 srlg-value 10011
user@R3# set srlg srlg12 srlg-value 10012

```

3. Configure the ID of the router.

```

[edit routing-options]
user@R3# set router-id 172.16.3.3

```

4. Apply the routing policy to all equal-cost multipaths exported from the routing table to the forwarding table.

```
[edit routing-options]
user@R3# set forwarding-table export ecmp
```

5. Configure attributes of the backup selection policy.

```
[edit routing-options backup-selection]
user@R3# set destination 10.1.1.0/30 interface xe-1/3/0.0 admin-group include-all c2
user@R3# set destination 10.1.1.0/30 interface all admin-group exclude c3
user@R3# set destination 10.1.1.0/30 interface all srlg strict
user@R3# set destination 10.1.1.0/30 interface all protection-type node
user@R3# set destination 10.1.1.0/30 interface all bandwidth-greater-equal-primary
user@R3# set destination 10.1.1.0/30 interface all neighbor preference 172.16.7.7
user@R3# set destination 10.1.1.0/30 interface all root-metric lowest
user@R3# set destination 10.1.1.0/30 interface all metric-order root

user@R3# set destination 172.16.30.0/30 interface all admin-group exclude c5
user@R3# set destination 172.16.30.0/30 interface all srlg strict
user@R3# set destination 172.16.30.0/30 interface all protection-type node
user@R3# set destination 172.16.30.0/30 interface all bandwidth-greater-equal-primary
user@R3# set destination 172.16.30.0/30 interface all neighbor preference 172.16.7.7
user@R3# set destination 172.16.30.0/30 interface all root-metric lowest
user@R3# set destination 172.16.30.0/30 interface all metric-order root

user@R3# set destination 192.168.45.0/30 interface all admin-group exclude c5
user@R3# set destination 192.168.45.0/30 interface all srlg strict
user@R3# set destination 192.168.45.0/30 interface all protection-type node
user@R3# set destination 192.168.45.0/30 interface all bandwidth-greater-equal-primary
user@R3# set destination 192.168.45.0/30 interface all neighbor preference 172.16.7.7
user@R3# set destination 192.168.45.0/30 interface all root-metric lowest
user@R3# set destination 192.168.45.0/30 interface all metric-order root
```

6. Enable RSVP on all the interfaces.

```
[edit protocols]
user@R3# set rsvp interface all
```

7. Configure administrative groups.

```
[edit protocols mpls]
user@R3# set admin-groups c0 0
user@R3# set admin-groups c1 1
user@R3# set admin-groups c2 2
user@R3# set admin-groups c3 3
user@R3# set admin-groups c4 4
user@R3# set admin-groups c5 5
user@R3# set admin-groups c6 6
user@R3# set admin-groups c7 7
user@R3# set admin-groups c8 8
user@R3# set admin-groups c9 9
user@R3# set admin-groups c10 10
user@R3# set admin-groups c11 11
user@R3# set admin-groups c12 12
user@R3# set admin-groups c13 13
user@R3# set admin-groups c14 14
user@R3# set admin-groups c15 15
user@R3# set admin-groups c16 16
user@R3# set admin-groups c17 17
user@R3# set admin-groups c18 18
user@R3# set admin-groups c19 19
user@R3# set admin-groups c20 20
user@R3# set admin-groups c21 21
user@R3# set admin-groups c22 22
user@R3# set admin-groups c23 23
user@R3# set admin-groups c24 24
user@R3# set admin-groups c25 25
user@R3# set admin-groups c26 26
user@R3# set admin-groups c27 27
user@R3# set admin-groups c28 28
user@R3# set admin-groups c29 29
user@R3# set admin-groups c30 30
user@R3# set admin-groups c31 31
```

8. Enable MPLS on all the interfaces and configure administrative group for an interface.

```
[edit protocols mpls]
user@R3# set interface all
user@R3# set interface ge-0/0/5.0 admin-group c0
```

9. Enable link protection and configure metric values on all the interfaces for an OSPF area.

```
[edit protocols ospf]
user@R3# set area 0.0.0.0 interface ge-0/0/5.0 link-protection
user@R3# set area 0.0.0.0 interface ge-0/0/5.0 metric 10
user@R3# set area 0.0.0.0 interface xe-0/3/1.0 metric 21
user@R3# set area 0.0.0.0 interface ge-1/0/0.0 metric 13
user@R3# set area 0.0.0.0 interface ge-1/0/6.0 metric 15
user@R3# set area 0.0.0.0 interface xe-1/3/0.0 link-protection
user@R3# set area 0.0.0.0 interface xe-1/3/0.0 metric 22
```

10. Enable link protection and configure metric values on all the interfaces for an OSPF3 area.

```
[edit protocols ospf3]
user@R3# set area 0.0.0.0 interface ge-0/0/5.0 link-protection
user@R3# set area 0.0.0.0 interface ge-0/0/5.0 metric 10
user@R3# set area 0.0.0.0 interface xe-0/3/1.0 metric 21
user@R3# set area 0.0.0.0 interface ge-1/0/0.0 metric 13
user@R3# set area 0.0.0.0 interface ge-1/0/6.0 metric 15
user@R3# set area 0.0.0.0 interface xe-1/3/0.0 link-protection
user@R3# set area 0.0.0.0 interface xe-1/3/0.0 metric 22
```

11. Configure the routing policy.

```
[edit policy-options]
user@R3# set policy-statement ecmp term 1 then load-balance per-packet
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R3# show interfaces

If you are done configuring the device, enter **commit** from configuration mode.

Verification

IN THIS SECTION

- [Verifying the Routes | 226](#)
- [Verifying the OSPF Route | 230](#)
- [Verifying the OSPF3 Route | 230](#)
- [Verifying the Backup Selection Policy for Device R3 | 231](#)

Confirm that the configuration is working properly.

Verifying the Routes

Purpose

Verify that the expected routes are learned.

Action

From operational mode, run the **show route** command for the routing table.

```
user@R3> show route
```

```

inet.0: 48 destinations, 48 routes (48 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

172.16.3.3/32          *[Direct/0] 02:22:27

```

```

```

Meaning

The output shows all Device R3 routes.

Verifying the OSPF Route

Purpose

Verify the routing table of OSPF.

Action

From operational mode, run the **show ospf route detail** command for Device R3.

user@R3> **show ospf route detail**

```
Topology default Route Table:

Prefix          Path  Route      NH      Metric NextHop      Nexthop
                Type  Type       Type
172.16.50.0/30   Intra Network  IP      10 ge-0/0/5.0
    area 0.0.0.0, origin 172.16.3.3, priority low
172.16.75.0/30   Intra Network  IP      21 xe-0/3/1.0
    area 0.0.0.0, origin 172.16.3.3, priority low
```

Meaning

The output displays the routing table of OSPF routers.

Verifying the OSPF3 Route

Purpose

Verify the routing table of OSPF3.

Action

From operational mode, run the **show ospf3 route detail** command for Device R3.

```
user@R3> show ospf3 route detail
```

```

Prefix                                Path  Route      NH  Metric
                                Type  Type       Type
2001:db8:50:1:1::/64                Intra Network  IP   10
  NH-interface ge-0/0/5.0
  Area 0.0.0.0, Origin 172.16.3.3, Priority low
2001:db8:75:1:1::/64                Intra Network  IP   21
  NH-interface xe-0/3/1.0
  Area 0.0.0.0, Origin 172.16.3.3, Priority low

```

Meaning

The output displays the routing table of OSPF3 routers.

Verifying the Backup Selection Policy for Device R3

Purpose

Verify the backup selection policy for Device R3.

Action

From operational mode, run the **show backup-selection** command for Device R3.

```
user@R3> show backup-selection
```

```

Understanding How a Routing Policy Chain Is Evaluated

Figure 15 on page 234 shows how a chain of routing policies is evaluated. These routing policies consist of multiple terms. Each term consists of match conditions and actions to apply to matching routes. Each route is evaluated against the policies as follows:

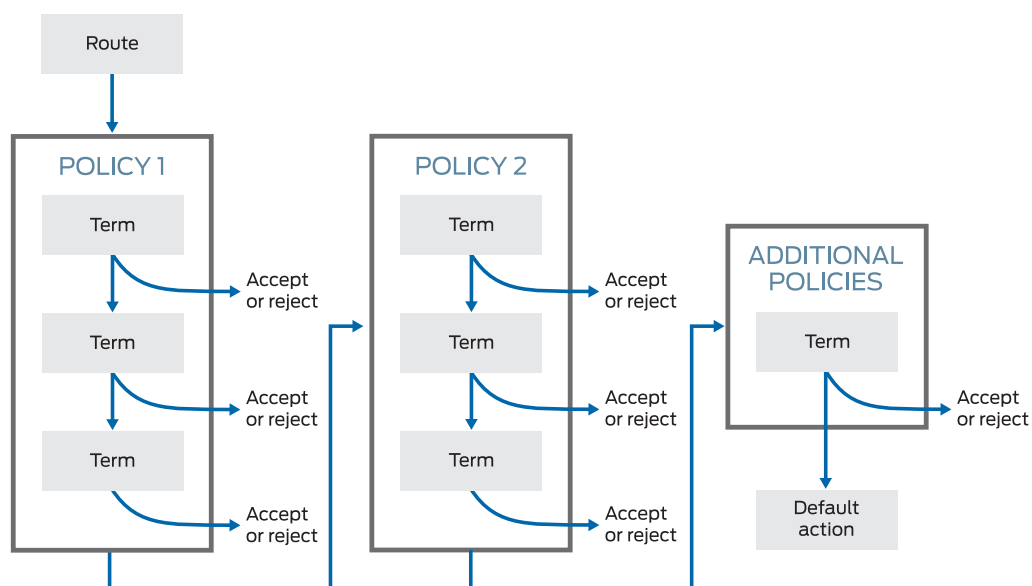

NOTE: On Junos OS Evolved, **next term** cannot appear as the last term of the action. A filter term where **next term** is specified as an action but without any match conditions configured is not supported.

1. The route is evaluated against the first term in the first routing policy. If it matches, the specified action is taken. If the action is to accept or reject the route, that action is taken and the evaluation of the route ends. If the **next term** action is specified, if no action is specified, or if the route does not match, the evaluation continues as described in Step 2. If the **next policy** action is specified, any accept or reject action specified in this term is skipped, all remaining terms in this policy are skipped, all other actions are taken, and the evaluation continues as described in Step 3.
2. The route is evaluated against the second term in the first routing policy. If it matches, the specified action is taken. If the action is to accept or reject the route, that action is taken and the evaluation of the route ends. If the **next term** action is specified, if no action is specified, or if the route does not

match, the evaluation continues in a similar manner against the last term in the first routing policy. If the **next policy** action is specified, any accept or reject action specified in this term is skipped, all remaining terms in this policy are skipped, all other actions are taken, and the evaluation continues as described in Step 3.

3. If the route does not match a term or matches a term with a **next policy** action in the first routing policy, it is evaluated against the first term in the second routing policy.
4. The evaluation continues until the route matches a term with an accept or reject action defined or until there are no more routing policies to evaluate. If there are no more routing policies, then the accept or reject action specified by the default policy is taken.

Example: Configuring Policy Chains and Route Filters

IN THIS SECTION

- [Requirements | 235](#)
- [Overview | 235](#)
- [Configuration | 237](#)
- [Verification | 246](#)

A *policy chain* is the application of multiple policies within a specific section of the configuration. A *route filter* is a collection of match prefixes.

Requirements

No special configuration beyond device initialization is required before configuring this example.

Overview

An example of a policy chain applied to BGP is as follows:

```
user@R1# show protocols bgp
group int {
  type internal;
  local-address 192.168.0.1;
  export [ adv-statics adv-large-aggregates adv-small-aggregates ];
  neighbor 192.168.0.2;
  neighbor 192.168.0.3;
}
```

The **adv-statics**, **adv-large-aggregates**, and **adv-small-aggregates** policies, in addition to the default BGP policy, make up the policy chain applied to the BGP peers of Device R1. Two of the policies demonstrate route filters with different match types. The other policy matches all static routes, so no route filter is needed.

```
user@R1# show policy-options
policy-statement adv-large-aggregates {
  term between-16-and-18 {
```

```

        from {
            protocol aggregate;
            route-filter 172.16.0.0/16 upto /18;
        }
        then accept;
    }
}
policy-statement adv-small-aggregates {
    term between-19-and-24 {
        from {
            protocol aggregate;
            route-filter 172.16.0.0/16 prefix-length-range /19-/24;
        }
        then accept;
    }
}
policy-statement adv-statics {
    term statics {
        from protocol static;
        then accept;
    }
}

```

Optionally, you can convert this policy chain into a single multiterm policy for the internal BGP (IBGP) peers. If you do this, one of the advantages of a policy chain is lost—the ability to reuse policies for different purposes.

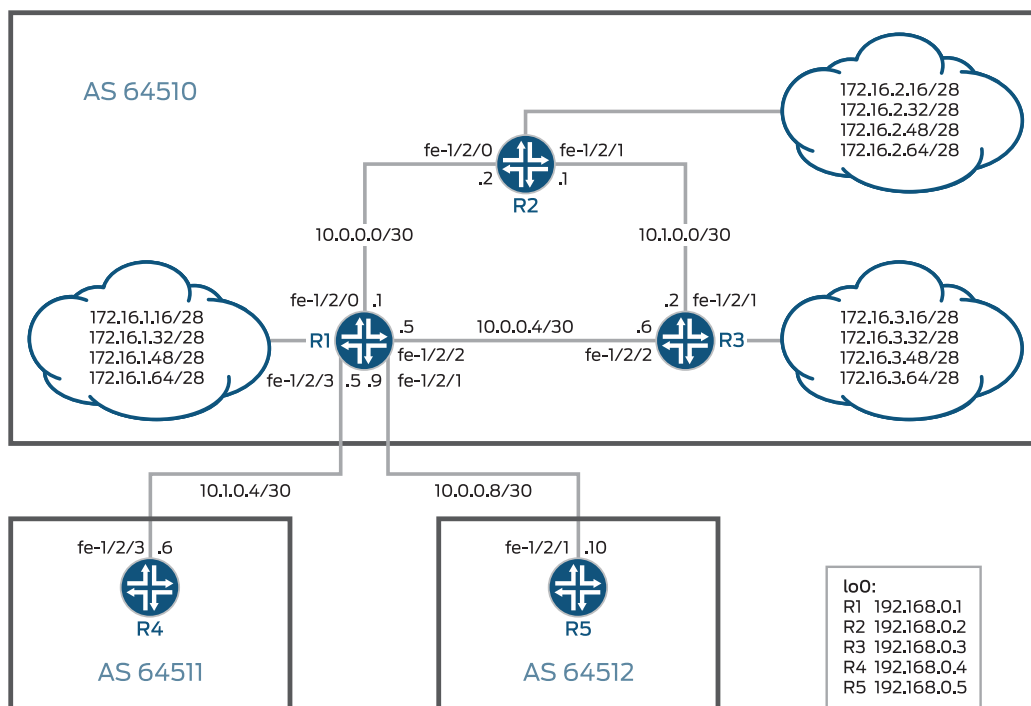

[Figure 16 on page 237](#) displays Device R1 in AS 64510 with its IBGP peers, Device R2 and Device R3. Device R1 also has external BGP (EBGP) connections to Device R4 in AS 64511 and Device R5 in AS 64512. The current administrative policy within AS 64510 is to send the customer static routes only to other IBGP peers. Any EBGP peer providing transit service only receives aggregate routes with mask lengths smaller than 18 bits. Any EBGP peer providing peering services receives all customer routes and all aggregates whose mask length is larger than 19 bits. Each portion of these administrative policies is configured in a separate routing policy within the **[edit policy-options]** configuration hierarchy. These policies provide the administrators of AS 64510 with multiple configuration options for advertising routes to peers.

Device R4 is providing transit service to AS 64510, which allows the AS to advertise its assigned routing space to the Internet. On the other hand, the peering service provided by Device R5 allows AS 64510 to route traffic directly between the autonomous systems (ASs) for all customer routes.

Topology

[Figure 16 on page 237](#) shows the sample network.

Figure 16: BGP Topology for Policy Chains

“CLI Quick Configuration” on page 237 shows the configuration for all of the devices in Figure 16 on page 237.

The section “Step-by-Step Procedure” on page 240 describes the steps on Device R1.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level.

Device R1

```
set interfaces fe-1/2/0 unit 0 description to_R2
set interfaces fe-1/2/0 unit 0 family inet address 10.0.0.1/30
set interfaces fe-1/2/2 unit 0 description to_R3
set interfaces fe-1/2/2 unit 0 family inet address 10.0.0.5/30
set interfaces fe-1/2/3 unit 0 description to_R4
set interfaces fe-1/2/3 unit 0 family inet address 10.1.0.5/30
set interfaces fe-1/2/1 unit 0 description to_R5
set interfaces fe-1/2/1 unit 0 family inet address 10.0.0.10/30
```

```

set interfaces lo0 unit 0 family inet address 192.168.0.1/32
set protocols bgp group int type internal

set routing-options autonomous-system 64512

```

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure Device R1:

1. Configure the device interfaces.

```
[edit interfaces]
user@R1# set fe-1/2/0 unit 0 description to_R2
user@R1# set fe-1/2/0 unit 0 family inet address 10.0.0.1/30
user@R1# set fe-1/2/2 unit 0 description to_R3
user@R1# set fe-1/2/2 unit 0 family inet address 10.0.0.5/30
user@R1# set fe-1/2/3 unit 0 description to_R4
user@R1# set fe-1/2/3 unit 0 family inet address 10.1.0.5/30
user@R1# set fe-1/2/1 unit 0 description to_R5
user@R1# set fe-1/2/1 unit 0 family inet address 10.0.0.10/30
user@R1# set lo0 unit 0 family inet address 192.168.0.1/32
```

2. Configure the IBGP connections to Device R2 and Device R3.

```
[edit protocols bgp group int]
user@R1# set type internal
user@R1# set local-address 192.168.0.1
user@R1# set neighbor 192.168.0.2
user@R1# set neighbor 192.168.0.3
```

3. Apply the export policies for the internal peers.

```
[edit protocols bgp group int]
user@R1# set export adv-statics
user@R1# set export adv-large-aggregates
user@R1# set export adv-small-aggregates
```

4. Configure the EBGp connection to Device R4.

```
[edit protocols bgp group to_64511]
user@R1# set type external
user@R1# set neighbor 10.1.0.6 peer-as 64511
```

5. Apply the export policy for Device R4.

```
[edit protocols bgp group to_64511]
user@R1# set export adv-large-aggregates
```

6. Configure the EBGp connection to Device R5.

```
[edit protocols bgp group to_64512]
user@R1# set type external
user@R1# set neighbor 10.0.0.9 peer-as 64512
```

7. Apply the export policies for Device R5.

```
[edit protocols bgp group to_64512]
user@R1# set export adv-small-aggregates
user@R1# set export adv-statics
```

8. Configure OSPF connections to Device R2 and Device R3.

```
[edit protocols ospf area 0.0.0.0]
user@R1# set interface fe-1/2/0.0
user@R1# set interface fe-1/2/2.0
user@R1# set interface lo0.0 passive
```

9. Configure the routing policies.

```
[edit policy-options policy-statement adv-large-aggregates term between-16-and-18]
user@R1# set from protocol aggregate
user@R1# set from route-filter 172.16.0.0/16 upto /18
user@R1# set then accept
[edit policy-options policy-statement adv-small-aggregates term between-19-and-24]
user@R1# set from protocol aggregate
user@R1# set from route-filter 172.16.0.0/16 prefix-length-range /19-/24
user@R1# set then accept
[edit policy-options policy-statement adv-statics term statics]
user@R1# set from protocol static
user@R1# set then accept
```

10. Configure the static and aggregate routes.

```
[edit routing-options static]
user@R1# set route 172.16.1.16/28 discard
user@R1# set route 172.16.1.32/28 discard
user@R1# set route 172.16.1.48/28 discard
user@R1# set route 172.16.1.64/28 discard
[edit routing-options aggregate]
user@R1# set route 172.16.0.0/16
```

```
user@R1# set route 172.16.1.0/24
```

11. Configure the autonomous system (AS) number and router ID.

```
[edit routing-options]
user@R1# set router-id 192.168.0.1
user@R1# set autonomous-system 64510
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R1# show interfaces
fe-1/2/0 {
  unit 0 {
    description to_R2;
    family inet {
      address 10.0.0.1/30;
    }
  }
}
fe-1/2/2 {
  unit 0 {
    description to_R3;
    family inet {
      address 10.0.0.5/30;
    }
  }
}
fe-1/2/3 {
  unit 0 {
    description to_R4;
    family inet {
      address 10.1.0.5/30;
    }
  }
}
fe-1/2/1 {
  unit 0 {
    description to_R5;
    family inet {
```

```

        address 10.0.0.10/30;
    }
}
lo0 {
    unit 0 {
        family inet {
            address 192.168.0.1/32;
        }
    }
}

```

user@R1# **show protocols**

```

bgp {
    group int {
        type internal;
        local-address 192.168.0.1;
        export [ adv-statics adv-large-aggregates adv-small-aggregates ];
        neighbor 192.168.0.2;
        neighbor 192.168.0.3;
    }
    group to_64511 {
        type external;
        export adv-large-aggregates;
        neighbor 10.1.0.6 {
            peer-as 64511;
        }
    }
    group to_64512 {
        type external;
        export [ adv-small-aggregates adv-statics ];

Confirm that the configuration is working properly.

Verifying the Route Advertisement to Device R4

Purpose

On Device R1, make sure that the customer routes are advertised to Device R4.

Action

```
user@R1> show route advertising-protocol bgp 10.1.0.6
```

```
inet.0: 29 destinations, 31 routes (29 active, 0 holddown, 0 hidden)
  Prefix                Nexthop          MED      Lclpref    AS path
* 172.16.0.0/16         Self              I
* 172.16.2.0/24         Self              I
* 172.16.2.16/28        Self              I
* 172.16.2.32/28        Self              I
* 172.16.2.48/28        Self              I
* 172.16.2.64/28        Self              I
* 172.16.3.0/24         Self              I
* 172.16.3.16/28        Self              I
* 172.16.3.32/28        Self              I
* 172.16.3.48/28        Self              I
* 172.16.3.64/28        Self              I
```

Meaning

The **adv-large-aggregates** policy is applied to the peering session with Device R4 to advertise the aggregate routes with a subnet mask length between 16 and 18 bits. The 172.16.0.0/16 aggregate route is being sent as defined by the administrative policy, but a number of other routes with larger subnet masks are also being sent to Device R4.

Checking Where the Longer Routes Are Originating

Purpose

On Device R1, find where the other routes are coming from.

Action

user@R1> **show route 172.16.3.16/28**

```
inet.0: 29 destinations, 31 routes (29 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

172.16.3.16/28      *[BGP/170] 20:16:00, localpref 100, from 192.168.0.3
                    AS path: I, validation-state: unverified
                    > to 10.0.0.6 via fe-1/2/2.0
```

Meaning

Device R1 has learned this route through its BGP session with Device R3. Because it is an active BGP route, it is automatically advertised by the BGP default policy. Remember that the default policy is always applied to the end of every policy chain. What is needed is a policy to block the more specific routes from being advertised.

Blocking the More Specific Routes

Purpose

Create a policy called **not-larger-than-18** that rejects all routes within the 172.16.0.0 /16 address space that have a subnet mask length greater than or equal to 19 bits. This ensures that all aggregates with a mask between 16 and 18 bits are advertised, thus accomplishing the goal of the administrative policy.

Action

1. On Device R1, configure the **not-larger-than-18** policy.

```
[edit policy-options policy-statement not-larger-than-18 term reject-greater-than-18-bits]
user@R1# set from route-filter 172.16.0.0/16 prefix-length-range /19-/32
user@R1# set then reject
```

2. On Device R1, apply the policy to the peering session with Device R4.

```
[edit protocols bgp group to_64511]
user@R1# set export not-larger-than-18
user@R1# commit
```

3. On Device R1, check which routes are advertised to Device R4.

```
user@R1> show route advertising-protocol bgp 10.1.0.6
```

```
inet.0: 29 destinations, 31 routes (29 active, 0 holddown, 0 hidden)
  Prefix                Nexthop          MED      Lclpref    AS path
* 172.16.0.0/16         Self                                I
```

Meaning

The policy chain is working correctly. Only the 172.16.0.0 /16 route is advertised to Device R4.

Verifying the Route Advertisement to Device R5

Purpose

On Device R1, make sure that the customer routes are advertised to Device R5.

Device R5 is Device R1's EBGp peer in AS 64512. The administrative policy states that this peer receives only aggregate routes larger than 18 bits in length and all customer routes. In anticipation of encountering a problem similar to the problem on Device R4, you can create a policy called **not-smaller- than-18** that rejects all aggregates with mask lengths between 16 and 18 bits.

Action

1. On Device R2, configure an aggregate route for 172.16.128.0/17.

```
[edit routing-options aggregate]
user@R2# set route 172.16.128.0/17 discard
user@R2# commit
```

2. On Device R1, check which routes are advertised to Device R5.

```
user@R1> show route advertising-protocol bgp 10.0.0.9
```

```
inet.0: 30 destinations, 32 routes (30 active, 0 holddown, 0 hidden)
  Prefix                Nexthop          MED      Lclpref    AS path
* 172.16.1.0/24         Self                                I
* 172.16.1.16/28        Self                                I
* 172.16.1.32/28        Self                                I
* 172.16.1.48/28        Self                                I
* 172.16.1.64/28        Self                                I
* 172.16.2.0/24         Self                                I
* 172.16.2.16/28        Self                                I
* 172.16.2.32/28        Self                                I
* 172.16.2.48/28        Self                                I
```

* 172.16.2.64/28	Self	I
* 172.16.3.0/24	Self	I
* 172.16.3.16/28	Self	I
* 172.16.3.32/28	Self	I
* 172.16.3.48/28	Self	I
* 172.16.3.64/28	Self	I
* 172.16.128.0/17	Self	I

The aggregate route 172.16.128.0/17 is advertised, in violation of the administrative policy

3. On Device R1, configure the **not-smaller-than-18** policy.

```
[edit policy-options policy-statement not-smaller-than-18 term reject-less-than-18-bits]
user@R1# set from protocol aggregate
user@R1# set from route-filter 172.16.0.0/16 upto /18
user@R1# set then reject
```

4. On Device R1, apply the policy to the peering session with Device R5.

```
[edit protocols bgp group to_64512]
user@R1# set export not-smaller-than-18
user@R1# commit
```

5. On Device R1, check which routes are advertised to Device R5.

```
user@R1> show route advertising-protocol bgp 10.0.0.9
```

```
inet.0: 29 destinations, 31 routes (29 active, 0 holddown, 0 hidden)
  Prefix                Nexthop          MED      Lclpref    AS path
* 172.16.1.0/24          Self              I
* 172.16.1.16/28         Self              I
* 172.16.1.32/28         Self              I
* 172.16.1.48/28         Self              I
* 172.16.1.64/28         Self              I
* 172.16.2.0/24          Self              I
* 172.16.2.16/28         Self              I
* 172.16.2.32/28         Self              I
* 172.16.2.48/28         Self              I
* 172.16.2.64/28         Self              I
* 172.16.3.0/24          Self              I
* 172.16.3.16/28         Self              I
* 172.16.3.32/28         Self              I
```

* 172.16.3.48/28	Self	I
* 172.16.3.64/28	Self	I

Meaning

The policy chain is working correctly. Only aggregate routes larger than 18 bits in length and all customer routes are advertised to Device R5.

Understanding Route Filters for Use in Routing Policy Match Conditions 276
Route Filter Match Conditions 65
Example: Configuring Routing Policy Prefix Lists 361
Example: Configuring a Policy Subroutine 263

Example: Using Firewall Filter Chains

IN THIS SECTION

- [Requirements | 250](#)
- [Overview | 251](#)
- [Configuration | 251](#)
- [Verification | 256](#)

This example shows the use of firewall filter chains. Firewall filters filter1, filter2, and filter3, are applied to interface ge-0/1/1.0 using the **input-chain** and the **output-chain** configuration statements.

Requirements

Before you begin:

- You should have a MX Series router with MPCs and running Junos release 18.4R1 or later.

- The router should be configured for IP version 4 (IPv4) protocol (**family inet**) and configured the logical interface with an interface address. All other initial router configurations should be complete, with basic IPv4 connectivity between the devices confirmed.
- The traffic you send should be compatible with the firewall filter rules so the rules you configure can match the test traffic you send.

Overview

This examples shows how to chain multiple firewall filters for both ingress and egress so they can be applied to a given interface and evaluated in sequence. Each filter in chain acts the same as the CLI filter. The order of execution occurs in the same order as the chain, from left to right.

Topology

In this example, you configure multiple firewall filters and then apply them in sequence by chaining them to a given interface. This example uses **ge-0/1/1.0** configured with the IP address 172.16.1.1/30 for both the input and output chain. If a packet does not match any of the filters in the chain list, the packet is dropped.

Configuration

IN THIS SECTION

- [Configure IPv4 Firewall Filters | 252](#)
- [Apply the Chain of Input Filters | 253](#)
- [Confirm and Commit Your Candidate Configuration | 254](#)

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#).

CLI Quick Configuration

To quickly configure this example, copy the following commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level. The filter names used here are **filter1**, and so on, while the term names are **t1_f1** (term1, using filter1), and so on.

```
set firewall family inet filter filter1 term t1_f1 from protocol tcp
set firewall family inet filter filter1 term t1_f1 then count f1_t1_cnt
set firewall family inet filter filter1 term t2_f1 from precedence 7
```

```

set firewall family inet filter filter1 term t2_f1 then count f1_t2_cnt
set firewall family inet filter filter2 term t1_f2 from dscp 0
set firewall family inet filter filter2 term t1_f2 then count f2_t1_cnt
set firewall family inet filter filter2 term t2_f2 from source-port 1020
set firewall family inet filter filter2 term t2_f2 then count f2_t2_cnt
set firewall family inet filter filter3 term t1_f3 from destination-address 172.30.1.1/31
set firewall family inet filter filter3 term t1_f3 then count f3_t1_cnt
set firewall family inet filter filter3 term t2_f3 from destination-port 5454
set firewall family inet filter filter3 term t2_f3 then count f3_t2_cnt
set firewall family inet filter filter3 term t2_f3 then accept
set firewall policer policer1 if-exceeding bandwidth-limit 5m
set firewall policer policer1 if-exceeding burst-size-limit 100k
set firewall policer p1 then discard
set interfaces ge-0/1/1 unit 0 family inet address 172.16.1.1/30
set interfaces ge-0/1/1 unit 0 family inet filter input-chain [ filter1 filter2 filter3 ]
set interfaces ge-0/1/1 unit 0 family inet filter output-chain [ filter1 filter2 filter3 ]

```

Configure IPv4 Firewall Filters

Here we configure the firewall filters. Each has different match conditions and count actions. The first two filters have multiple terms with the non-terminating action of **count**, which means matching packets will be passed on to the next filter in the chain, while the third has an action of **accept**. Packets that don't match any of the specified conditions would be dropped.

Step-by-Step Procedure

To configure the firewall filters:

1. Navigate the CLI to the hierarchy level at which you configure IPv4 firewall filters.

```

[edit]
user@host# edit firewall family inet

```

2. Configure the first firewall filter to count TCP packets, or packets with a precedence of 7, before sending them on to the next filter in the chain.

```

[edit firewall family inet]
user@host# set filter filter1 term t1_f1 from protocol tcp
user@host# set filter filter1 term t1_f1 then count f1_t1_cnt
user@host# set filter filter1 term t2_f1 from precedence 7
user@host# set filter filter1 term t2_f1 then count f1_t2_cnt

```

3. Configure the second firewall filter to count DSCP packets, or packets with a source port of 1020, before sending them on to the next filter in the chain.

```
[edit firewall family inet]
user@host#set filter filter2 term t1_f2 from dscp 0
user@host#set filter filter2 term t1_f2 then count f2_t1_cnt
user@host#set filter filter2 term t2_f2 from source-port 1020
user@host#set filter filter2 term t2_f2 then count f2_t2_cnt
```

4. Configure the last firewall filter to count and accept packets with a destination address of 172.30.1.1/31, or a destination port of 5454.

```
[edit firewall family inet]
user@host#set filter filter3 term t1_f3 from destination-address 172.30.1.1/31
user@host#set filter filter3 term t1_f3 then count f3_t1_cnt
user@host#set filter filter3 term t2_f3 from destination-port 5454
user@host#set filter filter3 term t2_f3 then count f3_t2_cnt
user@host#set filter filter3 term t2_f3 then accept
```

5. [Optional] Configure a policer to shape traffic flow.

```
[edit firewall]
set policer policer1 if-exceeding bandwidth-limit 5m
set policer policer1 if-exceeding burst-size-limit 100k
set policer policer1 then discard
```

Apply the Chain of Input Filters

Here we attach the firewall filters to a given interface. The order of execution occurs in the same order as the chain, from left to right.

Step-by-Step Procedure

To assign the interface an IP address:

1. Navigate to the interface we are using for the filters, **ge-0/1/1.0**.

```
[edit]
user@host# edit interfaces ge-0/1/1 unit 0 family inet
```

2. Assign an IPv4 address to the logical interface.

```
[edit interfaces ge-0/1/1 unit 0 family inet]
user@host# set address 172.16.1.1/30
```

3. Apply the filters as a list of input filters.

```
[edit interfaces ge-0/1/1 unit 0 family inet]
user@host# set filter input-chain [ filter1 filter2 filter3 ]
user@host# set filter out-chain [ filter1 filter2 filter3 ]
```

Confirm and Commit Your Candidate Configuration

Step-by-Step Procedure

To confirm and then commit your candidate configuration:

1. Confirm the configuration of the firewall filters by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit firewall]
user@host# show
family inet {
}
filter filter1 {
  term t1_f1 {
    from {
      protocol tcp;
    }
    then count f1_t1_cnt;
  }
  term t2_f1 {
    from {
      precedence 7;
    }
    then count f1_t2_cnt;
  }
}
filter filter2 {
  term t1_f2 {
    from {
      dscp 0;
    }
  }
}
```

2. Confirm the configuration of the interface by entering the **show interfaces** configuration mode command.

```
[edit]
user@host# show interfaces
ge-0/1/1 {
  unit 0 {
    family inet {
      filter {
        input-chain [ filter1 filter2 filter3 ];
      }
      address 172.16.1.1/30;
    }
  }
}
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Verification

IN THIS SECTION

- [Send Traffic Through the Firewall Filters | 256](#)

Confirm that the configuration works as expected, that is, that the matching traffic is evaluated by each of the filters filter1, filter2, and filter3, and that the expected action (count or accept) has been taken.

Send Traffic Through the Firewall Filters

Purpose

Send traffic from one device to the router you have configured to see whether matching packets are being evaluated by all relevant filters in the chain.

Action

To verify that input packets are evaluated by filter1, filter2, and filter3:

1. From the remote host that is connected to **ge-0/1/1.0**, send a packet with a precedence of 7. The packet should be counted and then evaluated by filter2.
2. From the remote host that is connected to **ge-0/1/1.0**, send a packet with DSCP value of 0. The packet should be counted and then evaluated by filter3.
3. From the remote host that is connected to **ge-0/1/1.0**, send a packet with a destination address of 172.30.1.1/31 and a destination port number of 5454. The packet should be counted and then accepted.
4. To display counter information for the filters you configured, enter the **show firewall filter ge-0/1/1.0-i** operational mode command. The command output displays the number of bytes and packets that match filter terms associated with the following counters:
 - **pkts_f1-ge-0/1/1.0-i**
 - **pkts_f2-ge-0/1/1.0-i**
 - **pkts_f3-ge-0/1/1.0-i**
 - **pkts_discard-ge-0/1/1.0-i**

Understanding Policy Subroutines in Routing Policy Match Conditions

You can use a routing policy called from another routing policy as a match condition. This process makes the called policy a *subroutine*.

In some ways, the Junos OS policy framework is similar to a programming language. This similarity includes the concept of nesting policies into a policy subroutine. A subroutine in a software program is a section of code that you reference on a regular basis. A policy subroutine works in the same fashion—you reference an existing policy as a match criterion in another policy. The routing device first evaluates the subroutine and then evaluates the main policy. The evaluation of the subroutine returns a true or false Boolean result to the main policy. Because you are referencing the subroutine as a match criterion, a true result means that the main policy has a match and can perform any configured actions. A false result from the subroutine, however, means that the main policy does not have a match.

Configuring Subroutines

To configure a subroutine in a routing policy to be called from another routing policy, create the subroutine and specify its name using the **policy** match condition in the **from** or **to** statement of another routing policy.

NOTE: Do not evaluate a routing policy within itself. The result is that no prefixes ever match the routing policy.

The action specified in a subroutine is used to provide a match condition to the calling policy. If the subroutine specifies an action of accept, the calling policy considers the route to be a match. If the subroutine specifies an action of reject, the calling policy considers the route not to match. If the subroutine specifies an action that is meant to manipulate the route characteristics, the changes are made.

Possible Consequences of Termination Actions in Subroutines

A subroutine with particular statements can behave differently from a routing policy that contains the same statements. With a subroutine, you must remember that the possible termination actions of accept or reject specified by the subroutine or the default policy can greatly affect the expected results.

In particular, you must consider what happens if a match does not occur with routes specified in a subroutine and if the default policy action that is taken is the action that you expect and want.

For example, imagine that you are a network administrator at an Internet service provider (ISP) that provides service to Customer A. You have configured several routing policies for the different classes of neighbors that Customer A presents on various links. To save time maintaining the routing policies for Customer A, you have configured a subroutine that identifies their routes and various routing policies that call the subroutine, as shown below:

```
[edit]
policy-options {
  policy-statement customer-a-subroutine {
    from {
      route-filter 10.1/16 exact;
      route-filter 10.5/16 exact;
      route-filter 192.168.10/24 exact;
    }
    then accept;
  }
}
policy-options {
  policy-statement send-customer-a-default {
    from {
      policy customer-a-subroutine;
```

```

    }
    then {
        set metric 500;
        accept;
    }
}
}
policy-options {
    policy-statement send-customer-a-primary {
        from {
            policy customer-a-subroutine;
        }
        then {
            set metric 100;
            accept;
        }
    }
}
policy-options {
    policy-statement send-customer-a-secondary {
        from {
            policy customer-a-subroutine;
        }
        then {
            set metric 200;
            accept;
        }
    }
}
protocols {
    bgp {
        group customer-a {
            export send-customer-a-default;
            neighbor 10.1.1.1;
            neighbor 10.1.2.1;
            neighbor 10.1.3.1 {
                export send-customer-a-primary;
            }
            neighbor 10.1.4.1 {
                export send-customer-a-secondary;
            }
        }
    }
}
}

```

The following results occur with this configuration:

- The group-level **export** statement resets the metric to 500 when advertising all BGP routes to neighbors 10.1.1.1 and 10.1.2.1 rather than just the routes that match the subroutine route filters.
- The neighbor-level **export** statements reset the metric to 100 and 200 when advertising all BGP routes to neighbors 10.1.3.1 and 10.1.4.1, respectively, rather than just the BGP routes that match the subroutine route filters.

These unexpected results occur because the subroutine policy does not specify a termination action for routes that do not match the route filter and therefore, the default BGP export policy of accepting all BGP routes is taken.

If the statements included in this particular subroutine had been contained within the calling policies themselves, only the desired routes would have their metrics reset.

This example illustrates the differences between routing policies and subroutines and the importance of the termination action in a subroutine. Here, the default BGP export policy action for the subroutine was not carefully considered. A solution to this particular example is to add one more term to the subroutine that rejects all other routes that do not match the route filters:

```
[edit]
policy-options {
  policy-statement customer-a-subroutine {
    term accept-exact {
      from {
        route-filter 10.1/16 exact;
        route-filter 10.5/16 exact;
        route-filter 192.168.10/24 exact;
      }
      then accept;
    }
    term reject-others {
      then reject;
    }
  }
}
```

Termination action strategies for subroutines in general include the following:

- Depend upon the default policy action to handle all other routes.
- Add a term that accepts all other routes.
- Add a term that rejects all other routes.

The option that you choose depends upon what you want to achieve with your subroutine. Plan your subroutines carefully.

[Example: Configuring a Policy Subroutine | 263](#)

How a Routing Policy Subroutine Is Evaluated

Figure 17 on page 262 shows how a subroutine is evaluated. The subroutine is included in the first term of the first routing policy in a chain. Each route is evaluated against the subroutine as follows:

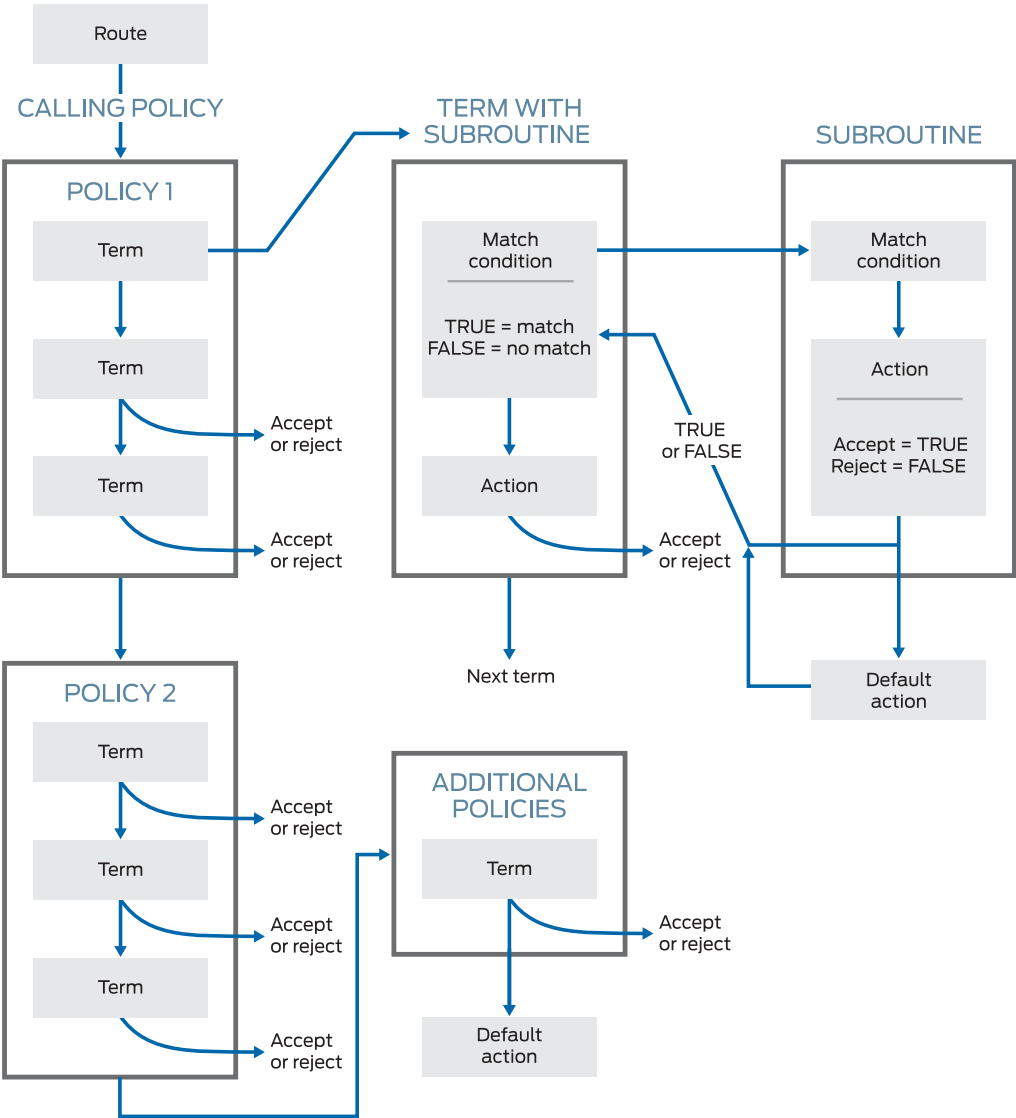

1. The route is evaluated against the first term in the first routing policy. If the route does not match all match conditions specified before the subroutine, the subroutine is skipped and the next term in the routing policy is evaluated (see Step 2). If the route matches all match conditions specified before the subroutine, the route is evaluated against the subroutine. If the route matches the match conditions in any of the subroutine terms, two levels of evaluation occur in the following order:
 - a. The actions in the subroutine term are evaluated. If one of the actions is **accept**, evaluation of the subroutine ends and a Boolean value of **TRUE** is returned to the calling policy. If one of the actions is **reject**, evaluation of the subroutine ends and **FALSE** is returned to the calling policy.

If the subroutine does not specify the **accept**, **reject** or **next-policy** action, it uses the **accept** or **reject** action specified by the default policy, and the values of **TRUE** or **FALSE** are returned to the calling policy as described in the previous paragraph.
 - b. The calling policy's subroutine match condition is evaluated. During this part of the evaluation, **TRUE** equals a match and **FALSE** equals no match. If the subroutine returns **TRUE** to the calling policy, then the evaluation of the calling policy continues. If the subroutine returns **FALSE** to the calling policy, then the evaluation of the current term ends and the next term is evaluated.
2. The route is evaluated against the second term in the first routing policy.

If you specify a policy chain as a subroutine, the entire chain acts as a single subroutine. As with other chains, the action specified by the default policy is taken only when the entire chain does not accept or reject a route.

If a term defines multiple match conditions, including a subroutine, and a route does not match a condition specified before the subroutine, the evaluation of the term ends and the subroutine is not called and evaluated. In this situation, an action specified in the subroutine that manipulates a route's characteristics is not implemented.

Example: Configuring a Policy Subroutine

IN THIS SECTION

- [Requirements | 263](#)
- [Overview | 263](#)
- [Configuration | 265](#)
- [Verification | 272](#)

This example demonstrates the use of a policy subroutine in a routing policy match condition.

Requirements

No special configuration beyond device initialization is required before configuring this example.

Overview

On Device R1, a policy called **main** is configured.

```
user@R1# show policy-options
policy-statement main {
  term subroutine-as-a-match {
    from policy subroutine;
    then accept;
  }
  term nothing-else {
    then reject;
  }
}
```

This main policy calls a subroutine called **subroutine**.

```
user@R1# show policy-options
policy-statement subroutine {
  term get-routes {
    from protocol static;
    then accept;
  }
}
```

```

term nothing-else {
    then reject;
}

```

The router evaluates the logic of **main** in a defined manner. The match criterion of **from policy subroutine** allows the routing device to locate the subroutine. All terms of the subroutine are evaluated, in order, following the normal policy processing rules. In this example, all static routes in the routing table match the subroutine with an action of accept. This returns a true result to the original, or calling, policy which informs the device that a positive match has occurred. The actions in the calling policy are executed and the route is accepted. All other routes in the routing table do not match the subroutine and return a false result to the calling policy. The device evaluates the second term of **main** and rejects the routes.

The actions in the subroutine do not actually accept or reject a specific route. The subroutine actions are only translated into a true or a false result. Actions that modify a route's attributes, however, are applied to the route regardless of the outcome of the subroutine.

Device R1 in AS 64510 has multiple customer routes, some of which are static routes configured locally, and some of which are received from Device R2 and Device R3 through internal BGP (IBGP). AS 64510 is connected to Device R4 in AS 64511. The policy **main** is applied as an export policy in Device R1's BGP peering session with Device R4. This causes Device R1 to send only its own static routes to Device R4. Because of the policy **main**, Device R1 does not send the routes received from its internal peers, Device R2 and Device R3.

When you are working with policy subroutines, it is important to remember that the default EBGp export policy is to advertise all learned BGP routes to all EBGp peers. This default policy is in effect in the main policy and also in the subroutine. Therefore, as shown in this example, if you do not want the default EBGp export policy to take effect, you must configure a **then reject** terminating action as the final term in both the main policy and in the policy subroutine. This example demonstrates what happens when the final **then reject** term is missing either from the main policy or from the policy subroutine.

Topology

[Figure 18 on page 265](#) shows the sample network.

Figure 18: BGP Topology for Policy Subroutine

"CLI Quick Configuration" on page 265 shows the configuration for all of the devices in Figure 18 on page 265.

The section "Step-by-Step Procedure" on page 268 describes the steps on Device R1.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level.

Device R1

```
set interfaces fe-1/2/0 unit 0 description to_R2
set interfaces fe-1/2/0 unit 0 family inet address 10.0.0.1/30
set interfaces fe-1/2/2 unit 0 description to_R3
set interfaces fe-1/2/2 unit 0 family inet address 10.0.0.5/30
set interfaces fe-1/2/3 unit 0 description to_R4
set interfaces fe-1/2/3 unit 0 family inet address 10.1.0.5/30
set interfaces lo0 unit 0 family inet address 192.168.0.1/32
set protocols bgp group int type internal
```

```

set protocols bgp group int local-address 192.168.0.1
set protocols bgp group int neighbor 192.168.0.2
set protocols bgp group int neighbor 192.168.0.3
set protocols bgp group to_64511 type external
set protocols bgp group to_64511 export main
set protocols bgp group to_64511 neighbor 10.1.0.6 peer-as 64511
set protocols ospf area 0.0.0.0 interface fe-1/2/0.0
set protocols ospf area 0.0.0.0 interface fe-1/2/2.0
set protocols ospf area 0.0.0.0 interface lo0.0 passive
set policy-options policy-statement main term subroutine-as-a-match from policy subroutine
set policy-options policy-statement main term subroutine-as-a-match then accept
set policy-options policy-statement main term nothing-else then reject
set policy-options policy-statement subroutine term get-routes from protocol static
set policy-options policy-statement subroutine term get-routes then accept
set policy-options policy-statement subroutine term nothing-else then reject
set routing-options static route 172.16.1.16/28 discard
set routing-options static route 172.16.1.32/28 discard
set routing-options static route 172.16.1.48/28 discard
set routing-options static route 172.16.1.64/28 discard
set routing-options router-id 192.168.0.1
set routing-options autonomous-system 64510

```

Device R2

```

set interfaces fe-1/2/0 unit 0 description to_R1
set interfaces fe-1/2/0 unit 0 family inet address 10.0.0.2/30
set interfaces fe-1/2/1 unit 0 description to_R3
set interfaces fe-1/2/1 unit 0 family inet address 10.1.0.1/30
set interfaces lo0 unit 0 family inet address 192.168.0.2/32
set protocols bgp group int type internal
set protocols bgp group int local-address 192.168.0.2
set protocols bgp group int neighbor 192.168.0.1 export send-static
set protocols bgp group int neighbor 192.168.0.3
set protocols ospf area 0.0.0.0 interface fe-1/2/0.0
set protocols ospf area 0.0.0.0 interface fe-1/2/1.0
set protocols ospf area 0.0.0.0 interface lo0.0 passive
set policy-options policy-statement send-static term 1 from protocol static
set policy-options policy-statement send-static term 1 then accept
set routing-options static route 172.16.2.16/28 discard
set routing-options static route 172.16.2.32/28 discard

```

```

set routing-options static route 172.16.2.48/28 discard
set routing-options static route 172.16.2.64/28 discard
set routing-options router-id 192.168.0.2
set routing-options autonomous-system 64510

```

Device R3

```

set interfaces fe-1/2/1 unit 0 description to_R2
set interfaces fe-1/2/1 unit 0 family inet address 10.1.0.2/30
set interfaces fe-1/2/2 unit 0 description to_R1
set interfaces fe-1/2/2 unit 0 family inet address 10.0.0.6/30
set interfaces lo0 unit 0 family inet address 192.168.0.3/32
set protocols bgp group int type internal
set protocols bgp group int local-address 192.168.0.3
set protocols bgp group int neighbor 192.168.0.1 export send-static
set protocols bgp group int neighbor 192.168.0.2
set protocols ospf area 0.0.0.0 interface fe-1/2/2.6
set protocols ospf area 0.0.0.0 interface fe-1/2/0.4
set protocols ospf area 0.0.0.0 interface lo0.0 passive
set policy-options policy-statement send-static from protocol static
set policy-options policy-statement send-static then accept
set routing-options static route 172.16.3.16/28 discard
set routing-options static route 172.16.3.32/28 discard
set routing-options static route 172.16.3.48/28 discard
set routing-options static route 172.16.3.64/28 discard
set routing-options router-id 192.168.0.3
set routing-options autonomous-system 64510

```

Device R4

```

set interfaces fe-1/2/3 unit 0 description to_R1
set interfaces fe-1/2/3 unit 0 family inet address 10.1.0.6/30
set interfaces lo0 unit 0 family inet address 192.168.0.4/32
set protocols bgp group ext type external
set protocols bgp group ext peer-as 64510
set protocols bgp group ext neighbor 10.1.0.5
set routing-options autonomous-system 64511

```

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure Device R1:

1. Configure the device interfaces.

```
[edit interfaces]
user@R1# set fe-1/2/0 unit 0 description to_R2
user@R1# set fe-1/2/0 unit 0 family inet address 10.0.0.1/30
user@R1# set fe-1/2/2 unit 0 description to_R3
user@R1# set fe-1/2/2 unit 0 family inet address 10.0.0.5/30
user@R1# set fe-1/2/3 unit 0 description to_R4
user@R1# set fe-1/2/3 unit 0 family inet address 10.1.0.5/30
user@R1# set lo0 unit 0 family inet address 192.168.0.1/32
```

2. Configure the internal BGP (IBGP) connections to Device R2 and Device R3.

```
[edit protocols bgp group int]
user@R1# set type internal
user@R1# set local-address 192.168.0.1
user@R1# set neighbor 192.168.0.2
user@R1# set neighbor 192.168.0.3
```

3. Configure the EBGP connection to Device R4.

```
[edit protocols bgp group to_64511]
user@R1# set type external
user@R1# set export main
user@R1# set neighbor 10.1.0.6 peer-as 64511
```

4. Configure OSPF connections to Device R2 and Device R3.

```
[edit protocols ospf area 0.0.0.0]
user@R1# set interface fe-1/2/0.0
user@R1# set interface fe-1/2/2.0
user@R1# set interface lo0.0 passive
```

5. Configure the policy **main**.

```
[edit policy-options policy-statement main term subroutine-as-a-match]
user@R1# set from policy subroutine
user@R1# set then accept
[edit policy-options policy-statement main term nothing-else]
user@R1# set then reject
```

6. Configure the policy **subroutine**.

```
[edit policy-options policy-statement subroutine term get-routes]
user@R1# set from protocol static
user@R1# set then accept
[edit policy-options policy-statement subroutine term nothing-else]
user@R1# set then reject
```

7. Configure the static route to the 172.16.5.0/24 network.

```
[edit routing-options static]
user@R1# set route 172.16.1.16/28 discard
user@R1# set route 172.16.1.32/28 discard
user@R1# set route 172.16.1.48/28 discard
user@R1# set route 172.16.1.64/28 discard
```

8. Configure the autonomous system (AS) number and router ID.

```
[edit routing-options]
user@R1# set router-id 192.168.0.1
user@R1# set autonomous-system 64510
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R1# show interfaces
fe-1/2/0 {
  unit 0 {
    description to_R2;
    family inet {
      address 10.0.0.1/30;
```

```

    }
  }
}
fe-1/2/2 {
  unit 0 {
    description to_R3;
    family inet {
      address 10.0.0.5/30;
    }
  }
}
fe-1/2/3 {
  unit 0 {
    description to_R4;
    family inet {
      address 10.1.0.5/30;
    }
  }
}
lo0 {
  unit 0 {
    family inet {
      address 192.168.0.1/32;
    }
  }
}

```

```

user@R1# show protocols
bgp {
  group int {
    type internal;
    local-address 192.168.0.1;
    neighbor 192.168.0.2;
    neighbor 192.168.0.3;
  }
  group to_64511 {
    type external;
    export main;
    neighbor 10.1.0.6 {
      peer-as 64511;
    }
  }
}
ospf {

```

```

area 0.0.0.0 {
    interface fe-1/2/0.0;
    interface fe-1/2/2.0;
    interface lo0.0 {
        passive;
    }
}
}

```

```

user@R1# show policy-options
policy-statement main {
    term subroutine-as-a-match {
        from policy subroutine;
        then accept;
    }
    term nothing-else {
        then reject;
    }
}
policy-statement subroutine {
    term get-routes {
        from protocol static;
        then accept;
    }
    term nothing-else {
        then reject;
    }
}

```

```

user@R1# show routing-options
static {
    route 172.6.1.16/28 discard;
    route 172.6.1.32/28 discard;
    route 172.6.1.48/28 discard;
    route 172.6.1.64/28 discard;
}
router-id 192.168.0.1;
autonomous-system 64510;

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

IN THIS SECTION

- [Verifying the Routes on Device R1 | 272](#)
- [Verifying the Route Advertisement to Device R4 | 272](#)
- [Experimenting with the Default BGP Export Policy | 273](#)

Confirm that the configuration is working properly.

Verifying the Routes on Device R1

Purpose

On Device R1, check the static routes in the routing table.

Action

```
user@R1> show route protocol static
```

```
inet.0: 23 destinations, 23 routes (23 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

172.16.1.16/28      *[Static/5] 1d 02:02:13
                    Discard
172.16.1.32/28      *[Static/5] 1d 02:02:13
                    Discard
172.16.1.48/28      *[Static/5] 1d 02:02:13
                    Discard
172.16.1.64/28      *[Static/5] 1d 02:02:13
                    Discard
```

Meaning

Device R1 has four static routes.

Verifying the Route Advertisement to Device R4

Purpose

On Device R1, make sure that the static routes are advertised to Device R4.

Action

```
user@R1> show route advertising-protocol bgp 10.1.0.6
```

```
inet.0: 23 destinations, 23 routes (23 active, 0 holddown, 0 hidden)
  Prefix                Nexthop          MED      Lclpref    AS path
* 172.16.1.16/28        Self
* 172.16.1.32/28        Self
* 172.16.1.48/28        Self
* 172.16.1.64/28        Self
```

Meaning

As expected, Device R1 only advertises its static routes to Device R4.

Experimenting with the Default BGP Export Policy

Purpose

See what can happen when you remove the final **then reject** term from the policy **main** or the policy **subroutine**.

Action

1. On Device R1, deactivate the final term in the policy **main**.

```
[edit policy-options policy-statement main]
user@R1# deactivate term nothing-else
user@R1# commit
```

2. On Device R1, check to see which routes are advertised to Device R4.

```
user@R1> show route advertising-protocol bgp 10.1.0.6
```

```
inet.0: 23 destinations, 23 routes (23 active, 0 holddown, 0 hidden)
  Prefix                Nexthop          MED      Lclpref    AS path
* 172.16.1.16/28        Self
* 172.16.1.32/28        Self
* 172.16.1.48/28        Self
* 172.16.1.64/28        Self
* 172.16.2.16/28        Self
* 172.16.2.32/28        Self
* 172.16.2.48/28        Self
* 172.16.2.64/28        Self
* 172.16.3.16/28        Self
```

```
* 172.16.3.32/28      Self      I
* 172.16.3.48/28      Self      I
* 172.16.3.64/28      Self      I
```

Now, all the BGP routes from Device R1 are sent to Device R4. This is because after the processing is returned to policy **main**, the default BGP export policy takes effect.

3. On Device R1, reactivate the final term in the policy **main**, and deactivate the final term in the policy **subroutine**.

```
[edit policy-options policy-statement main]
user@R1# activate term nothing-else
[edit policy-options policy-statement subroutine]
user@R1# deactivate term nothing-else
user@R1# commit
```

4. On Device R1, check to see which routes are advertised to Device R4.

```
user@R1> show route advertising-protocol bgp 10.1.0.6
```

```
inet.0: 23 destinations, 23 routes (23 active, 0 holddown, 0 hidden)
  Prefix                Nexthop          MED      Lclpref    AS path
* 172.16.1.16/28        Self              I
* 172.16.1.32/28        Self              I
* 172.16.1.48/28        Self              I
* 172.16.1.64/28        Self              I
* 172.16.2.16/28        Self              I
* 172.16.2.32/28        Self              I
* 172.16.2.48/28        Self              I
* 172.16.2.64/28        Self              I
* 172.16.3.16/28        Self              I
* 172.16.3.32/28        Self              I
* 172.16.3.48/28        Self              I
* 172.16.3.64/28        Self              I
```

Now, all the BGP routes from Device R1 are sent to Device R4. This is because before the processing is returned to policy **main**, the default BGP export policy takes effect in the policy **subroutine**.

Meaning

To prevent the default BGP export policy from taking effect, you must include a final **then reject** term in the main policy and in all referenced subroutines.

Understanding Route Filters for Use in Routing Policy Match Conditions

IN THIS SECTION

- [Radix Trees | 277](#)
- [Configuring Route Filters | 279](#)

- How Route Filters Are Evaluated in Routing Policy Match Conditions | 285
- Route Filter Examples | 288

A *route filter* is a collection of match prefixes. When specifying a match prefix, you can specify an exact match with a particular route or a less precise match. You can configure either a common action that applies to the entire list or an action associated with each prefix.

NOTE: Because the configuration of route filters includes setting up prefixes and prefix lengths, we strongly recommend that you have a thorough understanding of IP addressing, including supernetting, before proceeding with the configuration.

It is also important to understand how a route filter is evaluated, particularly if the route filter includes multiple **route-filter** options in a **from** statement. We strongly recommend that you read “[How Route Filters Are Evaluated in Routing Policy Match Conditions](#)” on page 285 before proceeding with the configuration. Not fully understanding the evaluation process can result in faulty configuration and unexpected results.

This section discusses the following topics:

Radix Trees

To understand the operation of a route filter, you need to be familiar with a device used for binary number matching known as a radix tree (sometimes called a patricia trie or radix trie). A radix tree uses binary lookups to identify IP addresses (routes). Remember that an IP address is a 32-bit number represented in a dotted decimal format for easy comprehension by humans. These 8-bit groupings can each have a value between 0 and 255. A radix tree can be a graphical representation of these binary numbers.

In [Figure 19 on page 277](#), the radix tree starts with no configured value (starts at 0) and is at the leftmost position of the binary IP address. This is shown as 0/0, which is often referred to as the default route.

Figure 19: Beginning of a Radix Tree

Because this is binary, each bit can have only one of two possible values—a 0 or a 1. Moving down the left branch represents a value of 0, while moving to the right represents a value of 1. The first step is shown in [Figure 20 on page 278](#). At the first position, the first octet of the IP address has a value of 00000000 or 10000000—a 0 or 128, respectively. This is represented in [Figure 20 on page 278](#) by the values 0/1 and 128/1.

Figure 20: First Step of a Radix Tree

The second step is shown in [Figure 21 on page 278](#). This second level of the tree has four possible binary values for the first octet: 00000000, 01000000, 10000000, and 11000000. These decimal values of 0, 64, 128, and 192 are represented by the IP addresses of 0/2, 64/2, 128/2, and 192/2 on the radix tree.

Figure 21: Second Step of a Radix Tree

This step-by-step process continues for 33 total levels to represent every possible IP address.

The radix tree structure is helpful when locating a group of routes that all share the same most significant bits. [Figure 22 on page 279](#) shows the point in the radix tree that represents the 192.168.0.0/16 network. All of the routes that are more specific than 192.168.0.0/16 are shown in the highlighted section.

Figure 22: Locating a Group of Routes

Configuring Route Filters

NOTE: The topic, [Configuring Route Filters](#), describes default Junos OS behavior. The walkup feature, which is not covered in this topic, alters the evaluation results discussed in this topic by allowing the router to consider shorter match conditions configured within the same term. See [“Walkup for Route Filters Overview” on page 301](#) for details.

To configure a route filter, include one or more **route-filter** or **source-address-filter** statements:

```
[edit policy-options policy-statement policy-name term term-name from]
route-filter destination-prefix match-type {
  actions;
}
```

The **route-filter** option is typically used to match an incoming route address to destination match prefixes of any type except for unicast source addresses.

The **destination-prefix** address is the IP version 4 (IPv4) or IP version 6 (IPv6) address prefix specified as **prefix/prefix-length**. If you omit **prefix-length** for an IPv4 prefix, the default is /32. If you omit **prefix-length** for an IPv6 prefix, the default is /128. Prefixes specified in a **from** statement must be either all IPv4 addresses or all IPv6 addresses.

The **source-address-filter** option is typically used to match an incoming route address to unicast source addresses in multiprotocol BGP (MBGP) and Multicast Source Discovery Protocol (MSDP) environments.

```
source-address-filter source-prefix match-type {
  actions;
```

```
}
```

source-prefix address is the IPv4 or IPv6 address prefix specified as **prefix/prefix-length**. If you omit **prefix-length** for an IPv4 prefix, the default is /32**prefix-length**. If you omit **prefix-length** for an IPv6 prefix, the default is /128. Prefixes specified in a **from** statement must be either all IPv4 addresses or all IPv6 addresses.

match-type is the type of match to apply to the source or destination prefix. It can be one of the match types listed in [Table 16 on page 281](#). For examples of the match types and the results when presented with various routes, see [Table 17 on page 284](#).

actions are the actions to take if a route address matches the criteria specified for a destination match prefix (specified as part of a **route-filter** option) or for a source match prefix (specified as part of a **destination-address-filter** option). The actions can consist of one or more of the actions described in [“Actions in Routing Policy Terms” on page 67](#).

In a route filter you can specify actions in two ways:

- In the **route-filter** or **source-address-filter** option—These actions are taken immediately after a match occurs, and the **then** statement is not evaluated.
- In the **then** statement—These actions are taken after a match occurs but no actions are specified for the **route-filter** or **source-address-filter** option.

The **upto** and **prefix-length-range** match types are similar in that both specify the most-significant bits and provide a range of prefix lengths that can match. The difference is that **upto** allows you to specify an upper limit only for the prefix length range, whereas **prefix-length-range** allows you to specify both lower and upper limits.

For more examples of these route filter match types, see [“Route Filter Examples” on page 288](#).

Table 16: Route Filter Match Types for a Prefix List

Match Type	Match Criteria
address-mask netmask-value	<p>All of the following are true:</p> <ul style="list-style-type: none"> • The bit-wise logical AND of the netmask-value pattern and the incoming IPv4 or IPv6 route address and the bit-wise logical AND of the netmask-value pattern and the destination-prefix address are the same. The bits set in the netmask-value pattern do not need to be contiguous. • The prefix-length component of the incoming IPv4 or IPv6 route address and the prefix-length component of the destination-prefix address are the same. <p>NOTE: The address-mask routing policy match type is valid only for matching an incoming IPv4 (family inet) or IPv6 (family inet6) route address to a list of destination match prefixes specified in a route-filter statement.</p> <p>The address-mask routing policy match type enables you to match an incoming IPv4 or IPv6 route address on a configured netmask address in addition to the length of a configured destination match prefix. The length of the route address must match exactly with the length of the configured destination match prefix, as the address-mask match type does not support prefix length variations for a range of prefix lengths.</p> <p>When the longest-match lookup is performed on a route filter, the lookup evaluates an address-mask match type differently from other routing policy match types. The lookup does not consider the length of the destination match prefix. Instead, the lookup considers the number of contiguous high-order bits set in the netmask value.</p> <p>For more information about this route filter match type, see “How an Address Mask Match Type Is Evaluated” on page 287.</p> <p>For example configurations showing route filters that contain the address-mask match type, see the following topics:</p> <ul style="list-style-type: none"> • “Accepting Incoming IPv4 Routes by Applying an Address Mask to the Route Address and the Destination Match Prefix” on page 293. • “Accepting Incoming IPv4 Routes with Similar Patterns But Different Prefix Lengths” on page 295. • “Evaluation of an Address Mask Match Type with Longest-Match Lookup” on page 296.
exact	<p>All of the following are true:</p> <ul style="list-style-type: none"> • The route address shares the same most-significant bits as the match prefix (destination-prefix or source-prefix). The number of significant bits is described by the prefix-length component of the match prefix. • The prefix-length component of the match prefix is equal to the route's prefix length.

Table 16: Route Filter Match Types for a Prefix List (*continued*)

Match Type	Match Criteria
longer	<p>All of the following are true:</p> <ul style="list-style-type: none"> • The route address shares the same most-significant bits as the match prefix (<i>destination-prefix</i> or <i>source-prefix</i>). The number of significant bits is described by the <i>prefix-length</i> component of the match prefix. • The route's prefix length is greater than the <i>prefix-length</i> component of the match prefix.
orlonger	<p>All of the following are true:</p> <ul style="list-style-type: none"> • The route address shares the same most-significant bits as the match prefix (<i>destination-prefix</i> or the <i>source-prefix</i>). The number of significant bits is described by the <i>prefix-length</i> component of the match prefix. • The route's prefix length is equal to or greater than the <i>prefix-length</i> component of the configured match prefix.
prefix-length-range <i>prefix-length2-prefix-length3</i>	<p>All of the following are true:</p> <ul style="list-style-type: none"> • The route address shares the same most-significant bits as the match prefix (<i>destination-prefix</i> or <i>source-prefix</i>). The number of significant bits is described by the <i>prefix-length</i> component of the match prefix. • The route's prefix length falls between <i>prefix-length2</i> and <i>prefix-length3</i>, inclusive.
through { <i>destination-prefix2</i> <i>source-prefix2</i> }	<p>All of the following are true:</p> <ul style="list-style-type: none"> • The route address shares the same most-significant bits as the first match prefix (<i>destination-prefix</i> or <i>source-prefix</i>). The number of significant bits is described by the <i>prefix-length</i> component of the first match prefix. • The route address shares the same most-significant bits as the second match prefix (<i>destination-prefix2</i> or <i>source-prefix2</i>). The number of significant bits is described by the <i>prefix-length</i> component of the second match prefix. • The route's prefix length is less than or equal to the <i>prefix-length</i> component of the second match prefix. <p>You do not use the through match type in most routing policy configurations. For an example, see “Rejecting Routes from Specific Hosts” on page 290.</p>
upto prefix-length2	<p>All of the following are true:</p> <ul style="list-style-type: none"> • The route address shares the same most-significant bits as the match prefix (<i>destination-prefix</i> or <i>source-prefix</i>). The number of significant bits is described by the <i>prefix-length</i> component of the match prefix. • The route's prefix length falls between the <i>prefix-length</i> component of the first match prefix and <i>prefix-length2</i>.

Figure 23 on page 283 shows the detailed radix tree for the route 192.168.0.0/16.

Figure 23: Portion of the Radix Tree

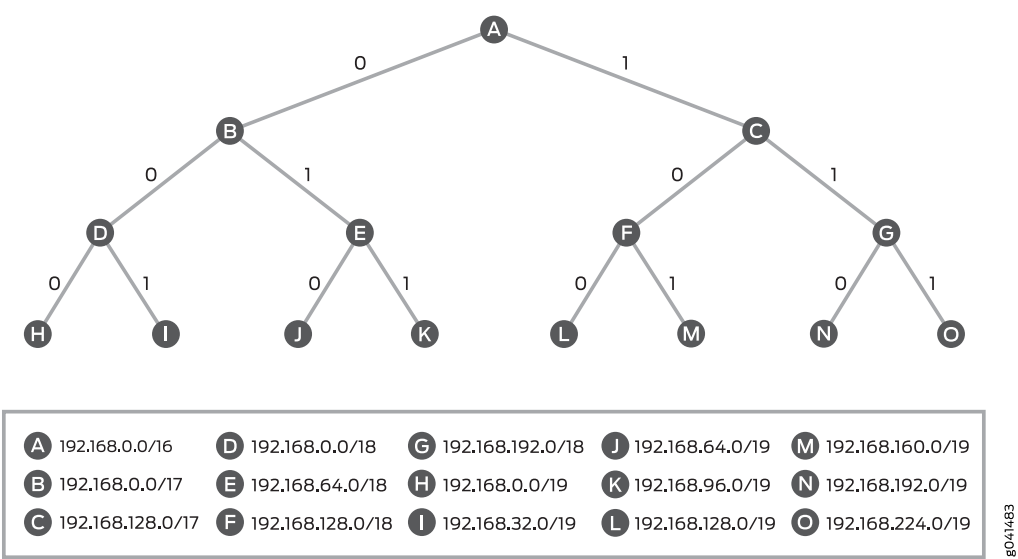

Figure 24 on page 284 and Table 17 on page 284 demonstrate the operation of the various route filter match types.

Figure 24: Route Filter Match Types

Table 17: Match Type Examples

Prefix	192.168/16 exact	192.168/16 longer	192.168/16 orlonger	192.168/16 upto /24	192.168/16 prefix-length-range 18-20	192.168/16 through 192.168/20	192.168/19 at least 252500

How Route Filters Are Evaluated in Routing Policy Match Conditions

During route filter evaluation, the policy framework software compares each route's source address with the destination prefixes in the route filter. The evaluation occurs in two steps:

1. The policy framework software performs a *longest-match lookup*, which means that the software searches for the prefix in the list with the longest length.

The longest-match lookup considers the **prefix** and **prefix-length** components of the configured match prefix only, and not the **match-type** component. The following sample route filter illustrates this point:

```
from {
  route-filter 192.168.0.0/14 upto /24 reject;
  route-filter 192.168.0.0/15 exact;
}
then accept;
```

The longest match for the candidate route 192.168.1.0/24 is the second route-filter, 192.168.0.0/15, which is based on prefix and prefix length only.

2. When an incoming route matches a prefix (longest first), the following actions occur:

1. The route filter stops evaluating other prefixes, even if the match type fails.
2. The software examines the match type and action associated with that prefix.

NOTE: When a route source address is evaluated against a match criteria that uses the **address-mask** match type, both steps of the evaluation include the configured netmask value. For more information, see [“How an Address Mask Match Type Is Evaluated” on page 287](#).

In Step 1, if route 192.168.1.0/24 were evaluated, it would fail to match. It matches the longest prefix of 192.168.0.0/15, but it does not match **exact**. The route filter is finished because it matched a prefix, but the result is a failed match because the match type failed.

If a match occurs, the action specified with the prefix is taken. If an action is not specified with the prefix, the action in the **then** statement is taken. If neither action is specified, the software evaluates the next term or routing policy, if present, or takes the **accept** or **reject** action specified by the default policy. For more information about the default routing policies, see [“Default Routing Policies” on page 37](#).

NOTE: If you specify multiple prefixes in the route filter, only one prefix needs to match for a match to occur. The route filter matching is effectively a logical OR operation.

If a match does not occur, the software evaluates the next term or routing policy, if present, or takes the **accept** or **reject** action specified by the default policy.

For example, compare the prefix 192.168.254.0/24 against the following route filter:

```
route-filter 192.168.0.0/16 orlonger;  
route-filter 192.168.254.0/23 exact;
```

The prefix 192.168.254.0/23 is determined to be the longest prefix. When the software evaluates 192.168.254.0/24 against the longest prefix, a match occurs (192.168.254.0/24 is a subset of 192.168.254.0/23). Because of the match between 192.168.254.0/24 and the longest prefix, the evaluation continues. However, when the software evaluates the match type, a match does not occur between 192.168.254.0/24 and 192.168.254.0/23 exact. The software concludes that the term does not match and goes on to the next term or routing policy, if present, or takes the **accept** or **reject** action specified by the default policy.

NOTE: The walkup feature allows terms with multiple route filters to “walk-up” the evaluation process to include less-specific routes as well as the longest match. In other words, enabling walkup changes the default behavior from “if one fails, then the term fails” to “if one matches, then the term matches.” For more information about the [walkup](#) feature, see “[Walkup for Route Filters Overview](#)” on page 301.

How Prefix Order Affects Route Filter Evaluation

The order in which the prefixes are specified (from top to bottom) typically does not matter, because the policy framework software scans the route filter looking for the longest prefix during evaluation. An exception to this rule is when you use the same destination prefix multiple times in a list. In this case, the order of the prefixes is important, because the list of identical prefixes is scanned from top to bottom, and the first match type that matches the route applies.

NOTE: The walkup feature allows terms with multiple route filters to “walk-up” the evaluation process to include less-specific routes as well as the longest match. In other words, enabling walkup changes the default behavior from “if one fails, then the term fails” to “if one matches, then the term matches.” For more information about the [walkup](#) feature, see “[Walkup for Route Filters Overview](#)” on page 301.

In the following example, different match types are specified for the same prefix. The route 0.0.0.0/0 would be rejected, the route 0.0.0.0/8 would be marked with **next-hop self**, and the route 0.0.0.0/25 would be rejected.

```
route-filter 0.0.0.0/0 upto /7 reject;
route-filter 0.0.0.0/0 upto /24 next-hop self;
route-filter 0.0.0.0/0 orlonger reject;
```

How an Address Mask Match Type Is Evaluated

The **address-mask** routing policy match type enables you to match incoming IPv4 or IPv6 route addresses on a configured netmask value in addition to the length of a configured destination match prefix. During route filter evaluation, an **address-mask** match type is processed differently from other routing policy match types, taking into consideration the configured netmask value:

- When a longest-match lookup evaluates an **address-mask** routing policy match type, the **prefix-length** component of the configured match prefix is not considered. Instead, the lookup considers the number of contiguous high-order bits set in the configured netmask value.

- When an incoming IPv4 or IPv6 route address is evaluated against a route filter match criteria that uses the **address-mask** routing policy match type, the match succeeds if the following values are identical:
 - The bit-wise logical AND of the configured netmask value and the incoming IPv4 or IPv6 route address
 - The bit-wise logical AND of the configured netmask value and the configured destination match prefix

For an example configuration of a route filter that contains two **address-mask** match types, see [“Evaluation of an Address Mask Match Type with Longest-Match Lookup” on page 296](#).

Common Configuration Problem with the Longest-Match Lookup

A common problem when defining a route filter is including a shorter prefix that you want to match with a longer, similar prefix in the same list. For example, imagine that the prefix 192.168.254.0/24 is compared against the following route filter:

```
route-filter 192.168.0.0/16 orlonger;
route-filter 192.168.254.0/23 exact;
```

Because the policy framework software performs longest-match lookup, the prefix 192.168.254.0/23 is determined to be the longest prefix. An exact match does not occur between 192.168.254.0/24 and 192.168.254.0/23 exact. The software determines that the term does not match and goes on to the next term or routing policy, if present, or takes the **accept** or **reject** action specified by the default policy. (For more information about the default routing policies, see [“Default Routing Policies” on page 37](#).) The shorter prefix 192.168.0.0/16 orlonger that you wanted to match is inadvertently ignored.

One solution to this problem is to remove the prefix 192.168.0.0/16 orlonger from the route filter in this term and move it to another term where it is the only prefix or the longest prefix in the list.

Another solution is to enable the **walkup** feature. See [“Walkup for Route Filters Overview” on page 301](#) for details.

- [Accepting Incoming IPv4 Routes with Similar Patterns But Different Prefix Lengths | 295](#)
- [Evaluation of an Address Mask Match Type with Longest-Match Lookup | 296](#)

The examples in this section show only fragments of routing policies. Normally, you would combine these fragments with other terms or routing policies.

In all examples, remember that the following actions apply to nonmatching routes:

- Evaluate next term, if present.
- Evaluate next policy, if present.
- Take the **accept** or **reject** action specified by the default policy. For more information about the default routing policies, see [“Default Routing Policies” on page 37](#).

The following examples show how to configure route filters for various purposes:

Rejecting Routes with Specific Destination Prefixes and Mask Lengths

Reject routes with a destination prefix of 0.0.0.0 and a mask length from 0 through 8, and accept all other routes:

```
[edit]
policy-options {
  policy-statement policy-statement from-hall2 {
    term 1 {
      from {
        route-filter 0.0.0.0/0 upto /8 reject;
      }
    }
    then accept;
  }
}
```

Rejecting Routes with a Mask Length Greater than Eight

Reject routes with a mask of /8 and greater (that is, /8, /9, /10, and so on) that have the first 8 bits set to 0 and accept routes less than 8 bits in length:

```
[edit]
policy-options {
  policy-statement from-hall3 {
    term term1 {
      from {
        route-filter 0/0 upto /7 accept;
        route-filter 0/8 orlonger;
      }
      then reject;
    }
  }
}
```

Rejecting Routes with Mask Length Between 26 and 29

Reject routes with the destination prefix of 192.168.10/24 and a mask between /26 and /29 and accept all other routes:

```
[edit]
policy-options {
  policy-statement from-customer-a {
    term term1 {
      from {
        route-filter 192.168.10/24 prefix-length-range /26-/29 reject;
      }
      then accept;
    }
  }
}
```

Rejecting Routes from Specific Hosts

Reject a range of routes from specific hosts, and accept all other routes:

```
[edit]
policy-options {
  policy-statement hosts-only {
    from {
      route-filter 10.125.0.0/16 upto /31 reject;
      route-filter 0/0;
    }
    then accept;
  }
}
```

You do not use the **through** match type in most routing policy configurations. You should think of **through** as a tool to group a contiguous set of exact matches. For example, instead of specifying four exact matches:

```
from route-filter 0.0.0.0/1 exact
from route-filter 0.0.0.0/2 exact
from route-filter 0.0.0.0/3 exact
from route-filter 0.0.0.0/4 exact
```

You could represent them with the following single match:

```
from route-filter 0.0.0.0/1 through 0.0.0.0/4
```

Accepting Routes with a Defined Set of Prefixes

Explicitly accept a limited set of prefixes (in the first term) and reject all others (in the second term):

```
policy-options {
  policy-statement internet-in {
    term 1 {
      from {
        route-filter 192.168.231.0/24 exact accept;
        route-filter 192.168.244.0/24 exact accept;
        route-filter 192.168.198.0/24 exact accept;
        route-filter 192.168.160.0/24 exact accept;
        route-filter 192.168.59.0/24 exact accept;
      }
    }
    term 2 {
      then {
        reject;
      }
    }
  }
}
```

Rejecting Routes with a Defined Set of Prefixes

Reject a few groups of prefixes, and accept the remaining prefixes:

```
[edit policy-options]
policy-statement drop-routes {
  term 1{
    from { # first, reject a number of prefixes:
      route-filter default exact reject; # reject 0.0.0.0/0 exact
      route-filter 0.0.0.0/8 orlonger reject; # reject prefix 0, mask /8 or longer
```

```

route-filter 10.0.0.0/8 orlonger reject; # reject loopback addresses
}
route-filter 10.105.0.0/16 exact { # accept 10.105.0.0/16
  as-path-prepend "1 2 3";
  accept;
}
route-filter 192.0.2.0/24 orlonger reject; # reject test network packets
route-filter 172.16.233.0/3 orlonger reject; # reject multicast and higher
route-filter 0.0.0.0/0 upto /24 accept; # accept everything up to /24
route-filter 0.0.0.0/0 orlonger accept; # accept everything else
}
}
}
}

```

Rejecting Routes with Prefixes Longer than 24 Bits

Reject all prefixes longer than 24 bits. You would install this routing policy in a sequence of routing policies in an **export** statement. The first term in this filter passes on all routes with a prefix length of up to 24 bits. The second, unnamed term rejects everything else.

```

[edit policy-options]
policy-statement 24bit-filter {
  term acl20 {
    from {
      route-filter 0.0.0.0/0 upto /24;
    }
    then next policy;
  }
  then reject;
}

```

If, in this example, you were to specify **route-filter 0.0.0.0/0 upto /24 accept**, matching prefixes would be accepted immediately and the next routing policy in the **export** statement would never get evaluated.

If you were to include the **then reject** statement in the term **acl20**, prefixes greater than 24 bits would never get rejected because the policy framework software, when evaluating the term, would move on to evaluating the next statement before reaching the **then reject** statement.

Rejecting PIM Multicast Traffic Joins

Configure a routing policy for rejecting Protocol Independent Multicast (PIM) multicast traffic joins for a source destination prefix from a neighbor:

```

[edit]

```

```

policy-options {
  policy-statement join-filter {
    from {
      neighbor 10.14.12.20;
      source-address-filter 10.83.0.0/16 orlonger;
    }
    then reject;
  }
}

```

Rejecting PIM Traffic

Configure a routing policy for rejecting PIM traffic for a source destination prefix from an interface:

```

[edit]
policy-options {
  policy-statement join-filter {
    from {
      interface so-1/0/0.0;
      source-address-filter 10.83.0.0/16 orlonger;
    }
    then reject;
  }
}

```

The following routing policy qualifiers apply to PIM:

- **interface**—Interface over which a join is received
- **neighbor**—Source from which a join originates
- **route-filter**—Group address
- **source-address-filter**—Source address for which to reject a join

For more information about importing a PIM join filter in a PIM protocol definition, see the *Multicast Protocols User Guide*.

Accepting Incoming IPv4 Routes by Applying an Address Mask to the Route Address and the Destination Match Prefix

Accept incoming IPv4 routes with a destination prefix of 10.1.0/24 and the third byte an even number from 0 to 14, inclusive:

```

[edit]
policy-options {
  policy-statement from_customer_a {

```

```

term term_1 {
  from {
    route-filter 10.1.0.0/24 address-mask 255.255.241.0;
  }
  then {
    ...
    reject;
  }
}
}

```

The route filter in routing policy term **term_1** matches the following incoming IPv4 route addresses:

- 10.1.0.0/24
- 10.1.2.0/24
- 10.1.4.0/24
- 10.1.6.0/24
- 10.1.8.0/24
- 10.1.10.0/24
- 10.1.12.0/24
- 10.1.14.0/24

The bit-wise logical AND of the netmask value and the candidate route address must match the bit-wise logical AND of the netmask value and the match prefix address. That is, where the netmask bit pattern 255.255.241.0 contains a set bit, the incoming IPv4 route address being evaluated must match the value of the corresponding bit in the destination prefix address 10.1.0.0/24.

- The first two bytes of the netmask value are binary 1111 1111 1111 1111, which means that a candidate route address will fail the match if the first two bytes are not 10.1.
- The third byte of the netmask value is binary 1111 0001, which means that a candidate route address will fail the match if the third byte is greater than 15 (decimal), an odd number, or both.
- The prefix length of the match prefix address is 24 (decimal), which means that a candidate route address will fail the match if its prefix length is not exactly 24.

As an example, suppose that the candidate route address being tested in the policy is 10.1.8.0/24 (binary 0000 1010 0000 0001 0000 1000).

- When the netmask value is applied to this candidate route address, the result is binary 0000 1010 0000 0001 0000 0000.
- When the netmask value is applied to the configured destination prefix address, the result is also binary 0000 1010 0000 0001 0000 0000.
- Because the results of both AND operations are the same, the match continues to the second match criteria.
- Because the prefix lengths of the candidate address and the configured destination prefix address are the same (24 bits), the match succeeds.

As another example, suppose that the candidate route address being tested in the policy is 10.1.3.0/24 (binary 0000 1010 0000 0001 0000 0011).

- When the netmask value is applied to this candidate route address, the result is binary 0000 1010 0000 0001 0000 0001.
- However, when the netmask value is applied to the configured destination prefix address, the result is binary 0000 1010 0000 0001 0000 0000.
- Because the results of the two AND operations are different (in the third byte), the match fails.

Accepting Incoming IPv4 Routes with Similar Patterns But Different Prefix Lengths

Accept incoming IPv4 route addresses of the form 10.*.1/24 or 10.*.1.* /32:

```
[edit]
policy-options {
  policy-statement from_customer_b {
    term term_2 {
      from {
        route-filter 10.0.1.0/24 address-mask 255.0.255.0;
        route-filter 10.0.1.0/32 address-mask 255.0.255.0;
      }
      then {
        ...
        reject;
      }
    }
  }
}
```

The route filter match criteria **10.0.1.0/24 address-mask 255.0.255.0** matches an incoming IPv4 route address of the form 10.*.1/24. The route's prefix length must be exactly 24 bits long, and any value is acceptable in the second byte.

The route filter match criteria **10.0.1.0/32 address-mask 255.0.255.0** matches an incoming IPv4 route address of the form 10.*.1.* /32. The route's prefix length must be exactly 32 bits long, and any value is acceptable in the second byte and the fourth byte.

Evaluation of an Address Mask Match Type with Longest-Match Lookup

This example illustrates how a longest-match lookup evaluates a route filter that contains two **address-mask** match types. Consider the route filter configured in the routing policy term **term_3** below:

```
[edit]
policy-options {
  policy-statement from_customer_c {
    term term_3 {
      from {
        route-filter 10.0.1.0/24 address-mask 255.0.255.0;
        route-filter 10.0.2.0/24 address-mask 255.240.255.0;
      }
      then {
        ...
      }
    }
  }
}
```

Suppose that the incoming IPv4 route source address 10.1.1.0/24 is tested against the route filter configured in the policy term **term_3**:

1. The longest-match lookup tree for routing policy term **term_3** contains two match prefixes: one prefix for **10.0.1.0/24 address-mask 255.0.255.0** and one prefix for **10.0.2.0/24 address-mask 255.240.255.0**. When searching the tree for the longest-prefix match for a candidate, the longest-match lookup considers the number of contiguous high-order bits in the configured **netmask-value** instead of the length of the configured **destination-prefix**:

- For the first route filter match criteria, the longest-match lookup entry is 10.0.0.0/8 because the netmask value contains 8 contiguous high-order bits.
- For second route filter match criteria, the longest-match lookup entry is 10.0.0.0/12 because the netmask value contains 12 contiguous high-order bits.

For the candidate route address 10.1.1.0/24, the longest-match lookup returns the tree entry 10.0.0.0/12, which corresponds to the route filter match criteria **10.0.2.0/24 address-mask 255.240.255.0**.

2. Now that the longest-match prefix in **term_3** has been identified for the candidate route address, the candidate route address is evaluated against the route filter match criteria **10.0.2.0/24 address-mask 255.240.255.0**:
 - a. To test the incoming IPv4 route address 10.1.1.0/24, the netmask value 255.240.255.0 is applied to 10.1.1.0/24. The result is 10.0.1.0.
 - b. To test the configured destination prefix address 10.0.2.0/24, the netmask value 255.240.255.0 is applied to 10.0.2.0/24. The result is 10.0.2.0.
 - c. Because the results are different, the route filter match fails. No actions, whether specified with the match criteria or with the **then** statement, are taken. The incoming IPv4 route address is not evaluated against any other match criteria.

Understanding Route Filter and Source Address Filter Lists for Use in Routing Policy Match Conditions

Existing route filters and source address filters are configured and processed inline within the term of the policy statement. When route policies are changed, the entire policy is purged and rebuilt during the configuration parsing operation. When this happens on routing policies that include hundreds or even thousands of route filters and source address filters, a significant amount of time is added to the rebuild of the policy.

In order to speed the parsing operation, the **route-filter-list** and **source-address-filter-list** statements are available as another means of configuring route filters and source address filters. These statements maintain all the capabilities of the **route-filter** and **source-address-filter** statements, including consideration of the prefix length and match type of the individual prefixes in the list.

Route filters and route filter lists are typically used to match an incoming route address to destination match prefixes of any type except for unicast source addresses.

Source address filters and source address filter lists are typically used to match an incoming route address to unicast source addresses in Multiprotocol BGP (MBGP) and Multicast Source Discovery Protocol (MSDP) environments.

Multiple route filter lists and source address filter lists can be used within the same policy statements. Route filter lists and source address filter lists can also be used in conjunction with route filters and source address filters.

Understanding Load Balancing Using Source or Destination IP Only

In deep packet inspection (DPI) networks with per-subscriber awareness or transparent caches, all of the PE routers in the service provider network should route all traffic to and from a particular subscriber through the specific content server that maintains subscriber state for that subscriber. To reach the same server consistently, the traffic must be hashed onto the same link towards that specific server for traffic in both directions.

In order to accomplish this consistency, certain MX Series routers can be configured to make load-balancing decisions based solely on the source IP address or the destination IP address of the traffic. From a service provider perspective, using only the source IP for inbound traffic, and the destination IP for outbound traffic limits the criteria used in hashing, making it more likely that a particular link will be chosen to forward the traffic.

NOTE: This feature will only work on IP-based traffic. In the case of L3VPN traffic, only MPLS lookup will be performed on the PE routers when the default label assignment scheme is used. In order to use source-or-destination only load-balancing with L3VPN, you can either configure **vrf-table-label** or add a vt- interface in the routing instance.

[Configuring Load Balancing Using Source or Destination IP Only](#) | 299

vrf-table-label

interface

Configuring Load Balancing Using Source or Destination IP Only

In equal-cost multipath, (ECMP) per-subscriber aware environments such as content service providers who service residential customers, traffic in both directions within the service provider network should always pass through the content servers that maintain the subscriber state information for a given subscriber. This is accomplished by calculating the load balancing hash based solely on source address for traffic coming into the service provider network and calculating the load balancing hash based solely on the destination address for traffic leaving the service provider network.

Source and destination only load balancing is generally configured in an ECMP or aggregated ethernet (AE) environment on a service provider network. It is usually applied to all of the PE routers. It is only supported for IPv4 (**inet**) and IPv6 (**inet6**) traffic.

You do not need any special configuration in place before starting this configuration.

NOTE: This feature will only work on IP-based traffic. In the case of L3VPN traffic, only MPLS lookup will be performed on the PE routers when the default label assignment scheme is used. In order to use source-or-destination only load-balancing with L3VPN, you can either configure **vrf-table-label** or add a vt- interface in the routing instance.

To configure load balancing using source or destination IP only, you first configure system-wide forwarding options with a prefix-length to use when calculating the hash-key. Then, you configure a policy action of either **load-balance source-ip-only** or **load-balance destination-ip-only** within a policy statement.

1. To configure system-wide prefix length for use with source and destination IP only load balancing, insert the **source-destination-only-load-balancing** configuration statement at the [edit forwarding-options enhanced-hash-key] hierarchy level and add a prefix length:

```
[edit forwarding-options enhanced-hash-key]
source-destination-only-load-balancing {
  family inet {
    prefix-length prefix-length;
  }
  family inet6 {
    prefix-length prefix-length;
  }
}
```

2. To configure routing policy to use load balancing based on source or destination IP only, insert either the **source-ip-only** or **destination-ip-only** as an action statement within a policy statement at the [edit policy-options policy-statement *policy-name*] hierarchy level:

```
[edit policy-options policy-statement policy-name]  
term term-name {  
  from {  
    route-filter filter-spec  
  }  
  then {  
    load-balance (source-ip-only | destination-ip-only);  
  }  
}
```

NOTE: The **source-ip-only** and **destination-ip-only** configuration elements cannot be used together in the same term. This is because of the directional nature of the traffic that we are load balancing. To use the two elements in the same policy statement, you create two separate terms, each using a route filter specification that addresses the same traffic. Then use **source-ip-only** for the inbound traffic and **destination-ip-only** for the outbound traffic.

Walkup for Route Filters Overview

Use the walkup feature if you have concerns about policy performance because of split route filters across multiple policy terms. The walkup feature enables the consolidation of route filters under one policy term.

By default, Junos evaluates multiple route filters in a policy statement term by first finding the longest match prefix and then evaluating the conditions attached to the route filter, such as prefix range. If the route filter condition is false (for example, the prefix is not in the specified range), then the whole term is false, even if there are potentially true shorter route filter prefixes. Due to this behavior, there can be performance issues if route filters are split into individual policy statement terms. The walkup feature changes the default route filter behavior.

Some automated policy tools — for example, those used for autonomous system border routers in the Border Gateway Protocol (BGP) — break up route filters into multiple terms because of the default route filter behavior. Route filters are also used in routing protocols other than BGP; the walkup feature is not limited to BGP route filters.

NOTE: Technically, BGP does not deal with routes in the same way as OSPF or IS-IS. BGP “routes” are more properly called network layer reachability information (NLRI) updates. However, the term “route” is used in most documentation and is used here.

Route filters consist of three major parts:

1. A prefix and prefix length (for example, **10.0.0.0/8**)
2. A match condition (for example, **exact**)
3. An action that is carried out if both previous parts — the prefix and match condition — both evaluate to true (for example, **accept**)

So the **10.0.0.0/8 exact accept** route filter succeeds if and only if the prefix considered is **10.0.0.0/8** exactly. This route filter rejects routes with all other longer prefixes, such as **10.0.0.0/10**, although there might be other route filter terms in the policy chain that accept the **10.0.0.0/10** route.

NOTE: Although the **10.0.0.0/8** route and variations are not specifically reserved for documentation, the private RFC 1918 **10.0.0.0/8** address space is used in this topic because of the flexibility and realistic scenarios that this address spaces provides.

Route filters can be combined in a single policy statement term. In that case, evaluation becomes more complex. Consider the following routing policy:

```
[edit policy-options]
policy-statement RouteFilter-A {
  term RouteFilter-1 {
    from {
      route-filter 10.0.0.0/16 prefix-length-range /22-/24;
      route-filter 10.0.0.0/8 orlonger;
    }
    then accept;
  }
  term default {
    then reject;
  }
}
```

Note that the **10.0.0.0/8 orlonger** filter includes the **10.0.0.0/16 prefix-length-range /22-/24** filter in its scope. That is, any **10.0.0.0** route with a prefix of 8 bits or longer could also be a route with a prefix in the range between 22 and 24 bits.

By default, evaluation of a policy statement term with multiple route filters is a two-step process:

1. The policy framework software performs a longest-match lookup on the list based on prefix and prefix-length values.
2. The software considers the route filter condition (**orlonger**, **exact**, and so on). The route either fulfills the route filter condition (success) or does not match the route filter condition (failure).

Based on the results of these two steps, the action determined by the match or failure is applied to the route. In **Route-Filter-A**, this means that any route that is “true” is accepted and any route that is “false” in the **RouteFilter-1** term is rejected. This route becomes a hidden (filtered) route.

For example, consider what happens when the route **10.0.0.0/18** is evaluated by the policy statement **RouteFilter-A**:

First, the **10.0.0.0/18** route is evaluated by the **RouteFilter-1** term. Because **10.0.0.0/16** is longer than **10.0.0.0/8**, the **10.0.0.0/18** route matches the longer and more specific route prefix. Next, the match fails because the **10.0.0.0/18** route does not match the **prefix-length-range /22-/24** condition. So the route match fails in the **RouteFilter-1** term, and the policy examines the next term, the default term. The **10.0.0.0/18** route is rejected by the default term.

As a result, the **10.0.0.0/18** route is hidden (filtered). (The **10.0.0.0/18** route can still be found with the **show route hidden** command.)

The issue is that the user might actually want the **10.0.0.0/18** route to be accepted, not rejected. Naturally, a route filter with a **10.0.0.0/18 exact** configuration could be added. But in a backbone routing table with 100,000 or more entries, it is not possible to configure a route filter tuned to every possible route or every possible new route added to the network.

The default workaround to achieve the proper behavior from the example routing policy is to configure a separate term for each route filter. This is frequently done, as follows:

```
[edit policy-options]
policy-statement RouteFilter-A {
  term RouteFilter-1 {
    from {
      route-filter 10.0.0.0/16 prefix-length-range /22-/24;
    }
    then accept;
  }
  term RouteFilter-2 {
    from {
      route-filter 10.0.0.0/8 orlonger;
    }
    then accept;
  }
  term default {
    then reject;
  }
}
```

Now the **10.0.0.0/18** route is accepted because, although it still fails the **RouteFilter-1** match condition, it matches the new **RouteFilter-2** term (**10.0.0.0/8** is the longest match, and the **orlonger** condition is true). The problem with this approach is that the complete routing policy now takes more time to evaluate than when multiple route filters are grouped. This method also makes maintenance more complex.

The issues with the one-term-per-route-filters approach are solved with the walkup statement and feature. Walkup alters the default behavior of route filter evaluation globally or on a per-policy basis.

The walkup feature allows terms with multiple route filters to “walk-up” the evaluation process to include less-specific routes as well as the longest match. In other words, the walkup knob changes the default behavior from “if one fails, then the term fails” to if “one matches, then the term matches.”

Consider the application of the walkup feature to the example policy statement (you can also apply walk-up globally to all policies configured):

```
[edit policy-options]
policy-statement RouteFilter-A {
  defaults {
    route-filter walkup;
  }
  term RouteFilter-1 {
    from {
```

```

    route-filter 10.0.0.0/16 prefix-length-range /22-/24;
    route-filter 10.0.0.0/8 orlonger;
  }
  then accept;
}
term default {
  then reject;
}
}

```

This is what happens when the route prefix **10.0.0.0/18** is evaluated by the policy statement **RouteFilter-A**:

The default behavior is altered by the walkup knob. As before, the **10.0.0.0/18** route matches the longer and more specific route prefix because **10.0.0.0/16** is longer than **10.0.0.0/8**. As before, this match fails because the **10.0.0.0/18** route does not match the **prefix-length-range /22-/24** condition. However, this time the process continues by a “walk up” and examines the less specific **10.0.0.0/8** route filter. The route condition of **orlonger** matches this filter and therefore the route is accepted by the **RouteFilter-1** term.

This can be verified (for a BGP route) by the **show route protocol bgp 10.0.0.0/18** command. This time, the route is not hidden.

If you enable the walkup feature globally, you can override it locally on a per-policy basis with the **[edit policy-options policy-statements policy-statement-name defaults route-filter no-walkup]** statement.

Configuring Walkup for Route Filters to Improve Operational Efficiency

Use the walkup feature if you have concerns about policy performance because of split route filters across multiple policy terms. The walkup feature enables the consolidation of route filters under one policy term.

If policy statements have been split into multiple terms because of the default route filter behavior, the route filter walkup feature allows you to consolidate multiple route filters into one policy statement term. By default, Junos OS evaluates multiple route filters in a policy statement term by first finding the longest match prefix and then evaluating the conditions attached to the route filter, such as the prefix range. If the route filter condition is false (for example, the prefix is not in the specified range), then the whole term is false, even if there are potentially true shorter route filter prefixes. The walkup feature alters this default behavior, locally or globally.

The route filter walkup feature is used anywhere multiple route filters are used in a policy statement. The walkup option is supported in the main routing instance at the **[edit policy-options]** hierarchy level and in logical systems at the **[edit logical-systems policy-options]** hierarchy level.

Before you begin configuring route filter walkup, be sure you have:

- A properly configured routing policy or set of routing policies
- A need to consolidate multiple route filter terms into fewer routing policy terms

Route filter walkup can be configured in two different ways. You can configure the **walkup** option globally at the **[edit policy-options default route-filter]** hierarchy level or in logical systems at the **[edit logical-systems policy-options default route-filter]** hierarchy level. When you configure the **walkup** option globally, you alter the policy route filter behavior in every policy statement. Instead of the default policy statement behavior (if the longest match route filter is false, then the term is false), the **walkup** option changes this behavior globally (to “walk up” from the longest match route filter to less specific, and if any is true, then the term is true).

If you configure the **walkup** option globally, you can still override it locally on a per-routing-policy basis. So if you have enabled **walkup** globally, you can override it in a routing policy by configuring the **no-walkup** option statement at the **[edit policy-options policy-statement default route-filter]** hierarchy level. The **no-walkup** option restores the default route filter behavior locally for this policy statement.

NOTE: At the **[edit policy-options default route-filter]** global level, the only option is the **walkup** statement because the default behavior globally is “no walkup.” However, for an individual policy statement at the **[edit policy-options policy-statement default route-filter]** hierarchy level, you can configure either the **walkup** or **no-walkup** option statement. In this way, at the local level, you can control whether the policy statement performs a walkup (with the **walkup** statement configured) or no walkup (with the **no-walkup** statement configured). This gives the user maximum control over the **walkup** option

You configure the walkup feature globally with:

```
user@host> set policy-options defaults route-filter walkup
```

Alternatively, configure the walkup feature globally in a logical system with:

```
user@host> set logical-systems logical-system-name policy-options defaults route-filter walkup
```

You configure the walkup or no-walkup feature locally in a policy statement with:

```
user@host> set policy-options policy-statement policy-statement-name defaults route-filter [ no-walkup  
| walkup ]
```

Alternatively, configure the walkup feature locally in a logical system with:

```
user@host> set logical-systems logical-system-name policy-options policy-statement policy-statement-name  
defaults route-filter [ no-walkup | walkup ]
```

Route filter walkup behavior can be complex when the statements are configured at the global and local level at the same time. [Table 18 on page 306](#) shows the behavior of a policy statement with all six possible combinations of the walkup option when you configure the feature both globally and locally.

Table 18: Route Filter Walkup and Policy Statements

Case:	Global Configuration	Local Configuration	Result
1	(none)	(none)	The device does not perform a walkup for any policy (default operation).
2	(none)	walkup	The device performs a walkup for this policy.
3	(none)	no-walkup	The device does not perform a walkup for any policy (default operation).
4	walkup	(none)	The device performs a walkup for all policies.
5	walkup	walkup	The device performs a walkup for all policies.
6	walkup	no-walkup	The device does not perform a walkup for this policy only.

Each row forms a possible use case numbered 1 through 6. Each walkup case is configured as follows:

- Case #1: This is a trivial configuration for backward compatibility. No route filter walkup is enabled either globally or locally. The device behaves exactly as it did before the feature was introduced. No route filter walkup occurs in any policy.
- Case #2: Route filter walkup is not enabled globally, but is enabled locally for a specific policy named **RouteFilter-Case2**. Route filter walkup occurs in this policy.

To configure the route filter walkup locally for a specific policy:

1. Enable the walkup feature locally for this policy statement.

```
[edit policy-options]
user@host# set policy-statement RouteFilter-Case2 defaults route-filter walkup
```

2. Configure policy terms locally (walkup applies to all terms in this policy).

```
[edit policy-options]
user@host# set policy-statement RouteFilter-Case2 term ...
```

3. Apply the policy statement to a routing protocol.

- Case #3: Route filter **walkup** is not enabled globally, but **no-walkup** is enabled locally for a specific policy named **RouteFilter-Case3**. (This case is not particularly helpful, because no walkup takes place in all policies by default, but does make local behavior explicit, even if walkup is enabled globally in the future.)

To configure the route filter no-walkup locally for a specific policy:

1. Enable the **no-walkup** feature locally for this policy statement.

```
[edit policy-options]
user@host# set policy-statement RouteFilter-Case3 defaults route-filter no-walkup
```

2. Configure policy terms locally (**no-walkup** applies to this policy).

```
[edit policy-options]
user@host# set policy-statement RouteFilter-Case3 term ...
```

3. Apply the policy statement to a routing protocol.

- Case #4: Route filter **walkup** is enabled globally, but not enabled locally for a specific policy named **RouteFilter-Case4**. Because of the global configuration, route filter **walkup** occurs in this policy.

To configure the route filter walkup globally for a device:

1. Enable the walkup feature globally for this device.

```
[edit policy-options]
user@host# set defaults route-filter walkup
```

NOTE: Global **walkup**, in contrast to the **walkup** or **no-walkup** statements configured locally in a policy statement, is configured at the **[edit policy-options defaults]** or **[edit logical-systems logical-system-name policy-options defaults]** hierarchy level and applies to all policies.

2. Configure policy statement **RouteFilter-Case4** and terms locally (walkup applies to this policy).

```
[edit policy-options]
user@host# set policy-statement RouteFilter-Case4 term ...
```

3. Apply the policy statement to a routing protocol.

- Case #5: Route filter **walkup** is enabled globally, and enabled locally for a specific policy named **RouteFilter-Case5**. Although this configuration might appear redundant (walkup enabled globally as well as locally), this ensures that route filter walkup occurs in this policy even if route filter walkup is deleted at the global level.

To configure the route filter walkup globally for a device and locally for a specific policy:

1. Enable the **walkup** feature globally for this device.

```
[edit policy-options]
user@host# set defaults route-filter walkup
```

NOTE: Global walkup is configured at the **[edit policy-options defaults]** or **[edit logical-systems logical-system-name policy-options defaults]** hierarchy level and applies to all policies.

2. Configure policy statement **RouteFilter-Case5** and enable **walkup** locally (**walkup** applies to this policy).

```
[edit policy-options]
user@host# set policy-statement Route-Filter-Case5 defaults route-filter walkup
```

3. Configure policy statement **RouteFilter-Case5** and terms locally (walkup applies to this policy).

```
[edit policy-options]
user@host# set policy-statement RouteFilter-Case5 term ...
```

4. Apply the policy statement to a routing protocol.

- Case #6: Route filter **walkup** is enabled globally, but overridden locally with **no-walkup** for a specific policy named **RouteFilter-Case6**. Because of the local configuration, no route filter walkup occurs in this policy. This case is useful to make sure that a local policy still functions exactly as before global walkup was enabled.

To configure the route filter walkup globally for a device and the no-walkup feature locally for a specific policy:

1. Enable the walkup feature globally for this device.

```
[edit policy-options]
user@host# set defaults route-filter walkup
```

NOTE: Global walkup is configured at the **[edit policy-options defaults]** or **[edit logical-systems logical-system-name policy-options defaults]** hierarchy level and applies to all policies.

2. Configure policy statement **RouteFilter-Case6** and disable walkup locally with the **no-walkup** statement (no walkup is performed in this policy).

```
[edit policy-options]
user@host# set policy-statement Route-Filter-Case6 defaults route-filter walkup
```

3. Configure policy statement **RouteFilter-Case6** and terms locally.

```
[edit policy-options]
```

```
user@host# set policy-statement RouteFilter-Case6 term ...
```

4. Apply the policy statement to a routing protocol.

NOTE: Keep in mind that a policy statement does nothing until it is applied as an import or export policy for the routing protocol itself. For BGP, this can be done at the global, group or neighbor level.

- [Verification | 313](#)

Junos OS has long supported route filters for use in policy statements. Whenever policies are changed, the route filters have to be processed inline with the policy. Policies that contain large numbers of route filters take time to load.

This example shows how to create a route filter list and use that list in a policy statement. Route filter lists reduce the amount of time needed to reload a given policy.

NOTE: There is no speed benefit to using route filter lists in place of individual route filter entries when there are only a few route filters to process. The speed benefit is seen mainly in environments where there are hundreds or thousands of route filters listed within the policies.

Requirements

- A router configured with a routing protocol such as BGP or OSPF that is actively exchanging route information with its peers.
- The router that is configured with route filter lists must be running Junos OS Release 15.2 or later.

Overview

The **route-filter-list** statement allows for the creation of a pre-defined list of route filters for use in routing policies. You configure the list at the **[edit policy-options]** hierarchy level. The configured route filter list is then referenced as a match condition in the **from** section of a policy statement at the **[edit policy-options policy-statement *policy-statement-name* term *term-name* from]** hierarchy level.

In this example, the router that you are configuring is receiving some routes from its BGP neighbor 192.0.2.1. This is shown in the output of the **show route receive-protocol bgp 192.0.2.1** operational command.

user@router> show route receive-protocol bgp 192.0.2.1

```
inet.0: 17 destinations, 18 routes (16 active, 0 holddown, 1 hidden)
  Prefix                Nexthop          MED      Lclpref    AS path
* 198.151.100.0/29      192.0.2.1              103 I
* 198.151.100.8/29      192.0.2.1              103 I
* 203.0.113.0/29        192.0.2.1              103 I
* 203.0.113.8/29        192.0.2.1              103 I
* 203.0.113.16/29       192.0.2.1              103 I
```

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
set policy-options route-filter-list rf-list-1 203.0.113.0/29 exact
set policy-options route-filter-list rf-list-1 203.0.113.8/29 exact
set policy-options route-filter-list rf-list-1 203.0.113.16/29 orlonger accept
set policy-options policy-statement rf-test-policy term term2 from route-filter 198.51.100.0/29 upto
  198.51.100.0/30
set policy-options policy-statement rf-test-policy term term2 from route-filter 198.51.100.8/29 upto
  198.51.100.8/30 accept
set policy-options policy-statement rf-test-policy term term2 from route-filter-list rf-list-1
set policy-options policy-statement rf-test-policy then reject
set protocols bgp group test-group import rf-test-policy
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

The following step-by-step procedure will lead you through the steps needed to:

- Configure a route filter list named **rf-list-1** and populate the list for later use in a route policy.
- Configure a routing policy statement named **rf-test-policy** that uses route filters and the configured route filter list.
- Configure BGP to use **rf-test-policy** as an import filter.

1. Configure a route filter list named **rf-list-1** for later use in a route policy.

```
[edit policy-options]
user@router# set route-filter-list rf-list-1
```

2. Populate the list **rf-list-1**.

Note that one of the statements in the list has an action configured. This action will be carried out immediately upon a match with a received destination prefix.

```
[edit policy-options]
user@router# set route-filter-list rf-list-1 203.0.113.0/29 exact
user@router# set route-filter-list rf-list-1 203.0.113.8/29 exact
user@router# set route-filter-list rf-list-1 203.0.113.16/29 orlonger accept
```

3. Configure a routing policy statement named **rf-test-policy** that uses route filters and the configured route filter list.

The overall action for this policy is **reject**. There are individual route filters and elements of the route filter list that have a configured action of **accept**. The actions configured in the individual route filter statements and elements of the route filter list are carried out immediately upon matching a received destination prefix.

```
[edit policy-options]
user@router# set policy-statement rf-test-policy term term2 from route-filter 198.51.100.0/29 upto
198.51.100.0/30
user@router# set policy-statement rf-test-policy term term2 from route-filter 198.51.100.8/29 upto
198.51.100.8/30 accept
user@router# set policy-statement rf-test-policy term term2 from route-filter-list rf-list-1
user@router# set policy-statement rf-test-policy then reject
```

4. Configure BGP to use the configured policy as an import filter to selectively allow some routes and reject other routes from being added to the routing table.

```
[edit protocols bgp group test-group]
user@router# set import rf-test-policy
```

Verification

IN THIS SECTION

- [Verifying the Configured Route Filter List | 313](#)
- [Verifying the Configured Policy Statement | 314](#)
- [Verifying That the Policy Statement Is Applied as an Import Policy in the BGP Protocol | 314](#)
- [Verifying That the Route Filter List Is Operating as Expected | 315](#)

Verifying the Configured Route Filter List

Purpose

To confirm that the route filter list is properly configured, issue the **show policy-options route-filter-list route-filter-list-name** command at the [edit] hierarchy level.

Action

```
[edit]
user@router# show policy-options route-filter-list rf-list-1
203.0.113.0/29 exact;
203.0.113.8/29 exact;
203.0.113.16/29 orlonger accept;
```

Meaning

The output shows that the stored configuration is correct.

Verifying the Configured Policy Statement

Purpose

To confirm that the policy statement is properly configured, issue the **show policy-options policy-statement *policy-statement-name*** command at the **[edit]** hierarchy level.

Action

```
[edit]
user@router# show policy-options policy-statement rf-test-policy
from {
  route-filter 198.51.100.0/29 upto 198.51.100.0/30;
  route-filter 198.51.100.8/29 upto 198.51.100.8/30 accept;
  route-filter-list rf-list-1;
}
then reject;
```

Meaning

The output confirms that the stored configuration is correct.

Verifying That the Policy Statement Is Applied as an Import Policy in the BGP Protocol

Purpose

To confirm that the configured policy statement is applied as an import policy in the BGP Protocol, issue the **show protocols bgp import** command at the **[edit]** hierarchy level.

Action

```
[edit]
user@router# show protocols bgp import
import rf-test-policy;
```

Meaning

The output confirms that the stored configuration is correct.

If you have not already done so, you can issue the **commit** command at the **[edit]** hierarchy level so that the configuration is made active.

Verifying That the Route Filter List Is Operating as Expected

Purpose

Now that the configuration has been verified and committed, confirm the operation of the route filter list by issuing the **show route receive-protocol bgp 192.0.2.1** operational command.

Action

If you compare this output with the output of the same command issued prior to configuring the route filter list and policy statement, you see that some routes are no longer installed in the routing table.

user@router> show route receive-protocol bgp 192.0.2.1

```
inet.0: 14 destinations, 15 routes (13 active, 0 holddown, 1 hidden)
  Prefix                Nexthop          MED      Lclpref    AS path
* 198.151.100.8/29      192.0.2.1              103 I
* 203.0.113.16/29      192.0.2.1              103 I
```

Meaning

The output shows that three of the five previously installed BGP routes have been rejected by the policy statement **rf-test-policy**. The only routes that remain from the previous list are the two that had **accept** actions listed as part of the filter definition. The other routes were rejected by the action of the **policy-statement**.

Example: Configuring Walkup for Route Filters Globally to Improve Operational Efficiency

IN THIS SECTION

- [Requirements | 316](#)
- [Overview | 316](#)
- [Configuring Route Filter Walkup Globally | 317](#)
- [Verification | 320](#)
- [Troubleshooting | 321](#)

Use the walkup feature if you have concerns about policy performance because of split route filters across multiple policy terms. The walkup feature enables the consolidation of route filters under one policy term.

This example shows how to configure the route filter walkup feature globally for policy statements with route filters. When configured at the global level, the route filter walkup option applies to all policy statements. This example changes the default behavior of policy terms with multiple route filters globally, so that any reversion to the default “no walkup” behavior must be established locally.

Requirements

This example uses the following hardware and software components:

- A Juniper Networks router
- A Junos operating system from 13.3 or above

Before you configure route filter walkup locally, be sure you have:

- A properly configured routing policy or set of routing policies
- A need to consolidate multiple route filter terms into fewer routing policy terms

Overview

Routing protocols exchange information with other routers running the same routing protocols. In many cases, route filters are used in routing policy statements to filter prefixes for import or export. In some cases, when route filters are split into many separate terms, performance is impacted. The route filter walkup feature allows consolidation of policy statement terms for operational efficiency.

This example uses BGP, but the same walkup feature applies to any routing protocol that supports route filtering of input or output.

You can configure a Juniper Networks router to change the default operation of a term in a policy statement with route filters. By default, only a single longest match attempt is made for all route filters in a term. The walkup feature allows the router to “walk up” the route filters in a term from longest match to less specific in search of a true condition. This allows consolidation of multiple terms in a policy statement and corresponding operational efficiency.

This example changes the default behavior globally, for all policy statements. You can still configure **no-walkup** for an individual policy.

Topology

In the sample network in [Figure 25 on page 317](#), the router CE1 is a router from another vendor. The rest are Juniper Networks routers. The walkup feature can be configured on any router in the figure, except for router CE1. The vendor of router CE1 might or not might support a similar feature.

Figure 25: Topology for the Global Walkup Example

In the example, the following addresses are used:

- 10.0.0.0/16
- 10.0.0.0/8

NOTE: Although the **10.0.0.0/8** address space is not specifically reserved for documentation, the private RFC 1918 **10.0.0.0/8** address space is used in this topic because of the flexibility and realistic scenarios that this address spaces provides.

Configuring Route Filter Walkup Globally

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details such as addresses and interfaces to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

Device PE1

```
set policy-options defaults route-filter walkup
set policy-options policy-statement routeset1-import term prefixes1 from route-filter 10.0.0.0/16
  prefix-length-range /22-/24
set policy-options policy-statement routeset1-import term prefixes1 from route-filter 10.0.0.0/8
  orlonger
set policy-options policy-statement routeset1-import term prefixes1 then accept
set policy-options policy-statement routeset1-import term reject-the-rest then reject
set policy-options policy-statement import-route-filter-a term import-routes from protocol bgp
set policy-options policy-statement import-route-filter-a term import-routes from policy
  routeset1-import
set policy-options policy-statement import-route-filter-a term import-routes then next policy
set policy-options policy-statement import-route-filter-a term all-others then reject
set policy-options policy-statement route-filter-a-export term all then reject
set protocols bgp group routeset1 type external
set protocols bgp group routeset1 neighbor 10.0.10.13 import import-route-filter-a
set protocols bgp group routeset1 neighbor 10.0.10.13 family inet unicast
set protocols bgp group routeset1 neighbor 10.0.10.13 export route-filter-a-export
set protocols bgp group routeset1 neighbor 10.0.10.13 peer-as 64506
```

Step-by-Step Procedure

The following example requires that you navigate to various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure router PE1 to perform walkup globally and combine multiple route filters in one term:

1. Configure the walkup feature globally.

```
[edit policy-options defaults]
user@PE1# set route-filter walkup
```

2. Configure the policy statements for an import policy named **routeset1-import**.

```
[edit policy-options]
```

```

user@PE1# set policy-statement routeset1-import term prefixes1 from route-filter 10.0.0.0/16
        prefix-length-range /22-/24
user@PE1# set policy-statement routeset1-import term prefixes1 from route-filter 10.0.0.0/8 orlonger
user@PE1# set policy-statement routeset1-import term prefixes1 then accept
user@PE1# set policy-statement routeset1-import term reject-the-rest then reject

```

3. Configure the policy options for the import and export policy statements.

```

[edit policy-options]
user@PE1# set policy-statement import-route-filter-a term import-routes from protocol bgp
user@PE1# set policy-statement import-route-filter-a term import-routes from policy routeset1-import
user@PE1# set policy-statement import-route-filter-a term import-routes then next policy
user@PE1# set policy-statement route-filter-a-export term all-others then reject

```

4. Apply the import and export policies to a BGP neighbor.

```

[edit protocols bgp]
user@PE1# set group routeset1 type external
user@PE1# set group routeset1 neighbor 10.0.10.13 import import-route-filter-a
user@PE1# set group routeset1 neighbor 10.0.10.13 family inet unicast
user@PE1# set group routeset1 neighbor 10.0.10.13 export route-filter-a-export
user@PE1# set group routeset1 neighbor 10.0.10.13 peer-as 64506

```

Results

From configuration mode, confirm your configuration by entering the **show protocols** and **show policy-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

user@PE1# show policy-options
defaults {
    route-filter walkup;
}
policy-statement routeset1-import {
term prefixes1 {
    from {
        route-filter 10.0.0.0/16 prefix-length-range /22-/24;
        route-filter 10.0.0.0/8 orlonger;
    }
    then accept;
}

```

```

    }
    term reject-the-rest {
        then reject;
    }
}

policy-statement import-route-filter-a {
    term import-routes {
        from {
            protocol bgp;
            policy routeset1-import;
        }
        then next policy;
    }
    term all-others {
        then reject;
    }
}
policy-statement route-filter-a-export {
    term all {
        then reject;
    }
}

```

```

user@PE!# show protocols bgp
group routeset1 {
    type external;
    neighbor 10.0.10.13 {
        import import-route-filter-a;
        family inet {
            unicast;
        }
        export router-filter-a-export;
        peer-as 64506;
    }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Verifying Route Filter Operation

Purpose

Display expected information about the routes to confirm the route filters are working as expected.

Notice that the **10.0.0.0/8 orlonger** filter includes the **10.0.0.0/16 prefix-length-range /22-/24** filter in its scope. That is, any **10.0.0.0** route with a prefix of 8 bits or longer could also be a route with a prefix in the range between 22 and 24 bits. Without the walkup feature enabled, a route such as **10.0.0.0/16** would be rejected and become a hidden route. If the walkup feature is working as expected, then a route such as **10.0.0.0/16** would be accepted by the policy.

Action

From operational mode, enter the **show route protocol bgp 10.0.0.0/16** command. Make sure that **10.0.0.0/16** is not a hidden route.

user@PE1>**show route protocol bgp 10.0.0.0/16**

```
inet.0: 520762 destinations, 520764 routes (520760 active, 0 holddown, 2 hidden)
+ = Active Route, - = Last Active, * = Both

10.0.0.0/16      *[BGP/170] 01:07:37, localpref 100
                  AS path: 64506, I, validation-state:  unverified
                  > to 10.0.100.13 via xe-0/2/0.0
```

As a further check, make sure that no routes that should be accepted are hidden routes. From operational mode, enter the **show route protocol bgp ip-address-prefix hidden** command to verify this.

Meaning

The presence of routes that are not the longest match in the configured policy route filter term shows that the walkup feature is functioning globally.

Troubleshooting

IN THIS SECTION

- [Troubleshooting BGP | 322](#)
- [Troubleshooting Policy Statements | 322](#)

Example: Configuring Walkup for Route Filters Locally to Improve Operational Efficiency

IN THIS SECTION

- [Requirements | 323](#)
- [Overview | 323](#)
- [Configuring Route Filter Walkup Locally | 324](#)
- [Verification | 327](#)
- [Troubleshooting | 328](#)

Use the walkup feature if you have concerns about policy performance because of split route filters across multiple policy terms. The walkup feature enables the consolidation of route filters under one policy term.

This example shows how to configure the route filter walkup feature locally for policy statements with route filters. When configured at the local level, the route filter walkup option applies only to the policy statement in which it is configured. This example does *not* change the default behavior of policy terms with route filters globally. This example establishes route filter walkup locally.

Requirements

This example uses the following hardware and software components:

- A Juniper Networks router
- A Junos operating system from 13.3 or above

Before you configure route filter walkup globally, be sure you have:

- A properly configured routing policy or set of routing policies
- A need to consolidate multiple route filter terms into fewer routing policy terms

Overview

Routing protocols exchange information with other routers running the same routing protocols. In many cases, route filters are used in routing policy statements to filter prefixes for import or export. In some cases, when route filters are split into many separate terms, performance is impacted. The route filter walkup feature allows consolidation of policy statement terms for operational efficiency.

This example uses BGP, but the same walkup feature applies to any routing protocol that supports route filtering of input or output.

You can configure a Juniper Networks router to change the default operation of a term in a policy statement with route filters. By default, only a single longest match attempt is made for all route filters in a term. The walkup feature allows the router to “walk up” the route filters in a term from longest match to less specific in search of a true condition. This allows consolidation of multiple terms in a policy statement and corresponding operational efficiency.

This example changes the default behavior locally in a single policy statement. It does not affect the behavior of other policy statements.

Topology

In the sample network in [Figure 25 on page 317](#), the router CE1 is a router from another vendor. The rest are Juniper Networks routers. The walkup feature can be configured on any router in the figure, except for router CE1. The vendor of router CE1 might or not might support a similar feature.

Figure 26: Topology for the Local Walkup Example

In the example, the following addresses are used:

- 10.0.0.0/16
- 10.0.0.0/8

NOTE: Although the **10.0.0.0/8** address space is not specifically reserved for documentation, the private RFC 1918 **10.0.0.0/8** address space is used in this topic because of the flexibility and realistic scenarios that this address spaces provides.

Configuring Route Filter Walkup Locally

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details such as addresses and interfaces to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

Device PE1

```
set policy-options policy-statement routeset1-import defaults route-filter walkup
set policy-options policy-statement routeset1-import term prefixes1 from route-filter 10.0.0.0/16
  prefix-length-range /22-/24
set policy-options policy-statement routeset1-import term prefixes1 from route-filter 10.0.0.0/8
  orlonger
set policy-options policy-statement routeset1-import term prefixes1 then accept
set policy-options policy-statement routeset1-import term reject-the-rest then reject
set policy-options policy-statement import-route-filter-a term import-routes from protocol bgp
set policy-options policy-statement import-route-filter-a term import-routes from policy
  routeset1-import
set policy-options policy-statement import-route-filter-a term import-routes then next policy
set policy-options policy-statement import-route-filter-a term all-others then reject
set policy-options policy-statement route-filter-a-export term all then reject
set protocols bgp group routeset1 type external
set protocols bgp group routeset1 neighbor 10.0.10.13 import import-route-filter-a
set protocols bgp group routeset1 neighbor 10.0.10.13 family inet unicast
set protocols bgp group routeset1 neighbor 10.0.10.13 export route-filter-a-export
set protocols bgp group routeset1 neighbor 10.0.10.13 peer-as 64506
```

Step-by-Step Procedure

The following example requires that you navigate to various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure router PE1 to perform walkup locally for multiple route filters in one term:

1. Configure the walkup feature locally in a policy named **routeset1-import**.

```
[edit policy-options policy-statement routeset1-import defaults]
user@PE1# set route-filter walkup
```

2. Configure the policy statements for an import policy named **routeset1-import**.

```
[edit policy-options ]
```

```

user@PE1# set policy-statement routeset1-import term prefixes1 from route-filter 10.0.0.0/16
      prefix-length-range /22-/24
user@PE1# set policy-statement routeset1-import term prefixes1 from route-filter 10.0.0.0/8 orlonger
user@PE1# set policy-statement routeset1-import term prefixes1 then accept
user@PE1# set policy-statement routeset1-import term reject-the-rest then reject

```

3. Configure the policy options for the import and export policy statements.

```

[edit policy-options]
user@PE1# set policy-statement import-route-filter-a term import-routes from protocol bgp
user@PE1# set policy-statement import-route-filter-a term import-routes from policy routeset1-import
user@PE1# set policy-statement import-route-filter-a term import-routes then next policy
user@PE1# set policy-statement route-filter-a-export term all-others then reject

```

4. Apply the import and export policies to a BGP neighbor.

```

[edit protocols bgp]
user@PE1# set group routeset1 type external
user@PE1# set group routeset1 neighbor 10.0.10.13 import import-route-filter-a
user@PE1# set group routeset1 neighbor 10.0.10.13 family inet unicast
user@PE1# set group routeset1 neighbor 10.0.10.13 export route-filter-a-export
user@PE1# set group routeset1 neighbor 10.0.10.13 peer-as 64506

```

Results

From configuration mode, confirm your configuration by entering the **show protocols** and **show policy-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

user@PE1# show policy-options
policy-statement routeset1-import {
  defaults {
    route-filter walkup;
  }
  term prefixes1 {
    from {
      route-filter 10.0.0.0/16 prefix-length-range /22-/24;
      route-filter 10.0.0.0/8 orlonger;
    }
    then accept;
  }
}

```

```

    }
    term reject-the-rest {
        then reject;
    }
}

policy-statement import-route-filter-a {
    term import-routes {
        from {
            protocol bgp;
            policy routeset1-import;
        }
        then next policy;
    }
    term all-others {
        then reject;
    }
}
policy-statement route-filter-a-export {
    term all {
        then reject;
    }
}

```

```

user@PE!# show protocols bgp
group routeset1 {
    type external;
    neighbor 10.0.10.13 {
        import import-route-filter-a;
        family inet {
            unicast;
        }
        export router-filter-a-export;
        peer-as 64506;
    }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Verifying Route Filter Operation

Purpose

Display expected information about the routes to confirm the route filters are working as expected.

Notice that the **10.0.0.0/8 orlonger** filter includes the **10.0.0.0/16 prefix-length-range /22-/24** filter in its scope. That is, any **10.0.0.0** route with a prefix of 8 bits or longer could also be a route with a prefix in the range between 22 and 24 bits. Without the walkup feature enabled in the policy example given, a route such as **10.0.0.0/16** would be rejected and become a hidden route. If the walkup feature is working as expected, then a route such as **10.0.0.0/16** would be accepted by the policy.

Action

From operational mode, enter the **show route protocol bgp 10.0.0.0/16** command. Make sure that **10.0.0.0/16** is not a hidden route.

user@PE1>**show route protocol bgp 10.0.0.0/16**

```
inet.0: 520762 destinations, 520764 routes (520760 active, 0 holddown, 2 hidden)
+ = Active Route, - = Last Active, * = Both

10.0.0.0/16      *[BGP/170] 01:07:37, localpref 100
                  AS path: 64506, I, validation-state:  unverified
                  > to 10.0.100.13 via xe-0/2/0.0
```

As a further check, make sure that no routes that should be accepted are hidden routes. From operational mode, enter the **show route protocol bgp ip-address-prefix hidden** command to verify this.

Meaning

The presence of routes that are not the longest match in the configured policy route filter term shows that the walkup feature is functioning locally.

Troubleshooting

IN THIS SECTION

- [Troubleshooting BGP | 329](#)
- [Troubleshooting Policy Statements | 329](#)
- [Troubleshooting Route Filters | 329](#)

To troubleshoot route filter walkup locally:

Troubleshooting BGP

Problem

BGP is not functioning as expected.

Solution

See the *BGP Configuration Overview* topic, examples, and troubleshooting.

Troubleshooting Policy Statements

Problem

The policy statements are not functioning as expected.

Solution

See the *Verify That a Particular BGP Route Is Received on Your Router* and *Example: Configuring BGP Route Advertisement* topics, related examples, and troubleshooting.

Troubleshooting Route Filters

Problem

The route filters are not functioning as expected.

Solution

See the [“Route Filter Match Conditions” on page 65](#) topic, examples, and troubleshooting.

Example: Configuring a Route Filter Policy to Specify Priority for Prefixes Learned Through OSPF

IN THIS SECTION

- [Requirements | 330](#)
- [Overview | 330](#)
- [Configuration | 331](#)
- [Verification | 335](#)

This example shows how to create an OSPF import policy that prioritizes specific prefixes learned through OSPF.

Requirements

Before you begin:

- Configure the device interfaces. See the *Interfaces User Guide for Security Devices*.
- Configure the router identifiers for the devices in your OSPF network. See *Example: Configuring an OSPF Router Identifier*.
- Control OSPF designated router election See *Example: Controlling OSPF Designated Router Election*
- Configure a single-area OSPF network. See *Example: Configuring a Single-Area OSPF Network* .
- Configure a multiarea OSPF network. See *Example: Configuring a Multiarea OSPF Network*.

Overview

In a network with a large number of OSPF routes, it can be useful to control the order in which routes are updated in response to a network topology change. In Junos OS Release 9.3 and later, you can specify a priority of high, medium, or low for prefixes included in an OSPF import policy. In the event of an OSPF topology change, high priority prefixes are updated in the routing table first, followed by medium and then low priority prefixes.

OSPF import policy can only be used to set priority or to filter OSPF external routes. If an OSPF import policy is applied that results in a **reject** terminating action for a nonexternal route, then the **reject** action is ignored and the route is accepted anyway. By default, such a route is now installed in the routing table

with a priority of low. This behavior prevents traffic black holes, that is, silently discarded traffic, by ensuring consistent routing within the OSPF domain.

In general, OSPF routes that are not explicitly assigned a priority are treated as priority medium, except for the following:

- Summary discard routes have a default priority of low.
- Local routes that are not added to the routing table are assigned a priority of low.
- External routes that are rejected by import policy and thus not added to the routing table are assigned a priority of low.

Any available match criteria applicable to OSPF routes can be used to determine the priority. Two of the most commonly used match criteria for OSPF are the **route-filter** and **tag** statements.

In this example, the routing device is in area 0.0.0.0, with interfaces **fe-0/1/0** and **fe-1/1/0** connecting to neighboring devices. You configure an import routing policy named **ospf-import** to specify a priority for prefixes learned through OSPF. Routes associated with these prefixes are installed in the routing table in the order of the prefixes' specified priority. Routes matching **192.0.2.0/24 orlonger** are installed first because they have a priority of **high**. Routes matching **198.51.100.0/24 orlonger** are installed next because they have a priority of **medium**. Routes matching **203.0.113.0/24 orlonger** are installed last because they have a priority of **low**. You then apply the import policy to OSPF.

NOTE: The priority value takes effect when a new route is installed, or when there is a change to an existing route.

Configuration

CLI Quick Configuration

To quickly configure an OSPF import policy that prioritizes specific prefixes learned through OSPF, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the [edit] hierarchy level, and then enter **commit** from configuration mode.

```
[edit]
set interfaces fe-0/1/0 unit 0 family inet address 192.168.8.4/30
set interfaces fe-0/1/0 unit 0 family inet address 192.168.8.5/30
set policy-options policy-statement ospf-import term t1 from route-filter 203.0.113.0/24 orlonger
set policy-options policy-statement ospf-import term t1 then priority low
set policy-options policy-statement ospf-import term t1 then accept
set policy-options policy-statement ospf-import term t2 from route-filter 198.51.100.0/24 orlonger
set policy-options policy-statement ospf-import term t2 then priority medium
```

```

set policy-options policy-statement ospf-import term t2 then accept
set policy-options policy-statement ospf-import term t3 from route-filter 192.0.2.0/24 orlonger
set policy-options policy-statement ospf-import term t3 then priority high
set policy-options policy-statement ospf-import term t3 then accept
set protocols ospf import ospf-import
set protocols ospf area 0.0.0.0 interface fe-0/1/0
set protocols ospf area 0.0.0.0 interface fe-1/1/0

```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Modifying the Junos OS Configuration* in the *CLI User Guide*.

To configure an OSPF import policy that prioritizes specific prefixes:

1. Configure the interfaces.

```

[edit]
user@host# set interfaces fe-0/1/0 unit 0 family inet address 192.168.8.4/30
user@host# set interfaces fe-0/2/0 unit 0 family inet address 192.168.8.5/30

```

2. Enable OSPF on the interfaces.

NOTE: For OSPFv3, include the **ospf3** statement at the **[edit protocols]** hierarchy level.

```

[edit]
user@host# set protocols ospf area 0.0.0.0 interface fe-0/1/0
user@host# set protocols ospf area 0.0.0.0 interface fe-0/2/0

```

3. Configure the policy to specify the priority for prefixes learned through OSPF.

```

[edit ]
user@host# set policy-options policy-statement ospf-import term t1 from route-filter 203.0.113.0/24
orlonger
user@host# set policy-options policy-statement ospf-import term t1 then priority low
user@host# set policy-options policy-statement ospf-import term t1 then accept
user@host# set policy-options policy-statement ospf-import term t2 from route-filter 198.51.100.0/24
orlonger
user@host# set policy-options policy-statement ospf-import term t2 then priority medium
user@host# set policy-options policy-statement ospf-import term t2 then accept

```

```

user@host# set policy-options policy-statement ospf-import term t3 from route-filter 192.0.2.0/24 orlonger
user@host# set policy-options policy-statement ospf-import term t3 then priority high
user@host# set policy-options policy-statement ospf-import term t3 then accept

```

4. Apply the policy to OSPF.

```

[edit]
user@host# set protocols ospf import ospf-import

```

5. If you are done configuring the device, commit the configuration.

```

[edit]
user@host# commit

```

Results

Confirm your configuration by entering the **show interfaces**, **show policy-options**, and the **show protocols ospf** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

user@host# show interfaces
fe-0/1/0 {
  unit 0 {
    family inet {
      address 192.168.8.4/30;
    }
  }
}
fe-0/2/0 {
  unit 0 {
    family inet {
      address 192.168.8.5/30;
    }
  }
}

```

```

user@host# show protocols ospf
import ospf-import;
area 0.0.0.0 {
  interface fe-0/1/0.0;
  interface fe-0/2/0.0;
}

```

```
}
```

```
user@host# show policy-options
policy-statement ospf-import {
  term t1 {
    from {
      route-filter 203.0.113.0/24 orlonger;
    }
    then {
      priority low;
      accept;
    }
  }
  term t2 {
    from {
      route-filter 198.51.100.0/24 orlonger;
    }
    then {
      priority medium;
      accept;
    }
  }
  term t3 {
    from {
      route-filter 192.0.2.0/24 orlonger;
    }
    then {
      priority high;
      accept;
    }
  }
}
```

```
user@host# show protocols ospf
import ospf-import;
area 0.0.0.0 {
  interface fe-0/1/0.0;
  interface fe-0/2/0.0;
}
```

To confirm your OSPFv3 configuration, enter the **show interfaces**, **show policy-options**, and **show protocols ospf3** commands.

Verification

Confirm that the configuration is working properly.

Verifying the Prefix Priority in the OSPF Routing Table

Purpose

Verify the priority assigned to the prefix in the OSPF routing table.

Action

From operational mode, enter the **show ospf route detail** for OSPFv2, and enter the **show ospf3 route detail** command for OSPFv3.

Example: Configuring the MED Using Route Filters

IN THIS SECTION

- [Requirements | 335](#)
- [Overview | 335](#)
- [Configuration | 336](#)
- [Verification | 350](#)

This example shows how to configure a policy that uses route filters to modify the multiple exit discriminator (MED) metric to advertise in BGP update messages.

Requirements

No special configuration beyond device initialization is required before you configure this example.

Overview

To configure a route-filter policy that modifies the advertised MED metric in BGP update messages, include the **metric** statement in the policy action.

Figure 27 on page 336 shows a typical network with internal peer sessions and multiple exit points to a neighboring autonomous system (AS).

Figure 27: Typical Network with IBGP Sessions and Multiple Exit Points

Device R4 has multiple loopback interfaces configured to simulate advertised prefixes. The extra loopback interface addresses are 172.16.44.0/32 and 172.16.144.0/32. This example shows how to configure Device R4 to advertise a MED value of 30 to Device R3 for all routes except 172.16.144.0. For 172.16.144.0, a MED value of 10 is advertised to Device 3. A MED value of 20 is advertised to Device R2, regardless of the route prefix.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

Device R1

```
set interfaces fe-1/2/0 unit 1 family inet address 172.16.12.1/24
set interfaces fe-1/2/1 unit 2 family inet address 172.16.13.1/24
set interfaces lo0 unit 1 family inet address 192.168.1.1/32
set protocols bgp group internal type internal
```

```

set protocols bgp group internal local-address 192.168.1.1
set protocols bgp group internal export send-direct
set protocols bgp group internal neighbor 192.168.2.1
set protocols bgp group internal neighbor 192.168.3.1
set protocols ospf area 0.0.0.0 interface lo0.1 passive
set protocols ospf area 0.0.0.0 interface fe-1/2/0.1
set protocols ospf area 0.0.0.0 interface fe-1/2/1.2
set policy-options policy-statement send-direct term 1 from protocol direct
set policy-options policy-statement send-direct term 1 then accept
set routing-options autonomous-system 123
set routing-options router-id 192.168.1.1

```

Device R2

```

set interfaces fe-1/2/0 unit 3 family inet address 172.16.12.2/24
set interfaces fe-1/2/1 unit 4 family inet address 172.16.24.2/24
set interfaces lo0 unit 2 family inet address 192.168.2.1/32
set protocols bgp group internal type internal
set protocols bgp group internal local-address 192.168.2.1
set protocols bgp group internal export send-direct
set protocols bgp group internal neighbor 192.168.1.1
set protocols bgp group internal neighbor 192.168.3.1
set protocols bgp group external type external
set protocols bgp group external export send-direct
set protocols bgp group external peer-as 4
set protocols bgp group external neighbor 172.16.24.4
set protocols ospf area 0.0.0.0 interface lo0.2 passive
set protocols ospf area 0.0.0.0 interface fe-1/2/0.3
set protocols ospf area 0.0.0.0 interface fe-1/2/1.4
set policy-options policy-statement send-direct term 1 from protocol direct
set policy-options policy-statement send-direct term 1 then accept
set routing-options autonomous-system 123
set routing-options router-id 192.168.2.1

```

Device R3

```

set interfaces fe-1/2/0 unit 5 family inet address 172.16.13.3/24

```

```

set interfaces fe-1/2/1 unit 6 family inet address 172.16.34.3/24
set interfaces lo0 unit 3 family inet address 192.168.3.1/32
set protocols bgp group internal type internal
set protocols bgp group internal local-address 192.168.3.1
set protocols bgp group internal export send-direct
set protocols bgp group internal neighbor 192.168.1.1
set protocols bgp group internal neighbor 192.168.2.1
set protocols bgp group external type external
set protocols bgp group external export send-direct
set protocols bgp group external peer-as 4
set protocols bgp group external neighbor 172.16.34.4
set protocols ospf area 0.0.0.0 interface lo0.3 passive
set protocols ospf area 0.0.0.0 interface fe-1/2/0.5
set protocols ospf area 0.0.0.0 interface fe-1/2/1.6
set policy-options policy-statement send-direct term 1 from protocol direct
set policy-options policy-statement send-direct term 1 then accept
set routing-options autonomous-system 123
set routing-options router-id 192.168.3.1

```

Device R4

```

set interfaces fe-1/2/0 unit 7 family inet address 172.16.24.4/24
set interfaces fe-1/2/1 unit 8 family inet address 172.16.34.4/24
set interfaces lo0 unit 4 family inet address 192.168.4.1/32
set interfaces lo0 unit 4 family inet address 172.16.44.0/32
set interfaces lo0 unit 4 family inet address 172.16.144.0/32
set protocols bgp group external type external
set protocols bgp group external export send-direct
set protocols bgp group external peer-as 123
set protocols bgp group external neighbor 172.16.34.3 export med-10
set protocols bgp group external neighbor 172.16.34.3 export med-30
set protocols bgp group external neighbor 172.16.24.2 metric-out 20
set policy-options policy-statement med-10 from route-filter 172.16.144.0/32 exact
set policy-options policy-statement med-10 then metric 10
set policy-options policy-statement med-10 then accept
set policy-options policy-statement med-30 from route-filter 0.0.0.0/0 longer
set policy-options policy-statement med-30 then metric 30
set policy-options policy-statement med-30 then accept
set policy-options policy-statement send-direct term 1 from protocol direct
set policy-options policy-statement send-direct term 1 then accept

```

```
set routing-options autonomous-system 4
set routing-options router-id 192.168.4.1
```

Configuring Device R1

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure Device R1:

1. Configure the device interfaces.

```
[edit interfaces fe-1/2/0 unit 1]
user@R1# set family inet address 172.16.12.1/24
[edit interfaces fe-1/2/1 unit 2]
user@R1# set family inet address 172.16.13.1/24
[edit interfaces lo0 unit 1]
user@R1# set family inet address 192.168.1.1/32
```

2. Configure BGP.

```
[edit protocols bgp group internal]
user@R1# set type internal
user@R1# set local-address 192.168.1.1
user@R1# set export send-direct
user@R1# set neighbor 192.168.2.1
user@R1# set neighbor 192.168.3.1
```

3. Configure OSPF.

```
[edit protocols ospf area 0.0.0.0]
user@R1# set interface lo0.1 passive
user@R1# set interface fe-1/2/0.1
user@R1# set interface fe-1/2/1.2
```

4. Configure a policy that accepts direct routes.

Other useful options for this scenario might be to accept routes learned through OSPF or local routes.

```
[edit policy-options policy-statement send-direct term 1]
user@R1# set from protocol direct
user@R1# set then accept
```

5. Configure the router ID and autonomous system (AS) number.

```
[edit routing-options]
user@R1# set autonomous-system 123
user@R1# set router-id 192.168.1.1
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R1# show interfaces
fe-1/2/0 {
  unit 1 {
    family inet {
      address 172.16.12.1/24;
    }
  }
}
fe-1/2/1 {
  unit 2 {
    family inet {
      address 172.16.13.1/24;
    }
  }
}
lo0 {
  unit 1 {
    family inet {
      address 192.168.1.1/32;
    }
  }
}
```

```
user@R1# show protocols
bgp {
  group internal {
```

```

    type internal;
    local-address 192.168.1.1;
    export send-direct;
    neighbor 192.168.2.1;
    neighbor 192.168.3.1;
  }
}
ospf {
  area 0.0.0.0 {
    interface lo0.1 {
      passive;
    }
    interface fe-1/2/0.1;
    interface fe-1/2/1.2;
  }
}

```

```

user@R1# show policy-options
policy-statement send-direct {
  term 1 {
    from protocol direct;
    then accept;
  }
}

```

```

user@R1# show routing-options
autonomous-system 123;
router-id 192.168.1.1;

```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring Device R2

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure Device R2:

1. Configure the device interfaces.

```
[edit interfaces fe-1/2/0 unit 3]
```

```

user@R2# set family inet address 172.16.12.21/24
[edit interfaces fe-1/2/1 unit 4]
user@R2# set family inet address 172.16.24.2/24
[edit interfaces lo0 unit 2]
user@R2# set family inet address 192.168.2.1/32

```

2. Configure BGP.

```

[edit protocols bgp group internal]
user@R2# set type internal
user@R2# set local-address 192.168.2.1
user@R2# set export send-direct
user@R2# set neighbor 192.168.1.1
user@R2# set neighbor 192.168.3.1
[edit protocols bgp group external]
user@R2# set type external
user@R2# set export send-direct
user@R2# set peer-as 4
user@R2# set neighbor 172.16.24.4

```

3. Configure OSPF.

```

[edit protocols ospf area 0.0.0.0]
user@R2# set interface lo0.2 passive
user@R2# set interface fe-1/2/0.3
user@R2# set interface fe-1/2/1.4

```

4. Configure a policy that accepts direct routes.

Other useful options for this scenario might be to accept routes learned through OSPF or local routes.

```

[edit policy-options policy-statement send-direct term 1]
user@R2# set from protocol direct
user@R2# set then accept

```

5. Configure the router ID and autonomous system (AS) number.

```

[edit routing-options]
user@R2# set autonomous-system 123
user@R2# set router-id 192.168.2.1

```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R2# show interfaces
fe-1/2/0 {
  unit 3 {
    family inet {
      address 172.16.12.2/24;
    }
  }
}
fe-1/2/1 {
  unit 4 {
    family inet {
      address 172.16.24.2/24;
    }
  }
}
lo0 {
  unit 2 {
    family inet {
      address 192.168.2.1/32;
    }
  }
}
```

```
user@R2# show protocols
bgp {
  group internal {
    type internal;
    local-address 192.168.2.1;
    export send-direct;
    neighbor 192.168.1.1;
    neighbor 192.168.3.1;
  }
  group external {
    type external;
    export send-direct;
    peer-as 4;
    neighbor 172.16.24.4;
  }
}
```

```

}
ospf {
  area 0.0.0.0 {
    interface lo0.2 {
      passive;
    }
    interface fe-1/2/0.3;
    interface fe-1/2/1.4;
  }
}

```

```

user@R2# show policy-options
policy-statement send-direct {
  term 1 {
    from protocol direct;
    then accept;
  }
}

```

```

user@R2# show routing-options
autonomous-system 123;
router-id 192.168.2.1;

```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring Device R3

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure Device R3:

1. Configure the device interfaces.

```

[edit interfaces fe-1/2/0 unit 5]
user@R3# set family inet address 172.16.13.3/24
[edit interfaces fe-1/2/1 unit 6]
user@R3# set family inet address 172.16.34.3/24
[edit interfaces lo0 unit 3]
user@R3# set family inet address 192.168.3.1/32

```

2. Configure BGP.

```
[edit protocols bgp group internal]
user@R3# set type internal
user@R3# set local-address 192.168.3.1
user@R3# set export send-direct
user@R3# set neighbor 192.168.1.1
user@R3# set neighbor 192.168.2.1
[edit protocols bgp group external]
user@R3# set type external
user@R3# set export send-direct
user@R3# set peer-as 4
user@R3# set neighbor 172.16.34.4
```

3. Configure OSPF.

```
[edit protocols ospf area 0.0.0.0]
user@R3# set interface lo0.3 passive
user@R3# set interface fe-1/2/0.5
user@R3# set interface fe-1/2/1.6
```

4. Configure a policy that accepts direct routes.

Other useful options for this scenario might be to accept routes learned through OSPF or local routes.

```
[edit policy-options policy-statement send-direct term 1]
user@R3# set from protocol direct
user@R3# set then accept
```

5. Configure the router ID and autonomous system (AS) number.

```
[edit routing-options]
user@R3# set autonomous-system 123
user@R3# set router-id 192.168.3.1
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R3# show interfaces
fe-1/2/0 {
  unit 5 {
    family inet {
      address 172.16.13.3/24;
    }
  }
}
fe-1/2/1 {
  unit 6 {
    family inet {
      address 172.16.34.3/24;
    }
  }
}
lo0 {
  unit 3 {
    family inet {
      address 192.168.3.1/32;
    }
  }
}
```

```
user@R3# show protocols
bgp {
  group internal {
    type internal;
    local-address 192.168.3.1;
    export send-direct;
    neighbor 192.168.1.1;
    neighbor 192.168.2.1;
  }
  group external {
    type external;
    export send-direct;
    peer-as 4;
    neighbor 172.16.34.4;
  }
}
ospf {
  area 0.0.0.0 {
    interface lo0.3 {
      passive;
    }
  }
}
```

```

interface fe-1/2/0.5;
interface fe-1/2/1.6;
}
}

```

```

user@R3# show policy-options
policy-statement send-direct {
  term 1 {
    from protocol direct;
    then accept;
  }
}

```

```

user@R3# show routing-options
autonomous-system 123;
router-id 192.168.3.1;

```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring Device R4

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure Device R4:

1. Configure the device interfaces.

```

[edit interfaces fe-1/2/0 unit 7]
user@R4# set family inet address 172.16.24.4/24
[edit interfaces fe-1/2/1 unit 8]
user@R4# set family inet address 172.16.34.4/24
[edit interfaces lo0 unit 4]
user@R4# set family inet address 192.168.4.1/32
user@R4# set family inet address 172.16.44.0/32
user@R4# set family inet address 172.16.144.0/32

```

Device R4 has multiple loopback interface addresses to simulate advertised prefixes.

2. Configure a policy that accepts direct routes.

Other useful options for this scenario might be to accept routes learned through OSPF or local routes.

```
[edit policy-options policy-statement send-direct term 1]
user@R4# set from protocol direct
user@R4# set then accept
```

3. Configure BGP.

```
[edit protocols bgp group external]
user@R4# set type external
user@R4# set export send-direct
user@R4# set peer-as 123
```

4. Configure the two MED policies.

```
[edit policy-options]
set policy-statement med-10 from route-filter 172.16.144.0/32 exact
set policy-statement med-10 then metric 10
set policy-statement med-10 then accept
set policy-statement med-30 from route-filter 0.0.0.0/0 longer
set policy-statement med-30 then metric 30
set policy-statement med-30 then accept
```

5. Configure the two EBGP neighbors, applying the two MED policies to Device R3, and a MED value of 20 to Device R2.

```
[edit protocols bgp group external]
user@R4# set neighbor 172.16.34.3 export med-10
user@R4# set neighbor 172.16.34.3 export med-30
user@R4# set neighbor 172.16.24.2 metric-out 20
```

6. Configure the router ID and autonomous system (AS) number.

```
[edit routing-options]
user@R4# set autonomous-system 4
user@R4# set router-id 192.168.4.1
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

user@R4# show interfaces
fe-1/2/0 {
  unit 7 {
    family inet {
      address 172.16.24.4/24;
    }
  }
}
fe-1/2/1 {
  unit 8 {
    family inet {
      address 172.16.34.4/24;
    }
  }
}
lo0 {
  unit 4 {
    family inet {
      address 192.168.4.1/32;
      address 172.16.44.0/32;
      address 172.16.144.0/32;
    }
  }
}

```

```

user@R4# show protocols
bgp {
  group external {
    type external;
    export send-direct;
    peer-as 123;
    neighbor 172.16.24.2 {
      metric-out 20;
    }
    neighbor 172.16.34.3 {
      export [ med-10 med-30 ];
    }
  }
}

```

```

user@R4# show policy-options
policy-statement med-10 {
  from {

```

```
    route-filter 172.16.144.0/32 exact;
  }
  then {
    metric 10;
    accept;
  }
}
policy-statement med-30 {
  from {
    route-filter 0.0.0.0/0 longer;
  }
  then {
    metric 30;
    accept;
  }
}
policy-statement send-direct {
  term 1 {
    from protocol direct;
    then accept;
  }
}
```

```
user@R4# show routing-options
autonomous-system 4;
router-id 192.168.4.1;
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

IN THIS SECTION

- [Checking the Active Path from Device R1 to Device R4 | 351](#)
- [Verifying That Device R4 Is Sending Its Routes Correctly | 352](#)

Confirm that the configuration is working properly.

Checking the Active Path from Device R1 to Device R4

Purpose

Verify that the active path goes through Device R2.

Action

From operational mode, enter the **show route protocol bgp** command.

user@R1> **show route protocol bgp**

```
inet.0: 13 destinations, 19 routes (13 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

172.16.12.0/24      [BGP/170] 4d 01:13:32, localpref 100, from 192.168.2.1
                   AS path: I
                   > to 172.16.12.2 via fe-1/2/0.1
172.16.13.0/24      [BGP/170] 3d 05:36:10, localpref 100, from 192.168.3.1
                   AS path: I
                   > to 172.16.13.3 via fe-1/2/1.2
172.16.24.0/24      [BGP/170] 4d 01:13:32, localpref 100, from 192.168.2.1
                   AS path: I
                   > to 172.16.12.2 via fe-1/2/0.1
172.16.34.0/24      [BGP/170] 3d 05:36:10, localpref 100, from 192.168.3.1
                   AS path: I
                   > to 172.16.13.3 via fe-1/2/1.2
172.16.44.0/32      *[BGP/170] 00:06:03, MED 20, localpref 100, from 192.168.2.1
                   AS path: 4 I
                   > to 172.16.12.2 via fe-1/2/0.1
172.16.144.0/32    *[BGP/170] 00:06:03, MED 10, localpref 100, from 192.168.3.1
                   AS path: 4 I
                   > to 172.16.13.3 via fe-1/2/1.2
192.168.2.1/32      [BGP/170] 4d 01:13:32, localpref 100, from 192.168.2.1
                   AS path: I
                   > to 172.16.12.2 via fe-1/2/0.1
192.168.3.1/32      [BGP/170] 3d 05:36:10, localpref 100, from 192.168.3.1
                   AS path: I
                   > to 172.16.13.3 via fe-1/2/1.2
192.168.4.1/32      *[BGP/170] 00:06:03, MED 20, localpref 100, from 192.168.2.1
                   AS path: 4 I
                   > to 172.16.12.2 via fe-1/2/0.1
```

Meaning

The output shows that the preferred path to the routes advertised by Device R4 is through Device R2 for all routes except 172.16.144.0/32. For 172.16.144.0/32, the preferred path is through Device R3.

Verifying That Device R4 Is Sending Its Routes Correctly

Purpose

Make sure that Device R4 is sending update messages with a value of 20 to Device R2 and a value of 30 to Device R3.

Action

From operational mode, enter the **show route advertising-protocol bgp** command.

user@R4> **show route advertising-protocol bgp 172.16.24.2**

```
inet.0: 11 destinations, 13 routes (11 active, 0 holddown, 0 hidden)
  Prefix                Nexthop          MED      Lclpref    AS path
* 172.16.24.0/24        Self              20                I
* 172.16.34.0/24        Self              20                I
* 172.16.44.0/32        Self              20                I
* 172.16.144.0/32       Self              20                I
* 192.168.4.1/32        Self              20                I
```

user@R4> **show route advertising-protocol bgp 172.16.34.3**

```
inet.0: 11 destinations, 13 routes (11 active, 0 holddown, 0 hidden)
  Prefix                Nexthop          MED      Lclpref    AS path
* 172.16.24.0/24        Self              30                I
* 172.16.34.0/24        Self              30                I
* 172.16.44.0/32        Self              30                I
* 172.16.144.0/32       Self              10                I
* 192.168.4.1/32        Self              30                I
```

Meaning

The MED column shows that Device R4 is sending the correct MED values to its two EBGP neighbors.

Example: Configuring Layer 3 VPN Protocol Family Qualifiers for Route Filters

IN THIS SECTION

- [Requirements | 353](#)
- [Overview | 353](#)
- [Configuration | 354](#)
- [Verification | 357](#)

This example shows how to control the scope of BGP import policies by configuring a family qualifier for the BGP import policy. The family qualifier specifies routes of type **inet**, **inet6**, **inet-vpn**, or **inet6-vpn**.

Requirements

This example uses Junos OS Release 10.0 or later.

Before you begin:

- Configure the device interfaces.
- Configure an interior gateway protocol. See the *Junos OS Routing Protocols Library*.
- Configure a BGP session for multiple route types. For example, configure the session for both family **inet** routes and family **inet-vpn** routes. See *Configuring IBGP Sessions Between PE Routers in VPNs* and *Configuring Layer 3 VPNs to Carry IPv6 Traffic*.

Overview

Family qualifiers cause a route filter to match only one specific family. When you configure an IPv4 route filter without a family qualifier, as shown here, the route filter matches **inet** and **inet-vpn** routes.

```
route-filter ipv4-address/mask;
```

Likewise, when you configure an IPv6 route filter without a family qualifier, as shown here, the route filter matches **inet6** and **inet6-vpn** routes.

```
route-filter ipv6-address/mask;
```

Consider the case in which a BGP session has been configured for both family **inet** routes and family **inet-vpn** routes, and an import policy has been configured for this BGP session. This means that both family **inet** and family **inet-vpn** routes, when received, share the same import policy. The policy term might look as follows:

```
from {
    route-filter 0.0.0.0/0 exact;
}
then {
    next-hop self;
    accept;
}
```

This route-filter logic matches an **inet** route of 0.0.0.0 and an **inet-vpn** route whose IPv4 address portion is 0.0.0.0. The 8-byte route distinguisher portion of the **inet-vpn** route is not considered in the route-filter matching. This is a change in Junos OS behavior that was introduced in Junos OS Release 10.0.

If you do not want your policy to match both types of routes, add a family qualifier to your policy. To have the route-filter match only **inet** routes, add the family **inet** policy qualifier. To have the route-filter match only **inet-vpn** routes, add the family **inet-vpn** policy qualifier.

The family qualifier is evaluated before the route-filter is evaluated. Thus, the route-filter is not evaluated if the family match fails. The same logic applies to family **inet6** and family **inet6-vpn**. The route-filter used in the **inet6** example must use an IPv6 address. There is a potential efficiency gain in using a family qualifier because the family qualifier is tested before most other qualifiers, quickly eliminating routes from undesired families.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

inet Example

```
set policy-options policy-statement specific-family from family inet
set policy-options policy-statement specific-family from route-filter 0.0.0.0/0 exact
set policy-options policy-statement specific-family then next-hop self
set policy-options policy-statement specific-family then accept
set protocols bgp import specific-family
```

Inet-vpn Example

```
set policy-options policy-statement specific-family from family inet-vpn
set policy-options policy-statement specific-family from route-filter 0.0.0.0/0 exact
set policy-options policy-statement specific-family then next-hop self
set policy-options policy-statement specific-family then accept
set protocols bgp import specific-family
```

inet6 Example

```
set policy-options policy-statement specific-family from family inet6
set policy-options policy-statement specific-family from route-filter 0::0/0 exact
set policy-options policy-statement specific-family then next-hop self
set policy-options policy-statement specific-family then accept
set protocols bgp import specific-family
```

Inet6-vpn Example

```
set policy-options policy-statement specific-family from family inet6-vpn
set policy-options policy-statement specific-family from route-filter 0::0/0 exact
set policy-options policy-statement specific-family then next-hop self
set policy-options policy-statement specific-family then accept
set protocols bgp import specific-family
```

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure a flow map:

1. Configure the family qualifier.

```
[edit policy-options]
user@host# set policy-statement specific-family from family inet
```

2. Configure the route filter.

```
[edit policy-options]
user@host# set policy-statement specific-family from route-filter 0.0.0.0/0 exact
```

3. Configure the policy actions.

```
[edit policy-options]
user@host# set policy-statement specific-family then next-hop self
user@host# set policy-statement specific-family then accept
```

4. Apply the policy.

```
[edit protocols bgp]
user@host# set import specific-family
```

Results

From configuration mode, confirm your configuration by issuing the **show protocols** and **show policy-options** command. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@host# show protocols
bgp {
  import specific-family;
}
user@host# show policy-options
policy-statement specific-family {
  from {
    family inet;
    route-filter 0.0.0.0/0 exact;
  }
  then {
    next-hop self;
    accept;
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Repeat the procedure for every protocol family for which you need a specific route-filter policy.

Verification

To verify the configuration, run the following commands:

- `show route advertising-protocol bgp neighbor detail`
- `show route instance instance-name detail`

Understanding Prefix Lists for Use in Routing Policy Match Conditions

IN THIS SECTION

- [Configuring Prefix Lists | 358](#)
- [How Prefix Lists Are Evaluated in Routing Policy Match Conditions | 359](#)
- [Configuring Prefix List Filters | 360](#)

A *prefix list* is a named list of IP addresses. You can specify an exact match with incoming routes and apply a common action to all matching prefixes in the list.

Suppose, for example, that you configure the following prefix list:

```
prefix-list bgp179 {
  apply-path "protocols bgp group <*> neighbor <*>";
}
```

This works well when all neighbors on the device are in the same address family.

When the neighbors are in different address families, for example when both IPv4 and IPv6 neighbors are configured, you can use a prefix list as follows:

```
prefix-list IPV4-BGP-NEIGHBORS {
  apply-path "protocols bgp group <*> neighbor <*.*.*.*>";
}
prefix-list IPV6-BGP-NEIGHBORS {
  apply-path "protocols bgp group <*> neighbor <*:.*:>";
}
```

One prefix list matches IPv4 addresses. The other matches IPv6 addresses. You can run the **show configuration policy-options prefix-list prefix-list name | display inheritance** command to verify the configuration.

A prefix list functions like a route list that contains multiple instances of the **exact** match type only. The differences between these two extended match conditions are summarized in [Table 19 on page 358](#).

Table 19: Prefix List and Route List Differences

Feature	Prefix List	Route Lists
Action	Can specify action in a then statement only. These actions are applied to all prefixes that match the term.	Can specify action that is applied to a particular prefix in a route-filter match condition in a from statement, or to all prefixes in the list using a then statement.

For information about configuring route lists, see [“Understanding Route Filters for Use in Routing Policy Match Conditions” on page 276](#).

This section includes the following information:

Configuring Prefix Lists

You can create a named prefix list and include it in a routing policy with the **prefix-list** match condition (described in [“Routing Policy Match Conditions” on page 54](#)).

To define a prefix list, include the **prefix-list** statement:

```
[edit policy-options]
  prefix-list prefix-list-name {
    apply-path path;
    ip-addresses;
  }
```

You can use the **apply-path** statement to include all prefixes (and their associated network mask) pointed to by a defined path, or you can specify one or more addresses, or both.

To include a prefix list in a routing policy, specify the **prefix-list** match condition in the **from** statement at the **[edit policy-options policy-statement policy-name term term-name]** hierarchy level:

```
[edit policy-options policy-statement policy-name term term-name]
  from {
    prefix-list prefix-list-name;
  }
```

then *actions*;

name identifies the prefix list. It can contain letters, numbers, and hyphens (-) and can be up to 255 characters long. To include spaces in the name, enclose the entire name in quotation marks (" ").

ip-addresses are the IPv4 or IP version 6 (IPv6) prefixes specified as **prefix/prefix-length**. If you omit **prefix-length** for an IPv4 prefix, the default is /32**prefix-length**. If you omit **prefix-length** for an IPv6 prefix, the default is /128. Prefixes specified in a **from** statement must be either all IPv4 addresses or all IPv6 addresses.

NOTE: You cannot apply actions to individual prefixes in the list.

You can specify the same prefix list in the **from** statement of multiple routing policies or firewall filters. For information about firewall filters, see [“Guidelines for Configuring Firewall Filters” on page 736](#) and [“Guidelines for Applying Standard Firewall Filters” on page 743](#).

Use the **apply-path** statement to configure a prefix list comprising all IP prefixes pointed to by a defined path. This eliminates most of the effort required to maintain a group prefix list.

The path consists of elements separated by spaces. Each element matches a configuration keyword or an identifier, and you can use wildcards to match more than one identifier. Wildcards must be enclosed in angle brackets, for example, <*>.

NOTE: You cannot add a path element, including wildcards, after a leaf statement in the **apply-path** statement. Path elements, including wildcards, can only be used after a container statement.

NOTE: When you use **apply-path** to define a prefix list, you can also use the same prefix list in a policy statement.

For examples of configuring a prefix list, see [“Example: Configuring Routing Policy Prefix Lists” on page 361](#).

How Prefix Lists Are Evaluated in Routing Policy Match Conditions

During prefix list evaluation, the policy framework software performs a *longest-match lookup*, which means that the software searches for the prefix in the list with the longest length. The order in which you specify the prefixes, from top to bottom, does not matter. The software then compares a route's source address to the longest prefix.

You can use prefix list qualifiers for prefixes contained in a prefix list by configuring a prefix list filter. For more information, see *Configuring Prefix Lists for Use in Routing Policy Match Conditions*.

If a match occurs, the evaluation of the current term continues. If a match does not occur, the evaluation of the current term ends.

NOTE: If you specify multiple prefixes in the prefix list, only one prefix must match for a match to occur. The prefix list matching is effectively a logical OR operation.

Configuring Prefix List Filters

A prefix list filter allows you to apply prefix list qualifiers to a list of prefixes within a prefix list. The prefixes within the list are evaluated using the specified qualifiers. You can configure multiple prefix list filters under the same policy term.

To configure a prefix list filter, include the **prefix-list-filter** statement at the **[edit policy-options policy-statement *policy-name* from]** hierarchy level:

```
[edit policy-options policy-statement policy-name]
from {
  prefix-list-filter prefix-list-name match-type actions;
}
```

The ***prefix-list-name*** option is the name of the prefix list to be used for evaluation. You can specify only one prefix list.

The ***match-type*** option is the type of match to apply to the prefixes in the prefix list. It can be one of the match types listed in [Table 20 on page 360](#).

The ***actions*** option is the action to take if the prefix list matches. It can be one or more of the actions listed in [“Configuring Flow Control Actions” on page 69](#) and [“Configuring Actions That Manipulate Route Characteristics” on page 70](#).

Table 20: Route List Match Types for a Prefix List Filter

Match Type	Match Condition
exact	The route shares the same most-significant bits (described by <i>prefix-length</i>), and <i>prefix-length</i> is equal to the route's prefix length.
longer	The route shares the same most-significant bits (described by <i>prefix-length</i>), and <i>prefix-length</i> is greater than the route's prefix length.

Table 20: Route List Match Types for a Prefix List Filter (*continued*)

Match Type	Match Condition
orlonger	The route shares the same most-significant bits (described by <i>prefix-length</i>), and <i>prefix-length</i> is equal to or greater than the route's prefix length.

Example: Configuring Routing Policy Prefix Lists

IN THIS SECTION

- [Requirements | 361](#)
- [Overview | 361](#)
- [Configuration | 364](#)
- [Verification | 371](#)

In Junos OS, prefix lists provide one method of defining a set of routes. Junos OS provides other methods of accomplishing the same task, such as route filters. A prefix list is a listing of IP prefixes that represent a set of routes that are used as match criteria in an applied policy. Such a list might be useful for representing a list of customer routes in your autonomous system (AS). A prefix list is given a name and is configured within the **[edit policy-options]** configuration hierarchy.

Requirements

No special configuration beyond device initialization is required before configuring this example.

Overview

Prefix lists are similar to a list of route filters. The functional difference between route filters and prefix lists is that you cannot specify a range using a prefix list. You can simulate a range using a prefix list by

including additional prefixes in the list, or by using two prefix lists, one shorter and one longer, setting one to accept and the other to reject. You can also filter a prefix list using the **prefix-list-filter** match condition. Your choices are **exact**, **longer**, and **orlonger**.

The benefit of a prefix list over a list of route filters is seen when the prefixes are referenced in several different locations. For instance, a prefix list can be referenced in a BGP import policy, an export policy, an RPF policy, in firewall filters, in loopback filters, in setting a multicast scope, and so on.

When your list of prefixes changes, rather than trying to remember the many different locations prefixes are configured, you can instead update the prefix list, changing the prefix one time instead of multiple times. This helps to reduce the likelihood of configuration errors, such as mistyping the address in a location or forgetting to update one or more locations.

Prefix lists also help when managing a large number of devices. You can write the various filters and policies as generically as possible, referencing prefix lists instead of specific IP addresses. The more complex logic in the filters and policies has to be written only one time, with minimal per-device and per-site customizations.

As shown in [Figure 28 on page 364](#), each router in AS 64510 has customer routes. Device R1 assigns customer routes within the 172.16.1.0/24 subnet. Device R2 and Device R3 assign customer routes within the 172.16.2.0/24 and 172.16.3.0/24 subnets, respectively. Device R1 has been designated the central point in AS 64510 to maintain a complete list of customer routes. Device R1 has a prefix list called **customers**, as follows:

```
user@R1# show policy-options
prefix-list customers {
  172.16.1.16/28;
  172.16.1.32/28;
  172.16.1.48/28;
  172.16.1.64/28;
  172.16.2.16/28;
  172.16.2.32/28;
  172.16.2.48/28;
  172.16.2.64/28;
  172.16.3.16/28;
  172.16.3.32/28;
  172.16.3.48/28;
  172.16.3.64/28;
}
```

As you can see, the prefix list does not contain a match type for each route (as you would see with a route filter). This is an important point when using a prefix list in a policy. Routes match only if they exactly match one of the prefixes in the list. In other words, each route in the list must appear in the routing table exactly as it is configured in the prefix list.

You reference the prefix list as a match criterion within a policy like this:

```
user@R1# show policy-options
policy-statement customer-routes {
  term get-routes {
    from {
      prefix-list customers;
    }
    then accept;
  }
  term others {
    then reject;
  }
}
```

In this example, all the routes in the **customers** prefix list appear in the routing table on Device R1. Device R2 and Device R3 export to Device R1 static routes to their customers.

As previously mentioned, you can use the **prefix-list-filter** match condition with the **exact**, **longer**, or **orlonger** match type. This provides a way to avoid the prefix list exact-match limitation of prefix lists. For example:

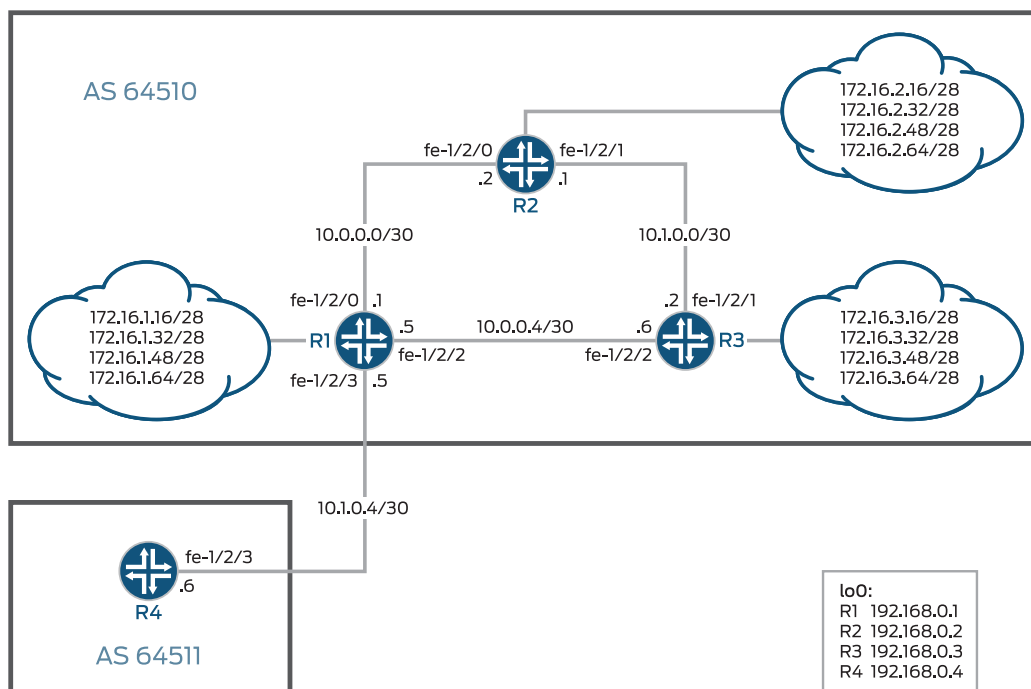

```
user@R1# show policy-options
policy-statement customer-routes {
  term get-routes {
    from {
      prefix-list-filter customers orlonger;
    }
    then accept;
  }
  term others {
    then reject;
  }
}
```

The example demonstrates the effects of both the **prefix-list** match condition and the **prefix-list-filter** match condition.

Topology

[Figure 28 on page 364](#) shows the sample network.

Figure 28: BGP Topology for Policy Prefix Lists

"CLI Quick Configuration" on page 364 shows the configuration for all of the devices in Figure 28 on page 364.

The section "Step-by-Step Procedure" on page 367 describes the steps on Device R1.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level.

Device R1

```
set interfaces fe-1/2/0 unit 0 description to_R2
set interfaces fe-1/2/0 unit 0 family inet address 10.0.0.1/30
set interfaces fe-1/2/2 unit 0 description to_R3
set interfaces fe-1/2/2 unit 0 family inet address 10.0.0.5/30
set interfaces fe-1/2/3 unit 0 description to_R4
set interfaces fe-1/2/3 unit 0 family inet address 10.1.0.5/30
set interfaces lo0 unit 0 family inet address 192.168.0.1/32
set protocols bgp group int type internal
```

```

set protocols bgp group int local-address 192.168.0.1
set protocols bgp group int neighbor 192.168.0.2

```

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure Device R1:

1. Configure the device interfaces.

```

[edit interfaces]
user@R1# set interfaces fe-1/2/0 unit 0 description to_R2
user@R1# set interfaces fe-1/2/0 unit 0 family inet address 10.0.0.1/30
user@R1# set interfaces fe-1/2/2 unit 0 description to_R3
user@R1# set interfaces fe-1/2/2 unit 0 family inet address 10.0.0.5/30
user@R1# set interfaces fe-1/2/3 unit 0 description to_R4
user@R1# set interfaces fe-1/2/3 unit 0 family inet address 10.1.0.5/30
user@R1# set interfaces lo0 unit 0 family inet address 192.168.0.1/32

```

2. Configure the internal BGP (IBGP) connections to Device R2 and Device R3.

```

[edit protocols bgp group int]
user@R1# set type internal
user@R1# set local-address 192.168.0.1
user@R1# set neighbor 192.168.0.2
user@R1# set neighbor 192.168.0.3

```

3. Configure the EBGP connection to Device R4.

```

[edit protocols bgp group to_64511]
user@R1# set type external
user@R1# set neighbor 10.1.0.6 peer-as 64511

```

```
user@R1# set export customer-routes
```

4. Configure OSPF connections to Device R2 and Device R3.

```
[edit protocols ospf area 0.0.0.0]
user@R1# set interface fe-1/2/0.0
user@R1# set interface fe-1/2/2.0
user@R1# set interface lo0.0 passive
```

5. Configure the prefix list.

```
[edit policy-options prefix-list 64510-customers]
user@R1# set 172.16.1.16/28
user@R1# set 172.16.1.32/28
user@R1# set 172.16.1.48/28
user@R1# set 172.16.1.64/28
user@R1# set 172.16.2.16/28
user@R1# set 172.16.2.32/28
user@R1# set 172.16.2.48/28
user@R1# set 172.16.2.64/28
user@R1# set 172.16.3.16/28
user@R1# set 172.16.3.32/28
user@R1# set 172.16.3.48/28
user@R1# set 172.16.3.64/28
```

6. Configure the routing policy that references the prefix list as a match criterion.

```
[edit policy-options policy-statement customer-routes term get-routes]
user@R1# set from prefix-list 64510-customers
user@R1# set then accept
[edit policy-options policy-statement customer-routes term others]
user@R1# set then reject
```

7. Configure the static route to the 172.16.5.0/24 network.

```
[edit routing-options static]
user@R1# set route 172.16.1.16/28 discard
user@R1# set route 172.16.1.32/28 discard
user@R1# set route 172.16.1.48/28 discard
user@R1# set route 172.16.1.64/28 discard
```

8. Configure the autonomous system (AS) number and router ID.

```
[edit routing-options]
user@R1# set router-id 192.168.0.1
user@R1# set autonomous-system 64510
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R1# show interfaces
fe-1/2/0 {
  unit 0 {
    description to_R2;
    family inet {
      address 10.0.0.1/30;
    }
  }
}
fe-1/2/2 {
  unit 0 {
    description to_R3;
    family inet {
      address 10.0.0.5/30;
    }
  }
}
fe-1/2/3 {
  unit 0 {
    description to_R4;
    family inet {
      address 10.1.0.5/30;
    }
  }
}
lo0 {
  unit 0 {
    family inet {
      address 192.168.0.1/32;
    }
  }
}
```

```
user@R1# show protocols
bgp {
  group int {
    type internal;
    local-address 192.168.0.1;
    neighbor 192.168.0.2;
    neighbor 192.168.0.3;
  }
  group to_64511 {
    type external;
    export customer-routes;
    neighbor 10.1.0.6 {
      peer-as 64511;
    }
  }
}
ospf {
  area 0.0.0.0 {
    interface fe-1/2/0.0;
    interface fe-1/2/2.0;
    interface lo0.0 {
      passive;
    }
  }
}
```

```
user@R1# show policy-options
prefix-list 64510-customers {
  172.16.1.16/28;
  172.16.1.32/28;
  172.16.1.48/28;
  172.16.1.64/28;
  172.16.2.16/28;
  172.16.2.32/28;
  172.16.2.48/28;
  172.16.2.64/28;
  172.16.3.16/28;
  172.16.3.32/28;
  172.16.3.48/28;
  172.16.3.64/28;
}
policy-statement customer-routes {
  term get-routes {
    from {
```

```

        prefix-list 64510-customers;
    }
    then accept;
}
term others {
    then reject;
}
}

```

```

user@R1# show routing-options
static {
    route 172.16.1.16/28 discard;
    route 172.16.1.32/28 discard;
    route 172.16.1.48/28 discard;
    route 172.16.1.64/28 discard;
}
router-id 192.168.0.1;
autonomous-system 64510;

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

IN THIS SECTION

- [Verifying the Routes on Device R1 | 371](#)
- [Verifying the Route Advertisement to Device R4 | 372](#)
- [Experimenting with the prefix-list-filter Statement | 373](#)

Confirm that the configuration is working properly.

Verifying the Routes on Device R1

Purpose

On Device R1, check the routes in the routing table.

Action

```
user@R1> show route terse 172.16/16
```

```

inet.0: 26 destinations, 26 routes (26 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

* 172.16.3.32/28        Self
* 172.16.3.48/28        Self
* 172.16.3.64/28        Self
```

Meaning

As expected, only the routes from the customer prefix list are advertised to Device R4.

Experimenting with the *prefix-list-filter* Statement

Purpose

See what can happen when you use **prefix-list-filter** instead of **prefix-list**.

Action

1. On Device R2, add a static route that is longer than one of the existing static routes.

```
[edit routing-options static route]
user@R2# set 172.16.2.65/32 discard
user@R2# commit
```

2. On Device R1, deactivate the prefix list and configure a prefix list filter with the **orlonger** match type.

```
[edit policy-options policy-statement customer-routes term get-routes]
user@R1# deactivate from prefix-list 64510-customers
user@R1# set from prefix-list-filter 64510-customers orlonger
user@R1# commit
```

3. On Device R1, check which routes are advertised to Device R4.

```
user@R1> show route advertising-protocol bgp 10.1.0.6
```

```
inet.0: 27 destinations, 27 routes (27 active, 0 holddown, 0 hidden)
  Prefix                Nexthop          MED      Lclpref    AS path
* 172.16.1.16/28        Self
* 172.16.1.32/28        Self
* 172.16.1.48/28        Self
* 172.16.1.64/28        Self
* 172.16.2.16/28        Self
* 172.16.2.32/28        Self
* 172.16.2.48/28        Self
* 172.16.2.64/28        Self
* 172.16.2.65/32        Self
* 172.16.3.16/28        Self
* 172.16.3.32/28        Self
* 172.16.3.48/28        Self
* 172.16.3.64/28        Self
```

Meaning

As expected, Device R1 is now advertising the 172.16.2.65/32 route to Device R4, even though 172.16.2.65/32 is not in the prefix list.

Example: Configuring the Priority for Route Prefixes in the RPD Infrastructure

IN THIS SECTION

- [Requirements | 375](#)
- [Overview | 375](#)
- [Configuration | 376](#)
- [Verification | 382](#)

This example shows how to configure priority for route prefixes in the RPD infrastructure for the OSPF, LDP, and BGP protocols.

Requirements

This example uses the following hardware and software components:

- Three routers in a combination of ACX Series, M Series, MX Series, PTX Series, and T Series.
- Junos OS Release 16.1 or later running on all devices.

Before you begin:

1. Configure the device interfaces.
2. Configure the following protocols:
 - BGP
 - MPLS
 - OSPF
 - LDP

Overview

In a network with a large number of routes, it is sometimes important to control the order in which routes get updated for better convergence and to provide differentiated services. Prefix prioritization helps users to prioritize certain routes/prefixes over others and have control over the order in which routes get updated in the RIB (routing table) and the FIB (forwarding table). In Junos OS Release 16.1 and later, you can control the order in which the routes get updated from LDP/OSPF to rpd and rpd to kernel. You can specify a priority of **high** or **low** through the existing import policy in the protocols. In the event of a topology change, high priority prefixes are updated in the routing table first, followed by low priority prefixes. In general, routes that are not explicitly assigned a priority are treated as medium priority. Within the same priority level, routes will continue to be updated in lexicographic order.

In this example, the routing device is in area 0.0.0.0, with interface ge-1/3/0 connected to the neighboring device. You configure three import routing policies: next-hop-self, ospf-prio, and prio_for_bgp. The routing policy next-hop-self accepts routes from BGP. For the OSPF routing policy, routes matching 172.16.25.3/32 are installed first because they have a priority of high. LDP imports routes from OSPF. For BGP prioritization, routes matching 172.16.50.1/32 are installed first because they have a priority of high. Routes associated with these prefixes are installed in the routing table in the order of the specified priority of the prefix.

Topology

[Figure 29 on page 376](#) shows the sample topology.

Figure 29: Priority for Route Prefixes in the rpd Infrastructure

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from the configuration mode.

R1

```
set interfaces ge-1/3/0 unit 0 family inet address 172.16.12.1/24
set interfaces ge-1/3/0 unit 0 family mpls
set interfaces lo0 unit 0 family inet address 172.16.25.1/32
set protocols mpls interface ge-1/3/0.0

set routing-options router-id 172.16.25.3
set routing-options autonomous-system 2525

```

Configuring Device R1

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure Device R1:

1. Configure the interfaces.

```

[edit interfaces]
user@R1# set interfaces ge-1/3/0 unit 0 family inet address 172.16.12.1/24
user@R1# set interfaces ge-1/3/0 unit 0 family mpls
user@R1# set interfaces lo0 unit 0 family inet address 172.16.25.1/32

```

2. Assign the loopback address to the device.

```

[edit lo0 unit 0 family]
user@R1# set address 172.16.25.1/32

```

3. Configure MPLS.

```

[edit protocols]
user@R1# set protocols mpls interface ge-1/3/0.0

```

4. Configure the router ID and autonomous system of Router R1.

```
[edit routing-options]
user@R1# set router-id 172.16.7.7
user@R1# set autonomous-system 100
```

5. Enable OSPF on the interfaces of Router R1.

```
[edit protocols]
user@R1# set protocols ospf import ospf_prio
user@R1# set protocols ospf area 0.0.0.0 interface ge-1/3/0.0
user@R1# set protocols ospf area 0.0.0.0 interface lo0.0 passive
```

6. Configure LDP protocols on the interfaces.

```
[edit protocols]
user@R1# set protocols ldp interface ge-1/3/0.0
user@R1# set protocols ldp interface lo0.0
```

7. Configure BGP.

```
[edit protocols]
user@R1# set protocols bgp group prio_internal type internal
user@R1# set protocols bgp group prio_internal local-address 172.16.25.1
user@R1# set protocols bgp group prio_internal import prio_for_bgp
user@R1# set protocols bgp group prio_internal neighbor 172.16.25.3 family inet unicast
user@R1# set protocols bgp group prio_internal neighbor 172.16.25.3 export next-hop-self
```

8. Configure the policy options to prioritize the routes. The policy next-hop-self accepts routes from BGP. You configure three import routing policies: next-hop-self, ospf-prio, and prio_for_bgp. The routing policy next-hop-self accepts routes from BGP. For the ospf-prio routing policy, routes matching 172.16.25.3/32 are installed first because they have a priority of high. LDP imports routes from OSPF. For prio_for_bgp policy, routes matching 172.16.50.1/32 are installed first because they have a priority of high.

```
[edit policy-options policy-statement]
user@R1# set policy-options policy-statement next-hop-self term nhself from protocol bgp
user@R1# set policy-options policy-statement next-hop-self term nhself then next-hop self
user@R1# set policy-options policy-statement next-hop-self term nhself then accept
```

```

user@R1# set policy-options policy-statement ospf_prio term ospf_ldp from protocol ospf
user@R1# set policy-options policy-statement ospf_prio term ospf_ldp from route-filter 172.16.25.3/32
exact
set policy-options policy-statement ospf_prio term ospf_ldp then priority high

set policy-options policy-statement ospf_prio term ospf_ldp then accept
set policy-options policy-statement prio_for_bgp term bgp_prio from protocol bgp
set policy-options policy-statement prio_for_bgp term bgp_prio from route-filter 172.16.50.1/32 exact
set policy-options policy-statement prio_for_bgp term bgp_prio then priority high

```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show routing-options**, and **show policy-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

[edit]
user@R1# show interfaces
ge-1/3/0 {
  unit 0 {
    family inet {
      address 172.16.12.1/24;
    }
    family mpls;
  }
}
lo0 {
  unit 0 {
    family inet {
      address address 172.16.25.1/32;
    }
  }
}

```

```

[edit]
user@R1# show protocols
mpls {
  interface ge-1/3/0.0;
}
bgp {

```

```

group prio_internal {
    type internal;
    local-address 172.16.25.1;
import prio_for_bgp
    neighbor 172.16.25.3 {
        family inet {
            unicast;
        }
        export next-hop-self;
    }
}
ospf {
    import ospf_prio;
    area 0.0.0.0 {
        interface ge-1/3/0.0;
        interface lo0.0 {
            passive;
        }
    }
}
ldp {
    interface ge-1/3/0.0;
    interface lo0.0;
}
}

```

```

[edit]
user@R1# show routing-options
nonstop-routing;
router-id 172.16.25.1;
autonomous-system 2525;

```

```

[edit]
user@R1# show policy-options
policy-statement next-hop-self {
    term nhself {
        from protocol bgp;
        then {
            next-hop self;
            accept;
        }
    }
}

```

```
}  
policy-statement ospf_prio {  
  term ospf_ldp {  
    from {  
      protocol ospf;  
      route-filter 172.16.25.3/32 exact;  
    }  
    then {  
      priority high;  
      accept;  
    }  
  }  
}  
policy-statement prio_for_bgp {  
  term bgp_prio {  
    from {  
      protocol bgp;  
      route-filter 172.16.50.1/32 exact;  
    }  
    then priority high;  
  }  
}
```

If you are done configuring the device, enter **commit** from the configuration mode.

Verification

IN THIS SECTION

- [Verifying the Priority for OSPF Routes | 382](#)
- [Verifying the Priority for LDP Routes | 383](#)
- [Verifying the Priority for BGP Routes | 385](#)

Confirm that the configuration is working properly.

Verifying the Priority for OSPF Routes

Purpose

Verify that the priority is set for the expected route in OSPF.

Action

On Device R1, from operational mode, run the **show ospf route 172.16.25.3/32 extensive** command. A priority of high is applied to OSPF route 172.16.25.3.

```
user@R1> show ospf route 172.16.25.3/32 extensive
```

Topology default Route Table:

Prefix	Path Type	Route Type	NH Type	Metric	NextHop Interface	Nexthop Address/LSP
172.16.25.3	Intra	Router	IP		2 ge-1/3/0.0	172.16.12.2
area 0.0.0.0, origin 172.16.25.3, optional-capability 0x0						
172.16.25.3/32	Intra	Network	IP		2 ge-1/3/0.0	172.16.12.2
area 0.0.0.0, origin 172.16.25.3, priority high						

Meaning

The output shows priority **high** is applied for OSPF route 172.16.25.3.

Verifying the Priority for LDP Routes

Purpose

Verify if LDP inherits from OSPF.

Action

From operational mode, enter the **show route 172.16.25.3** command to verify if LDP has inherited routes from OSPF.

```
user@R1> show route 172.16.25.3
```

```
inet.0: 24 destinations, 24 routes (24 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

172.16.25.3/32      *[OSPF/10] 00:10:27, metric 2
                   > to 172.16.25.2 via ge-1/3/0.0

inet.3: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

172.16.25.3/32      *[LDP/9] 00:10:24, metric 1
                   > to 172.16.25.2 via ge-1/3/0.0, Push 299824
```

From operational mode, enter the **show route 172.16.25.3 extensive** command to verify if LDP has inherited priority.

user@R1> **show route 172.16.25.3 extensive**

```
inet.0: 24 destinations, 24 routes (24 active, 0 holddown, 0 hidden)

[Configuring Priority for Route Prefixes in RPD Infrastructure | 387](#)

Configuring Priority for Route Prefixes in RPD Infrastructure

Prefix prioritization helps users to prioritize certain routes or prefixes for better convergence and to provide differentiated services. In a network with a large number of routes, it is sometimes important to control the order in which routes get updated due to changes in the network topology. At a system level, Junos OS implements reasonable defaults based on heuristics to determine the order in which routes get updated. However, the default behavior is not always optimal. Prefix prioritization provides the user the ability to control the order in which the routes get updated from LDP or OSPF to rpd, and rpd to kernel. The Junos OS policy language is extended to let the user set relative priority (high and low) for prefixes through the existing import policy in protocols. Based on the tagged priority, the routes are placed in different priority queues. In the event of a topology change, high priority prefixes are updated in the routing table first, followed by low priority prefixes. Within the same priority level, routes will continue to be updated in lexicographic order. Routes that are not explicitly assigned a priority are treated as medium priority.

Before you begin to configure prefix prioritization in rpd for protocols such as OSPF, LDP, and BGP:

- Configure the router interfaces.
- Configure MPLS.
- Configure the OSPF, BGP, and LDP protocols.

To configure the priority **high** for the OSPF protocol:

1. Configure the policy term.

```
[edit policy-options policy-statement policy-name]  
user@host# set term term-name
```

For example:

```
[edit policy-options policy-statement ospf-prio]
user@host# set term t1
```

2. Configure the policy term to accept routes from OSPF.

```
[edit policy-options policy-statement ospf-prio term t1]
user@host# set from protocol ospf
```

3. Specify the desired route as a match condition for which you want to set priority **high**.

```
[edit policy-options policy-statement ospf-prio term t1]
user@host# set from route-filter destination-prefix match-type
```

For example:

```
[edit policy-options policy-statement ospf-prio term t1]
user@host# set from route-filter 172.16.25.3/32 exact
```

4. Specify that the route is to be accepted and set priority **high** for the route if the previous conditions are matched.

```
[edit policy-options policy-statement ospf-prio term t1]
user@host# set then priority high
user@host# set then accept
```

5. Verify the configuration.

```
[edit]
user@host# show policy-options
policy-statement ospf-prio {
  term t1 {
    from {
      route-filter 172.16.25.3/32 exact;
    }
    then {
      priority high;
      accept;
    }
  }
}
```

```
}
```

LDP inherits from OSPF.

To configure priority **high** for LDP:

1. Configure the policy term that imports from OSPF.

```
[edit policy-options policy-statement policy-name]
user@host# set term term-name
```

For example:

```
[edit policy-options policy-statement ospf-import]
user@host# set term ospf_ldp
```

2. Configure the term to accept routes and priority from OSPF.

```
[edit policy-options policy-statement ospf_import term ospf_ldp]
user@host# set from protocol ospf
user@host# set from route-filter destination-prefix match-type
```

For example:

```
[edit policy-options policy-statement ospf_import term ospf_ldp]
user@host# set from protocol ospf
user@host# set from route-filter 172.16.25.3/32 exact
```

3. Verify the configuration.

```
[edit]
user@host# show policy-options
policy-statement ospf-import {
  term ospf_ldp {
    from {
      protocol ospf ;
      route-filter 172.16.25.3/32 exact;
    }
    then {
      priority high;
      accept;
```

```

    }
  }
}

```

To configure the priority **high** for the BGP protocol:

1. Configure the policy term.

```

[edit policy-options policy-statement policy-name]
user@host# set term term-name

```

For example:

```

[edit policy-options policy-statement prio-for-bgp]
user@host# set term bgp_prio

```

2. Specify the desired route as a match condition.

```

[edit policy-options policy-statement prio-for-bgp term bgp_prio]
user@host# set from protocol bgp
user@host# set from route-filter destination-prefix match-type

```

For example:

```

[edit policy-options policy-statement prio-for-bgp term bgp_prio]
user@host# set from protocol bgp
user@host# set from route-filter 172.16.50.1/32 exact

```

3. Specify that the route is to be accepted and set the priority **high** for the route if the previous conditions are matched.

```

[edit policy-options policy-statement prio-for-bgp term bgp_prio]
user@host# set then priority high
user@host# set then accept

```

4. Verify the configuration.

```

policy-statement prio_for_bgp {
  term bgp_prio {

```

```

    from {
      protocol bgp;
      route-filter 172.16.50.1/32 exact;
    }
    then {
      priority high;
      accept;
    }
  }
}

```

NOTE: For BGP, you can also configure priority based on the route-distinguisher (RD) value in case of L3VPN. For example, you can configure priority for BGP with route-distinguisher 51.51.51.51:111.

To configure priority for BGP based on the route-distinguisher (RD) value:

1. Configure the policy term.

```

[edit policy-options policy-statement policy-name]
user@host# set term term-name

```

For example:

```

[edit policy-options policy-statement prio-for-bgp]
user@host# set term bgp_prio

```

2. Specify the desired route as a match condition.

```

[edit policy-options policy-statement prio-for-bgp term bgp_prio]
user@host# set from rib bgp.l3vpn.0
user@host# set from route-filter destination-prefix match-type
user@host# set from route-distinguisher route-distinguisher value

```

For example:

```

[edit policy-options policy-statement prio-for-bgp term bgp_prio]
user@host# set from rib bgp.l3vpn.0
user@host# set from route-filter 172.16.1.1/32 exact

```

```
user@host# set from route-distinguisher RD1
```

3. Specify that the route is to be accepted and set the priority **high** for the route if the previous conditions are matched.

```
[edit policy-options policy-statement prio-for-bgp term bgp_prio]  
user@host# set then priority high  
user@host# set then accept
```

4. Verify the configuration.

```
policy-statement prio_for_bgp {  
  term bgp_prio {  
    from {  
      protocol rib bgp.l3vpn.0;  
      route-filter 172.16.1.1/32 exact;  
      route-distinguisher RD1;  
    }  
    then {  
      priority high;  
      accept;  
    }  
  }  
}
```

NOTE: Low priority prefixes are installed only after the high priority prefixes in the routing table. You can also configure priority **low** similarly to priority **high** for the routes you want to set to low priority.

NOTE: Priority is applied only when routes are pushed from RIB to FIB. Therefore, you cannot modify the priority of routes that are already installed. Changing the priority of routes already installed does not make sense. If you try changing the priority of routes already installed, there is a show output difference:

```
user@R1> show route 172.16.25.3 extensive | match state
```

```
State: <FlashAll>
      State:    <Active Int HighPriority>      <=== OSPF

Validation State: unverified
State: <FlashAll>
      State:    <Active Int>                  <=== LDP

Validation State: unverified
```

As the route is already installed in FIB, LDP does not show the priority as High.

Restarting the routing daemon to remove the routes and adding it again reflects the proper priority from both the OSPF and LDP protocol perspective.

```
user@R1> restart routing
```

```
Routing protocols process signalled but still running, waiting 8 seconds
more
Routing protocols process started, pid 4512
```

```
user@R1> show route 172.16.25.3 extensive |match state
```

```
State: <FlashAll>
      State:    <Active Int HighPriority>      <=== OSPF

Validation State: unverified
State: <FlashAll>
      State:    <Active Int HighPriority>      <=== LDP

Validation State: unverified
```

Understanding AS Path Regular Expressions for Use as Routing Policy Match Conditions

IN THIS SECTION

- [Configuration of AS Path Regular Expressions | 396](#)
- [How AS Path Regular Expressions Are Evaluated | 401](#)
- [Examples: Configuring AS Path Regular Expressions | 402](#)

A BGP *AS path* is the sequence of autonomous systems that network packets traverse to get to a specified router. AS numbers are assembled in a sequence that is read from right to left. For example, for a packet to reach a destination using a route with an AS path 5 4 3 2 1, the packet first traverses AS 1 and so on until it reaches AS 5. In this case, AS 5 is the last AS before the packet destination; it is the AS that the source of the packet would peer with.

When working with AS paths and routing policy match conditions, you can use regular expressions to locate routes. To do so, create one or more match conditions based on some or all of the AS path, and then include it in a routing policy.

The following sections describe AS path regular expressions and provide configuration examples.

Configuration of AS Path Regular Expressions

You can create a named AS path regular expression and then include it in a routing policy with the **as-path** match condition (described in [“Routing Policy Match Conditions” on page 54](#)). To create a named AS path regular expression, include the **as-path** statement:

```
[edit policy-options]
as-path name regular-expression;
```

To include the AS path regular expression in a routing policy, include the **as-path** match condition in the **from** statement.

Additionally, you can create a named AS path group made up of AS path regular expressions and then include it in a routing policy with the **as-path-group** match condition. To create a named AS path group, include the **as-path-group** statement.

```
[edit policy-options]
as-path-group group-name {
  name [ regular-expressions ];
}
```

To include the AS path regular expressions within the AS path group in a routing policy, include the **as-path-group** match condition in the **from** statement.

NOTE: You cannot include both of the **as-path** and **as-path-group** statements in the same policy term.

NOTE: You can include the names of multiple AS path regular expressions in the **as-path** match condition in the **from** statement. If you do this, only one AS path regular expression needs to match for a match to occur. The AS path regular expression matching is effectively a logical OR operation.

The AS path name identifies the regular expression. It can contain letters, numbers, and hyphens (-), and can be up to 65,536 characters. To include spaces in the name, enclose the entire name in quotation marks (" ").

The regular expression is used to match all or portions of the AS path. It consists of two components, which you specify in the following format:

term <operator>

- **term**—Identifies an AS. You can specify it in one of the following ways:
 - AS number—The entire AS number composes one term. You cannot reference individual characters within an AS number, which differs from regular expressions as defined in POSIX 1003.2.
 - Wildcard character—Matches any single AS number. The wildcard character is a period (.). You can specify multiple wildcard characters.
 - AS path—A single AS number or a group of AS numbers enclosed in parentheses. Grouping the regular expression in this way allows you to perform a common operation on the group as a whole and to give the group precedence. The grouped path can itself include operators.

In Junos OS Release 9.1 and later, you can specify 4-byte AS numbers as defined in RFC 4893, *BGP Support for Four-octet AS Number Space*, as well as the 2-byte AS numbers that are supported in earlier releases of the Junos OS. You can configure a value in the range from 1 through 4,294,967,295.

- **operator**—(Optional) An operator specifying how the term must match. Most operators describe how many times the term must be found to be considered a match (for example, any number of occurrences, or zero, or one occurrence). [Table 21 on page 397](#) lists the regular expression operators supported for AS paths. You place operators immediately after **term** with no intervening space, except for the pipe (|) and dash (-) operators, which you place between two terms, and parentheses, with which you enclose terms.

You can specify one or more term-operator pairs in a single regular expression.

[Table 22 on page 398](#) shows examples of how to define regular expressions to match AS paths.

Table 21: AS Path Regular Expression Operators

Operator	Match Definition
{m,n}	At least m and at most n repetitions of term . Both m and n must be positive integers, and m must be smaller than n .
{m}	Exactly m repetitions of term . m must be a positive integer.
{m,}	m or more repetitions of term . m must be a positive integer.
*	Zero or more repetitions of term . This is equivalent to {0,}.
+	One or more repetitions of term . This is equivalent to {1,}.
?	Zero or one repetition of term . This is equivalent to {0,1}.
 	One of two terms on either side of the pipe.

Table 21: AS Path Regular Expression Operators (*continued*)

Operator	Match Definition
-	Between a starting and ending range, inclusive.
^	A character at the beginning of a community attribute regular expression. This character is added implicitly; therefore, the use of it is optional.
\$	A character at the end of a community attribute regular expression. This character is added implicitly; therefore, the use of it is optional.
()	A group of terms that are enclosed in the parentheses. Intervening space between the parentheses and the terms is ignored. If a set of parentheses is enclosed in quotation marks with no intervening space "()", it indicates a null path.
[]	Set of AS numbers. One AS number from the set must match. To specify the start and end of a range, use a hyphen (-). A caret (^) may be used to indicate that it does not match a particular AS number in the set, for example [^123].

Table 22: Examples of AS Path Regular Expressions

AS Path to Match	Regular Expression	Sample Matches
AS path is 1234	1234	1234
Zero or more occurrences of AS number 1234	1234*	1234 1234 1234 1234 1234 1234 Null AS path
Zero or one occurrence of AS number 1234	1234? or 1234{0,1}	1234 Null AS path
One through four occurrences of AS number 1234	1234{1,4}	1234 1234 1234 1234 1234 1234 1234 1234 1234 1234

Table 22: Examples of AS Path Regular Expressions (*continued*)

AS Path to Match	Regular Expression	Sample Matches
One through four occurrences of AS number 12, followed by one occurrence of AS number 34	12{1,4} 34	12 34 12 12 34 12 12 12 34 12 12 12 12 34
Range of AS numbers to match a single AS number	123-125	123 124 125
	[123-125]*	Null AS path 123 124 124 125 125 125 123 124 125 123
Path whose second AS number must be 56 or 78	(. 56) (. 78) or . (56 78)	1234 56 1234 78 9876 56 3857 78
Path whose second AS number might be 56 or 78	. (56 78)?	1234 56 52 34 56 1234 1234 78 39 794 78 2
Path whose first AS number is 123 and second AS number is either 56 or 78	123 (56 78)	123 56 123 78
Path of any length, except nonexistent, whose second AS number can be anything, including nonexistent	. .* or . {0,}	1234 1234 5678 1234 5 6 7 8

Table 22: Examples of AS Path Regular Expressions (*continued*)

AS Path to Match	Regular Expression	Sample Matches
AS path is 1 2 3	1 2 3	1 2 3
One occurrence of the AS numbers 1 and 2, followed by one or more occurrences of the AS number 3	1 2 3+	1 2 3 1 2 3 3 1 2 3 3 3
One or more occurrences of AS number 1, followed by one or more occurrences of AS number 2, followed by one or more occurrences of AS number 3	1+ 2+ 3+	1 2 3 1 1 2 3 1 1 2 2 3 1 1 2 2 3 3
Path of any length that begins with AS numbers 4, 5, 6	4 5 6 .*	4 5 6 4 5 6 7 8 9
Path of any length that ends with AS numbers 4, 5, 6	.* 4 5 6	4 5 6 1 2 3 4 5 6 4 9 4 5 6
AS path 5, 12, or 18	5 12 18	5 12 18

Configuring a Null AS Path

You can use AS path regular expressions to create a null AS path that matches routes (prefixes) that have originated in your AS. These routes have not been advertised to your AS by any external peers. To create a null AS path, use the parentheses operator enclosed in quotation marks with no intervening spaces:

"()

In the following example, locally administered AS 2 is connected to AS 1 (10.2.2.6) and AS 3. AS 3 advertises its routes to AS 2, but the administrator for AS 2 does not want to advertise AS 3 routes to AS 1 and thereby allow transit traffic from AS 1 to AS 3 through AS 2. To prevent transit traffic, the export policy **only-my-routes** is applied to AS 1. It permits advertisement of routes from AS 2 to AS 1 but prevents advertisement of routes for AS 3 (or routes for any other connected AS) to AS 1:

```
[edit policy-options]
null-as "";
policy-statement only-my-routes {
  term just-my-as {
    from {
      protocol bgp;
      as-path null-as;
    }
    then accept;
  }
  term nothing-else {
    then reject;
  }
}
protocol {
  bgp {
    neighbor 10.2.2.6 {
      export only-my-routes;
    }
  }
}
```

How AS Path Regular Expressions Are Evaluated

AS path regular expressions implement the extended (modern) regular expressions as defined in POSIX 1003.2. They are identical to the UNIX regular expressions with the following exceptions:

- The basic unit of matching in an AS path regular expression is the AS number and not an individual character.
- A regular expression matches a route only if the AS path in the route exactly matches **regular-expression**. The equivalent UNIX regular expression is **^regular-expression\$**. For example, the AS path regular expression **1234** is equivalent to the UNIX regular expression **^1234\$**.
- You can specify a regular expression using wildcard operators.

Examples: Configuring AS Path Regular Expressions

Exactly match routes with the AS path 1234 56 78 9 and accept them:

```
[edit]
policy-options {
  as-path wellington "1234 56 78 9";
  policy-statement from-wellington {
    term term1 {
      from as-path wellington;
    }
    then {
      preference 200;
      accept;
    }
    term term2 {
      then reject;
    }
  }
}
```

Match alternate paths to an AS and accept them after modifying the preference:

```
[edit]
policy-options {
  as-path wellington-alternate "1234{1,6} (56|47)? (78|101|112)* 9+";
  policy-statement from-wellington {
    from as-path wellington-alternate;
  }
  then {
    preference 200;
    accept;
  }
}
```

Match routes with an AS path of 123, 124, or 125 and accept them after modifying the preference:

```
[edit]
policy-options {
  as-path addison "123-125";
  policy-statement from-addison {
    from as-path addison;
```

```
    }  
    then {  
        preference 200;  
        accept;  
    }  
}
```

Example: Using AS Path Regular Expressions

IN THIS SECTION

- [Requirements | 403](#)
- [Overview | 403](#)
- [Configuration | 404](#)
- [Verification | 413](#)

An autonomous system (AS) path is a route attribute used by BGP. The AS path is used both for route selection and to prevent potential routing loops. This example shows how to use regular expressions with AS path numbers to locate a set of routes.

Requirements

No special configuration beyond device initialization is required before configuring this example.

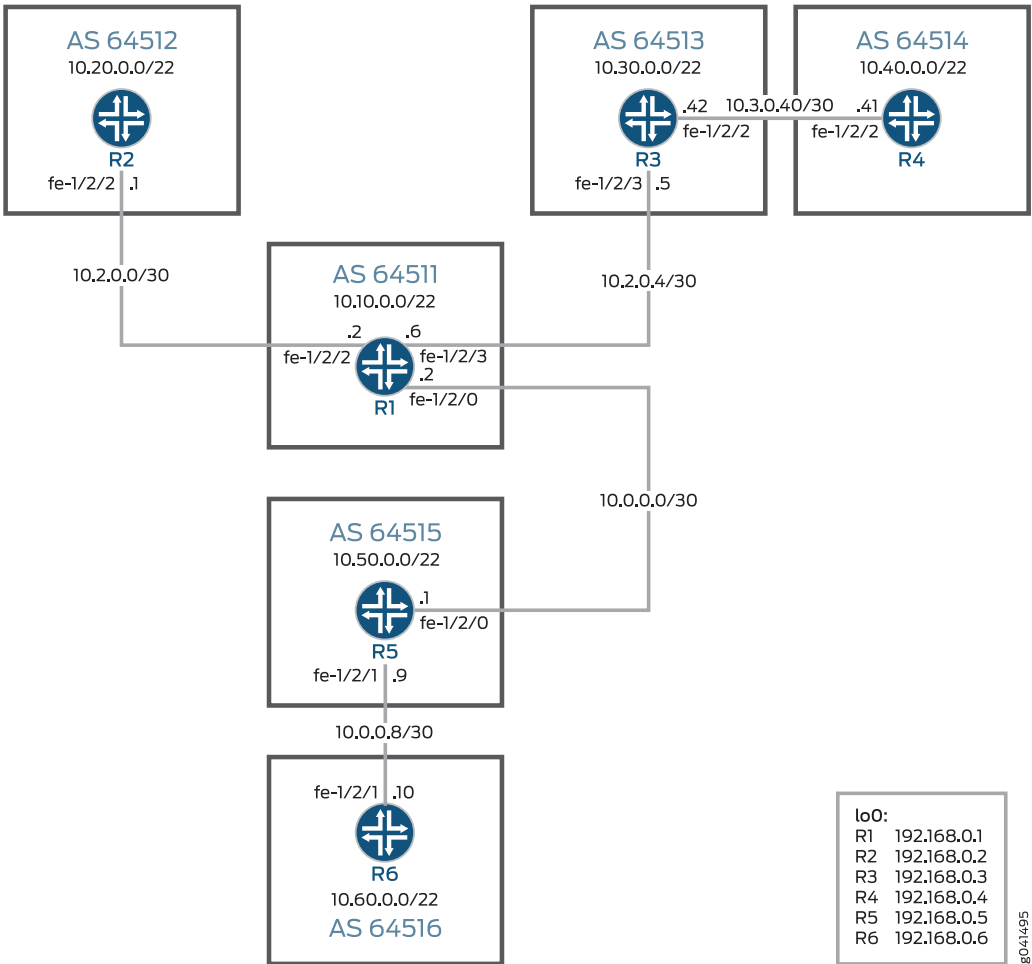

Overview

[Figure 30 on page 404](#) shows several ASs connected through external BGP (EBGP) peering sessions. Each device is generating customer routes within its assigned address space.

Topology

Figure 30 on page 404 shows the sample network.

Figure 30: BGP Topology AS Regular Expressions

The administrators of AS 64516 want to reject all routes originating in AS 64513 and AS 64514. Two AS path regular expressions called **orig-in-64513** and **orig-in-64514** are created and referenced in a policy called **reject-some-routes**. The routing policy is then applied as an import policy on Device R6.

“CLI Quick Configuration” on page 404 shows the configuration for all of the devices in Figure 30 on page 404.

The section “Step-by-Step Procedure” on page 408 describes the steps on Device R2 and Device R6. “Verification” on page 413 shows how to use the **aspath-regex** option with the **show route** command on Device R2 to locate routes using regular expressions.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

Device R1

```
set interfaces fe-1/2/2 unit 0 description to-R2
set interfaces fe-1/2/2 unit 0 family inet address 10.2.0.2/30
set interfaces fe-1/2/3 unit 0 description to-R3
set interfaces fe-1/2/3 unit 0 family inet address 10.2.0.6/30
set interfaces fe-1/2/0 unit 0 description to-R5
set interfaces fe-1/2/0 unit 0 family inet address 10.0.0.2/30
set interfaces lo0 unit 0 family inet address 192.168.0.1/32
set protocols bgp export send-static
set protocols bgp group 64512 type external
set protocols bgp group 64512 peer-as 64512
set protocols bgp group 64512 neighbor 10.2.0.1
set protocols bgp group 64513 type external
set protocols bgp group 64513 peer-as 64513
set protocols bgp group 64513 neighbor 10.2.0.5
set protocols bgp group 64515 type external
set protocols bgp group 64515 peer-as 64515
set protocols bgp group 64515 neighbor 10.0.0.1
set policy-options policy-statement send-static term 1 from protocol static
set policy-options policy-statement send-static term 1 then accept
set routing-options static route 10.10.1.0/24 reject
set routing-options static route 10.10.2.0/24 reject
set routing-options static route 10.10.3.0/24 reject
set routing-options autonomous-system 64511
```

Device R2

```
set interfaces fe-1/2/2 unit 0 description to-R1
set interfaces fe-1/2/2 unit 0 family inet address 10.2.0.1/30
set interfaces lo0 unit 0 family inet address 192.168.0.2/32
set protocols bgp export send-static
set protocols bgp group 64511 type external
set protocols bgp group 64511 peer-as 64511
set protocols bgp group 64511 neighbor 10.2.0.2
set policy-options policy-statement send-static term 1 from protocol static
```

```

set policy-options policy-statement send-static term 1 then accept
set routing-options static route 10.20.1.0/24 reject
set routing-options static route 10.20.2.0/24 reject
set routing-options static route 10.20.3.0/24 reject
set routing-options autonomous-system 64512

```

Device R3

```

set interfaces fe-1/2/3 unit 0 description to-R1

```

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure Device R2:

1. Configure the device interfaces.

```

[edit interfaces]
user@R2# set fe-1/2/2 unit 0 description to-R1
user@R2# set fe-1/2/2 unit 0 family inet address 10.2.0.1/30
user@R2# set lo0 unit 0 family inet address 192.168.0.2/32

```

2. Configure the EBGP connection to Device R1.

```

[edit protocols bgp]
user@R2# set export send-static
user@R2# set group 64511 type external
user@R2# set group 64511 peer-as 64511
user@R2# set group 64511 neighbor 10.2.0.2

```

3. Configure the routing policy.

```

[edit policy-options policy-statement send-static term 1]
user@R2# set from protocol static
user@R2# set then accept

```

4. Configure the static routes.

```
[edit routing-options static]
user@R2# set route 10.20.1.0/24 reject
user@R2# set route 10.20.2.0/24 reject
user@R2# set route 10.20.3.0/24 reject
```

5. Configure the AS number.

```
[edit routing-options]
user@R2# set autonomous-system 64512
```

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure Device R6:

1. Configure the device interfaces.

```
[edit interfaces]
user@R6# set fe-1/2/1 unit 0 description to-R5
user@R6# set fe-1/2/1 unit 0 family inet address 10.0.0.10/30
user@R6# set lo0 unit 0 family inet address 192.168.0.6/32
```

2. Configure the EBGP connection to Device R5.

```
[edit protocols bgp]
user@R6# set export send-static
user@R6# set group 64515 type external
user@R6# set group 64515 import reject-some-routes
user@R6# set group 64515 peer-as 64515
user@R6# set group 64515 neighbor 10.0.0.9
```

3. Configure the routing policy that sends static routes.

```
[edit policy-options policy-statement send-static term 1]
user@R6# set from protocol static
user@R6# set then accept
```

4. Configure the routing policy that rejects certain routes.

```
[edit policy-options policy-statement reject-some-routes term find-routes]
user@R6# set from as-path orig-in-64513
user@R6# set from as-path orig-in-64514
user@R6# set then reject
[edit policy-options]
user@R6# set as-path orig-in-64513 ".* 64513"
user@R6# set as-path orig-in-64514 ".* 64514"
```

5. Configure the static routes.

```
[edit routing-options static]
user@R6# set route 10.60.1.0/24 reject
user@R6# set route 10.60.2.0/24 reject
user@R6# set route 10.60.3.0/24 reject
```

6. Configure the AS number.

```
[edit routing-options]
user@R6# set autonomous-system 64516
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

Device R2

```
user@R2# show interfaces
fe-1/2/0 {
  unit 0 {
    description to-R1;
    family inet {
      address 10.2.0.1/30;
    }
  }
}
lo0 {
```

```
    unit 0 {  
        family inet {  
            address 192.168.0.2/32;  
        }  
    }  
}
```

```
user@R2# show protocols  
bgp {  
    export send-static;  
    group 64511 {  
        type external;  
        peer-as 64511;  
        neighbor 10.2.0.2;  
    }  
}
```

```
user@R2# show policy-options  
policy-statement send-static {  
    term 1 {  
        from protocol static;  
        then accept;  
    }  
}
```

```
user@R2# show routing-options  
static {  
    route 10.20.1.0/24 reject;  
    route 10.20.2.0/24 reject;  
    route 10.20.3.0/24 reject;  
}  
autonomous-system 64512;
```

Device R6

```
user@R6# show interfaces

```

```

    unit 0 {
        description to-R5;
        family inet {
            address 10.0.0.10/30;
        }
    }
}
lo0 {
    unit 0 {
        family inet {
            address 192.168.0.6/32;
        }
    }
}

```

```

user@R6# show protocols
bgp {
    export send-static;
    group 64515 {
        type external;
        import reject-some-routes;
        peer-as 64515;
        neighbor 10.0.0.9;
    }
}

```

```

user@R6# show policy-options
policy-statement reject-some-routes {
    term find-routes {
        from as-path [ orig-in-64513 orig-in-64514 ];
        then reject;
    }
}
policy-statement send-static {
    term 1 {
        from protocol static;
        then accept;
    }
}
as-path orig-in-64513 ".* 64513";

```

```
as-path orig-in-64514 ".* 64514";
```

```
user@R6# show routing-options
static {
  route 10.60.1.0/24 reject;
  route 10.60.2.0/24 reject;
  route 10.60.3.0/24 reject;
}
autonomous-system 64516;
```

If you are done configuring the devices, enter **commit** from configuration mode.

Verification

IN THIS SECTION

- [Finding Routes on Device R2 | 413](#)
- [Making Sure That Routes Are Excluded on Device R6 | 415](#)

Confirm that the configuration is working properly.

Finding Routes on Device R2

Purpose

On Device R2, use the [show route aspath-regex](#) command to locate routes using regular expressions.

Action

Look for routes that are originated by Device R6 in AS 64516.

```
user@R2> show route terse aspath-regex ".* 64516"
```

```
inet.0: 21 destinations, 21 routes (21 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

A V Destination      P Prf  Metric 1   Metric 2  Next hop      AS path
* ? 10.60.1.0/24      B 170      100
64516 I
  unverified          >10.2.0.2
```

```

* ? 10.60.2.0/24      B 170      100      64511 64515
64516 I
   unverified      >10.2.0.2
* ? 10.60.3.0/24      B 170      100      64511 64515
64516 I
   unverified      >10.2.0.2

```

Look for routes that are originated in either AS 64514 or AS 64516.

user@R2> **show route terse aspath-regex ".* (64514|64516)"**

```

inet.0: 21 destinations, 21 routes (21 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

A V Destination      P Prf    Metric 1   Metric 2  Next hop      AS path
* ? 10.40.1.0/24      B 170      100      64511 64513
64514 I
   unverified      >10.2.0.2
* ? 10.40.2.0/24      B 170      100      64511 64513
64514 I
   unverified      >10.2.0.2
* ? 10.40.3.0/24      B 170      100      64511 64513
64514 I
   unverified      >10.2.0.2
* ? 10.60.1.0/24      B 170      100      64511 64515
64516 I
   unverified      >10.2.0.2
* ? 10.60.2.0/24      B 170      100      64511 64515
64516 I
   unverified      >10.2.0.2
* ? 10.60.3.0/24      B 170      100      64511 64515
64516 I
   unverified      >10.2.0.2

```

Look for routes that use AS 64513 as a transit network.

user@R2> **show route terse aspath-regex ".* 64513 .+"**

```

inet.0: 21 destinations, 21 routes (21 active, 0 holddown, 0 hidden)

```

+ = Active Route, - = Last Active, * = Both

A	V	Destination	P	Prf	Metric 1	Metric 2	Next hop	AS path
*	?	10.40.1.0/24	B	170	100			64511 64513
64514	I	unverified					>10.2.0.2	
*	?	10.40.2.0/24	B	170	100			64511 64513
64514	I	unverified					>10.2.0.2	
*	?	10.40.3.0/24	B	170	100			64511 64513
64514	I	unverified						

Meaning

The output shows the routing table entries that match the specified AS path regular expressions.

Making Sure That Routes Are Excluded on Device R6

Purpose

On Device R6, use the [show route](#) and [show route hidden](#) commands to make sure that routes originating from AS 64513 and AS 64514 are excluded from Device R6's routing table.

Action

```
user@R6> show route 10.30.0/22
```

```
inet.0: 21 destinations, 21 routes (15 active, 0 holddown, 6 hidden)
```

```
user@R6> show route 10.40.0/22
```

```
inet.0: 21 destinations, 21 routes (15 active, 0 holddown, 6 hidden)
```

```
user@R6> show route hidden
```

```
inet.0: 21 destinations, 21 routes (15 active, 0 holddown, 6 hidden)
+ = Active Route, - = Last Active, * = Both

10.30.1.0/24          [BGP ] 02:24:47, localpref 100
                     AS path: 64515 64511 64513 I, validation-state: unverified
```

```

10.30.2.0/24      > to 10.0.0.9 via fe-1/2/1.0
                  [BGP ] 02:24:47, localpref 100
                  AS path: 64515 64511 64513 I, validation-state: unverified
10.30.3.0/24      > to 10.0.0.9 via fe-1/2/1.0
                  [BGP ] 02:24:47, localpref 100
                  AS path: 64515 64511 64513 I, validation-state: unverified
10.40.1.0/24      > to 10.0.0.9 via fe-1/2/1.0
                  [BGP ] 02:24:47, localpref 100
                  AS path: 64515 64511 64513 64514 I, validation-state:
unverified

Understanding Prepending AS Numbers to BGP AS Paths

You can *prepend* one or more autonomous system (AS) numbers at the beginning of an AS path. The AS numbers are added at the beginning of the path after the actual AS number from which the route originates has been added to the path. Prepending an AS path makes a shorter AS path look longer and therefore less preferable to BGP.

The BGP best path algorithm determines how the best path to an autonomous system (AS) is selected. The AS path length determines the best path when all of the following conditions are met:

- There are multiple potential routes to an AS.

- BGP has the lowest preference value (sometimes referred to as administrative distance) of the available routes.
- The local preferences of the available routes are equal.

When these conditions are met, the AS path length is used as the tie breaker in the best path algorithm. When two or more routes exist to reach a particular prefix, BGP prefers the route with the shortest AS Path length.

If you are an enterprise that has multihoming to one or more service providers, you might prefer that incoming traffic take a particular path to reach your network. Perhaps you have two connections, but one costs less than the other. Or you might have one fast connection and another, much slower connection that you only want to use as a backup if your primary connection is down. AS path prepending is an easy method that you can use to influence inbound routing to your AS.

In Junos OS Release 9.1 and later, you can specify 4-byte AS numbers as defined in RFC 4893, *BGP Support for Four-octet AS Number Space*, as well as the 2-byte AS numbers that are supported in earlier releases of the Junos OS. In plain-number format, you can configure a value in the range from 1 through 4,294,967,295.

If you have a router that does not support 4-byte AS numbers in the AS path, the prepended AS number displayed in the AS path is the AS_TRANS number, AS 23456. To display the route details, use the *show route* command.

Understanding BGP Path Selection

Example: Configuring a Routing Policy to Prepend the AS Path

IN THIS SECTION

- [Requirements | 418](#)
- [Overview | 418](#)
- [Configuration | 418](#)
- [Verification | 420](#)

This example shows how to configure a routing policy to prepend the AS path.

Requirements

Before you begin, make sure your router interfaces and protocols are correctly configured.

Overview

In this example, you create a routing policy called `prependpolicy1` and a term called `prependterm1`. The routing policy prepends the AS numbers `1 1 1 1` to routes that are greater than or equal to `172.16.0.0/12`, `192.168.0.0/16`, and `10.0.0.0/8`. The policy is applied as an import policy to all BGP routes and is evaluated when routes are imported to the routing table.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
set policy-options policy-statement prependpolicy1 term prependterm1 from route-filter 172.16.0.0/12 orlonger
set policy-options policy-statement prependpolicy1 term prependterm1 from route-filter 192.168.0.0/16
  orlonger
set policy-options policy-statement prependpolicy1 term prependterm1 from route-filter 10.0.0.0/8 orlonger
set policy-options policy-statement prependpolicy1 term prependterm1 then as-path-prepend "1 1 1 1"
set policy-options policy-statement prependpolicy1 term prependterm1 from protocol direct
set protocols bgp import prependpolicy1
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To create a routing policy that prepends AS numbers to multiple routes:

1. Create the routing policy.

```
[edit]
user@host# edit policy-options policy-statement prependpolicy1
```

2. Create the routing term.

```
[edit policy-options policy-statement prependpolicy1]
user@host# edit term prependterm1
```

3. Specify the routes to prepend with AS numbers.

```
[edit policy-options policy-statement prependpolicy1 term prependterm1]
user@host# set from route-filter 172.16.0.0/12 orlonger
user@host# set from route-filter 192.168.0.0/16 orlonger
user@host# set from route-filter 10.0.0.0/8 orlonger
```

4. Specify the AS numbers to prepend.

```
[edit policy-options policy-statement prependpolicy1 term prependterm1]
user@host# set then as-path-prepend "1 1 1"
```

NOTE: If you enter multiple numbers, you must separate each number with a space. Enclose the numbers in double quotation marks.

5. Apply the policy as an import policy for all BGP routes.

```
[edit]
user@host# set protocols bgp import prependpolicy1
```

NOTE: You can refer to the same routing policy one or more times in the same or different import statement.

Results

Confirm your configuration by entering the **show policy-options** and **show protocols bgp** commands from configuration mode. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
user@host# show policy-options
```

```

policy-statement prependpolicy1 {
  term prependterm1 {
    from {
      route-filter 172.16.0.0/12 orlonger;
      route-filter 192.168.0.0/16 orlonger;
      route-filter 10.0.0.0/8 orlonger;
    }
    then as-path-prepend "1 1 1 1";
  }
}

```

```

user@host# show protocols bgp
import prependpolicy1;

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

IN THIS SECTION

- [Verifying the AS Numbers to Prepend | 420](#)
- [Verifying the Routing Policy | 420](#)

To confirm that the configuration is working properly, perform these tasks:

Verifying the AS Numbers to Prepend

Purpose

Verify that the policy and term are configured on the device and that the appropriate routes are specified to prepend with AS numbers.

Action

From operational mode, enter the **show policy-options** command.

Verifying the Routing Policy

Purpose

Verify that the routing policy is applied to the routing protocol.

Action

From operational mode, enter the **show protocols bgp** command.

Understanding Adding AS Numbers to BGP AS Paths

You can expand or add one or more AS numbers to an AS sequence. The AS numbers are added before the local AS number has been added to the path. Expanding an AS path makes a shorter AS path look longer and therefore less preferable to BGP. The last AS number in the existing path is extracted and prepended n times, where n is a number from 1 through 32. This is similar to the AS path prepend action, except that the AS path expand action adds an arbitrary sequence of AS numbers.

For example, from AS 1 there are two equal paths (through AS 2 and AS 3) to reach AS 4. You might want packets from certain sources to use the path through AS 2. Therefore, you must make the path through AS 3 less preferable so that BGP chooses the path through AS 2. In AS 1, you can expand multiple AS numbers.

```
[edit]
policy-options {
  policy-statement as-path-expand {
    term expand {
      from {
        route-filter 192.168.0.0/16 orlonger;
        route-filter 172.16.0.0/12 orlonger;
        route-filter 10.0.0.0/8 orlonger;
      }
      then as-path-expand last-as count 4;
    }
  }
}
```

For routes from AS 2, this makes the route look like 1 2 2 2 2 2 when advertised, where 1 is from AS 1, the 2 from AS 2 is prepended four times, and the final 2 is the original 2 received from the neighbor router.

[Example: Advertising Multiple Paths in BGP | 422](#)

Example: Advertising Multiple Paths in BGP

IN THIS SECTION

- [Requirements | 422](#)
- [Overview | 422](#)
- [Configuration | 424](#)
- [Verification | 449](#)

In this example, BGP routers are configured to advertise multiple paths instead of advertising only the active path. Advertising multiple paths in BGP is specified in RFC 7911, *Advertisement of Multiple Paths in BGP*.

Requirements

This example uses the following hardware and software components:

- Eight BGP-enabled devices.
- Five of the BGP-enabled devices do not necessarily need to be routers. For example, they can be EX Series Ethernet Switches.
- Three of the BGP-enabled devices are configured to send multiple paths or receive multiple paths (or both send and receive multiple paths). These three BGP-enabled devices must be M Series Multiservice Edge Routers, MX Series 5G Universal Routing Platforms, or T Series Core Routers.
- The three routers must be running Junos OS Release 11.4 or later.

Overview

The following statements are used for configuring multiple paths to a destination:

```
[edit protocols bgp group group-name family family]  
add-path {  
    receive;  
    send {
```

```

include-backup-path include-backup-path;
multipath;
path-count path-count;
path-selection-mode {
    (all-paths | equal-cost-paths);
}
prefix-policy [ policy-names ... ];
}
}

```

In this example, Router R5, Router R6, and Router R7 redistribute static routes into BGP. Router R1 and Router R4 are route reflectors. Router R2 and Router R3 are clients to Route Reflector R1. Router R8 is a client to Route Reflector R4.

Route reflection is optional when multiple-path advertisement is enabled in BGP.

With the **add-path send path-count 6** configuration, Router R1 is configured to send up to six paths (per destination) to Router R4.

With the **add-path receive** configuration, Router R4 is configured to receive multiple paths from Router R1.

With the **add-path send path-count 6** configuration, Router R4 is configured to send up to six paths to Router R8.

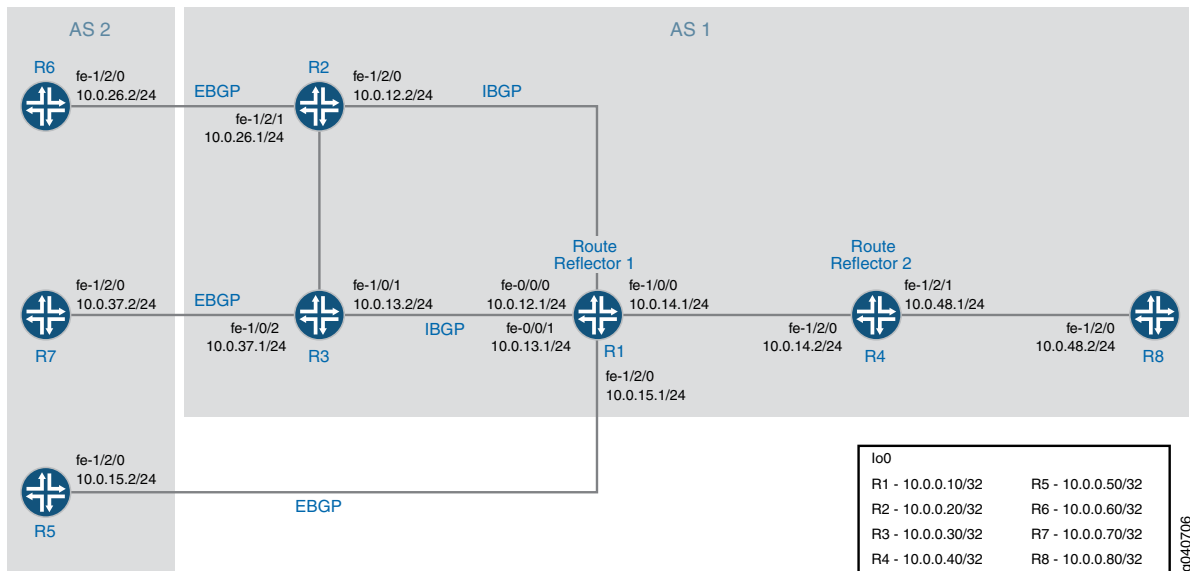

With the **add-path receive** configuration, Router R8 is configured to receive multiple paths from Router R4.

The **add-path send prefix-policy allow_199** policy configuration (along with the corresponding route filter) limits Router R4 to sending multiple paths for only the 172.16.199.1/32 route.

Topology Diagram

[Figure 31 on page 424](#) shows the topology used in this example.

Configuring Router R1

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure Router R1:

1. Configure the interfaces to Router R2, Router R3, Router R4, and Router R5, and configure the loopback (lo0) interface.

```

[edit interfaces]
user@R1# set fe-0/0/0 unit 12 family inet address 10.0.12.1/24
user@R1# set fe-0/0/1 unit 13 family inet address 10.0.13.1/24
user@R1# set fe-1/0/0 unit 14 family inet address 10.0.14.1/24
user@R1# set fe-1/2/0 unit 15 family inet address 10.0.15.1/24
user@R1# set lo0 unit 10 family inet address 10.0.0.10/32

```

2. Configure BGP on the interfaces, and configure IBGP route reflection.

```

[edit protocols bgp]

```

```

user@R1# set group rr type internal
user@R1# set group rr local-address 10.0.0.10
user@R1# set group rr cluster 10.0.0.10
user@R1# set group rr neighbor 10.0.0.20
user@R1# set group rr neighbor 10.0.0.30
user@R1# set group rr_rr type internal
user@R1# set group rr_rr local-address 10.0.0.10
user@R1# set group e1 type external
user@R1# set group e1 neighbor 10.0.15.2 local-address 10.0.15.1
user@R1# set group e1 neighbor 10.0.15.2 peer-as 2

```

3. Configure Router R1 to send up to six paths to its neighbor, Router R4.

The destination of the paths can be any destination that Router R1 can reach through multiple paths.

```

[edit protocols bgp]
user@R1# set group rr_rr neighbor 10.0.0.40 family inet unicast add-path send path-count 6

```

4. Configure OSPF on the interfaces.

```

[edit protocols ospf]
user@R1# set area 0.0.0.0 interface lo0.10 passive
user@R1# set area 0.0.0.0 interface fe-0/0/0.12
user@R1# set area 0.0.0.0 interface fe-0/0/1.13
user@R1# set area 0.0.0.0 interface fe-1/0/0.14
user@R1# set area 0.0.0.0 interface fe-1/2/0.15

```

5. Configure the router ID and the autonomous system number.

```

[edit routing-options]
user@R1# set router-id 10.0.0.10
user@R1# set autonomous-system 1

```

6. If you are done configuring the device, commit the configuration.

```

user@R1# commit

```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R1# show interfaces
fe-0/0/0 {
  unit 12 {
    family inet {
      address 10.0.12.1/24;
    }
  }
}
fe-0/0/1 {

    family inet {
      address 10.0.15.1/24;
    }
  }
}
lo0 {
  unit 10 {
    family inet {
      address 10.0.0.10/32;
    }
  }
}
```

```
user@R1# show protocols
bgp {
  group rr {
```

```

    type internal;
    local-address 10.0.0.10;
    cluster 10.0.0.10;
    neighbor 10.0.0.20;
    neighbor 10.0.0.30;
  }
  group e1 {
    type external;
    neighbor 10.0.15.2 {
      local-address 10.0.15.1;
      peer-as 2;
    }
  }
  group rr_rr {
    type internal;
    local-address 10.0.0.10;
    neighbor 10.0.0.40 {
      family inet {
        unicast {
          add-path {
            send {
              path-count 6;
            }
          }
        }
      }
    }
  }
}
ospf {
  area 0.0.0.0 {
    interface lo0.10 {
      passive;
    }
    interface fe-0/0/0.12;
    interface fe-0/0/1.13;
    interface fe-1/0/0.14;
    interface fe-1/2/0.15;
  }
}

```

```

user@R1# show routing-options
router-id 10.0.0.10;
autonomous-system 1;

```

Configuring Router R2

Step-by-Step Procedure

To configure Router R2:

1. Configure the loopback (lo0) interface and the interfaces to Router R6 and Router R1.

```
[edit interfaces]
user@R2# set fe-1/2/0 unit 21 family inet address 10.0.12.2/24
user@R2# set fe-1/2/1 unit 26 family inet address 10.0.26.1/24
user@R2# set lo0 unit 20 family inet address 10.0.0.20/32
```

2. Configure BGP and OSPF on Router R2's interfaces.

```
[edit protocols]
user@R2# set bgp group rr type internal
user@R2# set bgp group rr local-address 10.0.0.20
user@R2# set bgp group e1 type external
user@R2# set bgp group e1 neighbor 10.0.26.2 peer-as 2
user@R2# set ospf area 0.0.0.0 interface lo0.20 passive
user@R2# set ospf area 0.0.0.0 interface fe-1/2/0.21
user@R2# set ospf area 0.0.0.0 interface fe-1/2/1.28
```

3. For routes sent from Router R2 to Router R1, advertise Router R2 as the next hop, because Router R1 does not have a route to Router R6's address on the 10.0.26.0/24 network.

```
[edit]
user@R2# set policy-options policy-statement set_nh_self then next-hop self
user@R2# set protocols bgp group rr neighbor 10.0.0.10 export set_nh_self
```

4. Configure the autonomous system number.

```
[edit]
user@R2# set routing-options autonomous-system 1
```

5. If you are done configuring the device, commit the configuration.

```
user@R2# commit
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R2# show interfaces
fe-1/2/0 {
  unit 21 {
    family inet {
      address 10.0.12.2/24;
    }
  }
}
fe-1/2/1 {
  unit 26 {
    family inet {
      address 10.0.26.1/24;
    }
  }
}
lo0 {
  unit 20 {
    family inet {
      address 10.0.0.20/32;
    }
  }
}
```

```
user@R2# show protocols
bgp {
  group rr {
    type internal;
    local-address 10.0.0.20;
    neighbor 10.0.0.10 {
      export set_nh_self;
    }
  }
  group e1 {
    type external;
    neighbor 10.0.26.2 {
      peer-as 2;
    }
  }
}
```

```

}
ospf {
  area 0.0.0.0 {
    interface lo0.20 {
      passive;
    }
    interface fe-1/2/0.21;
    interface fe-1/2/1.28;
  }
}

```

```

user@R2# show policy-options
policy-statement set_nh_self {
  then {
    next-hop self;
  }
}

```

```

user@R2# show routing-options
autonomous-system 1;

```

Configuring Router R3

Step-by-Step Procedure

To configure Router R3:

1. Configure the loopback (lo0) interface and the interfaces to Router R7 and Router R1.

```

[edit interfaces]
user@R3# set fe-1/0/1 unit 31 family inet address 10.0.13.2/24
user@R3# set fe-1/0/2 unit 37 family inet address 10.0.37.1/24
user@R3# set lo0 unit 30 family inet address 10.0.0.30/32

```

2. Configure BGP and OSPF on Router R3's interfaces.

```

[edit protocols]
user@R3# set bgp group rr type internal
user@R3# set bgp group rr local-address 10.0.0.30
user@R3# set bgp group e1 type external
user@R3# set bgp group e1 neighbor 10.0.37.2 peer-as 2
user@R3# set ospf area 0.0.0.0 interface lo0.30 passive

```

```
user@R3# set ospf area 0.0.0.0 interface fe-1/0/1.31
user@R3# set ospf area 0.0.0.0 interface fe-1/0/2.37
```

3. For routes sent from Router R3 to Router R1, advertise Router R3 as the next hop, because Router R1 does not have a route to Router R7's address on the 10.0.37.0/24 network.

```
[edit]
user@R3# set policy-options policy-statement set_nh_self then next-hop self
user@R3# set protocols bgp group rr neighbor 10.0.0.10 export set_nh_self
```

4. Configure the autonomous system number.

```
[edit]
user@R3# set routing-options autonomous-system 1
```

5. If you are done configuring the device, commit the configuration.

```
user@R3# commit
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R3# show interfaces
fe-1/0/1 {
  unit 31 {
    family inet {
      address 10.0.13.2/24;
    }
  }
}
fe-1/0/2 {
  unit 37 {
    family inet {
      address 10.0.37.1/24;
    }
  }
}
```

```

lo0 {
  unit 30 {
    family inet {
      address 10.0.0.30/32;
    }
  }
}

```

```

user@R3# show protocols

```

Configuring Router R4

Step-by-Step Procedure

To configure Router R4:

1. Configure the interfaces to Router R1 and Router R8, and configure the loopback (lo0) interface.

```
[edit interfaces]
user@R4# set fe-1/2/0 unit 41 family inet address 10.0.14.2/24
user@R4# set fe-1/2/1 unit 48 family inet address 10.0.48.1/24
user@R4# set lo0 unit 40 family inet address 10.0.0.40/32
```

2. Configure BGP on the interfaces, and configure IBGP route reflection.

```
[edit protocols bgp]
user@R4# set group rr type internal
user@R4# set group rr local-address 10.0.0.40
user@R4# set group rr neighbor 10.0.0.10
user@R4# set group rr_client type internal
user@R4# set group rr_client local-address 10.0.0.40
user@R4# set group rr_client cluster 10.0.0.40
```

3. Configure Router R4 to send up to six paths to its neighbor, Router R8.

The destination of the paths can be any destination that Router R4 can reach through multiple paths.

```
[edit protocols bgp]
user@R4# set group rr_client neighbor 10.0.0.80 family inet unicast add-path send path-count 6
```

4. Configure Router R4 to receive multiple paths from its neighbor, Router R1.

The destination of the paths can be any destination that Router R1 can reach through multiple paths.

```
[edit protocols bgp group rr family inet unicast]
user@R4# set add-path receive
```

5. Configure OSPF on the interfaces.

```
[edit protocols ospf area 0.0.0.0]
user@R4# set interface fe-1/2/0.41
```

```
user@R4# set interface lo0.40 passive
user@R4# set interface fe-1/2/1.48
```

6. Configure a policy that allows Router R4 to send Router R8 multiple paths to the 172.16.199.1/32 route.

- Router R4 receives multiple paths for the 172.16.198.1/32 route and the 172.16.199.1/32 route. However, because of this policy, Router R4 only sends multiple paths for the 172.16.199.1/32 route.

```
[edit protocols bgp group rr_client neighbor 10.0.0.80 family inet unicast]
user@R4# set add-path send prefix-policy allow_199
[edit policy-options policy-statement allow_199]
user@R4# set from route-filter 172.16.199.1/32 exact
user@R4# set then accept
```

- Router R4 can also be configured to send up-to 20 BGP **add-path** routes for a subset of *add-path advertised prefixes*.

```
[edit policy-options policy-statement allow_199]
user@R4# set term match_199 from prefix-list match_199
user@R4# set then add-path send-count 20
```

7. Configure the autonomous system number.

```
[edit routing-options]
user@R4# set autonomous-system 1
```

8. If you are done configuring the device, commit the configuration.

```
user@R4# commit
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R4# show interfaces
fe-1/2/0 {
  unit 41 {
    family inet {
```

```

        address 10.0.14.2/24;
    }
}

Configuring Router R5

Step-by-Step Procedure

To configure Router R5:

1. Configure the loopback (lo0) interface and the interface to Router R1.

```

[edit interfaces]
user@R5# set fe-1/2/0 unit 51 family inet address 10.0.15.2/24
user@R5# set lo0 unit 50 family inet address 10.0.0.50/32

```

2. Configure BGP on Router R5's interface.

```
[edit protocols bgp group e1]
user@R5# set type external
user@R5# set neighbor 10.0.15.1 peer-as 1
```

3. Create static routes for redistribution into BGP.

```
[edit routing-options]
user@R5# set static route 172.16.199.1/32 reject
user@R5# set static route 172.16.198.1/32 reject
```

4. Redistribute static and direct routes into BGP.

```
[edit protocols bgp group e1 neighbor 10.0.15.1]
user@R5# set export s2b
[edit policy-options policy-statement s2b]
user@R5# set from protocol static
user@R5# set from protocol direct
user@R5# set then as-path-expand 2
user@R5# set then accept
```

5. Configure the autonomous system number.

```
[edit routing-options]
user@R5# set autonomous-system 2
```

6. If you are done configuring the device, commit the configuration.

```
user@R5# commit
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R5# show interfaces
fe-1/2/0 {
```

```

    unit 51 {
      family inet {
        address 10.0.15.2/24;
      }
    }
  }
  lo0 {
    unit 50 {
      family inet {
        address 10.0.0.50/32;
      }
    }
  }
}

```

```

user@R5# show protocols

```

Configuring Router R6

Step-by-Step Procedure

To configure Router R6:

1. Configure the loopback (lo0) interface and the interface to Router R2.

```
[edit interfaces]
user@R6# set fe-1/2/0 unit 62 family inet address 10.0.26.2/24
user@R6# set lo0 unit 60 family inet address 10.0.0.60/32
```

2. Configure BGP on Router R6's interface.

```
[edit protocols]
user@R6# set bgp group e1 type external
user@R6# set bgp group e1 neighbor 10.0.26.1 peer-as 1
```

3. Create static routes for redistribution into BGP.

```
[edit]
user@R6# set routing-options static route 172.16.199.1/32 reject
user@R6# set routing-options static route 172.16.198.1/32 reject
```

4. Redistribute static and direct routes from Router R6's routing table into BGP.

```
[edit protocols bgp group e1 neighbor 10.0.26.1]
user@R6# set export s2b
[edit policy-options policy-statement s2b]
user@R6# set from protocol static
user@R6# set from protocol direct
user@R6# set then accept
```

5. Configure the autonomous system number.

```
[edit routing-options]
user@R6# set autonomous-system 2
```

6. If you are done configuring the device, commit the configuration.

```
user@R6# commit
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R6# show interfaces
fe-1/2/0 {
  unit 62 {
    family inet {
      address 10.0.26.2/24;
    }
  }
}
lo0 {
  unit 60 {
    family inet {
      address 10.0.0.60/32;
    }
  }
}
```

```
user@R6# show protocols
bgp {
  group e1 {
    type external;
    neighbor 10.0.26.1 {
      export s2b;
      peer-as 1;
    }
  }
}
```

```

}
autonomous-system 2;

```

Configuring Router R7

Step-by-Step Procedure

To configure Router R7:

1. Configure the loopback (lo0) interface and the interface to Router R3.

```

[edit interfaces]
user@R7# set fe-1/2/0 unit 73 family inet address 10.0.37.2/24
user@R7# set lo0 unit 70 family inet address 10.0.0.70/32

```

2. Configure BGP on Router R7's interface.

```

[edit protocols bgp group e1]
user@R7# set type external
user@R7# set neighbor 10.0.37.1 peer-as 1

```

3. Create a static route for redistribution into BGP.

```

[edit]
user@R7# set routing-options static route 172.16.199.1/32 reject

```

4. Redistribute static and direct routes from Router R7's routing table into BGP.

```

[edit protocols bgp group e1 neighbor 10.0.37.1]
user@R7# set export s2b
[edit policy-options policy-statement s2b]
user@R7# set from protocol static
user@R7# set from protocol direct
user@R7# set then accept

```

5. Configure the autonomous system number.

```
[edit routing-options]
user@R7# set autonomous-system 2
```

6. If you are done configuring the device, commit the configuration.

```
user@R7# commit
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R7# show interfaces
fe-1/2/0 {
  unit 73 {
    family inet {
      address 10.0.37.2/24;
    }
  }
}
lo0 {

  route 172.16.199.1/32 reject;
}
autonomous-system 2;

```

Configuring Router R8

Step-by-Step Procedure

To configure Router R8:

1. Configure the loopback (lo0) interface and the interface to Router R4.

```

[edit interfaces]
user@R8# set fe-1/2/0 unit 84 family inet address 10.0.48.2/24
user@R8# set lo0 unit 80 family inet address 10.0.0.80/32

```

2. Configure BGP and OSPF on Router R8's interface.

```

[edit protocols]
user@R8# set bgp group rr type internal
user@R8# set bgp group rr local-address 10.0.0.80
user@R8# set ospf area 0.0.0.0 interface lo0.80 passive
user@R8# set ospf area 0.0.0.0 interface fe-1/2/0.84

```

3. Configure Router R8 to receive multiple paths from its neighbor, Router R4.

The destination of the paths can be any destination that Router R4 can reach through multiple paths.

```

[edit protocols]
user@R8# set bgp group rr neighbor 10.0.0.40 family inet unicast add-path receive

```

4. Configure the autonomous system number.

```
[edit]
user@R8# set routing-options autonomous-system 1
```

5. If you are done configuring the device, commit the configuration.

```
user@R8# commit
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R8# show interfaces
fe-1/2/0 {
  unit 84 {
    family inet {
      address 10.0.48.2/24;
    }
  }
}
lo0 {
  unit 80 {
    family inet {
      address 10.0.0.80/32;
    }
  }
}
```

```
user@R8# show protocols
bgp {
  group rr {
    type internal;
    local-address 10.0.0.80;
    neighbor 10.0.0.40 {
      family inet {
        unicast {
          add-path {
            receive;
```

```

    }
  }
}
}
}
}
ospf {
  area 0.0.0.0 {
    interface lo0.80 {

    }
    interface fe-1/2/0.84;
  }
}

```

```

user@R8# show routing-options
autonomous-system 1;

```

Verification

IN THIS SECTION

- [Verifying That the BGP Peers Have the Ability to Send and Receive Multiple Paths | 449](#)
- [Verifying That Router R1 Is Advertising Multiple Paths | 450](#)
- [Verifying That Router R4 Is Receiving and Advertising Multiple Paths | 451](#)
- [Verifying That Router R8 Is Receiving Multiple Paths | 452](#)
- [Checking the Path ID | 453](#)

Confirm that the configuration is working properly.

Verifying That the BGP Peers Have the Ability to Send and Receive Multiple Paths

Purpose

Make sure that one or both of the following strings appear in the output of the **show bgp neighbor** command:

- NLRI's for which peer can receive multiple paths: inet-unicast
- NLRI's for which peer can send multiple paths: inet-unicast

Action

user@R1> **show bgp neighbor 10.0.0.40**

```
Peer: 10.0.0.40+179 AS 1      Local: 10.0.0.10+64227 AS 1
  Type: Internal    State: Established    Flags: <Sync>
... NLRI's for which peer can receive multiple paths: inet-unicast
...
```

user@R4> **show bgp neighbor 10.0.0.10**

```
Peer: 10.0.0.10+64227 AS 1    Local: 10.0.0.40+179 AS 1
  Type: Internal    State: Established    Flags: <Sync>
...
  NLRI's for which peer can send multiple paths: inet-unicast
...
```

user@R4> **show bgp neighbor 10.0.0.80**

```
Peer: 10.0.0.80+55416 AS 1    Local: 10.0.0.40+179 AS 1
  Type: Internal    State: Established (route reflector client)Flags: <Sync>
'''
  NLRI's for which peer can receive multiple paths: inet-unicast
...
```

user@R8> **show bgp neighbor 10.0.0.40**

```
Peer: 10.0.0.40+179 AS 1      Local: 10.0.0.80+55416 AS 1
  Type: Internal    State: Established    Flags: <Sync>
...
  NLRI's for which peer can send multiple paths: inet-unicast
...
```

Verifying That Router R1 Is Advertising Multiple Paths

Purpose

Make sure that multiple paths to the 172.16.198.1/32 destination and multiple paths to the 172.16.199.1/32 destination are advertised to Router R4.

Action

```
user@R1> show route advertising-protocol bgp 10.0.0.40
```

```
inet.0: 21 destinations, 25 routes (21 active, 0 holddown, 0 hidden)
  Prefix            Nexthop          MED      Lclpref   AS path
* 10.0.0.50/32      10.0.15.2              100       2 2 I
* 10.0.0.60/32      10.0.0.20              100       2 I
* 10.0.0.70/32      10.0.0.30              100       2 I
* 172.16.198.1/32   10.0.0.20              100       2 I
                   10.0.15.2              100       2 2 I
* 172.16.199.1/32   10.0.0.20              100       2 I
                   10.0.0.30              100       2 I
                   10.0.15.2              100       2 2 I
* 172.16.200.0/30   10.0.0.20              100       2 I
```

Meaning

When you see one prefix and more than one next hop, it means that multiple paths are advertised to Router R4.

Verifying That Router R4 Is Receiving and Advertising Multiple Paths

Purpose

Make sure that multiple paths to the 172.16.199.1/32 destination are received from Router R1 and advertised to Router R8. Make sure that multiple paths to the 172.16.198.1/32 destination are received from Router R1, but only one path to this destination is advertised to Router R8.

Action

```
user@R4> show route receive-protocol bgp 10.0.0.10
```

```
inet.0: 19 destinations, 22 routes (19 active, 0 holddown, 0 hidden)
   Prefix                                Nexthop                          MED    Lclpref    AS path
* 10.0.0.50/32                         10.0.15.2                        100          2 2 I
* 10.0.0.60/32                         10.0.0.20                       100          2 I
* 10.0.0.70/32                         10.0.0.30                       100          2 I
* 172.16.198.1/32                     10.0.0.20                        100          2 I
                                     10.0.15.2                        100          2 2 I
* 172.16.199.1/32                     10.0.0.20                        100          2 I
                                     10.0.0.30                       100          2 I
                                     10.0.15.2                       100          2 2 I
```

```
* 172.16.200.0/30          10.0.0.20          100          2 I

                        10.0.0.30        100        2 I
                        10.0.15.2        100        2 2 I
* 172.16.200.0/30       10.0.0.20        100        2 I
```

Meaning

The **show route receive-protocol** command shows that Router R4 receives two paths to the 172.16.198.1/32 destination and three paths to the 172.16.199.1/32 destination. The **show route advertising-protocol** command shows that Router R4 advertises only one path to the 172.16.198.1/32 destination and advertises all three paths to the 172.16.199.1/32 destination.

Because of the prefix policy that is applied to Router R4, Router R4 does not advertise multiple paths to the 172.16.198.1/32 destination. Router R4 advertises only one path to the 172.16.198.1/32 destination even though it receives multiple paths to this destination.

Verifying That Router R8 Is Receiving Multiple Paths

Purpose

Make sure that Router R8 receives multiple paths to the 172.16.199.1/32 destination through Router R4. Make sure that Router R8 receives only one path to the 172.16.198.1/32 destination through Router R4.

Action

user@R8> **show route receive-protocol bgp 10.0.0.40**

```
inet.0: 18 destinations, 20 routes (18 active, 0 holddown, 0 hidden)
  Prefix                Nexthop          MED      Lclpref    AS path
* 10.0.0.50/32          10.0.15.2        100        2 2 I
* 10.0.0.60/32          10.0.0.20        100        2 I
* 10.0.0.70/32          10.0.0.30        100        2 I
```

```

* 172.16.198.1/32          10.0.0.20          100          2 I
* 172.16.199.1/32          10.0.0.20          100          2 I
                           10.0.0.30          100          2 I
                           10.0.15.2          100          2 2 I
* 200.1.1.0/30             10.0.0.20          100          2 I

```

Checking the Path ID

Purpose

On the downstream devices, Router R4 and Router R8, verify that a path ID uniquely identifies the path. Look for the **Addpath Path ID:** string.

Action

user@R4> **show route 172.16.199.1/32 detail**

```

Understanding BGP Communities, Extended Communities, and Large Communities as Routing Policy Match Conditions

A *BGP community* is a group of destinations that share a common property. Community information is included as a path attribute in BGP update messages. This information identifies community members and enables you to perform actions on a group without having to elaborate upon each member. You can use community and extended communities attributes to trigger routing decisions, such as acceptance, rejection, preference, or redistribution.

You can assign community tags to non-BGP routes through configuration (for static, aggregate, or generated routes) or an import routing policy. These tags can then be matched when BGP exports the routes.

A community value is a 32-bit field that is divided into two main sections. The first 16 bits of the value encode the AS number of the network that originated the community, while the last 16 bits carry a unique number assigned by the AS. This system attempts to guarantee a globally unique set of community values for each AS in the Internet. Junos OS uses a notation of *as-number:community-value*, where each value is a decimal number. The AS values of 0 and 65,535 are reserved, as are all of the community values within those AS numbers. Each community, or set of communities, is given a name within the **[edit policy-options]** configuration hierarchy. The name of the community uniquely identifies it to the routing device and serves as the method by which routes are categorized. For example, a route with a community value of 64510:1111

might belong to the community named **AS64510-routes**. The community name is also used within a routing policy as a match criterion or as an action. The command syntax for creating a community is: `policy-options community name members [community-ids]`. The *community-ids* are either a single community value or multiple community values. When more than one value is assigned to a community name, the routing device interprets this as a logical AND of the community values. In other words, a route must have all of the configured values before being assigned the community name.

The regular community attribute is four octets. Networking enhancements, such as VPNs, have functionality requirements that can be satisfied by an attribute such as a community. However, the 4-octet community value does not provide enough expansion and flexibility to accommodate VPN requirements. This leads to the creation of extended communities. An extended community is an 8-octet value that is also divided into two main sections. The first 2 octets of the community encode a type field while the last 6 octets carry a unique set of data in a format defined by the type field. Extended communities provide a larger range for grouping or categorizing communities.

The BGP extended communities attribute format has three fields: ***type:administrator:assigned-number***. The routing device expects you to use the words **target** or **origin** to represent the type field. The administrator field uses a decimal number for the AS or an IPv4 address, while the assigned number field expects a decimal number no larger than the size of the field (65,535 for 2 octets or 4,294,967,295 for 4 octets).

When specifying community IDs for standard and extended community attributes, you can use UNIX-style regular expressions. The only exception is for VPN import policies (**vrf-import**), which do not support regular expressions for the extended communities attribute.

Regular BGP communities attributes are a variable length attribute consisting of a set of one or more 4-byte values that was split into 16 bit values. The most significant word is interpreted as an AS number and least significant word is a locally defined value assigned by the operator of the AS. Since the adoption of 4-byte ASNs, the 4-byte BGP regular community and 6-byte BGP extended community can no longer support BGP community attributes. Operators often encode AS number in the local portion of the BGP community that means that sometimes the format of the community is ASN:ASN. With the 4-byte ASN, you need 8-bytes to encode it. Although BGP extended community permits a 4-byte AS to be encoded as the global administrator field, the local administrator field has only 2-byte of available space. Thus, 6-byte extended community attribute is also unsuitable. To overcome this, Junos OS allows you to configure optional transitive path attribute - a 12-byte BGP large community that provides the most significant 4-byte value to encode autonomous system number as the global administrator and the remaining two 4-byte assigned numbers to encode the local values as defined in RFC 8092. You can configure BGP large community at the `[edit policy-options community community-name members]` and `[edit routing-options static route ip-address community]` hierarchy levels. The BGP large community attributes format has four fields: ***large:global administrator:assigned number:assigned number***.

NOTE: The length of the BGP large communities attribute value should be a non-zero multiple of 12.

Understanding How to Define BGP Communities and Extended Communities

IN THIS SECTION

- [Defining BGP Communities for Use in Routing Policy Match Conditions | 459](#)
- [Defining BGP Extended Communities for Use in Routing Policy Match Conditions | 463](#)

To use a BGP community or extended community as a routing policy match condition, you define the community as described in the following sections:

Defining BGP Communities for Use in Routing Policy Match Conditions

To create a named BGP community and define the community members, include the **community** statement:

```
[edit policy-options]
community name {
  invert-match;
  members [ community-ids ];
}
```

name identifies the community. It can contain letters, numbers, and hyphens (-) and can be up to 255 characters long. To include spaces in the name, enclose the entire name in quotation marks (" ").

community-ids identifies one or more members of the community. Each community ID consists of two components, which you specify in the following format:

```
as-number:community-value;
```

- *as-number*—AS number of the community member. It can be a value from 0 through 65,535. You can use the following notation in specifying the AS number:
 - String of digits.
 - Asterisk (*)—A wildcard character that matches all AS numbers. (In the definition of the community attribute, the asterisk also functions as described in [Table 23 on page 461](#).)
 - Period (.)—A wildcard character that matches any single digit in an AS number.
 - Group of AS numbers—A single AS number or a group of AS numbers enclosed in parentheses. Grouping the numbers in this way allows you to perform a common operation on the group as a whole and to give the group precedence. The grouped numbers can themselves include regular expression operators. For more information about regular expressions, see “Using UNIX Regular Expressions in Community Names” on page 460.
- *community-value*—Identifier of the community member. It can be a number from 0 through 65,535. You can use the following notation in specifying the community ID:
 - String of digits.
 - Asterisk (*)—A wildcard character that matches all community values. (In the definition of the community attribute, the asterisk also functions as described in [Table 23 on page 461](#).)
 - Period (.)—A wildcard character that matches any single digit in a community value number.
 - Group of community value numbers—A single community value number or a group of community value numbers enclosed in parentheses. Grouping the regular expression in this way allows you to perform a common operation on the group as a whole and to give the group precedence. The grouped path can itself include regular expression operators.

You can also include one of the following well-known community names (defined in RFC 1997, *BGP Communities Attribute*) in the *community-ids* option for the **members** statement:

- no-advertise—Routes in this community name must not be advertised to other BGP peers.
- no-export—Routes in this community must not be advertised outside a BGP confederation boundary. A stand alone autonomous system that is not part of a confederation should be considered a confederation itself.
- no-export-subconfed—Routes in this community must not be advertised to external BGP peers, including peers in other members' ASs inside a BGP confederation.

Using UNIX Regular Expressions in Community Names

When specifying the members of a named BGP community (in the **members** [*community-ids*] statement), you can use UNIX-style regular expressions to specify the AS number and the member identifier. A regular expression consists of two components, which you specify in the following format:

```
term operator;
```

term identifies the string to match.

operator specifies how the term must match. [Table 23 on page 461](#) lists the regular expression operators supported in community IDs. You place an operator immediately after *term* with no intervening space, except for the pipe (|) and dash (-) operators, which you place between two terms, and parentheses, with which you enclose terms. [Table 24 on page 462](#) shows examples of how to define **community-ids** using community regular expressions. The operator is optional.

Community regular expressions are identical to the UNIX regular expressions. Both implement the extended (or modern) regular expressions as defined in POSIX 1003.2.

Community regular expressions evaluate the string specified in *term* on a character-by-character basis. For example, if you specify **1234:5678** as *term*, the regular expressions see nine discrete characters, including the colon (:), instead of two sets of numbers (**1234** and **5678**) separated by a colon.

NOTE: In Junos OS Release 9.1 and later, you can specify 4-byte AS numbers as defined in RFC 4893, *BGP Support for Four-octet AS Number Space*, as well as the 2-byte AS numbers that are supported in earlier releases of the Junos OS.

Table 23: Community Attribute Regular Expression Operators

Operator	Match Definition
{m,n}	At least <i>m</i> and at most <i>n</i> repetitions of <i>term</i> . Both <i>m</i> and <i>n</i> must be positive integers, and <i>m</i> must be smaller than <i>n</i> .
{m}	Exactly <i>m</i> repetitions of <i>term</i> . <i>m</i> must be a positive integer.
{m,}	<i>m</i> or more repetitions of <i>term</i> . <i>m</i> must be a positive integer.
*	Zero or more repetitions of <i>term</i> . This is equivalent to {0,} .
+	One or more repetitions of <i>term</i> . This is equivalent to {1,} .
?	Zero or one repetition of <i>term</i> . This is equivalent to {0,1} .
 	One of the two terms on either side of the pipe.

Table 23: Community Attribute Regular Expression Operators (*continued*)

Operator	Match Definition
-	Between a starting and ending range, inclusive.
^	Character at the beginning of a community attribute regular expression.
\$	Character at the end of a community attribute regular expression.
[]	Set of characters. One character from the set can match. To specify the start and end of a range, use a hyphen (-). To specify a set of characters that do not match, use the caret (^) as the first character after the opening square bracket ([].
()	Group of terms that are enclosed in parentheses. If enclosed in quotation marks with no intervening space ("()"), indicates a null. Intervening space between the parentheses and the terms is ignored.
" "	Characters (such as space, tab, question mark, and bracket) that are enclosed within quotation marks in a community attribute regular expression indicate special characters.

Table 24: Examples of Community Attribute Regular Expressions

Community Attribute to Match	Regular Expression	Sample Matches
AS number is 56 or 78. Community value is any number.	^((56) (78)):(.*)\$	56:1000 78:64500
AS number is 56. Community value is any number that starts with 2.	^56:(2.*)\$	56:2 56:222 56:234

Table 24: Examples of Community Attribute Regular Expressions (*continued*)

Community Attribute to Match	Regular Expression	Sample Matches
AS number is any number. Community value is any number that ends with 5, 7, or 9.	<code>^(.*):(.*[579])\$</code>	1234:5 78:2357 34:64509
AS number is 56 or 78. Community value is any number that starts with 2 and ends with 2 through 8.	<code>^((56) (78)):(2.*[2-8])\$</code>	56:22 56:21197 78:2678

Defining BGP Extended Communities for Use in Routing Policy Match Conditions

To create a named BGP community and define the community members, include the **community** statement:

```
[edit policy-options]
community name {
  members [ community-ids ];
}
```

name identifies the community. It can contain letters, numbers, and hyphens (-) and can be up to 255 characters long. To include spaces in the name, enclose the entire name in quotation marks (" ").

community-ids identifies one or more members of the community. Each community ID consists of three components, which you specify in the following format:

```
type:administrator:assigned-number
```

type is the type of extended community and can be either the 16-bit numerical identifier of a specific BGP extended community or one of these types:

- **bandwidth**—Sets up the bandwidth extended community. Specifying link bandwidth allows you to distribute traffic unequally among different BGP paths.

NOTE: The link bandwidth attribute does not work concurrently with per-prefix load balancing.

- **domain-id**—Identifies the OSPF domain from which the route originated.

- **origin**—Identifies where the route originated.
- **rt-import**—Identifies the route to install in the routing table.

NOTE: You must identify the route by an IP address, not an AS number.

- **src-as**—Identifies the AS from which the route originated. You must specify an AS number, not an IP address.

NOTE: You must identify the AS by an AS number, not an IP address.

- **target**—Identifies the destination to which the route is going.

NOTE: For an import policy for a VPN routing and forwarding (VRF) instance, you must include at least one route target. Additionally, you cannot use wildcard characters or regular expressions in the route target for a VRF import policy. Each value you configure for a route target for a VRF import policy must be a single value.

administrator is the administrator. It is either an AS number or an IP version 4 (IPv4) address prefix, depending on the type of extended community.

assigned-number identifies the local provider.

In Junos OS Release 9.1 and later, you can specify 4-byte AS numbers as defined in RFC 4893, *BGP Support for Four-octet AS Number Space*, as well as the 2-byte AS numbers that are supported in earlier releases of the Junos OS. In plain-number format, you can configure a value in the range from 1 through 4,294,967,295. To configure a **target** or **origin** extended community that includes a 4-byte AS number in the plain-number format, append the letter “L” to the end of number. For example, a target community with the 4-byte AS number 334,324 and an assigned number of 132 is represented as **target:334324L:132**.

In Junos OS Release 9.2 and later, you can also use AS-dot notation when defining a 4-byte AS number for the **target** and **origin** extended communities. Specify two integers joined by a period: *16-bit high-order value in decimal.16-bit low-order value in decimal*. For example, the 4-byte AS number represented in plain-number format as 65546 is represented in AS-dot notation as 1.10.

Examples: Defining BGP Extended Communities

Configure a target community with an administrative field of **10458** and an assigned number of **20**:

```
[edit policy-options]
```

```
community test-a members [ target:10458:20 ];
```

Configure a target community with an administrative field of 10.1.1.1 and an assigned number of 20:

```
[edit policy-options]
community test-a members [ target:10.1.1.1:20 ];
```

Configure an origin community with an administrative field of 10.1.1.1 and an assigned number of 20:

```
[edit policy-options]
community test-a members [ origin:10.1.1.1:20 ];
```

Configure a target community with a 4-byte AS number in the administrative field of 100000 and an assigned number of 130:

```
[edit policy-options]
community test-b members [ target:100000L:130 ];
```

[Example: Configuring Extended Communities in a Routing Policy | 490](#)

How BGP Communities and Extended Communities Are Evaluated in Routing Policy Match Conditions

When you use BGP communities and extended communities as match conditions in a routing policy, the policy framework software evaluates them as follows:

- Each route is evaluated against each named community in a routing policy **from** statement. If a route matches one of the named communities in the **from** statement, the evaluation of the current term continues. If a route does not match, the evaluation of the current term ends.
- The route is evaluated against each member of a named community. The evaluation of all members must be successful for the named community evaluation to be successful.
- Each member in a named community is identified by either a literal community value or a regular expression. Each member is evaluated against each community associated with the route. (Communities

are an unordered property of a route. For example, 1:2 3:4 is the same as 3:4 1:2.) Only one community from the route is required to match for the member evaluation to be successful.

- Community regular expressions are evaluated on a character-by-character basis. For example, if a route contains community 1234:5678, the regular expressions see nine discrete characters, including the colon (:), instead of two sets of numbers (1234 and 5678) separated by a colon. For example:

```
[edit]
policy-options {
  policy-statement one {
    from {
      community [comm-one comm-two];
    }
  }
  community comm-one members [ 1:2 "^4:(5|6)$" ];
  community comm-two members [ 7:8 9:10 ];
}
```

If a community member is a regular expression, a string match is made rather than a numeric match.

For example:

```
community example1 members 100:100
community example2 members 100:1..
```

Given a route with a community value of 1100:100, this route matches **community example2** but not **example1**.

- To match routing policy **one**, the route must match either **comm-one** or **comm-two**.
- To match **comm-one**, the route must have a community that matches 1:2 and a community that matches 4:5 or 4:6.
- To match **comm-two**, the route must have a community that matches 7:8 and a community that matches 9:10.

Multiple Matches

When multiple matches are found, label aggregation does not happen. Consider the following configuration:

```
family inet-vpn {
  unicast {
    aggregate-label {
      community community-name;
    }
  }
}
```

```
}
}
```

```
family inet-vpn {
  labeled-unicast {
    aggregate-label {
      community community-name;
    }
  }
}
```

Suppose, for instance, that two routes are received with community attributes **target:65000:1000** **origin:65200:2000** and that the community name is "5...:". In this case, both the extended community attributes, **target:65000:1000** and **origin:65200:2000** match the regular expression of the community name. In this case, label aggregation does not occur. In the following example, the **Label operation** field shows that the labels are not aggregated.

```
user@host> show route table VPN detail | match "^10 | Communities | Push"
```

```
10.1.1.0/30 (1 entry, 1 announced)
      Label operation: Push 101040
      Push 101040
      Communities: target:65000:1000 origin:65200:2000
10.1.1.4/30 (1 entry, 1 announced)
      Label operation: Push 101056
      Push 101056
      Communities: target:65000:1000 origin:65200:2000
```

You can resolve this issue in either of the following ways:

- Be more specific in the regular expression if the site-of-origin extended community attribute does not overlap with the target one.
- Specify the site of origin in the community name.

Both methods are shown in the following examples.

Be More Specific in the Regular Expression

```
user@host# set policy-options community community-name members "52...:"
```

```
user@host# commit
```

```
user@host> show route table VPN detail | match "^10 | Communities | Push"
```

```
10.1.1.0/30 (1 entry, 1 announced)
    Label operation: Push 101040
    Push 101040
    Communities: target:65000:1000 origin:65200:2000
10.1.1.4/30 (1 entry, 1 announced)
    Label operation: Push 101040
    Push 101040
    Communities: target:65000:1000 origin:65200:2000
```

Specify the Site of Origin in the Community Name

```
user@host# set policy-options community community-name members "origin:65....*"
user@host# commit
```

```
user@host> show route table VPN detail | match "^10 | Communities | Push"
```

```
10.1.1.0/30 (1 entry, 1 announced)
    Label operation: Push 101040
    Push 101040
    Communities: target:65000:1000 origin:65200:2000
10.1.1.4/30 (1 entry, 1 announced)
    Label operation: Push 101040
    Push 101040
    Communities: target:65000:1000 origin:65200:2000
```

Inverting Community Matches

The **community** match condition defines a regular expression and if it matches the community attribute of the received prefix, Junos OS returns a TRUE result. If not, Junos OS returns a FALSE result. The **invert-match** statement makes Junos OS behave to the contrary. If there is a match, Junos OS returns a

FALSE result. If there is no match, Junos OS returns a TRUE result. To invert the results of the community expression matching, include the **invert-match** statement in the community configuration.

```
[edit policy-options community name]
invert-match;
```

Extended Community Type

The extended community type is not taken into account by regular expressions. Consider, for instance, the following community attributes and community name.

Communities:

- 5200:1000
- **target:65000:1000**
- **origin:65200:2000**

Community attribute:

- community-name members "5....:"

In this case, both extended community attribute, **5200:1000** and the extended community attribute, **origin:65200:2000**, match the regular expression of the community name. Therefore, the label aggregation does not occur, as shown here:

```
user@host> show route table VPN detail | match "^10 | Communities | Push"
```

```
10.1.1.0/30 (1 entry, 1 announced)
    Label operation: Push 101040
    Push 101040
    Communities: 5200:1000 target:65000:1000 origin:65200:2000
10.1.1.4/30 (1 entry, 1 announced)
    Label operation: Push 101056
    Push 101056
    Communities: 5200:1000 target:65000:1000 origin:65200:2000
```

You can resolve this issue by using a more specific regular expression. For example, you can use the anchor character (^) to bind the location of the digits, as shown here:

```
user@host# set policy-options community community-name members "^5....:"
```

```
user@host# commit
```

```
user@host> show route table VPN detail | match "^10 | Communities | Push"
```

```
10.1.1.0/30 (1 entry, 1 announced)
    Label operation: Push 101040
    Push 101040
    Communities: 5200:1000 target:65000:1000 origin:65200:2000
10.1.1.4/30 (1 entry, 1 announced)
    Label operation: Push 101040
    Push 101040
    Communities: 5200:1000 target:65000:1000 origin:65200:2000
```

Multiple Communities Are Matched with Ex-OR Logic

This differs from the AND matching logic used for non-extended communities in BGP.

If, for instance, four routes are received with two sets of community attributes, the regular expression might match both community attributes. Consider the following example:

- Communities—5200:1000 target:65000:1000
- Communities—target:65000:1000 origin:65200:2000
- Community attribute—community community-name member ["^5....*" origin:65.*.*]

Both labels are aggregated, as shown here:

```
user@host> show route table VPN detail | match "^10 | Communities | Push"
```

```
10.1.1.0/30 (1 entry, 1 announced)
    Label operation: Push 101040
    Push 101040
    Communities: target:65000:1000 origin:65200:2000
10.1.1.4/30 (1 entry, 1 announced)
    Label operation: Push 101040
    Push 101040
    Communities: target:65000:1000 origin:65200:2000

10.1.1.16/30 (1 entry, 1 announced)
    Label operation: Push 121104
    Push 101104
    Communities: 5200:1000 target:65000:1000
```

```
10.1.1.20/30 (1 entry, 1 announced)
      Label operation: Push 121104
      Push 101104
      Communities: 5200:1000 target:65000:1000
```

A more complete example of community values is shown here:

```
user@host> show policy-options community community-name
```

```
members [ "(^1...:*)|(^3...:*)|(^4...:*)" origin:2.*:* origin:3.*:* origin:6.*:*
]
```

This regular expression matches community values starting with 1, 3, or 4, and matches extended community values of type origin whose administrative value starts with 2, 3, or 6.

Including BGP Communities and Extended Communities in Routing Policy Match Conditions

To include a BGP community or extended community in a routing policy match condition, include the **community** condition in the **from** statement of a policy term:

```
from {
  community [ names ];
}
```

Additionally, you can explicitly exclude BGP community information with a static route by using the **none** option. Include this option when configuring an individual route in the **route** portion to override a community option specified in the **defaults** portion.

You can include the names of multiple communities in the **community** match condition. If you do this, only one community needs to match for a match to occur (matching is effectively a logical OR operation).

Example: Configuring Communities in a Routing Policy

IN THIS SECTION

- [Requirements | 472](#)
- [Overview | 472](#)
- [Configuration | 474](#)
- [Verification | 485](#)

A community is a route attribute used by BGP to administratively group routes with similar properties.

Requirements

No special configuration beyond device initialization is required before configuring this example.

Overview

One main role of the community attribute is to be an administrative tag value used to associate routes together. Generally, these routes share some common properties, but that is not required. Communities are a flexible tool within BGP. An individual community value can be assigned to a single route or multiple routes. A route can be assigned a single community value or multiple values. Networks use the community attribute to assist in implementing administrative routing policies. A route's assigned value can allow it to be accepted into the network, or rejected from the network, or allow it to modify attributes.

[Figure 32 on page 473](#) shows Device R1, Device R2, and Device R3 as internal BGP (IBGP) peers in autonomous system (AS) 64510. Device R4 is advertising the 172.16.0.0/21 address space from AS 64511. The specific routes received by Device R1 from Device R4 are as follows:

```
user@R1> show route receive-protocol bgp 10.0.0.13
```

```
inet.0: 20 destinations, 28 routes (20 active, 0 holddown, 8 hidden)
  Prefix                Nexthop                  MED      Lclpref    AS path
* 172.16.0.0/24         10.0.0.13                0         0          64511 I
* 172.16.1.0/24         10.0.0.13                0         0          64511 I
* 172.16.2.0/24         10.0.0.13                0         0          64511 I
* 172.16.3.0/24         10.0.0.13                0         0          64511 I
* 172.16.4.0/24         10.0.0.13                0         0          64511 I
* 172.16.5.0/24         10.0.0.13                0         0          64511 I
```

* 172.16.6.0/24	10.0.0.13	64511 I
* 172.16.7.0/24	10.0.0.13	64511 I

The administrators of AS 64511 want to receive certain user traffic from Device R1, and other user traffic from Device R3. To accomplish this administrative goal, Device R4 attaches the community value of 64511:1 to some routes that it sends and attaches the community value 64511:3 to other routes that it sends. Routing policies within AS 64510 are configured using a community match criterion to change the local preference of the received routes to new values that alter the BGP route selection algorithm. The route with the highest local preference value is preferred.

On Device R1, routes with the 64511:1 community value are assigned a local preference of 200, and routes with the 64511:3 community value are assigned a local preference of 50. On Device R3, the reverse is done so that routes with the 64511:3 community value are assigned a local preference of 200, and routes with the 64511:1 community value are assigned a local preference of 50. This information is then communicated through IBGP by both Device R1 and Device R3 to Device R2.

Topology

Figure 32 on page 473 shows the sample network.

Figure 32: Topology for Regular BGP Communities

“CLI Quick Configuration” on page 474 shows the configuration for all of the devices in Figure 32 on page 473.

The section “Step-by-Step Procedure” on page 477 describes the steps on Device R1 and R4.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

Device R1

```

set interfaces fe-1/2/0 unit 0 family inet address 10.0.0.1/30
set interfaces fe-1/2/2 unit 0 family inet address 10.1.0.5/30
set interfaces fe-1/2/3 unit 0 family inet address 10.0.0.14/30
set interfaces lo0 unit 0 family inet address 192.168.0.1/32

set routing-options static route 172.16.7.0/24 reject
set routing-options router-id 192.168.0.4
set routing-options autonomous-system 64511

```

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure Device R1:

1. Configure the interfaces.

```

[edit interfaces]
user@R1# set fe-1/2/0 unit 0 family inet address 10.0.0.1/30
user@R1# set fe-1/2/2 unit 0 family inet address 10.1.0.5/30
user@R1# set fe-1/2/3 unit 0 family inet address 10.0.0.14/30
user@R1# set lo0 unit 0 family inet address 192.168.0.1/32

```

2. Configure internal gateway protocol (IGP) connections to Device R2 and Device R3.

```

[edit protocols ospf area 0.0.0.0]
user@R1# set interface fe-1/2/0.0
user@R1# set interface fe-1/2/2.0
user@R1# set interface lo0.0 passive

```

3. Configure the IBGP connections to Device R2 and Device R3.

```

[edit protocols bgp group int]
user@R1# set type internal
user@R1# set local-address 192.168.0.1
user@R1# set neighbor 192.168.0.2 export send-direct
user@R1# set neighbor 192.168.0.3

```

4. Configure the EBGP connection to Device R4.

```
[edit protocols bgp group ext]
user@R1# set type external
user@R1# set import change-local-preference
user@R1# set peer-as 64511
user@R1# set neighbor 10.0.0.13
```

5. Configure the policy **send-direct**.

This policy is referenced in the IBGP connection to Device R2 and enables Device R2 to have external reachability. An alternative is to configure a **next-hop self** policy on Device R1 and Device R3.

```
[edit policy-options policy-statement send-direct term 1]
user@R1# set from protocol direct
user@R1# set from route-filter 10.0.0.12/30 exact
user@R1# set then accept
```

6. Configure the policy that changes the local preference for routes with specified community tags.

```
[edit policy-options policy-statement change-local-preference]
user@R1# set term find-R1-routes from community from-R1
user@R1# set term find-R1-routes then local-preference 200
user@R1# set term find-R3-routes from community from-R3
user@R1# set term find-R3-routes then local-preference 50
[edit policy-options ]
user@R1# set community from-R1 members 64511:1
user@R1# set community from-R3 members 64511:3
```

7. Configure the autonomous system (AS) number and router ID.

```
[edit routing-options]
user@R1# set router-id 192.168.0.1
user@R1# set autonomous-system 64510
```

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure Device R4:

1. Configure the interfaces.

```
[edit interfaces]
user@R4# set fe-1/2/0 unit 0 family inet address 10.0.0.9/30
user@R4# set fe-1/2/3 unit 0 family inet address 10.0.0.13/30
user@R4# set lo0 unit 0 family inet address 192.168.0.4/32
```

2. Configure the EBGP connection to Device R1 and Device R3.

```
[edit protocols bgp]
user@R4# set group to-R1 type external
user@R4# set group to-R1 export send-static
user@R4# set group to-R1 peer-as 64510
user@R4# set group to-R1 neighbor 10.0.0.14
user@R4# set group to-R3 type external
user@R4# set group to-R3 export send-static
user@R4# set group to-R3 peer-as 64510
user@R4# set group to-R3 neighbor 10.0.0.10
```

3. Configure the community tags.

```
[edit policy-options ]
user@R4# set community from-R1 members 64511:1
user@R4# set community from-R3 members 64511:3
```

4. Configure the policy **send-static**.

This policy is referenced in the EBGP connections to Device R1 and Device R3. The policy attaches the 64511:1 (from-R1) community to some routes and the 64511:3 (from-R3) community to other routes.

```
[edit policy-options policy-statement send-static term 1]
user@R4# set from protocol static
user@R4# set from route-filter 172.16.0.0/24 exact
user@R4# set from route-filter 172.16.1.0/24 exact
user@R4# set from route-filter 172.16.2.0/24 exact
user@R4# set from route-filter 172.16.3.0/24 exact
user@R4# set then community add from-R1
user@R4# set then accept
[edit policy-options policy-statement send-static term 2]
user@R4# set from protocol static
user@R4# set from route-filter 172.16.4.0/24 exact
user@R4# set from route-filter 172.16.5.0/24 exact
```

```

user@R4# set from route-filter 172.16.6.0/24 exact
user@R4# set from route-filter 172.16.7.0/24 exact
user@R4# set then community add from-R3
user@R4# set then accept
[edit policy-options policy-statement send-static term 3]
user@R4# set then reject

```

5. Configure the static routes.

```

[edit routing-options static]
user@R4# set route 172.16.0.0/24 reject
user@R4# set route 172.16.1.0/24 reject
user@R4# set route 172.16.2.0/24 reject
user@R4# set route 172.16.3.0/24 reject
user@R4# set route 172.16.4.0/24 reject
user@R4# set route 172.16.5.0/24 reject
user@R4# set route 172.16.6.0/24 reject
user@R4# set route 172.16.7.0/24 reject

```

6. Configure the autonomous system (AS) number and router ID.

```

[edit routing-options]
user@R4# set router-id 192.168.0.4
user@R4# set autonomous-system 64511

```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

Example: Configuring Extended Communities in a Routing Policy

IN THIS SECTION

- [Requirements | 491](#)
- [Overview | 491](#)
- [Configuration | 491](#)
- [Verification | 496](#)

An extended community is similar in most ways to a regular community. Some networking implementations, such as virtual private networks (VPNs), use extended communities because the 4-octet regular community value does not provide enough expansion and flexibility. An extended community is an eight-octet value divided into two main sections.

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

Device R1

```
set interfaces fe-1/2/0 unit 0 family inet address 10.0.0.1/30
set interfaces fe-1/2/3 unit 0 family inet address 10.0.0.14/30
set interfaces lo0 unit 0 family inet address 192.168.0.1/32 primary
set protocols bgp group ext type external
set protocols bgp group ext export send-static
set protocols bgp group ext peer-as 64511
set protocols bgp group ext neighbor 10.0.0.13
set protocols ospf area 0.0.0.0 interface fe-1/2/0.0
set protocols ospf area 0.0.0.0 interface lo0.0 passive
set policy-options policy-statement send-static term 1 from protocol static
set policy-options policy-statement send-static term 1 then accept
set routing-options static route 172.16.1.0/24 next-hop 10.0.0.2
set routing-options static route 172.16.1.0/24 community 64510:1
set routing-options static route 172.16.2.0/24 next-hop 10.0.0.2
set routing-options static route 172.16.2.0/24 community 64510:2
set routing-options static route 172.16.3.0/24 next-hop 10.0.0.2

```

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure Device R3:

1. Configure the interfaces.

```

[edit interfaces]
user@R3# set fe-1/2/3 unit 0 family inet address 10.0.0.13/30
user@R3# set lo0 unit 0 family inet address 192.168.0.3/32

```

2. Configure the EBGp connection to Device R1.

```
[edit protocols bgp group to-R1]
user@R3# set type external
user@R3# set import set-ext-comms
user@R3# set peer-as 64510
user@R3# set neighbor 10.0.0.14
```

3. Configure the policy that adds extended community values to the routes received from Device R1.

An extended community uses a notation of *type:administrator:assigned-number*.

The specific community values can be anything that accomplishes your administrative goals, within certain parameters, as explained in [community](#).

```
[edit policy-options policy-statement set-ext-comms]
user@R3# set term route-1 from route-filter 172.16.1.0/24 exact
user@R3# set term route-1 then community add target-as
user@R3# set term route-1 then accept
user@R3# set term route-2 from route-filter 172.16.2.0/24 exact
user@R3# set term route-2 then community add target-ip
user@R3# set term route-2 then accept
user@R3# set term route-3 from route-filter 172.16.3.0/24 exact
user@R3# set term route-3 then community add origin-as
user@R3# set term route-3 then accept
user@R3# set term route-4 from route-filter 172.16.4.0/24 exact
user@R3# set term route-4 then community add origin-ip
user@R3# set term route-4 then accept
[edit policy-options]
user@R3# set community origin-as members origin:64511:3
user@R3# set community origin-ip members origin:172.16.7.7:4
user@R3# set community target-as members target:64511:1
user@R3# set community target-ip members target:172.16.7.7:2
```

4. Configure the autonomous system (AS) number and router ID.

```
[edit routing-options]
user@R3# set router-id 192.168.0.3
user@R3# set autonomous-system 64511
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

user@R3# show interfaces
fe-1/2/3 {
  unit 0 {
    family inet {
      address 10.0.0.13/30;
    }
  }
}
lo0 {
  unit 0 {
    family inet {
      address 192.168.0.3/32;
    }
  }
}

```

```

user@R3# show protocols

      accept;
    }
  }
  term route-2 {
    from {
      route-filter 172.16.2.0/24 exact;
    }
    then {
      community add target-ip;
    }
  }
}

```

```

        accept;
    }
}
term route-3 {
    from {
        route-filter 172.16.3.0/24 exact;
    }
    then {
        community add origin-as;
        accept;
    }
}
term route-4 {
    from {
        route-filter 172.16.4.0/24 exact;
    }
    then {
        community add origin-ip;
        accept;
    }
}
}
community origin-as members origin:64511:3;
community origin-ip members origin:172.16.7.7:4;
community target-as members target:64511:1;
community target-ip members target:172.16.7.7:2;

```

```

user@R3# show routing-options
router-id 192.168.0.3;
autonomous-system 64511;

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

IN THIS SECTION

- [Verifying the Routes on Device R1 | 497](#)
- [Verifying the Routes on Device R3 | 498](#)

Confirm that the configuration is working properly.

Verifying the Routes on Device R1

Purpose

On Device R1, check the 172.16. routes in the routing table.

Action

user@R1> **show route protocol static match-prefix 172.16.* detail**

```
inet.0: 15 destinations, 15 routes (15 active, 0 holddown, 0 hidden)
172.16.1.0/24 (1 entry, 1 announced)
  *Static Preference: 5
    Next hop type: Router, Next hop index: 835
    Address: 0x9260250
    Next-hop reference count: 19
    Next hop: 10.0.0.2 via fe-1/2/0.0, selected
    State: <Active Int Ext>
    Local AS: 64510
    Age: 2:06:08
    Task: RT
    Announcement bits (2): 2-KRT 3-BGP_RT_Background
    AS path: I
    Communities: 64510:1

172.16.2.0/24 (1 entry, 1 announced)
  *Static Preference: 5
    Next hop type: Router, Next hop index: 835
    Address: 0x9260250
    Next-hop reference count: 19
    Next hop: 10.0.0.2 via fe-1/2/0.0, selected
    State: <Active Int Ext>
    Local AS: 64510
    Age: 2:06:08
    Task: RT
    Announcement bits (2): 2-KRT 3-BGP_RT_Background
    AS path: I
    Communities: 64510:2

172.16.3.0/24 (1 entry, 1 announced)
  *Static Preference: 5
    Next hop type: Router, Next hop index: 835
    Address: 0x9260250
```

```

Next-hop reference count: 19
Next hop: 10.0.0.2 via fe-1/2/0.0, selected
State: <Active Int Ext>
Local AS: 64510
Age: 2:06:08
Task: RT
Announcement bits (2): 2-KRT 3-BGP_RT_Background
AS path: I
Communities: 64510:3

172.16.4.0/24 (1 entry, 1 announced)
  *Static Preference: 5
    Next hop type: Router, Next hop index: 835
    Address: 0x9260250
    Next-hop reference count: 19
    Next hop: 10.0.0.2 via fe-1/2/0.0, selected
    State: <Active Int Ext>
    Local AS: 64510
    Age: 2:06:08
    Task: RT
    Announcement bits (2): 2-KRT 3-BGP_RT_Background
    AS path: I
    Communities: 64510:4

```

Meaning

The output shows that the regular community values are attached to the routes.

NOTE: The communities are attached to static routes, thus demonstrating that communities can be attached to non-BGP routes.

Verifying the Routes on Device R3

Purpose

On Device R3, check the 172.16. routes in the routing table.

Action

Example: Configuring BGP Large Communities

IN THIS SECTION

- Requirements | 501
- Overview | 501
- Configuration | 502
- Verification | 507

This example shows you to configure optional transitive path attribute - a 12-byte BGP large community that provides the most significant 4-byte value to encode autonomous system number as the global administrator and the remaining two 4-byte assigned numbers to encode the local values as defined in RFC 8092. You can configure BGP large community at **[edit policy-options community community-name members]** and **[edit routing-options static route ip-address community]** hierarchy levels. The BGP large community attributes format has four fields: **large:global administrator:assigned number:assigned number**.

Requirements

This example uses the following hardware and software components:

- Three MX Series routers
- Junos OS Release 17.3 or later running on all devices

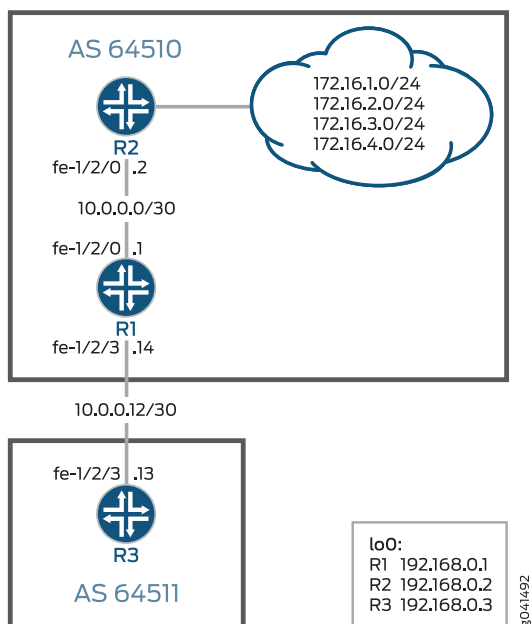

No special configuration beyond device initialization is required before configuring this example.

Overview

In this example, Device R1 and Device R2 are OSPF neighbors in autonomous system (AS) 64510. Device R3 has an external BGP (EBGP) connection to Device R1. Device R2 has customer networks in the 172.16/16 address space, simulated with addresses on its loopback interface (lo0). Device R1 has static routes to several 172.16.x/24 networks, and attaches regular community values to these routes. Device R1 then uses an export policy to advertise the routes to Device R3. Device R3 receives these routes and uses an import policy to add large community values to the routes.

Topology

Figure 1 shows the sample network.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level.

Device R1

```
set interfaces ge-0/0/0 unit 0 family inet address 10.0.0.1/30
set interfaces ge-0/0/1 unit 0 family inet address 10.0.0.14/30

```

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure Device R3:

1. Configure the interfaces.

```

[edit interfaces]
set ge-0/0/1 unit 0 family inet address 10.0.0.13/30
set lo0 unit 0 family inet address 192.168.0.3/32

```

2. Configure the autonomous system (AS) number and router ID.

```

[edit routing-options]
set router-id 192.168.0.3
set autonomous-system 64511

```

3. Configure the EBGP connection to Device R1.

```
[edit protocols bgp group to-R1]
set type external
set import set-large-comms
set peer-as 64510
set neighbor 10.0.0.14
```

4. Configure the policy that adds large community values to the routes received from Device R1.

A large community uses a notation of **large:global administrator:assigned number:assigned number**. The specific community values can be anything that accomplishes your administrative goals, within certain parameters.

```
[edit policy-options policy-statement set-large-comms]
set term route-1 from route-filter 172.16.1.0/24 exact
set term route-1 then community add large2-as
set term route-1 then accept
set term route-2 from route-filter 172.16.2.0/24 exact
set term route-2 then community add large2-ip
set term route-2 then accept
set term route-3 from route-filter 172.16.3.0/24 exact
set term route-3 then community add large1-as
set term route-3 then accept
set term route-4 from route-filter 172.16.4.0/24 exact
set term route-4 then community add large1-ip
set term route-4 then accept
```

```
[edit policy-options ]
set community large1-as members large:64511:3:1
set community large1-ip members large:7777:4:1
set community large2-as members large:64511:1:1
set community large2-ip members large:7777:2:1
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R3# show interfaces
ge-0/0/1 {
  unit 0 {
```

```

        family inet {
            address 10.0.0.13/30;
        }
    }
}
lo0 {
    unit 0 {
        family inet {
            address 192.168.0.3/32;
        }
    }
}

```

```

user@R3# show protocols
bgp {
    group to-R1 {
        type external;
        import set-large-comms;
        peer-as 64510;
        neighbor 10.0.0.14;
    }
}

```

```

user@R3# show policy-options
policy-statement set-large-comms {
    term route-1 {
        from {
            route-filter 172.16.1.0/24 exact;
        }
        then {
            community add large2-as;
            accept;
        }
    }
    term route-2 {
        from {

iso.0: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)

inet6.0: 3 destinations, 3 routes (3 active, 0 holddown, 0 hidden)

```

Meaning

The output shows that the regular community values remain attached to the routes, and the large community values are added.

RELATED DOCUMENTATION

[Understanding How to Define BGP Communities and Extended Communities | 459](#)
[community | 1999](#)

Example: Configuring a Routing Policy Based on the Number of BGP Communities

IN THIS SECTION

- [Requirements | 513](#)
- [Overview | 513](#)

- Configuration | 513
- Verification | 520

This example shows how to create a policy that accepts BGP routes based on the number of BGP communities.

Requirements

No special configuration beyond device initialization is required before you configure this example.

Overview

This example shows two routing devices with an external BGP (EBGP) connection between them. Device R2 uses the BGP session to send two static routes to Device R1. On Device R1, an import policy specifies that the BGP-received routes can contain up to five communities to be considered a match. For example, if a route contains three communities, it is considered a match and is accepted. If a route contains six or more communities, it is considered a nonmatch and is rejected.

It is important to remember that the default policy for EBGP is to accept all routes. To ensure that the nonmatching routes are rejected, you must include a **then reject** action at the end of the policy definition.

Topology

Figure 34 on page 513 shows the sample network.

Figure 34: BGP Policy with a Limit on the Number of Communities Accepted

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

Device R1

```
set interfaces fe-1/1/0 unit 0 description to-R2
set interfaces fe-1/1/0 unit 0 family inet address 10.0.0.1/30
set interfaces lo0 unit 0 family inet address 192.168.0.1/32
set protocols bgp group external-peers type external
set protocols bgp group external-peers peer-as 2
set protocols bgp group external-peers neighbor 10.0.0.2 import import-communities
set policy-options policy-statement import-communities term 1 from protocol bgp
set policy-options policy-statement import-communities term 1 from community-count 5 orlower
set policy-options policy-statement import-communities term 1 then accept
set policy-options policy-statement import-communities term 2 then reject
set routing-options router-id 192.168.0.1
set routing-options autonomous-system 1
```

Device R2

```
set interfaces fe-1/1/0 unit 0 description to-R1
set interfaces fe-1/1/0 unit 0 family inet address 10.0.0.2/30
set interfaces lo0 unit 0 family inet address 192.168.0.2/32
set protocols bgp group external-peers type external
set protocols bgp group external-peers export statics
set protocols bgp group external-peers peer-as 1
set protocols bgp group external-peers neighbor 10.0.0.1
set policy-options policy-statement statics from protocol static
set policy-options policy-statement statics then community add 1
set policy-options policy-statement statics then accept
set policy-options community 1 members 2:1
set policy-options community 1 members 2:2
set policy-options community 1 members 2:3
set policy-options community 1 members 2:4
set policy-options community 1 members 2:5
set policy-options community 1 members 2:6
set policy-options community 1 members 2:7
set policy-options community 1 members 2:8
set policy-options community 1 members 2:9
```

```

set policy-options community 1 members 2:10
set routing-options static route 10.2.0.0/16 reject
set routing-options static route 10.2.0.0/16 install
set routing-options static route 10.3.0.0/16 reject
set routing-options static route 10.3.0.0/16 install
set routing-options router-id 192.168.0.3
set routing-options autonomous-system 2

```

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure Device R1:

1. Configure the interfaces.

```

[edit interfaces]
user@R1# set fe-1/1/0 unit 0 description to-R2
user@R1# set fe-1/1/0 unit 0 family inet address 10.0.0.1/30
user@R1# set lo0 unit 0 family inet address 192.168.0.1/32

```

2. Configure BGP.

Apply the import policy to the BGP peering session with Device R2.

```

[edit protocols bgp group external-peers]
user@R1# set type external
user@R1# set peer-as 2
user@R1# set neighbor 10.0.0.2 import import-communities

```

3. Configure the routing policy that sends direct routes.

```

[edit policy-options policy-statement import-communities]
user@R1# set term 1 from protocol bgp
user@R1# set term 1 from community-count 5 orlower
user@R1# set term 1 then accept
user@R1# set term 2 then reject

```

4. Configure the autonomous system (AS) number and the router ID.

```
[edit routing-options ]
user@R1# set router-id 192.168.0.1
user@R1# set autonomous-system 1
```

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure Device R2:

1. Configure the interfaces.

```
[edit interfaces]
user@R2# set fe-1/1/0 unit 0 description to-R1
user@R2# set fe-1/1/0 unit 0 family inet address 10.0.0.2/30
user@R2# set lo0 unit 0 family inet address 192.168.0.2/32
```

2. Configure the router ID and the autonomous system (AS) number.

```
[edit routing-options]
user@R2# set router-id 192.168.0.3
user@R2# set autonomous-system 2
```

3. Configure BGP.

```
[edit protocols bgp group external-peers]
user@R2# set type external
user@R2# set peer-as 1
user@R2# set neighbor 10.0.0.1
```

4. Configure multiple communities, or configure a single community with multiple members.

```
[edit policy-options community 1]
user@R2# set members 2:1
user@R2# set members 2:2
user@R2# set members 2:3
user@R2# set members 2:4
user@R2# set members 2:5
```

```

user@R2# set members 2:6
user@R2# set members 2:7
user@R2# set members 2:8
user@R2# set members 2:9
user@R2# set members 2:10

```

5. Configure the static routes.

```

[edit routing-options static]
user@R2# set route 10.2.0.0/16 reject
user@R2# set route 10.2.0.0/16 install
user@R2# set route 10.3.0.0/16 reject
user@R2# set route 10.3.0.0/16 install

```

6. Configure a routing policy that advertises static routes into BGP and adds the BGP community to the routes.

```

[edit policy-options policy-statement statics]
user@R2# set from protocol static
user@R2# set then community add 1
user@R2# set then accept

```

7. Apply the export policy.

```

[edit protocols bgp group external-peers]
user@R2# set export statics

```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

Device R1

```

user@R1# show interfaces
fe-1/1/0 {
  unit 0{

```

```

        description to-R2;
        family inet {
            address 10.0.0.1/30;
        }
    }
}
lo0 {
    unit 0 {
        family inet {
            address 192.168.0.1/32;
        }
    }
}
}

```

user@R1# show protocols

```

bgp {
    group external-peers {
        type external;
        peer-as 2;
        neighbor 10.0.0.2 {
            import import-communities;
        }
    }
}

```

user@R1# show policy-options

```

policy-statement import-communities {
    term 1 {
        from {
            protocol bgp;
            community-count 5 orlower;
        }
        then accept;
    }
    term 2 {
        then reject;
    }
}

```

```

user@R1# show routing-options
router-id 192.168.0.1;
autonomous-system 1;

```

Device R2

```

user@R2# show interfaces
fe-1/1/0 {
  unit 0 {
    description to-R1;
    family inet {
      address 10.0.0.2/30;
    }
  }
}
lo0 {
  unit 0 {
    family inet {
      address 192.168.0.2/32;
    }
  }
}

```

```

user@R2# show protocols
bgp {
  group external-peers {
    type external;
    export statics;
    peer-as 1;
    neighbor 10.0.0.1;
  }
}

```

```

user@R2# show policy-options
policy-statement statics {
  from protocol static;
  then {
    community add 1;
    accept;
  }
}

```

```
}
community 1 members [ 2:1 2:2 2:3 2:4 2:5 2:6 2:7 2:8 2:9 2:10 ];
```

```
user@R2# show routing-options
static {
  route 10.2.0.0/16 {
    reject;
    install;
  }
  route 10.3.0.0/16 {
    reject;
    install;
  }
}
router-id 192.168.0.3;
autonomous-system 2;
```

If you are done configuring the devices, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

Verifying the BGP Routes

Purpose

Make sure that the routing table on Device R1 contains the expected BGP routes.

Action

1. On Device R1, run the **show route protocols bgp** command.

```
user@R1> show route protocols bgp
```

```
inet.0: 5 destinations, 5 routes (3 active, 0 holddown, 2 hidden)
```

2. On Device R1, change the **community-count** configuration in the import policy.

```
[edit policy-options policy-statement import-communities term 1]
user@R1# set from community-count 5 orhigher
user@R1# commit
```

3. On Device R1, run the **show route protocols bgp** command.

user@R1> **show route protocols bgp**

```
inet.0: 5 destinations, 5 routes (5 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.2.0.0/16      *[BGP/170] 18:29:53, localpref 100
                  AS path: 2 I, validation-state: unverified
                  > to 10.0.0.2 via fe-1/1/0.0
10.3.0.0/16      *[BGP/170] 18:29:53, localpref 100
                  AS path: 2 I, validation-state: unverified
                  > to 10.0.0.2 via fe-1/1/0.0
```

4. On Device R1, run the **show route protocols bgp extensive** command to view the advertised communities.

user@R1> **show route protocols bgp extensive**

```

Meaning

The output shows that in Device R1's routing table, the BGP routes sent from Device R2 are hidden. When the **community-count** setting in Device R1's import policy is modified, the BGP routes are no longer hidden.

Understanding External BGP Peering Sessions

Example: Configuring a Routing Policy That Removes BGP Communities

IN THIS SECTION

- Requirements | 523
- Overview | 523
- Configuration | 524
- Verification | 530

This example shows how to create a policy that accepts BGP routes, but removes BGP communities from the routes.

Requirements

No special configuration beyond device initialization is required before you configure this example.

Overview

This example shows two routing devices with an external BGP (EBGP) connection between them. Device R2 uses the BGP session to send two static routes to Device R1. On Device R1, an import policy specifies that all BGP communities must be removed from the routes.

By default, when communities are configured on EBGP peers, they are sent and accepted. To suppress the acceptance of communities received from a neighbor, you can remove all communities or a specified set of communities. When the result of a policy is an empty set of communities, the community attribute is not included. To remove all communities, first define a wildcard set of communities (here, the community is named **wild**):

```
[edit policy-options]
community wild members "*" : *;
```

Then, in the routing policy statement, specify the **community delete** action:

```
[edit policy-options]
policy-statement policy-name {
  term term-name {
    then community delete wild;
  }
}
```

To suppress a particular community from any autonomous system (AS), define the community as **community wild members "*:community-value"**.

Topology

[Figure 35 on page 524](#) shows the sample network.

Figure 35: BGP Policy That Removes Communities

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

Device R1

```
set interfaces fe-1/1/0 unit 0 description to-R2
set interfaces fe-1/1/0 unit 0 family inet address 10.0.0.1/30
set interfaces lo0 unit 0 family inet address 192.168.0.1/32
set protocols bgp group external-peers type external
set protocols bgp group external-peers peer-as 2
set protocols bgp group external-peers neighbor 10.0.0.2 import remove-communities
set policy-options policy-statement remove-communities term 1 from protocol bgp
set policy-options policy-statement remove-communities term 1 then community delete wild
set policy-options policy-statement remove-communities term 1 then accept
set policy-options policy-statement remove-communities term 2 then reject
set policy-options community wild members *.*
set routing-options router-id 192.168.0.1
set routing-options autonomous-system 1
```

Device R2

```
set interfaces fe-1/1/0 unit 0 description to-R1
set interfaces fe-1/1/0 unit 0 family inet address 10.0.0.2/30
```

```

set interfaces lo0 unit 0 family inet address 192.168.0.2/32
set protocols bgp group external-peers type external
set protocols bgp group external-peers export statics
set protocols bgp group external-peers peer-as 1
set protocols bgp group external-peers neighbor 10.0.0.1
set policy-options policy-statement statics from protocol static
set policy-options policy-statement statics then community add 1
set policy-options policy-statement statics then accept
set policy-options community 1 members 2:1
set policy-options community 1 members 2:2
set policy-options community 1 members 2:3
set policy-options community 1 members 2:4
set policy-options community 1 members 2:5
set policy-options community 1 members 2:6
set policy-options community 1 members 2:7
set policy-options community 1 members 2:8
set policy-options community 1 members 2:9
set policy-options community 1 members 2:10
set routing-options static route 10.2.0.0/16 reject
set routing-options static route 10.2.0.0/16 install
set routing-options static route 10.3.0.0/16 reject
set routing-options static route 10.3.0.0/16 install
set routing-options router-id 192.168.0.3
set routing-options autonomous-system 2

```

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure Device R1:

1. Configure the interfaces.

```

[edit interfaces]
user@R1# set fe-1/1/0 unit 0 description to-R2
user@R1# set fe-1/1/0 unit 0 family inet address 10.0.0.1/30
user@R1# set lo0 unit 0 family inet address 192.168.0.1/32

```

2. Configure BGP.

Apply the import policy to the BGP peering session with Device R2.

```
[edit protocols bgp group external-peers]
user@R1# set type external
user@R1# set peer-as 2
user@R1# set neighbor 10.0.0.2 import remove-communities
```

3. Configure the routing policy that deletes communities.

```
[edit policy-options policy-statement remove-communities]
user@R1# set term 1 from protocol bgp
user@R1# set term 1 then community delete wild
user@R1# set term 1 then accept
user@R1# set term 2 then reject
```

4. Configure the autonomous system (AS) number and the router ID.

```
[edit routing-options ]
user@R1# set router-id 192.168.0.1
user@R1# set autonomous-system 1
```

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure Device R2:

1. Configure the interfaces.

```
[edit interfaces]
user@R2# set fe-1/1/0 unit 0 description to-R1
user@R2# set fe-1/1/0 unit 0 family inet address 10.0.0.2/30
user@R2# set lo0 unit 0 family inet address 192.168.0.2/32
```

2. Configure the router ID and the autonomous system (AS) number.

```
[edit routing-options]
user@R2# set router-id 192.168.0.3
user@R2# set autonomous-system 2
```

3. Configure BGP.

```
[edit protocols bgp group external-peers]
user@R2# set type external
user@R2# set peer-as 1
user@R2# set neighbor 10.0.0.1
```

4. Configure multiple communities, or configure a single community with multiple members.

```
[edit policy-options community 1]
user@R2# set members 2:1
user@R2# set members 2:2
user@R2# set members 2:3
user@R2# set members 2:4
user@R2# set members 2:5
user@R2# set members 2:6
user@R2# set members 2:7
user@R2# set members 2:8
user@R2# set members 2:9
user@R2# set members 2:10
```

5. Configure the static routes.

```
[edit routing-options static]
user@R2# set route 10.2.0.0/16 reject
user@R2# set route 10.2.0.0/16 install
user@R2# set route 10.3.0.0/16 reject
user@R2# set route 10.3.0.0/16 install
```

6. Configure a routing policy that advertises static routes into BGP and adds the BGP community to the routes.

```
[edit policy-options policy-statement statics]
user@R2# set from protocol static
user@R2# set then community add 1
user@R2# set then accept
```

7. Apply the export policy.

```
[edit protocols bgp group external-peers]
user@R2# set export statics
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

Device R1

```
user@R1# show interfaces
fe-1/1/0 {
  unit 0 {
    description to-R2;
    family inet {
      address 10.0.0.1/30;
    }
  }
}
lo0 {
  unit 0 {
    family inet {
      address 192.168.0.1/32;
    }
  }
}
```

```
user@R1# show protocols
bgp {
  group external-peers {
    type external;
    peer-as 2;
    neighbor 10.0.0.2 {
      import remove-communities;
    }
  }
}
```

```
user@R1# show policy-options
policy-statement remove-communities {
  term 1 {
    from protocol bgp;
    then {
```

```

        community delete wild;
        accept;
    }
}
term 2 {
    then reject;
}
}
community wild members *.*;

```

```

user@R1# show routing-options
router-id 192.168.0.1;
autonomous-system 1;

```

Device R2

```

user@R2# show interfaces
fe-1/1/0 {
    unit 0 {
        description to-R1;
        family inet {
            address 10.0.0.2/30;
        }
    }
}
lo0 {
    unit 0 {
        family inet {
            address 192.168.0.2/32;
        }
    }
}

```

```

user@R2# show protocols
bgp {
    group external-peers {
        type external;
        export statics;
        peer-as 1;
        neighbor 10.0.0.1;
    }
}

```

```

    }
}

```

```

user@R2# show policy-options
policy-statement statics {
    from protocol static;
    then {
        community add 1;
        accept;
    }
}
community 1 members [ 2:1 2:2 2:3 2:4 2:5 2:6 2:7 2:8 2:9 2:10 ];

```

```

user@R2# show routing-options
static {
    route 10.2.0.0/16 {
        reject;
        install;
    }
    route 10.3.0.0/16 {
        reject;
        install;
    }
}
router-id 192.168.0.3;
autonomous-system 2;

```

If you are done configuring the devices, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

Verifying the BGP Routes

Purpose

Make sure that the routing table on Device R1 does not contain BGP communities.

Action

1. On Device R1, run the **show route protocols bgp extensive** command.

```

user@R1> show route protocols bgp extensive

```

```

Understanding Damping Parameters

BGP *route flapping* describes the situation in which BGP systems send an excessive number of update messages to advertise network reachability information. BGP *flap damping* is a method of reducing the number of update messages sent between BGP peers, thereby reducing the load on these peers, without adversely affecting the route convergence time for stable routes.

Flap damping reduces the number of update messages by marking routes as ineligible for selection as the active or preferable route. Marking routes in this way leads to some delay, or *suppression*, in the propagation of route information, but the result is increased network stability. You typically apply flap damping to external BGP (EBGP) routes (routes in different ASs). You can also apply flap damping within a confederation, between confederation member ASs. Because routing consistency within an AS is important, do not apply flap damping to internal BGP (IBGP) routes. (If you do, it is ignored.)

There is an exception that rule. Starting in Junos OS Release 12.2, you can apply flap damping at the address family level. In a Junos OS Release 12.2 or later installation, when you apply flap damping at the address family level, it works for both IBGP and EBGP.

By default, route flap damping is not enabled. Damping is applied to external peers and to peers at confederation boundaries.

When you enable damping, default parameters are applied, as summarized in [Table 25 on page 535](#).

Table 25: Damping Parameters

Damping Parameter	Description	Default Value	Possible Values
half-life <i>minutes</i>	Decay half-life—Number of minutes after which an arbitrary value is halved if a route stays stable.	15 (minutes)	1 through 45
max-suppress <i>minutes</i>	Maximum hold-down time for a route, in minutes.	60 (minutes)	1 through 720
reuse	Reuse threshold—Arbitrary value below which a suppressed route can be used again.	750	1 through 20,000
suppress	Cutoff (suppression) threshold—Arbitrary value above which a route can no longer be used or included in advertisements.	3000	1 through 20,000

To change the default BGP flap damping values, you define actions by creating a named set of damping parameters and including it in a routing policy with the damping action. For the damping routing policy to work, you also must enable BGP route flap damping.

Release History Table

Release	Description
12.2	Starting in Junos OS Release 12.2, you can apply flap damping at the address family level.

BGP *route flapping* describes the situation in which BGP systems send an excessive number of update messages to advertise network reachability information. BGP *flap damping* is a way to reduce the number of update messages sent between BGP peers, thereby reducing the load on these peers without adversely affecting the route convergence time.

Flap damping reduces the number of update messages by marking routes as ineligible for selection as the active or preferable route. Doing this leads to some delay, or *suppression*, in the propagation of route information, but the result is increased network stability. You typically apply flap damping to external BGP (EBGP) routes (that is, to routes in different ASs). You can also apply it within a confederation, between confederation member ASs. Because routing consistency within an AS is important, do not apply flap damping to IBGP routes. (If you do, it is ignored.)

BGP flap damping is defined in RFC 2439, *BGP Route Flap Damping*.

To effect changes to the default BGP flap damping values, you define actions by creating a named set of damping parameters and including it in a routing policy with the **damping** action (described in [“Configuring Actions That Manipulate Route Characteristics” on page 70](#)). For the damping routing policy to work, you also must enable BGP route flap damping.

The following sections discuss the following topics:

Configuring BGP Flap Damping Parameters

To define damping parameters, include the **damping** statement:

```
[edit policy-options]
damping name {
  disable;
  half-life minutes;
  max-suppress minutes;
  reuse number;
  suppress number;
}
```

The name identifies the group of damping parameters. It can contain letters, numbers, and hyphens (-) and can be up to 255 characters. To include spaces in the name, enclose the entire name in quotation marks (" ").

You can specify one or more of the damping parameters described in [Table 26 on page 537](#).

Table 26: Damping Parameters

Damping Parameter	Description	Default	Possible Values
half-life <i>minutes</i>	Decay half-life, in minutes	15 minutes	1 through 45 minutes
max-suppress <i>minutes</i>	Maximum hold-down time, in minutes	60 minutes	1 through 720 minutes
reuse	Reuse threshold	750 (unitless)	1 through 20,000 (unitless)
suppress	Cutoff (suppression) threshold	3000 (unitless)	1 through 20,000 (unitless)

If you do not specify one or more of the damping parameters, the default value of the parameter is used.

To understand how to configure these parameters, you need to understand how damping suppresses routes. How long a route can be suppressed is based on a *figure of merit*, which is a value that correlates to the probability of future instability of a route. Routes with higher figure-of-merit values are suppressed for longer periods of time. The figure-of-merit value decays exponentially over time.

A figure-of-merit value of zero is assigned to each new route. The value is increased each time the route is withdrawn or readvertised, or when one of its path attributes changes. With each incident of instability, the value increases as follows:

- Route is withdrawn—1000
- Route is readvertised—1000
- Route's path attributes change—500

NOTE: Other vendors' implementations for figure-of-merit increase the value only when a route is withdrawn. The Junos OS implementation for figure-of-merit increases the value for both route withdrawal and route readvertisement. To accommodate other implementations for figure-of-merit, multiply the **reuse** and **suppress** threshold values by 2.

When a route's figure-of-merit value reaches a particular level, called the *cutoff* or *suppression threshold*, the route is suppressed. If a route is suppressed, the routing table no longer installs the route into the forwarding table and no longer exports this route to any of the routing protocols. By default, a route is

suppressed when its figure-of-merit value reaches 3000. To modify this default, include the **suppress** option at the **[edit policy-options damping name]** hierarchy level.

If a route has flapped, but then becomes stable so that none of the incidents listed previously occur within a configurable amount of time, the figure-of-merit value for the route decays exponentially. The default half-life is 15 minutes. For example, for a route with a figure-of-merit value of 1500, if no incidents occur, its figure-of-merit value is reduced to 750 after 15 minutes and to 375 after another 15 minutes. To modify the default half-life, include the **half-life** option at the **[edit policy-options damping name]** hierarchy level.

NOTE: For the half-life, configure a value that is less than the max-suppress. If you do not, the configuration is rejected.

A suppressed route becomes reusable when its figure-of-merit value decays to a value below a *reuse threshold*, thus allowing routes that experience transient instability to once again be considered valid. The default reuse threshold is 750. When the figure-of-merit value passes below the reuse threshold, the route once again is considered usable and can be installed in the forwarding table and exported from the routing table. To modify the default reuse threshold, include the **reuse** option at the **[edit policy-options damping name]** hierarchy level.

The maximum suppression time provides an upper bound on the time that a route can remain suppressed. The default maximum suppression time is 60 minutes. To modify the default, include the **max-suppress** option at the **[edit policy-options damping name]** hierarchy level.

NOTE: For the max-suppress, configure a value that is greater than the half-life. If you do not, the configuration is rejected.

A route's figure-of-merit value stops increasing when it reaches a maximum suppression threshold, which is determined based on the route's suppression threshold level, half-life, reuse threshold, and maximum hold-down time.

The merit ceiling, ϵ_c , which is the maximum merit that a flapping route can collect, is calculated using the following formula:

$$\epsilon_c \leq \epsilon_r e^{(t/\lambda) (\ln 2)}$$

ϵ_r is the figure-of-merit reuse threshold, t is the maximum hold-down time in minutes, and λ is the half-life in minutes. For example, if you use the default figure-of-merit values in this formula, but use a half-life of 30 minutes, the calculation is as follows:

$$\epsilon_c \leq 750 e^{(60/30) (\ln 2)}$$

$$\epsilon_c \leq 3000$$

NOTE: The cutoff threshold, which you configure using the **suppress** option, must be less than or equal to the merit ceiling, ϵ_c . If the configured cutoff threshold or the default cutoff threshold is greater than the merit ceiling, the route is never suppressed and damping never occurs.

To display figure-of-merit information, use the **show policy damping** command.

A route that has been assigned a figure of merit is considered to have a damping state. To display the current damping information on the routing device, use the **show route detail** command.

Specifying BGP Flap Damping as the Action in Routing Policy Terms

To BGP flap damping as the action in a routing policy term, include the **damping** statement and the name of the configured damping parameters either as an option of the **route-filter** statement at the **[edit policy-options policy-statement *policy-name* term *term-name* from]** hierarchy level:

```
[edit policy-options policy-statement policy-name term term-name from]
route-filter destination-prefix match-type {
  damping damping-parameters;
}
```

or at the **[edit policy-options policy-statement *policy-name* term *term-name* then]** hierarchy level:

```
[edit policy-options policy-statement policy-name term term-name then]
damping damping-parameters;
```

Disabling Damping for Specific Address Prefixes

Normally, you enable or disable damping on a per-peer basis. However, you can disable damping for a specific prefix received from a peer by including the **disable** option:

```
[edit policy-options damping name]
disable;
```

Disabling Damping for a Specific Address Prefix

In this routing policy example, although damping is enabled for the peer, the **damping none** statement specifies that damping be disabled for prefix 10.0.0.0/8 in **Policy-A**. This route is not damped because the routing policy statement named **Policy-A** filters on the prefix 10.0.0.0/8 and the action points to the **damping** statement named **none**. The remaining prefixes are damped using the default parameters.

```
[edit]
policy-options {
  policy-statement Policy-A {
    from {
      route-filter 10.0.0.0/8 exact;
    }
    then damping none;
  }
  damping none {
    disable;
  }
}
```

Configuring BGP Flap Damping

Enable BGP flap damping and configure damping parameters:

```
[edit]
routing-options {
  autonomous-system 666;
}
protocols {
  bgp {
    damping;
    group group1 {
      traceoptions {
        file bgp-log size 1m files 10;
        flag damping;
      }
      import damp;
      type external;
      peer-as 10458;
      neighbor 192.168.2.30;
    }
  }
}
policy-options {
  policy-statement damp {
    from {
      route-filter 192.168.0.0/32 exact {
        damping high;
        accept;
      }
    }
  }
}
```

```

        route-filter 172.16.0.0/32 exact {
            damping medium;
            accept;
        }
        route-filter 10.0.0.0/8 exact {
            damping none;
            accept;
        }
    }
}
damping high {
    half-life 30;
    suppress 3000;
    reuse 750;
    max-suppress 60;
}
damping medium {
    half-life 15;
    suppress 3000;
    reuse 750;
    max-suppress 45;
}
damping none {
    disable;
}
}

```

To display damping parameters for this configuration, use the **show policy damping** command:

```
user@host> show policy damping
```

```

Damping information for "high":
  Halflife: 30 minutes
  Reuse merit: 750 Suppress/cutoff merit: 3000
  Maximum suppress time: 60 minutes
  Computed values:
    Merit ceiling: 3008
    Maximum decay: 24933
Damping information for "medium":
  Halflife: 15 minutes
  Reuse merit: 750 Suppress/cutoff merit: 3000
  Maximum suppress time: 45 minutes
  Computed values:
    Merit ceiling: 6024

```

```
Maximum decay: 12449
Damping information for "none":
Damping disabled
```

Example: Configuring BGP Route Flap Damping Parameters

IN THIS SECTION

- [Requirements | 542](#)
- [Overview | 542](#)
- [Configuration | 543](#)
- [Verification | 548](#)

This example shows how to configure damping parameters.

Requirements

Before you begin, configure router interfaces and configure routing protocols.

Overview

This example has three routing devices. Device R2 has external BGP (EBGP) connections with Device R1 and Device R3.

Device R1 and Device R3 have some static routes configured for testing purposes, and these static routes are advertised through BGP to Device R2.

Device R2 damps routes received from Device R1 and Device R3 according to these criteria:

- Damp all prefixes with a mask length equal to or greater than 17 more aggressively than routes with a mask length between 9 and 16.
- Damp routes with a mask length between 0 and 8, inclusive, less than routes with a mask length greater than 8.
- Do not damp the 10.128.0.0/9 prefix at all.

The routing policy is evaluated when routes are being exported from the routing table into the forwarding table. Only the active routes are exported from the routing table.

Figure 36 on page 543 shows the sample network.

Figure 36: BGP Flap Damping Topology

“CLI Quick Configuration” on page 543 shows the configuration for all of the devices in Figure 36 on page 543.

The section “Step-by-Step Procedure” on page 545 describes the steps on Device R2.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level.

Device R1

```
set interfaces fe-1/2/0 unit 0 family inet address 10.0.0.1/30
set interfaces lo0 unit 0 family inet address 192.168.0.1/32
set protocols bgp group ext type external
set protocols bgp group ext export send-direct-and-static
set protocols bgp group ext peer-as 200
set protocols bgp group ext neighbor 10.0.0.2
set policy-options policy-statement send-direct-and-static term 1 from protocol direct
set policy-options policy-statement send-direct-and-static term 1 from protocol static
set policy-options policy-statement send-direct-and-static term 1 then accept
```

```

set routing-options static route 172.16.0.0/16 reject
set routing-options static route 172.16.128.0/17 reject
set routing-options static route 172.16.192.0/20 reject
set routing-options static route 10.0.0.0/9 reject
set routing-options static route 172.16.233.0/7 reject
set routing-options static route 10.224.0.0/11 reject
set routing-options static route 0.0.0.0/0 reject
set routing-options autonomous-system 100

```

Device R2

```

set interfaces fe-1/2/0 unit 0 family inet address 10.0.0.2/30
set interfaces fe-1/2/1 unit 0 family inet address 10.1.0.1/30
set interfaces lo0 unit 0 family inet address 192.168.0.2/32
set protocols bgp damping
set protocols bgp group ext type external
set protocols bgp group ext import damp
set protocols bgp group ext export send-direct
set protocols bgp group ext neighbor 10.0.0.1 peer-as 100
set protocols bgp group ext neighbor 10.1.0.2 peer-as 300
set policy-options policy-statement damp term 1 from route-filter 10.128.0.0/9 exact damping dry
set policy-options policy-statement damp term 1 from route-filter 0.0.0.0/0 prefix-length-range /0-/8
  damping timid
set policy-options policy-statement damp term 1 from route-filter 0.0.0.0/0 prefix-length-range
  /17-/32 damping aggressive
set policy-options policy-statement send-direct term 1 from protocol direct
set policy-options policy-statement send-direct term 1 then accept
set policy-options damping aggressive half-life 30
set policy-options damping aggressive suppress 2500
set policy-options damping timid half-life 5
set policy-options damping dry disable
set routing-options autonomous-system 200

```

Device R3

```

set interfaces fe-1/2/1 unit 0 family inet address 10.1.0.2/30
set interfaces lo0 unit 0 family inet address 192.168.0.3/32

```

```

set protocols bgp group ext type external
set protocols bgp group ext export send-direct-and-static
set protocols bgp group ext peer-as 200
set protocols bgp group ext neighbor 10.1.0.1
set policy-options policy-statement send-direct-and-static term 1 from protocol direct
set policy-options policy-statement send-direct-and-static term 1 from protocol static
set policy-options policy-statement send-direct-and-static term 1 then accept
set routing-options static route 10.128.0.0/9 reject
set routing-options autonomous-system 300

```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure damping parameters:

1. Configure the interfaces.

```

[edit interfaces]
user@R2# set fe-1/2/0 unit 0 family inet address 10.0.0.2/30
user@R2# set fe-1/2/1 unit 0 family inet address 10.1.0.1/30
user@R2# set lo0 unit 0 family inet address 192.168.0.2/32

```

2. Configure the BGP neighbors.

```

[edit protocols bgp group ext]
user@R2# set type external
user@R2# set neighbor 10.0.0.1 peer-as 100
user@R2# set neighbor 10.1.0.2 peer-as 300

```

3. Create and configure the damping parameter groups.

```

[edit policy-options]
user@R2# set damping aggressive half-life 30
user@R2# set damping aggressive suppress 2500
user@R2# set damping timid half-life 5
user@R2# set damping dry disable

```

4. Configure the damping policy.

```
[edit policy-options policy-statement damp term 1]
user@R2# set from route-filter 10.128.0.0/9 exact damping dry
user@R2# set from route-filter 0.0.0.0/0 prefix-length-range /0-/8 damping timid
user@R2# set from route-filter 0.0.0.0/0 prefix-length-range /17-/32 damping aggressive
```

5. Enable damping for BGP.

```
[edit protocols bgp]
user@R2# set damping
```

6. Apply the policy as an import policy for the BGP neighbor.

```
[edit protocols bgp group ext]
user@R2# set import damp
```

NOTE: You can refer to the same routing policy one or more times in the same or different **import** statements.

7. Configure an export policy.

```
[edit policy-options policy-statement send-direct term 1]
user@R2# set from protocol direct
user@R2# set then accept
```

8. Apply the export policy.

```
[edit protocols bgp group ext]
user@R2# set export send-direct
```

9. Configure the autonomous system (AS) number.

```
[edit routing-options]
user@R2# set autonomous-system 200
```

Results

From configuration mode, confirm your configuration by issuing the **show interfaces**, **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R2# show interfaces
fe-1/2/0 {
  unit 0 {
    family inet {
      address 10.0.0.2/30;
    }
  }
}
fe-1/2/1 {
  unit 0 {
    family inet {
      address 10.1.0.1/30;
    }
  }
}
lo0 {
  unit 0 {
    family inet {
      address 192.168.0.2/32;
    }
  }
}
```

```
user@R2# show protocols
bgp {
  damping;
  group ext {
    type external;
    import damp;
    export send-direct;
    neighbor 10.0.0.1 {
      peer-as 100;
    }
    neighbor 10.1.0.2 {
      peer-as 300;
    }
  }
}
```

```
user@R2# show policy-options
policy-statement damp {
  term 1 {
    from {
      route-filter 10.128.0.0/9 exact damping dry;
      route-filter 0.0.0.0/0 prefix-length-range /0-/8 damping timid;
      route-filter 0.0.0.0/0 prefix-length-range /17-/32 damping aggressive;
    }
  }
}
policy-statement send-direct {
  term 1 {
    from protocol direct;
    then accept;
  }
}
damping aggressive {
  half-life 30;
  suppress 2500;
}
damping timid {
  half-life 5;
}
damping dry {
  disable;
}
```

```
user@R2# show routing-options
autonomous-system 200;
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

IN THIS SECTION

- [Causing Some Routes to Flap | 549](#)
- [Checking the Route Flaps | 549](#)
- [Verifying Route Flap Damping | 550](#)
- [Displaying the Details of a Damped Route | 551](#)

- [Verifying That Default Damping Parameters Are in Effect | 552](#)
- [Filtering the Damping Information | 553](#)

Confirm that the configuration is working properly.

Causing Some Routes to Flap

Purpose

To verify your route flap damping policy, some routes must flap. Having a live Internet feed almost guarantees that a certain number of route flaps will be present. If you have control over a remote system that is advertising the routes, you can modify the advertising router's policy to effect the advertisement and withdrawal of all routes or of a given prefix. In a test environment, you can cause routes to flap by clearing the BGP neighbors or by restarting the routing process on the BGP neighbors, as shown here.

Action

From operational mode on Device R1 and Device R3, enter the **restart routing** command.

CAUTION: Use this command cautiously in a production network.

```
user@R1> restart routing
```

```
R1 started, pid 10474
```

```
user@R3> restart routing
```

```
R3 started, pid 10478
```

Meaning

On Device R2, all of the routes from the neighbors are withdrawn and re-advertised.

Checking the Route Flaps

Purpose

View the number of neighbor flaps.

Action

From operational mode, enter the **show bgp summary** command.

```
user@R2> show bgp summary
```

```
Groups: 1 Peers: 2 Down peers: 0
Table          Tot Paths  Act Paths Suppressed    History Damp State   Pending
inet.0
              12         1         11         0         11         0
Peer          AS      InPkt   OutPkt   OutQ   Flaps Last Up/Dwn
State|#Active/Received/Accepted/Damped...
10.0.0.1      100         10        10        0        4        2:50
0/9/0/9      0/0/0/0
10.1.0.2      300         10        10        0        4        2:53
1/3/1/2      0/0/0/0
```

Meaning

This output was captured after the routing process was restarted on Device R2's neighbors four times.

Verifying Route Flap Damping

Purpose

Verify that routes are being hidden due to damping.

Action

From operational mode, enter the **show route damping suppressed** command.

```
user@R2> show route damping suppressed
```

```
inet.0: 15 destinations, 17 routes (6 active, 0 holddown, 11 hidden)
+ = Active Route, - = Last Active, * = Both

                  > to 10.0.0.1 via fe-1/2/0.0

```

Meaning

The output shows some routing instability. Eleven routes are hidden due to damping.

Displaying the Details of a Damped Route

Purpose

Display the details of damped routes.

Action

From operational mode, enter the **show route damping suppressed 172.16.192.0/20 detail** command.

```
user@R2> show route damping suppressed 172.16.192.0/20 detail
```

```

inet.0: 15 destinations, 17 routes (6 active, 0 holddown, 11 hidden)
172.16.192.0/20 (1 entry, 0 announced)
      BGP          /-101
      Next hop type: Router, Next hop index: 758

```

```

Address: 0x9414484
Next-hop reference count: 9
Source: 10.0.0.1
Next hop: 10.0.0.1 via fe-1/2/0.0, selected
Session Id: 0x100201
State: <Hidden Ext>
Local AS: 200 Peer AS: 100
Age: 52
Validation State: unverified
Task: BGP_100.10.0.0.1+55922
AS path: 100 I
Localpref: 100
Router ID: 192.168.0.1
Merit (last update/now): 4278/4196
damping-parameters: aggressive
Last update: 00:00:52 First update: 01:01:55
Flaps: 8
Suppressed. Reusable in: 01:14:40
Preference will be: 170

```

Meaning

This output indicates that the displayed route has a mask length that is equal to or greater than /17, and confirms that it has been correctly mapped to the aggressive damping profile. You can also see the route's current (and last) figure of merit value, and when the route is expected to become active if it remains stable.

Verifying That Default Damping Parameters Are in Effect

Purpose

Locating a damped route with a /16 mask confirms that the default parameters are in effect.

Action

From operational mode, enter the **show route damping suppressed detail | match 0/16** command.

```
user@R2> show route damping suppressed detail | match 0/16
```

```
172.16.0.0/16 (1 entry, 0 announced)
```

```
user@R2> show route damping suppressed 172.16.0.0/16 detail
```

```

inet.0: 15 destinations, 17 routes (6 active, 0 holddown, 11 hidden)
172.16.0.0/16 (1 entry, 0 announced)
      BGP                               /-101
      Next hop type: Router, Next hop index: 758
      Address: 0x9414484
      Next-hop reference count: 9
      Source: 10.0.0.1
      Next hop: 10.0.0.1 via fe-1/2/0.0, selected
      Session Id: 0x100201
      State: <Hidden Ext>
      Local AS: 200 Peer AS: 100
      Age: 1:58
      Validation State: unverified
      Task: BGP_100.10.0.0.1+55922
      AS path: 100 I
      Localpref: 100
      Router ID: 192.168.0.1
      Merit (last update/now): 3486/3202
      Default damping parameters used
      Last update: 00:01:58 First update: 01:03:01
      Flaps: 8
      Suppressed. Reusable in: 00:31:40
      Preference will be: 170

```

Meaning

Routes with a /16 mask are not impacted by the custom damping rules. Therefore, the default damping rules are in effect.

To repeat, the custom rules are as follows:

- Damp all prefixes with a mask length equal to or greater than 17 more aggressively than routes with a mask length between 9 and 16.
- Damp routes with a mask length between 0 and 8, inclusive, less than routes with a mask length greater than 8.
- Do not damp the 10.128.0.0/9 prefix at all.

Filtering the Damping Information

Purpose

Use OR groupings or cascaded piping to simplify the determination of what damping profile is being used for routes with a given mask length.

Action

From operational mode, enter the **show route damping suppressed** command.

```
user@R2> show route damping suppressed detail | match "0 announced | damp"
```

```
0.0.0.0/0 (1 entry, 0 announced)
    damping-parameters: timid
10.0.0.0/9 (1 entry, 0 announced)
    Default damping parameters used
    damping-parameters: aggressive
    damping-parameters: aggressive
10.224.0.0/11 (1 entry, 0 announced)
    Default damping parameters used
172.16.0.0/16 (1 entry, 0 announced)
    Default damping parameters used
172.16.128.0/17 (1 entry, 0 announced)
    damping-parameters: aggressive
172.16.192.0/20 (1 entry, 0 announced)
    damping-parameters: aggressive
192.168.0.1/32 (1 entry, 0 announced)
    damping-parameters: aggressive
192.168.0.3/32 (1 entry, 0 announced)
    damping-parameters: aggressive
172.16.233.0/7 (1 entry, 0 announced)
    damping-parameters: timid
```

Meaning

When you are satisfied that your EBGp routes are correctly associated with a damping profile, you can issue the **clear bgp damping** operational mode command to restore an active status to your damped routes, which will return your connectivity to normal operation.

Example: Configuring BGP Route Flap Damping Based on the MBGP MVPN Address Family

IN THIS SECTION

- [Requirements | 555](#)
- [Overview | 555](#)
- [Configuration | 556](#)
- [Verification | 567](#)

This example shows how to configure an multiprotocol BGP multicast VPN (also called Next-Generation MVPN) with BGP route flap damping.

Requirements

This example uses Junos OS Release 12.2. BGP route flap damping support for MBGP MVPN, specifically, and on an address family basis, in general, is introduced in Junos OS Release 12.2.

Overview

BGP route flap damping helps to diminish route instability caused by routes being repeatedly withdrawn and readvertised when a link is intermittently failing.

This example uses the default damping parameters and demonstrates an MBGP MVPN scenario with three provider edge (PE) routing devices, three customer edge (CE) routing devices, and one provider (P) routing device.

[Figure 37 on page 556](#) shows the topology used in this example.

Figure 37: MBGP MVPN with BGP Route Flap Damping

On PE Device R4, BGP route flap damping is configured for address family **inet-mvpn**. A routing policy called **dampPolicy** uses the **nlri-route-type** match condition to damp only MVPN route types 3, 4, and 5. All other MVPN route types are not damped.

This example shows the full configuration on all devices in the [“CLI Quick Configuration” on page 556](#) section. The [“Configuring Device R4” on page 561](#) section shows the step-by-step configuration for PE Device R4.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

Device R1

```
set interfaces ge-1/2/0 unit 1 family inet address 10.1.1.1/30
set interfaces ge-1/2/0 unit 1 family mpls
set interfaces lo0 unit 1 family inet address 172.16.1.1/32
set protocols ospf area 0.0.0.0 interface lo0.1 passive
set protocols ospf area 0.0.0.0 interface ge-1/2/0.1
set protocols pim rp static address 172.16.100.1
set protocols pim interface all
set routing-options router-id 172.16.1.1
```

Device R2

```

set interfaces ge-1/2/0 unit 2 family inet address 10.1.1.2/30
set interfaces ge-1/2/0 unit 2 family mpls
set interfaces ge-1/2/1 unit 5 family inet address 10.1.1.5/30
set interfaces ge-1/2/1 unit 5 family mpls
set interfaces vt-1/2/0 unit 2 family inet
set interfaces lo0 unit 2 family inet address 172.16.1.2/32

set routing-options router-id 172.16.1.7

```

Configuring Device R4

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure Device R4:

1. Configure the interfaces.

```

[edit interfaces]
user@R4# set ge-1/2/0 unit 10 family inet address 10.1.1.10/30
user@R4# set ge-1/2/0 unit 10 family mpls
user@R4# set ge-1/2/1 unit 17 family inet address 10.1.1.17/30
user@R4# set ge-1/2/1 unit 17 family mpls
user@R4# set vt-1/2/0 unit 4 family inet
user@R4# set lo0 unit 4 family inet address 172.16.1.4/32
user@R4# set lo0 unit 104 family inet address 172.16.100.4/32

```

2. Configure MPLS and the signaling protocols on the interfaces.

```

[edit protocols]
user@R4# set mpls interface all
user@R4# set mpls interface ge-1/2/0.10
user@R4# set rsvp interface all aggregate
user@R4# set ldp interface ge-1/2/0.10
user@R4# set ldp p2mp

```

3. Configure BGP.

The BGP configuration enables BGP route flap damping for the **inet-mvpn** address family. The BGP configuration also imports into the routing table the routing policy called **dampPolicy**. This policy is applied to neighbor PE Device R2.

```
[edit protocols bgp group ibgp]
user@R4# set type internal
user@R4# set local-address 172.16.1.4
user@R4# set family inet-vpn unicast
user@R4# set family inet-vpn any
user@R4# set family inet-mvpn signaling damping
user@R4# set neighbor 172.16.1.2 import dampPolicy
user@R4# set neighbor 172.16.1.5
```

4. Configure an interior gateway protocol.

```
[edit protocols ospf]
user@R4# set traffic-engineering
[edit protocols ospf area 0.0.0.0]
user@R4# set interface all
user@R4# set interface lo0.4 passive
user@R4# set interface ge-1/2/0.10
```

5. Configure a damping policy that uses the **nlri-route-type** match condition to damp only MVPN route types 3, 4, and 5.

```
[edit policy-options policy-statement dampPolicy term term1]
user@R4# set from family inet-mvpn
user@R4# set from nlri-route-type 3
user@R4# set from nlri-route-type 4
user@R4# set from nlri-route-type 5
user@R4# set then accept
```

6. Configure the **damping** policy to disable BGP route flap damping.

The **no-damp** policy (**damping no-damp disable**) causes any damping state that is present in the routing table to be deleted. The **then damping no-damp** statement applies the **no-damp** policy as an action and has no **from** match conditions. Therefore, all routes that are not matched by **term1** are matched by this term, with the result that all other MVPN route types are not damped.

```
[edit policy-options policy-statement dampPolicy]
user@R4# set then damping no-damp
user@R4# set then accept
[edit policy-options]
user@R4# set damping no-damp disable
```

7. Configure the **parent_vpn_routes** to accept all other BGP routes that are not from the **inet-mvpn** address family.

This policy is applied as an OSPF export policy in the routing instance.

```
[edit policy-options policy-statement parent_vpn_routes]
user@R4# set from protocol bgp
user@R4# set then accept
```

8. Configure the VPN routing and forwarding (VRF) instance.

```
[edit routing-instances vpn-1]
user@R4# set instance-type vrf
user@R4# set interface vt-1/2/0.4
user@R4# set interface ge-1/2/1.17
user@R4# set interface lo0.104
user@R4# set route-distinguisher 100:100
user@R4# set vrf-target target:1:1
user@R4# set protocols ospf export parent_vpn_routes
user@R4# set protocols ospf area 0.0.0.0 interface lo0.104 passive
user@R4# set protocols ospf area 0.0.0.0 interface ge-1/2/1.17
user@R4# set protocols pim rp static address 172.16.100.2
user@R4# set protocols pim interface ge-1/2/1.17 mode sparse
user@R4# set protocols mvpn
```

9. Configure the router ID and the autonomous system (AS) number.

```
[edit routing-options]
```

```
user@R4# set router-id 172.16.1.4
user@R4# set autonomous-system 1001
```

10. If you are done configuring the device, commit the configuration.

```
user@R4# commit
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, **show routing-instances**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R4# show interfaces
ge-1/2/0 {
  unit 10 {
    family inet {
      address 10.1.1.10/30;
    }
    family mpls;
  }
}
ge-1/2/1 {
  unit 17 {
    family inet {
      address 10.1.1.17/30;
    }
    family mpls;
  }
}
vt-1/2/0 {
  unit 4 {
    family inet;
  }
}
lo0 {
  unit 4 {
    family inet {
      address 172.16.1.4/32;
    }
  }
}
```

```

unit 104 {
    family inet {
        address 172.16.100.4/32;
    }
}

```

```

user@R4# show protocols

Verification

IN THIS SECTION

- [Verifying That Route Flap Damping Is Disabled | 567](#)
- [Verifying Route Flap Damping | 568](#)

Confirm that the configuration is working properly.

Verifying That Route Flap Damping Is Disabled

Purpose

Verify the presence of the **no-damp** policy, which disables damping for MVPN route types other than 3, 4, and 5.

Action

From operational mode, enter the **show policy damping** command.

```
user@R4> show policy damping
```

```
Default damping information:
  Halflife: 15 minutes
  Reuse merit: 750 Suppress/cutoff merit: 3000
  Maximum suppress time: 60 minutes
  Computed values:
    Merit ceiling: 12110
    Maximum decay: 6193
Damping information for "no-damp":
Damping disabled
```

Meaning

The output shows that the default damping parameters are in effect and that the **no-damp** policy is also in effect for the specified route types.

Verifying Route Flap Damping

Purpose

Check whether BGP routes have been damped.

Action

From operational mode, enter the **show bgp summary** command.

```
user@R4> show bgp summary
```

```
Groups: 1 Peers: 2 Down peers: 0

Understanding Source Class Usage and Destination Class Usage Options

You can maintain packet counts based on the entry and exit points for traffic passing through your network. Entry and exit points are identified by source and destination prefixes grouped into disjoint sets defined as source classes and *destination classes*. You can define classes based on a variety of parameters, such as routing neighbors, autonomous systems, and route filters.

Source class usage (SCU) counts packets sent to customers by performing lookups on the IP source address and the IP destination address. SCU makes it possible to track traffic originating from specific prefixes on the provider core and destined for specific prefixes on the customer edge. You must enable SCU accounting on both the inbound and outbound physical interfaces.

Destination class usage (DCU) counts packets from customers by performing lookups of the IP destination address. DCU makes it possible to track traffic originating from the customer edge and destined for specific prefixes on the provider core router.

On T Series Core Routers and M320 Multiservice Edge Routers, the source class and destination classes are not carried across the platform fabric. The implications of this are as follows:

- On T Series and M320 routers, SCU and DCU accounting is performed before the packet enters the fabric.
- On T Series and M320 routers, DCU is performed before output filters are evaluated.
- On M Series platforms, DCU is performed after output filters are evaluated.
- If an output filter drops traffic on M Series devices, the dropped packets are excluded from DCU statistics.
- If an output filter drops traffic on T Series and M320 routers, the dropped packets are included in DCU statistics.

NOTE: For PTX Series routers with FPC3, and PTX1000 routers, to support SCU and DCU, you must configure *enhanced-mode* on the chassis.

On MX Series platforms with MPC/MIC interfaces, SCU and DCU are performed after output filters are evaluated. Packets dropped by output filters are not included in SCU or DCU statistics.

On MX Series platforms with non-MPC/MIC interfaces, SCU and DCU are performed before output filters are evaluated. Packets dropped by output filters are included in SCU and DCU statistics.

On PTX Series platforms, SCU and DCU accounting is performed before output filters are evaluated. Packets dropped by output filters are included in SCU and DCU statistics.

On Enhanced Scaling FPCs (T640-FPC1-ES, T640-FPC2-ES, T640-FPC3-ES, T640-FPC4-1P-ES, and T1600-FPC4-ES), the source class accounting is performed at ingress. Starting with Junos OS Release 14.2, the SCU accounting is performed at ingress on a T4000 Type 5 FPC. The implications of this are as follows:

- SCU accounting is performed when packets traverse from T4000 Type 5 FPC (ingress FPC) to Enhanced Scaling FPCs (egress FPC).
- SCU accounting is performed when packets traverse from Enhanced Scaling FPCs (ingress FPC) to T4000 Type 5 FPC (egress FPC).

NOTE: When the interface statistics are cleared and then the routing engine is replaced, the SCU and DCU statistics will not match the statistics of the previous routing engine.

For more information about source class usage, see the *Routing Policies, Firewall Filters, and Traffic Policers User Guide* and the *Junos OS Network Interfaces Library for Routing Devices*.

Source Class Usage Overview

Source class usage (SCU) is a logical extension of the destination class usage (DCU) concept. DCU was created so that Juniper Networks customers could count on a per-interface basis how much traffic was sent to specified prefixes. [Figure 38 on page 572](#) shows a service provider edge (PE) router diagram.

Figure 38: DCU/SCU Concept

The Fast Ethernet interfaces contain inbound traffic from customers, and the SONET/SDH interfaces are connected to outbound public network prefixes. With DCU configured on the Fast Ethernet interfaces, you can track how much traffic is sent to a specific prefix in the core of the network originating from one of the specified interfaces (in this case, the Fast Ethernet interfaces).

However, DCU limits your ability to keep track of traffic moving in the reverse direction. It can account for all traffic that arrives on a core interface and heads toward a specific customer, but it cannot count traffic that arrives on a core interface from a specific prefix. For example, DCU can process cumulative

traffic headed toward interface **fe-0/0/0**, but cannot differentiate between traffic coming only from **10.3.0.0/16** and traffic coming from all prefixes.

You can track source-based traffic by using SCU, which allows you to monitor the amount of traffic originating from a specific prefix. With this feature, usage can be tracked and customers can be billed for the traffic they receive.

Guidelines for Configuring SCU

When you enable SCU or DCU, keep the following information in mind:

- In Junos OS Release 5.6 and later for M Series routers only, you can use a source class or a destination class as a match condition in a firewall filter. To configure, include the **destination-class** or **source-class** statement at the **[edit firewall filter *firewall-name* term *term-name* from]** hierarchy level. For more information about firewall filters, see the *Junos Policy Framework Configuration Guide*.
- You can assign up to 126 source classes and 126 destination classes.
- When configuring policy action statements, you can configure only one source class for each matching route. In other words, more than one source class cannot be applied to the same route.
- A source or destination class is applied to a packet only once during the routing table lookup. When a network prefix matches a class-usage policy, SCU is assigned to packets first; DCU is assigned only if SCU has not been assigned. Be careful when using both class types, since misconfiguration can result in uncounted packets. The following example explores one potential mishap:

A packet arrives on a router interface configured for both SCU and DCU. The packet's source address matches an SCU class, and its destination matches a DCU class. Consequently, the packet is subjected to a source lookup and is marked with the SCU class. The DCU class is ignored. As a result, the packet is forwarded to the outbound interface with only the SCU class still intact.

However, the outbound interface lacks an SCU configuration. When the packet is ready to leave the router, the router detects that the output interface is not configured for SCU and the packet is not

counted by SCU. Likewise, even though the prefix matched the DCU prefix, the DCU counters do not increment because DCU was superseded by SCU at the inbound interface.

To solve this problem, make sure you configure both the inbound and outbound interfaces completely or configure only one class type per interface per direction.

- Classes cannot be mapped to directly connected prefixes configured on local interfaces. This is true for DCU and SCU classes.
- If you use multiple terms within a single policy, you only need to configure the policy name and apply it to the forwarding table once. This makes it easier to change options within your terms without having to reconfigure the main policy.
- Execute command line interface (CLI) **show** commands and accounting profiles at the desired outbound interface to track SCU traffic. SCU counters increment at the SCU **output** interface.
- Apply your classes to the inbound and outbound interfaces by means of the **input** and **output** SCU interface parameters.
- On M320 and T Series routers, the source and destination classes are not carried across the platform fabric. For these routers, SCU and DCU accounting is performed before the packet enters the fabric and DCU is performed before output filters are evaluated.
- If an output filter drops traffic on M Series routers other than the M120 router and M320 router, the dropped packets are excluded from DCU statistics. If an output filter drops traffic on M320 and T Series routers, the dropped packets are included in DCU statistics.

System Requirements for SCU

To implement SCU, your system must meet these requirements:

- Junos OS Release 8.2 or later for M120 and MX Series router support
- Junos OS Release 6.2 or later for IPv6 SCU
- Junos OS Release 5.6 or later to use a source class or a destination class as a match condition in a firewall filter

- Junos OS Release 5.4 or later for IPv4 SCU
- Three Juniper Networks M Series, MX Series, or T Series routers for basic SCU and five routers for SCU with Layer 3 VPNs. One router acts as a source class usage transit router, and the other routers are used to generate traffic or participate in the Layer 3 VPN.
- For M Series and T Series routers, a Tunnel Services PIC for SCU with Layer 3 VPNs

Terms and Acronyms for SCU

D

destination address (DA)	The IP address of a device intended as the receiver for a packet. This address is included in the IP header and is the main address analyzed by the router during routing table lookups and DCU.
destination class usage (DCU)	A method of grouping certain types of traffic and monitoring these groups through CLI show commands, accounting profiles, or SNMP. DCU uses a destination address lookup when determining group membership. For more information about DCU, see the <i>Junos Policy Framework Configuration Guide</i> .

S

source address (SA)	The IP address of a device sending a packet. This address is included in the IP header and is analyzed by the router for a variety of services, including source-based filtering, policing, class of service (CoS), and SCU.
source class usage (SCU)	A method of grouping certain types of traffic and monitoring these groups through CLI show commands, accounting profiles, or SNMP. SCU uses a source address lookup when determining group membership. For more information about SCU, see the <i>Junos Policy Framework Configuration Guide</i> .

[Roadmap for Configuring SCU with Layer 3 VPNs | 576](#)

Roadmap for Configuring SCU

To configure source class usage (SCU), you must:

1. Create a routing policy that includes prefix route filters that indicate the IPv4 or IPv6 source addresses to monitor. See [“Configuring Route Filters and Source Classes in a Routing Policy” on page 577](#).
2. Apply the filters to the forwarding table. See [“Applying the Policy to the Forwarding Table” on page 578](#).
3. Enable accounting on the inbound and outbound interfaces. See [“Enabling Accounting on Inbound and Outbound Interfaces” on page 579](#).

RELATED DOCUMENTATION

[Source Class Usage Overview | 572](#)

[System Requirements for SCU | 574](#)

[SCU Configuration | 584](#)

Roadmap for Configuring SCU with Layer 3 VPNs

SCU can be implemented over regular interfaces; it is also used in combination with Layer 3 VPNs. When you view SCU traffic on an ingress provider edge (PE) router, use the standard procedure outlined in [“Roadmap for Configuring SCU” on page 576](#). However, when you enable packet counting for Layer 3 VPNs at the egress point of the MPLS tunnel, you need to take some additional steps, as follows:

1. Configure SCU on the virtual loopback tunnel (vt) interface of the egress PE router. See [“Configuring Input SCU on the vt Interface of the Egress PE Router” on page 580](#).
2. Map the SCU-enabled input interface of that router to the virtual routing and forwarding (VRF) instance. See [“Mapping the SCU-Enabled vt Interface to the VRF Instance” on page 580](#).
3. Configure SCU on the output interface of the egress router. See [“Configuring SCU on the Output Interface” on page 581](#).
4. Configure an accounting profile and associate the source class with that accounting profile. You can also specify the filename for the data capture, a class usage profile name, and an interval indicating

how often you want the SCU information to be saved. See [“Associating an Accounting Profile with SCU Classes” on page 582](#).

NOTE: SCU is not supported over Layer 2 VPNs.

Configuring Route Filters and Source Classes in a Routing Policy

Begin configuring SCU by creating prefix route filters in a policy statement. These prefixes indicate the IPv4 or IPv6 source addresses to monitor. Within the policy statement, you must define and name the source classes attached to the filters.

```
[edit policy-options]
policy-statement policy-name {
  term term-name {
    from {
      route-filter address/prefix;
    }
    then source-class class-name;
  }
}
```

NOTE: When configuring policy action statements, you can configure only one source class for each matching route. In other words, more than one source class cannot be applied to the same route.

An alternate configuration method, using the **forwarding-class** policy action, is even more flexible. It allows your IPv4 or IPv6 route filters to apply to an SCU profile, a DCU profile, or both simultaneously. Additionally, if you have only one term, you can implement the **from** and **then** statements at the **[edit policy-options policy-statement *policy-name*]** hierarchy level.

```
[edit policy-options]
policy-statement policy-name {
  from {
    route-filter 105.15.0.0/16 orlonger;
  }
  then forwarding-class class-name;
}
```

A third option is the existing DCU parameter of **destination-class**. For more information on DCU, see the *Junos Policy Framework Configuration Guide*.

Applying the Policy to the Forwarding Table

Next, apply the policy you created to the forwarding table. When you apply the policy, the network prefixes you defined are marked with the appropriate source class.

```
[edit routing-options]
forwarding-table {
  export policy-name;
}
```

RELATED DOCUMENTATION

[Source Class Usage Overview | 572](#)

[System Requirements for SCU | 574](#)

[Roadmap for Configuring SCU | 576](#)

[SCU Configuration | 584](#)

Enabling Accounting on Inbound and Outbound Interfaces

Unlike DCU, which only requires implementation on a single interface, accounting for SCU must be enabled on two interfaces: the inbound and outbound physical or logical interfaces traversed by the source class. You must define explicitly the two interfaces on which SCU monitored traffic is expected to arrive and depart. This is because SCU performs two lookups in the routing table: a source address (SA) and a destination address (DA) lookup. In contrast, DCU only has a single destination address lookup. By specifying the addresses involved in the additional SCU SA lookup, you minimize the performance impact on your router.

An individual SCU interface can be configured as an input interface, an output interface, or both. SCU can be enabled in an IPv4 (**family inet**) or IPv6 (**family inet6**) network. To configure SCU accounting, include the **source-class-usage** statement at the **[edit interfaces *interface-name* unit *logical-unit-number* family (inet | inet6) accounting]** hierarchy level:

```
[edit]
interfaces {
  interface-name {
    unit unit-number {
      family (inet | inet6) {
        accounting {
          source-class-usage {
            (input | output | input output);
          }
          destination-class-usage;
        }
      }
    }
  }
}
```

After the full SCU configuration is enabled, every packet arriving on an SCU input interface is subjected to an SA-based lookup and then a DA-based lookup. In addition, an individual set of counters for every configured SCU class is maintained by the router on a per-interface and per-protocol family basis.

[SCU Configuration | 584](#)

Configuring Input SCU on the vt Interface of the Egress PE Router

To enable SCU in a Layer 3 VPN, configure source class usage on the virtual loopback tunnel (**vt**) interface of the egress PE router that is either configured for or equipped with a Tunnel PIC. The interface is equivalent to the inbound SCU interface, so use the **input** statement at the **[edit interfaces vt-interface-number unit 0 family inet accounting source-class-usage]** hierarchy level:

```
[edit]
interfaces {
  vt-0/3/0 {
    unit 0 {
      family inet {
        accounting {
          source-class-usage {
            input;
          }
        }
      }
    }
  }
}
```

[SCU with Layer 3 VPNs Configuration | 595](#)

Mapping the SCU-Enabled vt Interface to the VRF Instance

Next, include the VPN loopback tunnel interface in the desired VRF instance at the **[edit routing-instances routing-instance-name]** hierarchy level:

```
[edit]
routing-instances {
  routing-instance-name {
    instance-type vrf;
```

```

interface at-2/1/1.0;
interface vt-0/3/0.0;
route-distinguisher 10.250.14.225:100;
vrf-import import-policy-name;
vrf-export export-policy-name;
protocols {
    bgp {
        group to-r4 {
            local-address 10.20.253.1;
            peer-as 400;
            neighbor 10.20.253.2;
        }
    }
}
}
}

```

RELATED DOCUMENTATION

[Roadmap for Configuring SCU with Layer 3 VPNs | 576](#)

[SCU with Layer 3 VPNs Configuration | 595](#)

Configuring SCU on the Output Interface

Since VPN traffic enters the egress router through the VPN loopback tunnel interface, you still need to determine the exit interface for this traffic. To complete your SCU configuration, configure the output version of source class usage on the exit interface of your egress router:

```

[edit interfaces]
at-1/1/0 {
    unit 0 {
        family inet {
            accounting {
                source-class-usage {
                    output;
                }
            }
        }
    }
}

```

```

    }
  }
}

```

RELATED DOCUMENTATION

[Roadmap for Configuring SCU with Layer 3 VPNs | 576](#)

[SCU with Layer 3 VPNs Configuration | 595](#)

Associating an Accounting Profile with SCU Classes

Once your source classes are defined, implemented on the inbound and outbound interfaces, and applied to the forwarding table, you are ready to associate the source class with an accounting profile. Configure the accounting profile at the **[edit accounting-options class-usage-profile]** hierarchy level. You can associate either an SCU source class or a DCU destination class with the accounting profile. You can also specify the filename for the data capture, a class usage profile name, and an interval (in minutes) indicating how often you want the SCU information to be saved to the file.

```

[edit]
accounting-options {
  file filename;
  class-usage-profile profile-name {
    file filename;
    interval minutes;
    source-classes {
      source-class-name;
    }
    destination-classes {
      destination-class-name;
    }
  }
}

```

NOTE: SCU accounting occurs on the outbound interface before output filter processing. If an SCU-marked packet is discarded in the router, the SCU counters can indicate more traffic than actually exists. You must use filter counters or traceoptions logs to ensure that all packets dropped by the SCU filter are recorded. If logged, you can subtract the discarded packets from the SCU counter tallies and calculate the true traffic profile.

Because DCU accounting occurs after the filtering process, DCU is unaffected by this disclaimer.

Verifying Your SCU Accounting Profile

Purpose

To view the results of the SCU accounting profile you created.

Action

Navigate to the **/var/log** directory of your router. It should contain the designated class usage profile log. The layout of an SCU profile looks like this:

```
profile_name,epoch-timestamp,interface-name,source-class-name,packet-count,
byte-count
```

An example of the actual output from a profile looks like this:

```
scu_profile,980313078,ge-1/0/0.0,gold,82,6888
scu_profile,980313078,ge-1/0/0.0,silver,164,13776
scu_profile,980313078,ge-1/0/0.0,bronze,0,0
scu_profile,980313678,ge-1/0/0.0,gold,82,6888
scu_profile,980313678,ge-1/0/0.0,silver,246,20664
scu_profile,980313678,ge-1/0/0.0,bronze,0,0
```

To view the parameters of your SCU accounting profile, you can use the **show accounting-options class-usage-profile *scu-profile-name*** command.

SCU Configuration

IN THIS SECTION

- [Configuring SCU | 584](#)
- [Verifying Your Work | 588](#)

Configuring SCU

Figure 39: SCU Topology Diagram

Figure 39 on page 584 shows a basic SCU configuration with three routers. Source routers A and B use loopback addresses as the prefixes to be monitored. Most of the configuration tasks and actual monitoring occurs on transit Router SCU.

Begin your configuration on Router A. The loopback address on Router A contains the origin of the prefix that is to be assigned to source class A on Router SCU. However, no SCU processing happens on this router. Therefore, configure Router A for basic OSPF routing and include your loopback interface and interface **so-0/0/2** in the OSPF process.

Router A:

```

[edit]
interfaces {
  so-0/0/2 {
    unit 0 {
      family inet {
        address 10.255.50.2/24;
      }
    }
  }
  lo0 {
    unit 0 {
      family inet {
        address 10.255.192.10/32;
      }
    }
  }
}
protocols {
  ospf {
    area 0.0.0.0 {
      interface so-0/0/2.0;
      interface lo0.0;
    }
  }
}

```

Router SCU handles the bulk of the activity in this example. On Router SCU, enable source class usage on the inbound and outbound interfaces at the **[edit interfaces interface-name unit unit-number family inet accounting]** hierarchy level. Make sure you specify the expected traffic: input, output, or, in this case, both.

Next, configure a route filter policy statement that matches the prefixes of the loopback addresses from routers A and B. Include statements in the policy that classify packets from Router A in one group named **scu-class-a** and packets from Router B in a second class named **scu-class-b**. Notice the efficient use of a single policy containing multiple terms.

Last, apply the policy to the forwarding table.

Router SCU

```

[edit]

```

```

interfaces {
  so-0/0/1 {
    unit 0 {
      family inet {
        accounting {
          source-class-usage {
            input;
            output;
          }
        }
        address 10.255.50.1/24;
      }
    }
  }
  so-0/0/3 {
    unit 0 {
      family inet {
        accounting {
          source-class-usage {
            input;
            output;
          }
        }
        address 10.255.10.3/24;
      }
    }
  }
  lo0 {
    unit 0 {
      family inet {
        address 10.255.6.111/32;
      }
    }
  }
}

protocols {
  ospf {
    area 0.0.0.0 {
      interface so-0/0/1.0;
      interface so-0/0/3.0;
    }
  }
}

```

```

}
routing-options {
  forwarding-table {
    export scu-policy;
  }
}
policy-options {
  policy-statement scu-policy {
    term 0 {
      from {
        route-filter 10.255.192.0/24 orlonger;
      }
      then source-class scu-class-a;
    }
    term 1 {
      from {
        route-filter 10.255.165.0/24 orlonger;
      }
      then source-class scu-class-b;
    }
  }
}
}

```

Complete the configuration tasks on Router B. Just as Router A provides a source prefix, Router B's loopback address matches the prefix assigned to **scu-class-b** on Router SCU. Again, no SCU processing happens on this router, so configure Router B for basic OSPF routing and include your loopback interface and interface **so-0/0/4** in the OSPF process.

Router B:

```

[edit]
interfaces {
  so-0/0/4 {
    unit 0 {
      family inet {
        address 10.255.10.4/24;
      }
    }
  }
}
lo0 {

```

```

    unit 0 {
        family inet {
            address 10.255.165.226/32;
        }
    }
}
protocols {
    ospf {
        area 0.0.0.0 {
            interface so-0/0/4.0;
            interface lo0.0;
        }
    }
}

```

Verifying Your Work

To verify that SCU is functioning properly, use the following commands:

- **show interfaces *interface-name* statistics**
- **show interfaces *interface-name* (extensive | detail)**
- **show route (extensive | detail)**
- **show interfaces source-class *source-class-name* *interface-name***
- **clear interface *interface-name* statistics**

You should always verify SCU statistics at the outbound SCU interface on which you configured the **output** statement. You can perform the following three steps to check the functionality of SCU:

1. Clear all counters on your SCU-enabled router and verify that they are empty.
2. Send a ping from one edge router to another edge router to generate SCU traffic across the SCU-enabled router.
3. Verify that the counters are incrementing correctly on the outbound interface.

The following section shows the output of these commands as used with the configuration example.

```
user@scu> clear interfaces statistics all
```

```
user@scu> show interfaces so-0/0/1.0 statistics
Logical interface so-0/0/1.0 (Index 4) (SNMP ifIndex 119)

Configuring SCU in a Layer 3 VPN

Figure 40: SCU in a Layer 3 VPN Topology Diagram

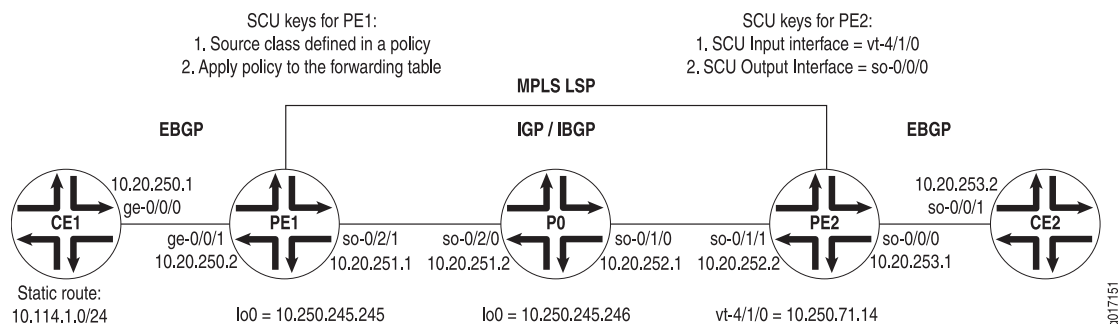

Figure 40 on page 596 displays a Layer 3 VPN topology. CE1 and CE2 are customer edge (CE) routers connected by a VPN through provider routers PE1, P0, and PE2. EBGP is established between routers CE1 and PE1, IBGP connects routers PE1 and PE2 over an IS-IS/MPLS/LDP core, and a second EBGP connection flows between routers PE2 and CE2.

On Router CE1, begin your VPN by setting up an EBGP connection to PE1. Install a static route of **10.114.1.0/24** and advertise this route to your EBGP neighbor.

Router CE1

```
[edit]
interfaces {
  ge-0/0/0 {
    unit 0 {
      family inet {
        address 10.20.250.1/30;
      }
    }
  }
}
routing-options {
  static {
    route 10.114.1.0/24 reject;
  }
  autonomous-system 100;
}
protocols {
  bgp {
    group to-pe1 {
```

```

        local-address 10.20.250.1;
        export inject-direct;
        peer-as 300;
        neighbor 10.20.250.2;
    }
}
}
policy-options {
    policy-statement inject-direct {
        term 1 {
            from {
                protocol static;
                route-filter 10.114.1.0/24 exact;
            }
            then accept;
        }
        term 2 {
            from protocol direct;
            then accept;
        }
    }
}
}

```

On PE1, complete the EBGp connection to CE1 through a VRF routing instance. Set an export policy for your VRF instance that puts BGP traffic into a community, and an import policy that accepts like community traffic from your VPN neighbor. Lastly, configure an IBGP relationship to Router PE2 that runs over an IS-IS, MPLS, and LDP core.

Router PE1

```

}

```

On PE2, complete the IBGP relationship to Router PE1. Establish an EBGP connection to CE2 through a VRF routing instance. Set an export policy for the VRF instance that places BGP traffic into a community, and an import policy that accepts like community traffic from the VPN neighbor. Next, establish a policy that adds the static route from CE1 to a source class called **GOLD1**. Also, export this SCU policy into the forwarding table. Finally, set your **vt** interface as the SCU input interface and establish the CE-facing interface **so-0/0/0** as the SCU output interface.

Router PE2

```

Verifying Your Work

To verify that SCU is functioning properly in the Layer 3 VPN, use the following commands:

- **show interfaces *interface-name* statistics**
- **show interfaces source-class *source-class-name* *interface-name***

- **show interfaces** *interface-name* (extensive | detail)
- **show route** (extensive | detail)
- **clear interface** *interface-name* statistics

You should always verify SCU statistics at the outbound SCU interface on which you configured the **output** statement. To check SCU functionality, follow these steps:

1. Clear all counters on your SCU-enabled router and verify they are empty.
2. Send a ping from the ingress CE router to the second CE router to generate SCU traffic across the SCU-enabled VPN route.
3. Verify that the counters are incrementing correctly on the outbound interface.

The following section shows the output of these commands used with the configuration example.

```
user@pe2> clear interfaces statistics all
```

```
user@pe2> show interfaces so-0/0/0.0 statistics
```

```
Logical interface so-0/0/0.0 (Index 6) (SNMP ifIndex 113)
```

```
Flags: Point-To-Point SNMP-Traps Encapsulation: PPP
```

```
Protocol inet, MTU: 4470
```

	Source class	Packets	Bytes
GOLD1	0	0	

Addresses, Flags: Is-Preferred Is-Primary

```
user@pe2> show interfaces source-class GOLD1 so-0/0/0.0
```

```
Protocol inet
```

	Source class	Packets	Bytes
GOLD1	0	0	

```
user@ce1> ping 10.20.253.2 source 10.114.1.1 rapid count 10000
```

```
user@scu> show interfaces source-class GOLD1 so-0/0/0.0
```

```
Protocol inet
```

	Source class	Packets	Bytes
GOLD1	20000	1680000	

```
user@scu> show interfaces so-0/0/0.0 statistics
```

```
Logical interface so-0/0/0.0 (Index 6) (SNMP ifIndex 113)
```

```
Flags: Point-To-Point SNMP-Traps Encapsulation: PPP
```

```
Protocol inet, MTU: 4470
```

	Source class	Packets	Bytes

GOLD1	20000	1680000

Source Class Usage Overview 572
System Requirements for SCU 574

Example: Grouping Source and Destination Prefixes into a Forwarding Class

IN THIS SECTION

- [Requirements | 606](#)
- [Overview | 606](#)
- [Configuration | 609](#)
- [Verification | 616](#)

This example shows how to group source and destination prefixes into a forwarding class.

Requirements

No special configuration beyond device initialization is required before configuring this example.

Overview

This example uses three routing devices: a customer edge (CE) device, a provider edge (PE) device, and a provider core (P) device.

[Figure 41 on page 607](#) shows the sample network.

Figure 41: SCU and DCU Sample Network

Source class usage (SCU) counts packets sent to the customer edge by performing lookup on the IP source address and the IP destination address. SCU makes it possible to track traffic originating from specific prefixes on the provider core and destined for specific prefixes on the customer edge.

DCU counts packets from customers by performing a lookup of the IP destination address. DCU makes it possible to track traffic originating from the customer edge and destined for specific prefixes on the provider core router.

On Device PE's fe-1/2/1 interface, facing the provider core (represented by Device P), SCU input is configured with the **source-class-usage input** statement to track traffic originating at Device P and destined to Device CE. On this same interface, the **destination-class-usage input** statement is configured to track traffic originating at Device CE destined to the provider core.

```
user@PE# show interfaces fe-1/2/1 unit 0 family inet
accounting {
  source-class-usage {
    input; # tracks traffic destined to customer edge
  }
  destination-class-usage; # tracks traffic destined to provider core
}
address 10.1.0.1/30;
```

Unlike destination class usage (DCU), which only requires implementation on a single interface, accounting for SCU must be enabled on two interfaces: the inbound and outbound interfaces traversed by the source class. You must define explicitly the two interfaces on which SCU monitored traffic is expected to arrive and depart. This is because SCU performs two lookups in the routing table: a source address (SA) and a destination address (DA) lookup. In contrast, DCU only has a single destination address lookup.

On Device PE's fe-1/2/0 interface, facing Device CE, SCU output is configured with the **source-class-usage output** statement.

```
user@PE# show interfaces fe-1/2/0 unit 0 family inet
accounting {
  source-class-usage {
    output;
  }
}
address 10.0.0.2/30;
```

To account for traffic destined to the customer, the policy called scu_class uses route filters to place traffic into the gold1, gold2, and gold3 classes.

```
user@PE# show policy-options
policy-statement scu_class {
  term gold1 {
    from {
      route-filter 172.16.2.0/24 orlonger;
    }
    then source-class gold1;
  }
  term gold2 {
    from {
      route-filter 172.16.3.0/24 orlonger;
    }
    then source-class gold2;
  }
  term gold3 {
    from {
      route-filter 172.16.4.0/24 orlonger;
    }
    then source-class gold3;
  }
}
```

To account for traffic destined to the provider, the policy called dcu_class uses route filters to place traffic into the silver1, silver2, and silver3 classes.

```
user@PE# show policy-options
policy-statement dcu_class {
  term silver1 {
    from {
```

```

        route-filter 172.16.5.0/24 orlonger;
    }
    then destination-class silver1;
}
term silver2 {
    from {
        route-filter 172.16.6.0/24 orlonger;
    }
    then destination-class silver2;
}
term silver3 {
    from {
        route-filter 172.16.7.0/24 orlonger;
    }
    then destination-class silver3;
}
}

```

The policies are then applied to the forwarding table.

```

forwarding-table {
    export [ dcu_class scu_class ];
}

```

The example uses static routes to provide connectivity and loopback interface addresses for testing the operation.

[“CLI Quick Configuration” on page 609](#) shows the configuration for all of the devices in [Figure 41 on page 607](#).

The section [“Step-by-Step Procedure” on page 611](#) describes the steps on Device PE.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

Device CE

```

set interfaces fe-1/2/0 unit 0 family inet address 10.0.0.1/30

```

```

set interfaces lo0 unit 0 family inet address 192.168.0.1/32

set routing-options static route 172.16.7.0/24 discard
set routing-options autonomous-system 300

```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To group source and destination prefixes in a forwarding class:

1. Create the router interfaces.

```
[edit interfaces]
user@PE# set fe-1/2/0 unit 0 family inet accounting source-class-usage output
user@PE# set fe-1/2/0 unit 0 family inet address 10.0.0.2/30
user@PE# set fe-1/2/1 unit 0 family inet accounting source-class-usage input
user@PE# set fe-1/2/1 unit 0 family inet accounting destination-class-usage
user@PE# set fe-1/2/1 unit 0 family inet address 10.1.0.1/30
user@PE# set lo0 unit 0 family inet address 192.168.0.2/32
```

2. Configure BGP.

```
[edit protocols bgp group ext]
user@PE# set type external
user@PE# set export send-direct
user@PE# set neighbor 10.0.0.1 peer-as 100
user@PE# set neighbor 10.1.0.2 peer-as 300
```

3. Configure the DCU policy.

```
[edit policy-options policy-statement dcu_class]
user@PE# set term silver1 from route-filter 172.16.5.0/24 orlonger
user@PE# set term silver1 then destination-class silver1
user@PE# set term silver2 from route-filter 172.16.6.0/24 orlonger
user@PE# set term silver2 then destination-class silver2
user@PE# set term silver3 from route-filter 172.16.7.0/24 orlonger
user@PE# set term silver3 then destination-class silver3
```

4. Configure the SCU policy.

```
[edit policy-options policy-statement scu_class]
user@PE# set term gold1 from route-filter 172.16.2.0/24 orlonger
user@PE# set term gold1 then source-class gold1
user@PE# set term gold2 from route-filter 172.16.3.0/24 orlonger
user@PE# set term gold2 then source-class gold2
user@PE# set term gold3 from route-filter 172.16.4.0/24 orlonger
```

```
user@PE# set term gold3 then source-class gold3
```

5. Apply the policies to the forwarding table.

```
[edit routing-options forwarding-table]
user@PE# set export dcu_class
user@PE# set export scu_class
```

NOTE: You can refer to the same routing policy one or more times in the same or different export statement.

6. (Optional) Configure a routing policy that advertises direct routes.

```
[edit policy-options policy-statement send-direct term 1]
user@PE# set from protocol direct
user@PE# set then accept
```

7. Configure the autonomous system (AS) number.

```
[edit routing-options]
user@PE# set autonomous-system 200
```

Results

From configuration mode, confirm your configuration by issuing the **show interfaces**, **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE# show interfaces
fe-1/2/0 {
  unit 0 {
    family inet {
      accounting {
        source-class-usage {
          output;
        }
      }
    }
    address 10.0.0.2/30;
```

```

    }
  }
}
fe-1/2/1 {
  unit 0 {
    family inet {
      accounting {
        source-class-usage {
          input;
        }
        destination-class-usage;
      }
      address 10.1.0.1/30;
    }
  }
}
lo0 {
  unit 0 {
    family inet {

If you are done configuring the device, enter **commit** from configuration mode.

Verification

IN THIS SECTION

- [Making Sure That the DCU Policy Is Working | 616](#)
- [Making Sure That the SCU Policy Is Working | 617](#)

Confirm that the configuration is working properly.

Making Sure That the DCU Policy Is Working

Purpose

Verify that traffic sent from the provider core into the customer network is causing the DCU policy counters to increment.

Action

1. From Device P, ping an address in the customer network.

```
user@P> ping rapid count 10000000 172.16.0.1
```

```

PING 172.16.0.1 (6.0.0.1): 56 data bytes
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!

```

2. On Device PE, check the interface statistics on the interface facing the provider core.

```
user@PE> show interfaces statistics fe-1/2/1.0
```

```

Logical interface fe-1/2/1.0 (Index 108) (SNMP ifIndex 546)
  Flags: SNMP-Traps 0x4000 Encapsulation: ENET2
  Input packets : 251956
  Output packets: 251961

```

```

- Example: Configuring a Routing Policy for Conditional Advertisement Enabling Conditional Installation of Prefixes in a Routing Table | 625

Conditional Advertisement and Import Policy (Routing Table) with certain match conditions

BGP accepts all non-looped routes learned from neighbors and imports them into the RIB-In table. If these routes are accepted by the BGP import policy, they are then imported into the inet.0 routing table. In cases where only certain routes are required to be imported, provisions can be made such that the peer routing device exports routes based on a condition or a set of conditions.

The condition for exporting a route can be based on:

- The peer the route was learned from
- The interface the route was learned on
- Some other required attribute

For example:

```
[edit]
policy-options {
  condition condition-name {
    if-route-exists address table table-name;
  }
}
```

This is known as conditional installation of prefixes and is described in [“Example: Configuring a Routing Policy for Conditional Advertisement Enabling Conditional Installation of Prefixes in a Routing Table”](#) on page 625.

The Juniper Networks® Junos® Operating System (Junos OS) supports conditional export of routes based on the existence of another route in the routing table. Junos OS does not, however, support policy conditions for import policy.

[Figure 42 on page 621](#) illustrates where BGP import and export policies are applied. An import policy is applied to inbound routes that are visible in the output of the **show route receive-protocol bgp neighbor-address** command. An export policy is applied to outbound routes that are visible in the output of the **show route advertising-protocol bgp neighbor-address** command.

Figure 42: BGP Import and Export Policies

To enable conditional installation of prefixes, an export policy must be configured on the device where

the prefix export has to take place. The export policy evaluates each route to verify that it satisfies all the match conditions under the **from** statement. It also searches for the existence of the route defined under the **condition** statement (also configured under the **from** statement).

If the route does not match the entire set of required conditions defined in the policy, or if the route defined under the **condition** statement does not exist in the routing table, the route is not exported to its BGP peers. Thus, a conditional export policy matches the routes for the desired route or prefix you want installed in the peers' routing table.

To configure the conditional installation of prefixes with the help of an export policy:

1. Create a **condition** statement to check prefixes.

```
[edit]
policy-options {
  condition condition-name {
    if-route-exists address table table-name;
  }
}
```

2. Create an export policy with the newly created condition using the **condition** statement.

```
[edit]
policy-options {
  policy-statement policy-name {
    term 1 {
      from {
        protocols bgp;
        condition condition-name;
      }
      then {
        accept;
      }
    }
  }
}
```

3. Apply the export policy to the device that requires only selected prefixes to be exported from the routing table.

```
[edit]
protocols bgp {
  group group-name {
    export policy-name;
  }
}
```

```
}
```

[Conditional Advertisement Enabling Conditional Installation of Prefixes Use Cases](#) | 623

Conditional Advertisement Enabling Conditional Installation of Prefixes Use Cases

Networks are usually subdivided into smaller, more-manageable units called autonomous systems (ASs). When BGP is used by routers to form peer relationships in the same AS, it is referred to as internal BGP (IBGP). When BGP is used by routers to form peer relationships in different ASs, it is referred to as external BGP (EBGP).

After performing route sanity checks, a BGP router accepts the routes received from its peers and installs them into the routing table. By default, all routers in IBGP and EBGP sessions follow the standard BGP advertisement rules. While a router in an IBGP session advertises only the routes learned from its direct peers, a router in an EBGP session advertises all routes learned from its direct and indirect peers (peers of peers). Hence, in a typical network configured with EBGP, a router adds all routes received from an EBGP peer into its routing table and advertises nearly all routes to all EBGP peers.

A service provider exchanging BGP routes with both customers and peers on the Internet is at risk of malicious and unintended threats that can compromise the proper routing of traffic, as well as the operation of the routers.

This has several disadvantages:

- **Non-aggregated route advertisements**—A customer could erroneously advertise all its prefixes to the ISP rather than an aggregate of its address space. Given the size of the Internet routing table, this must be carefully controlled. An edge router might also need only a default route out toward the Internet and instead be receiving the entire BGP routing table from its upstream peer.
- **BGP route manipulation**—If a malicious administrator alters the contents of the BGP routing table, it could prevent traffic from reaching its intended destination.

- **BGP route hijacking**—A rogue administrator of a BGP peer could maliciously announce a network's prefixes in an attempt to reroute the traffic intended for the victim network to the administrator's network to either gain access to the contents of traffic or to block the victim's online services.
- **BGP denial of service (DoS)**—If a malicious administrator sends unexpected or undesirable BGP traffic to a router in an attempt to use all of the router's available BGP resources, it might result in impairing the router's ability to process valid BGP route information.

Conditional installation of prefixes can be used to address all the problems previously mentioned. If a customer requires access to remote networks, it is possible to install a specific route in the routing table of the router that is connected with the remote network. This does not happen in a typical EBGp network and hence, conditional installation of prefixes becomes essential.

ASs are not only bound by physical relationships but by business or other organizational relationships. An AS can provide services to another organization, or act as a transit AS between two other ASs. These transit ASs are bound by contractual agreements between the parties that include parameters on how to connect to each other and most importantly, the type and quantity of traffic they carry for each other. Therefore, for both legal and financial reasons, service providers must implement policies that control how BGP routes are exchanged with neighbors, which routes are accepted from those neighbors, and how those routes affect the traffic between the ASs.

There are many different options available to filter routes received from a BGP peer to both enforce inter-AS policies and mitigate the risks of receiving potentially harmful routes. Conventional route filtering examines the attributes of a route and accepts or rejects the route based on such attributes. A policy or filter can examine the contents of the AS-Path, the next-hop value, a community value, a list of prefixes, the address family of the route, and so on.

In some cases, the standard "acceptance condition" of matching a particular attribute value is not enough. The service provider might need to use another condition outside of the route itself, for example, another route in the routing table. As an example, it might be desirable to install a default route received from an upstream peer, only if it can be verified that this peer has reachability to other networks further upstream. This conditional route installation avoids installing a default route that is used to send traffic toward this peer, when the peer might have lost its routes upstream, leading to black-holed traffic. To achieve this, the router can be configured to search for the presence of a particular route in the routing table, and based on this knowledge accept or reject another prefix.

["Example: Configuring a Routing Policy for Conditional Advertisement Enabling Conditional Installation of Prefixes in a Routing Table" on page 625](#) explains how the conditional installation of prefixes can be configured and verified.

Example: Configuring a Routing Policy for Conditional Advertisement Enabling Conditional Installation of Prefixes in a Routing Table

IN THIS SECTION

- Requirements | 625
- Overview | 625
- Configuration | 628
- Verification | 638

This example shows how to configure conditional installation of prefixes in a routing table using BGP export policy.

Requirements

This example uses the following hardware and software components:

- M Series Multiservice Edge Routers, MX Series 5G Universal Routing Platforms, or T Series Core Routers
- Junos OS Release 9.0 or later

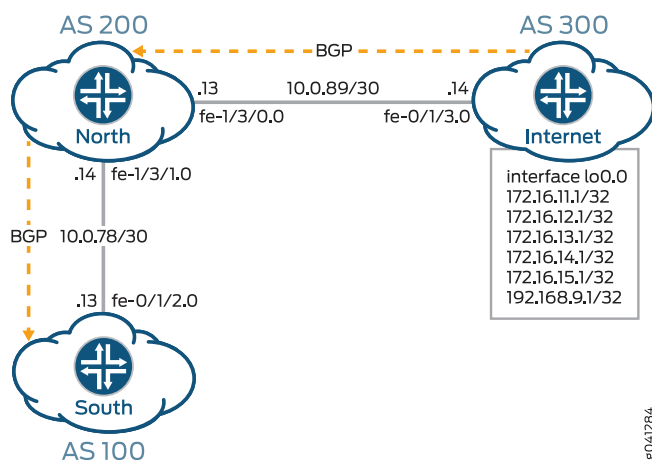

Overview

In this example, three routers in three different autonomous systems (ASs) are connected and configured with the BGP protocol. The router labeled Internet, which is the upstream router, has five addresses configured on its lo0.0 loopback interface (172.16.11.1/32, 172.16.12.1/32, 172.16.13.1/32, 172.16.14.1/32, and 172.16.15.1/32), and an extra loopback address (192.168.9.1/32) is configured as the router ID. These six addresses are exported into BGP to emulate the contents of a BGP routing table of a router connected to the Internet, and advertised to North.

The North and South routers use the 10.0.89.12/30 and 10.0.78.12/30 networks, respectively, and use 192.168.7.1 and 192.168.8.1 for their respective loopback addresses.

[Figure 43 on page 626](#) shows the topology used in this example.

Figure 43: Conditional Installation of Prefixes

Router North exports a default route into BGP, and advertises the default route and the five BGP routes to Router South, which is the downstream router. Router South receives the default route and only one other route (172.16.11.1/32), and installs this route and the default route in its routing table.

To summarize, the example meets the following requirements:

- On North, send 0/0 to South only if a particular route is also sent (in the example 172.16.11.1/32).
- On South, accept the default route and the 172.16.11.1/32 route. Drop all other routes. Consider that South might be receiving the entire Internet table, while the operator only wants South to have the default and one other specific prefix.

The first requirement is met with an export policy on North:

```
user@North# show policy-options
policy-statement conditional-export-bgp {
  term prefix_11 {
    from {
      protocol bgp;
      route-filter 10.11.0.0/5 orlonger;
    }
    then accept;
  }
  term conditional-default {
    from {
      route-filter 0.0.0.0/0 exact;
      condition prefix_11;
    }
    then accept;
  }
}
```

```

    term others {
        then reject;
    }
}
condition prefix_11 {
    if-route-exists {
        172.16.11.1/32;
        table inet.0;
    }
}

```

The logic of the conditional export policy can be summarized as follows: If 0/0 is present, and if 172.16.11.1/32 is present, then send the 0/0 prefix. This implies that if 172.16.11.1/32 is not present, then do not send 0/0.

The second requirement is met with an import policy on South:

```

user@South# show policy-options
policy-statement import-selected-routes {
    term 1 {
        from {
            rib inet.0;
            neighbor 10.0.78.14;
            route-filter 0.0.0.0/0 exact;
            route-filter 10.11.0.0/8 orlonger;
        }
        then accept;
    }
    term 2 {
        then reject;
    }
}

```

In this example, four routes are dropped as a result of the import policy on South. This is because the export policy on North leaks all of the routes received from Internet, and the import policy on South excludes some of these routes.

It is important to understand that in Junos OS, although an import policy (inbound route filter) might reject a route, not use it for traffic forwarding, and not include it in an advertisement to other peers, the router retains these routes as hidden routes. These hidden routes are not available for policy or routing purposes. However, they do occupy memory space on the router. A service provider filtering routes to control the amount of information being kept in memory and processed by a router might want the router to entirely drop the routes being rejected by the import policy.

Hidden routes can be viewed by using the **show route receive-protocol bgp neighbor-address hidden** command. The hidden routes can then be retained or dropped from the routing table by configuring the **keep all | none** statement at the **[edit protocols bgp]** or **[edit protocols bgp group group-name]** hierarchy level.

The rules of BGP route retention are as follows:

- By default, all routes learned from BGP are retained, except those where the AS path is looped. (The AS path includes the local AS.)
- By configuring the **keep all** statement, all routes learned from BGP are retained, even those with the local AS in the AS path.
- By configuring the **keep none** statement, BGP discards routes that were received from a peer and that were rejected by import policy or other sanity checking. When this statement is configured and the inbound policy changes, Junos OS re-advertises all the routes advertised by the peer.

When you configure **keep all** or **keep none** and the peers support route refresh, the local speaker sends a refresh message and performs an import evaluation. For these peers, the sessions do not restart. To determine if a peer supports refresh, check for **Peer supports Refresh capability** in the output of the **show bgp neighbor** command.

CAUTION: If you configure **keep all** or **keep none** and the peer does not support session restart, the associated BGP sessions are restarted (flapped).

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

Router Internet

```
set interfaces lo0 unit 0 family inet address 172.16.11.1/32
set interfaces lo0 unit 0 family inet address 172.16.12.1/32
set interfaces lo0 unit 0 family inet address 172.16.13.1/32
set interfaces lo0 unit 0 family inet address 172.16.14.1/32
set interfaces lo0 unit 0 family inet address 172.16.15.1/32
set interfaces lo0 unit 0 family inet address 192.168.9.1/32
set interfaces fe-0/1/3 unit 0 family inet address 10.0.89.14/30
```

```

set protocols bgp group toNorth local-address 10.0.89.14
set protocols bgp group toNorth peer-as 200
set protocols bgp group toNorth neighbor 10.0.89.13
set protocols bgp group toNorth export into-bgp
set policy-options policy-statement into-bgp term 1 from interface lo0.0
set policy-options policy-statement into-bgp term 1 then accept
set routing-options router-id 192.168.9.1
set routing-options autonomous-system 300

```

Router North

```

set interfaces fe-1/3/1 unit 0 family inet address 10.0.78.14/30
set interfaces fe-1/3/0 unit 0 family inet address 10.0.89.13/30
set interfaces lo0 unit 0 family inet address 192.168.8.1/32
set protocols bgp group toInternet local-address 10.0.89.13
set protocols bgp group toInternet peer-as 300
set protocols bgp group toInternet neighbor 10.0.89.14
set protocols bgp group toSouth local-address 10.0.78.14
set protocols bgp group toSouth export conditional-export-bgp
set protocols bgp group toSouth peer-as 100
set protocols bgp group toSouth neighbor 10.0.78.13
set policy-options policy-statement conditional-export-bgp term prefix_11 from protocol bgp
set policy-options policy-statement conditional-export-bgp term prefix_11 from route-filter 10.11.0.0/5
  orlonger
set policy-options policy-statement conditional-export-bgp term prefix_11 then accept
set policy-options policy-statement conditional-export-bgp term conditional-default from route-filter
  0.0.0.0/0 exact
set policy-options policy-statement conditional-export-bgp term conditional-default from condition
  prefix_11
set policy-options policy-statement conditional-export-bgp term conditional-default then accept
set policy-options policy-statement conditional-export-bgp term others then reject
set policy-options condition prefix_11 if-route-exists 172.16.11.1/32
set policy-options condition prefix_11 if-route-exists table inet.0
set routing-options static route 0/0 reject
set routing-options router-id 192.168.8.1
set routing-options autonomous-system 200

```

Router South

```

set interfaces fe-0/1/2 unit 0 family inet address 10.0.78.13/30
set interfaces lo0 unit 0 family inet address 192.168.7.1/32
set protocols bgp group toNorth local-address 10.0.78.13
set protocols bgp group toNorth import import-selected-routes
set protocols bgp group toNorth peer-as 200
set protocols bgp group toNorth neighbor 10.0.78.14
set policy-options policy-statement import-selected-routes term 1 from neighbor 10.0.78.14
set policy-options policy-statement import-selected-routes term 1 from route-filter 10.11.0.0/8
  orlonger
set policy-options policy-statement import-selected-routes term 1 from route-filter 0.0.0.0/0 exact
set policy-options policy-statement import-selected-routes term 1 then accept
set policy-options policy-statement import-selected-routes term 2 then reject
set routing-options router-id 192.168.7.1
set routing-options autonomous-system 100

```

Configuring Conditional Installation of Prefixes

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the Junos OS CLI User Guide.

To configure conditional installation of prefixes:

1. Configure the router interfaces forming the links between the three routers.

Router Internet

[edit interfaces]

```
user@Internet# set fe-0/1/3 unit 0 family inet address 10.0.89.14/30
```

Router North

[edit interfaces]

```
user@North# set fe-1/3/1 unit 0 family inet address 10.0.78.14/30
```

```
user@North# set fe-1/3/0 unit 0 family inet address 10.0.89.13/30
```

Router South

[edit interfaces]

```
user@South# set fe-0/1/2 unit 0 family inet address 10.0.78.13/30
```

2. Configure five loopback interface addresses on Router Internet to emulate BGP routes learned from the Internet that are to be imported into the routing table of Router South, and configure an additional address (192.168.9.1/32) that will be configured as the router ID.

Router Internet

```
[edit interfaces lo0 unit 0 family inet]
user@Internet# set address 172.16.11.1/32
user@Internet# set address 172.16.12.1/32
user@Internet# set address 172.16.13.1/32
user@Internet# set address 172.16.14.1/32
user@Internet# set address 172.16.15.1/32
user@Internet# set address 192.168.9.1/32
```

Also, configure the loopback interface addresses on Routers North and South.

Router North

```
[edit interfaces lo0 unit 0 family inet]
user@North# set address 192.168.8.1/32
```

Router South

```
[edit interfaces lo0 unit 0 family inet]
user@South# set address 192.168.7.1/32
```

3. Configure the static default route on Router North to be advertised to Router South.

```
[edit routing-options]
user@North# set static route 0/0 reject
```

4. Define the condition for exporting prefixes from the routing table on Router North.

```
[edit policy-options condition prefix_11]
user@North# set if-route-exists 172.16.11.1/32
user@North# set if-route-exists table inet.0
```

5. Define export policies (**into-bgp** and **conditional-export-bgp**) on Routers Internet and North respectively, to advertise routes to BGP.

NOTE: Ensure that you reference the condition, **prefix_11** (configured in Step 4), in the export policy.

Router Internet

```
[edit policy-options policy-statement into-bgp ]
user@Internet# set term 1 from interface lo0.0
user@Internet# set term 1 then accept
```

Router North

```
[edit policy-options policy-statement conditional-export-bgp]
user@North# set term prefix_11 from protocol bgp
user@North# set term prefix_11 from route-filter 10.11.0.0/5 orlonger
user@North# set term prefix_11 then accept
user@North# set term conditional-default from route-filter 0.0.0.0/0 exact
user@North# set term conditional-default from condition prefix_11
user@North# set term conditional-default then accept
user@North# set term others then reject
```

6. Define an import policy (**import-selected-routes**) on Router South to import some of the routes advertised by Router North into its routing table.

```
[edit policy-options policy-statement import-selected-routes ]
user@South# set term 1 from neighbor 10.0.78.14
user@South# set term 1 from route-filter 10.11.0.0/8 orlonger
user@South# set term 1 from route-filter 0.0.0.0/0 exact
user@South# set term 1 then accept
user@South# set term 2 then reject
```

7. Configure BGP on all three routers to enable the flow of prefixes between the autonomous systems.

NOTE: Ensure that you apply the defined import and export policies to the respective BGP groups for prefix advertisement to take place.

Router Internet

```
[edit protocols bgp group toNorth]
user@Internet# set local-address 10.0.89.14
user@Internet# set peer-as 200
user@Internet# set neighbor 10.0.89.13
user@Internet# set export into-bgp
```

Router North

```
[edit protocols bgp group toInternet]
user@North# set local-address 10.0.89.13
user@North# set peer-as 300
user@North# set neighbor 10.0.89.14
```

```
[edit protocols bgp group toSouth]
user@North# set local-address 10.0.78.14
user@North# set peer-as 100
user@North# set neighbor 10.0.78.13
user@North# set export conditional-export-bgp
```

Router South

```
[edit protocols bgp group toNorth]
user@South# set local-address 10.0.78.13
user@South# set peer-as 200
user@South# set neighbor 10.0.78.14
user@South# set import import-selected-routes
```

8. Configure the router ID and autonomous system number for all three routers.

NOTE: In this example, the router ID is configured based on the IP address configured on the lo0.0 interface of the router.

Router Internet

```
[edit routing options]
user@Internet# set router-id 192.168.9.1
user@Internet# set autonomous-system 300
```

Router North

```
[edit routing options]
user@North# set router-id 192.168.8.1
user@North# set autonomous-system 200
```

Router South

```
[edit routing options]
user@South# set router-id 192.168.7.1
user@South# set autonomous-system 100
```

Results

From configuration mode, confirm your configuration by issuing the **show interfaces**, **show protocols bgp**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

Device Internet

```
user@Internet# show interfaces
fe-0/1/3 {
  unit 0 {
    family inet {
      address 10.0.89.14/30;
    }
  }
}
lo0 {
  unit 0 {
    family inet {
      address 172.16.11.1/32;
      address 172.16.12.1/32;
      address 172.16.13.1/32;
      address 172.16.14.1/32;
      address 172.16.15.1/32;
      address 192.168.9.1/32;
    }
  }
}
```

```
user@Internet# show protocols bgp
group toNorth {
  local-address 10.0.89.14;
  export into-bgp;
  peer-as 200;
  neighbor 10.0.89.13;
}
```

```
user@Internet# show policy-options
policy-statement into-bgp {
  term 1 {
    from interface lo0.3;
```

```

    then accept;
  }
}

```

```

user@Internet# show routing-options
router-id 192.168.9.1;
autonomous-system 300;

```

Device North

```

user@North# show interfaces
fe-1/3/1 {
  unit 0 {
    family inet {
      address 10.0.78.14/30;
    }
  }
}
fe-1/3/0 {
  unit 0 {
    family inet {
      address 10.0.89.13/30;
    }
  }
}
lo0 {
  unit 0 {
    family inet {
      address 192.168.8.1/32;
    }
  }
}

```

```

user@North# show protocols bgp
group toInternet {
  local-address 10.0.89.13;
  peer-as 300;
  neighbor 10.0.89.14;
}
group toSouth {

```

```

local-address 10.0.78.14;
export conditional-export-bgp;
peer-as 100;
neighbor 10.0.78.13;
}

```

```

user@North# show policy-options
policy-statement conditional-export-bgp {
  term prefix_11 {
    from {
      protocol bgp;
      route-filter 10.11.0.0/5 orlonger;
    }
    then accept;
  }
  term conditional-default {
    from {
      route-filter 0.0.0.0/0 exact;
      condition prefix_11;
    }
    then accept;
  }
  term others {
    then reject;
  }
}
condition prefix_11 {
  if-route-exists {
    172.16.11.1/32;
    table inet.0;
  }
}

```

```

user@North# show routing-options
static {
  route 0.0.0.0/0 reject;
}
router-id 192.168.8.1;
autonomous-system 200;

```

Device South

```

user@South# show interfaces
fe-0/1/2 {
  unit 0 {
    family inet {
      address 10.0.78.13/30;
    }
  }
}
lo0 {
  unit 0 {
    family inet {
      address 192.168.7.1/32;
    }
  }
}

```

```

user@South# show protocols bgp
bgp {
  group toNorth {
    local-address 10.0.78.13;
    import import-selected-routes;
    peer-as 200;
    neighbor 10.0.78.14;
  }
}

```

```

user@South# show policy-options
policy-statement import-selected-routes {
  term 1 {
    from {
      neighbor 10.0.78.14;
      route-filter 10.11.0.0/8 orlonger;
      route-filter 0.0.0.0/0 exact;
    }
    then accept;
  }
  term 2 {
    then reject;
  }
}

```

```
user@South# show routing-options
router-id 192.168.7.1;
autonomous-system 100;
```

If you are done configuring the routers, enter **commit** from configuration mode.

Verification

IN THIS SECTION

- [Verifying BGP | 638](#)
- [Verifying Prefix Advertisement from Router Internet to Router North | 640](#)
- [Verifying Prefix Advertisement from Router North to Router South | 641](#)
- [Verifying BGP Import Policy for Installation of Prefixes | 642](#)
- [Verifying Conditional Export from Router North to Router South | 643](#)
- [Verifying the Presence of Routes Hidden by Policy \(Optional\) | 644](#)

Confirm that the configuration is working properly.

Verifying BGP

Purpose

Verify that BGP sessions have been established between the three routers.

Action

From operational mode, run the **show bgp neighbor neighbor-address** command.

1. Check the BGP session on Router Internet to verify that Router North is a neighbor.

```
user@Internet> show bgp neighbor 10.0.89.13
```

```
Peer: 10.0.89.13+179 AS 200 Local: 10.0.89.14+56187 AS 300
Type: External State: Established Flags: [ImportEval Sync]
Last State: OpenConfirm Last Event: RecvKeepAlive
Last Error: None
Export: [ into-bgp ]
Options: [Preference LocalAddress PeerAS Refresh]
Local Address: 10.0.89.14 Holdtime: 90 Preference: 170
Number of flaps: 0
```

```

Peer ID: 192.168.8.1      Local ID: 192.168.9.1      Active Holdtime: 90
Keepalive Interval: 30      Group index: 0      Peer index: 0
BFD: disabled, down
Local Interface: fe-0/1/3.0
NLRI for restart configured on peer: inet-unicast
NLRI advertised by peer: inet-unicast
NLRI for this session: inet-unicast
Peer supports Refresh capability (2)
Stale routes from peer are kept for: 300
Peer does not support Restarter functionality
NLRI that restart is negotiated for: inet-unicast
NLRI of received end-of-rib markers: inet-unicast
NLRI of all end-of-rib markers sent: inet-unicast
Peer supports 4 byte AS extension (peer-as 200)
Peer does not support Addpath
Table inet.0 Bit: 10000
  RIB State: BGP restart is complete
  Send state: in sync
  Active prefixes:          0
  Received prefixes:        0
  Accepted prefixes:        0
  Suppressed due to damping: 0

Output messages: Total 14      Updates 1      Refreshes 0      Octets 383
Output Queue[0]: 0

```

2. Check the BGP session on Router North to verify that Router Internet is a neighbor.

```
user@North> show bgp neighbor 10.0.89.14
```

```

Peer: 10.0.89.14+56187 AS 300 Local: 10.0.89.13+179 AS 200
Type: External      State: Established      Flags: [ImportEval Sync]
Last State: OpenConfirm  Last Event: RecvKeepAlive
Last Error: None
Options: [Preference LocalAddress PeerAS Refresh]
Local Address: 10.0.89.13 Holdtime: 90 Preference: 170
Number of flaps: 0
Peer ID: 192.168.9.1      Local ID: 192.168.8.1      Active Holdtime: 90

Output messages: Total 15   Updates 0   Refreshes 0   Octets 348
Output Queue[0]: 0

```

Check the following fields in these outputs to verify that BGP sessions have been established:

- **Peer**—Check if the peer AS number is listed.
- **Local**—Check if the local AS number is listed.
- **State**—Ensure that the value is **Established**. If not, check the configuration again and see **show bgp neighbor** for more details on the output fields.

Similarly, verify that Routers North and South form peer relationships with each other.

Meaning

BGP sessions are established between the three routers.

Verifying Prefix Advertisement from Router Internet to Router North

Purpose

Verify that the routes sent from Router Internet are received by Router North.

Action

1. From operational mode on Router Internet, run the **show route advertising-protocol bgp neighbor-address** command.

```
user@Internet> show route advertising-protocol bgp 10.0.89.13
```

```
inet.0: 8 destinations, 8 routes (8 active, 0 holddown, 0 hidden)
  Prefix                Nexthop          MED      Lclpref    AS path
* 172.16.11.1/32        Self                      I
* 172.16.12.1/32        Self                      I
* 172.16.13.1/32        Self                      I
* 172.16.14.1/32        Self                      I
* 172.16.15.1/32        Self                      I
* 192.168.9.1/32        Self                      I
```

The output verifies that Router Internet advertises the routes 172.16.11.1/32, 172.16.12.1/32, 172.16.13.1/32, 172.16.14.1/32, 172.16.15.1/32, and 192.168.9.1/32 (the loopback address used as router ID) to Router North.

2. From operational mode on Router North, run the **show route receive-protocol bgp neighbor-address** command.

```
user@North> show route receive-protocol bgp 10.0.89.14
```

```
inet.0: 12 destinations, 12 routes (12 active, 0 holddown, 0 hidden)
  Prefix                Nexthop          MED      Lclpref    AS path
* 172.16.11.1/32        10.0.89.14      300 I
* 172.16.12.1/32        10.0.89.14      300 I
* 172.16.13.1/32        10.0.89.14      300 I
* 172.16.14.1/32        10.0.89.14      300 I
* 172.16.15.1/32        10.0.89.14      300 I
* 192.168.9.1/32        10.0.89.14      300 I
```

The output verifies that Router North has received all the routes advertised by Router Internet.

Meaning

Prefixes sent by Router Internet have been successfully installed into the routing table on Router North.

Verifying Prefix Advertisement from Router North to Router South

Purpose

Verify that the routes received from Router Internet and the static default route are advertised by Router North to Router South.

Action

1. From operational mode on Router North, run the **show route 0/0 exact** command.

```
user@North> show route 0/0 exact
```

```
inet.0: 12 destinations, 12 routes (12 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

0.0.0.0/0          *[Static/5] 00:10:22
                   Reject
```

The output verifies the presence of the static default route (0.0.0.0/0) in the routing table on Router North.

2. From operational mode on Router North, run the **show route advertising-protocol bgp neighbor-address** command.

```
user@North> show route advertising-protocol bgp 10.0.78.13
```

```
inet.0: 12 destinations, 12 routes (12 active, 0 holddown, 0 hidden)
  Prefix                Nexthop          MED      Lclpref    AS path
* 0.0.0.0/0             Self                      I
* 172.16.11.1/32        Self                      300 I
* 172.16.12.1/32        Self                      300 I
* 172.16.13.1/32        Self                      300 I
* 172.16.14.1/32        Self                      300 I
* 172.16.15.1/32        Self                      300 I
```

The output verifies that Router North is advertising the static route and the 172.16.11.1/32 route received from Router Internet, as well as many other routes, to Router South.

Verifying BGP Import Policy for Installation of Prefixes

Purpose

Verify that the BGP import policy successfully installs the required prefixes.

Action

See if the import policy on Router South is operational by checking if only the static default route from Router North and the 172.16.11.1/32 route from Router South are installed in the routing table.

From operational mode, run the **show route receive-protocol bgp neighbor-address** command.

```
user@South> show route receive-protocol bgp 10.0.78.14
```

```
inet.0: 10 destinations, 11 routes (6 active, 0 holddown, 4 hidden)
  Prefix                Nexthop          MED      Lclpref    AS path
* 0.0.0.0/0             10.0.78.14      200 I
* 172.16.11.1/32        10.0.78.14      200 300 I
```

The output verifies that the BGP import policy is operational on Router South, and only the static default route of 0.0.0.0/0 from Router North and the 172.16.11.1/32 route from Router Internet have leaked into the routing table on Router South.

Meaning

The installation of prefixes is successful because of the configured BGP import policy.

Verifying Conditional Export from Router North to Router South

Purpose

Verify that when Device Internet stops sending the 172.16.11.1/32 route, Device North stops sending the default 0/0 route.

Action

1. Cause Device Internet to stop sending the 172.16.11.1/32 route by deactivating the 172.16.11.1/32 address on the loopback interface.

```
[edit interfaces lo0 unit 0 family inet]
user@Internet# deactivate address 172.16.11.1/32
user@Internet# commit
```

2. From operational mode on Router North, run the **show route advertising-protocol bgp neighbor-address** command.

```
user@North> show route advertising-protocol bgp 10.0.78.13
```

```
inet.0: 11 destinations, 11 routes (11 active, 0 holddown, 0 hidden)
  Prefix                Nexthop          MED      Lclpref    AS path
* 172.16.12.1/32        Self                      300 I
* 172.16.13.1/32        Self                      300 I
* 172.16.14.1/32        Self                      300 I
* 172.16.15.1/32        Self                      300 I
```

The output verifies that Router North is not advertising the default route to Router South. This is the expected behavior when the 172.16.11.1/32 route is not present.

3. Reactivate the 172.16.11.1/32 address on Device Internet's loopback interface.

```
[edit interfaces lo0 unit 0 family inet]
user@Internet# activate address 172.16.11.1/32
user@Internet# commit
```

Verifying the Presence of Routes Hidden by Policy (Optional)

Purpose

Verify the presence of routes hidden by the import policy configured on Router South.

NOTE: This section demonstrates the effects of various changes you can make to the configuration depending on your needs.

Action

View routes hidden from the routing table of Router South by:

- Using the **hidden** option for the **show route receive-protocol bgp neighbor-address** command.
 - Deactivating the import policy.
1. From operational mode, run the **show route receive-protocol bgp neighbor-address hidden** command to view hidden routes.

```
user@South> show route receive-protocol bgp 10.0.78.14 hidden
```

```
inet.0: 10 destinations, 11 routes (6 active, 0 holddown, 4 hidden)
  Prefix                Nexthop          MED      Lclpref    AS path
  172.16.12.1/32         10.0.78.14             200 300 I
  172.16.13.1/32         10.0.78.14             200 300 I
  172.16.14.1/32         10.0.78.14             200 300 I
  172.16.15.1/32         10.0.78.14             200 300 I
```

The output verifies the presence of routes hidden by the import policy (172.16.12.1/32, 172.16.13.1/32, 172.16.14.1/32, and 172.16.15.1/32) on Router South.

2. Deactivate the BGP import policy by configuring the **deactivate import** statement at the **[edit protocols bgp group group-name]** hierarchy level.

```
[edit protocols bgp group toNorth]
user@South# deactivate import
user@South# commit
```

3. Run the **show route receive-protocol bgp neighbor-address** operational mode command to check the routes after deactivating the import policy.

```
user@South> show route receive-protocol bgp 10.0.78.14
```

```
inet.0: 10 destinations, 11 routes (10 active, 0 holddown, 0 hidden)
  Prefix                Nexthop          MED      Lclpref    AS path
* 0.0.0.0/0             10.0.78.14                200 I
* 172.16.11.1/32        10.0.78.14                200 300 I
* 172.16.12.1/32        10.0.78.14                200 300 I
* 172.16.13.1/32        10.0.78.14                200 300 I
* 172.16.14.1/32        10.0.78.14                200 300 I
* 172.16.15.1/32        10.0.78.14                200 300 I
```

The output verifies the presence of previously hidden routes (172.16.12.1/32, 172.16.13.1/32, 172.16.14.1/32, and 172.16.15.1/32).

4. Activate the BGP import policy and remove the hidden routes from the routing table by configuring the **activate import** and **keep none** statements respectively at the **[edit protocols bgp group group-name]** hierarchy level.

```
[edit protocols bgp group toNorth]
user@South# activate import
user@South# set keep none
user@South# commit
```

5. From operational mode, run the **show route receive-protocol bgp neighbor-address hidden** command to check the routes after activating the import policy and configuring the **keep none** statement.

```
user@South> show route receive-protocol bgp 10.0.78.14 hidden
```

```
inet.0: 6 destinations, 7 routes (6 active, 0 holddown, 0 hidden)
```

The output verifies that the hidden routes are not maintained in the routing table because of the configured **keep none** statement.

Protecting Against DoS Attacks by Forwarding Traffic to the Discard Interface

IN THIS CHAPTER

- [Assigning Forwarding Classes and Loss Priority | 647](#)
- [Understanding Forwarding Packets to the Discard Interface | 648](#)
- [Example: Forwarding Packets to the Discard Interface | 650](#)

Assigning Forwarding Classes and Loss Priority

You can configure firewall filters to assign packet loss priority (PLP) and forwarding classes so that if congestion occurs, the marked packets can be dropped according to the priority you set. The valid match conditions are one or more of the six packet header fields: destination address, source address, IP protocol, source port, destination port, and DSCP. In other words, you can set the forwarding class and the PLP for each packet entering or an interface with a specific destination address, source address, IP protocol, source port, destination port, or DSCP.

NOTE: Junos OS assigns forwarding classes and PLP on ingress only. Do not use a filter that assigns forwarding classes or PLP as an egress filter.

When tricolor marking is enabled, a switch supports four PLP designations: **low**, **medium-low**, **medium-high**, and **high**. You can also specify any of the forwarding classes listed in [Table 27 on page 647](#)

Table 27: Unicast Forwarding Classes

Unicast Forwarding Class	For CoS Traffic Type
be	Best-effort traffic
no-loss	Guaranteed delivery for TCP traffic
fcoe	Guaranteed delivery for Fibre Channel over Ethernet (FCoE) traffic
nc	Network-control traffic

To assign forwarding classes in firewall filters:

1. Configure the family address type and filter name:

```
[edit]
user@switch# edit firewall family inetfilter ingress-filter
```

2. Configure the terms of the filter as appropriate, including the **forwarding-class** and **loss-priority** action modifiers. For example, each of the following terms in the filter examines various packet header fields and assigns the appropriate forwarding class and packet loss priority:

- The term **corp-traffic** matches all IPv4 packets with a **10.1.1.0/24** source address and assigns the packets to forwarding class **no-loss** with a loss priority of **low**:

```
[edit firewall family inet filter ingress-filter]
user@switch# set term corp-traffic from source-address 10.1.1.0/24;
```

```
user@switch# set term corp-traffic then forwarding-class no-loss
```

```
user@switch# set term corp-traffic then loss-priority low
```

- The term **data-traffic** matches all IPv4 packets with a **10.1.2.0/24** source address and assigns the packets to forwarding class **be** (best effort) with a loss priority of **medium-high**:

```
[edit firewall family inet filter ingress-filter]
```

```
user@switch# set term data-traffic from source-address 10.1.2.0/24;
```

```
user@switch# set term data-traffic then forwarding-class be
```

```
user@switch# set term data-traffic then loss-priority medium-high
```

- The last term **accept-traffic** matches any packets that did not match on any of the preceding terms and assigns the packets to forwarding class **be** with a loss priority of **high**:

```
[edit firewall family inet filter ingress-filter]
```

```
user@switch# set term accept-traffic then forwarding-class be
```

```
user@switch# set term accept-traffic then loss-priority high
```

3. Apply the filter **ingress-filter** to a Layer 3 interface. For information about applying the filter, see [“Configuring Firewall Filters” on page 1579](#). (Assigning forwarding classes and PLP is supported only on ingress filters.)

Understanding Forwarding Packets to the Discard Interface

The discard (**dsc**) interface is a virtual interface that can silently discard forwarded packets as they are received (no ICMP message is sent). It is useful in the case of a denial-of-service (DoS) attacks. Once you know the IP address that is being targeted, you can configure a policy to forward all packets received on that interface to the discard interface, where they will be dropped. Likewise, silently discarding packets that have no valid route in the associated forwarding table can prevent the device from becoming a

distributed denial-of-service (DDoS) reflector, in which a spoofed source IP address is used to trigger a flood of ICMP error messages from the device.

The **dsc** interface can be only be configured on unit 0 of the given physical interface, and only one **dsc** instance per device is supported.

Configure an input filter if, for example, you want to take an action such as logging the discard to better understand the nature of the attack.

```
[edit interfaces interface-name]
dsc {
  unit 0 {
    family inet {
      filter {
        output filter-name;
      }
    }
  }
}
```

You can configure an input policy to associate a BGP community with the discard interface. To configure an input policy to associate a community with the discard interface:

```
[edit]
policy-options {
  community community-name members [ community-id ];
  policy-statement statement-name {
    term term-name {
      from community community-name;
      then {
        next-hop address; # Remote end of the point-to-point interface
        accept;
      }
    }
  }
}
```

Configure an output policy to set up the community on the routes injected into the network:

```
[edit]
policy-options {
  policy-statement statement-name {
    term term-name {
      from prefix-list name;
    }
  }
}
```

```
        then community (set | add | delete) community-name;  
    }  
}  
}
```

Example: Forwarding Packets to the Discard Interface

IN THIS SECTION

- [Requirements](#) | 650
- [Overview](#) | 650
- [Configuration](#) | 654
- [Verification](#) | 659

This example shows how to use discard routing to mitigate denial of service (DoS) attacks, protect vital network resources from outside attack, provide protection services for customers so that each customer can initiate its own protection, and log and track DoS attempts.

Requirements

No special configuration beyond device initialization is required before configuring this example.

Overview

In discard routing, routers are configured with rules that disallow millions of requests in a short period of time from being sent to the same address. If too many requests are received in a short period of time, the router simply discards the requests without forwarding them. The requests are sent to a router that does not forward the packets. The problematic routes are sometimes referred to as discard routes or black-holed routes. The types of routes that should be discarded are identified as attacks to customers from peers or

other customers, attacks from customers to peers or other customers, attack controllers, which are hosts providing attack instructions, and unallocated address spaces, known as bogons or invalid IP addresses.

After the attack attempt is identified, operators can put a configuration in place to mitigate the attack. One way to configure discard routing in Junos OS is to create a discard static route for each next hop used for discard routes. A discard static route uses the **discard** option.

For example:

```
user@host# show routing-options
static {
  route 192.0.2.101/32 discard;
  route 192.0.2.103/32 discard;
  route 192.0.2.105/32 discard;
}
```

user@host> show route protocol static terse

```
inet.0: 3 destinations, 3 routes (3 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
```

A	V	Destination	P	Prf	Metric 1	Metric 2	Next hop	AS path
*	?	192.0.2.101/32	S	5			Discard	
*	?	192.0.2.103/32	S	5			Discard	
*	?	192.0.2.105/32	S	5			Discard	

Another strategy, which is the main focus of this example, is to use routing policy and the discard interface. In this approach, the discard interface contains the next hop you are assigning to the black-hole routes. A discard interface can have only one logical unit (unit 0), but you can configure multiple IP addresses on unit 0.

For example:

```
user@host# show interfaces dsc
unit 0 {
  family inet {
    address 192.0.2.102/32 {
      destination 192.0.2.101;
    }
    address 192.0.2.104/32 {
      destination 192.0.2.103;
    }
    address 192.0.2.106/32 {
```

```

        destination 192.0.2.105;
    }
}
}

```

user@host> **show interfaces terse dsc**

```

b
Interface          Admin Link Proto  Local          Remote
dsc                 up    up
dsc.0               up    up   inet    192.0.2.102    --> 192.0.2.101
                   192.0.2.104    --> 192.0.2.103
                   192.0.2.106    --> 192.0.2.105

```

The advantage of using a discard interface instead of using discard static routes is that the discard interface allows you to configure and assign filters to the interface for counting, logging, and sampling the traffic. This is demonstrated in this example.

To actually discard packets requires a routing policy attached to the BGP sessions. To locate discard-eligible routes, you can use a route filter, an access list, or a BGP community value.

For example, here is how you would use a route filter:

Route Filter

```

protocols {
    bgp {
        import blackhole-by-route;
    }
}
policy-options {
    policy-statement blackhole-by-route {
        term specific-routes {
            from {
                route-filter 10.10.10.1/32 exact;
                route-filter 10.20.20.2/32 exact;
                route-filter 10.30.30.3/32 exact;
                route-filter 10.40.40.4/32 exact;
            }
            then {

```

```

        next-hop 192.0.2.101
    }
}
}
}

```

Figure 44 on page 653 shows the sample network.

Figure 44: Discard Interface Sample Network

The example includes three routers with external BGP (EBGP) sessions established.

Device R1 represents the attacking device. Device R3 represents the router closest to the device that is being attacked. Device R2 mitigates the attack by forwarding packets to the discard interface.

The example shows an outbound filter applied to the discard interface.

NOTE: An issue with using a single black-hole filter is visibility. All discard packets increment the same counter. To see which categories of packets are being discarded, use destination class usage (DCU), and associate a user-defined class with each black-hole community. Then reference the DCU classes in a firewall filter. For related examples, see [“Example: Grouping Source and Destination Prefixes into a Forwarding Class”](#) on page 606 and [“Example: Configuring a Rate-Limiting Filter Based on Destination Class”](#) on page 1060.

Compared to using route filters and access lists, using a community value is the least administratively difficult and the most scalable approach. Therefore, this is the approach shown in this example.

By default, the next hop must be equal the external BGP (EBGP) peer address. Altering the next hop for black-hole services requires the multihop feature to be configured on the EBGP sessions.

“CLI Quick Configuration” on page 654 shows the configuration for all of the devices in Figure 44 on page 653.

The section “Step-by-Step Procedure” on page 655 describes the steps on Device R2.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

Device R1

```
set interfaces fe-1/2/0 unit 0 family inet address 10.0.0.1/30
set interfaces lo0 unit 0 family inet address 192.168.0.1/32
set protocols bgp group ext type external
set protocols bgp group ext peer-as 200
set protocols bgp group ext neighbor 10.0.0.2
set routing-options autonomous-system 100
```

Device R2

```
set interfaces fe-1/2/0 unit 0 family inet address 10.0.0.2/30
set interfaces fe-1/2/1 unit 0 family inet address 10.1.0.1/30
set interfaces dsc unit 0 family inet filter output log-discard
set interfaces dsc unit 0 family inet address 192.0.2.102/32 destination 192.0.2.101
set interfaces lo0 unit 0 family inet address 192.168.0.2/32
set protocols bgp import blackhole-policy
set protocols bgp group ext type external
set protocols bgp group ext multihop
set protocols bgp group ext export dsc-export
set protocols bgp group ext neighbor 10.0.0.1 peer-as 100
set protocols bgp group ext neighbor 10.1.0.2 peer-as 300
set policy-options policy-statement blackhole-policy term blackhole-communities from community
    blackhole-all-routers
set policy-options policy-statement blackhole-policy term blackhole-communities then next-hop
    192.0.2.101
set policy-options policy-statement dsc-export from route-filter 192.0.2.101/32 exact
set policy-options policy-statement dsc-export from route-filter 192.0.2.102/32 exact
set policy-options policy-statement dsc-export then community set blackhole-all-routers
```

```

set policy-options policy-statement dsc-export then accept
set policy-options community blackhole-all-routers members 100:5555
set routing-options static route 192.0.2.102/32 next-hop 192.0.2.101
set routing-options autonomous-system 200
set firewall filter log-discard term one then count counter
set firewall filter log-discard term one then log

```

Device R3

```

set interfaces fe-1/2/1 unit 0 family inet address 10.1.0.2/30
set interfaces lo0 unit 0 family inet address 192.168.0.3/32
set interfaces lo0 unit 0 family inet address 192.0.2.102/32
set protocols bgp group ext type external
set protocols bgp group ext peer-as 200
set protocols bgp group ext neighbor 10.1.0.1
set routing-options autonomous-system 300

```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure Device R2:

1. Create the router interfaces.

```

[edit interfaces]
user@R2# set fe-1/2/0 unit 0 family inet address 10.0.0.2/30
user@R2# set fe-1/2/1 unit 0 family inet address 10.1.0.1/30
user@R2# set lo0 unit 0 family inet address 192.168.0.2/32

```

2. Configure a firewall filter that matches all packets and counts and logs the packets.

```

[edit firewall filter log-discard term one]
user@R2# set then count counter
user@R2# set then log

```

3. Create a discard interface and apply the output firewall filter.

Input firewall filters have no impact in this context.

```
[edit interfaces dsc unit 0 family inet]
user@R2# set filter output log-discard
user@R2# set address 192.0.2.102/32 destination 192.0.2.101
```

4. Configure a static route that sends the next hop to the destination address that is specified in the discard interface.

```
[edit routing-options static]
user@R2# set route 192.0.2.102/32 next-hop 192.0.2.101
```

5. Configure BGP peering.

```
[edit protocols bgp ]
user@R2# set group ext type external
user@R2# set group ext multihop
user@R2# set group ext neighbor 10.0.0.1 peer-as 100
user@R2# set group ext neighbor 10.1.0.2 peer-as 300
```

6. Configure the routing policies.

```
[edit policy-options policy-statement blackhole-policy term blackhole-communities]
user@R2# set from community blackhole-all-routers
user@R2# set then next-hop 192.0.2.101
[edit policy-options policy-statement dsc-export]
user@R2# set from route-filter 192.0.2.101/32 exact
user@R2# set from route-filter 192.0.2.102/32 exact
user@R2# set then community set blackhole-all-routers
user@R2# set then accept
[edit policy-options community blackhole-all-routers]
user@R2# set members 100:5555
```

7. Apply the routing policies.

```
[edit protocols bgp ]
user@R2# set import blackhole-policy
```

```
user@R2# set group ext export dsc-export
```

8. Configure the autonomous system (AS) number.

```
[edit routing-options]
user@R2# set autonomous-system 200
```

Results

From configuration mode, confirm your configuration by issuing the **show interfaces**, **show protocols**, **show policy-options**, **show routing-options**, and **show firewall** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@R2# show interfaces
fe-1/2/0 {
  unit 0 {
    family inet {
      address 10.0.0.2/30;
    }
  }
}
fe-1/2/1 {
  unit 0 {
    family inet {
      address 10.1.0.1/30;
    }
  }
}
dsc {
  unit 0 {
    family inet {
      filter {
        output log-discard;
      }
      address 192.0.2.102/32 {
        destination 192.0.2.101;
      }
    }
  }
}
lo0 {
```

```

unit 0 {
    family inet {
        address 192.168.0.2/32;
    }
}

```

user@R2# **show protocols**

```

bgp {
    import blackhole-policy;
    group ext {
        type external;
        multihop;
        export dsc-export;
        neighbor 10.0.0.1 {
            peer-as 100;
        }
        neighbor 10.1.0.2 {
            peer-as 300;
        }
    }
}

```

user@R2# **show policy-options**

```

policy-statement blackhole-policy {
    term blackhole-communities {
        from community blackhole-all-routers;
        then {
            next-hop 192.0.2.101;
        }
    }
}
policy-statement dsc-export {
    from {
        route-filter 192.0.2.101/32 exact;
        route-filter 192.0.2.102/32 exact;
    }
    then {
        community set blackhole-all-routers;
        accept;
    }
}
community blackhole-all-routers members 100:5555;

```

```
user@R2# show routing-options
static {
  route 192.0.2.102/32 next-hop 192.0.2.101;
}
autonomous-system 200;
```

```
user@R2# show firewall
filter log-discard {
  term one {
    then {
      count counter;
      log;
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

IN THIS SECTION

- [Clearing the Firewall Counters | 659](#)
- [Pinging the 192.0.2.101 Address | 660](#)
- [Checking the Output Filter | 660](#)
- [Checking the Community Attribute | 661](#)

Confirm that the configuration is working properly.

Clearing the Firewall Counters

Purpose

Clear the counters to make sure you are starting from a known zero (0) state.

Action

1. From Device R2, run the **clear firewall** command.

```
user@R2> clear firewall filter log-discard
```

2. From Device R2, run the **show firewall** command.

```
user@R2> show firewall filter log-discard
```

```
Filter: /log-discard
Counters:
Name                                     Bytes      Packets
counter                                0           0
```

Pinging the 192.0.2.101 Address

Purpose

Send packets to the destination address.

Action

From Device R1, run the **ping** command.

```
user@R1> ping 192.0.2.101
```

```
PING 192.0.2.101 (192.0.2.101): 56 data bytes
^C
--- 192.0.2.101 ping statistics ---
4 packets transmitted, 0 packets received, 100% packet loss
```

Meaning

As expected, the ping request fails, and no response is sent. The packets are being discarded.

Checking the Output Filter

Purpose

Verify that Device R2's firewall filter is functioning properly.

Action

From Device R2, enter the **show firewall filter log-discard** command.

```
user@R2> show firewall filter log-discard
```

```
Filter: log-discard
Counters:
Name                                     Bytes      Packets
counter                                336         4
```

Meaning

As expected, the counter is being incremented.

NOTE: The ping packet carries an additional 20 bytes of IP overhead as well as 8 bytes of ICMP header.

Checking the Community Attribute

Purpose

Verify that the route is being tagged with the community attribute.

Action

From Device R1, enter the **show route extensive** command, using the neighbor address for Device R2, 192.0.2.101.

```
user@R1> show route 192.0.2.101 extensive
```

```
inet.0: 4 destinations, 4 routes (4 active, 0 holddown, 0 hidden)
192.0.2.101/32 (1 entry, 1 announced)
TSI:
KRT in-kernel 192.0.2.101/32 -> {10.0.0.2}
    *BGP      Preference: 170/-101
              Next hop type: Router, Next hop index: 684
              Address: 0x94141d8
              Next-hop reference count: 2
              Source: 10.0.0.2
              Next hop: 10.0.0.2 via fe-1/2/0.0, selected
              Session Id: 0x8000a
              State: <Active Ext>
              Local AS:   100 Peer AS:   200
              Age: 53:03
              Validation State: unverified
              Task: BGP_200.10.0.0.2+63097
              Announcement bits (1): 2-KRT
              AS path: 200 I
              Communities: 100:5555
              Accepted
              Localpref: 100
              Router ID: 192.168.0.2
```

Meaning

As expected, when Device R2 advertises the 192.0.2.101 route to Device R1, Device R2 adds the 100:5555 community tag.

- [Preventing Reestablishment of BGP Peering Sessions After NSR Routing Engine Switchover | 667](#)

The verification process required to commit configuration changes can entail a significant amount of overhead and time. For example, changing a prefix in one line of a routing policy that is 20,000 lines long can take up to 20 seconds to commit. It can be useful to be able to commit routing policy changes much more quickly.

In Junos OS Release 9.5 and later, you can configure routing policies and certain routing policy objects in a dynamic database that is not subject to the same verification required in the standard configuration database. As a result, the time it takes to commit changes to the dynamic database is much shorter than for the standard configuration database. You can then reference these policies and policy objects in routing policies you configure in the standard database. BGP is the only protocol to which you can apply routing policies that reference policies and policy objects configured in the dynamic database. After you configure and commit a routing policy based on the objects configured in the dynamic database, you can quickly update any existing routing policy by making changes to the dynamic database configuration.

CAUTION: Because the Junos OS does not validate configuration changes to the dynamic database, when you use this feature, you should test and verify all configuration changes before committing them.

Configuring Routing Policies and Policy Objects in the Dynamic Database

Junos OS Release 9.5 and later support a configuration database, the *dynamic database*, which can be edited in a similar way to the standard configuration database but which is not subject to the same verification process to commit configuration changes. As a result, the time it takes to commit a configuration change is much faster. The policies and policy objects defined in the dynamic database can then be referenced in routing policies configured in the standard configuration. The dynamic database is stored in the `/var/run/db/juniper.dyn` directory.

To configure the dynamic database, enter the **configure dynamic** command to enter the configuration mode for the dynamic database:

```
user@host> configure dynamic
```

```
Entering configuration mode
```

```
[edit dynamic]
```

```
user@host#
```

In this dynamic configuration database, you can configure the following statements at the **[edit policy-options]** hierarchy level:

- **as-path** *name*
- **as-path-group** *group-name*
- **community** *community-name*
- **condition** *condition-name*
- **prefix-list** *prefix-list-name*
- **policy-statement** *policy-statement-name*

NOTE: No other configuration is supported at the **[edit dynamic]** hierarchy level.

Use the **policy-statement** *policy-statement-name* statement to configure routing policies as you would in the standard configuration database.

To exit configuration mode for the dynamic database, issue the **exit configuration-mode** command from any level within the **[edit dynamic]** hierarchy, or use the **exit** command from the top level.

Configuring Routing Policies Based on Dynamic Database Configuration

In the standard configuration mode, you can configure routing policies that reference policies and policy objects configured at the **[edit dynamic]** hierarchy level in the dynamic database. To define a routing policy that references the dynamic database configuration, include the **dynamic-db** statement at the **[edit policy-options policy-statement *policy-statement-name*]** hierarchy level:

```
[edit policy-options]
policy-statement policy-statement-name {
    dynamic-db;
}
```

You can also define specific policy objects based on the configuration of these objects in the dynamic database. To define a policy object based on the dynamic database, include the **dynamic-db** statement with the following statements at the **[edit policy-options]** hierarchy level:

- **as-path** *name*
- **as-path-group** *group-name*
- **community** *community-name*
- **condition** *condition-name*
- **prefix-list** *prefix-list-name*

In the standard configuration, you can also define a routing policy that references any policy object you have configured in the standard configuration that references an object configured in the dynamic database.

For example, in standard configuration mode, you configure a prefix list **prefix-list pl2** that references a prefix list, also named **prefix-list pl2**, that has been configured in the dynamic database:

```
[edit policy-options]
prefix-list pl2 {
  dynamic-db; # Reference a prefix list configured in the dynamic database.
}
```

You then configure a routing policy in the standard configuration that includes **prefix-list pl2**:

```
[edit policy-options]
policy-statement one {
  term term1 {
    from {
      prefix-list pl2; # Include the prefix list configured in the standard configuration
                       # database, but which references a prefix list configured in the dynamic database.
    }
    then accept;
  }
  then reject;
}
```

If you need to update the configuration of **prefix-list pl2**, you do so in the dynamic database configuration using the **[edit dynamic]** hierarchy level. This enables you to make commit configuration changes to the prefix list more quickly than you can in the standard configuration database.

NOTE: If you are downgrading the Junos OS to Junos OS Release 9.4 or earlier, you must first delete any routing policies that reference the dynamic database. That is, you must delete any routing policies or policy objects configured with the **dynamic-db** statement.

Applying Dynamic Routing Policies to BGP

BGP is the only routing protocol to which you can apply routing policies that reference the dynamic database configuration. You must apply these policies in the standard configuration. Dynamic policies can be applied to BGP export or import policy. They can also be applied at the global, group, or neighbor hierarchy level.

To apply a BGP export policy, include the **export [*policy-names*]** statement at the **[edit protocols bgp]**, **[edit protocols bgp group *group-name*]**, or **[edit protocols bgp group *group-name* neighbor *address*]** hierarchy level.

```
[edit]
protocols
  bgp {
    export [ policy-names ];
  }
}
```

To apply a BGP import policy, include the **import [policy-names]** statement at the **[edit protocols bgp]**, **[edit protocols bgp group group-name]**, or **[edit protocols bgp group group-name neighbor address]** hierarchy level.

```
[edit]
protocols
  bgp {
    import [ policy-names ];
  }
}
```

Include one or more policy names configured in that standard configuration at the **[edit policy-options policy-statement]** hierarchy level that reference policies configured in the dynamic database.

Preventing Reestablishment of BGP Peering Sessions After NSR Routing Engine Switchover

If you have active nonstop routing (NSR) enabled, the dynamic database is not synchronized with the backup Routing Engine. As a result, if a switchover to a backup Routing Engine occurs, import and export policies running on the master Routing Engine at the time of the switchover might no longer be available. Therefore, you might want to prevent a BGP peering session from automatically being reestablished as soon as a switchover occurs.

You can configure the router not to reestablish a BGP peering session after an active nonstop routing switchover either for a specified period or until you manually reestablish the session. Include the **idle-after-switch-over (seconds | forever)** statement at the **[edit protocols bgp]**, **[edit protocols bgp group group-name]**, or **[edit protocols bgp group group-name neighbor address]** hierarchy level:

```
[edit]
bgp {
  protocols {
    idle-after-switch-over (seconds | never);
  }
}
```

For **seconds**, specify a value from 1 through 4,294,967,295 ($2^{32} - 1$). The BGP peering session is not reestablished until after the specified period. If you specify the **forever** option, the BGP peering session is not established until you issue the **clear bgp neighbor** command.

Example: Configuring Dynamic Routing Policies

IN THIS SECTION

- [Requirements | 668](#)
- [Overview | 668](#)
- [Configuration | 670](#)
- [Verification | 680](#)

This example shows how to configure routing policy objects in a dynamic database that is not subject to the same verification required in the standard configuration database.

Requirements

No special configuration beyond device initialization is required before configuring this example.

Overview

The verification process required to commit configuration changes can entail a significant amount of overhead and time.

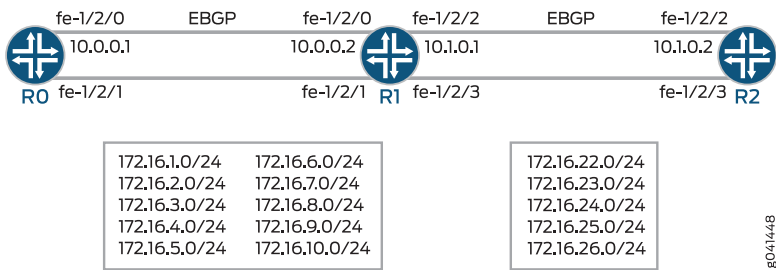

The time it takes to commit changes to the dynamic database is much shorter than for the standard configuration database. You can reference these policies and policy objects in routing policies you configure in the standard database. BGP is the only protocol to which you can apply routing policies that reference policies and policy objects configured in the dynamic database. After you configure and commit a routing

policy based on the objects configured in the dynamic database, you can quickly update any existing routing policy by making changes to the dynamic database configuration.

CAUTION: Because Junos OS does not validate configuration changes to the dynamic database, when you use this feature, you should test and verify all configuration changes before committing them.

Figure 45 on page 669 shows the sample network.

Figure 45: Dynamic Routing Policy Sample Network

The example includes three routers with external BGP (EBGP) sessions established. Only Device R1 makes use of the dynamic database.

On Device R0's fe-1/2/1 interface, multiple IPv4 interfaces are configured, and a routing policy injects these prefixes into BGP, using the **from interface fe-1/2/1.0** policy condition as a shorthand method for specifying all of the IP addresses configured on Device R0's fe-1/2/1 interface.

Likewise, on Device R2's fe-1/2/3 interface, multiple IPv4 addresses are configured, and a routing policy injects these prefixes into BGP. Device R2's configuration is slightly different from Device R0's in that Device R2's configuration demonstrates the use of a prefix list.

On Device R1, in the dynamic database, two prefix lists are defined, one for the interface addresses learned from Device R0 and another for the interface addresses learned from Device R2. Device R1's standard database contains routing policies with prefix lists that are similar to those defined in the dynamic database.

In its peer session with Device R0, Device R1 has the static-database policies applied. In contrast, in its peer session with Device R2, Device R1's configuration references the dynamic database.

The results of these different configurations are analyzed in the ["Verification" on page 680](#) section.

["CLI Quick Configuration" on page 670](#) shows the configuration for all of the devices in [Figure 45 on page 669](#).

The section ["Step-by-Step Procedure" on page 673](#) describes the steps on Device R1's dynamic database.

The section ["Step-by-Step Procedure" on page 674](#) describes the steps on Device R1's standard database.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

Device R0

```
set interfaces fe-1/2/0 unit 0 family inet address 10.0.0.1/30
set interfaces fe-1/2/1 unit 0 family inet address 172.16.4.1/24
set interfaces fe-1/2/1 unit 0 family inet address 172.16.3.1/24
set interfaces fe-1/2/1 unit 0 family inet address 172.16.2.1/24
set interfaces fe-1/2/1 unit 0 family inet address 172.16.1.1/24
set interfaces fe-1/2/1 unit 0 family inet address 172.16.5.1/24
set interfaces fe-1/2/1 unit 0 family inet address 172.16.6.1/24
set interfaces fe-1/2/1 unit 0 family inet address 172.16.7.1/24
set interfaces fe-1/2/1 unit 0 family inet address 172.16.8.1/24
set interfaces fe-1/2/1 unit 0 family inet address 172.16.9.1/24
set interfaces fe-1/2/1 unit 0 family inet address 172.16.10.1/24
set interfaces lo0 unit 0 family inet address 10.255.14.151/32
set protocols bgp group ext type external
set protocols bgp group ext neighbor 10.0.0.2 export t2
set protocols bgp group ext neighbor 10.0.0.2 peer-as 200
set policy-options policy-statement t2 from interface fe-1/2/0.0
set policy-options policy-statement t2 from interface fe-1/2/1.0
set policy-options policy-statement t2 then accept
set routing-options router-id 10.255.14.151
set routing-options autonomous-system 100
```

Device R1 Dynamic Database

```
[edit dynamic]
set policy-options prefix-list dyn_prfx1 172.16.1.0/24
set policy-options prefix-list dyn_prfx1 172.16.2.0/24
set policy-options prefix-list dyn_prfx1 172.16.3.0/24
set policy-options prefix-list dyn_prfx1 172.16.4.0/24
set policy-options prefix-list dyn_prfx1 172.16.5.0/24
set policy-options prefix-list dyn_prfx1 172.16.6.0/24
set policy-options prefix-list dyn_prfx1 172.16.7.0/24
```

```

set policy-options prefix-list dyn_prfx1 172.16.8.0/24
set policy-options prefix-list dyn_prfx2 172.16.2.0/24

set policy-options policy-statement p1 term t1 from prefix-list ppx1
set policy-options policy-statement p1 term t1 then accept
set routing-options autonomous-system 300

```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure Device R1’s dynamic database:

1. Enter configuration mode for the dynamic database.

```
user@R1> configure dynamic  
Entering configuration mode  
[edit dynamic]
```

2. Create a prefix list for the interface addresses learned from Device R0.

```
[edit dynamic policy-options prefix-list dyn_prfx1]  
user@R1# set 172.16.1.0/24  
user@R1# set 172.16.2.0/24  
user@R1# set 172.16.3.0/24  
user@R1# set 172.16.4.0/24  
user@R1# set 172.16.5.0/24  
user@R1# set 172.16.6.0/24  
user@R1# set 172.16.7.0/24  
user@R1# set 172.16.8.0/24
```

3. Create a prefix list for the interface addresses learned from Device R2.

```
[edit dynamic policy-options prefix-list dyn_prfx2]  
user@R1# set 172.16.2.0/24  
user@R1# set 172.16.3.0/24  
user@R1# set 172.16.4.0/24  
user@R1# set 172.16.5.0/24  
user@R1# set 172.16.6.0/24
```

4. Configure the routing policies.

```
[edit dynamic policy-options policy-statement dyn_policy1]  
user@R1# set term t1 from prefix-list dyn_prfx1  
user@R1# set term t1 then accept  
user@R1# set term t2 then reject  
user@R1# set term t1 from prefix-list dyn_prfx2  
user@R1# set term t1 then accept
```

```
user@R1# set term t2 then reject
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure Device R1's standard database:

1. Create the router interfaces.

```
[edit interfaces]
user@R1# set fe-1/2/0 unit 0 family inet address 10.0.0.2/30
user@R1# set fe-1/2/2 unit 0 family inet address 10.1.0.1/30
user@R1# set fe-1/2/1 unit 0 family inet address 172.16.4.2/24
user@R1# set fe-1/2/1 unit 0 family inet address 172.16.3.2/24
user@R1# set fe-1/2/1 unit 0 family inet address 172.16.2.2/24
user@R1# set fe-1/2/1 unit 0 family inet address 172.16.1.2/24
user@R1# set fe-1/2/1 unit 0 family inet address 172.16.5.2/24
user@R1# set fe-1/2/1 unit 0 family inet address 172.16.6.2/24
user@R1# set fe-1/2/1 unit 0 family inet address 172.16.7.2/24
user@R1# set fe-1/2/1 unit 0 family inet address 172.16.8.2/24
user@R1# set fe-1/2/1 unit 0 family inet address 172.16.9.2/24
user@R1# set fe-1/2/1 unit 0 family inet address 172.16.10.2/24
user@R1# set fe-1/2/3 unit 0 family inet address 172.16.2.2/24
user@R1# set fe-1/2/3 unit 0 family inet address 172.16.3.2/24
user@R1# set fe-1/2/3 unit 0 family inet address 172.16.4.2/24
user@R1# set fe-1/2/3 unit 0 family inet address 172.16.5.2/24
user@R1# set fe-1/2/3 unit 0 family inet address 172.16.6.2/24
user@R1# set lo0 unit 0 family inet address 192.168.0.2/32
```

2. Create routing policies that reference the policies in the dynamic database.

```
[edit policy-options]
user@R1# set policy-statement dyn_policy1 dynamic-db
user@R1# set policy-statement dyn_policy2 dynamic-db
```

3. Configure BGP peering with Device R0.

```
[edit protocols bgp group to_r0]
user@R1# set neighbor 10.0.0.1 peer-as 100
```

4. Apply the dynamic database policies to the BGP peering with Device R0.

```
[edit protocols bgp group to_r0]
user@R1# set neighbor 10.0.0.1 import dyn_policy1
user@R1# set neighbor 10.0.0.1 export dyn_policy2
```

5. Configure a prefix list for prefixes learned from Device R0.

```
[edit policy-options prefix-list static_prfx2]
user@R1# set 172.16.1.0/24
user@R1# set 172.16.2.0/24
user@R1# set 172.16.3.0/24
user@R1# set 172.16.4.0/24
```

6. Configure a prefix list for prefixes learned from Device R2.

```
[edit policy-options prefix-list static_prfx1]
user@R1# set 172.16.2.0/24
user@R1# set 172.16.3.0/24
user@R1# set 172.16.4.0/24
user@R1# set 172.16.5.0/24
```

7. Configure the static database policies.

```
[edit policy-options policy-statement static_policy1]
user@R1# set term t1 from prefix-list static_prfx1
user@R1# set term t1 then accept
user@R1# set term t2 then reject
[edit policy-options policy-statement static_policy2]
user@R1# set term t1 from prefix-list static_prfx2
user@R1# set term t1 then accept
user@R1# set term t2 then reject
```

8. Configure BGP peering with Device R2.

```
[edit protocols bgp group to_R2]
user@R1# set neighbor 10.1.0.2 peer-as 300
```

9. Apply the static database policies to the BGP peering with Device R2.

```
[edit protocols bgp group to_R2]
user@R1# set import static_policy1
user@R1# set export static_policy2
```

10. (Optional) Configure the router not to reestablish the BGP peering sessions after an active nonstop routing switchover either for a specified period or until you manually reestablish the session.

This statement is particularly useful with dynamic routing policies because the dynamic database is not synchronized with the backup Routing Engine when nonstop active routing (NSR) is enabled. As a result, if a switchover to a backup Routing Engine occurs, import and export policies running on the master Routing Engine at the time of the switchover might no longer be available. Therefore, you might want to prevent a BGP peering session from automatically being reestablished as soon as a switchover occurs.

```
[edit protocols bgp]
user@R1# set group to_r0 idle-after-switch-over 300
user@R1# set group to_R2 idle-after-switch-over 300
```

11. Configure the autonomous system (AS) number.

```
[edit routing-options]
user@R1# set routing-options autonomous-system 200
```

Results

Confirm your configuration by entering the **show** command from configuration mode in the dynamic database, and the **show interfaces**, **show protocols**, **show policy-options** and **show routing-options** commands from configuration mode in the standard database. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

Device R1 Dynamic

```
[edit dynamic]
user@R1# show
policy-options {
  prefix-list dyn_prfx1 {
    172.16.1.0/24;
    172.16.2.0/24;
    172.16.3.0/24;
```

```
172.16.4.0/24;
172.16.5.0/24;
172.16.6.0/24;
172.16.7.0/24;
172.16.8.0/24;
}
prefix-list dyn_prfx2 {
  172.16.2.0/24;
  172.16.3.0/24;
  172.16.4.0/24;

- [Checking the Routes That Device R1 Is Advertising to Device R0 | 685](#)
- [Checking the Routes That Device R1 Is Advertising to Device R2 | 686](#)

Confirm that the configuration is working properly.

Checking the Configured Policies on Device R1

Purpose

Verify that Device R1 has the dynamic and static policies in effect.

Action

From Device R1, enter the **show policy** command.

```
user@R1> show policy
```

```
Configured policies:
dyn_policy1
dyn_policy2
static_policy1
static_policy2
dyn_policy1
dyn_policy2
```

Meaning

The dynamic policies are listed two times because they are configured two times, the first and central configuration in the dynamic database. The secondary configuration is in the static database, where the dynamic database is referenced, as shown here:

Configured in the Dynamic Database

```
policy-statement dyn_policy1 {
  term t1 {
    from {
      prefix-list dyn_prfx1;
    }
  }
}
```

```

        then accept;
    }
    term t2 {
        then reject;
    }
}
policy-statement dyn_policy2 {
    term t1 {
        from {
            prefix-list dyn_prfx2;
        }
        then accept;
    }
    term t2 {
        then reject;
    }
}

```

Referenced from the Static Database

```

policy-statement dyn_policy1 {
    dynamic-db;
}
policy-statement dyn_policy2 {
    dynamic-db;
}

```

Checking the Routes Advertised from Device R0 to Device R1

Purpose

Verify that Device R0's routing policy is working.

Action

From Device R0, enter the **show route advertising-protocol bgp** command, using the neighbor address for Device R1.

```
user@R0> show route advertising-protocol bgp 10.0.0.2
```

```
inet.0: 28 destinations, 28 routes (28 active, 0 holddown, 0 hidden)
  Prefix                Nexthop          MED      Lclpref    AS path
* 172.16.1.0/24          Self                      I
* 172.16.2.0/24          Self                      I
* 172.16.3.0/24          Self                      I
* 172.16.4.0/24          Self                      I
* 172.16.5.0/24          Self                      I
* 172.16.6.0/24          Self                      I
* 172.16.7.0/24          Self                      I
* 172.16.8.0/24          Self                      I
* 172.16.9.0/24          Self                      I
* 172.16.10.0/24         Self                      I
* 10.0.0.0/30            Self                      I
```

Meaning

Device R0 is sending the expected routes to Device R1.

Checking the Routes That Device R1 Is Receiving from Device R0

Purpose

Verify that Device R1's import routing policy is working.

Action

From Device R1, enter the **show route receive-protocol bgp** command, using the neighbor address for Device R0.

```
user@R1> show route receive-protocol bgp 10.0.0.1
```

```
inet.0: 35 destinations, 51 routes (35 active, 0 holddown, 4 hidden)
  Prefix                Nexthop          MED      Lclpref    AS path
172.16.1.0/24           10.0.0.1          100      I
172.16.2.0/24           10.0.0.1          100      I
172.16.3.0/24           10.0.0.1          100      I
172.16.4.0/24           10.0.0.1          100      I
172.16.5.0/24           10.0.0.1          100      I
172.16.6.0/24           10.0.0.1          100      I
172.16.7.0/24           10.0.0.1          100      I
172.16.8.0/24           10.0.0.1          100      I
```

Meaning

Some of the routes that are sent by Device R0 are not received by Device R1. The routes 172.16.9.0/24, 172.16.10.0/24, and 10.0.0.0/30 are missing. This is because Device R1's import policy, applied to the

BGP peering session with Device R0 using the **import dyn_policy1** statement, specifically defines a prefix list limited to the following routes:

```
prefix-list dyn_prfx1 {
  172.16.1.0/24;
  172.16.2.0/24;
  172.16.3.0/24;
  172.16.4.0/24;
  172.16.5.0/24;
  172.16.6.0/24;
  172.16.7.0/24;
  172.16.8.0/24;
}
```

Checking the Routes Advertised from Device R2 to Device R1

Purpose

Verify that Device R2's routing policy is working.

Action

From Device R2, enter the **show route advertising-protocol bgp** command, using the neighbor address for Device R1.

```
user@R2> show route advertising-protocol bgp 10.1.0.1
```

```
inet.0: 17 destinations, 17 routes (17 active, 0 holddown, 0 hidden)
  Prefix                Nexthop          MED      Lclpref    AS path
* 172.16.2.0/24         Self              I
* 172.16.3.0/24         Self              I
* 172.16.4.0/24         Self              I
* 172.16.5.0/24         Self              I
* 172.16.6.0/24         Self              I
```

Meaning

Device R2 is sending the expected routes to Device R1.

Checking the Routes That Device R1 Is Receiving from Device R2

Purpose

Verify that Device R1's import routing policy is working.

Action

From Device R1, enter the **show route receive-protocol bgp** command, using the neighbor address for Device R0.

```
user@R1> show route receive-protocol bgp 10.1.0.2
```

```
inet.0: 35 destinations, 51 routes (35 active, 0 holddown, 4 hidden)
  Prefix                Nexthop          MED      Lclpref    AS path
  172.16.2.0/24         10.1.0.2                300 I
  172.16.3.0/24         10.1.0.2                300 I
  172.16.4.0/24         10.1.0.2                300 I
  172.16.5.0/24         10.1.0.2                300 I
```

Meaning

One of the routes that is sent by Device R2 is not received by Device R1. The route 172.16.6.0/24 is missing. This is because Device R1's import policy, applied to the BGP peering session with Device R2 using the **import static_policy1** statement, specifically defines a prefix list limited to the following routes:

```
prefix-list static_prfx1 {
  172.16.2.0/24;
  172.16.3.0/24;
  172.16.4.0/24;
  172.16.5.0/24;
}
```

Checking the Routes That Device R1 Is Advertising to Device R0

Purpose

Verify that Device R1's export routing policy is working.

Action

From Device R1, enter the **show route advertising-protocol bgp** command, using the neighbor address for Device R0.

```
user@R1> show route advertising-protocol bgp 10.0.0.1
```

```
inet.0: 35 destinations, 51 routes (35 active, 0 holddown, 4 hidden)
  Prefix                Nexthop          MED      Lclpref    AS path
  * 172.16.2.0/24        Self              I
  * 172.16.3.0/24        Self              I
  * 172.16.4.0/24        Self              I
  * 172.16.5.0/24        Self              I
  * 172.16.6.0/24        Self              I
```

Meaning

Perhaps unexpectedly, the route that Device R1 did not receive through BGP from Device R2 (172.16.6.0/24) is nonetheless being advertised by Device R1 through BGP to Device R0. This is happening for two reasons. The first reason is that route 172.16.6.0/24 is in Device R1's routing table, albeit as a direct route, as shown here:

```
user@R1> show route 172.16.6.0/24 protocol direct
```

```
inet.0: 35 destinations, 51 routes (35 active, 0 holddown, 4 hidden)
+ = Active Route, - = Last Active, * = Both

172.16.6.0/24          *[Direct/0] 2d 22:51:41
                        > via fe-1/2/3.0
```

The second reason is that Device R1's export policy, applied to the BGP peering session with Device R0 using the **export dyn_policy2** statement, specifically defines a prefix list limited to the following routes:

```
prefix-list dyn_prfx2 {
  172.16.2.0/24;
  172.16.3.0/24;
  172.16.4.0/24;
  172.16.5.0/24;
  172.16.6.0/24;
}
```

Note the inclusion of 172.16.6.0/24.

Checking the Routes That Device R1 Is Advertising to Device R2

Purpose

Verify that Device R1's export routing policy is working.

Action

From Device R1, enter the **show route advertising-protocol bgp** command, using the neighbor address for Device R2.

```
user@R1> show route advertising-protocol bgp 10.1.0.2
```

```
inet.0: 35 destinations, 51 routes (35 active, 0 holddown, 4 hidden)
  Prefix                Nexthop          MED      Lclpref    AS path
* 172.16.1.0/24         Self              0
* 172.16.2.0/24         Self              0
```

* 172.16.3.0/24	Self	I
* 172.16.4.0/24	Self	I

Meaning

Device R1 is sending the expected routes to Device R2. Device R1's export policy, applied to the BGP peering session with Device R2 using the **export static_policy2** statement, specifically defines a prefix list limited to the following routes:

```
prefix-list static_prfx2 {  
  172.16.1.0/24;  
  172.16.2.0/24;  
  172.16.3.0/24;  
  172.16.4.0/24;  
}
```

Understanding Routing Policy Tests

Routing policy tests provide a method for verifying the effectiveness of your policies before applying them on the routing device. Before applying a routing policy, you can issue the **test policy** command to ensure that the policy produces the results that you expect:

```
user@host> test policy policy-name prefix
```

Keep in mind that different protocols have different default policies that get applied if the prefix does not match the configured policy. For BGP this is accept, but for RIP it is reject. The **test policy** command always uses accept as the default policy, so unless you explicitly reject all routes that you do not want to match you might see more routes matching than you want.

The default policy of the **test policy** command accepts all routes from all protocols. Test output can be misleading when you are evaluating protocol-specific conditions. For example, if you define a policy for BGP that accepts routes of a specified prefix and apply it to BGP as an export policy, BGP routes that match the prefix are advertised to BGP peers. However, if you test the same policy using the **test policy** command, the test output might indicate that non-BGP routes have been accepted.

Example: Testing a Routing Policy

Test the following policy, which looks for unwanted routes and rejects them:

```
[edit policy-options]
policy-statement reject-unwanted-routes {
  term drop-these-routes {
    from {
```

```

route-filter 0/0 exact;
route-filter 10/8 orlonger;
route-filter 172.16/12 orlonger;
route-filter 192.168/16 orlonger;
route-filter 224/3 orlonger;
}
then reject;
}
}

```

Test this policy against all routes in the routing table:

```
user@host> test policy reject-unwanted-routes 0/0
```

Test this policy against a specific set of routes:

```
user@host> test policy reject-unwanted-routes 10.49.0.0/16
```

Example: Testing a Routing Policy with Complex Regular Expressions

IN THIS SECTION

- [Requirements](#) | 690
- [Overview](#) | 690
- [Configuration](#) | 692
- [Verification](#) | 697

This example shows how to test a routing policy using the **test policy** command to ensure that the policy produces the results that you expect before you apply it in a production environment. Regular expressions,

especially complex ones, can be tricky to get right. This example shows how to use the **test policy** command to make sure that your regular expressions have the intended effect.

Requirements

No special configuration beyond device initialization is required before you configure this example.

Overview

This example shows two routing devices with an external BGP (EBGP) connection between them. Device R2 uses the BGP session to send customer routes to Device R1. These static routes have multiple community values attached.

user@R2> **show route match-prefix 172.16.* detail**

```

To test a complex regular expression, Device R2 has a policy called **test-regex** that locates routes. The policy is configured like this:

```

policy-statement test-regex {
  term find-routes {
    from community complex-regex;
    then accept;
  }
  term reject-the-rest {
    then reject;
  }
}
community complex-regex members "^64510:[13].*$";

```

This regular expression matches community values beginning with either 1 or 3.

Topology

Figure 46 on page 692 shows the sample network.

Figure 46: Routing Policy Test for Complex Regular Expressions

"CLI Quick Configuration" on page 692 shows the configuration for all of the devices in Figure 46 on page 692.

The section "Step-by-Step Procedure" on page 693 describes the steps on Device R2.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level.

Device R1

```
set interfaces fe-1/2/0 unit 0 family inet address 10.0.0.1/30
set interfaces lo0 unit 0 family inet address 192.168.0.1/32
set protocols bgp group ext type external
set protocols bgp group ext peer-as 64511

```

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure Device R2:

1. Configure the interfaces.

```
[edit interfaces]
user@R2# set fe-1/2/0 unit 0 family inet address 10.0.0.2/30
user@R2# set lo0 unit 0 family inet address 192.168.0.2/32
```

2. Configure BGP.

Apply the import policy to the BGP peering session with Device R2.

```
[edit protocols bgp group ext]
user@R2# set type external
user@R2# set peer-as 64510
user@R2# set neighbor 10.0.0.1
```

3. Configure the routing policy that sends static routes.

```
[edit policy-options policy-statement send-static]
user@R2# set term 1 from protocol static
user@R2# set term 1 then accept
user@R2# set term 2 then reject
```

4. Configure the routing policy that tests a regular expression.

```
[edit policy-options policy-statement test-regex]
user@R2# set term find-routes from community complex-regex
user@R2# set term find-routes then accept
user@R2# set term reject-the-rest then reject
[edit policy-options community]
user@R2# set complex-regex members "^64510:[13].*$"
```

5. Configure the static routes and attaches community values.

```
[edit routing-options static route 172.16.1.0/24]
user@R2# set reject
```

```

user@R2# set community [ 64510:1 64510:10 64510:11 64510:100 64510:111 ]
[edit routing-options static route 172.16.2.0/24]
user@R2# set reject
user@R2# set community [ 64510:2 64510:20 64510:22 64510:200 64510:222 ]
[edit routing-options static route 172.16.3.0/24]
user@R2# set reject
user@R2# set community [ 64510:3 64510:30 64510:33 64510:300 64510:333 ]
[edit routing-options static route 172.16.4.0/24]
user@R2# set reject
user@R2# set community [ 64510:4 64510:40 64510:44 64510:400 64510:444 ]

```

6. Configure the autonomous system (AS) number and the router ID.

This affects Device R2's routing table, and as no impact on Device R1 and Device R3.

```

[edit routing-options ]
user@R2# set router-id 192.168.0.2
user@R2# set autonomous-system 64511

```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

user@R2# show interfaces
fe-1/2/0 {
  unit 0 {
    family inet {
      address 10.0.0.2/30;
    }
  }
}
lo0 {
  unit 0 {
    family inet {
      address 192.168.0.2/32;
    }
  }
}

```

```

user@R2# show protocols

```

```

bgp {
  group ext {
    type external;
    peer-as 64510;
    neighbor 10.0.0.1;
  }
}

```

```

user@R2# show policy-options
policy-statement send-static {
  term 1 {
    from protocol static;
    then accept;
  }
  term 2 {
    then reject;
  }
}
policy-statement test-regex {
  term find-routes {
    from community complex-regex;
    then accept;
  }
  term reject-the-rest {
    then reject;
  }
}
community complex-regex members "^64510:[13].*$";

```

```

user@R2# show routing-options
static {
  route 172.16.1.0/24 {
    reject;
    community [ 64510:1 64510:10 64510:11 64510:100 64510:111 ];
  }
  route 172.16.2.0/24 {
    reject;
    community [ 64510:2 64510:20 64510:22 64510:200 64510:222 ];
  }
  route 172.16.3.0/24 {
    reject;
    community [ 64510:3 64510:30 64510:33 64510:300 64510:333 ];
  }
}

```

```

route 172.16.4.0/24 {
    reject;
    community [ 64510:4 64510:40 64510:44 64510:400 64510:444 ];
}
}
router-id 192.168.0.2;
autonomous-system 64511;

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

Test to See Which Communities Match the Regular Expression

Purpose

You can test the regular expression and its policy by using the **test policy policy-name** command.

Action

1. On Device R2, run the **test policy test-regex 0/0** command.

```
user@R2> test policy test-regex 0/0
```

```

inet.0: 7 destinations, 7 routes (7 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

172.16.1.0/24      *[Static/5] 1d 00:32:50
                   Reject
172.16.3.0/24      *[Static/5] 1d 00:32:50
                   Reject

Policy test-regex: 2 prefix accepted, 5 prefix rejected

```

2. On Device R2, change the regular expression to match a community value containing any number of instances of the digit 2.

```

[edit policy-options community complex-regex]
user@R2# delete members "^64510:[13].*$"
user@R2# set members "^65020:2+ $"
user@R2# commit

```

3. On Device R2, rerun the **test policy test-regex 0/0** command.

```
user@R2> test policy test-regex 0/0
```

```
inet.0: 7 destinations, 7 routes (7 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

172.16.2.0/24      *[Static/5] 1d 00:31:36
                   Reject

Policy test-regex: 1 prefix accepted, 6 prefix rejected
```

Meaning

The 172.16.1.0 /24 and 172.16.3.0/24 routes both have communities attached that match the ^64510:[13].*\$ expression. The 172.16.2.0/24 route has communities that match the ^65020:2+\$ expression.

Firewall Filters Overview

Firewall filters provide a means of protecting your router (and switch) from excessive traffic transiting the router (and switch) to a network destination or destined for the Routing Engine. Firewall filters that control local packets can also protect your router (and switch) from external incidents.

You can configure a firewall filter to do the following:

- Restrict traffic destined for the Routing Engine based on its source, protocol, and application.

- Limit the traffic rate of packets destined for the Routing Engine to protect against flood, or denial-of-service (DoS) attacks.
- Address special circumstances associated with fragmented packets destined for the Routing Engine. Because the device evaluates every packet against a firewall filter (including fragments), you must configure the filter to accommodate fragments that do not contain packet header information. Otherwise, the filter discards all but the first fragment of a fragmented packet.

The Junos[®] operating system (Junos OS) provides a *policy framework*, which is a collection of Junos OS policies that enable you to control flows of routing information and packets within the router.

Flow of Routing Information

Routing information is the information about routes learned by the routing protocols from a router's neighbors. This information is stored in routing tables. The routing protocols advertise active routes only

from the routing tables. An *active route* is a route that is chosen from all routes in the routing table to reach a destination.

To control which routes the routing protocols place in the routing tables and which routes the routing protocols advertise from the routing tables, you can configure *routing policies*, which are sets of rules that the policy framework uses to preempt default routing policies.

The Routing Engine, which runs the router's control plane software, handles the flow of routing information between the routing protocols and the routing tables and between the routing tables and the forwarding table. The Routing Engine runs the Junos OS and routing policies and stores the active router configuration, the master routing table, and the master forwarding table,

Flow of Data Packets

Data packets are chunks of data that transit the router as they are being forwarded from a source to a destination. When a router receives a data packet on an interface, it determines where to forward the packet by looking in the forwarding table for the best route to a destination. The router then forwards the data packet toward its destination through the appropriate interface.

The Packet Forwarding Engine, which is the central processing element of the router's forwarding plane, handles the flow of data packets in and out of the router's physical interfaces. Although the Packet Forwarding Engine contains Layer 3 and Layer 4 header information, it does not contain the packet data itself (the packet's payload).

To control the flow of data packets transiting the device as the packets are being forwarded from a source to a destination, you can apply stateless firewall filters to the input or output of the router's or switch's physical interfaces.

To enforce a specified bandwidth and maximum burst size for traffic sent or received on an interface, you can configure policers. Policers are a specialized type of stateless firewall filter and a primary component of the Junos OS class-of-service (CoS).

Flow of Local Packets

Local packets are chunks of data that are destined for or sent by the router. Local packets usually contain routing protocol data, data for IP services such as Telnet or SSH, and data for administrative protocols such as the Internet Control Message Protocol (ICMP). When the Routing Engine receives a local packet, it forwards the packet to the appropriate process or to the kernel, which are both part of the Routing Engine, or to the Packet Forwarding Engine.

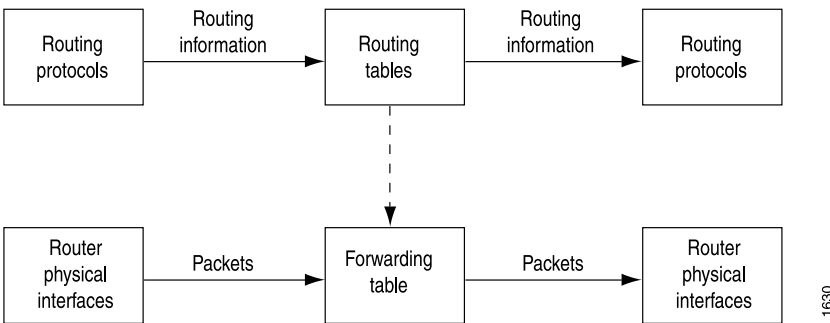

The Routing Engine handles the flow of local packets from the router's physical interfaces and to the Routing Engine.

To control the flow of local packets between the physical interfaces and the Routing Engine, you can apply stateless firewall filters to the input or output of the loopback interface. The loopback interface (lo0) is the interface to the Routing Engine and carries no data packets.

Interdependent Flows of Routing Information and Packets

Figure 47 on page 704 illustrates the flow of data through a router. Although routing information flows and packet flows are very different from one another, they are also interdependent.

Figure 47: Flows of Routing Information and Packets

Routing policies determine which routes the Routing Engine places in the forwarding table. The forwarding table, in turn, has an integral role in determining the appropriate physical interface through which to forward a packet.

Stateless and Stateful Firewall Filters

A stateless firewall filter, also known as an access control list (ACL), does not statefully inspect traffic. Instead, it evaluates packet contents statically and does not keep track of the state of network connections. In contrast, a stateful firewall filter uses connection state information derived from other applications and past communications in the data flow to make dynamic control decisions.

The basic purpose of a stateless firewall filter is to enhance security through the use of packet filtering. Packet filtering enables you to inspect the components of incoming or outgoing packets and then perform the actions you specify on packets that match the criteria you specify. The typical use of a stateless firewall filter is to protect the Routing Engine processes and resources from malicious or untrusted packets.

Stateless Firewall Filter Application Points

After you define the firewall filter, you must apply it to an application point. These application points include logical interfaces, physical interfaces, routing interfaces, and routing instances.

In most cases, you can apply a firewall filter as an *input* filter or an *output* filter, or both at the same time. Input filters take action on packets being received on the specified interface, whereas output filters take action on packets that are transmitted through the specified interface.

You typically apply one filter with multiple terms to a single logical interface, to incoming traffic, outbound traffic, or both. However, there are times when you might want to chain together multiple firewall filters (with single or multiple terms) and apply them to an interface. You use an *input list* to apply multiple firewall filters to the incoming traffic on an interface. You use an *output list* to apply multiple firewall filters to the outbound traffic on an interface. You can include up to 16 filters in an input list or an output list.

There is no limit to the number of filters and counters you can set, but there are some practical considerations. More counters require more terms, and a large number of terms can take a long time to process during a commit operation. However, filters with more than 4000 terms and counters have been implemented successfully.

[Table 28 on page 706](#) describes each point to which you can apply a firewall filter. For each application point, the table describes the types of firewall filters supported at that point, the router (or switch) hierarchy level at which the filter can be applied, and any platform-specific limitations.

Table 28: Stateless Firewall Filter Configuration and Application Summary

Filter Type	Application Point	Restrictions

Understanding How Firewall Filters Control Packet Flows

A switch supports firewall filters that allow you to control flows of data packets and local packets. *Data packets* transit a switch as they are forwarded from a source to a destination. *Local packets* are destined for or sent by a Routing Engine (they do not transit a switch). Local packets usually contain routing protocol data, data for IP services such as Telnet or SSH, or data for administrative protocols such as the Internet Control Message Protocol (ICMP).

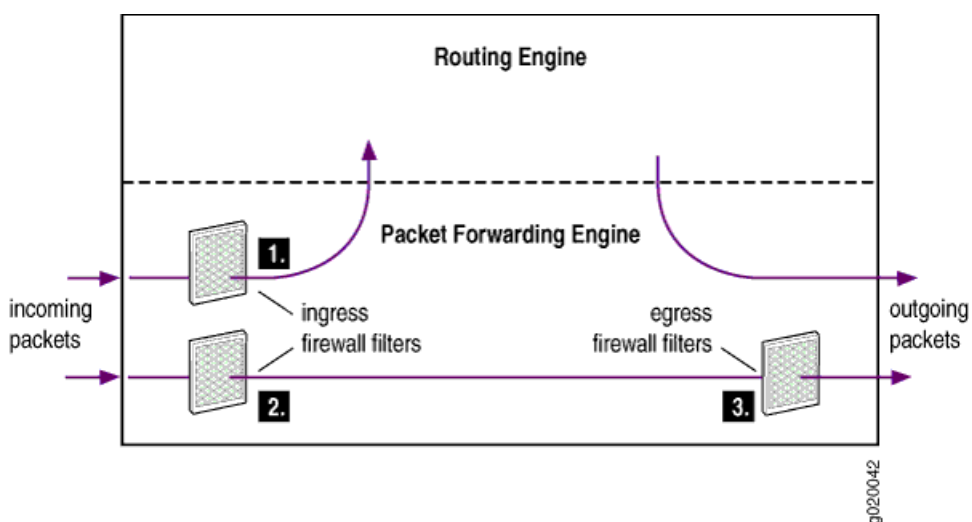

Firewall filters affect packet flows entering into or exiting from a switch as follows:

- Ingress firewall filters affect the flow of data packets that are received on switch interfaces. When a switch receives a data packet, the Packet Forwarding Engine in the system that contains the ingress interface determines where to forward the packet by looking in its Layer 2 or Layer 3 forwarding table for the best route to the destination. Data packets are forwarded to an egress interface. Locally destined packets are forwarded to the Routing Engine.
- Egress firewall filters affect data packets that are transiting a switch but do not affect packets sent by the Routing Engine. These filters are applied by the Packet Forwarding Engine in the system that contains the egress interface.

Figure 48 on page 711 illustrates the application of ingress and egress firewall filters to control the flow of packets through a switch:

1. Ingress firewall filter applied to locally destined packets that are received on switch interfaces and are destined for the Routing Engine.
2. Ingress firewall filter applied to data packets that are received on switch interfaces and will transit the switch.
3. Egress firewall filter applied to data packets that are transiting the switch.

Stateless Firewall Filter Overview

IN THIS SECTION

- [Packet Flow Control | 712](#)
- [Stateless and Stateful Firewall Filters | 713](#)
- [Purpose of Stateless Firewall Filters | 713](#)

Packet Flow Control

To influence which packets are allowed to transit the system and to apply special actions to packets as necessary, you can configure *stateless firewall filters*. A stateless firewall specifies a sequence of one or more packet-filtering rules, called *filter terms*. A filter term specifies *match conditions* to use to determine a match and *actions* to take on a matched packet. A stateless firewall filter enables you to manipulate any packet of a particular protocol family, including fragmented packets, based on evaluation of Layer 3 and Layer 4 header fields. You typically apply a stateless firewall filter to one or more interfaces that have been configured with protocol family features. You can apply a stateless firewall filter to an ingress interface, an egress interface, or both.

Data Packet Flow Control

To control the flow of data packets transiting the device as the packets are being forwarded from a source to a destination, you can apply stateless firewall filters to the input or output of the router's or switch's physical interfaces.

To enforce a specified bandwidth and maximum burst size for traffic sent or received on an interface, you can configure *policers*. Policers are a specialized type of stateless firewall filter and a primary component of the Junos OS *class-of-service* (CoS).

Local Packet Flow Control

To control the flow of local packets between the physical interfaces and the Routing Engine, you can apply stateless firewall filters to the input or output of the *loopback interface*. The loopback interface (**lo0**) is the interface to the Routing Engine and carries no data packets.

Junos OS Evolved Local Packet Flow Control

In Junos OS Evolved, you can have two different filters: one for network control traffic (loopback traffic) and one for management traffic. With two filters, you have more flexibility. For example, you can configure a stricter filter on management interface traffic than on network control traffic.

Management filtering uses Routing Engine filters based on netfilters, a framework provided by the Linux kernel. This difference results in only certain matches and actions being supported.

NOTE: You must explicitly add the filter on the management interface as for Junos OS Evolved, the `lo` filter no longer applies on the management traffic, as is the case for Junos OS.

Stateless and Stateful Firewall Filters

A stateless firewall filter, also known as an *access control list* (ACL), does not statefully inspect traffic. Instead, it evaluates packet contents statically and does not keep track of the state of network connections. In contrast, a *stateful firewall filter* uses connection state information derived from other applications and past communications in the data flow to make dynamic control decisions.

The *Routing Policies, Firewall Filters, and Traffic Policers User Guide* describes *stateless firewall filters*.

Purpose of Stateless Firewall Filters

The basic purpose of a stateless firewall filter is to enhance security through the use of packet filtering. Packet filtering enables you to inspect the components of incoming or outgoing packets and then perform the actions you specify on packets that match the criteria you specify. The typical use of a stateless firewall filter is to protect the Routing Engine processes and resources from malicious or untrusted packets.

Understanding How to Use Standard Firewall Filters

IN THIS SECTION

- [Using Standard Firewall Filters to Affect Local Packets | 714](#)
- [Using Standard Firewall Filters to Affect Data Packets | 714](#)

Using Standard Firewall Filters to Affect Local Packets

On a router, you can configure one physical loopback interface, **lo0**, and one or more addresses on the interface. The loopback interface is the interface to the Routing Engine, which runs and monitors all the control protocols. The loopback interface carries local packets only. Standard firewall filters applied to the loopback interface affect the local packets destined for or transmitted from the Routing Engine.

NOTE: When you create an additional loopback interface, it is important to apply a filter to it so the Routing Engine is protected. We recommend that when you apply a filter to the loopback interface, you include the **apply-groups** statement. Doing so ensures that the filter is automatically inherited on every loopback interface, including **lo0** and other loopback interfaces.

Trusted Sources

The typical use of a standard stateless firewall filter is to protect the Routing Engine processes and resources from malicious or untrusted packets. To protect the processes and resources owned by the Routing Engine, you can use a standard stateless firewall filter that specifies which protocols and services, or applications, are allowed to reach the Routing Engine. Applying this type of filter to the loopback interface ensures that the local packets are from a trusted source and protects the processes running on the Routing Engine from an external attack.

Flood Prevention

You can create standard stateless firewall filters that limit certain TCP and ICMP traffic destined for the Routing Engine. A router without this kind of protection is vulnerable to TCP and ICMP flood attacks, which are also called denial-of-service (DoS) attacks. For example:

- A TCP flood attack of SYN packets initiating connection requests can overwhelm the device until it can no longer process legitimate connection requests, resulting in denial of service.
- An ICMP flood can overload the device with so many echo requests (ping requests) that it expends all its resources responding and can no longer process valid network traffic, also resulting in denial of service.

Applying the appropriate firewall filters to the Routing Engine protects against these types of attacks.

Using Standard Firewall Filters to Affect Data Packets

Standard firewall filters that you apply to your router's transit interfaces evaluate only the user data packets that transit the router from one interface directly to another as they are being forwarded from a source to a destination. To protect the network as a whole from unauthorized access and other threats at specific interfaces, you can apply firewall filters router transit interfaces .

Understanding How Firewall Filters Control Packet Flows

A switch supports firewall filters that allow you to control flows of data packets and local packets. *Data packets* transit a switch as they are forwarded from a source to a destination. *Local packets* are destined for or sent by a Routing Engine (they do not transit a switch). Local packets usually contain routing protocol data, data for IP services such as Telnet or SSH, or data for administrative protocols such as the Internet Control Message Protocol (ICMP).

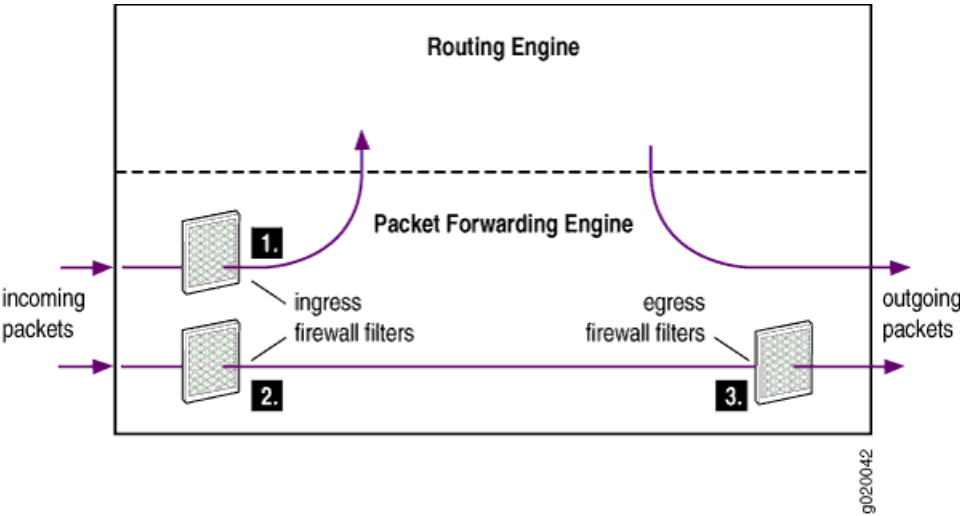

Firewall filters affect packet flows entering into or exiting from a switch as follows:

- Ingress firewall filters affect the flow of data packets that are received on switch interfaces. When a switch receives a data packet, the Packet Forwarding Engine in the system that contains the ingress interface determines where to forward the packet by looking in its Layer 2 or Layer 3 forwarding table for the best route to the destination. Data packets are forwarded to an egress interface. Locally destined packets are forwarded to the Routing Engine.
- Egress firewall filters affect data packets that are transiting a switch but do not affect packets sent by the Routing Engine. These filters are applied by the Packet Forwarding Engine in the system that contains the egress interface.

[Figure 48 on page 711](#) illustrates the application of ingress and egress firewall filters to control the flow of packets through a switch:

1. Ingress firewall filter applied to locally destined packets that are received on switch interfaces and are destined for the Routing Engine.
2. Ingress firewall filter applied to data packets that are received on switch interfaces and will transit the switch.
3. Egress firewall filter applied to data packets that are transiting the switch.

Stateless Firewall Filter Components

IN THIS SECTION

- [Protocol Family | 716](#)
- [Filter Type | 717](#)
- [Terms | 719](#)
- [Match Conditions | 719](#)
- [Actions | 720](#)

This topic covers the following information:

Protocol Family

Under the **firewall** statement, you can specify the protocol family for which you want to filter traffic.

[Table 29 on page 717](#) describes the firewall filter protocol families.

Table 29: Firewall Filter Protocol Families

Type of Traffic to Be Filtered	Configuration Statement	Comments
Protocol Independent	family any	All protocol families configured on a logical interface.
Internet Protocol version 4 (IPv4)	family inet	The family inet statement is optional for IPv4.
Internet Protocol version 6 (IPv6)	family inet6	
MPLS	family mpls	
MPLS-tagged IPv4	family mpls	Supports matching on IP addresses and ports, up to five MPLS stacked labels.
MPLS-tagged IPv6	family mpls	Supports matching on IP addresses and ports, up to five MPLS stacked labels.
Virtual private LAN service (VPLS)	family vpls	
Layer 2 Circuit Cross-Connection	family ccc	
Layer 2 Bridging	family bridge (for MX Series routers) and family ethernet-switching (for EX Series switches)	MX Series routers and EX Series switches only.

Filter Type

Under the **family *family-name*** statement, you can specify the type and name of the filter you want to configure.

[Table 30 on page 718](#) describes the firewall filter types.

Table 30: Filter Types

Filter Type	Configuration Statement	Description
Standard Firewall Filter	filter <i>filter-name</i>	<p>Filters the following traffic types:</p> <ul style="list-style-type: none"> • Protocol independent • IPv4 • IPv6 • MPLS • MPLS-tagged IPv4 • MPLS-tagged IPv6 • VPLS • Layer 2 CCC • Layer 2 bridging (MX Series routers and EX Series switches only)
Service Filter	service-filter <i>service-filter-name</i>	<p>Defines packet-filtering to be applied to ingress or egress before it is accepted for service processing or applied to returning service traffic after service processing has completed.</p> <p>Filters the following traffic types:</p> <ul style="list-style-type: none"> • IPv4 • IPv6 <p>Supported at logical interfaces configured on the following hardware only:</p> <ul style="list-style-type: none"> • Adaptive Services (AS) PICs on M Series and T Series routers • Multiservices (MS) PICs on M Series and T Series routers • Multiservices (MS) DPCs on MX Series routers (and EX Series switches)
Simple Filter	simple-filter <i>simple-filter-name</i>	<p>Defines packet filtering to be applied to ingress traffic only.</p> <p>Filters the following traffic type:</p> <ul style="list-style-type: none"> • IPv4 <p>Supported at logical interfaces configured on the following hardware only:</p> <ul style="list-style-type: none"> • Gigabit Ethernet Intelligent Queuing (IQ2) PICs installed on M120, M320, or T Series routers • Enhanced Queuing Dense Port Concentrators (EQ DPCs) installed on MX Series routers (and EX Series switches)

Terms

Under the **filter**, **service-filter**, or **simple-filter** statement, you must configure at least one firewall filter *term*. A term is a named structure in which match conditions and actions are defined. Within a firewall filter, you must configure a unique name for each term.

TIP: For each protocol family on an interface, you can apply no more than one filter in each direction. If you try to apply additional filters for the same protocol family in the same direction, the last filter overwrites the previous filter. You can, however, apply filters from the same protocol family to the input and output direction of the same interface.

All stateless firewall filters contain one or more terms, and each term consists of two components—match conditions and actions. The match conditions define the values or fields that the packet must contain to be considered a match. If a packet is a match, the corresponding action is taken. By default, a packet that does not match a firewall filter is discarded.

If a packet arrives on an interface for which no firewall filter is applied for the incoming traffic on that interface, the packet is accepted by default.

NOTE: A firewall filter with a large number of terms can adversely affect both the configuration commit time and the performance of the Routing Engine.

Additionally, you can configure a stateless firewall filter within the term of another filter. This method enables you to add common terms to multiple filters without having to modify all filter definitions. You can configure one filter with the desired common terms, and configure this filter as a term in other filters. Consequently, to make a change in these common terms, you need to modify only one filter that contains the common terms, instead of multiple filters.

Match Conditions

A firewall filter term must contain at least one packet-filtering criteria, called a *match condition*, to specify the field or value that a packet must contain in order to be considered a match for the firewall filter term. For a match to occur, the packet must match all the conditions in the term. If a packet matches a firewall filter term, the router (or switch) takes the configured action on the packet.

If a firewall filter term contains multiple match conditions, a packet must meet *all* match conditions to be considered a match for the firewall filter term.

If a single match condition is configured with multiple values, such as a range of values, a packet must match only *one* of the values to be considered a match for the firewall filter term.

The scope of match conditions you can specify in a firewall filter term depends on the protocol family under which the firewall filter is configured. You can define various match conditions, including the IP source address field, IP destination address field, TCP or UDP source port field, IP protocol field, Internet Control Message Protocol (ICMP) packet type, IP options, TCP flags, incoming logical or physical interface, and outgoing logical or physical interface. These are pre-defined, or fixed, match conditions.

On MX Series 3D Universal Edge Routers with MPCs or MICs, it is possible to build flexible match conditions for IPv4, IPv6, Layer 2 bridge, CCC, and VPLS protocol families. These flexible match conditions allow a user to specify start location, byte offset, match length, and other parameters within the packet.

Each protocol family supports a different set of match conditions, and some match conditions are supported only on certain routing devices. For example, a number of match conditions for VPLS traffic are supported only on the MX Series 3D Universal Edge Routers.

In the **from** statement in a firewall filter term, you specify characteristics that the packet must have for the action in the subsequent **then** statement to be performed. The characteristics are referred to as *match conditions*. The packet must match all conditions in the **from** statement for the action to be performed, which also means that the order of the conditions in the **from** statement is not important.

If an individual match condition can specify a list of values (such as multiple source and destination addresses) or a range of numeric values, a match occurs if any of the values matches the packet.

If a filter term does not specify match conditions, the term accepts all packets and the actions specified in the term's **then** statement are optional.

NOTE:

Some of the numeric range and bit-field match conditions allow you to specify a text synonym. For a complete list of synonyms:

- If you are using the J-Web interface, select the synonym from the appropriate list.
- If you are using the CLI, type a question mark (?) after the **from** statement.

Actions

The actions specified in a firewall filter term define the actions to take for any packet that matches the conditions specified in the term.

Actions that are configured within a single term are all taken on traffic that matches the conditions configured.

BEST PRACTICE: We strongly recommend that you explicitly configure one or more actions per firewall filter term. Any packet that matches all the conditions of the term is automatically accepted unless the term specifies other or additional actions.

Firewall filter actions fall into the following categories:

Filter-Terminating Actions

A filter-terminating action halts all evaluation of a firewall filter for a specific packet. The router (or switch) performs the specified action, and no additional terms are examined.

Nonterminating Actions

Nonterminating actions are used to perform other functions on a packet, such as incrementing a counter, logging information about the packet header, sampling the packet data, or sending information to a remote host using the system log functionality.

The presence of a nonterminating action, such as **count**, **log**, or **syslog**, without an explicit terminating action, such as **accept**, **discard**, or **reject**, results in a default terminating action of **accept**. If you do not want the firewall filter action to terminate, use the **next term** action after the nonterminating action.

NOTE: On Junos OS Evolved, **next term** cannot appear as the last term of the action. A filter term where **next term** is specified as an action but without any match conditions configured is not supported.

In this example, term 2 is never evaluated, because term 1 has the implicit default **accept** terminating action.

```
[edit firewall filter test]
term 1 {
  from {
    source-address {
      0.0.0.0/0;
    }
  }
  then {
    log;
    <accept> #By default if not specified
  }
}
term 2 {
  then {
```

```

    reject;
  }
}

```

In this example, term 2 is evaluated, because term 1 has the explicit **next term** flow control action.

```

[edit firewall filter test]
term 1 {
  from {
    source-address {
      0.0.0.0/0;
    }
  }
  then {
    log;
    next term;
  }
}
term 2 {
  then {
    reject;
  }
}

```

Flow Control Action

For standard stateless firewall filters only, the action **next term** enables the router (or switch) to perform configured actions on the packet and then evaluate the following term in the filter, rather than terminating the filter.

A maximum of 1024 **next term** actions are supported per standard stateless firewall filter configuration. If you configure a standard filter that exceeds this limit, your candidate configuration results in a commit error.

Stateless Firewall Filter Types

[Firewall Filter Flexible Match Conditions | 777](#)

Inserting a New Identifier in a Junos OS Configuration in the CLI User Guide

Stateless Firewall Filter Application Points

After you define the firewall filter, you must apply it to an application point. These application points include logical interfaces, physical interfaces, routing interfaces, and routing instances.

In most cases, you can apply a firewall filter as an *input* filter or an *output* filter, or both at the same time. Input filters take action on packets being received on the specified interface, whereas output filters take action on packets that are transmitted through the specified interface.

You typically apply one filter with multiple terms to a single logical interface, to incoming traffic, outbound traffic, or both. However, there are times when you might want to chain together multiple firewall filters (with single or multiple terms) and apply them to an interface. You use an *input list* to apply multiple firewall filters to the incoming traffic on an interface. You use an *output list* to apply multiple firewall filters to the outbound traffic on an interface. You can include up to 16 filters in an input list or an output list.

There is no limit to the number of filters and counters you can set, but there are some practical considerations. More counters require more terms, and a large number of terms can take a long time to process during a commit operation. However, filters with more than 4000 terms and counters have been implemented successfully.

[Table 28 on page 706](#) describes each point to which you can apply a firewall filter. For each application point, the table describes the types of firewall filters supported at that point, the router (or switch) hierarchy level at which the filter can be applied, and any platform-specific limitations.

This topic covers the following information:

Firewall Filter Packet Evaluation Overview

The following sequence describes how the device evaluates a packet entering or exiting an interface if the input or output traffic at a device interface is associated with a firewall filter. Packet evaluation proceeds as follows:

1. The device evaluates the packet against the terms in the firewall filter sequentially, beginning with the first term in the filter.
 - If the packet matches all the conditions specified in a term, the device performs all the actions specified in that term.
 - If the packet does not match all the conditions specified in a term, the device proceeds to the next term in the filter (if a subsequent term exists) and evaluates the packet against that term.
 - If the packet does not match any term in the firewall filter, the device implicitly discards the packet.
2. Unlike service filters and simple filters, firewall filters support the **next term** action, which is neither a terminating action nor a nonterminating action but a flow control action.

NOTE: On Junos OS Evolved, **next term** cannot appear as the last term of the action. A filter term where **next term** is specified as an action but without any match conditions configured is not supported.

- If the matched term includes the **next term** action, the device continues evaluation of the packet at the next term within the firewall filter.
- If the matched term does not include the **next term** action, evaluation of the packet against the given firewall filter ends at this term. The device does not evaluate the packet against any subsequent terms in this filter.

A maximum of 1024 **next term** actions are supported per firewall filter configuration. If you configure a firewall filter that exceeds this limit, your candidate configuration results in a commit error.

3. The device stops evaluating a packet against a given firewall filter when either the packet matches a term without the **next term** action or the packet fails to match the last term in the firewall filter.
4. If a local packet arrives at a router interface that is associated with an ingress firewall filter, the filter evaluates the packet twice. The first evaluation occurs in the Packet Forwarding Engine, which is the central processing element of the router's forwarding plane, and the second evaluation occurs in the Routing Engine, which runs the router's control plane software.

NOTE: Local packets--chunks of data that are destined for or sent by the router itself--usually contain routing protocol data, data for IP services such as Telnet or SSH, and data for administrative protocols such as the Internet Control Message Protocol (ICMP).

If the first evaluation of the firewall filter modifies the incoming local packet or packet context values, the second evaluation of the firewall filter is based on the updated packet or packet context values.

For example, suppose that the filter includes a match condition based on the forwarding class or loss priority value associated with the packet and that the filter includes an action that modifies the forwarding class or loss priority value associated with the packet. If an ingress local packet arrives at an associated interface and the filter evaluation in the Packet Forwarding Engine modifies (rather than drops) the packet, then the filter evaluation in the Routing Engine is based on the modified packet context (rather than the original packet context).

Packet Evaluation at a Single Firewall Filter

Table 32 on page 730 describes packet-filtering behaviors at a device interface associated with a single firewall filter.

NOTE: On Junos OS Evolved, **next term** cannot appear as the last term of the action. A filter term where **next term** is specified as an action but without any match conditions configured is not supported.

Table 32: Packet Evaluation at a Single Firewall Filter

Firewall Filter Event	Action	Subsequent Action
The firewall filter term does not specify any match conditions.	The term matches all packets by default, and so the device performs the actions specified by that term.	If the term actions include the next term action, the device continues evaluation of the packet against the next term within the firewall filter (if a subsequent term exists).
The packet matches all conditions specified by the firewall filter term.	The device performs the actions specified by that term.	If the term actions include the next term action, the device continues evaluation of the packet against the next term within the

Table 32: Packet Evaluation at a Single Firewall Filter (*continued*)

Firewall Filter Event	Action	Subsequent Action
		firewall filter (if a subsequent term exists).
The packet matches all conditions specified by the firewall filter term, but the term does not specify any actions.	The device implicitly accepts the packet.	If the term actions include the next term action, the device continues evaluation of the packet against the next term within the firewall filter (if a subsequent term exists).
The packet does not match all conditions specified by the firewall filter term.	The device does not perform the actions specified by that term.	The device continues evaluation of the packet against the next term within the filter (if a subsequent term exists).
The packet does not match any term in the filter	<p>The device implicitly discards the packet</p> <p>Every firewall filter configuration includes an implicit discard action at the end of the filter. This implicit terminating action is equivalent to including the following example term t_explicit_discard as the final term in the firewall filter:</p> <pre>term t_explicit_discard { then discard; }</pre>	

Best Practice: Explicitly Accept Any Traffic That Is Not Specifically Discarded

You might want a firewall filter to accept any traffic that the filter does not specifically discard. In this case, we recommend that you configure the firewall filter with a final term that specifies the **accept** terminating action.

In the following example snippet, configuring the **t_allow_all_else** term as the final term in the firewall filter explicitly configures the firewall filter to accept any traffic that the filter did not specifically discard :

```
term t_allow_all_else {
    then accept;
}
```

Following this best practice can simplify troubleshooting of the firewall filter.

Best Practice: Explicitly Reject Any Traffic That Is Not Specifically Accepted

On the other hand, you might want a firewall filter to reject any traffic that the firewall filter does not specifically accept. In this case, we recommend that you configure the firewall filter with a final term that specifies the **reject** terminating action.

In the following example snippet, configuring the **t_deny_all_else** term as the final term in the firewall filter explicitly configures the firewall filter to reject any traffic that the filter did not specifically accept:

```
term t_deny_all_else {  
    then reject;  
}
```

Following this best practice can simplify troubleshooting of the firewall filter.

Multiple Firewall Filters Attached to a Single Interface

On supported device interfaces, you can attach multiple firewall filters to a single interface. For more information, see [“Understanding Multiple Firewall Filters Applied as a List” on page 1149](#).

NOTE: On supported interfaces, you can attach a protocol-independent (**family any**) firewall filter and a protocol-specific (**family inet** or **family inet6**) firewall filter to the same interface. The protocol-independent firewall filter executes first. For more information, see [“Guidelines for Applying Standard Firewall Filters” on page 743](#).

Single Firewall Filter Attached to Multiple Interfaces

On supported interfaces, you can associate a single firewall filter with multiple interfaces, and Junos OS creates an *interface-specific instance* of that firewall filter for each associated interface.

- Junos OS associates each interface-specific instantiation of a firewall filter with a system-generated, interface-specific name.
- For any **count** actions in the filter terms, the Packet Forwarding Engine maintains separate, interface-specific counters, and Junos OS associates each counter with a system-generated, interface-specific name.
- For any **policer** actions in the filter terms, Junos OS creates separate, interface-specific instances of the policer actions.

For more information, see [“Interface-Specific Firewall Filter Instances Overview” on page 1179](#).

Understanding Firewall Filter Fast Lookup Filter

In order to enhance the speed at which specific firewall filters are processed, you can use the filter block hardware available on certain modular port concentrators (MPCs). See the [MX Series Interface Module Reference manual](#) for details. This hardware allows for an increase in the number of firewall filter operations per second that can be accomplished.

Using the **fast-lookup-filter** option in environments with hundreds or thousands of terms per filter can increase performance of those filters by utilizing the filter block hardware.

There are 4096 hardware filters available per MPC. The number of firewall filters that can be installed in hardware depends on the number of terms in each filter. One hardware filter is needed for every group of 255 terms in a firewall filter. The total number of terms supported per firewall filter is 8000. However, attaching a given firewall filter with less than 256 terms to multiple interfaces will only result in one instance of that firewall filter being installed in the filter block. This is true for interface-specific filters as well as for filter lists.

You designate specific firewall filters to be processed in the filter block hardware by including the **fast-lookup-filter** option when configuring the firewall.

When this option is used, firewall parameters are stored in the filter block hardware which accelerates the lookup process. **fast-lookup-filter** is only available for the inet and inet6 protocol families. The match conditions are limited to 5-tuples: **protocol**, **source-address**, **destination-address**, **source-port**, and **destination-port**.

Ranges, prefix lists, and the except keyword are supported within the firewall filters and terms when using this option.

NOTE: Firewall filters that are configured using the **fast-lookup-filter** option are not optimized by the firewall compiler.

Understanding Egress Firewall Filters with PVLANs

If you apply firewall filters to private VLANs in the output direction, the behavior of the filters might be unexpected. This topic explains how egress filters behave when applied to private VLANs.

If you apply a firewall filter in the output direction to a primary VLAN, the filter also applies to the secondary VLANs that are members of the primary VLAN when the traffic egresses with the primary VLAN tag or isolated VLAN tag, as listed below:

- Traffic forwarded from a secondary VLAN trunk port to a promiscuous port (trunk or access)
- Traffic forwarded from a secondary VLAN trunk port to a PVLAN trunk port.
- Traffic forwarded from a promiscuous port (trunk or access) to a secondary VLAN trunk port
- Traffic forwarded from a PVLAN trunk port. to a secondary VLAN trunk port
- Traffic forwarded from a community port to a promiscuous port (trunk or access)

If you apply a firewall filter in the output direction to a primary VLAN, the filter does *not* apply to traffic that egresses with a community VLAN tag, as listed below:

- Traffic forwarded from a community trunk port to a PVLAN trunk port
- Traffic forwarded from a promiscuous port (trunk or access) to a community trunk port
- Traffic forwarded from a PVLAN trunk port. to a community trunk port

If you apply a firewall filter in the output direction to a community VLAN, the following behaviors apply:

- The filter is applied to traffic forwarded from a promiscuous port (trunk or access) to a community trunk port (because the traffic egresses with the community VLAN tag).
- The filter is applied to traffic forwarded from a community port to a PVLAN trunk port (because the traffic egresses with the community VLAN tag).
- The filter is *not* applied to traffic forwarded from a community port to a promiscuous port (because the traffic egresses with the primary VLAN tag or untagged).

Multifield Classifier for Ingress Queuing on MX Series Routers with MPC

Beginning with Junos OS Release 16.1, the multifield classifier for ingress queuing is an implementation point for firewall filters configured with specific traffic shaping actions. These filters allow you to set the forwarding class and packet loss priority for packets, or drop the packets prior to ingress queue selection. The filters are applied as ingress queue filters. Class-of-service (CoS) commands can then be used to select ingress queue, set rate limiting and so forth.

Firewall filters configured at the protocol family level are able to distinguish specific types of traffic from other types by matching on multiple fields within the packet header. The number and types of matches available depend on which protocol family is used in the filter. Before the introduction of the ingress queuing filter, these firewall filters could only be applied to traffic after the ingress queue had been selected based solely on the behavior aggregate (BA). With the introduction of the ingress queuing filter, firewall filters can be used to set forwarding classification and packet loss priority based on multiple fields within the packet header prior to forwarding queue selection. CoS functions provide traffic classification options and the ability to assign that classified traffic to specific forwarding queues.

NOTE: Ingress queuing filters are only available when the traffic manager mode is set to **ingress-and-egress** at the **[edit chassis fpc *fpc-id* pic *pic-id* traffic-manager mode]** hierarchy level.

The **ingress-queuing-filter** configuration statement is used at the **[edit interfaces *interface-name* unit *unit-number* family *family-name*]** hierarchy level to designate a previously configured firewall filter to be used as an ingress queuing filter. The following list shows which protocol families are compatible with the **ingress-queuing-filter** statement:

- **bridge**
- **ccc**
- **inet**
- **inet6**
- **mpls**
- **vpls**

The named firewall filter is a normal firewall filter that must be configured with at least one of the following actions: **accept**, **discard**, **forwarding-class**, and **loss-priority**.

This topic covers the following information:

Statement Hierarchy for Configuring Firewall Filters

To configure a standard firewall filter, you can include the following statements. For an IPv4 standard firewall filter, the **family inet** statement is optional. For an IPv6 standard firewall filter, the **family inet6** statement is mandatory.

```

firewall {
  family family-name {
    filter filter-name {
      accounting-profile name;
      instance-shared;
      interface-specific;
      physical-interface-filter;
      term term-name {
        filter filter-name;
      }
      term term-name {
        from {
          match-conditions;
          ip-version ip-version {
            match-conditions;
            protocol (tcp | udp) {
              match conditions;
            }
          }
        }
        then {
          actions;
        }
      }
    }
  }
}

```

You can include the firewall configuration at one of the following hierarchy levels:

- [edit]
- [edit logical-systems *logical-system-name*]

NOTE: For stateless firewall filtering, you must allow the output tunnel traffic through the firewall filter applied to input traffic on the interface that is the next-hop interface toward the tunnel destination. The firewall filter affects only the packets exiting the router (or switch) by way of the tunnel.

Firewall Filter Protocol Families

A firewall filter configuration is specific to a particular protocol family. Under the **firewall** statement, include one of the following statements to specify the protocol family for which you want to filter traffic:

- **family any**—To filter protocol-independent traffic.
- **family inet**—To filter Internet Protocol version 4 (IPv4) traffic.
- **family inet6**—To filter Internet Protocol version 6 (IPv6) traffic.
- **family mpls**—To filter MPLS traffic.
- **family vpls**—To filter virtual private LAN service (VPLS) traffic.
- **family ccc**—To filter Layer 2 circuit cross-connection (CCC) traffic.
- **family bridge**—To filter Layer 2 bridging traffic for MX Series 3D Universal Edge Routers only.
- **family ethernet-switching**—To filter Layer 2 (Ethernet) traffic.

The **family family-name** statement is required only to specify a protocol family other than IPv4. To configure an IPv4 firewall filter, you can configure the filter at the **[edit firewall]** hierarchy level without including the **family inet** statement, because the **[edit firewall]** and **[edit firewall family inet]** hierarchy levels are equivalent.

NOTE: For bridge family filter, the *ip-protocol* match criteria is supported only for IPv4 and not for IPv6. This is applicable for line cards that support the Junos Trio chipset such as the MX 3D MPC line cards.

Firewall Filter Names and Options

Under the **family family-name** statement, you can include **filter filter-name** statements to create and name firewall filters. The filter name can contain letters, numbers, and hyphens (-) and be up to 64 characters long. To include spaces in the name, enclose the entire name in quotation marks (" ").

At the `[edit firewall family family-name filter filter-name]` hierarchy level, the following statements are optional:

- `accounting-profile`
- `instance-shared` (MX Series routers with Modular Port Concentrators (MPCS) only)
- `interface-specific`
- `physical-interface-filter`

Firewall Filter Terms

Under the `filter filter-name` statement, you can include `term term-name` statements to create and name filter terms.

- You must configure at least one term in a firewall filter.
- You must specify a unique name for each term within a firewall filter. The term name can contain letters, numbers, and hyphens (-) and can be up to 64 characters long. To include spaces in the name, enclose the entire name in quotation marks (" ").
- The order in which you specify terms within a firewall filter configuration is important. Firewall filter terms are evaluated in the order in which they are configured. By default, new terms are always added to the end of the existing filter. You can use the `insert` configuration mode command to reorder the terms of a firewall filter.

At the `[edit firewall family family-name filter filter-name term term-name]` hierarchy level, the `filter filter-name` statement is not valid in the same term as `from` or `then` statements. When included at this hierarchy level, the `filter filter-name` statement is used to *nest* firewall filters.

Firewall Filter Match Conditions

Firewall filter match conditions are specific to the type of traffic being filtered.

With the exception of MPLS-tagged IPv4 or IPv6 traffic, you specify the term's match conditions under the `from` statement. For MPLS-tagged IPv4 traffic, you specify the term's IPv4 address-specific match conditions under the `ip-version ipv4` statement and the term's IPv4 port-specific match conditions under the `protocol (tcp | udp)` statement.

For MPLS-tagged IPv6 traffic, you specify the term's IPv6 address-specific match conditions under the `ip-version ipv6` statement and the term's IPv6 port-specific match conditions under the `protocol (tcp | udp)` statement.

[Table 33 on page 740](#) describes the types of traffic for which you can configure firewall filters.

Table 33: Firewall Filter Match Conditions by Protocol Family

Traffic Type	Hierarchy Level at Which Match Conditions Are Specified
Protocol-independent	<p>[edit firewall family any filter <i>filter-name</i> term <i>term-name</i>]</p> <p>For the complete list of match conditions, see “Firewall Filter Match Conditions for Protocol-Independent Traffic” on page 833.</p>
IPv4	<p>[edit firewall family inet filter <i>filter-name</i> term <i>term-name</i>]</p> <p>For the complete list of match conditions, see “Firewall Filter Match Conditions for IPv4 Traffic” on page 835.</p>
IPv6	<p>[edit firewall family inet6 filter <i>filter-name</i> term <i>term-name</i>]</p> <p>For the complete list of match conditions, see “Firewall Filter Match Conditions for IPv6 Traffic” on page 851.</p>
MPLS	<p>[edit firewall family mpls filter <i>filter-name</i> term <i>term-name</i>]</p> <p>For the complete list of match conditions, see “Firewall Filter Match Conditions for MPLS Traffic” on page 888.</p>
IPv4 addresses in MPLS flows	<p>[edit firewall family mpls filter <i>filter-name</i> term <i>term-name</i> ip-version ipv4]</p> <p>For the complete list of match conditions, see “Firewall Filter Match Conditions for MPLS-Tagged IPv4 or IPv6 Traffic” on page 892.</p>
IPv4 ports in MPLS flows	<p>[edit firewall family mpls filter <i>filter-name</i> term <i>term-name</i> ip-version ipv4 protocol (tcp udp)]</p> <p>For the complete list of match conditions, see “Firewall Filter Match Conditions for MPLS-Tagged IPv4 or IPv6 Traffic” on page 892.</p>
IPv6 addresses in MPLS flows	<p>[edit firewall family mpls filter <i>filter-name</i> term <i>term-name</i> ip-version ipv6]</p> <p>For the complete list of match conditions, see “Firewall Filter Match Conditions for MPLS-Tagged IPv4 or IPv6 Traffic” on page 892.</p>
IPv6 ports in MPLS flows	<p>[edit firewall family mpls filter <i>filter-name</i> term <i>term-name</i> ip-version ipv6 protocol (tcp udp)]</p> <p>For the complete list of match conditions, see “Firewall Filter Match Conditions for MPLS-Tagged IPv4 or IPv6 Traffic” on page 892.</p>

Table 33: Firewall Filter Match Conditions by Protocol Family (*continued*)

Traffic Type	Hierarchy Level at Which Match Conditions Are Specified
VPLS	<p><code>[edit firewall family vpls filter <i>filter-name</i> term <i>term-name</i>]</code></p> <p>For the complete list of match conditions, see “Firewall Filter Match Conditions for VPLS Traffic” on page 895.</p>
Layer 2 CCC	<p><code>[edit firewall family ccc filter <i>filter-name</i> term <i>term-name</i>]</code></p> <p>For the complete list of match conditions, see “Firewall Filter Match Conditions for Layer 2 CCC Traffic” on page 909.</p>
Layer 2 Bridging (MX Series routers and EX Series switches only)	<p><code>[edit firewall family bridge filter <i>filter-name</i> term <i>term-name</i>]</code></p> <p><code>[edit firewall family ethernet-switching filter <i>filter-name</i> term <i>term-name</i>]</code> (for EX Series switches only)</p> <p>For the complete list of match conditions, see “Firewall Filter Match Conditions for Layer 2 Bridging Traffic” on page 914.</p>

If you specify an IPv6 address in a match condition (the **address**, **destination-address**, or **source-address** match conditions), use the syntax for text representations described in RFC 4291, *IP Version 6 Addressing Architecture*. For more information about IPv6 addresses, see *IPv6 Overview* and *Supported IPv6 Standards*.

Firewall Filter Actions

Under the **then** statement for a firewall filter term, you can specify the actions to be taken on a packet that matches the term.

[Table 34 on page 742](#) summarizes the types of actions you can specify in a firewall filter term.

Table 34: Firewall Filter Action Categories

Type of Action	Description	Comment
Terminating	<p>Halts all evaluation of a firewall filter for a specific packet. The router (or switch) performs the specified action, and no additional terms are used to examine the packet.</p> <p>You can specify only one <i>terminating action</i> in a firewall filter term. You can, however, specify one terminating action with one or more <i>nonterminating actions</i> in a single term. For example, within a term, you can specify accept with count and syslog. Regardless of the number of terms that contain terminating actions, once the system processes a terminating action within a term, processing of the entire firewall filter halts.</p>	See “Firewall Filter Terminating Actions” on page 794 .
Nonterminating	Performs other functions on a packet (such as incrementing a counter, logging information about the packet header, sampling the packet data, or sending information to a remote host using the system log functionality), but any additional terms are used to examine the packet.	<p>All nonterminating actions include an implicit accept action. This accept action is carried out if no other terminating action is configured in the same term.</p> <p>See “Firewall Filter Nonterminating Actions” on page 785.</p>
Flow control	<p>For standard firewall filters only, the next term action directs the router (or switch) to perform configured actions on the packet and then, rather than terminate the filter, use the next term in the filter to evaluate the packet. If the next term action is included, the matching packet is evaluated against the next term in the firewall filter. Otherwise, the matching packet is not evaluated against subsequent terms in the firewall filter.</p> <p>For example, when you configure a term with the nonterminating action count, the term's action changes from an implicit discard to an implicit accept. The next term action forces the continued evaluation of the firewall filter.</p>	<p>You cannot configure the next term action with a terminating action in the same filter term. However, you can configure the next term action with another nonterminating action in the same filter term.</p> <p>A maximum of 1024 next term actions are supported per standard firewall filter configuration. If you configure a standard firewall filter that exceeds this limit, your candidate configuration results in a commit error.</p> <p>NOTE: On Junos OS Evolved, next term cannot appear as the last term of the action. A filter term where next term is specified as an action but without any match conditions configured is not supported.</p>

- [Statement Hierarchy for Applying Firewall Filters | 744](#)
- [Restrictions on Applying Firewall Filters | 746](#)

Applying Firewall Filters Overview

You can apply a standard firewall filter to a loopback interface on the router or to a physical or logical interface on the router. You can apply a firewall filter to a single interface or to multiple interfaces on the router. [Table 35 on page 743](#) summarizes the behavior of firewall filters based on the point to which you attach the filter.

Table 35: Firewall Filter Behavior by Filter Attachment Point

Filter Attachment Point	Filter Behavior
Loopback interface	<p>The router's loopback interface, lo0, is the interface to the Routing Engine and carries no data packets. When you apply a firewall filter to the loopback interface, the filter evaluates the local packets received or transmitted by the Routing Engine.</p> <p>NOTE:</p> <ul style="list-style-type: none">● ACX5048 and ACX5096 routers do not support the evaluation of packets transmitted by the Routing engine for loopback interface filter.
Physical interface or logical interface	<p>When you apply a filter to a physical interface on the router or to a logical interface (or member of an aggregated Ethernet bundle defined on the interface), the filter evaluates all data packet that pass through that interface.</p>

Table 35: Firewall Filter Behavior by Filter Attachment Point (*continued*)

Filter Attachment Point	Filter Behavior
Multiple interfaces	<p>You can use the same firewall filter one or more times.</p> <p>On M Series routers, except the M120 and M320 routers, if you apply a firewall filter to multiple interfaces, the filter acts on the sum of traffic entering or exiting those interfaces.</p> <p>On T Series, M120, M320, and MX Series routers, interfaces are distributed among multiple packet-forwarding components. On these routers, you can configure firewall filters and service filters that, when applied to multiple interfaces, act on the individual traffic streams entering or exiting each interface, regardless of the sum of traffic on the multiple interfaces.</p> <p>For more information, see “Interface-Specific Firewall Filter Instances Overview” on page 1179.</p>
Single interface with protocol-independent and protocol-specific firewall filters attached	<p>For interfaces hosted on the following hardware only, you can attach a protocol-independent (family any) firewall filter and a protocol-specific (family inet or family inet6) firewall filter simultaneously. The protocol-independent firewall executes first.</p> <ul style="list-style-type: none"> • ACX Series Universal Metro Routers • Flexible PIC Concentrators (FPCs) in M7i and M10i Multiservice Edge Routers • Modular Interface Cards (MICs) and Modular Port Concentrators (MPCs) in MX Series 5G Universal Routing Platforms • T Series Core Routers <p>NOTE:</p> <p>Interfaces hosted on the following hardware do not support protocol-independent firewall filters:</p> <ul style="list-style-type: none"> • Forwarding Engine Boards (FEBs) in M120 routers • Enhanced III FPCs in M320 routers • FPC2 and FPC3 modules in MX Series routers • Dense Port Concentrators (DPCs) in MX Series routers • PTX Series Packet Transport Routers

Statement Hierarchy for Applying Firewall Filters

To apply a standard firewall filter to a logical interface, configure the **filter** statement for the logical interface defined under either the **[edit]** or **[edit logical-systems logical-system-name]** hierarchy level. Under the **filter** statement, you can include one or more of the following statements: **group group-number**, **input filter-name**, **input-list filter-name**, **output filter-name**, or **output-list filter-name**. The hierarchy level at which you attach the **filter** statement depends on the filter type and device type you are configuring.

Protocol-Independent Firewall Filters on MX Series Routers

To apply a protocol-independent firewall filter to a logical interface on an MX Series router, configure the **filter** statement *directly* under the logical unit:

```

interfaces {
  interface-name {
    unit logical-unit-number {
      filter {
        group group-number;
        input filter-name;
        input-list [ filter-names ];
        output filter-name;
        output-list [ filter-names ];
      }
    }
  }
}

```

All Other Firewall Filters on Logical Interfaces

To apply a standard firewall filter to a logical interface for all cases *other than* a protocol-independent filter on an MX Series router, configure the **filter** statement under the protocol family:

```

interfaces {
  interface-name {
    unit logical-unit-number {
      family family-name {
        ...
        filter {
          group group-number;
          input filter-name;
          input-list [ filter-names ];
          output filter-name;
          output-list [ filter-names ];
        }
      }
    }
  }
}

```

Restrictions on Applying Firewall Filters

IN THIS SECTION

- [Number of Input and Output Filters Per Logical Interface | 746](#)
- [MPLS and Layer 2 CCC Firewall Filters in Lists | 746](#)
- [Layer 2 CCC Firewall Filters on MX Series Routers and EX Series Switches | 746](#)
- [IPv6 Firewall Filters on PTX Series Packet Transport Routers | 747](#)

Number of Input and Output Filters Per Logical Interface

Input filters—Although you can use the same filter multiple times, you can apply only one input filter or one input filter list to an interface.

- To specify a single firewall filter to be used to evaluate packets received on the interface, include the **input *filter-name*** statement in the **filter** stanza.
- To specify an ordered list of firewall filters to be used to evaluate packets received on the interface, include the **input-list [*filter-names*]** statement in the **filter** stanza. You can specify up to 16 firewall filters for the filter input list.

Output filters—Although you can use the same filter multiple times, you can apply only one output filter or one output filter list to an interface.

- To specify a single firewall filter to be used to evaluate packets transmitted on the interface, include the **output *filter-name*** statement in the **filter** stanza.
- To specify an ordered list of firewall filters to be used to evaluate packets transmitted on the interface, include the **output-list [*filter-names*]** statement in the **filter** stanza. You can specify up to 16 firewall filters in a filter output list.

MPLS and Layer 2 CCC Firewall Filters in Lists

The **input-list *filter-names*** and **output-list *filter-names*** statements for firewall filters for the **ccc** and **mpls** protocol families are supported on all interfaces with the exception of the following:

- Management interfaces and internal Ethernet interfaces (**fxp** or **em0**)
- Loopback interfaces (**lo0**)
- USB modem interfaces (**umd**)

Layer 2 CCC Firewall Filters on MX Series Routers and EX Series Switches

Only on MX Series routers and EX Series switches, you cannot apply a Layer 2 CCC stateless firewall filter (a firewall filter configured at the **[edit firewall filter family ccc]** hierarchy level) as an output filter. On

MX Series routers and EX Series switches, firewall filters configured for the **family ccc** statement can be applied only as input filters.

IPv6 Firewall Filters on PTX Series Packet Transport Routers

On PTX10001-20C routers, you cannot apply IPv6 firewall filters to:

- Tunnel interfaces
- IRB interfaces
- Egress interfaces
- Interface-specific filters, configured at the **[edit firewall family inet6 filter filter-name]** hierarchy level.
- Traffic policers
- Junos Telemetry Interface

Supported Standards for Filtering

The Junos OS supports the following RFCs related to filtering:

- RFC 792, *Internet Control Message Protocol*
- RFC 2460, *Internet Protocol, Version 6 (IPv6)*
- RFC 2474, *Definition of the Differentiated Services (DS) Field*
- RFC 2475, *An Architecture for Differentiated Services*
- RFC 2597, *Assured Forwarding PHB Group*
- RFC 3246, *An Expedited Forwarding PHB (Per-Hop Behavior)*
- RFC 4291, *IP Version 6 Addressing Architecture*
- RFC 4443, *Internet Control Message Protocol (ICMPv6) for the Internet Protocol Version 6 (IPv6) Specification*

NOTE: ACX Series routers do not support RFC 2460, RFC 4291, and RFC 4443 standards.

Verifying That Firewall Filters Are Operational

Purpose

Verify that firewall filters are working properly.

Action

Use the **show firewall** operational mode command to verify that the firewall filters are working properly:

user@switch> **show firewall**

```
Filter: egress-vlan-watch-employee
Counters:
Name                               Bytes      Packets
counter-employee-web                0           0
Filter: ingress-port-limit-tcp-icmp
Counters:
Name                               Bytes      Packets
icmp-counter                        560         10
Policers:
Name                               Packets
icmp-connection-policer             10
tcp-connection-policer              0
Filter: ingress-vlan-rogue-block
Filter: ingress-vlan-limit-guest
```

Meaning

The **show firewall** command displays the names of all firewall filters, counters, and policers that are configured. For each counter that is specified in a filter configuration, the output field shows the byte count and packet count for the term in which the counter is specified. In the above example, the **icmp-counter** in the filter **ingress-port-limit-tcp-icmp** shows that the filter matched 10 packets. For each policer that is specified in a filter configuration, the output field shows the packet count for packets that exceed the specified rate limits. The policer **icmp-connection-policer** shows that 10 ICMP packets were policed.

Monitoring Firewall Filter Traffic

You can use operational mode commands to monitor firewall filter traffic.

- [Monitoring Traffic for All Firewall Filters and Policers That Are Configured | 749](#)
- [Monitoring Traffic for a Specific Firewall Filter | 750](#)
- [Monitoring Traffic for a Specific Policer | 750](#)

Monitoring Traffic for All Firewall Filters and Policers That Are Configured

Purpose

Monitor the number of packets and bytes that matched the firewall filters and monitor the number of packets that exceeded policer rate limits:

Action

Use the **show firewall** operational mode command:

```
user@switch> show firewall
```

```
Filter: egress-vlan-watch-employee
Counters:
Name                               Bytes          Packets
counter-employee-web              3348            27
Filter: ingress-port-limit-tcp-icmp
```

```

Counters:
Name                               Bytes          Packets
icmp-counter                       560            10
Policers:
Name                               Packets
icmp-connection-policer           10
tcp-connection-policer            0
Filter: ingress-vlan-rogue-block
Filter: ingress-vlan-limit-guest

```

Meaning

The **show firewall** command displays the names of all firewall filters, counters, and policers that are configured. For each counter that is specified in a filter configuration, the output field shows the byte count and packet count for the term in which the counter is specified. For each policer that is specified in a filter configuration, the output field shows the packet count for packets that exceed the specified rate limits.

Monitoring Traffic for a Specific Firewall Filter

Purpose

Monitor the number of packets and bytes that matched a firewall filter and monitor the number of packets that exceeded policer rate limits.

Action

Use the **show firewall filter *filter-name*** operational mode command:

```
user@switch> show firewall filter ingress-port-limit-tcp-icmp
```

```

Filter: ingress-port-limit-tcp-icmp
Counters:
Name                               Bytes          Packets
icmp-counter                       560            10

```

Meaning

The **show firewall filter *filter-name*** command limits the display information to the counters and policers that are defined for the specified filter.

Monitoring Traffic for a Specific Policer

Purpose

Monitor the number of packets that exceeded the rate limits of a policer:

Action

Use the **show firewall policer *policer-name*** operational mode command:

```
user@switch> show firewall policer icmp-connection-policer
```

```
Filter: ingress-port-limit-tcp-icmp
Policers:
Name                               Packets
icmp-connection-policer           10
```

Meaning

The **show firewall policer *policer-name*** command displays the number of packets that exceeded the rate limits for the specified policer.

- [Do Not Combine Match Conditions for Different Layers | 752](#)
- [Layer 2 Packets Cannot be Discarded with Firewall Filters | 752](#)
- [Protect-RE \(loopback\) Firewall Filter Does Not Filter Packets Applied to EM0 Interfaces | 752](#)

This section describes issues specific to QFX10000 switches:

Do Not Combine Match Conditions for Different Layers

On QFX10000 switches, do not combine match conditions for Layer 2 and any other layer in a **family ethernet-switching** filter. (For example, do not include conditions that match MAC addresses and IP addresses in the same filter.) If you do so, the filter will commit successfully but will not work. You will also see the following log message: **L2 filter *filter-name* doesn't support mixed L2 and L3/L4 match conditions. Please re-config.**

Layer 2 Packets Cannot be Discarded with Firewall Filters

Problem

Description: Layer 2 (L2) control packets such as Link Layer Discovery Protocol (LLDP) and bridge protocol data unit (BPDU) cannot be discarded with firewall filters.

Solution

Configure distributed denial-of-service (DDoS) protection on the L2 control packet and set the aggregate policer bandwidth and burst values to the minimum value of 1. For example,

```
[edit system ddos-protection protocols protocol name]
```

```
user@host# set aggregate bandwidth 1
```

```
[edit system ddos-protection protocols protocol name]
```

```
user@host# set aggregate burst 1
```

Protect-RE (loopback) Firewall Filter Does Not Filter Packets Applied to EM0 Interfaces

Problem

Description: On QFX10000 switches, the Protect-RE (loopback) firewall filter does not filter packets applied to EM0 interfaces including SNMP, Telnet, and other services.

Solution

This is expected behavior.

Firewall Filter Configuration Returns a No Space Available in TCAM Message

Problem

Description: When a firewall filter configuration exceeds the amount of available Ternary Content Addressable Memory (TCAM) space, the system returns the following **syslogd** message:

```
No space available in tcam.
Rules for filter filter-name will not be installed.
```

A switch returns this message during the commit operation if the firewall filter that has been applied to a port, VLAN, or Layer 3 interface exceeds the amount of space available in the TCAM table. The filter is not applied, but the commit operation for the firewall filter configuration is completed in the CLI module.

Solution

When a firewall filter configuration exceeds the amount of available TCAM table space, you must configure a new firewall filter with fewer filter terms so that the space requirements for the filter do not exceed the available space in the TCAM table.

You can perform either of the following procedures to correct the problem:

To delete the filter and its binding and apply the new smaller firewall filter to the same binding:

1. Delete the filter and its binding to ports, VLANs, or Layer 3 interfaces. For example:

```
[edit]
user@switch# delete firewall family ethernet-switching filter ingress-vlan-rogue-block
user@switch# delete vlans employee-vlan description "filter to block rogue devices on
employee-vlan"
user@switch# delete vlans employee-vlan filter input ingress-vlan-rogue-block
```

2. Commit the changes:

```
[edit]
user@switch# commit
```

3. Configure a smaller filter with fewer terms that does not exceed the amount of available TCAM space. For example:

```
[edit]
user@switch# set firewall family ethernet-switching filter new-ingress-vlan-rogue-block ...
```

4. Apply (bind) the new firewall filter to a port, VLAN , or Layer 3 interface. For example:

```
[edit]
user@switch# set vlans employee-vlan description "filter to block rogue devices on employee-vlan"
user@switch# set vlans employee-vlan filter input new-ingress-vlan-rogue-block
```

5. Commit the changes:

```
[edit]
user@switch# commit
```

To apply a new firewall filter and overwrite the existing binding but not delete the original filter:

1. Configure a firewall filter with fewer terms than the original filter:

```
[edit]
user@switch# set firewall family ethernet-switching filter new-ingress-vlan-rogue-block...
```

2. Apply the firewall filter to the port, VLAN, or Layer 3 interfaces to overwrite the binding of the original filter—for example:

```
[edit]
user@switch# set vlans employee-vlan description "smaller filter to block rogue devices on
employee-vlan"
user@switch# set vlans employee-vlan filter input new-ingress-vlan-rogue-block
```

Because you can apply no more than one firewall filter per VLAN per direction, the binding of the original firewall filter to the VLAN is overwritten with the new firewall filter **new-ingress-vlan-rogue-block**.

3. Commit the changes:

```
[edit]
user@switch# commit
```

NOTE: The original filter is not deleted and is still available in the configuration.

Filter Counts Previously Dropped Packet

Problem

Description: If you configure two or more filters in the same direction for a physical interface and one of the filters includes a counter, the counter will be incorrect if the following circumstances apply:

- You configure the filter that is applied to packets first to discard certain packets. For example, imagine that you have a VLAN filter that accepts packets sent to 10.10.1.0/24 addresses and implicitly discards packets sent to any other addresses. You apply the filter to the **admin** VLAN in the output direction, and interface xe-0/0/1 is a member of that VLAN.
- You configure a subsequent filter to accept and count packets that are dropped by the first filter. In this example, you have a port filter that accepts and counts packets sent to 192.168.1.0/24 addresses that is also applied to xe-0/0/1 in the output direction.

The egress VLAN filter is applied first and correctly discards packets sent to 192.168.1.0/24 addresses. The egress port filter is applied next and counts the discarded packets as matched packets. The packets are not forwarded, but the counter displayed by the egress port filter is incorrect.

Remember that the order in which filters are applied depends on the direction in which they are applied, as indicated here:

Ingress filters:

1. Port (Layer 2) filter

2. VLAN filter

3. Router (Layer 3) filter

Egress filters:

1. Router (Layer 3) filter

2. VLAN filter

3. Port (Layer 2) filter

Solution

This is expected behavior.

Matching Packets Not Counted

Problem

Description: If you configure two egress filters with counters for a physical interface and a packet matches both of the filters, only one of the counters includes that packet.

For example:

- You configure an egress port filter with a counter for interface xe-0/0/1.
- You configure an egress VLAN filter with a counter for the **adminVLAN**, and interface xe-0/0/1 is a member of that VLAN.
- A packet matches both filters.

In this case, the packet is counted by only one of the counters even though it matched both filters.

Solution

This is expected behavior.

Counter Reset When Editing Filter

Problem

Description: If you edit a firewall filter term, the value of any counter associated with any term in the same filter is set to 0, including the implicit counter for any policer referenced by the filter. Consider the following examples:

- Assume that your filter has **term1**, **term2**, and **term3**, and each term has a counter that has already counted matching packets. If you edit any of the terms in any way, the counters for all the terms are reset to 0.
- Assume that your filter has **term1** and **term2**. Also assume that **term2** has a **policer** action modifier and the implicit counter of the policer has already counted 1000 matching packets. If you edit **term1** or **term2** in any way, the counter for the policer referenced by **term2** is reset to 0.

Solution

This is expected behavior.

Cannot Include loss-priority and policer Actions in Same Term

Problem

Description: You cannot include both of the following actions in the same firewall filter term in a QFX Series switch:

- **loss-priority**
- **policer**

If you do so, you see the following error message when you attempt to commit the configuration: “cannot support policer action if loss-priority is configured.”

Solution

This is expected behavior.

Cannot Egress Filter Certain Traffic Originating on QFX Switch

Problem

Description: On a QFX Series switch, you cannot filter certain traffic with a firewall filter applied in the output direction if the traffic originates on the QFX switch. This limitation applies to control traffic for protocols such as ICMP (ping), STP, LACP, and so on.

Solution

This is expected behavior.

Firewall Filter Match Condition Not Working with Q-in-Q Tunneling

Problem

Description: If you create a firewall filter that includes a match condition of **dot1q-tag** or **dot1q-user-priority** and apply the filter on input to a trunk port that participates in a service VLAN, the match condition does not work if the Q-in-Q EtherType is not 0x8100. (When Q-in-Q tunneling is enabled, trunk interfaces are assumed to be part of the service provider or data center network and therefore participate in service VLANs.)

Solution

This is expected behavior. To set the Q-in-Q EtherType to 0x8100, enter the **set dot1q-tunneling ethertype 0x8100** statement at the **[edit ethernet-switching-options]** hierarchy level. You must also configure the other end of the link to use the same EtherType.

Egress Firewall Filters with Private VLANs

Problem

Description: If you apply a firewall filter in the output direction to a primary VLAN, the filter also applies to the secondary VLANs that are members of the primary VLAN when the traffic egresses with the primary VLAN tag or isolated VLAN tag, as listed below:

- Traffic forwarded from a secondary VLAN trunk port to a promiscuous port (trunk or access)
- Traffic forwarded from a secondary VLAN trunk port that carries an isolated VLAN to a PVLAN trunk port.
- Traffic forwarded from a promiscuous port (trunk or access) to a secondary VLAN trunk port
- Traffic forwarded from a PVLAN trunk port. to a secondary VLAN trunk port
- Traffic forwarded from a community port to a promiscuous port (trunk or access)

If you apply a firewall filter in the output direction to a primary VLAN, the filter does *not* apply to traffic that egresses with a community VLAN tag, as listed below:

- Traffic forwarded from a community trunk port to a PVLAN trunk port
- Traffic forwarded from a secondary VLAN trunk port that carries a community VLAN to a PVLAN trunk port
- Traffic forwarded from a promiscuous port (trunk or access) to a community trunk port
- Traffic forwarded from a PVLAN trunk port. to a community trunk port

If you apply a firewall filter in the output direction to a community VLAN, the following behaviors apply:

- The filter is applied to traffic forwarded from a promiscuous port (trunk or access) to a community trunk port (because the traffic egresses with the community VLAN tag).
- The filter is applied to traffic forwarded from a community port to a PVLAN trunk port (because the traffic egresses with the community VLAN tag).
- The filter is *not* applied to traffic forwarded from a community port to a promiscuous port (because the traffic egresses with the primary VLAN tag or untagged).

Solution

These are expected behaviors. They occur only if you apply a firewall filter to a private VLAN in the output direction and do not occur if you apply a firewall filter to a private VLAN in the input direction.

Egress Filtering of L2PT Traffic Not Supported

Problem

Description: Egress filtering of L2PT traffic is not supported on the QFX3500 switch. That is, if you configure L2PT to tunnel a protocol on an interface, you cannot also use a firewall filter to filter traffic for that protocol on that interface in the output direction. If you commit a configuration for this purpose, the firewall filter is not applied to the L2PT-tunneled traffic.

Solution

This is expected behavior.

Cannot Drop BGP Packets in Certain Circumstances

Problem

Description: BGP packets with a time-to-live (TTL) value greater than 1 cannot be discarded using a firewall filter applied to a loopback interface or applied on input to a Layer 3 interface. BGP packets with TTL value of 1 or 0 can be discarded using a firewall filter applied to a loopback interface or applied on input to a Layer 3 interface.

Solution

This is expected behavior.

Invalid Statistics for Policer

Problem

Description: If you apply a single-rate two-color policer in more than 128 terms in a firewall filter, the output of the **show firewall** command displays incorrect data for the policer.

Solution

This is expected behavior.

Policers can Limit Egress Filters

Problem

Description: On some switches, the number of egress policers you configure can affect the total number of allowed egress firewall filters. Every policer has two implicit counters that take up two entries in a 1024-entry TCAM. These are used for counters, including counters that are configured as action modifiers in firewall filter terms. (Policers consume two entries because one is used for green packets and one is used for nongreen packets regardless of policer type.) If the TCAM becomes full, you are unable to commit any more egress firewall filters that have terms with counters. For example, if you configure and commit 512 egress policers (two-color, three-color, or a combination of both policer types), all of the memory entries for counters get used up. If later in your configuration file you insert additional egress firewall filters with terms that also include counters, *none* of the terms in those filters are committed because there is no available memory space for the counters.

Here are some additional examples:

- Assume that you configure egress filters that include a total of 512 policers and no counters. Later in your configuration file you include another egress filter with 10 terms, 1 of which has a counter action modifier. None of the terms in this filter are committed because there is not enough TCAM space for the counter.
- Assume that you configure egress filters that include a total of 500 policers, so 1000 TCAM entries are occupied. Later in your configuration file you include the following two egress filters:
 - Filter A with 20 terms and 20 counters. All the terms in this filter are committed because there is enough TCAM space for all the counters.

- Filter B comes after Filter A and has five terms and five counters. *None* of the terms in this filter are committed because there is not enough memory space for *all* the counters. (Five TCAM entries are required but only four are available.)

Solution

You can prevent this problem by ensuring that egress firewall filter terms with counter actions are placed earlier in your configuration file than terms that include policers. In this circumstance, Junos OS commits policers even if there is not enough TCAM space for the implicit counters. For example, assume the following:

- You have 1024 egress firewall filter terms with counter actions.
- Later in your configuration file you have an egress filter with 10 terms. None of the terms have counters but one has a policer action modifier.

You can successfully commit the filter with 10 terms even though there is not enough TCAM space for the implicit counters of the policer. The policer is committed without the counters.

Overview of Firewall Filters

IN THIS SECTION

- [Where You Can Apply Filters | 762](#)
- [Firewall Filter Components | 763](#)
- [Firewall Filter Processing | 764](#)

Firewall filters provide rules that define whether to accept or discard packets that are transiting an interface. If a packet is accepted, you can configure additional actions to perform on the packet, such as class-of-service (CoS) marking (grouping similar types of traffic together and treating each type of traffic as a class with its own level of service priority) and traffic policing (controlling the maximum rate of traffic sent or received). You configure firewall filters to determine whether to accept or discard a packet before it enters or exits a Layer 3 (routed) interface.

An *ingress* firewall filter is applied to packets that are entering an interface, and an *egress* firewall filter is applied to packets that are exiting an interface .

NOTE: Firewall filters are sometimes called *access control lists* (ACLs).

Where You Can Apply Filters

You can apply a router firewall filter in both ingress and egress directions on IPv4 or IPv6 Layer 3 (routed) interfaces and a loopback interface, which filters traffic sent to the switch itself or generated by the switch.

You apply a filter to a loopback interface in the input direction to protect the switch from unwanted traffic. You also might want to apply a filter to a loopback interface in the output direction so that you can set the forwarding class and DSCP bit value for packets that originate on the switch itself. This feature gives you very fine control over the classification of CPU generated packets. For example, you might want to assign different DSCP values and forwarding classes to traffic generated by different routing protocols so the traffic for those protocols can be treated in a differentiated manner by other devices.

NOTE: On QFX5220 switches, you can only apply a filter to a loopback interface in the ingress direction.

NOTE: If you apply ingress and egress filters to the same interface, the ingress filter is processed first.

To apply a firewall filter:

1. Configure the firewall filter.
2. Apply the firewall filter to a Layer 3 interface and specify the direction. If you specify the **input** direction, traffic is filtered on ingress. If you specify the **output** direction, traffic is filtered on egress.

NOTE: You can apply only one firewall filter to a Layer 3 interface for a given direction. For example, for a given **family inet** interface, you can apply one filter for input and one for output.

OCX switches support the maximum numbers of firewall filter terms per type of attachment point shown in [Table 36 on page 763](#).

Table 36: Supported Firewall Filter Numbers

Filter Type	Maximum Number of Filters
Ingress	1536
Egress	1024

Firewall Filter Components

In a firewall filter, you first define the family address type (**inet** for IPv4 or **inet6** for IPv6) and then define one or more terms that specify the filtering criteria and the action to take if a match occurs.

Each term consists of the following components:

- Match conditions—Specify values that a packet must contain to be considered a match.
- Action—Specifies what to do if a packet matches the match conditions. A filter can accept, discard, or reject a matching packet and then perform additional actions, such as counting, classifying, and policing. If no action is specified for a term, the default is to accept the matching packet.

Firewall Filter Processing

If there are multiple terms in a filter, the order of the terms is important. If a packet matches the first term, the switch executes the action defined by that term, and no other terms are evaluated. If the switch does not find a match between the packet and the first term, it compares the packet to the next term. If no match occurs between the packet and the second term, the system continues to compare the packet to each successive term in the filter until a match is found. If the packet does not match any terms in the filter, the switch discards the packet by default.

Understanding Firewall Filter Match Conditions

IN THIS SECTION

- [Filter Match Conditions | 765](#)
- [Numeric Filter Match Conditions | 765](#)
- [Interface Filter Match Conditions | 766](#)
- [IP Address Filter Match Conditions | 766](#)
- [Bit-Field Filter Match Conditions | 767](#)

Before you define terms for firewall filters, you must understand how the conditions in a term are handled and how to specify interface, numeric, address, and bit-field filter match conditions to achieve the desired filter results.

Filter Match Conditions

In the **from** statement of a firewall filter term, you specify the conditions that the packet must match for the action in the **then** statement to be taken. All conditions must match for the action to be implemented. The order in which you specify match conditions is not important, because a packet must match all the conditions in a term for a match to occur.

If you specify multiple values for the same condition, a match on any one of those values matches that condition. For example, if you specify multiple IP source addresses using the **source-address** statement, a packet that contains any one of those IP source addresses matches the condition. In some cases you can specify multiple values for the same condition by enclosing the possible values in square brackets, as in:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set protocol (icmp | udp)
```

In other cases you must enter multiple statements, as in:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set source-address 10.1.1.1
user@switch# set source-address 10.1.1.2
```

If you specify no match conditions in a term, that term matches all packets.

NOTE: Unlike traditional Junos OS firewall filters, you cannot use **except** in a condition statement to negate the condition.

Numeric Filter Match Conditions

You can specify numeric filter match conditions that are identified by a numeric value, such as port and protocol numbers. For numeric filter match conditions, you specify the condition and a single value that a field in a packet must contain to be considered a match.

You can specify the numeric value in one of the following ways:

- **Single number**—A match occurs if the value of the field matches the number. For example, to match Telnet traffic:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set source-port 23
```

- Text synonym for a single number—A match occurs if the value of the field matches the number that corresponds to the synonym. For example, to match Telnet traffic:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set source-port telnet
```

- To specify multiple values for the same match condition in a filter term, enter each value in its own match statement. For example, a match occurs in the following term if the value of the source port in the packet is 22 or 23.

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set source-port 22
user@switch# set source-port 23
```

Interface Filter Match Conditions

You can specify an interface filter match condition to match an interface on which a packet is received or transmitted. In this example, the final character (0) specifies the logical unit. You can include the wildcard (*) as part of the interface name. For example:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set interface ge-0/*/6.0
user@switch# set interface ge-0/1/*.0
user@switch# set interface ge-0/0/6.*
```

Note that you must specify a value or a wildcard for the logical unit.

IP Address Filter Match Conditions

You can specify an address filter match condition to match an IP source or destination address or prefix in a packet. Specify the address or prefix type and the address or prefix itself. For example:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set destination-address 10.2.1.0/24;
```

If you omit the prefix length, it defaults to /32. For example:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set destination-address 10
[edit firewall family family-name filter filter-name term term-name from]
user@switch# show
```

```
destination-address {
10.0.0.0/32;
}
```

To specify more than one IP address or prefix in a filter term, enter each address or prefix in its own match statement. For example, a match occurs in the following term if the source address of a packet matches either of the following prefixes:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set source-address 10.1.0.0/16
user@switch# set source-address 10.2.0.0/16
```

Bit-Field Filter Match Conditions

You can specify bit-field filter match conditions to match particular bits within certain fields in Ethernet frames and IP, TCP, UDP, and ICMP headers. You usually specify the field and the bit within the field that must be set in a packet to be considered a match.

In most cases you can use a keyword to specify the bit you want to match on. For example, to match on a TCP SYN packet you can enter **syn**, as in:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set tcp-flags syn
```

You can also enter **0x02** because the SYN bit is the third least-significant bit of the 8-bit tcp-flags field:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set tcp-flags 0x02
```

To match multiple bit-field values, use the logical operators, which are described in [Table 37 on page 767](#). The operators are listed in order from highest precedence to lowest precedence. Operations are evaluated from left to right.

Table 37: Actions for Firewall Filters

Logical Operators	Description
!	Negation
&	Logical AND
	Logical OR

If you use a logical operator, enclose the values in quotation marks and do not include any spaces. For example, the following statement matches the second packet of a TCP handshake:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set tcp-flags "syn&ack"
```

To negate a match, precede the value with an exclamation point. For example, the following statement matches only the initial packet of a TCP handshake:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set tcp-flags "syn&!ack"
```

You can use text synonyms to specify some common bit-field matches. For example, the following statement also matches the initial packet of a TCP handshake:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set tcp-initial
```

[Configuring Firewall Filters](#) | 1579

Understanding Firewall Filter Planning

Before you create a firewall filter and apply it, determine what you want the filter to accomplish and how to use its match conditions and actions to achieve your goals. It is important that you understand how packets are matched, the default and configured actions of the firewall filter, and where to apply the firewall filter.

You can apply no more than one firewall filter per router interface per direction (input and output). For example, for a given interface you can apply at most one filter in the input direction and one filter in the output direction. You should try to be conservative in the number of terms (rules) that you include in each firewall filter, because a large number of terms requires longer processing time during a commit operation and can make testing and troubleshooting more difficult.

Before you configure and apply firewall filters, answer the following questions for each of them:

1. What is the purpose of the filter?

For example, the system can drop packets based on header information, rate-limit traffic, classify packets into forwarding classes, log and count packets, or prevent denial-of-service attacks.

2. What are the appropriate match conditions? Determine the packet header fields that the packet must contain for a match. Possible fields include:

- Layer 3 header fields—Source and destination IP addresses, protocols, and IP options (IP precedence, IP fragmentation flags, or TTL type).
- TCP header fields—Source and destination ports and flags.
- ICMP header fields—Packet type and code.

3. What are the appropriate actions to take if a match occurs?

The system can accept, discard, or reject packets.

4. What additional action modifiers might be required?

For example, you can configure the system to mirror (copy) packets to a specified port, count matching packets, apply traffic management, or police packets.

5. On what Layer 3 interface should the firewall filter be applied?

Before you choose the interface on which to apply a firewall filter, understand how that placement can affect traffic flow to other interfaces. In general, apply a filter close to the source device if the filter matches on source or destination IP addresses, IP protocols, or protocol information—such as ICMP message types, and TCP or UDP port numbers. However, you should apply a filter close to the destination device if the filter matches *only* on a source IP address. When you apply a filter too close to the source device, the filter could prevent that source device from accessing other services that are available on the network.

6. In which direction should the firewall filter be applied?

You typically configure different actions for traffic entering an interface than you configure for traffic exiting an interface.

7. How many filters should I create?

Understanding How Firewall Filters Are Evaluated

A firewall filter consists of one or more terms, and the order of the terms within a filter is important. Before you configure firewall filters, you should understand how switches evaluate the terms within a filter and how packets are evaluated against the terms.

When a firewall filter consists of a single term, the filter is evaluated as follows:

- If the packet matches all the conditions, the action in the **then** statement is taken.
- If the packet matches all the conditions, and no action is specified in the **then** statement, the default action **accept** is taken.
- If the packet does not match all the conditions, the switch discards it.

When a firewall filter consists of more than one term, the filter is evaluated sequentially:

1. The packet is evaluated against the conditions in the **from** statement in the first term.
2. If the packet matches all the conditions in the term, the action in the **then** statement is taken and the evaluation ends. Subsequent terms in the filter are not evaluated.
3. If the packet does not match all the conditions in the term, the packet is evaluated against the conditions in the **from** statement in the second term.

This process continues until the packet matches all the conditions in the **from** statement in one of the subsequent terms or there are no more terms in the filter.

4. If a packet passes through all the terms in the filter without a match, the switch discards it.

NOTE: The order of conditions in a **from** statement is not important because a packet must match all the conditions to be considered a match.

Figure 50 on page 771 shows how switches evaluate the terms within a firewall filter.

Figure 50: Evaluation of Terms Within a Firewall Filter

If you do not include a **from** statement in a term, all packets will match the term and be processed by the **then** statement. If a term does not contain a **then** statement or if an action has not been configured in the **then** statement, the term accepts any matching packets.

Every firewall filter contains an implicit **deny** statement at the end of the filter, which is equivalent to the following explicit filter term:

```
term implicit-rule {
  then discard;
}
```

Consequently, a packet that does not match any of the terms in a firewall filter is discarded. If you configure a filter that has no terms, all packets that pass through the filter are discarded.

NOTE: Firewall filtering is supported on packets that are at least 64 bytes long.

Understanding Firewall Filter Match Conditions

IN THIS SECTION

- [Filter Match Conditions | 772](#)
- [Numeric Filter Match Conditions | 773](#)
- [Interface Filter Match Conditions | 774](#)
- [IP Address Filter Match Conditions | 774](#)
- [MAC Address Filter Match Conditions | 775](#)
- [Bit-Field Filter Match Conditions | 775](#)

Before you define terms for firewall filters, you must understand how the conditions in a term are handled and how to specify interface, numeric, address, and bit-field filter match conditions to achieve the desired filter results.

Filter Match Conditions

In the **from** statement of a firewall filter term, you specify the conditions that the packet must match for the action in the **then** statement to be taken. All conditions must match for the action to be implemented. The order in which you specify match conditions is not important, because a packet must match all the conditions in a term for a match to occur.

If you specify multiple values for the same condition, a match on any one of those values matches that condition. For example, if you specify multiple IP source addresses using the **source-address** statement, a packet that contains any one of those IP source addresses matches the condition. In some cases you can specify multiple values for the same condition by enclosing the possible values in square brackets, as in:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set protocol (icmp | udp)
```

In other cases you must enter multiple statements, as in:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set source-address 10.1.1.1
user@switch# set source-address 10.1.1.2
```

If you specify no match conditions in a term, that term matches all packets.

NOTE: Unlike traditional Junos OS firewall filters, you cannot use **except** in a condition statement to negate the condition.

Numeric Filter Match Conditions

You can specify numeric filter match conditions that are identified by a numeric value, such as port and protocol numbers. For numeric filter match conditions, you specify the condition and a single value that a field in a packet must contain to be considered a match.

You can specify the numeric value in one of the following ways:

- **Single number**—A match occurs if the value of the field matches the number. For example, to match Telnet traffic:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set source-port 23
```

- **Text synonym for a single number**—A match occurs if the value of the field matches the number that corresponds to the synonym. For example, to match Telnet traffic:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set source-port telnet
```

- **To specify multiple values for the same match condition in a filter term**, enter each value in its own match statement. For example, a match occurs in the following term if the value of the source port in the packet is 22 or 23.

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set source-port 22
user@switch# set source-port 23
```

Interface Filter Match Conditions

You can specify an interface filter match condition to match an interface on which a packet is received or transmitted. For example, if you apply a filter to a VLAN you might want the filter to match on some interfaces that participate in the VLAN and not match on other interfaces in the VLAN. When you specify the name of the interface, you must include a logical unit.

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set interface ge-0/0/6.0
```

In this example, the final character (0) specifies the logical unit. You can include the wildcard (*) as part of the interface name. For example:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set interface ge-0/*/6.0
user@switch# set interface ge-0/1/*.0
user@switch# set interface ge-0/0/6.*
```

Note that you must specify a value or a wildcard for the logical unit.

IP Address Filter Match Conditions

You can specify an address filter match condition to match an IP source or destination address or prefix in a packet. Specify the address or prefix type and the address or prefix itself. For example:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set destination-address 10.2.1.0/24;
```

If you omit the prefix length, it defaults to /32. For example:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set destination-address 10
[edit firewall family family-name filter filter-name term term-name from]
user@switch# show
destination-address {
10.0.0.0/32;
}
```

To specify more than one IP address or prefix in a filter term, enter each address or prefix in its own match statement. For example, a match occurs in the following term if the source address of a packet matches either of the following prefixes:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set source-address 10.1.0.0/16
user@switch# set source-address 10.2.0.0/16
```

MAC Address Filter Match Conditions

You can specify a MAC address filter match condition to match a source or destination MAC address. You specify the address type and value that a packet must contain to be considered a match.

You can specify the MAC address as six hexadecimal bytes in any of the following formats:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set destination-mac-address 00:11:22:33:44:55
```

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set destination-mac-address 0011.2233.4455
```

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set destination-mac-address 001122334455
```

Regardless of the formats you use, the system resolves the address to the standard format, in this case 00:11:22:33:44:55.

To specify more than one MAC address in a filter term, enter each MAC address in its own match statement. For example, a match occurs in the following term if the value of the MAC source address matches either of the following addresses:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set source-mac-address 00:11:22:33:44:55
user@switch# set source-mac-address 00:11:22:33:20:15
```

Bit-Field Filter Match Conditions

You can specify bit-field filter match conditions to match particular bits within certain fields in Ethernet frames and IP, TCP, UDP, and ICMP headers. You usually specify the field and the bit within the field that must be set in a packet to be considered a match.

In most cases you can use a keyword to specify the bit you want to match on. For example, to match on a TCP SYN packet you can enter **syn**, as in:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set tcp-flags syn
```

You can also enter **0x02** because the SYN bit is the third least-significant bit of the 8-bit tcp-flags field:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set tcp-flags 0x02
```

To match multiple bit-field values, use the logical operators, which are described in [Table 37 on page 767](#). The operators are listed in order from highest precedence to lowest precedence. Operations are evaluated from left to right.

Table 38: Actions for Firewall Filters

Logical Operators	Description
!	Negation
&	Logical AND
	Logical OR

If you use a logical operator, enclose the values in quotation marks and do not include any spaces. For example, the following statement matches the second packet of a TCP handshake:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set tcp-flags "syn&ack"
```

To negate a match, precede the value with an exclamation point. For example, the following statement matches only the initial packet of a TCP handshake:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set tcp-flags "syn&!ack"
```

You can use text synonyms to specify some common bit-field matches. For example, the following statement also matches the initial packet of a TCP handshake:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set tcp-initial
```

Firewall Filter Flexible Match Conditions

IN THIS SECTION

- [Statement Hierarchy | 778](#)
- [Flexible Filter Match Types | 779](#)
- [Flexible Filter Match Start Locations | 780](#)
- [Flexible Filter Match Examples | 781](#)

Standard firewall filter match conditions vary based on the protocol family of the traffic being matched. For example, the terms available for bridge protocol traffic are different from those available for the inet or inet6 protocol families. The fields available for matching within each protocol family are, however, fixed or pre-defined. This means that filters can match on patterns within those pre-defined fields only.

Using flexible match conditions, firewall filters can be constructed that start the match at layer-2, layer-3, layer-4 or payload locations. From there, additional offset criteria can be specified thereby enabling pattern matches at custom, user-defined locations within a packet.

Flexible match filter terms are applied to MPC or MIC interfaces as either input or output filters just as any other firewall filter terms. Flexible match filter terms can also be created as templates at the **[edit firewall]** hierarchy level. These templates can then be referenced within a flexible match term.

NOTE: For MX series routers, flexible match conditions are only supported with MPCs or MICs. For environments where FPCs, PICs, and or DPCs are installed along with MPCs or MICs, be sure to only apply the flexible match firewall filter criteria to the MPC or MIC interfaces.

For MX Series routers with MPCs, you need to initialize Trio-only match filters (that is, a filter that includes at least one match condition or action that is only supported by the Trio chipset) by walking the corresponding SNMP MIB. For example, for any filter that is configured or changed with respect to their Trio only filters, you need to run a command such as the following: **show snmp mib walk (ascii | decimal) object-id**. This forces Junos to learn the filter counters and ensure that the filter statistics are displayed.

This guidance applies to all **enhanced-mode** firewall filters. It also applies to [“Firewall Filter Match Conditions for IPv4 Traffic” on page 835](#) with flexible match filter terms for offset-range or offset-mask, **gre-key**, and [“Firewall Filter Match Conditions for IPv6 Traffic” on page 851](#) with any of the following match conditions: **payload-protocol**, **extension headers**, **is_fragment**. It also applies to filters with either of the following [“Firewall Filter Terminating Actions” on page 794](#): **encapsulate** or **decapsulate**, or either of the following [“Firewall Filter Nonterminating Actions” on page 785](#): **policy-map**, and **clear-policy-map**.

NOTE:

Statement Hierarchy

Flexible match filter terms are available in three variations as shown in [Table 39 on page 779](#). The **flexible-match** variation is configured at the **[edit firewall]** hierarchy level. It is used to define flexible match templates. The **flexible-filter-match-mask** and **flexible-match-range** are configured at the **[edit firewall]**

family [inet|inet6|bridge|ethernet-switching|ccc|vpls] filter <filter-name> term <term-name> from] hierarchy.
Use the family ethernet-switching filter for EX9200 switches.

Flexible Filter Match Types

Table 39: Flexible Filter Match Types

Flexible Filter Match Type	Available Attributes	Description
flexible-match	<name>	Create a flexible-match template named as the <name> attribute.
	bit-length	Length of the data to be matched in bits, not needed for string input (0..32)
	bit-offset	Bit offset after the (match-start + byte) offset (0..7)
	byte-offset	Byte offset after the match start point
	match-start	Start point to match in packet
flexible-match-mask	bit-length	Length of the data to be matched in bits, not needed for string input (0..128)
	bit-offset	Bit offset after the (match-start + byte) offset (0..7)
	byte-offset	Byte offset after the match start point
	flexible-mask-name	Select a flexible match from predefined template field. Required unless match-start is configured.
	mask-in-hex	Mask out bits in the packet data to be matched.
	match-start	Start point to match in packet. Required unless flexible-mask-name is configured.
	prefix	Value data/string to be matched.

Table 39: Flexible Filter Match Types (*continued*)

Flexible Filter Match Type	Available Attributes	Description
flexible-match-range	bit-length	Length of the data to be matched in bits. (0..32) Required unless flexible-range-name is configured.
	bit-offset	Bit offset after the (match-start + byte) offset. (0..7)
	byte-offset	Byte offset after the match start point
	flexible-range-name	Select a flexible match from predefined template.
	match-start	Start point to match in packet. Required unless flexible-range-name is configured.
	range	Range of values to be matched.
	range-except	Range of values to be not matched.

Flexible Filter Match Start Locations

Flexible match filter terms are constructed by giving a start location or anchor point within the packet. The start locations can be any of: layer-2, layer-3, layer-4 or payload, depending on the protocol family in use. [Table 40 on page 780](#) shows available flexible filter match start locations by protocol family. You use these available start locations as the **match-start** locations for the flexible match filter terms.

From these start locations, specific byte and bit offsets can be utilized to allow the filter to match patterns at very specific locations within the packet.

Table 40: Flexible Filter Match Start Locations

Protocol Family	Available Start Locations
inet	layer-3, layer-4 and payload
inet6	layer-3, layer-4 and payload
bridge	layer-2, layer-3, layer-4 and payload
ccc	layer-2, layer-3, layer-4 and payload
mpls	layer-3 and payload

Table 40: Flexible Filter Match Start Locations (*continued*)

Protocol Family	Available Start Locations
vpls	layer-2, layer-3, layer-4 and payload
ethernet-switching	(EX9200 switches) layer-2, layer-3, layer-4 and payload For QFX5100, QFX5120, and EX4650 switches, support for layer-2 and layer-3 flexible match filters was added in Junos Release 20.1R1. An example of using a layer-2 packet offset and match length can be found below.

Flexible Filter Match Examples

The following example illustrates the use and context for **flexible-match-mask**.

```

from {
    flexible-match-mask {
        flexible-mask-name <mask-name>;
        mask-in-hex <mask>;
        prefix <pattern>;
    }
}

```

The *<mask-name>* specifies for *flexible-mask-name* which predefined template is used for the flexible match condition. Templates can be defined to specify at which place (position) in the packet the flexible match condition should be executed.

The *<mask>* for *mask-in-hex* is in hexadecimal format. For example, a configured mask of **0xf0fc** specifies a match for the first four bits in first byte (as referred by *<mask-name>*), and for the first six bits in the second byte. If the packet is IPv4 packet, and *<mask-name>* refers to first two bytes in L3 header, the search is for the IP version field and DSCP field. As another example, a configured mask **0xffc0** specifies a search for entire first byte and for two bits from the second byte. If the *<mask-name>* refers to first two bytes in L3 header, and the packet is IPv6 packet, this specifies the IP version field and DSCP in the Traffic Class field.

The *<pattern>* specified for *prefix* is an ASCII string. If first two characters are **0x**, then the string is processed as a hexadecimal number encoding appropriate bits. For example, the configured prefix **0x40c0** in combination with mask **0xf0fc** and *<mask-name>* referring first two bytes in L3 header, indicates a search for **0100** in the first four bits (version field is equal to 4) and **1100 00** in IPv4 DSCP field (DSCP is equal to cs6). Or, using the configured prefix **0x6c00** in combination with mask **0xffc0** and *<mask-name>* referring first two bytes in L3 header, specifies a search for **0110** in the first four bits (version field is equal to 6), and **1100 00** in IPv6 DSCP field (DSCP is equal to cs6).

The first example defines a mask template that selects first two bytes (16 bits) from L3 header for flexible match:

```
firewall {
    flexible-match FM-FIRST-TWO-L3-BYTES {
        match-start layer-3;
        byte-offset 0;
        bit-offset 0;
        bit-length 16;
    }
}
```

The next example defines a mask template that selects the third through sixth byte (32 bits) of the packet payload for flexible match:

```
firewall {
    flexible-match FM-FOUR-PAYLOAD-BYTES {
        match-start payload;
        byte-offset 2;
        bit-offset 0;
        bit-length 32;
    }
}
```

This example shows an ASCII character match for the string *JNPR* (ASCII characters: 0x4a, 0x4e, 0x50, 0x52) in the third through sixth byte of the packet payload. The filter uses the **FM-FOUR-PAYLOAD-BYTES** mask template defined in the previous example.

```
firewall {
    family ccc filter FF-COUNT-JNPR-PACKETS {
        term JNPR-STRING {
            from {
                flexible-match-mask {
                    mask-in-hex 0xffffffff;
                    prefix JNPR;
                    flexible-mask-name FM-FOUR-PAYLOAD-BYTES;
                }
            }
            then {
                count CNT-JNPR-YES
                accept;
            }
        }
    }
}
```

```

        term DEAFULT {
            then {
                count CNT-JNPR-NO
                accept;
            }
        }
    }
}

```

This example shows a family ccc filter looking for DSCP equal to **cs6** and DSCP **ef**, regardless whether the encapsulated packets are IPv4 or IPv6. It uses the the **FM-FIRST-TWO-L3-BYTES** mask template defined in the first example.

```

firewall {
    family ccc filter FF-DSCP-CLASSIFY {
        term ROUTING-IPV4 {
            from {
                flexible-match-mask {
                    mask-in-hex 0xf0fc;
                    prefix 0x40c0;      # DSCP=cs6 in IPv4 header
                    flexible-mask-name FM-FIRST-TWO-L3-BYTES;
                }
            }
            then {
                count ROUTING-IPV4;
                accept;
            }
        }
        term ROUTING-IPV6 {
            from {
                flexible-match-mask {
                    mask-in-hex 0xffc0;
                    prefix 0x6c00;      # DSCP=cs6 in IPv6 header
                    flexible-mask-name FM-FIRST-TWO-L3-BYTES;
                }
            }
            then {
                count ROUTING-IPV6;
                accept;
            }
        }
        term VOICE-IPV4 {
            from {
                flexible-match-mask {

```

```

        mask-in-hex 0xf0fc;
        prefix 0x40b8;          # DSCP=ef in IPv4 header
        flexible-mask-name FM-FIRST-TWO-L3-BYTES;
    }
}
then {
    count VOICE-IPV4;
    accept;
}
}
term VOICE-IPV6 {
    from {
        flexible-match-mask {
            mask-in-hex 0xffc0;
            prefix 0x6b80;          # DSCP=ef in IPv6 header
            flexible-mask-name FM-FIRST-TWO-L3-BYTES;
        }
    }
    then {
        count VOICE-IPV6;
        accept;
    }
}
term DEFAULT {
    then {
        accept;
    }
}
}
}
}

```

This example shows how to use a match length, starting from a layer-2 packet offset, in a firewall filter for a QFX5120-32C, QFX5120-48Y, or EX4650 device running Junos Release 20.1R1. Here, we use a bit-length of 32 bits; the maximum value is 4 bytes, or 64 bits.

```

user@device# show firewall family ethernet-switching
filter udf_eth {
    term t1 {
        from {
            flexible-match-mask {
                match-start layer-2;
                byte-offset 8;
                bit-length 32;
                prefix 168430090;
            }
        }
    }
}

```

```

        }
    }
    then count c1;
}

```

Release History Table

Release	Description
20.1R1	For QFX5100, QFX5120, and EX4650 switches, support for layer-2 and layer-3 flexible match filters was added in Junos Release 20.1R1.

Firewall Filter Match Conditions for VPLS Traffic 895

Firewall Filter Nonterminating Actions

Firewall filters support different sets of nonterminating actions for each protocol family.

NOTE: You cannot configure the **next term** action with a *terminating* action in the same filter term. However, you can configure the **next term** action with another *nonterminating* action in the same filter term.

Nonterminating actions carry with them an implicit accept action. In this context, *nonterminating* means that other actions can follow these actions whereas no other actions can follow a *terminating* action.

NOTE: On Junos OS Evolved, **next term** cannot appear as the last term of the action. A filter term where **next term** is specified as an action but without any match conditions configured is not supported.

Table 41 on page 786 describes the nonterminating actions you can configure for a firewall filter term.

Table 41: Nonterminating Actions for Firewall Filters

Nonterminating Action	Description	Protocol Families

[Firewall Filter Terminating Actions | 794](#)

Firewall Filter Terminating Actions

Firewall filters support a set of terminating actions for each protocol family. A filter-terminating action halts all evaluation of a firewall filter for a specific packet. The router performs the specified action, and no additional terms are examined.

NOTE: You cannot configure the **next term** action with a *terminating* action in the same filter term. However, you can configure the **next term** action with another *nonterminating* action in the same filter term.

On Junos OS Evolved, **next term** cannot appear as the last term of the action. A filter term where **next term** is specified as an action but without any match conditions configured is not supported.

For MX Series routers with MPCs, you need to initialize certain new firewall filters by walking the corresponding SNMP MIB, for example, **show snmp mib walk name ascii**. This forces Junos to learn the filter counters and ensure that the filter statistics are displayed. This guidance applies to all enhanced mode firewall filters, filters with flexible conditions, and filters with the certain terminating actions. See those topics, listed under Related Documentation, for details.

[Table 42 on page 794](#) describes the terminating actions you can specify in a firewall filter term.

Table 42: Terminating Actions for Firewall Filters

- [Terminating Actions \(ACX Series Routers\)](#) | 832

On ACX Series Universal Metro Routers, you can configure firewall filters to filter packets and to perform an action on packets that match the filter. The match conditions specified to filter the packets are specific to the type of traffic being filtered.

NOTE: On ACX Series routers, the filter for the exiting traffic (egress filter) can be applied only for interface-specific instances of the firewall filter.

Overview of Firewall Filter Match Conditions and Actions on ACX Series Routers

[Table 43 on page 813](#) describes the types of traffic for which you can configure standard stateless firewall filters.

Table 43: Standard Firewall Filter Match Conditions by Protocol Family for ACX Series Routers

Traffic Type	Hierarchy Level at Which Match Conditions Are Specified
Protocol-independent	<p>[edit firewall family any filter <i>filter-name</i> term <i>term-name</i>]</p> <p>No match conditions are supported for this traffic type on ACX Series routers.</p>
IPv4	<p>[edit firewall family inet filter <i>filter-name</i> term <i>term-name</i>]</p> <p>For the complete list of match conditions, see “Match Conditions for IPv4 Traffic (ACX Series Routers)” on page 817.</p>
MPLS	<p>[edit firewall family mpls filter <i>filter-name</i> term <i>term-name</i>]</p> <p>For the complete list of match conditions, see “Match Conditions for MPLS Traffic (ACX Series Routers)” on page 827.</p>
Layer 2 CCC	<p>[edit firewall family ccc filter <i>filter-name</i> term <i>term-name</i>]</p> <p>No match conditions are supported for this traffic type on ACX Series routers.</p>
Bridge	<p>[edit firewall family bridge filter <i>filter-name</i> term <i>term-name</i>]</p> <p>[edit firewall family ethernet-switching filter <i>filter-name</i> term <i>term-name</i>] (Applicable to ACX5048 and ACX5096 routers only.)</p>

On ACX5448 router, the following ingress family filters can be scaled based on the availability of external-tcam:

- family **ethernet-switching**
- family **ccc**
- family **inet**
- family **inet6**
- family **mpls**
- family **vpls**

Under the **then** statement for a standard stateless firewall filter term, you can specify the actions to be taken on a packet that matches the term.

[Table 44 on page 814](#) summarizes the types of actions you can specify in a standard stateless firewall filter term.

Table 44: Standard Firewall Filter Action Categories for ACX Series Routers

Type of Action	Description	Comment
Terminating	<p>Halts all evaluation of a firewall filter for a specific packet. The router performs the specified action, and no additional terms are used to examine the packet.</p> <p>You can specify only one <i>terminating action</i> in a standard firewall filter. You can, however, specify one terminating action with one or more <i>nonterminating actions</i> in a single term. For example, within a term, you can specify accept with count and syslog.</p>	See “Terminating Actions (ACX Series Routers)” on page 832 .
Nonterminating	Performs other functions on a packet (such as incrementing a counter, logging information about the packet header, sampling the packet data, or sending information to a remote host using the system log functionality), but any additional terms are used to examine the packet.	See “Nonterminating Actions (ACX Series Routers)” on page 828 .

Match Conditions for Bridge Family Firewall Filters (ACX Series Routers)

Bridge Family Firewall Filters on ACX Series Routers

Bridge family firewall filters can be configured at the IFL-family level on ACX series routers. Bridge family filters are used to match the L2 bridge flows based on the supported Layer2/Layer3 fields and take firewall action. The maximum number of terms supported for bridge firewall filters on ACX Series routers is 124.

[Table 45 on page 814](#) shows the match conditions supported for bridge family filters.

Table 45: Bridge Family Firewall Filter Match Conditions for ACX Series Routers

Match Condition	Description
apply-groups	Set the groups from which to inherit configuration data
apply-groups-except	Set which groups will not broadcast configuration data
destination-mac-address	Set the destination MAC address

Table 45: Bridge Family Firewall Filter Match Conditions for ACX Series Routers (*continued*)

Match Condition	Description
destination-port	Match the TCP/UDP destination port
destination-prefix-list	Match IP destination prefixes in named list.
dscp	Match the Differentiated Services (DiffServ) code point
ether-type	Match the Ethernet type
icmp-code	Match a ICMP message code
icmp-type	Match a ICMP message type
interface-group	Match an interface group
ip-destination-address	Match an IP destination address
ip-precedence	Match an IP precedence value
ip-protocol	Match an IP protocol type
ip-source-address	Match an IP source address
learn-vlan-1p-priority	Match the learned 802.1p VLAN Priority
learn-vlan-dei	Match user VLAN ID DEI bit
learn-vlan-id	Match a learnt VLAN ID
source-mac-address	Set the source MAC address
source-prefix-list	Match IP source prefixes in named list.
source-port	Match a TCP/UDP source port
user-vlan-1p-priority	Match user 802.1p VLAN Priority
user-vlan-id	Match a user VLAN ID
vlan-ether-type	Match a VLAN Ethernet type

Table 46 on page 816 shows the action fields supported.

Table 46: Bridge Family Firewall Filter Action Fields for ACX Series Routers

Action Field	Description
accept	Accept the packet
count	Count the packet in the named counter
discard	Discard the packet
forwarding-class	Classify packet to forwarding class
loss-priority	Packet's loss priority
log	Log the packet header information in a buffer within the Packet Forwarding Engine. You can access this information by issuing the show firewall log command at the command-line interface (CLI).
policer	Name of policer to use to rate-limit traffic
syslog	Log the packet to the system log file.
three-color-policer	Police the packet using a three-colo-policer

NOTE: Bridge family firewall filters can be applied as an output filter on Layer 2 interfaces. When the Layer 2 interface is on a bridge-domain configured with the **vlan-id** statement, ACX series routers can match the outer-vlan of the packet using the user vlan-id match specified in the bridge family firewall filter.

Match Conditions for CCC Firewall Family Filters (ACX Series Routers)

Match Conditions for CCC Family Firewall Filters

On ACX Series routers, you can configure a standard firewall filter with match conditions for circuit cross-connection (CCC) traffic (family ccc).

[Table 47 on page 817](#) describes the match conditions you can configure at the **[edit firewall family ccc filter filter-name term term-name]** hierarchy level.

Table 47: CCC Family Firewall Filter Match Conditions for ACX Series Routers

Field	Description
destination-mac-address	Destination MAC address
destination-port	Matches TCP/UDP destination port
dscp	Matches differentiated services (DiffServ) code point
icmp-code	Matches ICMP message code
icmp-type	Matches ICMP message type
ip-destination-address	Matches destination IP address
ip-precedence	Matches IP precedence value
ip-protocol	Matches IP protocol type
ip-source-address	Matches source IP address
learn-vlan-1p-priority	Matches learned 802.1p VLAN priority
source-mac-address	Source MAC address
source-port	Matches TCP/UDP source port
user-vlan-1p-priority	Matches user 802.1p VLAN priority

Match Conditions for IPv4 Traffic (ACX Series Routers)

On ACX Series routers, you can configure a standard stateless firewall filter with match conditions for IP version 4 (IPv4) traffic (**family inet**). [Table 48 on page 817](#) describes the match conditions you can configure at the `[edit firewall family inet filter filter-name term term-name from]` hierarchy level.

Table 48: Firewall Filter Match Conditions for IPv4 Traffic on ACX Series Routers

Match Condition	Description
destination-address address	<p>Match the IPv4 destination address field.</p> <p>NOTE: On ACX Series routers, you can specify only one destination address. A list of IPv4 destination addresses is not supported.</p>

Table 48: Firewall Filter Match Conditions for IPv4 Traffic on ACX Series Routers (*continued*)

Match Condition	Description
destination-port <i>number</i>	<p>Match the UDP or TCP destination port field.</p> <p>If you configure this match condition, we recommend that you also configure the protocol udp or protocol tcp match statement in the same term to specify which protocol is being used on the port.</p> <p>NOTE: On ACX Series routers, you can specify only one destination port number. A list of port numbers is not supported.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the port numbers are also listed): afs (1483), bgp (179), biff (512), bootpc (68), bootps (67), cmd (514), cvspserver (2401), dhcp (67), domain (53), eklogin (2105), ekshell (2106), exec (512), finger (79), ftp (21), ftp-data (20), http (80), https (443), ident (113), imap (143), kerberos-sec (88), klogin (543), kpasswd (761), krb-prop (754), krbupdate (760), kshell (544), ldap (389), ldp (646), login (513), mobileip-agent (434), mobilip-mn (435), msdp (639), netbios-dgm (138), netbios-ns (137), netbios-ssn (139), nfsd (2049), nntp (119), ntalk (518), ntp (123), pop3 (110), pptp (1723), printer (515), radacct (1813), radius (1812), rip (520), rkinit (2108), smtp (25), snmp (161), snmptrap (162), snpp (444), socks (1080), ssh (22), sunrpc (111), syslog (514), tacacs (49), tacacs-ds (65), talk (517), telnet (23), tftp (69), timed (525), who (513), or xdmcp (177).</p>
destination-prefix-list	Match IP destination prefixes in named list.
dscp <i>number</i>	<p>Match the Differentiated Services code point (DSCP). The DiffServ protocol uses the type-of-service (ToS) byte in the IP header. The most significant 6 bits of this byte form the DSCP. For more information, see <i>Understanding How Behavior Aggregate Classifiers Prioritize Trusted Traffic</i>.</p> <p>You can specify a numeric value from 0 through 63. To specify the value in hexadecimal form, include 0x as a prefix. To specify the value in binary form, include b as a prefix.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed):</p> <ul style="list-style-type: none"> • RFC 3246, <i>An Expedited Forwarding PHB (Per-Hop Behavior)</i>, defines one code point: ef (46). • RFC 2597, <i>Assured Forwarding PHB Group</i>, defines 4 classes, with 3 drop precedences in each class, for a total of 12 code points: <ul style="list-style-type: none"> • af11 (10), af12 (12), af13 (14) • af21 (18), af22 (20), af23 (22) • af31 (26), af32 (28), af33 (30) • af41 (34), af42 (36), af43 (38)

Table 48: Firewall Filter Match Conditions for IPv4 Traffic on ACX Series Routers (*continued*)

Match Condition	Description
fragment-flags number	<p>(Ingress only) Match the three-bit IP fragmentation flags field in the IP header.</p> <p>In place of the numeric field value, you can specify one of the following keywords (the field values are also listed): dont-fragment (0x4), more-fragments (0x2), or reserved (0x8).</p>
icmp-code number	<p>Match the ICMP message code field.</p> <p>If you configure this match condition, we recommend that you also configure the protocol icmp match condition in the same term.</p> <p>If you configure this match condition, you must also configure the icmp-type message-type match condition in the same term. An ICMP message code provides more specific information than an ICMP message type, but the meaning of an ICMP message code is dependent on the associated ICMP message type.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed). The keywords are grouped by the ICMP type with which they are associated:</p> <ul style="list-style-type: none"> • parameter-problem: ip-header-bad (0), required-option-missing (1) • redirect: redirect-for-host (1), redirect-for-network (0), redirect-for-tos-and-host (3), redirect-for-tos-and-net (2) • time-exceeded: ttl-eq-zero-during-reassembly (1), ttl-eq-zero-during-transit (0) • unreachable: communication-prohibited-by-filtering (13), destination-host-prohibited (10), destination-host-unknown (7), destination-network-prohibited (9), destination-network-unknown (6), fragmentation-needed (4), host-precedence-violation (14), host-unreachable (1), host-unreachable-for-TOS (12), network-unreachable (0), network-unreachable-for-TOS (11), port-unreachable (3), precedence-cutoff-in-effect (15), protocol-unreachable (2), source-host-isolated (8), source-route-failed (5)
icmp-type number	<p>Match the ICMP message type field.</p> <p>If you configure this match condition, we recommend that you also configure the protocol icmp match condition in the same term.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): echo-reply (0), echo-request (8), info-reply (16), info-request (15), mask-request (17), mask-reply (18), parameter-problem (12), redirect (5), router-advertisement (9), router-solicit (10), source-quench (4), time-exceeded (11), timestamp (13), timestamp-reply (14), or unreachable (3).</p>

Table 48: Firewall Filter Match Conditions for IPv4 Traffic on ACX Series Routers (*continued*)

Match Condition	Description
ip-options values	<p>Match the 8-bit IP option field, if present, to the specified value.</p> <p>ACX Series routers support only the ip-options_any match condition, which ensures that the packets are sent to the Packet Forwarding Engine for processing.</p> <p>NOTE: On ACX Series routers, you can specify only one IP option value. Configuring multiple values is not supported.</p>
precedence ip-precedence-field	<p>Match the IP precedence field.</p> <p>In place of the numeric field value, you can specify one of the following text synonyms (the field values are also listed): critical-ecp (0xa0), flash (0x60), flash-override (0x80), immediate (0x40), internet-control (0xc0), net-control (0xe0), priority (0x20), or routine (0x00). You can specify precedence in hexadecimal, binary, or decimal form.</p>
protocol number	<p>Match the IP protocol type field. In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): dstopts (60), egp (8), esp (50), fragment (44), gre (47), hop-by-hop (0), icmp (1), icmp6 (58), icmpv6 (58), igmp (2), ipip (4), ipv6 (41), no-next-header, ospf (89), pim (103), routing, rsvp (46), sctp (132), tcp (6), udp (17), or vrrp (112).</p>
source-address address	<p>Match the IPv4 address of the source node sending the packet.</p>
source-port number	<p>Match the UDP or TCP source port field.</p> <p>If you configure this match condition for IPv4 traffic, we recommend that you also configure the protocol udp or protocol tcp match statement in the same term to specify which protocol is being used on the port.</p> <p>In place of the numeric value, you can specify one of the text synonyms listed with the destination-port number match condition.</p>
source-prefix-list	<p>Match IP source prefixes in named list.</p>

Table 48: Firewall Filter Match Conditions for IPv4 Traffic on ACX Series Routers (*continued*)

Match Condition	Description
tcp-flags value	<p>Match one or more of the low-order 6 bits in the 8-bit TCP flags field in the TCP header.</p> <p>To specify individual bit fields, you can specify the following text synonyms or hexadecimal values:</p> <ul style="list-style-type: none"> • fin (0x01) • syn (0x02) • rst (0x04) • push (0x08) • ack (0x10) • urgent (0x20) <p>In a TCP session, the SYN flag is set only in the initial packet sent, while the ACK flag is set in all packets sent after the initial packet.</p> <p>You can string together multiple flags using the bit-field logical operators.</p> <p>For combined bit-field match conditions, see the tcp-initial match conditions.</p> <p>If you configure this match condition, we recommend that you also configure the protocol tcp match statement in the same term to specify that the TCP protocol is being used on the port.</p>
tcp-initial	<p>Match the initial packet of a TCP connection. This is an alias for tcp-flags "(!ack & syn)".</p> <p>This condition does not implicitly check that the protocol is TCP. If you configure this match condition, we recommend that you also configure the protocol tcp match condition in the same term.</p>
ttl number	<p>Match the IPv4 time-to-live number. Specify a TTL value or a range of TTL values. For number, you can specify one or more values from 2 through 255.</p>

Match Conditions for IPv6 Traffic (ACX Series Routers)

You can configure a firewall filter with match conditions for Internet Protocol version 6 (IPv6) traffic (**family inet6**). [Table 49 on page 822](#) describes the match conditions you can configure at the **[edit firewall family inet6 filter filter-name term term-name from]** hierarchy level.

Table 49: Firewall Filter Match Conditions for IPv6 Traffic

Match Condition	Description
destination-address <i>address</i>	Match the IPv6 destination address field.
destination-port <i>number</i>	<p>Match the UDP or TCP destination port field.</p> <p>You cannot specify both the port and destination-port match conditions in the same term.</p> <p>If you configure this match condition, we recommend that you also configure the next-header udp or next-header tcp match condition in the same term to specify which protocol is being used on the port.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the port numbers are also listed): afs (1483), bgp (179), biff (512), bootpc (68), bootps (67), cmd (514), cvspserver (2401), dhcp (67), domain (53), eklogin (2105), ekshell (2106), exec (512), finger (79), ftp (21), ftp-data (20), http (80), https (443), ident (113), imap (143), kerberos-sec (88), klogin (543), kpasswd (761), krb-prop (754), krbupdate (760), kshell (544), ldap (389), ldp (646), login (513), mobileip-agent (434), mobilip-mn (435), msdp (639), netbios-dgm (138), netbios-ns (137), netbios-ssn (139), nfsd (2049), nntp (119), ntalk (518), ntp (123), pop3 (110), pptp (1723), printer (515), radacct (1813), radius (1812), rip (520), rkinit (2108), smtp (25), snmp (161), snmptrap (162), snpp (444), socks (1080), ssh (22), sunrpc (111), syslog (514), tacacs (49), tacacs-ds (65), talk (517), telnet (23), tftp (69), timed (525), who (513), or xdmcp (177).</p>
destination-prefix-list	Match IP destination prefixes in named list.
extension-headers <i>header-type</i>	<p>Match an extension header type that is contained in the packet by identifying a Next Header value.</p> <p>In the first fragment of a packet, the filter searches for a match in any of the extension header types. When a packet with a fragment header is found (a subsequent fragment), the filter only searches for a match of the next extension header type because the location of other extension headers is unpredictable.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): ah (51), destination (60), esp (50), fragment (44), hop-by-hop (0), mobility (135), or routing (43).</p> <p>To match <i>any</i> value for the extension header option, use the text synonym any.</p> <p>NOTE: Only the first extension header of the IPv6 packet can be matched. L4 header beyond one IPv6 extension header will be matched.</p>
hop-limit <i>hop-limit</i>	Match the hop limit to the specified hop limit or set of hop limits. For hop-limit , specify a single value or a range of values from 0 through 255.

Table 49: Firewall Filter Match Conditions for IPv6 Traffic (*continued*)

Match Condition	Description
icmp-code <i>message-code</i>	<p>Match the ICMP message code field.</p> <p>If you configure this match condition, we recommend that you also configure the next-header icmp or next-header icmp6 match condition in the same term.</p> <p>If you configure this match condition, you must also configure the icmp-type <i>message-type</i> match condition in the same term. An ICMP message code provides more specific information than an ICMP message type, but the meaning of an ICMP message code is dependent on the associated ICMP message type.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed). The keywords are grouped by the ICMP type with which they are associated:</p> <ul style="list-style-type: none"> • parameter-problem: ip6-header-bad (0), unrecognized-next-header (1), unrecognized-option (2) • time-exceeded: ttl-eq-zero-during-reassembly (1), ttl-eq-zero-during-transit (0) • destination-unreachable: administratively-prohibited (1), address-unreachable (3), no-route-to-destination (0), port-unreachable (4)
icmp-type <i>message-type</i>	<p>Match the ICMP message type field.</p> <p>If you configure this match condition, we recommend that you also configure the next-header icmp or next-header icmp6 match condition in the same term.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): certificate-path-advertisement (149), certificate-path-solicitation (148), destination-unreachable (1), echo-reply (129), echo-request (128), home-agent-address-discovery-reply (145), home-agent-address-discovery-request (144), inverse-neighbor-discovery-advertisement (142), inverse-neighbor-discovery-solicitation (141), membership-query (130), membership-report (131), membership-termination (132), mobile-prefix-advertisement-reply (147), mobile-prefix-solicitation (146), neighbor-advertisement (136), neighbor-solicit (135), node-information-reply (140), node-information-request (139), packet-too-big (2), parameter-problem (4), private-experimentation-100 (100), private-experimentation-101 (101), private-experimentation-200 (200), private-experimentation-201 (201), redirect (137), router-advertisement (134), router-renumbering (138), router-solicit (133), or time-exceeded (3).</p> <p>For private-experimentation-201 (201), you can also specify a range of values within square brackets.</p>

Table 49: Firewall Filter Match Conditions for IPv6 Traffic (*continued*)

Match Condition	Description
next-header <i>header-type</i>	<p>Match the first 8-bit Next Header field in the packet. Support for the next-header firewall match condition is available in Junos OS Release 13.3R6 and later.</p> <p>For IPv6, we recommend that you use the payload-protocol term rather than the next-header term when configuring a firewall filter with match conditions. Although either can be used, payload-protocol provides the more reliable match condition because it uses the actual payload protocol to find a match, whereas next-header simply takes whatever appears in the first header following the IPv6 header, which may or may not be the actual protocol. In addition, if next-header is used with IPv6, the accelerated filter block lookup process is bypassed and the standard filter used instead.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): ah (51), dstops (60), egp (8), esp (50), fragment (44), gre (47), hop-by-hop (0), icmp (1), icmp6 (58), icmpv6 (58), igmp (2), ipip (4), ipv6 (41), mobility (135), no-next-header (59), ospf (89), pim (103), routing (43), rsvp (46), sctp (132), tcp (6), udp (17), or vrrp (112).</p> <p>NOTE: next-header icmp6 and next-header icmpv6 match conditions perform the same function. next-header icmp6 is the preferred option. next-header icmpv6 is hidden in the Junos OS CLI.</p>
source-address <i>address</i>	Match the IPv6 address of the source node sending the packet.
source-port <i>number</i>	<p>Match the UDP or TCP source port field.</p> <p>You cannot specify the port and source-port match conditions in the same term.</p> <p>If you configure this match condition, we recommend that you also configure the next-header udp or next-header tcp match condition in the same term to specify which protocol is being used on the port.</p> <p>In place of the numeric value, you can specify one of the text synonyms listed with the destination-port number match condition.</p>
source-prefix-list	Match IP source prefixes in named list.

Table 49: Firewall Filter Match Conditions for IPv6 Traffic *(continued)*

Match Condition	Description
tcp-flags flags	<p>Match one or more of the low-order 6 bits in the 8-bit TCP flags field in the TCP header.</p> <p>To specify individual bit fields, you can specify the following text synonyms or hexadecimal values:</p> <ul style="list-style-type: none"> • fin (0x01) • syn (0x02) • rst (0x04) • push (0x08) • ack (0x10) • urgent (0x20) <p>In a TCP session, the SYN flag is set only in the initial packet sent, while the ACK flag is set in all packets sent after the initial packet.</p> <p>You can string together multiple flags using the bit-field logical operators.</p> <p>For combined bit-field match conditions, see the tcp-established and tcp-initial match conditions.</p> <p>If you configure this match condition, we recommend that you also configure the next-header tcp match condition in the same term to specify that the TCP protocol is being used on the port.</p>
tcp-initial	<p>Match the initial packet of a TCP connection. This is a text synonym for tcp-flags "(lack & syn)".</p> <p>This condition does not implicitly check that the protocol is TCP. If you configure this match condition, we recommend that you also configure the next-header tcp match condition in the same term.</p>

Table 49: Firewall Filter Match Conditions for IPv6 Traffic *(continued)*

Match Condition	Description
traffic-class <i>number</i>	<p>Match the 8-bit field that specifies the class-of-service (CoS) priority of the packet.</p> <p>This field was previously used as the type-of-service (ToS) field in IPv4.</p> <p>You can specify a numeric value from 0 through 63. To specify the value in hexadecimal form, include 0x as a prefix. To specify the value in binary form, include b as a prefix.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed):</p> <ul style="list-style-type: none"> • RFC 3246, <i>An Expedited Forwarding PHB (Per-Hop Behavior)</i>, defines one code point: ef (46). • RFC 2597, <i>Assured Forwarding PHB Group</i>, defines 4 classes, with 3 drop precedences in each class, for a total of 12 code points: <ul style="list-style-type: none"> • af11 (10), af12 (12), af13 (14) • af21 (18), af22 (20), af23 (22) • af31 (26), af32 (28), af33 (30) • af41 (34), af42 (36), af43 (38)

NOTE: If you specify an IPv6 address in a match condition (the **address**, **destination-address**, or **source-address** match conditions), use the syntax for text representations described in RFC 4291, *IP Version 6 Addressing Architecture*. For more information about IPv6 addresses, see *IPv6 Overview* and *Supported IPv6 Standards*.

The following is a sample firewall family inet6 configuration:

```
user@host# show firewall family inet6
filter ipv6-filter {
  term t1 {
    from {
      source-address {
        2001:0000:0020:0020:0000:0000:0000:0150/128;
      }
      destination-address {
        2001:0000:0040:0040:0000:0000:0000:0150/128;
      }
      next-header tcp;
      source-port 1000;
      destination-port 2000;
      extension-header dstopts;
      traffic-class ef;
      tcp-flags 0x20;
      hop-limit 254;
    }
    then count ipv6-t1-count;
  }
  term t2 {
    from {
      icmp-type neighbor-solicit;
    }
    then count ipv6-t2-count;
  }
}
```

Match Conditions for MPLS Traffic (ACX Series Routers)

On ACX Series routers, you can configure a standard stateless firewall filter with match conditions for MPLS traffic (**family mpls**).

NOTE: The **input-list *filter-names*** and **output-list *filter-names*** statements for firewall filters for the **mpls** protocol family are supported on all interfaces with the exception of management interfaces and internal Ethernet interfaces (**fxp** or **em0**), loopback interfaces (**lo0**), and USB modem interfaces (**umd**).

Table 50 on page 828 describes the match conditions you can configure at the [edit firewall family mpls filter *filter-name* term *term-name* from] hierarchy level.

Table 50: Standard Firewall Filter Match Conditions for MPLS Traffic on ACX Series Routers

Match Condition	Description
exp <i>number</i>	Experimental (EXP) bit number or range of bit numbers in the MPLS header. For <i>number</i> , you can specify one or more values from 0 through 7 in decimal, binary, or hexadecimal format.

Nonterminating Actions (ACX Series Routers)

Standard stateless firewall filters support different sets of nonterminating actions for each protocol family.

NOTE: ACX Series routers do not support the **next term** action.

ACX Series routers support log and syslog actions in ingress and egress directions for family **inet** and family **bridge**.

Table 51 on page 828 describes the nonterminating actions you can configure for a standard firewall filter term.

Table 51: Nonterminating Actions for Standard Firewall Filters on ACX Series Routers

Nonterminating Action	Description	Protocol Families
count <i>counter-name</i>	Count the packet in the named counter.	<ul style="list-style-type: none"> • family any • family inet • family mpls • family ccc • family bridge • family vpls

Table 51: Nonterminating Actions for Standard Firewall Filters on ACX Series Routers (*continued*)

Nonterminating Action	Description	Protocol Families
forwarding-class <i>class-name</i>	<p>Classify the packet based on the specified forwarding class:</p> <ul style="list-style-type: none"> • assured-forwarding • best-effort • expedited-forwarding • network-control <p>NOTE: This action is supported on ingress only.</p>	<ul style="list-style-type: none"> • family inet • family inet6 • family mpls • family ccc • family bridge • family vpls
log	<p>Log the packet header information in a buffer within the Packet Forwarding Engine. You can access this information by issuing the show firewall log command at the command-line interface (CLI).</p> <p>NOTE: This action is supported on ingress and egress. The action on egress is not supported for family inet6.</p>	<ul style="list-style-type: none"> • family inet • family inet6 • family bridge

Table 51: Nonterminating Actions for Standard Firewall Filters on ACX Series Routers (*continued*)

Nonterminating Action	Description	Protocol Families
loss-priority (high medium-high low)	<p>Set the packet loss priority (PLP) level.</p> <p>You cannot also configure the three-color-policer nonterminating action for the same firewall filter term. These two nonterminating actions are mutually exclusive.</p> <p>You must include the tri-color statement at the [edit class-of-service] hierarchy level to commit a PLP configuration with any of the four levels specified. If the tri-color statement is not enabled, you can configure only the high and low levels. This applies to all protocol families.</p> <p>For information about the tri-color statement, see <i>Configuring and Applying Tricolor Marking Policers</i>. For information about using behavior aggregate (BA) classifiers to set the PLP level of incoming packets, see <i>Understanding How Forwarding Classes Assign Classes to Output Queues</i>.</p> <p>NOTE: This action is supported on ingress only.</p>	<ul style="list-style-type: none"> • family any • family inet • family inet6 • family mpls • family ccc • family bridge • family vpls

Table 51: Nonterminating Actions for Standard Firewall Filters on ACX Series Routers (*continued*)

Nonterminating Action	Description	Protocol Families
policer <i>policer-name</i>	Name of policer to use to rate-limit traffic.	<ul style="list-style-type: none"> • family any • family inet • family inet6 • family mpls • family ccc • family bridge • family vpls
port-mirror	<p>Port-mirror the packet based on the specified family.</p> <p>NOTE: This action is supported on ingress only.</p> <p>ACX5048 and ACX5096 routers do not support port-mirror.</p>	family inet
syslog	<p>Log the packet to the system log file.</p> <p>NOTE: This action is supported on ingress and egress. The action on egress is not supported for family inet6.</p>	<ul style="list-style-type: none"> • family inet • family inet6 • family bridge
three-color-policer (single-rate two-rate) <i>policer-name</i>	<p>Police the packet using the specified single-rate or two-rate three-color policer.</p> <p>You cannot also configure the loss-priority action for the same firewall filter term. These two actions are mutually exclusive.</p>	<ul style="list-style-type: none"> • family any • family inet • family inet6 • family mpls • family ccc • family bridge • family vpls
traffic-class	<p>Set traffic-class code point</p> <p>NOTE: This action is supported on ingress only.</p>	family inet6

Terminating Actions (ACX Series Routers)

Standard stateless firewall filters support different sets of terminating actions for each protocol family.

NOTE: ACX Series routers do not support the **next term** action.

Table 52 on page 832 describes the terminating actions you can specify in a standard firewall filter term.

Table 52: Terminating Actions for Standard Firewall Filters on ACX Series Routers

Terminating Action	Description	Protocols
accept	Accept the packet.	<ul style="list-style-type: none"> • family any • family inet • family mpls • family ccc
discard	Discard a packet silently, without sending an Internet Control Message Protocol (ICMP) message. Discarded packets are available for logging and sampling.	<ul style="list-style-type: none"> • family any • family inet • family mpls • family ccc
reject <i>message-type</i>	<p>Reject the packet and return an ICMPv4 or ICMPv6 message:</p> <ul style="list-style-type: none"> • If no message type is specified, a destination-unreachable message is returned by default. • If tcp-reset is specified as the message type, tcp-reset is returned only if the packet is a TCP packet. Otherwise, the administratively-prohibited message, which has a value of 13, is returned. • If any other message type is specified, that message is returned. <p>NOTE:</p> <ul style="list-style-type: none"> • Rejected packets can be sampled or logged if you configure the sample or syslog action. • This action is supported on ingress only. <p>The <i>message-type</i> option can have one of the following values: address-unreachable, administratively-prohibited, bad-host-tos, bad-network-tos, beyond-scope, fragmentation-needed, host-prohibited, host-unknown, host-unreachable, network-prohibited, network-unknown, network-unreachable, no-route, port-unreachable, precedence-cutoff, precedence-violation, protocol-unreachable, source-host-isolated, source-route-failed, or tcp-reset.</p>	family inet

Firewall Filter Match Conditions for Protocol-Independent Traffic

You can configure a firewall filter with match conditions for protocol-independent traffic (**family any**).

To apply a protocol-independent firewall filter to a logical interface, configure the **filter** statement under the logical unit.

NOTE:

On MX Series routers, attach a protocol-independent firewall filter to a logical interface by configuring the **filter** statement *directly* under the logical unit:

- [edit interfaces *name* unit *number* filter]
- [edit logical-systems *name* interfaces *name* unit *number* filter]

On all other supported devices, attach a protocol-independent firewall filter to a logical interface by configuring the **filter** statement under the protocol family (**family any**):

- [edit interfaces *name* unit *number* family any filter]
- [edit logical-systems *name* interfaces *name* unit *number* family any filter]

Table 53 on page 834 describes the *match-conditions* you can configure at the [edit firewall family any filter *filter-name* term *term-name* from] hierarchy level.

Table 53: Firewall Filter Match Conditions for Protocol-Independent Traffic

Match Condition	Description
forwarding-class <i>class</i>	<p>Match the forwarding class of the packet.</p> <p>Specify assured-forwarding, best-effort, expedited-forwarding, or network-control.</p> <p>For information about forwarding classes and router-internal output queues, see <i>Understanding How Forwarding Classes Assign Classes to Output Queues</i>.</p> <p>NOTE: On T4000 Type 5 FPCs, a filter attached at the Layer 2 application point (that is, at the logical interface level) is unable to match with the forwarding class of a packet that is set by a Layer 3 classifier such as DSCP, DSCP V6, inet-precedence, and mpls-exp.</p>
forwarding-class-except <i>class</i>	<p>Do not match on the forwarding class. For details, see the forwarding-class match condition.</p>
interface <i>interface-name</i>	<p>Match the interface on which the packet was received.</p> <p>NOTE: If you configure this match condition with an interface that does not exist, the term does not match any packet.</p>
interface-set <i>interface-set-name</i>	<p>Match the interface on which the packet was received to the specified interface set.</p> <p>To define an interface set, include the interface-set statement at the [edit firewall] hierarchy level. For more information, see “Filtering Packets Received on an Interface Set Overview” on page 1182.</p>
loss-priority <i>level</i>	<p>Match the packet loss priority (PLP) level.</p> <p>Specify a single level or multiple levels: low, medium-low, medium-high, or high.</p> <p>Supported on M120 and M320 routers; M7i and M10i routers with the Enhanced CFEB (CFEB-E); and MX Series routers.</p> <p>For IP traffic on M320, MX Series, and T Series routers with Enhanced II Flexible PIC Concentrators (FPCs), you must include the tri-color statement at the [edit class-of-service] hierarchy level to commit a PLP configuration with any of the four levels specified. If the tri-color statement is not enabled, you can only configure the high and low levels. This applies to all protocol families.</p> <p>NOTE: This match condition is not supported on PTX series packet transport routers.</p> <p>For information about the tri-color statement, see <i>Configuring and Applying Tricolor Marking Policers</i>. For information about using behavior aggregate (BA) classifiers to set the PLP level of incoming packets, see <i>Understanding How Forwarding Classes Assign Classes to Output Queues</i>.</p>

Table 53: Firewall Filter Match Conditions for Protocol-Independent Traffic (*continued*)

Match Condition	Description
loss-priority-except <i>level</i>	Do not match the PLP level. For details, see the loss-priority match condition. NOTE: This match condition is not supported on PTX series packet transport routers.
packet-length <i>bytes</i>	Match the length of the received packet, in bytes. The length refers only to the IP packet, including the packet header, and does not include any Layer 2 encapsulation overhead. You can also specify a range of values to be matched.
packet-length-except <i>bytes</i>	Do not match on the received packet length, in bytes. For details, see the packet-length match type.

Firewall Filter Match Conditions for IPv4 Traffic

You can configure a firewall filter with match conditions for Internet Protocol version 4 (IPv4) traffic (**family inet**).

NOTE: For MX Series routers with MPCs, you need to initialize certain new firewall filters by walking the corresponding SNMP MIB, for example, **show snmp mib walk *name* ascii**. This forces Junos to learn the filter counters and ensure that the filter statistics are displayed. This guidance applies to all enhanced mode firewall filters, filters with flexible conditions, and filters with the certain terminating actions. See those topics, listed under Related Documentation, for details.

Table 54 on page 836 describes the **match-conditions** you can configure at the **[edit firewall family inet filter *filter-name* term *term-name* from]** hierarchy level.

Table 54: Firewall Filter Match Conditions for IPv4 Traffic

Match Condition	Description
address <i>address</i> [except]	Match the IPv4 source or destination address field unless the except option is included. If the option is included, do not match the IPv4 source or destination address field.
ah-spi <i>spi-value</i>	(M Series routers, except M120 and M320) Match the IPsec authentication header (AH) security parameter index (SPI) value. NOTE: This match condition is not supported on PTX series routers.
ah-spi-except <i>spi-value</i>	(M Series routers, except M120 and M320) Do not match the IPsec AH SPI value. NOTE: This match condition is not supported on PTX series routers.
apply-groups	Specify which groups to inherit configuration data from. You can specify more than one group name. You must list them in order of inheritance priority. The configuration data in the first group takes priority over the data in subsequent groups.
apply-groups-except	Specify which groups not to inherit configuration data from. You can specify more than one group name.
destination-address <i>address</i> [except]	Match the IPv4 destination address field unless the except option is included. If the option is included, do not match the IPv4 destination address field. You cannot specify both the address and destination-address match conditions in the same term.
destination-class <i>class-names</i>	Match one or more specified destination class names (sets of destination prefixes grouped together and given a class name). For more information, see “Firewall Filter Match Conditions Based on Address Classes” on page 881 .
destination-class-except <i>class-names</i>	Do not match one or more specified destination class names. For details, see the destination-class match condition.

Table 54: Firewall Filter Match Conditions for IPv4 Traffic (*continued*)

Match Condition	Description
destination-port <i>number</i>	<p>Match the UDP or TCP destination port field.</p> <p>You cannot specify both the port and destination-port match conditions in the same term.</p> <p>If you configure this match condition, we recommend that you also configure the protocol udp or protocol tcp match statement in the same term to specify which protocol is being used on the port.</p> <p>NOTE: For Junos OS Evolved, you must configure the protocol match statement in the same term.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the port numbers are also listed): afs (1483), bgp (179), biff (512), bootpc (68), bootps (67), cmd (514), cvspserver (2401), dhcp (67), domain (53), eklogin (2105), ekshell (2106), exec (512), finger (79), ftp (21), ftp-data (20), http (80), https (443), ident (113), imap (143), kerberos-sec (88), klogin (543), kpasswd (761), krb-prop (754), krbupdate (760), kshell (544), ldap (389), ldp (646), login (513), mobileip-agent (434), mobileip-mn (435), msdp (639), netbios-dgm (138), netbios-ns (137), netbios-ssn (139), nfsd (2049), nntp (119), ntalk (518), ntp (123), pop3 (110), pptp (1723), printer (515), radacct (1813), radius (1812), rip (520), rkinit (2108), smtp (25), snmp (161), snmptrap (162), snpp (444), socks (1080), ssh (22), sunrpc (111), syslog (514), tacacs (49), tacacs-ds (65), talk (517), telnet (23), tftp (69), timed (525), who (513), or xdmcp (177).</p>
destination-port-except <i>number</i>	<p>Do not match the UDP or TCP destination port field. For details, see the destination-port match condition.</p>
destination-prefix-list <i>name</i> [<i>except</i>]	<p>Match destination prefixes in the specified list unless the except option is included. If the option is included, do not match the destination prefixes in the specified list.</p> <p>Specify the name of a prefix list defined at the [edit policy-options prefix-list <i>prefix-list-name</i>] hierarchy level.</p>

Table 54: Firewall Filter Match Conditions for IPv4 Traffic (*continued*)

Match Condition	Description
dscp number	<p>Match the Differentiated Services code point (DSCP). The DiffServ protocol uses the type-of-service (ToS) byte in the IP header. The most significant 6 bits of this byte form the DSCP. For more information, see <i>Understanding How Behavior Aggregate Classifiers Prioritize Trusted Traffic</i>.</p> <p>Support was added for filtering on Differentiated Services Code Point (DSCP) and forwarding class for Routing Engine sourced packets, including IS-IS packets encapsulated in generic routing encapsulation (GRE). Subsequently, when upgrading from a previous version of Junos OS where you have both a class of service (CoS) and firewall filter, and both include DSCP or forwarding class filter actions, the criteria in the firewall filter automatically takes precedence over the CoS settings. The same is true when creating new configurations; that is, where the same settings exist, the firewall filter takes precedence over the CoS, regardless of which was created first.</p> <p>You can specify a numeric value from 0 through 63. To specify the value in hexadecimal form, include 0x as a prefix. To specify the value in binary form, include b as a prefix.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed):</p> <ul style="list-style-type: none"> • RFC 3246, <i>An Expedited Forwarding PHB (Per-Hop Behavior)</i>, defines one code point: ef (46). • RFC 2597, <i>Assured Forwarding PHB Group</i>, defines 4 classes, with 3 drop precedences in each class, for a total of 12 code points: <ul style="list-style-type: none"> • af11 (10), af12 (12), af13 (14) • af21 (18), af22 (20), af23 (22) • af31 (26), af32 (28), af33 (30) • af41 (34), af42 (36), af43 (38)
dscp-except number	Do not match on the DSCP number. For more information, see the dscp match condition.
esp-spi spi-value	<p>Match the IPsec encapsulating security payload (ESP) SPI value. Match on this specific SPI value. You can specify the ESP SPI value in hexadecimal, binary, or decimal form.</p> <p>NOTE: This match condition is not supported on PTX series routers.</p>
esp-spi-except spi-value	<p>Match the IPsec ESP SPI value. Do not match on this specific SPI value.</p> <p>NOTE: This match condition is not supported on PTX series routers.</p>

Table 54: Firewall Filter Match Conditions for IPv4 Traffic (*continued*)

Match Condition	Description	
first-fragment	<p>Match if the packet is the first fragment of a fragmented packet. Do not match if the packet is a trailing fragment of a fragmented packet. The first fragment of a fragmented packet has a fragment offset value of 0.</p> <p>This match condition is an alias for the bit-field match condition fragment-offset 0 match condition.</p> <p>To match both first and trailing fragments, you can use two terms that specify different match conditions: first-fragment and is-fragment.</p>	
flexible-match-mask <i>value</i>	bit-length	Length of the data to be matched in bits, not needed for string input (0..128)
	bit-offset	Bit offset after the (match-start + byte) offset (0..7)
	byte-offset	Byte offset after the match start point
	flexible-mask-name	Select a flexible match from predefined template field
	mask-in-hex	Mask out bits in the packet data to be matched
	match-start	Start point to match in packet
	prefix	Value data/string to be matched

Table 54: Firewall Filter Match Conditions for IPv4 Traffic (*continued*)

Match Condition	Description	
flexible-match-range <i>value</i>	bit-length	Length of the data to be matched in bits (0..32)
	bit-offset	Bit offset after the (match-start + byte) offset (0..7)
	byte-offset	Byte offset after the match start point
	flexible-range-name	Select a flexible match from predefined template field
	match-start	Start point to match in packet
	range	Range of values to be matched
	range-except	Do not match this range of values
forwarding-class <i>class</i>	<p>Match the forwarding class of the packet.</p> <p>Specify assured-forwarding, best-effort, expedited-forwarding, or network-control.</p> <p>For information about forwarding classes and router-internal output queues, see <i>Understanding How Forwarding Classes Assign Classes to Output Queues</i>.</p>	
forwarding-class-except <i>class</i>	Do not match the forwarding class of the packet. For details, see the forwarding-class match condition.	
fragment-flags <i>number</i>	<p>(Ingress only) Match the three-bit IP fragmentation flags field in the IP header.</p> <p>In place of the numeric field value, you can specify one of the following keywords (the field values are also listed): dont-fragment (0x4), more-fragments (0x2), or reserved (0x8).</p>	
fragment-offset <i>value</i>	<p>Match the 13-bit fragment offset field in the IP header. The value is the offset, in 8-byte units, in the overall datagram message to the data fragment. Specify a numeric value, a range of values, or a set of values. An offset value of 0 indicates the first fragment of a fragmented packet.</p> <p>The first-fragment match condition is an alias for the fragment-offset 0 match condition.</p> <p>To match both first and trailing fragments, you can use two terms that specify different match conditions (first-fragment and is-fragment).</p>	

Table 54: Firewall Filter Match Conditions for IPv4 Traffic (*continued*)

Match Condition	Description
fragment-offset-except number	Do not match the 13-bit fragment offset field.
gre-key range	<p>Match the gre-key field. The GRE key field is a 4 octet number inserted by the GRE encapsulator. It is an optional field for use in GRE encapsulation. The <i>range</i> can be a single GRE key number or a range of key numbers.</p> <p>For MX Series routers with MPCs, initialize new firewall filters that include this condition by walking the corresponding SNMP MIB.</p>

Table 54: Firewall Filter Match Conditions for IPv4 Traffic (*continued*)

Match Condition	Description
icmp-code <i>number</i>	<p>Match the ICMP message code field.</p> <p>NOTE: When using this match condition, you should also use the protocol icmp match condition in the same term (as shown below) to ensure that icmp packets are being evaluated.</p> <pre>term Allow _ICMP { from protocol icmp { icmp-code ip-header-bad; icmp-type echo-reply; } then { policer ICMP_Policier; count Allow_ICMP; } }</pre> <p>You must also configure the icmp-type <i>message-type</i> match condition in the same term. An ICMP message code provides more specific information than an ICMP message type, but the meaning of an ICMP message code is dependent on the associated ICMP message type.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed). The keywords are grouped by the ICMP type with which they are associated:</p> <ul style="list-style-type: none"> • parameter-problem: ip-header-bad (0), required-option-missing (1) • redirect: redirect-for-host (1), redirect-for-network (0), redirect-for-tos-and-host (3), redirect-for-tos-and-net (2) • time-exceeded: ttl-eq-zero-during-reassembly (1), ttl-eq-zero-during-transit (0) • unreachable: communication-prohibited-by-filtering (13), destination-host-prohibited (10), destination-host-unknown (7), destination-network-prohibited (9), destination-network-unknown (6), fragmentation-needed (4), host-precedence-violation (14), host-unreachable (1), host-unreachable-for-TOS (12), network-unreachable (0), network-unreachable-for-TOS (11), port-unreachable (3), precedence-cutoff-in-effect (15), protocol-unreachable (2), source-host-isolated (8), source-route-failed (5)
icmp-code-except <i>message-code</i>	<p>Do not match the ICMP message code field. For details, see the icmp-code match condition.</p>

Table 54: Firewall Filter Match Conditions for IPv4 Traffic (*continued*)

Match Condition	Description
icmp-type <i>number</i>	<p>Match the ICMP message type field.</p> <p>NOTE: When using this match condition, you should also use the protocol icmp match condition in the same term (as shown below) to ensure that icmp packets are being evaluated.</p> <pre>term Allow _ICMP { from protocol icmp { icmp-code ip-header-bad; icmp-type echo-reply; } then { policer ICMP_Policier; count Allow_ICMP; } }</pre> <p>You must also configure the icmp-type message-type match condition in the same term. An ICMP message code provides more specific information than an ICMP message type, but the meaning of an ICMP message code is dependent on the associated ICMP message type.</p> <p>NOTE: For Junos OS Evolved, you must configure the protocol match statement in the same term.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): echo-reply (0), echo-request (8), info-reply (16), info-request (15), mask-request (17), mask-reply (18), parameter-problem (12), redirect (5), router-advertisement (9), router-solicit (10), source-quench (4), time-exceeded (11), timestamp (13), timestamp-reply (14), or unreachable (3).</p>
icmp-type-except message-type	Do not match the ICMP message type field. For details, see the icmp-type match condition.
interface <i>interface-name</i>	<p>Match the interface on which the packet was received.</p> <p>NOTE: If you configure this match condition with an interface that does not exist, the term does not match any packet.</p>

Table 54: Firewall Filter Match Conditions for IPv4 Traffic (*continued*)

Match Condition	Description
interface-group <i>group-number</i>	<p>Match the logical interface on which the packet was received to the specified interface group or set of interface groups. For <i>group-number</i>, specify a single value or a range of values from 0 through 255.</p> <p>To assign a logical interface to an interface group <i>group-number</i>, specify the <i>group-number</i> at the [interfaces <i>interface-name</i> unit <i>number</i> family <i>family</i> filter group] hierarchy level.</p> <p>NOTE: This match condition is not supported on PTX series routers.</p> <p>For more information, see “Filtering Packets Received on a Set of Interface Groups Overview” on page 1181.</p>
interface-group-except <i>group-number</i>	<p>Do not match the logical interface on which the packet was received to the specified interface group or set of interface groups. For details, see the interface-group match condition.</p> <p>NOTE: This match condition is not supported on PTX series routers.</p>
interface-set <i>interface-set-name</i>	<p>Match the interface on which the packet was received to the specified interface set.</p> <p>To define an interface set, include the interface-set statement at the [edit firewall] hierarchy level.</p> <p>NOTE: This match condition is not supported on PTX series routers.</p> <p>For more information, see “Filtering Packets Received on an Interface Set Overview” on page 1182.</p>

Table 54: Firewall Filter Match Conditions for IPv4 Traffic (*continued*)

Match Condition	Description
ip-options values	<p>Match the 8-bit IP option field, if present, to the specified value or list of values.</p> <p>In place of a numeric value, you can specify one of the following text synonyms (the option values are also listed): loose-source-route (131), record-route (7), router-alert (148), security (130), stream-id (136), strict-source-route (137), or timestamp (68).</p> <p>To match <i>any</i> value for the IP option, use the text synonym any. To match on <i>multiple</i> values, specify the list of values within square brackets ('[' and ']'). To match a <i>range</i> of values, use the value specification [value1-value2].</p> <p>For example, the match condition ip-options [0-147] matches on an IP options field that contains the loose-source-route, record-route, or security values, or any other value from 0 through 147. However, this match condition does not match on an IP options field that contains only the router-alert value (148).</p> <p>For most interfaces, a filter term that specifies an ip-option match on one or more <i>specific</i> IP option values (a value other than any) causes packets to be sent to the Routing Engine so that the kernel can parse the IP option field in the packet header.</p> <ul style="list-style-type: none"> For a firewall filter term that specifies an ip-option match on one or more specific IP option values, you cannot specify the count, log, or syslog nonterminating actions <i>unless</i> you also specify the discard terminating action in the same term. This behavior prevents double-counting of packets for a filter applied to a transit interface on the router. Packets processed on the kernel might be dropped in case of a system bottleneck. To ensure that matched packets are instead sent to the Packet Forwarding Engine (where packet processing is implemented in hardware), use the ip-options any match condition. <p>The 10-Gigabit Ethernet Modular Port Concentrator (MPC), 100-Gigabit Ethernet MPC, 60-Gigabit Ethernet MPC, 60-Gigabit Queuing Ethernet MPC, and 60-Gigabit Ethernet Enhanced Queuing MPC on MX Series routers are capable of parsing the IP option field of the IPv4 packet header. For interfaces configured on those MPCs, <i>all</i> packets that are matched using the ip-options match condition are sent to the Packet Forwarding Engine for processing.</p> <p>NOTE: On M and T series routers, firewall filters cannot count ip-options packets on a per option type and per interface basis. A limited work around is to use the show pfe statistics ip options command to see ip-options statistics on a per PFE basis. See <i>show pfe statistics ip</i> for sample output.</p>
ip-options-except values	Do not match the IP option field to the specified value or list of values. For details about specifying the values , see the ip-options match condition.

Table 54: Firewall Filter Match Conditions for IPv4 Traffic (*continued*)

Match Condition	Description
is-fragment	<p>Match if the packet is a trailing fragment of a fragmented packet. Do not match the first fragment of a fragmented packet.</p> <p>NOTE: To match both first and trailing fragments, you can use two terms that specify different match conditions (first-fragment and is-fragment).</p>
loss-priority level	<p>Match the packet loss priority (PLP) level.</p> <p>Specify a single level or multiple levels: low, medium-low, medium-high, or high.</p> <p>Supported on M120 and M320 routers; M7i and M10i routers with the Enhanced CFEB (CFEB-E); and MX Series routers.</p> <p>For IP traffic on M320, MX Series, and T Series routers with Enhanced II Flexible PIC Concentrators (FPCs), you must include the tri-color statement at the [edit class-of-service] hierarchy level to commit a PLP configuration with any of the four levels specified. If the tri-color statement is not enabled, you can only configure the high and low levels. This applies to all protocol families.</p> <p>For information about the tri-color statement, see <i>Configuring and Applying Tricolor Marking Policies</i>. For information about using behavior aggregate (BA) classifiers to set the PLP level of incoming packets, see <i>Understanding How Behavior Aggregate Classifiers Prioritize Trusted Traffic</i>.</p>
loss-priority-except level	Do not match the PLP level. For details, see the loss-priority match condition.
packet-length bytes	<p>Match the length of the received packet, in bytes. The length refers only to the IP packet, including the packet header, and does not include any Layer 2 encapsulation overhead. You can also specify a range of values to be matched.</p>
packet-length-except bytes	Do not match the length of the received packet, in bytes. For details, see the packet-length match type.

Table 54: Firewall Filter Match Conditions for IPv4 Traffic (*continued*)

Match Condition	Description
port number	<p>Match the UDP or TCP source or destination port field.</p> <p>If you configure this match condition, you cannot configure the destination-port match condition or the source-port match condition in the same term.</p> <p>If you configure this match condition, we recommend that you also configure the protocol udp or protocol tcp match statement in the same term to specify which protocol is being used on the port.</p> <p>NOTE: For Junos OS Evolved, you must configure the protocol match statement in the same term.</p> <p>In place of the numeric value, you can specify one of the text synonyms listed under destination-port.</p>
port-except number	Do not match either the source or destination UDP or TCP port field. For details, see the port match condition.
precedence ip-precedence-value	<p>Match the IP precedence field.</p> <p>In place of the numeric field value, you can specify one of the following text synonyms (the field values are also listed): critical-ecp (0xa0), flash (0x60), flash-override (0x80), immediate (0x40), internet-control (0xc0), net-control (0xe0), priority (0x20), or routine (0x00). You can specify precedence in hexadecimal, binary, or decimal form.</p>
precedence-except ip-precedence-value	<p>Do not match the IP precedence field.</p> <p>In place of the numeric field value, you can specify one of the following text synonyms (the field values are also listed): critical-ecp (0xa0), flash (0x60), flash-override (0x80), immediate (0x40), internet-control (0xc0), net-control (0xe0), priority (0x20), or routine (0x00). You can specify precedence in hexadecimal, binary, or decimal form.</p>
prefix-list name [except]	<p>Match the prefixes of the source or destination address fields to the prefixes in the specified list unless the except option is included. If the option is included, do not match the prefixes of the source or destination address fields to the prefixes in the specified list.</p> <p>The prefix list is defined at the [edit policy-options prefix-list prefix-list-name] hierarchy level.</p> <p>NOTE: This match condition is not supported on PTX1000 routers.</p>
protocol number	Match the IP protocol type field. In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): ah (51), dstopts (60), egp (8), esp (50), fragment (44), gre (47), hop-by-hop (0), icmp (1), icmp6 (58), icmpv6 (58), igmp (2), ipip (4), ipv6 (41), ospf (89), pim (103), rsvp (46), sctp (132), tcp (6), udp (17), or vrp (112).

Table 54: Firewall Filter Match Conditions for IPv4 Traffic (*continued*)

Match Condition	Description
protocol-except <i>number</i>	Do not match the IP protocol type field. In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): ah (51), dstop (60), egp (8), esp (50), fragment (44), gre (47), hop-by-hop (0), icmp (1), icmp6 (58), icmpv6 (58), igmp (2), ipip (4), ipv6 (41), ospf (89), pim (103), rsvp (46), sctp (132), tcp (6), udp (17), or vrp (112).
rat-type <i>tech-type-value</i>	<p>Match the radio-access technology (RAT) type specified in the 8-bit Tech-Type field of Proxy Mobile IPv4 (PMIPv4) access technology type extension. The technology type specifies the access technology through which the mobile device is connected to the access network.</p> <p>Specify a single value, a range of values, or a set of values. You can specify a technology type as a numeric value from 0 through 255 or as a system keyword.</p> <ul style="list-style-type: none"> • The following numeric values are examples of well-known technology types: <ul style="list-style-type: none"> • Numeric value 1 matches IEEE 802.3. • Numeric value 2 matches IEEE 802.11a/b/g. • Numeric value 3 matches IEEE 802.16e • Numeric value 4 matches IEEE 802.16m. • Text string eutran matches 4G. • Text string geran matches 2G. • Text string utran matches 3G.
rat-type-except <i>tech-type-value</i>	Do not match the RAT Type.
service-filter-hit	<p>Match a packet received from a filter where a service-filter-hit action was applied.</p> <p>NOTE: This match condition is not supported on PTX series routers.</p>
source-address <i>address</i> [except]	<p>Match the IPv4 address of the source node sending the packet unless the except option is included. If the option is included, do not match the IPv4 address of the source node sending the packet.</p> <p>You cannot specify both the address and source-address match conditions in the same term.</p>
source-class <i>class-names</i>	Match one or more specified source class names (sets of source prefixes grouped together and given a class name). For more information, see “Firewall Filter Match Conditions Based on Address Classes” on page 881 .

Table 54: Firewall Filter Match Conditions for IPv4 Traffic (*continued*)

Match Condition	Description
source-class-except <i>class-names</i>	Do not match one or more specified source class names. For details, see the source-class match condition.
source-port <i>number</i>	<p>Match the UDP or TCP source port field.</p> <p>You cannot specify the port and source-port match conditions in the same term.</p> <p>If you configure this match condition for IPv4 traffic, we recommend that you also configure the protocol udp or protocol tcp match statement in the same term to specify which protocol is being used on the port.</p> <p>NOTE: For Junos OS Evolved, you must configure the protocol match statement in the same term.</p> <p>In place of the numeric value, you can specify one of the text synonyms listed with the destination-port <i>number</i> match condition.</p>
source-port-except <i>number</i>	Do not match the UDP or TCP source port field. For details, see the source-port match condition.
source-prefix-list <i>name</i> [except]	<p>Match source prefixes in the specified list unless the except option is included. If the option is included, do not match the source prefixes in the specified list.</p> <p>Specify the name of a prefix list defined at the [edit policy-options prefix-list <i>prefix-list-name</i>] hierarchy level.</p>
tcp-established	<p>Match TCP packets of an established TCP session (packets other than the first packet of a connection). This is an alias for tcp-flags "(ack rst)".</p> <p>This match condition does not implicitly check that the protocol is TCP. To check this, specify the protocol tcp match condition.</p>

Table 54: Firewall Filter Match Conditions for IPv4 Traffic (*continued*)

Match Condition	Description
tcp-flags value	<p>Match one or more of the low-order 6 bits in the 8-bit TCP flags field in the TCP header.</p> <p>To specify individual bit fields, you can specify the following text synonyms or hexadecimal values:</p> <ul style="list-style-type: none"> • fin (0x01) • syn (0x02) • rst (0x04) • push (0x08) • ack (0x10) • urgent (0x20) <p>In a TCP session, the SYN flag is set only in the initial packet sent, while the ACK flag is set in all packets sent after the initial packet.</p> <p>You can string together multiple flags using the bit-field logical operators.</p> <p>For combined bit-field match conditions, see the tcp-established and tcp-initial match conditions.</p> <p>If you configure this match condition, we recommend that you also configure the protocol tcp match statement in the same term to specify that the TCP protocol is being used on the port.</p> <p>For IPv4 traffic only, this match condition does not implicitly check whether the datagram contains the first fragment of a fragmented packet. To check for this condition for IPv4 traffic only, use the first-fragment match condition.</p>
tcp-initial	<p>Match the initial packet of a TCP connection. This is an alias for tcp-flags "(!ack & syn)".</p> <p>This condition does not implicitly check that the protocol is TCP. If you configure this match condition, we recommend that you also configure the protocol tcp match condition in the same term.</p>
ttl number	<p>Match the IPv4 time-to-live number. Specify a TTL value or a range of TTL values. For number, you can specify one or more values from 0 through 255. This match condition is supported only on M120, M320, MX Series, and T Series routers.</p>
ttl-except number	<p>Do not match on the IPv4 TTL number. For details, see the ttl match condition.</p>

Release History Table

Release	Description
13.3R7	Support was added for filtering on Differentiated Services Code Point (DSCP) and forwarding class for Routing Engine sourced packets, including IS-IS packets encapsulated in generic routing encapsulation (GRE).

Firewall Filter Match Conditions for IPv6 Traffic

You can configure a firewall filter with match conditions for Internet Protocol version 6 (IPv6) traffic (**family inet6**).

NOTE: For MX Series routers with MPCs, you need to initialize certain new firewall filters by walking the corresponding SNMP MIB, for example, **show snmp mib walk name ascii**. This forces Junos to learn the filter counters and ensure that the filter statistics are displayed. This guidance applies to all enhanced mode firewall filters, filters with flexible conditions, and filters with the certain terminating actions. See those topics, listed under Related Documentation, for details.

[Table 49 on page 822](#) describes the match conditions you can configure at the **[edit firewall family inet6 filter filter-name term term-name from]** hierarchy level.

Table 55: Firewall Filter Match Conditions for IPv6 Traffic

Match Condition	Description
address address [except]	Match the IPv6 source or destination address field unless the except option is included. If the option is included, do not match the IPv6 source or destination address field.

Table 55: Firewall Filter Match Conditions for IPv6 Traffic (*continued*)

Match Condition	Description
apply-groups	Specify which groups to inherit configuration data from. You can specify more than one group name. You must list them in order of inheritance priority. The configuration data in the first group takes priority over the data in subsequent groups.
apply-groups-except	Specify which groups not to inherit configuration data from. You can specify more than one group name.
destination-address address [except]	<p>Match the IPv6 destination address field unless the except option is included. If the option is included, do not match the IPv6 destination address field.</p> <p>You cannot specify both the address and destination-address match conditions in the same term.</p>
destination-class class-names	<p>Match one or more specified destination class names (sets of destination prefixes grouped together and given a class name).</p> <p>For more information, see “Firewall Filter Match Conditions Based on Address Classes” on page 881.</p>
destination-class-except class-names	Do not match one or more specified destination class names. For details, see the destination-class match condition.
destination-port number	<p>Match the UDP or TCP destination port field.</p> <p>You cannot specify both the port and destination-port match conditions in the same term.</p> <p>If you configure this match condition, we recommend that you also configure the next-header udp or next-header tcp match condition in the same term to specify which protocol is being used on the port.</p> <p>NOTE: For Junos OS Evolved, you must configure the protocol match statement in the same term.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the port numbers are also listed): afs (1483), bgp (179), biff (512), bootpc (68), bootps (67), cmd (514), cvspserver (2401), dhcp (67), domain (53), eklogin (2105), ekshell (2106), exec (512), finger (79), ftp (21), ftp-data (20), http (80), https (443), ident (113), imap (143), kerberos-sec (88), klogin (543), kpasswd (761), krb-prop (754), krbupdate (760), kshell (544), ldap (389), ldp (646), login (513), mobileip-agent (434), mobileip-mn (435), msdp (639), netbios-dgm (138), netbios-ns (137), netbios-ssn (139), nfsd (2049), nntp (119), ntalk (518), ntp (123), pop3 (110), pptp (1723), printer (515), radacct (1813), radius (1812), rip (520), rkinit (2108), smtp (25), snmp (161), snmptrap (162), snpp (444), socks (1080), ssh (22), sunrpc (111), syslog (514), tacacs (49), tacacs-ds (65), talk (517), telnet (23), tfpt (69), timed (525), who (513), or xdmcp (177).</p>

Table 55: Firewall Filter Match Conditions for IPv6 Traffic (*continued*)

Match Condition	Description
destination-port-except number	Do not match the UDP or TCP destination port field. For details, see the destination-port match condition.
destination-prefix-list prefix-list-name [except]	<p>Match the IPv6 destination prefix to the specified list unless the except option is included. If the option is included, do not match the IPv6 destination prefix to the specified list.</p> <p>The prefix list is defined at the [edit policy-options prefix-list prefix-list-name] hierarchy level.</p>
extension-headers header-type	<p>Match an extension header type that is contained in the packet by identifying a Next Header value.</p> <p>NOTE: This match condition is only supported on MPCs in MX Series routers.</p> <p>In the first fragment of a packet, the filter searches for a match in any of the extension header types. When a packet with a fragment header is found (a subsequent fragment), the filter only searches for a match of the next extension header type because the location of other extension headers is unpredictable.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): ah (51), destination (60), esp (50), fragment (44), hop-by-hop (0), mobility (135), or routing (43).</p> <p>To match <i>any</i> value for the extension header option, use the text synonym any.</p> <p>For MX Series routers with MPCs, initialize new firewall filters that include this condition by walking the corresponding SNMP MIB.</p>
first-fragment	Match if the packet is the first fragment.
extension-headers-except header-type	<p>Do not match an extension header type that is contained in the packet. For details, see the extension-headers match condition.</p> <p>NOTE: This match condition is only supported on MPCs in MX Series routers.</p>

Table 55: Firewall Filter Match Conditions for IPv6 Traffic (*continued*)

Match Condition	Description	
flexible-match-mask <i>value</i>	bit-length	Length of integer input (1..32 bits); (Optional) Length of string input (1..128 bits)
	bit-offset	Bit offset after the (match-start + byte) offset (0..7)
	byte-offset	Byte offset after the match start point
	flexible-mask-name	Select a flexible match from predefined template field
	mask-in-hex	Mask out bits in the packet data to be matched
	match-start	Start point to match in packet
	prefix	Value data/string to be matched
	See “Firewall Filter Flexible Match Conditions” on page 777 for details	
flexible-match-range <i>value</i> Ranges should use the following format: <i>Integer-Integer</i>	bit-length	Length of the data to be matched in bits (0..32)
	bit-offset	Bit offset after the (match-start + byte) offset (0..7)
	byte-offset	Byte offset after the match start point
	flexible-range-name	Select a flexible match from predefined template field
	match-start	Start point to match in packet
	range	Range of values to be matched
	range-except	Do not match this range of values
	See “Firewall Filter Flexible Match Conditions” on page 777 for details	
forwarding-class <i>class</i>	<p>Match the forwarding class of the packet.</p> <p>Specify assured-forwarding, best-effort, expedited-forwarding, or network-control.</p> <p>For information about forwarding classes and router-internal output queues, see <i>Understanding How Forwarding Classes Assign Classes to Output Queues</i>.</p>	

Table 55: Firewall Filter Match Conditions for IPv6 Traffic (*continued*)

Match Condition	Description
forwarding-class-except class	Do not match the forwarding class of the packet. For details, see the forwarding-class match condition.
hop-limit hop-limit	<p>Match the hop limit to the specified hop limit or set of hop limits. For hop-limit, specify a single value or a range of values from 0 through 255.</p> <p>Supported on interfaces hosted on MICs or MPCs in MX Series routers only.</p> <p>NOTE: This match condition is supported on PTX series routers when enhanced-mode is configured on the router.</p>
hop-limit-except hop-limit	<p>Do not match the hop limit to the specified hop limit or set of hop limits. For details, see the hop-limit match condition.</p> <p>Supported on interfaces hosted on MICs or MPCs in MX Series routers only.</p> <p>NOTE: This match condition is supported on PTX series routers when enhanced-mode is configured on the router.</p>
icmp-code message-code	<p>Match the ICMP message code field.</p> <p>If you configure this match condition, we recommend that you also configure the next-header icmp or next-header icmp6 match condition in the same term.</p> <p>If you configure this match condition, you must also configure the icmp-type message-type match condition in the same term. An ICMP message code provides more specific information than an ICMP message type, but the meaning of an ICMP message code is dependent on the associated ICMP message type.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed). The keywords are grouped by the ICMP type with which they are associated:</p> <ul style="list-style-type: none"> parameter-problem: ip6-header-bad (0), unrecognized-next-header (1), unrecognized-option (2) time-exceeded: ttl-eq-zero-during-reassembly (1), ttl-eq-zero-during-transit (0) destination-unreachable: administratively-prohibited (1), address-unreachable (3), no-route-to-destination (0), port-unreachable (4)
icmp-code-except message-code	Do not match the ICMP message code field. For details, see the icmp-code match condition.

Table 55: Firewall Filter Match Conditions for IPv6 Traffic (*continued*)

Match Condition	Description
icmp-type <i>message-type</i>	<p>Match the ICMP message type field.</p> <p>If you configure this match condition, we recommend that you also configure the next-header icmp or next-header icmp6 match condition in the same term.</p> <p>NOTE: For Junos OS Evolved, you must configure the protocol match statement in the same term.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): certificate-path-advertisement (149), certificate-path-solicitation (148), destination-unreachable (1), echo-reply (129), echo-request (128), home-agent-address-discovery-reply (145), home-agent-address-discovery-request (144), inverse-neighbor-discovery-advertisement (142), inverse-neighbor-discovery-solicitation (141), membership-query (130), membership-report (131), membership-termination (132), mobile-prefix-advertisement-reply (147), mobile-prefix-solicitation (146), neighbor-advertisement (136), neighbor-solicit (135), node-information-reply (140), node-information-request (139), packet-too-big (2), parameter-problem (4), private-experimentation-100 (100), private-experimentation-101 (101), private-experimentation-200 (200), private-experimentation-201 (201), redirect (137), router-advertisement (134), router-renumbering (138), router-solicit (133), or time-exceeded (3).</p> <p>For private-experimentation-201 (201), you can also specify a range of values within square brackets.</p>
icmp-type-except <i>message-type</i>	Do not match the ICMP message type field. For details, see the icmp-type match condition.
interface <i>interface-name</i>	<p>Match the interface on which the packet was received.</p> <p>NOTE: If you configure this match condition with an interface that does not exist, the term does not match any packet.</p>
interface-group <i>group-number</i>	<p>Match the logical interface on which the packet was received to the specified interface group or set of interface groups. For group-number, specify a single value or a range of values from 0 through 255.</p> <p>To assign a logical interface to an interface group group-number, specify the group-number at the [interfaces <i>interface-name</i> unit <i>number</i> family <i>family</i> filter group] hierarchy level.</p> <p>For more information, see “Filtering Packets Received on a Set of Interface Groups Overview” on page 1181.</p>

Table 55: Firewall Filter Match Conditions for IPv6 Traffic (*continued*)

Match Condition	Description
interface-group-except <i>group-number</i>	Do not match the logical interface on which the packet was received to the specified interface group or set of interface groups. For details, see the interface-group match condition.
interface-set <i>interface-set-name</i>	<p>Match the interface on which the packet was received to the specified interface set.</p> <p>To define an interface set, include the interface-set statement at the [edit firewall] hierarchy level.</p> <p>For more information, see “Filtering Packets Received on an Interface Set Overview” on page 1182.</p>

Table 55: Firewall Filter Match Conditions for IPv6 Traffic (*continued*)

Match Condition	Description	
ip-options values	<p>Match the 8-bit IP option field, if present, to the specified value or list of values.</p> <p>In place of a numeric value, you can specify one of the following text synonyms (the option values are also listed): loose-source-route (131), record-route (7), router-alert (148), security (130), stream-id (136), strict-source-route (137), or timestamp (68).</p> <p>To match <i>any</i> value for the IP option, use the text synonym any. To match on <i>multiple</i> values, specify the list of values within square brackets ('[' and ']'). To match a <i>range</i> of values, use the value specification [value1-value2].</p> <p>For example, the match condition ip-options [0-147] matches on an IP options field that contains the loose-source-route, record-route, or security values, or any other value from 0 through 147. However, this match condition does not match on an IP options field that contains only the router-alert value (148).</p> <p>For most interfaces, a filter term that specifies an ip-option match on one or more <i>specific</i> IP option values (a value other than any) causes packets to be sent to the Routing Engine so that the kernel can parse the IP option field in the packet header.</p> <ul style="list-style-type: none"> For a firewall filter term that specifies an ip-option match on one or more specific IP option values, you cannot specify the count, log, or syslog nonterminating actions <i>unless</i> you also specify the discard terminating action in the same term. This behavior prevents double-counting of packets for a filter applied to a transit interface on the router. Packets processed on the kernel might be dropped in case of a system bottleneck. To ensure that matched packets are instead sent to the Packet Forwarding Engine (where packet processing is implemented in hardware), use the ip-options any match condition. <p>The 10-Gigabit Ethernet Modular Port Concentrator (MPC), 100-Gigabit Ethernet MPC, 60-Gigabit Ethernet MPC, 60-Gigabit Queuing Ethernet MPC, and 60-Gigabit Ethernet Enhanced Queuing MPC on MX Series routers are capable of parsing the IP option field of the IPv4 packet header. For interfaces configured on those MPCs, <i>all</i> packets that are matched using the ip-options match condition are sent to the Packet Forwarding Engine for processing.</p>	
ip-options-except values	Do not match the IP option field to the specified value or list of values. For details about specifying the values , see the ip-options match condition.	
is-fragment	Match if the packet is a fragment.	
last-fragment	Match if the packet is the last fragment.	

Table 55: Firewall Filter Match Conditions for IPv6 Traffic (*continued*)

Match Condition	Description
loss-priority level	<p>Match the packet loss priority (PLP) level.</p> <p>Specify a single level or multiple levels: low, medium-low, medium-high, or high.</p> <p>Supported on M120 and M320 routers; M7i and M10i routers with the Enhanced CFEB (CFEB-E); and MX Series routers and EX Series switches.</p> <p>For IP traffic on M320, MX Series, T Series routers and EX Series switches with Enhanced II Flexible PIC Concentrators (FPCs), you must include the tri-color statement at the [edit class-of-service] hierarchy level to commit a PLP configuration with any of the four levels specified. If the tri-color statement is not enabled, you can only configure the high and low levels. This applies to all protocol families.</p> <p>For information about the tri-color statement, see <i>Configuring and Applying Tricolor Marking Policies</i>. For information about using behavior aggregate (BA) classifiers to set the PLP level of incoming packets, see <i>Understanding How Forwarding Classes Assign Classes to Output Queues</i>.</p>
loss-priority-except level	Do not match the PLP level. For details, see the loss-priority match condition.
next-header header-type	<p>Match the first 8-bit Next Header field in the packet. Support for the next-header firewall match condition is available in Junos OS Release 13.3R6 and later.</p> <p>For IPv6, we recommend that you use the payload-protocol term rather than the next-header term when configuring a firewall filter with match conditions. Although either can be used, payload-protocol provides the more reliable match condition because it uses the actual payload protocol to find a match, whereas next-header simply takes whatever appears in the first header following the IPv6 header, which may or may not be the actual protocol. In addition, if next-header is used with IPv6, the accelerated filter block lookup process is bypassed and the standard filter used instead.</p> <p>Match the first 8-bit Next Header field in the packet.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): ah (51), dstops (60), egp (8), esp (50), fragment (44), gre (47), hop-by-hop (0), icmp (1), icmp6 (58), icmpv6 (58), igmp (2), ipip (4), ipv6 (41), mobility (135), no-next-header (59), ospf (89), pim (103), routing (43), rsvp (46), sctp (132), tcp (6), udp (17), or vrp (112).</p> <p>NOTE: next-header icmp6 and next-header icmpv6 match conditions perform the same function. next-header icmp6 is the preferred option. next-header icmpv6 is hidden in the Junos OS CLI.</p>
next-header-except header-type	Do not match the 8-bit Next Header field that identifies the type of header between the IPv6 header and payload. For details, see the next-header match type.

Table 55: Firewall Filter Match Conditions for IPv6 Traffic (*continued*)

Match Condition	Description
packet-length bytes	Match the length of the received packet, in bytes. The length refers only to the IP packet, including the packet header, and does not include any Layer 2 encapsulation overhead.
packet-length-except bytes	Do not match the length of the received packet, in bytes. For details, see the packet-length match type.
payload-protocol protocol-type	<p>Match the payload protocol type.</p> <p>In place of the protocol-type numeric value, you can specify one of the following text synonyms (the field values are also listed): specify one or a set of of the following: ah (51), egp (8), esp (50), gre (47), icmp (1), icmp6 (58), igmp (2), ipip (4), ipv6 (41), no-next-header, ospf (89), pim (103), rsvp (46), sctp (132), tcp (6), udp (17), or vrp (112).</p> <p>dstopts (60), fragment (44), hop-by-hop (0), and routing are not available in Junos 16.1 and later.</p> <p>You can also use the payload-protocol condition to match an extension header type that the Juniper Networks firmware cannot interpret. You can specify a range of extension header values within square brackets. When the firmware finds the first extension header type that it cannot interpret in a packet, the payload-protocol value is set to that extension header type. The firewall filter only examines the first extension header type that the firmware cannot interpret in the packet.</p> <p>NOTE: This match condition is only supported on MPCs on MX Series Routers. Initialize new firewall filters that include this condition by walking the corresponding SNMP MIB.</p>
payload-protocol-except protocol-type	<p>Do not match the payload protocol type. For details, see the payload-protocol match type.</p> <p>NOTE: This match condition is only supported on MPCs on MX Series Routers</p>
port number	<p>Match the UDP or TCP source or destination port field.</p> <p>If you configure this match condition, you cannot configure the destination-port match condition or the source-port match condition in the same term.</p> <p>If you configure this match condition, we recommend that you also configure the next-header udp or next-header tcp match condition in the same term to specify which protocol is being used on the port.</p> <p>NOTE: For Junos OS Evolved, you must configure the protocol match statement in the same term.</p> <p>In place of the numeric value, you can specify one of the text synonyms listed under destination-port.</p>

Table 55: Firewall Filter Match Conditions for IPv6 Traffic (*continued*)

Match Condition	Description
port-except <i>number</i>	Do not match the UDP or TCP source or destination port field. For details, see the port match condition.
prefix-list <i>prefix-list-name</i> [except]	<p>Match the prefixes of the source or destination address fields to the prefixes in the specified list unless the except option is included. If the option is included, do not match the prefixes of the source or destination address fields to the prefixes in the specified list.</p> <p>The prefix list is defined at the [edit policy-options prefix-list <i>prefix-list-name</i>] hierarchy level.</p>
service-filter-hit	Match a packet received from a filter where a service-filter-hit action was applied.
source-address <i>address</i> [except]	<p>Match the IPv6 address of the source node sending the packet unless the except option is included. If the option is included, do not match the IPv6 address of the source node sending the packet.</p> <p>You cannot specify both the address and source-address match conditions in the same term.</p>
source-class <i>class-names</i>	<p>Match one or more specified source class names (sets of source prefixes grouped together and given a class name).</p> <p>For more information, see “Firewall Filter Match Conditions Based on Address Classes” on page 881.</p>
source-class-except <i>class-names</i>	Do not match one or more specified source class names. For details, see the source-class match condition.
source-port <i>number</i>	<p>Match the UDP or TCP source port field.</p> <p>You cannot specify the port and source-port match conditions in the same term.</p> <p>If you configure this match condition, we recommend that you also configure the next-header udp or next-header tcp match condition in the same term to specify which protocol is being used on the port.</p> <p>NOTE: For Junos OS Evolved, you must configure the next-header udp or next-header tcp match statement in the same term.</p> <p>In place of the numeric value, you can specify one of the text synonyms listed with the destination-port number match condition.</p>
source-port-except <i>number</i>	Do not match the UDP or TCP source port field. For details, see the source-port match condition.

Table 55: Firewall Filter Match Conditions for IPv6 Traffic (*continued*)

Match Condition	Description
source-prefix-list <i>name</i> [except]	<p>Match the IPv6 address prefix of the packet source field unless the except option is included. If the option is included, do not match the IPv6 address prefix of the packet source field.</p> <p>Specify a prefix list name defined at the [edit policy-options prefix-list <i>prefix-list-name</i>] hierarchy level.</p>
tcp-established	<p>Match TCP packets other than the first packet of a connection. This is a text synonym for tcp-flags "(ack rst)" (0x14).</p> <p>NOTE: This condition does not implicitly check that the protocol is TCP. To check this, specify the protocol tcp match condition.</p> <p>If you configure this match condition, we recommend that you also configure the next-header tcp match condition in the same term.</p>
tcp-flags <i>flags</i>	<p>Match one or more of the low-order 6 bits in the 8-bit TCP flags field in the TCP header.</p> <p>To specify individual bit fields, you can specify the following text synonyms or hexadecimal values:</p> <ul style="list-style-type: none"> • fin (0x01) • syn (0x02) • rst (0x04) • push (0x08) • ack (0x10) • urgent (0x20) <p>In a TCP session, the SYN flag is set only in the initial packet sent, while the ACK flag is set in all packets sent after the initial packet.</p> <p>You can string together multiple flags using the bit-field logical operators.</p> <p>For combined bit-field match conditions, see the tcp-established and tcp-initial match conditions.</p> <p>If you configure this match condition, we recommend that you also configure the next-header tcp match condition in the same term to specify that the TCP protocol is being used on the port.</p>

Table 55: Firewall Filter Match Conditions for IPv6 Traffic (*continued*)

Match Condition	Description
tcp-initial	<p>Match the initial packet of a TCP connection. This is a text synonym for tcp-flags "(lack & syn)".</p> <p>This condition does not implicitly check that the protocol is TCP. If you configure this match condition, we recommend that you also configure the next-header tcp match condition in the same term.</p>
traffic-class number	<p>Match the 8-bit field that specifies the class-of-service (CoS) priority of the packet.</p> <p>This field was previously used as the type-of-service (ToS) field in IPv4.</p> <p>You can specify a numeric value from 0 through 63. To specify the value in hexadecimal form, include 0x as a prefix. To specify the value in binary form, include b as a prefix.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed):</p> <ul style="list-style-type: none"> • RFC 3246, <i>An Expedited Forwarding PHB (Per-Hop Behavior)</i>, defines one code point: ef (46). • RFC 2597, <i>Assured Forwarding PHB Group</i>, defines 4 classes, with 3 drop precedences in each class, for a total of 12 code points: <ul style="list-style-type: none"> • af11 (10), af12 (12), af13 (14) • af21 (18), af22 (20), af23 (22) • af31 (26), af32 (28), af33 (30) • af41 (34), af42 (36), af43 (38)
traffic-class-except number	<p>Do not match the 8-bit field that specifies the CoS priority of the packet. For details, see the traffic-class match description.</p>

NOTE: If you specify an IPv6 address in a match condition (the **address**, **destination-address**, or **source-address** match conditions), use the syntax for text representations described in RFC 4291, *IP Version 6 Addressing Architecture*. For more information about IPv6 addresses, see *IPv6 Overview and Supported IPv6 Standards*.

Release History Table

Release	Description
13.3R6	Support for the next-header firewall match condition is available in Junos OS Release 13.3R6 and later.

Firewall Filter Match Conditions Based on Numbers or Text Aliases

IN THIS SECTION

- [Matching on a Single Numeric Value | 864](#)
- [Matching on a Range of Numeric Values | 864](#)
- [Matching on a Text Alias for a Numeric Value | 865](#)
- [Matching on a List of Numeric Values or Text Aliases | 865](#)

Matching on a Single Numeric Value

You can specify a firewall filter match condition based on whether a particular packet field value is a specified numeric value. In the following example, a match occurs if the packet source port number is **25**:

```
[edit firewall family inet filter filter1 term term1 from]
user@host# set source-port 25
```

Matching on a Range of Numeric Values

You can specify a firewall filter match condition based on whether a particular packet field value falls within a specified range of numeric values. In the following example, a match occurs for source ports values from **1024** through **65,535**, inclusive:

```
[edit firewall family inet filter filter2 term term1 from]
user@host# set source-port 1024-65536
```

Matching on a Text Alias for a Numeric Value

You can specify a firewall filter match condition based on whether a particular packet field value is a numeric value that you specify by using a text string as an *alias* for the numeric value. In the following example, a match occurs if the packet source port number is **25**. For the **source-port** and **destination-port** match conditions, the text alias **smtp** corresponds to the numeric value **25**.

```
[edit firewall family inet filter filter3 term term1 from]
user@host# set source-port smtp
```

Matching on a List of Numeric Values or Text Aliases

You can specify a firewall filter match condition based on whether a particular packet field value matches any one of multiple numeric values or text aliases that you specify within square brackets and delimited by spaces. In the following example, a match occurs if the packet source port number is any of the following values: **20** (which corresponds to the text aliases **ftp-data**), **25**, or any value from **1024** through **65535**.

```
[edit firewall family inet filter filter3 term term1 from]
user@host# set source-port [ smtp ftp-data 25 1024-65535 ]
```

- [Grouping Bit-Field Match Conditions | 871](#)

Match Conditions for Bit-Field Values

Table 56 on page 866 lists the firewall filter match conditions that are based on whether certain bit fields in a packet are set or not set. The second and third columns list the types of traffic for which the match condition is supported.

Table 56: Binary and Bit-Field Match Conditions for Firewall Filters

Bit-Field Match Condition	Match Values	Protocol Families for Standard Stateless Firewall Filters	Protocol Families for Service Filters
fragment-flags flags	Hexadecimal values or text aliases for the three-bit IP fragmentation flags field in the IP header.	family inet	family inet
fragment-offset value	Hexadecimal values or text aliases for the 13-bit fragment offset field in the IP header.	family inet	family inet
tcp-flags value[†]	Hexadecimal values or text aliases for the low-order 6 bits of the 8-bit TCP flags field in the TCP header.	family inet family inet6 family vpls family bridge	family inet family inet6

[†] The Junos OS does not automatically check the first fragment bit when matching TCP flags for IPv4 traffic. To check the first fragment bit for IPv4 traffic only, use the **first-fragment** match condition.

Match Conditions for Common Bit-Field Values or Combinations

Table 57 on page 867 describes firewall filter match conditions that are based on whether certain commonly used values or *combinations* of bit fields in a packet are set or not set.

You can use text synonyms to specify some common bit-field matches. In the previous example, you can specify **tcp-initial** as the same match condition.

NOTE:

Some of the numeric range and bit-field match conditions allow you to specify a text synonym. For a complete list of synonyms:

- If you are using the J-Web interface, select the synonym from the appropriate list.
- If you are using the CLI, type a question mark (?) after the **from** statement.

Table 57: Bit-Field Match Conditions for Common Combinations

Match Condition	Description	Protocol Families for Standard Stateless Firewall Filters	Protocol Families for Service Filters
first-fragment	Text alias for the bit-field match condition fragment-offset 0 , which indicates the first fragment of a fragmented packet.	family inet	family inet
is-fragment	Text alias for the bit-field match condition fragment-offset 0 except , which indicates a trailing fragment of a fragmented packet.	family inet	family inet
tcp-established	Alias for the bit-field match condition tcp-flags "(ack rst)" , which indicates an established TCP session, but not the first packet of a TCP connection.	family inet family inet6	—

Table 57: Bit-Field Match Conditions for Common Combinations (*continued*)

Match Condition	Description	Protocol Families for Standard Stateless Firewall Filters	Protocol Families for Service Filters
tcp-initial	Alias for the bit-field match condition tcp-flags "(lack & syn)" , which indicates the first packet of a TCP connection, but not an established TCP session.	family inet family inet6	—

Logical Operators for Bit-Field Values

Table 58 on page 868 lists the logical operators you can apply to *single* bit-field values when specifying stateless firewall filter match conditions. The operators are listed in order, from highest precedence to lowest precedence. Operations are left-associative, meaning that the operations are processed from left to right.

Table 58: Bit-Field Logical Operators

Precedence Order	Bit-Field Logical Operator	Description
1	(<i>complex-match-condition</i>)	Grouping—The complex match condition is evaluated before any operators outside the parentheses are applied.
2	! <i>match-condition</i>	Negation—A match occurs if the match condition is false.
3	<i>match-condition-1</i> & <i>match-condition-2</i> or <i>match-condition-1</i> + <i>match-condition-2</i>	Logical AND—A match occurs if both match conditions are true.
4	<i>match-condition-1</i> <i>match-condition-2</i> or <i>match-condition-1</i> , <i>match-condition-2</i>	Logical OR—A match occurs if either match condition is true.

Matching on a Single Bit-Field Value or Text Alias

For the **fragment-flags** and **tcp-flags** bit-match conditions, you can specify firewall filter match conditions based on whether a particular bit in the packet field is set or not set.

- Numeric value to specify a single bit—You can specify a single bit-field match condition by using a numeric value that has one bit set. Depending on the match condition, you can specify a decimal value, a binary value, or a hexadecimal value. To specify a binary value, specify the number with the prefix **b**. To specify a hexadecimal value, specify the number with the prefix **0x**.

In the following example, a match occurs if the **RST** bit in the TCP flags field is set:

```
[edit firewall family inet filter filter_tcp_rst_number term term1 from]
user@host# set tcp-flags 0x04
```

- Text alias to specify a single bit—You generally specify a single bit-field match condition by using a text alias enclosed in double-quotation marks (" ").

In the following example, a match occurs if the **RST** bit in the TCP flags field is set:

```
[edit firewall family inet filter filter_tcp_rst_alias term term1 from]
user@host# set tcp-flags "rst"
```

Matching on Multiple Bit-Field Values or Text Aliases

You can specify a firewall filter match condition based on whether a particular set of bits in a packet field are set.

- Numeric values to specify multiple set bits—When you specify a numeric value whose binary representation has more than one set bit, the value is treated as a logical AND of the set bits.

In the following example, the two match conditions are the same. A match occurs if either bit **0x01** or **0x02** is not set:

```
[edit firewall family inet filter reset_or_not_initial_packet term term5 from]
user@host# set tcp-flags "!0x3"
user@host# set tcp-flags "!(0x01 & 0x02)"
```

- Text aliases that specify common bit-field matches—You can use text aliases to specify some common bit-field matches. You specify these matches as a single keyword.

In the following example, the **tcp-established** condition, which is an alias for “(ack | rst)”, specifies that a match occurs on TCP packets other than the first packet of a connection:

```
[edit firewall family inet filter reset_or_not_initial_packet term term6 from]
user@host# set tcp-established
```

Matching on a Negated Bit-Field Value

To negate a match, precede the value with an exclamation point.

In the following example, a match occurs if the **RST** bit in the TCP flags field is *not* set:

```
[edit firewall family inet filter filter_tcp_rst term term1 from]
user@host# set tcp-flags "!rst"
```

Matching on the Logical OR of Two Bit-Field Values

You can use the *logical OR operator* (| or ,) to specify that a match occurs if a bit field matches either of two bit-field values specified.

In the following example, a match occurs if the packet is *not* the initial packet in a TCP session:

```
[edit firewall family inet filter not_initial_packet term term3 from]
user@host# set tcp-flags "!syn | ack"
```

In a TCP session, the SYN flag is set only in the initial packet sent, while the ACK flag is set in all packets sent after the initial packet. In a packet that is not the initial packet in a TCP session, either the SYN flag is not set or the ACK flag is set.

Matching on the Logical AND of Two Bit-Field Values

You can use the *logical AND operator* (& or +) to specify that a match occurs if a bit field matches both of two bit-field values specified.

In the following example, a match occurs if the packet is the initial packet in a TCP session:

```
[edit firewall family inet filter initial_packet term term2 from]
user@host# set tcp-flags "syn & !ack"
```

In a TCP session, the SYN flag is set only in the initial packet sent, while the ACK flag is set in all packets sent after the initial packet. In a packet that is an initial packet in a TCP session, the SYN flag is set and the ACK flag is not set.

Grouping Bit-Field Match Conditions

You can use the *logical grouping notation* to specify that the complex match condition inside the parentheses is evaluated before any operators outside the parentheses are applied.

In the following example, a match occurs if the packet is a TCP reset or if the packet is not the initial packet in the TCP session:

```
[edit firewall family inet filter reset_or_not_initial_packet term term4 from]
user@host# set tcp-flags "!(syn & !ack) | rst"
```

In a TCP session, the SYN flag is set only in the initial packet sent, while the ACK flag is set in all packets sent after the initial packet. In a packet that is *not* the initial packet in a TCP session, the SYN flag is not set and the ACK field is set.

[Firewall Filter Match Conditions Based on Address Classes | 881](#)

Firewall Filter Match Conditions Based on Address Fields

IN THIS SECTION

- [Implied Match on the '0/0 except' Address for Firewall Filter Match Conditions Based on Address Fields | 872](#)
- [Matching an Address Field to a Subnet Mask or Prefix | 872](#)
- [Matching an Address Field to an Excluded Value | 873](#)
- [Matching Either IP Address Field to a Single Value | 877](#)
- [Matching an Address Field to Noncontiguous Prefixes | 878](#)
- [Matching an Address Field to a Prefix List | 880](#)

You can configure firewall filter match conditions that evaluate packet address fields—IPv4 source and destination addresses, IPv6 source and destination addresses, or media access control (MAC) source and destination addresses—against specified addresses or prefix values.

Implied Match on the '0/0 except' Address for Firewall Filter Match Conditions Based on Address Fields

Every firewall filter match condition based on a set of addresses or address prefixes is associated with an implicit match on the address **0.0.0.0/0 except** (for IPv4 or VPLS traffic) or **0:0:0:0:0:0:0:0 except** (for IPv6 traffic). As a result, any packet whose specified address field does not match any of the specified addresses or address prefixes fails to match the entire term.

Matching an Address Field to a Subnet Mask or Prefix

You can specify a single match condition to match a source address or destination address that falls within a specified address prefix.

IPv4 Subnet Mask Notation

For an IPv4 address, you can specify a subnet mask value rather than a prefix length. For example:

```
[edit firewall family inet filter filter_on_dst_addr term term3 from]
user@host# set address 10.0.0.10/255.0.0.255
```

Prefix Notation

To specify the address prefix, use the notation **prefix/prefix-length**. In the following example, a match occurs if a destination address matches the prefix **10.0.0.0/8**:

```
[edit firewall family inet filter filter_on_dst_addr term term1 from]
user@host# set destination-address 10.0.0.0/8
```

Default Prefix Length for IPv4 Addresses

If you do not specify **/prefix-length** for an IPv4 address, the prefix length defaults to **/32**. The following example illustrates the default prefix value:

```
[edit firewall family inet filter filter_on_dst_addr term term2 from]
user@host# set destination-address 10
user@host# show
destination-address {
  10.0.0.0/32;
}
```

Default Prefix Length for IPv6 Addresses

If you do not specify */prefix-length* for an IPv6 address, the prefix length defaults to */128*. The following example illustrates the default prefix value:

```
[edit firewall family inet6 filter filter_on_dst_addr term term1 from]
user@host# set destination-address ::10
user@host# show
destination-address {
    ::10/128;
}
```

Default Prefix Length for MAC Addresses

If you do not specify */prefix-length* for a media access control (MAC) address of a VPLS, Layer 2 CCC, or Layer 2 bridging packet, the prefix length defaults to */48*. The following example illustrates the default prefix value:

```
[edit firewall family vpls filter filter_on_dst_mac_addr term term1 from]
user@host# set destination-mac-address 01:00:0c:cc:cc:cd
user@host# show
destination-address {
    01:00:0c:cc:cc:cd/48;
}
```

Matching an Address Field to an Excluded Value

For the address-field match conditions, you can include the **except** keyword to specify that a match occurs for an address field that does not match the specified address or prefix.

Excluding IP Addresses in IPv4 or IPv6 Traffic

For the following IPv4 and IPv6 match conditions, you can include the **except** keyword to specify that a match occurs for an IP address field that does not match the specified IP address or prefix:

- **address address except**—A match occurs if either the source IP address or the destination IP address does not match the specified address or prefix.
- **source-address address except**—A match occurs if the source IP address does not match the specified address or prefix.
- **destination-address address except**—A match occurs if the destination IP address does not match the specified address or prefix.

In the following example, a match occurs for any IPv4 destination addresses that fall under the **192.168.10.0/8** prefix, except for addresses that fall under **192.168.0.0/16**. All other addresses implicitly do not match this condition.

```
[edit firewall family inet filter filter_on_dst_addr term term1 from]
user@host# set 192.168.0.0/16 except
user@host# set 192.168.10.0/8
user@host# show
destination-address {
    192.168.0.0/16 except;
    192.168.10.0/8;
}
```

In the following example, a match occurs for any IPv4 destination address that does not fall within the prefix **10.1.1.0/24**:

```
[edit firewall family inet filter filter_on_dst_addr term term24 from]
user@host# set destination-address 0.0.0.0/0
user@host# set destination-address 10.1.1.0/24 except
user@host# show
destination-address {
    0.0.0.0/0;
    10.1.1.0/24 except;
}
```

Excluding IP Addresses in VPLS or Layer 2 Bridging Traffic

For the following VPLS and Layer 2 bridging match conditions on MX Series routers only, you can include the **except** keyword to specify that a match occurs for an IP address field that does not match the specified IP address or prefix:

- **ip-address *address* except**—A match occurs if either the source IP address or the destination IP address does not match the specified address or prefix.
- **source-ip-address *address* except**—A match occurs if the source IP address does not match the specified address or prefix.
- **destination-ip-address *address* except**—A match occurs if the destination IP address does not match the specified address or prefix.

In the following example for filtering VPLS traffic on an MX Series router, a match occurs if the source IP address falls within the exception range of **55.0.1.0/255.0.255.0** and the destination IP address matches **5172.16.5.0/8**:

```
[edit]
firewall {
  family vpls {
    filter fvpls {
      term 1 {
        from {
          ip-address {
            55.0.0.0/8;
            55.0.1.0/255.0.255.0 except;
          }
        }
        then {
          count from-55/8;
          discard;
        }
      }
    }
  }
}
```

Excluding MAC Addresses in VPLS or Layer 2 Bridging Traffic

For the following VPLS or Layer 2 bridging traffic match conditions, you can include the **except** keyword to specify that a match occurs for a MAC address field that does not match the specified MAC address or prefix:

- **source-mac-address *address* except**—A match occurs if the source MAC address does not match the specified address or prefix.
- **destination-mac-address *address* except**—A match occurs if either the destination MAC address does not match the specified address or prefix.

Excluding All Addresses Requires an Explicit Match on the '0/0' Address

If you specify a firewall filter match condition that consists of one or more *address-exception* match conditions (address match conditions that use the **except** keyword) but no *matchable* address match conditions, packets that do not match any of the configured prefixes fails the overall match operation. To configure a firewall filter term of address-exception match conditions to match any address that is not in the prefix list, include an explicit match of **0/0** so that the term contain a matchable address.

For the following example firewall filter for IPv4 traffic, the **from-trusted-addresses** term fails to discard matching traffic, and the **INTRUDERS-COUNT** counter is missing from the output of the **show firewall** operational mode command:

```
[edit]
user@host# show policy-options
prefix-list TRUSTED-ADDRESSES {
    10.2.1.0/24;
    192.168.122.0/24;
}

[edit firewall family inet filter protect-RE]
user@host# show
term from-trusted-addresses {
    from {
        source-prefix-list {
            TRUSTED-ADDRESSES except;
        }
        protocol icmp;
    }
    then {
        count INTRUDERS-COUNT;
        discard;
    }
}
term other-icmp {
    from {
        protocol icmp;
    }
    then {
        count VALID-COUNT;
        accept;
    }
}
term all {
    then accept;
}
```

```
[edit]
```

```
user@host# run show firewall
```

```
Filter: protect-RE
Counters:
```

Name	Bytes	Packets
VALID-COUNT	2770	70
Filter: __default_bpdu_filter__		

To cause a filter term of address-exception match conditions to match any address that is not in the prefix list, include an explicit match of **0/0** in the set of match conditions:

```
[edit firewall family inet filter protect-RE]
user@host# show term from-trusted-addresses
from {
  source-prefix-list {
    0.0.0.0/0;
    TRUSTED-ADDRESSES except;
  }
  protocol icmp;
}
```

With the addition of the **0.0.0.0/0** source prefix address to the match condition, the **from-trusted-addresses** term discards matching traffic, and the **INTRUDERS-COUNT** counter displays in the output of the **show firewall** operational mode command:

```
[edit]
```

```
user@host# run show firewall
```

Filter: protect-RE		
Counters:		
Name	Bytes	Packets
VALID-COUNT	2770	70
INTRUDERS-COUNT	420	5
Filter: __default_bpdu_filter__		

Matching Either IP Address Field to a Single Value

For IPv4 and IPv6 traffic and for VPLS and Layer 2 bridging traffic on MX Series routers only, you can use a single match condition to match a single address or prefix value to either the source or destination IP address field.

Matching Either IP Address Field in IPv4 or IPv6 Traffic

For IPv4 or IPv6 traffic, you can use a single match condition to specify the same address or prefix value as the match for either the source or destination IP address field. Instead of creating separate filter terms

that specify the same address for the **source-address** and **destination-address** match conditions, you use only the **address** match condition. A match occurs if *either* the source IP address or the destination IP address matches the specified address or prefix.

If you use the **except** keyword with the **address** match condition, a match occurs if *both* the source IP address and the destination IP address match the specified value *before* the exception applies.

In a firewall filter term that specifies either the **source-address** or the **destination-address** match condition, you cannot also specify the **address** match condition.

Matching Either IP Address Field in VPLS or Layer 2 Bridging Traffic

For VPLS or Layer 2 bridging traffic on MX Series routers only, you can use a single match condition to specify the same address or prefix value as the match for either the source or destination IP address field. Instead of creating separate filter terms that specify the same address for the **source-ip-address** and **destination-ip-address** match conditions, you use only the **ip-address** match condition. A match occurs if *either* the source IP address or the destination IP address matches the specified address or prefix.

If you use the **except** keyword with the **ip-address** match condition, a match occurs if *both* the source IP address and the destination IP address match the specified value *before* the exception applies.

In a firewall filter term that specifies either the **source-ip-address** or the **destination-ip-address** match condition, you cannot also specify the **ip-address** match condition.

Matching an Address Field to Noncontiguous Prefixes

For IPv4 traffic only, specify a single match condition to match the IP source or destination address field to any prefix specified. The prefixes do not need to be contiguous. That is, the prefixes under the **source-address** or **destination-address** match condition do not need to be adjacent or neighboring to one another.

In the following example, a match occurs if a destination address matches either the **10.0.0.0/8** prefix or the **192.168.0.0/32** prefix:

```
[edit firewall family inet filter filter_on_dst_addr term term5 from]
user@host# set destination-address 10.0.0.0/8
user@host# set destination-address 192.168.0.0/32
user@host# show
destination-address {
    destination-address 10.0.0.0/8;
    destination-address 192.168.0.0/32;
}
```

The order in which you specify the prefixes within the match condition is not significant. Packets are evaluated against all the prefixes in the match condition to determine whether a match occurs. If prefixes overlap, longest-match rules are used to determine whether a match occurs. A match condition of

noncontiguous prefixes includes an implicit **0/0 except** statement, which means that any prefix that does not match any prefix included in the match condition is explicitly considered not to match.

Because the prefixes are order-independent and use longest-match rules, longer prefixes subsume shorter ones as long as they are the same type (whether you specify **except** or not). This is because anything that would match the longer prefix would also match the shorter one.

Consider the following example:

```
[edit firewall family inet filter filter_on_src_addr term term1 from]
source-address {
  172.16.0.0/10;
  172.16.2.0/24 except;
  192.168.1.0;
  192.168.1.192/26 except;
  192.168.1.254;
  172.16.3.0/24; # ignored
  10.2.2.2 except; # ignored
}
```

Within the **source-address** match condition, two addresses are ignored. The **172.16.3.0/16** value is ignored because it falls under the address **172.16.0.0/10**, which is the same type. The **10.2.2.2 except** value is ignored because it is subsumed by the implicit **0.0.0.0/0 except** match value.

Suppose the following source IP address are evaluated by this firewall filter:

- Source IP address **172.16.1.2**—This address matches the **172.16.0.0/10** prefix, and thus the action in the **then** statement is taken.
- Source IP address **172.16.2.2**—This address matches the **172.16.2.0/24** prefix. Because this prefix is negated (that is, includes the **except** keyword), an explicit *mismatch* occurs. The next term in the filter is evaluated, if there is one. If there are no more terms, the packet is discarded.
- Source IP address **10.1.2.3**—This address does not match any of the prefixes included in the **source-address** condition. Instead, it matches the implicit **0.0.0.0/0 except** at the end of the list of prefixes configured under the **source-address** match condition, and is considered to be a mismatch.

The **172.16.3.0/24** statement is ignored because it falls under the address **172.16.0.0/10**—both are the same type.

The **10.2.2.2 except** statement is ignored because it is subsumed by the implicit **0.0.0.0/0 except** statement at the end of the list of prefixes configured under the **source-address** match condition.

BEST PRACTICE: When a firewall filter term includes the **from address *address*** match condition and a subsequent term includes the **from source-address *address*** match condition for the same address, packets might be processed by the latter term before they are evaluated by any intervening terms. As a result, packets that should be rejected by the intervening terms might be accepted instead, or packets that should be accepted might be rejected instead.

To prevent this from occurring, we recommend that you do the following. For every firewall filter term that contains the **from address *address*** match condition, replace that term with two separate terms: one that contains the **from source-address *address*** match condition, and another that contains the **from destination-address *address*** match condition.

Matching an Address Field to a Prefix List

You can define a list of IPv4 or IPv6 address prefixes for use in a routing policy statement or in a stateless firewall filter match condition that evaluates packet address fields.

To define a list of IPv4 or IPv6 address prefixes, include the **prefix-list *prefix-list*** statement.

```
prefix-list name {
  ip-addresses;
  apply-path path;
}
```

You can include the statement at the following hierarchy levels:

- [edit policy-options]
- [edit logical-systems *logical-system-name* policy-options]

After you have defined a prefix list, you can use it when specifying a firewall filter match condition based on an IPv4 or IPv6 address prefix.

```
[edit firewall family family-name filter filter-name term term-name]
from {
  source-prefix-list {
    prefix-lists;
  }
  destination-prefix-list {
    prefix-lists;
  }
}
```

Firewall Filter Match Conditions Based on Address Classes

IN THIS SECTION

- [Source-Class Usage | 881](#)
- [Destination-Class Usage | 881](#)
- [Guidelines for Applying SCU or DCU Firewall Filters to Output Interfaces | 882](#)

For IPv4 and IPv6 traffic only, you can use class-based firewall filter conditions to match packet fields based on source class or destination class.

Source-Class Usage

A *source class* is a set of source prefixes grouped together and given a class name. To configure a firewall filter term that matches an IP source address field to one or more source classes, use the **source-class *class-name*** match condition under the **[edit firewall family (inet | inet6) filter *filter-name* term *term-name* from]** hierarchy level.

Source-class usage (SCU) enables you to monitor the amount of traffic originating from a specific prefix. With this feature, usage can be tracked and customers can be billed for the traffic they receive.

Destination-Class Usage

A *destination class* is a set of destination prefixes grouped together and given a class name. To configure a firewall filter term that matches an IP destination address field to one or more destination classes, use the **destination-class *class-name*** match condition at the **[edit firewall family (inet | inet6) filter *filter-name* term *term-name* from]** hierarchy level.

Destination-class usage (DCU) enables you can track how much traffic is sent to a specific prefix in the core of the network originating from one of the specified interfaces.

Note, however, that DCU limits your ability to keep track of traffic moving in the reverse direction. It can account for all traffic that arrives on a core interface and heads toward a specific customer, but it cannot count traffic that arrives on a core interface from a specific prefix.

Guidelines for Applying SCU or DCU Firewall Filters to Output Interfaces

When applying a SCU or DCU firewall filter to an interface, keep the following guidelines in mind:

- Output interfaces—Class-based firewall filter match conditions work only for firewall filters that you apply to output interfaces. This is because the SCU and DCU are determined after route lookup occurs.
- Input interfaces—Although you can specify a source class and destination class for an input firewall filter, the counters are incremented only if the firewall filter is applied on the output interface.
- Output interfaces for tunnel traffic—SCU and DCU are not supported on the interfaces you configure as the output interface for tunnel traffic for transit packets exiting the router (or switch) through the tunnel.

Understanding IP-Based Filtering and Selective Port Mirroring of MPLS Traffic

IN THIS SECTION

- [IP-Based Filtering of MPLS Traffic | 883](#)
- [Selective Port Mirroring of MPLS Traffic | 884](#)
- [Sample Configurations | 885](#)

In an MPLS packet, the IP header comes immediately after the MPLS header. The IP-based filtering feature provides a deep inspection mechanism, where a maximum of upto eight MPLS labels of the inner payload can be inspected to enable filtering of MPLS traffic based on IP parameters. The filtered MPLS traffic can also be port mirrored to a monitoring device to offer network-based services in the core MPLS network.

IP-Based Filtering of MPLS Traffic

Prior to Junos OS Release 18.4R1, filtering based on IP parameters was not supported for MPLS family filter. With the introduction of the IP-based filtering feature, you can apply inbound and outbound filters for MPLS-tagged IPv4 and IPv6 packets based on IP parameters, such as source and destination addresses, Layer 4 protocol type, and source and destination ports.

The IP-based filtering feature enables you to filter MPLS packets at the ingress of an interface, where the filtering is done using match conditions on the inner payload of the MPLS packet. The selective MPLS traffic can then be port mirrored to a remote monitoring device using logical tunnels.

To support IP-based filtering, additional match conditions are added that allow MPLS packets to be deep inspected to parse the inner payload with Layer 3 and Layer 4 headers before the appropriate filters are applied.

NOTE: The IP-based filtering feature is supported only for MPLS-tagged IPv4 and IPv6 packets. In other words, the MPLS filters match IP parameters only when the IP payload comes immediately after the MPLS labels.

In other scenarios, where the MPLS payload includes pseudowires, protocols other than inet and inet6, or other encapsulations like Layer 2 VPN or VPLS, the IP-based filtering feature is not supported.

The following match conditions are added for the IP-based filtering of MPLS traffic:

- IPv4 source address
- IPv4 destination address
- IPv6 source address
- IPv6 destination address
- Protocol
- Source port
- Destination port
- Source IPv4 prefix list
- Destination IPv4 prefix list

- Source IPv6 prefix list
- Destination IPv6 prefix list

NOTE: The following match combinations are supported for the IP-based filtering of MPLS traffic:

- Source and destination address match conditions with IPv4 and IPv6 prefix lists.
- Source and destination port address and protocol types match conditions with IPv4 and IPv6 prefix lists.

Selective Port Mirroring of MPLS Traffic

Port mirroring is the capability of mirroring a packet to a configured destination, in addition to the normal processing and forwarding of the packets. Port mirroring is applied as an action for a firewall filter, which is applied at the ingress or egress of any interface. Similarly, the selective port mirroring feature provides the capability to mirror MPLS traffic, which is filtered based on IP parameters, to a mirrored destination using logical tunnels.

To enable selective port mirroring, additional actions are configured at the **[edit firewall family mpls filter filter-name term term-name then]** hierarchy level, in addition to the existing **counter**, **accept**, and **discard** actions:

- **port-mirror**
- **port-mirror-instance**

Port Mirroring

The **port-mirror** action enables port mirroring globally on the device, which applies to all Packet Forwarding Engines (PFEs) and associated interfaces.

For MPLS family filter, the **port-mirror** action is enabled for global port mirroring.

Port Mirroring Instance

The **port-mirror-instance** action enables you to customize each instance with different properties for input sampling and port mirroring output destinations, instead of having to use a single system-wide configuration for port mirroring.

You can configure only two port mirroring instances per Flexible PIC Concentrator (FPC) by including the **instance port-mirror-instance-name** statement at the **[edit forwarding-options port-mirror]** hierarchy level. You can then associate individual port mirroring instances with an FPC, PIC, or (Forwarding Engine Board (FEB) depending on the device hardware.

For MPLS family filter, the **port-mirror-instance** action is enabled only for the port-mirroring instance.

NOTE: For both **port-mirror** and **port-mirror-instance** actions, the output interface must be enabled with Layer 2 family and not family MPLS (Layer 3) for the selective port mirroring feature to work.

Sample Configurations

IN THIS SECTION

- [IP-Based Filtering Configuration | 885](#)
- [Selective Port Mirroring Configuration | 887](#)
- [Mirrored Destination Configuration | 888](#)

IP-Based Filtering Configuration

```
[edit firewall family mpls filter mpls-filter]
term ipv4-term {
  from {
    ip-version {
      ipv4 {
        source-address {
          10.10.10.10/24;
        }
        destination-address {
          20.20.20.20/24;
        }
        protocol tcp {
          source-port 100;
          destination-port 200;
        }
        source-prefix-list ipv4-source-users;
        destination-prefix-list ipv4-destination-users;
      }
    }
  }
  exp 1;
}
```

```

        then port-mirror;
        then accept;
        then count;
    }
    term ipv6-term {
        from {
            ip-version {
                ipv6 {
                    source-address {
                        2000::1/128;
                    }
                    destination-address {
                        3000::1/128;
                    }
                    protocol tcp {
                        source-port 100;
                        destination-port 200;
                    }
                    source-prefix-list ipv6-source-users;
                    destination-prefix-list ipv6-destination-users;
                }
            }
        }
        exp 1;
    }
    then port-mirror-instance port-mirror-instance1;
    then accept;
    then count;
}

```

```

[edit policy-options]
prefix-list ipv4-source-users {
    172.16.1.16/28;
    172.16.2.16/28;
}
prefix-list ipv6-source-users {
    2001::1/128;
    3001::1/128;
}

```

```

[edit interfaces]
xe-0/0/1 {
    unit 0 {
        family inet {

```

```

        address 100.100.100.1/30;
    }
    family mpls {
        filter {
            input mpls-filter;
        }
    }
}

```

Selective Port Mirroring Configuration

```

[edit forwarding-options]
port-mirroring {
    input {
        rate 2;
        run-length 4;
        maximum-packet-length 500;
    }
    family any {
        output {
            interface xe-2/0/2.0;
        }
    }
}

```

```

[edit forwarding-options]
port-mirroring {
    instance {
        port-mirror-instance1 {
            input {
                rate 3;
                run-length 5;
                maximum-packet-length 500;
            }
            family any {
                output {
                    interface xe-2/0/2.0;
                }
            }
        }
    }
}

```

NOTE: The output interface **xe-2/0/2.0** is configured for Layer 2 family and not family MPLS.

For both **port-mirror** and **port-mirror-instance** actions, the output interface must be enabled with Layer 2 family and not family MPLS (Layer 3) for the selective port mirroring feature to work.

Mirrored Destination Configuration

```
[edit interfaces]
xe-2/0/2 {
  vlan-tagging;
  encapsulation extended-vlan-bridge;
  unit 0 {
    vlan-id 600;
  }
}
```

```
[edit bridge-domains]
bd {
  domain-type bridge;
  interface xe-2/0/2.0;
}
```

Firewall Filter Match Conditions for MPLS Traffic

You can configure a firewall filter with match conditions for MPLS traffic (**family mpls**).

- The **input-list filter-names** and **output-list filter-names** statements for firewall filters for the **mpls** protocol family are supported on all interfaces except for management interfaces and internal Ethernet interfaces (**fxp** or **em0**), loopback interfaces (**lo0**), and USB modem interfaces (**umd**)
- If a packet has multiple MPLS labels, the filter applies the match conditions to only the bottom label in the label stack.
- (QFX5100, QFX5110, QFX5200, QFX5210) If you are applying an MPLS filter on a loopback interface, you can only filter on the **label**, **exp**, **ttl=1**, and Layer 4 **tcp** and **udp** port number fields. For TTL, you must explicitly specify **ttl=1** under **family mpls** to match on TTL=1 packets. The only actions you can configure are **accept**, **discard**, and **count**. You can apply the filter only in the ingress direction.

Table 59 on page 889 describes the *match-conditions* you can configure at the [edit firewall family mpls filter *filter-name* term *term-name* from] hierarchy level.

Table 59: Firewall Filter Match Conditions for MPLS Traffic

Match Condition	Description
apply-groups	Specify which groups to inherit configuration data from. You can specify more than one group name. You must list them in order of inheritance priority. The configuration data in the first group takes priority over the data in subsequent groups.
apply-groups-except	Specify which groups not to inherit configuration data from. You can specify more than one group name.
destination-port <i>number</i>	<p>Match on the UDP or TCP destination port field.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the port numbers are also listed): afs (1483), bgp (179), biff (512), bootpc (68), bootps (67), cmd (514), cvspserver (2401), dhcp (67), domain (53), eklogin (2105), ekshell (2106), exec (512), finger (79), ftp (21), ftp-data (20), http (80), https (443), ident (113), imap (143), kerberos-sec (88), klogin (543), kpasswd (761), krb-prop (754), krbupdate (760), kshell (544), ldap (389), ldp (646), login (513), mobileip-agent (434), mobileip-mn (435), msdp (639), netbios-dgm (138), netbios-ns (137), netbios-ssn (139), nfsd (2049), nntp (119), ntalk (518), ntp (123), pop3 (110), pptp (1723), printer (515), radacct (1813), radius (1812), rip (520), rkinit (2108), smtp (25), snmp (161), snmptrap (162), snpp (444), socks (1080), ssh (22), sunrpc (111), syslog (514), tacacs (49), tacacs-ds (65), talk (517), telnet (23), tftp (69), timed (525), who (513), or xdmcp (177).</p>
exp <i>number</i>	<p>Experimental (EXP) bit number or range of bit numbers in the MPLS header of a packet.</p> <p>For <i>number</i>, you can specify one or more values from 0 through 7 in binary, decimal or hexadecimal format, as given below:</p> <ul style="list-style-type: none"> • A single EXP bit—for example, exp 3 • Several EXP bits—for example, exp 0,4 • A range of EXP bits—for example, exp [0-5]. These values are not supported on filters applied to the loopback interface. <p>NOTE: This match condition is not supported on PTX series packet transport routers.</p>
exp-except <i>number</i>	<p>Do not match on the EXP bit number or range of bit numbers in the MPLS header. For <i>number</i>, you can specify one or more values from 0 through 7.</p> <p>NOTE: This match condition is not supported on PTX series packet transport routers.</p>
forwarding-class <i>class</i>	Forwarding class. Specify assured-forwarding , best-effort , expedited-forwarding , or network-control .

Table 59: Firewall Filter Match Conditions for MPLS Traffic (*continued*)

Match Condition	Description
forwarding-class-except class	Do not match on the forwarding class. Specify assured-forwarding , best-effort , expedited-forwarding , or network-control .
interface interface-name	Interface on which the packet was received. You can configure a match condition that matches packets based on the interface on which they were received. NOTE: If you configure this match condition with an interface that does not exist, the term does not match any packet.
interface-set interface-set-name	Match the interface on which the packet was received to the specified interface set. To define an interface set, include the interface-set statement at the [edit firewall] hierarchy level. NOTE: This match condition is not supported on PTX series packet transport routers. For more information, see “Filtering Packets Received on an Interface Set Overview” on page 1182 .
ip-version number	(Interfaces on Enhanced Scaling flexible PIC concentrators [FPCs] on supported T Series routers only) Inner IP version. To match MPLS-tagged IPv4 packets, match on the text synonym ipv4 . NOTE: This match condition is not supported on PTX series packet transport routers.
label number	MPLS label value or range of label values in the MPLS header of a packet. For <i>number</i> , you can specify one or more values from 0 through 1048575 in decimal or hexadecimal format, as given below: <ul style="list-style-type: none"> • A single label—for example, label 3 • Several labels—for example, label 0,4 • A range of labels—for example, label [0-5]. These values are not supported on filters applied to the loopback interface.

Table 59: Firewall Filter Match Conditions for MPLS Traffic (*continued*)

Match Condition	Description
loss-priority level	<p>Match the packet loss priority (PLP) level.</p> <p>Specify a single level or multiple levels: low, medium-low, medium-high, or high.</p> <p>Supported on M120 and M320 routers; M7i and M10i routers with the Enhanced CFEB (CFEB-E); and MX Series routers and EX Series switches.</p> <p>For IP traffic on M320, MX Series, and T Series routers with Enhanced II Flexible PIC Concentrators (FPCs), and EX Series switches, you must include the tri-color statement at the [edit class-of-service] hierarchy level to commit a PLP configuration with any of the four levels specified. If the tri-color statement is not enabled, you can only configure the high and low levels. This applies to all protocol families.</p> <p>For information about the tri-color statement, see <i>Configuring and Applying Tricolor Marking Policers</i>. For information about using behavior aggregate (BA) classifiers to set the PLP level of incoming packets, see <i>Understanding How Forwarding Classes Assign Classes to Output Queues</i>.</p>
loss-priority-except level	<p>Do not match the PLP level. For details, see the loss-priority match condition.</p> <p>NOTE: This match condition is not supported on PTX series packet transport routers.</p>
source-port number	<p>Match on the TCP or UDP source port field.</p> <p>You cannot specify the port and source-port match conditions in the same term.</p> <p>If you configure this match condition for IPv4 traffic, we recommend that you also configure the protocol udp or protocol tcp match statement in the same term to specify which protocol is being used on the port.</p> <p>In place of the numeric field, you can specify one of the text synonyms listed under destination-port.</p>
ttl number	<p>Time To Live (TTL) is an 8-bit field in the MPLS label that signifies the remaining time that a packet has left before its life ends and is dropped.</p> <p>For <i>number</i>, you can specify a value from 0 through 255.</p>

Table 60 on page 892 describes the actions you can configure for MPLS firewall filters at the **[edit firewall family mpls filter filter-name term term-name then]** hierarchy level.

Table 60: Supported Actions for MPLS Firewall Filters

Action	Description
accept	Accept a packet
count <i>counter-name</i>	Count the number of packets that pass this filter or term. NOTE: We recommend that you configure a counter for each term in a firewall filter, so that you can monitor the number of packets that match the conditions specified in each filter term.
discard	Discard a packet silently without sending an Internet Control Message Protocol (ICMP) message
policer	Starting with Junos OS 13.2X51-D15, you can send traffic matched by an MPLS filter to a two-color policer.
three-color-policer	Starting with Junos OS 13.2X51-D15, you can send traffic matched by an MPLS filter to a three-color policer.

Matching on IPv4 or IPv6 Packet Header Address or Port Fields in MPLS Flows

To support network-based service in a core network, you can configure a firewall filter that matches Internet Protocol version 4 (IPv4) or version 6 (IPv6) packet header fields in MPLS traffic (**family mpls**). The firewall filter can match IPv4 or IPv6 packets as an inner payload of an MPLS packet that has a single MPLS label or up to five MPLS labels stacked together. You can configure match conditions based on IPv4 addresses and IPv4 port numbers or IPv6 addresses and IPv6 port numbers in the header.

Firewall filters based on MPLS-tagged IPv4 headers are supported for interfaces on Enhanced Scaling flexible PIC concentrators (FPCs) on T320, T640, T1600, TX Matrix, and TX Matrix Plus routers and switches only. However, the firewall filters based on MPLS-tagged IPv6 headers are supported for interfaces on the Type 5 FPC on T4000 Core Routers only. The feature is not supported for the router or switch loopback interface (**lo0**), the router or switch management interface (**fxp0** or **em0**), or USB modem interfaces (**umd**).

To configure a firewall filter term that matches an address or port fields in the Layer 4 header of packets in an MPLS flow, you use the **ip-version ipv4** match condition to specify that the term is to match packets based on inner IP fields:

- To match an MPLS-tagged IPv4 packet on the source or destination address field in the IPv4 header, specify the match condition at the **[edit firewall family mpls filter *filter-name* term *term-name* from ip-version ipv4]** hierarchy level.
- To match an MPLS-tagged IPv4 packet on the source or destination port field in the Layer 4 header, specify the match condition at the **[edit firewall family mpls filter *filter-name* term *term-name* from ip-version ipv4 protocol (udp | tcp)]** hierarchy level.

To configure a firewall filter term that matches an address or port fields in the IPv6 header of packets in an MPLS flow, you use the **ip-version ipv6** match condition to specify that the term is to match packets based on inner IP fields:

- To match an MPLS-tagged IPv6 packet on the source or destination address field in the IPv6 header, specify the match condition at the **[edit firewall family mpls filter *filter-name* term *term-name* from ip-version ipv6]** hierarchy level.
- To match an MPLS-tagged IPv6 packet on the source or destination port field in the Layer 4 header, specify the match condition at the **[edit firewall family mpls filter *filter-name* term *term-name* from ip-version ipv6 protocol (udp | tcp)]** hierarchy level.

IP Address Match Conditions for MPLS Traffic

[Table 61 on page 894](#) describes the IP address-specific match conditions you can configure at the **[edit firewall family mpls filter *filter-name* term *term-name* from ip-version *ip-version*]** hierarchy level.

Table 61: IP Address-Specific Firewall Filter Match Conditions for MPLS Traffic

Match Condition	Description
destination-address address	Match the address of the destination node to receive the packet.
destination-address address except	Do not match the address of the destination node to receive the packet.
protocol number	Match the IP protocol type field. In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): ah (51), dstopts (60), egp (8), esp (50), fragment (44), gre (47), hop-by-hop (0), icmp (1), icmp6 (58), icmpv6 (58), igmp (2), ipip (4), ipv6 (41), ospf (89), pim (103), rsvp (46), sctp (132), tcp (6), udp (17), or vrrp (112).
source-address address	Match the address of the source node sending the packet.
source-address address except	Do not match the address of the source node sending the packet.

IP Port Match Conditions for MPLS Traffic

Table 62 on page 894 describes the IP port-specific *match-conditions* you can configure at the `[edit firewall family mpls filter filter-name term term-name from ip-version ip-version protocol (udp | tcp)]` hierarchy level.

Table 62: IP Port-Specific Firewall Filter Match Conditions for MPLS Traffic

Match Condition	Description
destination-port number	<p>Match on the UDP or TCP destination port field.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the port numbers are also listed): afs (1483), bgp (179), biff (512), bootpc (68), bootps (67), cmd (514), cvspserver (2401), dhcp (67), domain (53), eklogin (2105), ekshell (2106), exec (512), finger (79), ftp (21), ftp-data (20), http (80), https (443), ident (113), imap (143), kerberos-sec (88), klogin (543), kpasswd (761), krb-prop (754), krbupdate (760), kshell (544), ldap (389), ldp (646), login (513), mobileip-agent (434), mobileip-mn (435), msdp (639), netbios-dgm (138), netbios-ns (137), netbios-ssn (139), nfsd (2049), nnpt (119), ntalk (518), ntp (123), pop3 (110), pptp (1723), printer (515), radacct (1813), radius (1812), rip (520), rkinit (2108), smtp (25), snmp (161), snmptrap (162), snpp (444), socks (1080), ssh (22), sunrpc (111), syslog (514), tacacs (49), tacacs-ds (65), talk (517), telnet (23), tftp (69), timed (525), who (513), or xdmcp (177).</p>

Table 62: IP Port-Specific Firewall Filter Match Conditions for MPLS Traffic (*continued*)

Match Condition	Description
destination-port-except number	Do not match on the UDP or TCP destination port field. In place of the numeric value, you can specify one of the text synonyms listed with the destination-port match condition.
source-port number	Match on the TCP or UDP source port field. In place of the numeric field, you can specify one of the text synonyms listed under destination-port .
source-port-except number	Do not match on the TCP or UDP source port field.

Firewall Filter Match Conditions for VPLS Traffic

In the **from** statement in the VPLS filter term, you specify conditions that the packet must match for the action in the **then** statement to be taken. All conditions in the **from** statement must match for the action to be taken. The order in which you specify match conditions is not important, because a packet must match all the conditions in a term for a match to occur.

If you specify no match conditions in a term, that term matches all packets.

An individual condition in a **from** statement can contain a list of values. For example, you can specify numeric ranges. You can also specify multiple source addresses or destination addresses. When a condition defines a list of values, a match occurs if one of the values in the list matches the packet.

Individual conditions in a **from** statement can be negated. When you negate a condition, you are defining an explicit mismatch. For example, the negated match condition for **forwarding-class** is **forwarding-class-except**. If a packet matches a negated condition, it is immediately considered not to match the **from** statement, and the next term in the filter is evaluated, if there is one. If there are no more terms, the packet is discarded.

You can configure a firewall filter with match conditions for Virtual Private LAN Service (VPLS) traffic (family `vpls`). Table 63 on page 896 describes the *match-conditions* you can configure at the [edit firewall family `vpls` filter *filter-name* term *term-name* from] hierarchy level.

NOTE: Not all match conditions for VPLS traffic are supported on all routing platforms or switching platforms. A number of match conditions for VPLS traffic are supported only on MX Series 5G Universal Routing Platforms.

In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

Table 63: Firewall Filter Match Conditions for VPLS Traffic

Match Condition	Description
destination-mac-address <i>address</i>	Match the destination media access control (MAC) address of a VPLS packet.
destination-port <i>number</i>	<p>(MX Series routers and EX Series switches only) Match the UDP or TCP destination port field.</p> <p>You cannot specify both the port and destination-port match conditions in the same term.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the port numbers are also listed): afs (1483), bgp (179), biff (512), bootpc (68), bootps (67), cmd (514), cvspserver (2401), dhcp (67), domain (53), eklogin (2105), ekshell (2106), exec (512), finger (79), ftp (21), ftp-data (20), http (80), https (443), ident (113), imap (143), kerberos-sec (88), klogin (543), kpasswd (761), krb-prop (754), krbupdate (760), kshell (544), ldap (389), ldp (646), login (513), mobileip-agent (434), mobileip-mn (435), msdp (639), netbios-dgm (138), netbios-ns (137), netbios-ssn (139), nfsd (2049), nntp (119), ntalk (518), ntp (123), pop3 (110), pptp (1723), printer (515), radacct (1813), radius (1812), rip (520), rkinit (2108), smtp (25), snmp (161), snmptrap (162), snpp (444), socks (1080), ssh (22), sunrpc (111), syslog (514), tacacs (49), tacacs-ds (65), talk (517), telnet (23), tftp (69), timed (525), who (513), or xdmcp (177).</p>
destination-port-except <i>number</i>	(MX Series routers and EX Series switches only) Do not match on the TCP or UDP destination port field. You cannot specify both the port and destination-port match conditions in the same term.

Table 63: Firewall Filter Match Conditions for VPLS Traffic (*continued*)

Match Condition	Description
destination-prefix-list name	<p>(ACX Series routers, MX Series routers, and EX Series switches only) Match destination prefixes in the specified list. Specify the name of a prefix list defined at the [edit policy-options prefix-list prefix-list-name] hierarchy level.</p> <p>NOTE: VPLS prefix lists support only IPv4 addresses. IPv6 addresses included in a VPLS prefix list will be discarded.</p>
destination-prefix-list name except	<p>(MX Series routers and EX Series switches only) Do not match destination prefixes in the specified list. For more information, see the destination-prefix-list match condition.</p>
dscp number	<p>(MX Series routers and EX Series switches only) Match the Differentiated Services code point (DSCP). The DiffServ protocol uses the type-of-service (ToS) byte in the IP header. The most significant 6 bits of this byte form the DSCP. For more information, see the <i>Understanding How Behavior Aggregate Classifiers Prioritize Trusted Traffic</i>.</p> <p>You can specify a numeric value from 0 through 63. To specify the value in hexadecimal form, include 0x as a prefix. To specify the value in binary form, include b as a prefix.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed):</p> <ul style="list-style-type: none"> • RFC 3246, <i>An Expedited Forwarding PHB (Per-Hop Behavior)</i>, defines one code point: ef (46). • RFC 2597, <i>Assured Forwarding PHB Group</i>, defines 4 classes, with 3 drop precedences in each class, for a total of 12 code points: af11 (10), af12 (12), af13 (14), af21 (18), af22 (20), af23 (22), af31 (26), af32 (28), af33 (30), af41 (34), af42 (36), af43 (38)
dscp-except number	<p>(MX Series routers and EX Series switches only) Do not match on the DSCP. For details, see the dscp match condition.</p>

Table 63: Firewall Filter Match Conditions for VPLS Traffic (*continued*)

Match Condition	Description	
ether-type values	<p>Match the 2-octet IEEE 802.3 Length/EtherType field to the specified value or list of values.</p> <p>You can specify decimal or hexadecimal values from 0 through 65535 (0xFFFF). A value from 0 through 1500 (0x05DC) specifies the length of an Ethernet Version 1 frame. A value from 1536 (0x0600) through 65535 specifies the EtherType (nature of the MAC client protocol) of an Ethernet Version 2 frame.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the hexadecimal values are also listed): aarp (0x80F3), appletalk (0x809B), arp (0x0806), ipv4 (0x0800), ipv6 (0x86DD), mpls-multicast (0x8848), mpls-unicast (0x8847), oam (0x8902), ppp (0x880B), pppoe-discovery (0x8863), pppoe-session (0x8864), or sna (0x80D5).</p>	
ether-type-except values	<p>Do not match the 2-octet Length/EtherType field to the specified value or list of values.</p> <p>For details about specifying the values, see the ether-type match condition.</p>	
flexible-match-mask value	bit-length	<p>Starting in Junos OS 14.2, flexible offset filters are supported in firewall hierarchy configurations.</p> <p>Length of the data to be matched in bits, not needed for string input (0..128)</p>
	bit-offset	Bit offset after the (match-start + byte) offset (0..7)
	byte-offset	Byte offset after the match start point
	flexible-mask-name	Select a flexible match from predefined template field
	mask-in-hex	Mask out bits in the packet data to be matched
	match-start	Start point to match in packet
	prefix	Value data/string to be matched

Table 63: Firewall Filter Match Conditions for VPLS Traffic (*continued*)

Match Condition	Description	
flexible-match-range <i>value</i>	bit-length	Length of the data to be matched in bits (0..32)
	bit-offset	Bit offset after the (match-start + byte) offset (0..7)
	byte-offset	Byte offset after the match start point
	flexible-range-name	Select a flexible match from predefined template field
	match-start	Start point to match in packet
	range	Range of values to be matched
	range-except	Do not match this range of values
forwarding-class <i>class</i>	Match the forwarding class. Specify assured-forwarding , best-effort , expedited-forwarding , or network-control .	
forwarding-class-except <i>class</i>	Do not match the forwarding class. For details, see the forwarding-class match condition.	

Table 63: Firewall Filter Match Conditions for VPLS Traffic (*continued*)

Match Condition	Description
icmp-code message-code	<p>Match the ICMP message code field.</p> <p>If you configure this match condition, we recommend that you also configure the next-header icmp or next-header icmp6 match condition in the same term.</p> <p>If you configure this match condition, you must also configure the icmp-type message-type match condition in the same term. An ICMP message code provides more specific information than an ICMP message type, but the meaning of an ICMP message code is dependent on the associated ICMP message type.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed). The keywords are grouped by the ICMP type with which they are associated:</p> <ul style="list-style-type: none"> parameter-problem: ip6-header-bad (0), unrecognized-next-header (1), unrecognized-option (2) time-exceeded: ttl-eq-zero-during-reassembly (1), ttl-eq-zero-during-transit (0) destination-unreachable: address-unreachable (3), administratively-prohibited (1), no-route-to-destination (0), port-unreachable (4)
icmp-code-except message-code	Do not match the ICMP message code field. For details, see the icmp-code match condition.
icmp-code number	<p>(MX Series routers and EX Series switches only) Match the ICMP message code field.</p> <p>If you configure this match condition, we recommend that you also configure the ip-protocol icmp or ip-protocol icmp6 match condition in the same term.</p> <p>If you configure this match condition, you must also configure the icmp-type message-type match condition in the same term. An ICMP message code provides more specific information than an ICMP message type, but the meaning of an ICMP message code is dependent on the associated ICMP message type.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed). The keywords are grouped by the ICMP type with which they are associated:</p> <ul style="list-style-type: none"> parameter-problem: ip6-header-bad (0), unrecognized-next-header (1), unrecognized-option (2) time-exceeded: ttl-eq-zero-during-reassembly (1), ttl-eq-zero-during-transit (0) destination-unreachable: address-unreachable (3), administratively-prohibited (1), no-route-to-destination (0), port-unreachable (4)
icmp-code-except number	(MX Series routers and EX Series switches only) Do not match on the ICMP code field. For details, see the icmp-code match condition.

Table 63: Firewall Filter Match Conditions for VPLS Traffic (*continued*)

Match Condition	Description
interface <i>interface-name</i>	<p>Interface on which the packet was received. You can configure a match condition that matches packets based on the interface on which they were received.</p> <p>NOTE: If you configure this match condition with an interface that does not exist, the term does not match any packet.</p>
interface-group <i>group-number</i>	<p>Match the logical interface on which the packet was received to the specified interface group or set of interface groups. For group-number, specify a single value or a range of values from 0 through 255.</p> <p>To assign a logical interface to an interface group group-number, specify the group-number at the [interfaces <i>interface-name</i> unit <i>number</i> family <i>family</i> filter group] hierarchy level.</p> <p>For more information, see “Filtering Packets Received on a Set of Interface Groups Overview” on page 1181.</p> <p>NOTE: This match condition is not supported on T4000 Type 5 FPCs.</p>
interface-group-except <i>group-name</i>	<p>Do not match the logical interface on which the packet was received to the specified interface group or set of interface groups. For details, see the interface-group match condition.</p> <p>NOTE: This match condition is not supported on T4000 Type 5 FPCs.</p>
interface-set <i>interface-set-name</i>	<p>Match the interface on which the packet was received to the specified interface set.</p> <p>To define an interface set, include the interface-set statement at the [edit firewall] hierarchy level. For more information, see “Filtering Packets Received on an Interface Set Overview” on page 1182.</p>
ip-address <i>address</i>	<p>(MX Series routers and EX Series switches only) 32-bit address that supports the standard syntax for IPv4 addresses.</p> <p>Note that when using this term, the match condition ether-type IPv4 must be defined on the same term.</p>
ip-destination-address <i>address</i>	<p>(MX Series routers and EX Series switches only) 32-bit address that is the final destination node address for the packet.</p> <p>Note that when using this term, the match condition ether-type IPv4 must be defined on the same term.</p>

Table 63: Firewall Filter Match Conditions for VPLS Traffic (*continued*)

Match Condition	Description
ip-precedence <i>ip-precedence-field</i>	(MX Series routers and EX Series switches only) IP precedence field. In place of the numeric field value, you can specify one of the following text synonyms (the field values are also listed): critical-ecp (0xa0), flash (0x60), flash-override (0x80), immediate (0x40), internet-control (0xc0), net-control (0xe0), priority (0x20), or routine (0x00).
ip-precedence-except <i>ip-precedence-field</i>	(MX Series routers and EX Series switches only) Do not match on the IP precedence field.
ip-protocol number	(MX Series routers and EX Series switches only) IP protocol field.
ip-protocol-except <i>number</i>	(MX Series routers and EX Series switches only) Do not match on the IP protocol field.
ip-source-address address	<p>(MX Series routers and EX Series switches only) IP address of the source node sending the packet.</p> <p>Note that when using this term, the match condition ether-type IPv4 must also be defined on the same term.</p>
ipv6-source-prefix-list <i>named-list</i>	(MX Series only) Match the IPv6 source address in a <i>named-list</i> .
ipv6-address address	(MX Series and EX9200 only) 128-bit address that supports the standard syntax for IPv6 addresses. Starting in Junos OS 14.2, firewall family bridge IPv6 match criteria is supported on MX Series and EX9200 switches.
ipv6-destination-address <i>address</i>	((MX Series and EX9200 only) 128-bit address that is the final destination node address for this packet. Note that when using this term, the match condition ether-type IPv6 must be defined on the same term.
ipv6-destination-prefix-list <i>named-list</i>	(MX Series only) Match the IPv6 destination addresses in a <i>named-list</i> .

Table 63: Firewall Filter Match Conditions for VPLS Traffic (*continued*)

Match Condition	Description
ipv6-next-header <i>protocol</i>	<p>(MX Series only) Match IPv6 next header protocol type.</p> <p>The following list shows the supported values for <i>protocol</i>:</p> <ul style="list-style-type: none"> • ah—IP Security authentication header • dstopts—IPv6 destination options • egp—Exterior gateway protocol • esp—IPSec Encapsulating Security Payload • fragment—IPv6 fragment header • gre—Generic routing encapsulation • hop-by-hop—IPv6 hop by hop options • icmp—Internet Control Message Protocol • icmp6—Internet Control Message Protocol Version 6 • igmp—Internet Group Management Protocol • ipip—IP in IP • ipv6—IPv6 in IP • no-next-header—IPv6 no next header • ospf—Open Shortest Path First • pim—Protocol Independent Multicast • routing—IPv6 routing header • rsvp—Resource Reservation Protocol • sctp—Stream Control Transmission Protocol • tcp—Transmission Control Protocol • udp—User Datagram Protocol • vrrp—Virtual Router Redundancy Protocol
ipv6-next-header-except <i>protocol</i>	(MX Series only) Do not match the IPv6 next header protocol type.

Table 63: Firewall Filter Match Conditions for VPLS Traffic (*continued*)

Match Condition	Description
ipv6-payload-protocol <i>protocol</i>	<p>(MX Series only) Match IPv6 payload protocol type.</p> <p>The following list shows the supported values for <i>protocol</i>:</p> <ul style="list-style-type: none"> • ah—IP Security authentication header • dstopts—IPv6 destination options • egp—Exterior gateway protocol • esp—IPSec Encapsulating Security Payload • fragment—IPv6 fragment header • gre—Generic routing encapsulation • hop-by-hop—IPv6 hop by hop options • icmp—Internet Control Message Protocol • icmp6—Internet Control Message Protocol Version 6 • igmp—Internet Group Management Protocol • ipip—IP in IP • ipv6—IPv6 in IP • no-next-header—IPv6 no next header • ospf—Open Shortest Path First • pim—Protocol Independent Multicast • routing—IPv6 routing header • rsvp—Resource Reservation Protocol • sctp—Stream Control Transmission Protocol • tcp—Transmission Control Protocol • udp—User Datagram Protocol • vrrp—Virtual Router Redundancy Protocol
ipv6-payload-protocol-except <i>protocol</i>	(MX Series only) Do not match the IPv6 payload protocol.
ipv6-prefix-list <i>named-list</i>	(MX Series only) Match the IPv6 address in a <i>named-list</i> .
ipv6-source-address <i>address</i>	(MX Series only) 128-bit address that is the originating source node address for this packet.

Table 63: Firewall Filter Match Conditions for VPLS Traffic (*continued*)

Match Condition	Description
ipv6-traffic-class <i>number</i>	<p>(MX Series only) Differentiated Services code point (DSCP). The DiffServ protocol uses the type-of-service (ToS) byte in the IP header. The most significant 6 bits of this byte form the DSCP. For more information, see <i>Understanding How Behavior Aggregate Classifiers Prioritize Trusted Traffic</i>.</p> <p>You can specify a numeric value from 0 through 63. To specify the value in hexadecimal form, include 0x as a prefix. To specify the value in binary form, include b as a prefix.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed):</p> <ul style="list-style-type: none"> • RFC 3246, <i>An Expedited Forwarding PHB (Per-Hop Behavior)</i>, defines one code point: ef (46). • RFC 2597, <i>Assured Forwarding PHB Group</i>, defines 4 classes, with 3 drop precedences in each class, for a total of 12 code points: af11 (10), af12 (12), af13 (14), af21 (18), af22 (20), af23 (22), af31 (26), af32 (28), af33 (30), af41 (34), af42 (36), af43 (38)
ipv6-traffic-class-except <i>number</i>	Do not match the DSCP number .
learn-vlan-1p-priority <i>number</i>	<p>(MX Series routers, M320 router, and EX Series switches only) Match on the IEEE 802.1p learned VLAN priority bits in the provider VLAN tag (the only tag in a single-tag frame with 802.1Q VLAN tags or the outer tag in a dual-tag frame with 802.1Q VLAN tags). Specify a single value or multiple values from 0 through 7.</p> <p>Compare with the user-vlan-1p-priority match condition.</p> <p>NOTE: This match condition supports the presence of a control word for MX Series routers and the M320 router.</p>
learn-vlan-1p-priority-except <i>number</i>	<p>(MX Series routers, M320 router, and EX Series switches only) Do not match on the IEEE 802.1p learned VLAN priority bits. For details, see the learn-vlan-1p-priority match condition.</p> <p>NOTE: This match condition supports the presence of a control word for MX Series routers and the M320 router.</p>

Table 63: Firewall Filter Match Conditions for VPLS Traffic (*continued*)

Match Condition	Description
learn-vlan-dei	(MX Series routers and EX Series switches only) Match the user VLAN ID drop eligibility indicator (DEI) bit.
learn-vlan-dei-except	(MX Series routers and EX Series switches only) Do not match the user VLAN ID DEI bit.
learn-vlan-id <i>number</i>	(MX Series routers and EX Series switches only) VLAN identifier used for MAC learning.
learn-vlan-id-except <i>number</i>	(MX Series routers and EX Series switches only) Do not match on the VLAN identifier used for MAC learning.
loss-priority <i>level</i>	<p>Packet loss priority (PLP) level. Specify a single level or multiple levels: low, medium-low, medium-high, or high.</p> <p>Supported on M120 and M320 routers; M7i and M10i routers with the Enhanced CFEB (CFEB-E); and MX Series routers.</p> <p>For IP traffic on M320, MX Series, and T Series routers with Enhanced II Flexible PIC Concentrators (FPCs) and EX Series switches, you must include the tri-color statement at the [edit class-of-service] hierarchy level to commit a PLP configuration with any of the four levels specified. If the tri-color statement is not enabled, you can only configure the high and low levels. This applies to all protocol families.</p> <p>For information about the tri-color statement and about using behavior aggregate (BA) classifiers to set the PLP level of incoming packets, see <i>Understanding How Forwarding Classes Assign Classes to Output Queues</i>.</p>
loss-priority-except <i>level</i>	<p>Do not match on the packet loss priority level. Specify a single level or multiple levels: low, medium-low, medium-high, or high.</p> <p>For information about using behavior aggregate (BA) classifiers to set the PLP level of incoming packets, see <i>Understanding How Behavior Aggregate Classifiers Prioritize Trusted Traffic</i>.</p>
port <i>number</i>	(MX Series routers and EX Series switches only) TCP or UDP source or destination port. You cannot specify both the port match condition and either the destination-port or source-port match condition in the same term.
port-except <i>number</i>	(MX Series routers and EX Series switches only) Do not match on the TCP or UDP source or destination port. You cannot specify both the port match condition and either the destination-port or source-port match condition in the same term.

Table 63: Firewall Filter Match Conditions for VPLS Traffic (*continued*)

Match Condition	Description
prefix-list name	<p>(MX Series routers and EX Series switches only) Match the destination or source prefixes in the specified list. Specify the name of a prefix list defined at the [edit policy-options prefix-list prefix-list-name] hierarchy level.</p> <p>NOTE: VPLS prefix lists support only IPV4 addresses. IPV6 addresses included in a VPLS prefix list will be discarded.</p>
prefix-list name except	(MX Series routers and EX Series switches only) Do not match the destination or source prefixes in the specified list. For more information, see the destination-prefix-list match condition.
source-mac-address address	Source MAC address of a VPLS packet.
source-port number	(MX Series routers and EX Series switches only) TCP or UDP source port field. You cannot specify the port and source-port match conditions in the same term.
source-port-except number	(MX Series routers and EX Series switches only) Do not match on the TCP or UDP source port field. You cannot specify the port and source-port match conditions in the same term.
source-prefix-list name	<p>(ACX Series routers, MX Series routers, and EX Series switches only) Match the source prefixes in the specified prefix list. Specify a prefix list name defined at the [edit policy-options prefix-list prefix-list-name] hierarchy level.</p> <p>NOTE: VPLS prefix lists support only IPV4 addresses. IPV6 addresses included in a VPLS prefix list will be discarded.</p>
source-prefix-list name except	(MX Series routers and EX Series switches only) Do not match the source prefixes in the specified prefix list. For more information, see the source-prefix-list match condition.

Table 63: Firewall Filter Match Conditions for VPLS Traffic (*continued*)

Match Condition	Description
tcp-flags flags	<p>Match one or more of the low-order 6 bits in the 8-bit TCP flags field in the TCP header.</p> <p>To specify individual bit fields, you can specify the following text synonyms or hexadecimal values:</p> <ul style="list-style-type: none"> • fin (0x01) • syn (0x02) • rst (0x04) • push (0x08) • ack (0x10) • urgent (0x20) <p>In a TCP session, the SYN flag is set only in the initial packet sent, while the ACK flag is set in all packets sent after the initial packet.</p> <p>You can string together multiple flags using the bit-field logical operators.</p> <p>If you configure this match condition for IPv6 traffic, we recommend that you also configure the next-header tcp match condition in the same term to specify that the TCP protocol is being used on the port.</p>
traffic-type type-name	(MX Series routers and EX Series switches only) Traffic type. Specify broadcast , multicast , unknown-unicast , or known-unicast .
traffic-type-except type-name	(MX Series routers and EX Series switches only) Do not match on the traffic type. Specify broadcast , multicast , unknown-unicast , or known-unicast .
user-vlan-1p-priority number	<p>(MX Series routers, M320 router, and EX Series switches only) Match on the IEEE 802.1p user priority bits in the customer VLAN tag (the inner tag in a dual-tag frame with 802.1Q VLAN tags). Specify a single value or multiple values from 0 through 7.</p> <p>Compare with the learn-vlan-1p-priority match condition.</p> <p>NOTE: This match condition supports the presence of a control word for MX Series routers and the M320 router.</p>
user-vlan-1p-priority-except number	<p>(MX Series routers, M320 router, and EX Series switches only) Do not match on the IEEE 802.1p user priority bits. For details, see the user-vlan-1p-priority match condition.</p> <p>NOTE: This match condition supports the presence of a control word for MX Series routers and the M320 router.</p>
user-vlan-id number	(MX Series routers and EX Series switches only) Match the first VLAN identifier that is part of the payload.

Table 63: Firewall Filter Match Conditions for VPLS Traffic (*continued*)

Match Condition	Description
user-vlan-id-except number	(MX Series routers and EX Series switches only) Do not match on the first VLAN identifier that is part of the payload.
vlan-ether-type value	VLAN Ethernet type field of a VPLS packet.
vlan-ether-type-except value	Do not match on the VLAN Ethernet type field of a VPLS packet.

Release History Table

Release	Description
14.2	Starting in Junos OS 14.2, flexible offset filters are supported in firewall hierarchy configurations.
14.2	Starting in Junos OS 14.2, firewall family bridge IPv6 match criteria is supported on MX Series and EX9200 switches.

Firewall Filter Match Conditions for Layer 2 CCC Traffic

You can configure a firewall filter with match conditions for Layer 2 circuit cross-connect (CCC) traffic (family ccc).

The following restrictions apply to firewall filters for Layer 2 CCC traffic:

- The **input-list *filter-names*** and **output-list *filter-names*** statements for firewall filters for the ccc protocol family are supported on all interfaces with the exception of management interfaces and internal Ethernet interfaces (**fxp** or **em0**), loopback interfaces (**lo0**), and USB modem interfaces (**umd**).
- Only on MX Series routers and EX Series switches, you cannot apply a Layer 2 CCC stateless firewall filter (a firewall filter configured at the **[edit firewall filter family ccc]** hierarchy level) as an output filter.

On MX Series routers and EX Series switches, firewall filters configured for the **family ccc** statement can be applied only as input filters.

Table 64 on page 910 describes the **match-conditions** you can configure at the [edit firewall family ccc filter filter-name term term-name from] hierarchy level.

Table 64: Firewall Filter Match Conditions for Layer 2 CCC Traffic

Match Condition	Description
apply-groups	Specify which groups to inherit configuration data from. You can specify more than one group name. You must list them in order of inheritance priority. The configuration data in the first group takes priority over the data in subsequent groups.
apply-groups-except	Specify which groups not to inherit configuration data from. You can specify more than one group name.
destination-mac-address address	<p>(MX Series routers and EX Series switches only) Match the destination media access control (MAC) address of a virtual private LAN service (VPLS) packet.</p> <p>To have packets correctly evaluated by this match condition when applied to egress traffic flowing over a CCC circuit from a logical interface on an I-chip DPC in a Layer 2 virtual private network (VPN) routing instance, you must make a configuration change to the Layer 2 VPN routing instance. You must explicitly disable the use of a control word for traffic flowing out over a Layer 2 circuit. The use of a control word is enabled by default for Layer 2 VPN routing instances to support the emulated virtual circuit (VC) encapsulation for Layer 2 circuits.</p> <p>To explicitly disable the use of a control word for Layer 2 VPNs, include the no-control-word statement at either of the following hierarchy levels:</p> <ul style="list-style-type: none"> • [edit routing-instances routing-instance-name protocols l2vpn] • [edit logical-systems logical-system-name routing-instances routing-instance-name protocols l2vpn] <p>NOTE: This match condition is not supported on PTX series packet transport routers.</p> <p>For more information, see <i>Disabling the Control Word for Layer 2 VPNs</i>.</p>

Table 64: Firewall Filter Match Conditions for Layer 2 CCC Traffic (*continued*)

Match Condition	Description	
flexible-match-mask <i>value</i>	bit-length	Length of the data to be matched in bits, not needed for string input (0..128)
	bit-offset	Bit offset after the (match-start + byte) offset (0..7)
	byte-offset	Byte offset after the match start point
	flexible-mask-name	Select a flexible match from predefined template field
	mask-in-hex	Mask out bits in the packet data to be matched
	match-start	Start point to match in packet
	prefix	Value data/string to be matched
flexible-match-range <i>value</i>	bit-length	Length of the data to be matched in bits (0..32)
	bit-offset	Bit offset after the (match-start + byte) offset (0..7)
	byte-offset	Byte offset after the match start point
	flexible-range-name	Select a flexible match from predefined template field
	match-start	Start point to match in packet
	range	Range of values to be matched
	range-except	Do not match this range of values
forwarding-class <i>class</i>	Forwarding class. Specify assured-forwarding , best-effort , expedited-forwarding , or network-control .	
forwarding-class-except <i>class</i>	Do not match on the forwarding class. Specify assured-forwarding , best-effort , expedited-forwarding , or network-control .	

Table 64: Firewall Filter Match Conditions for Layer 2 CCC Traffic (*continued*)

Match Condition	Description
interface-group group-number	<p>Match the logical interface on which the packet was received to the specified interface group or set of interface groups. For group-number, specify a single value or a range of values from 0 through 255.</p> <p>To assign a logical interface to an interface group group-number, specify the group-number at the [interfaces interface-name unit number family family filter group] hierarchy level.</p> <p>NOTE: This match condition is not supported on PTX series packet transport routers.</p> <p>For more information, see “Filtering Packets Received on a Set of Interface Groups Overview” on page 1181.</p>
interface-group-except number	<p>Do not match the logical interface on which the packet was received to the specified interface group or set of interface groups. For details, see the interface-group match condition.</p> <p>NOTE: This match condition is not supported on PTX series packet transport routers.</p>
learn-vlan-1p-priority number	<p>(MX Series routers, M320 router, and EX Series switches only) Match on the IEEE 802.1p learned VLAN priority bits in the provider VLAN tag (the only tag in a single-tag frame with 802.1Q VLAN tags or the outer tag in a dual-tag frame with 802.1Q VLAN tags). Specify a single value or multiple values from 0 through 7.</p> <p>Compare with the user-vlan-1p-priority match condition.</p> <p>NOTE: This match condition is not supported on PTX series packet transport routers.</p> <p>NOTE: This match condition supports the presence of a control word for MX Series and M320 routers.</p>
learn-vlan-1p-priority-except number	<p>(MX Series routers, M320 router, and EX Series switches only) Do not match on the IEEE 802.1p learned VLAN priority bits. For details, see the learn-vlan-1p-priority match condition.</p> <p>NOTE: This match condition is not supported on PTX series packet transport routers.</p> <p>NOTE: This match condition supports the presence of a control word for MX Series and M320 routers.</p>

Table 64: Firewall Filter Match Conditions for Layer 2 CCC Traffic (*continued*)

Match Condition	Description
loss-priority level	<p>Packet loss priority (PLP) level. Specify a single level or multiple levels: low, medium-low, medium-high, or high.</p> <p>Supported on M120 and M320 routers; M7i and M10i routers with the Enhanced CFEB (CFEB-E); and MX Series routers and EX Series switches.</p> <p>For IP traffic on M320, MX Series, and T Series routers with Enhanced II Flexible PIC Concentrators (FPCs), and EX Series switches, you must include the tri-color statement at the [edit class-of-service] hierarchy level to commit a PLP configuration with any of the four levels specified. If the tri-color statement is not enabled, you can only configure the high and low levels. This applies to all protocol families.</p> <p>For information about the tri-color statement, see <i>Configuring and Applying Tricolor Marking Policers</i>. For information about using behavior aggregate (BA) classifiers to set the PLP level of incoming packets, see <i>Understanding How Forwarding Classes Assign Classes to Output Queues</i>.</p>
loss-priority-except level	<p>Do not match on the packet loss priority level. Specify a single level or multiple levels: low, medium-low, medium-high, or high.</p> <p>NOTE: This match condition is not supported on PTX series packet transport routers.</p> <p>For information about using behavior aggregate (BA) classifiers to set the PLP level of incoming packets, see <i>Understanding How Behavior Aggregate Classifiers Prioritize Trusted Traffic</i>.</p>
user-vlan-1p-priority number	<p>(MX Series routers, M320 router, and EX Series switches only) Match on the IEEE 802.1p user priority bits in the customer VLAN tag (the inner tag in a dual-tag frame with 802.1Q VLAN tags). Specify a single value or multiple values from 0 through 7.</p> <p>Compare with the learn-vlan-1p-priority match condition.</p> <p>NOTE: This match condition is not supported on PTX series packet transport routers.</p> <p>NOTE: This match condition supports the presence of a control word for MX Series and M320 routers.</p>
user-vlan-1p-priority-except number	<p>(MX Series routers, M320 router, and EX Series switches only) Do not match on the IEEE 802.1p user priority bits. For details, see the user-vlan-1p-priority match condition.</p> <p>NOTE: This match condition is not supported on PTX series packet transport routers.</p> <p>NOTE: This match condition supports the presence of a control word for MX Series and M320 routers.</p>

Firewall Filter Match Conditions for Layer 2 Bridging Traffic

Only on MX Series routers and EX Series switches, you can configure a standard stateless firewall filter with match conditions for Layer 2 bridging traffic (**family bridge**). [Table 65 on page 914](#) describes the **match-conditions** you can configure at the `[edit firewall family bridge filter filter-name term term-name from]` hierarchy level.

Table 65: Standard Firewall Filter Match Conditions for Layer 2 Bridging (MX Series Routers and EX Series Switches Only)

Match Condition	Description
destination-mac-address <i>address</i>	Destination media access control (MAC) address of a Layer 2 packet in a bridging environment.
destination-port <i>number</i>	TCP or UDP destination port field. You cannot specify both the port and destination-port match conditions in the same term.
destination-port-except	Do not match the TCP/UDP destination port.
destination-prefix-list <i>named-list</i>	Match the IP destination prefixes in a <i>named-list</i> .

Table 65: Standard Firewall Filter Match Conditions for Layer 2 Bridging (MX Series Routers and EX Series Switches Only) (continued)

Match Condition	Description
dscp number	<p>Differentiated Services code point (DSCP). The DiffServ protocol uses the type-of-service (ToS) byte in the IP header. The most significant 6 bits of this byte form the DSCP. For more information, see <i>Understanding How Behavior Aggregate Classifiers Prioritize Trusted Traffic</i>.</p> <p>You can specify a numeric value from 0 through 63. To specify the value in hexadecimal form, include 0x as a prefix. To specify the value in binary form, include b as a prefix.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed):</p> <ul style="list-style-type: none"> • RFC 3246, <i>An Expedited Forwarding PHB (Per-Hop Behavior)</i>, defines one code point: ef (46). • RFC 2597, <i>Assured Forwarding PHB Group</i>, defines 4 classes, with 3 drop precedences in each class, for a total of 12 code points: af11 (10), af12 (12), af13 (14), af21 (18), af22 (20), af23 (22), af31 (26), af32 (28), af33 (30), af41 (34), af42 (36), af43 (38)
dscp-except number	<p>Do not match on the DSCP number. For more information, see the dscp-except match condition.</p>
ether-type value	<p>Match the 2-octet IEEE 802.3 Length/EtherType field to the specified value or list of values.</p> <p>You can specify decimal or hexadecimal values from 0 through 65535 (0xFFFF). A value from 0 through 1500 (0x05DC) specifies the length of an Ethernet Version 1 frame. A value from 1536 (0x0600) through 65535 specifies the EtherType (nature of the MAC client protocol) of an Ethernet Version 2 frame.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the hexadecimal values are also listed): aarp (0x80F3), appletalk (0x809B), arp (0x0806), ipv4 (0x0800), ipv6 (0x86DD), mpls-multicast (0x8848), mpls-unicast (0x8847), oam (0x8902), ppp (0x880B), pppoe-discovery (0x8863), pppoe-session (0x8864), sna (0x80D5).</p> <p>NOTE: When matching on ip-address or ipv6-address, the ether-type ipv4 or ipv6, respectively, must also be specified in order to limit matches to ip traffic only.</p>

Table 65: Standard Firewall Filter Match Conditions for Layer 2 Bridging (MX Series Routers and EX Series Switches Only) (continued)

Match Condition	Description	
ether-type-except value	<p>Do not match the 2-octet IEEE 802.3 Length/EtherType field to the specified value or list of values.</p> <p>For details about specifying the values, see the ether-type match condition.</p>	
flexible-match-mask value	bit-length	Length of the data to be matched in bits, not needed for string input (0..128)
	bit-offset	Bit offset after the (match-start + byte) offset (0..7)
	byte-offset	Byte offset after the match start point
	flexible-mask-name	Select a flexible match from predefined template field
	mask-in-hex	Mask out bits in the packet data to be matched
	match-start	Start point to match in packet
	prefix	Value data/string to be matched

Table 65: Standard Firewall Filter Match Conditions for Layer 2 Bridging (MX Series Routers and EX Series Switches Only) (continued)

Match Condition	Description	
flexible-match-range <i>value</i>	bit-length	Length of the data to be matched in bits (0..32)
	bit-offset	Bit offset after the (match-start + byte) offset (0..7)
	byte-offset	Byte offset after the match start point
	flexible-range-name	Select a flexible match from predefined template field
	match-start	Start point to match in packet
	range	Range of values to be matched
	range-except	Do not match this range of values
forwarding class <i>class</i>	Forwarding class. Specify assured-forwarding , best-effort , expedited-forwarding , or network-control .	
forwarding-class-except <i>class</i>	Ethernet type field of a Layer 2 packet environment. Specify assured-forwarding , best-effort , expedited-forwarding , or network-control .	

Table 65: Standard Firewall Filter Match Conditions for Layer 2 Bridging (MX Series Routers and EX Series Switches Only) (continued)

Match Condition	Description
icmp-code message-code	<p>Match the ICMP message code field.</p> <p>If you configure this match condition, we recommend that you also configure the ip-protocol icmp, ip-protocol icmp6, or ip-protocol icmpv6 match condition in the same term.</p> <p>If you configure this match condition, you must also configure the icmp-type message-type match condition in the same term. An ICMP message code provides more specific information than an ICMP message type, but the meaning of an ICMP message code is dependent on the associated ICMP message type.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed). The keywords are grouped by the ICMP type with which they are associated:</p> <ul style="list-style-type: none"> parameter-problem: ip6-header-bad (0), unrecognized-next-header (1), unrecognized-option (2) time-exceeded: ttl-eq-zero-during-reassembly (1), ttl-eq-zero-during-transit (0) destination-unreachable: address-unreachable (3), administratively-prohibited (1), no-route-to-destination (0), port-unreachable (4)
icmp-code-except message-code	Do not match the ICMP message code field. For details, see the icmp-code match condition.
icmp-type message-type	<p>Match the ICMP message type field.</p> <p>If you configure this match condition, we recommend that you also configure the ip-protocol icmp, ip-protocol icmp6, or ip-protocol icmpv6 match condition in the same term.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): destination-unreachable (1), echo-reply (129), echo-request (128), membership-query (130), membership-report (131), membership-termination (132), neighbor-advertisement (136), neighbor-solicit (135), node-information-reply (140), node-information-request (139), packet-too-big (2), parameter-problem (4), redirect (137), router-advertisement (134), router-renumbering (138), router-solicit (133), or time-exceeded (3).</p>
icmp-type-except message-type	Do not match the ICMP message type field. For details, see the icmp-type match condition.

Table 65: Standard Firewall Filter Match Conditions for Layer 2 Bridging (MX Series Routers and EX Series Switches Only) (continued)

Match Condition	Description
interface <i>interface-name</i>	<p>Interface on which the packet was received. You can configure a match condition that matches packets based on the interface on which they were received.</p> <p>NOTE: If you configure this match condition with an interface that does not exist, the term does not match any packet.</p>
interface-group <i>group-number</i>	<p>Match the logical interface on which the packet was received to the specified interface group or set of interface groups. For <i>group-number</i>, specify a single value or a range of values from 0 through 255.</p> <p>To assign a logical interface to an interface group <i>group-number</i>, specify the <i>group-number</i> at the [interfaces <i>interface-name</i> unit <i>number</i> family <i>family</i> filter group] hierarchy level.</p> <p>For more information, see “Filtering Packets Received on a Set of Interface Groups Overview” on page 1181.</p>
interface-group-except <i>number</i>	<p>Do not match the logical interface on which the packet was received to the specified interface group or set of interface groups. For details, see the interface-group match condition.</p>
interface-set <i>interface-set-name</i>	<p>Match the interface on which the packet was received to the specified interface set.</p> <p>To define an interface set, include the interface-set statement at the [edit firewall] hierarchy level. For more information, see “Filtering Packets Received on an Interface Set Overview” on page 1182.</p>
ip-address <i>address</i>	<p>32-bit address that supports the standard syntax for IPv4 addresses.</p> <p>NOTE: In order to limit matches to IPv4 traffic only, the ether-type ipv4 must also be specified in the same term.</p>
ip-destination-address <i>address</i>	<p>32-bit address that is the final destination node address for the packet.</p>
ip-precedence <i>ip-precedence-field</i>	<p>IP precedence field. In place of the numeric field value, you can specify one of the following text synonyms (the field values are also listed): critical-ecp (0xa0), flash (0x60), flash-override (0x80), immediate (0x40), internet-control (0xc0), net-control (0xe0), priority (0x20), or routine (0x00).</p>
ip-precedence-except <i>ip-precedence-field</i>	<p>Do not match on the IP precedence field.</p>

Table 65: Standard Firewall Filter Match Conditions for Layer 2 Bridging (MX Series Routers and EX Series Switches Only) (continued)

Match Condition	Description
ip-protocol <i>number</i>	IP protocol field.
ip-protocol-except	Do not match the IP protocol type.
ip-source-address <i>address</i>	IP address of the source node sending the packet.
ipv6-address <i>address</i>	(MX Series only) 128-bit address that supports the standard syntax for IPv6 addresses. NOTE: In order to limit matches to IPv6 traffic only, the ether-type ipv6 must also be specified in the same term.
ipv6-destination-address <i>address</i>	(MX Series only) 128-bit address that is the final destination node address for this packet.
ipv6-destination-prefix-list <i>named-list</i>	(MX Series only) Match the IPv6 destination addresses in a <i>named-list</i> .

Table 65: Standard Firewall Filter Match Conditions for Layer 2 Bridging (MX Series Routers and EX Series Switches Only) (continued)

Match Condition	Description
ipv6-next-header protocol	<p>(MX Series only) Match IPv6 next header protocol type.</p> <p>The following list shows the supported values for <i>protocol</i>:</p> <ul style="list-style-type: none"> • ah—IP Security authentication header • dstopts—IPv6 destination options • egp—Exterior gateway protocol • esp—IPSec Encapsulating Security Payload • fragment—IPv6 fragment header • gre—Generic routing encapsulation • hop-by-hop—IPv6 hop by hop options • icmp—Internet Control Message Protocol • icmp6—Internet Control Message Protocol Version 6 • igmp—Internet Group Management Protocol • ipip—IP in IP • ipv6—IPv6 in IP • no-next-header—IPv6 no next header • ospf—Open Shortest Path First • pim—Protocol Independent Multicast • routing—IPv6 routing header • rsvp—Resource Reservation Protocol • sctp—Stream Control Transmission Protocol • tcp—Transmission Control Protocol • udp—User Datagram Protocol • vrp—Virtual Router Redundancy Protocol
ipv6-next-header-except protocol	<p>(MX Series only) Do not match the IPv6 next header protocol type.</p>

Table 65: Standard Firewall Filter Match Conditions for Layer 2 Bridging (MX Series Routers and EX Series Switches Only) (continued)

Match Condition	Description
ipv6-payload-protocol <i>protocol</i>	<p>(MX Series only) Match IPv6 payload protocol type.</p> <p>The following list shows the supported values for <i>protocol</i>:</p> <ul style="list-style-type: none"> • ah—IP Security authentication header • dstopts—IPv6 destination options • egp—Exterior gateway protocol • esp—IPSec Encapsulating Security Payload • fragment—IPv6 fragment header • gre—Generic routing encapsulation • hop-by-hop—IPv6 hop by hop options • icmp—Internet Control Message Protocol • icmp6—Internet Control Message Protocol Version 6 • igmp—Internet Group Management Protocol • ipip—IP in IP • ipv6—IPv6 in IP • no-next-header—IPv6 no next header • ospf—Open Shortest Path First • pim—Protocol Independent Multicast • routing—IPv6 routing header • rsvp—Resource Reservation Protocol • sctp—Stream Control Transmission Protocol • tcp—Transmission Control Protocol • udp—User Datagram Protocol • vrrp—Virtual Router Redundancy Protocol
ipv6-payload-protocol-except <i>protocol</i>	(MX Series only) Do not match the IPv6 payload protocol.
ipv6-prefix-list <i>named-list</i>	(MX Series only) Match the IPv6 address in a <i>named-list</i> .
ipv6-source-address <i>address</i>	(MX Series only) 128-bit address that is the originating source node address for this packet.
ipv6-source-prefix-list <i>named-list</i>	(MX Series only) Match the IPv6 source address in a <i>named-list</i> .

Table 65: Standard Firewall Filter Match Conditions for Layer 2 Bridging (MX Series Routers and EX Series Switches Only) (continued)

Match Condition	Description
ipv6-traffic-class <i>number</i>	<p>(MX Series only) Differentiated Services code point (DSCP). The DiffServ protocol uses the type-of-service (ToS) byte in the IP header. The most significant 6 bits of this byte form the DSCP. For more information, see <i>Understanding How Behavior Aggregate Classifiers Prioritize Trusted Traffic</i>.</p> <p>You can specify a numeric value from 0 through 63. To specify the value in hexadecimal form, include 0x as a prefix. To specify the value in binary form, include b as a prefix.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed):</p> <ul style="list-style-type: none"> • RFC 3246, <i>An Expedited Forwarding PHB (Per-Hop Behavior)</i>, defines one code point: ef (46). • RFC 2597, <i>Assured Forwarding PHB Group</i>, defines 4 classes, with 3 drop precedences in each class, for a total of 12 code points: af11 (10), af12 (12), af13 (14), af21 (18), af22 (20), af23 (22), af31 (26), af32 (28), af33 (30), af41 (34), af42 (36), af43 (38)
ipv6-traffic-class-except <i>number</i>	Do not match the DSCP number .
isid <i>number</i>	(Supported with Provider Backbone Bridging [PBB]) Match internet service identifier.
isid-dei <i>number</i>	(Supported with PBB) Match the Internet service identifier drop eligibility indicator (DEI) bit.
isid-dei-except <i>number</i>	(Supported with PBB) Do not match the Internet service identifier DEI bit.
isid-priority-code-point <i>number</i>	(Supported with PBB) Match the Internet service identifier priority code point.
isid-priority-code-point-except <i>number</i>	(Supported with PBB) Do not match the Internet service identifier priority code point.

Table 65: Standard Firewall Filter Match Conditions for Layer 2 Bridging (MX Series Routers and EX Series Switches Only) (continued)

Match Condition	Description
learn-vlan-1p-priority value	<p>(MX Series routers and EX Series switches only) Match on the IEEE 802.1p learned VLAN priority bits in the provider VLAN tag (the only tag in a single-tag frame with 802.1Q VLAN tags or the outer tag in a dual-tag frame with 802.1Q VLAN tags). Specify a single value or multiple values from 0 through 7.</p> <p>Compare with the user-vlan-1p-priority match condition.</p>
learn-vlan-1p-priority-except value	(MX Series routers and EX Series switches only) Do not match on the IEEE 802.1p learned VLAN priority bits. For details, see the learn-vlan-1p-priority match condition.
learn-vlan-dei number	(Supported with bridging) Match user virtual LAN (VLAN) identifier DEI bit.
learn-vlan-dei-except number	(Supported with bridging) Do not match user VLAN identifier DEI bit.
learn-vlan-id number	VLAN identifier used for MAC learning.
learn-vlan-id-except number	Do not match on the VLAN identifier used for MAC learning.
loss-priority level	<p>Packet loss priority (PLP) level. Specify a single level or multiple levels: low, medium-low, medium-high, or high.</p> <p>Supported on M120 and M320 routers; M7i and M10i routers with the Enhanced CFEB (CFEB-E); and MX Series routers and EX Series switches.</p> <p>For IP traffic on M320, MX Series, and T Series routers with Enhanced II Flexible PIC Concentrators (FPCs), and EX Series switches, you must include the tri-color statement at the [edit class-of-service] hierarchy level to commit a PLP configuration with any of the four levels specified. If the tri-color statement is not enabled, you can only configure the high and low levels. This applies to all protocol families.</p> <p>For information about the tri-color statement, see <i>Configuring and Applying Tricolor Marking Policies</i>. For information about using behavior aggregate (BA) classifiers to set the PLP level of incoming packets, see <i>Understanding How Forwarding Classes Assign Classes to Output Queues</i>.</p>

Table 65: Standard Firewall Filter Match Conditions for Layer 2 Bridging (MX Series Routers and EX Series Switches Only) (continued)

Match Condition	Description
loss-priority-except level	<p>Do not match on the packet loss priority level. Specify a single level or multiple levels: low, medium-low, medium-high, or high.</p> <p>For information about using behavior aggregate (BA) classifiers to set the PLP level of incoming packets, see the <i>Understanding How Behavior Aggregate Classifiers Prioritize Trusted Traffic</i>.</p>
port number	TCP or UDP source or destination port. You cannot specify both the port match condition and either the destination-port or source-port match conditions in the same term.
source-mac-address address	Source MAC address of a Layer 2 packet.
source-port number	TCP or UDP source port field. You cannot specify the port and source-port match conditions in the same term.
source-port-except	Do not match the TCP/UDP source port.
tcp-flags flags	<p>Match one or more of the low-order 6 bits in the 8-bit TCP flags field in the TCP header.</p> <p>To specify individual bit fields, you can specify the following text synonyms or hexadecimal values:</p> <ul style="list-style-type: none"> • fin (0x01) • syn (0x02) • rst (0x04) • push (0x08) • ack (0x10) • urgent (0x20) <p>In a TCP session, the SYN flag is set only in the initial packet sent, while the ACK flag is set in all packets sent after the initial packet.</p> <p>You can string together multiple flags using the bit-field logical operators.</p> <p>Configuring the tcp-flags match condition requires that you configure the next-header-tcp match condition.</p>
traffic-type type	Traffic type. Specify broadcast , multicast , unknown-unicast , or known-unicast .
traffic-type-except type	Do not match on the traffic type.

Table 65: Standard Firewall Filter Match Conditions for Layer 2 Bridging (MX Series Routers and EX Series Switches Only) (continued)

Match Condition	Description
user-vlan-1p-priority value	(MX Series routers and EX Series switches only) Match on the IEEE 802.1p user priority bits in the customer VLAN tag (the inner tag in a dual-tag frame with 802.1Q VLAN tags). Specify a single value or multiple values from 0 through 7 . Compare with the learn-vlan-1p-priority match condition.
user-vlan-1p-priority-except value	(MX Series routers and EX Series switches only) Do not match on the IEEE 802.1p user priority bits. For details, see the user-vlan-1p-priority match condition.
user-vlan-id number	(MX Series routers and EX Series switches only) Match the first VLAN identifier that is part of the payload.
user-vlan-id-except number	(MX Series routers and EX Series switches only) Do not match on the first VLAN identifier that is part of the payload.
vlan-ether-type value	VLAN Ethernet type field of a Layer 2 bridging packet.
vlan-ether-type-except value	Do not match on the VLAN Ethernet type field of a Layer 2 bridging packet.

Firewall Filter Support on Loopback Interface

A loopback interface is a gateway for all the control traffic that enters the Routing Engine of the router. If you want to monitor this control traffic, you must configure a firewall filter on the loopback interface (lo0). Loopback firewall filters are applied only to packets that are sent to the Routing Engine CPU for further processing. Therefore, you can apply a firewall filter in the ingress and egress directions on the loopback interface. Loopback interfaces on ACX Routers support both inet and inet6 family filters.

NOTE: On ACX, the filter for loopback interface can be applied only for interface-specific instances of the firewall filter.

For standard firewall filter match conditions, see [“Match Conditions for IPv4 Traffic \(ACX Series Routers\)” on page 817](#).

The firewall filter on loopback interfaces handles only the following exception packets in ingress direction:

- TTL exception packets
- Multicast packets having 224.0.0.x as the destination IP address
- Broadcast packets
- IP option packets

NOTE: Though policer action can be attached to loopback filters in ingress direction, behavior will be dependent on CPU RX queue configurations. Rate limiting in ingress direction (through policer configuration) will be sub-set of CPU rate limiters.

The following is a sample configuration for attaching a firewall to the loopback interface:

```
[edit interfaces]
lo0 {
  unit 0 {
    family <inet | inet6> {
      filter {
        input f1;
      }
    }
  }
}
family <inet | inet6>{
  filter f1 {
    interface-specific; >> Mandatory Field.
    term t1 {
      from {
        protocol ospf;
      }
      then {
        count c1;
        discard;
      }
    }
  }
}
```

```
    }  
  }  
  term t2 {  
    then {  
      count c2;  
      accept;  
    }  
  }  
}  
}
```

Configuring Logical Units on the Loopback Interface for Routing Instances in Layer 3 VPNs

For Layer 3 VPNs (VRF routing instances), you can configure a logical unit on the loopback interface into each VRF routing instance that you have configured on the router. Associating a VRF routing instance with a logical unit on the loopback interface allows you to easily identify the VRF routing instance.

Doing this is useful for troubleshooting:

- It allows you to ping a remote CE router from a local PE router in a Layer 3 VPN. For more information, see *Example: Troubleshooting Layer 3 VPNs*.
- It ensures that a path maximum transmission unit (MTU) check on traffic originating on a VRF or virtual-router routing instance functions properly. For more information, see *Configuring Path MTU Checks for VPN Routing Instances*.

You can also configure a firewall filter for the logical unit on the loopback interface; this configuration allows you to filter traffic for the VRF routing instance associated with it.

The following describes how firewall filters affect the VRF routing instance depending on whether they are configured on the default loopback interface, the VRF routing instance, or some combination of the two. The “default loopback interface” refers to **lo0.0** (associated with the default routing table), and the “VRF loopback interface” refers to **lo0.n**, which is configured in the VRF routing instance.

- If you configure Filter A on the default loopback interface and Filter B on the VRF loopback interface, the VRF routing instance uses Filter B.
- If you configure Filter A on the default loopback interface but do not configure a filter on the VRF loopback interface, the VRF routing instance does not use a filter.
- If you configure Filter A on the default loopback interface but do not even configure a VRF loopback interface, the VRF routing instance uses Filter A.

To configure a logical unit on the loopback interface, include the **unit** statement:

```
unit number {
    family inet {
        address address;
    }
}
```

You can include this statement at the following hierarchy levels:

- **[edit interfaces lo0]**
- **[edit logical-systems *logical-system-name* interfaces lo0]**

To associate a firewall filter with the logical unit on the loopback interface, include the **filter** statement:

```
filter {
    input filter-name;
}
```

You can include this statement at the following hierarchy levels:

- **[edit interfaces lo0 unit *unit-number* family inet]**
- **[edit logical-systems *logical-system-name* interfaces lo0 unit *unit-number* family inet]**

To include the **lo0.n** interface (where **n** specifies the logical unit) in the configuration for the VRF routing instance, include the following statement:

```
interface lo0.n;
```

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name*]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name*]

Example: Configuring a Filter to Limit TCP Access to a Port Based On a Prefix List

IN THIS SECTION

- Requirements | 931
- Overview | 931
- Configuration | 931
- Verification | 934

This example shows how to configure a standard stateless firewall filter that limits certain TCP and Internet Control Message Protocol (ICMP) traffic destined for the Routing Engine by specifying a list of prefix sources that contain allowed BGP peers.

Requirements

No special configuration beyond device initialization is required before configuring this example.

Overview

In this example, you create a stateless firewall filter that blocks all TCP connection attempts to port 179 from all requesters except BGP peers that have a specified prefix.

A source prefix list, **plist_bgp179**, is created that specifies the list of source prefixes that contain allowed BGP peers.

The stateless firewall filter **filter_bgp179** matches all packets from the source prefix list **plist_bgp179** to the destination port number 179.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
set policy-options prefix-list plist_bgp179 apply-path "protocols bgp group <*> neighbor <*>"
set firewall family inet filter filter_bgp179 term 1 from source-address 0.0.0.0/0
set firewall family inet filter filter_bgp179 term 1 from source-prefix-list plist_bgp179 except
set firewall family inet filter filter_bgp179 term 1 from destination-port bgp
set firewall family inet filter filter_bgp179 term 1 then reject
set firewall family inet filter filter_bgp179 term 2 then accept
set interfaces lo0 unit 0 family inet filter input filter_bgp179
set interfaces lo0 unit 0 family inet address 127.0.0.1/32
```

Configure the Filter

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure the filter:

1. Expand the prefix list **bgp179** to include all prefixes pointed to by the BGP peer group defined by **protocols bgp group <*> neighbor <*>**.

```
[edit policy-options prefix-list plist_bgp179]
user@host# set apply-path " protocolsbgp group <*> neighbor <*>"
```

2. Define the filter term that rejects TCP connection attempts to port 179 from all requesters except the specified BGP peers.

```
[edit firewall family inet filter filter_bgp179]
user@host# set term term1 from source-address 0.0.0.0/0
user@host# set term term1 from source-prefix-list bgp179 except
user@host# set term term1 from destination-port bgp
user@host# set term term1 then reject
```

3. Define the other filter term to accept all packets.

```
[edit firewall family inet filter filter_bgp179]
user@host# set term term2 then accept
```

4. Apply the firewall filter to the loopback interface.

```
[edit interfaces lo0 unit 0 family inet]
user@host# set filter input filter_bgp179
user@host# set address 127.0.0.1/32
```

Results

From configuration mode, confirm your configuration by entering the **show firewall**, **show interfaces**, and **show policy-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@host# show firewall
family inet {
  filter filter_bgp179 {
    term 1 {
      from {
        source-address {
          0.0.0.0/0;
        }
        source-prefix-list {
          plist_bgp179 except;
        }
        destination-port bgp;
      }
      then {
        reject;
      }
    }
    term 2 {
      then {
        accept;
      }
    }
  }
}
```

```
user@host# show interfaces
lo0 {
  unit 0 {
    family inet {
      filter {
```

```

        input filter_bgp179;
    }
    address 127.0.0.1/32;
}
}
}

```

```

user@host# show policy-options
prefix-list plist_bgp179 {
    apply-path "protocols bgp group <*> neighbor <*>";
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

Displaying the Firewall Filter Applied to the Loopback Interface

Purpose

Verify that the firewall filter **filter_bgp179** is applied to the IPv4 input traffic at logical interface **lo0.0**.

Action

Use the **show interfaces statistics operational mode** command for logical interface **lo0.0**, and include the **detail** option. Under the **Protocol inet** section of the command output section, the **Input Filters** field displays the name of the stateless firewall filter applied to the logical interface in the input direction.

[edit]

```
user@host> show interfaces statistics lo0.0 detail
```

```

Example: Configuring a Stateless Firewall Filter to Accept Traffic from Trusted Sources

IN THIS SECTION

- [Requirements | 936](#)
- [Overview | 936](#)
- [Configuration | 936](#)
- [Verification | 939](#)

This example shows how to create a stateless firewall filter that protects the Routing Engine from traffic originating from untrusted sources.

Requirements

No special configuration beyond device initialization is required before configuring stateless firewall filters.

Overview

In this example, you create a stateless firewall filter called `protect-RE` that discards all traffic destined for the Routing Engine except SSH and BGP protocol packets from specified trusted sources. This example includes the following firewall filter terms:

- **ssh-term**—Accepts TCP packets with a source address of **192.168.122.0/24** and a destination port that specifies SSH.
- **bgp-term**—Accepts TCP packets with a source address of **10.2.1.0/24** and a destination port that specifies BGP.
- **discard-rest-term**—For all packets that are not accepted by **ssh-term** or **bgp-term**, creates a firewall filter log and system logging records, then discards all packets.

NOTE: You can move terms within the firewall filter using the **insert** command. See *insert* in the *CLI User Guide*.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall family inet filter protect-RE term ssh-term from source-address 192.168.122.0/24
set firewall family inet filter protect-RE term ssh-term from protocol tcp
set firewall family inet filter protect-RE term ssh-term from destination-port ssh
set firewall family inet filter protect-RE term ssh-term then accept
set firewall family inet filter protect-RE term bgp-term from source-address 10.2.1.0/24
set firewall family inet filter protect-RE term bgp-term from protocol tcp
set firewall family inet filter protect-RE term bgp-term from destination-port bgp
set firewall family inet filter protect-RE term bgp-term then accept
set firewall family inet filter protect-RE term discard-rest-term then log
set firewall family inet filter protect-RE term discard-rest-term then syslog
set firewall family inet filter protect-RE term discard-rest-term then discard
set interfaces lo0 unit 0 family inet filter input protect-RE
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure the stateless firewall filter:

1. Create the stateless firewall filter.

```
[edit]
user@host# edit firewall family inet filter protect-RE
```

2. Create the first filter term.

```
[edit firewall family inet filter protect-RE]
user@host# edit term ssh-term
```

3. Define the protocol, destination port, and source address match conditions for the term.

```
[edit firewall family inet filter protect-RE term ssh-term]
user@host# set from protocol tcp destination-port ssh source-address 192.168.122.0/24
```

4. Define the actions for the term.

```
[edit firewall family inet filter protect-RE term ssh-term]
user@host# set then accept
```

5. Create the second filter term.

```
[edit firewall family inet filter protect-RE]
user@host# edit term bgp-term
```

6. Define the protocol, destination port, and source address match conditions for the term.

```
[edit firewall family inet filter protect-RE term bgp-term]
user@host# set from protocol tcp destination-port bgp source-address 10.2.1.0/24
```

7. Define the action for the term.

```
[edit firewall family inet filter protect-RE term bgp-term]
user@host# set then accept
```

8. Create the third filter term.

```
[edit firewall family inet filter protect-RE]
user@host# edit term discard-rest-term
```

9. Define the action for the term.

```
[edit firewall family inet filter protect-RE term discard-rest]
user@host# set then log syslog discard
```

10. Apply the filter to the input side of the Routing Engine interface.

```
[edit]
user@host# set interfaces lo0 unit 0 family inet filter input protect-RE
```

Results

Confirm your configuration by entering the **show firewall** command and the **show interfaces lo0** command from configuration mode. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@host# show firewall
family inet {
  filter protect-RE {
    term ssh-term {
      from {
        source-address {
          192.168.122.0/24;
        }
        protocol tcp;
        destination-port ssh;
      }
      then accept;
    }
    term bgp-term {
```

```

    from {
        source-address {
            10.2.1.0/24;
        }
        protocol tcp;
        destination-port bgp;
    }
    then accept;
}
term discard-rest-term {
    then {
        log;
        syslog;
        discard;
    }
}
}
}

```

```

user@host# show interfaces lo0
unit 0 {
    family inet {
        filter {
            input protect-RE;
        }
        address 127.0.0.1/32;
    }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

```

[edit]
user@host# commit

```

Verification

IN THIS SECTION

- [Displaying Stateless Firewall Filter Configurations | 940](#)
- [Verifying a Services, Protocols, and Trusted Sources Firewall Filter | 940](#)
- [Displaying Stateless Firewall Filter Logs | 941](#)

To confirm that the configuration is working properly, perform these tasks:

Displaying Stateless Firewall Filter Configurations

Purpose

Verify the configuration of the firewall filter.

Action

From configuration mode, enter the **show firewall** command and the **show interfaces lo0** command.

Meaning

Verify that the output shows the intended configuration of the firewall filter. In addition, verify that the terms are listed in the order in which you want the packets to be tested. You can move terms within a firewall filter by using the **insert** CLI command.

Verifying a Services, Protocols, and Trusted Sources Firewall Filter

Purpose

Verify that the actions of the firewall filter terms are taken.

Action

Send packets to the device that match the terms. In addition, verify that the filter actions are *not* taken for packets that do not match.

- Use the **ssh host-name** command from a host at an IP address that matches **192.168.122.0/24** to verify that you can log in to the device using only SSH from a host with this address prefix.
- Use the **show route summary** command to verify that the routing table on the device does not contain any entries with a protocol other than **Direct**, **Local**, **BGP**, or **Static**.

Sample Output

% ssh 192.168.249.71

```
%ssh host
user@host's password:
--- JUNOS 6.4-20040518.0 (JSERIES) #0: 2004-05-18 09:27:50 UTC

user@host>
```

user@host> **show route summary**

```
Router ID: 192.168.249.71

inet.0: 34 destinations, 34 routes (33 active, 0 holddown, 1 hidden)
      Direct:    10 routes,      9 active
        Local:     9 routes,      9 active
          BGP:    10 routes,    10 active
        Static:     5 routes,      5 active
...

```

Meaning

Verify the following information:

- You can successfully log in to the device using SSH.
- The **show route summary** command does not display a protocol other than **Direct**, **Local**, **BGP**, or **Static**.

Displaying Stateless Firewall Filter Logs

Purpose

Verify that packets are being logged. If you included the **log** or **syslog** action in a term, verify that packets matching the term are recorded in the firewall log or your system logging facility.

Action

From operational mode, enter the **show firewall log** command.

Sample Output

```
user@host> show firewall log
```

```
Log :
Time      Filter  Action Interface  Protocol  Src Addr      Dest Addr
15:11:02  pfe           D    ge-0/0/0.0    TCP       172.17.28.19  192.168.70.71
15:11:01  pfe           D    ge-0/0/0.0    TCP       172.17.28.19  192.168.70.71
15:11:01  pfe           D    ge-0/0/0.0    TCP       172.17.28.19  192.168.70.71
15:11:01  pfe           D    ge-0/0/0.0    TCP       172.17.28.19  192.168.70.71
...

```

Meaning

Each record of the output contains information about the logged packet. Verify the following information:

- Under **Time**, the time of day the packet was filtered is shown.
- The **Filter** output is always **pfe**.
- Under **Action**, the configured action of the term matches the action taken on the packet—**A** (accept), **D** (discard), **R** (reject).
- Under **Interface**, the inbound (ingress) interface on which the packet arrived is appropriate for the filter.
- Under **Protocol**, the protocol in the IP header of the packet is appropriate for the filter.
- Under **Src Addr**, the source address in the IP header of the packet is appropriate for the filter.
- Under **Dest Addr**, the destination address in the IP header of the packet is appropriate for the filter.

show interfaces (Loopback)

Example: Configuring a Filter to Block Telnet and SSH Access

IN THIS SECTION

- [Requirements](#) | 942
- [Overview](#) | 943
- [Configuration](#) | 943
- [Verification](#) | 946

Requirements

You must have access to a remote host that has network connectivity with this device.

Overview

In this example, you create an IPv4 stateless firewall filter that logs and rejects Telnet or SSH access packets unless the packet is destined for or originates from the 192.168.1.0/24 subnet.

- To match packets destined for or originating from the **address 192.168.1.0/24** subnet, you use the **source-address 192.168.1.0/24** IPv4 match condition.
- To match packets destined for or originating from a TCP port, Telnet port, or SSH port, you use the **protocol tcp**, **port telnet**, and **telnet ssh** IPv4 match conditions.

Configuration

IN THIS SECTION

- [Configure the Stateless Firewall Filter | 944](#)
- [Apply the Firewall Filter to the Loopback Interface | 944](#)
- [Confirm and Commit Your Candidate Configuration | 945](#)

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#).

To configure this example, perform the following tasks:

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set firewall family inet filter local_acl term terminal_access from source-address 192.168.1.0/24
set firewall family inet filter local_acl term terminal_access from protocol tcp
set firewall family inet filter local_acl term terminal_access from port ssh
set firewall family inet filter local_acl term terminal_access from port telnet
set firewall family inet filter local_acl term terminal_access then accept
set firewall family inet filter local_acl term terminal_access_denied from protocol tcp
set firewall family inet filter local_acl term terminal_access_denied from port ssh
set firewall family inet filter local_acl term terminal_access_denied from port telnet
set firewall family inet filter local_acl term terminal_access_denied then log
set firewall family inet filter local_acl term terminal_access_denied then reject
set firewall family inet filter local_acl term default-term then accept
```

```
set interfaces lo0 unit 0 family inet filter input local_acl
set interfaces lo0 unit 0 family inet address 127.0.0.1/32
```

Configure the Stateless Firewall Filter

Step-by-Step Procedure

To configure the stateless firewall filter that selectively blocks Telnet and SSH access:

1. Create the stateless firewall filter **local_acl**.

```
[edit]
user@myhost# edit firewall family inet filter local_acl
```

2. Define the filter term **terminal_access**.

```
[edit firewall family inet filter local_acl]
user@myhost# set term terminal_access from source-address 192.168.1.0/24
user@myhost# set term terminal_access from protocol tcp
user@myhost# set term terminal_access from port ssh
user@myhost# set term terminal_access from port telnet
user@myhost# set term terminal_access then accept
```

3. Define the filter term **terminal_access_denied**.

```
[edit firewall family inet filter local_acl]
user@myhost# set term terminal_access_denied from protocol tcp
user@myhost# set term terminal_access_denied from port ssh
user@myhost# set term terminal_access_denied from port telnet
user@myhost# set term terminal_access_denied then log
user@myhost# set term terminal_access_denied then reject
user@myhost# set term default-term then accept
```

Apply the Firewall Filter to the Loopback Interface

Step-by-Step Procedure

- To apply the firewall filter to the loopback interface:

```
[edit]
user@myhost# set interfaces lo0 unit 0 family inet filter input local_acl
user@myhost# set interfaces lo0 unit 0 family inet address 127.0.0.1/32
```

Confirm and Commit Your Candidate Configuration

Step-by-Step Procedure

To confirm and then commit your candidate configuration:

1. Confirm the configuration of the stateless firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@myhost# show firewall
family inet {
  filter local_acl {
    term terminal_access {
      from {
        source-address {
          192.168.1.0/24;
        }
        protocol tcp;
        port [ssh telnet];
      }
      then accept;
    }
    term terminal_access_denied {
      from {
        protocol tcp;
        port [ssh telnet];
      }
      then {
        log;
        reject;
      }
    }
    term default-term {
      then accept;
    }
  }
}
```

2. Confirm the configuration of the interface by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
```

```

user@myhost# show interfaces
lo0 {
  unit 0 {
    family inet {
      filter {
        input local_acl;
      }
      source-address 127.0.0.1/32;
    }
  }
}

```

3. If you are done configuring the device, commit your candidate configuration.

```

[edit]
user@myhost# commit

```

Verification

IN THIS SECTION

- [Verifying Accepted Packets | 946](#)
- [Verifying Logged and Rejected Packets | 947](#)

Confirm that the configuration is working properly.

Verifying Accepted Packets

Purpose

Verify that the actions of the firewall filter terms are taken.

Action

1. Clear the firewall log on your router or switch.

```
user@myhost> clear firewall log
```

2. From a host at an IP address *within* the 192.168.1.0/24 subnet, use the **ssh *hostname*** command to verify that you can log in to the device using only SSH. This packet should be accepted, and the packet

header information for this packet should not be logged in the firewall filter log buffer in the Packet Forwarding Engine.

```
user@host-A> ssh myhost
```

```
user@myhosts's password:
--- JUNOS 11.1-20101102.0 built 2010-11-02 04:48:46 UTC
```

```
% cli
```

```
user@myhost>
```

3. From a host at an IP address *within* the 192.168.1.0/24 subnet, use the **telnet *hostname*** command to verify that you can log in to your router or switch using only Telnet. This packet should be accepted, and the packet header information for this packet should not be logged in the firewall filter log buffer in the Packet Forwarding Engine.

```
user@host-A> telnet myhost
```

```
Trying 192.168.249.71...
Connected to myhost-fxp0.example.net.
Escape character is '^['.
```

```
host (ttyp0)
```

```
login: user
```

```
Password:

--- JUNOS 11.1-20101102.0 built 2010-11-02 04:48:46 UTC
```

```
% cli
```

```
user@myhost>
```

4. Use the **show firewall log** command to verify that the routing table on the device does not contain any entries with a source address in the 192.168.1.0/24 subnet.

```
user@myhost> show firewall log
```

Verifying Logged and Rejected Packets

Purpose

Verify that the actions of the firewall filter terms are taken.

Action

1. Clear the firewall log on your router or switch.

```
user@myhost> clear firewall log
```

2. From a host at an IP address *outside of* the 192.168.1.0/24 subnet, use the **ssh *hostname*** command to verify that you cannot log in to the device using only SSH. This packet should be rejected, and the packet header information for this packet should be logged in the firewall filter log buffer in the Packet Forwarding Engine.

```
user@host-B ssh myhost
```

```
ssh: connect to host sugar port 22: Connection refused
--- JUNOS 11.1-20101102.0 built 2010-11-02 04:48:46 UTC
%
```

3. From a host at an IP address *outside of* the 192.168.1.0/24 subnet, use the **telnet *hostname*** command to verify that you can log in to the device using only Telnet. This packet should be rejected, and the packet header information for this packet should be logged in the firewall filter log buffer in the PFE.

```
user@host-B> telnet myhost
```

```
Trying 192.168.249.71...
telnet: connect to address 192.168.187.3: Connection refused
telnet: Unable to connect to remote host
%
```

4. Use the **show firewall log** command to verify that the routing table on the device does not contain any entries with a source address in the 192.168.1.0/24 subnet.

```
user@myhost> show firewall log
```

Time	Filter	Action	Interface	Protocol	Src Addr	Dest Addr

Example: Configuring a Filter to Block TFTP Access

IN THIS SECTION

- [Requirements | 949](#)
- [Overview | 949](#)
- [Configuration | 949](#)
- [Verification | 952](#)

Requirements

No special configuration beyond device initialization is required before configuring this example.

Overview

By default, to decrease vulnerability to denial-of-service (DoS) attacks, the Junos OS filters and discards Dynamic Host Configuration Protocol (DHCP) or Bootstrap Protocol (BOOTP) packets that have a source address of 0.0.0.0 and a destination address of 255.255.255.255. This default filter is known as a unicast RPF check. However, some vendors' equipment automatically accepts these packets.

To interoperate with other vendors' equipment, you can configure a filter that checks for both of these addresses and overrides the default RPF-check filter by accepting these packets. In this example, you block Trivial File Transfer Protocol (TFTP) access, logging any attempts to establish TFTP connections.

Configuration

IN THIS SECTION

- [Configure the Stateless Firewall Filter | 950](#)
- [Apply the Firewall Filter to the Loopback Interface | 950](#)
- [Confirm and Commit Your Candidate Configuration | 951](#)

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#).

To configure this example, perform the following tasks:

CLI Quick Configuration

To quickly configure this example, copy the following configuration commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall family inet filter tftp_access_control term one from protocol udp
set firewall family inet filter tftp_access_control term one from port tftp
set firewall family inet filter tftp_access_control term one then log
set firewall family inet filter tftp_access_control term one then discard
set interfaces lo0 unit 0 family inet filter input tftp_access_control
set interfaces lo0 unit 0 family inet address 127.0.0.1/32
```

Configure the Stateless Firewall Filter

Step-by-Step Procedure

To configure the stateless firewall filter that selectively blocks TFTP access:

1. Create the stateless firewall filter **tftp_access_control**.

```
[edit]
user@host# edit firewall family inet filter tftp_access_control
```

2. Specify a match on packets received on UDP port 69.

```
[edit firewall family inet filter tftp_access_control]
user@host# set term one from protocol udp
user@host# set term one from port tftp
```

3. Specify that matched packets be logged to the buffer on the Packet Forwarding Engine and then discarded.

```
[edit firewall family inet filter tftp_access_control]
user@host# set term one then log
user@host# set term one then discard
```

Apply the Firewall Filter to the Loopback Interface

Step-by-Step Procedure

To apply the firewall filter to the loopback interface:

- ```
[edit]
user@host# set interfaces lo0 unit 0 family inet filter input tftp_access_control
user@host# set interfaces lo0 unit 0 family inet address 127.0.0.1/32
```

### *Confirm and Commit Your Candidate Configuration*

#### **Step-by-Step Procedure**

To confirm and then commit your candidate configuration:

1. Confirm the configuration of the stateless firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show firewall
family inet {
 filter tftp_access_control {
 term one {
 from {
 protocol udp;
 port tftp;
 }
 then {
 log;
 discard;
 }
 }
 }
}
```

2. Confirm the configuration of the interface by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show interfaces
lo0 {
 unit 0 {
 family inet {
 filter {
```

```
 input tftp_access_control;
 }
 address 127.0.0.1/32;
}
}
```

3. If you are done configuring the device, commit your candidate configuration.

```
[edit]
user@host# commit
```

## Verification

### IN THIS SECTION

- [Verifying Logged and Discarded Packets | 952](#)

Confirm that the configuration is operating properly:

### *Verifying Logged and Discarded Packets*

#### Purpose

Verify that the actions of the firewall filter terms are taken.

#### Action

To

1. Clear the firewall log on your router or switch.

```
user@myhost> clear firewall log
```

2. From another host, send a packet to UDP port **69** on this router or switch.

## Example: Configuring a Filter to Accept Packets Based on IPv6 TCP Flags

### IN THIS SECTION

- [Requirements | 953](#)
- [Overview | 953](#)
- [Configuration | 953](#)
- [Verification | 956](#)

This example shows how to configure a standard stateless firewall filter to accept packets from a trusted source.

### Requirements

No special configuration beyond device initialization is required before configuring this example.

### Overview

In this example, you create a filter that accepts packets with specific IPv6 TCP flags.

### Configuration

#### IN THIS SECTION

- [Configure the Stateless Firewall Filter | 954](#)
- [Apply the Firewall Filter to the Loopback Interface | 955](#)
- [Confirm and Commit Your Candidate Configuration | 955](#)

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#).

### CLI Quick Configuration

To quickly configure this example, copy the following commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall family inet6 filter tcp_filter term 1 from next-header tcp
set firewall family inet6 filter tcp_filter term 1 from tcp-flags syn
set firewall family inet6 filter tcp_filter term 1 then count tcp_syn_pkt
set firewall family inet6 filter tcp_filter term 1 then log
set firewall family inet6 filter tcp_filter term 1 then accept
set interfaces lo0 unit 0 family inet6 filter input tcp_filter
set interfaces lo0 unit 0 family inet6 address ::10.34.1.0/120
```

### Configure the Stateless Firewall Filter

#### Step-by-Step Procedure

To configure the firewall filter

1. Create the IPv6 stateless firewall filter **tcp\_filter**.

```
[edit]
user@host# edit firewall family inet6 filter tcp_filter
```

2. Specify that a packet matches if it is the initial packet in a TCP session and the next header after the IPv6 header is type TCP.

```
[edit firewall family inet6 filter tcp_filter]
user@host# set term 1 from next-header tcp
user@host# set term 1 from tcp-flags syn
```

3. Specify that matched packets are counted, logged to the buffer on the Packet Forwarding Engine, and accepted.

```
[edit firewall family inet6 filter tcp_filter]
user@host# set term 1 then count tcp_syn_pkt
user@host# set term 1 then log
user@host# set term 1 then accept
```

### *Apply the Firewall Filter to the Loopback Interface*

#### **Step-by-Step Procedure**

To apply the firewall filter to the loopback interface:

- ```
[edit]
user@host# set interfaces lo0 unit 0 family inet6 filter input tcp_filter
user@host# set interfaces lo0 unit 0 family inet6 address ::10.34.1.0/120
```

Confirm and Commit Your Candidate Configuration

Step-by-Step Procedure

To confirm and then commit your candidate configuration:

1. Confirm the configuration of the stateless firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show firewall
family inet6 {
  filter tcp_filter {
    term 1 {
      from {
        next-header tcp;
        tcp-flags syn;
      }
      then {
        count tcp_syn_pkt;
        log;
        accept;
      }
    }
  }
}
```

2. Confirm the configuration of the interface by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show interfaces
```

```

lo0 {
  unit 0 {
    family inet6 {
      filter {
        input tcp_filter;
      }
      address ::10.34.1.0/120;
    }
  }
}

```

3. When you are done configuring the device, commit your candidate configuration.

```

[edit]
user@host# commit

```

Verification

To confirm that the configuration is working properly, enter the **show firewall** operational mode command.

[Example: Configuring a Stateless Firewall Filter to Protect Against TCP and ICMP Floods | 964](#)

[Example: Configuring a Filter to Block TCP Access to a Port Except from Specified BGP Peers | 956](#)

Example: Configuring a Filter to Block TCP Access to a Port Except from Specified BGP Peers

IN THIS SECTION

- [Requirements | 957](#)
- [Overview | 957](#)
- [Configuration | 957](#)
- [Verification | 962](#)

This example shows how to configure a standard stateless firewall filter that blocks all TCP connection attempts to port 179 from all requesters except from specified BGP peers.

Requirements

No special configuration beyond device initialization is required before you configure this example.

Overview

In this example, you create a stateless firewall filter that blocks all TCP connection attempts to port 179 from all requesters except the specified BGP peers.

The stateless firewall filter **filter_bgp179** matches all packets from the directly connected interfaces on Device A and Device B to the destination port number 179.

[Figure 51 on page 957](#) shows the topology used in this example. Device C attempts to make a TCP connection to Device E. Device E blocks the connection attempt. This example shows the configuration on Device E.

Figure 51: Typical Network with BGP Peer Sessions

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

Device C

```
set interfaces ge-1/2/0 unit 10 description to-E
set interfaces ge-1/2/0 unit 10 family inet address 10.10.10/30
set protocols bgp group external-peers type external
```

```

set protocols bgp group external-peers peer-as 17
set protocols bgp group external-peers neighbor 10.10.10.9
set routing-options autonomous-system 22

```

Device E

```

set interfaces ge-1/2/0 unit 0 description to-A
set interfaces ge-1/2/0 unit 0 family inet address 10.10.10.1/30
set interfaces ge-1/2/1 unit 5 description to-B
set interfaces ge-1/2/1 unit 5 family inet address 10.10.10.5/30
set interfaces ge-1/0/0 unit 9 description to-C
set interfaces ge-1/0/0 unit 9 family inet address 10.10.10.9/30
set interfaces lo0 unit 2 family inet filter input filter_bgp179
set interfaces lo0 unit 2 family inet address 192.168.0.1/32
set protocols bgp group external-peers type external
set protocols bgp group external-peers peer-as 22
set protocols bgp group external-peers neighbor 10.10.10.2
set protocols bgp group external-peers neighbor 10.10.10.6
set protocols bgp group external-peers neighbor 10.10.10.10
set routing-options autonomous-system 17
set firewall family inet filter filter_bgp179 term 1 from source-address 10.10.10.2/32
set firewall family inet filter filter_bgp179 term 1 from source-address 10.10.10.6/32
set firewall family inet filter filter_bgp179 term 1 from destination-port bgp
set firewall family inet filter filter_bgp179 term 1 then accept
set firewall family inet filter filter_bgp179 term 2 then reject

```

Configuring Device E

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure Device E with a stateless firewall filter that blocks all TCP connection attempts to port 179 from all requestors except specified BGP peers:

1. Configure the interfaces.

```

user@E# set interfaces ge-1/2/0 unit 0 description to-A

```

```

user@E# set interfaces ge-1/2/0 unit 0 family inet address 10.10.10.1/30
user@E# set interfaces ge-1/2/1 unit 5 description to-B
user@E# set interfaces ge-1/2/1 unit 5 family inet address 10.10.10.5/30
user@E# set interfaces ge-1/0/0 unit 9 description to-C
user@E# set interfaces ge-1/0/0 unit 9 family inet address 10.10.10.9/30

```

2. Configure BGP.

```

[edit protocols bgp group external-peers]
user@E# set type external
user@E# set peer-as 22
user@E# set neighbor 10.10.10.2
user@E# set neighbor 10.10.10.6
user@E# set neighbor 10.10.10.10

```

3. Configure the autonomous system number.

```

[edit routing-options]
user@E# set autonomous-system 17

```

4. Define the filter term that accepts TCP connection attempts to port 179 from the specified BGP peers.

```

[edit firewall family inet filter filter_bgp179]
user@E# set term 1 from source-address 10.10.10.2/32
user@E# set term 1 from source-address 10.10.10.6/32
user@E# set term 1 from destination-port bgp
user@E# set term 1 then accept

```

5. Define the other filter term to reject packets from other sources.

```

[edit firewall family inet filter filter_bgp179]
user@E# set term 2 then reject

```

6. Apply the firewall filter to the loopback interface.

```

[edit interfaces lo0 unit 2 family inet]
user@E# set filter input filter_bgp179
user@E# set address 192.168.0.1/32

```

Results

From configuration mode, confirm your configuration by entering the **show firewall**, **show interfaces**, **show protocols**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@E# show firewall
family inet {
  filter filter_bgp179 {
    term 1 {
      from {
        source-address {
          10.10.10.2/32;
          10.10.10.6/32;
        }
        destination-port bgp;
      }
      then accept;
    }
    term 2 {
      then {
        reject;
      }
    }
  }
}
```

```
user@E# show interfaces
lo0 {
  unit 2 {
    family inet {
      filter {
        input filter_bgp179;
      }
      address 192.168.0.1/32;
    }
  }
}
ge-1/2/0 {
  unit 0 {
    description to-A;
    family inet {
      address 10.10.10.1/30;
    }
  }
}
```

```

    }
}
ge-1/2/1 {
    unit 5 {
        description to-B;
        family inet {
            address 10.10.10.5/30;
        }
    }
}
ge-1/0/0 {
    unit 9 {
        description to-C;
        family inet {
            address 10.10.10.9/30;
        }
    }
}
}

```

```

user@E# show protocols
bgp {
    group external-peers {
        type external;
        peer-as 22;
        neighbor 10.10.10.2;
        neighbor 10.10.10.6;
        neighbor 10.10.10.10;
    }
}

```

```

user@E# show routing-options
autonomous-system 17;

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

IN THIS SECTION

- [Verifying That the Filter Is Configured | 962](#)
- [Verifying the TCP Connections | 962](#)
- [Monitoring Traffic on the Interfaces | 963](#)

Confirm that the configuration is working properly.

Verifying That the Filter Is Configured

Purpose

Make sure that the filter is listed in output of the **show firewall filter** command.

Action

```
user@E> show firewall filter filter_bgp179
```

```
Filter: filter_bgp179
```

Verifying the TCP Connections

Purpose

Verify the TCP connections.

Action

From operational mode, run the **show system connections extensive** command on Device C and Device E.

The output on Device C shows the attempt to establish a TCP connection. The output on Device E shows that connections are established with Device A and Device B only.

```
user@C> show system connections extensive | match 10.10.10
```

```
tcp4          0      0  10.10.10.9.51872    10.10.10.10.179    SYN_SENT
```

```
user@E> show system connections extensive | match 10.10.10
```

tcp4	0	0	10.10.10.5.179	10.10.10.6.62096	ESTABLISHED
tcp4	0	0	10.10.10.6.62096	10.10.10.5.179	ESTABLISHED
tcp4	0	0	10.10.10.1.179	10.10.10.2.61506	ESTABLISHED
tcp4	0	0	10.10.10.2.61506	10.10.10.1.179	ESTABLISHED

Monitoring Traffic on the Interfaces

Purpose

Use the **monitor traffic** command to compare the traffic on an interface that establishes a TCP connection with the traffic on an interface that does not establish a TCP connection.

Action

From operational mode, run the **monitor traffic** command on the Device E interface to Device B and on the Device E interface to Device C. The following sample output verifies that in the first example, acknowledgment (**ack**) messages are received. In the second example, **ack** messages are not received.

user@E> **monitor traffic size 1500 interface ge-1/2/1.5**

```
19:02:49.700912 Out IP 10.10.10.5.bgp > 10.10.10.6.62096: P

Example: Configuring a Stateless Firewall Filter to Protect Against TCP and ICMP Floods

IN THIS SECTION

- [Requirements | 964](#)
- [Overview | 965](#)
- [Configuration | 966](#)
- [Verification | 972](#)

This example shows how to create a stateless firewall filter that protects against TCP and ICMP denial-of-service attacks.

Requirements

No special configuration beyond device initialization is required before configuring stateless firewall filters.

Overview

In this example we create a stateless firewall filter called **protect-RE** to police TCP and ICMP packets. It uses the policers described here:

- **tcp-connection-policer**—This policer limits TCP traffic to 1,000,000 bits per second (bps) with a maximum burst size of 15,000 bytes. Traffic exceeding either limit is discarded.
- **icmp-policer**—This policer limits ICMP traffic to 1,000,000 bps with a maximum burst size of 15,000 bytes. Traffic exceeding either limit is discarded.

When specifying limits, the bandwidth limit can be from 32,000 bps to 32,000,000,000 bps and the burst-size limit can be from 1,500 bytes through 100,000,000 bytes. Use the following abbreviations when specifying limits: k (1,000), m (1,000,000), and g (1,000,000,000).

Each policer is incorporated into the action of a filter term. This example includes the following terms:

- **tcp-connection-term**—Policies certain TCP packets with a source address of 192.168.0.0/24 or 10.0.0.0/24. These addresses are defined in the **trusted-addresses** prefix list.

Filtered packets include **tcp-established** packets. The **tcp-established** match condition is an alias for the bit-field match condition **tcp-flags "(ack | rst)"**, which indicates an established TCP session, but not the first packet of a TCP connection.

- **icmp-term**—Policies ICMP packets. All ICMP packets are counted in the **icmp-counter** counter.

NOTE: You can move terms within the firewall filter by using the **insert** command. See *insert* in the *CLI User Guide*.

You can apply a stateless firewall to the input or output sides, or both, of an interface. To filter packets transiting the device, apply the firewall filter to any non-Routing Engine interface. To filter packets originating from, or destined for, the Routing Engine, apply the firewall filter to the loopback (lo0) interface.

[Figure 52 on page 966](#) shows the sample network.

Figure 52: Firewall Filter to Protect Against TCP and ICMP Floods

Because this firewall filter limits Routing Engine traffic to TCP packets, routing protocols that use other transport protocols for Layer 4 cannot successfully establish sessions when this filter is active. To demonstrate, this example sets up OSPF between Device R1 and Device R2.

“[CLI Quick Configuration](#)” on page 966 shows the configuration for all of the devices in [Figure 52 on page 966](#).

The section “[Step-by-Step Procedure](#)” on page 967 describes the steps on Device R2.

Configuration

CLI Quick Configuration

To quickly configure the stateless firewall filter, copy the following commands to a text file, remove any line breaks, and then paste the commands into the CLI.

Device R1

```
set interfaces fe-1/2/0 unit 0 family inet address 10.0.0.1/30
set interfaces lo0 unit 0 family inet address 192.168.0.1/32 primary
set interfaces lo0 unit 0 family inet address 172.16.0.1/32
set protocols bgp group ext type external
set protocols bgp group ext export send-direct
set protocols bgp group ext peer-as 200
set protocols bgp group ext neighbor 10.0.0.2
set protocols ospf area 0.0.0.0 interface fe-1/2/0.0
set protocols ospf area 0.0.0.0 interface lo0.0 passive
set policy-options policy-statement send-direct term 1 from protocol direct
set policy-options policy-statement send-direct term 1 then accept
set routing-options router-id 192.168.0.1
set routing-options autonomous-system 100
```

Device R2

```

set interfaces fe-1/2/0 unit 0 family inet address 10.0.0.2/30
set interfaces lo0 unit 0 family inet filter input protect-RE
set interfaces lo0 unit 0 family inet address 192.168.0.2/32 primary
set interfaces lo0 unit 0 family inet address 172.16.0.2/32
set protocols bgp group ext type external
set protocols bgp group ext export send-direct
set protocols bgp group ext neighbor 10.0.0.1 peer-as 100
set protocols ospf area 0.0.0.0 interface lo0.0 passive
set protocols ospf area 0.0.0.0 interface fe-1/2/0.0
set policy-options prefix-list trusted-addresses 10.0.0.0/24
set policy-options prefix-list trusted-addresses 192.168.0.0/24
set policy-options policy-statement send-direct term 1 from protocol direct
set policy-options policy-statement send-direct term 1 then accept
set routing-options router-id 192.168.0.2
set routing-options autonomous-system 200
set firewall family inet filter protect-RE term tcp-connection-term from source-prefix-list
    trusted-addresses
set firewall family inet filter protect-RE term tcp-connection-term from protocol tcp
set firewall family inet filter protect-RE term tcp-connection-term from tcp-established
set firewall family inet filter protect-RE term tcp-connection-term then policer tcp-connection-policer
set firewall family inet filter protect-RE term tcp-connection-term then accept
set firewall family inet filter protect-RE term icmp-term from source-prefix-list trusted-addresses
set firewall family inet filter protect-RE term icmp-term from protocol icmp
set firewall family inet filter protect-RE term icmp-term then policer icmp-policer
set firewall family inet filter protect-RE term icmp-term then count icmp-counter
set firewall family inet filter protect-RE term icmp-term then accept
set firewall policer tcp-connection-policer filter-specific
set firewall policer tcp-connection-policer if-exceeding bandwidth-limit 1m
set firewall policer tcp-connection-policer if-exceeding burst-size-limit 15k
set firewall policer tcp-connection-policer then discard
set firewall policer icmp-policer filter-specific
set firewall policer icmp-policer if-exceeding bandwidth-limit 1m
set firewall policer icmp-policer if-exceeding burst-size-limit 15k
set firewall policer icmp-policer then discard

```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#).

To configure stateless firewall filter to discard :

1. Configure the device interfaces.

```
[edit interfaces fe-1/2/0 unit 0 family inet ]
user@R2# set address 10.0.0.2/30
[edit interfaces lo0 unit 0 family inet]
user@R2# set address 192.168.0.2/32 primary
user@R2# set address 172.16.0.2/32
```

2. Configure the BGP peering session.

```
[edit protocols bgp group ext]
user@R2# set type external
user@R2# set export send-direct
user@R2# set neighbor 10.0.0.1 peer-as 100
```

3. Configure the autonomous system (AS) number and router ID.

```
[edit routing-options]
user@R2# set autonomous-system 200
user@R2# set router-id 192.168.0.2
```

4. Configure OSPF.

```
[edit protocols ospf area 0.0.0.0]
user@R2# set interface lo0.0 passive
user@R2# set interface fe-1/2/0.0
```

5. Define the list of trusted addresses.

```
[edit policy-options prefix-list trusted-addresses]
user@R2# set 10.0.0.0/24
user@R2# set 192.168.0.0/24
```

6. Configure a policy to advertise direct routes.

```
[edit policy-options policy-statement send-direct term 1]
user@R2# set from protocol direct
user@R2# set then accept
```

7. Configure the TCP policer.

```
[edit firewall policer tcp-connection-policer]
user@R2# set filter-specific
user@R2# set if-exceeding bandwidth-limit 1m
user@R2# set if-exceeding burst-size-limit 15k
user@R2# set then discard
```

8. Create the ICMP policer.

```
[edit firewall policer icmp-policer]
user@R2# set filter-specific
user@R2# set if-exceeding bandwidth-limit 1m
user@R2# set if-exceeding burst-size-limit 15k
user@R2# set then discard
```

9. Configure the TCP filter rules.

```
[edit firewall family inet filter protect-RE term tcp-connection-term]
user@R2# set from source-prefix-list trusted-addresses
user@R2# set from protocol tcp
user@R2# set from tcp-established
user@R2# set then policer tcp-connection-policer
user@R2# set then accept
```

10. Configure the ICMP filter rules.

```
[edit firewall family inet filter protect-RE term icmp-term]
user@R2# set from source-prefix-list trusted-addresses
user@R2# set from protocol icmp
user@R2# set then policer icmp-policer
user@R2# set then count icmp-counter
user@R2# set then accept
```

11. Apply the filter to the loopback interface.

```
[edit interfaces lo0 unit 0]
user@R2# set family inet filter input protect-RE
```

Results

Confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, **show routing-options**, and **show firewall** commands from configuration mode. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R2# show interfaces
fe-1/2/0 {
  unit 0 {
    family inet {
      address 10.0.0.2/30;
    }
  }
}
lo0 {
  unit 0 {
    family inet {
      filter {
        input protect-RE;
      }
      address 192.168.0.2/32 {
        primary;
      }
      address 172.16.0.2/32;
    }
  }
}
```

```
user@R2# show protocols
bgp {
  group ext {
    type external;
    export send-direct;
    neighbor 10.0.0.1 {
      peer-as 100;
    }
  }
}
```

```
ospf {
  area 0.0.0.0 {
    interface lo0.0 {
      passive;
    }
    interface fe-1/2/0.0;
  }
}
```

```
user@R2# show policy-options
prefix-list trusted-addresses {
  10.0.0.0/24;
  192.168.0.0/24;
}
policy-statement send-direct {
  term 1 {
    from protocol direct;
    then accept;
  }
}
```

```
user@R2# show routing-options
router-id 192.168.0.2;
autonomous-system 200;
```

```
user@R2# show firewall
family inet {
  filter protect-RE {
    term tcp-connection-term {
      from {
        source-prefix-list {
          trusted-addresses;
        }
        protocol tcp;
        tcp-established;
      }
      then {
        policer tcp-connection-policer;
        accept;
      }
    }
    term icmp-term {
```

- Using OSPF to Verify the TCP Firewall Filter | 976
- Verifying the ICMP Firewall Filter | 977

Confirm that the configuration is working properly.

NOTE: To verify the TCP policer, you can use a packet generation tool. This task is not shown here.

Displaying Stateless Firewall Filter That Are in Effect

Purpose

Verify the configuration of the firewall filter.

Action

From operational mode, enter the **show firewall** command.

user@R2> **show firewall**

```
Filter: protect-RE
Counters:
Name                               Bytes      Packets
icmp-counter                        0          0
Policers:
Name                               Bytes      Packets
icmp-policer                       0
tcp-connection-policer             0
```

Meaning

The output shows the filter, the counter, and the policers that are in effect on Device R2.

Using telnet to Verify the tcp-established Condition in the TCP Firewall Filter

Purpose

Make sure that telnet traffic works as expected.

Action

Verify that the device can establish only TCP sessions with hosts that meet the **from tcp-established** condition.

1. From Device R2, make sure that the BGP session with Device R1 is established.

```
user@R2> show bgp summary | match down
```

```
Groups: 1 Peers: 1 Down peers: 0
```

2. From Device R2, telnet to Device R1.

```
user@R2> telnet 192.168.0.1
```

```
Trying 192.168.0.1...
Connected to R1.example.net.
Escape character is '^]'.
```

```
R1 (ttyp4)
```

```
login:
```

3. From Device R1, telnet to Device R2.

```
user@R1> telnet 192.168.0.2
```

```
Trying 192.168.0.2...
telnet: connect to address 192.168.0.2: Operation timed out
telnet: Unable to connect to remote host
```

4. On Device R2, deactivate the **from tcp-established** match condition.

```
[edit firewall family inet filter protect-RE term tcp-connection-term]
user@R2# deactivate from tcp-established
user@R2# commit
```

5. From Device R1, try again to telnet to Device R2.

```
user@R1> telnet 192.168.0.1
```

```
Trying 192.168.0.2...
Connected to R2.example.net.
Escape character is '^]'.
```

```
R2 (ttyp4)
```

```
login:
```

Meaning

Verify the following information:

- As expected, the BGP session is established. The **from tcp-established** match condition is not expected to block BGP session establishment.
- From Device R2, you can telnet to Device R1. Device R1 has no firewall filter configured, so this is the expected behavior.
- From Device R1, you cannot telnet to Device R2. Telnet uses TCP as the transport protocol, so this result might be surprising. The cause for the lack of telnet connectivity is the **from tcp-established** match condition. This match condition limits the type of TCP traffic that is accepted of Device R2. After this match condition is deactivated, the telnet session is successful.

Using telnet to Verify the Trusted Prefixes Condition in the TCP Firewall Filter

Purpose

Make sure that telnet traffic works as expected.

Action

Verify that the device can establish only telnet sessions with a host at an IP address that matches one of the trusted source addresses. For example, log in to the device with the **telnet** command from another host with one of the trusted address prefixes. Also, verify that telnet sessions with untrusted source addresses are blocked.

1. From Device R1, telnet to Device R2 from an untrusted source address.

```
user@R1> telnet 172.16.0.2 source 172.16.0.1
```

```
Trying 172.16.0.2...
^C
```

2. From Device R2, add 172.16/16 to the list of trusted prefixes.

```
[edit policy-options prefix-list trusted-addresses]
user@R2# set 172.16.0.0/16
user@R2# commit
```

3. From Device R1, try again to telnet to Device R2.

```
user@R1> telnet 172.16.0.2 source 172.16.0.1
```

```
Trying 172.16.0.2...
Connected to R2.example.net.
Escape character is '^['.
```

```
R2 (ttyp4)
```

```
login:
```

Meaning

Verify the following information:

- From Device R1, you cannot telnet to Device R2 with an untrusted source address. After the 172.16/16 prefix is added to the list of trusted prefixes, the telnet request from source address 172.16.0.1 is accepted.
- OSPF session establishment is blocked. OSPF does not use TCP as its transport protocol. After the **from protocol tcp** match condition is deactivated, OSPF session establishment is not blocked.

Using OSPF to Verify the TCP Firewall Filter

Purpose

Make sure that OSPF traffic works as expected.

Action

Verify that the device cannot establish OSPF connectivity.

1. From Device R1, check the OSPF sessions.

```
user@R1> show ospf neighbor
```

Address	Interface	State	ID	Pri	Dead
10.0.0.2	fe-1/2/0.0	Init	192.168.0.2	128	34

2. From Device R2, check the OSPF sessions.

```
user@R2> show ospf neighbor
```

3. From Device R2, remove the **from protocol tcp** match condition.

```
[edit firewall family inet filter protect-RE term tcp-connection-term]
user@R2# deactivate from protocol
user@R2# commit
```

4. From Device R1, recheck the OSPF sessions.

```
user@R1> show ospf neighbor
```

3. From Device R2, check the firewall statistics.

```
user@R2> show firewall
```

```
Filter: protect-RE
Counters:
Name                               Bytes          Packets
icmp-counter                        1180804         1135
Policers:
Name                               Bytes          Packets
icmp-policer                       66
tcp-connection-policer             0
```

4. From an untrusted source address on Device R1, send a ping request to Device R2's loopback interface.

```
user@R1> ping 172.16.0.2 source 172.16.0.1
```

```
PING 172.16.0.2 (172.16.0.2): 56 data bytes
^C
--- 172.16.0.2 ping statistics ---
14 packets transmitted, 0 packets received, 100% packet loss
```

Meaning

Verify the following information:

- The ping output shows that 100% packet loss is occurring.
- The ICMP packet counter is incrementing, and the icmp-policer is incrementing.
- Device R2 does not send ICMP responses to the **ping 172.16.0.2 source 172.16.0.1** command.

[Two-Color Policer Configuration Overview | 1746](#)

Example: Protecting the Routing Engine with a Packets-Per-Second Rate Limiting Filter

IN THIS SECTION

- Requirements | 979
- Overview | 979
- Configuration | 980
- Verification | 982

This example shows how to configure a packets-per-second based rate-limiting filter to improve security. It will be applied to the loopback interface in order to help protect the Routing Engine from denial of service attacks.

BEST PRACTICE: This type of filter and policer combination is only one element in a multilayered approach that can be used to help protect the Routing Engine. Other layers of protection are needed in order to fully protect the Routing Engine. See [Day One: Securing the Routing Engine on M, MX, and T Series](#) for more information.

Requirements

No special configuration beyond device initialization is required before configuring this example.

Overview

In this example, you use a stateless firewall filter to set packets-per-second (pps) rate limits for any traffic destined for the Routing Engine through the loopback interface (lo0.0).

To activate a policer from within a stateless firewall filter configuration:

1. Create a template for the policer by including the **policer policer-name** statement at the **[edit firewall]** hierarchy.
2. Reference the policer in a filter term that specifies the policer in the **policer policer-name** nonterminating action.

You can also apply a policer by including the **policer (input | output) *policer-name*** statement in a logical interface configuration.

Configuration

IN THIS SECTION

- [Configuring the Policer and the Stateless Firewall Filter | 980](#)
- [Applying the Stateless Firewall Filter to the Loopback Logical Interface | 981](#)
- [Results | 981](#)

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall policer police_pps if-exceeding-pps pps-limit 1k
set firewall policer police_pps if-exceeding-pps packet-burst 150
set firewall policer police_pps then discard
set firewall family inet filter my_pps_filter term term1 then policer police_pps
set interfaces lo0 unit 0 family inet filter input my_pps_filter
set interfaces lo0 unit 0 family inet address 127.0.0.1/32
```

Configuring the Policer and the Stateless Firewall Filter

Step-by-Step Procedure

To configure the policer ***police_pps*** and stateless firewall filter ***my_pps_filter***:

1. Configure the policer template **police_pps**.

```
[edit firewall]
user@host# set policer police_pps if-exceeding-pps pps-limit 1k
user@host# set policer police_pps if-exceeding-pps packet-burst 150
user@host# set policer police_pps then discard
```

2. Create the stateless firewall filter **my_pps_filter**.

```
[edit]
user@host# edit firewall family inet filter my_pps_filter
```

3. Configure a filter term that uses policer **police_pps** to rate limit traffic by protocol family.

```
[edit firewall family inet filter my_pps_filter]
user@host# set term term1 then policer police_pps
```

Applying the Stateless Firewall Filter to the Loopback Logical Interface

Step-by-Step Procedure

To apply the filter **my_pps_filter** to the loopback interface:

1. Configure the logical loopback interface to which you will apply the stateless firewall filter.

```
[edit]
user@host# edit interfaces lo0 unit 0
```

2. Apply the stateless firewall filter to the loopback interface.

```
[edit interfaces lo0 unit 0]
user@host# set family inet filter input my_pps_filter
```

3. Configure the interface address for the loopback interface.

```
[edit interfaces lo0 unit 0]
user@host# set family inet address 127.0.0.1/32
```

Results

Confirm the configuration of the stateless firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@host# show firewall
family inet{
```

```
filter my_pps_filter {  
    term term1 {  
        then policer police_pps;  
    }  
}  
policer police_pps {  
    if-exceeding-pps {  
        pps-limit 1k;  
        packet-burst 150;  
    }  
    then discard;  
}
```

Confirm the configuration of the interface by entering the **show interfaces lo0** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@host# show interfaces lo0  
unit 0 {  
    family inet {  
        filter {  
            input my_pps_filter;  
        }  
        address 127.0.0.1/32;  
    }  
}
```

If you are done configuring the device, enter commit from configuration mode.

```
user@host# commit
```

Verification

Example: Configuring a Filter to Exclude DHCPv6 and ICMPv6 Control Traffic for LAC Subscriber

IN THIS SECTION

- [Requirements | 984](#)
- [Overview | 984](#)
- [Configuration | 984](#)

This example shows how to configure a standard stateless firewall filter that excludes DHCPv6 and ICMPv6 control packets from being considered for idle-timeout detection for tunneled subscribers at the LAC.

Requirements

No special configuration beyond device initialization is required before configuring this example.

Overview

Subscriber access on a LAC can be limited by configuring an idle timeout period that specifies the maximum period of time a subscriber can remain idle after the subscriber session is established. The LAC monitors the subscriber's upstream and downstream data traffic to determine whether the subscriber is inactive. Based on the session accounting statistics, the subscriber is not considered idle as long as data traffic is detected in either direction. When no traffic is detected for the duration of the idle time out, the subscriber is logged out gracefully similarly to a RADIUS-initiated disconnect or a CLI-initiated logout.

However, after a tunnel is established for L2TP subscribers, all packets through the tunnel at the LAC are treated as data packets. Consequently, the accounting statistics for the session are inaccurate and the subscriber is not considered to be idle as long as DHCPv6 and ICMPv6 control packets are being sent.

Starting in Junos OS Release 17.2R1, you can define a firewall filter for the **inet6** family with terms to match on these control packets. Include the use the **exclude-accounting** terminating action in the filter terms to drop these control packets.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
set access profile v6-exclude-idle session-options client-idle-timeout 10
set access profile v6-exclude-idle session-options client-idle-timeout-ingress-only
edit firewall family inet6 filter EXCLUDE-ACCT-INET6-FILTER
set interface-specific
set term EXCLUDE-ACCT-DHCP-INET6 from next-header udp
set term EXCLUDE-ACCT-DHCP-INET6 from source-port 546
set term EXCLUDE-ACCT-DHCP-INET6 from source-port 547
set term EXCLUDE-ACCT-DHCP-INET6 from destination-port 546
set term EXCLUDE-ACCT-DHCP-INET6 from destination-port 547
set term EXCLUDE-ACCT-DHCP-INET6 then count exclude-acct-dhcpv6
set term EXCLUDE-ACCT-DHCP-INET6 then exclude-accounting
set term EXCLUDE-ACCT-ICMP6 from next-header icmp6
```

```

set term EXCLUDE-ACCT-ICMP6 from icmp-type router-solicit
set term EXCLUDE-ACCT-ICMP6 from icmp-type neighbor-solicit
set term EXCLUDE-ACCT-ICMP6 from icmp-type neighbor-advertisement
set term EXCLUDE-ACCT-ICMP6 then count exclude-acct-icmpv6
set term EXCLUDE-ACCT-ICMP6 then exclude-accounting
set term default then accept
top
edit dynamic-profiles pppoe-dynamic-profile interfaces pp0 unit "$junos-interface-unit"
set family inet6 filter input EXCLUDE-ACCT-INET6-FILTER
set family inet6 filter output EXCLUDE-ACCT-INET6-FILTER
set actual-transit-statistics

```

Configure the Filter

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure the filter:

1. Set the idle timeout for subscriber sessions..

```

[edit access profile v6-exclude-idle]
user@host# set session-options client-idle-timeout 10

```

2. Specify the idle timeout applies only to ingress traffic.

```

[edit access profile v6-exclude-idle]
user@host# set session-options client-idle-timeout-ingress-only

```

3. Define the firewall filter term that excludes the DHCPv6 control packets from accounting statistics.
 - a. Specify a match on packets with the first Next Header field set to UDP (17).

```

[edit firewall family inet6 filter EXCLUDE-ACCT-INET6-FILTER]
user@host# set term EXCLUDE-ACCT-DHCP-INET6 from next-header udp

```

- b. Specify a match on packets with a source port of 546 or 547 (DHCPv6).

```

[edit firewall family inet6 filter EXCLUDE-ACCT-INET6-FILTER]
user@host# set term EXCLUDE-ACCT-DHCP-INET6 from source-port 546

```

```
user@host# set term EXCLUDE-ACCT-DHCP-INET6 from source-port 547
```

- c. Specify a match on packets with a DHCP destination port of 546 or 547 (DHCPv6).

```
[edit firewall family inet6 filter EXCLUDE-ACCT-INET6-FILTER]
user@host# set term EXCLUDE-ACCT-DHCP-INET6 from destination-port 546
user@host# set term EXCLUDE-ACCT-DHCP-INET6 from destination-port 547
```

- d. Count the matched DHCPv6 packets.

```
[edit firewall family inet6 filter EXCLUDE-ACCT-INET6-FILTER]
user@host# set term EXCLUDE-ACCT-DHCP-INET6 then count exclude-acct-dhcpv6
```

- e. Exclude the matched DHCPv6 packets from accounting statistics.

```
[edit firewall family inet6 filter EXCLUDE-ACCT-INET6-FILTER]
user@host# set term EXCLUDE-ACCT-DHCP-INET6 then exclude-accounting
```

4. Define the firewall filter term that excludes the ICMPv6 control packets from accounting statistics.

- a. Specify a match on packets with the first Next Header field set to ICMPv6 (58).

```
[edit firewall family inet6 filter EXCLUDE-ACCT-INET6-FILTER]
user@host# set term EXCLUDE-ACCT-ICMP6 from next-header icmp6
```

- b. Specify a match on packets with an ICMPv6 message type.

```
[edit firewall family inet6 filter EXCLUDE-ACCT-INET6-FILTER]
user@host# set term EXCLUDE-ACCT-ICMP6 from icmp-type router-solicit
user@host# set term EXCLUDE-ACCT-ICMP6 from icmp-type neighbor-solicit
user@host# set term EXCLUDE-ACCT-ICMP6 from icmp-type neighbor-advertisement
```

- c. Count the matched ICMPv6 packets.

```
[edit firewall family inet6 filter EXCLUDE-ACCT-INET6-FILTER]
user@host# set term EXCLUDE-ACCT-ICMP6 then count exclude-acct-icmpv6
```

- d. Exclude the matched ICMPv6 packets from accounting statistics.

```
[edit firewall family inet6 filter EXCLUDE-ACCT-INET6-FILTER]
user@host# set term EXCLUDE-ACCT-DHCP-INET6 then exclude-accounting
```

5. Define the default filter term to accept all other packets.

```
[edit firewall family inet6 filter EXCLUDE-ACCT-INET6-FILTER]
user@host# set term default then accept
```

6. Configure the dynamic profile to apply the filter to input and output interfaces for the **inet6** family.

```
[edit dynamic-profiles pppoe-dynamic-profile interfaces pp0 unit "$junos-interface-unit"]
user@host# set family inet6 filter input EXCLUDE-ACCT-INET6-FILTER
user@host# set family inet6 filter output EXCLUDE-ACCT-INET6-FILTER
```

7. Enable subscriber management accurate accounting.

```
[edit dynamic-profiles pppoe-dynamic-profile interfaces pp0 unit "$junos-interface-unit"]
user@host# set actual-transit-statistics
```

Results

From configuration mode, confirm your configuration by entering the **show access**, **show firewall**, and **show dynamic-profiles** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@host# show access
profile v6-exclude-idle {
  session-options {
    client-idle-timeout 10;
    client-idle-timeout-ingress-only;
  }
}
```

```
user@host# show firewall
family inet6 {
  filter EXCLUDE-ACCT-INET6-FILTER {
    interface-specific;
    term EXCLUDE-ACCT-DHCP-INET6 {
      from {
        next-header udp;
        source-port [ 546 547 ];
        destination-port [ 546 547 ];
      }
      then {
```

```

        count exclude-acct-dhcpv6;
        exclude-accounting
    }
}
term EXCLUDE-ACCT-ICMP6 {
    from {
        next-header icmp6;
        icmp-type [ router-solicit neighbor-solicit neighbor-advertisement ]
    }
    then {
        count exclude-acct-icmpv6;
        exclude-accounting;
    }
}
term default {
    then accept;
}
}
}

```

```

user@host# show dynamic-profiles
pppoe-dynamic-profile {
    interfaces {
        pp0 {
            unit "$junos-interface-unit" {
                actual-transit-statistics;
                family inet6 {
                    filter {
                        input EXCLUDE-ACCT-INET6-FILTER;
                        output EXCLUDE-ACCT-INET6-FILTER;
                    }
                }
            }
        }
    }
}
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Port Number Requirements for DHCP Firewall Filters

When you configure a firewall filter to perform some action on DHCP packets at the Routing Engine, such as protecting the Routing Engine by allowing only proper DHCP packets, you must specify both port 67 (bootps) and port 68 (bootpc) for both the source and destination. The firewall filter acts at both the line cards and the Routing Engine.

This requirement applies to both DHCP local server and DHCP relay, but it applies only when DHCP is provided by the `jdhcpd` process. MX Series routers use `jdhcpd`. For DHCP relay, that means the configuration is required only at the **[edit forwarding-options dhcp-relay]** hierarchy level and not at the **[edit forwarding-options helpers bootp]** hierarchy level.

DHCP packets received on the line cards are encapsulated by `jdhcpd` with a new UDP header where their source and destination addresses are set to port 68 before being forwarded to the Routing Engine.

For DHCP relay and DHCP proxy, packets sent to the DHCP server from the router have both the source and destination UDP ports set to 67. The DHCP server responds using the same ports. However, when the line card receives these DHCP response packets, it changes both port numbers from 67 to 68 before passing the packets to the Routing Engine. Consequently the filter needs to accept port 67 for packets relayed from the client to the server, and port 68 for packets relayed from the server to the client.

Failure to include both port 67 and port 68 as described here results in most DHCP packets not being accepted.

For complete information about configuring firewall filters in general, see *Routing Policies, Firewall Filters, and Traffic Policers User Guide*.

Understanding Dynamic Firewall Filters

Example: Configuring a DHCP Firewall Filter to Protect the Routing Engine

IN THIS SECTION

- [Requirements | 990](#)
- [Overview | 990](#)
- [Configuration | 991](#)
- [Verification | 994](#)

This example shows how to configure a firewall filter to ensure that proper DHCP packets can reach the Routing Engine on MX Series routers.

Requirements

This configuration example applies only to routers where DHCP local server and DHCP relay agent services are provided by the `jdhcpd` process rather than the legacy `dhcpd` process or `fud` (UDP forwarding) process. MX Series routers, M120 routers, and M320 routers use `jdhcpd`. For DHCP relay, that means the configuration is required only at the `[edit forwarding-options dhcp-relay]` hierarchy level and not at the `[edit forwarding-options helpers bootp]` hierarchy level.

No special configuration beyond device initialization is required before you can configure this feature.

Overview

Firewall filters that perform some action on DHCP packets at the Routing Engine, such as a filter to protect the Routing Engine by allowing only proper DHCP packets, require that both port 67 (bootps) and port 68 (bootpc) are configured as both source and destination ports.

DHCP packets received on the line cards are encapsulated by `jdhcpd` with a new UDP header where their source and destination addresses are set to port 68 before being forwarded to the Routing Engine. For DHCP relay and DHCP proxy, packets sent to the DHCP server from the router have both the source and destination UDP ports set to 67. The DHCP server responds using the same ports. However, when the line card receives these DHCP response packets, it changes both port numbers from 67 to 68 before passing the packets to the Routing Engine. Consequently the filter needs to accept port 67 for packets relayed from the client to the server, and port 68 for packets relayed from the server to the client.

In this example, you configure two filter terms, **`dhcp-client-accept`** and **`dhcp-server-accept`**. The match conditions for **`dhcp-client-accept`** specify a source address and destination address for broadcast packets, the UDP protocol used for DHCP packets, and the bootpc (68) source port. Packets that match these

conditions are counted and accepted. This term does not need to specify a match condition for the bootps (67) destination port. As configured below, this term can handle both the actual packet (port 68) passing to the Packet Forwarding Engine and the encapsulated packet (port 67 converted to 68 by jdhcpd) that reaches the DHCP daemon.

The match conditions for **dhcp-server-accept** specify the UDP protocol used for DHCP packets, and both port 67 and 68 for both source port and destination port. Packets that match these conditions are counted and accepted.

NOTE: This example does not show all possible configuration choices, nor does it show how the filter is applied in your configuration. This example applies to both static application of the filter as well as dynamic application with a dynamic profile.

Configuration

CLI Quick Configuration

To quickly configure the sample Routing Engine DHCP filter, copy the following commands, paste them in a text file, remove any line breaks, and then copy and paste the commands into the CLI.

```
[edit]
edit firewall family inet filter RE-protect
edit term dhcp-client-accept
set from source-address 0.0.0.0/32
set from destination-address 255.255.255.255/32
set from protocol udp
set from source-port 68
set then count dhcp-client-accept
set then accept
up
edit term dhcp-server-accept
set from protocol udp
set from source-port 67
set from source-port 68
set from destination-port 67
set from destination-port 68
set then count dhcp-server-accept
set then accept
top
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see [“Using the CLI Editor in Configuration Mode” on page 1632](#).

To configure a DHCP firewall filter to protect the Routing Engine:

1. Create or specify a firewall filter.

```
[edit firewall]
user@host# edit family inet filter RE-protect
```

2. Create a filter term for the client.

```
[edit firewall family inet filter RE-protect]
user@host# edit term dhcp-client-accept
```

3. Specify the match conditions for DHCP packets.

```
[edit firewall family inet filter RE-protect term dhcp-client-accept]
user@host# set from source-address 0.0.0.0/32
user@host# set from destination-address 255.255.255.255/32
user@host# set from protocol udp
user@host# set from source-port 68
user@host# set from destination-port 67
```

4. Specify the action to take for matched packets.

```
[edit firewall family inet filter RE-protect term dhcp-client-accept]
user@host# set then count dhcp-client-accept
user@host# set then accept
```

5. Create a filter term for the server.

```
[edit firewall family inet filter RE-protect]
user@host# edit term dhcp-server-accept
```

6. Specify the match conditions for DHCP packets.

```
[edit firewall family inet filter RE-protect term dhcp-server-accept]
user@host# set from protocol udp
user@host# set from source-port [67 68]
```

```
user@host# set from destination-port [67 68]
```

7. Specify the action to take for matched packets.

```
[edit firewall family inet filter RE-protect term dhcp-server-accept]
user@host# set then count dhcp-client-accept
user@host# set then accept
```

Results

From configuration mode, confirm your configuration by entering the **show firewall** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show firewall
family inet {
  filter RE-protect {
    term dhcp-client-accept {
      from {
        source-address {
          0.0.0.0/32;
        }
        destination-address {
          255.255.255.255/32;
        }
        protocol udp;
        source-port 68;
        destination-port 67;
      }
      then {
        count dhcp-client-accept;
        accept;
      }
    }
  }
  term dhcp-server-accept {
    from {
      protocol udp;
      source-port [ 67 68 ];
      destination-port [ 67 68 ];
    }
    then {
      count dhcp-server-accept;
```

```

    accept;
  }
}
}
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

IN THIS SECTION

- Verifying the DHCP Filter Operation | 994

To confirm that the Routing Engine DHCP protection filter is properly passing DHCP packets, perform these tasks:

Verifying the DHCP Filter Operation

Purpose

Verify that both counters increment as DHCP traffic passes to the Routing Engine.

Action

From operational mode, enter the **show firewall family inet filter RE-protect** command.

```
user@host> show firewall family inet filter RE-protect
```

```

Filter: RE-protect
Counters:
Name                               Bytes          Packets
dhcp-client-accept                 328             1
dhcp-server-accept                 574             1

```

```
user@host> show firewall family inet filter RE-protect
```

```
Filter: RE-protect
Counters:
```

Name	Bytes	Packets
------	-------	---------

dhcp-client-accept	660	2
dhcp-server-accept	1152	2

Meaning

The output lists both configured counters, dhcp-client-accept and dhcp-server-accept. By issuing the command more than once, you can see that the byte and packet fields both show that traffic is being accepted and counted.

Example: Configuring a Filter for Use as an Ingress Queuing Filter

IN THIS SECTION

- [Requirements | 997](#)
- [Overview | 997](#)
- [Configuration | 997](#)

This example shows how to configure a firewall filter for use as an ingress queuing filter. The ingress queuing filter assists in traffic shaping operations by enabling you to set the forwarding class and packet loss priority, or drop the packet before ingress queue selection. The firewall filter must be configured within one of the following protocol families: **bridge**, **cc**, **inet**, **inet6**, **mpls**, or **vpls** and have one or more of the following actions: **accept**, **discard**, **forwarding-class**, and **loss-priority**.

NOTE: Although the ingress queuing filter can be used with EX9200 switches and T-Series routers as well as MX-Series routers, it is used only on those MX Series routers that have MPCs. An error is generated at commit if the ingress queuing filter is applied to an interface on any other type of port concentrator.

Requirements

This example uses the following hardware and software components:

- An MX Series router with MPC

In order for ingress queuing filters to function, **ingress-and-egress** must be configured as the **traffic-manager** mode at the `[edit chassis fpc slot pic slot traffic-manager mode]` hierarchy level.

Overview

In this example, you create a firewall filter named **iqfilter1** in the **inet** protocol family that sets the loss priority and forwarding class of packets coming from the 192.168.2.0/24 network. You then apply the **iqfilter1** filter to the ge-0/0/0.0 logical interface as an ingress queuing filter.

To configure a firewall filter and apply it for use as an ingress queuing filter involves:

- Creating a firewall filter named **iqfilter1** in the **inet** protocol family with the following two actions: **forwarding-class** and **loss-priority**.
- Applying the firewall filter to the ge-0/0/0.0 interface as an ingress queuing filter.

Configuration

IN THIS SECTION

- [Configuring the Firewall Filter and Applying It to an Interface as an Input Queuing Filter | 998](#)
- [Results | 998](#)

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall family inet filter iqfilter1 term t1 from address 192.168.2.0/24
set firewall family inet filter iqfilter1 term t1 then loss-priority low
set firewall family inet filter iqfilter1 term t1 then forwarding-class expedited-forwarding
set interfaces ge-0/0/0 unit 0 family inet ingress-queuing-filter iqfilter1
```

Configuring the Firewall Filter and Applying It to an Interface as an Input Queuing Filter

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure the firewall filter, **iqfilter1**, and apply it to logical interface **ge-0/0/0** unit 0:

1. Create a firewall filter named **iqfilter1**.

```
[edit firewall family inet]
user@router# set filter iqfilter1 term t1 from address 192.168.2.0/24
user@router# set filter iqfilter1 term t1 then loss-priority low
user@router# set filter iqfilter1 term t1 then forwarding-class expedited-forwarding
```

2. Apply the firewall filter to the logical interface.

```
[edit]
user@router# set interfaces ge-0/0/0 unit 0 family inet ingress-queuing-filter iqfilter1
```

Results

From configuration mode, confirm your configuration by entering the **show firewall** and the **show interfaces ge-0/0/0.0** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@router# show firewall
family inet {
  filter iqfilter1 {
    term t1 {
      from {
```

```

        address {
            192.168.0.0/24;
        }
    }
    then {
        loss-priority low;
        forwarding-class expedited-forwarding;
    }
}
}
}
user@router# show interfaces ge-0/0/0.0
family inet {
    ingress-queuing-filter iqfilter1;
}

```

If you are done configuring the device, enter **commit** from configuration mode.

```
user@router# commit

Example: Configuring a Filter to Match on IPv6 Flags

IN THIS SECTION

- [Requirements | 1000](#)
- [Overview | 1000](#)
- [Configuration | 1000](#)
- [Verification | 1001](#)

This example shows how to configure a filter to match on IPv6 TCP flags.

Requirements

No special configuration beyond device initialization is required before configuring this example.

Overview

In this example, you configure a filter to match on IPv6 TCP flags. You can use this example to configure IPv6 TCP flags in M Series, MX Series, and T Series routing devices.

Configuration

Step-by-Step Procedure

To configure a filter to match on IPv6 TCP flags:

1. Include the family statement at the firewall hierarchy level, specifying **inet6** as the protocol family.

```
[edit]
user@host# edit firewall family inet6
```

2. Create the stateless firewall filter.

```
[edit firewall family inet6]
user@host# edit filter tcpfilt
```

3. Define the first term for the filter.

```
[edit firewall family inet6 filter tcpfilt]
user@host# edit term 1
```

4. Define the source address match conditions for the term.

```
[edit firewall family inet6 filter tcpfilt term 1]
user@host# set from next-header tcp tcp-flags syn
```

5. Define the actions for the term.

```
[edit firewall family inet6 filter tcpfilt term 1]
user@host# set then count tcp_syn_pkt log accept
```

6. If you are done configuring the device, commit the configuration.

```
[edit firewall family inet6 filter tcpfilt term 1]
user@host top

[edit]
user@host# commit
```

Verification

To confirm that the configuration is working properly, enter the **show firewall filter tcpfilt** command.

Example: Configuring a Filter to Match on Port and Protocol Fields

IN THIS SECTION

- [Requirements | 1001](#)
- [Overview | 1001](#)
- [Configuration | 1002](#)
- [Verification | 1005](#)

This example shows how to configure a standard stateless firewall filter to match on destination port and protocol fields.

Requirements

No special configuration beyond device initialization is required before configuring this example.

Overview

In this example, you configure a stateless firewall filter that accepts all IPv4 packets except for TCP and UDP packets. TCP and UDP packets are accepted if destined for the SSH port or the Telnet port. All other packets are rejected.

Configuration

IN THIS SECTION

- [Configure the Stateless Firewall Filter | 1002](#)
- [Apply the Stateless Firewall Filter to a Logical Interface | 1003](#)
- [Confirm and Commit Your Candidate Configuration | 1004](#)

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#).

CLI Quick Configuration

To quickly configure this example, copy the following configuration commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level:

```
set firewall family inet filter filter1 term term1 from protocol-except tcp
set firewall family inet filter filter1 term term1 from protocol-except udp
set firewall family inet filter filter1 term term1 then accept
set firewall family inet filter filter1 term term2 from address 192.168.0.0/16
set firewall family inet filter filter1 term term2 then reject
set firewall family inet filter filter1 term term3 from destination-port ssh
set firewall family inet filter filter1 term term3 from destination-port telnet
set firewall family inet filter filter1 term term3 then accept
set firewall family inet filter filter1 term term4 then reject
set interfaces ge-0/0/1 unit 0 family inet address 10.1.2.3/30
set interfaces ge-0/0/1 unit 0 family inet filter input filter1
```

Configure the Stateless Firewall Filter

Step-by-Step Procedure

To configure the stateless firewall filter **filter1**:

1. Create the IPv4 stateless firewall filter.

```
[edit]
user@host# edit firewall family inet filter filter1
```

2. Configure a term to accept all traffic except for TCP and UDP packets.

```
[edit firewall family inet filter filter1]
user@host# set term term1 from protocol-except tcp
user@host# set term term1 from protocol-except udp
user@host# set term term1 then accept
```

3. Configure a term to reject packets to or from the **192.168/16** prefix.

```
[edit firewall family inet filter filter1]
user@host# set term term2 from address 192.168.0.0/16
user@host# set term term2 then reject
```

4. Configure a term to accept packets destined for either the SSH port or the Telnet port.

```
[edit firewall family inet filter filter1]
user@host# set term term3 from destination-port ssh
user@host# set term term3 from destination-port telnet
user@host# set term term3 then accept
```

5. Configure the last term to reject all packets.

```
[edit firewall family inet filter filter1]
user@host# set term term4 then reject
```

Apply the Stateless Firewall Filter to a Logical Interface

Step-by-Step Procedure

To apply the stateless firewall filter to a logical interface:

1. Configure the logical interface to which you will apply the stateless firewall filter.

```
[edit]
user@host# edit interfaces ge-0/0/1 unit 0 family inet
```

2. Configure the interface address for the logical interface.

```
[edit interfaces ge-0/0/1 unit 0 family inet]
```

```
user@host# set address 10.1.2.3/30
```

3. Apply the stateless firewall filter to the logical interface.

```
[edit interfaces ge-0/0/1 unit 0 family inet]
user@host# set filter input filter1
```

Confirm and Commit Your Candidate Configuration

Step-by-Step Procedure

To confirm and then commit your candidate configuration:

1. Confirm the configuration of the stateless firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show firewall
family inet {
  filter filter1 {
    term term1 {
      from {
        protocol-except [tcp udp];
      }
      then {
        accept;
      }
    }
  }
  term term2 {
    from {
      address 192.168/16;
    }
    then {
      reject;
    }
  }
  term term3 {
    from {
      destination-port [ssh telnet];
    }
    then {
      accept;
    }
  }
}
```

```

    }
  }
  term term4 {
    then {
      reject;
    }
  }
}
}

```

2. Confirm the configuration of the interface by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

[edit]
user@host# show interfaces
ge-0/0/1 {
  unit 0 {
    family inet {
      filter {
        input filter1;
      }
      address 10.1.2.3/30;
    }
  }
}

```

3. If you are done configuring the device, commit your candidate configuration.

```

[edit]
user@host# commit

```

Verification

To confirm that the configuration is working properly, enter the **show firewall filter filter1** operational mode command.

Example: Configuring a Filter to Count Accepted and Rejected Packets

IN THIS SECTION

- [Requirements | 1006](#)
- [Overview | 1006](#)
- [Configuration | 1007](#)
- [Verification | 1010](#)

This example shows how to configure a firewall filter to count packets.

Requirements

No special configuration beyond device initialization is required before configuring this example.

Overview

In this example, you use a stateless firewall filter to reject all addresses except 192.168.5.0/24.

Topology

In the first term, the match condition **address 192.168.5.0/24 except** causes this address to be considered a mismatch, and this address is passed to the next term in the filter. The match condition **address 0.0.0.0/0** matches all other packets, and these are counted, logged, and rejected.

In the second term, all packets that passed through the first term (that is, packets whose address matches **192.168.5.0/24**) are counted, logged, and accepted.

Configuration

IN THIS SECTION

- [Configure the Stateless Firewall Filter | 1007](#)
- [Apply the Stateless Firewall Filter to a Logical Interface | 1008](#)
- [Confirm and Commit Your Candidate Configuration | 1008](#)

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#).

To configure this example, perform the following tasks:

CLI Quick Configuration

To quickly configure this example, copy the following configuration commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall family inet filter fire1 term 1 from address 192.168.5.0/24 except
set firewall family inet filter fire1 term 1 from address 0.0.0.0/0
set firewall family inet filter fire1 term 1 then count reject_pref1_1
set firewall family inet filter fire1 term 1 then log
set firewall family inet filter fire1 term 1 then reject
set firewall family inet filter fire1 term 2 then count reject_pref1_2
set firewall family inet filter fire1 term 2 then log
set firewall family inet filter fire1 term 2 then accept
set interfaces ge-0/0/1 unit 0 family inet filter input fire1
set interfaces ge-0/0/1 unit 0 family inet address 10.1.2.3/30
```

Configure the Stateless Firewall Filter

Step-by-Step Procedure

To configure the stateless firewall filter **fire1**:

1. Create the stateless firewall filter **fire1**.

```
[edit]
user@host# edit firewall family inet filter fire1
```

2. Configure the first term to reject all addresses except those to or from the **192.168.5.0/24** prefix and then count, log, and reject all other packets.

```
[edit firewall family inet filter fire1]
user@host# set term 1 from address 192.168.5.0/24 except
user@host# set term 1 from address 0.0.0.0/0
user@host# set term 1 then count reject_pref1_1
user@host# set term 1 then log
user@host# set term 1 then reject
```

3. Configure the next term to count, log, and accept packets in the **192.168.5.0/24** prefix.

```
[edit firewall family inet filter fire1]
user@host# set term 2 then count reject_pref1_2
user@host# set term 2 then log
user@host# set term 2 then accept
```

Apply the Stateless Firewall Filter to a Logical Interface

Step-by-Step Procedure

To apply the stateless firewall filter to a logical interface:

1. Configure the logical interface to which you will apply the stateless firewall filter.

```
[edit]
user@host# edit interfaces ge-0/0/1 unit 0 family inet
```

2. Configure the interface address for the logical interface.

```
[edit interfaces ge-0/0/1 unit 0 family inet]
user@host# set address 10.1.2.3/30
```

3. Apply the stateless firewall filter to the logical interface.

```
[edit interfaces ge-0/0/1 unit 0 family inet]
user@host# set filter input fire1
```

Confirm and Commit Your Candidate Configuration

Step-by-Step Procedure

To confirm and then commit your candidate configuration:

1. Confirm the configuration of the stateless firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show firewall
family inet {
  filter fire1 {
    term 1 {
      from {
        address {
          192.168.5.0/24 except;
          0.0.0.0/0;
        }
      }
      then {
        count reject_pref1_1;
        log;
        reject;
      }
    }
    term 2 {
      then {
        count reject_pref1_2;
        log;
        accept;
      }
    }
  }
}
```

2. Confirm the configuration of the interface by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show interfaces
ge-0/0/1 {
  unit 0 {
    family inet {
      filter {
```

```
        input fire1;  
    }  
    address 10.1.2.3/30;  
    }  
}  
}
```

3. If you are done configuring the device, commit your candidate configuration.

```
[edit]  
user@host# commit
```

Verification

To confirm that the configuration is working properly, enter the `show firewall filter fire1` operational mode command. You can also display the log and individual counters separately by using the following forms of the command:

- `show firewall counter reject_pref1_1`
- `show firewall counter reject_pref1_2`
- `show firewall log`

[Example: Configuring a Filter to Count and Discard IP Options Packets | 1010](#)

Example: Configuring a Filter to Count and Discard IP Options Packets

IN THIS SECTION

- [Requirements | 1011](#)
- [Overview | 1011](#)

- Configuration | 1011
- Verification | 1014

This example shows how to configure a standard stateless firewall to count packets.

Requirements

No special configuration beyond device initialization is required before configuring this example.

Because the filter term matches on *any* IP option value, the filter term can use the **count** nonterminating action without the **discard** terminating action or (alternatively) without requiring an interface on a 10-Gigabit Ethernet Modular Port Concentrator (MPC), 60-Gigabit Ethernet MPC, 60-Gigabit Queuing Ethernet MPC, or 60-Gigabit Ethernet Enhanced Queuing MPC on an MX Series router.

Overview

In this example, you use a standard stateless firewall filter to count and discard packets that include any IP option value but accept all other packets.

The IP option header field is an optional field in IPv4 headers only. The **ip-options** and **ip-options-except** match conditions are supported for standard stateless firewall filters and service filters only.

NOTE: On M and T series routers, firewall filters cannot count **ip-options** packets on a per option type and per interface basis. A limited work around is to use the **show pfe statistics ip options** command to see **ip-options** statistics on a per Packet Forwarding Engine (PFE) basis. See *show pfe statistics ip* for sample output.

Configuration

IN THIS SECTION

- Configure the Stateless Firewall Filter | 1012
- Apply the Stateless Firewall Filter to a Logical Interface | 1012
- Confirm and Commit Your Candidate Configuration | 1013

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#).

To configure this example, perform the following tasks:

CLI Quick Configuration

To quickly configure this example, copy the following configuration commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall family inet filter block_ip_options term 10 from ip-options any
set firewall family inet filter block_ip_options term 10 then count option_any
set firewall family inet filter block_ip_options term 10 then discard
set firewall family inet filter block_ip_options term 999 then accept
set interfaces ge-0/0/1 unit 0 family inet filter input block_ip_options
set interfaces ge-0/0/1 unit 0 family inet address 10.1.2.3/30
```

Configure the Stateless Firewall Filter

Step-by-Step Procedure

To configure the stateless firewall filter:

1. Create the stateless firewall filter **block_ip_options**.

```
[edit]
user@host# edit firewall family inet filter block_ip_options
```

2. Configure the first term to count and discard packets that include any IP options header fields.

```
[edit firewall family inet filter block_ip_options]
user@host# set term 10 from ip-options any
user@host# set term 10 then count option_any
user@host# set term 10 then discard
```

3. Configure the other term to accept all other packets.

```
[edit firewall family inet filter block_ip_options]
user@host# set term 999 then accept
```

Apply the Stateless Firewall Filter to a Logical Interface

Step-by-Step Procedure

To apply the stateless firewall filter to a logical interface:

1. Configure the logical interface to which you will apply the stateless firewall filter.

```
[edit]
user@host# edit interfaces ge-0/0/1 unit 0 family inet
```

2. Configure the interface address for the logical interface.

```
[edit interfaces ge-0/0/1 unit 0 family inet]
user@host# set address 10.1.2.3/30
```

3. Apply the stateless firewall filter to the logical interface.

```
[edit interfaces ge-0/0/1 unit 0 family inet]
user@host# set filter input block_ip_options
```

Confirm and Commit Your Candidate Configuration

Step-by-Step Procedure

To confirm and then commit your candidate configuration:

1. Confirm the configuration of the stateless firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show firewall
family inet {
  filter block_ip_options {
    term 10 {
      from {
        ip-options any;
      }
      then {
        count option_any;
        discard;
      }
    }
  }
  term 999 {
    then accept;
  }
}
```

```

    }
  }
}

```

2. Confirm the configuration of the interface by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

[edit]
user@host# show interfaces
ge-0/0/1 {
  unit 0 {
    family inet {
      filter {
        input block_ip_options;
      }
      address 10.1.2.3/30;
    }
  }
}

```

3. If you are done configuring the device, commit your candidate configuration.

```

[edit]
user@host# commit

```

Verification

To confirm that the configuration is working properly, enter the **show firewall filter block_ip_options** operational mode command. To display the count of discarded packets separately, enter the **show firewall count option_any** form of the command.

Example: Configuring a Filter to Count IP Options Packets

IN THIS SECTION

- Requirements | 1015
- Overview | 1015
- Configuration | 1016
- Verification | 1021

This example shows how use a stateless firewall filter to count individual IP options packets:

Requirements

This example uses an interface on a 10-Gigabit Ethernet Modular Port Concentrator (MPC), 60-Gigabit Ethernet MPC, 60-Gigabit Queuing Ethernet MPC, or 60-Gigabit Ethernet Enhanced Queuing MPC on an MX Series router. This interface enables you to apply an IPv4 firewall filter (standard or service filter) that can use the **count**, **log**, and **syslog** nonterminating actions on packets that match a *specific ip-option* value without having to also use the **discard** terminating action.

No special configuration beyond device initialization is required before configuring this example.

Overview

In this example, you use a stateless firewall filter to count IP options packets but not block any traffic. Also, the filter logs packets that have loose or strict source routing.

The IP option header field is an optional field in IPv4 headers only. The **ip-options** and **ip-options-except** match conditions are supported for standard stateless firewall filters and service filters only.

NOTE: On M and T series routers, firewall filters cannot count **ip-options** packets on a per option type and per interface basis. A limited work around is to use the **show pfe statistics ip options** command to see **ip-options** statistics on a per Packet Forwarding Engine (PFE) basis. See *show pfe statistics ip* for sample output.

Configuration

IN THIS SECTION

- [Configure the Stateless Firewall Filter | 1016](#)
- [Apply the Stateless Firewall Filter to a Logical Interface | 1018](#)
- [Confirm and Commit Your Candidate Configuration | 1018](#)

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#).

To configure this example, perform the following tasks:

CLI Quick Configuration

To quickly configure this example, copy the following configuration commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall family inet filter ip_options_filter term match_strict_source from ip-options strict-source-route
set firewall family inet filter ip_options_filter term match_strict_source then count strict_source_route
set firewall family inet filter ip_options_filter term match_strict_source then log
set firewall family inet filter ip_options_filter term match_strict_source then accept
set firewall family inet filter ip_options_filter term match_loose_source from ip-options loose-source-route
set firewall family inet filter ip_options_filter term match_loose_source then count loose_source_route
set firewall family inet filter ip_options_filter term match_loose_source then log
set firewall family inet filter ip_options_filter term match_loose_source then accept
set firewall family inet filter ip_options_filter term match_record from ip-options record-route
set firewall family inet filter ip_options_filter term match_record then count record_route
set firewall family inet filter ip_options_filter term match_record then accept
set firewall family inet filter ip_options_filter term match_timestamp from ip-options timestamp
set firewall family inet filter ip_options_filter term match_timestamp then count timestamp
set firewall family inet filter ip_options_filter term match_timestamp then accept
set firewall family inet filter ip_options_filter term match_router_alert from ip-options router-alert
set firewall family inet filter ip_options_filter term match_router_alert then count router_alert
set firewall family inet filter ip_options_filter term match_router_alert then accept
set firewall family inet filter ip_options_filter term match_all then accept
set interfaces ge-0/0/1 unit 0 family inet address 10.1.2.3/30
set interfaces ge-0/0/1 unit 0 family inet filter input ip_options_filter
```

Configure the Stateless Firewall Filter

Step-by-Step Procedure

To configure the stateless firewall filter **ip_option_filter**:

1. Create the stateless firewall filter **ip_option_filter**.

```
[edit]
user@host# edit firewall family inet filter ip_options_filter
```

2. Configure the first term to count, log, and accept packets with the **strict_source_route** IP optional header field.

```
[edit firewall family inet filter ip_option_filter]
user@host# set term match_strict_source from ip-options strict_source_route
user@host# set term match_strict_source then count strict_source_route
user@host# set term match_strict_source then log
user@host# set term match_strict_source then accept
```

3. Configure the next term to count, log, and accept packets with the **loose-source-route** IP optional header field.

```
[edit firewall family inet filter ip_option_filter]
user@host# set term match_loose_source from ip-options loose-source-route
user@host# set term match_loose_source then count loose_source_route
user@host# set term match_loose_source then log
user@host# set term match_loose_source then accept
```

4. Configure the next term to count and accept packets with the **record-route** IP optional header field.

```
[edit firewall family inet filter ip_option_filter]
user@host# set term match_record from ip-options record-route
user@host# set term match_record then count record_route
user@host# set term match_record then accept
```

5. Configure the next term to count and accept packets with the **timestamp** IP optional header field.

```
[edit firewall family inet filter ip_option_filter]
user@host# set term match_timestamp from ip-options timestamp
user@host# set term match_timestamp then count timestamp
user@host# set term match_timestamp then accept
```

6. Configure the next term to count and accept packets with the **router-alert** IP optional header field.

```
[edit firewall family inet filter ip_option_filter]
user@host# set term match_router_alert from ip-options router-alert
user@host# set term match_router_alert then count router_alert
user@host# set term match_router_alert then accept
```

7. Create the last term to accept any packet without incrementing any counters.

```
[edit firewall family inet filter ip_option_filter]
user@host# set term match_all then accept
```

Apply the Stateless Firewall Filter to a Logical Interface

Step-by-Step Procedure

To apply the stateless firewall filter to a logical interface:

1. Configure the logical interface to which you will apply the stateless firewall filter.

```
[edit]
user@host# edit interfaces ge-0/0/1 unit 0 family inet
```

2. Configure the interface address for the logical interface.

```
[edit interfaces ge-0/0/1 unit 0 family inet]
user@host# set address 10.1.2.3/30
```

3. Apply the stateless firewall filter to the logical interface.

```
[edit interfaces ge-0/0/1 unit 0 family inet]
user@host# set filter input ip_options_filter
```

Confirm and Commit Your Candidate Configuration

Step-by-Step Procedure

To confirm and then commit your candidate configuration:

1. Confirm the configuration of the stateless firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show firewall
family inet {
  filter ip_options_filter {
    term match_strict_source {
      from {
        ip-options strict-source-route;
      }
      then {
        count strict_source_route;
        log;
        accept;
      }
    }
    term match_loose_source {
      from {
        ip-options loose-source-route;
      }
      then {
        count loose_source_route;
        log;
        accept;
      }
    }
    term match_record {
      from {
        ip-options record-route;
      }
      then {
        count record_route;
        accept;
      }
    }
    term match_timestamp {
      from {
        ip-options timestamp;
      }
      then {
        count timestamp;
      }
    }
  }
}
```

```

        accept;
    }
}
term match_router_alert {
    from {
        ip-options router-alert;
    }
    then {
        count router_alert;
        accept;
    }
}
term match_all {
    then accept;
}
}
}

```

2. Confirm the configuration of the interface by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

[edit]
user@host# show interfaces
ge-0/0/1 {
    unit 0 {
        family inet {
            filter {
                input ip_option_filter;
            }
            address 10.1.2.3/30;
        }
    }
}

```

3. If you are done configuring the device, commit your candidate configuration.

```

[edit]
user@host# commit

```

Verification

To confirm that the configuration is working properly, enter the `show firewall filter ip_option_filter` operational mode command. You can also display the log and individual counters separately by using the following forms of the command:

- `show firewall counter strict_source_route`
- `show firewall counter loose_source_route`
- `show firewall counter record_route`
- `show firewall counter timestamp`
- `show firewall counter router_alert`
- `show firewall log`

Example: Configuring a Filter to Count and Sample Accepted Packets

IN THIS SECTION

- [Requirements | 1022](#)
- [Overview | 1022](#)
- [Configuration | 1022](#)
- [Verification | 1025](#)

This example shows how to configure a standard stateless firewall filter to count and sample accepted packets.

Requirements

No special configuration beyond device initialization is required before configuring this example.

Before you begin, configure traffic sampling by including the **sampling** statement at the **[edit forwarding-options]** hierarchy level.

Overview

In this example, you use a standard stateless firewall filter to count and sample all packets received on a logical interface.

NOTE: When you enable reverse path forwarding (RPF) on an interface with an input filter for firewall log and count, the input firewall filter does not log the packets rejected by RPF, although the rejected packets are counted. To log the rejected packets, use an RPF check fail filter.

WARNING: On MX Series routers with MPC3 or MPC4, if firewall filters are configured to count Two-Way Active Measurement Protocol (TWAMP) packets then the count is doubled for all TWAMP packets. There may also be a small increase in round trip time (RTT) when the TWAMP server is hosted on MPC3 or MPC4. This warning does not apply for routers with MPC1 or MPC2 cards.

Configuration

IN THIS SECTION

- [Configure the Stateless Firewall Filter | 1023](#)
- [Apply the Stateless Firewall Filter to a Logical Interface | 1023](#)
- [Confirm and Commit Your Candidate Configuration | 1024](#)

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#).

To configure this example, perform the following tasks:

CLI Quick Configuration

To quickly configure this example, copy the following configuration commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall family inet filter sam term all then count count_sam
set firewall family inet filter sam term all then sample
set interfaces at-2/0/0 unit 301 family inet address 10.1.2.3/30
set interfaces at-2/0/0 unit 301 family inet filter input sam
```

Configure the Stateless Firewall Filter

Step-by-Step Procedure

To configure the stateless firewall filter **sam**:

1. Create the stateless firewall filter **sam**.

```
[edit]
user@host# edit firewall family inet filter sam
```

2. Configure the term to count and sample all packets.

```
[edit firewall family inet filter sam]
user@host# set term all then count count_sam
user@host# set term all then sample
```

Apply the Stateless Firewall Filter to a Logical Interface

Step-by-Step Procedure

To apply the stateless firewall filter to a logical interface:

1. Configure the logical interface to which you will apply the stateless firewall filter.

```
[edit]
user@host# edit interfaces ge-0/0/1 unit 0 family inet
```

2. Configure the interface address for the logical interface.

```
[edit interfaces ge-0/0/1 unit 0 family inet]
user@host# set address 10.1.2.3/30
```

3. Apply the stateless firewall filter to the logical interface.

```
[edit interfaces ge-0/0/1 unit 0 family inet]
user@host# set filter input sam
```

NOTE: The Junos OS does not sample packets originating from the router or switch. If you configure a filter and apply it to the output side of an interface, then only the transit packets going through that interface are sampled. Packets that are sent from the Routing Engine to the Packet Forwarding Engine are not sampled.

Confirm and Commit Your Candidate Configuration

Step-by-Step Procedure

To confirm and then commit your candidate configuration:

1. Confirm the configuration of the stateless firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show firewall
family inet {
  filter sam {
    term all {
      then {
        count count_sam;
        sample; # default action is accept
      }
    }
  }
}
```

2. Confirm the configuration of the interface by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show interfaces
interfaces {
  at-2/0/0 {
```

```
unit 301 {  
    family inet {  
        filter {  
            input sam;  
        }  
        address 10.1.2.3/30;  
    }  
}
```

3. If you are done configuring the device, commit your candidate configuration.

```
[edit]  
user@host# commit
```

Verification

IN THIS SECTION

- [Displaying the Packet Counter | 1025](#)
- [Displaying the Firewall Filter Log Output | 1026](#)
- [Displaying the Sampling Output | 1027](#)

Confirm that the configuration is working properly.

Displaying the Packet Counter

Purpose

Verify that the firewall filter is evaluating packets.

Action

```
user@host> show firewall filter sam
```

```
Filter:  
Counters:
```

Name	Bytes	Packets
sam		
sam-1	98	8028

Displaying the Firewall Filter Log Output

Purpose

Display the packet header information for all packets evaluated by the firewall filter.

Action

```
user@host> show firewall log
```

Time	Filter	A	Interface	Pro	Source address	Destination address
23:09:09	-	A	at-2/0/0.301	TCP	10.2.0.25	10.211.211.1:80
23:09:07	-	A	at-2/0/0.301	TCP	10.2.0.25	10.211.211.1:56
23:09:07	-	A	at-2/0/0.301	ICM	10.2.0.25	10.211.211.1:49552
23:02:27	-	A	at-2/0/0.301	TCP	10.2.0.25	10.211.211.1:56
23:02:25	-	A	at-2/0/0.301	TCP	10.2.0.25	10.211.211.1:80
23:01:22	-	A	at-2/0/0.301	ICM	10.2.2.101	10.211.211.1:23251
23:01:21	-	A	at-2/0/0.301	ICM	10.2.2.101	10.211.211.1:16557
23:01:20	-	A	at-2/0/0.301	ICM	10.2.2.101	10.211.211.1:29471
23:01:19	-	A	at-2/0/0.301	ICM	10.2.2.101	10.211.211.1:26873

Meaning

This output file contains the following fields:

- **Time**—Time at which the packet was received (not shown in the default).
- **Filter**—Name of a filter that has been configured with the **filter** statement at the **[edit firewall]** hierarchy level. A hyphen (-) or the abbreviation **pfe** indicates that the packet was handled by the Packet Forwarding Engine. A space (no hyphen) indicates that the packet was handled by the Routing Engine.
- **A**—Filter action:
 - **A**—Accept (or next term)
 - **D**—Discard
 - **R**—Reject
- **Interface**—Interface on which the filter is configured.

NOTE: We strongly recommend that you always explicitly configure an action in the **then** statement.

- **Pro**—Packet's protocol name or number.
- **Source address**—Source IP address in the packet.
- **Destination address**—Destination IP address in the packet.

Displaying the Sampling Output

Purpose

Verify that the sampling output contains appropriate data.

Action

Example: Configuring a Filter to Set the DSCP Bit to Zero

IN THIS SECTION

- [Requirements | 1028](#)
- [Overview | 1028](#)
- [Configuration | 1028](#)
- [Verification | 1031](#)

This example shows how to configure a standard stateless firewall filter based on the Differentiated Services code point (DSCP).

Requirements

No special configuration beyond device initialization is required before configuring this example.

Overview

In this example, you use a stateless firewall filter to match packets on DSCP bit patterns. If the DSCP is **2**, the packet is classified to the **best-effort** forwarding class, and the DSCP is set to **0**. If the DSCP is **3**, the packet is classified to the **best-effort** forwarding class.

Configuration

IN THIS SECTION

- [Configure the Stateless Firewall Filter | 1029](#)
- [Apply the Stateless Firewall Filter to a Logical Interface | 1029](#)
- [Confirm and Commit Your Candidate Configuration | 1030](#)

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#).

To configure this example, perform the following tasks:

CLI Quick Configuration

To quickly configure this example, copy the following configuration commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall filter filter1 term 1 from dscp 2
set firewall filter filter1 term 1 then forwarding-class best-effort
set firewall filter filter1 term 1 then dscp 0
set firewall filter filter1 term 2 from dscp 3
set firewall filter filter1 term 2 then forwarding-class best-effort
set interfaces so-0/1/0 unit 0 family inet filter input filter1
```

Configure the Stateless Firewall Filter

Step-by-Step Procedure

To configure the stateless firewall filter **filter1**:

1. Create the stateless firewall filter.

```
[edit]
user@host# edit firewall filter filter1
```

2. Configure the first term to match a packet with a DSCP of **2**, change the DSCP to **0**, and classify the packet to the **best-effort** forwarding class.

```
[edit firewall filter filter1]
user@host# set term 1 from dscp 2
user@host# set term 1 then forwarding-class best-effort
user@host# set term 1 then dscp 0
```

3. Configure the other term to match a packet with a DSCP of **3** and classify the packet to the **best-effort** forwarding class.

```
[edit firewall filter filter1]
user@host# set term 2 from dscp 3
user@host# set term 2 then forwarding-class best-effort
```

Apply the Stateless Firewall Filter to a Logical Interface

Step-by-Step Procedure

To apply the stateless firewall filter to the logical interface corresponding to the VPN routing and forwarding (VRF) instance:

1. Configure the logical interface to which you will apply the stateless firewall filter.

```
[edit]
user@host# edit interfaces so-0/1/0 unit 0 family inet
```

2. Apply the stateless firewall filter to the logical interface.

```
[ input filter1]
user@host# set filter input filter1
```

Confirm and Commit Your Candidate Configuration

Step-by-Step Procedure

To confirm and then commit your candidate configuration:

1. Confirm the configuration of the stateless firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show firewall
filter filter1 {
  term term1 {
    from {
      dscp 2;
    }
    then {
      forwarding-class best-effort;
      dscp 0;
    }
  }
  term term2 {
    from {
      dscp 3;
    }
    then {
      forwarding-class best-effort;
    }
  }
}
```

2. Confirm the configuration of the interface by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show interfaces
so-0/1/0 {
  unit 0 {
    family inet {
      filter input filter1;
    }
  }
}
```

3. If you are done configuring the device, commit your candidate configuration.

```
[edit]
user@host# commit
```

Verification

To confirm that the configuration is working properly, enter the following operational mode commands:

- **show class-of-service**—Displays the entire class-of-service (CoS) configuration, including system-chosen defaults.
- **show class-of-service classifier type dscp**—Displays only the classifiers of the DSCP for IPv4 type.

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#).

To configure this example, perform the following tasks:

CLI Quick Configuration

To quickly configure this example, copy the following configuration commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall filter filter1 term 1 from dscp 2
set firewall filter filter1 term 1 then forwarding-class best-effort
set firewall filter filter1 term 1 then dscp 0
set firewall filter filter1 term 2 from dscp 3
set firewall filter filter1 term 2 then forwarding-class best-effort
set interfaces ge-0/1/0 unit 0 family inet filter input filter1
```

Configure the Stateless Firewall Filter

Step-by-Step Procedure

To configure the stateless firewall filter **filter1**:

1. Create the stateless firewall filter.

```
[edit]
user@host# edit firewall filter filter1
```

2. Configure the first term to match a packet with a DSCP of **2**, change the DSCP to **0**, and classify the packet to the **best-effort** forwarding class.

```
[edit firewall filter filter1]
user@host# set term 1 from dscp 2
user@host# set term 1 then forwarding-class best-effort
user@host# set term 1 then dscp 0
```

3. Configure the other term to match a packet with a DSCP of **3** and classify the packet to the **best-effort** forwarding class.

```
[edit firewall filter filter1]
user@host# set term 2 from dscp 3
user@host# set term 2 then forwarding-class best-effort
```

Apply the Stateless Firewall Filter to a Logical Interface

Step-by-Step Procedure

To apply the stateless firewall filter to the logical interface corresponding to the VPN routing and forwarding (VRF) instance:

1. Configure the logical interface to which you will apply the stateless firewall filter.

```
[edit]
user@host# edit interfaces ge-0/1/0 unit 0 family inet
```

2. Apply the stateless firewall filter to the logical interface.

```
[ input filter1]
user@host# set filter input filter1
```

Confirm and Commit Your Candidate Configuration

Step-by-Step Procedure

To confirm and then commit your candidate configuration:

1. Confirm the configuration of the stateless firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show firewall
filter filter1 {
  term term1 {
    from {
      dscp 2;
    }
    then {
      forwarding-class best-effort;
      dscp 0;
    }
  }
  term term2 {
    from {
      dscp 3;
    }
    then {
      forwarding-class best-effort;
    }
  }
}
```

2. Confirm the configuration of the interface by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show interfaces
ge-0/1/0 {
  unit 0 {
    family inet {
      filter input filter1;
    }
  }
}
```

3. If you are done configuring the device, commit your candidate configuration.

```
[edit]
user@host# commit
```

Verification

To confirm that the configuration is working properly, enter the following operational mode commands:

- **show class-of-service**—Displays the entire class-of-service (CoS) configuration, including system-chosen defaults.
- **show class-of-service classifier type dscp**—Displays only the classifiers of the DSCP for IPv4 type.

RELATED DOCUMENTATION

[Understanding How to Use Standard Firewall Filters | 713](#)

[Example: Configuring a Filter to Count and Sample Accepted Packets | 1021](#)

Example: Configuring a Filter to Match on Two Unrelated Criteria

IN THIS SECTION

- [Requirements | 1036](#)
- [Overview | 1036](#)
- [Configuration | 1036](#)
- [Verification | 1039](#)

This example shows how to configure a standard stateless firewall filter to match on two unrelated criteria.

Requirements

No special configuration beyond device initialization is required before configuring this example.

Overview

In this example, you use a standard stateless firewall filter to match IPv4 packets that are either OSPF packets or packets that come from an address in the prefix **10.108/16**, and send an **administratively-prohibited** ICMP message for all packets that do not match.

Configuration

IN THIS SECTION

- [Configuring the IPv4 Firewall Filter | 1037](#)
- [Applying the IPv4 Firewall Filter to a Logical Interface | 1038](#)

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#).

To configure this example, perform the following tasks:

CLI Quick Configuration

To quickly configure this example, copy the following configuration commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall family inet filter ospf_or_131 term protocol_match from protocol ospf
set firewall family inet filter ospf_or_131 term address_match from source-address 10.108.0.0/16
set interfaces ge-0/0/1 unit 0 family inet address 10.1.2.3/30
set interfaces ge-0/0/1 unit 0 family inet filter input ospf_or_131
```

Configuring the IPv4 Firewall Filter

Step-by-Step Procedure

To configure the IPv4 firewall filter:

1. Enable configuration of the IPv4 firewall filter.

```
[edit]
user@host# edit firewall family inet filter ospf_or_131
```

2. Configure the first term to accept OSPF packets.

```
[edit firewall family inet filter ospf_or_131]
user@host# set term protocol_match from protocol ospf
```

Packets that match the condition are accepted by default. Because another term follows this term, packets that do not match this condition are evaluated by the next term.

3. Configure the second term to accept packets from any IPv4 address in a particular prefix.

```
[edit firewall family inet filter ospf_or_131]
user@host# set term address_match from source-address 10.108.0.0/16
```

Packets that match this condition are accepted by default. Because this is the last term in the filter, packets that do not match this condition are discarded by default.

Results

Confirm the configuration of the stateless firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show firewall
```

```

family inet {
  filter ospf_or_131 {
    term protocol_match {
      from {
        protocol ospf;
      }
    }
    term address_match {
      from {
        source-address {
          10.108.0.0/16;
        }
      }
    }
  }
}

```

Applying the IPv4 Firewall Filter to a Logical Interface

Step-by-Step Procedure

To apply the stateless firewall filter to a logical interface:

1. Enable configuration of a logical interface.

```

[edit]
user@host# edit interfaces ge-0/0/1 unit 0 family inet

```

2. Configure an IP address for the logical interface.

```

[edit interfaces ge-0/0/1 unit 0 family inet]
user@host# set address 10.1.2.3/30

```

3. Apply the IPv4 firewall filter to the logical interface.

```

[edit interfaces ge-0/0/1 unit 0 family inet]
user@host# set filter input ospf_or_131

```

Results

Confirm the configuration of the interface by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show interfaces
ge-0/0/1 {
  unit 0 {
    family inet {
      filter {
        input ospf_or_131;
      }
      address 10.1.2.3/30;
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

To confirm that the configuration is working properly, enter the **show firewall filter ospf_or_131** operational mode command.

Example: Configuring a Filter to Accept DHCP Packets Based on Address

IN THIS SECTION

- [Requirements | 1040](#)
- [Overview | 1040](#)
- [Configuration | 1040](#)
- [Verification | 1043](#)

This example shows how to configure a standard stateless firewall filter to accept packets from a trusted source.

Requirements

This example is supported only on MX Series routers and EX Series switches.

Overview

In this example, you create a filter (**rpf_dhcp**) that accepts DHCP packets with a source address of **0.0.0.0** and a destination address of **255.255.255.255**.

Configuration

IN THIS SECTION

- [Configure the Stateless Firewall Filter | 1040](#)
- [Apply the Firewall Filter to the Loopback Interface | 1041](#)
- [Confirm and Commit Your Candidate Configuration | 1041](#)

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#).

CLI Quick Configuration

To quickly configure this example, copy the following configuration commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall family inet filter rpf_dhcp term dhcp_term from source-address 0.0.0.0/32
set firewall family inet filter rpf_dhcp term dhcp_term from destination-address 255.255.255.255/32
set firewall family inet filter rpf_dhcp term dhcp_term then accept
set interfaces ge-0/0/1 unit 0 family inet address 10.1.2.3/30
set interfaces ge-0/0/1 unit 0 family inet filter input sam
```

Configure the Stateless Firewall Filter

Step-by-Step Procedure

To configure the stateless firewall filter:

1. Create the stateless firewall filter **rpf_dhcp**.

```
[edit]
user@host# edit firewall family inet filter rpf_dhcp
```

2. Configure the term to match packets with a source address of **0.0.0.0** and a destination address of **255.255.255.255**.

```
[edit firewall family inet filter rpf_dhcp]
user@host# set term dhcp_term from source-address 0.0.0.0/32
user@host# set term dhcp_term from destination-address 255.255.255.255/32
```

3. Configure the term to accept packets that match the specified conditions.

```
[edit firewall family inet filter rpf_dhcp]
set term dhcp_term then accept
```

Apply the Firewall Filter to the Loopback Interface

Step-by-Step Procedure

To apply the filter to the input at the loopback interface:

1. Apply the **rpf_dhcp** filter if packets are not arriving on an expected path.

```
[edit]
user@host# set interfaces lo0 unit 0 family inet rpf-check fail-filter rpf_dhcp
```

2. Configure an address for the loopback interface.

```
[edit]
user@host# set interfaces lo0 unit 0 family inet address 127.0.0.1/32
```

Confirm and Commit Your Candidate Configuration

Step-by-Step Procedure

To confirm and then commit your candidate configuration:

1. Confirm the configuration of the stateless firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show firewall
family inet {
  filter rpf_dhcp {
    term dhcp_term {
      from {
        source-address {
          0.0.0.0/32;
        }
        destination-address {
          255.255.255.255/32;
        }
      }
      then accept;
    }
  }
}
```

2. Confirm the configuration of the interface by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show interfaces
lo0 {
  unit 0 {
    family inet {
      filter {
        rpf-check {
          fail-filter rpf_dhcp;
          mode loose;
        }
      }
      address 127.0.0.1/32;
    }
  }
}
```

3. When you are done configuring the device, commit your candidate configuration.

```
[edit]  
user@host# commit
```

Verification

To confirm that the configuration is working properly, enter the **show firewall** operational mode command.

Example: Configuring a Filter to Accept OSPF Packets from a Prefix

IN THIS SECTION

- [Requirements | 1043](#)
- [Overview | 1044](#)
- [Configuration | 1044](#)
- [Verification | 1047](#)

This example shows how to configure a standard stateless firewall filter to accept packets from a trusted source.

Requirements

No special configuration beyond device initialization is required before configuring this example.

Overview

In this example, you create a filter that accepts only OSPF packets from an address in the prefix 10.108.0.0/16, discarding all other packets with an **administratively-prohibited** ICMP message

Configuration

IN THIS SECTION

- [Configure the Stateless Firewall Filter | 1044](#)
- [Apply the Firewall Filter to the Loopback Interface | 1045](#)
- [Confirm and Commit Your Candidate Configuration | 1045](#)

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#).

To configure this example, perform the following tasks:

CLI Quick Configuration

To quickly configure this example, copy the following configuration commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall family inet filter ospf_filter term term1 from source-address 10.108.0.0/16
set firewall family inet filter ospf_filter term term1 from protocol ospf
set firewall family inet filter ospf_filter term term1 then accept
set firewall family inet filter ospf_filter term default-term then reject administratively-prohibited
set interfaces lo0 unit 0 family inet address 10.1.2.3/30
set interfaces lo0 unit 0 family inet filter input ospf_filter
```

Configure the Stateless Firewall Filter

Step-by-Step Procedure

To configure the stateless firewall filter **ospf_filter**:

1. Create the filter.

```
[edit]
user@host# edit firewall family inet filter ospf_filter
```

2. Configure the term that accepts packets.

```
[edit firewall family inet filter ospf_filter]
user@host# set term term1 from source-address 10.108.0.0/16
user@host# set term term1 from protocol ospf
user@host# set term term1 then accept
```

3. Configure the term that rejects all other packets.

```
[edit firewall family inet filter ospf_filter]
user@host# set term default_term then reject administratively-prohibited
```

Apply the Firewall Filter to the Loopback Interface

Step-by-Step Procedure

To apply the firewall filter to the loopback interface:

1. Configure the interface.

```
[edit]
user@host# edit interfaces lo0 unit 0 family inet
```

2. Configure the logical interface IP address.

```
[edit interfaces lo0 unit 0 family inet]
user@host# set address 10.1.2.3/30
```

3. Apply the filter to the input.

```
[edit interfaces lo0 unit 0 family inet]
user@host# set filter input ospf_filter
```

Confirm and Commit Your Candidate Configuration

Step-by-Step Procedure

To confirm and then commit your candidate configuration:

1. Confirm the configuration of the stateless firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show firewall
family inet {
  filter ospf_filter {
    term term1 {
      from {
        source-address {
          10.108.0.0/16;
        }
        protocol ospf;
      }
      then {
        accept;
      }
    }
    term default_term {
      then {
        reject administratively-prohibited; # default reject action
      }
    }
  }
}
```

2. Confirm the configuration of the interface by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show interfaces
lo0 {
  unit 0 {
    family inet {
      filter {
        input ospf_filter;
      }
      address 10.1.2.3/30;
    }
  }
}
```

```
}
}
```

3. If you are done configuring the device, commit your candidate configuration.

```
[edit]
user@host# commit
```

Verification

To confirm that the configuration is working properly, enter the [show firewall filter ospf_filter](#) operational mode command.

Example: Configuring a Stateless Firewall Filter to Handle Fragments

IN THIS SECTION

- [Requirements | 1048](#)
- [Overview | 1048](#)
- [Configuration | 1048](#)
- [Verification | 1052](#)

This example shows how to create a stateless firewall filter that handles packet fragments.

Requirements

No special configuration beyond device initialization is required before configuring stateless firewall filters.

Overview

In this example, you create a stateless firewall filter called **fragment-RE** that accepts fragmented packets originating from 10.2.1.0/24 and destined for the BGP port. This example includes the following firewall filter terms:

- **not-from-prefix-term**—Discards packets that are not from 10.2.1.0/24 to ensure that subsequent terms in the firewall filter are matched against packets from 10.2.1.0/24 only.
- **small-offset-term**—Discards small (1–5) offset packets to ensure that subsequent terms in the firewall filter can be matched against all the headers in the packet. In addition, the term adds a record to the system logging destinations for the firewall facility.
- **not-fragmented-term**—Accepts unfragmented TCP packets with a destination port that specifies the BGP protocol. A packet is considered unfragmented if the MF flag is not set and the fragment offset equals 0.
- **first-fragment-term**—Accepts the first fragment of a fragmented TCP packet with a destination port that specifies the BGP protocol.
- **fragment-term**—Accepts all fragments that were not discarded by **small-offset-term**. (packet fragments 6–8191). However, only those fragments that are part of a packet containing a first fragment accepted by **first-fragment-term** are reassembled by the destination device.

Packet fragments offset can be from 1 through 8191.

NOTE: You can move terms within the firewall filter by using the **insert** command. For more information, see “*insert*” in the *CLI User Guide*.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall family inet filter fragment-RE term not-from-prefix-term from source-address 0.0.0.0/0
set firewall family inet filter fragment-RE term not-from-prefix-term from source-address 10.2.1.0/24 except
```

```

set firewall family inet filter fragment-RE term not-from-prefix-term then discard
set firewall family inet filter fragment-RE term small-offset-term from fragment-offset 1-5
set firewall family inet filter fragment-RE term small-offset-term then syslog
set firewall family inet filter fragment-RE term small-offset-term then discard
set firewall family inet filter fragment-RE term not-fragmented-term from fragment-offset 0
set firewall family inet filter fragment-RE term not-fragmented-term from fragment-flags "!more-fragments"
set firewall family inet filter fragment-RE term not-fragmented-term from protocol tcp
set firewall family inet filter fragment-RE term not-fragmented-term from destination-port bgp
set firewall family inet filter fragment-RE term not-fragmented-term then accept
set firewall family inet filter fragment-RE term first-fragment-term from first-fragment
set firewall family inet filter fragment-RE term first-fragment-term from protocol tcp
set firewall family inet filter fragment-RE term first-fragment-term from destination-port bgp
set firewall family inet filter fragment-RE term first-fragment-term then accept
set firewall family inet filter fragment-RE term fragment-term from fragment-offset 6-8191
set firewall family inet filter fragment-RE term fragment-term then accept

```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure the stateless firewall filter:

1. Define the stateless firewall filter.

```

[edit]
user@host# edit firewall family inet filter fragment-RE

```

2. Configure the first term for the filter.

```

[edit firewall family inet filter fragment-RE ]
user@host# set term not-from-prefix-term from source-address 0.0.0.0/0
user@host# set term not-from-prefix-term from source-address 10.2.1.0/24 except
user@host# set term not-from-prefix-term then discard

```

3. Define the second term for the filter.

```

[edit firewall family inet filter fragment-RE]
user@host# edit term small-offset-term

```

4. Define the match conditions for the term.

```
[edit firewall family inet filter fragment-RE term small-offset-term]
user@host# set from fragment-offset 1-5
```

5. Define the action for the term.

```
[edit firewall family inet filter fragment-RE term small-offset-term]
user@host# set then syslog discard
```

6. Define the third term for the filter.

```
[edit]
user@host# edit firewall family inet filter fragment-RE term not-fragmented-term
```

7. Define the match conditions for the term.

```
[edit firewall family inet filter fragment-RE term not-fragmented-term]
user@host# set from fragment-flags "!more-fragments" fragment-offset 0 protocol tcp destination-port bgp
```

8. Define the action for the term.

```
[edit firewall family inet filter fragment-RE term not-fragmented-term]
user@host# set then accept
```

9. Define the fourth term for the filter.

```
[edit]
user@host# edit firewall family inet filter fragment-RE term first-fragment-term
```

10. Define the match conditions for the term.

```
[edit firewall family inet filter fragment-RE term first-fragment-term]
user@host# set from first-fragment protocol tcp destination-port bgp
```

11. Define the action for the term.

```
[edit firewall family inet filter fragment-RE term first-fragment-term]
user@host# set then accept
```

12. Define the last term for the filter.

```
[edit]
user@host# edit firewall family inet filter fragment-RE term fragment-term
```

13. Define the match conditions for the term.

```
[edit firewall family inet filter fragment-RE term fragment-term]
user@host# set from fragment-offset 6-8191
```

14. Define the action for the term.

```
[edit firewall family inet filter fragment-RE term fragment-term]
user@host# set then accept
```

Results

Confirm your configuration by entering the **show firewall** command from configuration mode. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@host# show firewall
family inet {
  filter fragment-RE {
    term not-from-prefix-term {
      from {
        source-address {
          0.0.0.0/0;
          10.2.1.0/24 except;
        }
      }
      then discard;
    }
    term small-offset-term {
      from {
```

```

        fragment-offset 1-5;
    }
    then {
        syslog;
        discard;
    }
}
term not-fragmented-term {
    from {
        fragment-offset 0;
        fragment-flags "!more-fragments";
        protocol tcp;
        destination-port bgp;
    }
    then accept;
}
term first-fragment-term {
    from {
        first-fragment;
        protocol tcp;
        destination-port bgp;
    }
    then accept;
}
term fragment-term {
    from {
        fragment-offset 6-8191;
    }
    then accept;
}
}
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

IN THIS SECTION

- [Displaying Stateless Firewall Filter Configurations | 1053](#)
- [Verifying a Firewall Filter that Handles Fragments | 1053](#)

To confirm that the configuration is working properly, perform these tasks:

Displaying Stateless Firewall Filter Configurations

Purpose

Verify the configuration of the firewall filter. You can analyze the flow of the filter terms by displaying the entire configuration.

Action

From configuration mode, enter the **show firewall** command.

Meaning

Verify that the output shows the intended configuration of the firewall filter. In addition, verify that the terms are listed in the order in which you want the packets to be tested. You can move terms within a firewall filter by using the **insert** CLI command.

Verifying a Firewall Filter that Handles Fragments

Purpose

Verify that the actions of the firewall filter terms are taken.

Action

Send packets to the device that match the terms.

Meaning

Verify that packets from 10.2.1.0/24 with small fragment offsets are recorded in the device's system logging destinations for the firewall facility.

RELATED DOCUMENTATION

| *show route summary*

Configuring a Firewall Filter to Prevent or Allow IPv4 Packet Fragmentation

This topic explains how to use the **dont-fragment (set | clear)** actions in an ingress firewall filter to modify the Don't Fragment flag in IPv4 packet headers. These actions are supported only on MPCs in MX Series routers.

You can use a firewall filter on an ingress interface to match IPv4 packets that have the Don't Fragment flag set to one or cleared to zero. Fragmentation is prevented when this flag is set in the packet header. Fragmentation is allowed when the flag is not set.

To prevent an IPv4 packet from being fragmented:

- Configure a filter term that modifies the Don't Fragment flag to one.

```
[edit firewall family inet filter dfSet]
user@host# set term t1 then dont-fragment set
```

To allow an IPv4 packet to be fragmented:

- Configure a filter term that modifies the Don't Fragment flag to zero.

```
[edit firewall family inet filter dfClear]
user@host# set term t1 then dont-fragment clear
```

In the following example, the dfSet firewall filter matches packets that are fragmented and changes the Don't Fragment flag to prevent fragmentation. The dfClear firewall filter matches packets that are not fragmented and changes the Don't Fragment flag to allow fragmentation.

```
[edit firewall family inet]
user@host# edit filter dfSet
user@host# set term t1 from fragment-flags is-fragment
user@host# set term t1 then dont-fragment set
user@host# up
user@host# edit filter dfClear
user@host# set term t1 from fragment-flags dont-fragment
user@host# set term t1 then dont-fragment clear
```

Configuring a Firewall Filter to Discard Ingress IPv6 Packets with a Mobility Extension Header

This topic explains how to configure a firewall filter to discard IPv6 packets that contain a mobility extension header. This feature is supported only on MPCs in MX Series routers.

To configure the stateless firewall filter:

1. Create the stateless firewall filter.

```
[edit]
user@host# edit firewall family inet6 filter filter-name
```

For example:

```
[edit]
user@host# edit firewall family inet6 filter drop-mobility
```

2. Configure a term to discard all traffic that contains a mobility extension header.

```
[edit firewall family inet6 filter drop-mobility]
user@host# set term term1 from extension-header mobility
user@host# set term term1 then discard
```

3. Configure a term to accept all other traffic.

```
[edit firewall family inet6 filter drop-mobility]
user@host# set term term2 then accept
```

4. Apply the firewall filter to a logical interface.

```
[edit interfaces ge-1/2/10 unit 0 family inet6]
user@host# set filter input drop-mobility
```

RELATED DOCUMENTATION

[Understanding How to Use Standard Firewall Filters](#) | 713

Example: Configuring an Egress Filter Based on IPv6 Source or Destination IP Addresses

IN THIS SECTION

- [Requirements | 1056](#)
- [Overview | 1056](#)
- [Configuration | 1056](#)

This example shows how to configure a firewall filter to accept IPv6 packets egressing an **inet6** interface.

Requirements

This topic describes a feature supported on EX4300 and QFX5100 that was introduced in Junos OS Release 19.1R1. No special configuration beyond device initialization is required before configuring this example.

Overview

In this example, you create a typical firewall filter to accept IPv6 source and destination packets in the egress direction of an **inet6** interface. To support filtering in the egress direction, however, you'll first need to set the **set system packet-forwarding-options eracl-ip6-match** using either the **srcip6-and-destip6** or **srcip6-only** option. You'll also need to restart the packet forwarding engine(PFE) after committing the configuration.

Configuration

IN THIS SECTION

- [Enable the system for IPv6 address filtering | 1057](#)
- [Apply the firewall filter to an egress interface | 1059](#)
- [Confirm and Commit Your Candidate Configuration | 1059](#)

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#).

CLI Quick Configuration

To quickly configure this example, copy the following commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set system packet-forwarding-options eracl-ip6-match srcip6-and-destip6
set firewall family inet6 filter ipv6_filter term t1 from source-address 3001::10/64
set firewall family inet6 filter ipv6_filter term t1 from destination-address 2001::10/64
set interfaces ge-0/0/0 unit 0 family inet6 filter output ipv6_filter
```

Enable the system for IPv6 address filtering

Step-by-Step Procedure

To configure a firewall filter for IPv6 filtering on an **inet6** egress interface:

1. Enable packet forwarding options for matching on either IPv6 source, or IPv6 source and destination IP addresses. In this example, we'll enable both source and destination IP address matching.

```
[edit]
user@host# set system packet-forwarding-options eracl-ip6-match srcip6-and-destip6
```

2. Check, and if appropriate, delete any existing firewall filters that are already bound to the interface you will use for the IPv6 firewall filter:

```
[edit]
user@host# delete interfaces ge-0/0/0 unit 0 family inet6 filter output tcp_filter.
```

3. Commit the changes above, then stop and restart the PFE to accept the **packet-forwarding-options** and clear the PFE for the IPv6 filter(s).

- For EX4300, use the following:

```
user@host# commit
user@host# run request restart pfe-manager
```

- For EX4300 virtual chassis, use the following:

```
user@host# commit
user@host# run request system reboot all-members
```

- For QFX5100, reboot the system:

```
user@host# commit
user@host# run request system reboot
```

4. Create a IPv6 firewall filter named **tcp_filter**.

```
[edit]
user@host# edit firewall family inet6 filter tcp_filter
```

5. Configure the required filter action, here to match packets with an IPv6 source or destination address within the configured range.

```
[edit firewall family inet6 filter tcp_filter]
user@host# set term t1 from source-address 3001::10/64
user@host# set term t1 from destination-address 2001::10/64
```

6. Specify that matched packets are counted, logged to the buffer on the PFE, and accepted.

```
[edit firewall family inet6 filter tcp_filter]
user@host# set term t1 then count egress_ipv6-packets
user@host# set term t1 then log
user@host# set term t1 then accept
```

*Apply the firewall filter to an egress interface***Step-by-Step Procedure**

To apply the firewall filter to an egress inet6 interface, type the following:

- `user@host# set interfaces ge-0/0/0 unit 0 family inet6 filter output tcp_filter`

*Confirm and Commit Your Candidate Configuration***Step-by-Step Procedure**

To confirm and then commit your candidate configuration:

1. Confirm the configuration of the firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show firewall
family inet6 {
  filter tcp_filter {
    term t1 {
      from {
        source-address 3001::10/64;
        destination-address 2001::10/64;
      }
      then {
        count egress_ipv6-packets;
        log;
        accept;
      }
    }
  }
}
```

2. Confirm the configuration of the interface by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show interfaces
ge-0/0/0 {
  unit 0 {
    family inet6 {
      filter {
```

```

        output tcp_filter;
    }
    source-address 3001::10/64;
    destination-address 2001::10/64;
}
}
}

```

3. When you are done configuring the device, commit the candidate configuration.

```

[edit]
user@host# commit

```

[Understanding How to Use Standard Firewall Filters | 713](#)

Example: Configuring a Rate-Limiting Filter Based on Destination Class

IN THIS SECTION

- [Requirements | 1060](#)
- [Overview | 1061](#)
- [Configuration | 1061](#)
- [Verification | 1064](#)

This example shows how to configure a rate-limiting stateless firewall filter.

Requirements

No special configuration beyond device initialization is required before configuring this example.

Before you begin, configure the destination class **class1**.

Overview

In this example, you use a stateless firewall filter to set rate limits based on a destination class.

To activate a policer from within a stateless firewall filter configuration:

- Create a template for the policer by including the **policer policer-name** statement.
- Reference the policer in a filter term that specifies the policer in the **policer policer-name** nonterminating action.

You can also activate a policer by including the **policer (input | output) policer-template-name** statement at a logical interface.

Configuration

IN THIS SECTION

- [Configure the Stateless Firewall Filter | 1062](#)
- [Apply the Stateless Firewall Filter to a Logical Interface | 1062](#)
- [Confirm and Commit Your Candidate Configuration | 1063](#)

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#).

CLI Quick Configuration

To quickly configure this example, copy the following commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall filter rl_dclass1 policer police_class1 if-exceeding bandwidth-limit 25
set firewall filter rl_dclass1 policer police_class1 if-exceeding burst-size-limit 1000
set firewall filter rl_dclass1 policer police_class1 then discard
set firewall filter rl_dclass1 term term1 from destination-class class1
set firewall filter rl_dclass1 term term1 then policer police_class1
set interfaces ge-0/0/1 unit 0 family inet address 10.1.2.3/30
set interfaces ge-0/0/1 unit 0 family inet filter input rl_dclass1
```

Configure the Stateless Firewall Filter

Step-by-Step Procedure

To configure the stateless firewall filter **rl_dclass1** with policer **police_class1** for destination class **class1**:

1. Create the stateless firewall filter **rl_dclass1**.

```
[edit]
user@host# edit firewall filter rl_dclass1
```

2. Configure the policer template **police_class1**.

```
[edit firewall filter rl_dclass1]
user@host# set policer police_class1 if-exceeding bandwidth-limit 25
user@host# set policer police_class1 if-exceeding burst-size-limit 1000
user@host# set policer police_class1 then discard
```

3. Configure a filter term that uses policer **police_class1** to rate-limit traffic for destination class **class1**.

```
[edit firewall filter rl_dclass1]
user@host# set term term1 from destination-class class1
user@host# set term term1 then policer police_class1
```

Apply the Stateless Firewall Filter to a Logical Interface

Step-by-Step Procedure

To apply the filter **rl_dclass1** to a logical interface:

1. Configure the logical interface to which you will apply the stateless firewall filter.

```
[edit]
user@host# edit interfaces ge-0/0/1 unit 0 family inet
```

2. Configure the interface address for the logical interface.

```
[edit interfaces ge-0/0/1 unit 0 family inet]
user@host# set address 10.1.2.3/30
```

3. Apply the stateless firewall filter to the logical interface.

```
[edit interfaces ge-0/0/1 unit 0 family inet]
user@host# set filter input rl_dclass1
```

Confirm and Commit Your Candidate Configuration

Step-by-Step Procedure

To confirm and then commit your candidate configuration:

1. Confirm the configuration of the stateless firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show firewall
filter rl_dclass1 {
  policer police_class1 {
    if-exceeding {
      bandwidth-limit 25;
      burst-size-limit 1000;
    }
    then {
      discard;
    }
  }
}
term term1 {
  from {
    destination-class class1;
  }
  then {
    policer police_class1;
  }
}
}
```

2. Confirm the configuration of the interface by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show interfaces
```

```
ge-0/0/1 {  
  unit 0 {  
    family inet {  
      filter {  
        input rl_dclass1;  
      }  
      address 10.1.2.3/30;  
    }  
  }  
}
```

3. If you are done configuring the device, commit your candidate configuration.

```
[edit]  
user@host# commit
```

Verification

To confirm that the configuration is working properly, enter the **show class-of-service ge-0/0/1** operational mode command.

Logical Systems

With the Junos OS, you can partition a single physical router or switch into multiple logical devices that perform independent routing tasks. Because logical systems perform a subset of the tasks once handled by the physical router or switch, logical systems offer an effective way to maximize the use of a single router or switch.

Firewall Filters in Logical Systems

You can configure a separate set of firewall filters for each logical system on a router or switch. To configure a filter in a logical system, you must define the filter in the **firewall** stanza at the **[edit logical-systems logical-system-name]** hierarchy level, and you must apply the filter to a logical interface that is also configured at the **[edit logical-systems logical-system-name]** hierarchy level.

Identifiers for Firewall Objects in Logical Systems

To identify firewall objects configured under logical systems, operational **show** commands and firewall-related SNMP MIB objects include a **__logical-system-name/** prefix in the object name. For example, firewall objects configured under the **ls1** logical system include **__ls1/** as the prefix.

Statement Hierarchy for Configuring Firewall Filters in Logical Systems

To configure a firewall filter in a logical system, include the **filter**, **service-filter**, or **simple-filter** statement at the `[edit logical-systems logical-system-name firewall family family-name]` hierarchy level.

```
[edit]
logical systems {
  logical-system-name {
    firewall {
      family family-name {
        filter filter-name {
          interface-specific;
          physical-interface-filter;
          term term-name {
            filter filter-name;
            from {
              match-conditions;
            }
            then {
              actions;
            }
          }
        }
      }
      service-filter filter-name { # For 'family inet' or 'family inet6' only.
        term term-name {
          from {
            match-conditions;
          }
          then {
            actions;
          }
        }
      }
      simple-filter filter-name { # For 'family inet' only.
        term term-name {
```

```

        from {
            match-conditions;
        }
        then {
            actions;
        }
    }
}
}
}
}
}
}
}
}
}

```

Filter Types in Logical Systems

There are no special restrictions on the types of stateless firewall filter types that you can configure in logical systems.

In a logical system, you can use the same types of stateless firewall filters that are available on a physical router or switch:

- Standard stateless firewall filters
- Service filters
- Simple filters

Firewall Filter Protocol Families in Logical Systems

There are no special restrictions on the protocol families supported with stateless firewall filters in logical systems.

In a logical system, you can filter the same protocol families as you can on a physical router or switch.

- Standard stateless firewall filters—In logical systems, you can filter the following traffic types: protocol-independent, IPv4, IPv6, MPLS, MPLS-tagged IPv4 or IPv6, VPLS, Layer 2 circuit cross-connection, and Layer 2 bridging.
- Service filters—In logical systems, you can filter IPv4 and IPv6 traffic.
- Simple filters—In logical systems, you can filter IPv4 traffic only.

Firewall Filter Match Conditions in Logical Systems

There are no special restrictions on the match conditions supported with stateless firewall filters in logical systems.

Firewall Filter Actions in Logical Systems

There are no special restrictions on the actions supported with stateless firewall filters in logical systems.

Statement Hierarchy for Applying Firewall Filters in Logical Systems

To apply a firewall filter in a logical system, include the **filter** *filter-name*, **service-filter** *service-filter-name*, or **simple-filter** *simple-filter-name* statement to a logical interface in the logical system.

The following configuration shows the hierarchy levels at which you can apply the statements:

```
[edit]
logical-systems logical-system-name {
  interfaces {
    interface-name {
      unit logical-unit-number {
        family family-name {
          filter {
            group group-name;
            input filter-name;
            input-list [ filter-names ];
            output filter-name;
            output-list [ filter-names ]
          }
          rpf-check { # For 'family inet' or 'family inet6' only.
            fail-filter filter-name;
            mode loose;
          }
          service { # For 'family inet' or 'family inet6' only.
            input {
              service-set service-set-name <service-filter service-filter-name>;
              post-service-filter service-filter-name;
            }
            output {
              service-set service-set-name <service-filter service-filter-name>;
            }
          }
          simple-filter { # For 'family inet' only.
            input simple-filter-name;
          }
        }
      }
    }
  }
}
```

```

    }
  }
}
}
}
}

```

References from a Firewall Filter in a Logical System to Subordinate Objects

IN THIS SECTION

- [Resolution of References from a Firewall Filter to Subordinate Objects | 1070](#)
- [Valid Reference from a Firewall Filter to a Subordinate Object | 1071](#)

Resolution of References from a Firewall Filter to Subordinate Objects

If a firewall filter defined in a logical system references a subordinate object (for example, a policer or prefix list), that subordinate object must be defined within the **firewall** stanza of the same logical system. For example, if a firewall filter configuration references a policer, the firewall filter and the policer must be configured under the same **[edit logical-systems *logical-system-name* firewall]** hierarchy level.

This rule applies even if the same policer is configured under the main firewall configuration or if the same policer is configured as part of a firewall in another logical system.

Valid Reference from a Firewall Filter to a Subordinate Object

In this example, the firewall filter **filter1** references the policer **pol1**. Both **filter1** and **pol1** are defined under the same firewall object. This configuration is valid. If **pol1** had been defined under another firewall object, the configuration would not be valid.

```
[edit]
logical systems {
  ls-A {
    firewall {
      policer pol1 {
        if-exceeding {
          bandwidth-limit 401k;
          burst-size-limit 50k;
        }
        then discard;
      }
      filter filter1 {
        term one {
          from {
            source-address 12.1.0.0/16;
          }
          then {
            reject host-unknown;
          }
        }
        term two {
          from {
            source-address 12.2.0.0/16;
          }
          then policer pol1;
        }
      }
    }
  }
}
```

References from a Firewall Filter in a Logical System to Nonfirewall Objects

IN THIS SECTION

- Resolution of References from a Firewall Filter to Nonfirewall Objects | 1072
- Valid Reference to a Nonfirewall Object Outside of the Logical System | 1072

Resolution of References from a Firewall Filter to Nonfirewall Objects

In many cases, a firewall configuration references objects outside the firewall configuration. As a general rule, the referenced object must be defined under the same logical system as the referencing object. However, there are cases when the configuration of the referenced object is not supported at the **[edit logical-systems *logical-system-name*]** hierarchy level.

Valid Reference to a Nonfirewall Object Outside of the Logical System

This example configuration illustrates an exception to the general rule that the objects referenced by a firewall filter in a logical system must be defined under the same logical system as the referencing object.

In the following scenario, the service filter **inetsf1** is applied to IPv4 traffic associated with the service set **fred** at the logical interface **fe-0/3/2.0**, which is on an adaptive services interface.

- Service filter **inetsf1** is defined in **ls-B** and references prefix list **prefix1**.
- Service set **fred** is defined at the main services hierarchy level, and the policy framework software searches the **[edit services]** hierarchy for the definition of the **fred** service set.

Because service rules cannot be configured in logical systems, firewall filter configurations in the **[edit logical-systems logical-system *logical-system-name*]** hierarchy are allowed to reference *service sets* outside the logical system hierarchy.

```
[edit]
logical-systems {
  ls-B {
    interfaces {
      fe-0/3/2 {
```

```

unit 0 {
    family inet {
        service {
            input {
                service-set fred service-filter inetsf1;
            }
        }
    }
}

policy-options {
    prefix-list prefix1 {
        1.1.0.0/16;
        1.2.0.0/16;
        1.3.0.0/16;
    }
}

firewall { # Under logical-system 'ls-B'.
    family inet {
        filter filter1 {
            term one {
                from {
                    source-address {
                        12.1.0.0/16;
                    }
                }
                then {
                    reject host-unknown;
                }
            }
            term two {
                from {
                    source-address {
                        12.2.0.0/16;
                    }
                }
                then policer pol1;
            }
        }
        service-filter inetsf1 {
            term term1 {
                from {
                    source-prefix-list {

```

```

        prefix1;
    }
}
    then count prefix1;
}
}
}

References from a Nonfirewall Object in a Logical System to a Firewall Filter

IN THIS SECTION

- [Resolution of References from a Nonfirewall Object to a Firewall Filter | 1075](#)
- [Invalid Reference to a Firewall Filter Outside of the Logical System | 1076](#)
- [Valid Reference to a Firewall Filter Within the Logical System | 1078](#)
- [Valid Reference to a Firewall Filter Outside of the Logical System | 1080](#)

Resolution of References from a Nonfirewall Object to a Firewall Filter

If a nonfirewall filter object in a logical system references an object in a firewall filter configured in a logical system, the reference is resolved using the following logic:

- If the nonfirewall filter object is configured in a logical system that includes firewall filter configuration statements, the policy framework software searches the **[edit logical-systems *logical-system-name* firewall]** hierarchy level. Firewall filter configurations that belong to *other* logical systems or to the main **[edit firewall]** hierarchy level are not searched.
- If the nonfirewall filter object is configured in a logical system that does not include any firewall filter configuration statements, the policy framework software searches the firewall configurations defined at the **[edit firewall]** hierarchy level.

Invalid Reference to a Firewall Filter Outside of the Logical System

This example configuration illustrates an unresolvable reference from a nonfirewall object in a logical system to a firewall filter.

In the following scenario, the stateless firewall filters **filter1** and **fred** are applied to the logical interface **fe-0/3/2.0** in the logical system **Is-C**.

- Filter **filter1** is defined in **Is-C**.
- Filter **fred** is defined in the main firewall configuration.

Because **Is-C** contains firewall filter statements (for **filter1**), the policy framework software resolves references to and from firewall filters by searching the **[edit logical systems Is-C firewall]** hierarchy level. Consequently, the reference from **fe-0/3/2.0** in the logical system to **fred** in the main firewall configuration cannot be resolved.

```
[edit]
logical-systems {
  Is-C {
    interfaces {
      fe-0/3/2 {
        unit 0 {
          family inet {
            filter {
              input-list [ filter1 fred ];
            }
          }
        }
      }
    }
  }
  firewall { # Under logical system 'Is-C'.
    family inet {
      filter filter1 {
        term one {
          from {
            source-address 12.1.0.0/16;
          }
          then {
            reject host-unknown;
          }
        }
        term two {
          from {
            source-address 12.2.0.0/16;
          }
        }
      }
    }
  }
}
```

```

        then policer pol1;
    }
}
}
policer pol1 {
    if-exceeding {
        bandwidth-limit 401k;
        burst-size-limit 50k;
    }
    then discard;
}
}
}
} # End of logical systems
firewall { # Under the main firewall hierarchy level
    family inet {
        filter fred {
            term one {
                from {
                    source-address 11.1.0.0/16;
                }
                then {
                    log;
                    reject host-unknown;
                }
            }
        }
    }
} # End of main firewall configurations.

```

Valid Reference to a Firewall Filter Within the Logical System

This example configuration illustrates resolvable references from a nonfirewall object in a logical system to two firewall filter.

In the following scenario, the stateless firewall filters **filter1** and **fred** are applied to the logical interface **fe-0/3/2.0** in the logical system **Is-C**.

- Filter **filter1** is defined in **Is-C**.
- Filter **fred** is defined in **Is-C** and also in the main firewall configuration.

Because **Is-C** contains firewall filter statements, the policy framework software resolves references to and from firewall filters by searching the **[edit logical systems Is-C firewall]** hierarchy level. Consequently, the references from **fe-0/3/2.0** in the logical system to **filter1** and **fred** use the stateless firewall filters configured in **Is-C**.

```
[edit]
logical-systems {
  Is-C {
    interfaces {
      fe-0/3/2 {
        unit 0 {
          family inet {
            filter {
              input-list [ filter1 fred ];
            }
          }
        }
      }
    }
  }
  firewall { # Under logical system 'Is-C'.
    family inet {
      filter filter1 {
        term one {
          from {
            source-address 12.1.0.0/16;
          }
          then {
            reject host-unknown;
          }
        }
        term two {
          from {
            source-address 12.2.0.0/16;
          }
        }
      }
    }
  }
}
```

Valid Reference to a Firewall Filter Outside of the Logical System

This example configuration illustrates resolvable references from a nonfirewall object in a logical system to two firewall filter.

In the following scenario, the stateless firewall filters **filter1** and **fred** are applied to the logical interface **fe-0/3/2.0** in the logical system **ls-C**.

- Filter **filter1** is defined in the main firewall configuration.
- Filter **fred** is defined in the main firewall configuration.

Because **ls-C** does not contain any firewall filter statements, the policy framework software resolves references to and from firewall filters by searching the **[edit firewall]** hierarchy level. Consequently, the references from **fe-0/3/2.0** in the logical system to **filter1** and **fred** use the stateless firewall filters configured in the main firewall configuration.

```
[edit]
logical-systems {
  ls-C {
    interfaces {
      fe-0/3/2 {
        unit 0 {
          family inet {
            filter {
              input-list [ filter1 fred ];
            }
          }
        }
      }
    }
  }
}
} # End of logical systems configurations.
firewall { # Main firewall hierarchy level.
  family inet {
    filter filter1 {
      term one {
        from {
          source-address 12.1.0.0/16;
        }
        then {
          reject host-unknown;
        }
      }
    }
    term two {
      from {
```

```
        source-address 12.2.0.0/16;
    }
    then policer pol1;
}
}
filter fred {
    term one {
        from {
            source-address 11.1.0.0/16;
        }
        then {
            log;
            reject host-unknown;
        }
    }
}
}
}
policer pol1 {
    if-exceeding {

Example: Configuring Filter-Based Forwarding

IN THIS SECTION

- [Requirements | 1082](#)
- [Overview | 1082](#)
- [Configuration | 1083](#)

Filter-based forwarding (FBF), which is also called [Policy Based Routing \(PBR\)](#), provides a simple but powerful way to route IP traffic to different interfaces on the basis of Layer-3 or Layer-4 parameters.

FBF works by using match conditions in a firewall filter to select certain traffic and then direct it to a given routing instance that points to the desired next hop. To ensure the next hop is resolvable, interface routes from the main routing table are shared via RIB group with the routing table(s) specified in the routing instance(s).

Match conditions can include the source or destination IP address, source or destination port, IP protocol, DSCP value, TCP flag, ICMP type, and packet length.

Requirements

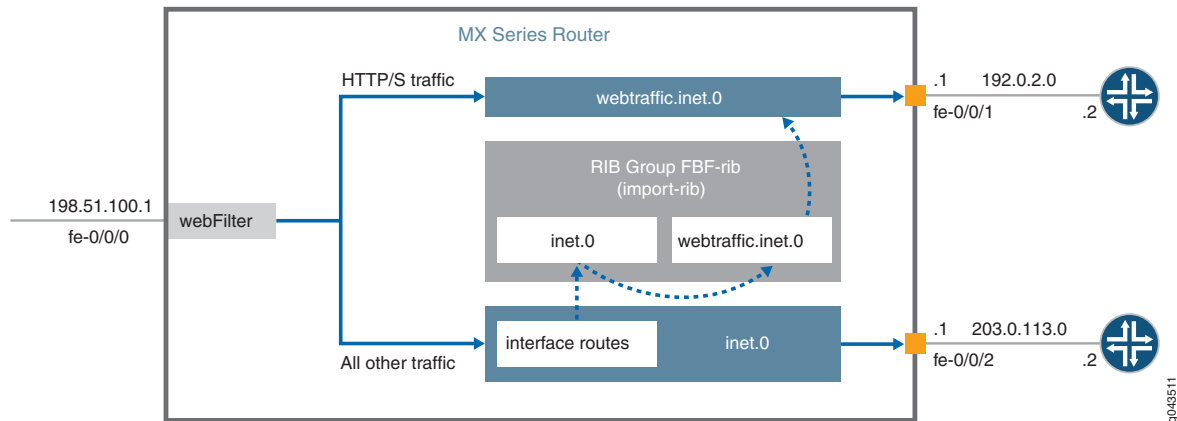

This example has the following hardware and software requirements:

- MX Series 5G Universal Routing Platform as the routing device with the firewall filter configured.
- Junos OS Release 13.3 or later running on the routing device with the firewall filter configured.

Overview

This example shows the configuration settings you need to set up filter-based forwarding on a single device. [Figure 53 on page 1083](#) shows the ingress and egress interfaces on an MX Series router and illustrates the logical flow of events as packets traverse the device.

Figure 53: Filter-Based Forwarding to Specified Interfaces

A firewall filter called **webFilter** is attached to the ingress interface, **fe-0/0/0**. Packets arriving over the interface are evaluated against the match conditions specified in the filter, the logic of which directs HTTP and HTTPS traffic to a routing instance called **webtraffic**. This routing instance accomplishes three things: first, it establishes a routing table called **webtraffic.inet.0**; second, it lets you define a static route and next hop; and third, lets you configure the instance for forwarding traffic to the next hop (here, `192.0.2.2` on interface **fe-0/0/1**).

Term 2 in the firewall filter, **then accept**, specifies that all non-matching traffic take a different path. We define a static route with next hop of `203.0.113.2` to have this traffic egress the device via **fe-0/0/2**. The route is automatically installed in the master routing table, **inet.0**.

The last (logical) step in setting up FBF is to ensure that both routes are resolvable. The RIB group (**FBF-rib** in this example) makes it so interface-routes from **inet.0** can be shared with **webtraffic.inet.0**.

For examples that focus on a specific use case or multi-device topologies, see the Related Topics.

Configuration

CLI Quick Configuration

Both copy-paste and step-by-step instructions for creating filter-based forwarding on a single device are provided.

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

Configure a device for filter-based forwarding

```

set interfaces fe-0/0/0 unit 0 family inet address 198.51.100.1/24
set interfaces fe-0/0/0 unit 0 family inet filter input webFilter
set interfaces fe-0/0/1 unit 0 family inet address 192.0.2.1/24
set interfaces fe-0/0/2 unit 0 family inet address 203.0.113.1/24
set firewall family inet filter webFilter term 1 from destination-port http
set firewall family inet filter webFilter term 1 from destination-port https
set firewall family inet filter webFilter term 1 then routing-instance webtraffic
set firewall family inet filter webFilter term 2 then accept
set routing-instances webtraffic routing-options static route 0.0.0.0/0 next-hop 192.0.2.2
set routing-instances webtraffic instance-type forwarding
set routing-options static route 0.0.0.0/0 next-hop 203.0.113.2
set routing-options rib-groups FBF-rib import-rib inet.0
set routing-options rib-groups FBF-rib import-rib webtraffic.inet.0
set routing-options interface-routes rib-group inet FBF-rib

```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure the device:

1. Configure the inbound interface and attach the **webFilter** firewall filter to it.

```

[edit interfaces fe-0/0/0 unit 0 family inet]
user@device# set filter input webFilter
user@device# set address 198.51.100.1/24

```

2. Configure the outbound interfaces, one for Web traffic and the other for all other traffic.

```

[edit interfaces]
user@device# set fe-0/0/1 unit 0 family inet address 192.0.2.1/24
user@device# set fe-0/0/2 unit 0 family inet address 203.0.113.1/24

```

3. Configure the firewall filter to pass Web traffic to the **webtraffic** routing instance and all other traffic to **203.0.113.1**.

```

[edit firewall family inet filter webFilter]
user@device# set term 1 from destination-port http

```

```

user@device# set term 1 from destination-port https
user@device# set term 1 then routing-instance webtraffic
user@device# set term 2 then accept

```

4. Optional: Monitor traffic handling of the firewall filter by adding a counter>

```

[edit interfaces fe-0/0/0 unit 0 family inet]
user@device# set firewall family inet filter webFilter term 1 then count webtraffic-count

```

5. Create the **webtraffic** routing instance and configure it to forward Web traffic to **fe-0/0/1**.

```

[edit routing-instances webtraffic]
user@device# set routing-options static route 0.0.0.0/0 next-hop 192.0.2.2
user@device# set instance-type forwarding

```

6. Create a route for non-Web traffic (the route is automatically installed in the **inet.0** routing table).

```

[edit routing-options]
user@device# set static route 0.0.0.0/0 next-hop 203.0.113.2

```

7. Create a RIB group called **FBF-rib**, and configure it so **inet.0** shares interface routes with **webtraffic.inet.0**, and then associate a routing table group with the routing device's interfaces, and specify routing table groups into which interface routes are imported..

```

[edit routing-options]
user@device# set rib-groups FBF-rib import-rib inet.0
user@device# set rib-groups FBF-rib import-rib webtraffic.inet.0

```

8. Associate a routing table group with the routing device's interfaces, and specify routing table groups into which interface routes are imported.

```

[edit routing-options]
user@device# set interface-routes rib-group inet FBF-rib

```

Results

From configuration mode, confirm your configuration by entering the **show firewall**, **show routing-instances**, **show routing-options**, and **show interfaces**, commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

If you are done configuring the device, enter **commit** from configuration mode.

```
user@device# show interfaces fe-0/0/0
unit 0 {
  family inet {
    filter {
      input webFilter;
    }
    address 198.51.100.1/24;
  }
}
user@device# show interfaces fe-0/0/1
unit 0 {
  family inet {
    address 192.0.2.1/24;
  }
}
user@device# show interfaces fe-0/0/2
unit 0 {
  family inet {
    address 203.0.113.1/24;
  }
}
user@device# show firewall
family inet {
  filter webFilter {
    term 1 {
      from {
        destination-port [ http https ];
      }
      then {
        routing-instance webtraffic;
      }
    }
    term 2 {
      then accept;
    }
  }
}
```

```
user@device# show routing-options
interface-routes {
  rib-group inet FBF-rib;
}
```

```
static {
    route 0.0.0.0/0 next-hop 203.0.113.2;
}
rib-groups {
    FBF-rib {
        import-rib [ inet.0 webtraffic.inet.0 ];
    }
}
```

```
user@device# show routing-instances
webtraffic {
    instance-type forwarding;
    routing-options {
        static {
            route 0.0.0.0/0 next-hop 192.0.2.2;
        }
    }
}
```

- [Configuration | 1090](#)
- [Verification | 1097](#)

This example shows how to configure filter-based forwarding within a logical system. The filter classifies packets to determine their forwarding path within the ingress routing device.

Requirements

In this example, no special configuration beyond device initialization is required.

Overview

Filter-based forwarding is supported for IP version 4 (IPv4) and IP version 6 (IPv6).

Use filter-based forwarding for service provider selection when customers have Internet connectivity provided by different ISPs yet share a common access layer. When a shared media (such as a cable modem) is used, a mechanism on the common access layer looks at Layer 2 or Layer 3 addresses and distinguishes between customers. You can use filter-based forwarding when the common access layer is implemented using a combination of Layer 2 switches and a single router.

With filter-based forwarding, all packets received on an interface are considered. Each packet passes through a filter that has match conditions. If the match conditions are met for a filter and you have created a routing instance, filter-based forwarding is applied to a packet. The packet is forwarded based on the next hop specified in the routing instance. For static routes, the next hop can be a specific LSP.

NOTE: Source-class usage filter matching and unicast reverse-path forwarding checks are not supported on an interface configured with filter-based forwarding (FBF).

To configure filter-based forwarding, perform the following tasks:

- Create a match filter on an ingress router or switch. To specify a match filter, include the **filter filter-name** statement at the **[edit firewall]** hierarchy level. A packet that passes through the filter is compared against a set of rules to classify it and to determine its membership in a set. Once classified, the packet is forwarded to a routing table specified in the accept action in the filter description language. The routing table then forwards the packet to the next hop that corresponds to the destination address entry in the table.
- Create routing instances that specify the routing table(s) to which a packet is forwarded, and the destination to which the packet is forwarded at the **[edit routing-instances]** or **[edit logical-systems logical-system-name routing-instances]** hierarchy level. For example:

```
[edit]
routing-instances {
  routing-table-name1 {
    instance-type forwarding;
```

```

routing-options {
  static {
    route 0.0.0.0/0 nexthop 10.0.0.1;
  }
}
routing-table-name2 {
  instance-type forwarding;
  routing-options {
    static {
      route 0.0.0.0/0 nexthop 10.0.0.2;
    }
  }
}
}

```

- Create a routing table group that adds interface routes to the forwarding routing instances used in filter-based forwarding (FBF), as well as to the default routing instance **inet.0**. This part of the configuration resolves the routes installed in the routing instances to directly connected next hops on that interface. Create the routing table group at the **[edit routing-options]** or **[edit logical-systems *logical-system-name* routing-options]** hierarchy level.

NOTE: Specify **inet.0** as one of the routing instances that the interface routes are imported into. If the default instance **inet.0** is not specified, interface routes are not imported into the default routing instance.

This example shows a packet filter that directs customer traffic to a next-hop router in the domains, SP 1 or SP 2, based on the packet's source address.

If the packet has a source address assigned to an SP 1 customer, destination-based forwarding occurs using the `sp1-route-table.inet.0` routing table. If the packet has a source address assigned to an SP 2 customer, destination-based forwarding occurs using the `sp2-route-table.inet.0` routing table. If a packet does not match either of these conditions, the filter accepts the packet, and destination-based forwarding occurs using the standard `inet.0` routing table.

One way to make filter-based forwarding work within a logical system is to configure the firewall filter on the logical system that receives the packets. Another way is to configure the firewall filter on the main router and then reference the logical system in the firewall filter. This example uses the second approach. The specific routing instances are configured within the logical system. Because each routing instance has its own routing table, you have to reference the routing instances in the firewall filter, as well. The syntax looks as follows:

```
[edit firewall filter filter-name term term-name]
```

```
user@host# set then logical-system logical-system-name routing-instance routing-instance-name
```

Figure 54 on page 1090 shows the topology used in this example.

On Logical System P1, an input filter classifies packets received from Logical System PE3 and Logical System PE4. The packets are routed based on the source addresses. Packets with source addresses in the 10.1.1.0/24 and 10.1.2.0/24 networks are routed to Logical System PE1. Packets with source addresses in the 10.2.1.0/24 and 10.2.2.0/24 networks are routed to Logical System PE2.

Figure 54: Logical Systems with Filter-Based Forwarding

To establish connectivity, OSPF is configured on all of the interfaces. For demonstration purposes, loopback interface addresses are configured on the routing devices to represent networks in the clouds.

The “[CLI Quick Configuration](#)” on page 1090 section shows the entire configuration for all of the devices in the topology. The “[Configuring the Routing Instances on the Logical System P1](#)” on page 1093 and “[Configuring the Firewall Filter on the Main Router](#)” on page 1092 sections shows the step-by-step configuration of the ingress routing device, Logical System P1.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall filter classify-customers term sp1-customers from source-address 10.1.1.0/24
set firewall filter classify-customers term sp1-customers from source-address 10.1.2.0/24
set firewall filter classify-customers term sp1-customers then log
set firewall filter classify-customers term sp1-customers then logical-system P1 routing-instance sp1-route-table
set firewall filter classify-customers term sp2-customers from source-address 10.2.1.0/24
```

```

set firewall filter classify-customers term sp2-customers from source-address 10.2.2.0/24
set firewall filter classify-customers term sp2-customers then log
set firewall filter classify-customers term sp2-customers then logical-system P1 routing-instance sp2-route-table
set firewall filter classify-customers term default then accept
set logical-systems P1 interfaces lt-1/2/0 unit 10 encapsulation ethernet

set logical-systems PE4 protocols ospf area 0.0.0.0 interface fxp0.0 disable

```

Configuring the Firewall Filter on the Main Router

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure the firewall filter on the main router:

1. Configure the source addresses for SP1 customers.

```

[edit firewall filter classify-customers term sp1-customers]
user@host# set from source-address 10.1.1.0/24
user@host# set from source-address 10.1.2.0/24

```

2. Configure the actions that are taken when packets are received with the specified source addresses.

To track the action of the firewall filter, a log action is configured. The sp1-route-table.inet.0 routing table on Logical System P1 routes the packets.

```

[edit firewall filter classify-customers term sp1-customers]
user@host# set then log
user@host# set then logical-system P1 routing-instance sp1-route-table

```

3. Configure the source addresses for SP2 customers.

```
[edit firewall filter classify-customers term sp2-customers]
user@host# set from source-address 10.2.1.0/24
user@host# set from source-address 10.2.2.0/24
```

4. Configure the actions that are taken when packets are received with the specified source addresses.

To track the action of the firewall filter, a log action is configured. The sp2-route-table.inet.0 routing table on Logical System P1 routes the packet.

```
[edit firewall filter classify-customers term sp2-customers]
user@host# set then log
user@host# set then logical-system P1 routing-instance sp2-route-table
```

5. Configure the action to take when packets are received from any other source address.

All of these packets are simply accepted and routed using the default IPv4 unicast routing table, inet.0.

```
[edit firewall filter classify-customers term default]
user@host# set then accept
```

Configuring the Routing Instances on the Logical System P1

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure the routing instances on a logical system:

1. Configure the interfaces on the logical system.

```
[edit logical-systems P1 interfaces lt-1/2/0]
user@host# set unit 10 encapsulation ethernet
user@host# set unit 10 peer-unit 9
user@host# set unit 10 family inet address 172.16.0.10/30
user@host# set unit 13 encapsulation ethernet
user@host# set unit 13 peer-unit 14
user@host# set unit 13 family inet address 172.16.0.13/30
user@host# set unit 17 encapsulation ethernet
user@host# set unit 17 peer-unit 18
user@host# set unit 17 family inet address 172.16.0.17/30
```

2. Assign the **classify-customers** firewall filter to router interface lt-1/2/0.10 as an input packet filter.

```
[edit logical-systems P1 interfaces lt-1/2/0]
user@host# set unit 10 family inet filter input classify-customers
```

3. Configure connectivity, using either a routing protocol or static routing.

As a best practice, disable routing on the management interface.

```
[edit logical-systems P1 protocols ospf area 0.0.0.0]
user@host# set interface all
user@host# set interface fxp0.0 disable
```

4. Create the routing instances.

These routing instances are referenced in the **classify-customers** firewall filter.

The forwarding instance type provides support for filter-based forwarding, where interfaces are not associated with instances. All interfaces belong to the default instance, in this case Logical System P1.

```
[edit logical-systems P1 routing-instances]
user@host# set sp1-route-table instance-type forwarding
user@host# set sp2-route-table instance-type forwarding
```

5. Resolve the routes installed in the routing instances to directly connected next hops.

```
[edit logical-systems P1 routing-instances]
user@host# set sp1-route-table routing-options static route 0.0.0.0/0 next-hop 172.16.0.13
user@host# set sp2-route-table routing-options static route 0.0.0.0/0 next-hop 172.16.0.17
```

6. Group together the routing tables to form a routing table group.

The first routing table, inet.0, is the primary routing table, and the additional routing tables are the secondary routing tables.

The primary routing table determines the address family of the routing table group, in this case IPv4.

```
[edit logical-systems P1 routing-options]
user@host# set rib-groups fbf-group import-rib inet.0
user@host# set rib-groups fbf-group import-rib sp1-route-table.inet.0
user@host# set rib-groups fbf-group import-rib sp2-route-table.inet.0
```

7. Apply the routing table group to OSPF.

This causes the OSPF routes to be installed into all the routing tables in the group.

```
[edit logical-systems P1 protocols ospf]
user@host# set rib-group fbf-group
```

8. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Results

Confirm your configuration by issuing the **show firewall** and **show logical-systems P1** commands.

```
user@host# show firewall
filter classify-customers {
  term sp1-customers {
    from {
      source-address {
        10.1.1.0/24;
        10.1.2.0/24;
      }
    }
    then {
      log;
      logical-system P1 routing-instance sp1-route-table;
    }
  }
  term sp2-customers {
    from {
      source-address {
        10.2.1.0/24;
        10.2.2.0/24;
      }
    }
    then {
      log;
      logical-system P1 routing-instance sp2-route-table;
    }
  }
}
```

```

term default {
    then accept;
}
}

```

user@host# **show logical-systems P1**

```

interfaces {
  lt-1/2/0 {
    unit 10 {
      encapsulation ethernet;
      peer-unit 9;
      family inet {
        filter {
          input classify-customers;
        }
        address 172.16.0.10/30;
      }
    }
    unit 13 {
      encapsulation ethernet;
      peer-unit 14;
      family inet {

    }
  }
}

```

Verification

Confirm that the configuration is working properly.

Pinging with Specified Source Addresses

Purpose

Send some ICMP packets across the network to test the firewall filter.

Action

1. Log in to Logical System PE3.

```
user@host> set cli logical-system PE3
```

```
Logical system: PE3
```

2. Run the **ping** command, pinging the lo0.3 interface on Logical System PE1.

The address configured on this interface is 172.16.1.1.

Specify the source address 10.1.2.1, which is the address configured on the lo0.1 interface on Logical System PE3.

```
user@host:PE3> ping 172.16.1.1 source 10.1.2.1
```

```
PING 172.16.1.1 (172.16.1.1): 56 data bytes
64 bytes from 172.16.1.1: icmp_seq=0 ttl=62 time=1.444 ms
64 bytes from 172.16.1.1: icmp_seq=1 ttl=62 time=2.094 ms
^C
--- 172.16.1.1 ping statistics ---
2 packets transmitted, 2 packets received, 0% packet loss
round-trip min/avg/max/stddev = 1.444/1.769/2.094/0.325 ms
```

3. Log in to Logical System PE4.

```
user@host:PE3> set cli logical-system PE4
```

```
Logical system: PE4
```

4. Run the **ping** command, pinging the lo0.4 interface on Logical System PE2.

The address configured on this interface is 172.16.2.2.

Specify the source address 10.2.1.1, which is the address configured on the lo0.2 interface on Logical System PE4.

```
user@host:PE4> ping 172.16.2.2 source 10.2.1.1
```

```
PING 172.16.2.2 (172.16.2.2): 56 data bytes
64 bytes from 172.16.2.2: icmp_seq=0 ttl=62 time=1.473 ms
64 bytes from 172.16.2.2: icmp_seq=1 ttl=62 time=1.407 ms
^C
--- 172.16.2.2 ping statistics ---
2 packets transmitted, 2 packets received, 0% packet loss
round-trip min/avg/max/stddev = 1.407/1.440/1.473/0.033 ms
```

Meaning

Sending these pings activates the firewall filter actions.

Verifying the Firewall Filter

Purpose

Make sure the firewall filter actions take effect.

Action

- 1. Log in to Logical System P1.

```
user@host> set cli logical-system P1
```

```
Logical system: P1
```

- 2. Run the **show firewall log** command on Logical System P1.

```
user@host:P1> show firewall log
```

Example: Configuring a Stateless Firewall Filter to Protect a Logical System Against ICMP Floods

IN THIS SECTION

- Requirements | 1100
- Overview | 1100
- Configuration | 1101
- Verification | 1103

This example shows how to configure a stateless firewall filter that protects against ICMP denial-of-service attacks on a logical system.

Requirements

In this example, no special configuration beyond device initialization is required.

Overview

This example shows a stateless firewall filter called protect-RE that polices ICMP packets. The **icmp-policer** limits the traffic rate of the ICMP packets to 1,000,000 bps and the burst size to 15,000 bytes. Packets that exceed the traffic rate are discarded.

The policer is incorporated into the action of a filter term called **icmp-term**.

In this example, a ping is sent from a directly connected physical router to the interface configured on the logical system. The logical system accepts the ICMP packets if they are received at a rate of up to 1 Mbps (bandwidth-limit). The logical system drops all ICMP packets when this rate is exceeded. The **burst-size-limit** statement accepts traffic bursts up to 15 Kbps. If bursts exceed this limit, all packets are dropped. When the flow rate subsides, ICMP packets are again accepted.

[Figure 55 on page 1101](#) shows the topology used in this example.

Figure 55: Logical System with a Stateless Firewall

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
set logical-systems LS1 interfaces so-0/0/2 unit 0 family inet policer input icmp-policer
set logical-systems LS1 interfaces so-0/0/2 unit 0 family inet address 10.0.45.2/30
set logical-systems LS1 firewall family inet filter protect-RE term icmp-term from protocol icmp
set logical-systems LS1 firewall family inet filter protect-RE term icmp-term then policer icmp-policer
set logical-systems LS1 firewall family inet filter protect-RE term icmp-term then accept
set logical-systems LS1 firewall policer icmp-policer if-exceeding bandwidth-limit 1m
set logical-systems LS1 firewall policer icmp-policer if-exceeding burst-size-limit 15k
set logical-systems LS1 firewall policer icmp-policer then discard
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure an ICMP firewall filter on a logical system:

1. Configure the interface on the logical system.

```
[edit]
user@host# set logical-systems LS1 interfaces so-0/0/2 unit 0 family inet address 10.0.45.2/30
```

2. Explicitly enable ICMP packets to be received on the interface.

```
[edit]
user@host# set logical-systems LS1 firewall family inet filter protect-RE term icmp-term from protocol icmp
user@host# set logical-systems LS1 firewall family inet filter protect-RE term icmp-term then accept
```

3. Create the policer.

```
[edit]
user@host# set logical-systems LS1 firewall policer icmp-policer if-exceeding bandwidth-limit 1m
user@host# set logical-systems LS1 firewall policer icmp-policer if-exceeding burst-size-limit 15k
user@host# set logical-systems LS1 firewall policer icmp-policer then discard
```

4. Apply the policer to a filter term.

```
[edit]
user@host# set logical-systems LS1 firewall family inet filter protect-RE term icmp-term then policer
icmp-policer
```

5. Apply the policer to the logical system interface.

```
[edit]
user@host# set logical-systems LS1 interfaces so-0/0/2 unit 0 family inet policer input icmp-policer
```

6. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Results

Confirm your configuration by issuing the **show logical-systems LS1** command.

```
user@host# show logical-systems LS1
interfaces {
  so-0/0/2 {
    unit 0 {
      family inet {
```

```

        policer {
            input icmp-policer;
        }
        address 10.0.45.2/30;
    }
}
}
}
}
firewall {
    family inet {
        filter protect-RE {
            term icmp-term {
                from {
                    protocol icmp;
                }
                then {
                    policer icmp-policer;
                    accept;
                }
            }
        }
    }
    policer icmp-policer {
        if-exceeding {
            bandwidth-limit 1m;
            burst-size-limit 15k;
        }
        then discard;
    }
}
}

```

Verification

Confirm that the configuration is working properly.

Verifying That Ping Works Unless the Limits Are Exceeded

Purpose

Make sure that the logical system interface is protected against ICMP-based DoS attacks.

Action

Log in to a system that has connectivity to the logical system and run the **ping** command.

```
user@R2> ping 10.0.45.2
```

```
PING 10.0.45.2 (10.0.45.2): 56 data bytes
64 bytes from 10.0.45.2: icmp_seq=0 ttl=64 time=1.316 ms
64 bytes from 10.0.45.2: icmp_seq=1 ttl=64 time=1.277 ms
64 bytes from 10.0.45.2: icmp_seq=2 ttl=64 time=1.269 ms
```

user@R2> **ping 10.0.45.2 size 20000**

```
PING 10.0.45.2 (10.0.45.2): 20000 data bytes
^C
--- 10.0.45.2 ping statistics ---
4 packets transmitted, 0 packets received, 100% packet loss
```

Meaning

When you send a normal ping, the packet is accepted. When you send a ping packet that exceeds the filter limit, the packet is discarded.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
set logical-systems LS1 interfaces ge-0/0/2 unit 0 family inet policer input icmp-policer
set logical-systems LS1 interfaces ge-0/0/2 unit 0 family inet address 10.0.45.2/30
```

```

set logical-systems LS1 firewall family inet filter protect-RE term icmp-term from protocol icmp
set logical-systems LS1 firewall family inet filter protect-RE term icmp-term then policer icmp-policer
set logical-systems LS1 firewall family inet filter protect-RE term icmp-term then accept
set logical-systems LS1 firewall policer icmp-policer if-exceeding bandwidth-limit 1m
set logical-systems LS1 firewall policer icmp-policer if-exceeding burst-size-limit 15k
set logical-systems LS1 firewall policer icmp-policer then discard

```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure an ICMP firewall filter on a logical system:

1. Configure the interface on the logical system.

```

[edit]
user@host# set logical-systems LS1 interfaces ge-0/0/2 unit 0 family inet address 10.0.45.2/30

```

2. Explicitly enable ICMP packets to be received on the interface.

```

[edit]
user@host# set logical-systems LS1 firewall family inet filter protect-RE term icmp-term from protocol icmp
user@host# set logical-systems LS1 firewall family inet filter protect-RE term icmp-term then accept

```

3. Create the policer.

```

[edit]
user@host# set logical-systems LS1 firewall policer icmp-policer if-exceeding bandwidth-limit 1m
user@host# set logical-systems LS1 firewall policer icmp-policer if-exceeding burst-size-limit 15k
user@host# set logical-systems LS1 firewall policer icmp-policer then discard

```

4. Apply the policer to a filter term.

```

[edit]
user@host# set logical-systems LS1 firewall family inet filter protect-RE term icmp-term then policer
icmp-policer

```

5. Apply the policer to the logical system interface.

```
[edit]
user@host# set logical-systems LS1 interfaces ge-0/0/2 unit 0 family inet policer input icmp-policer
```

6. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Results

Confirm your configuration by issuing the **show logical-systems LS1** command.

```
user@host# show logical-systems LS1
interfaces {
  ge-0/0/2 {
    unit 0 {
      family inet {
        policer {
          input icmp-policer;
        }
        address 10.0.45.2/30;
      }
    }
  }
}
firewall {
  family inet {
    filter protect-RE {
      term icmp-term {
        from {
          protocol icmp;
        }
        then {
          policer icmp-policer;
          accept;
        }
      }
    }
  }
}
policer icmp-policer {
```

```

    if-exceeding {
        bandwidth-limit 1m;
        burst-size-limit 15k;
    }
    then discard;
}
}

```

Verification

Confirm that the configuration is working properly.

Verifying That Ping Works Unless the Limits Are Exceeded

Purpose

Make sure that the logical system interface is protected against ICMP-based DoS attacks.

Action

Log in to a system that has connectivity to the logical system and run the **ping** command.

```
user@R2> ping 10.0.45.2
```

```

PING 10.0.45.2 (10.0.45.2): 56 data bytes
64 bytes from 10.0.45.2: icmp_seq=0 ttl=64 time=1.316 ms
64 bytes from 10.0.45.2: icmp_seq=1 ttl=64 time=1.277 ms
64 bytes from 10.0.45.2: icmp_seq=2 ttl=64 time=1.269 ms

```

```
user@R2> ping 10.0.45.2 size 20000
```

```

PING 10.0.45.2 (10.0.45.2): 20000 data bytes
^C
--- 10.0.45.2 ping statistics ---
4 packets transmitted, 0 packets received, 100% packet loss

```

Meaning

When you send a normal ping, the packet is accepted. When you send a ping packet that exceeds the filter limit, the packet is discarded.

Filter-Based Forwarding for Routing Instances

You can use stateless firewall filters in routing instances to control how packets travel in a network for IPv4 and IPv6 traffic. This is called filter-based forwarding.

You can define a firewall filtering term that directs matching packets to a specified routing instance. This type of filtering can be configured to route specific types of traffic through a firewall or other security device before the traffic continues on its path. To configure a stateless firewall filter to direct traffic to a routing instance, configure a term with the **routing-instance *routing-instance-name*** terminating action at the **[edit firewall family <inet | inet6>]** hierarchy level to specify the routing instance to which matching packets will be forwarded. You can apply a forwarding table filter to a routing instance of type forwarding and also to the default routing instance **inet.0**. To configure the filter to direct traffic to the master routing instance, use the **routing-instance default** statement at the **[edit firewall family <inet | inet6>]** hierarchy level.

The following limitations apply to filter-based forwarding table configured on routing instances:

- You cannot configure any of the following actions in a firewall filtering term when the filtering term contains the **routing-instance *routing-instance-name*** terminating action:
 - **count *counter-name***
 - **discard**
 - **forwarding-class *class-name***
 - **log**
 - **loss-priority (high | medium-high | low)**
 - **policer *policer-name***
 - **port-mirror**
 - **reject *message-type***
 - **syslog**
 - **three-color-policer (single-rate | two-rate) *policer-name***
- You cannot configure the **fragment-flags *number*** match condition in the filter term.
- You cannot attach a filter that is either default or physical interface-specific.
- You cannot attach a filter to the egress direction of routing instances.
- IPv6 filter-based forwarding does not support the following L4 matches:
 - source-port
 - destination-port

- icmp-type
- icmp-code

Although you can configure forwarding of packets from one VRF to another VRF, you cannot configure forwarding from a VRF to the global routing instance.

The maximum number of routing instances supported is 64, which is the same as the maximum number of virtual routers supported. Forwarding packets to the global table (default VRF) is not supported for filter-based forwarding.

NOTE: Filter-based forwarding on the interface will not work when source MAC address filter is configured because the source MAC address filter takes higher precedence over filter-based forwarding.

RELATED DOCUMENTATION

[Example: Configuring Filter-Based Forwarding on the Source Address](#) | 1297

Forwarding Table Filters for Routing Instances on ACX Series Routers

Forwarding table filter is a mechanism by which all the packets forwarded by a certain forwarding table are subjected to filtering and if a packet matches the filter condition, the configured action is applied on the packet. You can use the forwarding table filter mechanism to apply a filter on all interfaces associated with a single routing instance with a simple configuration. You can apply a forwarding table filter to a routing instance of type forwarding and also to the default routing instance **inet.0**. To configure a forwarding table filter, include the **filter *filter-name*** statement at the **[edit firewall family <inet | inet6>]** hierarchy level.

The following limitations apply to forwarding table filters configured on routing instances:

- You cannot attach the same filter to more than one routing instance.
- You cannot attach the same filter at both the **[edit interfaces *interface-name* family <inet | inet6> filter input *filter-name*]** and **[edit routing-instances *instance-name* forwarding-options family <inet | inet6> filter input *filter-name*]** hierarchy level.
- You cannot attach a filter that is either interface-specific or a physical interface filter.
- You cannot attach a filter to the egress direction of routing instances.

RELATED DOCUMENTATION

| [Configuring Forwarding Table Filters](#) | 1117

Configuring Forwarding Table Filters

Forwarding table filters are defined the same as other firewall filters, but you apply them differently:

- Instead of applying forwarding table filters to interfaces, you apply them to forwarding tables, each of which is associated with a routing instance and a virtual private network (VPN).
- Instead of applying input and output filters by default, you can apply an input forwarding table filter only.

All packets are subjected to the input forwarding table filter that applies to the forwarding table. A forwarding table filter controls which packets the router accepts and then performs a lookup for the forwarding table, thereby controlling which packets the router forwards on the interfaces.

When the router receives a packet, it determines the best route to the ultimate destination by looking in a forwarding table, which is associated with the VPN on which the packet is to be sent. The router then forwards the packet toward its destination through the appropriate interface.

NOTE: For transit packets exiting the router through the tunnel, forwarding table filtering is not supported on the interfaces you configure as the output interface for tunnel traffic.

A forwarding table filter allows you to filter data packets based on their components and to perform an action on packets that match the filter; it essentially controls which bearer packets the router accepts and forwards. To configure a forwarding table filter, include the **firewall** statement at the **[edit]** hierarchy level:

```
[edit]
firewall {
  family family-name {
    filter filter-name {
      term term-name {
        from {
          match-conditions;
        }
        then {
          action;
          action-modifiers;
        }
      }
    }
  }
}
```

```

    }
  }
}

```

family-name is the family address type: IPv4 (**inet**), IPv6 (**inet6**), Layer 2 traffic (**bridge**), or MPLS (**mpls**).

term-name is a named structure in which match conditions and actions are defined.

match-conditions are the criteria against which a bearer packet is compared; for example, the IP address of a source device or a destination device. You can specify multiple criteria in a match condition.

action specifies what happens if a packet matches all criteria; for example, the gateway GPRS support node (GGSN) accepting the bearer packet, performing a lookup in the forwarding table, and forwarding the packet to its destination; discarding the packet; and discarding the packet and returning a rejection message.

action-modifiers are actions that are taken in addition to the GGSN accepting or discarding a packet when all criteria match; for example, counting the packets and logging a packet.

To create a forwarding table, include the **instance-type** statement with the **forwarding** option at the **[edit routing-instances instance-name]** hierarchy level:

```

[edit]
routing-instances instance-name {
  instance-type forwarding;
}

```

To apply a forwarding table filter to a VPN routing and forwarding (VRF) table, include the **filter** and **input** statements at the **[edit routing-instance instance-name forwarding-options family family-name]** hierarchy level:

```

[edit routing-instances instance-name]
instance-type forwarding;
forwarding-options {
  family family-name {
    filter {
      input filter-name;
    }
  }
}

```

To apply a forwarding table filter to a forwarding table, include the **filter** and **input** statements at the **[edit forwarding-options family family-name]** hierarchy level:

```
[edit forwarding-options family family-name]  
filter {  
    input filter-name;  
}
```

To apply a forwarding table filter to the default forwarding table **inet.0**, which is not associated with a specific routing instance, include the **filter** and **input** statements at the **[edit forwarding-options family inet]** hierarchy level:

```
[edit forwarding-options family inet]  
filter {  
    input filter-name;  
}
```

Accounting for Firewall Filters Overview

Juniper Networks devices can collect various kinds of data about traffic passing through the device. You can set up one or more accounting profiles that specify some common characteristics of this data, including the following:

- Fields used in the accounting records.
- Number of files that the routing platform retains before discarding, and the number of bytes per file.
- Polling period that the system uses to record the data

There are several types of accounting profiles: interface, firewall filter, source class and destination class usage, and Routing Engine. If you apply the same profile name to both a firewall filter and an interface, it causes an error.

System Logging Overview

The Junos OS generates system log messages (also called *syslog messages*) to record *system events* that occur on the device. Events consist of routine operations, failure and error conditions, and critical conditions that might require urgent resolution. This system logging utility is similar to the UNIX **syslogd** utility.

Each Junos OS system log message belongs to a message category, called a *facility*, that reflects the hardware- or software-based source of the triggering event. A group of messages belonging to the same facility are either generated by the same software process or concern a similar hardware condition or user activity (such as authentication attempts). Each system log message is also preassigned a *severity*, which indicates how seriously the triggering event affects router (or switch) functions. Together, the facility and severity of an event are known as the message *priority*. The content of a syslog message identifies the Junos OS *process* that generates the message and briefly describes the operation or error that occurred.

By default, syslog messages that have a severity of **info** or more serious are written to the main system log file **messages** in the **/var/log** directory of the local Routing Engine. To configure global settings and facility-specific settings that override these default values, you can include statements at the **[edit system syslog]** hierarchy level.

For all syslog facilities or for a specified facility, you can configure the syslog message utility to redirect messages of a specified severity to a specified file instead of to the main system log file. You can also configure the syslog message utility to write syslog messages of a specified severity, for all syslog facilities or for a specified facility, to additional destinations. In addition to writing syslog messages to a log file, you can write syslog messages to the terminal sessions of any logged-in users, to the router (or switch) console, or to a remote host or the other Routing Engine.

At the global level—for all system logging messages, regardless of facility, severity, or destination—you can override the default values for file-archiving properties and the default timestamp format.

RELATED DOCUMENTATION

[System Logging of Events Generated for the Firewall Facility | 1121](#)

[Firewall Filter Logging Actions | 1124](#)

[Example: Configuring Logging for a Firewall Filter Term | 1134](#)

System Logging of Events Generated for the Firewall Facility

System log messages generated for firewall filter actions belong to the **firewall** facility. Just as you can for any other Junos OS system logging facility, you can direct **firewall** facility syslog messages to one or more specific destinations: to a specified file, to the terminal session of one or more logged in users (or to all

users), to the router (or switch) console, or to a remote host or the other Routing Engine on the router (or switch).

When you configure a syslog message destination for **firewall** facility syslog messages, you include a statement at the **[edit system syslog]** hierarchy level, and you specify the **firewall** facility name together with a severity level. Messages from the **firewall** that are rated at the specified level or more severe are logged to the destination.

System log messages with the **DFWD_** prefix are generated by the firewall process (**dfwd**), which manages compilation and downloading of Junos OS firewall filters. System log messages with the **PFE_FW_** prefix are messages about firewall filters, generated by the Packet Forwarding Engine controller, which manages packet forwarding functions. For more information, see the [System Log Explorer](#).

[Table 68 on page 1122](#) lists the system log destinations you can configure for the **firewall** facility.

Table 68: Syslog Message Destinations for the Firewall Facility

Destination	Description	Configuration Statements Under [edit system syslog]
File	<p>Configuring this option keeps the firewall syslog messages out of the main system log file.</p> <p>To include priority and facility with messages written to the file, include the explicit-priority statement.</p> <p>To override the default standard message format, which is based on a UNIX system log format, include the structured-data statement. When the structured-data statement is included, other statements that specify the format for messages written to the file are ignored (the explicit-priority statement at the [edit system syslog file filename] hierarchy level and the time-format statement at the [edit system syslog] hierarchy level).</p>	<pre>file filename { firewall severity; allow-duplicates; archive archive-options; explicit-priority; structured-data; } allow-duplicates; archive archive-options; time-format (option);</pre>
Terminal session	<p>Configuring this option causes a copy of the firewall syslog messages to be written to the specified terminal sessions. Specify one or more user names, or specify * for all logged in users.</p>	<pre>user (username *) { firewall severity; } time-format (option);</pre>

Table 68: Syslog Message Destinations for the Firewall Facility (*continued*)

Destination	Description	Configuration Statements Under [edit system syslog]
Router (or switch) console	Configuring this option causes a copy of the firewall syslog messages to be written to the router (or switch) console.	<pre>console { firewall severity; } time-format (option);</pre>
Remote host or the other Routing Engine	<p>Configuring this option causes a copy of the firewall syslog messages to be written to the specified remote host or to the other Routing Engine.</p> <p>To override the default alternative facility for forwarding firewall syslog messages to a remote machine (local3), include the facility-override firewall statement.</p> <p>To include priority and facility with messages written to the file, include the explicit-priority statement.</p>	<pre>host (hostname other-routing-engine) { firewall severity; allow-duplicates; archive archive-options; facility-override firewall; explicit-priority; } allow-duplicates; # All destinations archive archive-options; time-format (option);</pre>

By default, the timestamp recorded in a standard-format system log message specifies the month, date, hour, minute, and second when the message was logged, as in the example:

```
Sep 07 08:00:10
```

To include the year, the millisecond, or both in the timestamp for all system logging messages, regardless of the facility, include one of the following statement at the **[edit system syslog]** hierarchy level:

- **time-format year;**
- **time-format millisecond;**
- **time-format year millisecond;**

The following example illustrates the format for a timestamp that includes both the millisecond (**401**) and the year (**2010**):

```
Sep 07 08:00:10.401.2010
```

Firewall Filter Logging Actions

For IPv4 and IPv6 firewall filters, you can configure the filter to write a summary of matching packet headers to the log or syslog by specifying either the **syslog** or **log** action. The main difference between the two is the permanence of the record. Logs are only buffered in memory, and when that buffer is full, the oldest records are replaced with new ones as they come in. Syslogs, on the other hand, can be saved to disk or forwarded to a remote syslog server. In both cases, a summary of the packet header is logged (not a copy of the packet itself). Service filters and simple filters do not support either the **log** or **syslog** action.

NOTE: Both the **syslog** and **log** actions can consume significant CPU and/or disk space on the device. Juniper recommends that you off-load logs by writing them to a remote syslog server, and that you constrain logging by using it for diagnostics only.

Syslog

As noted, system logs can be written to disk and/or sent to a remote server. Saved logs are written to the **/var/log** directory. You can view a list of all available log files on the device by running the **show log** command without options. Note, that within a given log file, the firewall action logs may be interspersed with event messages.

The following **syslog** configuration shows system logs being sent to a remote server at 172.27.1.1, and also save them to a file named “firewall” on the local device.

```
host@device-RE0# show system syslog
host 172.27.1.1 {
    firewall any;
}
<...>
file firewall {
    firewall any;
}
```

To view system logs, run the **show syslog message** command.

To view the contents of a given system log file, run either the **show log filename** or the **file show /var/log/filename** command.

To clear system log file contents, run the **clear log filename** command. You can include the **all** option to delete all saved logs, including records being written to the current log file.

Configuration details are shown here:

```
firewall {
  family {
    filter filter-name {
      from {
        match-conditions;
      }
      then {
        ...
        syslog;
        terminating-action;
      }
    }
  }
}
```

Log

The **log** action writes log information to a buffer. There is no option for writing logs to a remote server, or for writing them to disk. Once the available buffer is full, new logs will replace the oldest, so a historical record is not kept. Logs are cleared whenever the device or PFE is restarted.

Configuration details are shown here:

```

firewall {
  family {
    filter filter-name {
      from {
        match-conditions;
      }
      then {
        ...
        log;
        terminating-action;
      }
    }
  }
}

```

To view the logs, run the **show firewall log** command.

Log Details

The following shows what kind of information is typically included in syslog and log entries:

```

user@host> show log messages_firewall_any

Mar 20 08:08:45 hostname feb FW: ge-1/1/0.0 A icmp 192.168.207.222 192.168.207.223
0 0 (1 packets)

```

The fields are explained here:

- **Date and Time**—Date and time at which the packet was received (not shown in the default).
- **Hostname**—Name of the device on which the match occurred..
- **Interface**—Physical interface that the packet traversed.
- Filter action. In the example above, it is A.
 - **A**—Accept (or next term)
 - **D**—Discard
 - **R**—Reject
- **Protocol**—Packet protocol. May be a name or number, and may also include the source and destination ports. In the example above, the protocol is ICMP, which may then include the ICMP type and code.
- **Source address**—Source IP address of the packet.
- **Destination address**—Destination IP address of the packet.

- **Source port**—Source port of the packet (TCP and UDP packets only). In the example above, the port is 0.

- **Destination port**—Destination port of the packet (TCP and UDP packets only). In the example above, the port is 0.

- **Packets in sample interval**—This example show only one matching packet was detected in the sample interval (about a second). If packets arrive at faster rate, the system log automatically compresses the information so that less output is generated.

- [Configuration | 1128](#)
- [Verification | 1133](#)

This example shows how to configure and apply a firewall filter that collects data according to parameters specified in an associated accounting profile.

Requirements

Firewall filter accounting profiles are supported for all traffic types except **family any**.

No special configuration beyond device initialization is required before configuring this example.

Overview

In this example, you create a firewall filter accounting profile and apply it to a firewall filter. The accounting profile specifies how frequently to collect packet and byte count statistics and the name of the file to which the statistics are written. The profile also specifies that statistics are to be collected for three firewall filter counters.

Topology

The firewall filter accounting profile **filter_acctg_profile** specifies that statistics are collected every 60 minutes, and the statistics are written to the file **/var/log/ff_accounting_file**. Statistics are collected for counters named **counter1**, **counter2**, and **counter3**.

The IPv4 firewall filter named **my_firewall_filter** increments a counter for each of three filter terms. The filter is applied to logical interface **ge-0/0/1.0**.

Configuration

- [Configure a Firewall Filter That References the Accounting Profile | 1130](#)
- [Apply the Firewall Filter to an Interface | 1131](#)
- [Confirm Your Candidate Configuration | 1131](#)
- [Clear the Counters and Commit Your Candidate Configuration | 1133](#)

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#).

To configure this example, perform the following tasks:

CLI Quick Configuration

To quickly configure this example, copy the following configuration commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set accounting-options filter-profile filter_acctg_profile file ff_accounting_file
set accounting-options filter-profile filter_acctg_profile interval 60
set accounting-options filter-profile filter_acctg_profile counters counter1
set accounting-options filter-profile filter_acctg_profile counters counter2
set accounting-options filter-profile filter_acctg_profile counters counter3
set firewall family inet filter my_firewall_filter accounting-profile filter_acctg_profile
set firewall family inet filter my_firewall_filter term term1 from protocol ospf
set firewall family inet filter my_firewall_filter term term1 then count counter1
set firewall family inet filter my_firewall_filter term term1 then discard
set firewall family inet filter my_firewall_filter term term2 from source-address 10.108.0.0/16
set firewall family inet filter my_firewall_filter term term2 then count counter2
set firewall family inet filter my_firewall_filter term term2 then discard
set firewall family inet filter my_firewall_filter term accept-all then count counter3
set firewall family inet filter my_firewall_filter term accept-all then accept
set interfaces ge-0/0/1 unit 0 family inet address 10.1.2.3/30
set interfaces ge-0/0/1 unit 0 family inet filter input my_firewall_filter
```

Configure an Accounting Profile

Step-by-Step Procedure

To configure an accounting profile:

1. Create the accounting profile **filter_acctg_profile**.

```
[edit]
user@host# edit accounting-options filter-profile filter_acctg_profile
```

2. Configure the accounting profile to filter and collect packet and byte count statistics every 60 minutes and write them to the **/var/log/ff_accounting_file** file.

```
[edit accounting-options filter-profile filter_acctg_profile]
user@host# set file ff_accounting_file
user@host# set interval 60
```

3. Configure the accounting profile to collect filter profile statistics (packet and byte counts) for three counters.

```
[edit accounting-options filter-profile filter_acctg_profile]
user@host# set counters counter1
```

```
user@host# set counters counter2
user@host# set counters counter3
```

Configure a Firewall Filter That References the Accounting Profile

Step-by-Step Procedure

To configure a firewall filter that references the accounting profile:

1. Create the firewall filter **my_firewall_filter**.

```
[edit]
user@host# edit firewall family inet filter my_firewall_filter
```

2. Apply the filter-accounting profile **filter_acctg_profile** to the firewall filter.

```
[edit firewall family inet filter my_firewall_filter]
user@host# set accounting-profile filter_acctg_profile
```

3. Configure the first filter term and counter.

```
[edit firewall family inet filter my_firewall_filter]
user@host# set term term1 from protocol ospf
user@host# set term term1 then count counter1
user@host# set term term1 then discard
```

4. Configure the second filter term and counter.

```
[edit firewall family inet filter my_firewall_filter]
user@host# set term term2 from source-address 10.108.0.0/16
user@host# set term term2 then count counter2
user@host# set term term2 then discard
```

5. Configure the third filter term and counter.

```
[edit firewall family inet filter my_firewall_filter]
user@host# set term accept-all then count counter3
user@host# set term accept-all then accept
```

Apply the Firewall Filter to an Interface

Step-by-Step Procedure

To apply the firewall filter to a logical interface:

1. Configure the logical interface to which you will apply the firewall filter.

```
[edit]
user@host# edit interfaces ge-0/0/1 unit 0 family inet
```

2. Configure the interface address for the logical interface.

```
[edit interfaces ge-0/0/1 unit 0 family inet]
user@host# set address 10.1.2.3/30
```

3. Apply the firewall filter to the logical interface.

```
[edit interfaces ge-0/0/1 unit 0 family inet]
user@host# set filter input my_firewall_filter
```

Confirm Your Candidate Configuration

Step-by-Step Procedure

To confirm your candidate configuration:

1. Confirm the configuration of the accounting profile by entering the **show accounting-options** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show accounting-options
filter-profile filter_acctg_profile {
  file ff_accounting_file;
  interval 60;
  counters {
    counter1;
    counter2;
    counter3;
  }
}
```

2. Confirm the configuration of the firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show firewall
family inet {
  filter my_firewall_filter {
    accounting-profile filter_acctg_profile;
    term term1 {
      from {
        protocol ospf;
      }
      then {
        count counter1;
        discard;
      }
    }
    term term2 {
      from {
        source-address {
          10.108.0.0/16;
        }
      }
      then {
        count counter2;
        discard;
      }
    }
    term accept-all {
      then {
        count counter3;
        accept;
      }
    }
  }
}
```

3. Confirm the configuration of the interfaces by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
```

```

user@host# show interfaces
ge-0/0/1 {
  unit 0 {
    family inet {
      filter {
        input my_firewall_filter;
      }
      address 10.1.2.3/30;
    }
  }
}

```

Clear the Counters and Commit Your Candidate Configuration

Step-by-Step Procedure

To clear the counters and commit your candidate configuration:

1. From operational command mode, use the **clear firewall all** command to clear the statistics for all firewall filters.

To clear only the counters incremented in this example, include the name of the firewall filter.

```

[edit]
user@host> clear firewall filter my_firewall_filter

```

2. Commit your candidate configuration.

```

[edit]
user@host# commit

```

Verification

To verify that the filter is applied to the logical interface, run the **show interfaces** command with the **detail** or **extensive** output level.

To verify that the three counters are collected separately, run the **show firewall filter my_firewall_filter** command.

```

user@host> show firewall filter my_firewall_filter

```

```
Filter: my_firewall_filter
```

```
Counters:
```

Name	Bytes	Packets
counter1	0	0
counter2	0	0
counter3	0	0

RELATED DOCUMENTATION

[Accounting for Firewall Filters Overview | 1120](#)

Example: Configuring Logging for a Firewall Filter Term

IN THIS SECTION

- [Requirements | 1134](#)
- [Overview | 1134](#)
- [Configuration | 1135](#)
- [Verification | 1139](#)

This example shows how to configure a firewall filter to log packet headers.

Requirements

No special configuration beyond device initialization is required before configuring this example.

Overview

In this example, you use a firewall filter that logs and counts ICMP packets that have **192.168.207.222** as either their source or destination.

Configuration

IN THIS SECTION

- [Configure the Syslog Messages File for the Firewall Facility | 1135](#)
- [Configure the Firewall Filter | 1136](#)
- [Apply the Firewall Filter to a Logical Interface | 1136](#)
- [Confirm and Commit Your Candidate Configuration | 1137](#)

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#).

To configure this example, perform the following tasks:

CLI Quick Configuration

To quickly configure this example, copy the following configuration commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set system syslog file messages_firewall_any firewall any
set system syslog file messages_firewall_any archive no-world-readable
set firewall family inet filter icmp_syslog term icmp_match from address 192.168.207.222/32
set firewall family inet filter icmp_syslog term icmp_match from protocol icmp
set firewall family inet filter icmp_syslog term icmp_match then count packets
set firewall family inet filter icmp_syslog term icmp_match then syslog
set firewall family inet filter icmp_syslog term icmp_match then accept
set firewall family inet filter icmp_syslog term default_term then accept
set interfaces ge-0/0/1 unit 0 family inet address 10.1.2.3/30
set interfaces ge-0/0/1 unit 0 family inet filter input icmp_syslog
```

Configure the Syslog Messages File for the Firewall Facility

Step-by-Step Procedure

To configure a syslog messages file for the **firewall** facility:

1. Configure a messages file for all syslog messages generated for the **firewall** facility.

```
user@host# set system syslog file messages_firewall_any firewall any
```

2. Restrict permission to the archived **firewall** facility syslog files to the root user and users who have the Junos OS maintenance permission.

```
user@host# set system syslog file messages_firewall_any archive no-world-readable
```

Configure the Firewall Filter

Step-by-Step Procedure

To configure the firewall filter **icmp_syslog** that logs and counts ICMP packets that have **192.168.207.222** as either their source or destination:

1. Create the firewall filter **icmp_syslog**.

```
[edit]
user@host# edit firewall family inet filter icmp_syslog
```

2. Configure matching on the ICMP protocol and an address.

```
[edit firewall family inet filter icmp_syslog]
user@host# set term icmp_match from address 192.168.207.222/32
user@host# set term icmp_match from protocol icmp
```

3. Count, log,, and accept matching packets.

```
[edit firewall family inet filter icmp_syslog]
user@host# set term icmp_match then count packets
user@host# set term icmp_match then syslog
user@host# set term icmp_match then accept
```

4. Accept all other packets.

```
[edit firewall family inet filter icmp_syslog]
user@host# set term default_term then accept
```

Apply the Firewall Filter to a Logical Interface

Step-by-Step Procedure

To apply the firewall filter to a logical interface:

1. Configure the logical interface to which you will apply the firewall filter.

```
[edit]
user@host# edit interfaces ge-0/0/1 unit 0 family inet
```

2. Configure the interface address for the logical interface.

```
[edit interfaces ge-0/0/1 unit 0 family inet]
user@host# set address 10.1.2.3/30
```

3. Apply the firewall filter to the logical interface.

```
[edit interfaces ge-0/0/1 unit 0 family inet]
user@host# set filter input icmp_syslog
```

Confirm and Commit Your Candidate Configuration

Step-by-Step Procedure

To confirm and then commit your candidate configuration:

1. Confirm the configuration of the syslog message file for the **firewall** facility by entering the **show system** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show system
syslog {
  file messages_firewall_any {
    firewall any;
    archive no-world-readable;
  }
}
```

2. Confirm the configuration of the firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
```

```

user@host# show firewall
family inet {
  filter icmp_syslog {
    term icmp_match {
      from {
        address {
          192.168.207.222/32;
        }
        protocol icmp;
      }
      then {
        count packets;
        syslog;
        accept;
      }
    }
    term default_term {
      then accept;
    }
  }
}

```

3. Confirm the configuration of the interface by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

[edit]
user@host# show interfaces
ge-0/0/1 {
  unit 0 {
    family inet {
      filter {
        input icmp_syslog;
      }
      address 10.1.2.3/30;
    }
  }
}

```

4. If you are done configuring the device, commit your candidate configuration.

```

[edit]

```

```
user@host# commit
```

Verification

To confirm that the configuration is working properly, enter the **show log filter** command:

```
user@host> show log messages_firewall_any
```

```
Mar 20 08:03:11 hostname feb FW: so-0/1/0.0   A icmp 192.168.207.222
```

```
192.168.207.223      0      0 (1 packets)
```

This output file contains the following fields:

- **Date and Time**—Date and time at which the packet was received (not shown in the default).
- **Filter action:**
 - **A**—Accept (or next term)
 - **D**—Discard
 - **R**—Reject
- **Protocol**—Packet's protocol name or number.
- **Source address**—Source IP address in the packet.
- **Destination address**—Destination IP address in the packet.

NOTE: If the protocol is ICMP, the ICMP type and code are displayed. For all other protocols, the source and destination ports are displayed.

The last two fields (both zero) are the source and destination TCP/UDP ports, respectively, and are shown for TCP or UDP packets only. This log message indicates that only one packet for this match has been detected in about a 1-second interval. If packets arrive faster, the system log function compresses the information so that less output is generated, and displays an output similar to the following:

```
user@host> show log messages_firewall_any
```

Mar 20 08:08:45 hostname feb FW: so-0/1/0.0 A icmp 192.168.207.222			
192.168.207.223	0	0	(515 packets)

Applying Firewall Filters to Interfaces

For a firewall filter to work, you must apply it to at least one Layer 3 interface. To do this, include the **filter** statement when configuring a logical interface at the **[edit interfaces]** hierarchy level:

```
[edit interfaces]  
user@switch# set interface-name unit logical-unit-number family (inet | inet6) filter (input | output)  
filter-name
```

In the **input** statement, specify a firewall filter to be evaluated when packets are received on the interface. Input filters applied to a loopback interface affect only traffic destined for the Routing Engine.

In the **output** statement, specify a filter to be evaluated when packets exit the interface.

NOTE: When you create a loopback interface, it is important to apply an ingress filter to it so the Routing Engine is protected. We recommend that when you apply a filter to the loopback interface **lo0**, you include the **apply-groups** statement. Doing so ensures that the filter is automatically inherited on every loopback interface, including **lo0** and other loopback interfaces.

RELATED DOCUMENTATION

[Configuring Firewall Filters | 1579](#)

Configuring Firewall Filters

You can configure firewall filters in a switch to control traffic that enters or exits Layer 3 (routed) interfaces. To use a firewall filter, you must configure the filter and then apply it to a Layer 3 interface.

- [Configuring a Firewall Filter | 1142](#)
- [Applying a Firewall Filter to a Layer 3 \(Routed\) Interface | 1144](#)

Configuring a Firewall Filter

To configure a firewall filter:

1. Configure the family address type, filter name, term name, and at least one match condition—for example, match on packets that contain a specific source address:

```
[edit]
user@switch# set firewall family (inet | inet6) filter ingress-port-filter term t1 from source-address
192.0.2.14
```

Specify the family address type **inet** for IPv4 or **inet6** for IPv6.

The filter and term names can contain letters, numbers, and hyphens (-) and can be up to 64 characters long. Each filter name must be unique. A filter can contain one or more terms, and each term name must be unique within a filter.

2. Configure additional match conditions. For example, match on packets that contain a specific source port:

```
[edit firewall family inet filter ingress-port-filter term t1 from]
```

```
user@switch# set source-port 80
```

You can specify one or more match conditions in a single **from** statement. For a match to occur, the packet must match all the conditions in the term. The **from** statement is optional, but if included in a term, it cannot be empty. If you omit the **from** statement, all packets are considered to match.

3. If you want to apply a firewall filter to multiple interfaces and be able to see counters specific to each interface, configure the **interface-specific** option:

```
[edit firewall family inet filter ingress-port-filter]
user@switch# set interface-specific
```

4. In each firewall filter term, specify the actions to take if the packet matches all the conditions in that term. You can specify an action and action modifiers:

- To specify a filter action, for example, to discard packets that match the conditions of the filter term:

```
[edit firewall family inet filter ingress-port-filter term t1 then]
user@switch# set discard
```

You can specify no more than one action (**accept**, **discard**, **reject**, **routing-instance**, or **vlan**) per term.

- To specify action modifiers, for example, to count and classify packets to a forwarding class. For example:

```
[edit firewall family inet filter ingress-port-filter term t1 then]
user@switch# set count counter-one
user@switch# set loss-priority high
```

If you omit the **then** statement or do not specify an action, packets that match all the conditions in the **from** statement are accepted. However, you should always explicitly configure an action in the **then** statement. You can include no more than one action statement, but you can use any combination of action modifiers. For an action or action modifier to take effect, all conditions in the **from** statement must match.

NOTE: Implicit discard is also applicable to a firewall filter applied to the loopback interface, **lo0**.

NOTE: For the complete list of match conditions, actions, and action modifiers, see [“Firewall Filter Match Conditions and Actions \(QFX5100, QFX5110, QFX5120, QFX5200, EX4600, EX4650\)” on page 1504](#). Note that on the OCX1100 switch you can use only those match conditions that are valid for IPv4 and IPv6 interfaces.

Applying a Firewall Filter to a Layer 3 (Routed) Interface

To apply a firewall filter to a Layer 3 interface:

1. Provide a meaningful description of the firewall filter in the configuration of the interface to which the filter will be applied:

```
[edit]
user@switch# set interfaces xe-0/0/1 description "filter to count and monitor traffic on layer 3 interface"
```

2. You can apply firewall filters to filter packets that enter or exit a Layer 3 interface:

- To apply a firewall filter to filter packets that enter a Layer 3 interface:

```
[edit]
user@switch# set interfaces xe-0/0/1 unit 0 family inet filter input ingress-router-filter
```

- To apply a firewall filter to filter packets that exit a Layer 3 interface:

```
[edit]
user@switch# set interfaces xe-0/0/2 unit 0 family inet filter output egress-router-filter
```

NOTE: You can apply only one filter to an interface for a given direction (ingress or egress).

Understanding Multiple Firewall Filters in a Nested Configuration

IN THIS SECTION

- [The Challenge: Simplify Large-Scale Firewall Filter Administration | 1145](#)
- [A Solution: Configure Nested References to Firewall Filters | 1145](#)
- [Configuration of Nested Firewall Filters | 1146](#)
- [Application of Nested Firewall Filters to a Router or Switch Interface | 1146](#)

The Challenge: Simplify Large-Scale Firewall Filter Administration

Typically, you apply a single firewall filter to an interface in the input or output direction or both. This approach might not be practical, however, when you have a router (or switch) configured with many, even hundreds of interfaces. In an environment of this scale, you want the flexibility of being able to modify filtering terms common to multiple interfaces without having to reconfigure the filter of every affected interface.

In general, the solution is to apply an effectively “chained” structure of multiple stateless firewall filters to a single interface. You partition your filtering terms into multiple firewall filters configured so that you can apply a unique filter to each router (or switch) interface but also apply common filters to multiple router (or switch) interfaces as required. The Junos OS policy framework provides two options for managing the application of multiple separate firewall filters to individual router (or switch) interfaces. One option is to apply multiple filters as a single input list or output list. The other option is to reference a stateless firewall filter from within the term of another stateless firewall filter.

A Solution: Configure Nested References to Firewall Filters

The most structured way to avoid configuring duplicate filtering terms common to multiple firewall filters is to configure multiple firewall filters so that each filter includes the shared filtering terms by *referencing* a separate filter that contains the common filtering terms. The Junos OS uses the filter terms—in the order in which they appear in the filter definition—to evaluate packets that transit the interface. If you need to modify filtering terms shared across multiple interfaces, you only need to modify one firewall filter.

NOTE: Similar to the alternative approach (applying a list of firewall filters), configuring a nested firewall filter combines multiple firewall filters into a new firewall filter definition.

Configuration of Nested Firewall Filters

Configuring a nested firewall filter for each router (or switch) interface involves separating shared packet-filtering rules from interface-specific packet-filtering rules as follows:

- For each set of packet-filtering rules common across multiple interfaces, configure a separate firewall filter that contains the shared filtering terms.
- For each router (or switch) interface, configure a separate firewall filter that contains:
 - All the filtering terms unique to that interface.
 - An additional filtering term that includes a **filter** reference to the firewall filter that contains the common filtering terms.

Application of Nested Firewall Filters to a Router or Switch Interface

Applying nested firewall filters is no different from applying an unnested firewall filter. For each interface, you can include an **input** or **output** statement (or both) within the **filter** stanza to specify the appropriate nested firewall filter.

Applying nested firewall filters to an interface, the shared filtering terms and the interface-specific firewall filters are applied through *a single nested firewall filter* that includes other filters through the **filter** statement within a separate filtering term.

- [Types of Filters Supported in Nested Configurations | 1148](#)
- [Number of Filter References in a Single Filter | 1148](#)
- [Depth of Filter Nesting | 1148](#)

Statement Hierarchy for Configuring Nested Firewall Filters

To reference a filter from within a filter, include the **filter** *filter-name* statement as a separate filter term:

```
firewall firewall-name {  
  family family-name {  
    filter filter-name {  
      term term-name {  
        filter filter-name;  
      }  
    }  
  }  
}
```

You can include the firewall configuration at one of the following hierarchy levels:

- [\[edit\]](#)
- [\[edit logical-systems *logical-system-name*\]](#)

Filter-Defining Terms and Filter-Referencing Terms

You cannot configure a firewall filter term that both references another firewall filter and defines a match condition or action. If a firewall filter term includes the **filter** statement, then it cannot also include the **from** or **then** statement.

For example, the firewall filter term **term term1** in the configuration is *not* valid:

```
[edit]
firewall {
  family inet {
    filter filter_1 {
      term term1 {
        filter filter_2;
        from {
          source-address 172.16.1.1/32;
        }
        then {
          accept;
        }
      }
    }
  }
}
```

In order for **term term1** to be a valid filter term, you must either remove the **filter filter_2** statement or remove both the **from** and **then** stanzas.

Types of Filters Supported in Nested Configurations

Nested configurations of firewall filters support firewall filters only. You cannot use service filters or simple filters in a nested firewall filter configuration.

Number of Filter References in a Single Filter

The total number of filters referenced from within a filter cannot exceed 256.

Depth of Filter Nesting

The Junos OS supports a single level of firewall filter nesting. If **filter_1** references **filter_2**, you cannot configure a filter that references a filter that references **filter_1**.

- [How Filter Lists Evaluate Packets When the List Includes Protocol-Independent and IP Firewall Filters | 1152](#)

This topic covers the following information:

The Challenge: Simplify Large-Scale Firewall Filter Administration

Typically, you apply a single firewall filter to an interface in the input or output direction or both. However, this approach might not be practical when you have a device configured with many interfaces. In large environments, you want the flexibility of being able to modify filtering terms common to multiple interfaces without having to reconfigure the filter of every affected interface.

In general, the solution is to apply an effectively “chained” structure of multiple firewall filters to a single interface. You partition your filtering terms into multiple firewall filters that each perform a filtering task. You can then choose which filtering tasks you want to perform for a given interface and apply the filtering tasks to that interface. In this way, you only manage the configuration for a filtering task in a single firewall filter.

The Junos OS policy framework provides two options for managing the application of multiple separate firewall filters to individual router interfaces. One option is to apply multiple filters as a single input list or output list. The other option is to reference a firewall filter from within the term of another firewall filter. This option is not supported on the PTX10003 router.

A Solution: Apply Lists of Firewall Filters

The most straightforward way to avoid configuring duplicate filtering terms common to multiple firewall filters is to configure multiple firewall filters and then apply a customized *list* of filters to each interface. The Junos OS uses the filters—in the order in which they appear in the list—to evaluate packets that transit

the interface. If you need to modify filtering terms shared across multiple interfaces, you only need to modify one firewall filter that contains those terms.

Configuration of Multiple Filters for Filter Lists

Configuring firewall filters to be applied in unique lists for each router interface involves separating shared packet-filtering rules from interface-specific packet-filtering rules as follows:

- **Unique filters**—For each set of packet-filtering rules unique to a specific interface, configure a separate firewall filter that contains only the filtering terms for that interface.
- **Shared filters**—For each set of packet-filtering rules common across two or more interfaces, consider configuring a separate firewall filter that contains the shared filtering terms.

TIP: When planning for a large number firewall filters to be applied using filter lists, administrators often organize the shared filters by filtering criteria, by the services to which customers subscribe, or by the purposes of the interfaces.

Application of Filter Lists to a Router Interface

Applying a list of firewall filters to an interface is a matter of selecting the filters that meet the packet-filtering requirements of that interface. For each interface, you can include an **input-list** or **output-list** statement (or both) within the **filter** stanza to specify the relevant filters in the order in which they are to be used:

- Include any filters that contain common filtering terms relevant to the interface.
- Include the filter that contain only the filtering terms unique to the interface.

Interface-Specific Names for Filter Lists

Because a filter list is configured under an interface, the resulting concatenated filter is *interface-specific*.

NOTE: When a filter list is configured under an interface, the resulting concatenated filter is interface-specific, regardless whether the firewall filters in the filter list are configured as interface-specific or not. Furthermore, the instantiation of interface-specific firewall filters not only creates separate instances of any firewall filter counters, but also separate instances of any policer actions. Any policers applied through an action specified in the firewall filter configuration are applied separately to each interface in the interface group.

The system-generated name of an interface-specific filter consists of the full interface name followed by either `'-i'` for an input filter list or `'-o'` for an output filter list.

- **Input filter list name**—For example, if you use the **input-list** statement to apply a chain of filters to logical interface **ge-1/3/0.0**, the Junos OS uses the following name for the filter:

```
ge-1/3/0.0-i
```

- **Output filter list name**—For example, if you use the **output-list** statement to apply a chain of filters to logical interface **fe-0/1/2.0**, the Junos OS uses the following name for the filter:

```
fe-0/1/2.0-o
```

NOTE: For Junos OS Evolved, the filter names are different. For example, if the filters are bound to the inet family, the filters are named **ge-1/3/0/0-inet-i** and **fe-0/1/2.0-inet-o**.

You can use the interface-specific name of a filter list when you enter a Junos OS operational mode command that specifies a firewall filter name.

How Filter Lists Evaluate Packets When the Matched Term Includes Terminating or Next Term Actions

The device evaluates a packet against the filters in a list sequentially, beginning with the first filter in the list until either a terminating action occurs or the packet is implicitly discarded.

[Table 69 on page 1152](#) describes how a firewall filter list evaluates a packet based on whether the matched term specifies a terminating action and the **next term** action. The **next term** action is neither a terminating action nor a nonterminating action but a *flow control* action.

Table 69: Firewall Filter List Behavior

Firewall Filter Actions Included in the Matched Term		Term Description	Packet-Filtering Behavior
Terminating	next term		
Yes	—	The matched term includes a terminating action (such as discard) but not the next term action	The device executes the terminating action. No subsequent terms in the filter and no subsequent filters in the list are used to evaluate the packet.
—	Yes	The matched term includes the next term action, but it does not include any terminating actions.	The device executes any nonterminating actions, then the device evaluates the packet against the next term in the filter or the next filter in the list. NOTE: On Junos OS Evolved, next term cannot appear as the last term of the action. A filter term where next term is specified as an action but without any match conditions configured is not supported.
—	—	The matched term includes neither the next term action nor any terminating actions.	The device executes any nonterminating actions, then the device implicitly accepts the packet. Because the accept action is a terminating action, no subsequent terms in the filter and no subsequent filters in the list are used to evaluate the packet.

For information about terminating actions, see [“Firewall Filter Terminating Actions” on page 794](#).

NOTE: You cannot configure the **next term** action with a terminating action in the same firewall filter term.

How Filter Lists Evaluate Packets When the List Includes Protocol-Independent and IP Firewall Filters

On a single interface associated with a protocol-independent (**family any**) firewall filter and a protocol-specific (**family inet** or **family inet6**) firewall filter simultaneously, the protocol-independent firewall filter executes first.

The terminating action of the first filter determines whether the second filter also evaluates the packet:

- If the first filter terminates by executing the **accept** action, the second filter also evaluates the packet.

- If the first filter terminates without any terms matching the packet (an *implicit discard* action), the second filter also evaluates the packet.
- If the first filter terminates by executing an *explicit discard* action, the second filter does not evaluate the packet.

The PTX10003 router does not support a combination of protocol-independent and other filters in filter-lists.

Guidelines for Applying Multiple Firewall Filters as a List

IN THIS SECTION

- [Statement Hierarchy for Applying Lists of Multiple Firewall Filters | 1153](#)
- [Filter Input Lists and Output Lists for Router or Switch Interfaces | 1154](#)
- [Types of Filters Supported in Lists | 1154](#)
- [Restrictions on Applying Filter Lists for MPLS or Layer 2 CCC Traffic | 1154](#)

Statement Hierarchy for Applying Lists of Multiple Firewall Filters

To apply a single filter to the input or output direction of a router (or switch) logical interface, you include the **input** *filter-name* or **output** *filter-name* statement under the **filter** stanza for a protocol family.

To apply a list of multiple filters to the input or output direction of a router (or switch) logical interface, include the **input-list** [*filter-names*] or **output-list** [*filter-names*] statement under the **filter** stanza for a protocol family:

```
interfaces {
  interface-name {
    unit logical-unit-number {
      family family-name {
```

```

filter {
    ...filter-options...
    input-list [ filter-names ];
    output-list [ filter-names ];
}
}
}
}
}

```

You can include the interface configuration at one of the following hierarchy levels:

- [edit]
- [edit logical-systems *logical-system-name*]

NOTE: (PTX10003) The router does not support **output-list** filter binding on the loopback address (lo0) or management interface.

Filter Input Lists and Output Lists for Router or Switch Interfaces

When applying a list of firewall filters as a list, the following limitations apply:

- You can specify up to 16 firewall filters for a filter input list.
- You can specify up to 16 firewall filters for a filter output list.

Types of Filters Supported in Lists

Lists of multiple firewall filters applied to a router (or switch) interface support standard stateless firewall filters only. You cannot apply lists containing service filters or simple filters to a router (or switch) interface.

Restrictions on Applying Filter Lists for MPLS or Layer 2 CCC Traffic

NOTE: These restrictions do not apply to the PTX10003 router. The router only supports applying filter lists on IPv4 (**inet**) or IPv6 (**inet6**) traffic.

When applying firewall filters that evaluate MPLS traffic (**family mpls**) or Layer 2 circuit cross-connection traffic (**family ccc**), you can use the **input-list [*filter-names*]** and **output-list [*filter-names*]** statements for all interfaces except the following:

- Management and internal Ethernet (**fxp**) interfaces
- Loopback (**lo0**) interfaces
- USB modem (**umd**) interfaces

RELATED DOCUMENTATION

[Understanding Multiple Firewall Filters Applied as a List | 1149](#)

[Example: Applying Lists of Multiple Firewall Filters | 1155](#)

Example: Applying Lists of Multiple Firewall Filters

IN THIS SECTION

- [Requirements | 1155](#)
- [Overview | 1156](#)
- [Configuration | 1157](#)
- [Verification | 1161](#)

This example shows how to apply lists of multiple firewall filters.

Requirements

Before you begin, be sure that you have:

- Installed your router or switch, and supported PIC, DPC, or MPC and performed the initial router or switch configuration.
- Configured basic Ethernet in the topology.
- Configured a logical interface to run the IP version 4 (IPv4) protocol (**family inet**) and configured the logical interface with an interface address. This example uses logical interface **ge-1/3/0.0** configured with the IP address 172.16.1.2/30.

NOTE: For completeness, the configuration section of this example includes setting an IP address for logical interface **ge-1/3/0.0**.

- Verified that traffic is flowing in the topology and that ingress and egress IPv4 traffic is flowing through logical interface **ge-1/3/0.0**.
- Verified that you have access to the remote host that is connected to this router's or switch's logical interface **ge-1/3/0.0**.

Overview

In this example, you configure three IPv4 firewall filters and apply each filter directly to the same logical interface by using a list.

Topology

This example applies the following firewall filters as a *list of input filters* at logical interface **ge-1/3/0.0**. Each filter contains a single term that evaluates IPv4 packets and accepts packets based on the value of the **destination port** field in the TCP header:

- Filter **filter_FTP** matches on the FTP port number (**21**).
- Filter **filter_SSH** matches on the SSH port number (**22**).
- Filter **filter_Telnet** matches on the Telnet port number (**23**).

If an inbound packet does not match any of the filters in the input list, the packet is discarded.

NOTE: The Junos OS uses filters in a list in the order in which the filter names appear in the list. In this simple example, the order is irrelevant because all of the filters specify the same action.

Any of the filters can be applied to other interfaces, either alone (using the **input** or **output** statement) or in combination with other filters (using the **input-list** or **output-list** statement). The objective is to configure multiple “minimalist” firewall filters that you can reuse in interface-specific filter lists.

Configuration

IN THIS SECTION

- [Configure Multiple IPv4 Firewall Filters | 1157](#)
- [Apply the Filters to a Logical Interface as an Input List and an Output List | 1158](#)
- [Confirm and Commit Your Candidate Configuration | 1159](#)

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#).

CLI Quick Configuration

To quickly configure this example, copy the following commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall family inet filter filter_FTP term 0 from protocol tcp
set firewall family inet filter filter_FTP term 0 from destination-port 21
set firewall family inet filter filter_FTP term 0 then count pkts_FTP
set firewall family inet filter filter_FTP term 0 then accept
set firewall family inet filter filter_SSH term 0 from protocol tcp
set firewall family inet filter filter_SSH term 0 from destination-port 22
set firewall family inet filter filter_SSH term 0 then count pkts_SSH
set firewall family inet filter filter_SSH term 0 then accept
set firewall family inet filter filter_Telnet term 0 from protocol tcp
set firewall family inet filter filter_Telnet term 0 from destination-port 23
set firewall family inet filter filter_Telnet term 0 then count pkts_Telnet
set firewall family inet filter filter_Telnet term 0 then accept
set firewall family inet filter filter_discard term 1 then count pkts_discarded
set firewall family inet filter filter_discard term 1 then discard
set interfaces ge-1/3/0 unit 0 family inet address 172.16.1.2/30
set interfaces ge-1/3/0 unit 0 family inet filter input-list filter_FTP
set interfaces ge-1/3/0 unit 0 family inet filter input-list filter_SSH
set interfaces ge-1/3/0 unit 0 family inet filter input-list filter_Telnet
set interfaces ge-1/3/0 unit 0 family inet filter input-list filter_discard
```

Configure Multiple IPv4 Firewall Filters

Step-by-Step Procedure

To configure the IPv4 firewall filters:

1. Navigate the CLI to the hierarchy level at which you configure IPv4 firewall filters.

```
[edit]
user@host# edit firewall family inet
```

2. Configure the first firewall filter to count and accept packets for port 21.

```
[edit firewall family inet]
user@host# set filter filter_FTP term 0 from protocol tcp
user@host# set filter filter_FTP term 0 from destination-port 21
user@host# set filter filter_FTP term 0 then count pkts_FTP
user@host# set filter filter_FTP term 0 then accept
```

3. Configure the second firewall filter to count and accept packets for port 22.

```
[edit firewall family inet]
user@host# set filter filter_SSH term 0 from protocol tcp
user@host# set filter filter_SSH term 0 from destination-port 22
user@host# set filter filter_SSH term 0 then count pkt_SSH
user@host# set filter filter_SSH term 0 then accept
```

4. Configure the third firewall filter to count and accept packets from port 23.

```
[edit firewall family inet]
user@host# set filter filter_Telnet term 0 from protocol tcp
user@host# set filter filter_Telnet term 0 from destination-port 23
user@host# set filter filter_Telnet term 0 then count pkts_Telnet
user@host# set filter filter_Telnet term 0 then accept
```

5. Configure the last firewall filter to count the discarded packets.

```
[edit firewall family inet]
user@host# set filter filter_discard term 1 then count pkts_discarded
user@host# set filter filter_discard term 1 then discard
```

Apply the Filters to a Logical Interface as an Input List and an Output List

Step-by-Step Procedure

To apply the six IPv4 firewall filters as a list of input filters and a list of output filters:

1. Navigate the CLI to the hierarchy level at which you apply IPv4 firewall filters to logical interface **ge-1/3/0.0**.

```
[edit]
user@host# edit interfaces ge-1/3/0 unit 0 family inet
```

2. Configure the IPv4 protocol family for the logical interface.

```
[edit interfaces ge-1/3/0 unit 0 family inet]
user@host# set address 172.16.1.2/30
```

3. Apply the filters as a list of input filters.

```
[edit interfaces ge-1/3/0 unit 0 family inet]
user@host# set filter input-list [ filter_FTP filter_SSH filter_Telnet filter_discard ]
```

Confirm and Commit Your Candidate Configuration

Step-by-Step Procedure

To confirm and then commit your candidate configuration:

1. Confirm the configuration of the firewall filters by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show firewall
family inet {
  filter filter_FTP {
    term 0 {
      from {
        protocol tcp;
        destination-port 21;
      }
      then {
        count pkts_FTP;
        accept;
      }
    }
  }
}
```

```

}
filter filter_SSH {
  term 0 {
    from {
      protocol tcp;
      destination-port 22;
    }
    then {
      count pkts_SSH;
      accept;
    }
  }
}
filter filter_Telnet {
  term 0 {
    from {
      protocol tcp;
      destination-port 23;
    }
    then {
      count pkts_Telnet;
      accept;
    }
  }
}
filter filter_discard {
  term 1 {
    then {
      count pkts_discarded;
      discard;
    }
  }
}
}
}

```

2. Confirm the configuration of the interface by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

[edit]
user@host# show interfaces
ge-1/3/0 {
  unit 0 {

```

```

family inet {
    filter {
        input-list [ filter_FTP filter_SSH filter_Telnet filter_discard ];
    }
    address 172.16.1.2/30;
}
}
}

```

3. If you are done configuring the device, commit your candidate configuration.

```

[edit]
user@host# commit

```

Verification

IN THIS SECTION

- [Verifying That Inbound Packets Are Accepted Only If Destined for the FTP, SSH or Telnet Port | 1161](#)

Confirm that the configuration is working properly.

Verifying That Inbound Packets Are Accepted Only If Destined for the FTP, SSH or Telnet Port

Purpose

Verify that all three filters are active for the logical interface.

Action

To verify that input packets are accepted according to the three filters:

1. From the remote host that is connected to this router's (or switch's) logical interface **ge-1/3/0.0**, send a packet with destination port number 21 in the header. The packet should be accepted.
2. From the remote host that is connected to this router's (or switch's) logical interface **ge-1/3/0.0**, send a packet with destination port number 22 in the header. The packet should be accepted.
3. From the remote host that is connected to this router's (or switch's) logical interface **ge-1/3/0.0**, send a packet with destination port number 23 in the header. The packet should be accepted.

4. From the remote host that is connected to this router's (or switch's) logical interface **ge-1/3/0.0**, send a packet with a destination port number *other than* 21, 22, or 23. The packet should be discarded.
5. To display counter information for the list of filters applied to the input at **ge-1/3/0.0-i** enter the [show firewall filter ge-1/3/0.0-i](#) operational mode command. The command output displays the number of bytes and packets that match filter terms associated with the following counters:
 - **pkts_FTP-ge-1/3/0.0-i**
 - **pkts_SSH-ge-1/3/0.0-i**
 - **pkts_Telnet-ge-1/3/0.0-i**
 - **pkts_discard-ge-1/3/0.0-i**

Example: Nesting References to Multiple Firewall Filters

IN THIS SECTION

- [Requirements | 1162](#)
- [Overview | 1163](#)
- [Configuration | 1163](#)
- [Verification | 1167](#)

This example shows how to configure nested references to multiple firewall filters.

Requirements

No special configuration beyond device initialization is required before configuring this example.

Overview

In this example, you configure a firewall filter for a match condition and action combination that can be shared among multiple firewall filters. You then configure two firewall filters that reference the first firewall filter. Later, if the common filtering criteria needs to be changed, you would modify only the one shared firewall filter configuration.

Topology

The **common_filter** firewall filter discards packets that have a UDP source or destination port field number of **69**. Both of the two additional firewall filters, **filter1** and **filter2**, reference the **common_filter**.

Configuration

IN THIS SECTION

- [Configure the Nested Firewall Filters | 1164](#)
- [Apply Both Nested Firewall Filters to Interfaces | 1164](#)
- [Confirm and Commit Your Candidate Configuration | 1165](#)

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#).

CLI Quick Configuration

To quickly configure this example, copy the following commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall family inet filter common_filter term common_term from protocol udp
set firewall family inet filter common_filter term common_term from port tftp
set firewall family inet filter common_filter term common_term then discard
set firewall family inet filter filter1 term term1 filter common-filter
set firewall family inet filter filter1 term term2 from address 192.168.0.0/16
set firewall family inet filter filter1 term term2 then reject
set firewall family inet filter filter2 term term1 filter common-filter
set firewall family inet filter filter2 term term2 from protocol udp
set firewall family inet filter filter2 term term2 from port bootps
set firewall family inet filter filter2 term term2 then accept
set interfaces ge-0/0/0 unit 0 family inet address 10.1.0.1/24
set interfaces ge-0/0/0 unit 0 family inet filter input filter1
set interfaces ge-0/0/3 unit 0 family inet address 10.1.3.1/24
```

```
set interfaces ge-0/0/0 unit 0 family inet filter input filter2
```

Configure the Nested Firewall Filters

Step-by-Step Procedure

To configure two nested firewall filters that share a common filter:

1. Navigate the CLI to the hierarchy level at which you configure IPv4 firewall filters.

```
[edit]
user@host# edit firewall family inet
```

2. Configure the common filter that will be referenced by multiple other filters.

```
[edit firewall family inet]
user@host# set filter common_filter term common_term from protocol udp
user@host# set filter common_filter term common_term from port tftp
user@host# set filter common_filter term common_term then discard
```

3. Configure a filter that references the common filter.

```
[edit firewall family inet]
user@host# set filter filter1 term term1 filter common-filter
user@host# set filter filter1 term term2 from address 192.168.0.0/16
user@host# set filter filter1 term term2 then reject
```

4. Configure a second filter that references the common filter.

```
[edit firewall family inet]
user@host# set filter filter2 term term1 filter common-filter
user@host# set filter filter2 term term2 from protocol udp
user@host# set filter filter2 term term2 from port bootps
user@host# set filter filter2 term term2 then accept
```

Apply Both Nested Firewall Filters to Interfaces

Step-by-Step Procedure

To apply both nested firewall filters to logical interfaces:

1. Apply the first nested filter to a logical interface input.

```
[edit]
user@host# set interfaces ge-0/0/0 unit 0 family inet address 10.1.0.1/24
user@host# set interfaces ge-0/0/0 unit 0 family inet filter input filter1
```

2. Apply the second nested filter to a logical interface input.

```
[edit]
user@host# set interfaces ge-0/0/3 unit 0 family inet address 10.1.3.1/24
user@host# set interfaces ge-0/0/0 unit 0 family inet filter input filter2
```

Confirm and Commit Your Candidate Configuration

Step-by-Step Procedure

To confirm and then commit your candidate configuration:

1. Confirm the configuration of the firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show firewall
family inet {
  filter common_filter {
    term common_term {
      from {
        protocol udp;
        port tftp;
      }
      then {
        discard;
      }
    }
  }
}
filter filter1 {
  term term1 {
    filter common-filter;
  }
  term term2 {
    from {
```

```

        address 192.168/16;
    }
    then {
        reject;
    }
}
}
filter filter2 {
    term term1 {
        filter common-filter;
    }
    term term2 {
        from {
            protocol udp;
            port bootps;
        }
        then {
            accept;
        }
    }
}
}

```

2. Confirm the configuration of the interface by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

[edit]
user@host# show interfaces
ge-0/0/0 {
    unit 0 {
        family inet {
            filter {
                input filter1;
            }
            address 10.1.0.1/24;
        }
    }
}
ge-0/0/3 {
    unit 0 {
        family inet {
            filter {

```

```
        input filter2;  
    }  
    address 10.1.3.1/24;  
}  
}  
}
```

3. If you are done configuring the device, commit your candidate configuration.

```
[edit]  
user@host# commit
```

Verification

To confirm that the configuration is working properly, enter the `show firewall filter filter1` and `show firewall filter filter2` operational mode commands.

RELATED DOCUMENTATION

[Understanding Multiple Firewall Filters in a Nested Configuration | 1145](#)

Example: Filtering Packets Received on an Interface Set

IN THIS SECTION

- [Requirements | 1168](#)
- [Overview | 1168](#)
- [Configuration | 1168](#)
- [Verification | 1175](#)

This example shows how to configure a standard stateless firewall filter to match packets tagged for a particular interface set.

Requirements

No special configuration beyond device initialization is required before configuring this example.

Overview

In this example, you apply a stateless firewall filter to the input of the router or switch loopback interface. The firewall filter includes a term that matches packets tagged for a particular interface set.

Topology

You create the firewall filter **L2_filter** to apply rate limits to the protocol-independent traffic received on the following interfaces:

- fe-0/0/0.0
- fe-1/0/0.0
- fe-1/1/0.0

NOTE: The interface type in this topic is just an example. The **fe-** interface type is not supported by EX Series switches.

First, for protocol-independent traffic received on **fe-0/0/0.0**, the firewall filter term **t1** applies policer **p1**.

For protocol-independent traffic received on any other Fast Ethernet interfaces, firewall filter term **t2** applies policer **p2**. To define an interface set that consists of all Fast Ethernet interfaces, you include the **interface-set interface-set-name interface-name** statement at the **[edit firewall]** hierarchy level. To define a packet-matching criteria based on the interface on which a packet arrives to a specified interface set, you configure a term that uses the **interface-set** firewall filter match condition.

Finally, for any other protocol-independent traffic, firewall filter term **t3** applies policer **p3**.

Configuration

IN THIS SECTION

- [Configuring the Interfaces for Which the Stateless Firewall Filter Terms Take Rate-Limiting Actions | 1169](#)
- [Configuring the Stateless Firewall Filter That Rate-Limits Protocol-Independent Traffic Based on the Interfaces on Which Packets Arrive | 1171](#)
- [Applying the Stateless Firewall Filter to the Routing Engine Input Interface | 1174](#)

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#).

To configure this example, perform the following tasks:

CLI Quick Configuration

To quickly configure this example, copy the following configuration commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set interfaces fe-0/0/0 unit 0 family inet address 10.1.1.1/30
set interfaces fe-1/0/0 unit 0 family inet address 10.2.2.1/30
set interfaces fe-1/1/0 unit 0 family inet address 10.4.4.1/30
set firewall policer p1 if-exceeding bandwidth-limit 5m
set firewall policer p1 if-exceeding burst-size-limit 10m
set firewall policer p1 then discard
set firewall policer p2 if-exceeding bandwidth-limit 40m
set firewall policer p2 if-exceeding burst-size-limit 100m
set firewall policer p2 then discard
set firewall policer p3 if-exceeding bandwidth-limit 600m
set firewall policer p3 if-exceeding burst-size-limit 1g
set firewall policer p3 then discard
set firewall interface-set ifset fe-*
set firewall family any filter L2_filter term t1 from interface fe-0/0/0.0
set firewall family any filter L2_filter term t1 then count c1
set firewall family any filter L2_filter term t1 then policer p1
set firewall family any filter L2_filter term t2 from interface-set ifset
set firewall family any filter L2_filter term t2 then count c2
set firewall family any filter L2_filter term t2 then policer p2
set firewall family any filter L2_filter term t3 then count c3
set firewall family any filter L2_filter term t3 then policer p3
set interfaces lo0 unit 0 family inet address 172.16.1.157/30
set interfaces lo0 unit 0 family inet address 172.16.1.157/30
set interfaces lo0 unit 0 filter input L2_filter
```

Configuring the Interfaces for Which the Stateless Firewall Filter Terms Take Rate-Limiting Actions

Step-by-Step Procedure

To configure the interfaces for which the stateless firewall filter terms take rate-limiting actions:

1. Configure the logical interface whose input traffic will be matched by the first term of the firewall filter.

```
[edit]
user@host# set interfaces fe-0/0/0 unit 0 family inet address 10.1.1.1/30
```

2. Configure the logical interfaces whose input traffic will be matched by the second term of the firewall filter.

```
[edit ]
user@host# set interfaces fe-1/0/0 unit 0 family inet address 10.2.2.1/30
user@host# set interfaces fe-1/1/0 unit 0 family inet address 10.4.4.1/30
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Results

Confirm the configuration of the router (or switch) transit interfaces by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show interfaces
fe-0/0/0 {
  unit 0 {
    family inet {
      address 10.1.1.1/30;
    }
  }
}
fe-1/0/0 {
  unit 0 {
    family inet {
      address 10.2.2.1/30;
    }
  }
}
fe-1/1/0 {
  unit 0 {
    family inet {
      address 10.4.4.1/30;
    }
  }
}
```

Configuring the Stateless Firewall Filter That Rate-Limits Protocol-Independent Traffic Based on the Interfaces on Which Packets Arrive

Step-by-Step Procedure

To configure the standard stateless firewall **L2_filter** that uses policers (**p1**, **p2**, and **p3**) to rate-limit protocol-independent traffic based on the interfaces on which the packets arrive:

1. Configure the firewall statements.

```
[edit]
user@host# edit firewall
```

2. Configure the policer **p1** to discard traffic that exceeds a traffic rate of **5m** bps or a burst size of **10m** bytes.

```
[edit firewall]
user@host# set policer p1 if-exceeding bandwidth-limit 5m
user@host# set policer p1 if-exceeding burst-size-limit 10m
user@host# set policer p1 then discard
```

3. Configure the policer **p2** to discard traffic that exceeds a traffic rate of **40m** bps or a burst size of **100m** bytes .

```
[edit firewall]
user@host# set policer p2 if-exceeding bandwidth-limit 40m
user@host# set policer p2 if-exceeding burst-size-limit 100m
user@host# set policer p2 then discard
```

4. Configure the policer **p3** to discard traffic that exceeds a traffic rate of **600m** bps or a burst size of **1g** bytes.

```
[edit firewall]
user@host# set policer p3 if-exceeding bandwidth-limit 600m
user@host# set policer p3 if-exceeding burst-size-limit 1g
user@host# set policer p3 then discard
```

5. Define the interface set **ifset** to be the group of all Fast Ethernet interfaces on the router.

```
[edit firewall]
user@host# set interface-set ifset fe-*
```

6. Create the stateless firewall filter **L2_filter**.

```
[edit firewall]
user@host# edit family any filter L2_filter
```

7. Configure filter term **t1** to match IPv4, IPv6, or MPLS packets received on interface **fe-0/0/0.0** and use policer **p1** to rate-limit that traffic.

```
[edit firewall family any filter L2_filter]
user@host# set term t1 from interface fe-0/0/0.0
user@host# set term t1 then count c1
user@host# set term t1 then policer p1
```

8. Configure filter term **t2** to match packets received on interface-set **ifset** and use policer **p2** to rate-limit that traffic.

```
[edit firewall family any filter L2_filter]
user@host# set term t2 from interface-set ifset
user@host# set term t2 then count c2
user@host# set term t2 then policer p2
```

9. Configure filter term **t3** to use policer **p3** to rate-limit all other traffic.

```
[edit firewall family any filter L2_filter]
user@host# set term t3 then count c3
user@host# set term t3 then policer p3
```

10. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Results

Confirm the configuration of the stateless firewall filter and the policers referenced as firewall filter actions by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show firewall
family any {
  filter L2_filter {
    term t1 {
      from {
        interface fe-0/0/0.0;
      }
      then {
        policer p1;
        count c1;
      }
    }
    term t2 {
      from {
        interface-set ifset;
      }
      then {
        policer p2;
        count c2;
      }
    }
    term t3 {
      then {
        policer p3;
        count c3;
      }
    }
  }
}
policer p1 {
  if-exceeding {
    bandwidth-limit 5m;
    burst-size-limit 10m;
  }
  then discard;
}
policer p2 {
  if-exceeding {
    bandwidth-limit 40m;
    burst-size-limit 100m;
```

```

    }
    then discard;
  }
  policer p3 {
    if-exceeding {
      bandwidth-limit 600m;
      burst-size-limit 1g;
    }
    then discard;
  }
  interface-set ifset {
    fe-*;
  }

```

Applying the Stateless Firewall Filter to the Routing Engine Input Interface

Step-by-Step Procedure

To apply the stateless firewall filter to the Routing Engine input interface:

1. Apply the stateless firewall filter to the Routing Engine interface in the input direction.

```

[edit]
user@host# set interfaces lo0 unit 0 family inet address 172.16.1.157/30
user@host# set interfaces lo0 unit 0 filter input L2_filter

```

2. If you are done configuring the device, commit the configuration.

```

[edit]
user@host# commit

```

Results

Confirm the application of the firewall filter to the Routing Engine input interface by entering the **show interfaces** command again. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```

user@host# show interfaces
fe-0/0/0 {
  ...
}
fe-1/0/0 {
  ...
}

```

```
}  
fe-1/1/0 {  
  ...  
}  
lo0 {  
  unit 0 {  
    filter {  
      input L2_filter;  
    }  
    family inet {  
      address 172.16.1.157/30;  
    }  
  }  
}
```

Verification

To confirm that the configuration is working properly, use the [show firewall filter L2_filter](#) operational mode command to monitor traffic statistics about the firewall filter and three counters.

Interface-Specific Firewall Filter Instances Overview

IN THIS SECTION

- [Instantiation of Interface-Specific Firewall Filters | 1176](#)
- [Interface-Specific Names for Firewall Filter Instances | 1177](#)
- [Interface-Specific Firewall Filter Counters | 1178](#)
- [Interface-Specific Firewall Filter Policers | 1178](#)

Instantiation of Interface-Specific Firewall Filters

On T Series, M120, M320, MX Series routers, and EX Series switches, you can enable the Junos OS to automatically create an interface-specific instance of a firewall filter for each interface to which you apply the filter. If you enable interface-specific instantiation of a firewall filter and then apply that filter to multiple interfaces, any **count** actions or **policer** actions configured in the filter terms act on the traffic stream entering or exiting each individual interface, regardless of the sum of traffic on the multiple interfaces.

You can enable this option per firewall filter by including the **interface-specific** statement in the filter configuration.

NOTE: On T Series, M120, M320, MX Series routers, and EX Series switches, interfaces are distributed among multiple packet-forwarding components.

Interface-specific firewall filtering is not supported on M Series routers other than the M120 and M320 routers. If you apply a firewall filter to multiple interfaces on an M Series router other than the M120 or M320 routers, the filter acts on the sum of traffic entering or exiting those interfaces.

Interface-specific firewall filtering is supported for standard stateless firewall filters and for service filters. Interface-specific instances are not supported for simple filters.

Interface-Specific Names for Firewall Filter Instances

When the Junos OS creates a separate instance of a firewall filter for a logical interface, the instance is associated with an interface-specific name. The system-generated name of a firewall filter instance consists of the name of the configured filter followed by a hyphen ('-'), the full interface name, and either '-i' for an input filter instance or '-o' for an output filter instance.

- **Input filter instance name**—For example, if you apply the interface-specific firewall filter **filter_s_tcp** to the input at logical interface **at-1/1/1.0**, the Junos OS instantiates an interface-specific filter instance with the following system-generated name:

```
filter_s_tcp-at-1/1/1.0-i
```

- **Output filter instance name**—For example, if you apply the interface-specific firewall filter **filter_s_tcp** to the output at logical interface **ge-2/2/2.2**, the Junos OS instantiates an interface-specific filter instance with the following system-generated name:

```
count_s_tcp-ge-2/2/2.2-o
```

You can use the interface-specific name of a filter instance when you enter a Junos OS operational mode command that specifies a stateless firewall filter name.

TIP: When you configure a firewall filter with interface-specific instances enabled, we recommend you limit the filter name to 52 bytes in length. This is because firewall filter names are restricted to 64 bytes in length. If a system-generated filter instance name exceeds this maximum length, the policy framework software might reject the instance name.

Interface-Specific Firewall Filter Counters

Instantiation of interface-specific firewall filters causes the Packet Forwarding Engine to maintain any counters for the firewall filter separately for each interface. You specify interface-specific counters per firewall filter term by specifying the **count** *counter-name* non-terminating action.

The system-generated name of an interface-specific firewall filter counter consists of the name of the configured counter followed by a hyphen ('-'), the full interface name, and either '-i' for an input filter instance or '-o' for an output filter instance.

- **Interface-specific input filter counter name**—For example, suppose you configure the filter counter **count_tcp** for an interface-specific firewall filter. If the filter is applied to the input at logical interface **at-1/1/1.0**, the Junos OS creates the following system-generated counter name:

```
count_tcp-at-1/1/1.0-i
```

- **Interface-specific output filter counter name**—For example, suppose you configure the filter counter **count_udp** for an interface-specific firewall filter. If the filter is applied to the output at logical interface **ge-2/2/2.2**, the Junos OS creates the following system-generated counter name:

```
count_udp-ge-2/2/2.2-o
```

Interface-Specific Firewall Filter Policers

Instantiation of interface-specific firewall filters not only creates separate instances of any firewall filter counters but also creates separate instances of any policer actions. Any policers applied through an action specified in the firewall filter configuration are applied separately to each interface in the interface group. You specify interface-specific policers per firewall filter term by specifying the **policer** *policer-name* non-terminating action.

Interface-Specific Firewall Filter Instances Overview

IN THIS SECTION

- [Instantiation of Interface-Specific Firewall Filters | 1179](#)
- [Interface-Specific Names for Firewall Filter Instances | 1180](#)
- [Interface-Specific Firewall Filter Counters | 1180](#)
- [Interface-Specific Firewall Filter Policers | 1181](#)

Instantiation of Interface-Specific Firewall Filters

On T Series, M120, M320, and MX Series routers, you can enable the Junos OS to automatically create an interface-specific instance of a firewall filter for each interface to which you apply the filter. If you enable interface-specific instantiation of a firewall filter and then apply that filter to multiple interfaces, any **count** actions or **policer** actions configured in the filter terms act on the traffic stream entering or exiting each individual interface, regardless of the sum of traffic on the multiple interfaces.

You can enable this option per firewall filter by including the **interface-specific** statement in the filter configuration.

NOTE: On T Series, M120, M320, and MX Series routers, interfaces are distributed among multiple packet-forwarding components.

Interface-specific firewall filtering is not supported on M Series routers other than the M120 and M320 routers. If you apply a firewall filter to multiple interfaces on an M Series router other than the M120 or M320 routers, the filter acts on the sum of traffic entering or exiting those interfaces.

Interface-specific firewall filtering is supported for standard stateless firewall filters and for service filters. Interface-specific instances are not supported for simple filters.

NOTE: A firewall filter cannot be both interface-specific and interface-shared.

Interface-Specific Names for Firewall Filter Instances

When the Junos OS creates a separate instance of a firewall filter for a logical interface, the instance is associated with an interface-specific name. The system-generated name of a firewall filter instance consists of the name of the configured filter followed by a hyphen ('-'), the full interface name, and either '-i' for an input filter instance or '-o' for an output filter instance.

- **Input filter instance name**—For example, if you apply the interface-specific firewall filter **filter_s_tcp** to the input at logical interface **at-1/1/1.0**, the Junos OS instantiates an interface-specific filter instance with the following system-generated name:

```
filter_s_tcp-at-1/1/1.0-i
```

- **Output filter instance name**—For example, if you apply the interface-specific firewall filter **filter_s_tcp** to the output at logical interface **so-2/2/2.2**, the Junos OS instantiates an interface-specific filter instance with the following system-generated name:

```
count_s_tcp-so-2/2/2.2-o
```

You can use the interface-specific name of a filter instance when you enter a Junos OS operational mode command that specifies a stateless firewall filter name.

TIP: When you configure a firewall filter with interface-specific instances enabled, we recommend you limit the filter name to 52 bytes in length. This is because firewall filter names are restricted to 64 bytes in length. If a system-generated filter instance name exceeds this maximum length, the policy framework software might reject the instance name.

Interface-Specific Firewall Filter Counters

Instantiation of interface-specific firewall filters causes the Packet Forwarding Engine to maintain any counters for the firewall filter separately for each interface. You specify interface-specific counters per firewall filter term by specifying the **count counter-name** non-terminating action.

The system-generated name of an interface-specific firewall filter counter consists of the name of the configured counter followed by a hyphen ('-'), the full interface name, and either '-i' for an input filter instance or '-o' for an output filter instance.

- **Interface-specific input filter counter name**—For example, suppose you configure the filter counter `count_tcp` for an interface-specific firewall filter. If the filter is applied to the input at logical interface `at-1/1/1.0`, the Junos OS creates the following system-generated counter name:

```
count_tcp-at-1/1/1.0-i
```

- **Interface-specific output filter counter name**—For example, suppose you configure the filter counter `count_udp` for an interface-specific firewall filter. If the filter is applied to the output at logical interface `so-2/2/2.2`, the Junos OS creates the following system-generated counter name:

```
count_udp-so-2/2/2.2-o
```

Interface-Specific Firewall Filter Policers

Instantiation of interface-specific firewall filters not only creates separate instances of any firewall filter counters but also creates separate instances of any policer actions. Any policers applied through an action specified in the firewall filter configuration are applied separately to each interface in the interface group. You specify interface-specific policers per firewall filter term by specifying the **policer *policer-name*** non-terminating action.

Filtering Packets Received on a Set of Interface Groups Overview

You can configure a firewall filter term that matches packets tagged for a specified *interface group* or set of interface groups. An interface group consists of one or more logical interfaces with the same group number. Packets received on an interface in an interface group are tagged as being part of that group.

NOTE: EX9200 switches do not support *interface groups*. Use the [interface-set](#) configuration command as a workaround.

For standard stateless firewall filters, you can filter packets received on an interface group for IPv4, IPv6, virtual private LAN service (VPLS), Layer 2 circuit cross-connection (CCC), and Layer 2 bridging traffic. For service filters, you can filter packets received on an interface group for either IPv4 or IPv6 traffic.

NOTE: You can also configure a firewall filter term that matches on packets tagged for a specified *interface set*. For more information, see [“Filtering Packets Received on an Interface Set Overview”](#) on page 1182.

Filtering Packets Received on an Interface Set Overview

You can configure a standard stateless firewall filter term that matches packets tagged for a specified *interface set*. An interface set groups two or more physical or logical interfaces into a single interface-set name. You can filter packets received on an interface set for protocol-independent, IPv4, IPv6, MPLS, VPLS, or bridging traffic.

NOTE: You can also configure a standard stateless firewall filter term or a service filter term that matches on packets tagged for a specified *interface group*. For more information, see [“Filtering Packets Received on a Set of Interface Groups Overview”](#) on page 1181.

Example: Configuring Interface-Specific Firewall Filter Counters

IN THIS SECTION

- [Requirements | 1183](#)
- [Overview | 1183](#)
- [Configuration | 1184](#)
- [Verification | 1187](#)

This example shows how to configure and apply an interface-specific standard stateless firewall filter.

Requirements

Interface-specific stateless firewall filters are supported on T Series, M120, M320, and MX Series routers only.

No special configuration beyond device initialization is required before configuring this example.

Overview

In this example, you create an interface-specific stateless firewall filter that counts and accepts packets with source or destination addresses in a specified prefix and the IP protocol type field set to a specific value.

Topology

You configure the interface-specific stateless firewall filter **filter_s_tcp** to count and accept packets with IP source or destination addresses in the **10.0.0.0/12** prefix and the IP protocol type field set to **tcp** (or the numeric value **6**).

The name of the firewall filter counter is **count_s_tcp**.

You apply the firewall filter to multiple logical interfaces:

- **at-1/1/1.0** input
- **so-2/2/2.2** output

Applying the filter to these two interfaces results in two instances of the filter: **filter_s_tcp-at-1/1/1.0-i** and **filter_s_tcp-so-2/2/2.2-o**, respectively.

Configuration

IN THIS SECTION

- [Configure the Interface-Specific Firewall Filter | 1184](#)
- [Apply the Interface-Specific Firewall Filter to Multiple Interfaces | 1185](#)
- [Confirm Your Candidate Configuration | 1185](#)
- [Clear the Counters and Commit Your Candidate Configuration | 1187](#)

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#).

To configure this example, perform the following tasks:

CLI Quick Configuration

To quickly configure this example, copy the following commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall family inet filter filter_s_tcp interface-specific
set firewall family inet filter filter_s_tcp term 1 from address 10.0.0.0/12
set firewall family inet filter filter_s_tcp term 1 from protocol tcp
set firewall family inet filter filter_s_tcp term 1 then count count_s_tcp
set firewall family inet filter filter_s_tcp term 1 then accept
set interfaces at-1/1/1 unit 0 family inet filter input filter_s_tcp
set interfaces so-2/2/2 unit 2 family inet filter filter_s_tcp
```

Configure the Interface-Specific Firewall Filter

Step-by-Step Procedure

To configure the interface-specific firewall filter:

1. Create the IPv4 firewall filter **filter_s_tcp**.

```
[edit]
user@host# edit firewall family inet filter filter_s_tcp
```

2. Enable interface-specific instances of the filter.

```
[edit firewall family inet filter filter_s_tcp]
user@host# set interface-specific
```

3. Configure the match conditions for the term.

```
[edit firewall family inet filter filter_s_tcp]
user@host# set term 1 from address 10.0.0.0/12
user@host# set term 1 from protocol tcp
```

4. Configure the actions for the term.

```
[edit firewall family inet filter filter_s_tcp]
user@host# set term 1 then count count_s_tcp
user@host# set term 1 then accept
```

Apply the Interface-Specific Firewall Filter to Multiple Interfaces

Step-by-Step Procedure

To apply the filter **filter_s_tcp** to logical interfaces **at-1/1/1.0** and **so-2/2/2.2**:

1. Apply the interface-specific filter to packets received on logical interface **at-1/1/1.0**.

```
[edit]
user@host# set interfaces at-1/1/1 unit 0 family inet filter input filter_s_tcp
```

2. Apply the interface-specific filter to packets transmitted from logical interface **so-2/2/2.2**.

```
[edit]
user@host# set interfaces so-2/2/2 unit 2 family inet filter filter_s_tcp
```

Confirm Your Candidate Configuration

Step-by-Step Procedure

To confirm your candidate configuration:

1. Confirm the configuration of the stateless firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show firewall
family inet {
  filter filter_s_tcp {
    interface-specific;
    term 1 {
      from {
        address {
          10.0.0.0/12;
        }
        protocol tcp;
      }
      then {
        count count_s_tcp;
        accept;
      }
    }
  }
}
```

2. Confirm the configuration of the interfaces by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show interfaces
at-1/1/1 {
  unit 0
    family inet {
      filter {
        input filter_s_tcp;
      }
    }
  ]
}
so-2/2/2 {
  unit 2
```

```
family inet {  
    filter {  
        output filter_s_tcp;  
    }  
}  
}
```

Clear the Counters and Commit Your Candidate Configuration

Step-by-Step Procedure

To clear the counters and commit your candidate configuration:

1. From operational command mode, use the **clear firewall all** command to clear the statistics for all firewall filters.

To clear only the counters used in this example, include the interface-specific filter instance names:

```
[edit]  
user@host> clear firewall filter filter_s_tcp-at-1/1/1.0-i  
user@host> clear firewall filter filter_s_tcp-so-2/2/2.2-o
```

2. Commit your candidate configuration.

```
[edit]  
user@host# commit
```

Verification

IN THIS SECTION

- [Verifying That the Filter Is Applied to Each of the Multiple Interfaces | 1188](#)
- [Verifying That the Counters Are Collected Separately by Interface | 1189](#)

Confirm that the configuration is working properly.

Verifying That the Filter Is Applied to Each of the Multiple Interfaces

Purpose

Verify that the filter is applied to each of the multiple interfaces.

Action

Run the **show interfaces** command with the **detail** or **extensive** output level.

1. Verify that the filter is applied to the input for **at-1/1/1.0**:

```
user@host> show interfaces at-1/1/1 detail
```

```
Physical interface: at-1/1/1, Enabled, Physical link is Up
Interface index: 300, SNMP ifIndex: 194, Generation: 183
```

...

```
Logical interface at-1/1/1.0 (Index 64) (SNMP ifIndex 204) (Generation 5)
Flags: Point-To-Point SNMP-Traps 0x4000 Encapsulation: ATM-SNAP
```

...

```
Protocol inet, MTU: 4470, Generation: 13, Route table: 0
Flags: Sendbroadcast-pkt-to-re
Input Filters: filter_s_tcp-at-1/1/1.0-i,,,,,
```

2. Verify that the filter is applied to the output for **so-2/2/2.2**:

```
user@host> show interfaces so-2/2/2 detail
```

```
Physical interface: so-2/2/2, Enabled, Physical link is Up
Interface index: 129, SNMP ifIndex: 502, Generation: 132
```

...

```
Logical interface so-2/2/2.2 (Index 70) (SNMP ifIndex 536) (Generation 135)
Flags: Point-To-Point SNMP-Traps 0x4000 Encapsulation: PPP
```

...

```
Protocol inet, MTU: 4470, Generation: 146, Route table: 0
Flags: Sendbroadcast-pkt-to-re
Output Filters: filter_s_tcp-so-2/2/2.2-o,,,,,
```

Verifying That the Counters Are Collected Separately by Interface

Purpose

Make sure that the `count_s_tcp` counters are collected separately for the two logical interfaces.

Action

Run the `show firewall` command.

`user@host> show firewall filter filter_s_tcp`

Filter: filter_s_tcp		
Counters:		
Name	Bytes	Packets
count_s_tcp-at-1/1/1.0-i	420	5
count_s_tcp-so-2/2/2.2-o	8888	101

Example: Configuring a Stateless Firewall Filter on an Interface Group

IN THIS SECTION

- [Requirements | 1190](#)
- [Overview | 1190](#)
- [Configuration | 1191](#)
- [Verification | 1195](#)

Firewall filters are essential for securing a network and simplifying network management. In Junos OS, you can configure a stateless firewall filters to control the transit of data packets through the system and to manipulate packets as necessary. Applying a stateless firewall filter to an interface group helps to filter packets transiting through each interface in the interface group. This example shows how to configure a standard stateless firewall filter to match packets tagged for a particular interface group.

Requirements

This example uses the following hardware and software components:

- Any two Juniper Networks routers or switches that are physically or logically connected to each other through interfaces belonging to a routing instance
- Junos OS Release 7.4 or later

Overview

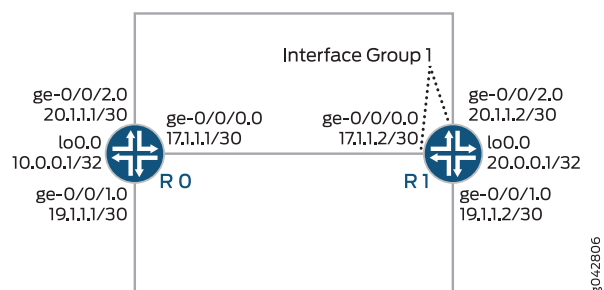

You can apply a stateless firewall filter to an interface group to apply it across all the interfaces in the interface group. This helps you to manage the packet filtering on various interfaces simultaneously.

In this example, you configure two router or switch interfaces to belong to the interface group. You also configure a stateless firewall filter with three terms. In term **term1**, the filter matches packets that have been tagged as received on that interface group and contain an ICMP protocol tag. The filter counts, logs, and rejects packets that match the conditions. In term **term2**, the filter matches packets that contain the ICMP protocol tag. The filter counts, logs, and accepts all packets that match the condition. In term **term3**, the filter counts all the transit packets.

By applying the firewall filter to the routing instance, you can simultaneously apply the filtering mechanism on all the interfaces in the interface group. For this to happen, all the interfaces in the interface group must belong to a single routing instance.

NOTE: When you apply a firewall filter to a loopback interface, the interface filters all the packets destined to the Routing Engine.

Figure 57: Configuring a Stateless Firewall Filter on an Interface Group

CLI Quick Configuration shows the configuration for all of the devices in [Figure 57 on page 1190](#). The section Step-by-Step Procedure describes the steps on Device R1.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

Device R0

```
set interfaces ge-0/0/0 unit 0 family inet address 172.16.17.1/30
set interfaces ge-0/0/1 unit 0 family inet address 172.16.19.1/30
set interfaces ge-0/0/2 unit 0 family inet address 20.1.1.1/30
set interfaces lo0 unit 0 family inet address 10.0.0.1/32
```

Device R1

```
set firewall family inet filter filter_if_group term term1 from interface-group 1
set firewall family inet filter filter_if_group term term1 from protocol icmp
set firewall family inet filter filter_if_group term term1 then count if_group_counter1
set firewall family inet filter filter_if_group term term1 then log
set firewall family inet filter filter_if_group term term1 then reject
set firewall family inet filter filter_if_group term term2 from protocol icmp
set firewall family inet filter filter_if_group term term2 then count if_group_counter2
set firewall family inet filter filter_if_group term term2 then log
set firewall family inet filter filter_if_group term term2 then accept
set firewall family inet filter filter_if_group term term3 then count default
set interfaces ge-0/0/0 unit 0 family inet filter group 1
set interfaces ge-0/0/0 unit 0 family inet address 172.16.17.2/30
set interfaces ge-0/0/1 unit 0 family inet address 172.16.19.2/30
set interfaces ge-0/0/2 unit 0 family inet filter group 1
set interfaces ge-0/0/2 unit 0 family inet address 20.1.1.2/30
set interfaces lo0 unit 0 family inet address 20.0.0.1/32
set forwarding-options family inet filter input filter_if_group
```

Configure and Apply the Stateless Firewall Filter on an Interface Group

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#) in the *CLI User Guide*.

To configure the stateless firewall filter **filter_if_group** on an interface group:

1. Create the stateless firewall filter **filter_if_group**.

```
[edit firewall]
user@R1# edit family inet filter filter_if_group
```

2. Configure the interfaces and assign two interfaces to interface group **1**.

```
[edit interfaces]
user@R1# set ge-0/0/0 unit 0 family inet filter group 1
user@R1# set ge-0/0/0 unit 0 family inet address 172.16.17.2/30

user@R1# set ge 0/0/1 unit 0 family inet address 172.16.19.2/30

user@R1# set ge-0/0/2 unit 0 family inet filter group 1
user@R1# set ge-0/0/2 unit 0 family inet address 20.1.1.2/30

user@R1# set lo0 unit 0 family inet address 20.0.0.1/32
```

3. Configure term **term1** to match packets received on interface group **1** and with the ICMP protocol.

```
[edit firewall]
user@R1# set family inet filter filter_if_group term term1 from interface-group 1
user@R1# set family inet filter filter_if_group term term1 from protocol icmp
```

4. Configure term **term1** to count, log, and reject all the matching packets.

```
[edit firewall]
user@R1# set family inet filter filter_if_group term term1 then count if_group_counter1
user@R1# set family inet filter filter_if_group term term1 then log
user@R1# set family inet filter filter_if_group term term1 then reject
```

5. Configure term **term2** to match packets with the ICMP protocol.

```
[edit firewall]
user@R1# set family inet filter filter_if_group term term2 from protocol icmp
```

6. Configure term **term2** to count, log, and accept all the matching packets.

```
[edit firewall]
user@R1# set family inet filter filter_if_group term term2 then count if_group_counter2
user@R1# set family inet filter filter_if_group term term2 then log
user@R1# set family inet filter filter_if_group term term2 then accept
```

7. Configure term **term3** to count all the transit packets.

```
[edit firewall]
user@R1# set family inet filter filter_if_group term term3 then count default
```

8. Apply the firewall filter to the router's (or switch's) interface group by applying it to the routing instance.

```
[edit]
user@R1# set forwarding-options family inet filter input filter_if_group
```

9. If you are done configuring the device, commit your candidate configuration.

```
[edit]
user@host# commit
```

Results

From configuration mode, confirm your configuration by issuing the **show interfaces**, **show firewall**, and **show forwarding-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@R1# show interfaces
ge-0/0/0 {
  unit 0 {
```

```

    family inet {
        filter {
            group 1;
        }
        address 172.16.17.2/30;
    }
}
ge-0/0/1 {
    unit 0 {
        family inet {
            address 172.16.19.2/30;
        }
    }
}
ge-0/0/2 {
    unit 0 {
        family inet {
            filter {
                group 1;
            }
            address 20.1.1.2/30;
        }
    }
}
lo0 {
    unit 0 {
        family inet {
            address 20.0.0.1/32;
        }
    }
}

```

```

[edit]
user@R1# show firewall
family inet {
    filter filter_if_group {
        term term1 {
            from {
                interface-group 1;
                protocol icmp;
            }
            then {
                count if_group_counter1;
            }
        }
    }
}

```

```
        log;
        reject;
    }
}
term term2 {
    from {
        protocol icmp;
    }
    then {
        count if_group_counter2;
        log;
        accept;
    }
}
term term3 {
    then count default;
}
}
```

```
[edit]
user@R1# show forwarding-options
family inet {
    filter {
        input filter_if_group;
    }
}
```

Verification

IN THIS SECTION

- [Verifying the Configuration of the Interfaces | 1195](#)
- [Verifying Stateless Firewall Filter Configuration | 1197](#)

Confirm that the configuration is working properly.

Verifying the Configuration of the Interfaces

Purpose

Verify that the interfaces are properly configured.

Action

To display the state of the interfaces, use the **show interfaces terse** operational mode command.

Device R0

```
user@R0> show interfaces terse
```

Interface	Admin	Link	Proto	Local	Remote
ge-0/0/0	up	up			
ge-0/0/0.0	up	up	inet	172.16.17.1/30	
			multiservice		
ge-0/0/1	up	up			
ge-0/0/1.0	up	up	inet	172.16.19.1/30	
			multiservice		
ge-0/0/2	up	up			
ge-0/0/2.0	up	up	inet	20.1.1.1/30	
			multiservice		
lo0	up	up			
lo0.0	up	up	inet	10.0.0.1	--> 0/0

Device R1

```
user@R1> show interfaces terse
```

Interface	Admin	Link	Proto	Local	Remote
ge-0/0/0	up	up			
ge-0/0/0.0	up	up	inet	172.16.17.2/30	
			multiservice		
...					
ge-0/0/1	up	up			
ge-0/0/1.0	up	up	inet	172.16.19.2/30

			multiservice		
...					

Meaning

All the interfaces on Devices R0 and R1 are physically connected and up. The interface group **1** on Device R1 consists of two interfaces, namely ge-0/0/0.0 and ge-0/0/2.0.

Verifying Stateless Firewall Filter Configuration

Purpose

Verify that the firewall filter match conditions are configured properly.

Action

- To display the firewall filter counters, enter the **show firewall filter filter_if_group** operational mode command.

```
user@R1> show firewall filter filter_if_group
```

```
Filter: filter_if_group
Counters:
Name                               Bytes           Packets
default                           192975          3396
if_group_counter1                  2520            30
if_group_counter2                  2604            41
```

- To display the local log of packet headers for packets evaluated by the firewall filter, enter the **show firewall log** operational mode command.

```
user@R1> show firewall log
```

```

Meaning

The stateless firewall filter is applied to all interfaces in interface group **1**. The term **term1** match condition in the stateless firewall filter counts, logs, and rejects packets that are received on or sent from the interfaces

in interface group **1** and with a source ICMP protocol. The term **term2** match condition matches packets tagged with the ICMP protocol and counts, logs, and accepts those packets. The term **term3** match condition counts all the transit packets.

Understanding Filter-Based Tunneling Across IPv4 Networks

Generic routing encapsulation (GRE) in its simplest form is the encapsulation of any network layer protocol over any other network layer protocol to connect disjointed networks that lack a native routing path between them. It is a connectionless and stateless Layer 3 encapsulation protocol, and it offers no mechanisms for reliability, flow control, or sequencing.

GRE tunneling is initiated with standard firewall filter actions. Traffic flows through the tunnel provided that the tunnel destination is routable. For MX series routers, this feature is also supported in logical systems.

For MX Series 5G Universal Routing Platforms, when you configure GRE tunneling with firewall filters, you do not need to create tunnel interfaces on Tunnel Services physical interface cards (PICs) or on MPC3E Modular Port Concentrators (MPCs). Instead, PFEs on the Modular Interface Cards (MICs) or MPCs handle the GRE payload encapsulation and decapsulation and provide the tunnel services to the relevant interfaces. As such, a pair of MX Series routers can be installed as provider edge (PE) routers to provide connectivity to customer edge (CE) routers on two disjoint networks.

For PTX Series routers, network services must be set to **enhanced-mode** for filter-based GRE tunneling to work. For more information on filter based tunneling on the PTX, see [tunnel-end-point](#).

Ingress Firewall Filter on the Ingress PE Router

On the ingress PE router, you configure a tunnel definition that specifies a unidirectional GRE tunnel. For MX series routers with a MIC or MPC ingress logical interface, you attach an encapsulating firewall filter. The firewall filter action references a tunnel definition and initiates the encapsulation of matched packets. The encapsulation process attaches an IPv4 header and a GRE header to the payload packet and then forwards the resulting GRE packet to the filter-specified tunnel.

Ingress Firewall Filter on the Egress PE Router

On the egress PE router, you attach a de-encapsulating firewall filter to the input of all MIC or MPC logical interfaces that are advertised addresses for the router. The firewall filter initiates the de-encapsulation of GRE protocol packets. De-encapsulation removes the inner GRE header and then forwards the original payload packet to its original destination on the destination customer network. If the action specifies an optional routing instance, route lookup is performed using that secondary table instead of the primary table.

Characteristics of Filter-Based Tunneling Across IPv4 Networks

Filter-based tunnels across IPv4 networks are unidirectional. They transport transit packets only, and they do not require tunnel interfaces.

Unidirectional Tunneling

To use filter-based GRE tunnels, start by attaching standard firewall filters at the *input* of each tunnel endpoint (at both the ingress PE router and the egress PE router). At the input to the ingress PE router, you apply an encapsulating firewall filter. At the input to the egress PE router, apply a de-encapsulating firewall filter.

Bidirectional Tunneling

For bidirectional GRE tunneling, you can use the same pair of PE routers, but you must configure a second tunnel in the reverse direction.

Transit Traffic Payloads

A filter-based GRE IPv4 tunnel can transport unicast or multicast transit traffic payloads only. Filter-initiated encapsulation and decapsulation operations execute on PFEs for Ethernet logical interfaces and aggregated Ethernet interfaces. This design enables more efficient use of PFE bandwidth as compared to GRE tunneling

using tunnel interfaces. Routing protocol sessions can not be configured on top of the firewall based tunnels.

The PFEs operate in the *forwarding plane* to process packets by forwarding them between input and output interfaces using a locally stored forwarding table, which is a local copy of the information from the Routing Engine (RE).

On the other hand, REs operate in the *control plane* to handle system management, user access to the router, and processes for routing protocols, router interface control, and some chassis component control. The Junos OS architecture separates the functions of these planes to enable flexibility of platform support and scalability of platform performance. Ingress control packets are directed to the control plane where the GRE encapsulation and de-encapsulation processes of the PFEs are not available.

Although you can apply firewall filters to loopback addresses, GRE encapsulating and de-encapsulating firewall filter actions are not supported on router loopback interfaces.

Compact Configuration for Multiple GRE Tunnels

Firewall filters support a wide variety of match criteria and, by extension, the ability to terminate multiple GRE tunnels that match criteria specified in a single firewall filter definition. By creating multiple tunnels, each with its own set of match conditions, you can create tunnels that do not interfere with customer GRE packets or with one another and that re-inject packets to separate routing tables after de-encapsulation.

Tunneling with Firewall Filters and Tunneling with Tunnel Interfaces

Tunneling with tunnel interfaces supports both router control traffic and transit traffic, as well as encryption. Tunneling with firewall filters does not. However, tunneling with firewall filters does provide benefits in performance and scaling.

Forwarding Performance

Filter-based tunneling across IPv4 networks enables more efficient use of PFE bandwidth as compared to GRE tunneling using tunnel interfaces. Encapsulation, de-encapsulation, and route lookup are packet header-processing activities that, for firewall filter-based tunneling, are performed on the PFE. Consequently, the encapsulator never needs to send payload packets to a separate tunnel interface (which might reside on a PIC in a different slot than the interface that receives payload packets).

Firewall Filter-Based L2TP Tunneling in IPv4 Networks Overview

IN THIS SECTION

- [Unidirectional Tunneling | 1206](#)
- [Tunnel Security | 1206](#)
- [Forwarding Performance | 1206](#)
- [Forwarding Scalability | 1206](#)

The Layer 2 Tunneling Protocol (L2TP) is a client-server protocol that allows the Point-to-Point Protocol (PPP) to be tunneled across a network. L2TP encapsulates Layer 2 packets, such as PPP, for transmission across a network. An L2TP access concentrator (LAC), configured on an access device, receives packets from a remote client and forwards them to an L2TP network server (LNS) on a remote network. L2TPv3 defines the base control protocol and encapsulation for tunneling multiple Layer 2 connections between two IPv6 nodes. The significant differences between L2TPv2 and L2TPv3 include the following:

- Separation of all PPP-related AVPs and references, which enables the inclusion of a portion of the L2TP data header that was specific to the needs of PPP.
- Transition from a 16-bit Session ID and Tunnel ID to a 32-bit Session ID and Control Connection ID respectively.
- Extension of the tunnel authentication mechanism to cover the entire control message rather than just a portion of certain messages.
- L2TPv3 is supported for IPv6 only.
- For firewall filters, only data plane L2TPv3 encapsulation/ decapsulation is supported.

L2TP is comprised of two types of messages, control messages and data messages (sometimes referred to as control packets and data packets respectively). Control messages are used in the establishment, maintenance, and clearing of control connections and sessions. These messages utilize a reliable control channel within L2TP to guarantee delivery. Data messages are used to encapsulate the L2 traffic being carried over the L2TP session.

You can configure an IPv4 network to transport IPv4, IPv6, or MPLS transit traffic by using GRE tunneling protocol mechanisms initiated by two standard firewall filter actions. This feature is also supported in logical systems. When you configure L2TP tunneling with firewall filters, you do not need to create tunnel interfaces on Tunnel Services physical interface cards (PICs) or on MPC3E Modular Port Concentrators (MPCs). Instead, Packet Forwarding Engines provide tunnel services to Ethernet logical interfaces or aggregated Ethernet interfaces hosted on Modular Interface Cards (MICs) or MPCs in MX Series 5G Universal Routing Platforms.

Two MX Series routers installed as provider edge (PE) routers provide connectivity to customer edge (CE) routers on two disjoint networks. MIC or MPC interfaces on the PE routers perform L2TP IPv4 encapsulation and de-encapsulation of payloads. After decapsulation, packets are sent to the local interface of a routing table specified in the action, or to the default routing table, based on the protocol field of the L2TP header. However, an L2TP packet can optionally be sent across the fabric with a token equal to an output interface index to perform Layer 2 cross- connect. You can specify the output interface specifier to be used for the L2TP packet to be sent by including the **decapsulate l2tp output-interface *interface-name* cookie l2tpv3-cookie** statement at the **[edit firewall family *family-name* filter *filter-name* term *term-name* then]** hierarchy level.

During decapsulation, the inner header must be Ethernet for L2TP tunnels. Forwarding class by default is applied before the firewall and it is not preserved for the decapsulated packet (by using the **forwarding-class *class-name*** statement at the **[edit firewall family *family-name*]** hierarchy level, which is a nonterminating filter action). However, you can specify the forwarding class that the packet must be classified against by including the filter action for a decapsulated packet by using the **decapsulate l2tp forwarding-class *class-name*** statement at the **[edit firewall family *family-name* filter *filter-name* term *term-name* then]** hierarchy level.

The following field definitions are defined for use in all L2TP Session Header encapsulations.

- The Session ID field is a 32-bit field containing a non-zero identifier for a session. L2TP sessions are named by identifiers that have local significance only. The same logical session will be given different Session IDs by each end of the control connection for the life of the session. When the L2TP control connection is used for session establishment, Session IDs are selected and exchanged as Local Session ID AVPs during the creation of a session. The Session ID alone provides the necessary context for all further packet processing, including the presence, size, and value of the Cookie, the type of L2-Specific Sublayer, and the type of payload being tunneled.
- The optional Cookie field contains a variable-length value (maximum 64 bits) used to check the association of a received data message with the session identified by the Session ID. The Cookie field must be set to the configured or signaled random value for this session. The Cookie provides an additional level of guarantee that a data message has been directed to the proper session by the Session ID. A well-chosen Cookie might prevent inadvertent misdirection of random packets with recently reused Session IDs or for Session IDs subject to packet corruption. The Cookie might also provide protection against some specific malicious packet insertion attacks. When the L2TP control connection is used for session establishment, random Cookie values are selected and exchanged as Assigned Cookie AVPs during session creation.

A session is a logical connection created between the LAC and the LNS when an end-to-end PPP connection is established between a remote system and the LNS. There is a one-to-one relationship between established L2TP sessions and their associated PPP connections. A tunnel is an aggregation of one or more L2TP sessions.

Starting with Junos OS Release 15.1, decapsulation of IP packets that are sent through an L2TP tunnel with standard firewall filter match conditions and actions specified is performed using a Layer 3 lookup.

In Junos OS release 14.2 and earlier, decapsulation of traffic over an L2TP tunnel with firewall filter actions configured is performed using Layer 2 interface properties.

Unidirectional Tunneling

Filter-based L2TP tunnels across IPv4 networks are unidirectional. They transport transit packets only, and they do not require tunnel interfaces. Although you can apply firewall filters to loopback addresses, GRE encapsulating and de-encapsulating firewall filter actions are not supported on router loopback interfaces. Filter-initiated encapsulation and decapsulation operations of L2TP packets execute on Packet Forwarding Engines for Ethernet logical interfaces and aggregated Ethernet interfaces. This design enables more efficient use of Packet Forwarding Engine bandwidth as compared to GRE tunneling using tunnel interfaces. Routing protocol sessions can not be configured on top of the firewall based tunnels.

Tunnel Security

Filter-based tunneling across IPv4 networks is not encrypted. If you require secure tunneling, you must use IP Security (IPsec) encryption, which is not supported on MIC or MPC interfaces. However, Multiservices DPC (MS-DPC) interfaces on MX240, MX480, and MX960 routers support IPsec tools for configuring manual or dynamic security associations (SAs) for encryption of data traffic as well as traffic destined to or originating at the Routing Engine.

Forwarding Performance

Filter-based tunneling across IPv4 networks enables more efficient use of Packet Forwarding Engine bandwidth as compared to L2TP tunneling using tunnel interfaces. Encapsulation, de-encapsulation, and route lookup are packet header-processing activities that, for firewall filter-based tunneling, are performed on the Junos Trio chipset-based Packet Forwarding Engine. Consequently, the encapsulator never needs to send payload packets to a separate tunnel interface (which might reside on a PIC in a different slot than the interface that receives payload packets).

Forwarding Scalability

Forwarding L2TP traffic with tunnel interfaces requires traffic to be sent to a slot that hosts the tunnel interfaces. When you use tunnel interfaces to forward GRE traffic, this requirement limits the amount of traffic that can be forwarded per GRE tunnel destination address. As an example, suppose you want to send 100 Gbps of L2TP traffic from Router A to Router B and you have only 10 Gbps interfaces. To ensure that your configuration does not encapsulate all the traffic on the same board going to the same 10 Gbps interface, you must distribute the traffic across multiple encapsulation points.

Release History Table

Release	Description
15.1	Starting with Junos OS Release 15.1, decapsulation of IP packets that are sent through an L2TP tunnel with standard firewall filter match conditions and actions specified is performed using a Layer 3 lookup.
14.2	In Junos OS release 14.2 and earlier, decapsulation of traffic over an L2TP tunnel with firewall filter actions configured is performed using Layer 2 interface properties.

Interfaces That Support Filter-Based Tunneling Across IPv4 Networks

IN THIS SECTION

- [Interfaces on MX240, MX480, MX960, MX2010, and MX2020 Routers | 1208](#)
- [Interfaces on MX5, MX10, MX40, and MX80 Routers | 1208](#)
- [CLI Commit Check for Filter-Based Tunneling Across IPv4 Networks | 1209](#)

You can attach IPv4 encapsulation and de-encapsulation firewall filters to the input of Ethernet logical interfaces or aggregated Ethernet interfaces hosted on Modular Interface Cards (MICs) or Modular Port Concentrators (MPCs) in MX Series routers.

NOTE: Filter-based generic routing encapsulation (GRE) tunneling is supported on PTX Series routers only when network services is set to **enhanced-mode**. For more information, see **enhanced-mode**.

Interfaces on MX240, MX480, MX960, MX2010, and MX2020 Routers

On MX240, MX480, MX960, MX2010, and MX2020 routers, firewall filter actions for IPv4 tunneling are supported on Ethernet logical interfaces or aggregated Ethernet interfaces configured on the following types of ports:

- Ports on MICs that insert into slots in MPCs, which have two Packet Forwarding Engines.
- Ports on a 16-port 10-Gigabit Ethernet MPC (MPC-3D-16XGE-SFPP), a specialized fixed-configuration MPC that has four Packet Forwarding Engines and contains no slots for MICs.

For these physical interfaces, Trio chipset-based Packet Forwarding Engine processes operate in *fabric mode* to provide forwarding and storage functions and lookup and processing functions between Ethernet interfaces and the routing fabric of the chassis.

For information about MPCs, see *MX Series MPC Overview* and *MPCs Supported by MX Series Routers*. For information about MICs, see *MX Series MIC Overview* and *MICs Supported by MX Series Routers*.

Interfaces on MX5, MX10, MX40, and MX80 Routers

On the MX Series midrange family of routers (MX5, MX10, MX40, and MX80 routers), firewall filter actions for IPv4 tunneling are supported on Ethernet logical interfaces and aggregated Ethernet interfaces configured on ports on a built-in MIC or on MICs that install into dedicated slots in the router chassis.

- The MX80 router—available as a modular (MX80) or fixed (MX80-48T) chassis—has a built-in 4-port 10-Gigabit Ethernet MIC. The modular chassis has two dedicated slots for MICs. The fixed chassis has 48 built-in tri-rate (10/100/1000Base-T) RJ-45 ports in place of two front-pluggable MIC slots.
- On the MX40 router, only the first two of the four built-in 10-Gigabit Ethernet MIC ports are enabled. As with the modular MX80, the two front-pluggable MIC slots are enabled and support dual-wide MICs that span the two slots.
- The MX5 and MX10 routers are pre-populated with a front-pluggable 20-port Gigabit Ethernet MIC with SFP, and none of the four built-in 10-Gigabit Ethernet MIC ports is enabled. The MX10 supports MICs in both front-pluggable slots, but the MX5 supports MICs in the second slot only.

For more information, see *MX5, MX10, MX40, and MX80 Modular Interface Card Description*.

The MX Series midrange routers have no switching fabric, and the single Packet Forwarding Engine resides on the base board of the chassis and operates in *standalone mode*. In standalone mode, the Packet

Forwarding Engine provides—in addition to forwarding and storage functions and lookup and processing functions—hierarchical queuing, congestion management, and granular statistical functions.

CLI Commit Check for Filter-Based Tunneling Across IPv4 Networks

If you commit a configuration that attaches an encapsulating or de-encapsulating firewall filter to an interface that does not support filter-based tunneling across IPv4 networks, a system event writes a syslog warning message that the interface does not support the filter.

Topology of Filter-Based Tunneling Across IPv4 Networks

NOTE: Filter-based generic routing encapsulation (GRE) tunneling is supported on PTX Series routers only when network services is set to **enhanced-mode**. For more information, see **enhanced-mode**.

Figure 58 on page 1210 shows the path of passenger protocol packets from customer network C1 as they are transported across a service provider IPv4 network to customer network C2.

Figure 58: Unidirectional Filter-Based Tunnel Across an IPv4 Network

In this example topology, C1 and C2 are disjoint networks that lack a native routing path between them. The IPv4 transport network is configured with a unidirectional generic routing encapsulation (GRE) tunnel from PE1 to PE2 using firewall filters and without requiring tunnel interfaces. The GRE tunnel from PE1 to PE2 provides a logical path from C1 to C2 across the IPv4 transport network.

Routing of GRE Packets Across the Tunnel

Traffic flows through the tunnel provided that PE2 is routable from PE1. Routing paths from PE1 to PE2 can be provided by static routes manually added to routing tables or by static or dynamic route-sharing protocols.

Routing of Passenger Protocol Packets from PE2 to C2

By default, PE2 forwards packets based on interface routes (direct routes) imported from the primary routing table. As an option, the de-encapsulating filter can specify that the Packet Forwarding Engine uses an alternate routing table to forward payload packets to the destination customer network. Specify the alternate routing table in a routing instance installed with routes into C2, then use a routing information base (RIB) group definition to share the primary routes with the alternate routes. A RIB group specifies the sharing of routing information (including routes learned from peers, local routes resulting from the application of protocol policies to the learned routes, and the routes advertised to peers) of multiple routing tables.

Terminology at the Network Layer Protocols Level

In filter-based tunneling across an IPv4 network, the network-layer protocols are described in the following terms:

passenger protocol—The type of protocol (IPv4, IPv6, or MPLS) used by the networks that are connected by a GRE tunnel. Packets that are encapsulated and routed across the transport network are *payload packets*.

encapsulation protocol—The type of network layer protocol (GRE) used to encapsulate passenger protocol packets so that the resulting GRE packets can be carried over the transport protocol network as the packet payload.

transport protocol—The type of protocol (IPv4) used by the network that routes passenger protocol packets through a GRE tunnel. The transport protocol is also called the *delivery protocol*.

Terminology at the Ingress PE Router

In filter-based tunneling across an IPv4 network, an egress PE router is described in the following terms:

encapsulator—A PE router that receives packets from a passenger protocol source network, adds an encapsulation protocol (GRE) header and a transport protocol (IPv4) header to this payload, and forwards the resulting GRE packet to the GRE tunnel. This ingress node is also known as the *tunnel source*.

encapsulating interface—On the encapsulator, an Ethernet logical interface or an aggregated Ethernet interface configured on a customer-facing interface hosted on a MIC or an MPC. The encapsulating interface receives passenger protocol packets from a CE router. For more information, see [“Interfaces That Support Filter-Based Tunneling Across IPv4 Networks” on page 1207](#).

encapsulation filter—On the encapsulator, a firewall filter that you apply to the input of the encapsulating interface. The encapsulating filter action causes the Packet Forwarding Engine to use information in the specified tunnel template to encapsulate matched packets and forward the resulting GRE packets.

tunnel source interface—On the encapsulator, one or more core-facing egress interfaces to the tunnel.

tunnel template—On the encapsulator, a named CLI construct that defines the characteristics of a tunnel:

- Transport protocol family (IPv4).
- IP address or address range of tunnel-facing *egress* interfaces on the encapsulator.
- IP address or address range of tunnel-facing *ingress* interfaces on the de-encapsulator (the egress PE router).
- Encapsulation protocol (GRE).

Terminology at the Egress PE Router

In filter-based tunneling across IPv4 networks, an egress PE router is described in the following terms:

de-encapsulator—A PE router that receives GRE packets routed through a filter-based GRE tunnel, removes the transport protocol header and GRE header, and forwards the resulting payload protocol packets to the destination network CE router. The de-encapsulator node is also known as a *de-encapsulating tunnel endpoint* or the *tunnel destination*.

de-encapsulating interfaces—On the de-encapsulator, any Ethernet logical interface or aggregated Ethernet interface configured on any core-facing ingress interface that can receive GRE packets from a GRE tunnel. The underlying physical interface must be hosted on a MIC or an MPC. For more information, see [“Interfaces That Support Filter-Based Tunneling Across IPv4 Networks” on page 1207](#).

de-encapsulation filter—On the de-encapsulator, a firewall filter that causes the Packet Forwarding Engine to de-encapsulate matched GRE packets and then forward the original passenger protocol packets to destination network CE routers.

GRE packets transported through a single GRE tunnel can arrive at the de-encapsulator node on any of multiple ingress interfaces, depending on how routing is configured. Therefore, you must apply the de-encapsulation firewall filter to the input of every core-facing interface that is an advertised address for the de-encapsulator.

GRE Protocol Format for Filter-Based Tunneling Across IPv4 Networks

In filter-based tunneling across IPv4 networks, the encapsulating interface is an *RFC 1701-compliant transmitter* and the de-encapsulating interfaces are *RFC 1701-compliant receivers*. The packet encapsulation structure implemented in this feature uses a GRE header format that complies with informational RFC 1701, *Generic Routing Encapsulation (GRE)*, October 1994, and with standards track RFC 2784, *Generic Routing Encapsulation (GRE)*, March 2000.

Packet Encapsulation Structure

Filter-based tunneling encapsulates the original passenger protocol packet in an outer shell. For filter-based tunneling across IPv4 networks, the shell adds 24 bytes or 28 bytes of overhead, including 20 bytes of IPv4 header. [Figure 59 on page 1213](#) shows the structure of a passenger protocol packet (the GRE payload) with a GRE header and IPv4 header attached.

Figure 59: Encapsulation Structure for Filter-Based Tunneling Across an IPv4 Network

As specified in RFC 1701, five GRE flag bits indicate whether a particular GRE header includes any optional fields (Checksum, Offset, Key, Sequence Number, and Routing). Of the five optional fields, filter-based GRE IPv4 tunneling uses the Key field only.

GRE Header Format

Figure 60 on page 1213 shows the format of the variable-size GRE header used for filter-based tunneling across IPv4 networks, with bit 0 the most significant bit and bit 15 the least significant bit.

Figure 60: GRE Header Format for Filter-Based Tunneling Across IPv4 Networks

The first two octets encode GRE flags, as described in Table 70 on page 1213.

The 2-octet Protocol Type field contains the value 0x0800 to specify the EtherType value for the IPv4 protocol.

The 4-octet Key field is included only if the Key Present bit is set to 1. The Key field carries the key value of the tunnel defined on the encapsulator. If the GRE tunnel definition specifies a key, the Packet Forwarding Engine for the encapsulating endpoint sets the Key Present bit and adds the Key to the GRE header.

Table 70: GRE Flag Values for Filter-Based Tunneling Across IPv4 Networks

Bit Offset and Field Name		Transmitted Value for Filter-Based GRE Tunneling	
0	C = Checksum Present	0	Checksum field is not used.
1	R = Routing Present	0	Offset and Routing fields are not used.
2	K = Key Present	0 or 1	Transmitted as 0 for a keyless tunnel or 1 for a keyed tunnel.

Table 70: GRE Flag Values for Filter-Based Tunneling Across IPv4 Networks (*continued*)

Bit Offset and Field Name		Transmitted Value for Filter-Based GRE Tunneling	
3	S = Sequence Number Present	0	Sequence Number field is not used.
4	s = Strict Source Route	0	Not all routing information is Strict Source Routes.
5 - 7	Recur = Recursion Control information	000	No additional encapsulations are permitted.
8 - 12	Flags = Flag bits	00000	Reserved.
13 - 15	Ver = Version number	000	Reserved.

When the Packet Forwarding Engine performs encapsulation for a keyed GRE IPv4 tunnel, the process constructs the first two octets of the GRE header as 0x0000. When the Packet Forwarding Engine performs encapsulation for a non-keyed GRE IPv4 tunnel, the process constructs the first two octets of the GRE header as 0x2000.

Example: Transporting IPv6 Traffic Across IPv4 Using Filter-Based Tunneling

IN THIS SECTION

● [Requirements | 1215](#)

● [Overview | 1216](#)

● [Configuration | 1219](#)

● [Verification | 1230](#)

This example shows how to configure a unidirectional generic routing encapsulation (GRE) tunnel to transport IPv6 unicast transit traffic across an IPv4 transport network. To provide network connectivity to the two disjoint IPv6 networks, two MX Series 5G Universal Routing Platforms are configured with interfaces that can originate and understand both IPv4 and IPv6 packets. The configuration does not require the creation of tunnel interfaces on Tunnel Services physical interface cards (PICs) or on MPC3E Modular Port Concentrators (MPCs). Instead, you attach firewall filters to Ethernet logical interfaces hosted on Modular Interface Cards (MICs) or MPCs in the two MX Series routers.

NOTE: Filter-based GRE tunneling is supported on PTX Series routers only when network services is set to **enhanced-mode**. For more information, see **enhanced-mode**.

Requirements

This example uses the following Juniper Networks hardware and Junos OS software:

- Transport network—An IPv4 network running Junos OS Release 12.3R2 or later.
- PE routers—Two MX80 routers installed as provider edge (PE) routers that connect the IPv4 network to two disjoint IPv6 networks that require a logical path from one network to the other.
- Encapsulating interface—On the encapsulator (the ingress PE router), one Ethernet logical interface configured on the built-in 10-Gigabit Ethernet MIC.
- De-encapsulating interfaces—On the de-encapsulator (the egress PE router), Ethernet logical interfaces configured on three ports of the built-in 10-Gigabit Ethernet MIC.

Before you begin configuring this example:

1. On each PE router, use the **show chassis fpc pic-status** operational mode command to determine which router line cards support filter-based GRE IPv4 tunneling and then use the **interfaces** configuration statement to configure encapsulating and de-encapsulating interfaces.
 - At PE1, the encapsulator, configure *one encapsulating interface* on a supported line card.
 - At PE2, the de-encapsulator, configure *three de-encapsulating interfaces* on a supported line card.
2. Check that IPv4 routing protocols are enabled across the network to support routing paths from the encapsulator to the de-encapsulator.

Configure routing information by manually adding static routes to route tables or by configuring static or dynamic route-sharing protocols. For more information, see *Transport and Internet Protocols User Guide for Routing Devices*.

3. At PE1, *ping* the PE2 IPv4 loopback address to verify that the de-encapsulator is reachable from the encapsulator.
4. At PE2, *ping* the CE2 router IPv6 loopback address to verify that the destination customer edge router is reachable from the de-encapsulator..

IPv6 routing paths from PE2 to CE2 can be provided by static routes manually added to routing tables or by static or dynamic route-sharing protocols.

- By default, PE2 forwards packets based on interface routes (direct routes) imported from the primary routing table.
- As an option, the de-encapsulating filter can specify that the Packet Forwarding Engine uses an alternate routing table to forward payload packets to the destination customer network. In an optional configuration task in this example, you specify an alternate routing table by installing static routes from PE2 to C1 in the routing instance **blue**. You configure the routing information base (RIB) group **blue_group** to specify that the route information of **inet6.0** is shared with **blue.inet6.0**, then you associate the PE2 interfaces with routes stored in both the default routes and the routing instance.

Overview

In this example you configure a unidirectional filter-based GRE IPv4 tunnel from Router PE1 to Router PE2, providing a logical path from IPv6 network C1 to IPv6 network C2.

NOTE: To enable *bidirectional* filter-based GRE tunneling, you must configure a second tunnel in the reverse direction.

As an optional task in this example, you can create a RIB group, which specifies the sharing of routing information (including routes learned from peers, local routes resulting from the application of protocol policies to the learned routes, and the routes advertised to peers) of multiple routing tables.

Topology

[Figure 61 on page 1217](#) shows the path of IPv6 traffic transported from network C1 to network C2, across an IPv4 transport network using a filter-based tunnel from PE1 to PE2 and without requiring tunnel interfaces.

Figure 61: Filter-Based Tunnel from PE1 to PE2 in an IPv4 Network

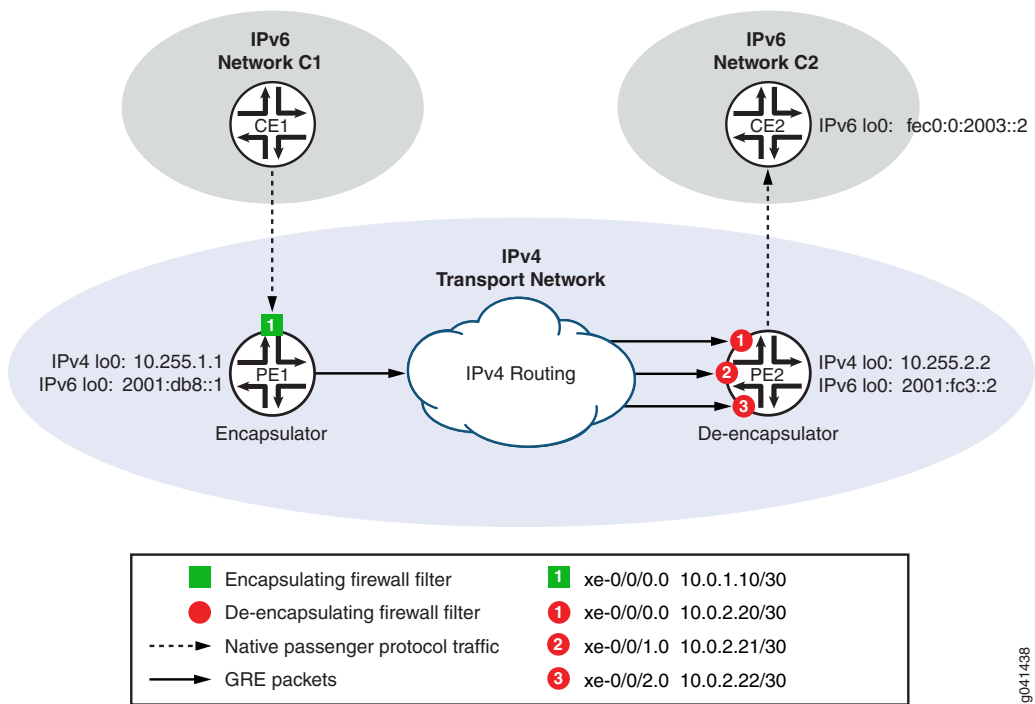

Table 71 on page 1218 summarizes the configuration of Router PE1 as the encapsulator. Table 72 on page 1219 summarizes the configuration of Router PE2 as the de-encapsulator.

Table 71: Encapsulator Components on PE1

Component	CLI Names		Description
Encapsulator	Device name: IPv4 loopback: IPv6 loopback:	PE1 10.255.1.1 2001:db8::1	MX80 router installed as an ingress PE router. PE1 connects the IPv4 network the customer edge router CE1 in the IPv6 source network C1.
Encapsulating interface	Interface name: IPv4 address: IPv6 address:	xe-0/0/0.0 10.0.1.10/30 ::10.34.1.10/120	Customer-facing logical interface hosted on a 10-Gigabit Ethernet MIC. CE1 sends this interface IPv6 traffic that originates at end-user hosts and is destined for applications or hosts on the IPv6 destination network C2.
Encapsulation filter	Filter name:	gre_encap_1	IPv6 firewall filter whose action causes the Packet Forwarding Engine to encapsulate matched packets using the specified tunnel characteristics. Encapsulation consists of adding a GRE header, adding an IPv4 packet header, and then forwarding the resulting GRE packet through the GRE IPv4 tunnel.
Tunnel source interface	Interface name: IPv4 address:	xe-0/0/2.0 10.0.1.12	Core-facing egress interface to the tunnel.
GRE tunnel template	Tunnel name:	tunnel_1	Defines the GRE IPv4 tunnel from Router PE1 (10.255.1.1) to Router PE2(10.255.2.2), using the tunneling protocol supported on IPv4 (gre).

Table 72: De-Encapsulator Components on PE2

Component	CLI Names		Description
De-encapsulator	Device name: IPv4 loopback: IPv6 loopback:	PE2 10.255.2.2 2001:fc3::2	MX80 router installed as an egress PE router to receive GRE packets forwarded from ingress router PE1 across a GRE IPv4 tunnel.
De-encapsulating interfaces	Interface name: IPv4 address: Interface name: IPv4 address: Interface name: IPv4 address:	xe-0/0/0.0 10.0.2.24/30 xe-0/0/1.0 10.0.2.21/30 xe-0/0/2.0 10.0.2.22/30	Core-facing ingress logical interfaces hosted on 10-Gigabit Ethernet MICs. The interfaces receive GRE packets routed through the GRE IPv4 tunnel from PE1.
De-encapsulation filter	Filter name:	gre_decap_1	IPv4 firewall filter that applies the decapsulate action to GRE packets. The filter action causes the Packet Forwarding Engine to de-encapsulate matched packets. De-encapsulation consists of removing the outer GRE header and then forwarding the inner IPv6 payload packet to its original destination on the destination IPv6 network by performing destination lookup on the default routing table.
Tunnel egress interface	Interface name: IPv4 address: IPv6 address:	xe-0/0/3.0 10.0.2.23/30 ::20.34.2.23/120	Customer-facing interface through which the router forwards de-encapsulated IPv6 packets to the destination IPv6 network C2.

Configuration

IN THIS SECTION

- [Configuring PE1 to Encapsulate IPv6 Packets | 1221](#)
- [Configuring PE2 to De-Encapsulate GRE Packets | 1224](#)
- [Optional: Configuring PE2 with an Alternate Routing Table | 1228](#)

To transport IPv6 packets from CE1 to CE2 across an IPv4 transport network using a filter-based tunnel from PE1 to PE2 and without configuring tunnel interfaces, perform these tasks:

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

Configuring PE1 to Encapsulate IPv6 Packets

```
set interfaces lo0 unit 0 family inet address 10.255.1.1
set interfaces lo0 unit 0 family inet6 address 2001:db8::1
set interfaces xe-0/0/0 unit 0 family inet address 10.0.1.10/30
set interfaces xe-0/0/0 unit 0 family inet6 address 2001::10.34.1.10/120
set interfaces xe-0/0/0 unit 0 family inet6 filter input gre_encap_1
set interfaces xe-0/0/2 unit 0 family inet address 10.0.1.12/30
set firewall family inet6 filter gre_encap_1 term t1 then count c_gre_encap_1
set firewall family inet6 filter gre_encap_1 term t1 then encapsulate tunnel_1
set firewall tunnel-end-point tunnel_1 ipv4 source-address 10.255.1.1
set firewall tunnel-end-point tunnel_1 ipv4 destination-address 10.255.2.2
set firewall tunnel-end-point tunnel_1 gre
```

Configuring PE2 to De-Encapsulate GRE Packets

```
set interfaces lo0 unit 0 family inet address 10.255.2.2
set interfaces lo0 unit 0 family inet6 address 2001:fc3::2
set interfaces xe-0/0/0 unit 0 family inet address 10.0.2.20/30
set interfaces xe-0/0/1 unit 0 family inet address 10.0.2.21/30
set interfaces xe-0/0/2 unit 0 family inet address 10.0.2.22/30
set interfaces xe-0/0/3 unit 0 family inet address 10.0.2.23/30
set interfaces xe-0/0/3 unit 0 family inet6 address ::20.34.2.23/120
set forwarding-options family inet filter input gre_decap_1
set firewall family inet filter gre_decap_1 term t1 from source-address
10.255.1.1/32
```

```
set firewall family inet filter gre_decap_1 term t1 from destination-address
10.255.2.2/32
```

```
set firewall family inet filter gre_decap_1 term t1 then count c_gre_decap_1
```

```
set firewall family inet filter gre_decap_1 term t1 then decapsulate gre
```

Optional: Configuring PE2 with an Alternate Routing Table

```
set routing-instances blue instance-type forwarding
```

```
set routing-instances blue routing-options rib blue.inet6.0 static route 0::/0
next-hop fec0:0:2003::2
```

```
set routing-options passive
```

```
set routing-options rib inet6.0
```

```
set routing-options rib-groups blue_group import-rib inet6.0
```

```
set routing-options rib-groups blue_group import-rib blue.inet6.0
```

```
set routing-options interface-routes rib-group inet6 blue_group
```

```
set firewall family inet filter gre_decap_1 term t1 then decapsulate gre
routing-instance blue
```

Configuring PE1 to Encapsulate IPv6 Packets

Step-by-Step Procedure

To configure Router PE1 to encapsulate IPv6 packets arriving from CE1:

1. Configure the router loopback addresses.

```
[edit]
user@PE1# set interfaces lo0 unit 0 family inet address 10.255.1.1
user@PE1# set interfaces lo0 unit 0 family inet6 address 2001:db8::1
```

2. Configure the encapsulating interface IPv4 and IPv6 addresses and attach the encapsulating filter to the IPv6 input.

```
[edit]
user@PE1# set interfaces xe-0/0/0 unit 0 family inet address 10.0.1.10/30
user@PE1# set interfaces xe-0/0/0 unit 0 family inet6 address ::10.34.1.10/120
user@PE1# set interfaces xe-0/0/0 unit 0 family inet6 filter input gre_encap_1
```

3. Configure the core-facing egress interface to the tunnel.

```
[edit]
user@PE2# set interfaces xe-0/0/2 unit 0 family inet address 10.0.1.12/30
```

4. Define an IPv6 firewall filter that causes the Packet Forwarding Engine to encapsulate all packets.

```
[edit]
user@PE1# set firewall family inet6 filter gre_encap_1 term t1 then count c_gre_encap_1
user@PE1# set firewall family inet6 filter gre_encap_1 term t1 then encapsulate tunnel_1
```

NOTE: The **encapsulate** firewall filter action is a *terminating* filter action. A filter-terminating action halts all evaluation of a firewall filter for a specific packet. The router performs the specified action, and no additional terms are examined.

5. Define a GRE IPv4 tunnel template named tunnel_1 that specifies the host IP addresses of the one tunnel source interface and three tunnel destination interfaces.

```
[edit]
user@PE1# set firewall tunnel-end-point tunnel_1 ipv4 source-address 10.255.1.1
user@PE1# set firewall tunnel-end-point tunnel_1 ipv4 destination-address 10.255.2.2
user@PE1# set firewall tunnel-end-point tunnel_1 gre
```

NOTE: You can tunnel multiple but distinct flows from 10.0.1.10 (the tunnel source interface on PE1) to 10.0.2.20 – 10.0.2.22 (the de-encapsulating interfaces on PE2) if you use the GRE option **key number** to uniquely identify each tunnel.

6. If you are done configuring the device, commit the configuration.

```
[edit]
user@PE1# commit
```

Results

From configuration mode, confirm your configuration by entering the **show firewall** and **show interfaces** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

Router PE1

Confirm the firewall filter and tunnel template on the encapsulator.

```
user@PE2# show firewall
family inet6 {
  filter gre_encap_1 {
    term t1 {
      then {
        count c_gre_encap_1;
        encapsulate tunnel_1;
      }
    }
  }
}
tunnel-end-point tunnel_1 {
  ipv4 {
    source-address 10.255.1.1;
    destination-address 10.255.2.2;
  }
  gre;
}
```

Router PE1

Confirm the interfaces on the encapsulator.

```
user@PE1# show interfaces
lo0 {
  unit 0 {
    family inet {
      address 10.255.1.1;
    }
    family inet6 {
      address 2001:db8::1;
    }
  }
}
```

```

}
xe-0/0/0 {
  unit 0 {
    family inet {
      address 10.0.1.10/30;
    }
    family inet6 {
      address ::10.34.1.10/120;
      filter input gre_encap_1;
    }
  }
}
xe-0/0/2 {
  unit 0 {
    family inet {
      address 10.0.1.12/30;
    }
  }
}

```

Configuring PE2 to De-Encapsulate GRE Packets

Step-by-Step Procedure

To configure Router PE2 to de-encapsulate GRE packets arriving from the IPv4 tunnel:

1. Configure the router loopback address.

```

[edit]
user@PE2# set interfaces lo0 unit 0 family inet address 10.255.2.2
user@PE2# set interfaces lo0 unit 0 family inet6 address 2001:fc3::2

```

2. Configure the de-encapsulating interfaces.

```

[edit]
user@PE2# set interfaces xe-0/0/0 unit 0 family inet address 10.0.2.20/30
user@PE2# set interfaces xe-0/0/1 unit 0 family inet address 10.0.2.21/30
user@PE2# set interfaces xe-0/0/2 unit 0 family inet address 10.0.2.22/30

```

3. Configure the customer-facing egress interface to CE2.

```
[edit]
user@PE2# set interfaces xe-0/0/3 unit 0 family inet address 10.0.2.23/30
user@PE2# set interfaces xe-0/0/3 unit 0 family inet6 address ::20.34.2.23/120
```

4. Apply the ingress de-encapsulating firewall filter to all forwarded packets.

```
[edit]
user@PE2# set forwarding-options family inet filter input gre_decap_1
```

5. Define IPv4 filter **gre_decap_1**.

Define an IPv4 filter that de-encapsulates and forwards all GRE packets.

```
[edit]
user@PE2# set firewall family inet filter gre_decap_1
```

6. Configure term **t1** to match packets transported across the tunnel **tunnel_1** defined on Router PE1. The tunnel sends packets from Router PE1 (configured with IPv4 loopback address 10.255.1.1) to Router PE2 (configured with IPv4 loopback address 10.255.2.2).

```
[edit firewall family inet filter gre_decap_1]
user@PE2# set term t1 from source-address 10.255.1.1
user@PE2# set term t1 from destination-address 10.255.2.2
```

7. Configure term **t1** to count and de-encapsulate matched packets.

```
[edit firewall family inet filter gre_decap_1]
user@PE2# set term t1 then count c_gre_decap_1
user@PE2# set term t1 then decapsulate gre
```

If the de-encapsulating filter action **decapsulate** references the **blue** routing instance, make sure that the routing instance is configured and that the RIB group **blue_group** defines the sharing of the alternate routes into the primary table.

8. If you are done configuring the device, commit the configuration.

```
[edit]
user@PE2# commit
```

Results

From configuration mode, confirm your configuration by entering the **show firewall**, **show forwarding-options**, and **show interfaces** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

Router PE2

Confirm the firewall filter on the de-encapsulator.

```
user@PE2# show firewall
family inet {
  filter gre_decap_1 {
    term t1 {
      from {
        source-address 10.255.1.1;
        destination-address 10.255.2.2;
      }
      then {
        count c_gre_decap_1;
        decapsulate gre routing-instance blue;
      }
    }
  }
}
```

NOTE: If the de-encapsulating filter action **decapsulate** references the **blue** routing instance, make sure that the routing instance is configured and that the RIB group **blue_group** defines the sharing of the alternate routes into the primary table.

Router PE2

Confirm the forwarding options (for attaching the de-encapsulating firewall filter to all input forwarded packets) on the de-encapsulator.

```
user@PE2# show forwarding-options
forwarding-options {
  family inet {
    filter {
      input gre_decap_1;
    }
  }
}
```

Router PE2

Confirm the interfaces on the de-encapsulator.

```
user@PE2# show interfaces
lo0 {
  unit 0 {
    family inet {
      address 10.255.2.2;
    }
    family inet6 {
      address 2001:fc3::2;
    }
  }
}
xe-0/0/0 {
  unit 0 {
    family inet {
      address 10.0.2.20/30;
      filter input gre_decap_1;
    }
  }
}
xe-0/0/1 {
  unit 0 {
    family inet {
      address 10.0.2.21/30;
      filter input gre_decap_1;
    }
  }
}
```

```

    }
  }
}
xe-0/0/2 {
  unit 0 {
    family inet {
      address 10.0.2.22/30;
      filter input gre_decap_1;
    }
  }
}
xe-0/0/3 {
  unit 0 {
    family inet {
      address 10.0.2.23/30;
    }
    family inet6 {
      address ::20.34.2.23/120;
    }
  }
}
}

```

Optional: Configuring PE2 with an Alternate Routing Table

Step-by-Step Procedure

To configure Router PE2 with an alternate routing table:

1. Configure the routing instance **blue**, and add static routes to CE2.

```

[edit ]
user@PE2# set routing-instances blue instance-type forwarding
user@PE2# set routing-instances blue routing-options rib blue.inet6.0 static route 0::/0 next-hop
fec0:0:2003::2

```

The Junos OS software generates the routing table **blue.inet6.0** using the routing information learned within the instance.

2. Enable routes to remain in routing and forwarding tables, even if the routes become inactive. This allows a static route to remain in the table if the next hop is unavailable.

```

[edit ]

```

```
user@PE2# set routing-options passive
```

3. Create a RIB group by explicitly creating the default routing table.

```
[edit ]
user@PE2# set routing-options rib inet6.0
```

4. Define the RIB group **blue_group**.

```
[edit ]
user@PE2# set routing-options rib-groups blue_group import-rib inet6.0
user@PE2# set routing-options rib-groups blue_group import-rib blue.inet6.0
```

In the **import-rib** statement, specify the primary routing table first.

5. Associate the router interfaces with routing information specified by the RIB group.

```
[edit ]
user@PE2# set routing-options interface-routes rib-group inet6 blue_group
```

6. If you are done configuring the device, commit the configuration.

```
[edit ]
user@PE2# commit
```

Results

From configuration mode, confirm your configuration by entering the **show firewall**, **show routing-instances**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

Router PE2

If you configured an alternate routing table on Router PE2, confirm the routing instance configuration.

```
user@PE2# show routing-instances
blue {
```

```
instance-type forwarding;
routing-options {
    static route 0::/0 next-hop fec0:0:2003::2;
}
}
```

Router PE2

If you configured an alternate routing table on Router PE2, confirm the RIB group and direct routing configurations.

```
user@PE2# show routing-options
interface-routes {
    rib-group blue_group;
}
passive;
rib inet6.0;
rib-groups {
    blue_group {
        import-rib [ inet6.0 blue.inet6.0 ];
    }
}
```

Verification

IN THIS SECTION

- [Verifying Routing Information | 1231](#)
- [Verifying Encapsulation on PE1 | 1232](#)
- [Verifying De-Encapsulation on PE2 | 1233](#)

Confirm that the configurations are working properly.

Verifying Routing Information

Purpose

Verify that the direct routes include the alternate routing table information.

Action

To perform the verification:

1. (Optional) To verify the routing instance **blue** on PE2, use the **show route instance** operational mode command to display the primary table and number of routes for that routing instance.

```
user@PE2> show route instance blue summary
```

Instance	Type	Active/holddown/hidden
Primary RIB		
blue	forwarding	
blue.inet6.0		2/0/0

2. (Optional) To view the routing table associated with the routing instance **blue** on PE2, use the **show route table** operational mode command

```
user@PE2> show route table blue.inet6.0
```

```
blue.inet6.0: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

2001:db8::192:168:239:17/128
    *[Direct/0] 00:02:26
    > via lo0.0
fe80::2a0:a50f:fc64:e032/128
    *[Direct/0] 00:02:26
    > via lo0.0
```

3. (Optional) To verify that the alternate routes from routing instance **blue** have been imported to the PE2 forwarding table, use the **show route forwarding-table** operational mode command to display the contents of the router forwarding table and the routing instance forwarding table.

```
user@PE2> show route forwarding-table blue
```

```
Routing table: blue.inet
Internet:
Destination      Type RtRef Next hop      Type Index NhRef Netif
default          perm    0                rjct   689    1
0.0.0.0/32       perm    0                dscd   687    1
```

```

172.16.233.0/4      perm      0          mdsc      688      1
172.16.233.1/32    perm      0 172.16.233.1    mcst      684      1
255.255.255.255/32 perm      0          bcst      685      1

Routing table: blue.iso
ISO:
Destination          Type RtRef Next hop          Type Index NhRef Netif
default              perm      0          rjct      695      1

Routing table: blue.inet6
Internet6:
Destination          Type RtRef Next hop          Type Index NhRef Netif
default              perm      0          rjct      701      1
::/128              perm      0          dscd      699      1
2001:db8::192:168:239:17/128
                        user      0          rtbl      2        3
fe80::2a0:a50f:fc64:e032/128
                        user      0          rtbl      2        3
ff00::/8            perm      0          mdsc      700      1
ff02::1/128         perm      0 ff02::1          mcst      697      1

```

Verifying Encapsulation on PE1

Purpose

Verify the encapsulating interface on PE1.

Action

To perform the verification:

1. Use the **show interfaces filters** operational mode command to verify that the encapsulating firewall filter is attached to the ingress of the encapsulating interface.

```
user@PE1> show interfaces filters xe-0/0/0.0
```

```

Interface      Admin  Link  Proto  Input Filter      Output Filter
xe-0/0/0.0     up     down  inet6  gre_encap_1

```

2. Use the **show interfaces** operational mode command to verify that the encapsulating interface is receiving packets.

```
user@PE1> show interfaces xe-0/0/0.0 detail | filter "Ingress traffic"
```

```

...
Physical interface: xe-0/0/0, Enabled, Physical link is Up

```

```
...
Ingress traffic statistics at Packet Forwarding Engine:
Input  bytes   :          6970299398          0 bps
Input  packets :          81049992          0 pps
Drop   bytes   :              0          0 bps
Drop   packets :              0          0 pps
...
```

3. Use the **show firewall filter** operational mode command to verify that ingress passenger protocol traffic triggers the encapsulating filter.

```
user@PE1> show firewall filter gre_encap_1
```

```
Filter: gre_encap_1
Counters:
Name                               Bytes          Packets
c_gre_encap_1                      6970299398     81049992
```

Meaning

If the encapsulating filter is attached to the encapsulating interface, and the encapsulating interface receives passenger protocol traffic, and the firewall filter statistics show that ingress passenger protocol traffic is being encapsulated, then GRE packets are being forwarded through the tunnel.

Verifying De-Encapsulation on PE2

Purpose

Verify the de-encapsulating interfaces on PE2.

Action

To perform the verification:

1. On PE1, use the **ping** operational mode command to verify that PE2 is reachable.

```
user@PE1> ping 10.255.2.2
```

```
PING 10.255.2.2 (10.255.2.2): 56 data bytes
64 bytes from 10.255.2.2: icmp_seq=0 ttl=64 time=0.576 ms
64 bytes from 10.255.2.2: icmp_seq=1 ttl=64 time=0.269 ms
^C [abort]
```

2. On PE2, use the **show interfaces filter** operational mode command to verify that the de-encapsulating firewall filter is attached to the ingress of the de-encapsulating interfaces.

```
user@PE2> show interfaces filter | match xe-
```

Interface	Admin	Link	Proto	Input Filter	Output Filter
xe-0/0/0.0	up	down	inet	gre_decap_1	
xe-0/0/1.0	up	down	inet	gre_decap_1	
xe-0/0/2.0	up	down	inet	gre_decap_1	

- On PE2, use the **show interfaces** operational mode command to verify that the de-encapsulating interfaces are receiving packets.

```
user@PE2> show interfaces xe-0/0/0.0 detail | filter "Ingress traffic"
```

```
Physical interface: xe-0/0/0, Enabled, Physical link is Up
...
Ingress traffic statistics at Packet Forwarding Engine:
Input  bytes   :                6970299398          0 bps
Input  packets :                81049992          0 pps
Drop   bytes   :                      0          0 bps
Drop   packets :                      0          0 pps
...
```

```
user@PE2> show interfaces xe-0/0/1.0 detail | filter "Ingress traffic"
```

```
Physical interface: xe-0/0/2, Enabled, Physical link is Up
...
```

```
user@PE2> show interfaces xe-0/0/2.0 detail | filter "Ingress traffic"
```

```
Physical interface: xe-0/0/2, Enabled, Physical link is Up
...
```

Depending on how routing is configured and which links are up and which links are down, some of the de-encapsulating interfaces might not be receiving packets although the tunnel is operating properly.

- On PE2, use the **show firewall filter** operational mode command to verify that ingress GRE traffic triggers the de-encapsulating filter.

```
user@PE2> show firewall filter gre_decap_1
```

```
Filter: gre_decap_1
Counters:
```

Name	Bytes	Packets
c_gre_decap_1	6970299398	81049992

Meaning

The verification confirms the following operational states and activities of the encapsulator:

- PE2 is reachable from the PE1.
- The de-encapsulating filter is attached to the input of all de-encapsulating interfaces.
- The de-encapsulator is receiving traffic at de-encapsulating interfaces as expected.
- GRE packets received at the de-encapsulating interfaces trigger the de-encapsulating firewall filter action.

- [Service Filter Counters | 1237](#)

Services

The Adaptive Services Physical Interface Cards (PICs), Multiservices PICs, and Multiservices Dense Port Concentrators (DPCs) provide *adaptive services interfaces*. Adaptive services interfaces enable you to coordinate a special range of services on a single PIC or DPC by configuring a set of services and applications.

NOTE: Service filters are not supported on T4000 routers.

Service Rules

A *service set* is an optional definition you can apply to the traffic at an adaptive services interface. A service set enables you to configure combinations of directional rules and default settings that control the behavior of each service in the service set.

Service Rule Refinement

When you apply a service set to the traffic at an adaptive services interface, you can optionally use *service filters* to refine the target of the set of services and also to process traffic. Service filters enable you to manipulate traffic by performing packet filtering to a defined set of services on an adaptive services interface before the traffic is delivered to its destination. You can apply a service filter to traffic before packets are accepted for input or output service processing or after packets return from input service processing.

Service Filter Counters

Like standard firewall filters, service filters support counting of matched packets. When you display counters for a service filter, however, the syntax for specifying the filter name includes the name of the *service set* to which the service filter is applied.

- To enable counting of the packets matched by a service filter term, specify the **count *counter-name*** nonterminating action in that term.
- To display counters for service filters, use the **show firewall filter *filter-name* <counter *counter-name*>** operational mode command, and specify the ***filter-name*** as follows:

```
__service-service-set-name:service-filter-name
```

For example, suppose you configure a service filter named **out_filter** with a counter named **out_counter** and apply that service filter to a logical interface to direct certain packets for processing by the output services associated with the service set **nat_set**. In this scenario, the syntax for using the **show firewall** operational mode command to display the counter is as follows:

```
[edit]
user@host> show firewall filter __service-nat_set:out_filter counter out_counter
```

Configuring Service Sets to be Applied to Services Interfaces

Configuring Service Rules

How Service Filters Evaluate Packets

IN THIS SECTION

- [Service Filters That Contain a Single Term | 1238](#)
- [Service Filters That Contain Multiple Terms | 1239](#)
- [Service Filter Terms That Do Not Contain Any Match Conditions | 1239](#)
- [Service Filter Terms That Do Not Contain Any Actions | 1239](#)
- [Service Filter Default Action | 1239](#)

Service Filters That Contain a Single Term

For a service filter that consists of a single term, the policy framework software evaluates a packet as follows:

- If the packet matches all the conditions, the actions are taken.
- If the packet matches all the conditions and no actions are specified, the packet is accepted.
- If the packet does not match all the conditions, it is discarded.

Service Filters That Contain Multiple Terms

For a service filter that consists of multiple terms, the policy framework software evaluates a packet against the terms in the filter sequentially, beginning with the first term in the filter, until either the packet matches all the conditions in one of the terms or there are no more terms in the filter.

- If the packet matches all the conditions in a term, the actions in that term are performed and evaluation of the packet ends at that term. Any subsequent terms in the filter are not used.
- If the packet does not match all the conditions in the term, evaluation of the packet proceeds to the next term in the filter.

Service Filter Terms That Do Not Contain Any Match Conditions

For service filters with a single term and for filters with multiple terms, if a term does not contain any match conditions, the actions are taken on any packet evaluated.

Service Filter Terms That Do Not Contain Any Actions

If a term does not contain any actions, and if the packet matches the conditions in the term, the packet is accepted.

Service Filter Default Action

Each service filter has an *implicit skip* action at the end of the filter, which is equivalent to including the following example term **explicit_skip** as the final term in the service filter:

```
term explicit_skip {  
    then skip;  
}
```

By default, if a packet matches none of the terms in a service filter, the packet bypasses service processing.

Guidelines for Configuring Service Filters

IN THIS SECTION

- [Statement Hierarchy for Configuring Service Filters | 1240](#)
- [Service Filter Protocol Families | 1241](#)
- [Service Filter Names | 1241](#)
- [Service Filter Terms | 1241](#)
- [Service Filter Match Conditions | 1241](#)
- [Service Filter Terminating Actions | 1241](#)

Statement Hierarchy for Configuring Service Filters

To configure a service filter, include the **service-filter *service-filter-name*** statement at the **[edit firewall family (inet | inet6)]** hierarchy level:

```
[edit]
firewall {
  family (inet | inet6) {
    service-filter service-filter-name {
      term term-name {
        from {
          match-conditions;
        }
        then {
          actions;
        }
      }
    }
  }
}
```

Individual statements supported under the **service-filter *service-filter-name*** statement are described separately in this topic and are illustrated in the example of configuring and applying a service filter.

Service Filter Protocol Families

You can configure service filters to filter IPv4 traffic (**family inet**) and IPv6 traffic (**family inet6**) only. No other protocol families are supported for service filters.

Service Filter Names

Under the **family inet** or **family inet6** statement, you can include **service-filter service-filter-name** statements to create and name service filters. The filter name can contain letters, numbers, and hyphens (-) and be up to 64 characters long. To include spaces in the name, enclose the entire name in quotation marks (" ").

Service Filter Terms

Under the **service-filter service-filter-name** statement, you can include **term term-name** statements to create and name filter terms.

- You must configure at least one term in a firewall filter.
- You must specify a unique name for each term within a firewall filter. The term name can contain letters, numbers, and hyphens (-) and can be up to 64 characters long. To include spaces in the name, enclose the entire name in quotation marks (" ").
- The order in which you specify terms within a firewall filter configuration is important. Firewall filter terms are evaluated in the order in which they are configured. By default, new terms are always added to the end of the existing filter. You can use the **insert** configuration mode command to reorder the terms of a firewall filter.

Service Filter Match Conditions

Service filter terms support only a subset of the IPv4 and IPv6 match conditions that are supported for standard stateless firewall filters.

If you specify an IPv6 address in a match condition (the **address**, **destination-address**, or **source-address** match conditions), use the syntax for text representations described in RFC 4291, *IP Version 6 Addressing Architecture*. For more information about IPv6 addresses, see "IPv6 Overview" in the *Junos OS Routing Protocols Library*.

Service Filter Terminating Actions

When configuring a service filter term, you must specify one of the following filter-terminating actions:

- **service**
- **skip**

NOTE: These actions are unique to service filters.

Service filter terms support only a subset of the IPv4 and IPv6 nonterminating actions that are supported for standard stateless firewall filters:

- **count** *counter-name*
- **log**
- **port-mirror**
- **sample**

Service filters do not support the **next** action.

Guidelines for Applying Service Filters

IN THIS SECTION

- [Restrictions for Adaptive Services Interfaces | 1243](#)
- [Statement Hierarchy for Applying Service Filters | 1243](#)
- [Associating Service Rules with Adaptive Services Interfaces | 1244](#)
- [Filtering Traffic Before Accepting Packets for Service Processing | 1244](#)
- [Postservice Filtering of Returning Service Traffic | 1245](#)

Restrictions for Adaptive Services Interfaces

The following restrictions apply to adaptive services interfaces and service filters.

Adaptive Services Interfaces

You can apply a service filter to IPv4 or IPv6 traffic associated with a service set at an *adaptive services interface* only. Adaptive services interfaces are supported for the following hardware only:

- Adaptive Services (AS) PICs on M Series and T Series routers
- Multiservices (MS) PICs on M Series and T Series routers
- MS DPCs on MX Series routers and EX Series switches
- MS MPCs and MICs on MX Series routers

System Logging to a Remote Host from M Series Routers

Logging of adaptive services interfaces messages to an external server by means of the **fxp0** or **em0** port is not supported on M Series routers. The architecture does not support system logging traffic out of a management interface. Instead, access to an external server is supported on a Packet Forwarding Engine interface.

Statement Hierarchy for Applying Service Filters

You can enable packet filtering of IPv4 or IPv6 traffic before a packet is accepted for input or output service processing. To do this, apply a service filter to the adaptive services interface input or output in conjunction with an interface service set.

You can also enable packet filtering of IPv4 or IPv6 traffic that is returning to the Packet Forwarding Engine after input service processing completes. To do this, apply a post-service filter to the adaptive services interface input.

The following configuration shows the hierarchy levels at which you can apply the service filters to adaptive services interfaces:

```
[edit]
interfaces {
  interface-name {
    unit unit-number {
      family (inet | inet6) {
        service {
          input {
            service-set service-set-name service-filter service-filter-name;
            post-service-filter service-filter-name;
          }
          output {
```

```

        service-set service-set-name service-filter service-filter-name;
    }
}
}
}
}
}

```

Associating Service Rules with Adaptive Services Interfaces

To define and group the service rules be applied to an adaptive services interface, you define an *interface service set* by including the **service-set service-set-name** statement at the **[edit services]** hierarchy level.

To apply an interface service set to the input and output of an adaptive services interface, you include the **service-set service-set-name** at the following hierarchy levels:

- **[edit interfaces interface-name unit unit-number input]**
- **[edit interfaces interface-name unit unit-number output]**

If you apply a service set to one direction of an adaptive services interface but do not apply a service set to the other direction, an error occurs when you commit the configuration.

The adaptive services PIC performs different actions depending on whether the packet is sent to the PIC for input service or for output service. For example, you can configure a single service set to perform Network Address Translation (NAT) in one direction and destination NAT (dNAT) in the other direction.

Filtering Traffic Before Accepting Packets for Service Processing

To filter IPv4 or IPv6 traffic before accepting packets for input or output service processing, include the **service-set service-set-name service-filter service-filter-name** at one of the following interfaces:

- **[edit interfaces interface-name unit unit-number family (inet | inet6) service input]**
- **[edit interfaces interface-name unit unit-number family (inet | inet6) service output]**

For the **service-set-name**, specify a service set configured at the **[edit services service-set]** hierarchy level.

The service set retains the input interface information even after services are applied, so that functions such as filter-class forwarding and destination class usage (DCU) that depend on input interface information continue to work.

The following requirements apply to filtering inbound or outbound traffic before accepting packets for service processing:

- You configure the same service set on the input and output sides of the interface.

- If you include the **service-set** statement without an optional **service-filter** definition, the Junos OS assumes the match condition is true and selects the service set for processing automatically.
- The service filter is applied only if a service set is configured and selected.

You can include more than one service set definition on each side of an interface. The following guidelines apply:

- If you include multiple service sets, the router (or switch) software evaluates them in the order in which they appear in the configuration. The system executes the first service set for which it finds a match in the service filter and ignores the subsequent definitions.
- A maximum of six service sets can be applied to an interface.
- When you apply multiple service sets to an interface, you must also configure and apply a service filter to the interface.

Postservice Filtering of Returning Service Traffic

As an option to filtering of IPv4 or IPv6 input service traffic, you can apply a service filter to IPv4 or IPv6 traffic that is returning to the services interface after the service set is executed. To apply a service filter in this manner, include the **post-service-filter service-filter-name** statement at the **[edit interfaces interface-name unit unit-number family (inet | inet6) service input]** hierarchy level.

- [Configuration | 1247](#)
- [Verification | 1251](#)

This example shows how to configure and apply service filters.

Requirements

This example use the logical interface **xe-0/1/0.0** on any of the following hardware components:

- Adaptive Services (AS) PIC on an M Series or T Series router
- Multiservices (MS) PIC on an M Series or T Series router
- Multiservices (MS) DPC on an MX Series router
- EX Series switch

Before you begin, make sure that you have:

- Installed your supported router (or switch) and PICs or DPCs and performed the initial router (or switch) configuration.
- Configured basic Ethernet in the topology, and verified that traffic is flowing in the topology and that IPv4 traffic is flowing through logical interface **xe-0/1/0.0**.
- Configured the service set **vrf_svcs** with service input and output rules and default settings for services at a service interface.

For guidelines for configuring service sets, see *Configuring Service Sets to be Applied to Services Interfaces*.

Overview

In this example, you create three types of service filters for IPv4 traffic: one input service filter, one postservice input filter, and one output service filter.

Topology

You apply the input service filter and postservice input filter to input traffic at logical interface **xe-0/1/0.0**, and you apply the output service filter to the output traffic at the same logical interface.

- Filtering IPv4 traffic before it is accepted for input service processing—At logical interface **xe-0/1/0.0**, you use the service filter **in_filter_presvc** to filter IPv4 input traffic before the traffic can be accepted for processing by services associated with service set **vrf_svcs**. The **in_filter_presvc** service filter counts packets sent from ICMP port 179, directs these packets to the input services associated with the service set **vrf_svcs**, and discards all other packets.
- Filtering IPv4 traffic after it has completed input service processing—At logical interface **xe-0/1/0.0**, you use the service filter **in_filter_postsvc** to filter traffic that is returning to the services interface after the input service set **in_filter_presvc** is executed. The **in_filter_postsvc** service filter counts packets sent from ICMP port 179 and then discards them.
- Filtering IPv4 traffic before it is accepted for output service processing—At logical interface **xe-0/1/0.0**, you use the service-filter **out_filter_presvc** to filter IPv4 output traffic before the traffic can be accepted for processing by the services associated with service set **vrf_svcs**. The **out_filter_presvc** service filter counts packets destined for TCP port 179 and then directs the packets to the output services associated with the service set **vrf_svcs**.

Configuration

IN THIS SECTION

- [Configuring the Three Service Filters | 1248](#)
- [Applying the Three Service Filters | 1250](#)

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#).

To configure this example, perform the following tasks:

CLI Quick Configuration

To quickly configure this example, copy the following commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall family inet service-filter in_filter_presvc term t1 from protocol tcp
set firewall family inet service-filter in_filter_presvc term t1 from source-port bgp
set firewall family inet service-filter in_filter_presvc term t1 then count svc_in_pkts
```

```

set firewall family inet service-filter in_filter_presvc term t1 then service
set firewall family inet service-filter in_filter_postsvc term t2 from protocol tcp
set firewall family inet service-filter in_filter_postsvc term t2 from source-port bgp
set firewall family inet service-filter in_filter_postsvc term t2 then count svc_in_pkts_rtn
set firewall family inet service-filter in_filter_postsvc term t2 then skip
set firewall family inet service-filter out_filter_presvc term t3 from protocol icmp
set firewall family inet service-filter out_filter_presvc term t3 from destination-port bgp
set firewall family inet service-filter out_filter_presvc term t3 then count svc_out_pkts
set firewall family inet service-filter out_filter_presvc term t3 then service
set interfaces xe-0/1/0 unit 0 family inet service input service-set vrf_svcs service-filter in_filter_presvc
set interfaces xe-0/1/0 unit 0 family inet service input post-service-filter in_filter_postsvc
set interfaces xe-0/1/0 unit 0 family inet service output service-set vrf_svcs service-filter out_filter_presvc

```

Configuring the Three Service Filters

Step-by-Step Procedure

To configure the three service filters:

1. Configure the input service filter.

```

[edit]
user@host# edit firewall family inet service-filter in_filter_presvc

[edit firewall family inet service-filter in_filter_presvc]
user@host# set term t1 from protocol tcp
user@host# set term t1 from source-port bgp
user@host# set term t1 then count svc_in_pkts
user@host# set term t1 then service

```

2. Configure the postservice input filter.

```

[edit]
user@host# edit firewall family inet service-filter in_filter_postsvc

[edit firewall family inet service-filter in_filter_postsvc]
user@host# set term t2 from protocol tcp
user@host# set term t2 from source-port bgp
user@host# set term t2 then count svc_in_pkts_rtn
user@host# set term t2 then skip

```

3. Configure the output service filter.

```
[edit]
user@host# edit firewall family inet service-filter out_filter_presvc

[edit firewall family inet service-filter out_filter_presvc]
user@host# set term t3 from protocol icmp
user@host# set term t3 from destination-port bgp
user@host# set term t3 then count svc_out_pkts
user@host# set term t3 then service
```

Results

Confirm the configuration of the input and output service filters and the postservice input filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show firewall
family inet {
  service-filter in_filter_presvc {
    term t1 {
      from {
        protocol tcp;
        source-port bgp;
      }
      then {
        count svc_in_pkts;
        service;
      }
    }
  }
  service-filter in_filter_postsvc {
    term t2 {
      from {
        protocol tcp;
        source-port bgp;
      }
      then {
        count svc_in_pkts_rtn;
        skip;
      }
    }
  }
}
```

```

service-filter out_filter_presvc {
  term t3 {
    from {
      protocol icmp;
      destination-port bgp;
    }
    then {
      count svc_out_pkts;
      service;
    }
  }
}

```

Applying the Three Service Filters

Step-by-Step Procedure

To apply the three service filters:

1. Access the IPv4 protocol on the input interface **xe-0/1/0.0**.

```

[edit]
user@host# edit interfaces xe-0/1/0 unit 0 family inet

```

2. Apply the input service filter and the postservice input filter.

```

[edit interfaces xe-0/1/0 unit 0 family inet]
user@host# set service input service-set vrf_svcs service-filter in_filter_presvc
user@host# set service input post-service-filter in_filter_postsvc
user@host# set service output service-set vrf_svcs service-filter out_filter_presvc

```

Results

Confirm the configuration of the interfaces by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

[edit]
user@host# show interfaces
xe-0/1/0 {
  unit 0 {
    family inet {

```

```

service {
  input {
    service-set vrf_svcs service-filter in_filter_presvc;
    post-service-filter in_filter_postsvc;
  }
  output {
    service-set vrf_svcs service-filter out_filter_presvc;
  }
}
}
}
}

```

When you are done configuring the device, commit your candidate configuration.

Verification

IN THIS SECTION

- [Verifying That Inbound Traffic Is Filtered Before Input Service | 1251](#)
- [Verifying That Inbound Traffic Is Filtered After Input Service Processing | 1252](#)
- [Verifying That Outbound Traffic Is Filtered Before Output Service Processing | 1252](#)

Confirm that the configuration is working properly.

Verifying That Inbound Traffic Is Filtered Before Input Service

Purpose

Verify that inbound packets sent from TCP port 179 are sent for processing by the *input* services associated with the service set **vrf_svcs**.

Action

Display the count of packets sent for processing by the *input* services associated with the service set **vrf_svcs**.

```

[edit]
user@host> show firewall filter in_filter_presvc-vrf_svcs counter svc_in_pkts

```

Verifying That Inbound Traffic Is Filtered After Input Service Processing

Purpose

Verify that inbound packets sent from TCP port 179 are returned from processing by the *input* services associated with the service set **vrf_svcs**.

Action

Display the count of packets returned from processing by the *input* services associated with the service set **vrf_svcs**.

```
[edit]
user@host> show firewall filter in_filter_postsvc-vrf_svcs counter svc_in_pkts_rtn
```

Verifying That Outbound Traffic Is Filtered Before Output Service Processing

Purpose

Verify that outbound packets sent to ICMP port 179 are sent for processing by the *output* services associated with the service set **vrf_svcs**.

Action

Display the count of packets sent for processing by the *output* services associated with the service set **vrf_svcs**.

```
[edit]
user@host> show firewall filter out_filter_presvc-vrf_svcs counter svc_out_pkts
```

ip-options <i>values</i>		family inet	• family inet

Table 73: Service Filter Match Conditions for IPv4 or IPv6 Traffic (*continued*)

Match Condition	Description	Protocol Families
	<p>Match the 8-bit IP option field, if present, to the specified value or list of values.</p> <p>In place of a numeric value, you can specify one of the following text synonyms (the option values are also listed): loose-source-route (131), record-route (7), router-alert (148), security (130), stream-id (136), strict-source-route (137), or timestamp (68).</p> <p>To match <i>any</i> value for the IP option, use the text synonym any. To match on <i>multiple</i> values, specify the list of values within square brackets ('[' and ']'). To match a <i>range</i> of values, use the value specification [<i>value1-value2</i>].</p> <p>For example, the match condition ip-options [0-147] matches on an IP options field that contains the loose-source-route, record-route, or security values, or any other value from 0 through 147. However, this match condition does not match on an IP options field that contains only the router-alert value (148).</p> <p>For most interfaces, a filter term that specifies an ip-option match on one or more <i>specific</i> IP option values (a value other than any) causes packets to be sent to the Routing Engine so that the kernel can parse the IP option field in the packet header.</p> <ul style="list-style-type: none"> • For a firewall filter term that specifies an ip-option match on one or more specific IP option values, you cannot specify the count, log, or syslog nonterminating actions <i>unless</i> you also specify the discard terminating action in the same term. This behavior prevents double-counting of packets for a filter applied to a transit interface on the router (or switch). • Packets processed on the kernel might be dropped in case of a system bottleneck. To ensure that matched packets are instead sent to the Packet Forwarding Engine (where packet processing is implemented in hardware), use the ip-options any match condition. <p>The 10-Gigabit Ethernet Modular Port Concentrator (MPC), 60-Gigabit Ethernet MPC, 60-Gigabit Queuing Ethernet MPC, 60-Gigabit Ethernet Enhanced Queuing MPC on MX Series routers and EX Series switches are capable of parsing the IP option field of the IPv4 packet header. This capability is supported on EX Series switches also. For interfaces configured on those MPCs, <i>all</i> packets that are matched using the ip-options match condition are sent to</p>

Service Filter Terminating Actions

Service filters support different sets of terminating actions than standard stateless firewall filters or simple filters.

NOTE: Service filters do not support the **next term** action.

Table 75 on page 1264 describes the terminating actions you can configure in a service filter term.

Table 75: Terminating Actions for Service Filters

Terminating Action	Description	Protocol Families
service	Direct the packet to service processing.	<ul style="list-style-type: none">• inet• inet6
skip	Let the packet bypass service processing.	<ul style="list-style-type: none">• inet• inet6

Simple Filter Overview

Simple filters are supported on Gigabit Ethernet intelligent queuing 2 (IQ2) and Enhanced Queuing Dense Port Concentrator (DPC) interfaces only.

Simple filters are recommended for metropolitan Ethernet applications.

Simple Filters That Contain a Single Term

For a simple filter that consists of a single term, the policy framework software evaluates a packet as follows:

- If the packet matches all the conditions, the actions are taken.
- If the packet matches all the conditions and no actions are specified, the packet is accepted.
- If the packet does not match all the conditions, it is discarded.

Simple Filters That Contain Multiple Terms

For a simple filter that consists of multiple terms, the policy framework software evaluates a packet against the terms in the filter sequentially, beginning with the first term in the filter, until either the packet matches all the conditions in one of the terms or there are no more terms in the filter.

- If the packet matches all the conditions in a term, the actions in that term are performed and evaluation of the packet ends at that term. Any subsequent terms in the filter are not used.
- If the packet does not match all the conditions in the term, evaluation of the packet proceeds to the next term in the filter.

Simple Filter Terms That Do Not Contain Any Match Conditions

For simple filters with a single term and for filters with multiple terms, if a term does not contain any match conditions, the actions are taken on any packet evaluated.

Simple Filter Terms That Do Not Contain Any Actions

If a simple filter term does not contain any actions, and if the packet matches the conditions in the term, the packet is accepted.

Simple Filter Default Action

Each simple filter has an *implicit* **discard** action at the end of the filter, which is equivalent to including the following example term **explicit_discard** as the final term in the simple filter:

```
term explicit_discard {  
    then discard;  
}
```

By default, if a packet matches none of the terms in a simple filter, the packet is discarded.

Statement Hierarchy for Configuring Simple Filters

To configure a simple filter, include the **simple-filter** *simple-filter-name* statement at the [edit firewall family inet] hierarchy level.

```
[edit]
firewall {
  family inet {
    simple-filter simple-filter-name {
      term term-name {
        from {
          match-conditions;
        }
        then {
          actions;
        }
      }
    }
  }
}
```

Individual statements supported under the **simple-filter** *simple-filter-name* statement are described separately in this topic and are illustrated in the example of configuring and applying a simple filter.

Simple Filter Protocol Families

You can configure simple filters to filter IPv4 traffic (**family inet**) only. No other protocol family is supported for simple filters.

Simple Filter Names

Under the **family inet** statement, you can include **simple-filter** *simple-filter-name* statements to create and name simple filters. The filter name can contain letters, numbers, and hyphens (-) and be up to 64 characters long. To include spaces in the name, enclose the entire name in quotation marks (" ").

Simple Filter Terms

Under the **simple-filter** *simple-filter-name* statement, you can include **term** *term-name* statements to create and name filter terms.

- You must configure at least one term in a firewall filter.

- You must specify a unique name for each term within a firewall filter. The term name can contain letters, numbers, and hyphens (-) and can be up to 64 characters long. To include spaces in the name, enclose the entire name in quotation marks (" ").
- The order in which you specify terms within a firewall filter configuration is important. Firewall filter terms are evaluated in the order in which they are configured. By default, new terms are always added to the end of the existing filter. You can use the **insert** configuration mode command to reorder the terms of a firewall filter.

Simple filters do *not* support the **next term** action.

Simple Filter Match Conditions

Simple filter terms support only a subset of the IPv4 match conditions that are supported for standard stateless firewall filters.

Unlike standard stateless firewall filters, the following restrictions apply to simple filters:

- On MX Series routers with the Enhanced Queuing DPC and on EX Series switches, simple filters do *not* support the **forwarding-class** match condition.
- Simple filters support only one **source-address** and one **destination-address** prefix for each filter term. If you configure multiple prefixes, only the last one is used.
- Simple filters do *not* support multiple source addresses and destination addresses in a single term. If you configure multiple addresses, only the last one is used.
- Simple filters do *not* support negated match conditions, such as the **protocol-except** match condition or the **exception** keyword.
- Simple filters support a range of values for **source-port** and **destination-port** match conditions only. For example, you can configure **source-port 400-500** or **destination-port 600-700**.
- Simple filters do *not* support noncontiguous mask values.

[Table 76 on page 1269](#) lists the simple filter match conditions.

Table 76: Simple Filter Match Conditions

Match Condition	Description
destination-address <i>destination-address</i>	Match IP destination address.

Table 76: Simple Filter Match Conditions (*continued*)

Match Condition	Description
destination-port <i>number</i>	<p>TCP or UDP destination port field.</p> <p>If you configure this match condition, we recommend that you also configure the protocol match statement to determine which protocol is being used on the port.</p> <p>In place of the numeric value, you can specify one of the following text aliases (the port numbers are also listed): afs (1483), bgp (179), biff (512), bootpc (68), bootps (67), cmd (514), cvspserver (2401), dhcp (67), domain (53), eklogin (2105), ekshell (2106), exec (512), finger (79), ftp (21), ftp-data (20), http (80), https (443), ident (113), imap (143), kerberos-sec (88), klogin (543), kpasswd (761), krb-prop (754), krbupdate (760), kshell (544), ldap (389), login (513), mobileip-agent (434), mobileip-mn (435), msdp (639), netbios-dgm (138), netbios-ns (137), netbios-ssn (139), nfsd (2049), nntp (119), ntalk (518), ntp (123), pop3 (110), pptp (1723), printer (515), radacct (1813), radius (1812), rip (520), rkinet (2108), smtp (25), snmp (161), snmptrap (162), snpp (444), socks (1080), ssh (22), sunrpc (111), syslog (514), tacacs-ds (65), talk (517), telnet (23), tftp (69), timed (525), who (513), or xmcp (177).</p>
forwarding-class <i>class</i>	<p>Match the forwarding class of the packet.</p> <p>Specify assured-forwarding, best-effort, expedited-forwarding, or network-control.</p> <p>For information about forwarding classes and router-internal output queues, see <i>Understanding How Forwarding Classes Assign Classes to Output Queues</i>.</p>
protocol <i>number</i>	<p>IP protocol field. In place of the numeric value, you can specify one of the following text aliases (the field values are also listed): ah (51), dstopts (60), egp (8), esp (50), fragment (44), gre (47), hop-by-hop (0), icmp (1), icmp6 (58), icmpv6 (58), igmp (2), ipip (4), ipv6 (41), ospf (89), pim (103), rsvp (46), sctp (132), tcp (6), udp (17), or vrrp (112).</p>
source-address <i>ip-source-address</i>	Match the IP source address.
source-port <i>number</i>	<p>Match the UDP or TCP source port field.</p> <p>If you configure this match condition, we recommend that you also configure the protocol match statement to determine which protocol is being used on the port.</p> <p>In place of the numeric field, you can specify one of the text aliases listed for destination-port.</p>

Simple Filter Terminating Actions

Simple filters do *not* support explicitly configurable terminating actions, such as **accept**, **reject**, and **discard**. Terms configured in a simple filter always accept packets.

Simple filters do *not* support the **next** action.

Simple Filter Nonterminating Actions

Simple filters support only the following nonterminating actions:

- **forwarding-class** (*forwarding-class* | **assured-forwarding** | **best-effort** | **expedited-forwarding** | **network-control**)

NOTE: On the MX Series routers and EX Series switches with the Enhanced Queuing DPC, the forwarding class is not supported as a **from** match condition.

- **loss-priority** (**high** | **low** | **medium-high** | **medium-low**)

Simple filters do not support actions that perform other functions on a packet (such as incrementing a counter, logging information about the packet header, sampling the packet data, or sending information to a remote host using the system log functionality).

Statement Hierarchy for Applying Simple Filters

You can apply a simple filter to the IPv4 ingress traffic at a logical interface by including the **simple-filter input *simple-filter-name*** statement at the [edit interfaces *interface-name* unit *unit-number* family inet] hierarchy level.

```
[edit]
interfaces {
  interface-name {
    unit logical-unit-number {
      family inet {
        simple-filter {
          input filter-name;
        }
      }
    }
  }
}
```

Restrictions for Applying Simple Filters

You can apply a simple filter to the ingress IPv4 traffic at a logical interface configured on the following hardware only:

- Gigabit Ethernet intelligent queuing (IQ2) PICs installed on M120, M320, or T Series routers.
- Enhanced Queuing Dense Port Concentrators (EQ DPCs) installed on MX Series routers and EX Series switches.

The following additional restrictions pertain to applying simple filters:

- Simple filters are not supported on Modular Port Concentrator (MPC) interfaces, including Enhanced Queuing MPC interfaces.
- Simple filters are not supported for interfaces in an aggregated-Ethernet bundle.
- You can apply simple filters to **family inet** traffic only. No other protocol family is supported.
- You can apply simple filters to ingress traffic only. Egress traffic is not supported.
- You can apply only a single simple filter to a supported logical interface. Input lists are not supported.

Example: Configuring and Applying a Simple Filter

IN THIS SECTION

- [Requirements | 1273](#)
- [Overview | 1273](#)
- [Configuration | 1274](#)
- [Verification | 1278](#)

This example shows how to configure a simple filter.

Requirements

This example uses one of the following hardware components:

- One Gigabit Ethernet intelligent queuing (IQ2) PIC installed on an M120, M320, or T Series router
- One Enhanced Queuing Dense Port Concentrator (EQ DPC) installed on an MX Series router or an EX Series switch

Before you begin, make sure that you have:

- Installed your supported router (or switch) and PIC or DPC and performed the initial router (or switch) configuration.
- Configured basic Ethernet in the topology, and verified that traffic is flowing in the topology and that ingress IPv4 traffic is flowing into logical interface **ge-0/0/1.0**.

Overview

This simple filter sets the loss priority to low for TCP traffic with source address **172.16.1.1**, sets the loss priority to high for HTTP (Web) traffic with source addresses in the 172.16.4.0/8 range, and sets the loss priority to low for all traffic with destination address **172.16.6.6**.

Topology

The simple filter is applied as an input filter (arriving packets are checking for destination address **6.6.6.6**, not queued output packets) on interface **ge-0/0/1.0**.

Configuration

IN THIS SECTION

- [Configuring the Simple Firewall Filter | 1274](#)
- [Applying the Simple Filter to the Logical Interface Input | 1276](#)

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 1632](#).

To configure this example, perform the following tasks:

CLI Quick Configuration

To quickly configure this example, copy the following commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall family inet simple-filter sf_classify_1 term 1 from source-address 172.16.1.1/32
