You must configure this statement at the `[edit protocols rsvp]` hierarchy level.

Tracing RSVP Protocol Traffic

IN THIS SECTION

- Examples: Tracing RSVP Protocol Traffic | **1234**

To trace RSVP protocol traffic, include the `traceoptions` statement:

```
traceoptions {
    file filename <files number> <size size> <world-readable | no-world-readable>;
    flag flag <flag-modifier> <disable>;
}
```

You can include this statement at the following hierarchy levels:

- `[edit protocols rsvp]`
- `[edit logical-systems logical-system-name protocols rsvp]`

You can specify the following RSVP-specific flags in the RSVP `traceoptions` statement:

Use the `file` statement to specify the name of the file that receives the output of the tracing operation. All files are placed in the directory `/var/log`. We recommend that you place RSVP tracing output in the file `rsvp-log`.

- `all`—All tracing operations.
- `error`—All detected error conditions
- `event`—RSVP-related events (helps to trace events related to RSVP graceful restart)
- `lmp`—RSVP-Link Management Protocol (LMP) interactions
- `packets`—All RSVP packets

- `path`—All path messages
- `pathtear`—PathTear messages
- `resv`—Resv messages
- `resvtear`—ResvTear messages
- `route`—Routing information
- `state`—Session state transitions, including when RSVP-signaled LSPs come up and go down.

> **NOTE**: Use the `all` trace flag and the `detail` flag modifier with caution because these might cause the CPU to become very busy.

To view the log file generated when you enable RSVP traceoptions, issue the `show log` *`file-name`* command, where *`file-name`* is the file you specified using the `traceoptions` statement.

For general information about tracing and global tracing options, see the Junos OS Routing Protocols Library for Routing Devices.

Examples: Tracing RSVP Protocol Traffic

Trace RSVP path messages in detail:

```
[edit]
protocols {
    rsvp {
        traceoptions {
            file rsvp size 10m files 5;
            flag path;
        }
    }
}
```

Trace all RSVP messages:

```
[edit]
protocols {
    rsvp {
        traceoptions {
            file rsvp size 10m files 5;
```

```
            flag packets;
        }
    }
}
```

Trace all RSVP error conditions:

```
[edit]
protocols {
    rsvp {
        traceoptions {
            file rsvp size 10m files 5;
            flag error;
        }
    }
}
```

Trace RSVP state transitions:

```
[edit]
protocols {
    rsvp {
        traceoptions {
            file rsvp-data;
            flag state;
        }
    }
}
```

RSVP Log File Output

The following is sample output generated by issuing the `show log` *file-name* command on a router on which RSVP traceoptions have been enabled with the `state` flag configured. The RSVP-signaled LSP E-D is shown being torn down on Mar 11 14:04:36.707092. On Mar 11 14:05:30.101492, it is shown coming back up.

```

```

RSVP Graceful Restart

RSVP graceful restart allows a router undergoing a restart to inform its adjacent neighbors of its condition. The restarting router requests a grace period from the neighbor or peer, which can then cooperate with the restarting router. The restarting router can still forward MPLS traffic during the restart period; convergence in the network is not disrupted. The restart is not visible to the rest of the network, and the restarting router is not removed from the network topology. RSVP graceful restart can

be enabled on both transit routers and ingress routers. It is available for both point-to-point LSPs and point-to-multipoint LSPs.

RSVP graceful restart is described in the following sections:

- RSVP Graceful Restart Standard
- "RSVP Graceful Restart Terminology" on page 1237
- "RSVP Graceful Restart Operation" on page 1238
- "Processing the Restart Cap Object" on page 1239

RSVP Graceful Restart Terminology

IN THIS SECTION

- Restart time (in milliseconds) | **1237**
- Recovery time (in milliseconds) | **1237**

Restart time (in milliseconds)

The default value is 60,000 milliseconds (1 minute). The restart time is advertised in the hello message. The time indicates how long a neighbor should wait to receive a hello message from a restarting router before declaring that router dead and purging states.

The Junos OS can override a neighbor's advertised restart time if the time is greater than one-third the local restart time. For example, given the default restart time of 60 seconds, a router would wait 20 seconds or less to receive a hello message from a restarting neighbor. If the restart time is zero, the restarting neighbor can immediately be declared dead.

Recovery time (in milliseconds)

Applies only when the control channel is up (the hello exchange is complete) before the restart time. Applies only to nodal faults.

When a graceful restart is in progress, the time left to complete a recovery is advertised. At other times, this value is zero. The maximum advertised recovery time is 2 minutes (120,000 milliseconds).

During the recovery time, a restarting node attempts to recover its lost states with assistance from its neighbors. The neighbor of the restarting node must send the path messages with the recovery labels to the restarting node within a period of one-half the recovery time. The restarting node considers its graceful restart complete after its advertised recovery time.

RSVP Graceful Restart Operation

For RSVP graceful restart to function, the feature must be enabled on the global routing instance. RSVP graceful restart can be disabled at the protocol level (for RSVP alone) or at the global level for all protocols.

RSVP graceful restart requires the following of a restarting router and the router's neighbors:

- For the restarting router, RSVP graceful restart attempts to maintain the routes installed by RSVP and the allocated labels, so that traffic continues to be forwarded without disruption. RSVP graceful restart is done quickly enough to reduce or eliminate the impact on neighboring nodes.
- The neighboring routers must have RSVP graceful restart helper mode enabled, thus allowing them to assist a router attempting to restart RSVP.

An object called Restart Cap that is sent in RSVP hello messages advertises a node's restart capability. The neighboring node sends a Recover Label object to the restarting node to recover its forwarding state. This object is essentially the old label that the restarting node advertised before the node went down.

The following lists the RSVP graceful restart behaviors, which vary depending on the configuration and on which features are enabled:

- If you disable helper mode, the Junos OS does not attempt to help a neighbor restart RSVP. Any information that arrives with a Restart Cap object from a neighbor is ignored.
- When you enable graceful restart under the routing instance configuration, the router can restart gracefully with the help of its neighbors. RSVP advertises a Restart Cap object (RSVP RESTART) in hello messages in which restart and recovery times are specified (neither value is 0).
- If you explicitly disable RSVP graceful restart under the `[protocols rsvp]` hierarchy level, the Restart Cap object is advertised with restart and recovery times specified as 0. The restart of neighboring routers is supported (unless helper mode is disabled), but the router itself does not preserve the RSVP forwarding state and cannot recover its control state.
- If after a restart RSVP realizes that no forwarding state has been preserved, the Restart Cap object is advertised with restart and recovery times specified as 0.
- If graceful restart and helper mode are disabled, RSVP graceful restart is completely disabled. The router neither recognizes nor advertises the RSVP graceful restart objects.

You cannot explicitly configure values for the restart and recovery times.

Unlike other protocols, there is no way for RSVP to determine that it has completed a restart procedure, other than a fixed timeout. All RSVP graceful restart procedures are timer-based. A `show rsvp version` command might indicate that the restart is still in progress even if all RSVP sessions are back up and the routes are restored.

Processing the Restart Cap Object

The following assumptions are made about a neighbor based on the Restart Cap object (assuming that a control channel failure can be distinguished unambiguously from a node restart):

- A neighbor that does not advertise the Restart Cap object in its hello messages cannot assist a router with state or label recovery, nor can it perform an RSVP graceful restart.
- After a restart, a neighbor advertising a Restart Cap object with a restart time equal to any value and a recovery time equal to 0 has not preserved its forwarding state. When a recovery time equals 0, the neighbor is considered dead and any states related to this neighbor are purged, regardless of the value of the restart time.
- After a restart, a neighbor advertising its recovery time with a value other than 0 can keep or has kept the forwarding state. If the local router is helping its neighbor with restart or recovery procedures, it sends a Recover Label object to this neighbor.

Configuring RSVP Graceful Restart

IN THIS SECTION

- Enabling Graceful Restart for All Routing Protocols | **1240**
- Disabling Graceful Restart for RSVP | **1240**
- Disabling RSVP Helper Mode | **1240**
- Configuring the Maximum Helper Recovery Time | **1241**
- Configuring the Maximum Helper Restart Time | **1241**

The following RSVP graceful restart configurations are possible:

- Graceful restart and helper mode are both enabled (the default).
- Graceful restart is enabled but helper mode is disabled. A router configured in this way can restart gracefully, but cannot help a neighbor with its restart and recovery procedures.
- Graceful restart is disabled but helper mode is enabled. A router configured in this way cannot restart gracefully, but can help a restarting neighbor.
- Graceful restart and helper mode both are disabled. This configuration completely disables RSVP graceful restart (including restart and recovery procedures and helper mode). The router behaves like a router that does not support RSVP graceful restart.

NOTE: In order to turn on RSVP graceful restart, you must set the global graceful restart timer to at least 180 seconds.

The following sections describe how to configure RSVP graceful restart:

Enabling Graceful Restart for All Routing Protocols

To enable graceful restart for RSVP, you need to enable graceful restart for all the protocols that support graceful restart on the router. For more information about graceful restart, see the Junos OS Routing Protocols Library for Routing Devices.

To enable graceful restart on the router, include the `graceful-restart` statement:

```
graceful-restart;
```

You can include this statement at the following hierarchy levels:

- `[edit routing-options]`
- `[edit logical-systems` *`logical-system-name`* `routing-options]`

Disabling Graceful Restart for RSVP

By default, RSVP graceful restart and RSVP helper mode are enabled when you enable graceful restart. However, you can disable one or both of these capabilities.

To disable RSVP graceful restart and recovery, include the `disable` statement at the `[edit protocols rsvp graceful-restart]` hierarchy level:

```
disable;
```

Disabling RSVP Helper Mode

To disable RSVP helper mode, include the `helper-disable` statement at the `[edit protocols rsvp graceful-restart]` hierarchy level:

```
helper-disable;
```

Configuring the Maximum Helper Recovery Time

To configure the amount of time the router retains the state of its RSVP neighbors while they undergo a graceful restart, include the `maximum-helper-recovery-time` statement at the `[edit protocols rsvp graceful-restart]` hierarchy level. This value is applied to all neighboring routers, so it should be based on the time required by the slowest RSVP neighbor to recover.

```
maximum-helper-recovery-time seconds;
```

Configuring the Maximum Helper Restart Time

To configure the delay between when the router discovers that a neighboring router has gone down and when it declares the neighbor down, include the `maximum-helper-restart-time` statement at the `[edit protocols rsvp graceful-restart]` hierarchy level. This value is applied to all neighboring routers, so it should be based on the time required by the slowest RSVP neighbor to restart.

```
maximum-helper-restart-time seconds;
```

RSVP LSP Tunnels Overview

A Resource Reservation Protocol (RSVP) label-switched path (LSP) tunnel enables you to send RSVP LSPs inside other RSVP LSPs. This enables a network administrator to provide traffic engineering from one end of the network to the other. A useful application for this feature is to connect customer edge (CE) routers with provider edge (PE) routers by using an RSVP LSP, and then tunnel this edge LSP inside a second RSVP LSP traveling across the network core.

You should have a general understanding of MPLS and label switching concepts. For more information about MPLS, see the *Junos MPLS Applications Configuration Guide*.

An RSVP LSP tunnel adds the concept of a forwarding adjacency, similar to the one used for generalized Multiprotocol Label Switching (GMPLS). (For more information about GMPLS, see *Junos GMPLS User Guide*.

The forwarding adjacency creates a tunneled path for sending data between peer devices in an RSVP LSP network. Once a forwarding adjacency LSP (FA-LSP) has been established, other LSPs can be sent over the FA-LSP by using Constrained Shortest Path First (CSPF), Link Management Protocol (LMP), Open Shortest Path First (OSPF), and RSVP.

To enable an RSVP LSP tunnel, the Junos OS uses the following mechanisms:

- LMP—Originally designed for GMPLS, LMP establishes forwarding adjacencies between RSVP LSP tunnel peers, and maintains and allocates resources for traffic engineering links.

- OSPF extensions—OSPF was designed to route packets to physical and logical interfaces related to a *Physical Interface Card* (PIC). This protocol has been extended to route packets to virtual peer interfaces defined in an LMP configuration.
- RSVP-TE extensions—RSVP-TE was designed to signal the setup of packet LSPs to physical interfaces. The protocol has been extended to request path setup for packet LSPs traveling to virtual peer interfaces defined in an LMP configuration.

> **NOTE**: Beginning with Junos OS Release 15.1, multi-instance support is extended to MPLS RSVP-TE. This support is available only for virtual router instance type. A router can create and participate in multiple independent TE topology partitions, which allows each partitioned TE domain to scale independently. Multi-instance RSVP-TE provides the flexibility to hand pick the control-plane entities that need to be instance-aware, for example, a router can participate in multiple TE instances while still running a single BGP instance.

The Junos OS implementation of MPLS RSVP-TE is scaled to enhance the usability, visibility, configuration, and troubleshooting of LSPs in Junos OS Release 16.1.

These enhancements make the RSVP-TE configuration easier at scale by:

- Ensuring the LSP data-plane readiness during LSP resignaling before traffic traverses the LSP with the RSVP-TE LSP self-ping mechanism.

  An LSP should not start to carry traffic unless it is known to have been programmed in the data plane. Data exchange in the LSP data plane, such as LSP ping requests, happens at the ingress router before switching traffic to an LSP, or to its MBB instance. In large networks, this traffic can overwhelm an LSP egress router, as the egress LSP needs to respond to the LSP ping requests. The LSP self-ping mechanism enables the ingress LER to create LSP ping response messages and send them over the LSP data plane. On receiving these messages, the egress LER forwards them to the ingress, indicating the liveliness of the LSP data plane. This ensures that the LSP does not start to carry traffic before the data plane has been programmed.

- Removing the current hard limit of 64K LSPs on an ingress router and scaling the total number of LSPs with RSVP-TE signaled LSPs. There can be up to 64K LSPs configured on a per-egress basis. Earlier, this limit was the aggregate number of LSPs that could be configured on the ingress LER.
- Preventing abrupt tearing down of LSPs by the ingress router because of delay in signaling the LSP at the transit routers.
- Enabling a flexible view of LSP data-sets to facilitate LSP characteristic data visualization.

NOTE: Starting with Junos OS Release 17.4, a default timer of 1800 seconds for self-ping is introduced.

The following limitations exist for LSP hierarchies:

- Circuit cross-connect (CCC)-based LSPs are not supported.
- Graceful restart is not supported.
- Link protection is not available for FA-LSPs or at the egress point of the forwarding adjacency.
- Point-to-multipoint LSPs are not supported across FA-LSPs.

Example: RSVP LSP Tunnel Configuration

IN THIS SECTION

- Verifying Your Work | **1261**

Figure 71: RSVP LSP Tunnel Topology Diagram

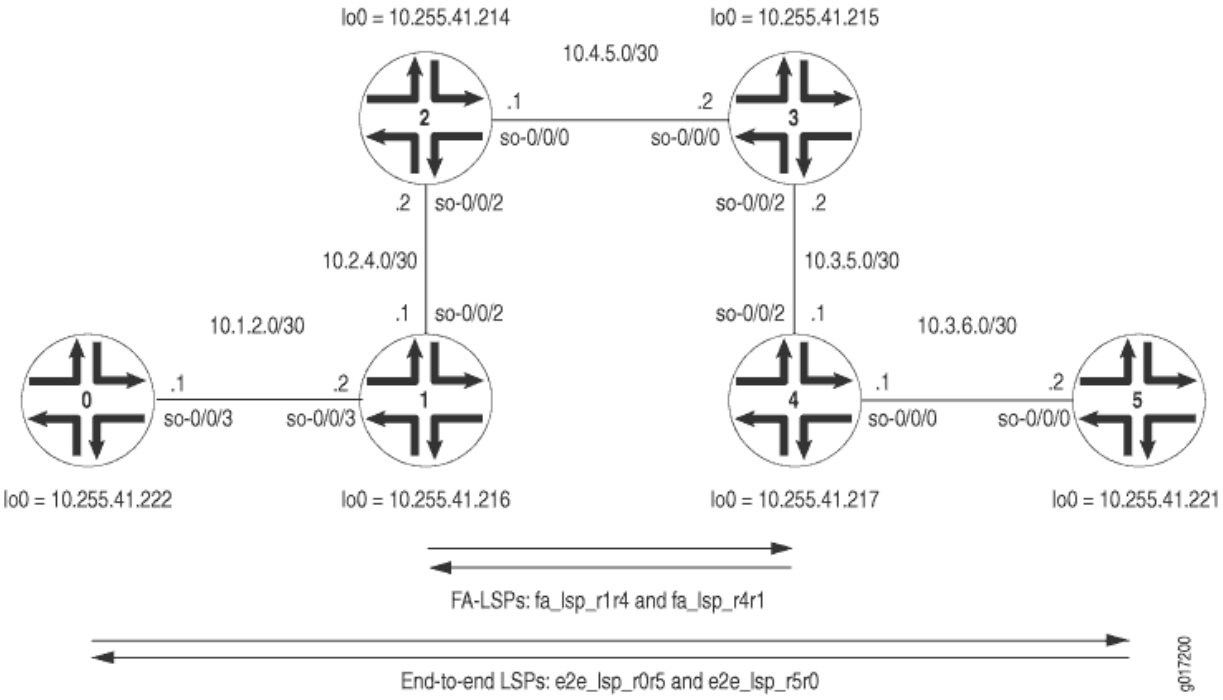

Figure 71 on page 1245 shows an end-to-end RSVP LSP called e2e_lsp_r0r5 that originates on Router 0 and terminates on Router 5. In transit, this LSP traverses the FA-LSP fa_lsp_r1r4. The return path is represented by the end-to-end RSVP LSP e2e_lsp_r5r0 that travels over the FA-LSP fa_lsp_r4r1.

On Router 0, configure the end-to-end RSVP LSP that travels to Router 5. Use a strict path that traverses Router 1 and the LMP traffic engineering link traveling from Router 1 to Router 4.

Router 0

```

    }
}
policy-options {
    policy-statement pplb {
        then {
            load-balance per-packet;
        }
    }
}
```

On Router 4, configure a return path FA-LSP to reach Router 1. Establish an LMP traffic engineering link and LMP peer relationship with Router 1. Reference the FA-LSP in the traffic engineering link and add the peer interface into both OSPF and RSVP.

When the initial end-to-end LSP arrives at Router 4, the routing platform performs a routing lookup and can forward traffic to Router 5. Make sure you configure OSPF correctly between Router 4 and Router 5.

Router 4

```

    }
}
```

Verifying Your Work

To verify that your RSVP LSP tunnel is working correctly, issue the following commands:

- show ted database (extensive)
- show rsvp session name (extensive)
- show link-management
- show link-management te-link name (detail)

To see these commands used with the configuration example, see the following sections:

Router 0

On Router 0, you can verify that the FA-LSPs appear as valid paths in the traffic engineering database. In this case, look for the paths from Router 1 (10.255.41.216) and Router 4 (10.255.41.217) that reference the LMP traffic engineering link addresses of 172.16.30.1 and 172.16.30.2. You can also issue the show rsvp session extensive command to look for the path of the end-to-end LSP as it travels to Router 5 over the FA-LSP.

```
user@router0> show ted database
TED database: 0 ISIS nodes 8 INET nodes

Router 1

On Router 1, verify that your LMP traffic engineering link configuration is working and that the end-to-end LSP is traversing the traffic engineering link by issuing the `show link-management` set of commands. You can also issue the `show rsvp session extensive` command to confirm that the FA-LSP is operational.

```
user@router1> show link-management

Configuring Link Management Protocol Peers

After you set up traffic engineering links, configure LMP network peers with the `peer` *peer-name* statement at the `[edit protocols link-management]` hierarchy level. A peer is the network device with which your routing platform communicates and establishes an FA-LSP. Designate a peer name, configure the peer router ID as the address (often a loopback address), and apply the traffic engineering link to be associated with this peer. Remember to configure both sides of a peering relationship to enable bidirectional communication.

Unlike GMPLS, you must not configure a control channel for a peer. If you include a control channel, the commit operation fails.

```
[edit]
protocols {
    link-management {
        peer peer-name { # Configure the name of your network peer.
            address ip-address; # Include the router ID of the peer.
            te-link te-link-name; # Assign a TE link to this peer.
        }
```

```
    }
}
```

Configuring Link Management Protocol Traffic Engineering Links

To begin your RSVP LSP tunnel configuration, configure LMP traffic engineering links on both the ingress and egress routing platforms. Because traffic engineering links define a unidirectional connection between peer devices, you must configure traffic engineering links in both directions between peers to enable the bidirectional transport of packets.

To configure traffic engineering links in LMP, include the `te-link` *`te-link-name`* statement at the [`edit protocols link-management`] hierarchy level. Define the traffic engineering link options shown below, especially the label-switched path to be used as the FA-LSP to reach the peer. Optionally, you can specify the traffic engineering metric for the traffic engineering link (TE link). By default, the traffic engineering metric is derived from the CSPF computation.

```
[edit]
protocols {
    link-management {
        te-link te-link-name { # Name of the TE link.
            label-switched-path lsp-name; # LSP used for the forwarding adjacency.
            local-address ip-address; # Local IP address associated with the TE link.
            remote-address ip-address; # Remote IP address mapped to the TE link.
            te-metric value; # Traffic engineering metric used for the TE link.
        }
    }
}
```

Configuring Peer Interfaces in OSPF and RSVP

After you establish LMP peers, you must add peer interfaces to OSPF and RSVP. A peer interface is a virtual interface used to support the control adjacency between two peers.

The peer interface name must match the `peer` *`peer-name`* statement configured in LMP at the [`edit protocols link-management`] hierarchy level. Because actual protocol packets are sent and received by peer interfaces, the peer interfaces can be signaled and advertised to peers like any other physical interface configured for OSPF and RSVP. To configure OSPF routing for LMP peers, include the `peer-interface` statement at the [`edit protocols ospf area` *`area-number`*] hierarchy level. To configure RSVP signaling for LMP peers, include the `peer-interface` statement at the [`edit protocols rsvp`] hierarchy level.

```
[edit]
protocols {
```

```
    rsvp {
        peer-interface peer-name { # Configure the name of your LMP peer.
        }
        ospf {
            area                    area-number                 {
                peer-interface peer-name { # Configure the name of your LMP peer.
                }
            }
        }
    }
}
```

Defining Label-Switched Paths for the FA-LSP

Next, define your FA-LSP by including the `label-switched-path` statement at the `[edit protocols mpls]` hierarchy level. Include the router ID of the peer in the `to` statement at the `[edit protocols mpls label-switched-path]` hierarchy level. Because packet LSPs are unidirectional, you must create one FA-LSP to reach the peer and a second FA-LSP to return from the peer.

```
[edit]
protocols {
    mpls {
        label-switched-path lsp-name {
            from ip-address;
            to ip-address;
            primary path-name;
            secondary path-name;
            no-cspf; # This statement to disable CSPF is optional.
        }
    }
}
```

Establishing FA-LSP Path Information

When you configure explicit LSP paths for an FA-LSP, you must use the traffic engineering link remote address as your next-hop address. When CSPF is supported, you can use any path option you wish. However, when CSPF is disabled with the `no-cspf` statement at the `[edit protocols mpls label-switched-path lsp-name]` hierarchy level, you must use strict paths.

```
[edit]
protocols {
```

```
    mpls {
        path path-name {
                            next-hop-address (strict | loose);
        }
    }
}
```

NOTE: If the end-to-end LSP originates on the same routing platform as the FA-LSP, you must disable CSPF and use strict paths.

Option: Tearing Down RSVP LSPs Gracefully

You can tear down an RSVP LSP in a two-step process that gracefully withdraws the RSVP session used by the LSP. For all neighbors that support graceful teardown, a request for the teardown is sent by the routing platform to the destination endpoint for the LSP and all RSVP neighbors in the path. The request is included within the `ADMIN_STATUS` field of the RSVP packet. When neighbors receive the request, they prepare for the RSVP session to be withdrawn. A second message is sent by the routing platform to complete the teardown of the RSVP session. If a neighbor does not support graceful teardown, the request is handled as a standard session teardown rather than a graceful one.

To perform a graceful teardown of an RSVP session, issue the `clear rsvp session gracefully` command. Optionally, you can specify the source and destination address of the RSVP session, the LSP identifier of the RSVP sender, and the tunnel identifier of the RSVP session. To use these qualifiers, include the `connection-source`, `connection-destination`, `lsp-id`, and `tunnel-id` options when you issue the `clear rsvp session gracefully` command.

You can also configure the amount of time that the routing platform waits for neighbors to receive the graceful teardown request before initiating the actual teardown by including the `graceful-deletion-timeout` statement at the `[edit protocols rsvp]` hierarchy level. The default graceful deletion timeout value is 30 seconds, with a minimum value of 1 second and a maximum value of 300 seconds. To view the current value configured for graceful deletion timeout, issue the `show rsvp version` operational mode command.

Release History Table

Release	Description
19.4R1	
16.1	However, starting from Junos OS Release 16.1, when RSVP hello messages time-out, the RSVP sessions are brought down.

LDP Introduction

The Label Distribution Protocol (LDP) is a protocol for distributing labels in non-traffic-engineered applications. LDP allows routers to establish label-switched paths (LSPs) through a network by mapping network-layer routing information directly to data link layer-switched paths.

These LSPs might have an endpoint at a directly attached neighbor (comparable to IP hop-by-hop forwarding), or at a network egress node, enabling switching through all intermediary nodes. LSPs established by LDP can also traverse traffic-engineered LSPs created by RSVP.

LDP associates a forwarding equivalence class (FEC) with each LSP it creates. The FEC associated with an LSP specifies which packets are mapped to that LSP. LSPs are extended through a network as each router chooses the label advertised by the next hop for the FEC and splices it to the label it advertises to all other routers. This process forms a tree of LSPs that converge on the egress router.

Understanding the LDP Signaling Protocol

LDP is a signaling protocol that runs on a device configured for MPLS support. The successful configuration of both MPLS and LDP initiates the exchange of TCP packets across the LDP interfaces. The packets establish TCP-based LDP sessions for the exchange of MPLS information within the network. Enabling both MPLS and LDP on the appropriate interfaces is sufficient to establish LSPs.

LDP is a simple, fast-acting signaling protocol that automatically establishes LSP adjacencies within an MPLS network. Routers then share LSP updates such as hello packets and LSP advertisements across the adjacencies. Because LDP runs on top of an IGP such as IS-IS or OSPF, you must configure LDP and the IGP on the same set of interfaces. After both are configured, LDP begins transmitting and receiving LDP messages through all LDP-enabled interfaces. Because of LDP's simplicity, it cannot perform the true traffic engineering which RSVP can perform. LDP does not support bandwidth reservation or traffic constraints.

When you configure LDP on a *label-switching router* (LSR), the router begins sending LDP discovery messages out all LDP-enabled interfaces. When an adjacent LSR receives LDP discovery messages, it establishes an underlying TCP session. An LDP session is then created on top of the TCP session. The TCP three-way handshake ensures that the LDP session has bidirectional connectivity. After they establish the LDP session, the LDP neighbors maintain, and terminate, the session by exchanging messages. LDP advertisement messages allow LSRs to exchange label information to determine the next hops within a particular LSP. Any topology changes, such as a router failure, generate LDP notifications that can terminate the LDP session or generate additional LDP advertisements to propagate an LSP change.

Starting in Junos OS Release 20.3R1, support for MPLS to provide LDP signaling protocol configuration with the control plane functionality.

Example: Configuring LDP-Signaled LSPs

IN THIS SECTION

- Requirements | 1276
- Overview | 1276
- Configuration | 1277

This example shows how to create and configure LDP instances within an MPLS network.

Requirements

Before you begin:

- Configure network interfaces. See Interfaces User Guide for Security Devices.
- Configure an IGP across your network. (The LDP configuration is added to the existing IGP configuration and included in the MPLS configuration.)
- Configure a network to use LDP for LSP establishment by enabling MPLS on all transit interfaces in the MPLS network.

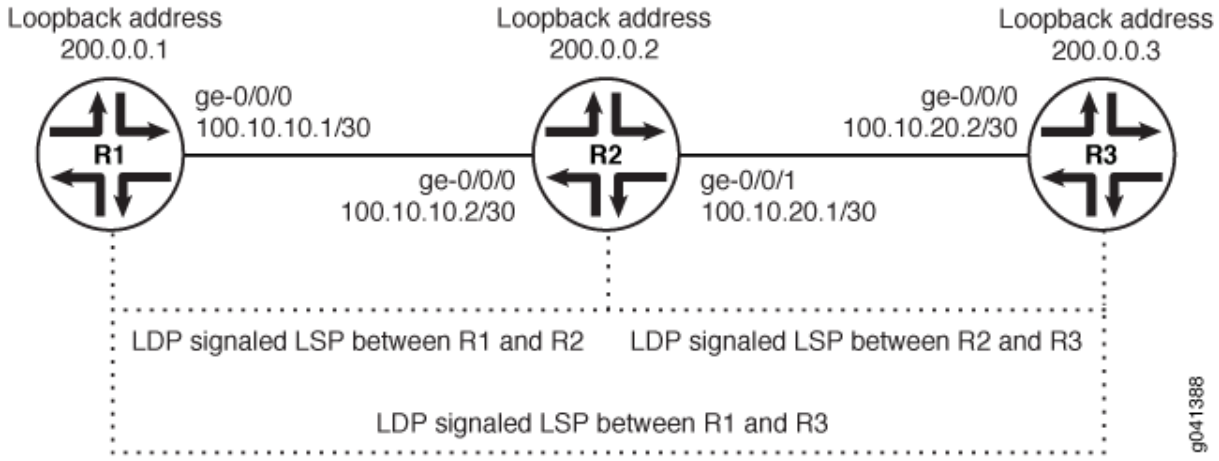
> **NOTE**: Because LDP runs on top of an IGP such as IS-IS or OSPF, you must configure LDP and the IGP on the same set of interfaces.

Overview

To configure LDP-signaled LSPs, you must enable the MPLS family on all transit interfaces in the MPLS network and include all the transit interfaces under the [`protocols mpls`] and [`protocols ldp`] hierarchy levels.

In this example, you enable the MPLS family and create an LDP instance on all the transit interfaces. Additionally, you enable the MPLS process on all the transit interfaces in the MPLS network. In this example, you configure a sample network as shown in Figure 72 on page 1277.

Figure 72: Typical LDP-Signaled LSP



Configuration

- Results | **1279**

Procedure

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the `[edit]` hierarchy level and then enter `commit` from configuration mode.

For Router R1, perform the following:

```
set interfaces ge-0/0/0 unit 0 family mpls
set protocols mpls ge-0/0/0 unit 0
set protocols ldp interface ge-0/0/0.0 unit 0
```

For Router R2, perform the following:

```
set interfaces ge-0/0/0 unit 0 family mpls
set protocols mpls ge-0/0/0 unit 0
set protocols ldp interface ge-0/0/0.0 unit 0
set interfaces ge-0/0/1 unit 0 family mpls
set protocols mpls ge-0/0/1 unit 0
set protocols ldp interface ge-0/0/0.1 unit 0
```

For Router R3, perform the following:

```
set interfaces ge-0/0/0 unit 0 family mpls
set protocols mpls ge-0/0/0 unit 0
set protocols ldp interface ge-0/0/0.0 unit 0
```

Step-by-Step Procedure

To enable LDP instances within an MPLS network:

1. Enable the MPLS family on the transit interface on Router R1.

```
[edit]
user@R1# set interfaces ge-0/0/0 unit 0 family mpls
```

2. Enable the MPLS process on the transit interface.

```
[edit]
user@R1# set protocols mpls interface ge-0/0/0 unit 0
```

3. Create the LDP instance on the transit interface.

```
[edit]
user@R1# set protocols ldp interface ge-0/0/0 unit 0
```

Results

Confirm your configuration by entering the `show` command from configuration mode. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

For brevity, this `show` output includes only the configuration that is relevant to this example. Any other configuration on the system has been replaced with ellipses (...).

```
user@R1# show
...
    interfaces {
        ge-0/0/0 {
            unit 0 {
                family inet {
                    address 10.100.37.20/24;
                }
                family mpls;
            }
        }
        }
    ...
        protocols {
            mpls {
                interface all;
            }
            ldp {
                interface ge-0/0/0.0;
            }
        }
```

If you are done configuring the device, enter the `commit` command from the configuration mode to activate the configuration.

Results

Junos OS LDP Protocol Implementation

The Junos OS implementation of LDP supports LDP version 1. The Junos OS supports a simple mechanism for tunneling between routers in an interior gateway protocol (IGP), to eliminate the required distribution of external routes within the core. The Junos OS allows an MPLS tunnel next hop to all egress routers in the network, with only an IGP running in the core to distribute routes to egress routers. Edge routers run BGP but do not distribute external routes to the core. Instead, the recursive route lookup at the edge resolves to an LSP switched to the egress router. No external routes are necessary on the transit LDP routers.

LDP Operation

You must configure LDP for each interface on which you want LDP to run. LDP creates LSP trees rooted at each egress router for the router ID address that is the subsequent BGP next hop. The ingress point is at every router running LDP. This process provides an inet.3 route to every egress router. If BGP is running, it will attempt to resolve next hops by using the inet.3 table first, which binds most, if not all, of the BGP routes to MPLS tunnel next hops.

Two adjacent routers running LDP become neighbors. If the two routers are connected by more than one interface, they become neighbors on each interface. When LDP routers become neighbors, they establish an LDP session to exchange label information. If per-router labels are in use on both routers, only one LDP session is established between them, even if they are neighbors on multiple interfaces. For this reason, an LDP session is not related to a particular interface.

LDP operates in conjunction with a unicast routing protocol. LDP installs LSPs only when both LDP and the routing protocol are enabled. For this reason, you must enable both LDP and the routing protocol on the same set of interfaces. If this is not done, LSPs might not be established between each egress router and all ingress routers, which might result in loss of BGP-routed traffic.

You can apply policy filters to labels received from and distributed to other routers through LDP. Policy filters provide you with a mechanism to control the establishment of LSPs.

For LDP to run on an interface, MPLS must be enabled on a *logical interface* on that interface. For more information, see the Logical Interfaces.

LDP Message Types

IN THIS SECTION

- Discovery Messages | **1281**
- Session Messages | **1281**
- Advertisement Messages | **1281**

Notification Messages | 1282

LDP uses the message types described in the following sections to establish and remove mappings and to report errors. All LDP messages have a common structure that uses a type, length, and value (TLV) encoding scheme.

Discovery Messages

Discovery messages announce and maintain the presence of a router in a network. Routers indicate their presence in a network by sending hello messages periodically. Hello messages are transmitted as UDP packets to the LDP port at the group multicast address for all routers on the subnet.

LDP uses the following discovery procedures:

- Basic discovery—A router periodically sends LDP link hello messages through an interface. LDP link hello messages are sent as UDP packets addressed to the LDP discovery port. Receipt of an LDP link hello message on an interface identifies an adjacency with the LDP peer router.
- Extended discovery—LDP sessions between routers not directly connected are supported by LDP extended discovery. A router periodically sends LDP targeted hello messages to a specific address. Targeted hello messages are sent as UDP packets addressed to the LDP discovery port at the specific address. The targeted router decides whether to respond to or ignore the targeted hello message. A targeted router that chooses to respond does so by periodically sending targeted hello messages to the initiating router.

Session Messages

Session messages establish, maintain, and terminate sessions between LDP peers. When a router establishes a session with another router learned through the hello message, it uses the LDP initialization procedure over TCP transport. When the initialization procedure is completed successfully, the two routers are LDP peers and can exchange advertisement messages.

Advertisement Messages

Advertisement messages create, change, and delete label mappings for forwarding equivalence classes (FECs). Requesting a label or advertising a label mapping to a peer is a decision made by the local router. In general, the router requests a label mapping from a neighboring router when it needs one and advertises a label mapping to a neighboring router when it wants the neighbor to use a label.

Notification Messages

Notification messages provide advisory information and signal error information. LDP sends notification messages to report errors and other events of interest. There are two kinds of LDP notification messages:

- Error notifications, which signal fatal errors. If a router receives an error notification from a peer for an LDP session, it terminates the LDP session by closing the TCP transport connection for the session and discarding all label mappings learned through the session.
- Advisory notifications, which pass information to a router about the LDP session or the status of some previous message received from the peer.

Tunneling LDP LSPs in RSVP LSPs

You can tunnel LDP LSPs over RSVP LSPs. The following sections describe how tunneling of LDP LSPs in RSVP LSPs works:

- "Tunneling LDP LSPs in RSVP LSPs Overview" on page 1282
- "Label Operations" on page 1317

Tunneling LDP LSPs in RSVP LSPs Overview

IN THIS SECTION

- Benefits of Tunneling LDP LSPs in RSVP LSPs | **1283**

If you are using RSVP for traffic engineering, you can run LDP simultaneously to eliminate the distribution of external routes in the core. The LSPs established by LDP are tunneled through the LSPs established by RSVP. LDP effectively treats the traffic-engineered LSPs as single hops.

When you configure the router to run LDP across RSVP-established LSPs, LDP automatically establishes sessions with the router at the other end of the LSP. LDP control packets are routed hop-by-hop, rather than carried through the LSP. This routing allows you to use simplex (one-way) traffic-engineered LSPs. Traffic in the opposite direction flows through LDP-established LSPs that follow unicast routing rather than through traffic-engineered tunnels.

If you configure LDP over RSVP LSPs, you can still configure multiple OSPF areas and IS-IS levels in the traffic engineered core and in the surrounding LDP cloud.

Beginning with Junos OS Release 15.1, multi-instance support is extended to LDP over RSVP tunneling for a virtual router routing instance. This allows splitting of a single routing and MPLS domain into

multiple domains so that each domain can be scaled independently. BGP labeled unicast can be used to stitch these domains for service forwarding equivalence classes (FECs). Each domain uses intra-domain LDP-over-RSVP LSP for MPLS forwarding.

NOTE: With the introduction of the multi-instance support for LDP-over-RSVP LSPs, you cannot enable MPLS on an interface that is already assigned to another routing instance. Adding an interface that is part of another routing instance at the `[edit protocols mpls]` hierarchy level, throws a configuration error at the time of commit.

Benefits of Tunneling LDP LSPs in RSVP LSPs

Tunneling LDP LSPs in RSVP LSPs provides the following benefits:

- Provides convergence of different traffic types such as IPv4, IPv6, unicast, and multicast across Layer 2 and Layer 3 VPNs.
- Enables flexible access connectivity options that can accommodate multiple topologies, different protocols, and multiple administrative boundaries.
- Enables secure interworking among multiple providers.
- Enables provision of differentiated services on a per customer basis because RSVP-TE supports traffic engineering, bandwidth guarantees, and link and node redundancy capabilities.
- Reduces the number of LSPs required in the core, which reduces the resource requirements of the protocols and routers as well as reducing convergence time.
- Provides cost-efficient rollouts with minimal network disruption because the LSPs are built using point-to-point TE tunnels to directly attached neighbors. These TE tunnels only go to the next hop, not end to end. Then when LDP is run over those tunnels, the sessions are built to the directly connected neighbor. When there is a change in the network, such as adding a new node, the directly connected neighbors of the new node have RSVP and LDP sessions. Thus, the RSVP LSPs are only to the next hop, and LDP takes care of advertising labels for the new addresses.

Tunneling LDP over SR-TE

IN THIS SECTION

- Benefits of Tunneling LDP over SR-TE | **1284**
- Tunneling LDP over SR-TE Overview | **1284**

Learn about the benefits and get an overview of tunneling LDP over SR-TE.

Benefits of Tunneling LDP over SR-TE

- Enables seamless integration of LDP over SR-TE in the core network.
- Provides flexible connectivity options to accommodate multiple topologies, protocols, and domains.
- Enables interoperability between LDP and SR capable devices.
- Leverages SR-TE load sharing capabilities.
- Provides faster restoration of network connectivity using Topology Independent Loop-Free Alternate (TI-LFA) within the SR-TE domain. SR using TI-LFA routes the traffic instantly to a backup or an alternate path if the primary path fails or becomes unavailable.

Tunneling LDP over SR-TE Overview

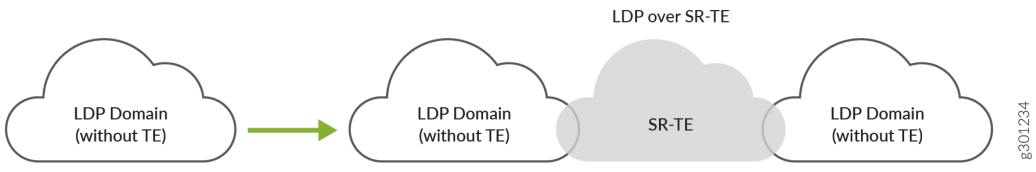
It's common for service providers to use the LDP signaling protocol with MPLS transport at the edges of their networks. LDP offers the advantage of being simple, but LDP lacks traffic engineering (TE) and sophisticated path repair capabilities that are often desired in the network's core. Many service providers are migrating from RSVP to segment routing traffic engineering (SR-TE) in the core. SR-TE is also referred to as source routing in packet networks (SPRING).

It's possible that the routers running LDP at the edge may not support SR capabilities. The service provider may wish to continue using LDP on these routers to avoid the need for an upgrade. In such scenarios, the LDP over SR-TE tunneling feature provides the ability to integrate routers that are not SR capable (running LDP) with routers that are SR capable (running SR-TE).

The LDP LSPs are tunneled through the SR-TE network, enabling interworking of LDP LSPs with SR-TE LSPs. For example, if you have LDP domains on the provider edge network and SR-TE in the core network, then you can connect the LDP domains over SR-TE, as shown in Figure 73 on page 1284.

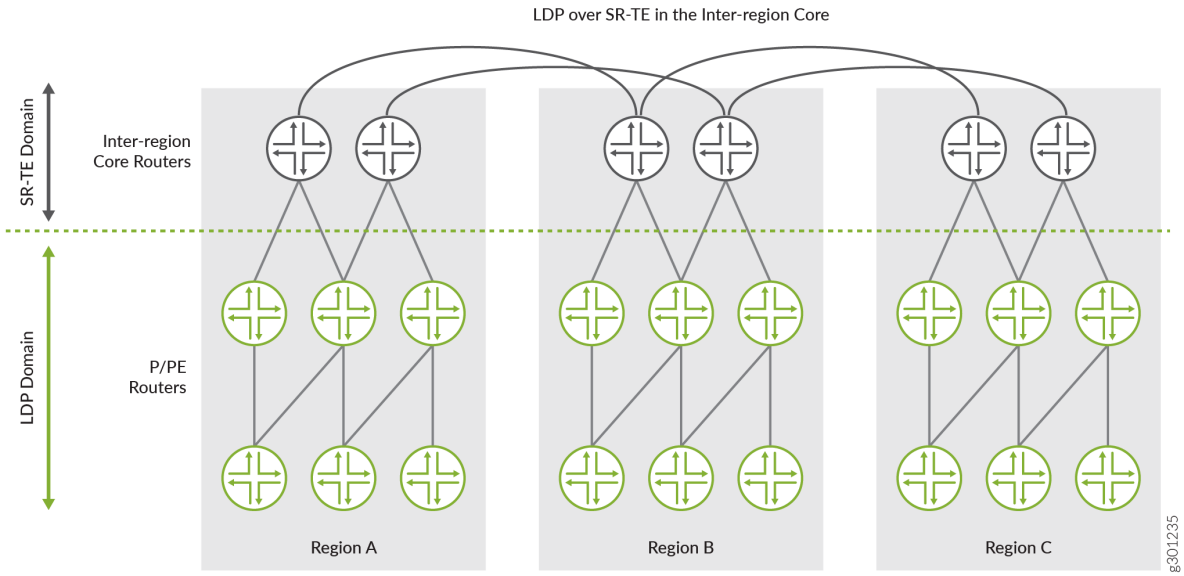
Tunneling LDP over SR-TE supports co-existence of both LDP LSPs and SR-TE LSPs.

Figure 73: Interconnect LDP Domains over SR-TE in the Core Network



You can also tunnel LDP over SR-TE between LDP domains connected to inter-region core networks. For example, if you have multiple regional LDP domains connected to the inter-region SR-TE core networks, you can tunnel LDP across the inter-region SR-TE core network, as shown in Figure 74 on page 1285.

Figure 74: LDP over SR-TE between Inter-region Core Networks



In Figure 74 on page 1285, you have three regional networks (A, B, and C) running LDP. These regional LDP domains are connected to their respective regional core networks running SR-TE. The regional SR-TE core networks are further interconnected to other regional SR-TE core networks (inter-region core network). You can tunnel LDP over these inter-region SR-TE core networks and deploy services, such as Layer 3 VPNs, seamlessly. This scenario could be used in a mobile backhaul network, where the core aggregation layer runs LDP tunneled over SR-TE while the access layer runs LDP only.

To enable LDP tunneling over SR-TE, you need to configure the following statements:

- `ldp-tunneling` at the [`edit protocols source-packet-routing source-routing-path` *`source-routing-path-name`*] hierarchy level to enable LDP tunneling over SR-TE.
- `spring-te` at the [`edit protocols isis traffic-engineering tunnel-source-protocol`] hierarchy level selects LDP over SR-TE LSPs as the tunnel source protocol.

You can configure more than one tunnel source protocol for IGPs to create shortcut routes. When more than one tunnel source protocol is configured and if the tunnels from more than one protocol are available to a destination, the tunnel with the most preferred route is established. For example, if the core network has both RSVP LSPs and SR-TE LSPs and LDP tunneling is enabled for both RSVP and SR-TE LSPs, then the `tunnel-source-protocol` configuration selects the tunnel based on the preference value.

The tunnel with the lowest preference value is most preferred. You can override this route preference with a specific protocol for all destinations by configuring the preference value, as shown in the following example:

```
[edit]
user@host#set protocols isis traffic-engineering tunnel-source-protocol spring-te preference 2
user@host#set protocols isis traffic-engineering tunnel-source-protocol rsvp preference 5
```

In this example, you can see the preference value configured for the SR-TE tunnel source protocol is 2 and the preference value for RSVP tunnel source protocol is 5. In this case, the SR-TE tunnel are preferred because they have the lowest preference value as compared to RSVP tunnel source protocol.

NOTE: It is not mandatory to configure the tunnel source protocol preference value. If more than one tunnel source protocol has the same preference value, then the tunnel is established based on the preferred route to the destination.

The targeted LDP session is established and is triggered when the SR-TE LSP comes up. The LSP session remains established until the LDP tunneling (`ldp-tunneling`) configuration is removed, or the SR-TE LSP is removed from the configuration.

NOTE: Junos OS currently does not support LDP over colored SR-TE LSPs.

Example: Tunneling LDP over SR-TE

IN THIS SECTION

- Requirements | **1287**
- Overview | **1287**
- Configuration | **1288**
- Verification | **1309**

Use this example to learn how to tunnel LDP LSPs over SR-TE in your core network.

NOTE: Our content testing team has validated and updated this example.

Requirements

This example uses the following hardware and software components:

- MX Series routers as CE, PE, and core routers.
- Junos OS Release 20.3R1 or later running on all devices.
  - Updated and revalidated using vMX on Junos OS Release 21.1R1.

NOTE: Are you interested in getting hands-on experience on this feature?

To tunnel LDP LSP over SR-TE in your core network, perform these tasks:

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the `[edit]` hierarchy level, and then enter `commit` from configuration mode.

Device CE1

```
set chassis network-services enhanced-ip
set interfaces ge-0/0/1 description CE1-to-PE1
set interfaces ge-0/0/1 unit 0 family inet address 10.1.1.1/24
set interfaces lo0 unit 0 family inet address 192.168.100.11/32
set protocols ospf area 0.0.0.0 interface ge-0/0/1.0
set protocols ospf area 0.0.0.0 interface lo0.0 passive
set routing-options router-id 192.168.100.11
```

Device PE1

```

set routing-options router-id 192.168.100.22
```

Configuring PE1

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see Using the CLI Editor in Configuration Mode in the CLI User Guide.

To configure device PE1:

1. Configure the network services mode as Enhanced IP. Enhanced IP sets the router's network services to enhanced Internet Protocol and uses enhanced mode capabilities.

```
[edit chassis]
user@PE1#set network-services enhanced-ip
```

After you configure the `enhanced-ip` statement and commit the configuration, the following warning message appears prompting you to reboot the router:

```
'chassis'
WARNING: Chassis configuration for network services has been changed. A system reboot is
mandatory. Please reboot the system NOW. Continuing without a reboot might result in
unexpected system behavior.
commit complete
```

The reboot brings up the FPCs on the router.

2. Configure the device's interfaces.

```
[edit interfaces]
user@PE1#set ge-0/0/1 description PE1-to-CE1
user@PE1#set ge-0/0/1 unit 0 family inet address 10.1.1.2/24
user@PE1#set ge-0/0/1 unit 0 family iso

user@PE1#set ge-0/0/3 description PE1-to-R1
user@PE1#set ge-0/0/3 unit 0 family inet address 10.1.2.1/24
user@PE1#set ge-0/0/3 unit 0 family iso
user@PE1#set ge-0/0/3 unit 0 family mpls

user@PE1#set lo0 unit 0 family inet address 192.168.100.5/32
user@PE1#set lo0 unit 0 family iso address 49.0004.0192.0168.0005.00
user@PE1#set lo0 unit 0 family mpls
```

3. Configure policy options to export BGP routes to the CE router, which runs the OSPF protocol in this example.

```
[edit policy-options]
user@PE1#set policy-statement export_bgp term a from protocol bgp
user@PE1#set policy-statement export_bgp term a from protocol direct
user@PE1#set policy-statement export_bgp term a then accept
```

4. Configure a Layer 3 VPN routing instance to support the OSPF-based CE1 device.

```
[edit routing-instances]
user@PE1#set CE1_vpn1 instance-type vrf
user@PE1#set CE1_vpn1 protocols ospf area 0.0.0.0 interface ge-0/0/1.0
```

```
user@PE1#set CE1_vpn1 protocols ospf export export_bgp
user@PE1#set CE1_vpn1 interface ge-0/0/1.0
user@PE1#set CE1_vpn1 route-distinguisher 192.168.100.5:1
user@PE1#set CE1_vpn1 vrf-target target:100:4
user@PE1#set CE1_vpn1 vrf-table-label
```

5. Configure the router ID and autonomous system number for Device PE1.

```
[edit routing-options]
user@PE1#set router-id 192.168.100.5
userPE1# set autonomous-system 65410
```

6. Configure ISIS, LDP, and MPLS on the interfaces connected to the core network.

```
[edit protocols]
user@PE1#set isis interface ge-0/0/3.0 point-to-point
user@PE1#set isis interface lo0.0 passive

user@PE1#set ldp interface ge-0/0/3.0
user@PE1#set ldp interface lo0.0

user@PE1#set mpls interface ge-0/0/3.0
user@PE1#set mpls interface lo0.0
```

7. Configure BGP between the PE devices.

```
[edit protocols]
user@PE1#set bgp group ibgp1 type internal
user@PE1#set bgp group ibgp1 local-address 192.168.100.5
user@PE1#set bgp group ibgp1 family inet unicast
user@PE1#set bgp group ibgp1 family inet-vpn unicast
user@PE1#set bgp group ibgp1 neighbor 192.168.100.6
```

Results

From configuration mode, confirm your configuration by entering the `show chassis`, `show interfaces`, `show policy-options`, `show routing-instances`,`show routing-options`, and `show protocols` commands. If the output does

not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1#show chassis
network-services enhanced-ip;
```

```
user@PE1#show interfaces
ge-0/0/1 {

```

Configuring R1 Device

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see Using the CLI Editor in Configuration Mode in the CLI User Guide.

To configure device R1:

1. Configure the network services mode as Enhanced IP. Enhanced IP sets the router's network services to enhanced Internet Protocol and uses enhanced mode capabilities.

```
[edit chassis]
user@R1#set network-services enhanced-ip
```

After you configure the `enhanced-ip` statement and commit the configuration, the following warning message appears prompting you to reboot the router:

```
'chassis'
WARNING: Chassis configuration for network services has been changed. A system reboot is
mandatory. Please reboot the system NOW. Continuing without a reboot might result in
unexpected system behavior.
commit complete
```

The reboot brings up the FPCs on the router.

2. Configure the device's interfaces.

```
[edit interfaces]
user@R1#set ge-0/0/1 description R1-to-R2
user@R1#set ge-0/0/1 unit 0 family inet address 10.1.3.1/24
user@R1#set ge-0/0/1 unit 0 family iso
user@R1#set ge-0/0/1 unit 0 family mpls maximum-labels 8

user@R1#set ge-0/0/2 description R1-to-R3
user@R1#set ge-0/0/2 unit 0 family inet address 10.1.4.1/24
user@R1#set ge-0/0/2 unit 0 family iso
user@R1#set ge-0/0/2 unit 0 family mpls maximum-labels 8

user@R1#set ge-0/0/3 description R1-to-PE1
user@R1#set ge-0/0/3 unit 0 family inet address 10.1.2.2/24
user@R1#set ge-0/0/3 unit 0 family iso
user@R1#set ge-0/0/3 unit 0 family mpls maximum-labels 8

user@R1#set lo0 unit 0 family inet address 192.168.100.1/32
user@R1#set lo0 unit 0 family iso address 49.0004.0192.0168.0001.00
user@R1#set lo0 unit 0 family mpls
```

3. Configure routing options to identify the router in the domain.

```
[edit routing-options]
user@R1#set router-id 192.168.100.1
```

4. Configure ISIS adjacency SIDs on the interfaces and allocate SRGB labels to enable segment routing. The labels in the entire SRGB are available for ISIS. Prefix SIDs (and Node SIDs) are indexed from the SRGB.

```
[edit protocols]
user@R1#set isis interface ge-0/0/1.0 level 2 ipv4-adjacency-segment protected index 108
user@R1#set isis interface ge-0/0/1.0 level 2 ipv4-adjacency-segment unprotected index 110
user@R1#set isis interface ge-0/0/1.0 level 2 ipv6-adjacency-segment protected index 109
user@R1#set isis interface ge-0/0/1.0 level 2 ipv6-adjacency-segment unprotected index 111
user@R1#set isis interface ge-0/0/1.0 level 2 post-convergence-lfa
user@R1#set isis interface ge-0/0/1.0 point-to-point

user@R1#set isis interface ge-0/0/2.0 level 2 ipv4-adjacency-segment protected index 104
user@R1#set isis interface ge-0/0/2.0 level 2 ipv4-adjacency-segment unprotected index 106
user@R1#set isis interface ge-0/0/2.0 level 2 ipv6-adjacency-segment protected index 105
user@R1#set isis interface ge-0/0/2.0 level 2 ipv6-adjacency-segment unprotected index 107
user@R1#set isis interface ge-0/0/2.0 level 2 post-convergence-lfa
user@R1#set isis interface ge-0/0/2.0 point-to-point

user@R1#set isis interface ge-0/0/3.0 level 2 ipv4-adjacency-segment protected index 100
user@R1#set isis interface ge-0/0/3.0 level 2 ipv4-adjacency-segment unprotected index 102
user@R1#set isis interface ge-0/0/3.0 level 2 ipv6-adjacency-segment protected index 101
user@R1#set isis interface ge-0/0/3.0 level 2 ipv6-adjacency-segment unprotected index 103
user@R1#set isis interface ge-0/0/3.0 level 2 post-convergence-lfa
user@R1#set isis interface ge-0/0/3.0 point-to-point

user@R1#set isis interface lo0.0 passive

user@R1#set isis source-packet-routing srgb start-label 80000
user@R1#set isis source-packet-routing srgb index-range 50000
user@R1#set isis source-packet-routing node-segment ipv4-index 5001
user@R1#set isis source-packet-routing node-segment ipv6-index 5501
user@R1#set isis level 1 disable
```

5. Configure TI-LFA to enable protection against link and node failures. SR using TI-LFA provides faster restoration of network connectivity by routing the traffic instantly to a backup or an alternate path if the primary path fails or becomes unavailable.

```
[edit protocols]
user@R1#set isis backup-spf-options use-post-convergence-lfa
user@R1#set isis backup-spf-options use-source-packet-routing
```

6. Configure ISIS traffic engineering parameters.

```
[edit protocols]
user@R1#set isis traffic-engineering l3-unicast-topology
user@R1#set isis traffic-engineering credibility-protocol-preference
```

7. Enable LDP tunneling over SR-TE.

```
[edit protocols]
user@R1#set isis traffic-engineering tunnel-source-protocol spring-te
```

8. Configure MPLS and LDP protocols on the interfaces in the LDP domain to exchange labels in the LDP domain.

```
[edit protocols]
user@R1#set ldp preference 1
user@R1#set ldp interface ge-0/0/3.0
user@R1#set ldp interface lo0.0

user@R1#set mpls interface ge-0/0/1.0
user@R1#set mpls interface ge-0/0/2.0
user@R1#set mpls interface ge-0/0/3.0
user@R1#set mpls interface lo0.0
```

9. Enable targeted LDP session between the edge routers in the LDP domain.

```
[edit protocols]
user@R1#set ldp auto-targeted-session
```

10. Configure a segment list to route the traffic to a specific path.

```
[edit protocols]
user@R1#set source-packet-routing segment-list seg1 inherit-label-nexthops
user@R1#set source-packet-routing segment-list seg1 auto-translate
user@R1#set source-packet-routing segment-list seg1 hop1 ip-address 192.168.4.2
user@R1#set source-packet-routing segment-list seg1 hop2 ip-address 192.168.5.2
user@R1#set source-packet-routing segment-list seg1 hop3 ip-address 192.168.6.2
```

11. Configure SR-TE LSP to the remote edge routers to enable LDP tunneling over SR-TE.

```
[edit protocols]
user@R1#set source-packet-routing source-routing-path sr_static_r5 ldp-tunneling
user@R1#set source-packet-routing source-routing-path sr_static_r5 to 192.168.66.66
user@R1#set source-packet-routing source-routing-path sr_static_r5 binding-sid 1003001
user@R1#set source-packet-routing source-routing-path sr_static_r5 primary seg1
```

Results

From configuration mode, confirm your configuration by entering the `show chassis`, `show interfaces`, `show routing-options`, and `show protocols` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R1#show chassis
network-services enhanced-ip;
```

```
user@R1#show interfaces

Verification

IN THIS SECTION

- Verifying LDP Tunneling over SR-TE | **1309**
- Verify LDP Forwarding to the Remote PE Device | **1311**
- Verifying the Advertised Label | **1313**

To confirm that the configuration is working properly, perform the following tasks:

Verifying LDP Tunneling over SR-TE

Purpose

Verify that the LDP over SR-TE tunnel is enabled and the LDP tunnel to the remote edge router is taking the right path.

Action

From operational mode, run the `show spring-traffic-engineering lsp detail` command.

On R1

```
user@R1>show spring-traffic-engineering lsp detail
Name: sr_static_r5
  Tunnel-source: Static configuration
```

```
  To: 192.168.100.2
  State: Up
  LDP-tunneling enabled
    Path: seg1
    Outgoing interface: NA
    Auto-translate status: Enabled Auto-translate result: Success
    Compute Status:Disabled , Compute Result:N/A , Compute-Profile Name:N/A
    BFD status: N/A BFD name: N/A
    ERO Valid: true
      SR-ERO hop count: 3
        Hop 1 (Strict):
          NAI: IPv4 Adjacency ID, 0.0.0.0 -> 10.1.4.2
          SID type: 20-bit label, Value: 80104
        Hop 2 (Strict):
          NAI: IPv4 Adjacency ID, 0.0.0.0 -> 10.1.5.2
          SID type: 20-bit label, Value: 80204
        Hop 3 (Strict):
          NAI: IPv4 Adjacency ID, 0.0.0.0 -> 10.1.6.2
          SID type: 20-bit label, Value: 80304

Total displayed LSPs: 1 (Up: 1, Down: 0)
```

On R2

```
user@R2>show spring-traffic-engineering lsp detail

Name: sr_static_r1
  Tunnel-source: Static configuration
  To: 192.168.100.1
  State: Up
  LDP-tunneling enabled
    Path: seg1
    Outgoing interface: NA
    Auto-translate status: Enabled Auto-translate result: Success
    Compute Status:Disabled , Compute Result:N/A , Compute-Profile Name:N/A
    BFD status: N/A BFD name: N/A
    ERO Valid: true
      SR-ERO hop count: 3
        Hop 1 (Strict):
          NAI: IPv4 Adjacency ID, 0.0.0.0 -> 10.1.6.1
```

```
          SID type: 20-bit label, Value: 80504
        Hop 2 (Strict):
          NAI: IPv4 Adjacency ID, 0.0.0.0 -> 10.1.5.1
          SID type: 20-bit label, Value: 80300
        Hop 3 (Strict):
          NAI: IPv4 Adjacency ID, 0.0.0.0 -> 10.1.4.1
          SID type: 20-bit label, Value: 80200

Total displayed LSPs: 1 (Up: 1, Down: 0)
```

Meaning

- On R1, the LDP tunnel is established with the remote edge router **192.168.100.2** in the SR-TE core network. You can also see the SID label values **80104, 80204, 80304** in the output.
- On R2, the LDP tunnel is established with the remote edge router **192.168.100.1** in the SR-TE core network. You can also see the SID label values **80504, 80300, 80200** in the output.

Verify LDP Forwarding to the Remote PE Device

Purpose

Verify that the route to the remote PE router uses LDP forwarding and is tunneled over SR-TE.

Action

From operational mode, run the `show route` *destination-prefix* command.

On R1

Verify that the route to the remote PE (**PE2**) router is through LDP over SR-TE tunnel.

```
user@R1>show route 192.168.100.6

inet.0: 24 destinations, 24 routes (24 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192.168.100.6/32   *[IS-IS/18] 5d 13:10:09, metric 20
                    >  to 10.1.3.2 via ge-0/0/1.0

inet.3: 8 destinations, 13 routes (5 active, 0 holddown, 6 hidden)
```

```
+ = Active Route, - = Last Active, * = Both

192.168.100.6/32   *[LDP/1] 5d 13:10:09, metric 1
                    >  to 10.1.4.2 via ge-0/0/2.0, Push 16, Push 80304, Push 80204(top)
                       to 10.1.3.2 via ge-0/0/1.0, Push 16, Push 80304, Push 80204, Push 85003,
Push 85004(top)
```

On R2

Verify that the route to the remote PE (**PE1**) router is through LDP over SR-TE tunnel.

```
user@R2>show route 192.168.100.5

inet.0: 24 destinations, 24 routes (24 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192.168.100.5/32   *[IS-IS/18] 5d 13:20:15, metric 20
                    >  to 10.1.3.1 via ge-0/0/1.0

inet.3: 8 destinations, 13 routes (5 active, 0 holddown, 6 hidden)
+ = Active Route, - = Last Active, * = Both

192.168.100.5/32   *[LDP/9] 5d 13:20:15, metric 1
                    >  to 10.1.6.1 via ge-0/0/2.0, Push 16, Push 80200, Push 80300(top)
                       to 10.1.3.1 via ge-0/0/1.0, Push 16, Push 80200, Push 80300, Push 85004,
Push 85003(top)
```

On PE1

Verify that the route to the remote PE (**PE2**) router is through a targeted LDP session to the remote PE.

```
user@PE1>show route 192.168.100.6

inet.0: 22 destinations, 22 routes (22 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192.168.100.6/32   *[IS-IS/18] 1w3d 15:58:20, metric 30
                    >  to 10.1.2.2 via ge-0/0/3.0

inet.3: 3 destinations, 3 routes (3 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
```

```
192.168.100.6/32   *[LDP/9] 1w0d 16:00:05, metric 1
                    >  to 10.1.2.2 via ge-0/0/3.0, Push 18
```

On PE2

Verify that the route to the remote PE (**PE1**) router is through a targeted LDP session to the remote PE.

```
user@PE2>show route 192.168.100.5

inet.0: 22 destinations, 22 routes (22 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192.168.100.5/32   *[IS-IS/18] 1w3d 15:59:19, metric 30
                    >  to 10.1.7.1 via ge-0/0/3.0

inet.3: 3 destinations, 3 routes (3 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192.168.100.5/32   *[LDP/9] 1w0d 16:01:14, metric 1
                    >  to 10.1.7.1 via ge-0/0/3.0, Push 18
```

Meaning

- On R1, you can see the LDP label as **16** and the SR-TE label stacks as **80304, 80204, 85003, 85004**.
- On R2, you can see the LDP label as **16** and the SR-TE label stacks as **80200, 80300, 85004, 85003**.
- On PE1 and PE2, you can see the LDP label as **18** and **19**, respectively.

Verifying the Advertised Label

Purpose

Verify the labels advertised for the forwarding equivalence class (FEC).

Action

From operational mode, run the `show ldp database` command.

On R1

Verify the labels advertised towards the directly connected PE (PE1) and the labels received from remote edge router (R2).

```
user@R1>show ldp database

Input label database, 192.168.100.1:0--192.168.100.2:0
Labels received: 4
  Label     Prefix
     17      192.168.100.1/32
      3      192.168.100.2/32

Label Operations

Figure 76 on page 1318 depicts an LDP LSP being tunneled through an RSVP LSP. (For definitions of label operations, see "MPLS Label Overview" on page 509.) The shaded inner oval represents the RSVP domain, whereas the outer oval depicts the LDP domain. RSVP establishes an LSP through routers B, C, D, and E, with the sequence of labels L3, L4. LDP establishes an LSP through Routers A, B, E, F, and G, with the sequence of labels L1, L2, L5. LDP views the RSVP LSP between Routers B and E as a single hop.

When the packet arrives at Router A, it enters the LSP established by LDP, and a label (L1) is pushed onto the packet. When the packet arrives at Router B, the label (L1) is swapped with another label (L2). Because the packet is entering the traffic-engineered LSP established by RSVP, a second label (L3) is pushed onto the packet.

This outer label (L3) is swapped with a new label (L4) at the intermediate router (C) within the RSVP LSP tunnel, and when the penultimate router (D) is reached, the top label is popped. Router E swaps the

label (L2) with a new label (L5), and the penultimate router for the LDP-established LSP (F) pops the last label.

Figure 76: Swap and Push When LDP LSPs Are Tunneled Through RSVP LSPs

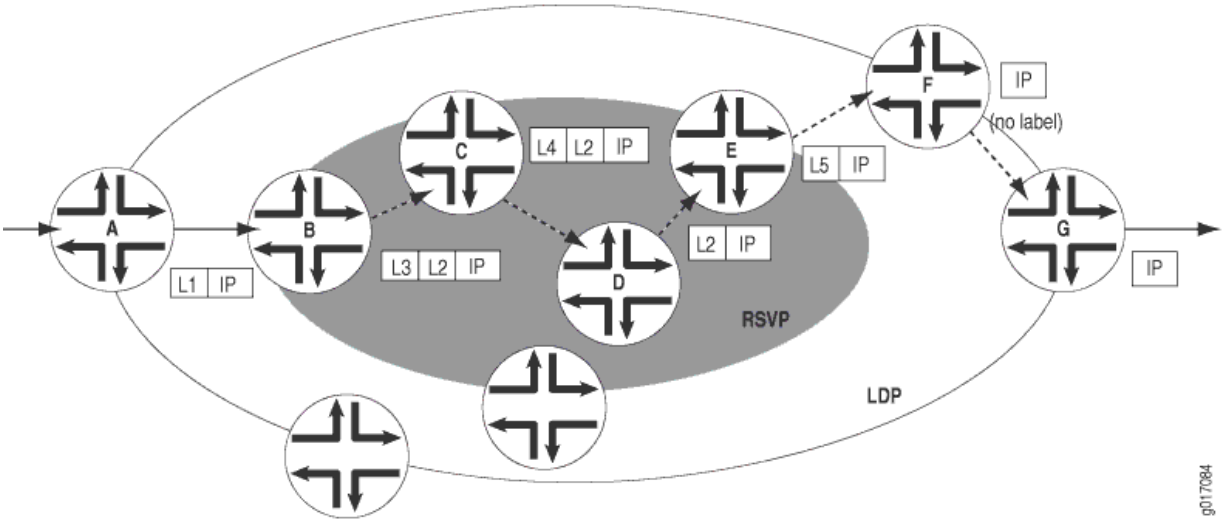

Figure 77 on page 1318 depicts a double push label operation (L1L2). A double push label operation is used when the ingress router (A) for both the LDP LSP and the RSVP LSP tunneled through it is the same device. Note that Router D is the penultimate hop for the LDP-established LSP, so L2 is popped from the packet by Router D.

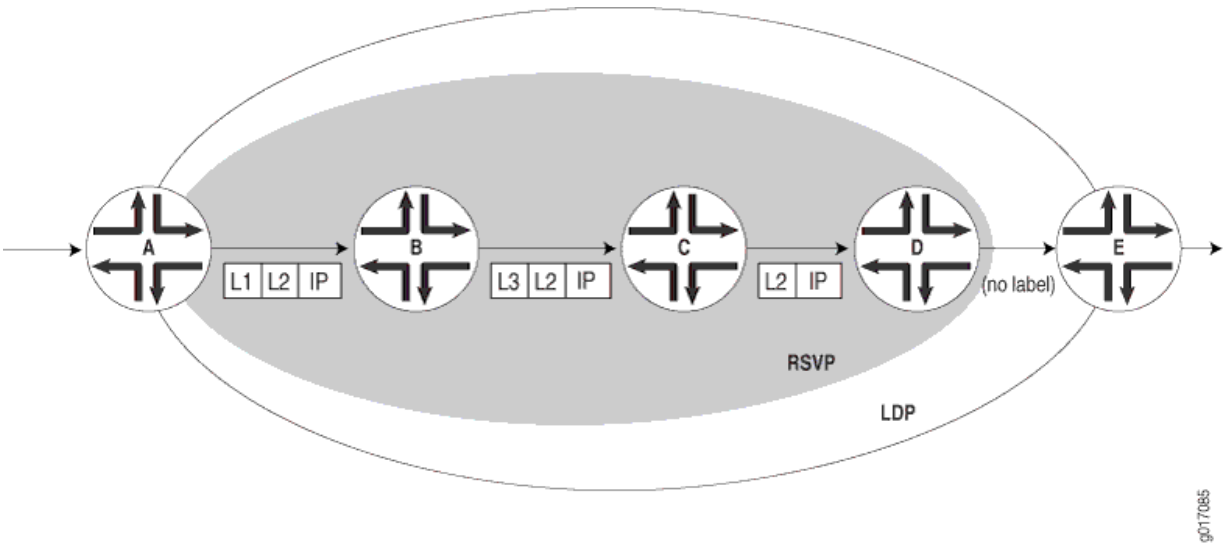
Figure 77: Double Push When LDP LSPs Are Tunneled Through RSVP LSPs



LDP Session Protection

LDP session protection is based on the LDP targeted hello functionality defined in RFC 5036, *LDP Specification*, and is supported by the Junos OS as well as the LDP implementations of most other vendors. It involves sending unicast User Datagram Protocol (UDP) hello packets to a remote neighbor address and receiving similar packets from the neighbor router.

If you configure LDP session protection on a router, the LDP sessions are maintained as follows:

1. An LDP session is established between a router and a remote neighboring router.
2. If all of the direct links between the routers go down, the LDP session remains up so long as there is IP connectivity between the routers based on another connection over the network.
3. When the direct link between the routers is reestablished, the LDP session is not restarted. The routers simply exchange LDP hellos with each other over the direct link. They can then begin forwarding LDP-signaled MPLS packets using the original LDP session.

By default, LDP targeted hellos are set to the remote neighbor so long as the LDP session is up, even if there are no more link neighbors to that router. You can also specify the duration you would like to maintain the remote neighbor connection in the absence of link neighbors. When the last link neighbor for a session goes down, the Junos OS starts an LDP session protection timer. If this timer expires before any of the link neighbors come back up, the remote neighbor connection is taken down and the LDP session is terminated. If you configure a different value for the timer while it is currently running, the Junos OS updates the timer to the specified value without disrupting the current state of the LDP session.

LDP Native IPv6 Support Overview

IPv6 connectivity often relies on tunneling IPv6 over an IPv4 MPLS core with IPv4-signaled MPLS label-switched paths (LSPs). This requires the IPv4-signaled LSPs to be configured statically or established dynamically by IPv6 provider edge routers. Because of the growing demand of IPv6, it has become imperative to deploy an IPv6 MPLS core with an IPv6-signaled LSP to provide IPv6 connectivity. In Junos OS, LDP is supported in an IPv6 network only, and in an IPv6/IPv4 dual-stack network as described in *RFC 7552*. Apart from providing a single session for both IPv4 and IPv6 networks, Junos OS LDP supports separate IPv4 sessions for IPv4 only, and IPv6 sessions for IPv6 only.

You can configure the address family as `inet` for IPv4 or `inet6` for IPv6, or both. If the family address is not configured, then the default address of family inet is enabled. When both IPv4 and IPv6 are configured, you can use the `transport-preference` statement to configure the prefered transport to be either `IPv4` or `IPv6`. Based on the preference, LDP attempts to establish a TCP connection using IPv4 or IPv6. By default, IPv6 is selected. The `dual-transport` statement allows Junos OS LDP to establish the TCP connection over IPv4 with IPv4 neighbors, and over IPv6 with IPv6 neighbors as a single-stack LSR. The `inet-lsr-id` and `inet6-lsr-id` IDs are the two LSR IDs that have to be configured to establish an LDP

session over IPv4 and IPv6 TCP transport. These two IDs should be non-zero and must be configured with different values.

Longest Match Support for LDP Overview

LDP is often used to establish MPLS label-switched paths (LSPs) throughout a complete network domain using an IGP such as OSPF or IS-IS. In such a network, all links in the domain have IGP adjacencies as well as LDP adjacencies. LDP establishes the LSPs on the shortest path to a destination as determined by IGP. In Junos OS, the LDP implementation does an exact match lookup on the IP address of the forwarding equivalence class (FEC) in the routing information base (RIB) or IGP routes for label mapping. This exact mapping requires MPLS end-to-end LDP endpoint IP addresses to be configured in all the label edge routers (LERs). This defeats the purpose of IP hierarchical design or default routing in access devices. Configuring `longest-match` allows LDP to set up LSP based on the routes aggregated or summarized across OSPF areas or IS-IS levels in the inter-domain.

Release History Table

Release	Description
20.3R1	Starting in Junos OS Release 20.3R1, support for MPLS to provide LDP signaling protocol configuration with the control plane functionality.
15.1	Beginning with Junos OS Release 15.1, multi-instance support is extended to LDP over RSVP tunneling for a virtual router routing instance.

Minimum LDP Configuration

To enable LDP with minimal configuration:

1. Enable all relevant interfaces under family MPLS. In the case of directed LDP, the loopback interface needs to be enabled with family MPLS.
2. (Optional) Configure the relevant interfaces under the `[edit protocol mpls]` hierarchy level.
3. Enable LDP on a single interface, include the `ldp` statement and specify the interface using the `interface` statement.

This is the minimum LDP configuration. All other LDP configuration statements are optional.

```
ldp {
    interface interface-name;
}
```

To enable LDP on all interfaces, specify `all` for *`interface-name`*.

For a list of hierarchy levels at which you can include these statements, see the statement summary sections.

Enabling and Disabling LDP

LDP is routing-instance-aware. To enable LDP on a specific interface, include the following statements:

```
ldp {
    interface interface-name;
}
```

For a list of hierarchy levels at which you can include these statements, see the statement summary sections.

To enable LDP on all interfaces, specify `all` for *`interface-name`*.

If you have configured interface properties on a group of interfaces and want to disable LDP on one of the interfaces, include the `interface` statement with the `disable` option:

```
interface interface-name {
    disable;
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section.

Configuring the LDP Timer for Hello Messages

IN THIS SECTION

- Configuring the LDP Timer for Link Hello Messages | **1324**
- Configuring the LDP Timer for Targeted Hello Messages | **1324**

LDP hello messages enable LDP nodes to discover one another and to detect the failure of a neighbor or the link to the neighbor. Hello messages are sent periodically on all interfaces where LDP is enabled.

There are two types of LDP hello messages:

- Link hello messages—Sent through the LDP interface as UDP packets addressed to the LDP discovery port. Receipt of an LDP link hello message on an interface identifies an adjacency with the LDP peer router.
- Targeted hello messages—Sent as UDP packets addressed to the LDP discovery port at a specific address. Targeted hello messages are used to support LDP sessions between routers that are not directly connected. A targeted router determines whether to respond or ignore a targeted hello message. A targeted router that chooses to respond does so by periodically sending targeted hello messages back to the initiating router.

By default, LDP sends hello messages every 5 seconds for link hello messages and every 15 seconds for targeted hello messages. You can configure the LDP timer to alter how often both types of hello messages are sent. However, you cannot configure a time for the LDP timer that is greater than the LDP hold time. For more information, see "Configuring the Delay Before LDP Neighbors Are Considered Down" on page 1324.

Configuring the LDP Timer for Link Hello Messages

To modify how often LDP sends link hello messages, specify a new link hello message interval for the LDP timer using the `hello-interval` statement:

```
hello-interval seconds;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Configuring the LDP Timer for Targeted Hello Messages

To modify how often LDP sends targeted hello messages, specify a new targeted hello message interval for the LDP timer by configuring the `hello-interval` statement as an option for the `targeted-hello` statement:

```
targeted-hello {
    hello-interval seconds;
}
```

For a list of hierarchy levels at which you can include these statements, see the statement summary sections for these statements.

Configuring the Delay Before LDP Neighbors Are Considered Down

IN THIS SECTION

- Configuring the LDP Hold Time for Link Hello Messages | **1325**
- Configuring the LDP Hold Time for Targeted Hello Messages | **1326**

The hold time determines how long an LDP node should wait for a hello message before declaring a neighbor to be down. This value is sent as part of a hello message so that each LDP node tells its neighbors how long to wait. The values sent by each neighbor do not have to match.

The hold time should normally be at least three times the hello interval. The default is 15 seconds for link hello messages and 45 seconds for targeted hello messages. However, it is possible to configure an LDP hold time that is close to the value for the hello interval.

NOTE: By configuring an LDP hold time close to the hello interval (less than three times the hello interval), LDP neighbor failures might be detected more quickly. However, this also increases the possibility that the router might declare an LDP neighbor down that is still functioning normally. For more information, see "Configuring the LDP Timer for Hello Messages" on page 1323.

The LDP hold time is also negotiated automatically between LDP peers. When two LDP peers advertise different LDP hold times to one another, the smaller value is used. If an LDP peer router advertises a shorter hold time than the value you have configured, the peer router's advertised hold time is used. This negotiation can affect the LDP keepalive interval as well.

If the local LDP hold time is not shortened during LDP peer negotiation, the user-configured keepalive interval is left unchanged. However, if the local hold time is reduced during peer negotiation, the keepalive interval is recalculated. If the LDP hold time has been reduced during peer negotiation, the keepalive interval is reduced to one-third of the new hold time value. For example, if the new hold-time value is 45 seconds, the keepalive interval is set to 15 seconds.

This automated keepalive interval calculation can cause different keepalive intervals to be configured on each peer router. This enables the routers to be flexible in how often they send keepalive messages, because the LDP peer negotiation ensures they are sent more frequently than the LDP hold time.

When you reconfigure the hold-time interval, changes do not take effect until after the session is reset. The hold time is negotiated when the LDP peering session is initiated and cannot be renegotiated as long as the session is up (required by RFC 5036, *LDP Specification*). To manually force the LDP session to reset, issue the `clear ldp session` command.

Configuring the LDP Hold Time for Link Hello Messages

To modify how long an LDP node should wait for a link hello message before declaring the neighbor down, specify a new time in seconds using the `hold-time` statement:

```
hold-time seconds;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Configuring the LDP Hold Time for Targeted Hello Messages

To modify how long an LDP node should wait for a targeted hello message before declaring the neighbor down, specify a new time in seconds using the `hold-time` statement as an option for the `targeted-hello` statement:

```
targeted-hello {
    hold-time seconds;
}
```

For a list of hierarchy levels at which you can include these statements, see the statement summary sections for these statements.

Enabling Strict Targeted Hello Messages for LDP

Use strict targeted hello messages to prevent LDP sessions from being established with remote neighbors that have not been specifically configured. If you configure the `strict-targeted-hellos` statement, an LDP peer does not respond to targeted hello messages coming from a source that is not one of its configured remote neighbors. Configured remote neighbors can include:

- Endpoints of RSVP tunnels for which LDP tunneling is configured
- Layer 2 circuit neighbors

If an unconfigured neighbor sends a hello message, the LDP peer ignores the message and logs an error (with the `error` trace flag) indicating the source. For example, if the LDP peer received a targeted hello from the Internet address 10.0.0.1 and no neighbor with this address is specifically configured, the following message is printed to the LDP log file:

```
LDP: Ignoring targeted hello from 10.0.0.1
```

To enable strict targeted hello messages, include the `strict-targeted-hellos` statement:

```
strict-targeted-hellos;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Configuring the Interval for LDP Keepalive Messages

The keepalive interval determines how often a message is sent over the session to ensure that the keepalive timeout is not exceeded. If no other LDP traffic is sent over the session in this much time, a keepalive message is sent. The default is 10 seconds. The minimum value is 1 second.

The value configured for the keepalive interval can be altered during LDP session negotiation if the value configured for the LDP hold time on the peer router is lower than the value configured locally. For more information, see "Configuring the Delay Before LDP Neighbors Are Considered Down" on page 1324.

To modify the keepalive interval, include the `keepalive-interval` statement:

```
keepalive-interval seconds;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Configuring the LDP Keepalive Timeout

After an LDP session is established, messages must be exchanged periodically to ensure that the session is still working. The keepalive timeout defines the amount of time that the neighbor LDP node waits before deciding that the session has failed. This value is usually set to at least three times the keepalive interval. The default is 30 seconds.

To modify the keepalive interval, include the `keepalive-timeout` statement:

```
keepalive-timeout seconds;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

The value configured for the `keepalive-timeout` statement is displayed as the hold time when you issue the `show ldp session detail` command.

Configuring Longest Match for LDP

In order to allow LDP to learn the routes aggregated or summarized across OSPF areas or ISIS levels in inter -domain, Junos OS allows you to configure longest match for LDP based on *RFC5283*.

Before you configure longest match for LDP, you must do the following:

1. Configure the device interfaces.
2. Configure the MPLS protocol.

3. Configure the OSPF protocol.

To configure longest match for LDP, you must do the following:

1. Configure longest match for the LDP protocol.

```
[edit protocols ldp]
user@host# set longest-match
```

2. Configure the LDP protocol on the interface.

```
[edit protocols ldp]
user@host# set interface interface-name
```

For example, to configure the interfaces:

```
[edit protocols ldp]
user@host# set interface ge-0/0/2.0
user@host# set interface lo0.0
```

Example: Configuring Longest Match for LDP

IN THIS SECTION

- Requirements | 1328
- Overview | 1329
- Configuration | 1330
- Verification | 1337

This example shows how to configure longest match for LDP based on *RFC5283*. This allows LDP to learn the routes aggregated or summarized across OSPF areas or ISIS levels in inter-domain.. The longest match policy provides per prefix granularity.

Requirements

This example uses the following hardware and software components:

- Six MX Series routers with OSPF protocol, and LDP enabled on the connected interfaces.
- Junos OS Release 16.1 or later running on all devices.

Before you begin:

- Configure the device interfaces.
- Configure OSPF.

Overview

IN THIS SECTION

- Topology | **1330**

LDP is often used to establish MPLS label-switched paths (LSPs) throughout a complete network domain using an IGP such as OSPF or IS-IS. In such a network, all links in the domain have IGP adjacencies as well as LDP adjacencies. LDP establishes the LSPs on the shortest path to a destination as determined by IP forwarding. In Junos OS, the LDP implementation does an exact match lookup on the IP address of the FEC in the RIB or IGP routes for label mapping. This exact mapping requires MPLS end-to-end LDP endpoint IP addresses to be configured in all the LERs. This defeats the purpose of IP hierarchical design or default routing in access devices. Configuring `longest-match` helps to overcome this by suppressing the exact match behaviour and setup LSP based on the longest matching route on per-prefix basis.

Topology

In the topology, Figure 78 on page 1330shows the longest match for LDP is configured on Device R0 .

Configuring Device R0

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the CLI User Guide.

To configure Device R0:

1. Configure the interfaces.

```
[edit interfaces]
set ge-0/0/0 unit 0 family inet address 22.22.22.1/24
set ge-0/0/1 unit 0 family inet address 15.15.15.1/24
set ge-0/0/2 unit 0 family inet address 11.11.11.1/24
set ge-0/0/2 unit 0 family iso
set ge-0/0/2 unit 0 family mpls
```

2. Assign the loopback addresses to the device.

```
[edit interfaces lo0 unit 0 family]
set inet address 10.255.112.1/32 primary
set inet address 10.255.112.1/32 preferred
set iso address 49.0002.0192.0168.0001.00
```

3. Configure the router ID.

```
[edit routing-options]
set router-id 10.255.112.1
```

4. Configure the MPLS protocol on the interface.

```
[edit protocols mpls]
set interface ge-0/0/2.0
```

5. Configure the OSPF protocol on the interface.

```
[edit protocols ospf]
set area 0.0.0.1 interface ge-0/0/2.0
set area 0.0.0.1 interface lo0.0 passive
```

6. Configure longest match for the LDP protocol.

```
[edit protocols ldp]
set longest-match
```

7. Configure the LDP protocol on the interface.

```
[edit protocols ldp]
set interface ge-0/0/2.0
set interface lo0.0
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R0# show interfaces
ge-0/0/0 {
    unit 0 {
        family inet {
            address 22.22.22.1/24;
        }
    }
}
ge-0/0/1 {
    unit 0 {
        family inet {
            address 15.15.15.1/24;
        }
    }
}
ge-0/0/2 {
    unit 0 {
        family inet {
            address 11.11.11.1/24;
        }
        family iso;
        family mpls;
    }
}
lo0 {
    unit 0 {
        family inet {
            address 10.255.112.1/32 {
                primary;
                preferred;
            }
        }
        family iso {
            address 49.0002.0192.0168.0001.00;
        }
```

```
    }
}
```

```
user@R0# show protocols
mpls {
    interface ge-0/0/2.0;
}
ospf {
    area 0.0.0.1 {
        interface ge-0/0/2.0;
        interface lo0.0 {
            passive;
        }
    }
}
ldp {
    longest-match;
    interface ge-0/0/2.0;
    interface lo0.0;
}
```

```
user@R0# show routing-options
router-id 10.255.112.1;
```

If you are done configuring the device, enter `commit` from the configuration mode.

Verification

IN THIS SECTION

- Verifying the Routes | **1338**
- Verifying LDP Overview Information | **1342**
- Verify the LDP Entries in the Internal Topology Table | **1344**
- Verify Only FEC Information of LDP Route | **1346**
- Verify FEC and Shadow Routes of LDP | **1347**

Confirm that the configuration is working properly.

Verifying the Routes

Purpose

Verify that the expected routes are learned.

Action

On Device R0, from operational mode, run the `show route` command to display the routes in the routing table.

```
user@R0> show route

inet.0: 62 destinations, 62 routes (62 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

    Total number of LDP label allocation failure: 0
    Current number of labels allocated by all protocols: 5
```

Meaning

The output displays the LDP overview information of Device R0

Verify the LDP Entries in the Internal Topology Table

Purpose

Display the route entries in the Label Distribution Protocol (LDP) internal topology table.

Action

On Device R0, from operational mode, run the `show ldp route` command to display the internal topology table of LDP.

```
user@R0> show ldp route

Meaning

The output displays the route entries in the Label Distribution Protocol (LDP) internal topology table of Device R0.

Verify Only FEC Information of LDP Route

Purpose

Display only the FEC information of LDP route.

Action

On Device R0, from operational mode, run the `show ldp route fec-only` command to display the routes in the routing table.

```
user@R0> show ldp route fec-only

Destination         Next-hop intf/lsp/table          Next-hop address
 10.255.111.1/32    ge-0/0/2.0                       11.11.11.2

Configuring LDP Route Preferences

When several protocols calculate routes to the same destination, route preferences are used to select which route is installed in the forwarding table. The route with the lowest preference value is selected. The preference value can be a number in the range 0 through 255. By default, LDP routes have a preference value of 9.

To modify the route preferences, include the `preference` statement:

```
preference preference;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

LDP Graceful Restart

LDP graceful restart enables a router whose LDP control plane is undergoing a restart to continue to forward traffic while recovering its state from neighboring routers. It also enables a router on which helper mode is enabled to assist a neighboring router that is attempting to restart LDP.

During session initialization, a router advertises its ability to perform LDP graceful restart or to take advantage of a neighbor performing LDP graceful restart by sending the graceful restart TLV. This TLV contains two fields relevant to LDP graceful restart: the reconnect time and the recovery time. The values of the reconnect and recovery times indicate the graceful restart capabilities supported by the router.

When a router discovers that a neighboring router is restarting, it waits until the end of the recovery time before attempting to reconnect. The recovery time is the length of time a router waits for LDP to restart gracefully. The recovery time period begins when an initialization message is sent or received. This time period is also typically the length of time that a neighboring router maintains its information about the restarting router, allowing it to continue to forward traffic.

You can configure LDP graceful restart in both the master instance for the LDP protocol and for a specific routing instance. You can disable graceful restart at the global level for all protocols, at the

protocol level for LDP only, and on a specific routing instance. LDP graceful restart is disabled by default, because at the global level, graceful restart is disabled by default. However, helper mode (the ability to assist a neighboring router attempting a graceful restart) is enabled by default.

The following are some of the behaviors associated with LDP graceful restart:

- Outgoing labels are not maintained in restarts. New outgoing labels are allocated.
- When a router is restarting, no label-map messages are sent to neighbors that support graceful restart until the restarting router has stabilized (label-map messages are immediately sent to neighbors that do not support graceful restart). However, all other messages (keepalive, address-message, notification, and release) are sent as usual. Distributing these other messages prevents the router from distributing incomplete information.
- Helper mode and graceful restart are independent. You can disable graceful restart in the configuration, but still allow the router to cooperate with a neighbor attempting to restart gracefully.

Configuring LDP Graceful Restart

IN THIS SECTION

- Enabling Graceful Restart | **1351**
- Disabling LDP Graceful Restart or Helper Mode | **1351**
- Configuring Reconnect Time | **1352**
- Configuring Recovery Time and Maximum Recovery Time | **1353**

When you alter the graceful restart configuration at either the `[edit routing-options graceful-restart]` or `[edit protocols ldp graceful-restart]` hierarchy levels, any running LDP session is automatically restarted to apply the graceful restart configuration. This behavior mirrors the behavior of BGP when you alter its graceful restart configuration.

By default, graceful restart helper mode is enabled, but graceful restart is disabled. Thus, the default behavior of a router is to assist neighboring routers attempting a graceful restart, but not to attempt a graceful restart itself.

To configure LDP graceful restart, see the following sections:

Enabling Graceful Restart

To enable LDP graceful restart, you also need to enable graceful restart on the router. To enable graceful restart, include the `graceful-restart` statement:

```
graceful-restart;
```

You can include this statement at the following hierarchy levels:

- `[edit routing-options]`
- `[edit logical-systems` *`logical-system-name`* `routing-options]`

> **NOTE**: ACX Series routers do not support `[edit logical-systems logical-system-name routing-options]` hierarchy level.

The `graceful-restart` statement enables graceful restart for all protocols supporting this feature on the router. For more information about graceful restart, see the Junos OS Routing Protocols Library for Routing Devices.

By default, LDP graceful restart is enabled when you enable graceful restart at both the LDP protocol level and on all the routing instances. However, you can disable both LDP graceful restart and LDP graceful restart helper mode.

Disabling LDP Graceful Restart or Helper Mode

To disable LDP graceful restart and recovery, include the `disable` statement:

```
ldp {
    graceful-restart {
        disable;
    }
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

You can disable helper mode at the LDP protocols level only. You cannot disable helper mode for a specific routing instance. To disable LDP helper mode, include the `helper-disable` statement:

```
ldp {
    graceful-restart {
        helper-disable;
    }
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

The following LDP graceful restart configurations are possible:

- LDP graceful restart and helper mode are both enabled.
- LDP graceful restart is disabled but helper mode is enabled. A router configured in this way cannot restart gracefully but can help a restarting neighbor.
- LDP graceful restart and helper mode are both disabled. The router does not use LDP graceful restart or the graceful restart type, length, and value (TLV) sent in the initialization message. The router behaves as a router that cannot support LDP graceful restart.

A configuration error is issued if you attempt to enable graceful restart and disable helper mode.

Configuring Reconnect Time

After the LDP connection between neighbors fails, neighbors wait a certain amount of time for the gracefully restarting router to resume sending LDP messages. After the wait period, the LDP session can be reestablished. You can configure the wait period in seconds. This value is included in the fault tolerant session TLV sent in LDP initialization messages when LDP graceful restart is enabled.

Suppose that Router A and Router B are LDP neighbors. Router A is the restarting Router. The reconnect time is the time that Router A tells Router B to wait after Router B detects that Router A restarted.

To configure the reconnect time, include the `reconnect-time` statement:

```
graceful-restart {
    reconnect-time seconds;
}
```

You can set the reconnect time to a value in the range from 30 through 300 seconds. By default, it is 60 seconds.

For a list of hierarchy levels at which you can configure these statements, see the statement summary sections for these statements.

Configuring Recovery Time and Maximum Recovery Time

The recovery time is the amount of time a router waits for LDP to restart gracefully. The recovery time period begins when an initialization message is sent or received. This period is also typically the amount of time that a neighboring router maintains its information about the restarting router, allowing it to continue to forward traffic.

To prevent a neighboring router from being adversely affected if it receives a false value for the recovery time from the restarting router, you can configure the maximum recovery time on the neighboring router. A neighboring router maintains its state for the shorter of the two times. For example, Router A is performing an LDP graceful restart. It has sent a recovery time of 900 seconds to neighboring Router B. However, Router B has its maximum recovery time configured at 400 seconds. Router B will only wait for 400 seconds before it purges its LDP information from Router A.

To configure recovery time, include the `recovery-time` statement and the `maximum-neighbor-recovery-time` statement:

```
graceful-restart {
    maximum-neighbor-recovery-time seconds;
    recovery-time seconds;
}
```

For a list of hierarchy levels at which you can configure these statements, see the statement summary sections for these statements.

Filtering Inbound LDP Label Bindings

IN THIS SECTION

- Examples: Filtering Inbound LDP Label Bindings | **1355**

You can filter received LDP label bindings, applying policies to accept or deny bindings advertised by neighboring routers. To configure received-label filtering, include the `import` statement:

```
import [ policy-names ];
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

The named policy (configured at the `[edit policy-options]` hierarchy level) is applied to all label bindings received from all LDP neighbors. All filtering is done with `from` statements. Table 23 on page 1354 lists the only `from` operators that apply to LDP received-label filtering.

Table 23: from Operators That Apply to LDP Received-Label Filtering

from Operator	Description
`interface`	Matches on bindings received from a neighbor that is adjacent over the specified interface
`neighbor`	Matches on bindings received from the specified LDP router ID
`next-hop`	Matches on bindings received from a neighbor advertising the specified interface address
`route-filter`	Matches on bindings with the specified prefix

If a binding is filtered, it still appears in the LDP database, but is not considered for installation as part of a label-switched path (LSP).

Generally, applying policies in LDP can be used only to block the establishment of LSPs, not to control their routing. This is because the path that an LSP follows is determined by unicast routing, and not by LDP. However, when there are multiple equal-cost paths to the destination through different neighbors, you can use LDP filtering to exclude some of the possible next hops from consideration. (Otherwise, LDP chooses one of the possible next hops at random.)

LDP sessions are not bound to interfaces or interface addresses. LDP advertises only per-router (not per-interface) labels; so if multiple parallel links exist between two routers, only one LDP session is established, and it is not bound to a single interface. When a router has multiple adjacencies to the same neighbor, take care to ensure that the filter does what is expected. (Generally, using `next-hop` and `interface` is not appropriate in this case.)

If a label has been filtered (meaning that it has been rejected by the policy and is not used to construct an LSP), it is marked as filtered in the database:

```
user@host> show ldp database
Input label database, 10.10.255.1:0-10.10.255.6:0
Label Prefix
```

```
3 10.10.255.6/32 (Filtered)
Output label database, 10.10.255.1:0-10.10.255.6:0
Label Prefix
3 10.10.255.1/32 (Filtered)
```

For more information about how to configure policies for LDP, see the Routing Policies, Firewall Filters, and Traffic Policers User Guide.

Examples: Filtering Inbound LDP Label Bindings

Accept only /32 prefixes from all neighbors:

```
[edit]
protocols {
    ldp {
        import only-32;
        ...
    }
}
policy-options {
    policy-statement only-32 {
        term first {
            from {
                route-filter 0.0.0.0/0 upto /31;
            }
            then reject;
        }
        then accept;
    }
}
```

Accept `131.108/16` or longer from router ID `10.10.255.2` and accept all prefixes from all other neighbors:

```
[edit]
protocols {
    ldp {
        import nosy-neighbor;
        ...
    }
}
policy-options {
```

```
    policy-statement nosy-neighbor {
        term first {
            from {
                neighbor 10.10.255.2;
                route-filter 131.108.0.0/16 orlonger accept;
                route-filter 0.0.0.0/0 orlonger reject;
            }
        }
        then accept;
    }
}
```

Filtering Outbound LDP Label Bindings

IN THIS SECTION

- Examples: Filtering Outbound LDP Label Bindings | **1357**

You can configure export policies to filter LDP outbound labels. You can filter outbound label bindings by applying routing policies to block bindings from being advertised to neighboring routers. To configure outbound label filtering, include the `export` statement:

```
export [policy-name];
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

The named export policy (configured at the `[edit policy-options]` hierarchy level) is applied to all label bindings transmitted to all LDP neighbors. The only `from` operator that applies to LDP outbound label filtering is `route-filter`, which matches bindings with the specified prefix. The only `to` operators that apply to outbound label filtering are the operators in Table 24 on page 1356.

Table 24: to Operators for LDP Outbound-Label Filtering

to Operator	Description
`interface`	Matches on bindings sent to a neighbor that is adjacent over the specified interface

Table 24: to Operators for LDP Outbound-Label Filtering *(Continued)*

to Operator	Description
`neighbor`	Matches on bindings sent to the specified LDP router ID
`next-hop`	Matches on bindings sent to a neighbor advertising the specified interface address

If a binding is filtered, the binding is not advertised to the neighboring router, but it can be installed as part of an LSP on the local router. You can apply policies in LDP to block the establishment of LSPs, but not to control their routing. The path an LSP follows is determined by unicast routing, not by LDP.

LDP sessions are not bound to interfaces or interface addresses. LDP advertises only per-router (not per-interface) labels. If multiple parallel links exist between two routers, only one LDP session is established, and it is not bound to a single interface.

Do not use the `next-hop` and `interface` operators when a router has multiple adjacencies to the same neighbor.

Filtered labels are marked in the database:

```
user@host> show ldp database
Input label database, 10.10.255.1:0-10.10.255.3:0
Label Prefix
100007 10.10.255.2/32
3 10.10.255.3/32
Output label database, 10.10.255.1:0-10.10.255.3:0
Label Prefix
3 10.10.255.1/32
100001 10.10.255.6/32 (Filtered)
```

For more information about how to configure policies for LDP, see the Routing Policies, Firewall Filters, and Traffic Policers User Guide.

Examples: Filtering Outbound LDP Label Bindings

Block transmission of the route for `10.10.255.6/32` to any neighbors:

```
[edit protocols]
ldp {
    export block-one;
```

```
}
policy-options {
    policy-statement block-one {
        term first {
            from {
                route-filter 10.10.255.6/32 exact;
            }
            then reject;
        }
        then accept;
    }
}
```

Send only `131.108/16` or longer to router ID `10.10.255.2`, and send all prefixes to all other routers:

```
[edit protocols]
ldp {
    export limit-lsps;
}
policy-options {
    policy-statement limit-lsps {
        term allow-one {
            from {
                route-filter 131.108.0.0/16 orlonger;
            }
            to {
                neighbor 10.10.255.2;
            }
            then accept;
        }
        term block-the-rest {
            to {
                neighbor 10.10.255.2;
            }
            then reject;
        }
        then accept;
    }
}
```

Specifying the Transport Address Used by LDP

Routers must first establish a TCP session between each other before they can establish an LDP session. The TCP session enables the routers to exchange the label advertisements needed for the LDP session. To establish the TCP session, each router must learn the other router's transport address. The transport address is an IP address used to identify the TCP session over which the LDP session will run.

To configure the LDP transport address, include the transport-address statement:

```
transport-address (router-id | interface);
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

If you specify the `router-id` option, the address of the router identifier is used as the transport address (unless otherwise configured, the router identifier is typically the same as the loopback address). If you specify the `interface` option, the interface address is used as the transport address for any LDP sessions to neighbors that can be reached over that interface. Note that the router identifier is used as the transport address by default.

You cannot specify the `interface` option when there are multiple parallel links to the same LDP neighbor, because the LDP specification requires that the same transport address be advertised on all interfaces to the same neighbor. If LDP detects multiple parallel links to the same neighbor, it disables interfaces to that neighbor one by one until the condition is cleared, either by disconnecting the neighbor on an interface or by specifying the `router-id` option.

Control Transport Address Used for Targeted-LDP Session

IN THIS SECTION

- Benefits of Controlling Transport Address Used for Targeted-LDP Session | **1360**
- Targeted-LDP Transport Address Overview | **1360**
- Transport Address Preference | **1360**
- Troubleshooting Transport Address Configuration | **1361**

To establish a TCP session between two devices, each device must learn the other device's transport address. The transport address is an IP address used to identify the TCP session over which the LDP session operates. Earlier, this transport address could only be the router-ID or an interface address. With the LDP transport-address feature, you can explicitly configure any IP address as the transport address

for targeted LDP neighbors for Layer 2 circuit, MPLS, and VPLS adjacencies. This enables you to control the targeted-LDP sessions using transport-address configuration.

Benefits of Controlling Transport Address Used for Targeted-LDP Session

Configuring transport address for establishing targeted-LDP sessions has the following benefits:

- **Flexible interface configurations**—Provides the flexibility of configuring multiple IP addresses for one loopback interface without interrupting the creation of LDP session between the targeted-LDP neighbors.
- **Ease of operation**—Transport address configured at the interface-level, allows you to use more than one protocol in the IGP backbone for LDP. This enables smooth and easy operations.

Targeted-LDP Transport Address Overview

Prior to Junos OS Release 19.1R1, LDP provided support only for router-ID or the interface address as the transport address on any LDP interface. The adjacencies formed on that interface used one of the IP addresses assigned to the interface or the router-ID. In case of targeted adjacency, the interface is the loopback interface. When multiple loopback addresses were configured on the device, the transport address could not be derived for the interface, and as a result, the LDP session could not be established.

Starting in Junos OS Release 19.1R1, in addition to the default IP addresses used for transport address of targeted-LDP sessions, you can configure any other IP address as the transport address under the `session`, `session-group`, and `interface` configuration statements. The transport address configuration is applicable for configured neighbors only including Layer 2 circuits, MPLS, and VPLS adjacencies. This configuration does not apply to discovered adjacencies (targeted or not).

Transport Address Preference

You can configure transport address for targeted-LDP sessions at the session, session-group, and interface level.

After the transport address is configured, the targeted-LDP session is established based on the transport address preference of LDP.

The order of preference of transport address for targeted neighbor (configured through Layer 2 circuit, MPLS, VPLS, and LDP configuration) is as follows:

1. Under `[edit protocols ldp session]` hierarchy.
2. Under `[edit protocols ldp session-group]` hierarchy.
3. Under `[edit protocols ldp interfcae lo0]` hierarchy.
4. Under `[edit protocols ldp]` hierarchy.

5. Default address.

The order of preference of transport address for the discovered neighbors is as follows:

1. Under `[edit protocols ldp interfcae]` hierarchy.
2. Under `[edit protocols ldp]` hierarchy.
3. Default address.

The order of preference of transport address for auto-targeted neighbors where LDP is configured to accept hello packets is as follows:

1. Under `[edit protocols ldp interfcae lo0]` hierarchy.
2. Under `[edit protocols ldp]` hierarchy.
3. Default address.

Troubleshooting Transport Address Configuration

You can use the following show command outputs to troubleshoot targeted-LDP sessions:

- `show ldp session`
- `show ldp neighbor`

  The `detail` level of output of the `show ldp neighbor` command displays the transport address sent in the hello messages to the targeted neighbor. If this address is not reachable from the neighbor, the LDP session does not come up.

- `show configuration protocols ldp`

You can also enable LDP traceoptions for further troubleshooting.

- If the configuration is changed from using a transport address that is invalid (non reachable) to transport address that is valid, the following traces can be observed:

```
May 29 10:47:11.569722 Incoming connect from 10.55.1.4
May 29 10:47:11.570064 Connection 10.55.1.4 state Closed -> Open
May 29 10:47:11.570727 Session 10.55.1.4 state Nonexistent -> Initialized
May 29 10:47:11.570768 Session 10.55.1.4 state Initialized -> OpenRec
May 29 10:47:11.570799 LDP: Session param Max PDU length 4096 from 10.55.1.4, negotiated 4096
May 29 10:47:11.570823 Session 10.55.1.4 GR state Nonexistent -> Operational
May 29 10:47:11.669295 Session 10.55.1.4 state OpenRec -> Operational
May 29 10:47:11.669387 RPD_LDP_SESSIONUP: LDP session 10.55.1.4 is up
```

- If the configuration is changed from using a transport address that is valid to transport address that is invalid (non reachable),the following traces can be observed:

```
May 29 10:42:36.317942 Session 10.55.1.4 GR state Operational -> Nonexistent
May 29 10:42:36.318171 Session 10.55.1.4 state Operational -> Closing
May 29 10:42:36.318208 LDP session 10.55.1.4 is down, reason: received notification from peer
May 29 10:42:36.318236 RPD_LDP_SESSIONDOWN: LDP session 10.55.1.4 is down, reason: received
notification from peer
May 29 10:42:36.320081 Connection 10.55.1.4 state Open -> Closed
May 29 10:42:36.322411 Session 10.55.1.4 state Closing -> Nonexistent
```

In case of faulty configuration, perform the following troubleshooting tasks:

- Check the `address family`. The transport address that is configured under the `session` statement must belong to the same address family as the neighbor or session.
- The address that is configured as the transport address under a `neighbor` or `session` statement must be local to the router for the targeted hello messages to start. You can check if the address is configured. If the address is not configured under any interface, the configuration is rejected.

Configuring the Prefixes Advertised into LDP from the Routing Table

IN THIS SECTION

- Example: Configuring the Prefixes Advertised into LDP | **1363**

You can control the set of prefixes that are advertised into LDP and cause the router to be the egress router for those prefixes. By default, only the loopback address is advertised into LDP. To configure the set of prefixes from the routing table to be advertised into LDP, include the `egress-policy` statement:

```
egress-policy policy-name;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

NOTE: If you configure an egress policy for LDP that does not include the loopback address, it is no longer advertised in LDP. To continue to advertise the loopback address, you need to explicitly configure it as a part of the LDP egress policy.

The named policy (configured at the `[edit policy-options]` or `[edit logical-systems *logical-system-name* policy-options]` hierarchy level) is applied to all routes in the routing table. Those routes that match the policy are advertised into LDP. You can control the set of neighbors to which those prefixes are advertised by using the `export` statement. Only **from** operators are considered; you can use any valid **from** operator. For more information, see the Junos OS Routing Protocols Library for Routing Devices.

NOTE: ACX Series routers do not support `[edit logical-systems]` hierarchy level.

Example: Configuring the Prefixes Advertised into LDP

Advertise all connected routes into LDP:

```
[edit protocols]
ldp {
    egress-policy connected-only;
}
policy-options {
    policy-statement connected-only {
        from {
            protocol direct;
        }
        then accept;
    }
}
```

Configuring FEC Deaggregation

When an LDP egress router advertises multiple prefixes, the prefixes are bound to a single label and aggregated into a single forwarding equivalence class (FEC). By default, LDP maintains this aggregation as the advertisement traverses the network.

Normally, because an LSP is not split across multiple next hops and the prefixes are bound into a single LSP, load-balancing across equal-cost paths does not occur. You can, however, load-balance across equal-cost paths if you configure a load-balancing policy and deaggregate the FECs.

Deaggregating the FECs causes each prefix to be bound to a separate label and become a separate LSP.

To configure deaggregated FECs, include the `deaggregate` statement:

```
deaggregate;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

For all LDP sessions, you can configure deaggregated FECs only globally.

Deaggregating a FEC allows the resulting multiple LSPs to be distributed across multiple equal-cost paths and distributes LSPs across the multiple next hops on the egress segments but installs only one next hop per LSP.

To aggregate FECs, include the `no-deaggregate` statement:

```
no-deaggregate;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

For all LDP sessions, you can configure aggregated FECs only globally.

Configuring Policers for LDP FECs

You can configure the Junos OS to track and police traffic for LDP FECs. LDP FEC policers can be used to do any of the following:

- Track or police the ingress traffic for an LDP FEC.
- Track or police the transit traffic for an LDP FEC.
- Track or police LDP FEC traffic originating from a specific forwarding class.
- Track or police LDP FEC traffic originating from a specific virtual routing and forwarding (VRF) site.
- Discard false traffic bound for a specific LDP FEC.

To police traffic for an LDP FEC, you must first configure a filter. Specifically, you need to configure either the `interface` statement or the `interface-set` statement at the `[edit firewall family` *`protocol-family`* `filter` *`filter-name`* `term` *`term-name`* `from]` hierarchy level. The `interface` statement allows you to match the filter to a single interface. The `interface-set` statement allows you to match the filter to multiple interfaces.

For more information on how to configure the `interface` statement, the `interface-set` statement, and policers for LDP FECs, see the Routing Policies, Firewall Filters, and Traffic Policers User Guide.

Once you have configured the filters, you need to include them in the `policing` statement configuration for LDP. To configure policers for LDP FECs, include the `policing` statement:

```
policing {
    fec fec-address {
        ingress-traffic filter-name;
        transit-traffic filter-name;
    }
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

The `policing` statement includes the following options:

- `fec`—Specify the FEC address for the LDP FEC you want to police.
- `ingress-filter`—Specify the name of the ingress traffic filter.
- `transit-traffic`—Specify the name of the transit traffic filter.

Configuring LDP IPv4 FEC Filtering

By default, when a targeted LDP session is established, the Junos OS always exchanges both the IPv4 forwarding equivalence classes (FECs) and the Layer 2 circuit FECs over the targeted LDP session. For an LDP session to an indirectly connected neighbor, you might only want to export Layer 2 circuit FECs to the neighbor if the session was specifically configured to support Layer 2 circuits or VPLS.

In a mixed vendor network where all non-BGP prefixes are advertised into LDP, the LDP database can become large. For this type of environment, it can be useful to prevent the advertisement of IPv4 FECs over LDP sessions formed because of Layer 2 circuit or LDP VPLS configuration. Similarly, it can be useful to filter any IPv4 FECs received in this sort of environment.

If all the LDP neighbors associated with an LDP session are Layer 2 only, you can configure the Junos OS to advertise only Layer 2 circuit FECs by configuring the `l2-smart-policy` statement. This feature also automatically filters out the IPv4 FECs received on this session. Configuring an explicit export or import policy that is activated for `l2-smart-policy` disables this feature in the corresponding direction.

If one of the LDP session's neighbors is formed because of a discovered adjacency or if the adjacency is formed because of an LDP tunneling configuration on one or more RSVP LSPs, the IPv4 FECs are advertised and received using the default behavior.

To prevent LDP from exporting IPv4 FECs over LDP sessions with Layer 2 neighbors only and to filter out IPv4 FECs received over such sessions, include the `l2-smart-policy` statement:

```
l2-smart-policy;
```

For a list of hierarchy levels at which you can configure this statement, see the statement summary for this statement.

Configuring BFD for LDP LSPs

You can configure Bidirectional Forwarding Detection (BFD) for LDP LSPs. The BFD protocol is a simple hello mechanism that detects failures in a network. Hello packets are sent at a specified, regular interval. A neighbor failure is detected when the router stops receiving a reply after a specified interval. BFD works with a wide variety of network environments and topologies. The failure detection timers for BFD have shorter time limits than the failure detection mechanisms of static routes, providing faster detection.

An error is logged whenever a BFD session for a path fails. The following shows how BFD for LDP LSP log messages might appear:

```
RPD_LDP_BFD_UP: LDP BFD session for FEC  10.255.16.14/32 is up
RPD_LDP_BFD_DOWN: LDP BFD session for FEC  10.255.16.14/32 is down
```

You can also configure BFD for RSVP LSPs, as described in "Configuring BFD for RSVP-Signaled LSPs" on page 206.

The BFD failure detection timers are adaptive and can be adjusted to be more or less aggressive. For example, the timers can adapt to a higher value if the adjacency fails, or a neighbor can negotiate a higher value for a timer than the configured value. The timers adapt to a higher value when a BFD session flap occurs more than three times in a span of 15 seconds. A back-off algorithm increases the receive (Rx) interval by two if the local BFD instance is the reason for the session flap. The transmission (Tx) interval is increased by two if the remote BFD instance is the reason for the session flap. You can use the `clear bfd adaptation` command to return BFD interval timers to their configured values. The `clear bfd adaptation` command is hitless, meaning that the command does not affect traffic flow on the routing device.

To enable BFD for LDP LSPs, include the `oam` and `bfd-liveness-detection` statements:

```
oam {
    bfd-liveness-detection {
        detection-time threshold milliseconds;
        ecmp;
```

```
        failure-action {
            remove-nexthop;
            remove-route;
        }
        holddown-interval seconds;
        ingress-policy ingress-policy-name;
        minimum-interval milliseconds;
        minimum-receive-interval milliseconds;
        minimum-transmit-interval milliseconds;
        multiplier detection-time-multiplier;
        no-adaptation;
        transmit-interval {
            minimum-interval milliseconds;
            threshold milliseconds;
        }
        version (0 | 1 | automatic);
    }
    fec fec-address {
        bfd-liveness-detection {
            detection-time threshold milliseconds;
            ecmp;
            failure-action {
                remove-nexthop;
                remove-route;
            }
            holddown-interval milliseconds;
            ingress-policy ingress-policy-name;
            minimum-interval milliseconds;
            minimum-receive-interval milliseconds;
            minimum-transmit-interval milliseconds;
            multiplier detection-time-multiplier;
            no-adaptation;
            transmit-interval {
                minimum-interval milliseconds;
                threshold milliseconds;
            }
            version (0 | 1 | automatic);
        }
        no-bfd-liveness-detection;
        periodic-traceroute {
            disable;
            exp exp-value;
            fanout fanout-value;
```

```
            frequency minutes;
            paths number-of-paths;
            retries retry-attempts;
            source address;
            ttl ttl-value;
            wait seconds;
        }
    }
    lsp-ping-interval seconds;
    periodic-traceroute {
        disable;
        exp exp-value;
        fanout fanout-value;
        frequency minutes;
        paths number-of-paths;
        retries retry-attempts;
        source address;
        ttl ttl-value;
        wait seconds;
    }
}
```

You can enable BFD for the LDP LSPs associated with a specific forwarding equivalence class (FEC) by configuring the FEC address using the `fec` option at the `[edit protocols ldp]` hierarchy level. Alternatively, you can configure an Operation Administration and Management (OAM) ingress policy to enable BFD on a range of FEC addresses. For more information, see "Configuring OAM Ingress Policies for LDP" on page 1762.

You cannot enable BFD LDP LSPs unless their equivalent FEC addresses are explicitly configured or OAM is enabled on the FECs using an OAM ingress policy. If BFD is not enabled for any FEC addresses, the BFD session will not come up.

You can configure the `oam` statement at the following hierarchy levels:

- `[edit protocols ldp]`
- `[edit logical-systems logical-system-name protocols ldp]`

NOTE: ACX Series routers do not support `[edit logical-systems]` hierarchy level.

The `oam` statement includes the following options:

- `fec`—Specify the FEC address. You must either specify a FEC address or configure an OAM ingress policy to ensure that the BFD session comes up.
- `lsp-ping-interval`—Specify the duration of the LSP ping interval in seconds. To issue a ping on an LDP-signaled LSP, use the `ping mpls ldp` command. For more information, see the CLI Explorer.

The `bfd-liveness-detection` statement includes the following options:

- `ecmp`—Cause LDP to establish BFD sessions for all ECMP paths configured for the specified FEC. If you configure the `ecmp` option, you must also configure the `periodic-traceroute` statement for the specified FEC. If you do not do so, the commit operation fails. You can configure the `periodic-traceroute` statement at the global hierarchy level (`[edit protocols ldp oam]`) while only configuring the `ecmp` option for a specific FEC (`[edit protocols ldp oam fec` *address* `bfd-liveness-detection]`).
- "holddown-interval" on page 2891—Specify the duration the BFD session should remain up before adding the route or next hop. Specifying a time of 0 seconds causes the route or next hop to be added as soon as the BFD session comes back up.
- `minimum-interval`—Specify the minimum transmit and receive interval. If you configure the `minimum-interval` option, you do not need to configure the `minimum-receive-interval` option or the `minimum-transmit-interval` option.
- `minimum-receive-interval`—Specify the minimum receive interval. The range is from 1 through 255,000 milliseconds.
- `minimum-transmit-interval`—Specify the minimum transmit interval. The range is from 1 through 255,000 milliseconds.
- `multiplier`—Specify the detection time multiplier. The range is from 1 through 255.
- "version" on page 2970—Specify the BFD version. The options are BFD version 0 or BFD version 1. By default, the Junos OS software attempts to automatically determine the BFD version.

Configuring ECMP-Aware BFD for LDP LSPs

When you configure BFD for a FEC, a BFD session is established for only one active local next-hop for the router. However, you can configure multiple BFD sessions, one for each FEC associated with a specific equal-cost multipath (ECMP) path. For this to function properly, you also need to configure LDP LSP periodic traceroute. (See "Configuring LDP LSP Traceroute" on page 1522.) LDP LSP traceroute is used to discover ECMP paths. A BFD session is initiated for each ECMP path discovered. Whenever a BFD session for one of the ECMP paths fails, an error is logged.

LDP LSP traceroute is run periodically to check the integrity of the ECMP paths. The following might occur when a problem is discovered:

- If the latest LDP LSP traceroute for a FEC differs from the previous traceroute, the BFD sessions associated with that FEC (the BFD sessions for address ranges that have changed from previous run)

are brought down and new BFD sessions are initiated for the destination addresses in the altered ranges.

- If the LDP LSP traceroute returns an error (for example, a timeout), all the BFD sessions associated with that FEC are torn down.

To configure LDP to establish BFD sessions for all ECMP paths configured for the specified FEC, include the `ecmp` statement.

```
ecmp;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Along with the `ecmp` statement, you must also include the `periodic-traceroute` statement, either in the global LDP OAM configuration (at the `[edit protocols ldp oam]` or `[edit logical-systems` *`logical-system-name`* `protocols ldp oam]` hierarchy level) or in the configuration for the specified FEC (at the `[edit protocols ldp oam fec` *`address`*`]` or `[edit logical-systems` *`logical-system-name`* `protocols ldp oam fec` *`address`*`]` hierarchy level). Otherwise, the commit operation fails.

NOTE: ACX Series routers do not support `[edit logical-systems]` hierarchy level.

Configuring a Failure Action for the BFD Session on an LDP LSP

You can configure route and next-hop properties in the event of a BFD session failure event on an LDP LSP. The failure event could be an existing BFD session that has gone down or could be a BFD session that never came up. LDP adds back the route or next hop when the relevant BFD session comes back up.

You can configure one of the following failure action options for the `failure-action` statement in the event of a BFD session failure on the LDP LSP:

- `remove-nexthop`—Removes the route corresponding to the next hop of the LSP's route at the ingress node when a BFD session failure event is detected.

- `remove-route`—Removes the route corresponding to the LSP from the appropriate routing tables when a BFD session failure event is detected. If the LSP is configured with ECMP and a BFD session corresponding to any path goes down, the route is removed.

To configure a failure action in the event of a BFD session failure on an LDP LSP, include either the `remove-nexthop` option or the `remove-route` option for the `failure-action` statement:

```
failure-action {
    remove-nexthop;
    remove-route;
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Configuring the Holddown Interval for the BFD Session

You can specify the duration the BFD session should be up before adding a route or next hop by configuring the `holddown-interval` statement at either the `[edit protocols ldp oam bfd-livenesss-detection]` hierarchy level or at the `[edit protocols ldp oam fec address bfd-livenesss-detection]` hierarchy level. Specifying a time of 0 seconds causes the route or next hop to be added as soon as the BFD session comes back up.

```
holddown-interval seconds;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Configuring LDP Link Protection

You can configure Label Distribution Protocol (LDP) link protection for both unicast and multicast LDP label-switched paths (LSPs) to provide resiliency during link or node failure.

Before you begin:

1. Configure the device interfaces.
2. Configure the router ID and autonomous system number for the device.
3. Configure the following protocols:
   a. RSVP
   b. MPLS with traffic engineering capability.
   c. OSPF with traffic engineering capability.

NOTE: For multicast LDP link protection with loop-free alternative (LFA), enable link protection.

```
[edit protocols]
user@R0# set ospf area 0 interface all link-protection
```

To configure LDP link protection:

1. Enable point-to-multipoint LDP LSPs.

```
[edit protocols]
user@R0# set ldp p2mp
```

2. Enable LDP on all the interfaces of Router R0 (excluding the management interface) and configure link protection with dynamic RSVP bypass LSP.

```
[edit protocols]
user@R0# set ldp interface all link-protection dynamic-rsvp-lsp
user@R0# set ldp interface fxp0.0 disable
```

3. Verify and commit the configuration.

   For example:

```
[edit protocols]
user@R0# show protocols
rsvp {
    interface all;
    interface fxp0.0 {
        disable;
    }
}
mpls {
    traffic-engineering;
    interface all;
    interface fxp0.0 {
        disable;
    }
}
ospf {
```

```
    traffic-engineering;
    area 0.0.0.0 {
        interface all {
            metric 1;
        }
        interface fxp0.0 {
            disable;
        }
    }
}
ldp {
    interface all {
        link-protection {
            dynamic-rsvp-lsp;
        }
    }
    interface fxp0.0 {
        disable;
    }
    p2mp;
}
```

```
[edit]
user@R0# commit
commit complete
```

Introduction to LDP

The Label Distribution Protocol (LDP) is a protocol for distributing labels in non-traffic-engineered applications. LDP allows routers to establish label-switched paths (LSPs) through a network by mapping network-layer routing information directly to the data link LSPs.

These LSPs might have an endpoint at a directly attached neighbor (comparable to IP hop-by-hop forwarding) or at a network egress node, enabling switching through all intermediary nodes. LSPs established by LDP can also traverse traffic-engineered LSPs created by RSVP.

LDP associates a forwarding equivalence class (FEC) with each LSP it creates. The FEC associated with an LSP specifies which packets are mapped to that LSP. LSPs are extended through a network as each router chooses the label advertised by the next hop for the FEC and splices it to the label it advertises to all other routers. This process forms a tree of LSPs that converge on the egress router.

Junos OS LDP Protocol Implementation

The Junos OS implementation of LDP supports LDP version 1. Junos OS supports a simple mechanism for tunneling between routers in an interior gateway protocol (IGP), to eliminate the required distribution of external routes within the core. Junos OS allows an MPLS tunnel next hop to all egress

routers in the network, with only an IGP running in the core to distribute routes to egress routers. Edge routers run BGP but do not distribute external routes to the core. Instead, the recursive route lookup at the edge resolves to an LSP switched to the egress router. No external routes are necessary on the transit LDP routers.

Understanding Multipoint Extensions to LDP

An LDP defines mechanisms for setting up point-to-point, multipoint-to-point, point-to-multipoint, and multipoint-to-multipoint LSPs in the network. The point-to-multipoint and multipoint-to-multipoint LSPs are collectively referred to as multipoint LSPs, where traffic flows from a single source to multiple destinations, and from multiple sources to multiple destinations, respectively. The destination or egress routers are called leaf nodes, and traffic from the source traverses one or more transit nodes before reaching the leaf nodes.

NOTE: Junos OS does not provide support for multipoint-to-multipoint LSPs.

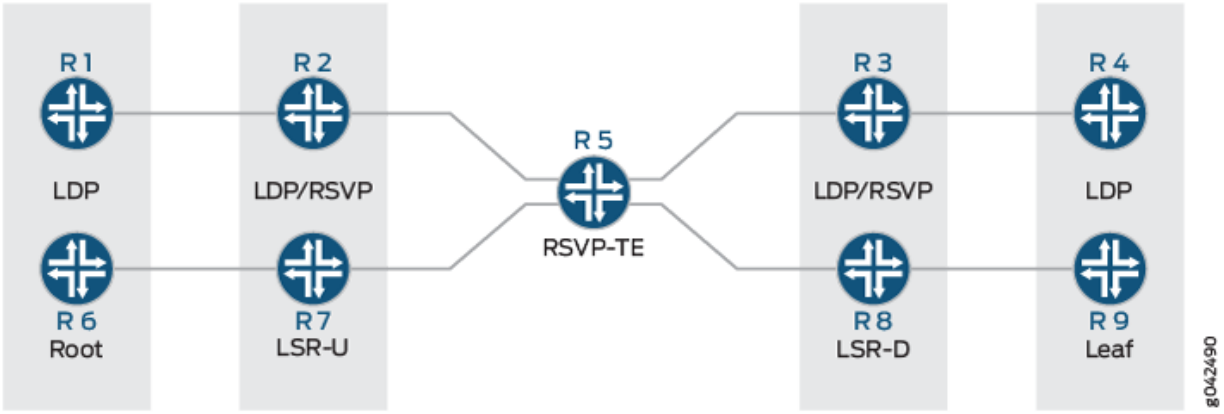
By taking advantage of the MPLS packet replication capability of the network, multipoint LSPs avoid unnecessary packet replication at the ingress router. Packet replication takes place only when packets are forwarded to two or more different destinations requiring different network paths.

Using Multipoint Extensions to LDP on Targeted LDP Sessions

The specification for the multipoint extensions to LDP requires that the two endpoints of an LDP session are directly connected by a Layer 2 medium, or are considered to be neighbors by the network's IGP. This is referred to as an LDP link session. When the two endpoints of an LDP session are not directly connected, the session is referred to as a targeted LDP session.

Past Junos OS implementations support multicast LDP for link sessions only. With the introduction of the LDP link protection feature, the multicast LDP capabilities are extended to targeted LDP sessions. *Figure 2* shows a sample topology.

Figure 79: Multicast LDP Support for Targeted LDP Session



Routers R7 and R8 are the upstream (LSR-U) and downstream (LSR-D) label-switched routers (LSRs), respectively, and deploy multicast LDP. The core router, Router R5, has RSVP-TE enabled.

When LSR-D is setting up the point-to-multipoint LSP with root and LSP ID attributes, it determines the upstream LSR-U as a next-hop on the best path to the root (currently, this next-hop is assumed to be an IGP next hop).

With the multicast LDP support on targeted LDP sessions, you can determine if there is an LSP next hop to LSR-U which is on LSR-D's path to root, where LSR-D and LSR-U are not directly connected neighbors, but targeted LDP peers. The point-to-multipoint label advertised on the targeted LDP session between LSR-D and LSR-U is not used unless there is an LSP between LSR-D and LSR-U. Therefore, a corresponding LSP in the reverse direction from LSR-U to LSR-D is required.

Data is transmitted on the point-to-multipoint LSP using unicast replication of packets, where LSR-U sends one copy to each downstream LSR of the point-to-multipoint LSP.

The data transmission is implemented in the following ways:

1. The point-to-multipoint capabilities on the targeted LDP session are negotiated.
2. The algorithm to select the upstream LSR is changed, where if IGP next hops are unavailable, or in other words, there is no LDP link session between LSR-D and LSR-U, an RSVP LSP is used as the next hop to reach LSR-U.

3. The incoming labels received over the targeted LDP sessions are installed as a branch next hop for this point-to-multipoint FEC route with the LDP label as the inner label and the RSVP label as the outer label.

Current Limitations of LDP Link Protection

When there is a link or node failure in an LDP network deployment, fast traffic recovery should be provided to recover impacted traffic flows for mission-critical services. In the case of multipoint LSPs, when one of the links of the point-to-multipoint tree fails, the subtrees might get detached until the IGP reconverges and the multipoint LSP is established using the best path from the downstream router to the new upstream router.

In fast reroute using local repair for LDP traffic, a backup path (repair path) is pre-installed in the Packet Forwarding Engine. When the primary path fails, traffic is rapidly moved to the backup path without having to wait for the routing protocols to converge. Loop-free alternate (LFA) is one of the methods used to provide IP fast reroute capability in the core and service provider networks.

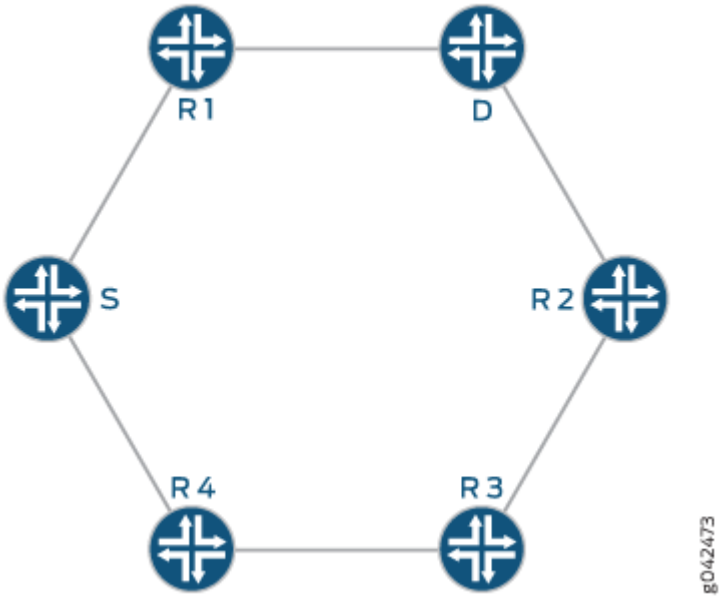
Without LFA, when a link or a router fails or is returned to service, the distributed routing algorithms compute the new routes based on the changes in the network. The time during which the new routes are computed is referred to as routing transition. Until the routing transition is completed, the network connectivity is interrupted because the routers adjacent to a failure continue to forward the data packets through the failed component until an alternative path is identified.

However, LFA does not provide full coverage in all network deployments because of the IGP metrics. As a result, this is a limitation to the current LDP link protection schemes.

Figure 3 illustrates a sample network with incomplete LFA coverage, where traffic flows from the source router (S) to the destination router (D) through Router R1. Assuming that each link in the network has the same metric, if the link between the Router S and Router R1 fails, Router R4 is not an LFA that

protects the S-R1 link, so traffic resiliency is lost. Thus, full coverage is not achieved by using plain LFA. In typical networks, there is always some percentage of LFA coverage gap with plain LFA.

Figure 80: Incomplete Coverage Problem with LFA



Using RSVP LSP as a Solution

The key to protect the traffic flowing through LDP LSPs is to have an explicit tunnel to re-route the traffic in the event of a link or node failure. The explicit path has to terminate on the next downstream router, and the traffic needs to be accepted on the explicit path, where the RPF check should pass.

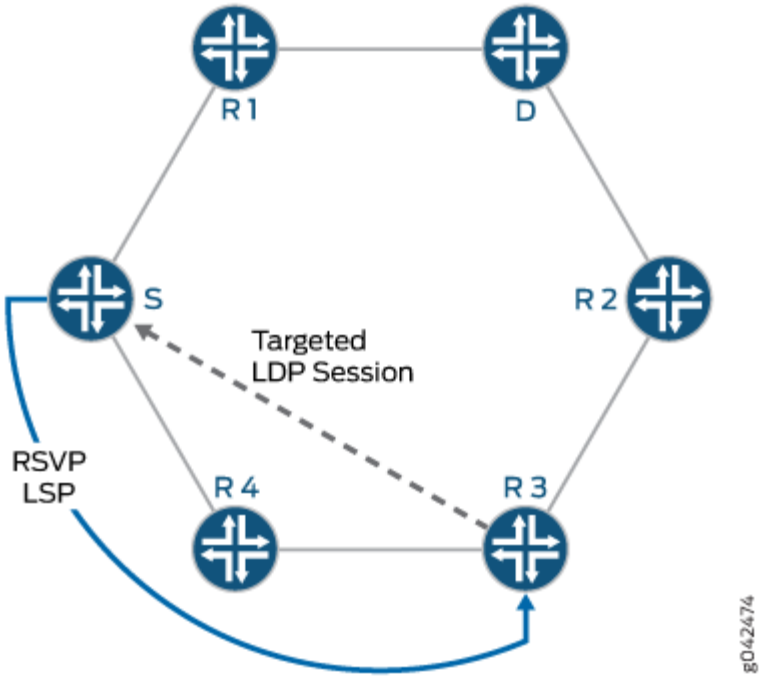
RSVP LSPs help overcome the current limitations of loop-free alternate (LFA) for both point-to-point and point-to-multipoint LDP LSPs by extending the LFA coverage in the following methods:

Manually Configured RSVP LSPs

Considering the example used in *Figure 3*, when the S-R1 link fails, and Router R4 is not an LFA for that particular link, a manually created RSVP LSP is used as a patch to provide complete LFA coverage. The

RSVP LSP is pre-signaled and pre-installed in the Packet Forwarding Engine of Router S, so that it can be used as soon as Router S detects that the link has failed.

Figure 81: Manually Configured RSVP LSP Coverage



In this case, an RSVP LSP is created between Routers S, R4, and R3 as illustrated in *Figure 4*. A targeted LDP session is created between Router S and Router R3, as a result of which, when the S-R1 link fails, traffic reaches Router R3. Router R3 forwards the traffic to Router R2, as it is the shortest path to reach the destination, Router D.

Dynamically Configured RSVP LSPs

In this method, the RSVP LSPs are created automatically and pre-installed in the system so that they can be used immediately when there is a link failure. Here, the egress is the node on the other side of the link being protected, thereby improving the LFA coverage.

Benefits of Enabling Dynamic RSVP LSPs

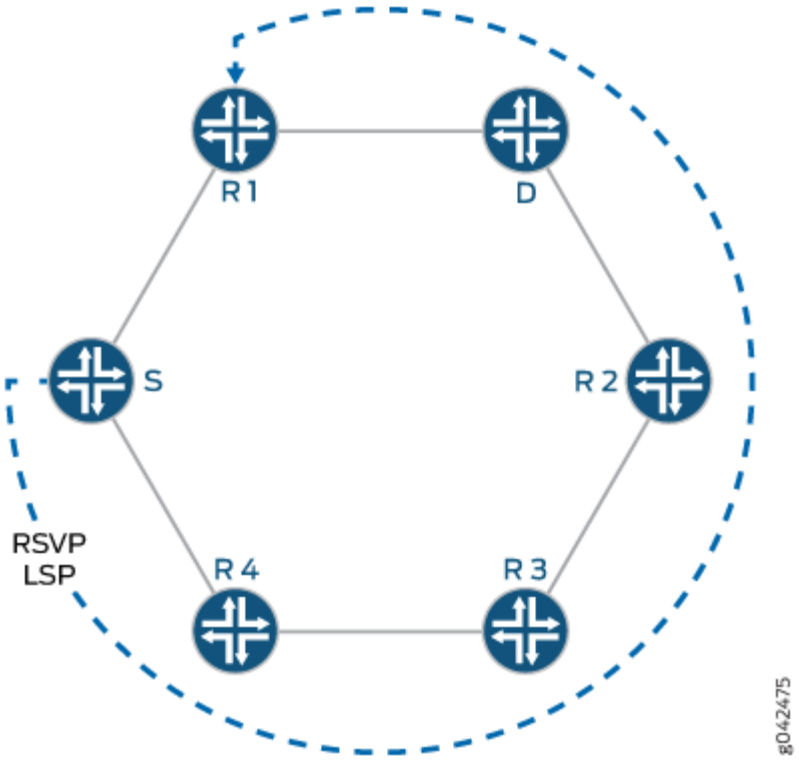
- Ease of configuration.
- 100 percent coverage against link failure as long as there is an alternate path to the far end of the link being protected.

- Setting up and tearing down of the RSVP bypass LSP is automatic.
- RSVP LSP only used for link protection and not for forwarding traffic while the link being protected is up.
- Reduces the total number of RSVP LSPs required on the system.

Considering the example used in *Figure 3*, in order to protect traffic against the potential failure of the S-R1 link, because Router R4 is not an LFA for that particular link, an RSVP bypass LSP is automatically created to Router R1, which is the node on the far side of the protected link as illustrated in *Figure 5*. From Router R1, traffic is forwarded to its original destination, Router D.

The RSVP LSP is pre-signaled and pre-installed in the Packet Forwarding Engine of Router S so that it can be used as soon as Router S detects that the link has failed.

Figure 82: Dynamically Configured RSVP LSP Coverage



An alternative mode of operation is not to use LFA at all, and to always have the RSVP LSP created to cover all link failures.

To enable dynamic RSVP LSPs, include the `dynamic-rsvp-lsp` statement at the `[edit protocols ldp interface` *`interface-name`* `link-protection]` hierarchy level, in addition to enabling the RSVP protocol on the appropriate interfaces.

Understanding Multicast LDP Link Protection

A point-to-multipoint LDP label-switched path (LSP) is an LDP-signaled LSP that is point-to-multipoint, and is referred to as multicast LDP.

A multicast LDP LSP can be used to send traffic from a single root or ingress node to a number of leaf or egress nodes traversing one or more transit nodes. Multicast LDP link protection enables fast reroute of traffic carried over point-to-multipoint LDP LSPs in case of a link failure. When one of the links of the point-to-multipoint tree fails, the subtrees might get detached until the IGP reconverges and the multipoint LSP is established using the best path from the downstream router to the new upstream router.

To protect the traffic flowing through the multicast LDP LSP, you can configure an explicit tunnel to re-route the traffic in the event of link failure. The explicit path has to terminate on the next downstream router. The reverse path forwarding for the traffic should be successful.

Multicast LDP link protection introduces the following features and functionality:

- Use of dynamic RSVP LSP as bypass tunnels

  The RSVP LSP's Explicit Route Object (ERO) is calculated using Constrained Shortest Path First (CSPF) with the constraint as the link to avoid. The LSP is signaled and torn down dynamically whenever link protection is necessary.

- Make-before-break

  The make-before-break feature ensures that there is minimum packet loss when attempting to signal a new LSP path before tearing down the old LSP path for the multicast LDP LSP.

- Targeted LDP session

  A targeted adjacency to the downstream label-switching router (LSR) is created for two reasons:

  - To keep the session up after link failure.
  - To use the point-to-multipoint label received from the session to send traffic to the downstream LSR on the RSVP LSP bypass tunnel.

    When the downstream LSR sets up the multicast LDP LSP with the root node and LSP ID, it uses that upstream LSR, which is on the best path toward the root.

NOTE: Multicast LDP link protection is not required when there are multiple link adjacencies (parallel links) to the downstream LSR.

Different Modes for Providing LDP Link Protection

Following are three different modes of operation available for unicast and multicast LDP link protection:

- **Case A: LFA only**

  Under this mode of operation, multicast LDP link protection is provided using an existing viable loop-free alternate (LFA). In the absence of a viable LFA, link protection is not provided for the multicast LDP LSP.

- **Case B: LFA and Dynamic RSVP LSP**

  Under this mode of operation, multicast LDP link protection is provided using an existing viable LFA. In the absence of a viable LFA, an RSVP bypass LSP is created automatically to provide link protection for the multicast LDP LSP.

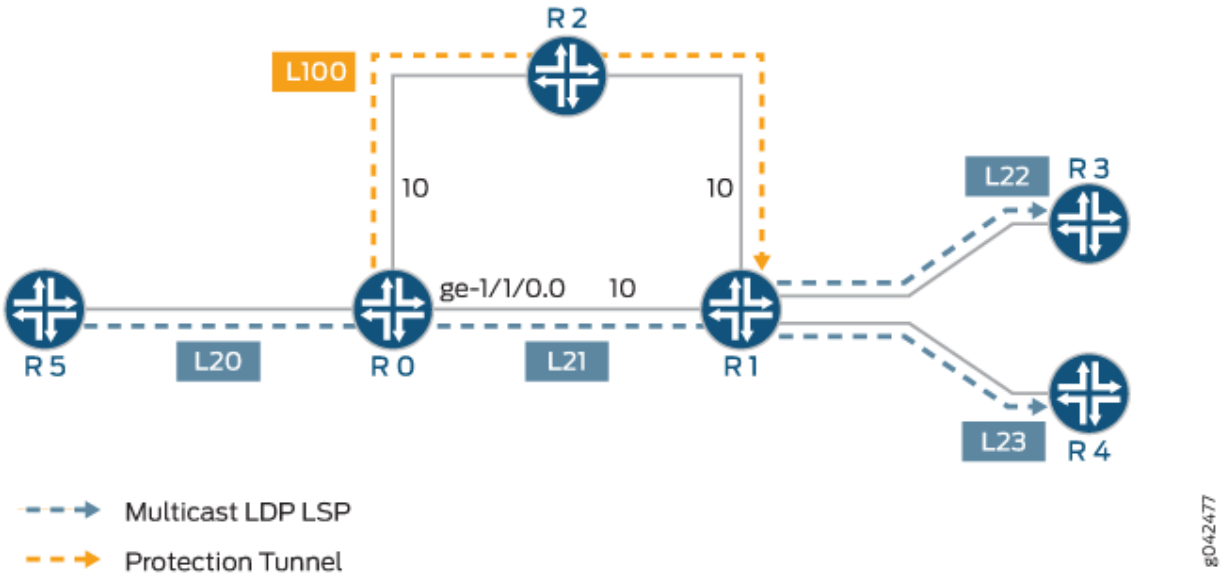
- **Case C: Dynamic RSVP LSP only**

  Under this mode of operation, LFA is not used for link protection. Multicast LDP link protection is provided by using automatically created RSVP bypass LSP.

Figure 6 is a sample topology illustrating the different modes of operation for multicast LDP link protection. Router R5 is the root connecting to two leaf nodes, Routers R3 and R4. Router R0 and

Router R1 are the upstream and downstream label-switched routers (LSRs), respectively. A multicast LDP LSP runs among the root and leaf nodes.

Figure 83: Multicast LDP Link Protection Sample Topology



Considering that Router R0 needs to protect the multicast LDP LSP in the case that the R0-R1 link fails, the different modes of link protection operate in the following manner:

- **Case A: LFA only**

  Router R0 checks if a viable LFA path exists that can avoid the R0-R1 link to reach Router R1. Based on the metrics, Router R2 is a valid LFA path for the R0-R1 link and is used to forward unicast LDP traffic. If multiple multicast LDP LSPs use the R0-R1 link, the same LFA (Router R2) is used for multicast LDP link protection.

  When the R0-R1 link fails, the multicast LDP LSP traffic is moved onto the LFA path by Router R0, and the unicast LDP label to reach Router R1 (L100) is pushed on top of the multicast LDP label (L21).

- **Case B: LFA and Dynamic RSVP LSP**

  Router R0 checks if a viable LFA path exists that can avoid the R0-R1 link to reach Router R1. Based on the metrics, Router R2 is a valid LFA path for the R0-R1 link and is used to forward unicast LDP traffic. If multiple multicast LDP LSPs use the R0-R1 link, the same LFA (Router R2) is used for multicast LDP link protection. When the R0-R1 link fails, the multicast LDP LSP traffic is moved onto the LFA path by Router R0.

However, if the metric on the R2-R1 link was 50 instead of 10, Router 2 is a not a valid LFA for the R0-R1 link. In this case, an RSVP LSP is automatically created to protect the multicast LDP traffic traveling between Routers R0 and R1.

- **Case C: Dynamic RSVP LSP only**

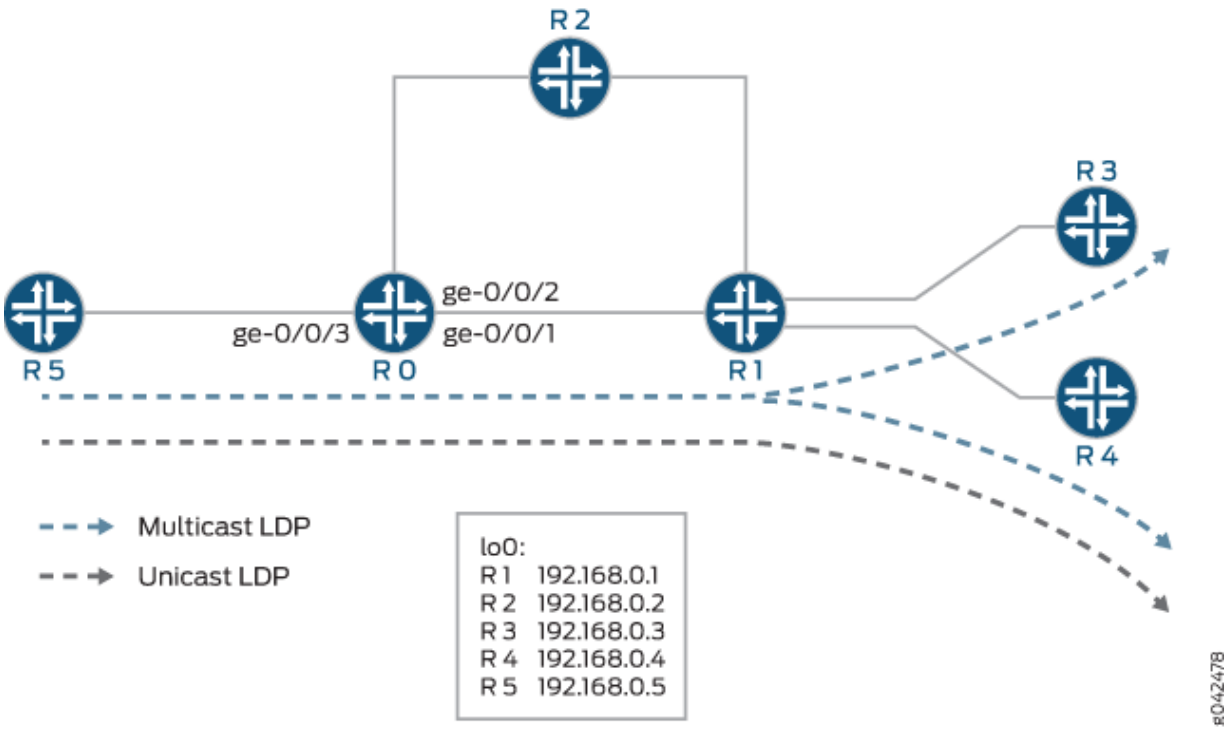
  An RSVP LSP is signaled automatically from Router R0 to Router R1 through Router R2, avoiding interface ge-1/1/0. If multiple multicast LDP LSPs use the R0-R1 link, the same RSVP LSP is used for multicast LDP link protection.

  When the R0-R1 link fails, the multicast LDP LSP traffic is moved onto the RSVP LSP by Router R0, and the RSVP label to reach Router R1 (L100) is pushed on top of the multicast LDP label (L21).

Label Operation for LDP Link Protection

Using the same network topology as in Figure 5, *Figure 7* illustrates the label operation for unicast and multicast LDP link protection.

Figure 84: LDP Label Operation Sample Topology



Router R5 is the root connecting to two leaf nodes, Routers R3 and R4. Router R0 and Router R1 are the upstream and downstream label-switched routers (LSRs), respectively. A multicast LDP LSP runs among the root and leaf nodes. An unicast LDP path connects Router R1 to Router R5.

The label operation is performed differently under the following modes of LDP link protection:

Case A: LFA Only

Using the `show route detail` command output on Router R0, the unicast LDP traffic and multicast LDP traffic can be derived.

```
user@R0> show route detail

                Announcement bits (1): 0-KRT
                AS path: I
                FECs bound to route: P2MP root-addr 192.168.0.5, lsp-id 99
```

Label 299840 is traffic arriving at Router R0 that corresponds to unicast LDP traffic to Router R1. Label 299856 is traffic arriving at Router 0 that corresponds to multicast LDP traffic from the root node R5 to the leaf egress nodes, R3 and R4.

The main path for both unicast and multicast LDP LSPs is through interface ge-0/0/1 (the link to Router R1), and the LFA path is through interface ge-0/0/2 (the link to Router R2). The LFA path is not used unless the ge-0/0/1 interface goes down.

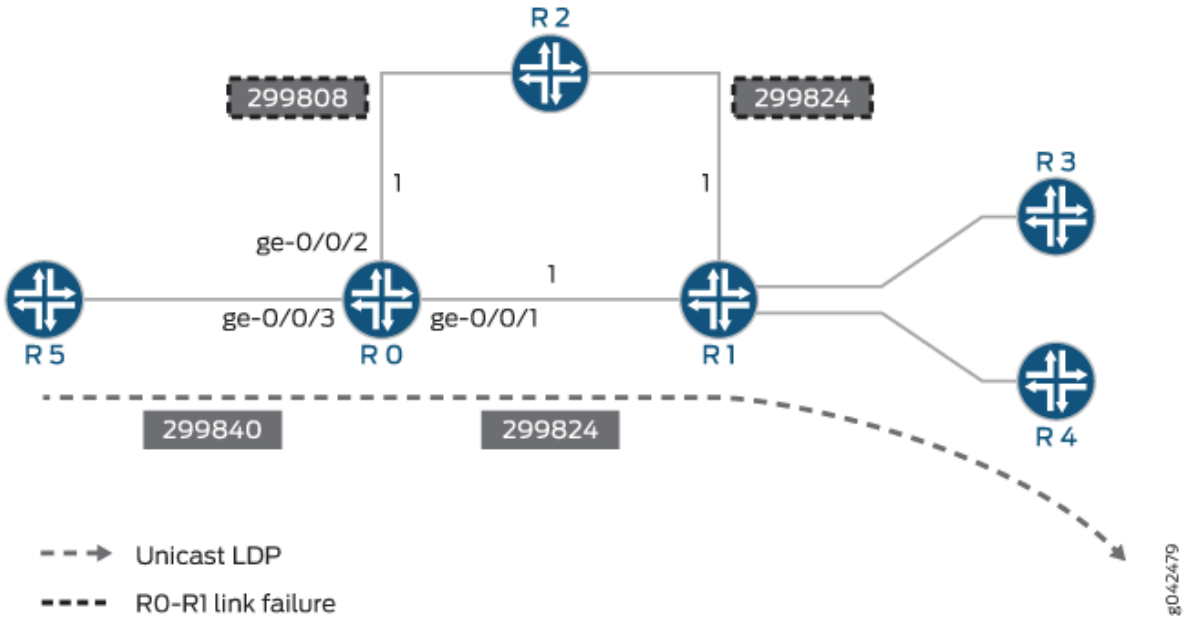
In the label operation for Case A, the LFA-only mode of operation is different for unicast and multicast LDP traffic:

- Unicast label operation

  For unicast LDP traffic, the FECs and associated labels are advertised on all the links in the network on which LDP is enabled. This means that in order to provide LFA action for the unicast LDP traffic to Router R4, instead of swapping the incoming label for label 299824 advertised by Router R1 for FEC R4, Router R0 simply swaps the incoming label for label 299808 advertised by Router R2 for FEC R4. This is the standard Junos OS LFA operation for unicast LDP traffic.

Figure 8 illustrates the label operation for unicast traffic when the R0-R1 link fails. The grey boxes show the label operation for unicast LDP traffic under normal condition, and the dotted boxes show the label operation for unicast LDP traffic when the R0-R1 link fails.

Figure 85: Unicast LDP Label Operation



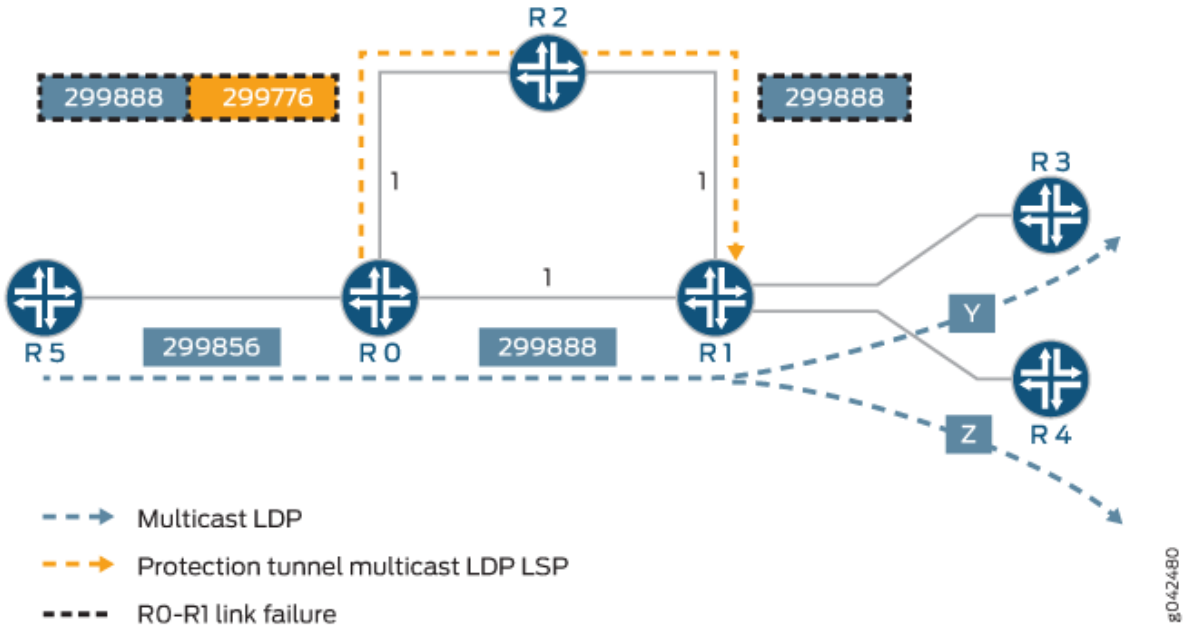
- Multicast label operation

  The label operation for multicast LDP traffic differs from the unicast LDP label operation, because multipoint LSP labels are only advertised along the best path from the leaf node to the ingress node. As a result, Router R2 has no knowledge of the multicast LDP. To overcome this, the multicast LDP LSP traffic is simply tunneled inside the unicast LDP LSP path through Router R2 that terminates at Router R1.

  In order to achieve this, Router R0 first swaps the incoming multicast LDP LSP label 299856 to label 299888 advertised by Router R1. Label 299776 is then pushed on top, which is the LDP label advertised by Router R2 for FEC R1. When the packet arrives at Router R2, the top label is popped out due to penultimate hop-popping. This means that the packet arrives at Router R1 with the multicast LDP label 299888 that Router R1 had originally advertised to Router R0.

Figure 9 illustrates the label operation for multicast LDP traffic when the R0-R1 link fails. The blue boxes show the label operation for multicast LDP traffic under normal condition, and the dotted boxes show the label operation for multicast LDP traffic when the R0-R1 link fails.

Figure 86: Multicast LDP Label Operation



When the metric on the R2-R1 link is set to 1000 instead of 1, Router R2 is not a valid LFA for Router R0. In this case, if Router R2 receives a packet destined for Router R1, R3, or R4 before its IGP has converged, the packet is sent back to Router R0, resulting in looping packets.

Because Router R0 has no viable LFA, no backup paths are installed in the Packet Forwarding Engine. If the R0-R1 link fails, traffic flow is interrupted until the IGP and LDP converge and new entries are installed on the affected routers.

The `show route detail` command displays the state when no LFA is available for link protection.

```

                AS path: I
                FECs bound to route: P2MP root-addr 192.168.0.5, lsp-id 99
```

Case B: LFA and Dynamic RSVP LSP

In this mode of operation, if there is a viable LFA neighbor, the label operation behavior is similar to that of Case A, LFA only mode. However, if there is no viable LFA neighbor, an RSVP bypass tunnel is automatically created.

If the metric on the link R2-R1 is set to 1000 instead of 1, Router R2 is not an LFA for Router R0. On learning that there are no LFA paths to protect the R0-R1 link failure, an RSVP bypass tunnel is automatically created with Router R1 as the egress node and follows a path that avoids the R0-R1 link (for instance, R0-R2-R1).

If the R0-R1 link fails, the unicast LDP and multicast LDP traffic is tunneled through the RSVP bypass tunnel. The RSVP bypass tunnel is not used for normal forwarding and is used only to provide link protection to LDP traffic in the case of R0-R1 link failure.

Using the `show route detail` command, the unicast and multicast LDP traffic can be derived.

```
user@host> show route detail
299840 (1 entry, 1 announced)
        *LDP    Preference: 9
                Next hop type: Router

                Label TTL action: prop-ttl, prop-ttl(top)
                State: < Active Int AckRequest>
                Age: 20         Metric: 1
                Validation State: unverified
                Task: LDP
```

```
                Announcement bits (1): 0-KRT
                AS path: I
                FECs bound to route: P2MP root-addr 192.168.0.5, lsp-id 99
```

The main path for both unicast and multicast LDP LSP is through interface ge-0/0/1 (the link to Router R1), and the LFA path is through interface ge-0/0/2 (the link to Router R2). The LFA path is not used unless the ge-0/0/1 interface goes down.

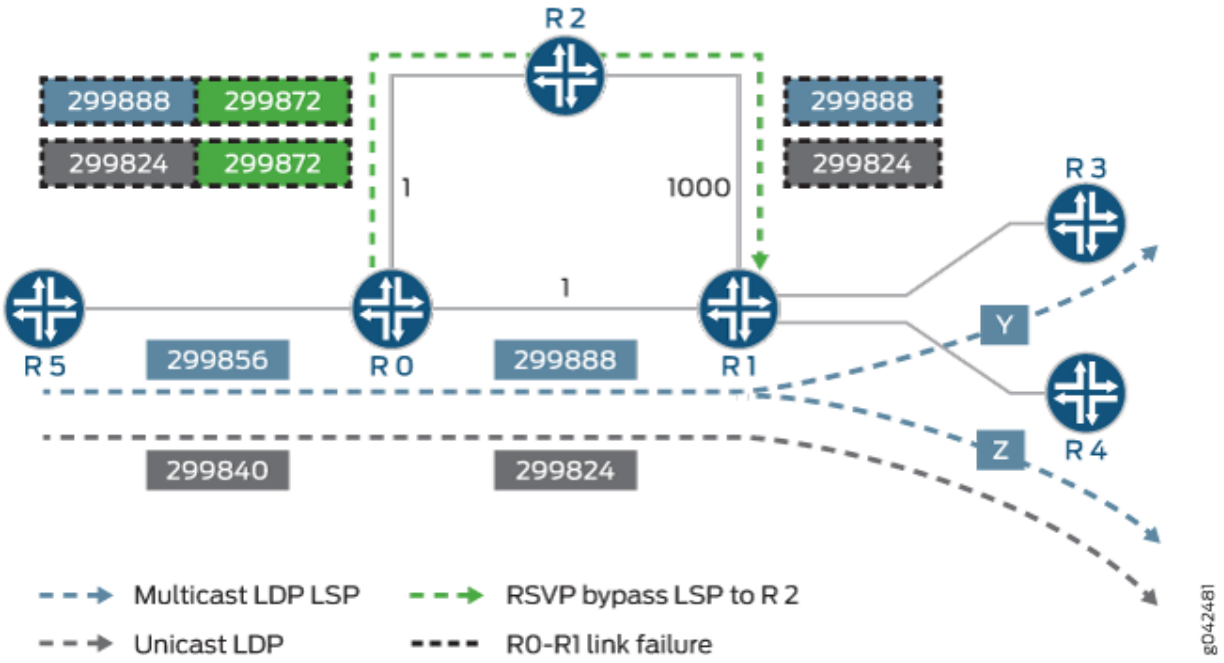
Label 299840 is traffic arriving at Router R0 that corresponds to unicast LDP traffic to Router R4. Label 299856 is traffic arriving at Router 0 that corresponds to multicast LDP traffic from the root node R5 to the leaf egress nodes, R3 and R4.

As seen in the `show route detail` command output, the label operations for the protection path are the same for unicast LDP and multicast LDP traffic. The incoming LDP label at Router R0 is swapped to the LDP label advertised by Router R1 to Router R0. The RSVP label 299872 for the bypass tunnel is then pushed onto the packet. Penultimate hop-popping is used on the bypass tunnel, causing Router R2 to pop that label. Thus the packet arrives at Router R1 with the LDP label that it had originally advertised to Router R0.

Figure 10 illustrates the label operation for unicast LDP and multicast LDP traffic protected by the RSVP bypass tunnel. The grey and blue boxes represent label values used under normal conditions for unicast

and multicast LDP traffic, respectively. The dotted boxes represent label values used when the R0-R1 link fails.

Figure 87: LDP Link Protection Label Operation



Case C: Dynamic RSVP LSP Only

In this mode of operation, LFA is not used at all. A dynamic RSVP bypass LSP is automatically created in order to provide link protection. The output from the `show route detail` command and the label operations are similar to Case B, LFA and dynamic RSVP LSP mode.

Sample Multicast LDP Link Protection Configuration

To enable multicast LDP link protection, the following configuration is required on Router R0:

> **NOTE**: In this sample, multicast LDP link protection is enabled on the ge-1/0/0 interface of Router R0 that connects to Router R1, although typically all the interfaces need to be configured for link protection.

Router R0

```
protocols {
    rsvp {
        interface all;
        interface ge-0/0/0.0 {
            disable;
        }
    }
    mpls {
        interface all;
        interface ge-0/0/0.0 {
            disable;
        }
    }
    ospf {
        traffic-engineering;
        area 0.0.0.0 {
            interface lo0.0;
            interface ge-0/0/1.0 {
                link-protection;
            }
            interface ge-0/0/2.0;
            interface ge-0/0/3.0;
        }
    }
    ldp {
        make-before-break {
            timeout seconds;
            switchover-delay seconds;
        }
        interface ge-1/1/0.0 {
            link-protection {
                disable;
                dynamic-rsvp-lsp;
            }
        }
    }
}
```

The following configuration statements apply to the different modes of multicast LDP protection as follows:

- `link-protection` statement at `[edit protocols ospf interface ge-0/0/1.0]`

  This configuration is applied only for Case A (LFA only) and Case B (LFA and dynamic RSVP LSP) modes of multicast LDP link protection. Configuring link protection under an IGP is not required for Case C (dynamic RSVP LSP only).

- `link-protection` statement at `[edit protocols ldp interface ge-0/0/1.0]`

  This configuration is required for all modes of multicast LDP protection. However, if the only LDP traffic present is unicast, and dynamic RSVP bypasses are not required, then this configuration is not required, as the `link-protection` statement at the `[edit protocols ospf interface ge-0/0/1.0]` hierarchy level results in LFA action for the LDP unicast traffic.

- `dynamic-rsvp-lsp` statement at `[edit protocols ldp interface ge-0/0/1.0 link-protection]`

  This configuration is applied only for Case B (LFA and dynamic RSVP LSP) and Case C (dynamic RSVP LSP only) modes of LDP link protection. Dynamic RSVP LSP configuration does not apply to Case A (LFA only).

Make-Before-Break

The make-before-break feature is enabled by default on Junos OS and provides some benefits for point-to-multipoint LSPs.

For a point-to-multipoint LSP, a label-switched router (LSR) selects the LSR that is its next hop to the root of the LSP as its upstream LSR. When the best path to reach the root changes, the LSR chooses a new upstream LSR. During this period, the LSP might be temporarily broken, resulting in packet loss until the LSP reconverges to a new upstream LSR. The goal of make-before-break in this case is to minimize the packet loss. In cases where the best path from the LSR to the root changes but the LSP continues to forward traffic to the previous next hop to the root, a new LSP should be established before the old LSP is withdrawn to minimize the duration of packet loss.

Taking for example, after a link failure, a downstream LSR (for instance, LSR-D) still receives and/or forwards packets to the other downstream LSRs, as it continues to receive packets from the one hop RSVP LSP. Once routing converges, LSR-D selects a new upstream LSR (LSR-U) for this point-to-multipoint LSP's FEC (FEC-A). The new LSR might already be forwarding packets for FEC-A to the downstream LSRs other than LSR-D. After LSR-U receives a label for FEC-A from LSR-D, it notifies LSR-D when it has learnt that LSP for FEC-A has been established from the root to itself. When LSR-D receives such a notification, it changes its next hop for the LSP root to LSR-U. This is a route delete and add operation on LSR-D. At this point, LSR-D does an LSP switchover, and traffic tunneled through RSVP LSP or LFA is dropped, and traffic from LSR-U is accepted. The new transit route for LSR-U is added. The RPF check is changed to accept traffic from LSR-U and to drop traffic from the old upstream LSR, or the old route is deleted and the new route is added.

The assumption is that LSR-U has received a make-before-break notification from its upstream router for the FEC-A point-to-multipoint LSP and has installed a forwarding state for the LSP. At that point it

should signal LSR-D by means of make-before-break notification that it has become part of the tree identified by FEC-A and that LSR-D should initiate its switchover to the LSP. Otherwise, LSR-U should remember that it needs to send notification to LSR-D when it receives a make-before-break notification from the upstream LSR for FEC-A and installs a forwarding state for this LSP. LSR-D continues to receive traffic from the old next hop to the root node using one hop RSVP LSP or LFA path until it switches over to the new point-to-multipoint LSP to LSR-U.

The make-before-break functionality with multicast LDP link protection includes the following features:

- Make-before-break capability

  An LSR advertises that it is capable of handling make-before-break LSPs using the capability advertisement. If the peer is not make-before-break capable, the make-before-break parameters are not sent to this peer. If an LSR receives a make-before-break parameter from a downstream LSR (LSR-D) but the upstream LSR (LSR-U) is not make-before-break capable, the LSR immediately sends a make-before-break notification to LSR-D, and the make-before-break capable LSP is not established. Instead, the normal LSP is established.

- Make-before-break status code

  The make-before-break status code includes:

  - 1—make-before-break request
  - 2—make-before-break acknowledgment

  When a downstream LSR sends a label-mapping message for point-to-multipoint LSP, it includes the make-before-break status code as 1 (request). When the upstream LSR updates the forwarding state for the point-to-multipoint LSP, it informs the downstream LSR with a notification message containing the make-before-break status code as 2 (acknowledgment). At that point, the downstream LSR does an LSP switchover.

Caveats and Limitations

The Junos OS implementation of the LDP link protection feature has the following caveats and limitations:

- Make-before-break is not supported for the following point-to-multipoint LSPs on an egress LSR:
  - Next-generation multicast virtual private network (MVPN) with virtual routing and forwarding (VRF) label
  - Static LSP
- The following features are not supported:
  - Nonstop active routing for point-to-multipoint LSP in Junos OS Releases 12.3, 13.1 and 13.2

- Graceful restart switchover point-to-multipoint LSP
- Link protection for routing instance

Example: Configuring LDP Link Protection

IN THIS SECTION

- Requirements | **1396**
- Overview | **1397**
- Configuration | **1398**
- Verification | **1405**

This example shows how to configure Label Distribution Protocol (LDP) link protection for both unicast and multicast LDP label-switched paths (LSPs).

Requirements

This example uses the following hardware and software components:

- Six routers that can be a combination of M Series, MX Series, or T Series routers with one root node and two leaf nodes running a point-to-multipoint LDP LSP.
- Junos OS Release 12.3 or later running on all the routers.

Before you begin:

1. Configure the device interfaces.
2. Configure the following protocols:
   a. RSVP
   b. MPLS
   c. OSPF or any other IGP
   d. LDP

Overview

IN THIS SECTION

- Topology | **1398**

LDP link protection enables fast reroute of traffic carried over LDP LSPs in case of a link failure. LDP point-to-multipoint LSPs can be used to send traffic from a single root or ingress node to a number of leaf nodes or egress nodes traversing one or more transit nodes. When one of the links of the point-to-multipoint tree fails, the subtrees can get detached until the IGP reconverges and multicast LDP initiates label mapping using the best path from the downstream router to the new upstream router. To protect the traffic in the event of a link failure, you can configure an explicit tunnel so that traffic can be rerouted using the tunnel. Junos OS supports make-before-break capabilities to ensure minimum packet loss when attempting to signal a new LSP path before tearing down the old LSP path. This feature also adds targeted LDP support for multicast LDP link protection.

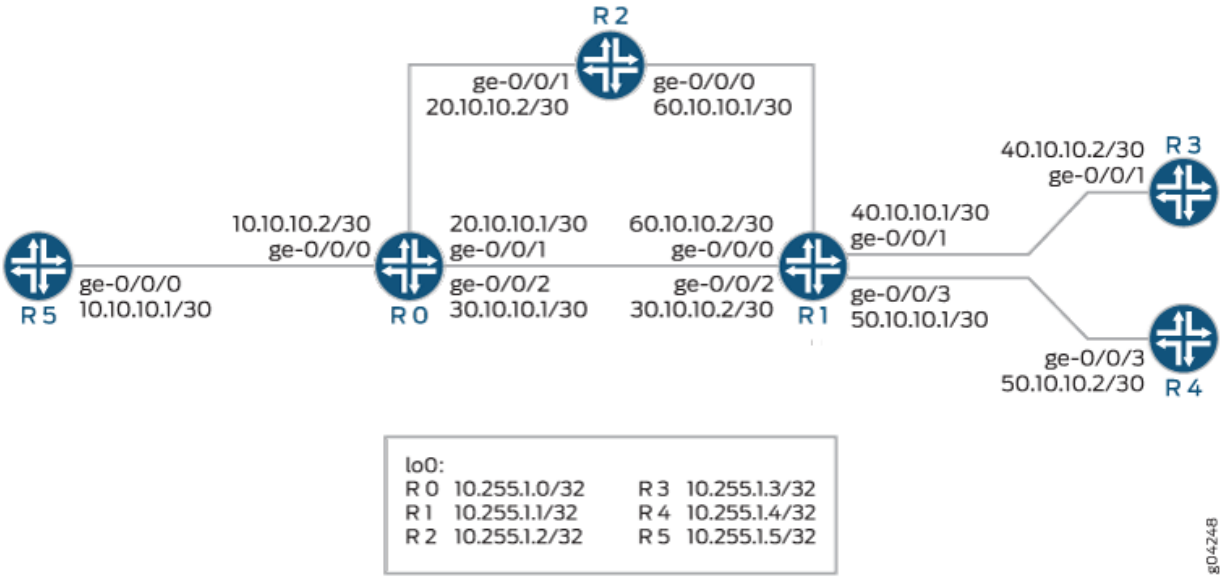
When configuring LDP link protection, be aware of the following considerations:

- Configure traffic engineering under IGP (if it is not supported by default), and include the interfaces configured for MPLS and RSVP so that constrained-based link protected dynamic RSVP LSP is signaled by RSVP using Constrained Shortest Path First (CSPF). When this condition is not satisfied, RSVP LSP might not come up and LDP cannot use it as a protected next hop.
- Configure a path between two label-switched routers (LSRs) to provide IP connectivity between the routers when there is a link failure. This enables CSPF to calculate an alternate path for link protection. When the connectivity between the routers is lost, the LDP targeted adjacency does not come up and dynamic RSVP LSP cannot be signaled, resulting in no protection for the LDP forwarding equivalence class (FEC) for which the peer is the downstream LSR.
- If link protection is active only on one LSR, then the other LSR should not be configured with the `strict-targeted-hellos` statement. This enables the LSR without link protection to allow asymmetric remote neighbor discovery and send periodic targeted hellos to the LSR that initiated the remote neighbor. When this condition is not satisfied, LDP targeted adjacency is not formed.
- LDP must be enabled on the loopback interface of the LSR to create remote neighbors based on LDP tunneling, LDP-based virtual private LAN service (VPLS), Layer 2 circuits, or LDP session protection. When this condition is not satisfied, LDP targeted adjacency is not formed.
- For unicast LDP LSP, loop-free alternate (LFA) should be configured in IGP.
- The ingress route to merge point should have at least one next hop avoiding the primary link between the merge point and the point of local repair for unicast LDP LSP.

- Point of local repair should have a unicast LDP label for the backup next hop to reach the merge point.

Topology

Figure 88: LDP Link Protection



In this example, Router R5 is the root connecting to two leaf nodes, Routers R3 and R4. Router R0 is the point of local repair.

Configuration

IN THIS SECTION

- CLI Quick Configuration | **1398**
- Procedure | **1402**

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the `[edit]` hierarchy level, and then enter `commit` from configuration mode.

Procedure

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure Router R0:

1. Configure the Router R0 interfaces.

```
[edit interfaces]
user@R0# set ge-0/0/0 unit 0 family inet address 10.10.10.2/30
user@R0# set ge-0/0/0 unit 0 family mpls
user@R0# set ge-0/0/1 unit 0 family inet address 20.10.10.1/30
user@R0# set ge-0/0/1 unit 0 family mpls
user@R0# set ge-0/0/2 unit 0 family inet address 30.10.10.1/30
user@R0# set ge-0/0/2 unit 0 family mpls
user@R0# set lo0 unit 0 family inet address 10.255.1.0/32
```

2. Configure the router ID and autonomous system of Router R0.

```
[edit routing-options]
user@R0# set router-id 10.255.1.0
user@R0# set autonomous-system 100
```

3. Enable RSVP on all the interfaces of Router R0 (excluding the management interface).

```
[edit protocols]
user@R0# set rsvp interface all
user@R0# set rsvp interface fxp0.0 disable
```

4. Enable MPLS on all the interfaces of Router R0 (excluding the management interface) along with traffic engineering capabilities.

```
[edit protocols]
user@R0# set mpls traffic-engineering
user@R0# set mpls interface all
user@R0# set mpls interface fxp0.0 disable
```

5. Enable OSPF on all the interfaces of Router R0 (excluding the management interface), assign equal cost metric for the links, and enable traffic engineering capabilities.

```
[edit protocols]
user@R0# set ospf traffic-engineering
user@R0# set ospf area 0.0.0.0 interface all metric 1
user@R0# set ospf area 0.0.0.0 interface fxp0.0 disable
```

NOTE: For multicast LDP link protection with loop-free alternative (LFA), enable the following configuration under the `[edit protocols]` hierarchy level:

```
set ospf area 0 interface all link-protection
```

6. Enable LDP on all the interfaces of Router R0 (excluding the management interface) and configure link protection with dynamic RSVP bypass LSP.

```
[edit protocols]
user@R0# set ldp interface all link-protection dynamic-rsvp-lsp
user@R0# set ldp interface fxp0.0 disable
user@R0# set ldp p2mp
```

Results

From configuration mode, confirm your configuration by entering the `show interfaces`, `show routing-options`, and `show protocols` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R0# show interfaces
ge-0/0/0 {
    unit 0 {
        family inet {
            address 10.10.10.2/30;
        }
        family mpls;
    }
}
ge-0/0/1 {
```

```
    unit 0 {
        family inet {
            address 20.10.10.1/30;
        }
        family mpls;
    }
}
ge-0/0/2 {
    unit 0 {
        family inet {
            address 30.10.10.1/30;
        }
        family mpls;
    }
}
lo0 {
    unit 0 {
        family inet {
            address 10.255.1.0/32;
        }
    }
}
```

```
user@R0# show routing-options
router-id 10.255.1.0;
autonomous-system 100;
```

```
user@R0# show protocols
rsvp {
    interface all;
    interface fxp0.0 {
        disable;
    }
}
mpls {
    traffic-engineering;
    interface all;
    interface fxp0.0 {
        disable;
    }
```

```
}
ospf {
    traffic-engineering;
    area 0.0.0.0 {
        interface all {
            metric 1;
        }
        interface fxp0.0 {
            disable;
        }
    }
}
ldp {
    interface all {
        link-protection {
            dynamic-rsvp-lsp;
        }
    }
    interface fxp0.0 {
        disable;
    }
    p2mp;
}
```

Verification

IN THIS SECTION

- Verifying the Bypass RSVP LSP Path | **1405**
- Verifying Label Operation | **1407**

Verify that the configuration is working properly.

Verifying the Bypass RSVP LSP Path

Purpose

Verify that the bypass RSVP LSP path has been created on the point of local repair (PLR).

Action

From operational mode, run the `show route tale mpls.0` command.

```
user@R0> show route tale mpls.0
mpls.0: 17 destinations, 17 routes (17 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

0                  *[MPLS/0] 05:28:13, metric 1
                      Receive
1                  *[MPLS/0] 05:28:13, metric 1
                      Receive
2                  *[MPLS/0] 05:28:13, metric 1
                      Receive
13                 *[MPLS/0] 05:28:13, metric 1
                      Receive
299792             *[LDP/9] 00:41:41, metric 1
                    > to 30.10.10.2 via ge-0/0/2.0, Pop
299792(S=0)        *[LDP/9] 00:41:41, metric 1
                    > to 30.10.10.2 via ge-0/0/2.0, Pop

```

```
299984             *[LDP/9] 00:05:38, metric 1
                    > to 30.10.10.2 via ge-0/0/2.0, Swap 300000
300000             *[LDP/9] 00:05:15, metric 1
                    > to 30.10.10.2 via ge-0/0/2.0, Swap 300016
```

Meaning

When the R0-R1 link goes down, the RSVP bypass LSP is used to route traffic.

Verifying Label Operation

Purpose

Verify the label swapping at the PLR.

Action

From operational mode, run the `show route table mpls.0 label label extensive` command.

```
user@R0> show route table mpls.0 label 300000 extensive
mpls.0: 17 destinations, 17 routes (17 active, 0 holddown, 0 hidden)
300000 (1 entry, 1 announced)
TSI:
KRT in-kernel 300000 /52 -> {Swap 300016}
        *LDP    Preference: 9
                Next hop type: Router, Next hop index: 589
                Address: 0x9981610
                Next-hop reference count: 2
                Next hop: 30.10.10.2 via ge-0/0/2.0, selected
                Label operation: Swap 300016
                Load balance label: Label 300016: None;
                Session Id: 0x2
                State: <Active Int>
                Local AS:   100
                Age: 12:50      Metric: 1
                Validation State: unverified
                Task: LDP
                Announcement bits (1): 1-KRT
                AS path: I
                Prefixes bound to route: 10.255.1.4/32
```

Meaning

The label is bound to reach Router R4, which is a leaf node.

Understanding Multicast-Only Fast Reroute

IN THIS SECTION

- MoFRR Overview | **1409**
- PIM Functionality | **1411**
- Multipoint LDP Functionality | **1412**
- Packet Forwarding | **1413**
- Limitations and Caveats | **1415**

Multicast-only fast reroute (MoFRR) minimizes packet loss for traffic in a multicast distribution tree when link failures occur, enhancing multicast routing protocols like Protocol Independent Multicast (PIM) and multipoint Label Distribution Protocol (multipoint LDP) on devices that support these features.

NOTE: On switches, MoFRR with MPLS label-switched paths and multipoint LDP is not supported.

For MX Series routers, MoFRR is supported only on MX Series routers with MPC line cards. As a prerequisite, you must configure the router into *network-services* enhanced-ip mode, and all the line cards in the router must be MPCs.

With MoFRR enabled, devices send join messages on primary and backup upstream paths toward a multicast source. Devices receive data packets from both the primary and backup paths, and discard the redundant packets based on priority (weights that are assigned to the primary and backup paths). When a device detects a failure on the primary path, it immediately starts accepting packets from the secondary interface (the backup path). The fast switchover greatly improves convergence times upon primary path link failures.

One application for MoFRR is streaming IPTV. IPTV streams are multicast as UDP streams, so any lost packets are not retransmitted, leading to a less-than-satisfactory user experience. MoFRR can improve the situation.

MoFRR Overview

With fast reroute on unicast streams, an upstream routing device preestablishes MPLS label-switched paths (LSPs) or precomputes an IP loop-free alternate (LFA) fast reroute backup path to handle failure of a segment in the downstream path.

In multicast routing, the receiving side usually originates the traffic distribution graphs. This is unlike unicast routing, which generally establishes the path from the source to the receiver. PIM (for IP), multipoint LDP (for MPLS), and RSVP-TE (for MPLS) are protocols that are capable of establishing multicast distribution graphs. Of these, PIM and multipoint LDP receivers initiate the distribution graph setup, so MoFRR can work with these two multicast protocols where they are supported.

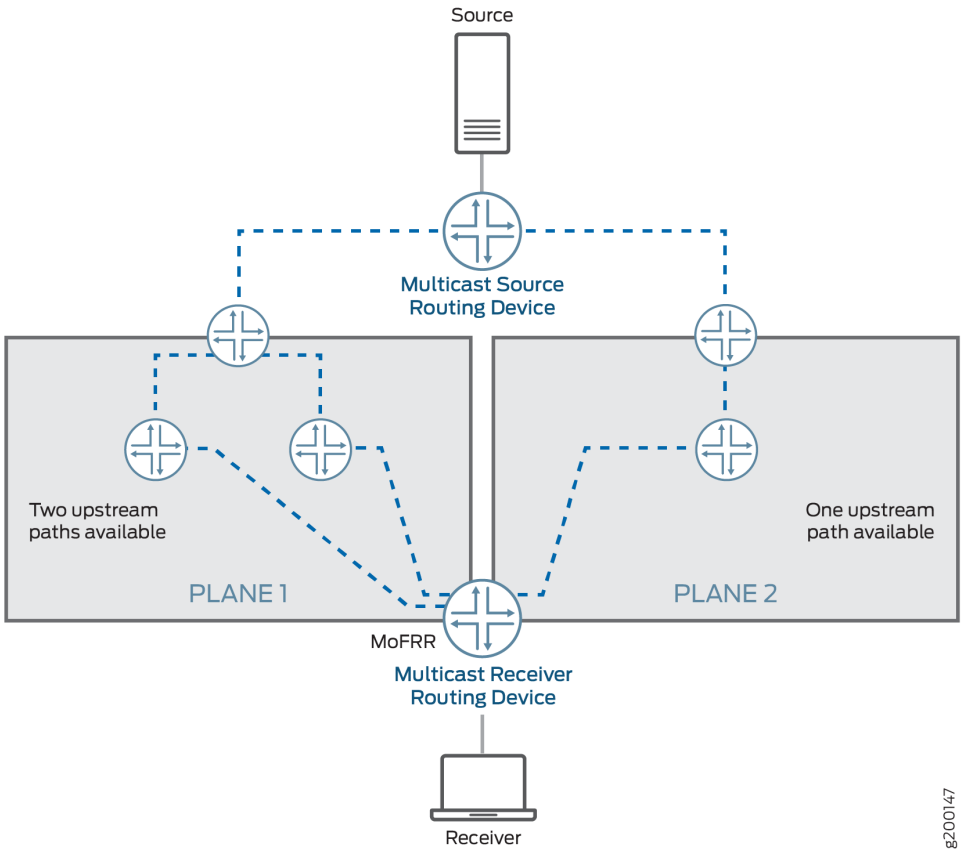
In a multicast tree, if the device detects a network component failure, it takes some time to perform a reactive repair, leading to significant traffic loss while setting up an alternate path. MoFRR reduces traffic loss in a multicast distribution tree when a network component fails. With MoFRR, one of the downstream routing devices sets up an alternative path toward the source to receive a backup live stream of the same multicast traffic. When a failure happens along the primary stream, the MoFRR routing device can quickly switch to the backup stream.

With MoFRR enabled, for each (S,G) entry, the device uses two of the available upstream interfaces to send a join message and to receive multicast traffic. The protocol attempts to select two disjoint paths if two such paths are available. If disjoint paths are not available, the protocol selects two non-disjoint paths. If two non-disjoint paths are not available, only a primary path is selected with no backup. MoFRR prioritizes the disjoint backup in favor of load balancing the available paths.

MoFRR is supported for both IPv4 and IPv6 protocol families.

Figure 89 on page 1410 shows two paths from the multicast receiver routing device (also referred to as the egress provider edge (PE) device) to the multicast source routing device (also referred to as the ingress PE device).

Figure 89: MoFRR Sample Topology



With MoFRR enabled, the egress (receiver side) routing device sets up two multicast trees, a primary path and a backup path, toward the multicast source for each (S,G). In other words, the egress routing device propagates the same (S,G) join messages toward two different upstream neighbors, thus creating two multicast trees.

One of the multicast trees goes through plane 1 and the other through plane 2, as shown in Figure 89 on page 1410. For each (S,G), the egress routing device forwards traffic received on the primary path and drops traffic received on the backup path.

MoFRR is supported on both equal-cost multipath (ECMP) paths and non-ECMP paths. The device needs to enable unicast loop-free alternate (LFA) routes to support MoFRR on non-ECMP paths. You enable LFA routes using the `link-protection` statement in the interior gateway protocol (IGP)

configuration. When you enable link protection on an OSPF or IS-IS interface, the device creates a backup LFA path to the primary next hop for all destination routes that traverse the protected interface.

Junos OS implements MoFRR in the IP network for IP MoFRR and at the MPLS label-edge routing device (LER) for multipoint LDP MoFRR.

Multipoint LDP MoFRR is used at the egress device of an MPLS network, where the packets are forwarded to an IP network. With multipoint LDP MoFRR, the device establishes two paths toward the upstream PE routing device for receiving two streams of MPLS packets at the LER. The device accepts one of the streams (the primary), and the other one (the backup) is dropped at the LER. IF the primary path fails, the device accepts the backup stream instead. Inband signaling support is a prerequisite for MoFRR with multipoint LDP (see Understanding Multipoint LDP Inband Signaling for Point-to-Multipoint LSPs).

PIM Functionality

Junos OS supports MoFRR for shortest-path tree (SPT) joins in PIM source-specific multicast (SSM) and any-source multicast (ASM). MoFRR is supported for both SSM and ASM ranges. To enable MoFRR for (*,G) joins, include the `mofrr-asm-starg` configuration statement at the `[edit routing-options multicast stream-protection]` hierarchy. For each group G, MoFRR will operate for either (S,G) or (*,G), but not both. (S,G) always takes precedence over (*,G).

With MoFRR enabled, a PIM routing device propagates join messages on two upstream reverse-path forwarding (RPF) interfaces to receive multicast traffic on both links for the same join request. MoFRR gives preference to two paths that do not converge to the same immediate upstream routing device. PIM installs appropriate multicast routes with upstream RPF next hops with two interfaces (for the primary and backup paths).

When the primary path fails, the backup path is upgraded to primary status, and the device forwards traffic accordingly. If there are alternate paths available, MoFRR calculates a new backup path and updates or installs the appropriate multicast route.

You can enable MoFRR with PIM join load balancing (see the *join-load-balance* `automatic` statement). However, in that case the distribution of join messages among the links might not be even. When a new ECMP link is added, join messages on the primary path are redistributed and load-balanced. The join messages on the backup path might still follow the same path and might not be evenly redistributed.

You enable MoFRR using the `stream-protection` configuration statement at the `[edit routing-options multicast]` hierarchy. MoFRR is managed by a set of filter policies.

When an egress PIM routing device receives a join message or an IGMP report, it checks for an MoFRR configuration and proceeds as follows:

- If the MoFRR configuration is not present, PIM sends a join message upstream toward one upstream neighbor (for example, plane 2 in Figure 89 on page 1410).

- If the MoFRR configuration is present, the device checks for a policy configuration.
- If a policy is not present, the device checks for primary and backup paths (upstream interfaces), and proceeds as follows:
  - If primary and backup paths are not available—PIM sends a join message upstream toward one upstream neighbor (for example, plane 2 in Figure 89 on page 1410).
  - If primary and backup paths are available—PIM sends the join message upstream toward two of the available upstream neighbors. Junos OS sets up primary and secondary multicast paths to receive multicast traffic (for example, plane 1 in Figure 89 on page 1410).
- If a policy is present, the device checks whether the policy allows MoFRR for this (S,G), and proceeds as follows:
  - If this policy check fails—PIM sends a join message upstream toward one upstream neighbor (for example, plane 2 in Figure 89 on page 1410).
  - If this policy check passes—The device checks for primary and backup paths (upstream interfaces).
    - If the primary and backup paths are not available, PIM sends a join message upstream toward one upstream neighbor (for example, plane 2 in Figure 89 on page 1410).
    - If the primary and backup paths are available, PIM sends the join message upstream toward two of the available upstream neighbors. The device sets up primary and secondary multicast paths to receive multicast traffic (for example, plane 1 in Figure 89 on page 1410).

Multipoint LDP Functionality

To avoid MPLS traffic duplication, multipoint LDP usually selects only one upstream path. (See section 2.4.1.1. Determining One's 'upstream LSR' in RFC 6388, *Label Distribution Protocol Extensions for Point-to-Multipoint and Multipoint-to-Multipoint Label Switched Paths*.)

For multipoint LDP with MoFRR, the multipoint LDP device selects two separate upstream peers and sends two separate labels, one to each upstream peer. The device uses the same algorithm described in RFC 6388 to select the primary upstream path. The device uses the same algorithm to select the backup upstream path but excludes the primary upstream LSR as a candidate. The two different upstream peers send two streams of MPLS traffic to the egress routing device. The device selects only one of the upstream neighbor paths as the primary path from which to accept the MPLS traffic. The other path becomes the backup path, and the device drops that traffic. When the primary upstream path fails, the device starts accepting traffic from the backup path. The multipoint LDP device selects the two upstream paths based on the interior gateway protocol (IGP) root device next hop.

A *forwarding equivalency class (FEC)* is a group of IP packets that are forwarded in the same manner, over the same path, and with the same forwarding treatment. Normally, the label that is put on a particular packet represents the FEC to which that packet is assigned. In MoFRR, two routes are placed

into the mpls.0 table for each FEC—one route for the primary label and the other route for the backup label.

If there are parallel links toward the same immediate upstream device, the device considers both parallel links to be the primary. At any point in time, the upstream device sends traffic on only one of the multiple parallel links.

A *bud node* is an LSR that is an egress LSR, but also has one or more directly connected downstream LSRs. For a bud node, the traffic from the primary upstream path is forwarded to a downstream LSR. If the primary upstream path fails, the MPLS traffic from the backup upstream path is forwarded to the downstream LSR. This means that the downstream LSR next hop is added to both MPLS routes along with the egress next hop.

As with PIM, you enable MoFRR with multipoint LDP using the `stream-protection` configuration statement at the `[edit routing-options multicast]` hierarchy, and it's managed by a set of filter policies.

If you have enabled the multipoint LDP point-to-multipoint FEC for MoFRR, the device factors the following considerations into selecting the upstream path:

- The targeted LDP sessions are skipped if there is a nontargeted LDP session. If there is a single targeted LDP session, the targeted LDP session is selected, but the corresponding point-to-multipoint FEC loses the MoFRR capability because there is no interface associated with the targeted LDP session.
- All interfaces that belong to the same upstream LSR are considered to be the primary path.
- For any root-node route updates, the upstream path is changed based on the latest next hops from the IGP. If a better path is available, multipoint LDP attempts to switch to the better path.

Packet Forwarding

For either PIM or multipoint LDP, the device performs multicast source stream selection at the ingress interface. This preserves fabric bandwidth and maximizes forwarding performance because it:

- Avoids sending out duplicate streams across the fabric
- Prevents multiple route lookups (that result in packet drops).

For PIM, each IP multicast stream contains the same destination address. Regardless of the interface on which the packets arrive, the packets have the same route. The device checks the interface upon which each packet arrives and forwards only those that are from the primary interface. If the interface matches a backup stream interface, the device drops the packets. If the interface doesn't match either the primary or backup stream interface, the device handles the packets as exceptions in the control plane.

Figure 90 on page 1414 shows this process with sample primary and backup interfaces for routers with PIM. Figure 91 on page 1414 shows this similarly for switches with PIM.

Figure 90: MoFRR IP Route Lookup in the Packet Forwarding Engine on Routers

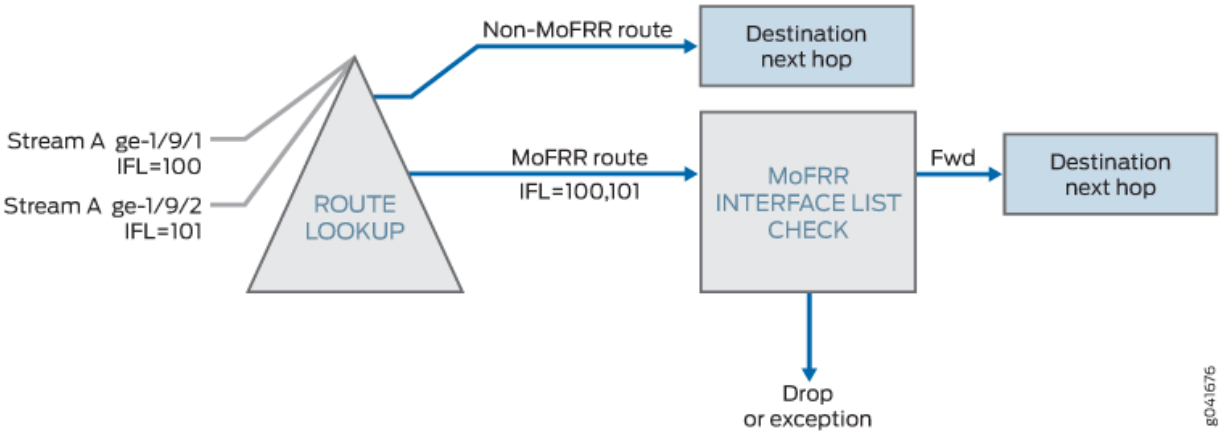


Figure 91: MoFRR IP Route Handling in the Packet Forwarding Engine on Switches

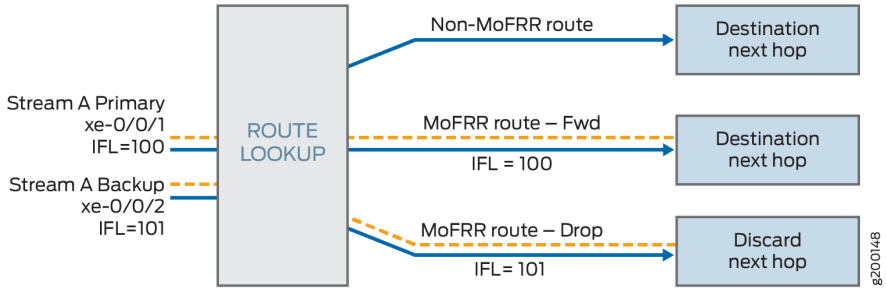
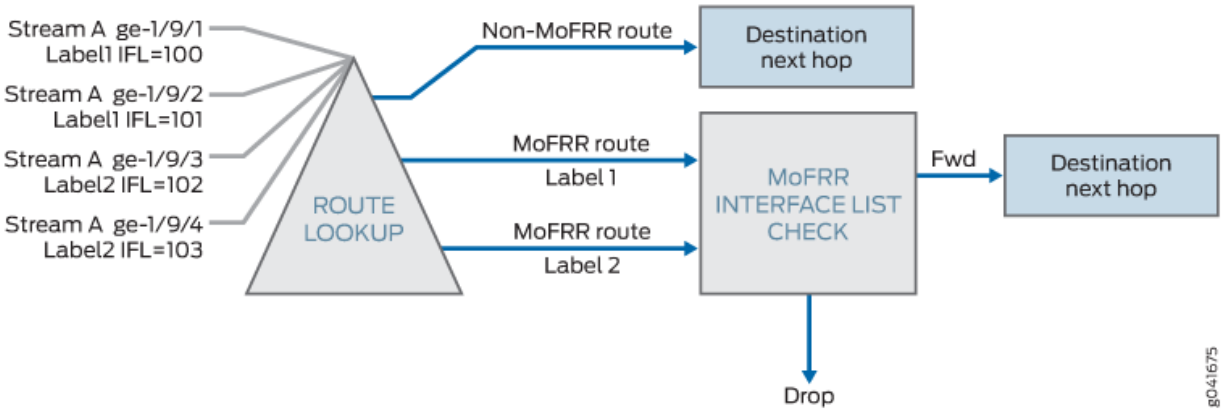


For MoFRR with multipoint LDP on routers, the device uses multiple MPLS labels to control MoFRR stream selection. Each label represents a separate route, but each references the same interface list check. The device only forwards the primary label, and drops all others. Multiple interfaces can receive packets using the same label.

Figure 92 on page 1415 shows this process for routers with multipoint LDP.

Figure 92: MoFRR MPLS Route Lookup in the Packet Forwarding Engine



Limitations and Caveats

MoFRR Limitations and Caveats on Switching and Routing Devices

MoFRR has the following limitations and caveats on routing and switching devices:

- MoFRR failure detection is supported for immediate link protection of the routing device on which MoFRR is enabled and not on all the links (end-to-end) in the multicast traffic path.
- MoFRR supports fast reroute on two selected disjoint paths toward the source. Two of the selected upstream neighbors cannot be on the same interface—in other words, two upstream neighbors on a LAN segment. The same is true if the upstream interface happens to be a multicast tunnel interface.
- Detection of the maximum end-to-end disjoint upstream paths is not supported. The receiver side (egress) routing device only makes sure that there is a disjoint upstream device (the immediate previous hop). PIM and multipoint LDP do not support the equivalent of explicit route objects (EROs). Hence, disjoint upstream path detection is limited to control over the immediately previous hop device. Because of this limitation, the path to the upstream device of the previous hop selected as primary and backup might be shared.
- You might see some traffic loss in the following scenarios:
  - A better upstream path becomes available on an egress device.
  - MoFRR is enabled or disabled on the egress device while there is an active traffic stream flowing.
- PIM join load balancing for join messages for backup paths are not supported.

- For a multicast group G, MoFRR is not allowed for both (S,G) and (*,G) join messages. (S,G) join messages have precedence over (*,G).
- MoFRR is not supported for multicast traffic streams that use two different multicast groups. Each (S,G) combination is treated as a unique multicast traffic stream.
- The bidirectional PIM range is not supported with MoFRR.
- PIM dense-mode is not supported with MoFRR.
- Multicast statistics for the backup traffic stream are not maintained by PIM and therefore are not available in the operational output of `show` commands.
- Rate monitoring is not supported.

MoFRR Limitations on Switching Devices with PIM

MoFRR with PIM has the following limitations on switching devices:

- MoFRR is not supported when the upstream interface is an integrated routing and bridging (IRB) interface, which impacts other multicast features such as Internet Group Management Protocol version 3 (IGMPv3) snooping.
- Packet replication and multicast lookups while forwarding multicast traffic can cause packets to recirculate through PFEs multiple times. As a result, displayed values for multicast packet counts from the `show pfe statistics traffic` command might show higher numbers than expected in output fields such as `Input packets` and `Output packets`. You might notice this behavior more frequently in MoFRR scenarios because duplicate primary and backup streams increase the traffic flow in general.

MoFRR Limitations and Caveats on Routing Devices with Multipoint LDP

MoFRR has the following limitations and caveats on routers when used with multipoint LDP:

- MoFRR does not apply to multipoint LDP traffic received on an RSVP tunnel because the RSVP tunnel is not associated with any interface.
- Mixed upstream MoFRR is not supported. This refers to PIM multipoint LDP in-band signaling, wherein one upstream path is through multipoint LDP and the second upstream path is through PIM.
- Multipoint LDP labels as inner labels are not supported.
- If the source is reachable through multiple ingress (source-side) provider edge (PE) routing devices, multipoint LDP MoFRR is not supported.
- Targeted LDP upstream sessions are not selected as the upstream device for MoFRR.

- Multipoint LDP link protection on the backup path is not supported because there is no support for MoFRR inner labels.

Configuring Multicast-Only Fast Reroute

You can configure multicast-only fast reroute (MoFRR) to minimize packet loss in a network when there is a link failure.

When fast reroute is applied to unicast streams, an upstream router preestablishes MPLS label-switched paths (LSPs) or precomputes an IP loop-free alternate (LFA) fast reroute backup path to handle failure of a segment in the downstream path.

In multicast routing, the traffic distribution graphs are usually originated by the receiver. This is unlike unicast routing, which usually establishes the path from the source to the receiver. Protocols that are capable of establishing multicast distribution graphs are PIM (for IP), multipoint LDP (for MPLS) and RSVP-TE (for MPLS). Of these, PIM and multipoint LDP receivers initiate the distribution graph setup, and therefore:

- On the QFX series, MoFRR is supported in PIM domains.
- On the MX Series and SRX Series, MoFRR is supported in PIM and multipoint LDP domains.

The configuration steps are the same for enabling MoFRR for PIM on all devices that support this feature, unless otherwise indicated. Configuration steps that are not applicable to multipoint LDP MoFRR are also indicated.

(For MX Series routers only) MoFRR is supported on MX Series routers with MPC line cards. As a prerequisite,all the line cards in the router must be MPCs.

To configure MoFRR on routers or switches:

1. (For MX Series and SRX Series routers only) Set the router to enhanced IP mode.

```
[edit chassis]
user@host# set network-services enhanced-ip
```

2. Enable MoFRR.

```
[edit routing-options multicast]
user@host# set stream-protection
```

3. (Optional) Configure a routing policy that filters for a restricted set of multicast streams to be affected by your MoFRR configuration.

   You can apply filters that are based on source or group addresses.

For example:

```
[edit policy-options]
policy-statement mofrr-select {
    term A {
        from {
            source-address-filter 225.1.1.1/32 exact;
        }
        then {
            accept;
        }
    }
    term B {
        from {
            source-address-filter 226.0.0.0/8 orlonger;
        }
        then {
            accept;
        }
    }
    term C {
        from {
            source-address-filter 227.1.1.0/24 orlonger;
            source-address-filter 227.4.1.0/24 orlonger;
            source-address-filter 227.16.1.0/24 orlonger;
        }
        then {
            accept;
        }
    }
    term D {
        from {
            source-address-filter 227.1.1.1/32 exact
        }
        then {
            reject; #MoFRR disabled
        }
    }
    ...
}
```

4. (Optional) If you configured a routing policy to filter the set of multicast groups to be affected by your MoFRR configuration, apply the policy for MoFRR stream protection.

```
[edit routing-options multicast stream-protection]
user@host# set policy policy-name
```

For example:

```
routing-options {
    multicast {
        stream-protection {
            policy mofrr-select
        }
    }
}
```

5. (Optional) In a PIM domain with MoFRR, allow MoFRR to be applied to any-source multicast (ASM) (*,G) joins.

This is not supported for multipoint LDP MoFRR.

```
[edit routing-options multicast stream-protection]
user@host# set mofrr-asm-starg
```

6. (Optional) In a PIM domain with MoFRR, allow only a disjoint RPF (an RPF on a separate plane) to be selected as the backup RPF path.

This is not supported for multipoint LDP MoFRR. In a multipoint LDP MoFRR domain, the same label is shared between parallel links to the same upstream neighbor. This is not the case in a PIM domain, where each link forms a neighbor. The `mofrr-disjoint-upstream-only` statement does not allow a backup RPF path to be selected if the path goes to the same upstream neighbor as that of the primary RPF path. This ensures that MoFRR is triggered only on a topology that has multiple RPF upstream neighbors.

```
[edit routing-options multicast stream-protection]
user@host# set mofrr-disjoint-upstream-only
```

7. (Optional) In a PIM domain with MoFRR, prevent sending join messages on the backup path, but retain all other MoFRR functionality.

This is not supported for multipoint LDP MoFRR.

```
[edit routing-options multicast stream-protection]
user@host# set mofrr-no-backup-join
```

8. (Optional) In a PIM domain with MoFRR, allow new primary path selection to be based on the unicast gateway selection for the unicast route to the source and to change when there is a change in the unicast selection, rather than having the backup path be promoted as primary. This ensures that the primary RPF hop is always on the best path.

   When you include the `mofrr-primary-selection-by-routing` statement, the backup path is not guaranteed to get promoted to be the new primary path when the primary path goes down.

   This is not supported for multipoint LDP MoFRR.

```
[edit routing-options multicast stream-protection]
user@host# set mofrr-primary-path-selection-by-routing
```

Example: Configuring Multicast-Only Fast Reroute in a Multipoint LDP Domain

IN THIS SECTION

- Requirements | **1421**
- Overview | **1421**
- CLI Quick Configuration | **1422**
- Configuration | **1431**
- Verification | **1438**

This example shows how to configure multicast-only fast reroute (MoFRR) to minimize packet loss in a network when there is a link failure.

Multipoint LDP MoFRR is used at the egress node of an MPLS network, where the packets are forwarded to an IP network. In the case of multipoint LDP MoFRR, the two paths toward the upstream provider edge (PE) router are established for receiving two streams of MPLS packets at the label-edge router (LER). One of the streams (the primary) is accepted, and the other one (the backup) is dropped at the LER. The backup stream is accepted if the primary path fails.

Requirements

No special configuration beyond device initialization is required before configuring this example.

In a multipoint LDP domain, for MoFRR to work, only the egress PE router needs to have MoFRR enabled. The other routers do not need to support MoFRR.

MoFRR is supported on MX Series platforms with MPC line cards. As a prerequisite, the router must be set to *network-services* enhanced-ip mode, and all the line-cards in the platform must be MPCs.

This example requires Junos OS Release 14.1 or later on the egress PE router.

Overview

IN THIS SECTION

- Topology | 1422

In this example, Device R3 is the egress edge router. MoFRR is enabled on this device only.

OSPF is used for connectivity, though any interior gateway protocol (IGP) or static routes can be used.

For testing purposes, routers are used to simulate the source and the receiver. Device R4 and Device R8 are configured to statically join the desired group by using the `set protocols igmp interface interface-name static group` *group* command. In the case when a real multicast receiver host is not available, as in this example, this static IGMP configuration is useful. On the receivers, to make them listen to the multicast group address, this example uses `set protocols sap listen` *group*.

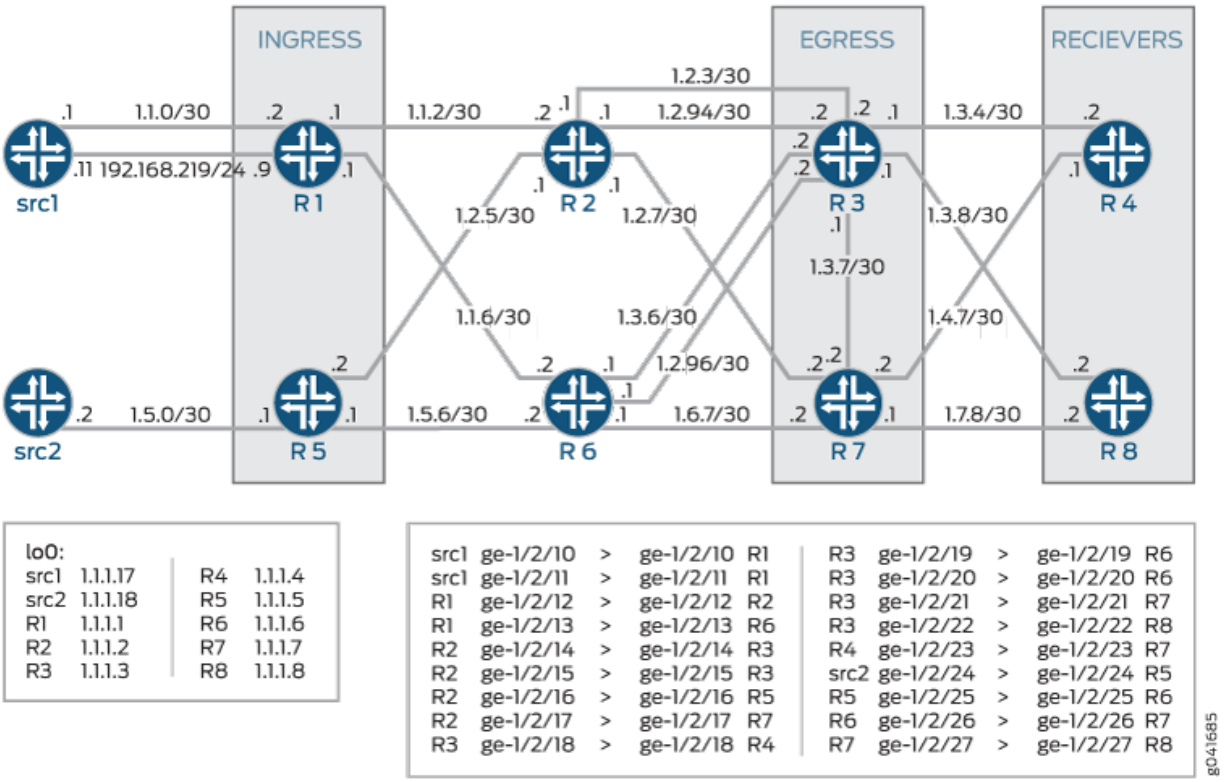
MoFRR configuration includes a policy option that is not shown in this example, but is explained separately. The option is configured as follows:

```
stream-protection {
    policy policy-name;
}
```

Topology

Figure 93 on page 1422 shows the sample network.

Figure 93: MoFRR in a Multipoint LDP Domain



"CLI Quick Configuration" on page 1422 shows the configuration for all of the devices in Figure 93 on page 1422.

The section "Configuration" on page 1431 describes the steps on Device R3.

CLI Quick Configuration

IN THIS SECTION

- CLI Quick Configuration | **1423**

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the `[edit]` hierarchy level.

Device src1

```
set interfaces ge-1/2/10 unit 0 description src1-to-R1
set interfaces ge-1/2/10 unit 0 family inet address 1.1.0.1/30
set interfaces ge-1/2/11 unit 0 description src1-to-R1
set interfaces ge-1/2/11 unit 0 family inet address 192.168.219.11/24
set interfaces lo0 unit 0 family inet address 1.1.1.17/32
set protocols ospf area 0.0.0.0 interface all
set protocols ospf area 0.0.0.0 interface lo0.0 passive
```

Device src2

```
set interfaces ge-1/2/24 unit 0 description src2-to-R5
set interfaces ge-1/2/24 unit 0 family inet address 1.5.0.2/30
set interfaces lo0 unit 0 family inet address 1.1.1.18/32
set protocols rsvp interface all
set protocols ospf area 0.0.0.0 interface all
set protocols ospf area 0.0.0.0 interface lo0.0 passive
```

Device R1

```
set interfaces ge-1/2/12 unit 0 description R1-to-R2

Configuration

IN THIS SECTION

- Procedure | 1431

Procedure

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the Junos OS CLI User Guide.

To configure Device R3:

1. Enable enhanced IP mode.

```
[edit chassis]
user@R3# set network-services enhanced-ip
```

2. Configure the device interfaces.

```
[edit interfaces]
user@R3# set ge-1/2/14 unit 0 description R3-to-R2
user@R3# set ge-1/2/14 unit 0 family inet address 1.2.3.2/30
user@R3# set ge-1/2/14 unit 0 family mpls
user@R3# set ge-1/2/18 unit 0 description R3-to-R4
user@R3# set ge-1/2/18 unit 0 family inet address 1.3.4.1/30
user@R3# set ge-1/2/18 unit 0 family mpls
user@R3# set ge-1/2/19 unit 0 description R3-to-R6
user@R3# set ge-1/2/19 unit 0 family inet address 1.3.6.2/30
user@R3# set ge-1/2/19 unit 0 family mpls
user@R3# set ge-1/2/21 unit 0 description R3-to-R7
user@R3# set ge-1/2/21 unit 0 family inet address 1.3.7.1/30
```

```
user@R3# set ge-1/2/21 unit 0 family mpls
user@R3# set ge-1/2/22 unit 0 description R3-to-R8
user@R3# set ge-1/2/22 unit 0 family inet address 1.3.8.1/30
user@R3# set ge-1/2/22 unit 0 family mpls
user@R3# set ge-1/2/15 unit 0 description R3-to-R2
user@R3# set ge-1/2/15 unit 0 family inet address 1.2.94.2/30
user@R3# set ge-1/2/15 unit 0 family mpls
user@R3# set ge-1/2/20 unit 0 description R3-to-R6
user@R3# set ge-1/2/20 unit 0 family inet address 1.2.96.2/30
user@R3# set ge-1/2/20 unit 0 family mpls
user@R3# set lo0 unit 0 family inet address 1.1.1.3/32 primary
```

3. Configure the autonomous system (AS) number.

```
user@R3# set routing-options autonomous-system 10
```

4. Configure the routing policies.

```
[edit policy-options policy-statement mldppim-ex]
user@R3# set term B from source-address-filter 192.168.0.0/24 orlonger
user@R3# set term B from source-address-filter 192.168.219.11/32 orlonger
user@R3# set term B then accept
user@R3# set term A from source-address-filter 1.1.0.1/30 orlonger
user@R3# set term A then accept
[edit policy-options policy-statement static-route-tobgp]
user@R3# set  term static from protocol static
user@R3# set  term static from protocol direct
user@R3# set term static then accept
```

5. Configure PIM.

```
[edit protocols pim]
user@R3# set mldp-inband-signalling policy mldppim-ex
user@R3# set interface lo0.0
user@R3# set interface ge-1/2/18.0
user@R3# set interface ge-1/2/22.0
```

6. Configure LDP.

```
[edit protocols ldp]
user@R3# set interface all
user@R3# set p2mp
```

7. Configure an IGP or static routes.

```
[edit protocols ospf]
user@R3# set traffic-engineering
user@R3# set area 0.0.0.0 interface all
user@R3# set area 0.0.0.0 interface fxp0.0 disable
user@R3# set area 0.0.0.0 interface lo0.0 passive
```

8. Configure internal BGP.

```
[edit protocols bgp group ibgp]
user@R3# set local-address 1.1.1.3
user@R3# set peer-as 10
user@R3# set neighbor 1.1.1.1
user@R3# set neighbor 1.1.1.5
```

9. Configure MPLS and, optionally, RSVP.

```
[edit protocols mpls]
user@R3# set interface all
[edit protocols rsvp]
user@R3# set interface all
```

10. Enable MoFRR.

```
[edit routing-options multicast]
user@R3# set stream-protection
```

Results

From configuration mode, confirm your configuration by entering the `show chassis`, `show interfaces`, `show protocols`, `show policy-options`, and `show routing-options` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R3# show chassis
network-services enhanced-ip;
```

```
user@R3# show interfaces

user@R3# show policy-options
policy-statement mldppim-ex {
    term B {
        from {
            source-address-filter 192.168.0.0/24 orlonger;
            source-address-filter 192.168.219.11/32 orlonger;
        }
        then accept;
    }
    term A {
        from {
            source-address-filter 1.1.0.1/30 orlonger;
        }
        then accept;
    }
}
policy-statement static-route-tobgp {
    term static {
        from protocol [ static direct ];
        then accept;
    }
}
```

```
user@R3# show routing-options
autonomous-system 10;
multicast {
    stream-protection;
}
```

If you are done configuring the device, enter `commit` from configuration mode.

Verification

IN THIS SECTION

- Checking the LDP Point-to-Multipoint Forwarding Equivalency Classes | **1438**
- Examining the Label Information | **1439**
- Checking the Multicast Routes | **1441**
- Checking the LDP Point-to-Multipoint Traffic Statistics | **1442**

Confirm that the configuration is working properly.

Checking the LDP Point-to-Multipoint Forwarding Equivalency Classes

Purpose

Make sure the MoFRR is enabled, and determine what labels are being used.

Action

```
user@R3> show ldp p2mp fec

LDP P2MP FECs:
 P2MP root-addr 1.1.1.1, grp: 232.1.1.1, src: 192.168.219.11
  MoFRR enabled
  Fec type: Egress (Active)
  Label: 301568
 P2MP root-addr 1.1.1.1, grp: 232.1.1.2, src: 192.168.219.11
  MoFRR enabled
  Fec type: Egress (Active)
  Label: 301600
```

Meaning

The output shows that MoFRR is enabled, and it shows that the labels 301568 and 301600 are being used for the two multipoint LDP point-to-multipoint LSPs.

Examining the Label Information

Purpose

Make sure that the egress device has two upstream interfaces for the multicast group join.

Action

```
user@R3> show route label 301568 detail

mpls.0: 18 destinations, 18 routes (18 active, 0 holddown, 0 hidden)
301568 (1 entry, 1 announced)

                   Interface ge-1/2/20.0, 1.2.96.1, 301600, 1
                   Interface ge-1/2/14.0, 1.2.3.1, 301616, 65534
                   Interface ge-1/2/19.0, 1.3.6.1, 301600, 1
  Attached FECs:  P2MP root-addr 1.1.1.1, grp: 232.1.1.2, src: 192.168.219.11 (Active)
```

Meaning

The output shows primary and backup sessions, and RPF next hops.

Checking the LDP Point-to-Multipoint Traffic Statistics

Purpose

Make sure that both primary and backup statistics are listed.

Action

```
user@R3> show ldp traffic-statistics p2mp

P2MP FEC Statistics:

FEC(root_addr:lsp_id/grp,src)     Nexthop              Packets             Bytes Shared
1.1.1.1:232.1.1.1,192.168.219.11, Label: 301568
                                  1.3.8.2                    0                 0 No
                                  1.3.4.2                    0                 0 No
1.1.1.1:232.1.1.1,192.168.219.11, Label: 301584, Backup route
                                  1.3.4.2                    0                 0 No
                                  1.3.8.2                    0                 0 No
1.1.1.1:232.1.1.2,192.168.219.11, Label: 301600
                                  1.3.8.2                    0                 0 No
                                  1.3.4.2                    0                 0 No
1.1.1.1:232.1.1.2,192.168.219.11, Label: 301616, Backup route
                                  1.3.4.2                    0                 0 No
                                  1.3.8.2                    0                 0 No
```

Meaning

The output shows both primary and backup routes with the labels.

Example: Configuring LDP Downstream on Demand

IN THIS SECTION

- Requirements | **1443**
- Overview | **1443**
- Configuration | **1444**
- Verification | **1448**

This example shows how to configure *LDP* downstream on demand. LDP is commonly configured using downstream unsolicited advertisement mode, meaning label advertisements for all routes are received from all LDP peers. As service providers integrate the access and aggregation networks into a single MPLS domain, LDP downstream on demand is needed to distribute the bindings between the access and aggregation networks and to reduce the processing requirements for the control plane.

Downstream nodes could potentially receive tens of thousands of label bindings from upstream aggregation nodes. Instead of learning and storing all label bindings for all possible loopback addresses within the entire MPLS network, the downstream aggregation node can be configured using LDP downstream on demand to only request the label bindings for the FECs corresponding to the loopback addresses of those egress nodes on which it has services configured.

Requirements

This example uses the following hardware and software components:

- M Series router
- Junos OS 12.2

Overview

You can enable LDP downstream on demand label advertisement for an LDP session by including the "downstream-on-demand" on page 2876 statement at the `[edit protocols ldp session]` hierarchy level. If you have configured downstream on demand, the Juniper Networks router advertises the downstream on demand request to its peer routers. For a downstream on demand session to be established between two routers, both have to advertise downstream on demand mode during LDP session establishment. If

one router advertises downstream unsolicited mode and the other advertises downstream on demand, downstream unsolicited mode is used.

Configuration

IN THIS SECTION

- Configuring LDP Downstream on Demand | **1444**
- Distributing LDP Downstream on Demand Routes into Labeled BGP | **1445**

Configuring LDP Downstream on Demand

Step-by-Step Procedure

To configure a LDP downstream on demand policy and then configure that policy and enable LDP downstream on demand on the LDP session:

1. Configure the downstream on demand policy (DOD-Request-Loopbacks in this example).

   This policy causes the router to forward label request messages only to the FECs that are matched by the DOD-Request-Loopbacks policy.

   ```
   [edit policy-options]
   user@host# set prefix-list Request-Loopbacks 10.1.1.1/32
   user@host# set prefix-list Request-Loopbacks 10.1.1.2/32
   user@host# set prefix-list Request-Loopbacks 10.1.1.3/32
   user@host# set prefix-list Request-Loopbacks 10.1.1.4/32
   user@host# set policy-statement DOD-Request-Loopbacks term 1 from prefix-list Request-
   Loopbacks
   user@host# set policy-statement DOD-Request-Loopbacks term 1 then accept
   ```

2. Specify the DOD-Request-Loopbacks policy using the `dod-request-policy` statement at the `[edit protocols ldp]` hierarchy level.

   The policy specified with the `dod-request-policy` statement is used to identify the prefixes to send label request messages. This policy is similar to an egress policy or an import policy. When processing routes from the inet.0 routing table, the Junos OS software checks for routes matching the `DOD-Request-Loopbacks` policy (in this example). If the route matches the policy and the LDP session is

negotiated with DOD advertisement mode, label request messages are sent to the corresponding downstream LDP session.

```
[edit protocols ldp]
user@host# set dod-request-policy DOD-Request-Loopbacks
```

3. Include the `downstream-on-demand` statement in the configuration for the LDP session to enable downstream on demand distribution mode.

```
[edit protocols ldp]
user@host# set session 1.1.1.1 downstream-on-demand
```

Distributing LDP Downstream on Demand Routes into Labeled BGP

Step-by-Step Procedure

To distribute LDP downstream on demand routes into labeled BGP, use a BGP export policy.

1. Configure the LDP route policy (`redistribute_ldp` in this example).

```
[edit policy-options]
user@host# set policy-statement redistribute_ldp term 1 from protocol ldp
user@host# set policy-statement redistribute_ldp term 1 from tag 1000
user@host# set policy-statement redistribute_ldp term 1 then accept
```

2. Include the LDP route policy, `redistribute_ldp` in the BGP configuration (as a part of the BGP group configuration `ebgp-to-abr` in this example).

   BGP forwards the LDP routes based on the `redistribute_ldp` policy to the remote PE router

```
[edit protocols bgp]
user@host# set group ebgp-to-abr type external
user@host# set group ebgp-to-abr local-address 192.168.0.1
user@host# set group ebgp-to-abr peer-as 65319
user@host# set group ebgp-to-abr local-as 65320
user@host# set group ebgp-to-abr neighbor 192.168.6.1 family inet unicast
user@host# set group ebgp-to-abr neighbor 192.168.6.1 family inet labeled-unicast rib inet.3
user@host# set group ebgp-to-abr neighbor 192.168.6.1 export redistribute_ldp
```

Step-by-Step Procedure

To restrict label propagation to other routers configured in downstream unsolicited mode (instead of downstream on demand), configure the following policies:

1. Configure the `dod-routes` policy to accept routes from LDP.

```
user@host# set policy-options policy-statement dod-routes term 1 from protocol ldp
user@host# set policy-options policy-statement dod-routes term 1 from tag 1145307136
user@host# set policy-options policy-statement dod-routes term 1 then accept
```

2. Configure the `do-not-propagate-du-sessions` policy to not forward routes to neighbors `1.1.1.1`, `2.2.2.2`, and `3.3.3.3`.

```
user@host# set policy-options policy-statement do-not-propagate-du-sessions term 1 to
neighbor 1.1.1.1
user@host# set policy-options policy-statement do-not-propagate-du-sessions term 1 to
neighbor 2.2.2.2
user@host# set policy-options policy-statement do-not-propagate-du-sessions term 1 to
neighbor 3.3.3.3
user@host# set policy-options policy-statement do-not-propagate-du-sessions term 1 then reject
```

3. Configure the `filter-dod-on-du-sessions` policy to prevent the routes examined by the `dod-routes` policy from being forwarded to the neighboring routers defined in the `do-not-propagate-du-sessions` policy.

```
user@host# set policy-options policy-statement filter-dod-routes-on-du-sessions term 1 from
policy dod-routes
user@host# set policy-options policy-statement filter-dod-routes-on-du-sessions term 1 to
policy do-not-propagate-du-sessions
```

4. Specify the `filter-dod-routes-on-du-sesssion` policy as the export policy for BGP broup `ebgp-to-abr`.

```
[edit protocols bgp]
user@host# set group ebgp-to-abr neighbor 192.168.6.2 export filter-dod-routes-on-du-sessions
```

Results

From configuration mode, confirm your configuration by entering the `show policy-options` and `show protocols ldp` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@host#
show policy-options
prefix-list Request-Loopbacks {
    10.1.1.1/32;
    10.1.1.2/32;
    10.1.1.3/32;
    10.1.1.4/32;
}
policy-statement DOD-Request-Loopbacks {
    term 1 {
        from {
            prefix-list Request-Loopbacks;
        }
        then accept;
    }
}
policy-statement redistribute_ldp {
    term 1 {
        from {
            protocol ldp;
            tag 1000;
        }
        then accept;
    }
}
```

```
user@host#
show protocols ldp
dod-request-policy DOD-Request-Loopbacks;
session 1.1.1.1 {
```

```
    downstream-on-demand;
}
```

```
user@host#
show protocols bgp
group ebgp-to-abr {
    type external;
    local-address 192.168.0.1;
    peer-as 65319;
    local-as 65320;
    neighbor 192.168.6.1 {
        family inet {
            unicast;
            labeled-unicast {
                rib {
                    inet.3;
                }
            }
        }
        export redistribute_ldp;
    }
}
```

Verification

- Verifying Label Advertisement Mode | **1448**

Verifying Label Advertisement Mode

Purpose

Confirm that the configuration is working properly.

Use the `show ldp session` command to verify the status of the label advertisement mode for the LDP session.

Action

Issue the `show ldp session` and `show ldp session detail` commands:

- The following command output for the `show ldp session` command indicates that the `Adv. Mode` (label advertisement mode) is `DOD` (meaning the LDP downstream on demand session is operational):

```
user@host> show ldp session
  Address          State        Connection     Hold time  Adv. Mode
1.1.1.2            Operational  Open             22          DOD
```

- The following command output for the `show ldp session detail` command indicates that the `Local Label Advertisement mode` is `Downstream unsolicited`, the default value (meaning downstream on demand is not configured on the local session). Conversely, the `Remote Label Advertisement mode` and the `Negotiated Label Advertisement mode` both indicate that `Downstream on demand` is configured on the remote session

```
user@host> show ldp session detail
Address: 1.1.1.2, State: Operational, Connection: Open, Hold time: 24
  Session ID: 1.1.1.1:0--1.1.1.2:0
  Next keepalive in 4 seconds
  Passive, Maximum PDU: 4096, Hold time: 30, Neighbor count: 1
  Neighbor types: configured-tunneled
  Keepalive interval: 10, Connect retry interval: 1
  Local address: 1.1.1.1, Remote address: 1.1.1.2
  Up for 17:54:52
  Capabilities advertised: none
  Capabilities received: none
  Protection: disabled
  Local - Restart: disabled, Helper mode: enabled,
  Remote - Restart: disabled, Helper mode: enabled
  Local maximum neighbor reconnect time: 120000 msec
  Local maximum neighbor recovery time: 240000 msec
  Local Label Advertisement mode: Downstream unsolicited
  Remote Label Advertisement mode: Downstream on demand
  Negotiated Label Advertisement mode: Downstream on demand
  Nonstop routing state: Not in sync
```

```
  Next-hop addresses received:
    1.1.1.2
```

Configuring LDP Native IPv6 Support

LDP is supported in an IPv6-only network, and in an IPv6 or IPv4 dual-stack network as described in *RFC 7552*. Configure the address family as `inet` for IPv4 or `inet6` for IPv6 or both, and the transport preference to be either `IPv4` or `IPv6`. The `dual-transport` statement allows Junos OS LDP to establish the TCP connection over IPv4 with IPv4 neighbors, and over IPv6 with IPv6 neighbors as a single-stack LSR. The `inet-lsr-id` and `inet6-lsr-id` IDs are the two LSR IDs that have to be configured to establish an LDP session over IPv4 and IPv6 TCP transport. These two IDs should be non-zero and must be configured with different values.

Before you configure IPv6 as dual-stack, be sure you configure the routing and signaling protocols.

To configure LDP native IPv6 support, you must do the following:

1. Enable forwarding equivalence class (FEC) deaggregation in order to use different labels for different address families.

```
[edit protocols ldp]
set deaggregate
```

2. Configure LDP address families.

```
[edit protocols ldp]
set family inet6
set family inet
```

3. Configure the `transport-preference` statement to select the preferred transport for the TCP connection when both IPv4 and IPv6 are enabled. By default, IPv6 is used as the TCP transport for establishing an LDP connection.

```
[edit protocols ldp]
set transport-preference ipv4
```

4. (Optional) Configure dual-transport to allow LDP to establish a separate IPv4 session with an IPv4 neighbor, and an IPv6 session with an IPv6 neighbor. Configure `inet-lsr-id` as the LSR ID for IPv4, and `inet6-lsr-id` as the LSR ID for IPv6.

```
[edit protocols ldp dual-transport]
set inet-lsr-id inet-lsr-id
set inet6-lsr-id inet6-lsr-id
```

For example, configure inet-lsr-id as 10.255.0.1, and inet6-lsr-id as 1.1.1.1.

```
[edit protocols ldp dual-transport]
set inet-lsr-id 10.255.0.1
set inet6-lsr-id 1.1.1.1
```

Example: Configuring LDP Native IPv6 Support

IN THIS SECTION

- Requirements | 1451
- Overview | 1452
- Configuration | 1452

This example shows how to allow the Junos OS Label Distribution Protocol (LDP) to establish the TCP connection over IPv4 with IPv4 neighbors, and over IPv6 with IPv6 neighbors as a single-stack LSR. This helps avoid tunneling of IPv6 over IPv4 MPLS core with IPv4-signaled MPLS label-switched paths (LSPs).

Requirements

This example uses the following hardware and software components:

- Two MX Series routers
- Junos OS Release 16.1 or later running on all devices

Before you configure IPv6 as dual-stack, be sure you configure the routing and signaling protocols.

Overview

IN THIS SECTION

- Topology | 1452

LDP is supported in an IPv6 only network, and in an IPv6 or IPv4 dual-stack network as described in *RFC 7552*. Configure the address family as `inet` for IPv4 or `inet6` for IPv6. By default, IPv6 is used as the TCP transport for the LDP session with its peers when both IPv4 and IPv6 are enabled . The dual-transport statement allows Junos LDP to establish the TCP connection over IPv4 with IPv4 neighbors, and over IPv6 with IPv6 neighbors as a single-stack LSR. The `inet-lsr-id` and `inet6-lsr-id` are the two LSR IDs that have to be configured to establish an LDP session over IPv4 and IPv6 TCP transport. These two IDs should be non-zero and must be configured with different values.

Topology

Figure 94 on page 1452 shows the LDP IPv6 configured as dual-stack on Device R1 and Device R2.

Figure 94: Example LDP Native IPv6 Support

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter `commit` from configuration mode.

R1

```
set interfaces ge-1/0/0 unit 0 family inet address 192.168.12.1/24
set interfaces ge-1/0/0 unit 0 family iso
set interfaces ge-1/0/0 unit 0 family inet6 address 2001:db8:0:12::/64 eui-64
set interfaces ge-1/0/0 unit 0 family mpls
set interfaces lo0 unit 0 family inet address 10.255.0.1/32
set interfaces lo0 unit 0 family iso address 49.0001.1720.1600.1010.00
set interfaces lo0 unit 0 family inet6 address 2001:db8::1/128
set protocols isis interface ge-1/0/0.0
set protocols isis interface lo0.0
set protocols mpls interface ge-1/0/0.0
set protocols ldp deaggregate
set protocols ldp interface ge-1/0/0.0
set protocols ldp interface lo0.0
set protocols ldp family inet6
set protocols ldp family inet
```

R2

```
set interfaces ge-1/0/1 unit 0 family inet address 192.168.12.2/24
set interfaces ge-1/0/1 unit 0 family iso
set interfaces ge-1/0/1 unit 0 family inet6 address 2001:db8:0:12::/64 eui-64
set interfaces ge-1/0/1 unit 0 family mpls
set interfaces lo0 unit 0 family inet address 10.255.0.2/32
set interfaces lo0 unit 0 family iso address 49.0001.1720.1600.2020.00
set interfaces lo0 unit 0 family inet6 address 2001:db8::2/128
set protocols isis interface ge-1/0/1.0
set protocols isis interface lo0.0
set protocols mpls interface ge-1/0/1.0
set protocols ldp deaggregate
set protocols ldp interface ge-1/0/1.0
set protocols ldp interface lo0.0
set protocols ldp family inet6
set protocols ldp family inet
```

Configuring R1

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see "*Using the CLI Editor in Configuration Mode*" in the Junos OS CLI User Guide.

To configure Device R1:

1. Configure the interfaces.

```
[edit interfaces]
set ge-1/0/0 unit 0 family inet address 192.168.12.1/24
set ge-1/0/0 unit 0 family iso
set ge-1/0/0 unit 0 family inet6 address 2001:db8:0:12::/64 eui-64
set ge-1/0/0 unit 0 family mpls
```

2. Assign a loopback address to the device.

```
[edit interfaces lo0 unit 0]
set family inet address 10.255.0.1/32
set family iso address 49.0001.1720.1600.1010.00
set family inet6 address 2001:db8::1/128
```

3. Configure the IS-IS interfaces.

```
[edit protocols isis]
set interface ge-1/0/0.0
set interface lo0.0
```

4. Configure MPLS to use LDP interfaces on the device.

```
[edit protocols mpls]
set protocols mpls interface ge-1/0/0.0
set interface ge-1/0/0.0
set interface lo0.0
```

5. Enable forwarding equivalence class (FEC) deaggregation in order to use different labels for different address families.

```
[edit protocols ldp]
set deaggregate
```

6. Configure LDP address families.

```
[edit protocols ldp]
set family inet6
set family inet
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces** and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R1# show interfaces
    ge-1/0/0 {
        unit 0 {
            family inet {
                address 192.168.12.1/24;
            }
            family iso;
            family inet6 {
                address 2001:db8:0:12::/64 {
                    eui-64;
                }
            }
            family mpls;
        }
    }
    lo0 {
        unit 0 {
            family inet {
                address 10.255.0.1/32;
```

```
            }
            family iso {
                address 49.0001.1720.1600.1010.00
            }
            family inet6 {
                address 2001:db8::1/128;
            }
        }
    }
```

```
user@R1# show protocols
    mpls {
        interface ge-1/0/0.0;
    }
    isis {
        interface ge-1/0/0.0;
        interface lo0.0;
    }
    ldp {
        deaggregate;
        interface ge-1/0/0.0;
        interface lo0.0;
        family {
            inet6;
            inet;
        }
    }
```

Configure transport-preference to Select the Preferred Transport

CLI Quick Configuration

Step-by-Step Procedure

You can configure the `transport-preference` statement to select the preferred transport for a TCP connection when both IPv4 and IPv6 are enabled. By default, IPv6 is used as TCP transport for establishing an LDP connection.

- (Optional) Configure the transport preference for an LDP connection.

```
[edit protocols ldp]
set transport-preference ipv4
```

Step-by-Step Procedure

Results

From configuration mode, confirm your configuration by entering the **show protocols** command. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R1# show protocols
    mpls {
        interface ge-1/0/0.0;
    }
    isis {
        interface ge-1/0/0.0;
        interface lo0.0;
    }
    ldp {
        deaggregate;
        interface ge-1/0/0.0;
        interface lo0.0;
        family {
            inet6;
            inet;
        }
        transport-preference ipv4;
    }
```

Configure dual-transport to Establish Separate Sessions for IPv4 with an IPv4 Neighbor and IPv6 with an IPv6 Neighbor

Step-by-Step Procedure

You can configure the `dual-transport` statement to allow LDP to establish a separate IPv4 session with an IPv4 neighbor, and an IPv6 session with an IPv6 neighbor. This requires the configuration of `inet-lsr-id` as the LSR ID for IPv4, and `inet6-lsr-id` as the LSR ID for IPv6.

- (Optional) Configure dual-transport to allow LDP to establish the TCP connection over IPv4 with IPv4 neighbors, and over IPv6 with IPv6 neighbors as a single-stack LSR.

```
[edit protocols ldp dual-transport]
set inet-lsr-id 10.255.0.1
set inet6-lsr-id 1.1.1.1
```

Results

From configuration mode, confirm your configuration by entering the **show protocols** command. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R1# show protocols
    mpls {
        interface ge-1/0/0.0;
    }
    isis {
        interface ge-1/0/0.0;
        interface lo0.0;
    }
    ldp {
        deaggregate;
        interface ge-1/0/0.0;
        interface lo0.0;
        family {
            inet6;
            inet;
        }
```

```
        dual-transport {
            inet-lsr-id 10.255.0.1;
            inet6-lsr-id 1.1.1.1;
        }
    }
```

Verification

Confirm that the configuration is working properly.

Verifying the Route Entries in the mpls.0 Table

Purpose

Display mpls.0 route table information.

Action

On Device R1, from operational mode, run the `show route table mpls.0` command to display mpls.0 route table information.

```
user@R1> show route table mpls.0
mpls.0: 8 destinations, 8 routes (8 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

0                  *[MPLS/0] 05:19:58, metric 1
                      Receive
1                  *[MPLS/0] 05:19:58, metric 1
                      Receive
```

```
2                  *[MPLS/0] 05:19:58, metric 1
                      Receive
13                 *[MPLS/0] 05:19:58, metric 1
                      Receive
299824             *[LDP/9] 04:28:45, metric 1
                    > to fe80::21f:1200:cb6:4c8d via ge-1/0/0.0, Pop
299824(S=0)        *[LDP/9] 04:28:45, metric 1
                    > to fe80::21f:1200:cb6:4c8d via ge-1/0/0.0, Pop
299888             *[LDP/9] 00:56:12, metric 1
                    > to 192.168.12.2 via ge-1/0/0.0, Pop
299888(S=0)        *[LDP/9] 00:56:12, metric 1
                    > to 192.168.12.2 via ge-1/0/0.0, Pop
```

Meaning

The output shows the mpls.0 route table information.

Verifying the Route Entries in the inet.3 Table

Purpose

Display inet.3 route table information.

Action

On Device R1, from operational mode, run the `show route table inet.3` command to display inet.3 route table information.

```
user@R1> show route table inet.3
inet.3: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.255.0.2/32      *[LDP/9] 00:58:38, metric 1
                    > to 192.168.12.2 via ge-1/0/0.0
```

Meaning

The output shows the inet.3 route table information.

Verifying the Route Entries in the inet6.3 Table

Purpose

Display inet6.3 route table information.

Action

On Device R1, from operational mode, run the `show route table inet6.3` command to display inet6.3 route table information.

```
user@R1> show route table inet6.3

inet6.3: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

2001:db8::2/128    *[LDP/9] 04:31:17, metric 1
                    > to fe80::21f:1200:cb6:4c8d via ge-1/0/0.0
```

Meaning

The output shows the inet6.3 route table information.

Verifying the LDP Database

Purpose

Display the LDP database information.

Action

On Device R1, from operational mode, run the `show ldp database` command to display LDP database information.

```
user@R1> show ldp database

Input label database, 10.255.0.1:0--10.255.0.2:0
Labels received: 3
  Label     Prefix
 299840      10.255.0.1/32
```

```
      3      10.255.0.2/32
 299808      2001:db8::1/128
      3      2001:db8::2/128

Output label database, 10.255.0.1:0--10.255.0.2:0
Labels advertised: 3
  Label     Prefix
      3      10.255.0.1/32
 299888      10.255.0.2/32
      3      2001:db8::1/128
 299824      2001:db8::2/128
```

Meaning

The output shows the entries in the LDP database.

Verifying the LDP Neighbor Information

Purpose

Display the LDP neighbor information.

Action

On Device R1, from operational mode, run the `show ldp neighbor` and `show ldp neighbor extensive` commands to display LDP neighbor information.

```
user@R1> show ldp neighbor
Address                          Interface       Label space ID     Hold time
fe80::21f:1200:cb6:4c8d          ge-1/0/0.0      10.255.0.2:0         12
192.168.12.2                     ge-1/0/0.0      10.255.0.2:0         11

user@R1> show ldp neighbor extensive

Address                          Interface       Label space ID     Hold time
192.168.12.2                     ge-1/0/0.0      10.255.0.2:0         11
  Transport address: 10.255.0.2, Transport preference: IPv6, Configuration sequence: 10
  Up for 00:04:35
  Reference count: 1
  Hold time: 15, Proposed local/peer: 15/15
```

```
  Hello flags: none
  Neighbor types: discovered
Address                          Interface       Label space ID     Hold time
fe80::21f:1200:cb6:4c8d          ge-1/0/0.0      10.255.0.2:0         14
  Transport address: 2001:db8::2, Transport preference: IPv6, Configuration sequence: 10
  Up for 00:04:35
  Reference count: 1
  Hold time: 15, Proposed local/peer: 15/15
  Hello flags: none
  Neighbor types: discovered
```

Meaning

The output shows LDP neighbor information of both IPv4 and IPv6 addresses.

Verifying the LDP Session Information

Purpose

Display the LDP session information.

Action

On Device R1, from operational mode, run the `show ldp session` and `show ldp session extensive` commands to display LDP session information.

```
user@R1> show ldp session
session

Label request             0             0             0             0
Label withdraw            0             0             0             0
Label release             0             0             0             0
Label abort               0             0             0             0
```

Meaning

The output displays information for the LDP session using IPv6 as the TCP transport.

Verification

IN THIS SECTION

- Verifying the LDP Neighbor Information | **1465**
- Verifying the LDP Session Information | **1466**

Confirm that the configuration is working properly.

Verifying the LDP Neighbor Information

Purpose

Display the LDP neighbor information.

Action

On Device R1, from operational mode, run the `show ldp neighbor extensive` command to display LDP neighbor information.

```
user@R1> show ldp neighbor extensive
Address                          Interface       Label space ID     Hold time
192.168.12.2                     ge-1/0/0.0      10.255.0.2:0         14
  Transport address: 10.255.0.2, Transport preference: IPv4, Configuration sequence: 9
  Up for 00:00:14
  Reference count: 1
  Hold time: 15, Proposed local/peer: 15/15
  Hello flags: none
  Neighbor types: discovered
Address                          Interface       Label space ID     Hold time
fe80::21f:1200:cb6:4c8d          ge-1/0/0.0      10.255.0.2:0         14
  Transport address: 2001:db8::2, Transport preference: IPv4, Configuration sequence: 9
  Up for 00:00:14

The Multipoint Label Distribution Protocol (M-LDP) for point-to-multipoint label-switched paths (LSPs) with in-band signaling is useful in a deployment with an existing IP/MPLS backbone, in which you need to carry multicast traffic, for IPTV for example.

For years, the most widely used solution for transporting multicast traffic has been to use native IP multicast in the service provider core with multipoint IP tunneling to isolate customer traffic. A multicast routing protocol, usually Protocol Independent Multicast (PIM), is deployed to set up the forwarding paths. IP multicast routing is used for forwarding, using PIM signaling in the core. For this model to work, the core network has to be multicast enabled. This allows for effective and stable deployments even in inter-autonomous system (AS) scenarios.

However, in an existing IP/MPLS network, deploying PIM might not be the first choice. Some service providers are interested in replacing IP tunneling with MPLS label encapsulation. The motivations for moving to MPLS label switching is to leverage MPLS traffic engineering and protection features and to reduce the amount of control traffic overhead in the provider core.

To do this, service providers are interested in leveraging the extension of the existing deployments to allow multicast traffic to pass through. The existing multicast extensions for IP/MPLS are point-to-

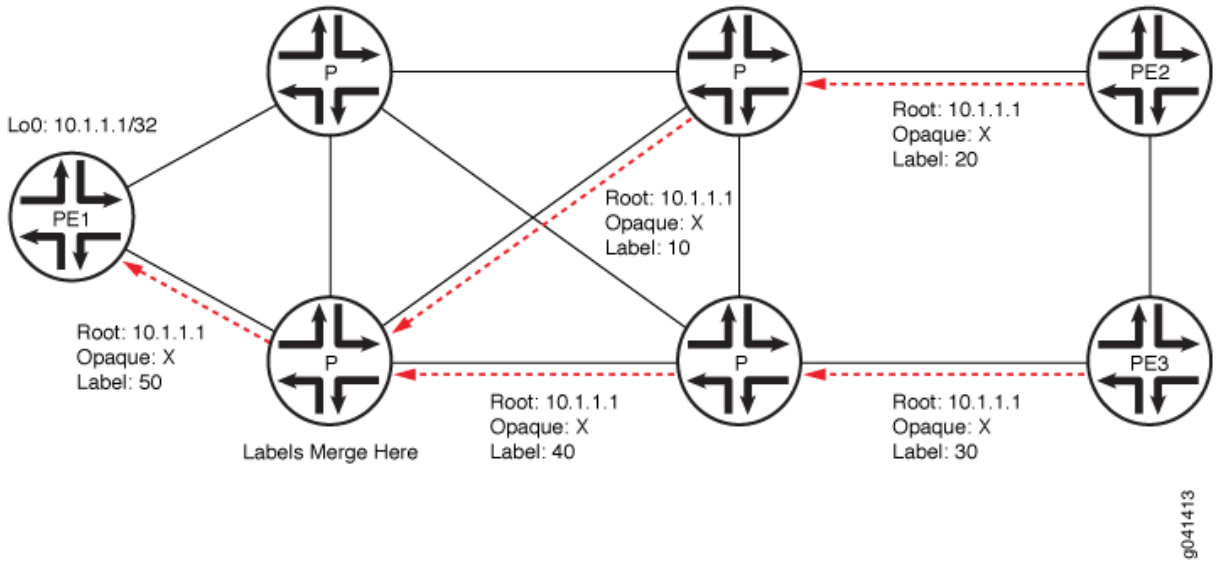
multipoint extensions for RSVP-TE and point-to-multipoint and multipoint-to-multipoint extensions for LDP. These deployment scenarios are discussed in RFC 6826, *Multipoint LDP In-Band Signaling for Point-to-Multipoint and Multipoint-to-Multipoint Label Switched Paths*. This feature overview is limited to point-to-multipoint extensions for LDP.

How M-LDP Works

Label Bindings in M-LDP Signaling

The multipoint extension to LDP uses point-to-multipoint and multipoint-to-multipoint forwarding equivalence class (FEC) elements (defined in RFC 5036, *LDP Specification*) along with capability advertisements, label mapping, and signaling procedures. The FEC elements include the idea of the LSP root, which is an IP address, and an "opaque" value, which is a selector that groups together the leaf nodes sharing the same opaque value. The opaque value is transparent to the intermediate nodes, but has meaning for the LSP root. Every LDP node advertises its local incoming label binding to the upstream LDP node on the shortest path to the root IP address found in the FEC. The upstream node receiving the label bindings creates its own local label and outgoing interfaces. This label allocation process might result in packet replication, if there are multiple outgoing branches. As shown in *Figure 18*, an LDP node merges the label bindings for the same opaque value if it finds downstream nodes sharing the same upstream node. This allows for effective building of point-to-multipoint LSPs and label conservation.

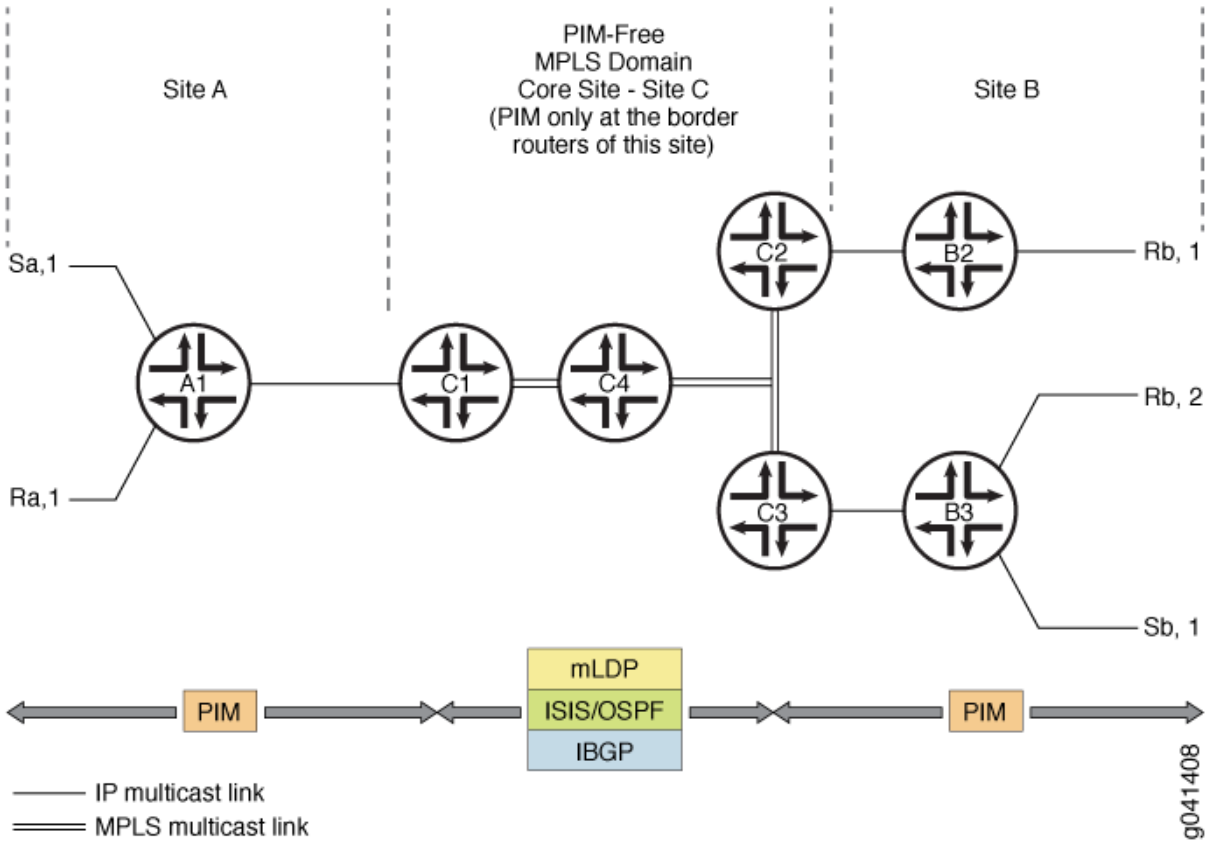
Figure 95: Label Bindings in M-LDP Signaling



M-LDP in PIM-Free MPLS Core

Figure 19 shows a scaled-down deployment scenario. Two separate PIM domains are interconnected by a PIM-free core site. The border routers in this core site support PIM on the border interfaces. Further, these border routers collect and distribute the routing information from the adjacent sites to the core network. The edge routers in Site C run BGP for root-node discovery. Interior gateway protocol (IGP) routes cannot be used for ingress discovery because in most cases the forwarding next hop provided by the IGP would not provide information about the ingress device toward the source. M-LDP inband signaling has a one-to-one mapping between the point-to-multipoint LSP and the (S,G) flow. With in-band signaling, PIM messages are directly translated into M-LDP FEC bindings. In contrast, out-of-band signaling is based on manual configuration. One application for M-LDP inband signaling is to carry IPTV multicast traffic in an MPLS backbone.

Figure 96: Sample M-LDP Topology in PIM-Free MPLS Core



Configuration

The *configuration statement* `mldp-inband-signalling` on the label-edge router (LER) enables PIM to use M-LDP in-band signaling for the upstream neighbors when the LER does not detect a PIM upstream

neighbor. Static configuration of the MPLS LSP root is included in the PIM configuration, using policy. This is needed when IBGP is not available in the core site or to override IBGP-based LSP root detection.

For example:

```
protocols {
    pim {
        mldp-inband-signalling {
            policy lsp-mapping-policy-example;
        }
    }
}
```

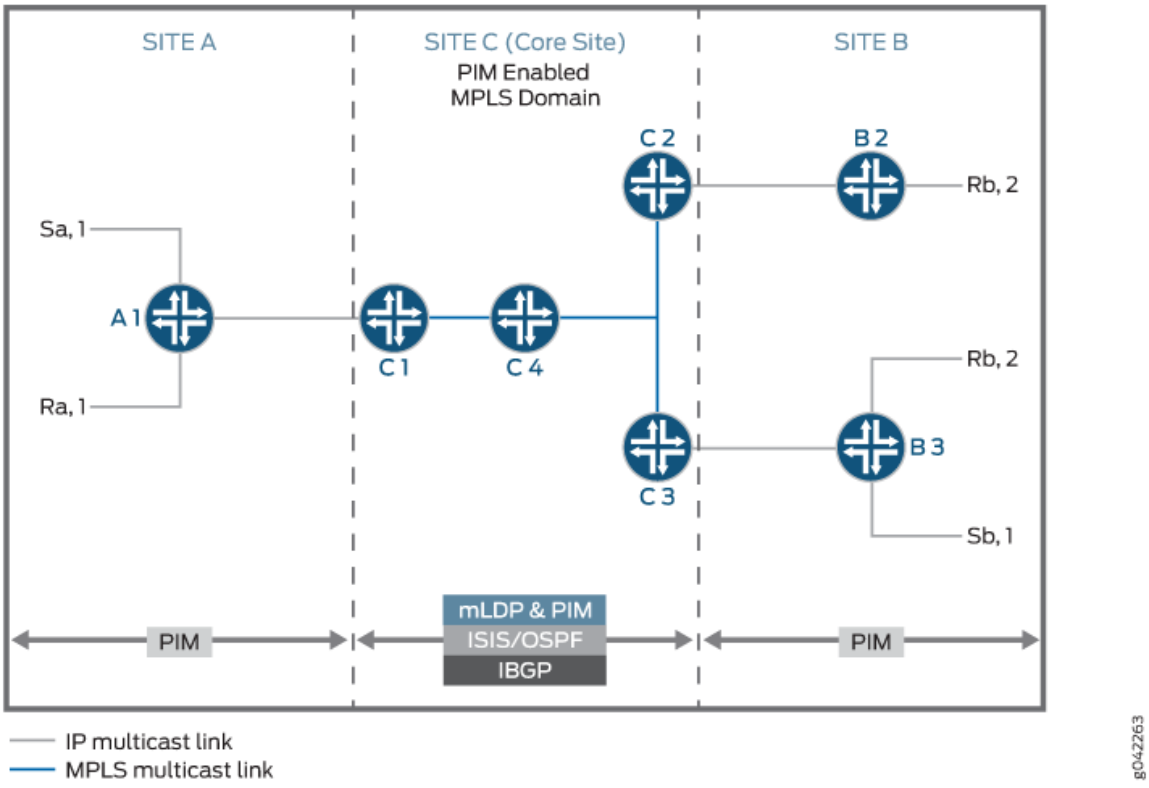
```
policy-options {
    policy-statement lsp-mapping-policy-example {
        term channel1 {
            from {
                source-address-filter ip-prefix</prefix-length>;  #policy filter for channel1
            }
            then {
                p2mp-lsp-root {
                    # Statically configured ingress address of edge
                    # used by channel1
                    address ip-address;
                }
                accept;
            }
        }
    }
}
```

M-LDP in PIM-Enabled MPLS Core

Starting in Junos OS Release 14.1, in order to migrate existing IPTV services from native IP multicast to MPLS multicast, you need to smoothly transition from PIM to M-LDP point-to-multipoint LSPs with minimal outage. *Figure 20* shows a similar M-LDP topology as *Figure 19*, but with a different scenario. The core is enabled with PIM, with one source streaming all the IPTV channels. The TV channels are

sent as ASM streams with each channel identified by its group address. Previously, these channels were streamed on the core as IP streams and signaled using PIM.

Figure 97: Sample M-LDP Topology in PIM-Enabled MPLS Core



By configuring the `mldp-inband-signaling` in this scenario, M-LDP signaling is initiated only when there is no PIM neighbor towards the source. However, because there is always a PIM neighbor towards the source unless PIM is deactivated on the upstream interfaces of the egress PE, PIM takes precedence over M-LDP and M-LDP does not take effect.

Configuration

To progressively migrate channel by channel to M-LDP MPLS core with few streams using M-LDP upstream and other streams using existing PIM upstream, include the `selected-mldp-egress` configuration statement along with group based filters in the policy filter for M-LDP inband signaling.

NOTE: The M-LDP inband signaling policy filter can include either the `source-address-filter` statement or the `route-filter` statement, or a combination of both.

For example:

```
protocols {
    pim {
        mldp-inband-signalling {
            policy lsp-mapping-policy-example;
        }
    }
}
```

```
policy-options {
    policy-statement lsp-mapping-policy-example {
        term channel1 {
            from {
                source-address-filter ip-prefix</prefix-length>;  #policy filter for channel1
            }
            then {
                selected-mldp-egress;
                accept;
            }
        }
        term channel2 {
            from {
                source-address-filter ip-prefix</prefix-length>;  #policy filter for channel2
                route-filter ip-prefix</prefix-length>;  #policy filter on multicast group
address
            }
            then {
                selected-mldp-egress;
                p2mp-lsp-root {
                    # Statically configured ingress address of edge
                    # used by channel2
                    address ip-address;
                }
                accept;
            }
        }
        term channel3 {
            from {
                route-filter ip-prefix</prefix-length>;  #policy filter on multicast group
address
```

```
            }
            then {
                selected-mldp-egress;
                accept;
            }
        }
    }
}
```

NOTE: Some of the limitations of the above configuration are as follows:

- The `selected-mldp-egress` statement should be configured only on the LER. Configuring the `selected-mldp-egress` statement on non-egress PIM routers can cause path setup failures.
- When policy changes are made to switch traffic from PIM upstream to M-LDP upstream and vice-versa, packet loss can be expected as break-and-make mechanism is performed at the control plane.

Terminology

The following terms are important for an understanding of M-LDP in-band signaling for multicast traffic.

Point-to-point LSP	An LSP that has one ingress label-switched router (LSR) and one egress LSR.
Multipoint LSP	Either a point-to-multipoint or a multipoint-to-multipoint LSP.
Point-to-multipoint LSP	An LSP that has one ingress LSR and one or more egress LSRs.
Multipoint-to-point LSP	An LSP that has one or more ingress LSRs and one unique egress LSR.
Multipoint-to-multipoint LSP	An LSP that connects a set of nodes, such that traffic sent by any node in the LSP is delivered to all others.
Ingress LSR	An ingress LSR for a particular LSP is an LSR that can send a data packet along the LSP. Multipoint-to-multipoint LSPs can have multiple ingress LSRs. Point-to-multipoint LSPs have only one, and that node is often referred to as the root node.
Egress LSR	An egress LSR for a particular LSP is an LSR that can remove a data packet from that LSP for further processing. Point-to-point and multipoint-to-point LSPs have only a single egress node. Point-to-multipoint and multipoint-to-multipoint LSPs can have multiple egress nodes.

Transit LSR	An LSR that has reachability to the root of the multipoint LSP through a directly connected upstream LSR and one or more directly connected downstream LSRs.
Bud LSR	An LSR that is an egress but also has one or more directly connected downstream LSRs.
Leaf node	Either an egress or bud LSR in the context of a point-to-multipoint LSP. In the context of a multipoint-to-multipoint LSP, an LSR is both ingress and egress for the same multipoint-to-multipoint LSP and can also be a bud LSR.

Ingress Join Translation and Pseudo Interface Handling

At the ingress LER, LDP notifies PIM about the (S,G) messages that are received over the in-band signaling. PIM associates each (S,G) messagewith a pseudo interface. Subsequently, a shortest-path-tree (SPT) join message is initiated toward the source. PIM treats this as a new type of local receiver. When the LSP is torn down, PIM removes this local receiver based on notification from LDP.

Ingress Splicing

LDP provides PIM with a next hop to be associated with each (S,G) entry. PIM installs a PIM (S,G) multicast route with the LDP next hop and other PIM receivers. The next hop is a composite next hop of local receivers + the list of PIM downstream neighbors + a sub-level next hopfor the LDP tunnel.

Reverse Path Forwarding

PIM's reverse-path-forwarding (RPF) calculation is performed at the egress node.

PIM performs M-LDP in-band signaling when all of the following conditions are true:

- There are no PIM neighbors toward the source.
- The M-LDP in-band signaling statement is configured.
- The next hop is learned through BGP, or is present in the static mapping (specified in an M-LDP in-band signaling policy).

Otherwise, if LSP root detection fails, PIM retains the (S,G) entry with an RPF state of unresolved.

PIM RPF registers this source address each time unicast routing information changes. Therefore, if the route toward the source changes, the RPF recalculation recurs. BGP protocol next hops toward the source too are monitored for changes in the LSP root. Such changes might cause traffic disruption for short durations.

LSP Root Detection

If the RPF operation detects the need for M-LDP in-band signaling upstream, the LSP root (ingress) is detected. This root is a parameter for LDP LSP signaling.

The root node is detected as follows:

1. If the existing static configuration specifies the source address, the root is taken as given in configuration.
2. A lookup is performed in the unicast routing table. If the source address is found, the protocol next hop toward the source is used as the LSP root.

   Prior to Junos OS Release 16.1, M-LDP point-to-multipoint LSP is signaled from an egress to ingress using the root address of the ingress LSR. This root address is reachable through IGP only, thereby confining the M-LDP point-to-multipoint LSP to a single autonomous system. If the root address is not reachable through an IGP, but reachable through BGP, and if that BGP route is recursively resolved over an MPLS LSP, then the point-to-multipoint LSP is not signaled further from that point towards the ingress LSR root address.

   There is a need for these non-segmented point-to-multipoint LSPs to be signaled across multiple autonomous systems, which can be used for the following applications:

   - Inter-AS MVPN with non-segmented point-to-multipoint LSPs.
   - Inter-AS M-LDP inband signaling between client networks connected by an MPLS core network.
   - Inter-area MVPN or M-LDP inband signaling with non-segmented point-to-multipoint LSPs (seamless MPLS multicast).

   Starting from Junos OS Release 16.1, M-LDP can signal point-to-multipoint LSPs at ASBR or transit or egress when root address is a BGP route which is further recursively resolved over an MPLS LSP.

Egress Join Translation and Pseudo Interface Handling

At the egress LER, PIM notifies LDP of the (S,G) message to be signaled along with the LSP root. PIM creates a pseudo interface as the upstream interface for this (S,G) message. When an (S,G) prune message is received, this association is removed.

Egress Splicing

At the egress node of the core network, where the (S,G) join message from the downstream site is received, this join message is translated to M-LDP in-band signaling parameters and LDP is notified. Further, LSP teardown occurs when the (S,G) entry is lost, when the LSP root changes, or when the (S,G) entry is reachable over a PIM neighbor.

Supported Functionality

For M-LDP in-band signaling, Junos OS supports the following functionality:

- Egress splicing of the PIM next hop with the LDP route
- Ingress splicing of the PIM route with the LDP next hop
- Translation of PIM join messages to LDP point-to-multipoint LSP setup parameters
- Translation of M-LDP in-band LSP parameters to set up PIM join messages
- Statically configured and BGP protocol next hop-based LSP root detection
- PIM (S,G) states in the PIM source-specific multicast (SSM) and anysource multicsast (ASM) ranges
- Configuration statements on ingress and egress LERs to enable them to act as edge routers
- IGMP join messages on LERs
- Carrying IPv6 source and group address as opaque information toward an IPv4 root node
- Static configuration to map an IPv6 (S,G) to an IPv4 root address

Unsupported Functionality

For M-LDP in-band signaling, Junos OS does *not* support the following functionality:

- Full support for PIM ASM
- The `mpls lsp point-to-multipoint ping` command with an (S,G) option
- *Nonstop active routing* (NSR)
- Make-before-break (MBB) for PIM
- IPv6 LSP root addresses (LDP does not support IPv6 LSPs.)
- Neighbor relationship between PIM speakers that are not directly connected
- Graceful restart
- PIM dense mode
- PIM bidirectional mode

LDP Functionality

The PIM (S,G) information is carried as M-LDP opaque type-length-value (TLV) encodings. The point-to-multipoint FEC element consists of the root-node address. In the case of next-generation multicast VPNs (NGEN MVPNs), the point-to-multipoint LSP is identified by the root node address and the LSP ID.

Egress LER Functionality

On the egress LER, PIM triggers LDP with the following information to create a point-to-multipoint LSP:

- Root node
- (S,G)
- Next hop

PIM finds the root node based on the source of the multicast tree. If the root address is configured for this (S,G) entry, the configured address is used as the point-to-multipoint LSP root. Otherwise, the routing table is used to look up the route to the source. If the route to the source of the multicast tree is a BGP-learned route, PIM retrieves the BGP next hop address and uses it as the root node for the point-to-multipoint LSP.

LDP finds the upstream node based on the root node, allocates a label, and sends the label mapping to the upstream node. LDP does not use penultimate hop popping (PHP) for in-band M-LDP signaling.

If the root addresses for the source of the multicast tree changes, PIM deletes the point-to-multipoint LSP and triggers LDP to create a new point-to-multipoint LSP. When this happens, the outgoing interface list becomes NULL, PIM triggers LDP to delete the point-to-multipoint LSP, and LDP sends a label withdraw message to the upstream node.

Transit LSR Functionality

The transit LSR advertises a label to the upstream LSR toward the source of the point-to-multipoint FEC and installs the necessary forwarding state to forward the packets. The transit LSR can be any M-LDP capable router.

Ingress LER Functionality

On the ingress LER, LDP provides the following information to PIM upon receiving the label mapping:

- (S,G)
- Flood next hop

Then PIM installs the forwarding state. If the new branches are added or deleted, the flood next hop is updated accordingly. If all branches are deleted due to a label being withdrawn, LDP sends updated information to PIM. If there are multiple links between the upstream and downstream neighbors, the point-to-multipoint LSP is not load balanced.

Example: Configuring Multipoint LDP In-Band Signaling for Point-to-Multipoint LSPs

IN THIS SECTION

- Requirements | 1482
- Overview | 1483
- Configuration | 1483
- Verification | 1496

This example shows how to configure multipoint LDP (M-LDP) in-band signaling for multicast traffic, as an extension to the Protocol Independent Multicast (PIM) protocol or as a substitute for PIM.

Requirements

This example can be configured using the following hardware and software components:

- Junos OS Release 13.2 or later
- MX Series 5G Universal Routing Platforms or M Series Multiservice Edge Routers for the Provider Edge (PE) Routers
- PTX Series Packet Transport Routers acting as transit label-switched routers
- T Series Core Routers for the Core Routers

NOTE: The PE routers could also be T Series Core Routers but that is not typical. Depending on your scaling requirements, the core routers could also be MX Series 5G Universal Routing Platforms or M Series Multiservice Edge Routers. The Customer Edge (CE) devices could be other routers or switches from Juniper Networks or another vendor.

No special configuration beyond device initialization is required before configuring this example.

Overview

"CLI Quick Configuration" on page 1484 shows the configuration for all of the devices in Figure 98 on page 1483. The section "No Link Title" on page 1489 describes the steps on Device EgressPE.

Procedure

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the `[edit]` hierarchy level.

Device src1

```
set logical-systems src1 interfaces fe-1/2/0 unit 0 family inet address 1.2.7.7/24
set logical-systems src1 interfaces lo0 unit 0 family inet address 1.1.1.7/32
set logical-systems src1 protocols ospf area 0.0.0.0 interface all
```

Device IngressPE

```
set interfaces so-0/1/2 unit 0 family inet address 192.168.93.9/28
set interfaces fe-1/2/0 unit 0 family inet address 1.2.3.2/24
set interfaces fe-1/2/0 unit 0 family mpls
set interfaces fe-1/2/1 unit 0 family inet address 1.2.5.2/24
set interfaces fe-1/2/2 unit 0 family inet address 1.2.6.2/24
set interfaces fe-1/2/2 unit 0 family mpls
set interfaces fe-1/2/3 unit 0 family inet address 1.2.7.2/24

set protocols pim interface all
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the CLI User Guide.

To configure Device EgressPE:

1. Configure the interfaces.

   Enable MPLS on the core-facing interfaces. On the egress next hops, you do not need to enable MPLS.

```
[edit interfaces]
user@EgressPE# set fe-1/2/0 unit 0 family inet address 1.1.3.1/24
user@EgressPE# set fe-1/2/0 unit 0 family mpls
user@EgressPE# set fe-1/2/2 unit 0 family inet address 1.1.6.1/24
user@EgressPE# set fe-1/2/2 unit 0 family mpls
user@EgressPE# set so-0/1/3 unit 0 point-to-point
user@EgressPE# set so-0/1/3 unit 0 family inet address 192.168.92.9/28
user@EgressPE# set fe-1/2/1 unit 0 family inet address 1.1.4.1/24
user@EgressPE# set fe-1/3/0 unit 0 family inet address 192.168.209.9/28
user@EgressPE# set lo0 unit 0 family inet address 1.1.1.1/32
```

2. Configure IGMP on the egress interfaces.

   For testing purposes, this example includes static group and source addresses.

```
[edit protocols igmp]
user@EgressPE# set interface fe-1/3/0.0 version 3
user@EgressPE# set interface fe-1/3/0.0 static group 232.1.1.1 group-count 3
user@EgressPE# set interface fe-1/3/0.0 static group 232.1.1.1 source 192.168.219.11
user@EgressPE# set interface fe-1/3/0.0 static group 227.1.1.1
user@EgressPE# set interface so-0/1/3.0 version 3
user@EgressPE# set interface so-0/1/3.0 static group 232.1.1.1 group-count 2
user@EgressPE# set interface so-0/1/3.0 static group 232.1.1.1 source 192.168.219.11
user@EgressPE# set interface so-0/1/3.0 static group 232.2.2.2 source 1.2.7.7
```

3. Configure MPLS on the core-facing interfaces.

```
[edit protocols mpls]
user@EgressPE# set interface fe-1/2/0.0
user@EgressPE# set interface fe-1/2/2.0
```

4. Configure BGP.

   BGP is a policy-driven protocol, so also configure and apply any needed routing policies.

For example, you might want to export static routes into BGP.

```
[edit protocols bgp group ibgp]
user@EgressPE# set type internal
user@EgressPE# set local-address 1.1.1.1
user@EgressPE# set family inet any
user@EgressPE# set neighbor 1.1.1.2
```

5. (Optional) Configure an MSDP peer connection with Device pr5 in order to interconnect the disparate PIM domains, thus enabling redundant RPs.

```
[edit protocols msdp]
user@EgressPE# set local-address 1.1.1.1
user@EgressPE# set peer 1.1.1.5
```

6. Configure OSPF.

```
[edit protocols ospf area 0.0.0.0]
user@EgressPE# set interface all
user@EgressPE# set interface fxp0.0 disable
```

7. Configure LDP on the core-facing interfaces and on the loopback interface.

```
[edit protocols ldp]
user@EgressPE# set interface fe-1/2/0.0
user@EgressPE# set interface fe-1/2/2.0
user@EgressPE# set interface lo0.0
```

8. Enable point-to-multipoint MPLS LSPs.

```
[edit protocols ldp]
user@EgressPE# set p2mp
```

9. Configure PIM on the downstream interfaces.

```
[edit protocols pim]
user@EgressPE# set interface lo0.0
```

```
user@EgressPE# set interface fe-1/3/0.0
user@EgressPE# set interface fe-1/2/1.0
user@EgressPE# set interface so-0/1/3.0
```

10. Configure the RP settings because this device serves as the PIM rendezvous point (RP).

```
[edit protocols pim]
user@EgressPE# set rp local address 1.1.1.1
user@EgressPE# set rp local group-ranges 227.0.0.0/8
user@EgressPE# set rp static address 1.1.1.4
user@EgressPE# set rp static address 1.2.7.7 group-ranges 226.0.0.0/8
```

11. Enable M-LDP in-band signaling and set the associated policy.

```
[edit protocols pim]
user@EgressPE# set mldp-inband-signalling policy mldppim-ex
```

12. Configure the routing policy that specifies the root address for the point-to-multipoint LSP and the associated source addresses.

```
[edit policy-options policy-statement mldppim-ex]
user@EgressPE# set term B from source-address-filter 192.168.0.0/24 orlonger
user@EgressPE# set term B from source-address-filter 192.168.219.11/32 orlonger
user@EgressPE# set term B then p2mp-lsp-root address 1.1.1.2
user@EgressPE# set term B then accept
user@EgressPE# set term A from source-address-filter 1.2.7.0/24 orlonger
user@EgressPE# set term A then accept
```

13. Configure the autonomous system (AS) ID.

```
[edit routing-options]
user@EgressPE# set autonomous-system 64510
```

Results

From configuration mode, confirm your configuration by entering the `show interfaces`, `show protocols`, `show policy-options`, and `show routing-options` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

Device EgressPE

```
user@EgressPE# show interfaces
so-0/1/3 {
    unit 0 {
        point-to-point;
        family inet {
            address 192.168.92.9/28;
        }
    }
}
fe-1/2/0 {

Similarly, configure the other egress devices.

If you are done configuring the devices, enter `commit` from configuration mode.

Verification

IN THIS SECTION

- Checking the PIM Join States | **1496**
- Checking the PIM Sources | **1501**
- Checking the LDP Database | **1503**
- Looking Up the Route Information for the MPLS Label | **1507**
- Checking the LDP Traffic Statistics | **1508**

Confirm that the configuration is working properly.

Checking the PIM Join States

Purpose

Display information about PIM join states to verify the M-LDP in-band upstream and downstream details. On the ingress device, the `show pim join extensive` command displays `Pseudo-MLDP` for the downstream interface. On the egress, the `show pim join extensive` command displays `Pseudo-MLDP` for the upstream interface.

Action

From operational mode, enter the `show pim join extensive` command.

```
user@IngressPE> show pim join extensive

Checking the PIM Sources

Purpose

Verify that the PIM sources have the expected M-LDP in-band upstream and downstream details.

Action

From operational mode, enter the `show pim source` command.

```
user@IngressPE> show pim source

Instance: PIM.master Family: INET

Source 1.1.1.1
```

```
    Prefix 1.1.1.1/32
    Upstream interface Local
    Upstream neighbor Local

Source 1.2.7.7
    Prefix 1.2.7.0/24
    Upstream protocol MLDP
    Upstream interface Pseudo MLDP
    Upstream neighbor MLDP LSP root <1.1.1.2>

Source 192.168.219.11
    Prefix 192.168.219.0/28
    Upstream protocol MLDP
    Upstream interface Pseudo MLDP
    Upstream neighbor MLDP LSP root <1.1.1.2>
```

```
user@EgressPE> show pim source
Instance: PIM.master Family: INET

LDP Mapping Server for Interoperability of Segment Routing with LDP Overview

IN THIS SECTION

- Interoperability of Segment Routing with LDP Using OSPF | **1509**
- Interoperability of Segment Routing with LDP Using ISIS | **1511**

In an LDP network with gradual deployment of segment routing, there can be islands of devices that support either only LDP, or only segment routing. For the devices to interwork, the LDP mapping server feature is required to be configured on any device in the segment routing network.

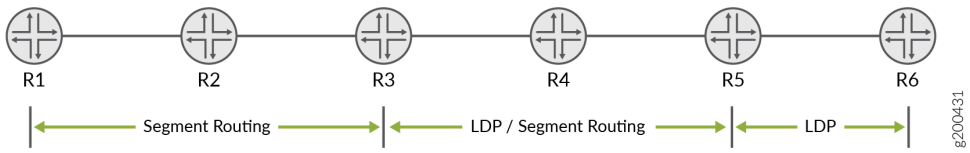
The LDP mapping server feature is implemented using either OSPF or ISIS.

Interoperability of Segment Routing with LDP Using OSPF

To implement interoperability of segment routing with LDP using OSPF, an extended prefix link-state advertisement (LSA) with Range type, length, and value (TLV) for all the LDP prefixes is generated, and mapping routes corresponding to the prefix is installed in the inet.3 and mpls.0 routing tables.

Figure 99 on page 1509 is a simple LDP network topology used to illustrate the interoperability of segment routing devices with LDP devices using OSPF. The topology has six devices (Devices R1, R2, R3, R4, R5, and R6) with LDP-to-segment routing migration.

Figure 99: Sample LDP Topology with Interoperability of Segment Routing with LDP Using OSPF



In the above topology, Devices R1, R2, and R3 are capable of only segment routing, Devices R5 and R6 are capable of only LDP, and Device R4 supports both LDP and segment routing. Here, Device R1 cannot interwork with Device R6 because of interoperability issues.

To enable interoperability between the LDP-capable devices and segment routing devices, any one interface of the device in the segment routing network segment is configured as the LDP mapping server. Currently, the mapping server configures prefixes under the `[edit routing-options source-packet-routing]` hierarchy level. With this feature, the LDP mapping server configuration if applied under the `[edit protocols ospf]` hierarchy level, where a new extended prefix LSA with range TLV for all LDP prefixes is advertised by OSPF. The device capable of segment routing analyze the extended prefix range TLV and mapping routes corresponding to the prefix are installed in the inet.3 and mpls.0 routing tables.

For example, in Figure 99 on page 1509, if Device R2 (in the segment routing network) is the LDP mapping server, the following configuration is included:

```
[edit routing-options]
user@R2# set source-packet-routing mapping-server-entry mapping-server-nameprefix-segment-range
prefix-range start-prefix loopback-address
user@R2# set source-packet-routing mapping-server-entry mp1 prefix-segment-range rg1 start-index
5
user@R2# set source-packet-routing mapping-server-entry mp1 prefix-segment-range rg1 size 1
```

NOTE: The IP address used as the `start-prefix` is the loopback address of the device in the LDP network (Device R5, in this example).

```
[edit protocols]
user@R2# set ospf source-packet-routing mapping-server mapping-server-name
```

When the LDP mapping server configuration is committed on Device R2, the extended prefix range TLV is flooded across the OSPF area. The devices capable of segment routing (Devices R1, R2, and R3) install OSPF segment routing routes for the specified loopback address with a segment ID (SID) index. The SID index is also updated in the mpls.0 routing table by the segment routing devices.

Starting in Junos OS Release 19.1R1, segment routing-LDP border router can stitch segment routing traffic to LDP next-hop and vice versa.

Unsupported Features and Functionality for Interoperability of Segment Routing with LDP using OSPF

- Prefix conflict is only detected at the source configuration. When there is a prefix range conflict, the prefix SID from the lower router ID prevails. In such cases, a system log error message—`RPD_OSPF_PFX_SID_RANGE_CONFLICT`—is generated.
- IPv6 prefixes are not supported.

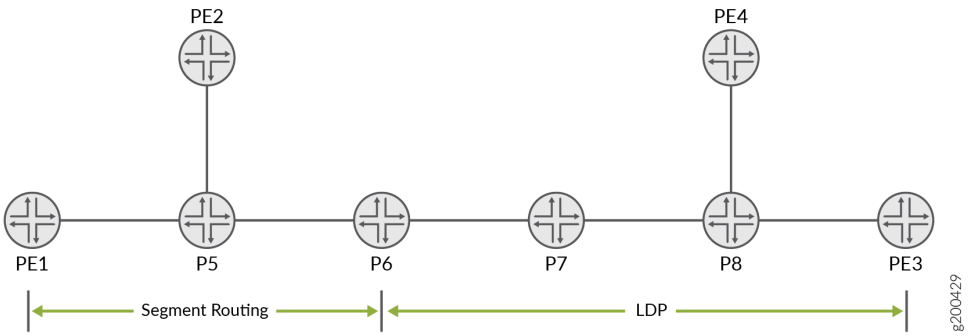
- Flooding of the OSPF Extended Prefix Opaque LSA generated by the segment routing mapping server for autonomous systems (ASs) is not supported.
- Inter-area LDP mapping server functionary is not supported.
- ABR functionality of Extended Prefix Opaque LSA is not supported.
- ASBR functionality of Extended Prefix Opaque LSA is not supported.
- Segment routing mapping server Preference TLV is not supported.

Interoperability of Segment Routing with LDP Using ISIS

To implement interoperability of segment routing with LDP using ISIS, a server-client configuration is required under protocols ISIS and LDP, respectively, and routes from the inet.3 or inet.0 routing tables are used for stitching of segment routing LSP with an LDP LSP and vice-versa.

Figure 100 on page 1511 is a simple LDP network topology used to illustrate the interoperability of segment routing devices with LDP devices using an LDP mapping server-client feature. The topology has four provider edge (PE) devices (Devices PE1, PE2, PE3, and PE4) and four provider (P) devices (Devices P5, P6, P7, and P8).

Figure 100: Sample LDP Topology with Interoperability of Segment Routing with LDP Using ISIS



Devices PE3, PE4, P6, P7 and P8 are the LDP capable devices. Devices PE1, PE2, P5 and P6 are capable of segment routing with segment routing global block (SRGB) value of 100 and 200, and node segment IDs (SIDs) value of 101, 102,105 and 106, respectively.

For a service flow to be tunneled to-and-from Device PE3 and Device PE1 using a continuous MPLS tunnel, the islands of devices supporting segment routing and LDP must interoperate.

LDP Mapping Client Functionality (LDP to Segment Routing)

The LDP client functionality is the LDP-to-segment routing mapping, that is the right-to-left traffic flow in Figure 100 on page 1511. On Device P6, an LDP egress policy is configured to advertise all node SIDs

and prefix SIDs from the segment routing network on the left. As a result, on Device P6, LDP advertises Devices PE1, PE2 and P5 as the egress FEC label bindings to Device P7.

Device PE3 has learned a service route with Device PE1 as the protocol next hop. Device PE3 has an LDP label binding from the P8 next hop for the PE1 FEC. As a result, Device PE3 sends its service packet to Device P8 as per classic LDP behavior. Device P8 has an LDP label binding from its P7 next hop for the PE1 FEC, therefore Device P8 forwards to Device P7 as per classic LDP behavior.

Device P7 has an LDP label binding from its P6 next hop the PE1 FEC, as a result, Device P7 forwards to Device P6 as per classic LDP behavior.

Device P6that is acting as an LDP egress for the PE1 FEC, stitches and swaps the incoming egress LDP label for the PE1 FEC with an equivalent segment routing node SID (101 in this example) to forward the traffic to Device P5.

Device P5 pops 101 SID assuming that Device PE1 advertised its node segment 101 with the penultimate-pop flag set, and then forwards traffic to Device PE1. Device PE1receives the tunneled packet and processes the service label.

As a result, the end-to-end MPLS tunnel is built from an LDP LSP from Device PE3 to Device P6, and the related node segment from Device P6 to Device PE1.

LDP Mapping Server Functionality (Segment Routing to LDP)

The LDP server functionality is the mapping of segment routing to LDP, that is the left-to-right traffic flow in Figure 100 on page 1511. On Device P6 the mapping server prefixes configuration is included under the `[edit routing-options source-packet-routing]` hierarchy level. When the configuration is applied under the specific IGP, the label binding type, length, and value (TLV) for all the LDP FEC-label bindings from the LDP network are advertised as inet.3 LDP routes.

Here, Device P6 acts as a Segment Routing Mapping Server (SRMS) and advertises the following mappings – (P7, 107), (P8, 108), (PE3, 103), (PE4, 104), and (P7, 107). If segment routing was supported on Device PE3, the node SID 103 would have been configured on Device PE3. Because Device PE3 does not support segment routing, the policy is configured at the SRMS on Device P6, and Device P6 is responsible for advertising the mappings.

These mapping server advertisements are only understood by the segment routing devices. The segment routing devices install the related node SIDs in the MPLS data plane exactly how the node segments had been advertised by the nodes themselves. For instance, Device PE1 installs the node SID 103 with P5 next hop exactly as if Device PE3 had advertised SID 103.

Device PE1 has a service route with PE3 as its protocol next hop. Device PE1 has a node segment for that IGP route – 103 with P5 next hop. As a result, Device PE1 sends its service packet to Device P5 with two labels – the bottom label, which is the service label, and the top label, which is SID 103. Device P5 swaps 103 for 103 and forwards to Device P6. The next-hop for Device P6 is the IGP route PE3, which is not capable of segment routing. (Device P7 does not advertise the segment routing capability).

However, Device P6 has an LDP label binding from that next hop for the same FEC (for example, LDP label 1037). As a result, on Device P6, the IGP swaps 103 for 1037 and forwards to Device P7.

Device P7 swaps this label with the LDP-label received from Device P8, and then forwards it to Device P8. The LDP label is popped by Device P8 and forwarded to Device PE3.

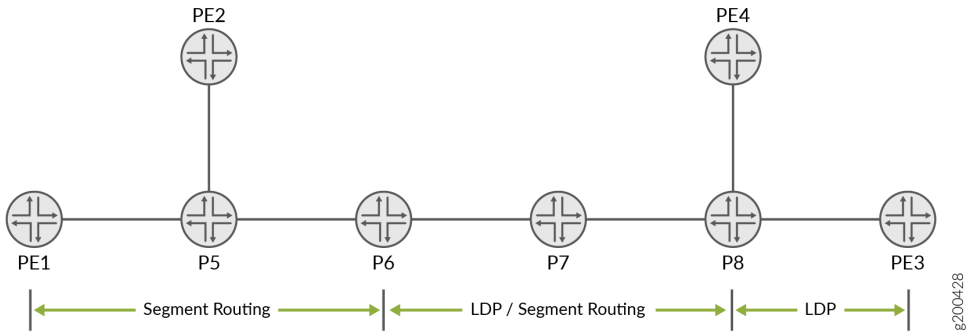
Device PE3 receives the tunneled packet and processes the service label. The end-to-end MPLS tunnel is built from a segment routing node from Devices PE1 to P6, and an LDP LSP from Devices P6 to PE3.

Segment Routing to LDP Stitching

When the IGP segment routing LSP's IP next hop does not support segment routing, the IGP looks at the inet.3 routing table to see if there is an LDP LSP to the same prefix. If the LDP LSP is present, the IGP stitches the segment routing LSP to the LDP LSP by programming a MPLS transit route that swaps the segment routing label with the LDP label to switch traffic from segment routing domain to the LDP domain.

Figure 101 on page 1513 illustrates the stitching of segment routing and LDP LSPs for enabling interoperability.

Figure 101: Stitching Segment Routing and LDP LSPs



In the topology, Device PE3 is LDP-capable and does not support segment routing. The mapping server in the segment routing domain can advertise label binding TLV for devices P7, P8 and PE4. In such a scenario, Device PE1 can have both prefix SID and remote label binding TLV and SID to reach Device PE4. However, Device PE1 prefers prefix SID over remote label binding TLV while programing its ingress segment routing route for Device PE4. As a result, Device PE1 uses the segment routing LSP end-to-end to send traffic to Device PE4, and uses the segment routing-to-LDP stitching while sending traffic to Device PE3.

Unsupported Features and Functionality for Interoperability of Segment Routing with LDP using ISIS

- Penultimate-hop popping behaviour for label binding TLV is not supported.
- Advertising of range of prefixes in label binding TLV is not supported.

- Segment Routing Conflict Resolution is not supported.
- LDP traffic statistics does not work.
- Nonstop active routing (NSR) and graceful Routing Engine switchover (GRES) is not supported.
- ISIS inter-level is not supported.
- RFC 7794, *IS-IS Prefix Attributes for Extended IPv4* is not supported.
- Redistributing LDP route as a prefix-sid at the stitching node is not supported.

Configuring Miscellaneous LDP Properties

IN THIS SECTION

- Configuring LDP to Use the IGP Route Metric | **1514**
- Preventing Addition of Ingress Routes to the inet.0 Routing Table | **1515**
- Multiple-Instance LDP and Carrier-of-Carriers VPNs | **1515**
- Configuring MPLS and LDP to Pop the Label on the Ultimate-Hop Router | **1515**
- Enabling LDP over RSVP-Established LSPs | **1516**
- Enabling LDP over RSVP-Established LSPs in Heterogeneous Networks | **1517**
- Configuring the TCP MD5 Signature for LDP Sessions | **1517**
- Configuring LDP Session Protection | **1519**
- Disabling SNMP Traps for LDP | **1519**
- Configuring LDP Synchronization with the IGP on LDP Links | **1520**
- Configuring LDP Synchronization with the IGP on the Router | **1520**
- Configuring the Label Withdrawal Timer | **1521**
- Ignoring the LDP Subnet Check | **1521**

The following sections describe how to configure a number of miscellaneous LDP properties:

Configuring LDP to Use the IGP Route Metric

Use the `track-igp-metric` statement if you want the interior gateway protocol (IGP) route metric to be used for the LDP routes instead of the default LDP route metric (the default LDP route metric is 1).

To use the IGP route metric, include the `track-igp-metric` statement:

```
track-igp-metric;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Preventing Addition of Ingress Routes to the inet.0 Routing Table

By configuring the `no-forwarding` statement, you can prevent ingress routes from being added to the inet.0 routing table instead of the inet.3 routing table even if you enabled the `traffic-engineering bgp-igp` statement at the `[edit protocols mpls]` or the `[edit logical-systems` *`logical-system-name`* `protocols mpls]` hierarchy level. By default, the `no-forwarding` statement is disabled.

NOTE: ACX Series routers do not support `[edit logical-systems]` hierarchy level.

To omit ingress routes from the inet.0 routing table, include the `no-forwarding` statement:

```
no-forwarding;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Multiple-Instance LDP and Carrier-of-Carriers VPNs

By configuring multiple LDP routing instances, you can use LDP to advertise labels in a carrier-of-carriers VPN from a service provider provider edge (PE) router to a customer carrier customer edge (CE) router. This is especially useful when the carrier customer is a basic Internet service provider (ISP) and wants to restrict full Internet routes to its PE routers. By using LDP instead of BGP, the carrier customer shields its other internal routers from the Internet. Multiple-instance LDP is also useful when a carrier customer wants to provide Layer 2 or Layer 3 VPN services to its customers.

For an example of how to configure multiple LDP routing instances for carrier-of-carriers VPNs, see the *Multiple Instances for Label Distribution Protocol User Guide*.

Configuring MPLS and LDP to Pop the Label on the Ultimate-Hop Router

The default advertised label is label 3 (Implicit Null label). If label 3 is advertised, the penultimate-hop router removes the label and sends the packet to the egress router. If ultimate-hop popping is enabled,

label 0 (IPv4 Explicit Null label) is advertised. Ultimate-hop popping ensures that any packets traversing an MPLS network include a label.

To configure ultimate-hop popping, include the `explicit-null` statement:

```
explicit-null;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

NOTE: Juniper Networks routers queue packets based on the incoming label. Routers from other vendors might queue packets differently. Keep this in mind when working with networks containing routers from multiple vendors.

For more information about labels, see "MPLS Label Overview" on page 509 and "MPLS Label Allocation" on page 509.

Enabling LDP over RSVP-Established LSPs

You can run LDP over LSPs established by RSVP, effectively tunneling the LDP-established LSP through the one established by RSVP. To do so, enable LDP on the lo0.0 interface (see "Enabling and Disabling LDP" on page 1322). You must also configure the LSPs over which you want LDP to operate by including the `ldp-tunneling` statement at the `[edit protocols mpls label-switched-path lsp-name]` hierarchy level:

```
[edit]
protocols {
    mpls {
        label-switched-path lsp-name {
            from source;
            to destination;
            ldp-tunneling;
        }
    }
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Enabling LDP over RSVP-Established LSPs in Heterogeneous Networks

Some other vendors use an OSPF metric of 1 for the loopback address. Juniper Networks routers use an OSPF metric of 0 for the loopback address. This might require that you manually configure the RSVP metric when deploying LDP tunneling over RSVP LSPs in heterogeneous networks.

When a Juniper Networks router is linked to another vendor's router through an RSVP tunnel, and LDP tunneling is also enabled, by default the Juniper Networks router might not use the RSVP tunnel to route traffic to the LDP destinations downstream of the other vendor's egress router if the RSVP path has a metric of 1 larger than the physical OSPF path.

To ensure that LDP tunneling functions properly in heterogeneous networks, you can configure OSPF to ignore the RSVP LSP metric by including the `ignore-lsp-metrics` statement:

```
ignore-lsp-metrics;
```

You can configure this statement at the following hierarchy levels:

- `[edit protocols ospf traffic-engineering shortcuts]`
- `[edit logical-systems` *`logical-system-name`* `protocols ospf traffic-engineering shortcuts]`

NOTE: ACX Series routers do not support `[edit logical-systems]` hierarchy level.

To enable LDP over RSVP LSPs, you also still need to complete the procedure in Section "Enabling LDP over RSVP-Established LSPs" on page 1516.

Configuring the TCP MD5 Signature for LDP Sessions

You can configure an MD5 signature for an LDP TCP connection to protect against the introduction of spoofed TCP segments into LDP session connection streams.

A router using the MD5 signature option is configured with a password for each peer for which authentication is required. The password is stored encrypted.

LDP hello adjacencies can still be created even when peering interfaces are configured with different security signatures. However, the TCP session cannot be authenticated and is never established.

Starting in Junos OS Release 16.1R1, support for Hashed Message Authentication Code (HMAC) and MD5 authentication for LDP sessions is extended from a per-session configuration to a subnet-match (that is, longest-prefix-match) configuration.

The support for subnet-match authentication provides flexibility in configuring authentication for automatically targeted LDP (TLDP) sessions, making the deployment of remote loop-free alternate (LFA) and FEC 129 pseudowires easy.

To configure an MD5 signature for an LDP TCP connection, include the `session-group` and `authentication-key` statement:

```
session-group prefix-length {
    authentication-key authentication-key;
}
```

Use the `session-group` statement to configure the address for the remote end of the LDP session.

The *md5-authentication-key* (password) can be up to 69 characters long. Characters can include any ASCII strings. If you include spaces, enclose all characters in quotation marks.

You can also configure an authentication key update mechanism for the LDP routing protocol. This mechanism allows you to update authentication keys without interrupting associated routing and signaling protocols such as Open Shortest Path First (*OSPF*) and Resource Reservation Setup Protocol (*RSVP*).

To configure the authentication key update mechanism, include the `key-chain` statement at the `[edit security authentication-key-chains]` hierarchy level, and specify the `key` option to create a keychain consisting of several authentication keys.

```
[edit security authentication-key-chains]
key-chain key-chain-name {
    key key {
        secret secret-data;
        start-time yyyy-mm-dd.hh:mm:ss;
    }
}
```

To configure the authentication key update mechanism for the LDP routing protocol, include the `authentication-key-chain` statement at the `[edit protocols ldp]` hierarchy level to associate the protocol with the `[edit security authentication-key-chains]` authentication keys. You must also configure the authentication algorithm by including the `authentication-algorithm` *algorithm* statement the `[edit protocols ldp]` hierarchy level.

```
[edit protocols ldp]
group group-name {
    neighbor address {
```

```
        authentication-algorithm algorithm;
        authentication-key-chain key-chain-name;
    }
}
```

For more information about the authentication key update feature, see *Configuring the Authentication Key Update Mechanism for BGP and LDP Routing Protocols*.

Configuring LDP Session Protection

An LDP session is normally created between a pair of routers that are connected by one or more links. The routers form one hello adjacency for every link that connects them and associate all the adjacencies with the corresponding LDP session. When the last hello adjacency for an LDP session goes away, the LDP session is terminated. You might want to modify this behavior to prevent an LDP session from being unnecessarily terminated and reestablished.

You can configure the Junos OS to leave the LDP session between two routers up even if there are no hello adjacencies on the links connecting the two routers by configuring the `session-protection` statement. You can optionally specify a time in seconds using the `timeout` option. The session remains up for the duration specified as long as the routers maintain IP network connectivity.

```
session-protection {
    timeout seconds;
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section.

Disabling SNMP Traps for LDP

Whenever an LDP LSP makes a transition from up to down, or down to up, the router sends an SNMP trap. However, it is possible to disable the LDP SNMP traps on a router, logical system, or routing instance.

For information about the LDP SNMP traps and the proprietary LDP MIB, see the SNMP MIB Explorer..

To disable SNMP traps for LDP, specify the `trap disable` option for the `log-updown` statement:

```
log-updown {
    trap disable;
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Configuring LDP Synchronization with the IGP on LDP Links

LDP is a protocol for distributing labels in non-traffic-engineered applications. Labels are distributed along the best path determined by the IGP. If synchronization between LDP and the IGP is not maintained, the LSP goes down. When LDP is not fully operational on a given link (a session is not established and labels are not exchanged), the IGP advertises the link with the maximum cost metric. The link is not preferred but remains in the network topology.

LDP synchronization is supported only on active point-to-point interfaces and LAN interfaces configured as point-to-point under the IGP. LDP synchronization is not supported during graceful restart.

To advertise the maximum cost metric until LDP is operational for synchronization, include the `ldp-synchronization` statement:

```
ldp-synchronization {
    disable;
    hold-time seconds;
}
```

To disable synchronization, include the `disable` statement. To configure the time period to advertise the maximum cost metric for a link that is not fully operational, include the `hold-time` statement.

For a list of hierarchy levels at which you can configure this statement, see the statement summary section for this statement.

Configuring LDP Synchronization with the IGP on the Router

You can configure the time the LDP waits before informing the IGP that the LDP neighbor and session for an interface are operational. For large networks with numerous FECs, you might need to configure a longer value to allow enough time for the LDP label databases to be exchanged.

To configure the time the LDP waits before informing the IGP that the LDP neighbor and session are operational, include the `igp-synchronization` statement and specify a time in seconds for the `holddown-interval` option:

```
igp-synchronization holddown-interval seconds;
```

For a list of hierarchy levels at which you can configure this statement, see the statement summary section for this statement.

Configuring the Label Withdrawal Timer

The label withdrawal timer delays sending a label withdrawal message for a FEC to a neighbor. When an IGP link to a neighbor fails, the label associated with the FEC has to be withdrawn from all the upstream routers if the neighbor is the next hop for the FEC. After the IGP converges and a label is received from a new next hop, the label is readvertised to all the upstream routers. This is the typical network behavior. By delaying label withdrawal by a small amount of time (for example, until the IGP converges and the router receives a new label for the FEC from the downstream next hop), the label withdrawal and sending a label mapping soon could be avoided. The `label-withdrawal-delay` statement allows you to configure this delay time. By default, the delay is 60 seconds.

If the router receives the new label before the timer runs out, the label withdrawal timer is canceled. However, if the timer runs out, the label for the FEC is withdrawn from all of the upstream routers.

By default, LDP waits for 60 seconds before withdrawing labels to avoid resignaling LSPs multiple times while the IGP is reconverging. To configure the label withdrawal delay time in seconds, include the `label-withdrawal-delay` statement:

```
label-withdrawal-delay seconds;
```

For a list of hierarchy levels at which you can configure this statement, see the statement summary section for this statement.

Ignoring the LDP Subnet Check

In Junos OS Release 8.4 and later releases, an LDP source address subnet check is performed during the neighbor establishment procedure. The source address in the LDP link hello packet is matched against the interface address. This causes an interoperability issue with some other vendors' equipment.

To disable the subnet check, include the `allow-subnet-mismatch` statement:

```
allow-subnet-mismatch;
```

This statement can be included at the following hierarchy levels:

- [edit protocols ldp interface *interface-name*]
- [edit logical-systems *logical-system-name* protocols ldp interface *interface-name*]

NOTE: ACX Series routers do not support [edit logical-systems] hierarchy level.

Tunneling LDP LSPs in RSVP LSPs Overview | 1282

Configuring LDP LSP Traceroute

You can trace the route followed by an LDP-signaled LSP. LDP LSP traceroute is based on RFC 4379, *Detecting Multi-Protocol Label Switched (MPLS) Data Plane Failures*. This feature allows you to periodically trace all paths in a FEC. The FEC topology information is stored in a database accessible from the CLI.

A topology change does not automatically trigger a trace of an LDP LSP. However, you can manually initiate a traceroute. If the traceroute request is for an FEC that is currently in the database, the contents of the database are updated with the results.

The periodic traceroute feature applies to all FECs specified by the `oam` statement configured at the `[edit protocols ldp]` hierarchy level. To configure periodic LDP LSP traceroute, include the `periodic-traceroute` statement:

```
periodic-traceroute {
    disable;
    exp exp-value;
    fanout fanout-value;
    frequency minutes;
    paths number-of-paths;
    retries retry-attempts;
    source address;
    ttl ttl-value;
    wait seconds;
}
```

You can configure this statement at the following hierarchy levels:

- `[edit protocols ldp oam]`
- `[edit protocols ldp oam fec address]`

You can configure the `periodic-traceroute` statement by itself or with any of the following options:

- `exp`—Specify the class of service to use when sending probes.
- `fanout`—Specify the maximum number of next hops to search per node.
- `frequency`—Specify the interval between traceroute attempts.
- `paths`—Specify the maximum number of paths to search.

- `retries`—Specify the number of attempts to send a probe to a specific node before giving up.
- `source`—Specify the IPv4 source address to use when sending probes.
- `ttl`—Specify the maximum time-to-live value. Nodes that are beyond this value are not traced.
- `wait`—Specify the wait interval before resending a probe packet.

Collecting LDP Statistics

IN THIS SECTION

- LDP Statistics Output | **1524**
- Disabling LDP Statistics on the Penultimate-Hop Router | **1524**
- LDP Statistics Limitations | **1525**

LDP traffic statistics show the volume of traffic that has passed through a particular FEC on a router.

When you configure the `traffic-statistics` statement at the `[edit protocols ldp]` hierarchy level, the LDP traffic statistics are gathered periodically and written to a file. You can configure how often statistics are collected (in seconds) by using the `interval` option. The default collection interval is 5 minutes. You must configure an LDP statistics file; otherwise, LDP traffic statistics are not gathered. If the LSP goes down, the LDP statistics are reset.

To collect LDP traffic statistics, include the `traffic-statistics` statement:

```
traffic-statistics {
    file filename <files number> <size size> <world-readable | no-world-readable>;
    interval interval;
    no-penultimate-hop;
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

This section includes the following topics:

LDP Statistics Output

The following sample output is from an LDP statistics file:

```
FEC                 Type       Packets     Bytes    Shared
10.255.350.448/32   Transit          0         0        No
                    Ingress          0         0        No
10.255.350.450/32   Transit          0         0       Yes
                    Ingress          0         0        No
10.255.350.451/32   Transit          0         0        No
                    Ingress          0         0        No
220.220.220.1/32    Transit          0         0       Yes
                    Ingress          0         0        No
220.220.220.2/32    Transit          0         0       Yes
                    Ingress          0         0        No
220.220.220.3/32    Transit          0         0       Yes
                    Ingress          0         0        No
May 28 15:02:05, read 12 statistics in  00:00:00 seconds
```

The LDP statistics file includes the following columns of data:

- `FEC`—FEC for which LDP traffic statistics are collected.
- `Type`—Type of traffic originating from a router, either `Ingress` (originating from this router) or `Transit` (forwarded through this router).
- `Packets`—Number of packets passed by the FEC since its LSP came up.
- `Bytes`—Number of bytes of data passed by the FEC since its LSP came up.
- `Shared`—A `Yes` value indicates that several prefixes are bound to the same label (for example, when several prefixes are advertised with an egress policy). The LDP traffic statistics for this case apply to all the prefixes and should be treated as such.
- `read`—This number (which appears next to the date and time) might differ from the actual number of the statistics displayed. Some of the statistics are summarized before being displayed.

Disabling LDP Statistics on the Penultimate-Hop Router

Gathering LDP traffic statistics at the penultimate-hop router can consume excessive system resources, on next-hop routes in particular. This problem is exacerbated if you have configured the `deaggregate`

statement in addition to the traffic-statistics statement. For routers reaching their limit of next-hop route usage, we recommend configuring the no-penultimate-hop option for the traffic-statistics statement:

```
traffic-statistics {
    no-penultimate-hop;
}
```

For a list of hierarchy levels at which you can configure the traffic-statistics statement, see the statement summary section for this statement.

NOTE: When you configure the no-penultimate-hop option, no statistics are available for the FECs that are the penultimate hop for this router.

Whenever you include or remove this option from the configuration, the LDP sessions are taken down and then restarted.

The following sample output is from an LDP statistics file showing routers on which the no-penultimate-hop option is configured:

```
FEC                 Type            Packets          Bytes       Shared
10.255.245.218/32   Transit               0              0           No
                    Ingress               4            246           No
10.255.245.221/32   Transit     statistics disabled
                    Ingress     statistics disabled
13.1.1.0/24         Transit     statistics disabled
                    Ingress     statistics disabled
13.1.3.0/24         Transit     statistics disabled
                    Ingress     statistics disabled
```

LDP Statistics Limitations

The following are issues related to collecting LDP statistics by configuring the traffic-statistics statement:

- You cannot clear the LDP statistics.
- If you shorten the specified interval, a new LDP statistics request is issued only if the statistics timer expires later than the new interval.

- A new LDP statistics collection operation cannot start until the previous one has finished. If the interval is short or if the number of LDP statistics is large, the time gap between the two statistics collections might be longer than the interval.

When an LSP goes down, the LDP statistics are reset.

Tracing LDP Protocol Traffic

IN THIS SECTION

- Tracing LDP Protocol Traffic at the Protocol and Routing Instance Levels | 1526
- Tracing LDP Protocol Traffic Within FECs | 1527
- Examples: Tracing LDP Protocol Traffic | 1528

The following sections describe how to configure the trace options to examine LDP protocol traffic:

Tracing LDP Protocol Traffic at the Protocol and Routing Instance Levels

To trace LDP protocol traffic, you can specify options in the global `traceoptions` statement at the `[edit routing-options]` hierarchy level, and you can specify LDP-specific options by including the `traceoptions` statement:

```
traceoptions {
    file filename <files number> <size size> <world-readable | no-world-readable>;
    flag flag <flag-modifier> <disable>;
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Use the `file` statement to specify the name of the file that receives the output of the tracing operation. All files are placed in the directory /var/log. We recommend that you place LDP-tracing output in the file **ldp-log**.

The following trace flags display the operations associated with the sending and receiving of various LDP messages. Each can carry one or more of the following modifiers:

- `address`—Trace the operation of address and address withdrawal messages.
- `binding`—Trace label-binding operations.

- `error`—Trace error conditions.
- `event`—Trace protocol events.
- `initialization`—Trace the operation of initialization messages.
- `label`—Trace the operation of label request, label map, label withdrawal, and label release messages.
- `notification`—Trace the operation of notification messages.
- `packets`—Trace the operation of address, address withdrawal, initialization, label request, label map, label withdrawal, label release, notification, and periodic messages. This modifier is equivalent to setting the `address`, `initialization`, `label`, `notification`, and `periodic` modifiers.

  You can also configure the `filter` flag modifier with the `match-on address` sub-option for the `packets` flag. This allows you to trace based on the source and destination addresses of the packets.
- `path`—Trace label-switched path operations.
- `path`—Trace label-switched path operations.
- `periodic`—Trace the operation of hello and keepalive messages.
- `route`—Trace the operation of route messages.
- `state`—Trace protocol state transitions.

Tracing LDP Protocol Traffic Within FECs

LDP associates a forwarding equivalence class (FEC) with each LSP it creates. The FEC associated with an LSP specifies which packets are mapped to that LSP. LSPs are extended through a network as each router chooses the label advertised by the next hop for the FEC and splices it to the label it advertises to all other routers.

You can trace LDP protocol traffic within a specific FEC and filter LDP trace statements based on an FEC. This is useful when you want to trace or troubleshoot LDP protocol traffic associated with an FEC. The following trace flags are available for this purpose: `route`, `path`, and `binding`.

The following example illustrates how you might configure the LDP `traceoptions` statement to filter LDP trace statements based on an FEC:

```
[edit protocols ldp traceoptions]
set flag route filter match-on fec policy "filter-policy-for-ldp-fec";
```

This feature has the following limitations:

- The filtering capability is only available for FECs composed of IP version 4 (IPv4) prefixes.

- Layer 2 circuit FECs cannot be filtered.
- When you configure both route tracing and filtering, MPLS routes are not displayed (they are blocked by the filter).
- Filtering is determined by the policy and the configured value for the `match-on` option. When configuring the policy, be sure that the default behavior is always `reject`.
- The only `match-on` option is `fec`. Consequently, the only type of policy you should include is a route-filter policy.

Examples: Tracing LDP Protocol Traffic

Trace LDP path messages in detail:

```
[edit]
protocols {
    ldp {
        traceoptions {
            file ldp size 10m files 5;
            flag path;
        }
    }
}
```

Trace all LDP outgoing messages:

```
[edit]
protocols {
    ldp {
        traceoptions {
            file ldp size 10m files 5;
            flag packets;
        }
    }
}
```

Trace all LDP error conditions:

```
[edit]
protocols {
```

```
    ldp {
        traceoptions {
            file ldp size 10m files 5;
            flag error;
        }
    }
}
```

Trace all LDP incoming messages and all label-binding operations:

```
[edit]
protocols {
    ldp {
        traceoptions {
            file ldp size 10m files 5 world-readable;
            flag packets receive;
            flag binding;
        }
        interface all {
        }
    }
}
```

Trace LDP protocol traffic for an FEC associated with the LSP:

```
[edit]
protocols {
    ldp {
        traceoptions {
            flag route filter match-on fec policy filter-policy-for-ldp-fec;
        }
    }
}
```

Release History Table

Release	Description
19.1	Starting in Junos OS Release 19.1R1, segment routing-LDP border router can stitch segment routing traffic to LDP next-hop and vice versa.

16.1R1	Starting in Junos OS Release 16.1R1, support for Hashed Message Authentication Code (HMAC) and MD5 authentication for LDP sessions is extended from a per-session configuration to a subnet-match (that is, longest-prefix-match) configuration.
16.1	Starting from Junos OS Release 16.1, M-LDP can signal point-to-multipoint LSPs at ASBR or transit or egress when root address is a BGP route which is further recursively resolved over an MPLS LSP.
14.1	Starting in Junos OS Release 14.1, in order to migrate existing IPTV services from native IP multicast to MPLS multicast, you need to smoothly transition from PIM to M-LDP point-to-multipoint LSPs with minimal outage.

Example: Configuring Multiple-Instance LDP

IN THIS SECTION

- Verifying Your Work | **1541**

The primary LDP instance is configured at the `[edit protocols]` hierarchy level.

You can configure a specific instance of LDP by using the `ldp` statement at the `[edit routing-instances` *`routing-instance-name`* `protocols]` hierarchy level. This creates an instance of LDP for the particular VRF routing instance. You must specify all the required VRF statements and apply export and import policies to your LDP instance for the configuration to commit properly.

Most of the LDP hierarchy levels available in a primary instance are also available for specific instances of LDP. However, the `no-forwarding` option does not work in a VRF-based instance of LDP.

Figure 102: Multiple-Instance LDP Topology Diagram

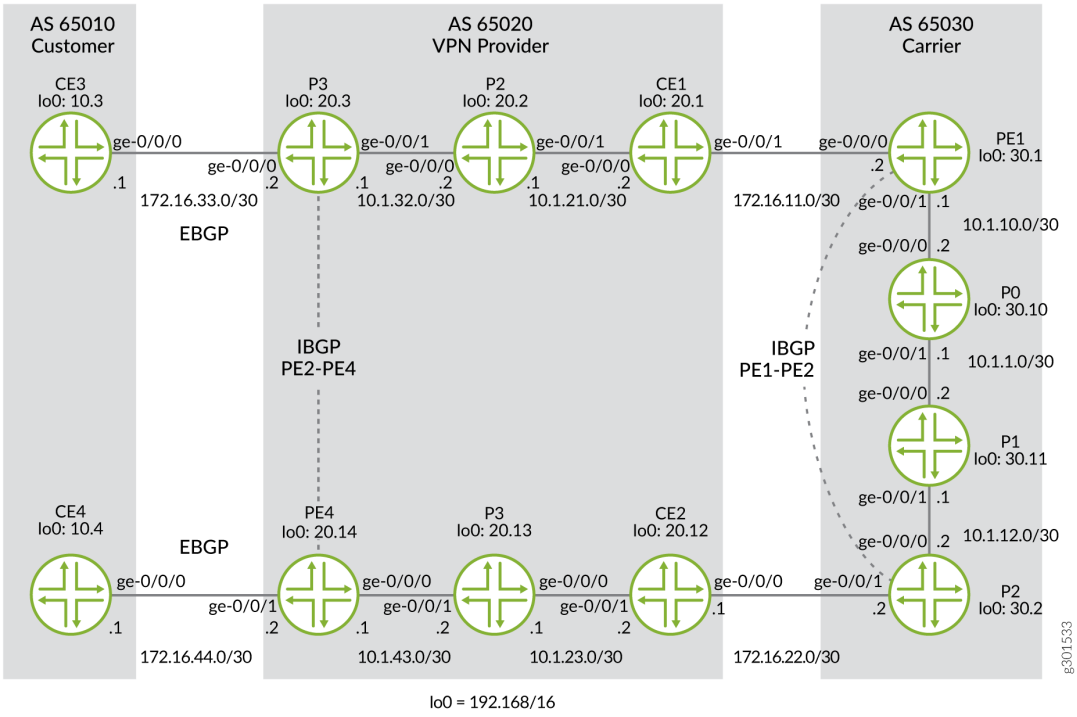

Figure 102 on page 1531 shows an example of a carrier-of-carriers network. CE3 and CE4 are end customer CE routers residing in AS 65010. The VPN provider in AS 65020 has three types of routers: PE3 and PE4 are PE routers that connect to the end customer, CE1 and CE2 act as the intermediate carrier CE routers, and P2 and P3 are internal transit routers. PE1 and PE2 in AS 65030 are PE routers servicing the intermediate VPN provider, and P0 and P1 are transit routers for the top-tier carrier.

To make this configuration work, you must complete three major tasks:

1. Configure external BGP between the VPN customer CE and the VPN provider PE.
2. Configure internal BGP using the VPN family between both pairs of PE routers (one IBGP connection between PE1 and PE2 and a second IBGP connection between Router PE3 and Router PE4).
3. Establish LDP and Interior Gateway Protocol (IGP) connections on all remaining links. This example uses OSPF as the IGP, but you can use the IGP of your choice.

Information supporting this carrier-of-carriers multiple-instance LDP example is summarized in Table 25 on page 1532.

Table 25: Multiple-Instance LDP Example—Routing Protocol Summary

Connection	Protocols
CE3 - PE3	EBGP family inet
PE3 - P2 - CE1	OSPF and LDP
CE1 - PE1	OSPF and LDP
PE1 - P0 - P1 - PE2	OSPF and LDP
PE1 - PE2	IBGP family inet-vpn
PE2 - CE2	OSPF and LDP
CE2 - P3 - PE4	OSPF and LDP
PE4 - CE4	EBGP family inet
PE3 - PE4	IBGP family inet-vpn

Your configuration tasks start at Router CE3 and move router by router through the first part of the VPN provider network, into the carrier AS, through the second VPN provider cluster of AS 65020, and end at the second VPN customer Router CE4.

Since Router CE3 is the first customer router, configure EBGP between Router CE3 and the connected VPN provider Router PE3. You must also advertise your loopback address into BGP with a routing policy to allow IP reachability with Router CE4.

Router CE3

```
user@CE3#
set interfaces ge-0/0/0 description to-PE3
set interfaces ge-0/0/0 unit 0 family inet address 172.16.33.1/30
set interfaces lo0 unit 0 family inet address 192.168.10.3/32
set policy-options policy-statement loopback term 1 from route-filter 192.168.10.3/32 exact
set policy-options policy-statement loopback term 1 then accept
```

```
set policy-options policy-statement loopback term 3 then reject
set protocols bgp group to-PE3 export loopback
set protocols bgp group to-PE3 peer-as 65020
set protocols bgp group to-PE3 neighbor 172.16.33.2
set routing-options router-id 192.168.10.3
set routing-options autonomous-system 65010
```

On Router PE3, the configuration tasks are more involved. You need to complete the EBGP connection to Router CE3 in a VRF instance, enable MPLS and LDP on the interface pointing toward the VPN provider Router CE1, and configure a primary instance of IBGP to reach Router PE4 at the far edge of AS 65020.

Finally, set up an outbound VRF policy that places all BGP traffic and directly connected interfaces into a BGP community and an inbound VRF policy that accepts similar BGP community traffic from Router PE4.

Router PE3

```
user@PE3#
set interfaces ge-0/0/0 description to-CE3
set interfaces ge-0/0/0 unit 0 family inet address 172.16.33.2/30
set interfaces ge-0/0/0 unit 0 family mpls
set interfaces ge-0/0/1 description to-P2
set interfaces ge-0/0/1 unit 0 family inet address 10.1.32.1/30
set interfaces ge-0/0/1 unit 0 family mpls
set interfaces lo0 unit 0 family inet address 192.168.20.3/32
set policy-options policy-statement vpn-customer-export term 1 from protocol bgp
set policy-options policy-statement vpn-customer-export term 1 from protocol direct
set policy-options policy-statement vpn-customer-export term 1 then community add vpn-customer-
comm
set policy-options policy-statement vpn-customer-export term 1 then accept
set policy-options policy-statement vpn-customer-export term 2 then reject
set policy-options policy-statement vpn-customer-import term 1 from protocol bgp
set policy-options policy-statement vpn-customer-import term 1 from community vpn-customer-comm
set policy-options policy-statement vpn-customer-import term 1 then accept
set policy-options policy-statement vpn-customer-import term 2 then reject
set policy-options community vpn-customer-comm members target:65020:1
set routing-instances vpn-customer instance-type vrf
set routing-instances vpn-customer protocols bgp group customer peer-as 65010
set routing-instances vpn-customer protocols bgp group customer as-override
set routing-instances vpn-customer protocols bgp group customer neighbor 172.16.33.1
set routing-instances vpn-customer interface ge-0/0/0.0
set routing-instances vpn-customer route-distinguisher 192.168.20.3:1
```

```
set routing-instances vpn-customer vrf-import vpn-customer-import
set routing-instances vpn-customer vrf-export vpn-customer-export
set protocols bgp group to-PE4 type internal
set protocols bgp group to-PE4 local-address 192.168.20.3
set protocols bgp group to-PE4 neighbor 192.168.20.14 family inet-vpn unicast
set protocols ldp interface ge-0/0/1.0
set protocols mpls interface ge-0/0/1.0
set protocols ospf area 0.0.0.0 interface ge-0/0/1.0
set protocols ospf area 0.0.0.0 interface lo0.0
set routing-options router-id 192.168.20.3
set routing-options autonomous-system 65020
```

On Router P2, enable LDP and the IGP used for transporting labels (in this case, OSPF). You will repeat these tasks on all transit core routers, both in the VPN provider network and the core carrier network.

Router P2

```
user@P2#
set interfaces ge-0/0/0 description to-PE3
set interfaces ge-0/0/0 unit 0 family inet address 10.1.32.2/30
set interfaces ge-0/0/0 unit 0 family mpls
set interfaces ge-0/0/1 description to-CE1
set interfaces ge-0/0/1 unit 0 family inet address 10.1.21.1/30
set interfaces ge-0/0/1 unit 0 family mpls
set interfaces lo0 unit 0 family inet address 192.168.20.2/32
set protocols ldp interface ge-0/0/0.0
set protocols ldp interface ge-0/0/1.0

set protocols ospf area 0.0.0.0 interface lo0.0
set routing-options router-id 192.168.20.1
set routing-options autonomous-system 65020
```

On core carrier Router PE1, configure a primary instance for OSPF, LDP, MPLS, and IBGP (with the `family inet-vpn` option) to connect the router to neighbor Router PE2. Next, implement multiple-instance LDP by establishing a secondary instance. Enable LDP and OSPF in this instance for Router PE1 to communicate with Router CE1. MPLS is not required in the secondary instance.

Finally, set up an outbound VRF policy that places all LDP traffic coming from Router CE1 into a BGP community, an export policy that sends this community traffic to Router PE2, and an inbound VRF policy that accepts similar BGP community traffic from Router PE2. This step tunnels the VPN provider's LDP traffic into the carrier's BGP session.

Router PE1

```
user@PE1#

```

Core carrier Router PE2 is a mirror image of Router PE1. First, configure a primary instance for OSPF, LDP, MPLS, and IBGP (with the `family inet-vpn` option) to connect Router PE2 to neighbor Router PE1. Next, implement multiple-instance LDP by establishing a secondary instance. Enable LDP and OSPF in this instance for Router PE2 to communicate with Router CE2. MPLS is not required in the secondary instance.

Finally, set up an outbound VRF policy that places all LDP traffic coming from Router CE2 into a BGP community, an export policy that sends this community traffic to Router PE1, and an inbound VRF policy that accepts similar BGP community traffic from Router PE1. This step tunnels the VPN provider's LDP traffic into the carrier's BGP session.

Router PE2

```
user@PE2#
set interfaces ge-0/0/0 description to-P1
set interfaces ge-0/0/0 unit 0 family inet address 10.1.12.2/30

set policy-options policy-statement loopback term 3 then reject
set protocols bgp group provider export loopback
set protocols bgp group provider peer-as 65020
set protocols bgp group provider neighbor 172.16.44.2
set routing-options router-id 192.168.10.4
set routing-options autonomous-system 65010
```

Verifying Your Work

To verify the proper operation of your multiple-instance LDP configuration, use the following commands:

- `show ldp database`
- `show ldp interface`
- `show ldp neighbor`
- `show ldp path`
- `show ldp route`
- `show ldp session`
- `show ldp statistics`

The display output for these commands is the same as in previous Junos OS Releases, except for one difference. An instance name can now be used as an argument.

If you include an instance name with these commands, you display information for the specified LDP instance. For example, the command `show ldp neighbor instance crockett` shows all the LDP neighbors for a

VRF instance named `crockett`. Conversely, `show ldp neighbor` without an instance name displays the LDP neighbors associated with the primary instance.

The following sections show the output of these commands used with the configuration example:

Example: Tunneling LDP over SR-TE

IN THIS SECTION

- Requirements | 1557
- Overview | 1558
- Configuration | 1559
- Verification | 1579

Use this example to learn how to tunnel LDP LSPs over SR-TE in your core network.

NOTE: Our content testing team has validated and updated this example.

Requirements

This example uses the following hardware and software components:

- MX Series routers as CE, PE, and core routers.
- Junos OS Release 20.3R1 or later running on all devices.
  - Updated and revalidated using vMX on Junos OS Release 21.1R1.

NOTE: Are you interested in getting hands-on experience on this feature?
Visit Juniper vLabs to reserve your pre-configured vLab Sandbox: Segment Routing - Basic and try it out for free!

Overview

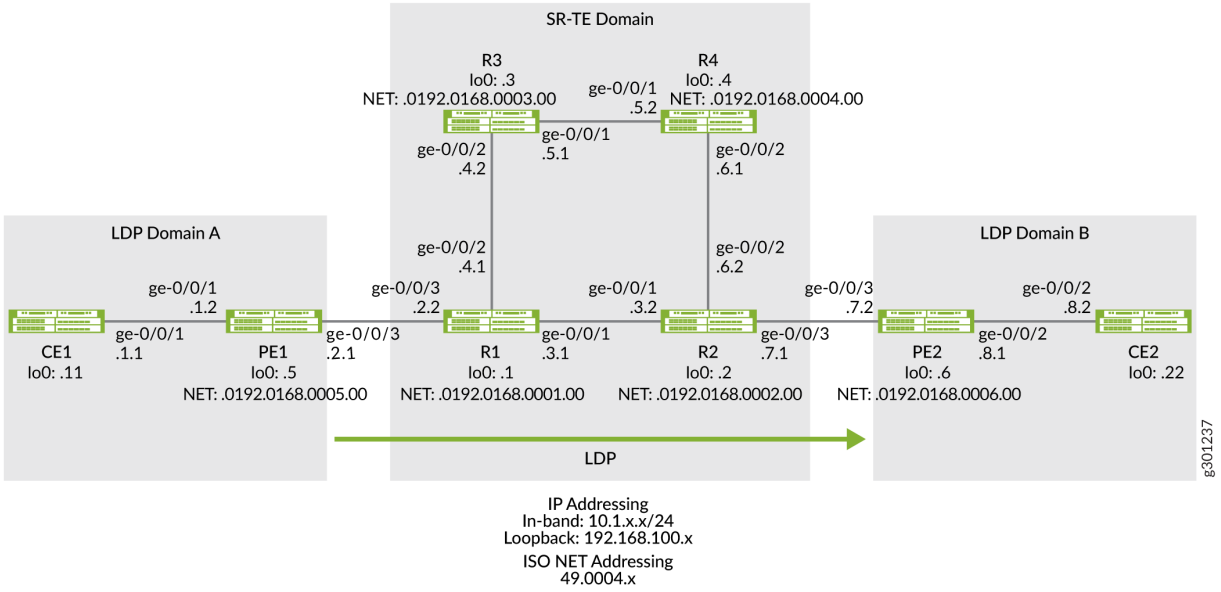
IN THIS SECTION

- Topology | **1558**

The following topology (Figure 103 on page 1558) shows two LDP domains (LDP Domain A and LDP Domain B) connected to the SR-TE core network, which extends the LSP session over the core by tunneling them over SR-TE.

Topology

Figure 103: Tunneling LDP over SR-TE in the Core Network



Configuration

IN THIS SECTION

- CLI Quick Configuration | 1559
- Configuring PE1 | 1567
- Configuring R1 Device | 1572

To tunnel LDP LSP over SR-TE in your core network, perform these tasks:

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the `[edit]` hierarchy level, and then enter `commit` from configuration mode.

Device CE1

```
set chassis network-services enhanced-ip

```

Configuring PE1

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see Using the CLI Editor in Configuration Mode in the CLI User Guide.

To configure device PE1:

1. Configure the network services mode as Enhanced IP. Enhanced IP sets the router's network services to enhanced Internet Protocol and uses enhanced mode capabilities.

   ```
   [edit chassis]
   user@PE1#set network-services enhanced-ip
   ```

   After you configure the `enhanced-ip` statement and commit the configuration, the following warning message appears prompting you to reboot the router:

   ```
   'chassis'
   WARNING: Chassis configuration for network services has been changed. A system reboot is
   mandatory. Please reboot the system NOW. Continuing without a reboot might result in
   unexpected system behavior.
   commit complete
   ```

   The reboot brings up the FPCs on the router.

2. Configure the device's interfaces.

   ```
   [edit interfaces]
   user@PE1#set ge-0/0/1 description PE1-to-CE1
   user@PE1#set ge-0/0/1 unit 0 family inet address 10.1.1.2/24
   user@PE1#set ge-0/0/1 unit 0 family iso

   user@PE1#set ge-0/0/3 description PE1-to-R1
   user@PE1#set ge-0/0/3 unit 0 family inet address 10.1.2.1/24
   user@PE1#set ge-0/0/3 unit 0 family iso
   user@PE1#set ge-0/0/3 unit 0 family mpls
   ```

```
user@PE1#set lo0 unit 0 family inet address 192.168.100.5/32
user@PE1#set lo0 unit 0 family iso address 49.0004.0192.0168.0005.00
user@PE1#set lo0 unit 0 family mpls
```

3. Configure policy options to export BGP routes to the CE router, which runs the OSPF protocol in this example.

```
[edit policy-options]
user@PE1#set policy-statement export_bgp term a from protocol bgp
user@PE1#set policy-statement export_bgp term a from protocol direct
user@PE1#set policy-statement export_bgp term a then accept
```

4. Configure a Layer 3 VPN routing instance to support the OSPF-based CE1 device.

```
[edit routing-instances]
user@PE1#set CE1_vpn1 instance-type vrf
user@PE1#set CE1_vpn1 protocols ospf area 0.0.0.0 interface ge-0/0/1.0
user@PE1#set CE1_vpn1 protocols ospf export export_bgp
user@PE1#set CE1_vpn1 interface ge-0/0/1.0
user@PE1#set CE1_vpn1 route-distinguisher 192.168.100.5:1
user@PE1#set CE1_vpn1 vrf-target target:100:4
user@PE1#set CE1_vpn1 vrf-table-label
```

5. Configure the router ID and autonomous system number for Device PE1.

```
[edit routing-options]
user@PE1#set router-id 192.168.100.5
userPE1# set autonomous-system 65410
```

6. Configure ISIS, LDP, and MPLS on the interfaces connected to the core network.

```
[edit protocols]
user@PE1#set isis interface ge-0/0/3.0 point-to-point
user@PE1#set isis interface lo0.0 passive

user@PE1#set ldp interface ge-0/0/3.0
user@PE1#set ldp interface lo0.0
```

```
user@PE1#set mpls interface ge-0/0/3.0
user@PE1#set mpls interface lo0.0
```

7. Configure BGP between the PE devices.

```
[edit protocols]
user@PE1#set bgp group ibgp1 type internal
user@PE1#set bgp group ibgp1 local-address 192.168.100.5
user@PE1#set bgp group ibgp1 family inet unicast
user@PE1#set bgp group ibgp1 family inet-vpn unicast
user@PE1#set bgp group ibgp1 neighbor 192.168.100.6
```

Results

From configuration mode, confirm your configuration by entering the `show chassis`, `show interfaces`, `show policy-options`, `show routing-instances`,`show routing-options`, and `show protocols` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1#show chassis
network-services enhanced-ip;
```

```
user@PE1#show interfaces

```

Configuring R1 Device

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see Using the CLI Editor in Configuration Mode in the CLI User Guide.

To configure device R1:

1. Configure the network services mode as Enhanced IP. Enhanced IP sets the router's network services to enhanced Internet Protocol and uses enhanced mode capabilities.

   ```
   [edit chassis]
   user@R1#set network-services enhanced-ip
   ```

   After you configure the `enhanced-ip` statement and commit the configuration, the following warning message appears prompting you to reboot the router:

   ```
   'chassis'
   WARNING: Chassis configuration for network services has been changed. A system reboot is
   mandatory. Please reboot the system NOW. Continuing without a reboot might result in
   unexpected system behavior.
   commit complete
   ```

   The reboot brings up the FPCs on the router.

2. Configure the device's interfaces.

   ```
   [edit interfaces]
   user@R1#set ge-0/0/1 description R1-to-R2
   user@R1#set ge-0/0/1 unit 0 family inet address 10.1.3.1/24
   user@R1#set ge-0/0/1 unit 0 family iso
   user@R1#set ge-0/0/1 unit 0 family mpls maximum-labels 8

   user@R1#set ge-0/0/2 description R1-to-R3
   user@R1#set ge-0/0/2 unit 0 family inet address 10.1.4.1/24
   user@R1#set ge-0/0/2 unit 0 family iso
   ```

```
user@R1#set ge-0/0/2 unit 0 family mpls maximum-labels 8

user@R1#set ge-0/0/3 description R1-to-PE1
user@R1#set ge-0/0/3 unit 0 family inet address 10.1.2.2/24
user@R1#set ge-0/0/3 unit 0 family iso
user@R1#set ge-0/0/3 unit 0 family mpls maximum-labels 8

user@R1#set lo0 unit 0 family inet address 192.168.100.1/32
user@R1#set lo0 unit 0 family iso address 49.0004.0192.0168.0001.00
user@R1#set lo0 unit 0 family mpls
```

3. Configure routing options to identify the router in the domain.

```
[edit routing-options]
user@R1#set router-id 192.168.100.1
```

4. Configure ISIS adjacency SIDs on the interfaces and allocate SRGB labels to enable segment routing. The labels in the entire SRGB are available for ISIS. Prefix SIDs (and Node SIDs) are indexed from the SRGB.

```
[edit protocols]
user@R1#set isis interface ge-0/0/1.0 level 2 ipv4-adjacency-segment protected index 108
user@R1#set isis interface ge-0/0/1.0 level 2 ipv4-adjacency-segment unprotected index 110
user@R1#set isis interface ge-0/0/1.0 level 2 ipv6-adjacency-segment protected index 109
user@R1#set isis interface ge-0/0/1.0 level 2 ipv6-adjacency-segment unprotected index 111
user@R1#set isis interface ge-0/0/1.0 level 2 post-convergence-lfa
user@R1#set isis interface ge-0/0/1.0 point-to-point

user@R1#set isis interface ge-0/0/2.0 level 2 ipv4-adjacency-segment protected index 104
user@R1#set isis interface ge-0/0/2.0 level 2 ipv4-adjacency-segment unprotected index 106
user@R1#set isis interface ge-0/0/2.0 level 2 ipv6-adjacency-segment protected index 105
user@R1#set isis interface ge-0/0/2.0 level 2 ipv6-adjacency-segment unprotected index 107
user@R1#set isis interface ge-0/0/2.0 level 2 post-convergence-lfa
user@R1#set isis interface ge-0/0/2.0 point-to-point

user@R1#set isis interface ge-0/0/3.0 level 2 ipv4-adjacency-segment protected index 100
user@R1#set isis interface ge-0/0/3.0 level 2 ipv4-adjacency-segment unprotected index 102
user@R1#set isis interface ge-0/0/3.0 level 2 ipv6-adjacency-segment protected index 101
user@R1#set isis interface ge-0/0/3.0 level 2 ipv6-adjacency-segment unprotected index 103
user@R1#set isis interface ge-0/0/3.0 level 2 post-convergence-lfa
user@R1#set isis interface ge-0/0/3.0 point-to-point
```

```
user@R1#set isis interface lo0.0 passive

user@R1#set isis source-packet-routing srgb start-label 80000
user@R1#set isis source-packet-routing srgb index-range 50000
user@R1#set isis source-packet-routing node-segment ipv4-index 5001
user@R1#set isis source-packet-routing node-segment ipv6-index 5501
user@R1#set isis level 1 disable
```

5. Configure TI-LFA to enable protection against link and node failures. SR using TI-LFA provides faster restoration of network connectivity by routing the traffic instantly to a backup or an alternate path if the primary path fails or becomes unavailable.

```
[edit protocols]
user@R1#set isis backup-spf-options use-post-convergence-lfa
user@R1#set isis backup-spf-options use-source-packet-routing
```

6. Configure ISIS traffic engineering parameters.

```
[edit protocols]
user@R1#set isis traffic-engineering l3-unicast-topology
user@R1#set isis traffic-engineering credibility-protocol-preference
```

7. Enable LDP tunneling over SR-TE.

```
[edit protocols]
user@R1#set isis traffic-engineering tunnel-source-protocol spring-te
```

8. Configure MPLS and LDP protocols on the interfaces in the LDP domain to exchange labels in the LDP domain.

```
[edit protocols]
user@R1#set ldp preference 1
user@R1#set ldp interface ge-0/0/3.0
user@R1#set ldp interface lo0.0

user@R1#set mpls interface ge-0/0/1.0
user@R1#set mpls interface ge-0/0/2.0
```

```
user@R1#set mpls interface ge-0/0/3.0
user@R1#set mpls interface lo0.0
```

9. Enable targeted LDP session between the edge routers in the LDP domain.

```
[edit protocols]
user@R1#set ldp auto-targeted-session
```

10. Configure a segment list to route the traffic to a specific path.

```
[edit protocols]
user@R1#set source-packet-routing segment-list seg1 inherit-label-nexthops
user@R1#set source-packet-routing segment-list seg1 auto-translate
user@R1#set source-packet-routing segment-list seg1 hop1 ip-address 192.168.4.2
user@R1#set source-packet-routing segment-list seg1 hop2 ip-address 192.168.5.2
user@R1#set source-packet-routing segment-list seg1 hop3 ip-address 192.168.6.2
```

11. Configure SR-TE LSP to the remote edge routers to enable LDP tunneling over SR-TE.

```
[edit protocols]
user@R1#set source-packet-routing source-routing-path sr_static_r5 ldp-tunneling
user@R1#set source-packet-routing source-routing-path sr_static_r5 to 192.168.66.66
user@R1#set source-packet-routing source-routing-path sr_static_r5 binding-sid 1003001
user@R1#set source-packet-routing source-routing-path sr_static_r5 primary seg1
```

Results

From configuration mode, confirm your configuration by entering the `show chassis`, `show interfaces`, `show routing-options`, and `show protocols` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

Verification

IN THIS SECTION

- Verifying LDP Tunneling over SR-TE | **1579**
- Verify LDP Forwarding to the Remote PE Device | **1581**
- Verifying the Advertised Label | **1584**

To confirm that the configuration is working properly, perform the following tasks:

Verifying LDP Tunneling over SR-TE

Purpose

Verify that the LDP over SR-TE tunnel is enabled and the LDP tunnel to the remote edge router is taking the right path.

Action

From operational mode, run the `show spring-traffic-engineering lsp detail` command.

On R1

```
user@R1>show spring-traffic-engineering lsp detail
Name: sr_static_r5
  Tunnel-source: Static configuration
  To: 192.168.100.2
  State: Up
  LDP-tunneling enabled
    Path: seg1
    Outgoing interface: NA
    Auto-translate status: Enabled Auto-translate result: Success
    Compute Status:Disabled , Compute Result:N/A , Compute-Profile Name:N/A
    BFD status: N/A BFD name: N/A
    ERO Valid: true
      SR-ERO hop count: 3
        Hop 1 (Strict):
          NAI: IPv4 Adjacency ID, 0.0.0.0 -> 10.1.4.2
          SID type: 20-bit label, Value: 80104
        Hop 2 (Strict):
          NAI: IPv4 Adjacency ID, 0.0.0.0 -> 10.1.5.2
          SID type: 20-bit label, Value: 80204
        Hop 3 (Strict):
          NAI: IPv4 Adjacency ID, 0.0.0.0 -> 10.1.6.2
          SID type: 20-bit label, Value: 80304

Total displayed LSPs: 1 (Up: 1, Down: 0)
```

On R2

```
user@R2>show spring-traffic-engineering lsp detail

Name: sr_static_r1
  Tunnel-source: Static configuration
  To: 192.168.100.1
  State: Up
  LDP-tunneling enabled
```

```
    Path: seg1
    Outgoing interface: NA
    Auto-translate status: Enabled Auto-translate result: Success
    Compute Status:Disabled , Compute Result:N/A , Compute-Profile Name:N/A
    BFD status: N/A BFD name: N/A
    ERO Valid: true

```

Meaning

- On R1, the LDP tunnel is established with the remote edge router **192.168.100.2** in the SR-TE core network. You can also see the SID label values **80104, 80204, 80304** in the output.
- On R2, the LDP tunnel is established with the remote edge router **192.168.100.1** in the SR-TE core network. You can also see the SID label values **80504, 80300, 80200** in the output.

Verify LDP Forwarding to the Remote PE Device

Purpose

Verify that the route to the remote PE router uses LDP forwarding and is tunneled over SR-TE.

Action

From operational mode, run the `show route` *`destination-prefix`* command.

On R1

Verify that the route to the remote PE (**PE2**) router is through LDP over SR-TE tunnel.

```
user@R1>show route 192.168.100.6

inet.0: 24 destinations, 24 routes (24 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192.168.100.6/32   *[IS-IS/18] 5d 13:10:09, metric 20
                    >  to 10.1.3.2 via ge-0/0/1.0

inet.3: 8 destinations, 13 routes (5 active, 0 holddown, 6 hidden)
+ = Active Route, - = Last Active, * = Both

192.168.100.6/32   *[LDP/1] 5d 13:10:09, metric 1
                    >  to 10.1.4.2 via ge-0/0/2.0, Push 16, Push 80304, Push 80204(top)
                       to 10.1.3.2 via ge-0/0/1.0, Push 16, Push 80304, Push 80204, Push 85003,
Push 85004(top)
```

On R2

Verify that the route to the remote PE (**PE1**) router is through LDP over SR-TE tunnel.

```
user@R2>show route 192.168.100.5

inet.0: 24 destinations, 24 routes (24 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192.168.100.5/32   *[IS-IS/18] 5d 13:20:15, metric 20
                    >  to 10.1.3.1 via ge-0/0/1.0

inet.3: 8 destinations, 13 routes (5 active, 0 holddown, 6 hidden)
+ = Active Route, - = Last Active, * = Both

192.168.100.5/32   *[LDP/9] 5d 13:20:15, metric 1
                    >  to 10.1.6.1 via ge-0/0/2.0, Push 16, Push 80200, Push 80300(top)
                       to 10.1.3.1 via ge-0/0/1.0, Push 16, Push 80200, Push 80300, Push 85004,
Push 85003(top)
```

On PE1

Verify that the route to the remote PE (**PE2**) router is through a targeted LDP session to the remote PE.

```
user@PE1>show route 192.168.100.6

inet.0: 22 destinations, 22 routes (22 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192.168.100.6/32   *[IS-IS/18] 1w3d 15:58:20, metric 30
                    >  to 10.1.2.2 via ge-0/0/3.0

inet.3: 3 destinations, 3 routes (3 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192.168.100.6/32   *[LDP/9] 1w0d 16:00:05, metric 1
                    >  to 10.1.2.2 via ge-0/0/3.0, Push 18
```

On PE2

Verify that the route to the remote PE (**PE1**) router is through a targeted LDP session to the remote PE.

```
user@PE2>show route 192.168.100.5

inet.0: 22 destinations, 22 routes (22 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192.168.100.5/32   *[IS-IS/18] 1w3d 15:59:19, metric 30
                    >  to 10.1.7.1 via ge-0/0/3.0

inet.3: 3 destinations, 3 routes (3 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192.168.100.5/32   *[LDP/9] 1w0d 16:01:14, metric 1
                    >  to 10.1.7.1 via ge-0/0/3.0, Push 18
```

Meaning

- On R1, you can see the LDP label as **16** and the SR-TE label stacks as **80304, 80204, 85003, 85004**.
- On R2, you can see the LDP label as **16** and the SR-TE label stacks as **80200, 80300, 85004, 85003**.
- On PE1 and PE2, you can see the LDP label as **18** and **19**, respectively.

Verifying the Advertised Label

Purpose

Verify the labels advertised for the forwarding equivalence class (FEC).

Action

From operational mode, run the `show ldp database` command.

On R1

Verify the labels advertised towards the directly connected PE (PE1) and the labels received from remote edge router (R2).

```
user@R1>show ldp database

Input label database, 192.168.100.1:0--192.168.100.2:0

MPLS and Traffic Engineering

Traffic engineering allows you to control the path that data packets follow, bypassing the standard routing model, which uses routing tables. Traffic engineering moves flows from congested links to alternate links that would not be selected by the automatically computed destination-based shortest path. With traffic engineering, you can:

- Make more efficient use of expensive long-haul fibers.
- Control how traffic is rerouted in the face of single or multiple failures.
- Classify critical and regular traffic on a per-path basis.

The core of the traffic engineering design is based on building label-switched paths (LSPs) among routers. An LSP is connection-oriented, like a virtual circuit in Frame Relay or ATM. LSPs are not reliable: Packets entering an LSP do not have delivery guarantees, although preferential treatment is possible. LSPs also are similar to unidirectional tunnels in that packets entering a path are encapsulated in an envelope and switched across the entire path without being touched by intermediate nodes. LSPs provide fine-grained control over how packets are forwarded in a network. To provide reliability, an LSP can use a set of primary and secondary paths.

LSPs can be configured for BGP traffic only (traffic whose destination is outside of an autonomous system [AS]). In this case, traffic within the AS is not affected by the presence of LSPs. LSPs can also be configured for both BGP and interior gateway protocol (IGP) traffic; therefore, both intra-AS and inter-AS traffic is affected by the LSPs.

MPLS Traffic Engineering and Signaling Protocols Overview

Traffic engineering facilitates efficient and reliable network operations while simultaneously optimizing network resources and traffic performance. Traffic engineering provides the ability to move traffic flow away from the shortest path selected by the interior gateway protocol (IGP) to a potentially less congested physical path across a network. To support traffic engineering, besides source routing, the network must do the following:

- Compute a path at the source by taking into account all the constraints, such as bandwidth and administrative requirements.
- Distribute the information about network topology and link attributes throughout the network once the path is computed.
- Reserve network resources and modify link attributes.

When transit traffic is routed through an IP network, MPLS is often used to engineer its passage. Although the exact path through the transit network is of little importance to either the sender or the receiver of the traffic, network administrators often want to route traffic more efficiently between certain source and destination address pairs. By adding a short label with specific routing instructions to each packet, MPLS switches packets from router to router through the network rather than forwarding

packets based on next-hop lookups. The resulting routes are called *label-switched paths (LSPs)*. LSPs control the passage of traffic through the network and speed traffic forwarding.

You can create LSPs manually, or through the use of signaling protocols. Signaling protocols are used within an MPLS environment to establish LSPs for traffic across a transit network. Junos OS supports two signaling protocols—LDP and the Resource Reservation Protocol (RSVP).

MPLS traffic engineering uses the following components:

- MPLS LSPs for packet forwarding
- IGP extensions for distributing information about the network topology and link attributes
- Constrained Shortest Path First (CSPF) for path computation and path selection
- RSVP extensions to establish the forwarding state along the path and to reserve resources along the path

Junos OS also supports traffic engineering across different OSPF regions.

Traffic Engineering Capabilities

The task of mapping traffic flows onto an existing physical topology is called *traffic engineering*. Traffic engineering provides the ability to move traffic flow away from the shortest path selected by the interior gateway protocol (IGP) and onto a potentially less congested physical path across a network.

Traffic engineering provides the capabilities to do the following:

- Route primary paths around known bottlenecks or points of congestion in the network.
- Provide precise control over how traffic is rerouted when the primary path is faced with single or multiple failures.
- Provide more efficient use of available aggregate bandwidth and long-haul fiber by ensuring that subsets of the network do not become overutilized while other subsets of the network along potential alternate paths are underutilized.
- Maximize operational efficiency.
- Enhance the traffic-oriented performance characteristics of the network by minimizing packet loss, minimizing prolonged periods of congestion, and maximizing throughput.
- Enhance statistically bound performance characteristics of the network (such as loss ratio, delay variation, and transfer delay) required to support a multiservices Internet.

Components of Traffic Engineering

In the Junos® operating system (OS), traffic engineering is implemented with MPLS and RSVP. Traffic engineering is composed of four functional components:

- "Packet Forwarding Component" on page 1599
- Information Distribution Component
- Path Selection Component
- Signaling Component

Configuring Traffic Engineering for LSPs

IN THIS SECTION

- Using LSPs for Both BGP and IGP Traffic Forwarding | **1592**
- Using LSPs for Forwarding in Virtual Private Networks | **1593**
- Using RSVP and LDP Routes for Forwarding but Not Route Selection | **1594**
- Advertising the LSP Metric in Summary LSAs | **1595**

When you configure an LSP, a host route (a 32-bit mask) is installed in the ingress router toward the egress router; the address of the host route is the destination address of the LSP. The `bgp` option for the `traffic engineering` statement at the `[edit protocols mpls]` hierarchy level is enabled by default (you can also explicitly configure the `bgp` option), allowing only BGP to use LSPs in its route calculations. The other `traffic-engineering` statement options allow you to alter this behavior in the master routing instance. This functionality is not available for specific routing instances. Also, you can enable only one of the `traffic-engineering` statement options (`bgp`, `bgp-igp`, `bgp-igp-both-ribs`, or `mpls-forwarding`) at a time.

NOTE: Enabling or disabling any of the `traffic-engineering` statement options causes all the MPLS routes to be removed and then reinserted into the routing tables.

You can configure OSPF and traffic engineering to advertise the LSP metric in summary link-state advertisements (LSAs) as described in the section "Advertising the LSP Metric in Summary LSAs" on page 1595.

The following sections describe how to configure traffic engineering for LSPs:

Using LSPs for Both BGP and IGP Traffic Forwarding

You can configure BGP and the IGPs to use LSPs for forwarding traffic destined for egress routers by including the `bgp-igp` option for the `traffic-engineering` statement. The `bgp-igp` option causes all inet.3 routes to be moved to the inet.0 routing table.

On the ingress router, include bgp-igp option for the traffic-engineering statement:

```
traffic-engineering bgp-igp;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls]
- [edit logical-systems *logical-system-name* protocols mpls]

> **NOTE**: The bgp-igp option for the traffic-engineering statement cannot be configured for VPN). VPNs require that routes be in the inet.3 routing table.

Using LSPs for Forwarding in Virtual Private Networks

VPNs require that routes remain in the inet.3 routing table to function properly. For VPNs, configure the bgp-igp-both-ribs option of the traffic-engineering statement to cause BGP and the IGPs to use LSPs for forwarding traffic destined for egress routers. The bgp-igp-both-ribs option installs the ingress routes in both the inet.0 routing table (for IPv4 unicast routes) and the inet.3 routing table (for MPLS path information).

On the ingress router, include the traffic-engineering bgp-igp-both-ribs statement:

```
traffic-engineering bgp-igp-both-ribs;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls]
- [edit logical-systems *logical-system-name* protocols mpls]

When you use the bgp-igp-both-ribs statement, the routes from the inet.3 table get copied into the inet.0 table. The copied routes are LDP-signaled or RSVP-signaled, and are likely to have a lower preference than other routes in inet.0. Routes with a lower preference are more likely to be chosen as the active routes. This can be a problem because routing policies only act upon active routes. To prevent this problem, use the mpls-forwarding option instead.

Using RSVP and LDP Routes for Forwarding but Not Route Selection

If you configure the `bgp-igp` or `bgp-igp-both-ribs` options for the `traffic-engineering` statement, high-priority LSPs can supersede IGP routes in the inet.0 routing table. IGP routes might no longer be redistributed since they are no longer the active routes.

If you configure the `mpls-forwarding` option for the `traffic-engineering` statement, LSPs are used for forwarding but are excluded from route selection. These routes are added to both the inet.0 and inet.3 routing tables. LSPs in the inet.0 routing table are given a low preference when the active route is selected. However, LSPs in the inet.3 routing table are given a normal preference and are therefore used for selecting forwarding next hops.

When you activate the `mpls-forwarding` option, routes whose state is `ForwardingOnly` are preferred for forwarding even if their preference is lower than that of the currently active route. To examine the state of a route, execute a `show route detail` command.

To use LSPs for forwarding but exclude them from route selection, include the `mpls-forwarding` option for the `traffic-engineering` statement:

```
traffic-engineering mpls-forwarding;
```

You can include this statement at the following hierarchy levels:

- `[edit protocols mpls]`
- `[edit logical-systems` *`logical-system-name`* `protocols mpls]`

When you configure the `mpls-forwarding` option, IGP shortcut routes are copied to the inet.0 routing table only.

Unlike the `bgp-igp-both-ribs` option, the `mpls-forwarding` option allows you to use the LDP-signaled and RSVP-signaled routes for forwarding, and keep the BGP and IGP routes active for routing purposes so that routing policies can act upon them.

For example, suppose a router is running BGP and it has a BGP route of 10.10.10.1/32 that it needs to send to another BGP speaker. If you use the `bgp-igp-both-ribs` option, and your router also has a label-switched-path (LSP) to 10.10.10.1, the MPLS route for 10.10.10.1 becomes active in the inet.0 routing table. This prevents your router from advertising the 10.10.10.1 route to the other BGP router. On the other hand, if you use the `mpls-forwarding` option instead of the `bgp-igp-both-ribs` option, the 10.10.10.1/32 BGP route is advertised to the other BGP speaker, and the LSP is still used to forward traffic to the 10.10.10.1 destination.

Advertising the LSP Metric in Summary LSAs

You can configure MPLS and OSPF to treat an LSP as a link. This configuration allows other routers in the network to use this LSP. To accomplish this goal, you need to configure MPLS and OSPF traffic engineering to advertise the LSP metric in summary LSAs.

For MPLS, include the `traffic-engineering bgp-igp` and `label-switched-path` statements:

```
traffic-engineering bgp-igp;
label-switched-path lsp-name {
    to address;
}

You can include these statements at the following hierarchy levels:

- `[edit protocols mpls]`
- `[edit logical-systems logical-system-name protocols mpls]`

For OSPF, include the `lsp-metric-into-summary` statement:

```
lsp-metric-into-summary;
```

You can include this statement at the following hierarchy levels:

- `[edit protocols ospf traffic-engineering shortcuts]`
- `[edit logical-systems logical-system-name protocols ospf traffic-engineering shortcuts]`

For more information about OSPF traffic engineering, see the Junos OS Routing Protocols Library for Routing Devices.

Enabling Interarea Traffic Engineering

The Junos OS can signal a contiguous traffic-engineered LSP across multiple OSPF areas. The LSP signaling must be done using either nesting or contiguous signaling, as described in RFC 4206, *Label-Switched Paths (LSP) Hierarchy with Generalized Multi-Protocol Label Switching (GMPLS) Traffic Engineering (TE)*. However, contiguous signaling support is limited to just basic signaling. Reoptimization is not supported with contiguous signaling.

The following describes some of the interarea traffic engineering features:

- Interarea traffic engineering can be enabled when the loose-hop area border routers (ABRs) are configured on the ingress router using CSPF for the Explicit Route Object (ERO) calculation within an OSPF area. ERO expansion is completed on the ABRs.

- Interarea traffic engineering can be enabled when CSPF is enabled, but without ABRs specified in the LSP configuration on the ingress router (ABRs can be automatically designated).
- Differentiated Services (DiffServ) traffic engineering is supported as long as the class type mappings are uniform across multiple areas.

To enable interarea traffic engineering, include the `expand-loose-hop` statement in the configuration for each LSP transit router:

```
expand-loose-hop;
```

You can include this statement at the following hierarchy levels:

- `[edit protocols mpls]`
- `[edit logical-systems` *`logical-system-name`* `protocols mpls]`

Enabling Inter-AS Traffic Engineering for LSPs

IN THIS SECTION

- Inter-AS Traffic Engineering Requirements | **1597**
- Inter-AS Traffic Engineering Limitations | **1597**
- Configuring OSPF Passive TE Mode | **1598**

Generally, traffic engineering is possible for LSPs that meet the following conditions:

- Both ends of the LSP are in the same OSPF area or at the same IS-IS level.
- The two ends of the LSP are in different OSPF areas within the same autonomous system (AS). LSPs that end in different IS-IS levels are not supported.
- The two ends of an explicit-path LSP are in different OSPF ASs and the autonomous system border routers (ASBRs) are configured statically as the loose hops supported on the explicit-path LSP. For more information, see "Configuring Explicit-Path LSPs" on page 656.

Without statically defined ASBRs on LSPs, traffic engineering is not possible between one routing domain, or AS, and another. However, when the ASs are under the control of single service provider, it is possible in some cases to have traffic engineered LSPs span the ASs and dynamically discover the OSPF ASBRs linking them (IS-IS is not supported with this feature).

Inter-AS traffic engineered LSPs are possible as long as certain network requirements are met, none of the limiting conditions apply, and OSPF passive mode is configured with EBGP. Details are provided in the following sections:

Inter-AS Traffic Engineering Requirements

The proper establishment and functioning of inter-AS traffic engineered LSPs depend on the following network requirements, all of which must be met:

- All ASs are under control of a single service provider.
- OSPF is used as the routing protocol within each AS, and EBGP is used as the routing protocol between the ASs.
- ASBR information is available inside each AS.
- EBGP routing information is distributed by OSPF, and an IBGP full mesh is in place within each AS.
- Transit LSPs are *not* configured on the inter-AS links, but *are* configured between entry and exit point ASBRs on each AS.
- The EBGP link between ASBRs in different ASs is a direct link and must be configured as a passive traffic engineering link under OSPF. The remote link address itself, not the loopback or any other link address, is used as the remote node identifier for this passive link. For more information about OSPF passive traffic engineering mode configuration, see "Configuring OSPF Passive TE Mode" on page 1598.

In addition, the address used for the remote node of the OSPF passive traffic engineering link must be the same as the address used for the EBGP link. For more information about OSPF and BGP in general, see the Junos OS Routing Protocols Library for Routing Devices.

Inter-AS Traffic Engineering Limitations

Only LSP hierarchical, or nested, signaling is supported for inter-AS traffic engineered LSPs. Only point-to-point LSPs are supported (there is no point-to-multipoint support).

In addition, the following limitations apply. Any one of these conditions is sufficient to render inter-AS traffic engineered LSPs impossible, even if the above requirements are met.

- The use of multihop BGP is not supported.
- The use of policers or topologies that prevent BGP routes from being known inside the AS is not supported.
- Multiple ASBRs on a LAN between EBGP peers are not supported. Only one ASBR on a LAN between EBGP peers is supported (others ASBRs can exist on the LAN, but cannot be advertised).

- Route reflectors or policies that hide ASBR information or prevent ASBR information from being distributed inside the ASs are not supported.
- Bidirectional LSPs are not supported (LSPs are unidirectional from the traffic engineering perspective).
- Topologies with both inter-AS and intra-AS paths to the same destination are not supported.

In addition, several features that are routine with all LSPs are not supported with inter-AS traffic engineering:

- Admin group link colors are not supported.
- Secondary standby is not supported.
- Reoptimization is not supported.
- Crankback on transit routers is not supported.
- Diverse path calculation is not supported.
- Graceful restart is not supported.

These lists of limitations or unsupported features with inter-AS traffic engineered LSPs are not exhaustive.

Configuring OSPF Passive TE Mode

Ordinarily, interior routing protocols such as OSPF are not run on links between ASs. However, for inter-AS traffic engineering to function properly, information about the inter-AS link, in particular, the address on the remote interface, must be made available inside the AS. This information is not normally included either in EBGP reachability messages or in OSPF routing advertisements.

To flood this link address information within the AS and make it available for traffic engineering calculations, you must configure OSPF passive mode for traffic engineering on each inter-AS interface. You must also supply the remote address for OSPF to distribute and include in the traffic engineering database.

To configure OSPF passive mode for traffic engineering on an inter-AS interface, include the `passive` statement for the link at the `[edit protocols ospf area` *`area-id`* `interface` *`interface-name`*`]` hierarchy level:

```
passive {
    traffic-engineering {
        remote-node-id ip-address;     /* IP address at far end of inter-AS link */
```

```
    }
}
```

OSPF must be properly configured on the router. The following example configures the inter-AS link so-1/1/0 to distribute traffic engineering information with OSPF within the AS. The remote IP address is 192.168.207.2.

```
[edit protocols ospf area 0.0.0.0]
interface so-1/1/0 {
    unit 0 {
        passive {
            traffic-engineering {
                remote-node-id 192.168.207.2;
            }
        }
    }
}
```

Packet Forwarding Component

IN THIS SECTION

- Packet Forwarding Based on Label Swapping | **1600**
- How a Packet Traverses an MPLS Backbone | **1600**
- Information Distribution Component | **1600**
- Path Selection Component | **1601**
- Signaling Component | **1602**

The packet forwarding component of the Junos traffic engineering architecture is MPLS, which is responsible for directing a flow of IP packets along a predetermined path across a network. This path is called a *label-switched path (LSP)*. LSPs are simplex; that is, the traffic flows in one direction from the head-end (ingress) router to a tail-end (egress) router. Duplex traffic requires two LSPs: one LSP to carry traffic in each direction. An LSP is created by the concatenation of one or more label-switched hops, allowing a packet to be forwarded from one router to another across the MPLS domain.

When an ingress router receives an IP packet, it adds an MPLS header to the packet and forwards it to the next router in the LSP. The labeled packet is forwarded along the LSP by each router until it reaches the tail end of the LSP, the egress router. At this point the MPLS header is removed, and the packet is

forwarded based on Layer 3 information such as the IP destination address. The value of this scheme is that the physical path of the LSP is not limited to what the IGP would choose as the shortest path to reach the destination IP address.

Packet Forwarding Based on Label Swapping

The packet forwarding process at each router is based on the concept of label swapping. This concept is similar to what occurs at each Asynchronous Transfer Mode (ATM) switch in a permanent virtual circuit (PVC). Each MPLS packet carries a 4-byte encapsulation header that contains a 20-bit, fixed-length label field. When a packet containing a label arrives at a router, the router examines the label and copies it as an index to its MPLS forwarding table. Each entry in the forwarding table contains an interface-inbound label pair mapped to a set of forwarding information that is applied to all packets arriving on the specific interface with the same inbound label.

How a Packet Traverses an MPLS Backbone

This section describes how an IP packet is processed as it traverses an MPLS backbone network.

At the entry edge of the MPLS backbone, the IP header is examined by the ingress router. Based on this analysis, the packet is classified, assigned a label, encapsulated in an MPLS header, and forwarded toward the next hop in the LSP. MPLS provides a high degree of flexibility in the way that an IP packet can be assigned to an LSP. For example, in the Junos traffic engineering implementation, all packets arriving at the ingress router that are destined to exit the MPLS domain at the same egress router are forwarded along the same LSP.

Once the packet begins to traverse the LSP, each router uses the label to make the forwarding decision. The MPLS forwarding decision is made independently of the original IP header: the incoming interface and label are used as lookup keys into the MPLS forwarding table. The old label is replaced with a new label, and the packet is forwarded to the next hop along the LSP. This process is repeated at each router in the LSP until the packet reaches the egress router.

When the packet arrives at the egress router, the label is removed and the packet exits the MPLS domain. The packet is then forwarded based on the destination IP address contained in the packet's original IP header according to the traditional shortest path calculated by the IP routing protocol.

Information Distribution Component

Traffic engineering requires detailed knowledge about the network topology as well as dynamic information about network loading. To implement the information distribution component, simple extensions to the IGPs are defined. Link attributes are included as part of each router's link-state advertisement. IS-IS extensions include the definition of new type length values (TLVs), whereas OSPF extensions are implemented with opaque link-state advertisements (LSAs). The standard flooding algorithm used by the link-state IGPs ensures that link attributes are distributed to all routers in the routing domain. Some of the traffic engineering extensions to be added to the IGP link-state

advertisement include maximum link bandwidth, maximum reserved link bandwidth, current bandwidth reservation, and link coloring.

Each router maintains network link attributes and topology information in a specialized traffic engineering database. The traffic engineering database is used exclusively for calculating explicit paths for the placement of LSPs across the physical topology. A separate database is maintained so that the subsequent traffic engineering computation is independent of the IGP and the IGP's link-state database. Meanwhile, the IGP continues its operation without modification, performing the traditional shortest-path calculation based on information contained in the router's link-state database.

Path Selection Component

After network link attributes and topology information are flooded by the IGP and placed in the traffic engineering database, each ingress router uses the traffic engineering database to calculate the paths for its own set of LSPs across the routing domain. The path for each LSP can be represented by either a strict or loose explicit route. An explicit route is a preconfigured sequence of routers that should be part of the physical path of the LSP. If the ingress router specifies all the routers in the LSP, the LSP is said to be identified by a strict explicit route. If the ingress router specifies only some of the routers in the LSP, the LSP is described as a loose explicit route. Support for strict and loose explicit routes allows the path selection process to be given broad latitude whenever possible, but to be constrained when necessary.

The ingress router determines the physical path for each LSP by applying a Constrained Shortest Path First (CSPF) algorithm to the information in the traffic engineering database. CSPF is a shortest-path-first algorithm that has been modified to take into account specific restrictions when the shortest path across the network is calculated. Input into the CSPF algorithm includes:

- Topology link-state information learned from the IGP and maintained in the traffic engineering database
- Attributes associated with the state of network resources (such as total link bandwidth, reserved link bandwidth, available link bandwidth, and link color) that are carried by IGP extensions and stored in the traffic engineering database
- Administrative attributes required to support traffic traversing the proposed LSP (such as bandwidth requirements, maximum hop count, and administrative policy requirements) that are obtained from user configuration

As CSPF considers each candidate node and link for a new LSP, it either accepts or rejects a specific path component based on resource availability or whether selecting the component violates user policy constraints. The output of the CSPF calculation is an explicit route consisting of a sequence of router addresses that provides the shortest path through the network that meets the constraints. This explicit route is then passed to the signaling component, which establishes the forwarding state in the routers along the LSP.

Signaling Component

An LSP is not known to be workable until it is actually established by the signaling component. The signaling component, which is responsible for establishing LSP state and distributing labels, relies on a number of extensions to RSVP:

- The Explicit Route object allows an RSVP path message to traverse an explicit sequence of routers that is independent of conventional shortest-path IP routing. The explicit route can be either strict or loose.
- The Label Request object permits the RSVP path message to request that intermediate routers provide a label binding for the LSP that it is establishing.
- The Label object allows RSVP to support the distribution of labels without changing its existing mechanisms. Because the RSVP Resv message follows the reverse path of the RSVP path message, the Label object supports the distribution of labels from downstream nodes to upstream nodes.

Offline Path Planning and Analysis

Despite the reduced management effort resulting from online path calculation, an offline planning and analysis tool is still required to optimize traffic engineering globally. Online calculation takes resource constraints into account and calculates one LSP at a time. The challenge with this approach is that it is not deterministic. The order in which LSPs are calculated plays a critical role in determining each LSP's physical path across the network. LSPs that are calculated early in the process have more resources available to them than LSPs calculated later in the process because previously calculated LSPs consume network resources. If the order in which the LSPs are calculated is changed, the resulting set of physical paths for the LSPs also can change.

An offline planning and analysis tool simultaneously examines each link's resource constraints and the requirements of each LSP. Although the offline approach can take several hours to complete, it performs global calculations, compares the results of each calculation, and then selects the best solution for the network as a whole. The output of the offline calculation is a set of LSPs that optimizes utilization of network resources. After the offline calculation is completed, the LSPs can be established in any order because each is installed according to the rules for the globally optimized solution.

Flexible LSP Calculation and Configuration

Traffic engineering involves mapping traffic flow onto a physical topology. You can determine the paths online using constraint-based routing. Regardless of how the physical path is calculated, the forwarding state is installed across the network through RSVP.

The Junos OS supports the following ways to route and configure an LSP:

- You can calculate the full path for the LSP offline and individually configure each router in the LSP with the necessary static forwarding state. This is analogous to the way some Internet service providers (ISPs) configure their IP-over-ATM cores.

- You can calculate the full path for the LSP offline and statically configure the ingress router with the full path. The ingress router then uses RSVP as a dynamic signaling protocol to install a forwarding state in each router along the LSP.
- You can rely on constraint-based routing to perform dynamic online LSP calculation. You configure the constraints for each LSP; then the network itself determines the path that best meets those constraints. Specifically, the ingress router calculates the entire LSP based on the constraints and then initiates signaling across the network.
- You can calculate a partial path for an LSP offline and statically configure the ingress router with a subset of the routers in the path; then you can permit online calculation to determine the complete path.

  For example, consider a topology that includes two east-west paths across the United States: one in the north through Chicago and one in the south through Dallas. If you want to establish an LSP between a router in New York and one in San Francisco, you can configure the partial path for the LSP to include a single loose-routed hop of a router in Dallas. The result is an LSP routed along the southern path. The ingress router uses CSPF to compute the complete path and RSVP to install the forwarding state along the LSP.
- You can configure the ingress router with no constraints whatsoever. In this case, normal IGP shortest-path routing is used to determine the path of the LSP. This configuration does not provide any value in terms of traffic engineering. However, it is easy and might be useful in situations when services such as virtual private networks (VPNs) are needed.

In all these cases, you can specify any number of LSPs as backups for the primary LSP, thus allowing you to combine more than one configuration approach. For example, you might explicitly compute the primary path offline, set the secondary path to be constraint-based, and have the tertiary path be unconstrained. If a circuit on which the primary LSP is routed fails, the ingress router notices the outage from error notifications received from a downstream router or by the expiration of RSVP soft-state information. Then the router dynamically forwards traffic to a hot-standby LSP or calls on RSVP to create a forwarding state for a new backup LSP.

Link-State Distribution Using BGP Overview

Role of an Interior Gateway Protocol

An interior gateway protocol (IGP) is a type of protocol used for exchanging routing information between devices within an autonomous system (AS). Based on the method of computing the best path to a destination, the IGPs are divided into two categories:

- Link-state protocols—Advertise information about the network topology (directly connected links and the state of those links) to all routers using multicast addresses and triggered routing updates until all the routers running the link-state protocol have identical information about the internetwork. The best path to a destination is calculated based on constraints such as maximum delay, minimum available bandwidth, and resource class affinity.

  OSPF and IS-IS are examples of link-state protocols.

- Distance vector protocols—Advertise complete routing table information to directly connected neighbors using a broadcast address. The best path is calculated based on the number of hops to the destination network.

  RIP is an example of a distance vector protocol.

As the name implies, the role of an IGP is to provide routing connectivity within or internal to a given routing domain. A routing domain is a set of routers under common administrative control that share a common routing protocol. An AS can consist of multiple routing domains, where IGP functions to advertise and learn network prefixes (routes) from neighboring routers to build a route table that ultimately contains entries for all sources advertising reachability for a given prefix. IGP executes a route selection algorithm to select the best path between the local router and each destination, and provides full connectivity among the routers making up a routing domain.

In addition to advertising internal network reachability, IGPs are often used to advertise routing information that is external to that IGP's routing domain through a process known as route redistribution. Route redistribution is the process of exchanging routing information among distinct routing protocols to tie multiple routing domains together when intra-AS connectivity is desired.

Limitations of an Interior Gateway Protocol

While each individual IGP has its own advantages and limitations, the biggest limitations of IGP in general are performance and scalability.

IGPs are designed to handle the task of acquiring and distributing network topology information for traffic engineering purposes. While this model has served well, IGPs have inherent scaling limitations when it comes to distributing large databases. IGPs can autodetect neighbors, with which they acquire intra-area network topology information. However, the link-state database or a traffic engineering database has the scope of a single area or AS, thereby limiting applications, such as end-to-end traffic engineering, the benefit of having external visibility to make better decisions.

For label-switched networks, such as MPLS and Generalized MPLS (GMPLS), most existing traffic engineering solutions work in a single routing domain. These solutions do not work when a route from the ingress node to the egress node leaves the routing area or AS of the ingress node. In such cases, the path computation problem becomes complicated because of the unavailability of the complete routing information throughout the network. This is because service providers usually choose not to leak routing information beyond the routing area or AS for scalability constraints and confidentiality concerns.

Need for Spanning Link-State Distribution

One of the limitations of IGP is its inability to span link-state distribution outside a single area or AS. However, spanning link-state information acquired by an IGP across multiple areas or ASs has the following needs:

- LSP path computation—This information is used to compute the path for MPLS LSPs across multiple routing domains, for example an inter-area TE LSP.
- External path computing entities—External path computing entities, such as Application Layer Traffic Optimization (ALTO) and Path Computation Elements (PCE), perform path computations based on the network topology and current state of connections within the network, including traffic engineering information. This information is typically distributed by IGPs within the network.

  However, because the external path computing entities cannot extract this information from the IGPs, they perform network monitoring to optimize network services.

Using BGP as a Solution

Overview

To meet the needs for spanning link-state distribution across multiple domains, an exterior gateway protocol (EGP) is required to collect link-state and traffic engineering information from an IGP area, share it with external component, and use it for computing paths for interdomain MPLS LSPs.

BGP is a standardized EGP designed to exchange routing and reachability information between autonomous systems (ASs). BGP is a proven protocol that has better scaling properties because it can distribute millions of entries (for example, VPN prefixes) in a scalable fashion. BGP is the only routing protocol in use today that is suited to carry all of the routes in the Internet. This is largely because BGP

runs on top of TCP and can make use of TCP flow control. In contrast, the internal gateway protocols (IGPs) do not have flow control. When IGPs have too much route information, they begin to churn. When BGP has a neighboring speaker that is sending information too quickly, BGP can throttle down the neighbor by delaying TCP acknowledgments.

Another benefit of BGP is that it uses type, length, value (TLV) tuples and network layer reachability information (NLRI) that provide seemingly endless extensibility without the need for the underlying protocol to be altered.

The distribution of link-state information across domains is regulated using policies to protect the interests of the service provider. This requires a control over the topology distribution using policies. BGP with its implemented policy framework serves well in the interdomain route distribution. In Junos OS, BGP is completely policy driven. The operator must explicitly configure neighbors to peer with and explicitly accept routes into BGP. Furthermore, routing policy is used to filter and modify routing information. Thus, routing policies provide complete administrative control over the routing tables.

Although, within an AS, both IGP-TE and BGP-TE provide the same set of information, BGP-TE has better scaling characteristics that are inherited from the standard BGP protocol. This makes BGP-TE a more scalable choice for acquiring multi-area/multi-AS topology information.

By using BGP as a solution, the IGP-acquired information is used for distribution into BGP. The ISPs can selectively expose this information with other ISPs, service providers, and content distribution networks (CDNs) through normal BGP peering. This allows for aggregation of the IGP-acquired information across multiple areas and ASs, such that an external path computing entity can access the information by passively listening to a route reflector.

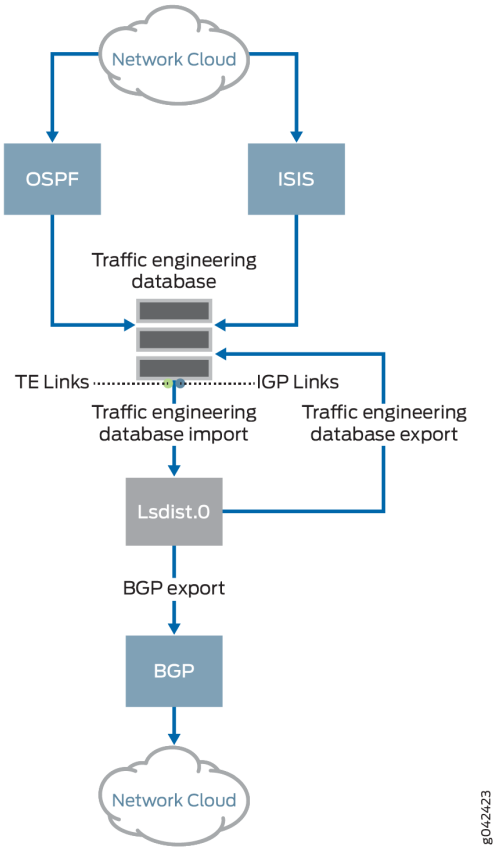
Implementation

In Junos OS, the IGPs install topology information into a database called the traffic engineering database. The traffic engineering database contains the aggregated topology information. To install IGP topology information into traffic engineering database, use the `set igp-topology` configuration statement at the `[edit protocols isis traffic-engineering]` and `[edit protocols ospf traffic-engineering]` hierarchy levels. The mechanism to distribute link-state information using BGP includes the process of advertising the traffic engineering database into BGP-TE (import), and installing entries from BGP-TE into the traffic engineering database (export).

Starting in Junos OS Release 20.4R1, you can configure IS-IS traffic engineering to store IPv6 information in the traffic engineering database (TED) in addition to IPv4 addresses. BGP-LS distributes this information as routes from the traffic engineering database to the lsdist.0 routing table using the traffic engineering database import policies. These routes are advertised to BGP-TE peers as network layer reachability information (NLRI) with IPv6 router ID type, length, and value (TLV). With addition of

IPv6 information, you can benefit from obtaining the complete network topology into the traffic engineering database.

Figure 104: Junos OS Implementation of BGP Link-State Distribution



Traffic Engineering Database Import

To advertise the traffic engineering database into BGP-TE, the link and node entries in the traffic engineering database are converted in the form of routes. These converted routes are then installed by the traffic engineering database on behalf of the corresponding IGP, into a user-visible routing table called `lsdist.0`, on conditions subject to route policies. The procedure of leaking entries from the traffic engineering database into `lsdist.0` is called traffic engineering database import as illustrated in Figure 104 on page 1607.

There are polices to govern the traffic engineering database import process. By default, no entries are leaked from the traffic engineering database into the `lsdist.0` table.

Starting in Junos OS Release 17.4R1, the traffic engineering database installs interior gateway protocol (IGP) topology information in addition to RSVP-TE topology information in the lsdist.0 routing table as illustrated in Figure 104 on page 1607. Prior to Junos OS Release 17.4R1, the traffic engineering database only exported RSVP-TE topology information. Now you can monitor both IGP and traffic engineering topology information. The BGP-LS reads IGP entries from lsdist.0 and advertises these entries to the BGP peers. To import IGP topology information into BGP-LS from lsdist.0, use the `set bgp-ls` configuration statement at the `[edit protocols mpls traffic-engineering database import igp-topology]` hierarchy level.

Traffic Engineering Database Export

BGP can be configured to export or advertise routes from the `lsdist.0` table, subject to policy. This is common for any kind of route origination in BGP. In order to advertise BGP-TE into the traffic engineering database, BGP needs to be configured with the BGP-TE address family, and an export policy that selects routes for redistribution into BGP.

BGP then propagates these routes like any other NLRI. BGP peers that have the BGP-TE family configured and negotiated receive BGP-TE NLRIs. BGP stores the received BGP-TE NLRIs in the form of routes in the `lsdist.0` table, which is the same table that stores locally originated BGP-TE routes. The BGP-installed routes in `lsdist.0` are then distributed to other peers like any other route. Thus, the standard route selection procedure applies to BGP-TE NLRIs received from multiple speakers.

To achieve interdomain TE, the routes in `lsdist.0` are leaked into the traffic engineering database through a policy. This process is called traffic engineering database export as illustrated in Figure 104 on page 1607.

There are polices to govern the traffic engineering database export process. By default, no entries are leaked from the `lsdist.0` table into the traffic engineering database.

> **NOTE**: For SDN applications, such as PCE and ALTO, the BGP-TE advertised information cannot leak into the traffic engineering database of a router. In such cases, an external server that peers with the routers using BGP-TE is used to move topology information up into the sky/orchestration system that spans the network. These external servers can be deemed as BGP-TE consumers, where they receive BGP-TE routes, but do not advertise them.

Assigning Credibility Values

Once the entries are installed in the traffic engineering database, the BGP-TE learned information is made available for CSPF path computation. The traffic engineering database uses a protocol preference scheme that is based on credibility values. A protocol with a higher credibility value is preferred over a protocol with a lower credibility value. BGP-TE has the capability to advertise information learned from multiple protocols at the same time, and so in addition to the IGP-installed entries in the traffic

engineering database, there can be BGP-TE installed entries that correspond to more than one protocol. The traffic engineering database export component creates a traffic engineering database protocol and credibility level for each protocol that BGP-TE supports. These credibility values are configurable in the CLI.

The credibility order for the BGP-TE protocols is as follows:

- Unknown—80
- OSPF—81
- ISIS Level 1—82
- ISIS Level 2—83
- Static—84
- Direct—85

Cross-Credibility Path Computation

After you assign credibility values, each credibility level is treated as an individual plane. The Constrained Shorted Path First algorithm starts with the highest assigned credibility to the lowest, finding a path within that credibility level.

With BGP-TE, it is essential to compute paths across credibility levels to compute inter-AS paths. For example, different credibility settings are seen on a device from area 0 that computes the path through area 1, because area 0 entries are installed by OSPF, and area 1 entries are installed by BGP-TE.

To enable path computation across credibility levels, include the `cross-credibility-cspf` statement at the `edit protocols mpls`, `[edit protocols mpls label-switched-path` *`lsp-name`*`]`, and `[edit protocols rsvp]` hierarchy levels. At the `[edit protocols rsvp]` hierarchy level, enabling `cross-credibility-cspf` impacts bypass LSPs and loose hop expansion in transit.

Configuring `cross-credibility-cspf` enables path computation across credibility levels using the Constrained Shortest Path First algorithm, wherein the constraint is not performed on a credibility-by-credibility basis, but as a single constraint ignoring the assigned credibility values.

BGP-TE NLRIs and TLVs

Like other BGP routes, BGP-TE NLRIs can also be distributed through a route reflector that speaks BGP-TE NLRI. Junos OS implements the route reflection support for the BGP-TE family.

The following is a list of supported NLRIs:

- Link NLRI

- Node NLRI
- IPv4 Prefix NLRI (receive and propagate)
- IPv6 Prefix NLRI (receive and propagate)

NOTE: Junos OS does not provide support for the route-distinguisher form of the above NRLIs.

The following is a list of supported fields in link and node NLRIs:

- Protocol-ID—NLRI originates with the following protocol values:
  - ISIS-L1
  - ISIS-L2
  - OSPF
- Identifier—This value is configurable. By default, the identifier value is set to `0`.
- Local/Remote node descriptor—These include:
  - Autonomous system
  - BGP-LS Identifier—This value is configurable. By default, the BGP-LS identifier value is set to `0`
  - Area-ID
  - IGP router-ID
- Link descriptors (Only for link NLRI)—This includes:
  - Link Local/Remote Identifiers
  - IPv4 interface address
  - IPv4 neighbor address
  - IPv6 neighbor/interface address—The IPv6 neighbor and interface addresses are not originated, but only stored and propagated when received.
  - Multi-topology ID—This value is not originated, but stored and propagated when received.

The following is a list of supported LINK_STATE attribute TLVs:

- Link attributes:
  - Administrative group

    - Max link bandwidth
    - Max reservable bandwidth
    - Unreserved bandwidth
    - TE default metric
    - SRLG
    - The following TLVs, which are not originated, but only stored and propagated when received:
        - Opaque link attributes
        - MPLS protocol mask
        - Metric
        - Link protection type
        - Link name attribute
- Node attributes:
    - IPv4 Router-ID
    - Node flag bits—Only the overload bit is set.
    - The following TLVs, which are not originated, but only stored and propagated when received:
        - Multi-topology
        - OSPF-specific node properties
        - Opaque node properties
        - Node name
        - IS-IS area identifier
        - IPv6 Router-ID
    - Prefix attributes—These TLVs are stored and propagated like any other unknown TLVs.

Supported and Unsupported Features

Junos OS supports the following features with link-state distribution using BGP:

- Advertisement of multiprotocol assured forwarding capability
- Transmission and reception of node and link-state BGP and BGP-TE NLRIs

- Nonstop active routing for BGP-TE NLRIs
- Policies

Junos OS does **not** support the following functionality for link-state distribution using BGP:

- Aggregated topologies, links, or nodes
- Route distinguisher support for BGP-TE NLRIs
- Multi-topology identifiers
- Multi-instance identifiers (excluding the default instance ID 0)
- Advertisement of the link and node area TLV
- Advertisement of MPLS signaling protocols
- Importing node and link information with overlapping address

BGP Link-State Extensions for Source Packet Routing in Networking (SPRING)

Starting in Junos OS Release 17.2R1, the BGP link-state address family is extended to distribute the source packet routing in networking (SPRING) topology information to software-defined networking (SDN) controllers. BGP typically learns the link-state information from IGP and distributes it to BGP peers. Besides BGP, the SDN controller can get link-state information directly from IGP if the controller is a part of an IGP domain. However, BGP link-state distribution provides a scalable mechanism to export the topology information. BGP link-state extensions for SPRING is supported on interdomain networks.

Source Packet Routing in Networking (SPRING)

SPRING is a control-plane architecture that enables an ingress router to steer a packet through a specific set of nodes and links in the network without relying on the intermediate nodes in the network to decide the actual path it must take. SPRING engages IGPs, such as IS-IS and OSPF, for advertising network segments. Network segments can represent any instruction, topological or service-based. Within IGP topologies, IGP segments are advertised by the link-state routing protocols. There are two types of IGP segments:

Adjacency segment	A one-hop path over a specific adjacency between two nodes in the IGP
Prefix segment	A multi-hop, equal-cost, multipath-aware shortest-path to a prefix, as per the state of the IGP topology

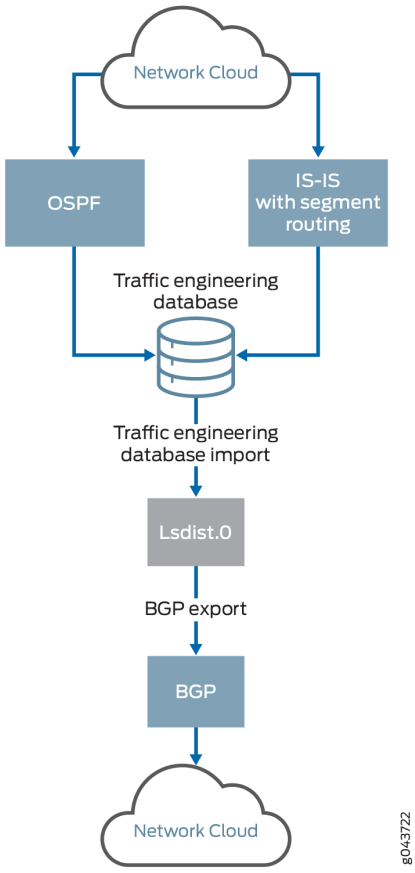
When SPRING in enabled in a BGP network, BGP link-state address family learns the SPRING information from the IGP link-state routing protocols and advertises segments in the form of segment

identifiers (SIDs). BGP link-state address family has been extended to carry SIDs and other SPRING-related information to BGP peers. The route reflector can steer a packet through a desired set of nodes and links by prepending the packet with an appropriate combination of tunnels. This feature allows BGP link-state address family to also advertise the SPRING information to BGP peers.

Flow of BGP Link-State SPRING Data

Figure 105 on page 1613 depicts the data flow of BGP link-state SPRING data that IS-IS pushes to the traffic engineering database.

Figure 105: BGP Link-State Source Packet Routing in Networking (SPRING)



- IGP pushes the SPRING attributes to the traffic engineering database.
- SPRING capabilities and algorithm information are carried forward as node attributes into the traffic engineering database.
- Adjacent SID and LAN adjacent SID information are carried as link attributes.

- Prefix SID or node-SID information is carried as prefix attributes.
- A new set or a change to existing attributes triggers IGP updates to the traffic engineering database with new data.
- RSVP is a prerequisite for link attributes.

> **CAUTION**: If traffic engineering is disabled at the IGP level, none of the attributes are pushed to the traffic engineering database.

- All parameters in the BGP traffic engineering NLRI, including the link, node, and prefix descriptors are derived from entries in the traffic engineering database.
- The traffic engineering database imports route entries into the `lsdist.0` routing table from IGP subject to policy.
- The default policy of BGP is to export routes, which are known to BGP only. You configure an export policy for non-BGP routes in the `lsdis.0` routing table. This policy advertises an entry learned from the traffic engineering database.

Supported BGP Link-State Attributes and TLVs, and Unsupported Features for BGP Link-State with SPRING

BGP link-state with SPRING supports the following attributes and type, length, and values (TLVs) that are originated, received, and propagated in the network:

Node attributes

- Segment routing Capabilities
- Segment routing Algorithm

Link attributes

- Adjacent-SID
- LAN Adjacent-SID

Prefix descriptors

- IP reachability information

Prefix attributes

- Prefix SID

The following list supports TLVs that are not originated, but only received and propagated in the network:

Prefix descriptors

- Multitopology ID
- OSPF route type

Prefix attributes

- Range
- Binding SID

Junos OS does not support the following features with BGP link-state with SPRING extensions:

- IPv6 prefix origination
- Multitopology identifiers
- Traffic engineering database export for SPRING parameters
- New TLVs with tcpdump (existing TLVs are also not supported).
- SPRING over IPv6

Verifying NLRI Node Learned Through BGP with OSPF as IGP

The following is a sample output to verify the NLRI node learned through BGP with OSPF as the IGP:

Purpose

Verify the lsdist.0 routing table entries.

Action

From operational mode, run the `show route table lsdist.0` command.

```
user@host> show route table lsdist.0 te-node-ip 7.7.7.7 extensive
lsdist.0: 216 destinations, 216 routes (216 active, 0 holddown, 0 hidden)
NODE { AS:100 Area:0.0.0.1 IPv4:7.7.7.7 OSPF:0 }/1536 (1 entry, 1 announced)
TSI:
LINK-STATE attribute handle 0x61d5da0
        *BGP    Preference: 170/-101
                Next hop type: Indirect, Next hop index: 0
```

```

                                2.2.2.2/32 Originating RIB: inet.0
                                  Metric: 2     Node path count: 1
```

```
                                    Forwarding nexthops: 1
                                          Nexthop: 11.1.1.2 via et-0/0/0.1
                                          Session Id: 143
```

Meaning

The routes are appearing in the lsdist.0 routing table.

Example: Configuring Link State Distribution Using BGP

IN THIS SECTION

- Requirements | **1618**
- Overview | **1619**
- Configuration | **1620**
- Verification | **1635**

This example shows how to configure BGP to carry link-state information across multiple domains, which is used for computing paths for MPLS LSPs spanning multiple domains, such as inter-area TE LSP, and providing a scalable and policy-controlled means for external path computing entities, such as ALTO and PCE, to acquire network topology.

Requirements

This example uses the following hardware and software components:

- Four routers that can be a combination of M Series, MX Series, or T Series routers
- Junos OS Release 14.2 or later running on all the routers

Before you begin:

1. Configure the device interfaces.
2. Configure the autonomous system numbers and router IDs for the devices.
3. Configure the following protocols:
   - RSVP
   - MPLS

- BGP
- IS-IS
- OSPF

Overview

IN THIS SECTION

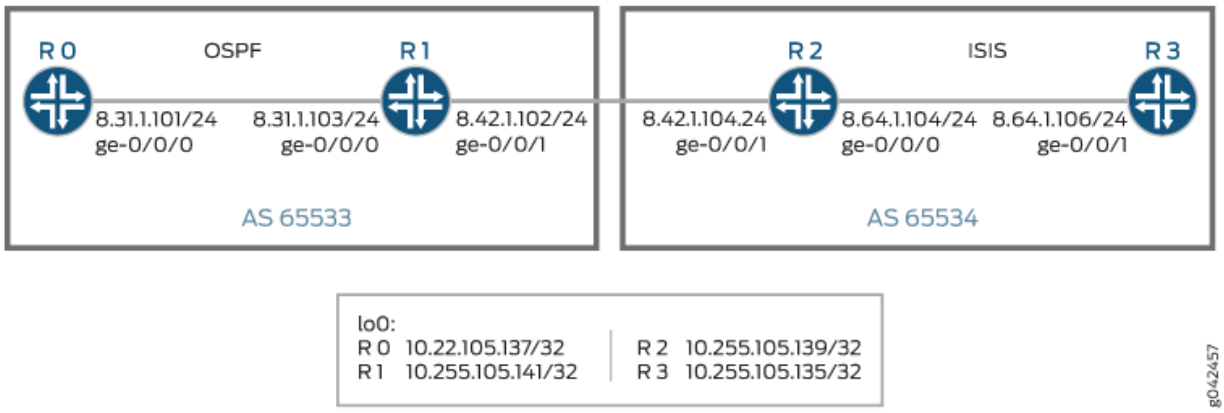
- Topology | **1620**

Starting with Junos OS Release 14.2, a new mechanism to distribute topology information across multiple areas and autonomous systems (ASs) is introduced by extending the BGP protocol to carry link - state information, which was initially acquired using IGP. The IGP protocols have scaling limitations when it comes to distributing large databases. BGP is not only a more scalable vehicle for carrying multi-area and multi-AS topology information, but also provides the policy controls that can be useful for multi-AS topology distribution. The BGP link-state topology information is used for computing paths for MPLS label-switched paths (LSPs) spanning multiple domains, such as inter-area TE LSP, and providing a scalable and policy-controlled means for external path computing entities, such as ALTO and PCE, to acquire network topology.

Starting with Junos OS Release 17.1R1, link state distribution using BGP is supported on QFX10000 switches.

Topology

Figure 106: Link-State Distribution Using BGP



In Figure 106 on page 1620, Routers R0 and R1 and Routers R2 and R3 belong to different autonomous systems. Routers R0 and R1 run OSPF, and Routers R2 and R3 run IS-IS.

Configuration

IN THIS SECTION

- CLI Quick Configuration | **1620**
- Procedure | **1624**
- Procedure | **1629**

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the `[edit]` hierarchy level, and then enter `commit` from configuration mode.

Procedure

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure Router R1:

1. Configure the Router R1 interfaces.

```
[edit interfaces]
user@R1# set ge-0/0/0 unit 0 family inet address 8.31.1.103/24
user@R1# set ge-0/0/0 unit 0 family iso
user@R1# set ge-0/0/0 unit 0 family mpls
user@R1# set ge-0/0/1 unit 0 family inet address 8.42.1.102/24
user@R1# set ge-0/0/1 unit 0 family iso
user@R1# set ge-0/0/1 unit 0 family mpls
user@R1# set lo0 unit 0 family inet address 10.255.105.141/32
```

2. Configure the router ID and autonomous system of Router R1.

```
[edit routing-options]
user@R1# set router-id 10.255.105.141
user@R1# set autonomous-system 65533
```

3. Enable RSVP on all the interfaces of Router R1 (excluding the management interface).

```
[edit protocols]
user@R1# set rsvp interface all
user@R1# set rsvp interface fxp0.0 disable
```

4. Enable MPLS on all the interfaces of Router R1 (excluding the management interface).

```
[edit protocols]
user@R1# set mpls interface all
user@R1# set mpls interface fxp0.0 disable
```

5. Configure the BGP group for Router R1 to peer with Router R0, and assign the local address and neighbor address.

```
[edit protocols]
user@R1# set bgp group ibgp type internal
user@R1# set bgp group ibgp local-address 10.255.105.141
user@R1# set bgp group ibgp neighbor 10.255.105.137
```

6. Include the BGP-TE signaling network layer reachability information (NLRI) to the ibgp BGP group.

```
[edit protocols]
user@R1# set bgp group ibgp family traffic-engineering unicast
```

7. Enable export of policy nlri2bgp on Router R1.

```
[edit protocols]
user@R1# set bgp group ibgp export nlri2bgp
```

8. Configure the BGP group for Router R1 to peer with Router R2, and assign the local address and neighbor autonomous system to the ebgp BGP group.

```
[edit protocols]
user@R1# set bgp group ebgp type external
user@R1# set bgp group ebgp neighbor 8.42.1.104 local-address 8.42.1.102
user@R1# set bgp group ebgp neighbor 8.42.1.104 peer-as 65534
```

9. Include the BGP-TE signaling NLRI to the ebgp BGP group.

```
[edit protocols]
user@R1# set bgp group ebgp family traffic-engineering unicast
```

10. Enable passive traffic-engineering on the inter-AS link.

```
[edit protocols]
user@R1# set isis interface ge-0/0/1.0 passive remote-node-iso 0102.5502.4211
user@R1# set isis interface ge-0/0/1.0 passive remote-node-id 8.42.1.104
```

11. Enable OSPF on the interface connecting Router R1 to Router R0 and on the loopback interface of Router R1, and enable traffic engineering capabilities.

```
[edit protocols]
user@R1# set ospf traffic-engineering
user@R1# set ospf area 0.0.0.0 interface lo0.0
user@R1# set ospf area 0.0.0.0 interface ge-0/0/0.0
```

12. Enable passive traffic-engineering on the inter-AS link.

```
[edit protocols]
user@R1# set ospf area 0.0.0.0 interface ge-0/0/1.0 passive traffic-engineering remote-node-
id 8.42.1.104
user@R1# set ospf area 0.0.0.0 interface ge-0/0/1.0 passive traffic-engineering remote-node-
router-id 10.255.105.139
```

13. Configure policies to accept traffic from BGP-TE NLRI.

```
[edit policy-options]
user@R1# set policy-statement accept-all from family traffic-engineering
user@R1# set policy-statement accept-all then accept
user@R1# set policy-statement nlri2bgp term 1 from family traffic-engineering
user@R1# set policy-statement nlri2bgp term 1 then accept
```

Results

From configuration mode, confirm your configuration by entering the `show interfaces`, `show routing-options`, `show protocols`, and `show policy-options` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R1# show interfaces
ge-0/0/0 {
    unit 0 {
        family inet {
            address 8.31.1.103/24;
        }
        family iso;
        family mpls;
    }
}

    }
}
```

Procedure

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure Router R2:

1. Configure the Router R2 interfaces.

```
[edit interfaces]
user@R2# set ge-0/0/0 unit 0 family inet address 8.64.1.104/24
user@R2# set ge-0/0/0 unit 0 family iso
```

```
user@R2# set ge-0/0/0 unit 0 family mpls
user@R2# set ge-0/0/1 unit 0 family inet address 8.42.1.104/24
user@R2# set ge-0/0/1 unit 0 family iso
user@R2# set ge-0/0/1 unit 0 family mpls
user@R2# set lo0 unit 0 family inet address 10.255.105.139/32
user@R2# set lo0 unit 0 family iso
```

2. Configure the router ID and autonomous system of Router R2.

```
[edit routing-options]
user@R2# set router-id 10.255.105.139
user@R2# set autonomous-system 65534
```

3. Enable RSVP on all the interfaces of Router R2 (excluding the management interface).

```
[edit routing-options]
user@R2# set rsvp interface all
user@R2# set rsvp interface fxp0.0 disable
```

4. Enable MPLS on all the interfaces of Router R2 (excluding the management interface).

```
[edit routing-options]
user@R2# set mpls interface all
user@R2# set mpls interface fxp0.0 disable
```

5. Enable import of traffic engineering database parameters using the ted2nlri policy.

```
[edit protocols]
user@R2# set mpls traffic-engineering database import policy ted2nlri
```

6. Configure the BGP group for Router R2 to peer with Router R1.

```
[edit protocols]
user@R2# set bgp group ebgp type external
```

7. Include the BGP-TE signaling NLRI to the ebgp BGP group.

```
[edit protocols]
user@R2# set bgp group ebgp family traffic-engineering unicast
```

8. Assign the local address and neighbor autonomous system to the ebgp BGP group.

```
[edit protocols]
user@R2# set bgp group ebgp peer-as 65533
user@R2# set bgp group ebgp neighbor 8.42.1.102
```

9. Enable export of policy nlri2bgp on Router R2.

```
[edit protocols]
user@R2# set bgp group ebgp export nlri2bgp
```

10. Enable IS-IS on the interface connecting Router R2 with Router R3 and the loopback interface of Router R2.

```
[edit protocols]
user@R2# set isis level 1 disable
user@R2# set isis interface ge-0/0/0.0
user@R2# set isis interface lo0.0
```

11. Enable only IS-IS advertising on the interface connecting Router R2 with Router R1.

```
[edit protocols]
user@R2# set isis interface ge-0/0/1.0 passive remote-node-iso 0102.5501.8181
user@R2# set isis interface ge-0/0/1.0 passive remote-node-id 8.42.1.102
```

12. Configure traffic engineering capability on Router R2.

```
[edit protocols]
user@R2# set ospf traffic-engineering
```

13. Enable only OSPF advertisements on the interface connecting Router R2 with Router R1.

```
[edit protocols]
user@R2# set ospf area 0.0.0.0 interface ge-0/0/1.0 passive traffic-engineering remote-node-id 8.42.1.102
user@R2# set ospf area 0.0.0.0 interface ge-0/0/1.0 passive traffic-engineering remote-node-router-id 10.255.105.141
```

14. Configure policies to accept traffic from the BGP-TE NLRI.

```
[edit policy-options]
user@R2# set policy-statement accept-all from family traffic-engineering
user@R2# set policy-statement accept-all then accept
user@R2# set policy-statement nlri2bgp term 1 from family traffic-engineering
user@R2# set policy-statement nlri2bgp term 1 then accept
user@R2# set policy-statement ted2nlri term 1 from protocol isis
user@R2# set policy-statement ted2nlri term 1 from protocol ospf
user@R2# set policy-statement ted2nlri term 1 then accept
user@R2# set policy-statement ted2nlri term 2 then reject
```

Results

From configuration mode, confirm your configuration by entering the `show interfaces`, `show routing-options`, `show protocols`, and `show policy-options` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R2# show interfaces
ge-0/0/0 {
    unit 0 {
        family inet {
            address 8.64.1.104/24;
        }
        family iso;
        family mpls;
    }
}
ge-0/0/1 {
    unit 0 {
        family inet {
```

```
            address 8.42.1.104/24;
        }
        family iso;
        family mpls;
    }
}
lo0 {
    unit 0 {
        family inet {
            address 10.255.105.139/32;
        }
        family iso;
    }
}
```

```
user@R2# show routing-options
router-id 10.255.105.139;
 autonomous-system 65534;
```

```
user@R2# show protocols
rsvp {
    interface all;
    interface fxp0.0 {
        disable;
    }
}
mpls {
    traffic-engineering {
        database {
            import {
                policy ted2nlri;
            }
        }
    }
    interface all;
    interface fxp0.0 {
        disable;
    }
}
bgp {
```

```
    group ebgp {
        type external;
        family traffic-engineering {
            unicast;
        }
        export nlri2bgp;
        peer-as 65533;
        neighbor 8.42.1.102;
    }
}
isis {
    level 1 disable;
    interface ge-0/0/0.0;
    interface ge-0/0/1.0 {
        passive {
            remote-node-iso 0102.5501.8181;
            remote-node-id 8.42.1.102;
        }
    }
    interface lo0.0;
}
ospf {
    traffic-engineering;
    area 0.0.0.0 {
        interface ge-0/0/1.0 {
            passive {
                traffic-engineering {
                    remote-node-id 8.42.1.102;
                    remote-node-router-id 10.255.105.141;
                }
            }
        }
    }
}
```

```
user@R2# show policy-options
policy-statement accept-all {
    from family traffic-engineering;
    then accept;
}
policy-statement nlri2bgp {
```

```
    term 1 {
        from family traffic-engineering;
        then {
            accept;
        }
    }
}
policy-statement ted2nlri {
    term 1 {
        from protocol [ isis ospf ];
        then accept;
    }
    term 2 {
        then reject;
    }
}
```

Verification

IN THIS SECTION

- Verifying the BGP Summary Status | **1635**
- Verifying the MPLS LSP Status | **1636**
- Verifying the lsdist.0 Routing Table Entries | **1637**
- Verifying the Traffic Engineering Database Entries | **1641**

Verify that the configuration is working properly.

Verifying the BGP Summary Status

Purpose

Verify that BGP is up and running on Routers R0 and R1.

Action

From operational mode, run the `show bgp summary` command.

```
user@R0> show bgp summary
Groups: 1 Peers: 1 Down peers: 0
Table          Tot Paths  Act Paths Suppressed    History Damp State    Pending
lsdist.0
                      10         10          0          0          0          0
Peer                    AS      InPkt     OutPkt    OutQ   Flaps Last Up/Dwn State|#Active/
Received/Accepted/Damped...
10.255.105.141        65533         20         14       0      79        5:18 Establ
  lsdist.0: 10/10/10/0
```

From operational mode, run the `show bgp summary` command.

```
user@R1> show bgp summary
Groups: 2 Peers: 2 Down peers: 0
Table          Tot Paths  Act Paths Suppressed    History Damp State    Pending
lsdist.0
                      10         10          0          0          0          0
Peer                    AS      InPkt     OutPkt    OutQ   Flaps Last Up/Dwn State|#Active/
Received/Accepted/Damped...
8.42.1.104            65534         24         17       0      70        6:43 Establ
  lsdist.0: 10/10/10/0
10.255.105.137        65533         15         23       0      79        6:19 Establ
  lsdist.0: 0/0/0/0
```

Meaning

Router R0 is peered with Router R1.

Verifying the MPLS LSP Status

Purpose

Verify the status of the MPLS LSP on Router R0.

Action

From operational mode, run the `show mpls lsp` command.

```
user@R0> show mpls lsp
Ingress LSP: 1 sessions
To              From            State Rt P     ActivePath       LSPname
10.255.105.135  10.255.105.137  Up     0 *                      to-R3-inter-as
Total 1 displayed, Up 1, Down 0

Egress LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Meaning

The MPLS LSP from Router R0 to Router R3 is established.

Verifying the lsdist.0 Routing Table Entries

Purpose

Verify the lsdist.0 routing table entries on Routers R0, R1, and R2.

Action

From operational mode, run the `show route table lsdist.0` command.

```
user@R0> show route table lsdist.0
lsdist.0: 10 destinations, 10 routes (10 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

Meaning

The routes are appearing in the traffic engineering database.

Configuring Link State Distribution Using BGP

You can enable distribution of topology information across multiple areas and autonomous systems (ASs) by extending the BGP protocol to carry link-state information, which was initially acquired using IGP. The IGP protocols have scaling limitations when it comes to distributing large databases. BGP is not only a more scalable vehicle for carrying multi-area and multi-AS topology information, but also provides the policy controls that can be useful for multi-AS topology distribution. The BGP link-state topology information is used for computing paths for MPLS LSPs spanning multiple domains, such as inter-area TE LSP, and providing a scalable and policy-controlled means for external path computing entities, such as ALTO and PCE, to acquire network topology.

Before you begin:

1. Configure the device interfaces.

2. Configure the router ID and autonomous system number for the device.
3. Configure the following protocols:
   - RSVP
   - MPLS
   - IS-IS
   - OSPF

To enable link-state distribution using BGP:

1. Configure an internal BGP group, and assign the local address and neighbor address for the group.

```
[edit protocols]
user@R1# set bgp group internal-group-name type internal
user@R1# set bgp group internal-group-name local-address ip-address
user@R1# set bgp group internal-group-name neighbor ip-address
```

2. Include the BGP-TE signaling network layer reachability information (NLRI) to the internal BGP group.

```
[edit protocols]
user@R1# set bgp group internal-group-name family traffic-engineering unicast
```

3. Enable export of policy on the device.

```
[edit protocols]
user@R1# set bgp group internal-group-name export second-policy-name
```

4. Configure an external BGP group, and assign the local address and neighbor autonomous system to the group.

```
[edit protocols]
user@R1# set bgp group external-group-name type external
user@R1# set bgp group external-group-name neighbor ip-address local-address ip-address
user@R1# set bgp group external-group-name neighbor ip-address peer-as as-number
```

5. Include the BGP-TE signaling NLRI to the external BGP group.

```
[edit protocols]
user@R1# set bgp group external-group-name family traffic-engineering unicast
```

6. In configuration mode, go to the following hierarchy level:

```
[edit]
user@R1# edit policy-options
```

7. Configure policies to accept traffic from the BGP-TE NLRI.

```
[edit policy-options]
user@R1# set policy-statement policy-name from family traffic-engineering
user@R1# set policy-statement policy-name then accept
user@R1# set policy-statement bgp-import-policy term 1 from family traffic-engineering
user@R1# set policy-statement bgp-import-policy term 1 then next-hop self
user@R1# set policy-statement bgp-import-policy term 1 then accept
```

8. On the remote connecting device, configure policy to accept the OSPF and IS-IS traffic.

```
[edit policy-options]
user@R2# set policy-statement bgp-export-policy term 1 from protocol isis
user@R2# set policy-statement bgp-export-policy term 1 from protocol ospf
user@R2# set policy-statement bgp-export-policy term 1 then accept
user@R2# set policy-statement bgp-export-policy term 2 then reject
```

9. Verify and commit the configuration.

   For example:

```
R1
[edit protocols]
user@R1# set rsvp interface all
user@R1# set rsvp interface fxp0.0 disable
user@R1# set mpls interface all
user@R1# set mpls interface fxp0.0 disable
user@R1# set bgp group ibgp type internal
user@R1# set bgp group ibgp local-address 10.255.105.141
user@R1# set bgp group ibgp family traffic-engineering unicast
user@R1# set bgp group ibgp export nlri2bgp
```

```
user@R1# set bgp group ibgp neighbor 10.255.105.137
user@R1# set bgp group ebgp type external
user@R1# set bgp group ebgp family traffic-engineering unicast
user@R1# set bgp group ebgp neighbor 8.42.1.104 local-address 8.42.1.102
user@R1# set bgp group ebgp neighbor 8.42.1.104 peer-as 65534
user@R1# set isis interface ge-0/0/1.0 passive remote-node-iso 0102.5502.4211
user@R1# set isis interface ge-0/0/1.0 passive remote-node-id 8.42.1.104
user@R1# set ospf traffic-engineering
user@R1# set ospf area 0.0.0.0 interface lo0.0
user@R1# set ospf area 0.0.0.0 interface ge-0/0/0.0
user@R1# set ospf area 0.0.0.0 interface ge-0/0/1.0 passive traffic-engineering remote-node-
id 8.42.1.104
user@R1# set ospf area 0.0.0.0 interface ge-0/0/1.0 passive traffic-engineering remote-node-
router-id 10.255.105.139
```

```
[edit policy-options]
user@R1# set policy-statement accept-all from family traffic-engineering
user@R1# set policy-statement accept-all then accept
user@R1# set policy-statement nlri2bgp term 1 from family traffic-engineering
user@R1# set policy-statement nlri2bgp term 1 then next-hop self
user@R1# set policy-statement nlri2bgp term 1 then accept
```

```
[edit]
user@R1# commit
commit complete
```

R2

```
[edit policy-options]
user@R2# set policy-statement accept-all from family traffic-engineering
user@R2# set policy-statement accept-all then accept
user@R2# set policy-statement nlri2bgp term 1 from family traffic-engineering
user@R2# set policy-statement nlri2bgp term 1 then next-hop self
user@R2# set policy-statement nlri2bgp term 1 then accept
user@R2# set policy-statement ted2nlri term 1 from protocol isis
user@R2# set policy-statement ted2nlri term 1 from protocol ospf
```

```
user@R2# set policy-statement ted2nlri term 1 then accept
user@R2# set policy-statement ted2nlri term 2 then reject
```

```
[edit]
user@R2# commit
commit complete
```

BGP Classful Transport Planes Overview

IN THIS SECTION

- BGP Classful Transport (BGP-CT) with Underlying Colored SR-TE Tunnels Overview | **1654**

Benefits of BGP Classful Transport Planes

- **Network-slicing**–Service and transport layers are decoupled from each other, laying the foundation for network-slicing and virtualization with the end-to-end slicing across multiple domains, thereby significantly reducing the CAPEX.
- **Inter-domain interoperability**–Extends transport class deployment across co-operating domains so the different transport signaling protocols in each domain interoperate. Reconciles any differences between extended community namespaces that may be in use in each domain.
- **Colored resolution with fallback**–Enables resolution over colored tunnels (RSVP, IS-IS flexible algorithm) with flexible fallback options over best-effort tunnels or any other color tunnel.
- **Quality-of-service**–Customizes and optimizes the network to achieve the end-to-end SLA requirements.
- **Leveraging existing deployments**–Supports well deployed tunneling protocols like RSVP along with new protocols, such as IS-IS flexible algorithm, preserving ROI and reducing OPEX.

Terminology of BGP Classful Transport Planes

This section provides a summary of commonly used terms for understanding BGP classful transport plane.

- **Service node**–Ingress Provider Edge (PE) devices that send and receive service routes (Internet and Layer 3 VPN).

- **Border node**–Device at the connection point of different domains (IGP areas or ASs).
- **Transport node**–Device that sends and receives BGP-Labeled Unicast (LU) routes.
- **BGP-VPN**–VPNs built using RFC4364 mechanisms.
- **Route Target (RT)**–Type of extended community used to define VPN membership.
- **Route Distinguisher (RD)**–Identifier used to distinguish to which VPN or virtual private LAN service (VPLS) a route belongs. Each routing instance must have a unique route distinguisher associated with it.
- **Resolution scheme**–Used to resolve protocol next-hop address (PNH) in resolution RIBs providing fallback.

  They map the routes to the different transport RIBs in the system based on mapping community.
- **Service family**–BGP address family used for advertising routes for data traffic, as opposed to tunnels.
- **Transport family** –BGP address family used for advertising tunnels, which are in turn used by service routes for resolution.
- **Transport tunnel**–A tunnel over which a service may place traffic, for example, GRE, UDP, LDP, RSVP, SR-TE, BGP-LU.
- **Tunnel domain**–A domain of the network containing service nodes and border nodes under a single administrative control that has a tunnel between them. An end-to-end tunnel spanning several adjacent tunnel domains can be created by stitching the nodes together using labels.
- **Transport class**–A group of transport tunnels offering the same type of service.
- **Transport class RT**–A new format of route target used to identify a specific transport class.

  A new format of Route Target used to identify a specific transport class.
- **Transport RIB**–At the service node and border node, a transport class has an associted transport RIB that holds its tunnel routes.
- **Transport RTI**–A routing instance; container of transport RIB, and associated transport class Route Target and Route Distinguisher.
- **Transport plane**–Set of transport RTIs importing same transport class RT. These are in turn stitched together to span across tunnel domain boundaries using a mechanism similar to Inter-AS option-b to swap labels at border nodes (nexthop-self), forming an end-to-end transport plane.
- **Mapping community**–Community on a service route that maps to resolve over a transport class.

Understanding BGP Classful Transport Planes

You can use BGP classful transport planes to configure transport classes for classifying a set of transport tunnels in an intra-AS network based on the traffic engineering characteristics and use these transport tunnels to map service routes with the desired SLA and intended fallback.

BGP classful transport planes can extend these tunnels to inter-domain networks that span across multiple domains (ASs or IGP areas) while preserving the transport class. To do this, you must configure the BGP classful trasport transport layer BGP family between the border and service nodes.

In both inter-AS and intra-AS implementations, there can be many transport tunnels (MPLS LSPs, IS-IS flexible algorithm, SR-TE) created from the service and border nodes. The LSPs may be signaled using different signaling protocols in different domains, and can be configured with different traffic engineering characteristics (class or color). The transport tunnel endpoint also acts as the service endpoint and can be present in the same tunnel domain as the service ingress node, or in an adjacent or non-adjacent domain. You can use BGP classful transport planes to resove services over LSPs with certain traffic engineering charateristics either inside a single domain or across multiple domains.

BGP classful transport planes reuse the BGP-VPN technology, keeping the tunneling-domains loosely coupled and coordinated.

- The network layer reachability information (NLRI) is **RD:TunnelEndpoint** used for path-hiding.
- The route target indicates the transport class of the LSPs, and leaks routes to the corresponding transport RIB on the destination device.
- Every transport tunneling protocol installs an ingress route into the transport-class.inet.3 routing table, models the tunnel transport class as a VPN route target, and collects the LSPs of the same transport class in the transport-class.inet.3 transport-rib routing table.
- Routes in this routing instance are advertised in the BGP classful transport plane (inet transport) AFI-SAFI following procedures similar to RFC-4364.
- When crossing inter-AS link boundary, you must follow Option-b procedures to stitch the transport tunnels in these adjacent domains.

  Similarly, when crossing intra-AS regions you must follow Option-b procedures to stitch the transport tunnels in the different TE-domains.
- You can define resolution schemes to specify the intent on the variety of transport classes in a fallback order.
- You can resolve service routes and BGP classful transport routes over these transport classes, by carrrying the mapping community on them.

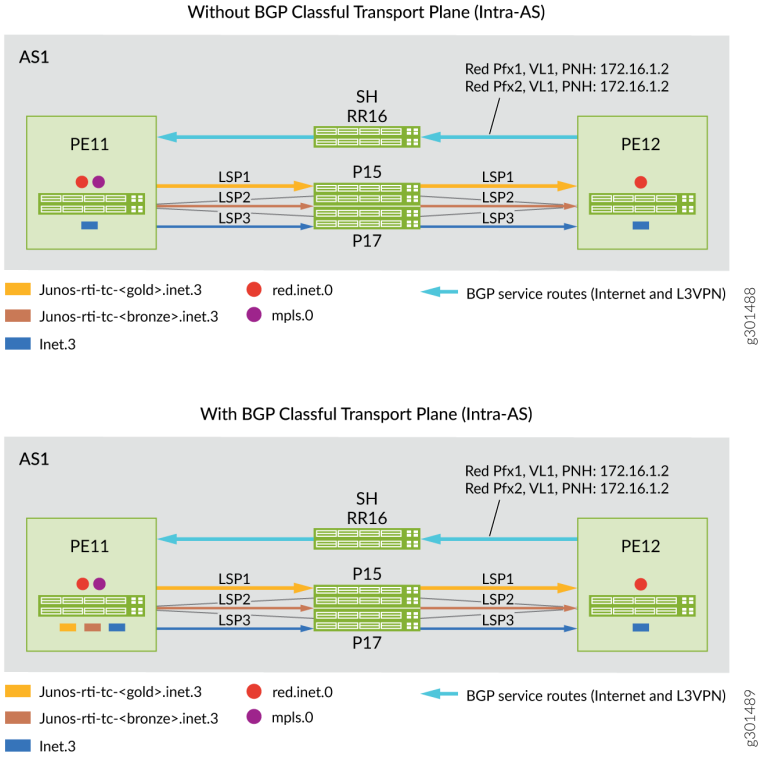
The BGP classful transport family runs along side the BGP-LU transport layer family. In a seamless MPLS network running BGP-LU, meeting stringent SLA requirements of 5G is a challenge as the traffic

engineering characteristics of the tunnels are not known or preserved across domain boundaries. BGP classful transport planes provide operationally easy and scalable means to advertise multiple paths for remote loopbacks along with the transport class information in the seamless MPLS architecture. In BGP classful tranport family routes, different SLA paths are represented using Transport Route-Target extended community, which carries the transport class color. This Transport Route-Target is used by the receiving BGP routers to associate the BGP classful transport route with the appropriate transport class. When re-advertising the BGP classful transport routes, MPLS swaps routes, inter connect the intra-AS tunnels of the same transport class, thereby forming an end-to-end tunnel that preserves the transport class.

Intra-AS Implementation of BGP Classful Transport Planes

Figure 107 on page 1649 illustrates a network topology with before-and-after scenarios of implementing BGP classful transport planes in an intra-AS domain. Devices PE11 and PE12 use RSVP LSPs as the transport tunnel and all transport tunnel routes are installed in inet.3 RIB. Implementing BGP classful transort planes enables RSVP transport tunnels to be color-aware similar to segment routing tunnels.

Figure 107: Intra-AS Domain: Before-and-After Scenarios For BGP Classful Transport Planes Implementation



To classify transport tunnels into BGP transport class in an intra-AS setup:

1. Define the transport class at the service node (ingress PE devices), for example, gold and bronze, and assign color community values to the defined transport class.
   Sample configuration:

```
pe11# show routing-options
route-distinguisher-id 172.16.1.1;
transport-class {
    name gold {
        color 100;
    }
    name bronze {
        color 200;
```

2. Associate the transport tunnel to a specific transport class at the ingress node of the tunnels.
   Sample configuration:

```
pe11# show protocols mpls
label-switched-path toPE12-bronze {
    transport-class bronze;
}
label-switched-path toPE12-gold {
    transport-class gold;
}
```

Intra-AS BGP classful transport plane functionality:

- BGP classful transport creates predefined transport RIBs per named transport class (gold and bronze) and auto derives mapping community from its color value (100 and 200).
- Intra-AS transport routes are populated in transport RIBs by the tunneling protocol when it is associated with a transport class.
  In this example, RSVP LSP routes associated with transport class gold (color 100) and transport class bronze (color 200) are installed in the transport RIBs **junos-rti-tc-<100>.inet.3** and **junos-rti-tc-<200>.inet.3**, respectively.
- Service node (ingress PEs) match extended color community (color:0:100 and color:0:200) of service route against the mapping community in predefined resolution RIBs and resolve the protocol next hop (PNH) in corresponding transport RIBs (either junos-rti-tc-<100>.inet.3, or junos-rti-tc-<200>.inet.3).

- BGP routes bind to a resolution scheme by carrying the assiocaited mapping community.
- Each transport class automatically creates two predefined resolution schemes and automatically derives the mapping community.

  One resolution scheme is for resolving service routes that use **Color:0:<val>** as the mapping community.

  The other resolution scheme is for resolving transport routes that use **Transport-Target:0:<val>** as the mapping community.
- If service route PNH cannot be resolved using RIBs listed in the predefined resolution scheme, then it can fall back to the inet.3 routing table.
- You can also configure fallback between different colored transport RIBs by using user-defined resolution schemes under the **[edit routing-options resolution scheme]** configuration hierarchy.

Inter-AS Implementation of BGP Classful Transport Planes

In an inter-AS network, BGP-LU is converted to BGP classful transport network after configuring a minimum of two transport classes (gold and bronze) on all service nodes or PE devices and border nodes (ABRs and ASBRs).

To convert the transport tunnels into BGP classful transport:

1. Define transport class at the service nodes (ingress PE devices) and the border nodes (ABRs and ASBRs), for example, gold and broze.

   Sample configuration:

```
pe11# show routing-options
route-distinguisher-id 172.16.1.1;
transport-class {
    name gold {
        color 100;
    }
    name bronze {
        color 200;
```

2. Associate the transport tunnels to a specific transport class at the ingress node of the tunnels (ingress PEs, ABRs,and ASBRs).

   Sample configuration:

For RSVP LSPs

```
abr23# show protocols mpls
label-switched-path toASBR21-bronze {
    transport-class bronze;
}
label-switched-path toASBR22-gold {
    transport-class gold;
```

For IS-IS flxible algorithm

```
asbr13# show routing-options
flex-algorithm 128 {
…
color 100;
use-transport-class;
}
flex-algorithm 129 {
…
color 200;
use-transport-class;
}
```

3. Enable new family for the BGP classful transport (inet transport) and BGP-LU (inet labeled-unicast) in the network.

   Sample configuration:

```
abr23# show protocols bgp
group toAs2-RR27 {
    family inet {
        labeled-unicast {
…
        }
        transport {
…
    }
    cluster 172.16.2.3;
    neighbor 172.16.2.7;
}
```

4. Advertise service routes from the egress PE device with appropriate extended color community. Sample configuration:

```
pe11# show policy-options policy-statement red
term 1 {
        from {
            route-filter 192.168.3.3/32 exact;
        }
        then {
            community add map2gold;
            next-hop self;
            accept;
        }
    }
    term 2 {
        from {
            route-filter 192.168.33.33/32 exact;
        }
        then {
            community add map2bronze;
            next-hop self;
            accept;
        }
    }
community map2bronze members color:0:200;
community map2gold members color:0:100;
```

Inter-AS BGP classful transport plane functionality:

1. BGP classful transport planes create predefined transport RIBs per named transport class (gold and bronze) and automatically derives mapping community from its color value.

2. Intra-AS transport routes are populated in transport RIBs by tunneling protocols when associated with a transport class.

   For example, transport tunnel routes associated with the transport class gold and bronze are installed in the transport RIBs **junos-rti-tc-<100>.inet.3** and **junos-rti-tc-<200>.inet.3**, respectively.

3. BGP classful transport planes use unique Route Distinguisher and Route Target when it copies the transport tunnel routes from each transport RIB to the bgp.transport.3 routing table.

4. Border nodes advertise routes from bgp.transport.3 routing table to its peers in other domains if family inet transport is negotiated in the BGP session.

5. Receiving border node installs these bgp-ct routes in the bgp.transport.3 routing table and copies these routes based on the transport Route Target to the appropriate transport RIBs.
6. Service node matches the color community in the service route against a mapping community in the resolution schemes and resolves PNH in the corresponding transport RIB (either **junos-rti-tc-<100>.inet.3**, or **junos-rti-tc-<200>.inet.3**).
7. Border nodes use predefined resolution schemes for transport route PNH resolution.
8. Predefined or user defined, both resolution schemes support service route PNH resolution. Predefined uses inet.3 as fallback, and user-defined resolution scheme allows list of transport RIBs to be used in the order specified while resolving PNH.
9. If service route PNH cannot be resolved using RIBs listed in the user-defined resolution scheme, then route is discarded.

BGP Classful Transport (BGP-CT) with Underlying Colored SR-TE Tunnels Overview

IN THIS SECTION

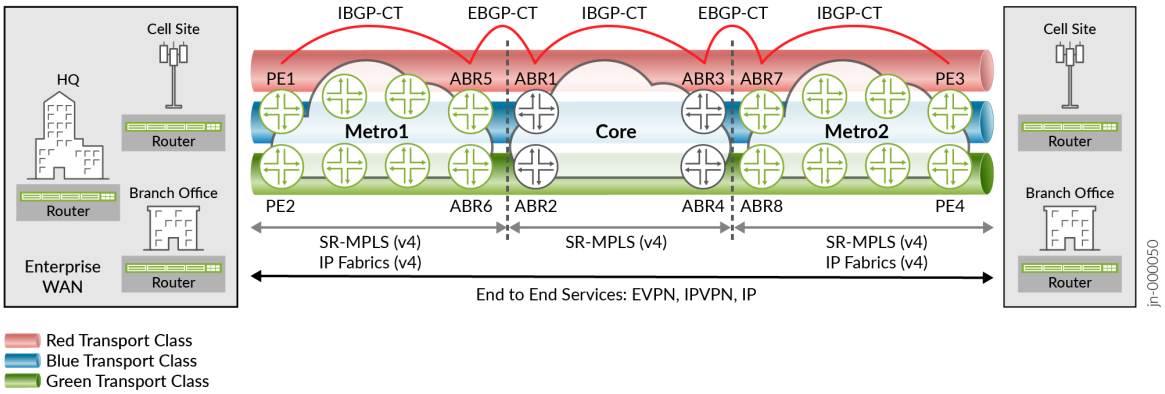
- Benefits of BGP-CT with underlying colored SR-TE Tunnels | **1654**

Benefits of BGP-CT with underlying colored SR-TE Tunnels

- Solves scale concerns that may arise in the future as the network grows.
- Provides inter-connectivity for domains that use different technologies.
- Decouples services and the transport layers resulting in a completely distributed network.
- Provides independent bandwidth management through an intra-domain traffic engineering controller for SR-TE.

Large networks that are growing and evolving continuously require a seamless segment routing architecture. Starting in Junos OS Release 21.2,R1 we support BGP-CT with underlying transport as colored SR-TE tunnels. BGP-CT can resolve service routes using the transport RIBs and compute the next hop. Services that are currently supported over BGP-CT can also use the underlying SR-TE colored tunnels for route resolution. The services can now use the underlying SR-TE colored tunnels such as the static colored, BGP SR-TE, programmable rpd and PCEP colored tunnels. BGP-CT uses the next-hop

reachability to resolve service routes over the desired transport class.



To enable BGP-CT service route resolution over underlying SR-TE colored tunnels, include the `use-transport-class` statement at the `[edit protocols source-packet-routing]` hierarchy level.

NOTE:

1. Enable the `use-transport-class` statement

   at the `[edit protocols source-packet-routing]` hierarchy level.

   along with the `auto-create` statement at the `[edit routing-options transport-class]` hierarchy level.

2. We don't support RIB groups for colored SR-TE with `use-transport-class` and color-only SR-TE tunnels with this feature.

Improving Traffic Engineering Database Accuracy with RSVP PathErr Messages

IN THIS SECTION

- PathErr Messages | **1656**
- Identifying the Problem Link | **1657**
- Configuring the Router to Improve Traffic Engineering Database Accuracy | **1657**

An essential element of RSVP-based traffic engineering is the traffic engineering database. The traffic engineering database contains a complete list of all network nodes and links participating in traffic engineering, and a set of attributes each of those links can hold. (For more information about the traffic engineering database, see "Constrained-Path LSP Computation" on page 570.) One of the most important link attributes is bandwidth.

Bandwidth availability on links changes quickly as RSVP LSPs are established and terminated. It is likely that the traffic engineering database will develop inconsistencies relative to the real network. These inconsistencies cannot be fixed by increasing the rate of IGP updates.

Link availability can share the same inconsistency problem. A link that becomes unavailable can break all existing RSVP LSPs. However, its unavailability might not readily be known by the network.

When you configure the `rsvp-error-hold-time` statement, a source node (ingress of an RSVP LSP) learns from the failures of its LSP by monitoring PathErr messages transmitted from downstream nodes. Information from the PathErr messages is incorporated into subsequent LSP computations, which can improve the accuracy and speed of LSP setup. Some PathErr messages are also used to update traffic engineering database bandwidth information, reducing inconsistencies between the traffic engineering database and the network.

You can control the frequency of IGP updates by using the `update-threshold` statement. See "Configuring the RSVP Update Threshold on an Interface" on page 1201.

This section discusses the following topics:

PathErr Messages

PathErr messages report a wide variety of problems by means of different code and subcode numbers. You can find a complete list of these PathErr messages in RFC 2205, *Resource Reservation Protocol (RSVP), Version 1, Functional Specification* and RFC 3209, *RSVP-TE: Extensions to RSVP for LSP Tunnels*.

When you configure the `rsvp-error-hold-time` statement, two categories of PathErr messages, which specifically represent link failures, are examined:

- Link bandwidth is low for this LSP: Requested bandwidth unavailable—code 1, subcode 2

  This type of PathErr message represents a global problem that affects all LSPs transiting the link. They indicate that the actual link bandwidth is lower than that required by the LSP, and that it is likely that the bandwidth information in the traffic engineering database is an overestimate.

  When this type of error is received, the available link bandwidth is reduced in the local traffic engineering database, affecting all future LSP computations.

- Link unavailable for this LSP:

  - Admission Control failure—code 1, any subcode except 2

- Policy Control failures—code 2
- Service Preempted—code 12
- Routing problem—no route available toward destination—code 24, subcode 5

These types of PathErr messages are generally pertinent to the specified LSP. The failure of this LSP does not necessarily imply that other LSPs could also fail. These errors can indicate maximum transfer unit (MTU) problems, service preemption (either manually initiated by the operator or by another LSP with a higher priority), that a next-hop link is down, that a next-hop neighbor is down, or service rejection because of policy considerations. It is best to route this particular LSP away from the link.

Identifying the Problem Link

Each PathErr message includes the sender's IP address. This information is propagated unchanged toward the ingress router. A lookup in the traffic engineering database can identify the node that originated the PathErr message.

Each PathErr message carries enough information to identify the RSVP session that triggered the message. If this is a transit router, it simply forwards the message. If this router is the ingress router (for this RSVP session), it has the complete list of all nodes and links the session should traverse. Coupled with the originating node information, the link can be uniquely identified.

Configuring the Router to Improve Traffic Engineering Database Accuracy

To improve the accuracy of the traffic engineering database, configure the `rsvp-error-hold-time` statement. When this statement is configured, a source node (ingress of an RSVP LSP) learns from the failures of its LSP by monitoring PathErr messages transmitted from downstream nodes. Information from the PathErr messages is incorporated into subsequent LSP computations, which can improve the accuracy and speed of LSP setup. Some PathErr messages also are used to update traffic engineering database bandwidth information, reducing inconsistencies between the traffic engineering database and the network.

To configure how long MPLS should remember RSVP PathErr messages and consider them in CSPF computation, include the `rsvp-error-hold-time` statement:

```
rsvp-error-hold-time seconds;
```

You can include this statement at the following hierarchy levels:

- `[edit protocols mpls]`
- `[edit logical-systems logical-system-name protocols mpls]`

The time can be a value from 1 to 240 seconds. The default is 25 seconds. Configuring a value of 0 disables the monitoring of PathErr messages.

Release History Table

Release	Description
20.4R1	Starting in Junos OS Release 20.4R1, you can configure IS-IS traffic engineering to store IPv6 information in the traffic engineering database (TED) in addition to IPv4 addresses.
17.4R1	Starting in Junos OS Release 17.4R1, the traffic engineering database installs interior gateway protocol (IGP) topology information in addition to RSVP-TE topology information in the lsdist.0 routing table
17.2R1	Starting in Junos OS Release 17.2R1, the BGP link-state address family is extended to distribute the source packet routing in networking (SPRING) topology information to software-defined networking (SDN) controllers.
17.1R1	Starting with Junos OS Release 17.1R1, link state distribution using BGP is supported on QFX10000 switches.

MPLS and Traffic Engineering

Traffic engineering allows you to control the path that data packets follow, bypassing the standard routing model, which uses routing tables. Traffic engineering moves flows from congested links to alternate links that would not be selected by the automatically computed destination-based shortest path. With traffic engineering, you can:

- Make more efficient use of expensive long-haul fibers.
- Control how traffic is rerouted in the face of single or multiple failures.
- Classify critical and regular traffic on a per-path basis.

The core of the traffic engineering design is based on building label-switched paths (LSPs) among routers. An LSP is connection-oriented, like a virtual circuit in Frame Relay or ATM. LSPs are not reliable: Packets entering an LSP do not have delivery guarantees, although preferential treatment is possible. LSPs also are similar to unidirectional tunnels in that packets entering a path are encapsulated in an envelope and switched across the entire path without being touched by intermediate nodes. LSPs provide fine-grained control over how packets are forwarded in a network. To provide reliability, an LSP can use a set of primary and secondary paths.

LSPs can be configured for BGP traffic only (traffic whose destination is outside of an autonomous system [AS]). In this case, traffic within the AS is not affected by the presence of LSPs. LSPs can also be configured for both BGP and interior gateway protocol (IGP) traffic; therefore, both intra-AS and inter-AS traffic is affected by the LSPs.

MPLS Traffic Engineering and Signaling Protocols Overview

Traffic engineering facilitates efficient and reliable network operations while simultaneously optimizing network resources and traffic performance. Traffic engineering provides the ability to move traffic flow away from the shortest path selected by the interior gateway protocol (IGP) to a potentially less

congested physical path across a network. To support traffic engineering, besides source routing, the network must do the following:

- Compute a path at the source by taking into account all the constraints, such as bandwidth and administrative requirements.
- Distribute the information about network topology and link attributes throughout the network once the path is computed.
- Reserve network resources and modify link attributes.

When transit traffic is routed through an IP network, MPLS is often used to engineer its passage. Although the exact path through the transit network is of little importance to either the sender or the receiver of the traffic, network administrators often want to route traffic more efficiently between certain source and destination address pairs. By adding a short label with specific routing instructions to each packet, MPLS switches packets from router to router through the network rather than forwarding packets based on next-hop lookups. The resulting routes are called *label-switched paths (LSPs)*. LSPs control the passage of traffic through the network and speed traffic forwarding.

You can create LSPs manually, or through the use of signaling protocols. Signaling protocols are used within an MPLS environment to establish LSPs for traffic across a transit network. Junos OS supports two signaling protocols—LDP and the Resource Reservation Protocol (RSVP).

MPLS traffic engineering uses the following components:

- MPLS LSPs for packet forwarding
- IGP extensions for distributing information about the network topology and link attributes
- Constrained Shortest Path First (CSPF) for path computation and path selection
- RSVP extensions to establish the forwarding state along the path and to reserve resources along the path

Junos OS also supports traffic engineering across different OSPF regions.

Traffic Engineering Capabilities

The task of mapping traffic flows onto an existing physical topology is called *traffic engineering*. Traffic engineering provides the ability to move traffic flow away from the shortest path selected by the interior gateway protocol (IGP) and onto a potentially less congested physical path across a network.

Traffic engineering provides the capabilities to do the following:

- Route primary paths around known bottlenecks or points of congestion in the network.
- Provide precise control over how traffic is rerouted when the primary path is faced with single or multiple failures.

- Provide more efficient use of available aggregate bandwidth and long-haul fiber by ensuring that subsets of the network do not become overutilized while other subsets of the network along potential alternate paths are underutilized.
- Maximize operational efficiency.
- Enhance the traffic-oriented performance characteristics of the network by minimizing packet loss, minimizing prolonged periods of congestion, and maximizing throughput.
- Enhance statistically bound performance characteristics of the network (such as loss ratio, delay variation, and transfer delay) required to support a multiservices Internet.

Components of Traffic Engineering

In the Junos® operating system (OS), traffic engineering is implemented with MPLS and RSVP. Traffic engineering is composed of four functional components:

- "Packet Forwarding Component" on page 1599
- Information Distribution Component
- Path Selection Component
- Signaling Component

Configuring Traffic Engineering for LSPs

IN THIS SECTION

- Using LSPs for Both BGP and IGP Traffic Forwarding | **1662**
- Using LSPs for Forwarding in Virtual Private Networks | **1662**
- Using RSVP and LDP Routes for Forwarding but Not Route Selection | **1663**
- Advertising the LSP Metric in Summary LSAs | **1664**

When you configure an LSP, a host route (a 32-bit mask) is installed in the ingress router toward the egress router; the address of the host route is the destination address of the LSP. The `bgp` option for the `traffic engineering` statement at the `[edit protocols mpls]` hierarchy level is enabled by default (you can also explicitly configure the `bgp` option), allowing only BGP to use LSPs in its route calculations. The other `traffic-engineering` statement options allow you to alter this behavior in the master routing instance. This functionality is not available for specific routing instances. Also, you can enable only one of the `traffic-engineering` statement options (`bgp`, `bgp-igp`, `bgp-igp-both-ribs`, or `mpls-forwarding`) at a time.

NOTE: Enabling or disabling any of the `traffic-engineering` statement options causes all the MPLS routes to be removed and then reinserted into the routing tables.

You can configure OSPF and traffic engineering to advertise the LSP metric in summary link-state advertisements (LSAs) as described in the section "Advertising the LSP Metric in Summary LSAs" on page 1595.

The following sections describe how to configure traffic engineering for LSPs:

Using LSPs for Both BGP and IGP Traffic Forwarding

You can configure BGP and the IGPs to use LSPs for forwarding traffic destined for egress routers by including the `bgp-igp` option for the `traffic-engineering` statement. The `bgp-igp` option causes all inet.3 routes to be moved to the inet.0 routing table.

On the ingress router, include `bgp-igp` option for the `traffic-engineering` statement:

```
traffic-engineering bgp-igp;
```

You can include this statement at the following hierarchy levels:

- `[edit protocols mpls]`
- `[edit logical-systems` *`logical-system-name`* `protocols mpls]`

NOTE: The `bgp-igp` option for the `traffic-engineering` statement cannot be configured for VPN). VPNs require that routes be in the inet.3 routing table.

Using LSPs for Forwarding in Virtual Private Networks

VPNs require that routes remain in the inet.3 routing table to function properly. For VPNs, configure the `bgp-igp-both-ribs` option of the `traffic-engineering` statement to cause BGP and the IGPs to use LSPs for forwarding traffic destined for egress routers. The `bgp-igp-both-ribs` option installs the ingress routes in both the inet.0 routing table (for IPv4 unicast routes) and the inet.3 routing table (for MPLS path information).

On the ingress router, include the `traffic-engineering bgp-igp-both-ribs` statement:

```
traffic-engineering bgp-igp-both-ribs;
```

You can include this statement at the following hierarchy levels:

- `[edit protocols mpls]`
- `[edit logical-systems` *`logical-system-name`* `protocols mpls]`

When you use the `bgp-igp-both-ribs` statement, the routes from the inet.3 table get copied into the inet.0 table. The copied routes are LDP-signaled or RSVP-signaled, and are likely to have a lower preference than other routes in inet.0. Routes with a lower preference are more likely to be chosen as the active routes. This can be a problem because routing policies only act upon active routes. To prevent this problem, use the `mpls-forwarding` option instead.

Using RSVP and LDP Routes for Forwarding but Not Route Selection

If you configure the `bgp-igp` or `bgp-igp-both-ribs` options for the `traffic-engineering` statement, high-priority LSPs can supersede IGP routes in the inet.0 routing table. IGP routes might no longer be redistributed since they are no longer the active routes.

If you configure the `mpls-forwarding` option for the `traffic-engineering` statement, LSPs are used for forwarding but are excluded from route selection. These routes are added to both the inet.0 and inet.3 routing tables. LSPs in the inet.0 routing table are given a low preference when the active route is selected. However, LSPs in the inet.3 routing table are given a normal preference and are therefore used for selecting forwarding next hops.

When you activate the `mpls-forwarding` option, routes whose state is `ForwardingOnly` are preferred for forwarding even if their preference is lower than that of the currently active route. To examine the state of a route, execute a `show route detail` command.

To use LSPs for forwarding but exclude them from route selection, include the `mpls-forwarding` option for the `traffic-engineering` statement:

```
traffic-engineering mpls-forwarding;
```

You can include this statement at the following hierarchy levels:

- `[edit protocols mpls]`
- `[edit logical-systems` *`logical-system-name`* `protocols mpls]`

When you configure the mpls-forwarding option, IGP shortcut routes are copied to the inet.0 routing table only.

Unlike the bgp-igp-both-ribs option, the mpls-forwarding option allows you to use the LDP-signaled and RSVP-signaled routes for forwarding, and keep the BGP and IGP routes active for routing purposes so that routing policies can act upon them.

For example, suppose a router is running BGP and it has a BGP route of 10.10.10.1/32 that it needs to send to another BGP speaker. If you use the bgp-igp-both-ribs option, and your router also has a label-switched-path (LSP) to 10.10.10.1, the MPLS route for 10.10.10.1 becomes active in the inet.0 routing table. This prevents your router from advertising the 10.10.10.1 route to the other BGP router. On the other hand, if you use the mpls-forwarding option instead of the bgp-igp-both-ribs option, the 10.10.10.1/32 BGP route is advertised to the other BGP speaker, and the LSP is still used to forward traffic to the 10.10.10.1 destination.

Advertising the LSP Metric in Summary LSAs

You can configure MPLS and OSPF to treat an LSP as a link. This configuration allows other routers in the network to use this LSP. To accomplish this goal, you need to configure MPLS and OSPF traffic engineering to advertise the LSP metric in summary LSAs.

For MPLS, include the traffic-engineering bgp-igp and label-switched-path statements:

```
traffic-engineering bgp-igp;
label-switched-path lsp-name {
    to address;
}
```

You can include these statements at the following hierarchy levels:

- [edit protocols mpls]
- [edit logical-systems *logical-system-name* protocols mpls]

For OSPF, include the lsp-metric-into-summary statement:

```
lsp-metric-into-summary;
```

You can include this statement at the following hierarchy levels:

- [edit protocols ospf traffic-engineering shortcuts]
- [edit logical-systems *logical-system-name* protocols ospf traffic-engineering shortcuts]

For more information about OSPF traffic engineering, see the Junos OS Routing Protocols Library for Routing Devices.

Enabling Interarea Traffic Engineering

The Junos OS can signal a contiguous traffic-engineered LSP across multiple OSPF areas. The LSP signaling must be done using either nesting or contiguous signaling, as described in RFC 4206, *Label-Switched Paths (LSP) Hierarchy with Generalized Multi-Protocol Label Switching (GMPLS) Traffic Engineering (TE)*. However, contiguous signaling support is limited to just basic signaling. Reoptimization is not supported with contiguous signaling.

The following describes some of the interarea traffic engineering features:

- Interarea traffic engineering can be enabled when the loose-hop area border routers (ABRs) are configured on the ingress router using CSPF for the Explicit Route Object (ERO) calculation within an OSPF area. ERO expansion is completed on the ABRs.
- Interarea traffic engineering can be enabled when CSPF is enabled, but without ABRs specified in the LSP configuration on the ingress router (ABRs can be automatically designated).
- Differentiated Services (DiffServ) traffic engineering is supported as long as the class type mappings are uniform across multiple areas.

To enable interarea traffic engineering, include the `expand-loose-hop` statement in the configuration for each LSP transit router:

```
expand-loose-hop;
```

You can include this statement at the following hierarchy levels:

- `[edit protocols mpls]`
- `[edit logical-systems logical-system-name protocols mpls]`

Enabling Inter-AS Traffic Engineering for LSPs

IN THIS SECTION

- Inter-AS Traffic Engineering Requirements | **1666**
- Inter-AS Traffic Engineering Limitations | **1667**
- Configuring OSPF Passive TE Mode | **1667**

Generally, traffic engineering is possible for LSPs that meet the following conditions:

- Both ends of the LSP are in the same OSPF area or at the same IS-IS level.
- The two ends of the LSP are in different OSPF areas within the same autonomous system (AS). LSPs that end in different IS-IS levels are not supported.
- The two ends of an explicit-path LSP are in different OSPF ASs and the autonomous system border routers (ASBRs) are configured statically as the loose hops supported on the explicit-path LSP. For more information, see "Configuring Explicit-Path LSPs" on page 656.

Without statically defined ASBRs on LSPs, traffic engineering is not possible between one routing domain, or AS, and another. However, when the ASs are under the control of single service provider, it is possible in some cases to have traffic engineered LSPs span the ASs and dynamically discover the OSPF ASBRs linking them (IS-IS is not supported with this feature).

Inter-AS traffic engineered LSPs are possible as long as certain network requirements are met, none of the limiting conditions apply, and OSPF passive mode is configured with EBGP. Details are provided in the following sections:

Inter-AS Traffic Engineering Requirements

The proper establishment and functioning of inter-AS traffic engineered LSPs depend on the following network requirements, all of which must be met:

- All ASs are under control of a single service provider.
- OSPF is used as the routing protocol within each AS, and EBGP is used as the routing protocol between the ASs.
- ASBR information is available inside each AS.
- EBGP routing information is distributed by OSPF, and an IBGP full mesh is in place within each AS.
- Transit LSPs are *not* configured on the inter-AS links, but *are* configured between entry and exit point ASBRs on each AS.
- The EBGP link between ASBRs in different ASs is a direct link and must be configured as a passive traffic engineering link under OSPF. The remote link address itself, not the loopback or any other link address, is used as the remote node identifier for this passive link. For more information about OSPF passive traffic engineering mode configuration, see "Configuring OSPF Passive TE Mode" on page 1598.

In addition, the address used for the remote node of the OSPF passive traffic engineering link must be the same as the address used for the EBGP link. For more information about OSPF and BGP in general, see the Junos OS Routing Protocols Library for Routing Devices.

Inter-AS Traffic Engineering Limitations

Only LSP hierarchical, or nested, signaling is supported for inter-AS traffic engineered LSPs. Only point-to-point LSPs are supported (there is no point-to-multipoint support).

In addition, the following limitations apply. Any one of these conditions is sufficient to render inter-AS traffic engineered LSPs impossible, even if the above requirements are met.

- The use of multihop BGP is not supported.
- The use of policers or topologies that prevent BGP routes from being known inside the AS is not supported.
- Multiple ASBRs on a LAN between EBGP peers are not supported. Only one ASBR on a LAN between EBGP peers is supported (others ASBRs can exist on the LAN, but cannot be advertised).
- Route reflectors or policies that hide ASBR information or prevent ASBR information from being distributed inside the ASs are not supported.
- Bidirectional LSPs are not supported (LSPs are unidirectional from the traffic engineering perspective).
- Topologies with both inter-AS and intra-AS paths to the same destination are not supported.

In addition, several features that are routine with all LSPs are not supported with inter-AS traffic engineering:

- Admin group link colors are not supported.
- Secondary standby is not supported.
- Reoptimization is not supported.
- Crankback on transit routers is not supported.
- Diverse path calculation is not supported.
- Graceful restart is not supported.

These lists of limitations or unsupported features with inter-AS traffic engineered LSPs are not exhaustive.

Configuring OSPF Passive TE Mode

Ordinarily, interior routing protocols such as OSPF are not run on links between ASs. However, for inter-AS traffic engineering to function properly, information about the inter-AS link, in particular, the address on the remote interface, must be made available inside the AS. This information is not normally included either in EBGP reachability messages or in OSPF routing advertisements.

To flood this link address information within the AS and make it available for traffic engineering calculations, you must configure OSPF passive mode for traffic engineering on each inter-AS interface. You must also supply the remote address for OSPF to distribute and include in the traffic engineering database.

To configure OSPF passive mode for traffic engineering on an inter-AS interface, include the `passive` statement for the link at the `[edit protocols ospf area area-id interface interface-name]` hierarchy level:

```
passive {
    traffic-engineering {
        remote-node-id ip-address;     /* IP address at far end of inter-AS link */
    }
}
```

OSPF must be properly configured on the router. The following example configures the inter-AS link `so-1/1/0` to distribute traffic engineering information with OSPF within the AS. The remote IP address is `192.168.207.2`.

```
[edit protocols ospf area 0.0.0.0]
interface so-1/1/0 {
    unit 0 {
        passive {
            traffic-engineering {
                remote-node-id 192.168.207.2;
            }
        }
    }
}
```

Packet Forwarding Component

- Packet Forwarding Based on Label Swapping | **1669**
- How a Packet Traverses an MPLS Backbone | **1669**
- Information Distribution Component | **1670**
- Path Selection Component | **1670**
- Signaling Component | **1671**

The packet forwarding component of the Junos traffic engineering architecture is MPLS, which is responsible for directing a flow of IP packets along a predetermined path across a network. This path is called a *label-switched path (LSP)*. LSPs are simplex; that is, the traffic flows in one direction from the head-end (ingress) router to a tail-end (egress) router. Duplex traffic requires two LSPs: one LSP to carry traffic in each direction. An LSP is created by the concatenation of one or more label-switched hops, allowing a packet to be forwarded from one router to another across the MPLS domain.

When an ingress router receives an IP packet, it adds an MPLS header to the packet and forwards it to the next router in the LSP. The labeled packet is forwarded along the LSP by each router until it reaches the tail end of the LSP, the egress router. At this point the MPLS header is removed, and the packet is forwarded based on Layer 3 information such as the IP destination address. The value of this scheme is that the physical path of the LSP is not limited to what the IGP would choose as the shortest path to reach the destination IP address.

Packet Forwarding Based on Label Swapping

The packet forwarding process at each router is based on the concept of label swapping. This concept is similar to what occurs at each Asynchronous Transfer Mode (ATM) switch in a permanent virtual circuit (PVC). Each MPLS packet carries a 4-byte encapsulation header that contains a 20-bit, fixed-length label field. When a packet containing a label arrives at a router, the router examines the label and copies it as an index to its MPLS forwarding table. Each entry in the forwarding table contains an interface-inbound label pair mapped to a set of forwarding information that is applied to all packets arriving on the specific interface with the same inbound label.

How a Packet Traverses an MPLS Backbone

This section describes how an IP packet is processed as it traverses an MPLS backbone network.

At the entry edge of the MPLS backbone, the IP header is examined by the ingress router. Based on this analysis, the packet is classified, assigned a label, encapsulated in an MPLS header, and forwarded toward the next hop in the LSP. MPLS provides a high degree of flexibility in the way that an IP packet can be assigned to an LSP. For example, in the Junos traffic engineering implementation, all packets arriving at the ingress router that are destined to exit the MPLS domain at the same egress router are forwarded along the same LSP.

Once the packet begins to traverse the LSP, each router uses the label to make the forwarding decision. The MPLS forwarding decision is made independently of the original IP header: the incoming interface and label are used as lookup keys into the MPLS forwarding table. The old label is replaced with a new label, and the packet is forwarded to the next hop along the LSP. This process is repeated at each router in the LSP until the packet reaches the egress router.

When the packet arrives at the egress router, the label is removed and the packet exits the MPLS domain. The packet is then forwarded based on the destination IP address contained in the packet's original IP header according to the traditional shortest path calculated by the IP routing protocol.

Information Distribution Component

Traffic engineering requires detailed knowledge about the network topology as well as dynamic information about network loading. To implement the information distribution component, simple extensions to the IGPs are defined. Link attributes are included as part of each router's link-state advertisement. IS-IS extensions include the definition of new type length values (TLVs), whereas OSPF extensions are implemented with opaque link-state advertisements (LSAs). The standard flooding algorithm used by the link-state IGPs ensures that link attributes are distributed to all routers in the routing domain. Some of the traffic engineering extensions to be added to the IGP link-state advertisement include maximum link bandwidth, maximum reserved link bandwidth, current bandwidth reservation, and link coloring.

Each router maintains network link attributes and topology information in a specialized traffic engineering database. The traffic engineering database is used exclusively for calculating explicit paths for the placement of LSPs across the physical topology. A separate database is maintained so that the subsequent traffic engineering computation is independent of the IGP and the IGP's link-state database. Meanwhile, the IGP continues its operation without modification, performing the traditional shortest-path calculation based on information contained in the router's link-state database.

Path Selection Component

After network link attributes and topology information are flooded by the IGP and placed in the traffic engineering database, each ingress router uses the traffic engineering database to calculate the paths for its own set of LSPs across the routing domain. The path for each LSP can be represented by either a strict or loose explicit route. An explicit route is a preconfigured sequence of routers that should be part of the physical path of the LSP. If the ingress router specifies all the routers in the LSP, the LSP is said to be identified by a strict explicit route. If the ingress router specifies only some of the routers in the LSP, the LSP is described as a loose explicit route. Support for strict and loose explicit routes allows the path selection process to be given broad latitude whenever possible, but to be constrained when necessary.

The ingress router determines the physical path for each LSP by applying a Constrained Shortest Path First (CSPF) algorithm to the information in the traffic engineering database. CSPF is a shortest-path-first algorithm that has been modified to take into account specific restrictions when the shortest path across the network is calculated. Input into the CSPF algorithm includes:

- Topology link-state information learned from the IGP and maintained in the traffic engineering database
- Attributes associated with the state of network resources (such as total link bandwidth, reserved link bandwidth, available link bandwidth, and link color) that are carried by IGP extensions and stored in the traffic engineering database
- Administrative attributes required to support traffic traversing the proposed LSP (such as bandwidth requirements, maximum hop count, and administrative policy requirements) that are obtained from user configuration

As CSPF considers each candidate node and link for a new LSP, it either accepts or rejects a specific path component based on resource availability or whether selecting the component violates user policy constraints. The output of the CSPF calculation is an explicit route consisting of a sequence of router addresses that provides the shortest path through the network that meets the constraints. This explicit route is then passed to the signaling component, which establishes the forwarding state in the routers along the LSP.

Signaling Component

An LSP is not known to be workable until it is actually established by the signaling component. The signaling component, which is responsible for establishing LSP state and distributing labels, relies on a number of extensions to RSVP:

- The Explicit Route object allows an RSVP path message to traverse an explicit sequence of routers that is independent of conventional shortest-path IP routing. The explicit route can be either strict or loose.
- The Label Request object permits the RSVP path message to request that intermediate routers provide a label binding for the LSP that it is establishing.
- The Label object allows RSVP to support the distribution of labels without changing its existing mechanisms. Because the RSVP Resv message follows the reverse path of the RSVP path message, the Label object supports the distribution of labels from downstream nodes to upstream nodes.

Offline Path Planning and Analysis

Despite the reduced management effort resulting from online path calculation, an offline planning and analysis tool is still required to optimize traffic engineering globally. Online calculation takes resource constraints into account and calculates one LSP at a time. The challenge with this approach is that it is not deterministic. The order in which LSPs are calculated plays a critical role in determining each LSP's physical path across the network. LSPs that are calculated early in the process have more resources available to them than LSPs calculated later in the process because previously calculated LSPs consume network resources. If the order in which the LSPs are calculated is changed, the resulting set of physical paths for the LSPs also can change.

An offline planning and analysis tool simultaneously examines each link's resource constraints and the requirements of each LSP. Although the offline approach can take several hours to complete, it performs global calculations, compares the results of each calculation, and then selects the best solution for the network as a whole. The output of the offline calculation is a set of LSPs that optimizes utilization of network resources. After the offline calculation is completed, the LSPs can be established in any order because each is installed according to the rules for the globally optimized solution.

Flexible LSP Calculation and Configuration

Traffic engineering involves mapping traffic flow onto a physical topology. You can determine the paths online using constraint-based routing. Regardless of how the physical path is calculated, the forwarding state is installed across the network through RSVP.

The Junos OS supports the following ways to route and configure an LSP:

- You can calculate the full path for the LSP offline and individually configure each router in the LSP with the necessary static forwarding state. This is analogous to the way some Internet service providers (ISPs) configure their IP-over-ATM cores.

- You can calculate the full path for the LSP offline and statically configure the ingress router with the full path. The ingress router then uses RSVP as a dynamic signaling protocol to install a forwarding state in each router along the LSP.

- You can rely on constraint-based routing to perform dynamic online LSP calculation. You configure the constraints for each LSP; then the network itself determines the path that best meets those constraints. Specifically, the ingress router calculates the entire LSP based on the constraints and then initiates signaling across the network.

- You can calculate a partial path for an LSP offline and statically configure the ingress router with a subset of the routers in the path; then you can permit online calculation to determine the complete path.

  For example, consider a topology that includes two east-west paths across the United States: one in the north through Chicago and one in the south through Dallas. If you want to establish an LSP between a router in New York and one in San Francisco, you can configure the partial path for the LSP to include a single loose-routed hop of a router in Dallas. The result is an LSP routed along the southern path. The ingress router uses CSPF to compute the complete path and RSVP to install the forwarding state along the LSP.

- You can configure the ingress router with no constraints whatsoever. In this case, normal IGP shortest-path routing is used to determine the path of the LSP. This configuration does not provide any value in terms of traffic engineering. However, it is easy and might be useful in situations when services such as virtual private networks (VPNs) are needed.

In all these cases, you can specify any number of LSPs as backups for the primary LSP, thus allowing you to combine more than one configuration approach. For example, you might explicitly compute the primary path offline, set the secondary path to be constraint-based, and have the tertiary path be unconstrained. If a circuit on which the primary LSP is routed fails, the ingress router notices the outage from error notifications received from a downstream router or by the expiration of RSVP soft-state information. Then the router dynamically forwards traffic to a hot-standby LSP or calls on RSVP to create a forwarding state for a new backup LSP.

Link-State Distribution Using BGP Overview

IN THIS SECTION

Role of an Interior Gateway Protocol

An interior gateway protocol (IGP) is a type of protocol used for exchanging routing information between devices within an autonomous system (AS). Based on the method of computing the best path to a destination, the IGPs are divided into two categories:

- Link-state protocols—Advertise information about the network topology (directly connected links and the state of those links) to all routers using multicast addresses and triggered routing updates until all the routers running the link-state protocol have identical information about the internetwork. The best path to a destination is calculated based on constraints such as maximum delay, minimum available bandwidth, and resource class affinity.

  OSPF and IS-IS are examples of link-state protocols.

- Distance vector protocols—Advertise complete routing table information to directly connected neighbors using a broadcast address. The best path is calculated based on the number of hops to the destination network.

  RIP is an example of a distance vector protocol.

As the name implies, the role of an IGP is to provide routing connectivity within or internal to a given routing domain. A routing domain is a set of routers under common administrative control that share a common routing protocol. An AS can consist of multiple routing domains, where IGP functions to advertise and learn network prefixes (routes) from neighboring routers to build a route table that ultimately contains entries for all sources advertising reachability for a given prefix. IGP executes a route selection algorithm to select the best path between the local router and each destination, and provides full connectivity among the routers making up a routing domain.

In addition to advertising internal network reachability, IGPs are often used to advertise routing information that is external to that IGP's routing domain through a process known as route redistribution. Route redistribution is the process of exchanging routing information among distinct routing protocols to tie multiple routing domains together when intra-AS connectivity is desired.

Limitations of an Interior Gateway Protocol

While each individual IGP has its own advantages and limitations, the biggest limitations of IGP in general are performance and scalability.

IGPs are designed to handle the task of acquiring and distributing network topology information for traffic engineering purposes. While this model has served well, IGPs have inherent scaling limitations when it comes to distributing large databases. IGPs can autodetect neighbors, with which they acquire intra-area network topology information. However, the link-state database or a traffic engineering database has the scope of a single area or AS, thereby limiting applications, such as end-to-end traffic engineering, the benefit of having external visibility to make better decisions.

For label-switched networks, such as MPLS and Generalized MPLS (GMPLS), most existing traffic engineering solutions work in a single routing domain. These solutions do not work when a route from the ingress node to the egress node leaves the routing area or AS of the ingress node. In such cases, the path computation problem becomes complicated because of the unavailability of the complete routing information throughout the network. This is because service providers usually choose not to leak routing information beyond the routing area or AS for scalability constraints and confidentiality concerns.

Need for Spanning Link-State Distribution

One of the limitations of IGP is its inability to span link-state distribution outside a single area or AS. However, spanning link-state information acquired by an IGP across multiple areas or ASs has the following needs:

- LSP path computation—This information is used to compute the path for MPLS LSPs across multiple routing domains, for example an inter-area TE LSP.
- External path computing entities—External path computing entities, such as Application Layer Traffic Optimization (ALTO) and Path Computation Elements (PCE), perform path computations based on the network topology and current state of connections within the network, including traffic engineering information. This information is typically distributed by IGPs within the network.

  However, because the external path computing entities cannot extract this information from the IGPs, they perform network monitoring to optimize network services.

Using BGP as a Solution

Overview

To meet the needs for spanning link-state distribution across multiple domains, an exterior gateway protocol (EGP) is required to collect link-state and traffic engineering information from an IGP area, share it with external component, and use it for computing paths for interdomain MPLS LSPs.

BGP is a standardized EGP designed to exchange routing and reachability information between autonomous systems (ASs). BGP is a proven protocol that has better scaling properties because it can distribute millions of entries (for example, VPN prefixes) in a scalable fashion. BGP is the only routing protocol in use today that is suited to carry all of the routes in the Internet. This is largely because BGP runs on top of TCP and can make use of TCP flow control. In contrast, the internal gateway protocols (IGPs) do not have flow control. When IGPs have too much route information, they begin to churn. When BGP has a neighboring speaker that is sending information too quickly, BGP can throttle down the neighbor by delaying TCP acknowledgments.

Another benefit of BGP is that it uses type, length, value (TLV) tuples and network layer reachability information (NLRI) that provide seemingly endless extensibility without the need for the underlying protocol to be altered.

The distribution of link-state information across domains is regulated using policies to protect the interests of the service provider. This requires a control over the topology distribution using policies. BGP with its implemented policy framework serves well in the interdomain route distribution. In Junos OS, BGP is completely policy driven. The operator must explicitly configure neighbors to peer with and explicitly accept routes into BGP. Furthermore, routing policy is used to filter and modify routing information. Thus, routing policies provide complete administrative control over the routing tables.

Although, within an AS, both IGP-TE and BGP-TE provide the same set of information, BGP-TE has better scaling characteristics that are inherited from the standard BGP protocol. This makes BGP-TE a more scalable choice for acquiring multi-area/multi-AS topology information.

By using BGP as a solution, the IGP-acquired information is used for distribution into BGP. The ISPs can selectively expose this information with other ISPs, service providers, and content distribution networks (CDNs) through normal BGP peering. This allows for aggregation of the IGP-acquired information across multiple areas and ASs, such that an external path computing entity can access the information by passively listening to a route reflector.

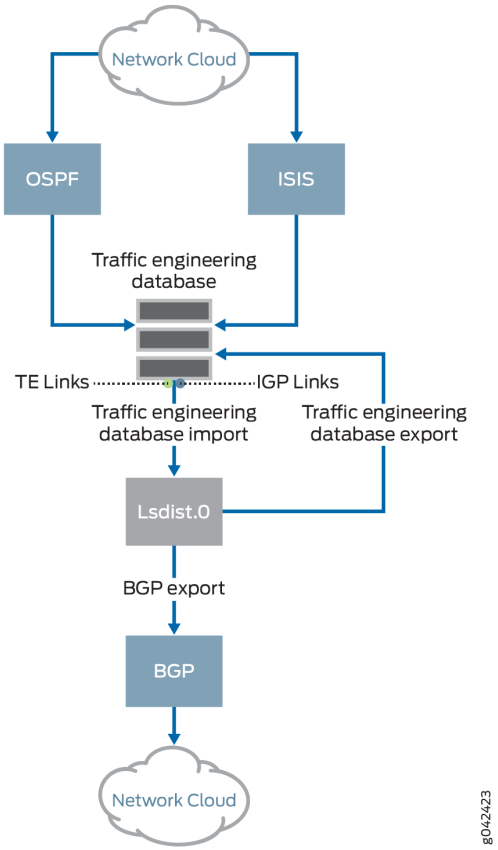
Implementation

In Junos OS, the IGPs install topology information into a database called the traffic engineering database. The traffic engineering database contains the aggregated topology information. To install IGP topology information into traffic engineering database, use the `set igp-topology` configuration statement at the `[edit protocols isis traffic-engineering]` and `[edit protocols ospf traffic-engineering]` hierarchy levels.

The mechanism to distribute link-state information using BGP includes the process of advertising the traffic engineering database into BGP-TE (import), and installing entries from BGP-TE into the traffic engineering database (export).

Starting in Junos OS Release 20.4R1, you can configure IS-IS traffic engineering to store IPv6 information in the traffic engineering database (TED) in addition to IPv4 addresses. BGP-LS distributes this information as routes from the traffic engineering database to the lsdist.0 routing table using the traffic engineering database import policies. These routes are advertised to BGP-TE peers as network layer reachability information (NLRI) with IPv6 router ID type, length, and value (TLV). With addition of IPv6 information, you can benefit from obtaining the complete network topology into the traffic engineering database.

Figure 108: Junos OS Implementation of BGP Link-State Distribution



Traffic Engineering Database Import

To advertise the traffic engineering database into BGP-TE, the link and node entries in the traffic engineering database are converted in the form of routes. These converted routes are then installed by

the traffic engineering database on behalf of the corresponding IGP, into a user-visible routing table called `lsdist.0`, on conditions subject to route policies. The procedure of leaking entries from the traffic engineering database into `lsdist.0` is called traffic engineering database import as illustrated in Figure 104 on page 1607.

There are polices to govern the traffic engineering database import process. By default, no entries are leaked from the traffic engineering database into the `lsdist.0` table.

Starting in Junos OS Release 17.4R1, the traffic engineering database installs interior gateway protocol (IGP) topology information in addition to RSVP-TE topology information in the lsdist.0 routing table as illustrated in Figure 104 on page 1607. Prior to Junos OS Release 17.4R1, the traffic engineering database only exported RSVP-TE topology information. Now you can monitor both IGP and traffic engineering topology information. The BGP-LS reads IGP entries from lsdist.0 and advertises these entries to the BGP peers. To import IGP topology information into BGP-LS from lsdist.0, use the `set bgp-ls` configuration statement at the `[edit protocols mpls traffic-engineering database import igp-topology]` hierarchy level.

Traffic Engineering Database Export

BGP can be configured to export or advertise routes from the `lsdist.0` table, subject to policy. This is common for any kind of route origination in BGP. In order to advertise BGP-TE into the traffic engineering database, BGP needs to be configured with the BGP-TE address family, and an export policy that selects routes for redistribution into BGP.

BGP then propagates these routes like any other NLRI. BGP peers that have the BGP-TE family configured and negotiated receive BGP-TE NLRIs. BGP stores the received BGP-TE NLRIs in the form of routes in the `lsdist.0` table, which is the same table that stores locally originated BGP-TE routes. The BGP-installed routes in `lsdist.0` are then distributed to other peers like any other route. Thus, the standard route selection procedure applies to BGP-TE NLRIs received from multiple speakers.

To achieve interdomain TE, the routes in `lsdist.0` are leaked into the traffic engineering database through a policy. This process is called traffic engineering database export as illustrated in Figure 104 on page 1607.

There are polices to govern the traffic engineering database export process. By default, no entries are leaked from the `lsdist.0` table into the traffic engineering database.

NOTE: For SDN applications, such as PCE and ALTO, the BGP-TE advertised information cannot leak into the traffic engineering database of a router. In such cases, an external server that peers with the routers using BGP-TE is used to move topology information up into the sky/orchestration system that spans the network. These external servers can be deemed as BGP-TE consumers, where they receive BGP-TE routes, but do not advertise them.

Assigning Credibility Values

Once the entries are installed in the traffic engineering database, the BGP-TE learned information is made available for CSPF path computation. The traffic engineering database uses a protocol preference scheme that is based on credibility values. A protocol with a higher credibility value is preferred over a protocol with a lower credibility value. BGP-TE has the capability to advertise information learned from multiple protocols at the same time, and so in addition to the IGP-installed entries in the traffic engineering database, there can be BGP-TE installed entries that correspond to more than one protocol. The traffic engineering database export component creates a traffic engineering database protocol and credibility level for each protocol that BGP-TE supports. These credibility values are configurable in the CLI.

The credibility order for the BGP-TE protocols is as follows:

- Unknown—80
- OSPF—81
- ISIS Level 1—82
- ISIS Level 2—83
- Static—84
- Direct—85

Cross-Credibility Path Computation

After you assign credibility values, each credibility level is treated as an individual plane. The Constrained Shorted Path First algorithm starts with the highest assigned credibility to the lowest, finding a path within that credibility level.

With BGP-TE, it is essential to compute paths across credibility levels to compute inter-AS paths. For example, different credibility settings are seen on a device from area 0 that computes the path through area 1, because area 0 entries are installed by OSPF, and area 1 entries are installed by BGP-TE.

To enable path computation across credibility levels, include the `cross-credibility-cspf` statement at the `edit protocols mpls`, `[edit protocols mpls label-switched-path` *`lsp-name`*`]`, and `[edit protocols rsvp]` hierarchy levels. At the `[edit protocols rsvp]` hierarchy level, enabling `cross-credibility-cspf` impacts bypass LSPs and loose hop expansion in transit.

Configuring `cross-credibility-cspf` enables path computation across credibility levels using the Constrained Shortest Path First algorithm, wherein the constraint is not performed on a credibility-by-credibility basis, but as a single constraint ignoring the assigned credibility values.

BGP-TE NLRIs and TLVs

Like other BGP routes, BGP-TE NLRIs can also be distributed through a route reflector that speaks BGP-TE NLRI. Junos OS implements the route reflection support for the BGP-TE family.

The following is a list of supported NLRIs:

- Link NLRI
- Node NLRI
- IPv4 Prefix NLRI (receive and propagate)
- IPv6 Prefix NLRI (receive and propagate)

NOTE: Junos OS does not provide support for the route-distinguisher form of the above NRLIs.

The following is a list of supported fields in link and node NLRIs:

- Protocol-ID—NLRI originates with the following protocol values:
  - ISIS-L1
  - ISIS-L2
  - OSPF
- Identifier—This value is configurable. By default, the identifier value is set to `0`.
- Local/Remote node descriptor—These include:
  - Autonomous system
  - BGP-LS Identifier—This value is configurable. By default, the BGP-LS identifier value is set to `0`
  - Area-ID
  - IGP router-ID
- Link descriptors (Only for link NLRI)—This includes:
  - Link Local/Remote Identifiers
  - IPv4 interface address
  - IPv4 neighbor address

- IPv6 neighbor/interface address—The IPv6 neighbor and interface addresses are not originated, but only stored and propagated when received.
- Multi-topology ID—This value is not originated, but stored and propagated when received.

The following is a list of supported LINK_STATE attribute TLVs:

- Link attributes:
  - Administrative group
  - Max link bandwidth
  - Max reservable bandwidth
  - Unreserved bandwidth
  - TE default metric
  - SRLG
  - The following TLVs, which are not originated, but only stored and propagated when received:
    - Opaque link attributes
    - MPLS protocol mask
    - Metric
    - Link protection type
    - Link name attribute
- Node attributes:
  - IPv4 Router-ID
  - Node flag bits—Only the overload bit is set.
  - The following TLVs, which are not originated, but only stored and propagated when received:
    - Multi-topology
    - OSPF-specific node properties
    - Opaque node properties
    - Node name
    - IS-IS area identifier

    - IPv6 Router-ID
- Prefix attributes—These TLVs are stored and propagated like any other unknown TLVs.

Supported and Unsupported Features

Junos OS supports the following features with link-state distribution using BGP:

- Advertisement of multiprotocol assured forwarding capability
- Transmission and reception of node and link-state BGP and BGP-TE NLRIs
- Nonstop active routing for BGP-TE NLRIs
- Policies

Junos OS does **not** support the following functionality for link-state distribution using BGP:

- Aggregated topologies, links, or nodes
- Route distinguisher support for BGP-TE NLRIs
- Multi-topology identifiers
- Multi-instance identifiers (excluding the default instance ID 0)
- Advertisement of the link and node area TLV
- Advertisement of MPLS signaling protocols
- Importing node and link information with overlapping address

BGP Link-State Extensions for Source Packet Routing in Networking (SPRING)

Starting in Junos OS Release 17.2R1, the BGP link-state address family is extended to distribute the source packet routing in networking (SPRING) topology information to software-defined networking (SDN) controllers. BGP typically learns the link-state information from IGP and distributes it to BGP peers. Besides BGP, the SDN controller can get link-state information directly from IGP if the controller is a part of an IGP domain. However, BGP link-state distribution provides a scalable mechanism to export the topology information. BGP link-state extensions for SPRING is supported on interdomain networks.

Source Packet Routing in Networking (SPRING)

SPRING is a control-plane architecture that enables an ingress router to steer a packet through a specific set of nodes and links in the network without relying on the intermediate nodes in the network to decide the actual path it must take. SPRING engages IGPs, such as IS-IS and OSPF, for advertising

network segments. Network segments can represent any instruction, topological or service-based. Within IGP topologies, IGP segments are advertised by the link-state routing protocols. There are two types of IGP segments:

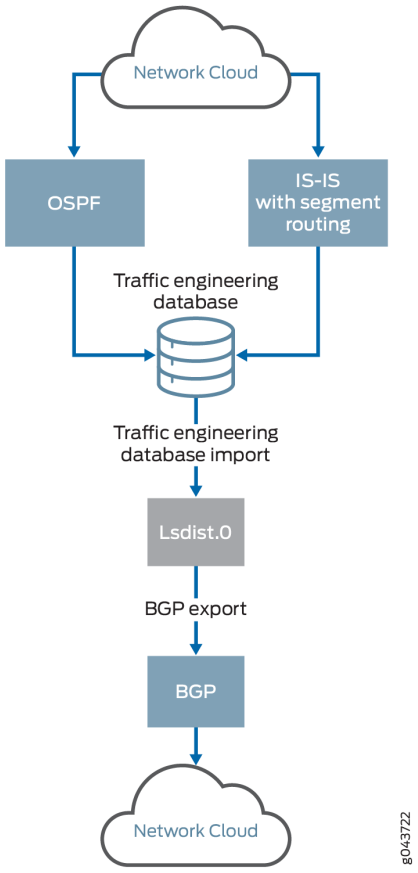
Adjacency segment	A one-hop path over a specific adjacency between two nodes in the IGP
Prefix segment	A multi-hop, equal-cost, multipath-aware shortest-path to a prefix, as per the state of the IGP topology

When SPRING in enabled in a BGP network, BGP link-state address family learns the SPRING information from the IGP link-state routing protocols and advertises segments in the form of segment identifiers (SIDs). BGP link-state address family has been extended to carry SIDs and other SPRING-related information to BGP peers. The route reflector can steer a packet through a desired set of nodes and links by prepending the packet with an appropriate combination of tunnels. This feature allows BGP link-state address family to also advertise the SPRING information to BGP peers.

Flow of BGP Link-State SPRING Data

Figure 105 on page 1613 depicts the data flow of BGP link-state SPRING data that IS-IS pushes to the traffic engineering database.

Figure 109: BGP Link-State Source Packet Routing in Networking (SPRING)



- IGP pushes the SPRING attributes to the traffic engineering database.
- SPRING capabilities and algorithm information are carried forward as node attributes into the traffic engineering database.
- Adjacent SID and LAN adjacent SID information are carried as link attributes.
- Prefix SID or node-SID information is carried as prefix attributes.
- A new set or a change to existing attributes triggers IGP updates to the traffic engineering database with new data.
- RSVP is a prerequisite for link attributes.

CAUTION: If traffic engineering is disabled at the IGP level, none of the attributes are pushed to the traffic engineering database.

- All parameters in the BGP traffic engineering NLRI, including the link, node, and prefix descriptors are derived from entries in the traffic engineering database.
- The traffic engineering database imports route entries into the `lsdist.0` routing table from IGP subject to policy.
- The default policy of BGP is to export routes, which are known to BGP only. You configure an export policy for non-BGP routes in the `lsdis.0` routing table. This policy advertises an entry learned from the traffic engineering database.

Supported BGP Link-State Attributes and TLVs, and Unsupported Features for BGP Link-State with SPRING

BGP link-state with SPRING supports the following attributes and type, length, and values (TLVs) that are originated, received, and propagated in the network:

Node attributes

- Segment routing Capabilities
- Segment routing Algorithm

Link attributes

- Adjacent-SID
- LAN Adjacent-SID

Prefix descriptors

- IP reachability information

Prefix attributes

- Prefix SID

The following list supports TLVs that are not originated, but only received and propagated in the network:

Prefix descriptors

- Multitopology ID

- OSPF route type

Prefix attributes

- Range
- Binding SID

Junos OS does not support the following features with BGP link-state with SPRING extensions:

- IPv6 prefix origination
- Multitopology identifiers
- Traffic engineering database export for SPRING parameters
- New TLVs with tcpdump (existing TLVs are also not supported).
- SPRING over IPv6

Verifying NLRI Node Learned Through BGP with OSPF as IGP

The following is a sample output to verify the NLRI node learned through BGP with OSPF as the IGP:

Purpose

Verify the lsdist.0 routing table entries.

Action

From operational mode, run the `show route table lsdist.0` command.

```
user@host> show route table lsdist.0 te-node-ip 7.7.7.7 extensive
lsdist.0: 216 destinations, 216 routes (216 active, 0 holddown, 0 hidden)
NODE { AS:100 Area:0.0.0.1 IPv4:7.7.7.7 OSPF:0 }/1536 (1 entry, 1 announced)

                                2.2.2.2/32 Originating RIB: inet.0
                                  Metric: 2     Node path count: 1
                                  Forwarding nexthops: 1
                                        Nexthop: 11.1.1.2 via et-0/0/0.1
                                        Session Id: 143
```

Meaning

The routes are appearing in the lsdist.0 routing table.

Example: Configuring Link State Distribution Using BGP

IN THIS SECTION

- Requirements | 1688
- Overview | 1689
- Configuration | 1690
- Verification | 1705

This example shows how to configure BGP to carry link-state information across multiple domains, which is used for computing paths for MPLS LSPs spanning multiple domains, such as inter-area TE LSP, and providing a scalable and policy-controlled means for external path computing entities, such as ALTO and PCE, to acquire network topology.

Requirements

This example uses the following hardware and software components:

- Four routers that can be a combination of M Series, MX Series, or T Series routers
- Junos OS Release 14.2 or later running on all the routers

Before you begin:

1. Configure the device interfaces.
2. Configure the autonomous system numbers and router IDs for the devices.
3. Configure the following protocols:
    - RSVP
    - MPLS
    - BGP
    - IS-IS
    - OSPF

Overview

IN THIS SECTION

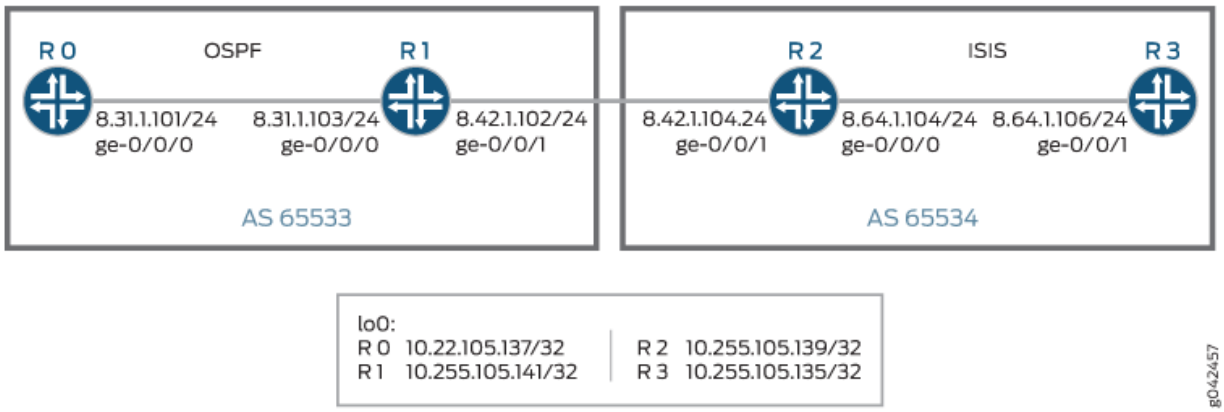
- Topology | 1689

Starting with Junos OS Release 14.2, a new mechanism to distribute topology information across multiple areas and autonomous systems (ASs) is introduced by extending the BGP protocol to carry link - state information, which was initially acquired using IGP. The IGP protocols have scaling limitations when it comes to distributing large databases. BGP is not only a more scalable vehicle for carrying multi-area and multi-AS topology information, but also provides the policy controls that can be useful for multi-AS topology distribution. The BGP link-state topology information is used for computing paths for MPLS label-switched paths (LSPs) spanning multiple domains, such as inter-area TE LSP, and providing a scalable and policy-controlled means for external path computing entities, such as ALTO and PCE, to acquire network topology.

Starting with Junos OS Release 17.1R1, link state distribution using BGP is supported on QFX10000 switches.

Topology

Figure 110: Link-State Distribution Using BGP



In Figure 106 on page 1620, Routers R0 and R1 and Routers R2 and R3 belong to different autonomous systems. Routers R0 and R1 run OSPF, and Routers R2 and R3 run IS-IS.

Configuration

IN THIS SECTION

- CLI Quick Configuration | 1690
- Procedure | 1693
- Procedure | 1699

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the `[edit]` hierarchy level, and then enter `commit` from configuration mode.

Procedure

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure Router R1:

1. Configure the Router R1 interfaces.

```
[edit interfaces]
user@R1# set ge-0/0/0 unit 0 family inet address 8.31.1.103/24
user@R1# set ge-0/0/0 unit 0 family iso
user@R1# set ge-0/0/0 unit 0 family mpls
```

```
user@R1# set ge-0/0/1 unit 0 family inet address 8.42.1.102/24
user@R1# set ge-0/0/1 unit 0 family iso
user@R1# set ge-0/0/1 unit 0 family mpls
user@R1# set lo0 unit 0 family inet address 10.255.105.141/32
```

2. Configure the router ID and autonomous system of Router R1.

```
[edit routing-options]
user@R1# set router-id 10.255.105.141
user@R1# set autonomous-system 65533
```

3. Enable RSVP on all the interfaces of Router R1 (excluding the management interface).

```
[edit protocols]
user@R1# set rsvp interface all
user@R1# set rsvp interface fxp0.0 disable
```

4. Enable MPLS on all the interfaces of Router R1 (excluding the management interface).

```
[edit protocols]
user@R1# set mpls interface all
user@R1# set mpls interface fxp0.0 disable
```

5. Configure the BGP group for Router R1 to peer with Router R0, and assign the local address and neighbor address.

```
[edit protocols]
user@R1# set bgp group ibgp type internal
user@R1# set bgp group ibgp local-address 10.255.105.141
user@R1# set bgp group ibgp neighbor 10.255.105.137
```

6. Include the BGP-TE signaling network layer reachability information (NLRI) to the ibgp BGP group.

```
[edit protocols]
user@R1# set bgp group ibgp family traffic-engineering unicast
```

7. Enable export of policy nlri2bgp on Router R1.

```
[edit protocols]
user@R1# set bgp group ibgp export nlri2bgp
```

8. Configure the BGP group for Router R1 to peer with Router R2, and assign the local address and neighbor autonomous system to the ebgp BGP group.

```
[edit protocols]
user@R1# set bgp group ebgp type external
user@R1# set bgp group ebgp neighbor 8.42.1.104 local-address 8.42.1.102
user@R1# set bgp group ebgp neighbor 8.42.1.104 peer-as 65534
```

9. Include the BGP-TE signaling NLRI to the ebgp BGP group.

```
[edit protocols]
user@R1# set bgp group ebgp family traffic-engineering unicast
```

10. Enable passive traffic-engineering on the inter-AS link.

```
[edit protocols]
user@R1# set isis interface ge-0/0/1.0 passive remote-node-iso 0102.5502.4211
user@R1# set isis interface ge-0/0/1.0 passive remote-node-id 8.42.1.104
```

11. Enable OSPF on the interface connecting Router R1 to Router R0 and on the loopback interface of Router R1, and enable traffic engineering capabilities.

```
[edit protocols]
user@R1# set ospf traffic-engineering
user@R1# set ospf area 0.0.0.0 interface lo0.0
user@R1# set ospf area 0.0.0.0 interface ge-0/0/0.0
```

12. Enable passive traffic-engineering on the inter-AS link.

```
[edit protocols]
user@R1# set ospf area 0.0.0.0 interface ge-0/0/1.0 passive traffic-engineering remote-node-
id 8.42.1.104
```

```
user@R1# set ospf area 0.0.0.0 interface ge-0/0/1.0 passive traffic-engineering remote-node-
router-id 10.255.105.139
```

13. Configure policies to accept traffic from BGP-TE NLRI.

```
[edit policy-options]
user@R1# set policy-statement accept-all from family traffic-engineering
user@R1# set policy-statement accept-all then accept
user@R1# set policy-statement nlri2bgp term 1 from family traffic-engineering
user@R1# set policy-statement nlri2bgp term 1 then accept
```

Results

From configuration mode, confirm your configuration by entering the `show interfaces`, `show routing-options`, `show protocols`, and `show policy-options` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R1# show interfaces
ge-0/0/0 {
    unit 0 {
        family inet {
            address 8.31.1.103/24;
        }
        family iso;
        family mpls;
    }
}
ge-0/0/1 {
    unit 0 {
        family inet {
            address 8.42.1.102/24;
        }
        family iso;
        family mpls;
    }
}
lo0 {
    unit 0 {
        family inet {

    }
}
```

Procedure

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure Router R2:

1. Configure the Router R2 interfaces.

```
[edit interfaces]
user@R2# set ge-0/0/0 unit 0 family inet address 8.64.1.104/24
user@R2# set ge-0/0/0 unit 0 family iso
user@R2# set ge-0/0/0 unit 0 family mpls
user@R2# set ge-0/0/1 unit 0 family inet address 8.42.1.104/24
user@R2# set ge-0/0/1 unit 0 family iso
user@R2# set ge-0/0/1 unit 0 family mpls
user@R2# set lo0 unit 0 family inet address 10.255.105.139/32
user@R2# set lo0 unit 0 family iso
```

2. Configure the router ID and autonomous system of Router R2.

```
[edit routing-options]
user@R2# set router-id 10.255.105.139
user@R2# set autonomous-system 65534
```

3. Enable RSVP on all the interfaces of Router R2 (excluding the management interface).

```
[edit routing-options]
user@R2# set rsvp interface all
user@R2# set rsvp interface fxp0.0 disable
```

4. Enable MPLS on all the interfaces of Router R2 (excluding the management interface).

```
[edit routing-options]
user@R2# set mpls interface all
user@R2# set mpls interface fxp0.0 disable
```

5. Enable import of traffic engineering database parameters using the ted2nlri policy.

```
[edit protocols]
user@R2# set mpls traffic-engineering database import policy ted2nlri
```

6. Configure the BGP group for Router R2 to peer with Router R1.

```
[edit protocols]
user@R2# set bgp group ebgp type external
```

7. Include the BGP-TE signaling NLRI to the ebgp BGP group.

```
[edit protocols]
user@R2# set bgp group ebgp family traffic-engineering unicast
```

8. Assign the local address and neighbor autonomous system to the ebgp BGP group.

```
[edit protocols]
user@R2# set bgp group ebgp peer-as 65533
user@R2# set bgp group ebgp neighbor 8.42.1.102
```

9. Enable export of policy nlri2bgp on Router R2.

```
[edit protocols]
user@R2# set bgp group ebgp export nlri2bgp
```

10. Enable IS-IS on the interface connecting Router R2 with Router R3 and the loopback interface of Router R2.

```
[edit protocols]
user@R2# set isis level 1 disable
user@R2# set isis interface ge-0/0/0.0
user@R2# set isis interface lo0.0
```

11. Enable only IS-IS advertising on the interface connecting Router R2 with Router R1.

```
[edit protocols]
user@R2# set isis interface ge-0/0/1.0 passive remote-node-iso 0102.5501.8181
user@R2# set isis interface ge-0/0/1.0 passive remote-node-id 8.42.1.102
```

12. Configure traffic engineering capability on Router R2.

```
[edit protocols]
user@R2# set ospf traffic-engineering
```

13. Enable only OSPF advertisements on the interface connecting Router R2 with Router R1.

```
[edit protocols]
user@R2# set ospf area 0.0.0.0 interface ge-0/0/1.0 passive traffic-engineering remote-node-
id 8.42.1.102
user@R2# set ospf area 0.0.0.0 interface ge-0/0/1.0 passive traffic-engineering remote-node-
router-id 10.255.105.141
```

14. Configure policies to accept traffic from the BGP-TE NLRI.

```
[edit policy-options]
user@R2# set policy-statement accept-all from family traffic-engineering
user@R2# set policy-statement accept-all then accept
user@R2# set policy-statement nlri2bgp term 1 from family traffic-engineering
user@R2# set policy-statement nlri2bgp term 1 then accept
user@R2# set policy-statement ted2nlri term 1 from protocol isis
user@R2# set policy-statement ted2nlri term 1 from protocol ospf
user@R2# set policy-statement ted2nlri term 1 then accept
user@R2# set policy-statement ted2nlri term 2 then reject
```

Results

From configuration mode, confirm your configuration by entering the `show interfaces`, `show routing-options`, `show protocols`, and `show policy-options` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R2# show interfaces
ge-0/0/0 {
    unit 0 {
        family inet {
            address 8.64.1.104/24;
        }
        family iso;
        family mpls;
    }
}
ge-0/0/1 {
    unit 0 {
        family inet {
            address 8.42.1.104/24;
        }
        family iso;
        family mpls;
    }
}
lo0 {
    unit 0 {
        family inet {
            address 10.255.105.139/32;
        }
        family iso;
```

```
    }
}
```

```
user@R2# show routing-options
router-id 10.255.105.139;
 autonomous-system 65534;
```

```
user@R2# show protocols
rsvp {
    interface all;
    interface fxp0.0 {
        disable;
    }
}

            remote-node-iso 0102.5501.8181;
            remote-node-id 8.42.1.102;
        }
    }
    interface lo0.0;
}
ospf {
    traffic-engineering;
    area 0.0.0.0 {
        interface ge-0/0/1.0 {
            passive {
                traffic-engineering {
                    remote-node-id 8.42.1.102;
                    remote-node-router-id 10.255.105.141;
                }
            }
        }
    }
}
```

```
user@R2# show policy-options
policy-statement accept-all {
    from family traffic-engineering;
    then accept;
}
policy-statement nlri2bgp {
    term 1 {
        from family traffic-engineering;
        then {
            accept;
        }
    }
}
policy-statement ted2nlri {
    term 1 {
        from protocol [ isis ospf ];
        then accept;
    }
```

```
    term 2 {
        then reject;
    }
}
```

Verification

IN THIS SECTION

- Verifying the BGP Summary Status | **1705**
- Verifying the MPLS LSP Status | **1706**
- Verifying the lsdist.0 Routing Table Entries | **1707**
- Verifying the Traffic Engineering Database Entries | **1711**

Verify that the configuration is working properly.

Verifying the BGP Summary Status

Purpose

Verify that BGP is up and running on Routers R0 and R1.

Action

From operational mode, run the `show bgp summary` command.

```
user@R0> show bgp summary
Groups: 1 Peers: 1 Down peers: 0
Table          Tot Paths  Act Paths Suppressed    History Damp State    Pending
lsdist.0
                      10         10          0          0          0          0
Peer                    AS      InPkt     OutPkt    OutQ   Flaps Last Up/Dwn State|#Active/
Received/Accepted/Damped...
10.255.105.141        65533         20         14       0      79        5:18 Establ
  lsdist.0: 10/10/10/0
```

From operational mode, run the `show bgp summary` command.

```
user@R1> show bgp summary
Groups: 2 Peers: 2 Down peers: 0
Table          Tot Paths  Act Paths Suppressed    History Damp State    Pending
lsdist.0
                      10         10          0          0          0          0
Peer                    AS      InPkt     OutPkt    OutQ   Flaps Last Up/Dwn State|#Active/
Received/Accepted/Damped...
8.42.1.104            65534         24         17       0      70        6:43 Establ
  lsdist.0: 10/10/10/0
10.255.105.137        65533         15         23       0      79        6:19 Establ
  lsdist.0: 0/0/0/0
```

Meaning

Router R0 is peered with Router R1.

Verifying the MPLS LSP Status

Purpose

Verify the status of the MPLS LSP on Router R0.

Action

From operational mode, run the `show mpls lsp` command.

```
user@R0> show mpls lsp
Ingress LSP: 1 sessions
To              From            State Rt P     ActivePath       LSPname
10.255.105.135  10.255.105.137  Up     0 *                      to-R3-inter-as
Total 1 displayed, Up 1, Down 0

Egress LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Meaning

The MPLS LSP from Router R0 to Router R3 is established.

Verifying the lsdist.0 Routing Table Entries

Purpose

Verify the lsdist.0 routing table entries on Routers R0, R1, and R2.

Action

From operational mode, run the `show route table lsdist.0` command.

```
user@R0> show route table lsdist.0
lsdist.0: 10 destinations, 10 routes (10 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

Meaning

The routes are appearing in the traffic engineering database.

Configuring Link State Distribution Using BGP

You can enable distribution of topology information across multiple areas and autonomous systems (ASs) by extending the BGP protocol to carry link-state information, which was initially acquired using IGP. The IGP protocols have scaling limitations when it comes to distributing large databases. BGP is not only a more scalable vehicle for carrying multi-area and multi-AS topology information, but also provides the policy controls that can be useful for multi-AS topology distribution. The BGP link-state topology information is used for computing paths for MPLS LSPs spanning multiple domains, such as inter-area TE LSP, and providing a scalable and policy-controlled means for external path computing entities, such as ALTO and PCE, to acquire network topology.

Before you begin:

1. Configure the device interfaces.
2. Configure the router ID and autonomous system number for the device.
3. Configure the following protocols:
   - RSVP
   - MPLS
   - IS-IS
   - OSPF

To enable link-state distribution using BGP:

1. Configure an internal BGP group, and assign the local address and neighbor address for the group.

```
[edit protocols]
user@R1# set bgp group internal-group-name type internal
```

```
user@R1# set bgp group internal-group-name local-address ip-address
user@R1# set bgp group internal-group-name neighbor ip-address
```

2. Include the BGP-TE signaling network layer reachability information (NLRI) to the internal BGP group.

```
[edit protocols]
user@R1# set bgp group internal-group-name family traffic-engineering unicast
```

3. Enable export of policy on the device.

```
[edit protocols]
user@R1# set bgp group internal-group-name export second-policy-name
```

4. Configure an external BGP group, and assign the local address and neighbor autonomous system to the group.

```
[edit protocols]
user@R1# set bgp group external-group-name type external
user@R1# set bgp group external-group-name neighbor ip-address local-address ip-address
user@R1# set bgp group external-group-name neighbor ip-address peer-as as-number
```

5. Include the BGP-TE signaling NLRI to the external BGP group.

```
[edit protocols]
user@R1# set bgp group external-group-name family traffic-engineering unicast
```

6. In configuration mode, go to the following hierarchy level:

```
[edit]
user@R1# edit policy-options
```

7. Configure policies to accept traffic from the BGP-TE NLRI.

```
[edit policy-options]
user@R1# set policy-statement policy-name from family traffic-engineering
user@R1# set policy-statement policy-name then accept
user@R1# set policy-statement bgp-import-policy term 1 from family traffic-engineering
```

```
user@R1# set policy-statement bgp-import-policy term 1 then next-hop self
user@R1# set policy-statement bgp-import-policy term 1 then accept
```

8. On the remote connecting device, configure policy to accept the OSPF and IS-IS traffic.

```
[edit policy-options]
user@R2# set policy-statement bgp-export-policy term 1 from protocol isis
user@R2# set policy-statement bgp-export-policy term 1 from protocol ospf
user@R2# set policy-statement bgp-export-policy term 1 then accept
user@R2# set policy-statement bgp-export-policy term 2 then reject
```

9. Verify and commit the configuration.

   For example:

```
R1
[edit protocols]
user@R1# set rsvp interface all
user@R1# set rsvp interface fxp0.0 disable
user@R1# set mpls interface all
user@R1# set mpls interface fxp0.0 disable
user@R1# set bgp group ibgp type internal
user@R1# set bgp group ibgp local-address 10.255.105.141
user@R1# set bgp group ibgp family traffic-engineering unicast
user@R1# set bgp group ibgp export nlri2bgp
user@R1# set bgp group ibgp neighbor 10.255.105.137
user@R1# set bgp group ebgp type external
user@R1# set bgp group ebgp family traffic-engineering unicast
user@R1# set bgp group ebgp neighbor 8.42.1.104 local-address 8.42.1.102
user@R1# set bgp group ebgp neighbor 8.42.1.104 peer-as 65534
user@R1# set isis interface ge-0/0/1.0 passive remote-node-iso 0102.5502.4211
user@R1# set isis interface ge-0/0/1.0 passive remote-node-id 8.42.1.104
user@R1# set ospf traffic-engineering
user@R1# set ospf area 0.0.0.0 interface lo0.0
user@R1# set ospf area 0.0.0.0 interface ge-0/0/0.0
user@R1# set ospf area 0.0.0.0 interface ge-0/0/1.0 passive traffic-engineering remote-node-
id 8.42.1.104
```

```
user@R1# set ospf area 0.0.0.0 interface ge-0/0/1.0 passive traffic-engineering remote-node-
router-id 10.255.105.139
```

```
[edit policy-options]
user@R1# set policy-statement accept-all from family traffic-engineering
user@R1# set policy-statement accept-all then accept
user@R1# set policy-statement nlri2bgp term 1 from family traffic-engineering
user@R1# set policy-statement nlri2bgp term 1 then next-hop self
user@R1# set policy-statement nlri2bgp term 1 then accept
```

```
[edit]
user@R1# commit
commit complete
```

```
R2
[edit policy-options]
user@R2# set policy-statement accept-all from family traffic-engineering
user@R2# set policy-statement accept-all then accept
user@R2# set policy-statement nlri2bgp term 1 from family traffic-engineering
user@R2# set policy-statement nlri2bgp term 1 then next-hop self
user@R2# set policy-statement nlri2bgp term 1 then accept
user@R2# set policy-statement ted2nlri term 1 from protocol isis
user@R2# set policy-statement ted2nlri term 1 from protocol ospf
user@R2# set policy-statement ted2nlri term 1 then accept
user@R2# set policy-statement ted2nlri term 2 then reject
```

```

BGP Classful Transport Planes Overview

IN THIS SECTION

- BGP Classful Transport (BGP-CT) with Underlying Colored SR-TE Tunnels Overview | **1724**

Benefits of BGP Classful Transport Planes

- **Network-slicing**–Service and transport layers are decoupled from each other, laying the foundation for network-slicing and virtualization with the end-to-end slicing across multiple domains, thereby significantly reducing the CAPEX.
- **Inter-domain interoperability**–Extends transport class deployment across co-operating domains so the different transport signaling protocols in each domain interoperate. Reconciles any differences between extended community namespaces that may be in use in each domain.
- **Colored resolution with fallback**–Enables resolution over colored tunnels (RSVP, IS-IS flexible algorithm) with flexible fallback options over best-effort tunnels or any other color tunnel.
- **Quality-of-service**–Customizes and optimizes the network to achieve the end-to-end SLA requirements.
- **Leveraging existing deployments**–Supports well deployed tunneling protocols like RSVP along with new protocols, such as IS-IS flexible algorithm, preserving ROI and reducing OPEX.

Terminology of BGP Classful Transport Planes

This section provides a summary of commonly used terms for understanding BGP classful transport plane.

- **Service node**–Ingress Provider Edge (PE) devices that send and receive service routes (Internet and Layer 3 VPN).
- **Border node**–Device at the connection point of different domains (IGP areas or ASs).
- **Transport node**–Device that sends and receives BGP-Labeled Unicast (LU) routes.
- **BGP-VPN**–VPNs built using RFC4364 mechanisms.
- **Route Target (RT)**–Type of extended community used to define VPN membership.
- **Route Distinguisher (RD)**–Identifier used to distinguish to which VPN or virtual private LAN service (VPLS) a route belongs. Each routing instance must have a unique route distinguisher associated with it.
- **Resolution scheme**–Used to resolve protocol next-hop address (PNH) in resolution RIBs providing fallback.

  They map the routes to the different transport RIBs in the system based on mapping community.
- **Service family**–BGP address family used for advertising routes for data traffic, as opposed to tunnels.
- **Transport family** –BGP address family used for advertising tunnels, which are in turn used by service routes for resolution.

- **Transport tunnel**–A tunnel over which a service may place traffic, for example, GRE, UDP, LDP, RSVP, SR-TE, BGP-LU.
- **Tunnel domain**–A domain of the network containing service nodes and border nodes under a single administrative control that has a tunnel between them. An end-to-end tunnel spanning several adjacent tunnel domains can be created by stitching the nodes together using labels.
- **Transport class**–A group of transport tunnels offering the same type of service.
- **Transport class RT**–A new format of route target used to identify a specific transport class.

  A new format of Route Target used to identify a specific transport class.
- **Transport RIB**–At the service node and border node, a transport class has an associted transport RIB that holds its tunnel routes.
- **Transport RTI**–A routing instance; container of transport RIB, and associated transport class Route Target and Route Distinguisher.
- **Transport plane**–Set of transport RTIs importing same transport class RT. These are in turn stitched together to span across tunnel domain boundaries using a mechanism similar to Inter-AS option-b to swap labels at border nodes (nexthop-self), forming an end-to-end transport plane.
- **Mapping community**–Community on a service route that maps to resolve over a transport class.

Understanding BGP Classful Transport Planes

You can use BGP classful transport planes to configure transport classes for classifying a set of transport tunnels in an intra-AS network based on the traffic engineering characteristics and use these transport tunnels to map service routes with the desired SLA and intended fallback.

BGP classful transport planes can extend these tunnels to inter-domain networks that span across multiple domains (ASs or IGP areas) while preserving the transport class. To do this, you must configure the BGP classful trasport transport layer BGP family between the border and service nodes.

In both inter-AS and intra-AS implementations, there can be many transport tunnels (MPLS LSPs, IS-IS flexible algorithm, SR-TE) created from the service and border nodes. The LSPs may be signaled using different signaling protocols in different domains, and can be configured with different traffic engineering characteristics (class or color). The transport tunnel endpoint also acts as the service endpoint and can be present in the same tunnel domain as the service ingress node, or in an adjacent or non-adjacent domain. You can use BGP classful transport planes to resove services over LSPs with certain traffic engineering charateristics either inside a single domain or across multiple domains.

BGP classful transport planes reuse the BGP-VPN technology, keeping the tunneling-domains loosely coupled and coordinated.

- The network layer reachability information (NLRI) is **RD:TunnelEndpoint** used for path-hiding.

- The route target indicates the transport class of the LSPs, and leaks routes to the corresponding transport RIB on the destination device.
- Every transport tunneling protocol installs an ingress route into the transport-class.inet.3 routing table, models the tunnel transport class as a VPN route target, and collects the LSPs of the same transport class in the transport-class.inet.3 transport-rib routing table.
- Routes in this routing instance are advertised in the BGP classful transport plane (inet transport) AFI-SAFI following procedures similar to RFC-4364.
- When crossing inter-AS link boundary, you must follow Option-b procedures to stitch the transport tunnels in these adjacent domains.

  Similarly, when crossing intra-AS regions you must follow Option-b procedures to stitch the transport tunnels in the different TE-domains.
- You can define resolution schemes to specify the intent on the variety of transport classes in a fallback order.
- You can resolve service routes and BGP classful transport routes over these transport classes, by carrrying the mapping community on them.

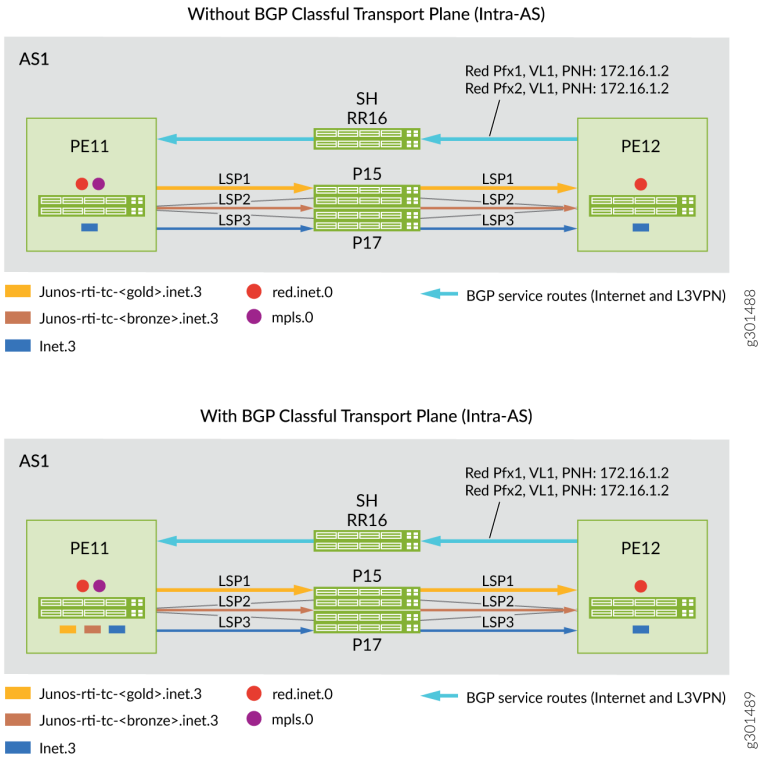
The BGP classful transport family runs along side the BGP-LU transport layer family. In a seamless MPLS network running BGP-LU, meeting stringent SLA requirements of 5G is a challenge as the traffic engineering characteristics of the tunnels are not known or preserved across domain boundaries. BGP classful transport planes provide operationally easy and scalable means to advertise multiple paths for remote loopbacks along with the transport class information in the seamless MPLS architecture. In BGP classful tranport family routes, different SLA paths are represented using Transport Route-Target extended community, which carries the transport class color. This Transport Route-Target is used by the receiving BGP routers to associate the BGP classful transport route with the appropriate transport class. When re-advertising the BGP classful transport routes, MPLS swaps routes, inter connect the intra-AS tunnels of the same transport class, thereby forming an end-to-end tunnel that preserves the transport class.

Intra-AS Implementation of BGP Classful Transport Planes

Figure 107 on page 1649 illustrates a network topology with before-and-after scenarios of implementing BGP classful transport planes in an intra-AS domain. Devices PE11 and PE12 use RSVP LSPs as the transport tunnel and all transport tunnel routes are installed in inet.3 RIB. Implementing

BGP classful transort planes enables RSVP transport tunnels to be color-aware similar to segment routing tunnels.

Figure 111: Intra-AS Domain: Before-and-After Scenarios For BGP Classful Transport Planes Implementation



To classify transport tunnels into BGP transport class in an intra-AS setup:

1. Define the transport class at the service node (ingress PE devices), for example, gold and bronze, and assign color community values to the defined transport class.

   Sample configuration:

```
pe11# show routing-options
route-distinguisher-id 172.16.1.1;
transport-class {
    name gold {
        color 100;
    }
    name bronze {
        color 200;
```

2. Associate the transport tunnel to a specific transport class at the ingress node of the tunnels.
   Sample configuration:

```
pe11# show protocols mpls
label-switched-path toPE12-bronze {
    transport-class bronze;
}
label-switched-path toPE12-gold {
    transport-class gold;
}
```

Intra-AS BGP classful transport plane functionality:

- BGP classful transport creates predefined transport RIBs per named transport class (gold and bronze) and auto derives mapping community from its color value (100 and 200).
- Intra-AS transport routes are populated in transport RIBs by the tunneling protocol when it is associated with a transport class.
  In this example, RSVP LSP routes associated with transport class gold (color 100) and transport class bronze (color 200) are installed in the transport RIBs **junos-rti-tc-<100>.inet.3** and **junos-rti-tc-<200>.inet.3**, respectively.
- Service node (ingress PEs) match extended color community (color:0:100 and color:0:200) of service route against the mapping community in predefined resolution RIBs and resolve the protocol next hop (PNH) in corresponding transport RIBs (either junos-rti-tc-<100>.inet.3, or junos-rti-tc-<200>.inet.3).
- BGP routes bind to a resolution scheme by carrying the assiocaited mapping community.
- Each transport class automatically creates two predefined resolution schemes and automatically derives the mapping community.
  One resolution scheme is for resolving service routes that use **Color:0:<val>** as the mapping community.

  The other resolution scheme is for resolving transport routes that use **Transport-Target:0:<val>** as the mapping community.
- If service route PNH cannot be resolved using RIBs listed in the predefined resolution scheme, then it can fall back to the inet.3 routing table.
- You can also configure fallback between different colored transport RIBs by using user-defined resolution schemes under the **[edit routing-options resolution scheme]** configuration hierarchy.

Inter-AS Implementation of BGP Classful Transport Planes

In an inter-AS network, BGP-LU is converted to BGP classful transport network after configuring a minimum of two transport classes (gold and bronze) on all service nodes or PE devices and border nodes (ABRs and ASBRs).

To convert the transport tunnels into BGP classful transport:

1. Define transport class at the service nodes (ingress PE devices) and the border nodes (ABRs and ASBRs), for example, gold and broze.

   Sample configuration:

```
pe11# show routing-options
route-distinguisher-id 172.16.1.1;
transport-class {
    name gold {
        color 100;
    }
    name bronze {
        color 200;
```

2. Associate the transport tunnels to a specific transport class at the ingress node of the tunnels (ingress PEs, ABRs,and ASBRs).

   Sample configuration:

   For RSVP LSPs

```
abr23# show protocols mpls
label-switched-path toASBR21-bronze {
    transport-class bronze;
}
label-switched-path toASBR22-gold {
    transport-class gold;
```

   For IS-IS flxible algorithm

```
asbr13# show routing-options
flex-algorithm 128 {
…
color 100;
use-transport-class;
```

```
}
flex-algorithm 129 {
…
color 200;
use-transport-class;
}
```

3. Enable new family for the BGP classful transport (inet transport) and BGP-LU (inet labeled-unicast) in the network.

   Sample configuration:

```
abr23# show protocols bgp
group toAs2-RR27 {
    family inet {
        labeled-unicast {
…
        }
        transport {
…
    }
    cluster 172.16.2.3;
    neighbor 172.16.2.7;
}
```

4. Advertise service routes from the egress PE device with appropriate extended color community.

   Sample configuration:

```
pe11# show policy-options policy-statement red
term 1 {
        from {
            route-filter 192.168.3.3/32 exact;
        }
        then {
            community add map2gold;
            next-hop self;
            accept;
        }
    }
    term 2 {
        from {
```

```
            route-filter 192.168.33.33/32 exact;
        }
        then {
            community add map2bronze;
            next-hop self;
            accept;
        }
    }
community map2bronze members color:0:200;
community map2gold members color:0:100;
```

Inter-AS BGP classful transport plane functionality:

1. BGP classful transport planes create predefined transport RIBs per named transport class (gold and bronze) and automatically derives mapping community from its color value.
2. Intra-AS transport routes are populated in transport RIBs by tunneling protocols when associated with a transport class.

   For example, transport tunnel routes associated with the transport class gold and bronze are installed in the transport RIBs **junos-rti-tc-<100>.inet.3** and **junos-rti-tc-<200>.inet.3**, respectively.
3. BGP classful transport planes use unique Route Distinguisher and Route Target when it copies the transport tunnel routes from each transport RIB to the bgp.transport.3 routing table.
4. Border nodes advertise routes from bgp.transport.3 routing table to its peers in other domains if family inet transport is negotiated in the BGP session.
5. Receiving border node installs these bgp-ct routes in the bgp.transport.3 routing table and copies these routes based on the transport Route Target to the appropriate transport RIBs.
6. Service node matches the color community in the service route against a mapping community in the resolution schemes and resolves PNH in the corresponding transport RIB (either **junos-rti-tc-<100>.inet.3**, or **junos-rti-tc-<200>.inet.3**).
7. Border nodes use predefined resolution schemes for transport route PNH resolution.
8. Predefined or user defined, both resolution schemes support service route PNH resolution. Predefined uses inet.3 as fallback, and user-defined resolution scheme allows list of transport RIBs to be used in the order specified while resolving PNH.
9. If service route PNH cannot be resolved using RIBs listed in the user-defined resolution scheme, then route is discarded.

BGP Classful Transport (BGP-CT) with Underlying Colored SR-TE Tunnels Overview

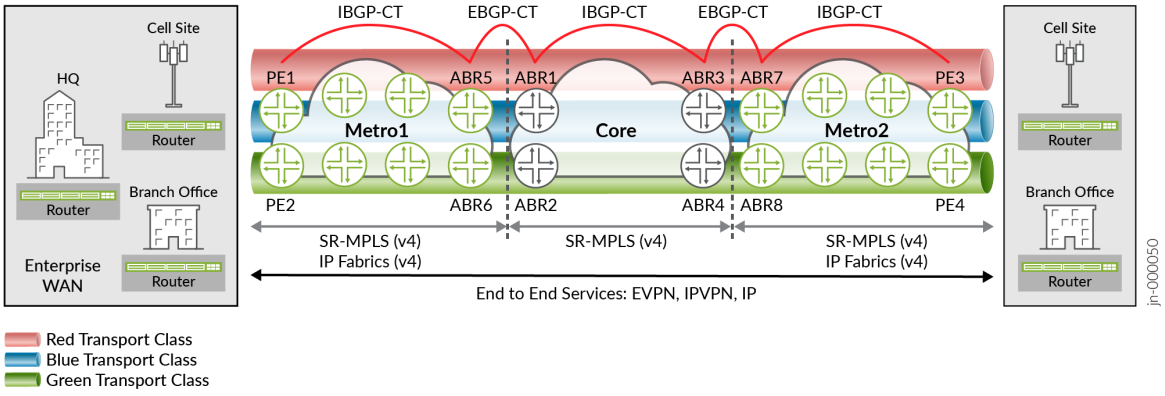
IN THIS SECTION

- Benefits of BGP-CT with underlying colored SR-TE Tunnels | **1724**

Benefits of BGP-CT with underlying colored SR-TE Tunnels

- Solves scale concerns that may arise in the future as the network grows.
- Provides inter-connectivity for domains that use different technologies.
- Decouples services and the transport layers resulting in a completely distributed network.
- Provides independent bandwidth management through an intra-domain traffic engineering controller for SR-TE.

Large networks that are growing and evolving continuously require a seamless segment routing architecture. Starting in Junos OS Release 21.2,R1 we support BGP-CT with underlying transport as colored SR-TE tunnels. BGP-CT can resolve service routes using the transport RIBs and compute the next hop. Services that are currently supported over BGP-CT can also use the underlying SR-TE colored tunnels for route resolution. The services can now use the underlying SR-TE colored tunnels such as the static colored, BGP SR-TE, programmable rpd and PCEP colored tunnels. BGP-CT uses the next-hop reachability to resolve service routes over the desired transport class.



To enable BGP-CT service route resolution over underlying SR-TE colored tunnels, include the `use-transport-class` statement at the `[edit protocols source-packet-routing]` hierarchy level.

NOTE:

1. Enable the `use-transport-class` statement

   at the `[edit protocols source-packet-routing]` hierarchy level.

   along with the `auto-create` statement at the `[edit routing-options transport-class]` hierarchy level.

2. We don't support RIB groups for colored SR-TE with `use-transport-class` and color-only SR-TE tunnels with this feature.

Improving Traffic Engineering Database Accuracy with RSVP PathErr Messages

IN THIS SECTION

- PathErr Messages | **1726**
- Identifying the Problem Link | **1727**
- Configuring the Router to Improve Traffic Engineering Database Accuracy | **1727**

An essential element of RSVP-based traffic engineering is the traffic engineering database. The traffic engineering database contains a complete list of all network nodes and links participating in traffic engineering, and a set of attributes each of those links can hold. (For more information about the traffic engineering database, see "Constrained-Path LSP Computation" on page 570.) One of the most important link attributes is bandwidth.

Bandwidth availability on links changes quickly as RSVP LSPs are established and terminated. It is likely that the traffic engineering database will develop inconsistencies relative to the real network. These inconsistencies cannot be fixed by increasing the rate of IGP updates.

Link availability can share the same inconsistency problem. A link that becomes unavailable can break all existing RSVP LSPs. However, its unavailability might not readily be known by the network.

When you configure the `rsvp-error-hold-time` statement, a source node (ingress of an RSVP LSP) learns from the failures of its LSP by monitoring PathErr messages transmitted from downstream nodes. Information from the PathErr messages is incorporated into subsequent LSP computations, which can

improve the accuracy and speed of LSP setup. Some PathErr messages are also used to update traffic engineering database bandwidth information, reducing inconsistencies between the traffic engineering database and the network.

You can control the frequency of IGP updates by using the `update-threshold` statement. See "Configuring the RSVP Update Threshold on an Interface" on page 1201.

This section discusses the following topics:

PathErr Messages

PathErr messages report a wide variety of problems by means of different code and subcode numbers. You can find a complete list of these PathErr messages in RFC 2205, *Resource Reservation Protocol (RSVP), Version 1, Functional Specification* and RFC 3209, *RSVP-TE: Extensions to RSVP for LSP Tunnels*.

When you configure the `rsvp-error-hold-time` statement, two categories of PathErr messages, which specifically represent link failures, are examined:

- Link bandwidth is low for this LSP: Requested bandwidth unavailable—code 1, subcode 2

  This type of PathErr message represents a global problem that affects all LSPs transiting the link. They indicate that the actual link bandwidth is lower than that required by the LSP, and that it is likely that the bandwidth information in the traffic engineering database is an overestimate.

  When this type of error is received, the available link bandwidth is reduced in the local traffic engineering database, affecting all future LSP computations.

- Link unavailable for this LSP:

  - Admission Control failure—code 1, any subcode except 2
  - Policy Control failures—code 2
  - Service Preempted—code 12
  - Routing problem—no route available toward destination—code 24, subcode 5

  These types of PathErr messages are generally pertinent to the specified LSP. The failure of this LSP does not necessarily imply that other LSPs could also fail. These errors can indicate maximum transfer unit (MTU) problems, service preemption (either manually initiated by the operator or by another LSP with a higher priority), that a next-hop link is down, that a next-hop neighbor is down, or service rejection because of policy considerations. It is best to route this particular LSP away from the link.

Identifying the Problem Link

Each PathErr message includes the sender's IP address. This information is propagated unchanged toward the ingress router. A lookup in the traffic engineering database can identify the node that originated the PathErr message.

Each PathErr message carries enough information to identify the RSVP session that triggered the message. If this is a transit router, it simply forwards the message. If this router is the ingress router (for this RSVP session), it has the complete list of all nodes and links the session should traverse. Coupled with the originating node information, the link can be uniquely identified.

Configuring the Router to Improve Traffic Engineering Database Accuracy

To improve the accuracy of the traffic engineering database, configure the `rsvp-error-hold-time` statement. When this statement is configured, a source node (ingress of an RSVP LSP) learns from the failures of its LSP by monitoring PathErr messages transmitted from downstream nodes. Information from the PathErr messages is incorporated into subsequent LSP computations, which can improve the accuracy and speed of LSP setup. Some PathErr messages also are used to update traffic engineering database bandwidth information, reducing inconsistencies between the traffic engineering database and the network.

To configure how long MPLS should remember RSVP PathErr messages and consider them in CSPF computation, include the `rsvp-error-hold-time` statement:

```
rsvp-error-hold-time seconds;
```

You can include this statement at the following hierarchy levels:

- `[edit protocols mpls]`
- `[edit logical-systems logical-system-name protocols mpls]`

The time can be a value from 1 to 240 seconds. The default is 25 seconds. Configuring a value of 0 disables the monitoring of PathErr messages.

Release History Table

Release	Description
20.4R1	Starting in Junos OS Release 20.4R1, you can configure IS-IS traffic engineering to store IPv6 information in the traffic engineering database (TED) in addition to IPv4 addresses.
17.4R1	Starting in Junos OS Release 17.4R1, the traffic engineering database installs interior gateway protocol (IGP) topology information in addition to RSVP-TE topology information in the lsdist.0 routing table

17.2R1	Starting in Junos OS Release 17.2R1, the BGP link-state address family is extended to distribute the source packet routing in networking (SPRING) topology information to software-defined networking (SDN) controllers.
17.1R1	Starting with Junos OS Release 17.1R1, link state distribution using BGP is supported on QFX10000 switches.

DiffServ-Aware Traffic Engineering Introduction

Differentiated Services (DiffServ)-aware traffic engineering provides a way to guarantee a specified level of service over an MPLS network. The routers providing DiffServ-aware traffic engineering are part of a differentiated services network domain. All routers participating in a differentiated services domain must have DiffServ-aware traffic engineering enabled.

To help ensure that the specified service level is provided, it is necessary to ensure that no more than the amount of traffic specified is sent over the differentiated services domain. You can accomplish this goal by configuring a policer to police or rate-limit the volume of traffic transiting the differentiated

service domain. For more information about how to configure policers for label-switched paths (LSPs), see *Configuring Policers for LSPs*.

This feature can help to improve the quality of Internet services such as voice over IP (VoIP). It also makes it possible to better emulate an Asynchronous Transfer Mode (ATM) circuit over an MPLS network.

DiffServ-Aware Traffic Engineering Terminology

IN THIS SECTION

- Bandwidth model | **1729**
- CAC | **1729**
- Class type | **1730**
- Differentiated Services | **1730**
- Differentiated Services domain | **1730**
- DiffServ-aware traffic engineering | **1730**
- Multiclass LSP | **1730**
- MAM | **1730**
- RDM | **1730**
- Traffic engineering class | **1730**
- Traffic engineering class map | **1731**

Bandwidth model

The bandwidth model determines the values of the available bandwidth advertised by the interior gateway protocols (IGPs).

CAC

Call admission control (CAC) checks to ensure there is adequate bandwidth on the path before the LSP is established. If the bandwidth is insufficient, the LSP is not established and an error is reported.

Class type

A collection of traffic flows that is treated equivalently in a differentiated services domain. A class type maps to a queue and is much like a class-of-service (CoS) forwarding class in concept. It is also known as a traffic class.

Differentiated Services

Differentiated Services make it possible to give different treatment to traffic based on the EXP bits in the MPLS header. Traffic must be marked appropriately and CoS must be configured.

Differentiated Services domain

The routers in a network that have Differentiated Services enabled.

DiffServ-aware traffic engineering

A type of constraint-based routing. It can enforce different bandwidth constraints for different classes of traffic. It can also do CAC on each traffic engineering class when an LSP is established.

Multiclass LSP

A multiclass LSP functions like a standard LSP, but it also allows you to reserve bandwidth from multiple class types. The EXP bits of the MPLS header are used to distinguish between class types.

MAM

The maximum allocation bandwidth constraint model divides the available bandwidth between the different classes. Sharing of bandwidth between the class types is not allowed.

RDM

The Russian dolls bandwidth constraint model makes efficient use of bandwidth by allowing the class types to share bandwidth.

Traffic engineering class

A paired class type and priority.

Traffic engineering class map

A map between the class types, priorities, and traffic engineering classes. The traffic engineering class mapping must be consistent across the Differentiated Services domain.

DiffServ-Aware Traffic Engineering Features

DiffServ-aware traffic engineering provides the following features:

- Traffic engineering at a per-class level rather than at an aggregate level
- Different bandwidth constraints for different class types (traffic classes)
- Different queuing behaviors per class, allowing the router to forward traffic based on the class type

In comparison, standard traffic engineering does not consider CoS, and it completes its work on an aggregate basis across all Differentiated Service classes.

DiffServ-aware traffic engineering provides the following advantages:

- Traffic engineering can be performed on a specific class type instead of at the aggregate level.
- Bandwidth constraints can be enforced on each specific class type.
- It forwards traffic based on the EXP bits.

This makes it possible to guarantee service and bandwidth across an MPLS network. With DiffServ-aware traffic engineering, among other services, you can provide ATM circuit emulation, VoIP, and a guaranteed bandwidth service.

The following describes how the IGP, Constrained Shortest Path First (CSPF), and RSVP participate in DiffServ-aware traffic engineering:

- The IGP can advertise the unreserved bandwidth for each traffic engineering class to the other members of the differentiated services domain. The traffic engineering database stores this information.
- A CSPF calculation is performed considering the bandwidth constraints for each class type. If all the constraints are met, the CSPF calculation is considered successful.
- When RSVP signals an LSP, it requests bandwidth for specified class types.

Configuring Link Down Notification for Optics Options Alarm or Warning

To configure this option, include the `alarm` or `warning` statement at the `[edit interfaces ge-` *`fpc/pic/port`* `optics-options]` hierarchy level:

```
[edit interfaces]
ge-fpc/pic/port {
    optics-options {
        alarm alarm-name {
            (syslog | link-down);
            }
        warning warning-name {
            (syslog | link-down);
            }
    }
}
```

DiffServ-Aware Traffic Engineered LSPs Overview

A DiffServ-aware traffic engineered LSP is an LSP configured with a bandwidth reservation for a specific class type. This LSP can carry traffic for a single class type. On the packets, the class type is specified by the EXP bits (also known as the class-of-service bits) and the per-hop behavior (PHB) associated with the EXP bits. The mapping between the EXP bits and the PHB is static, rather than being signaled in RSVP.

The class type must be configured consistently across the Differentiated Services domain, meaning the class type configuration must be consistent from router to router in the network. You can unambiguously map a class type to a queue. On each node router, the class-of-service queue configuration for an interface translates to the available bandwidth for a particular class type on that link.

For more information about topics related to LSPs and DiffServ-aware traffic engineering, see the following:

- For forwarding classes and *class of service*, see the Junos OS Class of Service User Guide for Routing Devices.
- For EXP bits, see "MPLS Label Allocation" on page 509.
- For differentiated services, see RFC 3270, *Multi-Protocol Label Switching (MPLS) Support of Differentiated Services*.

- For information about how the IGPs and RSVP have been modified to support Differentiated Services-aware MPLS traffic engineering, see RFC 4124, *Protocol Extensions for Support of Differentiated-Service-Aware MPLS Traffic Engineering*.

DiffServ-Aware Traffic Engineered LSPs Operation

When configuring a DiffServ-aware traffic engineered LSP, you specify the class type and the bandwidth associated with it. The following occurs when an LSP is established with bandwidth reservation from a specific class type:

1. The IGPs advertise how much unreserved bandwidth is available for the traffic engineering classes.
2. When calculating the path for an LSP, CSPF is used to ensure that the bandwidth constraints are met for the class type carried by the LSP at the specified priority level.

   CSPF also checks to ensure that the bandwidth model is configured consistently on each router participating in the LSP. If the bandwidth model is inconsistent, CSPF does not compute the path (except for LSPs from class type ct0).
3. Once a path is found, RSVP signals the LSP using the Classtype object in the path message. At each node in the path, the available bandwidth for the class types is adjusted as the path is set up.

An LSP that requires bandwidth from a particular class (except class type ct0) cannot be established through routers that do not understand the Classtype object. Preventing the use of routers that do not understand the Classtype object helps to ensure consistency throughout the Differentiated Services domain by preventing the LSP from using a router that cannot support Differentiated Services.

By default, LSPs are signaled with setup priority 7 and holding priority 0. An LSP configured with these values cannot preempt another LSP at setup time and cannot be preempted.

It is possible to have both LSPs configured for DiffServ-aware traffic engineering and regular LSPs configured at the same time on the same physical interfaces. For this type of heterogeneous environment, regular LSPs carry best-effort traffic by default. Traffic carried in the regular LSPs must have the correct EXP settings (either by remarking the EXP settings or by assuming that the traffic arrived with the correct EXP settings from the upstream router).

Configuring Routers for DiffServ-Aware Traffic Engineering

IN THIS SECTION

- Configuring the Bandwidth Model | **1735**
- Configuring Traffic Engineering Classes | **1736**
- Configuring Class of Service for DiffServ-Aware Traffic Engineering | **1738**

To configure DiffServ-aware traffic engineering, include the `diffserv-te` statement:

```
diffserv-te {
    bandwidth-model {
        extended-mam;
        mam;
        rdm;
    }
    te-class-matrix {
        traffic-class {
            te number {
                priority priority;
                traffic-class ct number priority priority;
            }
        }
    }
}
```

You can include this statement at the following hierarchy levels:

- `[edit protocols mpls]`
- `[edit logical-systems logical-system-name protocols mpls]`

You must include the `diffserv-te` statement in the configuration on all routers participating in the Differentiated Services domain. However, you are not required to configure the traffic engineering class matrix (by including the `te-class-matrix` statement at the `[edit protocols mpls diffserv-te]` or `[edit logical-systems logical-system-name protocols mpls diffserv-te]` hierarchy level).

NOTE: To prevent the possibility of an incorrect configuration when migrating to Diffserv-aware traffic engineering, a policy control failure error might be triggered if there is conflict between the old LSPs and the newly configured TE-class matrix.

An old node might request an LSP with setup and hold priorities in such a way that the combination of the ct0 class and the priority does not match with the configured TE-class matrix. All LSPs on the router that are configured prior to configuring diffserv-aware traffic engineering are designated as being from class ct0.

The error appears in the RSVP tracing logs as a `Session preempted` error. For the router where the error originates, the error could appear as follows:

```
Jun 17 16:35:59 RSVP error for session 10.255.245.6(port/tunnel ID 31133)  Proto 0: (class
ct0, priority 2) is not a valid TE-class  Jun 17 16:35:59 RSVP originate PathErr
192.168.37.22->192.168.37.23 Session preempted
```

For the router receiving the error, the error can appear as follows:

```
Jun 17 16:37:51 RSVP recv PathErr 192.168.37.22->192.168.37.23 Session  preempted LSP to-
f(2/31133)
```

To configure DiffServ-aware traffic engineering, complete the procedures in the following sections:

Configuring the Bandwidth Model

You must configure a bandwidth model on all routers participating in the Differentiated Services domain. The bandwidth models available are MAM, extended MAM, and RDM:

- Maximum allocation bandwidth constraints model (MAM)—Defined in RFC 4125, *Maximum Allocation Bandwidth Constraints Model for Diffserv-aware MPLS Traffic Engineering*.
- Extended MAM—A proprietary bandwidth model that behaves much like standard MAM. If you configure multiclass LSPs, you must configure the extended MAM bandwidth model.
- Russian-dolls bandwidth allocation model (RDM)—Makes efficient use of bandwidth by allowing the class types to share bandwidth. RDM is defined in RFC 4127, *Russian Dolls Bandwidth Constraints Model for Diffserv-aware MPLS Traffic Engineering*.

To configure a bandwidth model, include the `bandwidth-model` statement and specify one of the bandwidth model options:

```
bandwidth-model {
    extended-mam;
    mam;
    rdm;
}
```

You can include this statement at the following hierarchy levels:

- `[edit protocols mpls diffserv-te]`
- `[edit logical-systems logical-system-name protocols mpls diffserv-te]`

NOTE: If you change the bandwidth model on an ingress router, all the LSPs enabled on the router are taken down and resignaled.

Configuring Traffic Engineering Classes

Configuring traffic engineering classes is optional. Table 26 on page 1736 shows the default values for everything in the traffic engineering class matrix. The default mapping is expressed in terms of the default forwarding classes defined in the CoS configuration.

Table 26: Default Values for the Traffic Engineering Class Matrix

Traffic Engineering Class	Class Type	Queue	Priority
te0	ct0	0	7
te1	ct1	1	7
te2	ct2	2	7
te3	ct3	3	7
te4	ct0	0	0
te5	ct1	1	0
te6	ct2	2	0
te7	ct3	3	0

If you want to override the default mappings, you can configure traffic engineering classes 0 through 7. For each traffic engineering class, you configure a class type (or queue) from 0 through 3. For each class type, you configure a priority from 0 through 7.

To configure traffic engineering classes explicitly, include the `te-class-matrix` statement:

```
te-class-matrix {
    tenumber {
```

```
        priority priority;
        traffic-class {
            ctnumber priority priority;
        }
    }
}
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls diffserv-te]
- [edit logical-systems *logical-system-name* protocols mpls diffserv-te]

The following example shows how to configure traffic engineering class te0 with class type ct1 and a priority of 4:

```
[edit protocols mpls diffserv-te]
te-class-matrix {
    te0 traffic-class ct1 priority 4;
}
```

NOTE: If you explicitly configure a value for one of the traffic engineering classes, all the default values in the traffic engineering class matrix are dropped.

When you explicitly configure traffic engineering classes, you must also configure a bandwidth model; otherwise, the configuration commit operation fails.

Requirements and Limitations for the Traffic Engineering Class Matrix

When you configure a traffic engineering class matrix, be aware of the following requirements and limitations:

- A mapping configuration is local and affects only the router on which it is configured. It does not affect other systems participating in the differentiated services domain. However, for a Differentiated Services domain to function properly, you need to configure the same traffic engineering class matrix on all the routers participating in the same domain.
- When explicitly configuring traffic engineering classes, you must configure the classes in sequence (te0, te1, te2, te3, and so on); otherwise, the configuration commit operation fails.

The first traffic engineering class you configure must be te0; otherwise, the configuration commit operation fails.

Configuring Class of Service for DiffServ-Aware Traffic Engineering

To configure DiffServ-aware traffic engineering, you must also configure class of service. The following example illustrates a class-of-service configuration that would allocate 25 percent of the link bandwidth to each class:

```
class-of-service {
    interfaces {
        all {
            scheduler-map simple-map;
        }
    }
    scheduler-maps {
        simple-map {
            forwarding-class assured-forwarding scheduler simple_sched;
                forwarding-class best-effort scheduler simple_sched;
                forwarding-class network-control scheduler simple_sched;
            forwarding-class expedited-forwarding scheduler simple_sched;
        }
    }
    schedulers {
        simple_sched {
            transmit-rate percent 25;
            buffer-size percent 25;
        }
    }
}
```

Configuring LSPs for DiffServ-Aware Traffic Engineering

IN THIS SECTION

- Configuring IGP | **1740**
- Configuring Traffic-Engineered LSPs | **1740**
- Configuring Policing for LSPs | **1741**
- Configuring Fast Reroute for Traffic-Engineered LSPs | **1741**

You must configure the Differentiated Services domain (see "Configuring Routers for DiffServ-Aware Traffic Engineering" on page 1733) before you can enable DiffServ-aware traffic engineering for LSPs. The Differentiated Services domain provides the underlying class types and corresponding traffic engineering classes that you reference in the LSP configuration. The traffic engineering classes must be configured consistently on each router participating in the Differentiated Services domain for the LSP to function properly.

NOTE: You must configure either MAM or RDM as the bandwidth model when you configure DiffServ-aware traffic engineering for LSPs. See "Configuring the Bandwidth Model" on page 1733.

The actual data transmitted over this Differentiated Services domain is carried by an LSP. Each LSP relies on the EXP bits of the MPLS packets to enable DiffServ-aware traffic engineering. Each LSP can carry traffic for a single class type.

All the routers participating in the LSP must be Juniper Networks routers running Junos OS Release 6.3 or later. The network can include routers from other vendors and Juniper Networks routers running earlier versions of the Junos OS. However, the DiffServ-aware traffic engineering LSP cannot traverse these routers.

NOTE: You cannot simultaneously configure multiclass LSPs and DiffServ-aware traffic engineering LSPs on the same router.

To enable DiffServ-aware traffic engineering for LSPs, you need to configure the following:

Configuring Class of Service for the Interfaces

The existing class-of-service (CoS) infrastructure ensures that traffic that is consistently marked receives the scheduling guarantees for its class. The classification, marking, and scheduling necessary to accomplish this are configured using the existing Junos OS CoS features.

NOTE: The Junos OS does not support CoS on ATM interfaces.

For information about how to configure CoS, see the Junos OS Class of Service User Guide for Routing Devices.

Configuring IGP

You can configure either IS-IS or OSPF as the IGP. The IS-IS and OSPF configurations for routers supporting LSPs are standard. For information about how to configure these protocols, see the Junos OS Routing Protocols Library for Routing Devices.

Configuring Traffic-Engineered LSPs

You configure an LSP by using the standard LSP configuration statements and procedures. To configure DiffServ-aware traffic engineering for the LSP, specify a class type bandwidth constraint by including the `bandwidth` statement:

```
label-switched-path lsp-name {
    bandwidth {
        ctnumber bps;
    }
}
```

For a list of hierarchy levels at which you can include the `bandwidth` statement, see the statement summary sections for this statement.

If you do not specify a bandwidth for a class type, `ct0` is automatically specified as the queue for the LSP. You can configure only one class type for each LSP, unlike multiclass LSPs.

The class type statements specify bandwidth (in bits per second) for the following classes:

- `ct0`—Bandwidth reserved for class 0
- `ct1`—Bandwidth reserved for class 1
- `ct2`—Bandwidth reserved for class 2
- `ct3`—Bandwidth reserved for class 3

You can configure setup and holding priorities for an LSP, but the following restrictions apply:

- The combination of class and priority must be one of the configured traffic engineering classes. The default setup priority is 7 and the default holding priority is 0.
- Configuring an invalid combination of class type and priority causes the commit operation to fail.
- Automatic bandwidth allocation is not supported. If you configure automatic bandwidth allocation, the commit operation fails.
- LSPs configured with the `bandwidth` statement but without specifying a class type use the default class type `ct0`.

- For migration issues, see Internet draft draft-ietf-tewg-diff-te-proto-07.txt.

Configuring Policing for LSPs

Policing allows you to control the amount of traffic forwarded through a particular LSP. Policing helps to ensure that the amount of traffic forwarded through an LSP never exceeds the requested bandwidth allocation. You can configure multiple policers for each LSP.

For information about how to configure a policer for an LSP, see *Configuring Policers for LSPs*.

Configuring Fast Reroute for Traffic-Engineered LSPs

You can configure fast reroute for traffic engineered LSPs (LSPs carrying a single class of traffic). It is also possible to reserve bandwidth on the detour path for the class of traffic when fast reroute is enabled. The same class type number is used for both the traffic engineered LSP and its detour.

If you configure the router to reserve bandwidth for the detour path, a check is made to ensure that the link is capable of handling DiffServ-aware traffic engineering and for CoS capability before accepting it as a potential detour path. Unsupported links are not used.

You can configure the amount of bandwidth to reserve for detours using either the `bandwidth` statement or the `bandwidth-percent` statement. You can only configure one these statements at a time. If you do not configure either the `bandwidth` statement or the `bandwidth-percent` statement, the default setting is to not reserve bandwidth for the detour path (the bandwidth guarantee will be lost if traffic is switched to the detour).

When you configure the `bandwidth` statement, you can specify the specific amount of bandwidth (in bits per second [bps]) you want to reserve for the detour path. For information, see "Configuring Fast Reroute" on page 565.

The `bandwidth-percent` statement allows you to specify the bandwidth of the detour path as a percentage of the bandwidth configured for the protected path. For example, if you configure 100 millions bps of bandwidth for the protected path and configure 20 for the `bandwidth-percent` statement, the detour path will have 20 million bps of bandwidth reserved for its use.

To configure the percent of bandwidth used by the detour path based on the bandwidth of the protected path, include the `bandwidth-percent` statement:

```
bandwidth-percent percentage;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls label-switched-path *lsp-name* fast-reroute]
- [edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name* fast-reroute]

- MPLS Transport Profile Overview | **1744**
- Example: Configuring the MPLS Transport Profile for OAM | **1745**

MPLS Transport Profile Overview

RFC 5654, *Requirements of an MPLS Transport Profile*, describes the requirements for the MPLS Transport Profile (MPLS-TP) that extends capabilities for Operation, Administration, and Maintenance

(OAM) when MPLS is used for transport services and transport network operations. These capabilities help in troubleshooting and maintenance of a pseudowire or label-switched path (LSP).

MPLS-TP mechanisms for OAM contain two main components:

- Generic Associated Channel Label (GAL)—A special label that enables an exception mechanism that informs the egress *label-switching router* (LSR) that a packet it receives on an LSP belongs to an associated control channel or the control plane.
- Generic Associated Channel Header (G-Ach)—A special header field that identifies the type of payload contained in the MPLS label-switched paths (LSPs). G-Ach has the same format as a pseudowire associated control channel header.

For more information about MPLS-TP, see RFC 5654, *Requirements of an MPLS Transport Profile*. For specific information about GAL and G-Ach, see RFC 5586, *MPLS Generic Associated Channel*.

The following capabilities are supported in the Junos OS implementation of MPLS-TP:

- MPLS-TP OAM can send and receive packets with GAL and G-Ach, without IP encapsulation.
- Two unidirectional RSVP LSPs between a pair of routers can be associated with each other to create an associated bidirectional LSP for binding a path for the GAL and G-Ach OAM messages. A single Bidirectional Forwarding Detection (BFD) session is established for the associated bidirectional LSP.

Example: Configuring the MPLS Transport Profile for OAM

IN THIS SECTION

- Requirements | **1745**
- Overview | **1746**
- Configuration | **1748**
- Verification | **1759**

This example shows how to configure the MPLS Transport Profile (MPLS-TP) for sending and receiving of OAM GAL and G-Ach messages across a label-switched path (LSP).

Requirements

This example uses the following hardware and software components:

- Six devices that can be a combination of M Series, MX Series, and T Series routers
- Junos OS Release 12.1 or later running on the devices

Overview

IN THIS SECTION

- Topology | **1748**

Junos OS Release 12.1 and later support MPLS Transport Profile (MPLS-TP) Operation, Administration, and Maintenance (OAM) capabilities. MPLS-TP introduces new capabilities for OAM when MPLS is used for transport services and transport network operations. This includes configuring Generic Associated Channel Label (GAL) and Generic Associated Channel Header (G-Ach) for OAM messages.

This example shows how to configure MPLS-TP OAM capability to send and receive GAL and G-Ach OAM messages without IP encapsulation. In addition, it also shows how to associate two unidirectional RSVP label-switched paths (LSPs) between a pair of routers to create an associated bidirectional LSP for binding a path for the GAL and G-Ach OAM messages.

Junos OS Release 12.1 and later support the following MPLS-TP capabilities:

- MPLS-TP OAM capability and the infrastructure required for MPLS applications to send and receive packets with GAL and G-Ach, without IP encapsulation.
- LSP-ping and Bidirectional Forwarding Detection (BFD) applications to send and receive packets using GAL and G-Ach, without IP encapsulation on transport LSPs.
- The association of two unidirectional RSVP LSPs, between a pair of routers, with each other to create an associated bidirectional LSP for binding a path for the GAL and G-Ach OAM messages. The associated bidirectional LSP model is supported only for associating the primary paths. A single BFD session is established for the associated bidirectional LSP.

Junos OS Release 12.1 and later does not support the following MPLS-TP capabilities:

- Point-to-multipoint RSVP LSPs and BGP LSPs
- Loss Measurement and Delay Measurement

You can enable GAL and G-Ach OAM operation using the following configuration statements:

- `mpls-tp-mode`—Include this statement at the `[edit protocols mpls oam]` hierarchy level to enable GAL and G-Ach OAM operation, without IP encapsulation, on all LSPs in the MPLS network.

```
[edit protocols mpls oam]
mpls-tp-mode;
```

Include this statement at the [edit protocols mpls label-switched-path *lsp-name* oam] hierarchy level to enable GAL and G-Ach OAM operation without IP encapsulation on a specific LSP in the network.

```
[edit protocols mpls label-switched-path lsp-name oam]
mpls-tp-mode;
```

NOTE: Starting with Junos OS Release 16.1, MPLS-TP supports two additional channel types for the default LSPING (0x0008) channel type under the mpls-tp-mode statement. These additional channel types provide on-demand connectivity verification (CV) with and without IP/UDP encapsulation.

- On-demand CV (0x0025)—This channel type is a new pseudowire channel type and is used for on-demand CV without IP/UDP encapsulation, where IP addressing is not available or non-IP encapsulation is preferred.
- IPv4 (0x0021)—This channel type uses the IP/UDP encapsulation and provides interoperability support with other vendor devices using IP addressing.

The GACH-TLV is used along with the default LSPING channel type. As per RFC 7026, GACH-TLV is deprecated for 0x0021 and 0x0025 channel types.

To configure a channel type for MPLS-TP, include the lsping-channel-type *channel-type* statement at the [edit protocols mpls label-switched-path *lsp-name* oam mpls-tp-mode] and [edit protocols mpls oam mpls-tp-mode] hierarchy levels.

- associate-lsp *lsp-name* from *from-ip-address*—Include this statement at the [edit protocols mpls label-switched-path *lsp-name*] hierarchy level to configure associated bidirectional LSPs on the two ends of the LSP.

```
[edit protocols mpls label-switched-path lsp-name ]
associate-lsp lsp-name {
    from from-ip-address;
}
```

The from *from-ip-address* configuration for the LSP is optional. If omitted, it is derived from the to address of the ingress LSP configuration.

- transit-lsp-association—Include this statement at the [edit protocols mpls]

hierarchy level to associate two LSPs at a transit router.

```
[edit protocols mpls]
transit-lsp-association transit-association-lsp-group-name {
    lsp-name-1 name-of-associated-lsp-1;
    from-1     address-of-associated-lsp-1;
    lsp-name-2 name-of-associated-lsp-2;
    from-2     address-of-associated-lsp-2;
}
```

The association of the LSPs in the transit nodes is useful for the return LSP path for TTL-expired LSP ping packets or traceroute.

In this example, R0 is the ingress router and R4 is the egress router. R1, R2, R3, and R5 are transit routers. The associated bidirectional LSP is established between the transit routers for sending and receiving the GAL and G-Ach OAM messages.

Figure 112 on page 1748 shows the topology used in this example.

Configuration

IN THIS SECTION

- CLI Quick Configuration | **1749**
- Configuring Device R0 | **1753**
- Configuring Device R1 | **1756**

CLI Quick Configuration

NOTE: This example shows the configuration on all devices and shows step-by-step procedures for configuring the ingress router, R0, and transit router R1. Repeat the step-by-step procedure described for the ingress router, R0, on the egress router, R4. Repeat the step-by-step procedure for the transit router, R1, on the other transit routers, R2, R3, and R5. Be sure to modify the appropriate interface names, addresses, and other parameters appropriately.

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the `[edit]` hierarchy level.

Configuring Device R0

Step-by-Step Procedure

To configure the ingress router, R0:

1. Configure the interfaces.

```
[edit interfaces]
user@R0# set ge-4/1/1 unit 0 family inet address 10.10.11.1/30
user@R0# set ge-4/1/1 unit 0 family iso
user@R0# set ge-4/1/1 unit 0 family inet6
user@R0# set ge-4/1/1 unit 0 family mpls
user@R0# set ge-5/0/0 unit 0 family inet address 10.10.10.1/30
user@R0# set ge-5/0/0 unit 0 family iso
user@R0# set ge-5/0/0 unit 0 family inet6
user@R0# set ge-5/0/0 unit 0 family mpls
```

2. Configure MPLS on the interfaces.

```
[edit protocols mpls]
user@R0# set interface ge-5/0/0.0
user@R0# set interface ge-4/1/1.0
```

3. Configure an interior gateway protocol, such as OSPF.

```
[edit protocols ospf]
user@R0# set traffic-engineering
```

```
user@R0# set area 0.0.0.0 interface ge-5/0/0.0
user@R0# set area 0.0.0.0 interface ge-4/1/1.0
user@R0# set area 0.0.0.0 interface lo0.0 passive
```

4. Configure a signaling protocol, such as RSVP.

```
[edit protocols rsvp]
user@R0# set interface ge-5/0/0.0
user@R0# set interface ge-4/1/1.0
```

5. Configure the LSP.

```
[edit protocols mpls]
user@R0# set label-switched-path r0-to-r4 to 10.255.8.86
```

6. Enable GAL and G-Ach OAM operation without IP encapsulation on the LSPs.

```
[edit protocols mpls]
user@R0# set label-switched-path r0-to-r4 oam mpls-tp-mode
```

7. Configure associated bidirectional LSPs on the two ends of the LSP.

```
[edit protocols mpls]
user@R0# set label-switched-path r0-to-r4 associate-lsp to-r0 from 10.255.8.86
```

8. After you are done configuring the device, commit the configuration.

```
[edit]
user@R0#  commit
```

Results

Confirm your configuration by issuing the `show interfaces` and `show protocols` commands.

```
user@R0# show interfaces
ge-4/1/1 {
```

```
    unit 0 {
        family inet {
            address 10.10.11.1/30;
        }
        family iso;
        family inet6;
        family mpls;
    }
}
ge-5/0/0 {
    unit 0 {
        family inet {
            address 10.10.10.1/30;
        }
        family iso;
        family inet6;
        family mpls;
    }
}
```

```
user@R0# show protocols
rsvp {
    interface ge-5/0/0.0;
    interface ge-4/1/1.0;
}
mpls {
    label-switched-path r0-to-r4 {
        to 10.255.8.86;
        oam mpls-tp-mode;

```

Configuring Device R1

Step-by-Step Procedure

To configure the transit router, R1:

1. Configure the interfaces.

```
[edit interfaces]
user@R1# set ge-0/0/5 unit 0 family inet address 10.10.10.2/30
user@R1# set ge-0/0/5 unit 0 family iso
user@R1# set ge-0/0/5 unit 0 family inet6
user@R1# set ge-0/0/5 unit 0 family mpls
user@R1# set ge-0/2/2 unit 0 family inet address 10.10.12.2/30
user@R1# set ge-0/2/2 unit 0 family iso
user@R1# set ge-0/2/2 unit 0 family inet6
user@R1# set ge-0/2/2 unit 0 family mpls
user@R1# set ge-2/0/2 unit 0 family inet address 10.10.11.2/30
user@R1# set ge-2/0/2 unit 0 family iso
user@R1# set ge-2/0/2 unit 0 family inet6
user@R1# set ge-2/0/2 unit 0 family mpls
user@R1# set ge-1/0/2 unit 0 family inet address 10.10.13.2/30
user@R1# set ge-1/0/2 unit 0 family iso
user@R1# set ge-1/0/2 unit 0 family inet6
user@R1# set ge-1/0/2 unit 0 family mpls
```

2. Configure MPLS on the interfaces.

```
[edit protocols mpls]
user@R1# set interface ge-0/0/5.0
user@R1# set interface ge-2/0/2.0
user@R1# set interface ge-1/0/2.0
user@R1# set interface ge-0/2/2.0
```

3. Configure an interior gateway protocol, such as OSPF.

```
[edit protocols ospf]
user@R1# set traffic-engineering
user@R1# set area 0.0.0.0 interface ge-0/0/5.0
user@R1# set area 0.0.0.0 interface ge-2/0/2.0
user@R1# set area 0.0.0.0 interface ge-1/0/2.0
user@R1# set area 0.0.0.0 interface ge-0/2/2.0 metric 100
user@R1# set area 0.0.0.0 interface lo0.0 passive
```

4. Configure a signaling protocol, such as RSVP.

```
[edit protocols rsvp]
user@R1# set interface ge-0/0/5.0
user@R1# set interface ge-2/0/2.0
user@R1# set interface ge-1/0/2.0
user@R1# set interface ge-0/2/2.0
```

5. Configure the association of the two LSPs on the transit router.

```
[edit protocols mpls]
user@R1# set transit-lsp-association trace1 lsp-name-1 r0-to-r4
user@R1# set transit-lsp-association trace1 from-1 10.255.8.207
user@R1# set transit-lsp-association trace1 lsp-name-2 r4-to-r0
user@R1# set transit-lsp-association trace1 from-2 10.255.8.86
```

6. If you are done configuring the device, commit the configuration.

```
[edit]
user@R1# commit
```

Results

Confirm your configuration by issuing the `show interfaces` and `show protocols` commands.

```
user@R1# show interfaces

Meaning

The output of the `show mpls lsp`, `show mpls detail`, and `show mpls bidirectional` commands displays the details of the associated bidirectional LSPs and the LSP association information.

Configuring OAM Ingress Policies for LDP

Using the `ingress-policy` statement, you can configure an Operation, Administration, and Management (OAM) policy to choose which forwarding equivalence classes (FECs) need to have OAM enabled. If the FEC passes through the policy or if the FEC is explicitly configured, OAM is enabled for a FEC. For FECs chosen using a policy, the BFD parameters configured under `[edit protocols ldp oam bfd-liveness-detection]` are applied.

You configure the OAM ingress policy at the `[edit policy-options]` hierarchy level. To configure an OAM ingress policy, include the `ingress-policy` statement:

```
ingress-policy ingress-policy-name;
```

You can configure this statement at the following hierarchy levels:

- `[edit protocols ldp oam]`
- `[edit logical-systems logical-system-name protocols ldp oam]`

NOTE: ACX Series routers do not support `[edit logical-systems]` hierarchy level.

Tracing MPLS and LSP Packets and Operations

To trace MPLS and LSP packets and operations, include the `traceoptions` statement:

```
traceoptions {
    file filename <files number> <size size> <world-readable | no-world-readable>;
    flag flag;
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

You can specify the following MPLS-specific flags in the MPLS `traceoptions` statement:

- `all`—Trace all operations.
- `connection`—Trace all circuit cross-connect (CCC) activity.
- `connection-detail`—Trace detailed CCC activity.
- `cspf`—Trace CSPF computations.
- `cspf-link`—Trace links visited during CSPF computations.
- `cspf-node`—Trace nodes visited during CSPF computations.
- `error`—Trace MPLS error conditions.
- `graceful-restart`—Trace MPLS graceful restart events.
- `lsping`—Trace LSP ping packets and return codes.
- `nsr-synchronization`—Trace nonstop routing (NSR) synchronization events.
- `nsr-synchronization-detail`—Trace NSR synchronization events in detail.
- `state`—Trace all LSP state transitions.
- `static`—Trace static label-switched path.

When you configure trace options to track an MPLS LSP using the `cspf` option, the CSPF log displays information about the MPLS LSP using the term “generalized MPLS” (GMPLS). For example, a message in the CSPF log might state that the “link passes GMPLS constraints”. Generalized MPLS (GMPLS) is a superset of MPLS, so this message is normal and does not affect proper MPLS LSP operation.

Release History Table

Release	Description
16.1	Starting with Junos OS Release 16.1, MPLS-TP supports two additional channel types for the default LSPING (0x0008) channel type under the mpls-tp-mode statement.

Ethernet Pseudowire Overview

Starting in Junos OS Release 14.1X53 and Junos OS Release 16.1, an Ethernet pseudowire is used to carry Ethernet or 802.3 Protocol Data Units (PDUs) over an MPLS network enabling service providers to offer emulated Ethernet services over existing MPLS networks. Ethernet or 802.3 PDUs are encapsulated within the pseudowire to provide a point-to-point Ethernet service. For the point-to-point Ethernet service, the following fault management features are supported:

- The IEEE 802.3ah standard for Operation, Administration, and Management (OAM). You can configure IEEE 802.3ah OAM link-fault management on Ethernet point-to-point direct links or links across Ethernet repeaters.

  Ethernet OAM link-fault management can be used for physical link-level fault detection and management. It uses a new, optional sublayer in the data link layer of the OSI model. Ethernet OAM can be implemented on any full-duplex point-to-point or emulated point-to-point Ethernet link. A system-wide implementation is not required; OAM can be deployed on particular interfaces of a router. Transmitted Ethernet OAM messages or OAM PDUs are of standard length, untagged Ethernet frames within the normal frame length limits in the range 64–1518 bytes.

- Ethernet connectivity fault management (CFM) to monitor the physical link between two routers.

  - Connection protection using the continuity check protocol for fault monitoring . The continuity check protocol is a neighbor discovery and health check protocol that discovers and maintains adjacencies at the VLAN or link level.

  - Path protection using the linktrace protocol for path discovery and fault verification . Similar to IP traceroute, the linktrace protocol maps the path taken to a destination MAC address through one or more bridged networks between the source and destination.

IN THIS SECTION

- Requirements | **1766**
- Overview of an Ethernet Pseudowire Base Configuration | **1766**
- Configuring an Ethernet Pseudowire | **1767**

Requirements

The following is a list of the hardware and software requirements for this configuration.

- One ACX Series router
- Junos OS Release 12.2 or later

Overview of an Ethernet Pseudowire Base Configuration

The configuration shown here is the base configuration of an Ethernet pseudowire with Ethernet cross-connect for physical interface encapsulation on an ACX Series router. This configuration is for one

provider edge router. To complete the configuration of an Ethernet pseudowire, you need to repeat this configuration on an other provider edge router in the Multiprotocol Label Switched (MPLS) network.

Configuring an Ethernet Pseudowire

IN THIS SECTION

- Procedure | 1767
- Results | 1769

Procedure

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them in a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level:

```
set interfaces ge-0/1/1 encapsulation ethernet-ccc
set interfaces ge-0/1/1 unit 0
set interfaces ge-0/2/0 unit 0 family inet address 20.1.1.2/24
set interfaces ge-0/2/0 unit 0 family mpls
set interfaces lo0 unit 0 family inet address 70.1.1.1/32
set protocols rsvp interface ge-0/2/0.0
set protocols mpls no-cspf
set protocols mpls label-switched-path PE1-to-PE2 to 40.1.1.1
set protocols mpls interface ge-0/2/0.0
set protocols ospf traffic-engineering
set protocols ospf area 0.0.0.0 interface ge-0/2/0.0
set protocols ospf area 0.0.0.0 interface lo0.0 passive
set protocols ldp interface ge-0/2/0.0
set protocols ldp interface lo0.0
set protocols l2circuit neighbor 40.1.1.1 interface ge-0/1/1.0 virtual-circuit-id 1
```

NOTE: To configure an Ethernet pseudowire with 802.1Q tagging for cross-connect logical interface encapsulation, include the `vlan-ccc` statement at the [`edit interfaces ge-0/1/1 unit 0 encapsulation`] hierarchy level instead of the `ethernet-ccc` statement shown in this example.

Step-by-Step Procedure

1. Create two Gigabit Ethernet interfaces, set the encapsulation mode on one interface and MPLS on the other interface. Create the loopback (`lo0`) interface:

```
[edit]
user@host# edit interfaces
[edit interfaces]
user@host# set ge-0/1/1 encapsulation ethernet-ccc
user@host# set ge-0/1/1 unit 0
user@host# set ge-0/2/0 unit 0 family inet address 20.1.1.2/24
user@host# set ge-0/2/0 unit 0 family mpls
user@host# set lo0 unit 0 family inet address 70.1.1.1/32
```

2. Enable the MPLS and RSVP protocols on the interface configured with MPLS—`ge-0/2/0.0`:

```
[edit]
user@host# edit protocols
[edit protocols]
user@host# set rsvp interface ge-0/2/0.0
user@host# set mpls interface ge-0/2/0.0
```

3. Configure LDP. If you configure RSVP for a pseudowire, you must also configure LDP:

```
[edit protocols]
user@host# set protocols ldp interface ge-0/2/0.0
user@host# set protocols ldp interface lo0.0
```

4. Configure a point-to-point label-switched path (LSP) and disable constrained-path LSP computation:

```
[edit protocols]
user@host# set mpls label-switched-path PE1-to-PE2 to 40.1.1.1
user@host# set mpls no-cspf
```

5. Configure OSPF and enable traffic engineering on the MPLS interface—`ge-0/2/0.0`, and on the loopback (`lo0`) interface:

```
[edit protocols]
user@host# set ospf traffic-engineering
user@host# set ospf area 0.0.0.0 interface ge-0/2/0.0
user@host# set ospf area 0.0.0.0 interface lo0.0 passive
```

6. Uniquely identify a Layer 2 circuit for the Ethernet pseudowire:

```
[edit protocols]
user@host#  set l2circuit neighbor 40.1.1.1 interface ge-0/1/1.0 virtual-circuit-id 1
```

Results

```
[edit]
user@host# show
interfaces {
    ge-0/1/1 {
        encapsulation ethernet-ccc;
        unit 0;
    }
    ge-0/2/0 {
        unit 0 {
            family inet {
                address 20.1.1.2/24;
            }
            family mpls;
        }
    }
    lo0 {
        unit 0 {
```

```
            family inet {
                address 70.1.1.1/32;
            }
        }
    }
}
protocols {
    rsvp {
        interface ge-0/2/0.0;
    }
    mpls {
        no-cspf;
        label-switched-path PE1-to-PE2 {
            to 40.1.1.1;
        }
        interface ge-0/2/0.0;
    }
    ospf {
        traffic-engineering;
        area 0.0.0.0 {
            interface ge-0/2/0.0;
            interface lo0.0 {
                passive;
            }
        }
    }
    ldp {
        interface ge-0/2/0.0;
        interface lo0.0;
    }
    l2circuit {
        neighbor 40.1.1.1 {
            interface ge-0/1/1.0 {
                virtual-circuit-id 1;
            }
        }
    }
}
```

Pseudowire Overview for ACX Series Universal Metro Routers

A pseudowire is a Layer 2 circuit or service, which emulates the essential attributes of a telecommunications service— such as a T1 line, over an MPLS packet-switched network. The

pseudowire is intended to provide only the minimum necessary functionality to emulate the wire with the required degree of faithfulness for the given service definition. On the ACX Series routers, Ethernet, Asynchronous Transfer Mode (ATM), and time-division multiplexing (TDM) pseudowires are supported. The following pseudowire features are supported:

- Pseudowire transport service carrying Layer 1 and Layer 2 information over an IP and MPLS network infrastructure. Only similar end points are supported on the ACX Series—for example, T1 to T1, ATM to ATM, and Ethernet to Ethernet.
- Redundant pseudowires backup connections between PE routers and CE devices, maintaining Layer 2 circuits and services after certain types of failures. Pseudowire redundancy improves the reliability of certain types of networks (metro for example) where a single point of failure could interrupt service for multiple customers. The following pseudowire redundancy features are supported:
  - Maintenance of Layer 2 circuit services after certain types of failures with a standby pseudowire, which backs up the connection between PE routers and CE devices.
  - In case of failure, a protect interface, which backs up the primary interface. Network traffic uses the primary interface only so long as the primary interface functions. If the primary interface fails, traffic is switched to the protect interface.
  - Hot and cold standby enabling swift cut over to the backup or standby pseudowire.
- Ethernet connectivity fault management (CFM), which can be used to monitor the physical link between two routers. The following major features of CFM for Ethernet pseudowires only are supported:
  - Connection protection using the continuity check protocol for fault monitoring. The continuity check protocol is a neighbor discovery and health check protocol that discovers and maintains adjacencies at the VLAN or link level.
  - Path protection using the linktrace protocol for path discovery and fault verification. Similar to IP traceroute, the linktrace protocol maps the path taken to a destination MAC address through one or more bridged networks between the source and destination.

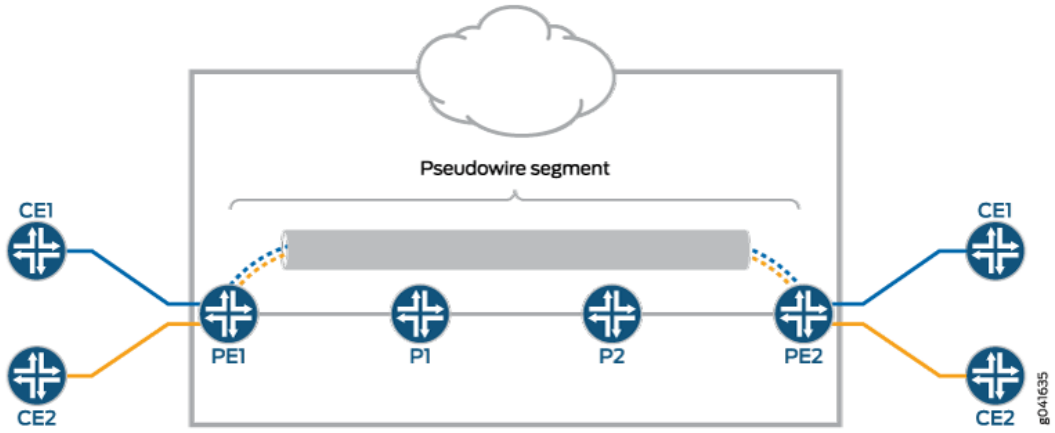
Understanding Multisegment Pseudowire

A pseudowire is a Layer 2 circuit or service that emulates the essential attributes of a telecommunications service, such as a T1 line, over an MPLS packet-switched network (PSN). The pseudowire is intended to provide only the minimum necessary functionality to emulate the wire with the required resiliency requirements for the given service definition.

When a pseudowire originates and terminates on the edge of the same PSN, the pseudowire label is unchanged between the originating and terminating provider edge (T-PE) devices. This is called a single-segment pseudowire (SS-PW). Figure 113 on page 1772 illustrates an SS-PW established between two PE routers. The pseudowires between the PE1 and PE2 routers are located within the same autonomous system (AS).

Figure 113: L2VPN Pseudowire



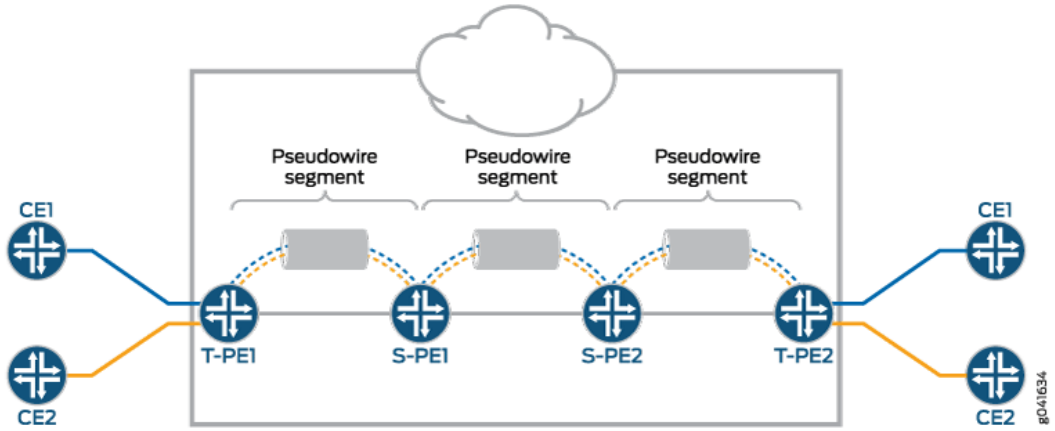
In cases where it is impossible to establish a single pseudowire from a local to a remote PE, either because it is unfeasible or undesirable to establish a single control plane between the two PEs, a multisegment pseudowire (MS-PW) is used.

An MS-PW is a set of two or more contiguous SS-PWs that are made to function as a single point-to-point pseudowire. It is also known as switched pseudowire. MS-PWs can go across different regions or network domains. A region can be considered as an interior gateway protocol (IGP) area or a BGP

autonomous system that belongs to the same or different administrative domain. An MS-PW spans multiple cores or ASs of the same or different carrier networks. A Layer 2 VPN MS-PW can include up to 254 pseudowire segments.

Figure 114 on page 1773 illustrates a set of two or more pseudowire segments that function as a single pseudowire. The end routers are called terminating PE (T-PE) routers, and the switching routers are called switching PE (S-PE) routers. The S-PE router terminates the tunnels of the preceding and succeeding pseudowire segments in an MS-PW. The S-PE router can switch the control and data planes of the preceding and succeeding pseudowire segments of the MS-PW. An MS-PW is declared to be up when all the single-segment pseudowires are up.

Figure 114: Multisegment Pseudowire



Using FEC 129 for Multisegment Pseudowire

Currently, there are two types of attachment circuit identifiers (AIIs) defined under FEC 129:

- Type 1 AII
- Type 2 AII

The support of an MS-PW for FEC 129 uses type 2 AII. A type 2 AII is globally unique by definition of RFC 5003.

Single-segment pseudowires (SS-PWs) using FEC 129 on an MPLS PSN can use both type 1 and type 2 AII. For an MS-PW using FEC 129, a pseudowire itself is identified as a pair of endpoints. This requires that the pseudowire endpoints be uniquely identified.

In the case of a dynamically placed MS-PW, there is a requirement for the identifiers of attachment circuits to be globally unique, for the purposes of reachability and manageability of the pseudowire.

Thus, individual globally unique addresses are allocated to all the attachment circuits and S-PEs that make up an MS-PW.

Type 2 AII is composed of three fields:

- Global_ID—Global identification, which is usually the AS number.
- Prefix—IPv4 address, which is usually the router ID.
- AC_ID—Local attachment circuit, which is a user-configurable value.

Since type 2 AII already contains the T-PE's IP address and it is globally unique, from the FEC 129 pseudowire signaling point of view, the combination (AGI, SAII, TAII) uniquely identifies an MS-PW across all interconnected pseudowire domains.

Establishing a Multisegment Pseudowire Overview

An MS-PW is established by dynamically and automatically selecting the predefined S-PEs and placing the MS-PW between two T-PE devices.

When S-PEs are dynamically selected, each S-PE is automatically discovered and selected using the BGP autodiscovery feature, without the requirement of provisioning the FEC 129 pseudowire-related information on all the S-PEs. BGP is used to propagate pseudowire address information throughout the PSN.

Since there is no manual provisioning of FEC 129 pseudowire information on the S-PEs, the Attachment Group Identifier (AGI) and Attachment Individual Identifier (AII) are reused automatically, and choosing the same set of S-PEs for the pseudowire in both the forwarding and reverse direction is achieved through the active and passive role of each T-PE device.

- Active—The T-PE initiates an LDP label mapping message.
- Passive—The T-PE does not initiate an LDP label mapping message until it receives a label mapping message initiated by the active T-PE. The passive T-PE sends its label mapping message to the same S-PE from where it received the label mapping message originated from its active T-PE. This ensures that the same set of S-PEs are used in the reverse direction.

Pseudowire Status Support for Multisegment Pseudowire

Pseudowire Status Behavior on T-PE

The following pseudowire status messages are relevant on the T-PE:

- 0x00000010—Local PSN-facing pseudowire (egress) transmit fault.

- 0x00000001—Generic nonforwarding fault code. This is set as the local fault code. The local fault code is set at the local T-PE, and LDP sends a pseudowire status TLV message with the same fault code to the remote T-PE.
- Fault codes are bit-wise OR'ed and stored as remote pseudowire status codes.

Pseudowire Status Behavior on S-PE

The S-PE initiates the pseudowire status messages that indicate the pseudowire faults. The SP-PE in the pseudowire notification message hints where the fault was originated.

- When a local fault is detected by the S-PE, a pseudowire status message is sent in both directions along the pseudowire. Since there are no attachment circuits on an S-PE, only the following status messages are relevant:
  - 0x00000008—Local PSN-facing pseudowire (ingress) receive fault.
  - 0x00000010—Local PSN-facing pseudowire (egress) transmit fault.
- To indicate which SS-PW is at fault, an LDP SP-PE TLV is attached with the pseudowire status code in the LDP notification message. The pseudowire status is passed along from one pseudowire to another unchanged by the control plane switching function.
- If an S-PE initiates a pseudowire status notification message with one particular pseudowire status bit, then for the pseudowire status code an S-PE receives, the same bit is processed locally and not forwarded until the S-PE's original status error is cleared.
- An S-PE keeps only two pseudowire status codes for each SS-PW it is involved in – local pseudowire status code and remote pseudowire status code. The value of the remote pseudowire status code is the result of logic or operation of the pseudowire status codes in the chain of SS-PWs preceding this segment. This status code is incrementally updated by each S-PE upon receipt and communicated to the next S-PE. The local pseudowire status is generated locally based on its local pseudowire status.
- Only transmit fault is detected at the SP-PE. When there is no MPLS LSP to reach the next segment, a local transmit fault is detected. The transmit fault is sent to the next downstream segment, and the receive fault is sent to the upstream segment.
- Remote failures received on an S-PE are just passed along the MS-PW unchanged. Local failures are sent to both segments of the pseudowire that the S-PE is involved in.

Pseudowire TLV Support for MS-PW

MS-PW provides the following support for the LDP SP-PE TLV [RFC 6073]:

- The LDP SP-PE TLVs for an MS-PW include:

  - Local IP address
  - Remote IP address
- An SP-PE adds the LDP SP-PE TLV to the label mapping message. Each SP-PE appends the local LDP SP-PE TLV to the SP-PE list it received from the other segment.
- The pseudowire status notification message includes the LDP SP-PE TLV when the notification is generated at the SP-PE.

Supported and Unsupported Features

Junos OS supports the following features with MS-PW:

- MPLS PSN for each SS-PW that builds up the MS-PW.
- The same pseudowire encapsulation for each SS-PW in an MS-PW – Ethernet or VLAN-CCC.
- The generalized PWid FEC with T-LDP as an end-to-end pseudowire signaling protocol to set up each SS-PW.
- MP-BGP to autodiscover the two endpoint PEs for each SS-PW associated with the MS-PW.
- Standard MPLS operation to stitch two side-by-side SS-PWs to form an MS-PW.
- Automatic discovery of S-PE so that the MS-PW can be dynamically placed.
- Minimum provisioning of S-PE.
- Operation, administration, and maintenance (OAM) mechanisms, including end-to-end MPLS ping or end-to-any-S-PE MPLS ping, MPLS path trace, end-to-end VCCV, and Bidirectional Forwarding Detection (BFD).
- Pseudowire swithing point (SP) PE TLV for the MS-PW.
- Composite next hop on MS-PW.
- Pseudowire status TLV for MS-PW.

Junos OS does not support the following MS-PW functionality:

- Mix of LDP FEC 128 and LDP FEC 129.
- Static pseudowire where each label is provisioned staticially.
- Graceful Routing Engine switchover.
- Nonstop active routing.

- Multihoming.
- Partial connectivity verification (originating from an S-PE) in OAM.

Example: Configuring a Multisegment Pseudowire

IN THIS SECTION

- Requirements | **1777**
- Overview | **1778**
- Configuration | **1784**
- Verification | **1812**
- Troubleshooting | **1823**

This example shows how to configure a dynamic multisegment pseudowire (MS-PW), where the stitching provider edge (S-PE) devices are automatically and dynamically discovered by BGP, and pseudowires are signaled by LDP using FEC 129. This arrangement requires minimum provisioning on the S-PEs, thereby reducing the configuration burden that is associated with statically configured Layer 2 circuits while still using LDP as the underlying signaling protocol.

Requirements

This example uses the following hardware and software components:

- Six routers that can be a combination of M Series Multiservice Edge Routers, MX Series 5G Universal Routing Platforms, T Series Core Routers, or PTX Series Packet Transport Routers.
  - Two remote PE devices configured as terminating PEs (T-PEs).
  - Two S-PEs configured as:
    - Route reflectors, in the case of interarea configuration.
    - AS boundary routers or route reflectors, in the case of inter-AS configuration.
- Junos OS Release 13.3 or later running on all the devices.

Before you begin:

1. Configure the device interfaces.
2. Configure OSPF or any other IGP protocol.

3. Configure BGP.
4. Configure LDP.
5. Configure MPLS.

Overview

Starting with Junos OS Release 13.3, you can configure an MS-PW using FEC 129 with LDP signaling and BGP autodiscovery in an MPLS packet-switched network (PSN). The MS-PW feature also provides operation, administration, and management (OAM) capabilities, such as ping, traceroute, and BFD, from the T-PE devices.

To enable autodiscovery of S-PEs in an MS-PW, include the `auto-discovery-mspw` statement at the `[edit protocols bgp group group-name family l2vpn]` hierarchy level.

```
family l2vpn {
    auto-discovery-mspw;
}
```

The automatic selection of S-PE and dynamic setting up of an MS-PW rely heavily on BGP. BGP network layer reachability information (NLRI) constructed for the FEC 129 pseudowire to autodiscover the S-PE is called an MS-PW NLRI [draft-ietf-pwe3-dynamic-ms-pw-15.txt]. The MS-PW NLRI is essentially a prefix consisting of a route distinguisher (RD) and FEC 129 source attachment identifier (SAII). It is referred to as a BGP autodiscovery (BGP-AD) route and is encoded as `RD:SAII`.

Only T-PEs that are provisioned with type 2 AIIs initiate their own MS-PW NLRI respectively. Since a type 2 AII is globally unique, an MS-PW NLRI is used to identify a PE device to which the type 2 AII is provisioned. The difference between a type 1 AII and a type 2 AII requires that a new address family indicator (AFI) and subsequent address family identifier (SAFI) be defined in BGP to support an MS-PW. The proposed AFI and SAFI value pair used to identify the MS-PW NLRI is 25 and 6, respectively (pending IANA allocation).

The AFI and SAFI values support autodiscovery of S-PEs and should be configured on both T-PEs that originate the routes, and the S-PEs that participate in the signaling.

Figure 115 on page 1779 illustrates an inter-area MS-PW setup between two remote PE routers—T-PE1 and T-PE2. The Provider (P) routers are P1 and P2, and the S-PE routers are S-PE1 and S-PE2. The MS-PW is established between T-PE1 and T-PE2, and all the devices belong to the same AS—AS 100. Since S-PE1 and S-PE2 belong to the same AS, they act as route reflectors and are also known as RR 1 and RR 2, respectively.

Figure 116 on page 1779 illustrates an inter-AS MS-PW setup. The MS-PW is established between T-PE1 and T-PE2, where T-PE1, P1, and S-PE1 belong to AS 1, and S-PE2, P2, and T-PE2 belong to AS 2.

Since S-PE1 and S-PE2 belong to different ASs, they are configured as ASBR routers and are also known as ASBR 1 and ASBR 2, respectively.

Figure 115: Interarea Multisegment Pseudowire

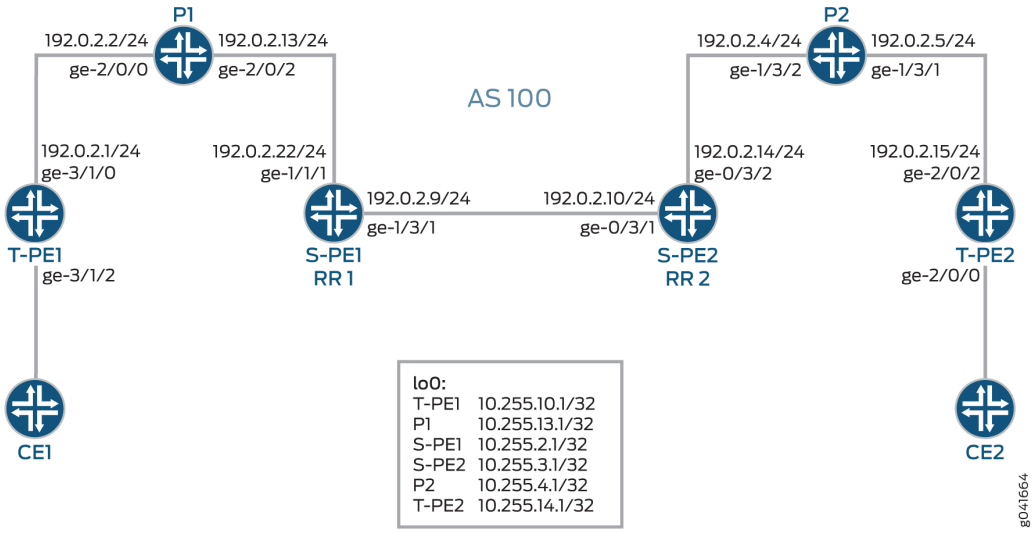


Figure 116: Inter-AS Multisegment Pseudowire

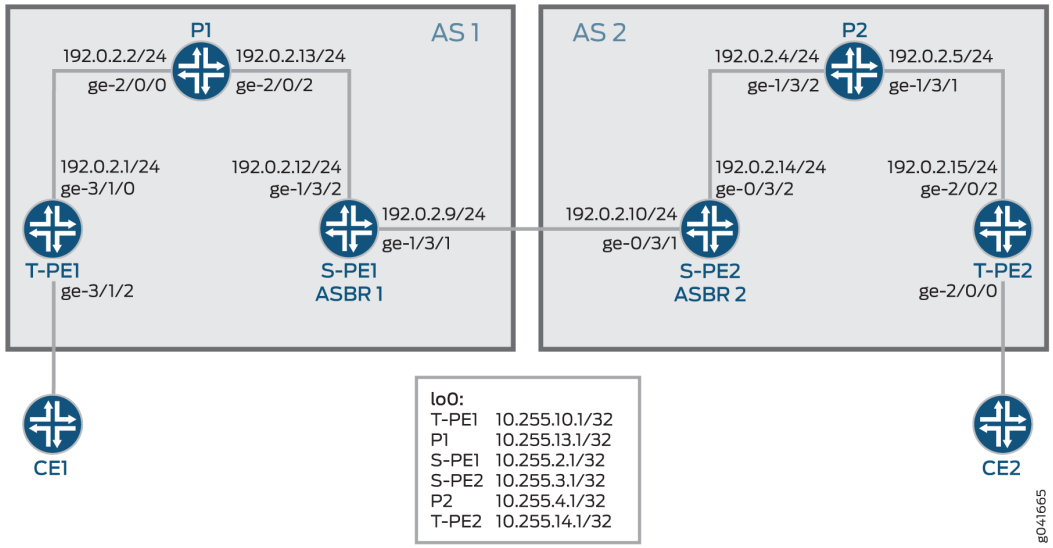

The following sections provide information about how an MS-PW is established in an interarea and inter-AS scenario.

Minimum Configuration Requirements on S-PE

In order to dynamically discover both ends of an SS-PW and set up a T-LDP session dynamically, the following is required:

- For interarea MS-PW, each S-PE plays both an ABR and BGP route reflector role.

  In the interarea case, as seen in Figure 115 on page 1779, the S-PE plays a BGP route reflector role and reflects the BGP-AD route to its client. A BGP-AD route advertised by one T-PE eventually reaches its remote T-PE. Because of the next-hop-self set by each S-PE, the S-PE or T-PE that receives a BGP-AD route can always discover the S-PE that advertises the BGP-AD in its local AS or local area through the BGP next hop.

- For inter-AS MS-PW, each S-PE plays either an ASBR or a BGP route reflector role.

  In an MS-PW, the two T-PEs initiate a BGP-AD route respectively. When the S-PE receives the BGP-AD route through either the IBGP session with the T-PE or through a regular BGP-RR, it sets the next-hop-self before re-advertising the BGP-AD route to one or more of its EBGP peers in the inter-AS case, as seen in Figure 116 on page 1779.

- Each S-PE must set next-hop-self when re-advertising or reflecting a BGP-AD route for the MS-PW.

Active and Passive Role of T-PE

To ensure that the same set of S-PEs are being used for a MS-PW in both directions, the two T-PEs play different roles in terms of FEC 129 signaling. This is to avoid different paths being chosen by T-PE1 and T-PE2 when each S-PE is dynamically selected for an MS-PW.

When an MS-PW is signaled using FEC 129, each T-PE might independently start signaling the MS-PW. The signaling procedure can result in an attempt to set up each direction of the MS-PW through different S-PEs.

To avoid this situation, one of the T-PEs must start the pseudowire signaling (active role), while the other waits to receive the LDP label mapping before sending the respective pseudowire LDP label mapping message (passive role). When the MS-PW path is dynamically placed, the active T-PE (the Source T-PE) and the passive T-PE (the Target T-PE) must be identified before signaling is initiated for a given MS-PW. The determination of which T-PE assumes the active role is done based on the SAII value, where the T-PE that has a larger SAII value plays the active role.

In this example, the SAII values of T-PE1 and T-PE 2 are `800:800:800` and `700:700:700`, respectively. Since T-PE1 has a higher SAII value, it assumes the active role and T-PE2 assumes the passive role.

Directions for Establishing an MS-PW

The directions used by the S-PE for setting up the MS-PW are:

- Forwarding direction—From an active T-PE to a passive T-PE.

In this direction, the S-PEs perform a BGP-AD route lookup to determine the next-hop S-PE to send the label mapping message.

- Reverse direction—From a passive T-PE to an active T-PE.

  In this direction, the S-PEs do not perform a BGP-AD route lookup, because the label mapping messages are received from the T-PEs, and the stitching routes are installed in the S-PEs.

In this example, the MS-PW is established in the forwarding direction from T-PE1 to T-PE2. When the MS-PW is placed from T-PE2 to T-PE1, the MS-PW is established in the reverse direction.

Autodiscovery and Dynamic Selection of S-PE

A new AFI and SAFI value is defined in BGP to support the MS-PWs based on type 2 AII. This new address family supports autodiscovery of S-PEs. This address family must be configured on both the TPEs and SPEs.

It is the responsibility of the Layer 2 VPN component to dynamically select the next S-PE to use along the MS-PW in the forwarding direction.

- In the forwarding direction, the selection of the next S-PE is based on the BGP-AD route advertised by the BGP and pseudowire FEC information sent by the LDP. The BGP-AD route is initiated by the passive T-PE (T-PE2) in the reverse direction while the pseudowire FEC information is sent by LDP from the active T-PE (T-PE1) in the forwarding direction.
- In the reverse direction, the next S-PE (S-PE2) or the active T-PE (T-PE1) is obtained by looking up the S-PE (S-PE1) that it used to set up the pseudowire in the forwarding direction.

Provisioning a T-PE

To support FEC 129 type 2 AII, the T-PE needs to configure its remote T-PE's IP address, a global ID, and an attachment circuit ID. Explicit paths where a set of S-PEs to use is explicitly specified on a T-PE is not supported. This eliminates the need to provision each S-PE with a type 2 AII.

Stitching an MS-PW

An S-PE performs the following MPLS label operations before forwarding the received label mapping message to the next S-PE:

1. Pops the MPLS tunnel label.
2. Pops the VC label.
3. Pushes a new VC label.
4. Pushes an MPLS tunnel label used for the next segment.

Establishing an MS-PW

After completing the necessary configuration, an MS-PW is established in the following manner:

1. The SAII values are exchanged between T-PE1 and T-PE2 using BGP.

   T-PE1 assumes the active T-PE role, because it is configured with a higher SAII value. T-PE2 becomes the passive T-PE.

2. T-PE1 receives the BGP-AD route originated by T-PE2. It compares the AII values obtained from T-PE2 in the received BGP-AD route against the AII values provisioned locally.

3. If the AII values match, T-PE1 performs a BGP-AD route lookup to elect the first S-PE (S-PE1).

4. T-PE1 sends an LDP label mapping message to S-PE1.

5. Using the BGP-AD route originated from T-PE2, and the LDP label mapping message received from T-PE1, S-PE1 selects the next S-PE (S-PE2) in the forwarding direction.

   To do this, S-PE1 compares SAII obtained from the BGP-AD route against the TAI from the LDP label mapping message.

6. If the AII values match, S-PE1 finds S-PE2 through the BGP next hop associated with the BGP-AD route.

7. The process of selecting S-PE goes on until the last S-PE establishes a T-LDP session with T-PE2. When T-PE2 receives the LDP label mapping message from the last S-PE (S-PE2), it initiates its own label mapping message and sends it back to S-PE2.

8. When all the label mapping messages are received on S-PE1 and S-PE2, the S-PEs install the stitching routes. Thus, when the MS-PW is established in the reverse direction, the S-PEs need not perform BGP-AD route lookup to determine its next hop as it did in the forwarding direction.

OAM Support for an MS-PW

After the MS-PW is established, the following OAM capabilities can be executed from the T-PE devices:

- Ping
  - End-to-End Connectivity Verification Between T-PEs

    If T-PE1, S-PEs, and T-PE2 support Control Word (CW), the pseudowire control plane automatically negotiates the use of the CW. Virtual Circuit Connectivity Verification (VCCV) Control Channel (CC) Type 3 will function correctly whether or not the CW is enabled on the pseudowire. However, VCCV Type 1, which is used for end-to-end verification only, is only supported if the CW is enabled.

    The following is a sample:

Ping from T-P1 to T-PE2

```
user@T-PE1> ping mpls l2vpn fec129 instance instance-name local-id SAII of T-PE1 remote-pe-address address of T-PE2 remote-id TAII of T-PE2
```

or

```
user@T-PE1> ping mpls l2vpn fec129 interface CE1-facing interface
```

- Partial Connectivity Verification from T-PE to Any S-PE

  To trace part of an MS-PW, the TTL of the pseudowire label can be used to force the VCCV message to pop out at an intermediate node. When the TTL expires, the S-PE can determine that the packet is a VCCV packet either by checking the CW or by checking for a valid IP header with UDP destination port 3502 (if the CW is not in use). The packet should then be diverted to VCCV processing.

  If T-PE1 sends a VCCV message with the TTL of the pseudowire label equal to 1, the TTL expires at the S-PE. T-PE1 can thus verify the first segment of the pseudowire.

  The VCCV packet is built according to RFC 4379. All the information necessary to build the VCCV LSP ping packet is collected by inspecting the S-PE TLVs. This use of the TTL is subject to the caution expressed in RFC 5085. If a penultimate LSR between S-PEs or between an S-PE and a T-PE manipulates the pseudowire label TTL, the VCCV message might not emerge from the MS-PW at the correct S-PE.

  The following is a sample:

  Ping from T-PE1 to S-PE

  ```
  user@T-PE1> ping mpls l2vpn fec129 interface CE1-facing interface bottom-label-ttl segment
  ```

  The `bottom-label-ttl` value is 1 for S-PE1 and 2 for S-PE2.

  The `bottom-label-ttl` statement sets the correct VC label TTL, so the packets are popped to the correct SS-PW for VCCV processing.

  NOTE: Junos OS supports VCCV Type 1 and Type 3 for the MS-PW OAM capability. VCCV Type 2 is not supported.

- Traceroute

Traceroute tests each S-PE along the path of the MS-PW in a single operation similar to LSP trace. This operation is able to determine the actual data path of the MS-PW, and is used for dynamically signaled MS-PWs.

```
user@T-PE1> traceroute mpls l2vpn fec129 interface CE1-facing interface
```

- Bidirectional Forwarding Detection

  Bidirectional Forwarding Detection (BFD) is a detection protocol designed to provide fast forwarding path failure detection times for all media types, encapsulations, topologies, and routing protocols. In addition to fast forwarding path failure detection, BFD provides a consistent failure detection method for network administrators. The router or switch can be configured to log a system log (syslog) message when BFD goes down.

```
user@T-PE1> show bfd session extensive
```

Configuration

```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure T-PE1 in the interarea scenario:

NOTE: Repeat this procedure for the T-PE2 device in the MPLS domain, after modifying the appropriate interface names, addresses, and other parameters.

1. Configure the T-PE1 interfaces.

```
[edit interfaces]
user@T-PE1# set ge-3/1/0 unit 0 family inet address 192.0.2.1/24
user@T-PE1# set ge-3/1/0 unit 0 family mpls
user@T-PE1# set ge-3/1/2 encapsulation ethernet-ccc
user@T-PE1# set ge-3/1/2 unit 0
user@T-PE1# set lo0 unit 0 family inet address 10.255.10.1/32 primary
```

2. Set the autonomous system number.

```
[edit routing-options]
user@T-PE1# set autonomous-system 100
```

3. Enable MPLS on all the interfaces of T-PE1, excluding the management interface.

```
[edit protocols]
user@T-PE1# set mpls interface all
user@T-PE1# set mpls interface fxp0.0 disable
```

4. Enable autodiscovery of intermediate S-PEs that make up the MS-PW using BGP.

```
[edit protocols]
user@T-PE1# set bgp family l2vpn auto-discovery-mspw
```

5. Configure the BGP group for T-PE1.

```
[edit protocols]
user@T-PE1# set bgp group mspw type internal
```

6. Assign local and neighbor addresses to the mspw group for T-PE1 to peer with S-PE1.

```
[edit protocols]
user@T-PE1# set bgp group mspw local-address 10.255.10.1
user@T-PE1# set bgp group mspw neighbor 10.255.2.1
```

7. Configure OSPF on all the interfaces of T-PE1, excluding the management interface.

```
[edit protocols]
user@T-PE1# set ospf area 0.0.0.0 interface lo0.0
user@T-PE1# set ospf area 0.0.0.0 interface all
user@T-PE1# set ospf area 0.0.0.0 interface fxp0.0 disable
```

8. Configure LDP on all the interfaces of T-PE1, excluding the management interface.

```
[edit protocols]
user@T-PE1# set ldp interface all
user@T-PE1# set ldp interface fxp0.0 disable
user@T-PE1# set ldp interface lo0.0
```

9. Configure the Layer 2 VPN routing instance on T-PE1.

```
[edit routing-instances]
user@T-PE1# set ms-pw instance-type l2vpn
```

10. Assign the interface name for the mspw routing instance.

```
[edit routing-instances]
user@T-PE1# set ms-pw interface ge-3/1/2.0
```

11. Configure the route distinguisher for the mspw routing instance.

```
[edit routing-instances]
user@T-PE1# set ms-pw route-distinguisher 10.10.10.10:15
```

12. Configure the Layer 2 VPN ID community for FEC 129 MS-PW.

```
[edit routing-instances]
user@T-PE1# set ms-pw l2vpn-id l2vpn-id:100:15
```

13. Configure a VPN routing and forwarding (VRF) target for the mspw routing instance.

```
[edit routing-instances]
user@T-PE1# set ms-pw vrf-target target:100:115
```

14. Configure the source attachment identifier (SAI) value using Layer 2 VPN as the routing protocol for the mspw routing instance.

```
[edit routing-instances]
user@T-PE1# set ms-pw protocols l2vpn site CE1 source-attachment-identifier 800:800:800
```

15. Assign the interface name that connects the CE1 site to the VPN, and configure the target attachment identifier (TAI) value using Layer 2 VPN as the routing protocol for the mspw routing instance.

```
[edit routing-instances]
user@T-PE1# set ms-pw protocols l2vpn site CE1 interface ge-3/1/2.0 target-attachment-
identifier 700:700:700
```

16. (Optional) Configure T-PE1 to send MS-PW status TLVs.

```
[edit routing-instances]
user@T-PE1# set ms-pw protocols l2vpn pseudowire-status-tlv
```

17. (Optional) Configure OAM capabilities for the VPN.

```
[edit routing-instances]
user@T-PE1# set ms-pw protocols l2vpn oam bfd-liveness-detection minimum-interval 300
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure S-PE1 (RR 1) in the interarea scenario:

NOTE: Repeat this procedure for the S-PE2 (RR 2) device in the MPLS domain, after modifying the appropriate interface names, addresses, and other parameters.

1. Configure the S-PE1 interfaces.

```
[edit interfaces]
user@S-PE1# set ge-1/3/1 unit 0 family inet address 192.0.2.9/24
user@S-PE1# set ge-1/3/1 unit 0 family mpls
user@S-PE1# set ge-1/3/2 unit 0 family inet address 192.0.2.22/24
user@S-PE1# set ge-1/3/2 unit 0 family mpls
user@S-PE1# set lo0 unit 0 family inet address 10.255.2.1/32 primary
```

2. Set the autonomous system number.

```
[edit routing-options]
user@S-PE1# set autonomous-system 100
```

3. Enable MPLS on all the interfaces of T-PE1, excluding the management interface.

```
[edit protocols]
user@S-PE1# set mpls interface all
user@S-PE1# set mpls interface fxp0.0 disable
```

4. Enable autodiscovery of S-PE using BGP.

```
[edit protocols]
user@S-PE1# set bgp family l2vpn auto-discovery-mspw
```

5. Configure the BGP group for S-PE1.

```
[edit protocols]
user@S-PE1# set bgp group mspw type internal
```

6. Configure S-PE1 to act as a route reflector.

```
[edit protocols]
user@S-PE1# set bgp group mspw export next-hop-self
user@S-PE1# set bgp group mspw cluster 203.0.113.0
```

7. Assign local and neighbor addresses to the mspw group for S-PE1 to peer with T-PE1 and S-PE2.

```
[edit protocols]
user@S-PE1# set bgp group mspw local-address 10.255.2.1
user@S-PE1# set bgp group mspw neighbor 10.255.10.1 (to T-PE1)
user@S-PE1# set bgp group mspw neighbor 10.255.3.1 (to S-PE2)
```

8. Configure OSPF on all the interfaces of S-PE1, excluding the management interface.

```
[edit protocols]
user@S-PE1# set ospf area 0.0.0.0 interface all
user@S-PE1# set ospf area 0.0.0.0 interface fxp0.0 disable
user@S-PE1# set ospf area 0.0.0.0 interface lo0.0
```

9. Configure LDP on all the interfaces of S-PE1, excluding the management interface.

```
[edit protocols]
user@S-PE1# set ldp interface all
user@S-PE1# set ldp interface fxp0.0 disable
user@S-PE1# set ldp interface lo0.0
```

10. Define the policy for enabling next-hop-self and accepting BGP traffic on S-PE1.

```
[edit policy-options]
user@S-PE1# set policy-statement next-hop-self then next-hop self
user@S-PE1# set policy-statement send-inet0 from protocol bgp
user@S-PE1# set policy-statement send-inet0 then accept
```

Results

From configuration mode, confirm your configuration by entering the `show interfaces`, `show protocols`, `show routing-instances`, `show routing-options`, and `show policy-options` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

T-PE1

```
user@T-PE1# show interfaces
ge-3/1/0 {
```

```
    unit 0 {
        family inet {
            address 192.0.2.1/24;

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure the T-PE1 router in the inter-AS scenario:

> **NOTE**: Repeat this procedure for the T-PE2 device in the MPLS domain, after modifying the appropriate interface names, addresses, and other parameters.

1. Configure the T-PE1 interfaces.

```
[edit interfaces]
user@T-PE1# set ge-3/1/0 unit 0 family inet address 192.0.2.1/24
user@T-PE1# set ge-3/1/0 unit 0 family mpls
user@T-PE1# set ge-3/1/2 encapsulation ethernet-ccc
user@T-PE1# set ge-3/1/2 unit 0
user@T-PE1# set lo0 unit 0 family inet address 10.255.10.1/32 primary
```

2. Set the autonomous system number.

```
[edit routing-options]
user@T-PE1# set autonomous-system 1
```

3. Enable MPLS on all the interfaces of T-PE1, excluding the management interface.

```
[edit protocols]
user@T-PE1# set mpls interface all
user@T-PE1# set mpls interface fxp0.0 disable
```

4. Enable autodiscovery of intermediate S-PEs that make up the MS-PW using BGP.

```
[edit protocols]
user@T-PE1# set bgp family l2vpn auto-discovery-mspw
```

5. Configure the BGP group for T-PE1.

```
[edit protocols]
user@T-PE1# set bgp group mspw type internal
```

6. Assign local and neighbor addresses to the mspw group for T-PE1 to peer with S-PE1.

```
[edit protocols]
user@T-PE1# set bgp group mspw local-address 10.255.10.1
user@T-PE1# set bgp group mspw neighbor 10.255.2.1
```

7. Configure OSPF on all the interfaces of T-PE1, excluding the management interface.

```
[edit protocols]
user@T-PE1# set ospf area 0.0.0.0 interface lo0.0
user@T-PE1# set ospf area 0.0.0.0 interface all
user@T-PE1# set ospf area 0.0.0.0 interface fxp0.0 disable
```

8. Configure LDP on all the interfaces of T-PE1, excluding the management interface.

```
[edit protocols]
user@T-PE1# set ldp interface all
user@T-PE1# set ldp interface fxp0.0 disable
user@T-PE1# set ldp interface lo0.0
```

9. Configure the Layer 2 VPN routing instance on T-PE1.

```
[edit routing-instances]
user@T-PE1# set ms-pw instance-type l2vpn
```

10. Assign the interface name for the mspw routing instance.

```
[edit routing-instances]
user@T-PE1# set ms-pw interface ge-3/1/2.0
```

11. Configure the route distinguisher for the mspw routing instance.

```
[edit routing-instances]
user@T-PE1# set ms-pw route-distinguisher 10.10.10.10:15
```

12. Configure the Layer 2 VPN ID community for FEC 129 MS-PW.

```
[edit routing-instances]
user@T-PE1# set ms-pw l2vpn-id l2vpn-id:100:15
```

13. Configure a VPN routing and forwarding (VRF) target for the mspw routing instance.

```
[edit routing-instances]
user@T-PE1# set ms-pw vrf-target target:100:115
```

14. Configure the source attachment identifier (SAI) value using Layer 2 VPN as the routing protocol for the mspw routing instance.

```
[edit routing-instances]
user@T-PE1# set ms-pw protocols l2vpn site CE1 source-attachment-identifier 800:800:800
```

15. Assign the interface name that connects the CE1 site to the VPN, and configure the target attachment identifier (TAI) value using Layer 2 VPN as the routing protocol for the mspw routing instance.

```
[edit routing-instances]
user@T-PE1# set ms-pw protocols l2vpn site CE1 interface ge-3/1/2.0 target-attachment-
identifier 700:700:700
```

16. (Optional) Configure T-PE1 to send MS-PW status TLVs.

```
[edit routing-instances]
user@T-PE1# set ms-pw protocols l2vpn pseudowire-status-tlv
```

17. (Optional) Configure OAM capabilities for the VPN.

```
[edit routing-instances]
user@T-PE1# set ms-pw protocols l2vpn oam bfd-liveness-detection minimum-interval 300
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure S-PE1 (ASBR 1) in the inter-AS scenario:

NOTE: Repeat this procedure for the S-PE2 (ASBR 2) device in the MPLS domain, after modifying the appropriate interface names, addresses, and other parameters.

1. Configure S-PE1 (ASBR 1) interfaces.

```
[edit interfaces]
user@S-PE1# set ge-1/3/1 unit 0 family inet address 192.0.2.9/24
user@S-PE1# set ge-1/3/1 unit 0 family mpls
user@S-PE1# set ge-1/3/2 unit 0 family inet address 192.0.2.22/24
user@S-PE1# set ge-1/3/2 unit 0 family mpls
user@S-PE1# set lo0 unit 0 family inet address 10.255.2.1/32 primary
```

2. Set the autonomous system number.

```
[edit routing-options]
user@S-PE1# set autonomous-system 1
```

3. Enable MPLS on all the interfaces of S-PE1 (ASBR 1), excluding the management interface.

```
[edit protocols]
user@S-PE1# set mpls interface all
user@S-PE1# set mpls interface fxp0.0 disable
```

4. Enable autodiscovery of S-PE using BGP.

```
[edit protocols]
user@S-PE1# set bgp family l2vpn auto-discovery-mspw
```

5. Configure the IBGP group for S-PE1 (ASBR 1) to peer with T-PE1.

```
[edit protocols]
user@S-PE1# set bgp group to_T-PE1 type internal
```

6. Configure the IBGP group parameters.

```
[edit protocols]
user@S-PE1# set bgp group to_T-PE1 local-address 10.255.2.1
user@S-PE1# set bgp group to_T-PE1 export next-hop-self
user@S-PE1# set bgp group to_T-PE1 neighbor 10.255.10.1
```

7. Configure the EBGP group for S-PE1 (ASBR 1) to peer with S-PE2 (ASBR 2).

```
[edit protocols]
user@S-PE1# set bgp group to_S-PE2 type external
```

8. Configure the EBGP group parameters.

```
[edit protocols]
user@S-PE1# set bgp group to_S-PE2 local-address 10.255.2.1
user@S-PE1# set bgp group to_S-PE2 peer-as 2
user@S-PE1# set bgp group to_S-PE2 neighbor 10.255.3.1 multihop ttl 1
```

9. Configure OSPF on all the interfaces of S-PE1 (ASBR 1), excluding the management interface.

```
[edit protocols]
user@S-PE1# set ospf area 0.0.0.0 interface all
user@S-PE1# set ospf area 0.0.0.0 interface fxp0.0 disable
user@S-PE1# set ospf area 0.0.0.0 interface lo0.0 passive
```

10. Configure LDP on all the interfaces of S-PE1 (ASBR 1), excluding the management interface.

```
[edit protocols]
user@S-PE1# set ldp interface all
user@S-PE1# set ldp interface fxp0.0 disable
user@S-PE1# set ldp interface lo0.0
```

11. Define the policy for enabling next-hop-self on S-PE1 (ASBR 1).

```
[edit policy-options]
user@S-PE1# set policy-statement next-hop-self then next-hop self
```

Results

From configuration mode, confirm your configuration by entering the `show interfaces`, `show protocols`, `show routing-instances`, `show routing-options`, and `show policy-options` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

T-PE1

```
user@T-PE1# show interfaces

```

```
user@T-PE1# show policy-options
policy-statement next-hop-self {
    then {
        next-hop self;
    }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

IN THIS SECTION

- Verifying the Routes | **1812**
- Verifying the LDP Database | **1815**
- Checking the MS-PW Connections on T-PE1 | **1816**
- Checking the MS-PW Connections on S-PE1 | **1818**
- Checking the MS-PW Connections on S-PE2 | **1820**
- Checking the MS-PW Connections on T-PE2 | **1821**

Confirm that the configuration is working properly.

Verifying the Routes

Purpose

Verify that the expected routes are learned.

Action

From operational mode, run the `show route` command for the `bgp.l2vpn.1`, `ldp.l2vpn.1`, `mpls.0`, and `ms-pw.l2vpn.1` routing tables.

From operational mode, run the `show route table bgp.l2vpn.1` command.

```
user@T-PE1> show route table bgp.l2vpn.1
bgp.l2vpn.1: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.10.10.10:15:700:0.0.2.188:700/160 AD2
                   *[BGP/170] 16:13:11, localpref 100, from 10.255.2.1
                      AS path: 2 I, validation-state: unverified
                    > to 203.0.113.2 via ge-3/1/0.0, Push 300016
```

From operational mode, run the `show route table ldp.l2vpn.1` command.

```
user@T-PE1> show route table ldp.l2vpn.1
ldp.l2vpn.1: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.255.2.1:CtrlWord:5:100:15:700:0.0.2.188:700:800:0.0.3.32:800/304 PW2
                   *[LDP/9] 16:21:27
                      Discard
```

From operational mode, run the `show route table mpls.0` command.

```
user@T-PE1> show route table mpls.0
mpls.0: 12 destinations, 12 routes (12 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

0                  *[MPLS/0] 1w6d 00:28:26, metric 1
                      Receive
1                  *[MPLS/0] 1w6d 00:28:26, metric 1
                      Receive
2                  *[MPLS/0] 1w6d 00:28:26, metric 1
                      Receive
13                 *[MPLS/0] 1w6d 00:28:26, metric 1
                      Receive
299920             *[LDP/9] 1w5d 01:26:08, metric 1
                    > to 203.0.113.2 via ge-3/1/0.0, Pop
299920(S=0)        *[LDP/9] 1w5d 01:26:08, metric 1
                    > to 203.0.113.2 via ge-3/1/0.0, Pop
299936             *[LDP/9] 1w5d 01:26:08, metric 1
                    > to 203.0.113.2 via ge-3/1/0.0, Swap 300016
300096             *[LDP/9] 16:22:35, metric 1
                    > to 203.0.113.2 via ge-3/1/0.0, Swap 300128
300112             *[LDP/9] 16:22:35, metric 1
                    > to 203.0.113.2 via ge-3/1/0.0, Swap 300144
300128             *[LDP/9] 16:22:35, metric 1
                    > to 203.0.113.2 via ge-3/1/0.0, Swap 300160
300144             *[L2VPN/7] 16:22:33
                    > via ge-3/1/2.0, Pop       Offset: 4
ge-3/1/2.0         *[L2VPN/7] 16:22:33, metric2 1
                    > to 203.0.113.2 via ge-3/1/0.0, Push 300176, Push 300016(top) Offset: 252
```

From operational mode, run the `show route table ms-pw.l2vpn.1` command.

```
user@T-PE1> show route table ms-pw.l2vpn.1
ms-pw.l2vpn.1: 4 destinations, 4 routes (4 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.10.10.10:15:700:0.0.2.188:700/160 AD2
                   *[BGP/170] 16:23:27, localpref 100, from 10.255.2.1
                      AS path: 2 I, validation-state: unverified
                    > to 203.0.113.2 via ge-3/1/0.0, Push 300016
10.10.10.10:15:800:0.0.3.32:800/160 AD2
                   *[L2VPN/170] 1w5d 23:25:19, metric2 1
                      Indirect
10.255.2.1:CtrlWord:5:100:15:700:0.0.2.188:700:800:0.0.3.32:800/304 PW2
                   *[LDP/9] 16:23:25
                      Discard
10.255.2.1:CtrlWord:5:100:15:800:0.0.3.32:800:700:0.0.2.188:700/304 PW2
                   *[L2VPN/7] 16:23:27, metric2 1
                    > to 203.0.113.2 via ge-3/1/0.0, Push 300016
```

Meaning

The output shows all the learned routes, including the autodiscovery (AD) routes.

The AD2 prefix format is `RD:SAII-type2`, where:

- `RD` is the route distinguisher value.
- `SAII-type2` is the type 2 source attachment identifier value.

The PW2 prefix format is `Neighbor_Addr:C:PWtype:l2vpn-id:SAII-type2:TAII-type2`, where:

- `Neighbor_Addr` is the loopback address of neighboring S-PE device.
- `C` indicates if Control Word (CW) is enabled or not.
  - `C` is `CtrlWord` if CW is set.
  - `C` is `NoCtrlWord` if CW is not set.
- `PWtype` indicates the type of the pseudowire.
  - `PWtype` is `4` if it is in Ethernet tagged mode.
  - `PWtype` is `5` if it is Ethernet only.

- `l2vpn-id` is the Layer 2 VPN ID for the MS-PW routing instance.
- `SAII-type2` is the type 2 source attachment identifier value.
- `TAII-type2` is the type 2 target attachment identifier value.

Verifying the LDP Database

Purpose

Verify the MS-PW labels received by T-PE1 from S-PE1 and sent from T-PE1 to S-PE1.

Action

From operational mode, run the `show ldp database` command.

```
user@T-PE1> show ldp database
Input label database, 10.255.10.1:0--10.255.2.1:0
  Label     Prefix
      3      10.255.2.1/32

      3      10.255.13.1/32
 300160      10.255.14.1/32

Output label database, 10.255.10.1:0--10.255.13.1:0
  Label     Prefix
 299936      10.255.2.1/32
 300096      10.255.3.1/32
 300112      10.255.4.1/32
      3      10.255.10.1/32
 299920      10.255.13.1/32
 300128      10.255.14.1/32
```

Meaning

The labels with `FEC129` prefix are related to the MS-PW.

Checking the MS-PW Connections on T-PE1

Purpose

Make sure that all of the FEC 129 MS-PW connections come up correctly.

Action

From operational mode, run the `show l2vpn connections extensive` command.

```
user@T-PE1> show l2vpn connections extensive
Layer-2 VPN connections:

Troubleshooting

IN THIS SECTION

- Ping | **1823**
- Bidirectional Forwarding Detection | **1824**
- Traceroute | **1825**

To troubleshoot the MS-PW connection, see:

Ping

Problem

How to check the connectivity between the T-PE devices and between a T-PE device and an intermediary device.

Solution

Verify that T-PE1 can ping T-PE2. The **ping mpls l2vpn fec129** command accepts SAIs and TAIs as integers or IP addresses and also allows you to use the CE-facing interface instead of the other parameters (**instance**, **local-id**, **remote-id**, **remote-pe-address**).

Checking Connectivity Between T-PE1 and T-PE2

```
user@T-PE1> ping mpls l2vpn fec129 instance FEC129-VPWS local-id 800:800:800 remote-pe-address
10.255.14.1 remote-id 700:700:700
!!!!!
--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
user@T-PE1> ping mpls l2vpn fec129 interface ge-3/1/2
!!!!!
--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
```

Checking Connectivity Between T-PE1 and S-PE2

```
user@T-PE1> ping mpls l2vpn fec129 interface ge-3/1/2 bottom-label-ttl 2
!!!!!
--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
```

Bidirectional Forwarding Detection

Problem

How to use BFD to troubleshoot the MS-PW connection from the T-PE device.

Solution

From operational mode, verify the `show bfd session extensive` command output.

```
user@T-PE1> show bfd session extensive

                                             Detect   Transmit
Address                 State     Interface      Time     Interval  Multiplier

MPLS Stitching For Virtual Machine Connection

IN THIS SECTION

- When Would I Use Stitching? | **1826**
- How Does MPLS Stitching Work? | **1827**
- How Do I Configure Stitching? | **1827**
- Which Switches Support Stitching? | **1828**
- Q&A | **1828**

By using MPLS, the stitching feature of Junos OS provides connectivity between virtual machines that reside either on opposite sides of data center routers or in different data centers. An external controller, programmed in the data-plane, assigns MPLS labels to both virtual machines and servers. Then, the signaled MPLS labels are used between the data center routers, generating static link switched paths (LSPs), resolved over either BGP labeled unicast, RSVP or LDP, to provide the routes dictated by the labels.

When Would I Use Stitching?

There are several ways to connect virtual machines. One option when you have virtual machines on opposite sides of a router (or different data centers) is to use MPLS stitching. A typical topology for using MPLS stitching is shown in Figure 117 on page 1826.

Figure 117: Virtual Machines on Either Side of Routers

The above topology consists of the following MPLS layers: VMs | Servers | ToRs | Router ..... Router | ToRs | Servers | VMs

NOTE: The label on the left is the top of the label stack.

How Does MPLS Stitching Work?

With stitching, the MPLS static allocation of labels demultiplexes incoming traffic onto any device/entity in the next layer in the direction of traffic flow. Essentially, there is a label hierarchy that picks up labels for the correct top-of-rack switch, server, and virtual machine that receives traffic. Static label assignments are done between the top-of-rack switches and the virtual machines.

For example, imagine that traffic is sent from VM1 to VM3 in Figure 117 on page 1826. When traffic exits Server1, its label stack is L1 | L2 | L3 where:

- L1 represents the egress top-of-rack switch ToR1.
- L2 represents the physical server, Server2, towards which the egress-side ToR will forward the traffic.
- L3: represents the virtual machine on Server2 to which the Server2 should deliver the traffic.

Traffic arriving at ToR1 needs to be sent to ToR2. Since ToR1 and ToR2 are not directly connected, traffic must flow from ToR1 to ToR2 using label-switching starting on the outermost (top) label. Stitching has been added to static-LSP functionality to SWAP L1 to a l-BGP label that ToR2 advertises to ToR1. The label stack now must contain another label at the top to enable forwarding of the labeled packets between ToR1 and ToR2. An L-Top label is added if L-BGP is resolved over RSVP/LDP. If static LSP is resolved over L-BGP, then the top label is swapped with the L-BGP label and there is no L-Top label. When the traffic exits ToR1, the stack is: L-top | L-BGP | L2 | L3.

Traffic from ToR1 to ToR2 is then label switched over any signaled LSP.

When traffic arrives at ToR2, the top label is removed with PHP (popped) and the label stack becomes L-BGP | L2 | L3. Since L-BGP is a implicit null label, ToR2 pops the static LSP label L2 that corresponds to the egress server and then forwards the packet to the egress server using the static-LSP configuration on ToR2, which corresponds to a single-hop implicit-NULL LSP.

The outgoing stack becomes L3 and the next-hop is the egress server Server2.

When traffic arrives at the egress server Server2, Server2 pops L3 and delivers the packet to VM3.

How Do I Configure Stitching?

The new keyword `stitch` has been added under `transit` to resolve the remote next-hop. For example, instead of `set protocols mpls static-label-switched-path static-to-ToR2 transit 1000000 next-hop 10.9.82.47`, a top-of-rack switch redirects packets to another top-of-rack switch with `set protocols mpls static-label-switched-path static-to-ToR2 transit 1000000 stitch`. The "show mpls static-lsp" on page 3256 command has

been extended to show the LSP state as 'InProgress' whenever the LSP is waiting for protocol next-hop resolution by resolver.

See the complete example for stitching at Using MPLS Stitching with BGP to Connect Virtual Machines for more information.

Which Switches Support Stitching?

See Feature Explorer for the list of switches that support the MPLS Stitching For Virtual Machine Connections feature.

Q&A

Q: Is link and node protection for the next-hop provided by MPLS stitching?
A: Link and node protection for the next-hop of transit LSP stitched to L-BGP LSP are not needed. That is provided by L-BGP LSP.

TDM Pseudowires Overview

A TDM pseudowire acts as Layer 2 circuit or service for T1 and E1 circuit signals across an MPLS packet-switched network. On ACX Series routers, you configure a TDM *pseudowire* with Structure-Agnostic Time Division Multiplexing (TDM) over Packet (SAToP) on the ACX Series built-in channelized T1 and E1 interfaces. When you configure a TDM pseudowire, the network between the customer edge (CE) routers appears transparent to the CE routers, making it seem that the CE routers are directly connected. With the SAToP configuration on the provider edge (PE) router's T1 and E1 interfaces, the interworking function (IWF) forms a payload (frame) that contains the CE router's T1 and E1 Layer 1 data and control word. This data is transported to the remote PE over the pseudowire. The remote PE removes all the Layer 2 and MPLS headers added in the network cloud and forwards the control word and the Layer 1 data to the remote IWF, which in turn forwards the data to the remote CE router.

Example: TDM Pseudowire Base Configuration

IN THIS SECTION

- Requirements | **1829**
- Overview of a TDM Pseudowire Base Configuration | **1829**
- Configuring an TDM Pseudowire | **1829**

Requirements

The following is a list of the hardware and software requirements for this configuration.

- One ACX Series router
- Junos OS Release 12.2 or later

Overview of a TDM Pseudowire Base Configuration

The configuration shown here is the base configuration of an TDM pseudowire with T1 framing on an ACX Series router. This configuration is for one provider edge router. To complete the TDM pseudowire configuration, you need to repeat this configuration on an other provider edge router in the Multiprotocol Label Switched (MPLS) network.

Configuring an TDM Pseudowire

IN THIS SECTION

- Procedure | 1829
- Results | 1832

Procedure

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them in a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level:

```
set chassis fpc 0 pic 0 framing t1
set interfaces ct1-0/0/0 no-partition interface-type t1
set interfaces t1-0/0/0 encapsulation satop
set interfaces t1-0/0/0 unit 0
set interfaces ge-0/2/0 unit 0 family inet address 20.1.1.2/24
set interfaces ge-0/2/0 unit 0 family mpls
set interfaces lo0 unit 0 family inet address 70.1.1.1/32
set protocols rsvp interface ge-0/2/0.0
set protocols mpls no-cspf
```

```
set protocols mpls label-switched-path PE1-to-PE2 to 40.1.1.1
set protocols mpls interface ge-0/2/0.0
set protocols ospf traffic-engineering
set protocols ospf area 0.0.0.0 interface ge-0/2/0.0
set protocols ospf area 0.0.0.0 interface lo0.0 passive
set protocols ldp interface ge-0/2/0.0
set protocols ldp interface lo0.0
set protocols l2circuit neighbor 40.1.1.1 interface t1-0/0/0.0 virtual-circuit-id 1
```

NOTE: To configure a TDM pseudowire with E1 framing, include the `e1` statement at the [`edit chassis fpc 0 pic 0 framing`] hierarchy level instead of the `t1` statement shown in this example.

Step-by-Step Procedure

1. Configure the framing format:

```
[edit]
user@host# edit chassis
[edit chassis]
user@host# set fpc 0 pic 0 framing t1
```

2. Create a T1 interface on a channelized T1 interface (`ct1`) and enable full channelization with the `no-partition` statement. On the logical T1 interface, set the Structure-Agnostic TDM over Packet (SAToP) encapsulation mode.

```
[edit]
user@host# edit interfaces
[edit interfaces]
user@host# set ct1-0/0/0 no-partition interface-type t1
user@host# set t1-0/0/0 encapsulation satop
user@host# set t1-0/0/0 unit 0
```

3. Create a Gigabit Ethernet interface and enable MPLS on that interface. Create the loopback (`lo0`) interface:

```
[edit interfaces]
user@host# set ge-0/2/0 unit 0 family inet address 20.1.1.2/24
user@host# set ge-0/2/0 unit 0 family mpls
user@host# set lo0 unit 0 family inet address 70.1.1.1/32
```

4. Enable the MPLS and RSVP protocols on the MPLS interface—`ge-0/2/0.0`:

```
[edit]
user@host# edit protocols
[edit protocols]
user@host# set rsvp interface ge-0/2/0.0
user@host# set mpls interface ge-0/2/0.0
```

5. Configure LDP. If you configure RSVP for a pseudowire, you must also configure LDP:

```
[edit protocols]
user@host# set ldp interface ge-0/2/0.0
user@host# set ldp interface lo0.0
```

6. Configure a point-to-point label-switched path (LSP) and disable constrained-path LSP computation:

```
[edit protocols]
user@host# set mpls label-switched-path PE1-to-PE2 to 40.1.1.1
user@host# set mpls no-cspf
```

7. Configure OSPF and enable traffic engineering on the MPLS interface—`ge-0/2/0.0`, and on the loopback (`lo0`) interface:

```
[edit protocols]
user@host# set ospf traffic-engineering
user@host# set ospf area 0.0.0.0 interface ge-0/2/0.0
user@host# set ospf area 0.0.0.0 interface lo0.0 passive
```

8. Uniquely identify a Layer 2 circuit for the TDM pseudowire:

```
[edit protocols]
user@host#  set l2circuit neighbor 40.1.1.1 interface t1-0/0/0.0 virtual-circuit-id 1
```

Results

```
[edit]
user@host# show
chassis {
    fpc 0 {
        pic 0 {
            framing t1;
        }
    }
}
interfaces {
    ct1-0/0/0 {
        no-partition interface-type t1;
    }
    t1-0/0/0 {
        encapsulation satop;
        unit 0;
    }
    ge-0/2/0 {
        unit 0 {
            family inet {
                address 20.1.1.2/24;
            }
            family mpls;
        }
    }
    lo0 {
        unit 0 {
            family inet {
                address 70.1.1.1/32;
            }
        }
    }
}
protocols {
```

```
    rsvp {
        interface ge-0/2/0.0;
    }
    mpls {
        no-cspf;
        label-switched-path PE1-to-PE2 {
            to 40.1.1.1;
        }
        interface ge-0/2/0.0;
    }
    ospf {
        traffic-engineering;
        area 0.0.0.0 {
            interface ge-0/2/0.0;
            interface lo0.0 {
                passive;
            }
        }
    }
    ldp {
        interface ge-0/2/0.0;
        interface lo0.0;
    }
    l2circuit {
        neighbor 40.1.1.1 {
            interface t1-0/0/0.0 {
                virtual-circuit-id 1;
            }
        }
    }
}
```

Configuring Load Balancing for Ethernet Pseudowires

You can configure load balancing for IPv4 traffic over Layer 2 Ethernet pseudowires. You can also configure load balancing for Ethernet pseudowires based on IP information. The option to include IP information in the hash key provides support for Ethernet circuit cross-connect (CCC) connections.

NOTE: This feature is supported only on M120, M320, MX Series, and T Series routers.

To configure load balancing for IPv4 traffic over Layer 2 Ethernet pseudowires, include the `ether-pseudowire` statement at the `[edit forwarding-options hash-key family mpls payload]` hierarchy level:

```
[edit forwarding-options]
hash-key {
    family mpls {
        (label-1 | no-labels);
        payload {
            ether-pseudowire;
        }
    }
}
```

NOTE: You must also configure either the `label-1` or the `no-labels` statement at the `[edit forwarding-options hash-key family mpls]` hierarchy level.

You can also configure load balancing for Ethernet pseudowires based on IP information. This functionality provides support for load balancing for Ethernet cross-circuit connect (CCC) connections. To include IP information in the hash key, include the `ip` statement at the `[edit forwarding-options hash-key family mpls payload]` hierarchy level:

```
[edit forwarding-options]
hash-key {
    family mpls {
        (label-1 | no-labels);
        payload {
            ip;
        }
    }
}
```

NOTE: You must also configure either the `label-1` or `no-labels` statement at the `[edit forwarding-options hash-key family mpls]` hierarchy level.

You can configure load balancing for IPv4 traffic over Ethernet pseudowires to include only Layer 3 IP information in the hash key. To include only Layer 3 IP information, include the `layer-3-only` option at the `[edit forwarding-options family mpls hash-key payload ip]` hierarchy level:

```
[edit forwarding-options]
hash-key {
    family mpls {
        (label-1 | no-labels);
        payload {
            ip {
                layer-3-only;
            }
        }
    }
}
```

NOTE: You must also configure either the `label-1` or `no-labels` statement at the `[edit forwarding-options hash-key family mpls]` hierarchy level.

Configuring Load Balancing Based on MAC Addresses

The hash key mechanism for load-balancing uses Layer 2 media access control (MAC) information such as frame source and destination address. To load-balance traffic based on Layer 2 MAC information, include the `family multiservice` statement at the `[edit forwarding-options hash-key]` hierarchy level:

```
family multiservice {
    destination-mac;
    source-mac;
}
```

To include the destination-address MAC information in the hash key, include the **destination-mac** option. To include the source-address MAC information in the hash key, include the **source-mac** option.

NOTE: Any packets that have the same source and destination address will be sent over the same path.

NOTE: You can configure per-packet load balancing to optimize VPLS traffic flows across multiple paths.

NOTE: Aggregated Ethernet member links will now use the physical MAC address as the source MAC address in 802.3ah OAM packets.

NOTE: ACX Series routers do not support VPLS.

Release History Table

Release	Description
14.1X53	Starting in Junos OS Release 14.1X53 and Junos OS Release 16.1, an Ethernet pseudowire is used to carry Ethernet or 802.3 Protocol Data Units (PDUs) over an MPLS network enabling service providers to offer emulated Ethernet services over existing MPLS networks.

Configuring Class of Service for MPLS LSPs

IN THIS SECTION

- Class of Service for MPLS Overview | **1838**
- Configuring the MPLS CoS Values | **1838**
- Rewriting IEEE 802.1p Packet Headers with the MPLS CoS Value | **1841**

The following sections provide an overview of MPLS class of service (CoS) and describe how to configure the MPLS CoS value:

Class of Service for MPLS Overview

When IP traffic enters an LSP tunnel, the ingress router marks all packets with a CoS value, which is used to place the traffic into a transmission priority queue. On the router, for SDH/SONET and T3 interfaces, each interface has four transmit queues. The CoS value is encoded as part of the MPLS header and remains in the packets until the MPLS header is removed when the packets exit from the egress router. The routers within the LSP utilize the CoS value set at the ingress router. The CoS value is encoded by means of the CoS bits (also known as the EXP or experimental bits). For more information, see MPLS Label Allocation.

MPLS class of service works in conjunction with the router's general CoS functionality. If you do not configure any CoS features, the default general CoS settings are used. For MPLS class of service, you might want to prioritize how the transmit queues are serviced by configuring weighted round-robin, and to configure congestion avoidance using random early detection (RED)..

Configuring the MPLS CoS Values

When traffic enters an LSP tunnel, the CoS value in the MPLS header is set in one of three ways:

- The number of the output queue into which the packet was buffered and the packet loss priority (PLP) bit are written into the MPLS header and are used as the packet's CoS value. This behavior is the default, and no configuration is required. *Default MPLS EXP Classifier* explains the default MPLS CoS values, and summarizes how the CoS values are treated.
- You set a fixed CoS value on all packets entering the LSP tunnel. A fixed CoS value means that all packets entering the LSP receive the same class of service.
- You set an MPLS EXP rewrite rule to override the default behavior.

To set a fixed CoS value on all packets entering the LSP, include the `class-of-service` statement:

```
class-of-service cos-value;
```

You can include this statement at the following hierarchy levels:

- `[edit protocols mpls]`
- `[edit protocols mpls label-switched-path path-name]`
- `[edit protocols mpls label-switched-path path-name primary path-name]`
- `[edit protocols mpls label-switched-path path-name secondary path-name]`
- `[edit protocols rsvp interface interface-name link-protection]`
- `[edit protocols rsvp interface interface-name link-protection bypass destination]`
- `[edit logical-systems logical-system-name protocols mpls]`
- `[edit logical-systems logical-system-name protocols mpls label-switched-path path-name]`
- `[edit logical-systems logical-system-name protocols mpls label-switched-path path-name primary path-name]`
- `[edit logical-systems logical-system-name protocols mpls label-switched-path path-name secondary path-name]`
- `[edit logical-systems logical-system-name protocols rsvp interface interface-name link-protection ]`
- `[edit logical-systems logical-system-name protocols rsvp interface interface-name link-protection bypass destination]`

The CoS value set using the `class-of-service` statement at the `[edit protocols mpls]` hierarchy level supersedes the CoS value set at the `[edit class-of-service]` hierarchy level for an interface. Effectively, the CoS value configured for an LSP overrides the CoS value set for an interface.

The `class-of-service` statement at the `[edit protocols mpls label-switched-path]` hierarchy level assigns an initial EXP value for the MPLS shim header of packets in the LSP. This value is initialized at the ingress routing device only and overrides the rewrite configuration established for that forwarding class. However, the CoS processing (weighted round robin [WRR] and RED) of packets entering the ingress routing device is not changed by the `class-of-service` statement on an MPLS LSP. Classification is still based on the behavior aggregate (BA) classifier at the `[edit class-of-service]` hierarchy level or the multifield classifier at the `[edit firewall]` hierarchy level.

BEST PRACTICE: We recommend configuring all routing devices along the LSP to have the same input classifier for EXP, and, if a rewrite rule is configured, all routing devices should have the same rewrite configuration. Otherwise, traffic at the next LSR might be classified into a different forwarding class, resulting in a different EXP value being written to the EXP header.

The CoS value can be a decimal number from 0 through 7. This number corresponds to a 3-bit binary number. The high-order 2 bits of the CoS value select which transmit queue to use on the outbound interface card.

The low-order bit of the CoS value is treated as the PLP bit and is used to select the RED drop profile to use on the output queue. If the low-order bit is 0, the non-PLP drop profile is used, and if the low-order bit is 1, the PLP drop profile is used. It is generally expected that RED will more aggressively drop packets that have the PLP bit set. For more information about RED and drop profiles, see *Managing Congestion Using RED Drop Profiles and Packet Loss Priorities*.

NOTE: Configuring the PLP drop profile to drop packets more aggressively (for example, setting the CoS value from 6 to 7) decreases the likelihood of traffic getting through.

Table 27 on page 1840 summarizes how MPLS CoS values correspond to the transmit queue and PLP bit. Note that in MPLS, the mapping between the CoS bit value and the output queue is hard-coded. You cannot configure the mapping for MPLS; you can configure it only for IPv4 traffic flows, as described in *Understanding How Forwarding Classes Assign Classes to Output Queues*.

Table 27: MPLS CoS Values

MPLS CoS Value	Bits	Transmit Queue	PLP Bit
0	000	0	Not set
1	001	0	Set
2	010	1	Not set
3	011	1	Set
4	100	2	Not set

Table 27: MPLS CoS Values *(Continued)*

MPLS CoS Value	Bits	Transmit Queue	PLP Bit
5	101	2	Set
6	110	3	Not set
7	111	3	Set

Because the CoS value is part of the MPLS header, the value is associated with the packets only as they travel through the LSP tunnel. The value is not copied back to the IP header when the packets exit from the LSP tunnel.

To configure class of service (CoS) for Multiprotocol Label Switching (MPLS) packets in a label-switched path (LSP):

1. Specify the CoS value

   If you do not specify a CoS value, the IP precedence bits from the packet's IP header are used as the packet's CoS value.

Rewriting IEEE 802.1p Packet Headers with the MPLS CoS Value

For Ethernet interfaces installed on a T Series router or an M320 router with a peer connection to an M Series router or a T Series router, you can rewrite both MPLS CoS and IEEE 802.1p values to a configured value (the MPLS CoS values are also known as the EXP or experimental bits). Rewriting these values allows you to pass the configured value to the Layer 2 VLAN path. To rewrite both the MPLS CoS and IEEE 802.1p values, you must include the EXP and IEEE 802.1p rewrite rules in the class of service interface configuration. The EXP rewrite table is applied when you configure the IEEE 802.1p and EXP rewrite rules.

For information about how to configure the EXP and IEEE 802.1p rewrite rules, see *Rewriting Packet Headers to Ensure Forwarding Behavior*.

Configuring MPLS Rewrite Rules

IN THIS SECTION

Rewriting the EXP Bits of All Three Labels of an Outgoing Packet | **1842**

- Rewriting MPLS and IPv4 Packet Headers | **1842**

You can apply a number of different rewrite rules to MPLS packets.

For more information about how to configure statements at the `[edit class-of-service]` hierarchy level, see the Junos OS Class of Service User Guide for Routing Devices.

The following sections describe how you can apply rewrite rules to MPLS packets:

Rewriting the EXP Bits of All Three Labels of an Outgoing Packet

In interprovider, carrier-of-carrier, and complex traffic engineering scenarios, it is sometimes necessary to push three labels on the next hop.

By default, on M Series routers except the M320, the top MPLS EXP label of an outgoing packet is not rewritten when you configure swap-push-push and triple-push operations. You can rewrite the EXP bits of all three labels of an outgoing packet, thereby maintaining the class of service (CoS) of an incoming MPLS or non-MPLS packet.

To push three labels on incoming MPLS packets, include the `exp-swap-push-push default` statement at the `[edit class-of-service interfaces` *`interface-name`* `unit` *`logical-unit-number`* `rewrite-rules]` hierarchy level:

```
[edit class-of-service interfaces interface-name unit logical-unit-number rewrite-rules]
exp-swap-push-push default;
```

To push three labels on incoming non-MPLS packets, include the `exp-push-push-push default` statement at the `[edit class-of-service interfaces` *`interface-name`* `unit` *`logical-unit-number`* `rewrite-rules]` hierarchy level:

```
[edit class-of-service interfaces interface-name unit logical-unit-number rewrite-rules]
exp-push-push-push default;
```

For more information about how to configure statements at the `[edit class-of-service]` hierarchy level, see the Junos OS Class of Service User Guide for Routing Devices.

Rewriting MPLS and IPv4 Packet Headers

You can apply a rewrite rule to MPLS and IPv4 packet headers simultaneously. This allows you to initialize MPLS EXP and IP precedence bits at LSP ingress. You can configure different rewrite rules depending on whether the traffic is VPN or non-VPN.

To rewrite MPLS and IPv4 packet headers, include the `protocol` statement at the `[edit class-of-service interfaces` *`interface-name`* `unit` *`logical-unit-number`* `rewrite-rules exp` *`rewrite-rule-name`*] hierarchy level:

```
[edit class-of-service interfaces interface-name unit logical-unit-number rewrite-rules exp
rewrite-rule-name]
protocol types;
```

Use the `protocol` statement to specify the types of MPLS packets and packet headers to which to apply the rewrite rule. The MPLS packet can be a standard MPLS packet or an MPLS packet with an IPv4 payload. Specify the type of MPLS packet by using the following options:

- `mpls-any`—Applies the rewrite rule to MPLS packets and writes the code point value to MPLS headers.
- `mpls-inet-both`—Applies the rewrite rule to VPN MPLS packets with IPv4 payloads. Writes the code point value to the MPLS and IPv4 headers in T Series (except T4000 routers) and M320 routers. On M Series routers, except the M320, the `mpls-inet-both` option causes all ingress MPLS LSP packets with IPv4 payloads to be initialized with 000 code points for IP precedence and MPLS EXP values.
- `mpls-inet-both-non-vpn`—Applies the rewrite rule to any non-VPN MPLS packets with IPv4 payloads. Writes the code point value to the MPLS and IPv4 headers in T Series and M320 routers. On M Series routers, except the M320, the `mpls-inet-both-non-vpn` option causes all ingress MPLS LSP packets with IPv4 payloads to be initialized with 000 code points for IP precedence and MPLS EXP values.

For a detailed example on how to configure rewrite rules for MPLS and IPv4 packets and for more information about how to configure class of service, see the Junos OS Class of Service User Guide for Routing Devices.

Configuring CoS Bits for an MPLS Network

When traffic enters a labeled-switch path (LSP) tunnel, the CoS bits in the MPLS header are set in one of two ways:

- The number of the output queue into which the packet was buffered and the packet loss priority (PLP) bit are written into the MPLS header and are used as the packet's CoS value. This behavior is the default, and no configuration is required. The *Junos OS Class of Service Configuration Guide* explains the IP CoS values, and summarizes how the CoS bits are treated.
- You set a fixed CoS value on all packets entering the LSP tunnel. A fixed CoS value means that all packets entering the LSP receive the same class of service.

To set a fixed CoS value on all packets entering the LSP:

1. Specify a class of service value for the LSP:

NOTE: The CoS value set using the `class-of-service` statement at the `[edit protocols mpls]` hierarchy level supersedes the CoS value set at the `[edit class-of-service]` hierarchy level for an interface. Effectively, the CoS value configured for an LSP overrides the CoS value set for an interface.

```
[edit protocols mpls]
user@switch# set class-of-service cos-value
```

Configuring CoS on an MPLS Provider Edge Switch Using IP Over MPLS

IN THIS SECTION

- Configuring CoS | **1844**
- Configuring an LSP Policer | **1845**

You can use class of service (CoS) within MPLS networks to prioritize certain types of traffic during periods of congestion. This topic describes configuring CoS components on a provider edge (PE) switch that is using IP Over MPLS.

This task describes how to create a custom DSCP classifier and a custom EXP rewrite rule on the ingress PE switch. It includes configuring a policer firewall filter and applying it to the customer-edge interface of the ingress PE switch. The policer firewall filter ensures that the amount of traffic forwarded through the MPLS tunnel never exceeds the requested bandwidth allocation.

Before you begin, configure the basic components for an MPLS network:

- Configure two PE switches. See Configuring MPLS on Provider Edge EX8200 and EX4500 Switches Using Circuit Cross-Connect.
- Configure one or more provider switches. See "Configuring MPLS on EX8200 and EX4500 Provider Switches" on page 94.

Configuring CoS

To configure CoS on a provider edge switch:

1. Import the default DSCP classifier classes to the custom DSCP classifier that you are creating:

```
[edit class-of-service]
user@switch# set classifiers dscp classifier-name import default
```

2. Add a forwarding class to this custom DSCP classifier and specify a loss priority and code point:

```
[edit class-of-service]
user@switch# set classifiers dscp classifier-name forwarding-class forwarding-class loss-
priority loss-priority code-points code-point
```

3. Specify the values for the custom EXP rewrite rule, `e1`:

```
[edit class-of-service]
user@switch# set rewrite-rules exp e1 forwarding-class forwarding-class loss-priority loss-
priority code-points code-point
```

4. On EX8200 switches only, bind the custom EXP rewrite rule to the interface:

```
[edit class-of-service]
user@switch# set class-of-service interfaces interface unit unit rewrite-rules exp e1
```

Configuring an LSP Policer

To configure an LSP policer:

NOTE: You cannot configure LSP policers on EX8200 switches. EX8200 switches do not support LSP policers.

1. Specify the number of bits per second permitted, on average, for the firewall policer, which will later be applied to the customer-edge-interface:

```
[edit firewall]
user@switch# set policer mypolicer if-exceeding bandwidth-limit 500m
```

2. Specify the maximum size permitted for bursts of data that exceed the given bandwidth limit for this policer:

```
[edit firewall policer]
user@switch# set mypolicer if-exceeding burst-size-limit 33553920
```

3. Discard traffic that exceeds the rate limits for this policer:

```
[edit firewall policer]
user@switch# set mypolicer then discard
```

4. To reference the policer, configure a filter term that includes the policer action:

```
[edit firewall]
user@switch# set family inet filter myfilter term t1 then policer mypolicer
```

5. Apply the filter to the customer-edge interface:

```
[edit interfaces]
user@switch# set ge-2/0/3 unit 0 family inet address 192.168.121.1/16 policing filter myfilter
```

NOTE: You can also configure schedulers and shapers as needed. See *Defining CoS Schedulers and Scheduler Maps (CLI Procedure)*.

Configuring CoS on an MPLS Provider Edge Switch Using Circuit Cross-Connect

IN THIS SECTION

- Configuring CoS | **1847**
- Configuring an LSP Policer | **1848**

You can use class of service (CoS) within MPLS networks to prioritize certain types of traffic during periods of congestion. This topic describes configuring CoS components on a provider edge (PE) switch that is using MPLS over circuit-cross connect (CCC).

NOTE: On EX Series switches other than EX8200 switches, if you are using MPLS over CCC, you can use only one DSCP or IP precedence classifier and only one IEEE 802.1p classifier on the CCC interfaces.

This procedure is for creating a custom DSCP classifier and a custom EXP rewrite rule on the ingress PE. It also includes enabling a policer on the label-switched path (LSP) of the ingress PE to ensure that the amount of traffic forwarded through the LSP never exceeds the requested bandwidth allocation.

This topic includes:

Configuring CoS

To configure CoS on a provider edge switch:

1. Import the default DSCP classifier classes to the custom DSCP classifier that you are creating:

```
[edit class-of-service]
user@switch# set classifiers dscp classifier-nameimport default
```

2. Add the expedited-forwarding class to this custom DSCP classifier, specifying a loss priority and code point:

```
[edit class-of-service]
user@switch# set classifiers dscp classifier-name forwarding-class forwarding-class loss-
priority loss-priority code-points code-point
```

3. Specify the values for the custom EXP rewrite rule, e1:

```
                          [edit class-of-service]
user@switch# set rewrite-rules exp e1 forwarding-class forwarding-class loss-priority loss-
priority code-point code-point
```

4. Bind the DSCP classifier to the CCC interface:

```
[edit ]
user@switch# set class-of-service interfaces interface unit unit classifier classifier-
name
```

5. On EX8200 switches only, bind the custom EXP rewrite rule to the interface:

```
[edit class-of-service]
user@switch# set class-of-service interfaces interface unit unit rewrite-rules exp e1
```

Configuring an LSP Policer

To configure an LSP policer:

> **NOTE**: You cannot configure LSP policers on EX8200 switches. EX8200 switches do not support LSP policers.

1. Specify the number of bits per second permitted, on average, for the policer, which will later be applied to the LSP:

```
[edit firewall]
set policer mypolicer if-exceeding bandwidth-limit 500m
```

2. Specify the maximum size permitted for bursts of data that exceed the given bandwidth limit for this policer:

```
[edit firewall policer]
set mypolicer if-exceeding burst-size-limit 33553920
```

3. Discard traffic that exceeds the rate limits for this policer:

```
[edit firewall policer]
set mypolicer then discard
```

4. To reference the policer, configure a filter term that includes the policer action:

```
                              [edit firewall]
user@switch# set family any filter myfilter term t1 then policer
mypolicer
```

5. Apply the filter to the LSP:

```
[edit protocols mpls]
set label-switched-path lsp_to_pe2_ge1 policing filter myfilter
```

NOTE: You can also configure schedulers and shapers as needed. See *Defining CoS Schedulers and Scheduler Maps (CLI Procedure)*.

Configuring CoS on Provider Switches of an MPLS Network

You can add class-of-service (CoS) components to your MPLS networks on EX Series switches to achieve end-to-end Differentiated Services to match your specific business requirements. The configuration of CoS components on the provider switches is the same regardless of whether the provider edge (PE) switches are using MPLS over CCC or IP over MPLS.

This task shows how to configure a custom EXP classifier and custom EXP rewrite rule on the provider switch.

1. Import the default EXP classifier classes to the custom EXP classifier that you are creating:

```
[edit class-of-service]
user@switch# set classifiers exp exp1 import default
```

2. Add the expedited-forwarding class to this custom EXP classifier, specifying a loss priority and code point:

```
[edit class-of-service]
user@switch# set classifiers exp exp1 forwarding-class expedited-forwarding loss-priority low
code-points 010
```

3. Specify the values for the custom EXP rewrite rule, **e1**:

```
[edit class-of-service]
user@switch# set rewrite-rules exp e1 forwarding-class expedited-forwarding loss-priority low
code-point 111
```

4. On EX8200 switches only, bind the custom EXP rewrite rule to the interface:

```
[edit class-of-service]
user@switch# set class-of-service interfaces ge-0/0/2 unit 0 rewrite-rules exp e1
```

NOTE: You can also configure schedulers and shapers as needed. See *Defining CoS Schedulers and Scheduler Maps (CLI Procedure)*.

Understanding Using CoS with MPLS Networks on EX Series Switches

IN THIS SECTION

- EXP Classifiers and EXP rewrite Rules | **1851**
- Guidelines for Using CoS Classifiers on CCCs | **1851**
- Using CoS Classifiers with IP over MPLS | **1852**
- Setting CoS Bits in an MPLS Header | **1852**
- EXP Rewrite Rules | **1854**
- Policer | **1854**
- Schedulers | **1854**

You can use *class of service* (CoS) within MPLS networks to prioritize certain types of traffic during periods of congestion. See EX Series Switch Software Features Overview for a complete list of the Junos OS MPLS features that are supported on specific EX Series switches.

Juniper Networks EX Series Ethernet Switches support Differentiated Service Code Point (DSCP) or IP precedence and IEEE 802.1p CoS classifiers on the customer-edge interfaces of the ingress provider edge (PE) switch. DSCP or IP precedence classifiers are used for Layer 3 packets. IEEE 802.1p is used for Layer 2 packets.

When a packet enters a customer-edge interface of the ingress PE switch, the switch associates the packet with a particular CoS servicing level before putting the packet onto the label-switched path (LSP). The switches within the LSP utilize the CoS value set at the ingress PE switch. The CoS value that was embedded in the classifier is translated and encoded in the MPLS header by means of the EXP or experimental bits. EX Series switches enable a default EXP classifier and a default EXP rewrite rule. For more information about EXP classifiers and EXP *rewrite rules*, see EXP Classifiers and EXP rewrite Rules.

This topic includes:

EXP Classifiers and EXP rewrite Rules

EX Series switches enable a default EXP classifier and a default EXP rewrite rule. You can configure a custom EXP classifier and a custom EXP rewrite rule if you prefer. However, the switch supports only one type of EXP classifier (default or custom) and only one EXP rewrite rule (default or custom).

You do not bind the EXP classifier or the EXP rewrite rule to individual interfaces. The switch automatically and implicitly applies the default or the custom EXP classifier and the default or the custom EXP rewrite rule to the appropriate MPLS-enabled interfaces. Because rewrite rules affect only egress interfaces, the switch applies the EXP rewrite rule only to those MPLS interfaces that are transmitting MPLS packets (not to the MPLS interfaces that are receiving the packets).

After traversing the MPLS tunnel, the traffic flows out from the egress provider edge (PE) switch. Before the traffic leaves the egress interface, the egress PE switch copies the EXP bits from the MPLS header to the most significant bits in the original IP packet--- that is, to the IP precedence bits. Note that this is the default behavior only on Juniper Networks EX8200 Ethernet Switches (standalone or *Virtual Chassis*) that are configured for MPLS.

Guidelines for Using CoS Classifiers on CCCs

When you are configuring CoS for MPLS over circuit cross-connect (CCC), there are some additional guidelines, as follows:

- You *must* explicitly bind a CoS classifier to the CCC interface on the ingress PE switch.
- You *must* use the same DSCP, IP precedence, or IEEE 802.1p classifier on CCC interfaces. However, if the CCC interfaces are on the same switch, you cannot configure both a DSCP and an IP precedence classifier on these interfaces. Thus, if you configure one CCC interface to use a DSCP classifier DSCP1, you cannot configure another CCC interface to use another DSCP classifier DSCP2. All the CCC interfaces on the switch must use the same DSCP (or IP precedence) classifier and the same IEEE 802.1p classifier.
- You *cannot* configure one CCC interface to use a DSCP classifier and another CCC interface to use an IP precedence classifier, because these classifier types overlap.
- You *can* configure one CCC interface to use a DSCP classifier and another CCC interface to use IEEE 802.1p classifier.
- You *can* configure one CCC interface to use both a DSCP and an IEEE 802.1p classifier. If you configure a CCC interface to use both these classifiers, the DSCP classifier is used for routing Layer 3 packets and the IEEE 802.1p classifier is used for routing Layer 2 packets.

- You *can* configure one CCC interface to use both an IP precedence and an IEEE 802.1p classifier. If you configure a CCC interface to use both these classifiers, the IP precedence classifier is used for routing Layer 3 packets and the IEEE 802.1p classifier is used for routing Layer 2 packets.

> **NOTE**: These guidelines are not applicable to Juniper Networks EX8200 Ethernet Switches (standalone or Virtual Chassis).

You can define multiple DSCP, IP precedence, and IEEE 802.1p classifiers for the non-CCC interfaces on a switch.

Using CoS Classifiers with IP over MPLS

When you are configuring CoS for IP over MPLS, the customer-edge interface uses the CoS configuration for the switch as the default. You do not have to bind a classifier to the customer-edge interface in this case. There are no restrictions on using multiple DSCP, IP precedence, and IEEE 802.1p classifiers on the same switch.

- You can modify the CoS classifier for a particular interface, but it is not required.
- You can configure a DSCP classifier, DSCP1 on the first interface, another DSCP classifier, DSCP2 on the second interface, and an IP precedence classifier on a third interface, and so forth.

Setting CoS Bits in an MPLS Header

When traffic enters an LSP tunnel, the CoS bits in the MPLS header are set in one of two ways:

- The number of the output queue into which the packet was buffered and the packet loss priority (PLP) bit are written into the MPLS header and are used as the packet's CoS value. This behavior is the default, and no configuration is required. The Junos OS Class of Service User Guide for Routing Devices explains the IP CoS values, and summarizes how the CoS bits are treated.
- You set a fixed CoS value on all packets entering the LSP tunnel. A fixed CoS value means that all packets entering the LSP receive the same class of service.

The CoS value can be a decimal number from 0 through 7. This number corresponds to a 3-bit binary number. The high-order 2 bits of the CoS value select which transmit queue to use on the outbound interface card.

The low-order bit of the CoS value is treated as the PLP bit and is used to select the RED drop profile to use on the output queue. If the low-order bit is 0, the non-PLP drop profile is used, and if the low-order bit is 1, the PLP drop profile is used. It is generally expected that random early detection (RED) will more aggressively drop packets that have the PLP bit set. For more information about RED and drop profiles, see the Junos OS Class of Service User Guide for Routing Devices.

NOTE: Configuring the PLP drop profile to drop packets more aggressively (for example, setting the CoS value from 6 to 7) decreases the likelihood of traffic getting through.

Table 28 on page 1853 summarizes how MPLS CoS values correspond to the transmit queue and PLP bit. Note that in MPLS, the mapping between the CoS bit value and the output queue is hard-coded. You cannot configure the mapping for MPLS; you can configure it only for IPv4 traffic flows, as described in the Junos OS Class of Service User Guide for Routing Devices.

Table 28: MPLS CoS Values

MPLS CoS Value	Bits	Transmit Queue	PLP Bit
0	000	0	Not set
1	001	0	Set
2	010	1	Not set
3	011	1	Set
4	100	2	Not set
5	101	2	Set
6	110	3	Not set
7	111	3	Set

Because the CoS value is part of the MPLS header, the value is associated with the packets only while they travel through the LSP tunnel. The value is not copied back to the IP header when the packets exit from the LSP tunnel.

NOTE: On EX8200 switches that run MPLS-based Layer 2 virtual private networks (VPNs):

- If you configure an LSP CoS, the EXP bits of the MPLS packet continue to use the same CoS values that are configured at the interface level.
- For Virtual Chassis, if the input and output interfaces are on different line cards, then the loss priority value that you configured on the first line card is not carried to the subsequent line cards. The loss priority for the outgoing traffic from the subsequent line cards is always set to low.

EXP Rewrite Rules

When traffic passes from the customer-edge interface to an MPLS interface, the DSCP, IP precedence, or IEEE 802.1p CoS classifier is translated into the EXP bits within the MPLS header. You cannot disable the default EXP rewrite rule, but you can configure your own custom EXP classifier and a custom EXP rewrite rule. You cannot bind the EXP classifier to individual MPLS interfaces; the switch applies it globally to all the MPLS-enabled interfaces on the switch.

Only one EXP rewrite rule (either default or custom) is supported on a switch. The switch applies it to all the egress interfaces on which MPLS is enabled.. This is, however, not the case with EX8200 switches. With EX8200 switches, you must explicitly apply the rewrite rule on each of the egress interfaces.

Policer

Policing helps to ensure that the amount of traffic forwarded through an LSP never exceeds the requested bandwidth allocation. During periods of congestion (when the total rate of queuing packets exceeds the rate of transmission), any new packets being sent to an interface can be dropped because there is no place to store them. You can configure a policer on the ingress PE switch to prevent this:

- If you are using MPLS over CCC, you bind the policer to the LSP. You cannot bind a policer to a CCC interface.
- If you are using IP over MPLS, you bind the policer to the **inet-family** customer-edge interface. You cannot bind a policer to the LSP when you are using IP over MPLS.

NOTE: You cannot configure LSP policers on EX8200 switches.

Schedulers

The schedulers for using CoS with MPLS are the same as for the other CoS configurations on EX Series switches. Default schedulers are provided for best-effort and network-control forwarding classes. If you

are using assured-forwarding, expedited-forwarding, or any custom forwarding class, we recommend that you configure a scheduler to support that forwarding class. See *Understanding CoS Schedulers*.

Example: Combining CoS with MPLS on EX Series Switches

IN THIS SECTION

- Requirements | **1855**
- Overview and Topology | **1856**
- Configuring the Local PE Switch | **1859**
- Configuring the Remote PE Switch | **1863**
- Configuring the Provider Switch | **1864**
- Verification | **1866**

You can use class of service (CoS) within MPLS networks to prioritize certain types of traffic during periods of congestion. The CoS value is included within the MPLS label, which is passed through the network, enabling end-to-end CoS across the network.

MPLS services are often used to ensure better performance for low-latency applications such as VoIP and other business-critical functions. These applications place specific demands on a network for successful transmission. CoS gives you the ability to control the mix of bandwidth, delay, jitter, and packet loss while taking advantage of the MPLS labeling mechanism.

This example shows how to configure CoS on an MPLS network that is using a unidirectional circuit cross-connect (CCC) from the ingress provider edge (PE) switch to the egress PE switch. for the customer-edge interface of the ingress provider edge (PE) switch. It describes adding the configuration of CoS components to the ingress PE switch, the egress PE switch, and the core provider switches of the existing MPLS network. Because of the unidirectional configuration, the DSCP classifier needs to be configured only on the ingress PE switch.

Requirements

This example uses the following hardware and software components:

- Junos OS Release 10.1 or later for EX Series switches
- Three EX Series switches

Before you configure CoS with MPLS, be sure you have:

Configured an MPLS network with two PE switches and one provider switch. See Example: Configuring MPLS on EX8200 and EX4500 Switches. This example assumes that an MPLS network has been configured using a cross circuit-connect (CCC).

Overview and Topology

IN THIS SECTION

- Topology | **1859**

This example describes adding custom classifiers and custom rewrite rules to switches in an MPLS network that is using MPLS over CCC.

It is a unidirectional configuration. Therefore, you need to configure custom classifiers and custom rewrite rules as follows:

- On the ingress PE switch: custom DSCP classifier and custom EXP rewrite rule
- On the egress PE switch: custom EXP classifier
- On the provider switch: customer EXP classifier and custom EXP rewrite rule

NOTE: You can also configure schedulers and shapers as needed. If you are using **assured-forwarding**, **expedited-forwarding**, or other custom forwarding classes, we recommend that you configure a scheduler to support that forwarding class. See *Defining CoS Schedulers and Scheduler Maps (CLI Procedure)*.

The example creates a custom DSCP classifier (**dscp1**) on the ingress PE switch and binds this classifier to the CCC interface. It includes configuration of a policer on the ingress PE switch. The policer is applied as a filter on the label-switched path (LSP) **lsp_to_pe2_ge1**(created in Example: Configuring MPLS on EX8200 and EX4500 Switches) to ensure that the amount of traffic forwarded through the LSP never exceeds the requested bandwidth allocation.

This example creates a custom EXP rewrite rule (**exp1**) on the ingress PE switch, specifying a loss-priority and code point to be used for the expedited-forwarding class as the packet travels through the LSP. The switch applies this custom rewrite rule on the core interfaces **ge-0/0/5.0** and **ge-0/0/6.0**, which are the egress interfaces for this switch.

Table 29 on page 1857 shows the CoS configuration components added to the ingress PE switch.

Table 29: CoS Configuration Components on the Ingress PE Switch

Property	Settings	Description
Local PE switch hardware	EX Series switch	PE-1
Policing filter configured and applied to the LSP.	**policing filter mypolicer** **filter myfilter**	Name of the rate-limiting policer. Name of the filter, which refers to the policer
Custom DSCP classifier	**dscp1**	Specifies the name of the custom DSCP classifier
Custom EXP rewrite rule	**e1**	Name of the custom EXP rewrite rule.
Customer-edge interface	**ge-0/0/1.0**	Interface that receives packets from devices outside the network. The custom DSCP classifier must be specified on this CCC interface.
Core interfaces	**ge-0/0/5.0** and **ge-0/0/6.0**	Interfaces that transmit MPLS packets to other switches within the MPLS network. The EXP rewrite rule is applied implicitly to these interfaces.

Table 30 on page 1857 shows the CoS configuration components added to the egress PE switch in this example.

Table 30: CoS Configuration Components of the Egress PE Switch

Property	Settings	Description
Remote provider edge switch hardware	EX Series switch	PE-2

Table 30: CoS Configuration Components of the Egress PE Switch *(Continued)*

Property	Settings	Description
Custom EXP classifier	**exp1**	Name of custom EXP classifier
Customer-edge interface	**ge-0/0/1.0**	Interface that transmits packets from this network to devices outside the network. No CoS classifier is specified for this interface. A scheduler can be specified.
Core interfaces	**ge-0/0/7.0** and **ge-0/0/8.0**	Core interfaces on PE-2 that receive MPLS packets from the provider switch. The EXP classifier is enabled by default on the switch and applied implicitly to these interfaces.

Table 31 on page 1858 shows the MPLS configuration components used for the provider switch in this example.

Table 31: CoS Configuration Components of the Provider Switch

Property	Settings	Description
Provider switch hardware	EX Series switch	Transit switch within the MPLS network configuration.
Custom EXP classifier	**exp1**	Name of the custom EXP classifier.
Custom EXP rewrite rule	**e1**	Name of the custom EXP rewrite rule.

Table 31: CoS Configuration Components of the Provider Switch *(Continued)*

Property	Settings	Description
Core interfaces receiving packets from other MPLS switches.	**ge-0/0/5.0** and **ge-0/0/6.0**	Interfaces that connect the provider switch to the ingress PE switch (PE-1). The EXP classifier is enabled by default on the switch and applied implicitly to these interfaces.
Core interfaces transmitting packets to other switches within the MPLS network.	**ge-0/0/7.0** and **ge-0/0/8.0**	Interfaces that transmit packets to the egress PE (PE-2). The EXP rewrite rule is applied implicitly on these interfaces. Schedulers can also be specified and will be applied to these interfaces.

Topology

Configuring the Local PE Switch

IN THIS SECTION

- Procedure | 1859

Procedure

CLI Quick Configuration

To quickly configure a custom DSCP classifier, custom EXP rewrite rule, and a policer on the local PE switch, copy the following commands and paste them into the switch terminal window of PE-1:

```
[edit]

set class-of-service classifiers dscpset class-of-service classifiers dscp dscp1 import default
```

```
set class-of-service classifiers dscp dscp1 forwarding-class expedited-forwarding loss-priority
low code-points 000111
set class-of-service rewrite-rules exp e1 forwarding-class expedited-forwarding loss-priority
low code-point 111
set class-of-service interfaces ge-0/0/1 unit 0 classifier dscp1
set firewall policer mypolicer if-exceeding bandwidth-limit 500m
set firewall policer mypolicer if-exceeding burst-size-limit 33553920
set firewall policer mypolicer then discard
set firewall family any filter myfilter term t1 then policer mypolicer
set protocols mpls label-switched-path lsp_to_pe2_ge1 to 127.1.1.3 policing filter myfilter
```

Step-by-Step Procedure

To configure a custom DSCP classifier, custom EXP rewrite rule, and a policer on the ingress PE switch:

1. Import the default DSCP classifier classes to the custom DSCP classifier that you are creating:

```
[edit class-of-service]
user@switch# set classifiers dscp dscp1 import default
```

2. Add the expedited-forwarding class to this custom DSCP classifier, specifying a loss priority and code point:

```
[edit class-of-service]
user@switch# set classifiers dscp dscp1 forwarding-class expedited-forwarding loss-priority
low code-points 000111
```

3. Specify the values for the custom EXP rewrite rule, **e1**:

```
[edit class-of-service]
user@switch# set rewrite-rules exp e1 forwarding-class expedited-forwarding loss-priority low
code-point 111
```

4. Bind the DSCP classifier to the CCC interface:

```
[edit class-of-service]
user@switch# set class-of-service interfaces ge-0/0/1 unit 0 classifier dscp1
```

5. Specify the number of bits per second permitted, on average, for the firewall policer, which will later be applied to the LSP:

```
[edit firewall]
set policer mypolicer if-exceeding bandwidth-limit 500m
```

6. Specify the maximum size permitted for bursts of data that exceed the given bandwidth limit for this policer:

```
[edit firewall policer]
set mypolicer if-exceeding burst-size-limit 33553920
```

7. Discard traffic that exceeds the rate limits for this policer:

```
[edit firewall policer]
set mypolicer then discard
```

8. To reference the policer, configure a filter term that includes the policer action:

```
[edit firewall]
user@switch# set family any filter myfilter term t1 then policer
mypolicer
```

9. Apply the filter to the LSP:

```
[edit protocols mpls]
set label-switched-path lsp_to_pe2_ge1 policing filter myfilter
```

Results

Display the results of the configuration:

```
[edit]
user@switch# show
class-of-service {
    classifiers {
        dscp dscp1 {
```

```
            import default;
            forwarding-class expedited-forwarding {
                loss-priority low code-points 000111;
            }
        }
    }
    interfaces {
        ge-0/0/1 {
            unit 0 {
                classifiers {
                    dscp dscp1;
                }
            }
        }
    }
    rewrite-rules {
        exp e1 {
            forwarding-class expedited-forwarding {
                loss-priority low code-point 111;
            }
        }
    }
}
firewall {
    family any {
        filter myfilter {
            term t1 {
                then policer mypolicer;
            }
        }
    }
    policer mypolicer {
        if-exceeding {
            bandwidth-limit 500m;
            burst-size-limit 33553920;
        }
        then discard;
    }
}
```

Configuring the Remote PE Switch

IN THIS SECTION

- Procedure | 1863

Procedure

CLI Quick Configuration

To quickly configure a custom EXP classifier on the remote PE switch, copy the following commands and paste them into the switch terminal window of PE-2:

```
[edit]
set class-of-service classifiers exp exp1 import default
set class-of-service classifiers exp exp1 forwarding-class expedited-forwarding loss-priority
low code-points 010
```

Step-by-Step Procedure

To configure a custom EXP classifier on the egress PE switch:

1. Import the default EXP classifier classes to the custom EXP classifier that you are creating:

```
[edit class-of-service]
user@switch# set classifiers exp exp1 import default
```

2. Add the expedited-forwarding class to this custom EXP classifier, specifying a loss priority and code point:

```
[edit class-of-service]
user@switch# set classifiers exp exp1 forwarding-class expedited-forwarding loss-priority low
code-points 010
```

Results

Display the results of the configuration:

```
[edit]
 user@switch# show
class-of-service {
    classifiers {
        exp exp1 {
            import default;
            forwarding-class expedited-forwarding {
                loss-priority low code-points 010;
            }
        }
    }
}
```

Configuring the Provider Switch

IN THIS SECTION

- Procedure | 1864

Procedure

CLI Quick Configuration

To quickly configure a custom EXP classifier and a custom EXP rewrite rule on the provider switch, copy the following commands and paste them into the switch terminal window of the provider switch:

```
[edit]
set class-of-service classifiers exp exp1 import default
set class-of-service classifiers exp exp1 forwarding-class expedited-forwarding loss-priority
low code-points 010
set class-of-service rewrite-rules exp e1 forwarding-class expedited-forwarding loss-priority
low code-point 111
```

Step-by-Step Procedure

To configure a custom EXP classifier and a custom EXP rewrite rule on the provider switch:

1. Import the default EXP classifier classes to the custom EXP classifier that you are creating:

```
[edit class-of-service]
user@switch# set classifiers exp exp1 import default
```

2. Add the expedited-forwarding class to this custom EXP classifier, specifying a loss priority and code point:

```
[edit class-of-service]
user@switch# set classifiers exp exp1 forwarding-class expedited-forwarding loss-priority low
code-points 010
```

3. Specify the values for the custom EXP rewrite rule, **e1**:

```
[edit class-of-service]
user@switch# set rewrite-rules exp e1 forwarding-class expedited-forwarding loss-priority low
code-point 111
```

Results

Display the results of the configuration:

```
[edit]
 user@switch# show
class-of-service {
    classifiers {
        exp exp1 {
            import default;
            forwarding-class expedited-forwarding {
                loss-priority low code-points 010;
            }
        }
    }
    rewrite-rules {
```

```
        exp e1 {
            forwarding-class expedited-forwarding {
                loss-priority low code-point 111;
            }
        }
    }
}
```

Verification

- Verifying That the Policer Firewall Filter Is Operational | **1866**
- Verifying That the CoS Classifiers Are Going to the Right Queue | **1867**
- Verifying the CoS Forwarding Table Mapping | **1871**
- Verifying the Rewrite Rules | **1872**

To confirm that the configuration is working properly, perform these tasks:

Verifying That the Policer Firewall Filter Is Operational

Purpose

Verify the operational state of the policer that is configured on the ingress PE switch.

Action

```
user@switch> show firewall

Filter: myfilter
Policers:
Name                                                Packets
mypolicer-t1                                              0
```

Meaning

This output shows that the firewall filter **mypolicer** has been created.

Verifying That the CoS Classifiers Are Going to the Right Queue

Purpose

Verify that the CoS classifiers are going to the right queue.

Action

```
user@switch> show class-of-service forwarding-table classifier

Classifier table index: 7, # entries: 64, Table type: DSCP
Entry #   Code point   Forwarding-class #   PLP
   0        000000        0       0
   1        000001        0       0
   2        000010        0       0
   3        000011        0       0
   4        000100        0       0
   5        000101        0       0
   6        000110        0       0

  63        111111        3       0
```

Meaning

This output shows that a new DSCP classifier has been created, index **9346**, on the ingress PE switch (PE-1).

Verifying the CoS Forwarding Table Mapping

Purpose

For each logical interface, display either the table index of the classifier for a given code point type or the queue number (if it is a fixed classification) in the forwarding table.

Action

```
user@switch> show class-of-service forwarding-table classifier mapping

                       Table Index/
Interface      Index      Q num      Table type
ge-0/0/1.0        92       9346      DSCP
```

Meaning

The results show that the new DSCP classifier, index number **9346**, is bound to interface **ge-0/0/1.0**.

Verifying the Rewrite Rules

Purpose

Display mapping of the queue number and loss priority to code point value for each rewrite rule as it exists in the forwarding table.

Action

```
user@switch>show class-of-service forwarding-table rewrite-rule

Rewrite table index: 31, # entries: 4, Table type: DSCP
FC#     Low bits  State      High bits  State
0       000000  Enabled       000000  Enabled

0          000  Enabled          000  Enabled
1          101  Enabled          101  Enabled
2          001  Enabled          001  Enabled
3          110  Enabled          111  Enabled

Rewrite table index: 9281, # entries: 1, Table type: EXP
FC#     Low bits  State      High bits  State
1          111  Enabled          000  Disabled
```

Meaning

This output shows that a new EXP classifier with the index number **9281** has been created.

Understanding CoS MPLS EXP Classifiers and Rewrite Rules

IN THIS SECTION

- EXP Classifiers | **1874**
- EXP Rewrite Rules | **1875**
- Schedulers | **1876**

You can use *class of service* (CoS) within MPLS networks to prioritize certain types of traffic during periods of congestion by applying packet classifiers and rewrite rules to the MPLS traffic. MPLS classifiers are global and apply to all interfaces configured as `family mpls` interfaces.

When a packet enters a customer-edge interface on the ingress provider edge (PE) switch, the switch associates the packet with a particular CoS servicing level before placing the packet onto the label-switched path (LSP). The switches within the LSP utilize the CoS value set at the ingress PE switch to determine the CoS service level. The CoS value embedded in the classifier is translated and encoded in the MPLS header by means of the experimental (EXP) bits.

EXP classifiers map incoming MPLS packets to a forwarding class and a loss priority, and assign MPLS packets to output queues based on the forwarding class mapping. EXP classifiers are behavior aggregate (BA) classifiers.

EXP rewrite rules change (rewrite) the CoS value of the EXP bits in outgoing packets on the egress queues of the switch so that the new (rewritten) value matches the policies of a targeted peer. Policy matching allows the downstream routing platform or switch in a neighboring network to classify each packet into the appropriate service group.

NOTE: On QFX5200, QFX5100, QFX3500, QF3600, and EX4600 switches, and on QFabric systems, there is no default EXP classifier. If you want to classify incoming MPLS packets using the EXP bits, you must configure a global EXP classifier. The global EXP classifier applies to all MPLS traffic on interfaces configured as `family mpls`.

On QFX10000 switches, there is a no default EXP classifier. If you want to classify incoming MPLS packets using the EXP bits, you must configure EXP classifiers and apply them to logical interfaces configured as `family mpls`. (You cannot apply classifiers to physical interfaces.). You can configure up to 64 EXP classifiers.

There is no default EXP rewrite rule. If you want to rewrite the EXP bit value at the egress interface, you must configure EXP rewrite rules and apply them to logical interfaces.

EXP classifiers and rewrite rules are applied only to interfaces that are configured as `family mpls` (for example, `set interfaces xe-0/0/35 unit 0 family mpls`.)

This topic includes:

EXP Classifiers

On QFX5200, QFX5100, EX4600, QFX3500, and QFX3600 switches, and on QFabric systems, unlike DSCP and IEEE 802.1p BA classifiers, EXP classifiers are global to the switch and apply to all switch interfaces that are configured as `family mpls`. On QFX10000 switches, you apply EXP classifiers to individual logical interfaces, and different interfaces can use different EXP classifiers.

When you configure and apply an EXP classifier, MPLS traffic on all `family mpls` interfaces uses the EXP classifier, even on interfaces that also have a fixed classifier. If an interface has both an EXP classifier and a fixed classifier, the EXP classifier is applied to MPLS traffic and the fixed classifier is applied to all other traffic.

Also unlike DSCP and IEEE 802.1p BA classifiers, there is no default EXP classifier. If you want to classify MPLS traffic based on the EXP bits, you must explicitly configure an EXP classifier and apply it to the switch interfaces. Each EXP classifier has eight entries that correspond to the eight EXP CoS values (0 through 7, which correspond to CoS bits 000 through 111).

You can configure up to 64 EXP classifiers.

However, on QFX5200, QFX5100, EX4600, and legacy CLI switches, the switch uses only one MPLS EXP classifier as a global classifier on all interfaces. After you configure an MPLS EXP classifier, you can configure that classifier as the global EXP classifier by including the EXP classifier in the `[edit class-of-service system-defaults classifiers exp]` hierarchy level. All switch interfaces configured as `family mpls` use the global EXP classifier to classify MPLS traffic.

On these switches, only one EXP classifier can be configured as the global EXP classifier at any time. If you want to change the global EXP classifier, delete the global EXP classifier configuration (use the **user@switch# delete class-of-service system-defaults classifiers exp** configuration statement), then configure the new global EXP classifier.

QFX10000 switches do not support global EXP classifiers. You can configure one EXP classifier and apply it to multiple logical interfaces, or configure multiple EXP classifiers and apply different EXP classifiers to different logical interfaces.

If an EXP classifier is not configured, then if a fixed classifier is applied to the interface, the MPLS traffic uses the fixed classifier. (Switches that have a default EXP classifier use the default classifier.) If no EXP classifier and no fixed classifier are applied to the interface, MPLS traffic is treated as best-effort traffic using the 802.1 default untrusted classifier. DSCP classifiers are not applied to MPLS traffic.

On QFX5200, QFX5100, EX4600, and legacy CLI switches, because the EXP classifier is global, you cannot configure some ports to use a fixed IEEE 802.1p classifier for MPLS traffic on some interfaces and the global EXP classifier for MPLS traffic on other interfaces. When you configure a global EXP classifier, all MPLS traffic on all interfaces uses the EXP classifier.

NOTE: The switch uses only the outermost label of incoming EXP packets for classification.

NOTE: MPLS packets with 802.1Q tags are not supported.

EXP Rewrite Rules

As MPLS packets enter or exit a network, edge switches might be required to alter the class-of-service (CoS) settings of the packets. EXP *rewrite rules* set the value of the EXP CoS bits within the header of the outgoing MPLS packet on `family mpls` interfaces. Each rewrite rule reads the current forwarding class and loss priority associated with the packet, locates the chosen CoS value from a table, and writes that CoS value into the packet header, replacing the old CoS value. EXP rewrite rules apply only to MPLS traffic.

EXP rewrite rules apply only to logical interfaces. You cannot apply EXP rewrite rules to physical interfaces.

There are no default EXP rewrite rules. If you want to rewrite the EXP value in MPLS packets, you must configure EXP rewrite rules and apply them to logical interfaces. If no rewrite rules are applied, all MPLS labels that are pushed have a value of zero (0). The EXP value remains unchanged on MPLS labels that are swapped.

You can configure up to 64 EXP rewrite rules, but you can only apply 16 EXP rewrite rules at any time on the switch. On a given logical interface, all pushed MPLS labels have the same EXP rewrite rule applied to them. You can apply different EXP rewrite rules to different logical interfaces on the same physical interface.

You can apply an EXP rewrite rule to an interface that has a DSCP, DSCP IPv6, or IEEE 802.1p rewrite rule. Only MPLS traffic uses the EXP rewrite rule. MPLS traffic does not use DSCP or DSCP IPv6 rewrite rules.

If the switch is performing penultimate hop popping (PHP), EXP rewrite rules do not take effect. If both an EXP classifier and an EXP rewrite rule are configured on the switch, then the EXP value from the last popped label is copied into the inner label. If either an EXP classifier or an EXP rewrite rule (but not both) is configured on the switch, then the inner label EXP value is sent unchanged.

NOTE: On each physical interface, either all forwarding classes that are being used on the interface must have rewrite rules configured or no forwarding classes that are being used on the interface can have rewrite rules configured. On any physical port, do not mix forwarding classes with rewrite rules and forwarding classes without rewrite rules.

Schedulers

The schedulers for using CoS with MPLS are the same as for the other CoS configurations on the switch. Default schedulers are provided only for the best-effort, fcoe, no-loss, and network-control default forwarding classes. If you configure a custom forwarding class for MPLS traffic, you need to configure a scheduler to support that forwarding class and provide bandwidth to that forwarding class.

Configuring Rewrite Rules for MPLS EXP Classifiers

You configure EXP rewrite rules to alter CoS values in outgoing MPLS packets on the outbound `family mpls` interfaces of a switch to match the policies of a targeted peer. Policy matching allows the downstream routing platform or switch in a neighboring network to classify each packet into the appropriate service group.

To configure an EXP CoS rewrite rule, create the rule by giving it a name and associating it with a forwarding class, loss priority, and code point. This creates a rewrite table. After the rewrite rule is created, enable it on a logical `family mpls` interface. EXP rewrite rules can only be enabled on logical `family mpls` interfaces, not on physical interfaces or on interfaces of other family types. You can also apply an existing EXP rewrite rule on a logical interface.

NOTE: There are no default rewrite rules.

You can configure up to 64 EXP rewrite rules, but you can only use 16 EXP rewrite rules at any time on the switch. On a given `family mpls` logical interface, all pushed MPLS labels have the same EXP rewrite rule applied to them. You can apply different EXP rewrite rules to different logical interfaces on the same physical interface.

NOTE: On each physical interface, either all forwarding classes that are being used on the interface must have rewrite rules configured, or no forwarding classes that are being used on the interface can have rewrite rules configured. On any physical port, do not mix forwarding classes with rewrite rules and forwarding classes without rewrite rules.

NOTE: To replace an existing rewrite rule on the interface with a new rewrite rule of the same type, first explicitly remove the existing rewrite rule and then apply the new rule.

To create an EXP rewrite rule for MPLS traffic and enable it on a logical interface:

1. Create an EXP rewrite rule:

```
user@switch# set class-of-service rewrite-rules exp rewrite-rule-name forwarding-class
forwarding-class-name loss-priority level code-points [aliases] [bit-patterns]
```

For example, to configure an EXP rewrite rule named `exp-rr-1` for a forwarding class named `mpls-1` with a loss priority of `low` that rewrites the EXP code point value to `001`:

```
user@switch# set class-of-service rewrite-rules exp exp-rr-1 forwarding-class mpls-1 loss-
priority low code-points 001
```

2. Apply the rewrite rule to a logical interface:

```
user@switch # set class-of-service interfaces interface-name unit logical-unit rewrite-rules
exp rewrite-rule-name
```

For example, to apply a rewrite rule named `exp-rr-1` to logical interface `xe-0/0/10.0`:

```
user@switch# set class-of-service interfaces xe-0/0/10 unit 0 rewrite-rules exp exp-rr-1
```

NOTE: In this example, all forwarding classes assigned to port xe-0/0/10 must have rewrite rules. Do not mix forwarding classes that have rewrite rules with forwarding classes that do not have rewrite rules on the same interface.

Configuring CoS Bits for an MPLS Network

When traffic enters a labeled-switch path (LSP) tunnel, the CoS bits in the MPLS header are set in one of two ways:

- The number of the output queue into which the packet was buffered and the packet loss priority (PLP) bit are written into the MPLS header and are used as the packet's CoS value. This behavior is

the default, and no configuration is required. The Junos OS Class of Service User Guide for Routing Devices explains the IP CoS values, and summarizes how the CoS bits are treated.

- You set a fixed CoS value on all packets entering the LSP tunnel. A fixed CoS value means that all packets entering the LSP receive the same class of service.

To set a fixed CoS value on all packets entering the LSP:

1. Specify a class of service value for the LSP:

> **NOTE**: The CoS value set using the `class-of-service` statement at the `[edit protocols mpls]` hierarchy level supersedes the CoS value set at the `[edit class-of-service]` hierarchy level for an interface. Effectively, the CoS value configured for an LSP overrides the CoS value set for an interface.

```
[edit protocols mpls]
user@switch# set class-of-service cos-value
```

Configuring a Global MPLS EXP Classifier

EXP packet classification associates incoming packets with a particular MPLS CoS servicing level. EXP behavior aggregate (BA) classifiers examine the MPLS EXP value in the packet header to determine the CoS settings applied to the packet. EXP BA classifiers allow you to set the forwarding class and loss priority of an MPLS packet based on the incoming CoS value.

You can configure up to 64 EXP classifiers, however, the switch uses only one MPLS EXP classifier as a global classifier, which is applied only on interfaces configured as `family mpls`. All `family mpls` switch interfaces use the global EXP classifier to classify MPLS traffic.

There is no default EXP classifier. If you want to classify incoming MPLS packets using the EXP bits, you must configure a global EXP classifier. The global classifier applies to all MPLS traffic on all `family mpls` interfaces.

If a global EXP classifier is configured, MPLS traffic on `family mpls` interfaces uses the EXP classifier. If a global EXP classifier is not configured, then if a fixed classifier is applied to the interface, the MPLS traffic uses the fixed classifier. If no EXP classifier and no fixed classifier is applied to the interface, MPLS traffic is treated as best-effort traffic. DSCP classifiers are not applied to MPLS traffic.

To configure an MPLS EXP classifier using the CLI:

1. Create an EXP classifier and associate it with a forwarding class, a loss priority, and a code point:

```
[edit class-of-service classifiers]
user@switch# set (dscp | ieee-802.1 | exp) classifier-name forwarding-class forwarding-class-name loss-priority level code-points [aliases] [bit-patterns]
```

2. Apply the EXP classifier to the switch interfaces:

```
[edit class-of-service]
user@switch# set system-defaults classifiers exp classifier-name
```

Introduction to GMPLS

Traditional MPLS is designed to carry Layer 3 IP traffic using established IP-based paths and associating these paths with arbitrarily assigned labels. These labels can be configured explicitly by a network administrator, or can be dynamically assigned by means of a protocol such as LDP or RSVP.

GMPLS generalizes MPLS in that it defines labels for switching varying types of Layer 1, Layer 2, or Layer 3 traffic. GMPLS nodes can have links with one or more of the following switching capabilities:

- Fiber-switched capable (FSC)
- Lambda-switched capable (LSC)
- Time-division multiplexing (TDM) switched-capable (TSC)
- Packet-switched capable (PSC)

Label-switched paths (LSPs) must start and end on links with the same switching capability. For example, routers can establish packet-switched LSPs with other routers. The LSPs might be carried over a TDM-switched LSP between SONET add/drop multiplexers (ADMs), which in turn might be carried over a lambda-switched LSP.

The result of this extension of the MPLS protocol is an expansion in the number of devices that can participate in label switching. Lower-layer devices, such as OXCs and SONET ADMs, can now participate in GMPLS signaling and set up paths to transfer data. A router can participate in signaling optical paths across a transport network.

Two service models determine the visibility that a client node (a router, for example) has into the optical core or transport network. The first is through a user-to-network interface (UNI), which is often referred to as the overlay model. The second is known as the peer model. Juniper Networks supports both models.

NOTE: There is not necessarily a one-to-one correspondence between a physical interface and a GMPLS interface. If a GMPLS connection uses a nonchannelized physical connector, the GMPLS label can use the physical port ID. However, the label for channelized interfaces often is based on a channel or time slot. Consequently, it is best to refer to GMPLS labels as identifiers for a resource on a traffic engineering link.

To establish LSPs, GMPLS uses the following mechanisms:

- An out-of-band control channel and a data channel—RSVP messages for LSP setup are sent over an out-of-band control network. Once the LSP setup is complete and the path is provisioned, the data channel is up and can be used to carry traffic. The Link Management Protocol (LMP) is used to define and manage the data channels between a pair of nodes. You can optionally use LMP to establish and maintain LMP control channels between peers running the same Junos OS Release.
- RSVP-TE extensions for GMPLS—RSVP-TE is already designed to signal the setup of packet LSPs. This has been extended for GMPLS to be able to request path setup for various kinds of LSPs (nonpacket) and request labels like wavelengths, time slots, and fibers as label objects.

- Bidirectional LSPs—Data can travel both ways between GMPLS devices over a single path, so nonpacket LSPs are signaled to be bidirectional.

GMPLS Terms and Acronyms

IN THIS SECTION

- Generalized MPLS (GMPLS) | **1882**
- Forwarding adjacency | **1882**
- GMPLS label | **1882**
- GMPLS LSP types | **1882**
- Link Management Protocol | **1883**
- Traffic engineering link | **1883**

Generalized MPLS (GMPLS)

An extension to MPLS that allows data from multiple layers to be switched over label-switched paths (LSPs). GMPLS LSP connections are possible between similar Layer 1, Layer 2, and Layer 3 devices.

Forwarding adjacency

A forwarding path for sending data between GMPLS-enabled devices.

GMPLS label

Layer 3 identifiers, fiber port, time-division multiplexing (TDM) time slot, or dense wavelength-division multiplexing (DWDM) wavelength of a GMPLS-enabled device used as a next-hop identifier.

GMPLS LSP types

The four types of GMPLS LSPs are:

- Fiber-switched capable (FSC)—LSPs are switched between two fiber-based devices, such optical cross-connects (OXCs) that operate at the level of individual fibers.
- Lambda-switched capable (LSC)—LSPs are switched between two DWDM devices, such as such as OXCs that operate at the level of individual wavelengths.

- TDM-switched capable (TDM)—LSPs are switched between two TDM devices, such as SONET ADMs.
- Packet-switched capable (PSC)—LSPs are switched between two packet-based devices, such as routers or ATM switches.

Link Management Protocol

A protocol used to define a forwarding adjacency between peers and to maintain and allocate resources on the traffic engineering links.

Traffic engineering link

A logical connection between GMPLS-enabled devices. Traffic engineering links can have addresses or IDs and are associated with certain resources or interfaces. They also have certain attributes (encoding-type, switching capability, bandwidth, and so on). The logical addresses can be routable, although this is not required because they are acting as link identifiers. Each traffic engineering link represents a forwarding adjacency between a pair of devices.

GMPLS Operation

The basic functionality of GMPLS requires close interaction between RSVP and LMP. It works in the following sequence:

1. LMP notifies RSVP of the new entities:
   - Traffic engineering link (forwarding adjacency)
   - Resources available for the traffic engineering link
   - Control peer
2. GMPLS extracts the LSP attributes from the configuration and requests RSVP to signal one or more specific paths, which are specified by the traffic engineering link addresses.
3. RSVP determines the local traffic engineering link, corresponding control adjacency and active control channel, and transmission parameters (such as IP destination). It requests that LMP allocate a resource from the traffic engineering link with the specified attributes. If LMP finds a resource matching the attributes, label allocation succeeds. RSVP sends a PathMsg hop by hop until it reaches the target router.
4. When the target router receives the PathMsg, RSVP again requests that LMP allocate a resource based on the signaled parameters. If label allocation succeeds, the router sends back a ResvMsg.
5. If the signaling is successful, a bidirectional optical path is provisioned.

GMPLS and OSPF

You can configure OSPF for GMPLS. OSPF is an interior gateway protocol (IGP) that routes packets within a single autonomous system (AS). OSPF uses link-state information to make routing decisions.

GMPLS and CSPF

GMPLS introduces extra constraints for computing paths for GMPLS LSPs that use CSPF. These additional constraints affect the following link attributes:

- Signal type (minimum LSP bandwidth)
- Encoding type
- Switching type

These new constraints are populated in the traffic engineering database with the exchange of an interface-switching capability descriptor type, length, value (TLV) through an IGP.

The ignored constraints that are exchanged through the interface switching capability descriptor include:

- Maximum LSP bandwidth
- Maximum transmission unit (MTU)

The CSPF path computation is the same as in non-GMPLS environments, except that the links are also limited by GMPLS constraints.

Each link can have multiple interface-switching capability descriptors. All the descriptors are checked before a link is rejected.

The constraints are checked in the following order:

1. The signal type configured for the GMPLS LSP signifies the amount of bandwidth requested. If the desired bandwidth is less than the minimum LSP bandwidth, the interface-switching descriptor is rejected.
2. The encoding type of the link for the ingress and the egress interfaces should match. The encoding type is selected and stored at the ingress node after all the constraints are satisfied by the link and is used to select the link on the egress node.
3. The switching type of the links of the intermediate switches should match that of the GMPLS LSP specified in the configuration.

GMPLS Features

The Junos OS includes the following GMPLS functionality:

- An out-of-band control plane makes it possible to signal LSP path setup.

- RSVP-TE extensions support additional objects beyond Layer 3 packets, such as ports, time slots, and wavelengths.
- The LMP protocol creates and maintains a database of traffic engineering links and peer information. Only the static version of this protocol is supported in the Junos OS. You can optionally configure LMP to establish and maintain LMP control channels between peers running the same Junos OS Release.
- Bidirectional LSPs are required between devices.
- Several GMPLS label types that are defined in RFC 3471, *Generalized MPLS—Signaling Functional Description*, such as MPLS, Generalized, SONET/SDH, Suggested, and Upstream, are supported. Generalized labels do not contain a type field, because the nodes should know from the context of their connection what type of label to expect.
- Traffic parameters facilitate GMPLS bandwidth encoding and SONET/SDH formatting.
- Other supported attributes include interface identification and errored interface identification, user-to-network (UNI)-style signaling, and secondary LSP paths.

Configuring MPLS Paths for GMPLS

As part of the configuration for GMPLS, you need to establish an MPLS path for each unique device connected through GMPLS. Configure the traffic engineering link remote address as the address at the `[edit protocols mpls path path-name]` hierarchy level. Constrained Shortest Path First (CSPF) is supported so you can choose either the `strict` or `loose` option with the address.

See LMP Configuration Overview for information about how to obtain a traffic engineering link remote address.

To configure the MPLS path, include the `path` statement at the `[edit protocols mpls]` hierarchy level:

```
[edit protocols mpls]
path path-name {
    next-hop-address (strict | loose);
}
```

For information about how to configure MPLS paths, see "Creating Named Paths" on page 579.

Tracing LMP Traffic

To trace LMP protocol traffic, include the `traceoptions` statement at the `[edit protocols link-management]` hierarchy level:

```
[edit protocols link-management]
traceoptions {
    file filename <files number> <size size> <world-readable | no-world-readable>;
    flag flag <flag-modifier> <disable>;
}
```

Use the `file` statement to specify the name of the file that receives the output of the tracing operation. All files are placed in the directory /var/log.

The following trace flags display the operations associated with the sending and receiving of various LMP messages:

- `all`—Trace all available operations
- `hello-packets`—Trace hello packets on any LMP control channel
- `init`—Output from the initialization messages
- `packets`—Trace all packets other than hello packets on any LMP control channel
- `parse`—Operation of the parser
- `process`—Operation of the general configuration
- `route-socket`—Operation of route socket events
- `routing`—Operation of the routing protocols
- `server`—Server processing operations
- `show`—Servicing operations for `show` commands
- `state`—Trace state transitions of the LMP control channels and traffic engineering links

Each flag can carry one or more of the following flag modifiers:

- `detail`—Provide detailed trace information
- `receive`—Packets being received
- `send`—Packets being transmitted

Configuring MPLS LSPs for GMPLS

IN THIS SECTION

- Configuring the Encoding Type | **1887**
- Configuring the GPID | **1888**
- Configuring the Signal Bandwidth Type | **1889**
- Configuring GMPLS Bidirectional LSPs | **1889**
- Allowing Nonpacket GMPLS LSPs to Establish Paths Through Routers Running Junos OS | **1889**

To enable the proper GMPLS switching parameters, configure the label-switched path (LSP) attributes that are appropriate for your network connection. The default value for `switching-type` is `psc-1`, which is also appropriate for standard MPLS.

To configure the LSP attributes, include the `lsp-attributes` statement at the `[edit protocols mpls label-switched-path` *`lsp-name`*`]` hierarchy level:

```
[edit protocols mpls label-switched-path lsp-name]
lsp-attributes {
    encoding-type type;
    gpid gpid;
    signal-bandwidth type;
    switching-type type;
}
```

If you include the `no-cspf` statement in the label-switched path configuration, you must also configure primary and secondary paths, or the configuration cannot be committed.

The following sections describe how to configure each of the LSP attributes for a GMPLS LSP:

Configuring the Encoding Type

You need to specify the encoding type of the payload carried by the LSP. It can be any of the following:

- `ethernet`—Ethernet
- `packet`—Packet
- `pdh`—Plesiochronous digital hierarchy (PDH)

- sonet-sdh—SONET/SDH

The default value is packet.

To configure the encoding type, include the encoding-type statement at the [edit protocols mpls label-switched-path *lsp-name* lsp-attributes] hierarchy level:

```
[edit protocols mpls label-switched-path lsp-name lsp-attributes]
encoding-type type;
```

Configuring the GPID

You need to specify the type of payload carried by the LSP. The payload is the type of packet underneath the MPLS label. The payload is specified by the generalized payload identifier (GPID).

You can specify the GPID with any of the following values:

- hdlc—High-Level Data Link Control (HDLC)
- ethernet—Ethernet
- ipv4—IP version 4 (default)
- pos-scrambling-crc-16—For interoperability with other vendors' equipment
- pos-no-scrambling-crc-16—For interoperability with other vendors' equipment
- pos-scrambling-crc-32—For interoperability with other vendors' equipment
- pos-no-scrambling-crc-32—For interoperability with other vendors' equipment
- ppp—Point-to-Point Protocol (PPP)

To configure the GPID, include the gpid statement at the [edit protocols mpls label-switched-path *lsp-name* lsp-attributes] hierarchy level:

```
[edit protocols mpls label-switched-path lsp-name lsp-attributes]
gpid gpid;
```

Configuring the Signal Bandwidth Type

The signal bandwidth type is the encoding used for path computation and admission control. To configure the signal bandwidth type, include the `signal-bandwidth` statement at the `[edit protocols mpls label-switched-path` *`lsp-name`* `lsp-attributes]` hierarchy level:

```
[edit protocols mpls label-switched-path lsp-name lsp-attributes]
signal-bandwidth type;
```

Configuring GMPLS Bidirectional LSPs

Because MPLS and GMPLS use the same configuration hierarchy for LSPs, it is helpful to know which LSP attributes control LSP functionality. Standard MPLS packet-switched LSPs are unidirectional, whereas GMPLS nonpacket LSPs are bidirectional.

If you use the default packet-switching type of `psc-1`, your LSP becomes unidirectional. To enable a GMPLS bidirectional LSP, you must select a non-packet-switching type option, such as `lambda`, `fiber`, or `ethernet`. Include the `switching-type` statement at the `[edit protocols mpls label-switched-path` *`lsp-name`* `lsp-attributes]` hierarchy level:

```
[edit protocols mpls label-switched-path lsp-name lsp-attributes]
switching-type (lambda | fiber | ethernet);
```

Allowing Nonpacket GMPLS LSPs to Establish Paths Through Routers Running Junos OS

By setting the A-bit in the Admin Status object. you can enable nonpacket GMPLS LSPs to establish paths through routers that run Junos. When an ingress router sends an RSVP PATH message with the Admin Status A-bit set, an external device (not a router running the Junos OS) can either perform a Layer 1 path setup test or help bring up an optical cross-connect.

When set, the A-bit in the Admin Status object indicates the administrative down status for a GMPLS LSP. This feature is used specifically by nonpacket GMPLS LSPs. It does not affect control path setup or data forwarding for packet LSPs.

Junos does not distinguish between the control path setup and data path setup. Other nodes along the network path use RSVP PATH signaling using the A-bit in a meaningful way.

To configure the Admin Status object for a GMPLS LSP, include the `admin-down` statement:

```
admin-down;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls label-switched-path *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name*]

Gracefully Tearing Down GMPLS LSPs

IN THIS SECTION

- Temporarily Deleting GMPLS LSPs | **1890**
- Permanently Deleting GMPLS LSPs | **1891**
- Configuring the Graceful Deletion Timeout Interval | **1891**

You can gracefully tear down nonpacket GMPLS LSPs. An LSP that is torn down abruptly, a common process in a packet-switched network, can cause stability problems in nonpacket-switched networks. To maintain the stability of nonpacket-switched networks, it might be necessary to tear down LSPs gracefully.

The following sections describe how to tear down GMPLS LSPs gracefully:

Temporarily Deleting GMPLS LSPs

You can gracefully tear down a GMPLS LSP using the `clear rsvp session gracefully` command.

This command gracefully tears down an RSVP session for a nonpacket LSP in two passes. In the first pass, the Admin Status object is signaled along the path to the endpoint of the LSP. During the second pass, the LSP is taken down. Using this command, the LSP is taken down temporarily. After the appropriate interval, the GMPLS LSP is resignaled and then reestablished.

The `clear rsvp session gracefully` command has the following properties:

- It only works on the ingress and egress routers of an RSVP session. If used on a transit router, it has the same behavior as the `clear rsvp session` command.
- It only works for nonpacket LSPs. If used with packet LSPs, it has the same behavior as the `clear rsvp session` command.

For more information, see the CLI Explorer.

Permanently Deleting GMPLS LSPs

When you disable an LSP in the configuration, the LSP is permanently deleted. By configuring the `disable` statement, you can disable a GMPLS LSP permanently. If the LSP being disabled is a nonpacket LSP, then the graceful LSP tear-down procedures that use the Admin Status object are used. If the LSP being disabled is a packet LSP, then the regular signaling procedures for LSP deletion are used.

To disable a GMPLS LSP, include the `disable` statement at any of the following hierarchy levels:

- `[edit protocols mpls label-switched-path` *lsp-name*`]`—Disable the LSP.
- `[edit protocols link-management te-link` *te-link-name*`]`—Disable a traffic engineering link.
- `[edit protocols link-management te-link` *te-link-name* `interface` *interface-name*`]`—Disable an interface used by a traffic engineering link.

Configuring the Graceful Deletion Timeout Interval

The router that initiates the graceful deletion procedure for an RSVP session waits for the graceful deletion timeout interval to ensure that all routers along the path (especially the ingress and egress routers) have prepared for the LSP to be taken down.

The ingress router initiates the graceful deletion procedure by sending the Admin Status object in the path message with the `D` bit set. The ingress router expects to receive an Resv message with the `D` bit set from the egress router. If the ingress router does not receive this message within the time specified by the graceful deletion timeout interval, it initiates a forced tear-down of the LSP by sending a PathTear message.

To configure the graceful deletion timeout interval, include the `graceful-deletion-timeout` statement at the `[edit protocols rsvp]` hierarchy level. You can configure a time between 1 through 300 seconds. The default value is 30 seconds.

```
graceful-deletion-timeout seconds;
```

You can configure this statement at the following hierarchy levels:

- `[edit protocols rsvp]`
- `[edit logical-systems` *logical-system-name* `protocols rsvp]`

You can use the `show rsvp version` command to determine the current value configured for the graceful deletion timeout.

GMPLS RSVP-TE VLAN LSP Signaling Overview

- Supported and Unsupported Features | **1898**

Understanding GMPLS RSVP-TE Signaling

Signaling is the process of exchanging messages within the control plane to set up, maintain, modify, and terminate data paths (label-switched paths (LSPs)) in the data plane. Generalized MPLS (GMPLS) is a protocol suite that extends the existing control plane of MPLS to manage further classes of interfaces and to support other forms of label switching, such as time-division multiplexing (TDM), fiber (port), Lambda, and so on.

GMPLS extends intelligent IP/MPLS connections from Layer 2 and Layer 3 all the way to Layer 1 optical devices. Unlike MPLS, which is supported mainly by routers and switches, GMPLS can also be supported by optical platforms, including SONET/SDH, optical cross-connects (OXCs), and dense wave division multiplexing (DWDM).

In addition to labels, which are primarily used to forward data in MPLS, other physical entries, such as wavelengths, time slots, and fibers can be used as label objects to forward data in GMPLS, thereby leveraging the existing control plane mechanisms to signal different kinds of LSPs. GMPLS uses RSVP-TE to be able to request the other label objects to signal the various kinds of LSPs (nonpacket). Bidirectional LSPs and an out-of-band control channel and a data channel using the Link Management Protocol (LMP) are the other mechanisms that are used by GMPLS to establish LSPs.

Need for GMPLS RSVP-TE VLAN LSP Signaling

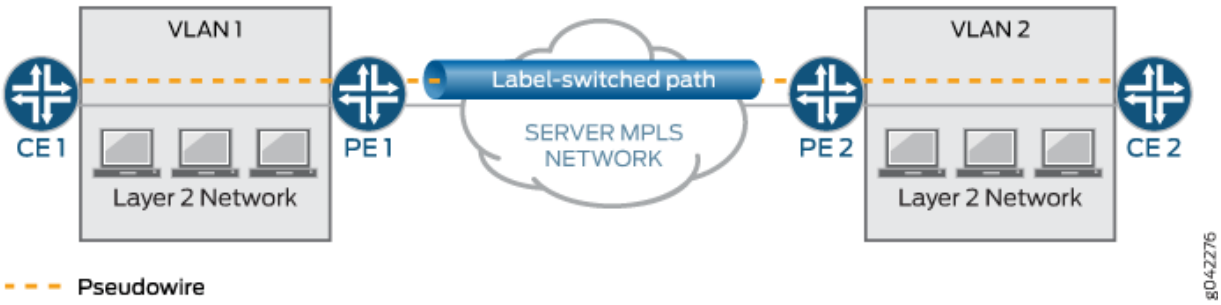
The traditional Layer 2 point-to-point services use Layer 2 circuits and Layer 2 VPN technologies that are based on LDP and BGP. In the traditional deployment, the customer edge (CE) devices do not

participate in the signaling of the Layer 2 service. The provider edge (PE) devices manage and provision the Layer 2 service to provide end-to-end connectivity between the CE devices.

One of the biggest challenges of having the PE devices provision the Layer 2 services for each Layer 2 circuit between a pair of CE devices is the network management burden on the provider network.

Figure 118 on page 1893 illustrates how the Layer 2 service is set up and used by the CE routers in a LDP/BGP-based Layer 2 VPN technology. Two CE routers CE1 and CE2 are connected to a provider MPLS network through the PE routers PE1 and PE2 respectively. The CE routers are connected to the PE routers by Ethernet links. Routers CE1 and CE2 are configured with VLAN1 and VLAN2 logical Layer 3 interfaces, so they appear to be directly connected. Routers PE1 and PE2 are configured with Layer 2 circuit (pseudowire) to carry the Layer 2 VLAN traffic between the CE routers. The PE routers use packet MPLS LSPs within the provider MPLS network to carry the Layer 2 VLAN traffic.

Figure 118: Traditional Layer 2 Point-to-Point Services



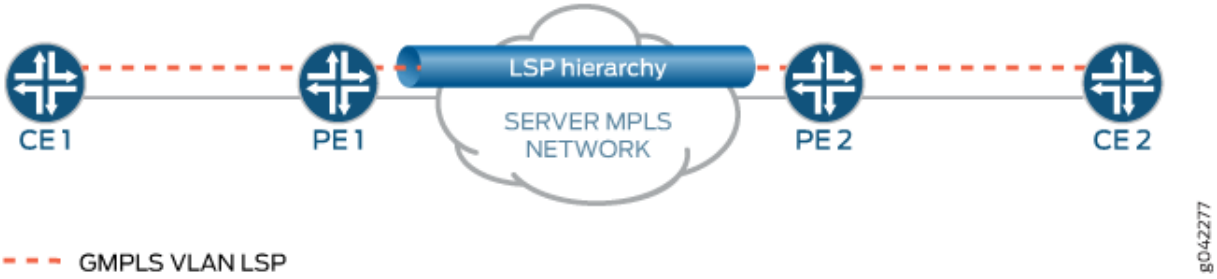
With the introduction of GMPLS-based VLAN LSP signaling, the need for the PE (also called server-layer) network to provision each individual Layer 2 connection between the CE (also called client) devices is minimized. The client router requests the server-layer router to which it is directly connected, for setting up the Layer 2 service to connect with a remote client router through GMPLS signaling.

The server-layer devices extend the signaling through the server-layer network to connect with the remote client routers. In the process, the server-layer device sets up the data plane for the Layer 2 service at the server-client border, and sets up the data plane for carrying the Layer 2 traffic within the server-layer network. With the Layer 2 service setup, the client routers can run IP/MPLS directly on top of the Layer 2 service and have IP/MPLS adjacency with each other.

In addition to reducing the provisioning activity needed on the server-layer devices, GMPLS signaling also provides the client routers with the flexibility of bringing up the Layer 2 circuits on an on-demand basis without depending on the server-layer administration for the provisioning of the Layer 2 service.

Using the same topology as in Figure 1, Figure 119 on page 1894 illustrates how the Layer 2 service is set up and used by the client routers in GMPL RSVP-TE-based Layer 2 VPN technology.

Figure 119: GMPLS RSVP-TE VLAN LSP



In Figure 119 on page 1894, instead of configuring a pseudowire to carry the Layer 2 VLAN traffic between the client routers, Routers PE1 and PE2 are configured with an IP-based communication channel and other GMPLS-specific configurations (identification of Ethernet links as TE-links) for allowing the exchange of GMPLS RSVP-TE signaling messages with the client routers. Routers CE1 and CE2 are also configured with an IP-based communication channel and relevant GMPLS configuration for exchanging the GMPLS RSVP-TE signaling messages with the server-layer routers. Routers CE1 and CE2 establish an IP/MPLS adjacency on top of this Layer 2 service.

GMPLS RSVP-TE VLAN LSP Signaling Functionality

Based on Figure 119 on page 1894, the client router establishes the Layer 2 service in the server-layer network as follows:

1. Router CE1 initiates GMPLS RSVP-TE signaling with Router PE1. In this signaling message, Router CE1 indicates the VLAN on the Ethernet link for which it needs the Layer 2 service and the remote CE router, Router CE2, with which the VLAN should be connected.

   Router CE1 also indicates the remote PE router, Router PE2, to which Router CE2 is connected, and the exact Ethernet link connecting Router CE2 to Router PE2 on which the Layer 2 service is required in the signaling message.

2. Router PE1 uses the information from Router CE1 in the signaling message and determines the remote PE router, Router PE2, with which Router CE2 is attached. Router PE1 then establishes a packet MPLS LSP (associated bidirectional) through the server-layer MPLS network for carrying the VLAN traffic and then passes the GMPLS RSVP-TE signaling message to Router PE2 using the LSP hierarchy mechanism.

3. Router PE2 propagates the GMPLS RSVP-TE signaling message to Router CE2 with the VLAN to be used on the PE2-CE2 Ethernet link.
4. Router CE2 responds with an acknowledgment to the GMPLS RSVP-TE signaling message to Router PE2. Router PE2 then propagates it to Router PE1, which in turn propagates it to Router CE1.
5. As part of this message propagation, Routers PE1 and PE2 set up the forwarding plane to enable bidirectional flow of VLAN Layer 2 traffic between Routers CE1 and CE2.

LSP Hierarchy with GMPLS RSVP-TE VLAN LSP

The Layer 2 service in GMPLS RSVP-TE VLAN LSP signaling is brought up using a hierarchy mechanism in which two different RSVP LSPs are created for the Layer 2 service:

- An end-to-end VLAN LSP that has state information at the client and server-layer routers.
- An associated bidirectional packet transport LSP that is present in the server-layer routers (PE and P) of the server-layer network.

The LSP hierarchy avoids sharing information about technology-specific LSP characteristics with the core nodes of the server-layer network. This solution cleanly separates the VLAN LSP state and the transport LSP state, and ensures that the VLAN LSP state is only present on the nodes (PE, CE) where it is needed.

Path Specification for GMPLS RSVP-TE VLAN LSP

The path for the GMPLS RSVP-TE LSP is configured as an Explicit Route Object (ERO) at the initiating client router. As this LSP traverses different network domains (initiating, terminating at client network, and traversing the server-layer network), the LSP setup falls under the category of an interdomain LSP setup. In an interdomain scenario, one network domain generally does not have full visibility into the topology of the other network domain. Hence, the ERO that gets configured at the initiating client router does not have full hop information for the server-layer portion. This feature requires that the ERO configured at the CE router has three hops, with the first hop being a strict hop identifying the CE1-PE1 Ethernet link, the second hop being a loose hop identifying the egress PE router (PE2), and the third hop being a strict hop identifying the CE2-PE2 Ethernet link.

GMPLS RSVP-TE VLAN LSP Configuration

The configuration required to set up a GMPLS VLAN LSP at the client and server routers uses the existing GMPLS configuration model with some extensions. The Junos OS GMPLS configuration model for nonpacket LSPs is targeted toward bringing the physical interfaces up and running through GMPLS RSVP-TE signaling, whereas signaling a GMPLS RSVP-TE VLAN LSP aims at bringing up individual VLANs on top of a physical interface. The `ethernet-vlan` configuration statement under the `[edit protocols link-management te-link]` hierarchy enables this.

The client router has physical interfaces connected to a server network, and the server network provides a point-to-point connection between two client routers over the attached physical interfaces. The physical interface is brought into an operational state by GMPLS RSVP-TE as follows:

1. The client router maintains a routing or signaling adjacency with the server network node to which the physical interface is connected, typically through a control channel different from the physical interface, because the physical interface itself is brought up and running only after the signaling.

2. The client router and the server network node identify the physical interfaces connecting them using the TE-link mechanism.

3. The client router and the server network node use the TE-link identifier (IP address) as the GMPLS RSVP hop and the physical interface identifier as the GMPLS label values in the GMPLS RSVP-TE signaling messages to bring the physical interface into an operational state.

In the existing GMPLS configuration, the server and client network nodes use the `protocols link-management peer` *`peer-name`* configuration statement to specify the adjacent peer node. Because a client router can have one or more physical interfaces connected to the server network node, these physical interfaces are grouped and identified by an IP address through the `protocols link-management te-link` *`link-name`* configuration statement. The TE-link is assigned a local IP address, a remote IP address, and a list of physical interfaces. The TE-link is then associated with the `protocols link-management peer` *`peer-name`* `te-link` *`te-link-list`* configuration statement.

The out-of-band control channel that is required for exchanging signaling messages is specified using the `protocols link-management peer` *`peer-name`* `control-channel` *`interface-name`* configuration statement. The existence of the server or client network node is made visible to the RSVP and IGP (OSPF) protocols through the `peer-interface` *`interface-name`* configuration statement under the `[edit protocols rsvp]` and `[edit protocols ospf]` hierarchy levels.

In the existing GMPLS configuration, the label (upstream label and resv label) that is carried in the signaling message is an integer identifier that identifies the physical interface that is required to be brought up. As the label is used to identify the physical interface, the existing GMPLS configuration allows multiple interfaces to be grouped under a single TE-link. In the existing GMPLS configuration, there is sufficient information in the GMPLS RSVP-TE signaling message, such as TE-link address and label value, to identify the physical interface that is required to be brought up. In contrast, for GMPLS RSVP-TE VLAN LSP configuration, the VLAN ID value is used as the label in the signaling message.

In the GMPLS RSVP-TE VLAN LSP configuration, if multiple interfaces are allowed to be configured under a single TE-link, using VLAN ID as the label value in the signaling message can cause ambiguity as to which physical interface on which the VLAN has to be provisioned. Therefore, the TE-link is configured with the `ethernet-vlan` configuration statement, if the number of physical interfaces that can be configured under the TE-link is restricted to only one.

In the existing GMPLS configuration, the bandwidth for a nonpacket LSP is a discrete quantity that corresponds to the bandwidth of the physical interface that needs to be brought up. So, the GMPLS LSP configuration does not allow any bandwidth to be specified, but allows the bandwidth to be specified

only through the `signal-bandwidth` configuration statement under the `[protocols mpls label-switched-path lsp-name lsp-attributes]` hierarchy level. In the GMPLS VLAN LSP configuration, bandwidth is specified similar to that of a packet LSP. In the GMPLS VLAN LSP configuration, the `bandwidth` option is supported and `signal-bandwidth` is not supported.

Associated Bidirectional Packet LSP

The GMPLS RSVP-TE VLAN LSP is carried on an associated bidirectional transport LSP within the server-layer network, which is a single-sided provisioned LSP. The transport LSP signaling is initiated as a unidirectional LSP from the source router to the destination router in the forward direction, and the destination router in turn initiates the signaling of the unidirectional LSP in the reverse direction back to the source router.

Make-Before-Break for Associated Bidirectional Packet and GMPLS RSVP-TE VLAN LSP

The make-before-break support for an associated bidirectional transport LSP follows a similar model, where the destination router for the forward direction of the bidirectional LSP does not perform any make-before-break operations on the reverse direction of the bidirectional LSP. It is the source router (initiator of the associated bidirectional LSP) that initiates the make-before-break newer instance of the associated bidirectional LSP, and the destination router in turn initiates the make-before-break newer instance in the other direction.

For instance, in Figure 119 on page 1894, the unidirectional transport LSP is initiated from Router PE1 to Router PE2 in the forwarding direction, and in turn Router PE2 initiates the transport LSP to Router PE1 in the reverse direction. When a make-before-break instance occurs, only Router PE1 as the initiating client router can establish a new instance of the associated bidirectional LSP. Router PE2 in turn initiates the make-before-break newer instance in the reverse direction.

The make-before-break support for the associated bidirectional transport LSP is used only in scenarios where the transport LSP gets into a state of being locally protected due to link or node failure on the path of the LSP. The GMPLS RSVP-TE VLAN LSP uses the make-before-break mechanism for adjusting seamless bandwidth changes.

NOTE: Periodic re-optimization is not enabled for the associated bidirectional transport LSPs.

The newer make-before-break instance of the GMPLS VLAN LSP is supported under the following constraints:

- It should originate from the same client router as the older instance and be destined to the same client router as the older instance.
- It should use the same server-client links at both the server-client ends as the older instance.

- It should use the same VLAN label at the server-client links as the older instance.
- The GMPLS VLAN LSP should be configured as `adaptive` when the bandwidth change is initiated from the CLI, or else the current instance of the VLAN LSP is torn down and a new VLAN LSP instance is established.

The make-before-break operation for the GMPLS VLAN LSP on the server-layer edge router is rejected if these constraints are not met.

On the server-layer edge routers, when a make-before-break instance of the GMPLS VLAN LSP is seen, a completely new, separate associated bidirectional transport LSP is created to support this make-before-break instance. The existing associated bidirectional LSP (supporting the older instance) is not triggered to initiate a make-before-break instance at the transport LSP level. An implication of this choice (of initiating a new transport LSP) is that at the server-layer resource/bandwidth sharing does not happen when a make-before-break operation is performed for the GMPLS VLAN LSP.

Supported and Unsupported Features

Junos OS supports the following features with the GMPLS RSVP-TE VLAN LSP:

- Request for specific bandwidth and local protection for the VLAN LSP on the client router to the server-layer router.
- Nonstop active routing (NSR) support for the GMPLS VLAN LSP at the client routers, server-layer edge routers, and associated bidirectional transport LSP at the server-layer edge routers.
- Multichassis support.

Junos OS does **not** support the following GMPLS RSVP-TE VLAN LSP functionality:

- Graceful restart support for associated bidirectional packet LSP and GMPLS VLAN LSP.
- End-to-end path computation for GMPLS VLAN LSP using CSPF algorithm at the client router.
- Non-CSPF routing-based discovery of next-hop routers by the different client, server-layer edge routers.
- Automatic provisioning of the client Layer 3 VLAN interfaces upon the successful setup of the VLAN LSP at the client routers.
- MPLS OAM (LSP-ping, BFD).
- Packet MPLS applications, such as next-hop in static route and in IGP shortcuts.
- Local cross connect mechanism, where a client router connects to a remote client router which is connected to the same server router.
- Junos OS Services Framework.

- IPv6 support.
- Logical systems.
- Aggregated Ethernet/SONET/IRB interfaces at the server-client link.

Example: Configuring GMPLS RSVP-TE VLAN LSP Signaling

IN THIS SECTION

- Requirements | **1899**
- Overview | **1900**
- Configuration | **1907**
- Verification | **1923**

This example shows how to configure GMPLS RSVP-TE VLAN LSP signaling on the client routers to enable one client router to connect with a remote client router through a server-layer network using the LSP hierarchy. This enables the client routers to establish, maintain, and provision the Layer 2 services, without depending on the server-layer administration, thereby reducing the burden on the operational expenses of the provider network.

Requirements

This example uses the following hardware and software components:

- Six routers that can be a combination of M Series Multiservice Edge Routers, MX Series 5G Universal Routing Platforms, T Series Core Routers, and PTX Series Packet Transport Routers
- Junos OS Release 14.2 or later running on the client routers and server-layer edge routers

Before you begin:

1. Configure the device interfaces.
2. Configure the interface-associated VLANs.
3. Configure the following routing protocols:
   - RSVP
   - MPLS
   - LMP

Overview

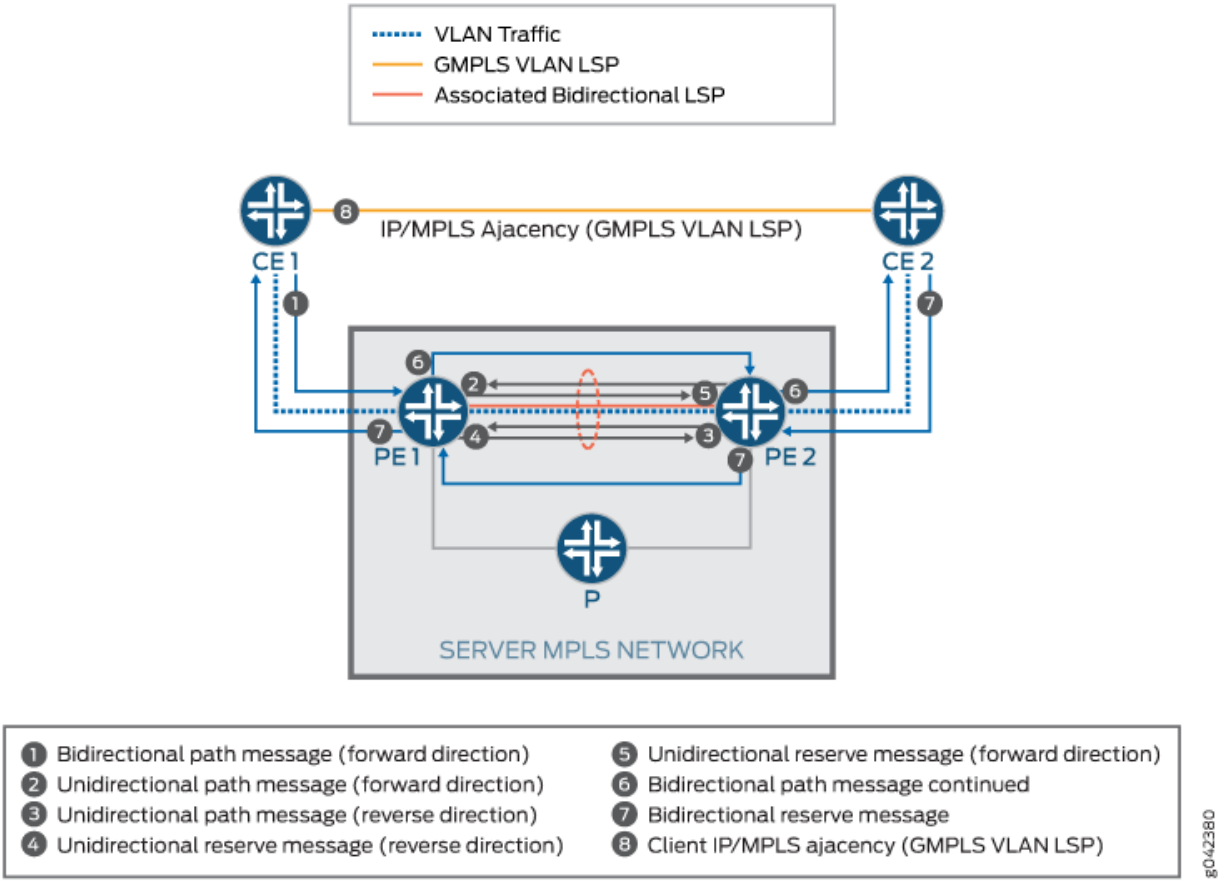
IN THIS SECTION

- Topology | **1906**

Starting with Junos OS Release 14.2, the Layer 2 services between two client routers across an external/third-party server-layer network are set up by the client routers on an on-demand basis through GMPLS RSVP-TE signaling. This feature provides the client routers the flexibility to establish, maintain, and provision the Layer 2 services, without depending on the server-layer administration, thereby reducing the burden on the operational expenses of the provider network. In traditional Layer 2 VPN technology based on LDP and BGP, the provider network handled the provisioning activity for each Layer 2 circuit established between two client routers.

Figure 120 on page 1901 illustrates the setting up and signaling of the GMPLS VLAN LSP between two client routers, CE1 and CE2, across a server-layer network with two server-layer edge routers, PE1 and PE2, and one server-layer core router, P.

Figure 120: Setting Up a GMPLS VLAN LSP



The signaling of GMPLS VLAN LSP is executed as follows:

1. `Initiating GMPLS VLAN LSP at CE1`

   Router CE1 initiates the GMPLS VLAN LSP setup by sending the GMPLS RSVP-TE path message to Router PE1. The signaling between CE1 and PE1 is over an out-of-band control channel, which is a separate control VLAN configured on the Ethernet link connecting the two routers.

   The GMPLS RSVP-TE path message initiated by Router CE1 is used to perform the following:

   a. Identify the Ethernet link on which the VLAN is active.

   b. Abstract the Ethernet link as a TE-link and assign an IP address to identify the Ethernet link.

c. Allocate a VLAN ID from the pool of free VLANs managed by Router CE1 for every Ethernet link connecting Router PE1 to the identified Ethernet link.

   This VLAN ID can also be used for the GMPLS VLAN LSP at the CE2-PE2 Ethernet link.

d. Identify the VLAN for which the Layer 2 service is required to be set up using the allocated VLAN ID as the upstream label object and the upstream direction label value.

e. Include an ERO object that helps Router PE1 in establishing the VLAN LSP through the server-layer network to the remote client router, CE2. The ERO object in the path message includes three hops:

   - First hop—Strict hop identifying the initiating client-server Ethernet link, PE1-CE1.
   - Second hop—Loose hop identifying the remote server-layer router, PE2.
   - Third hop—Strict hop identifying the remote clinet-server Ethernet link, PE2-CE2.

f. Include the bandwidth required for the GMPLS VLAN LSP.

g. Include any local-protection required within the server-layer network for the VLAN LSP.

2. `Initiating Associated Bidirectional Transport LSP at PE1`

   After Router PE1 receives the path message from Router CE1, the message is validated to check the availability of the Ethernet link and VLAN ID. In the server-layer network, the Layer 2 services between the server-layer routers, PE1 and PE2, are provided at the data plane in a manner similar to Layer 2 circuits. Router PE1 brings up a transport LSP to Router PE2 and then extends the GMPLS VLAN LSP as a hierarchical LSP running on top of the PE1-PE2 transport LSP. The PE1-PE2 transport LSP is a packet LSP and is bidirectional in nature. This is because the GMPLS VLAN LSP is bidirectional and each server-layer router needs to be able to do the following:

   - Receive traffic from the server-client Ethernet link (for example, the PE1-CE1 link) and send it to the remote server-layer router, PE2.
   - Receive traffic from remote Router PE2 and send it on the PE1-CE1 Ethernet link.

   For each GMPLS VLAN LSP, a packet transport LSP is set up within the server-layer network. The transport LSP is exclusively used to carry traffic of the GMPLS VLAN LSP for which it was created. The transport LSP is dynamically created at the time of receiving the GMPLS VLAN LSP; thus, no configuration is required to trigger its creation. The transport LSP established for the VLAN LSP inherits the bandwidth and the local-protection attributes from the VLAN LSP.

   Router PE1 signals the PE1-PE2 transport LSP to Router PE2. Router PE1 determines the destination for the transport LSP from the loose hop specified in the ERO object of the GMPLS RSVP-TE path message from Router CE1 and then signals the VLAN LSP. However, if the PE1-PE2 transport LSP fails to establish, Router PE1 sends back a path error message to Router CE1, and the GMPLS VLAN LSP is not established as well.

3. **Setting Up the Associated Bidirectional Transport LSP Between the Server-Layer Routers**

   The associated bidirectional LSP between routers PE1 and PE2 consists of two unidirectional packet LSPs:

   - PE1-to-PE2
   - PE2-to-PE1

   Router PE1 initiates signaling of a unidirectional packet LSP to Router PE2. This unidirectional packet LSP constitutes the forward direction (PE1-to-PE2) of the associated bidirectional LSP, and the path message carries the Extended Association Object indicating this is a single-sided provisioning model. On receiving the path message for the LSP, Router PE2 responds with a Resv message and triggers the signaling of a unidirectional packet LSP to Router PE1 with the same path as (PE1-to-PE2) in the reverse direction. This unidirectional packet LSP uses the PE2-to-PE1 direction of the associated bidirectional LSP, and this path message carries the same Extended Association Object seen in the PE1-to-PE2 path message.

   When Router PE1 receives the Resv message for the PE1-to-PE2 unidirectional LSP and the path message for the PE2-to-PE1 unidirectional LSP, PE1 binds the PE1-to-PE2 and PE2-to-PE1 unidirectional LSPs by matching the Extended Association Objects carried in the respective path messages. For the path message for the PE2-to-PE1 unidirectional LSP, Router PE1 responds with the Resv Message. On receiving the Resv message for the PE1-to-PE2 LSP and the path message for the PE2-to-PE1 LSP, Router PE1 has established the associated bidirectional packet transport LSP.

4. **Setting Up the GMPLS VLAN LSP at Router PE1**

   After successfully establishing the transport LSP, Router PE1 triggers the signaling of the GMPLS VLAN LSP. Router PE1 sends the GMPLS RSVP-TE path message corresponding to the VLAN LSP directly to Router PE2, which is bidirectional in nature and includes the upstream label object.

   Router PE2 is not aware of the association between the transport LSP and the VLAN LSP. This association is indicated to Router PE2 by Router PE1.

5. **Setting Up the GMPLS VLAN LSP at Router PE2**

   On receiving the VLAN LSP path message from Router PE1, Router PE2 verifies the availability of the transport LSP. If the transport LSP is not available or the LSP setup is in progress, the VLAN LSP processing is put on hold. When the transport LSP is available, Router PE2 processes the VLAN LSP path message. The ERO object in this path message indicates that the next hop is a strict hop identifying the PE2-to-CE2 Ethernet link. The ERO object can indicate the VLAN ID to be used on the PE2-to-CE2 Ethernet link by Router PE2.

   Router PE2 appropriately allocates the VLAN ID to be sent as the upstream label in the VLAN LSP path message to Router CE2, and sends it through an out-of-band control channel.

6. **Processing the GMPLS VLAN LSP at Router CE2**

   On receiving the GMPLS RSVP-TE LSP from Router PE2, Router CE2 validates the availability of VLAN ID for allocation on the PE2-to-CE2 link. Router CE2 then allocates the VLAN ID for this VLAN LSP and sends back a Resv message to Router PE2 with the VLAN ID as the label object in the Resv message.

7. **Processing the GMPLS VLAN LSP at Router PE2**

   On receiving the Resv message from Router CE2, Router PE2 validates that the label object in the Resv message has the same VLAN ID as in the path message. Router PE2 then allocates a 20-bit MPLS label, which is included in the Resv message sent to Router PE1.

   Router PE2 then programs the forwarding plane with the entries to provide the Layer 2 service functionality.

   NOTE: For all the VLAN IDs that can be allocated as labels on the PE1-to-CE1 and PE2-CE2 Ethernet links, you must manually configure logical interfaces for circuit cross-connect (CCC) purposes on the server-layer edge routers and not for other families, such as IPv4, IPv6, or MPLS.

8. **Processing the GMPLS VLAN LSP at Router PE1**

   On receiving the Resv message for the VLAN LSP from Router PE2, Router PE1 sends a Resv message to Router CE1 with the same VLAN ID it received as the upstream label from Router CE1. Router PE1 programs the forwarding plane with the entries to provide the Layer 2 service functionality as Router PE2.

9. **Processing the GMPLS VLAN LSP at Router CE1**

   On receiving the Resv message from Router PE1, Router CE1 validates that the VLAN ID received in the Resv message matches the VLAN ID in the upstream label in the path message it sent. This completes the setup of the GMPLS VLAN LSP from Router CE1 to Router CE2.

   NOTE:

   - The GMPLS VLAN LSP setup does not result in the addition of any forwarding plane entries at the client routers, CE1 and CE2. Only the server-layer routers, PE1 and PE2, add the forwarding plane entries for the GMPLS VLAN LSP.

- There is no routing information exchange between the client and the server-layer routers. The client and server-layer routers do not exchange their network topology information with each other.

10. **Accounting for Bandwidth of the GMPLS VLAN LSP**

    On successfully setting up the GMPLS VLAN LSP, both the client and server-layer routers reduce the amount of available bandwidth on the server-client Ethernet links by the bandwidth amount allocated for the GMPLS VLAN LSP. This bandwidth accounting information is used for admission control purposes when additional GMPLS VLAN LSPs are brought up on the server-client Ethernet links.

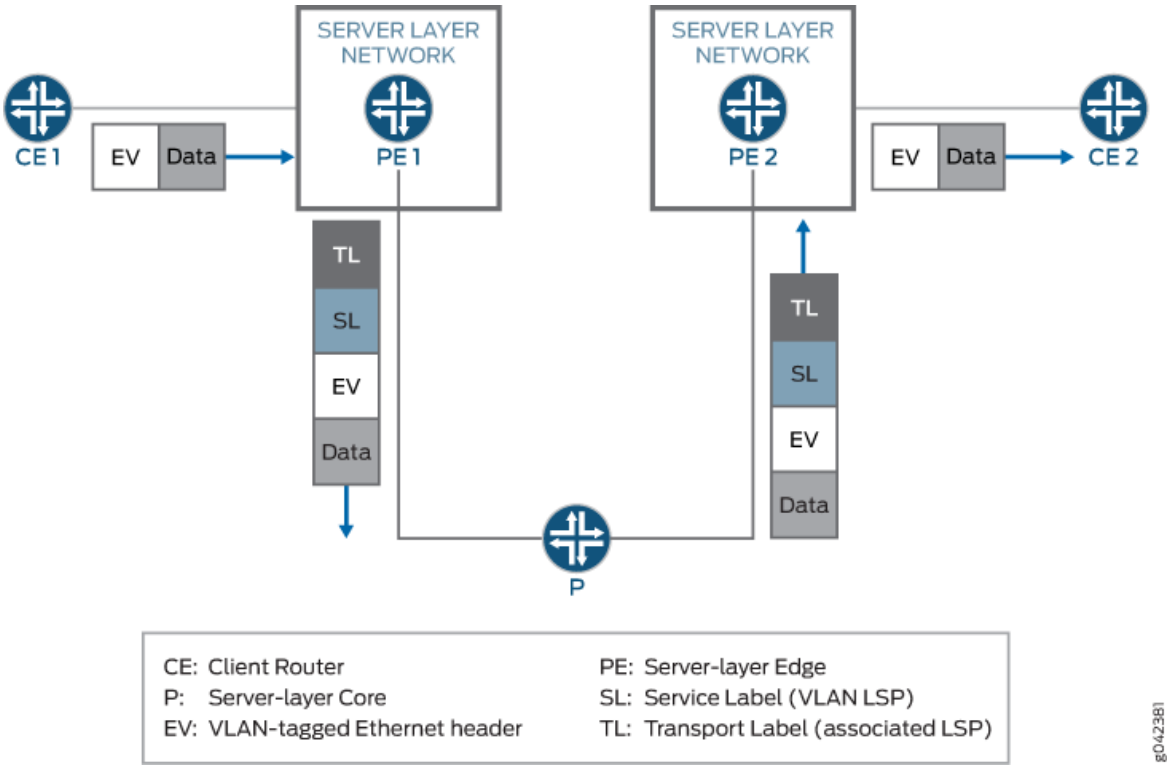
11. **Using GMPLS VLAN LSP by the Client Routers**

    After successfully setting up the GMPLS VLAN LSP, the client routers – CE1 and CE2 – need to be manually configured with the VLAN logical interface on top of the server-client Ethernet links with the signaled VLAN ID. This logical interface needs to be configured with the IP address and needs to be included in the IGP protocol. As a result of this configuration, Routers CE1 and CE2 establish IGP adjacency and exchange data traffic over the Layer 2 service established through the GMPLS signaling.

    Figure 121 on page 1906 illustrates the data traffic flow of the GMPLS VLAN LSP from Router CE1 to Router CE2 after the LSP setup is complete and the necessary CE1-to-CE2 IGP/MPLS adjacency has been established. The server-layer transport LSP originates from Router PE1, traverses a single server-layer core router, Router P, and reaches Router PE2. The server-layer transport LSP is shown

as a penultimate-hop pop LSP, where Router P pops off the transport LSP label, and only the service label is present on the P-to-PE2 link.

Figure 121: Data Traffic Flow of GMPLS VLAN LSP



Topology

In Figure 122 on page 1907, GMPLS RSVP-TE VLAN LSP signaling is used to establish the Layer 2 services between the client routers, Router CE1 and Router CE2. The server routers, Router PE1 and

Router PE2, have a GRE tunnel established with each of the directly connected client routers. Routers P1 and P2 are also server routers in the server-layer network.

Configuring the Client Router

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the CLI User Guide.

To configure Router CE1:

NOTE: Repeat this procedure for Router CE2 in the server-layer network, after modifying the appropriate interface names, addresses, and any other parameters for the router.

1. Configure the interface connecting Router CE1 to Router PE1.

```
[edit interfaces]
user@CE1# set ge-0/0/0 vlan-tagging
```

2. Configure the control VLAN for the ge-0/0/0 interface.

```
[edit interfaces]
user@CE1# set ge-0/0/0 unit 1 vlan-id 1
user@CE1# set ge-0/0/0 unit 1 family inet address 1.1.1.1/30
user@CE1# set ge-0/0/0 unit 1 family mpls
```

3. Configure the LSP VLAN on the ge-0/0/0 interface.

```
[edit interfaces]
user@CE1# set ge-0/0/0 unit 10 vlan-id 10
user@CE1# set ge-0/0/0 unit 10 family inet address 10.10.10.1/24
user@CE1# set ge-0/0/0 unit 10 family mpls
```

4. Configure the GRE tunnel as the controlling interface for Router CE1.

```
[edit interfaces]
user@CE1# set gre unit 0 tunnel source 1.1.1.1
user@CE1# set gre unit 0 tunnel destination 1.1.1.2
user@CE1# set gre unit 0 family inet address 10.35.100.25/30
```

5. Configure the loopback interface of Router CE1.

```
[edit interfaces]
user@CE1# set lo0 unit 0 family inet address 10.255.10.1/32
```

6. Configure the loopback address of Router CE1 as its router ID.

```
[edit routing-options]
user@CE1# set router-id 10.255.10.1
```

7. Enable RSVP on all the interfaces of Router CE1, excluding the management interface.

```
[edit protocols]
user@CE1# set rsvp interface all
user@CE1# set rsvp interface fxp0.0 disable
```

8. Configure the RSVP peer interface for Router CE1.

```
[edit protocols]
user@CE1# set rsvp peer-interface PE1
```

9. Disable automatic path computation for label-switched paths (LSPs).

```
[edit protocols]
user@CE1# set mpls no-cspf
```

10. Configure the LSP to connect Router CE1 to Router CE2.

```
[edit protocols]
user@CE1# set mpls label-switched-path CE1-to-CE2 from 10.255.10.1
user@CE1# set mpls label-switched-path CE1-to-CE2 to 10.255.10.6
```

11. Configure the CE1-to-CE2 LSP attributes.

```
[edit protocols]
user@CE1# set mpls label-switched-path CE1-to-CE2 lsp-attributes switching-type ethernet-
vlan
user@CE1# set mpls label-switched-path CE1-to-CE2 lsp-attributes upstream-label vlan-id 10
user@CE1# set mpls label-switched-path CE1-to-CE2 bandwidth 100m
```

12. Configure the CE1-to-CE2 LSP path and path parameters.

```
[edit protocols]
user@CE1# set mpls label-switched-path CE1-to-CE2 primary path1
user@CE1# set mpls path path1 10.35.1.2 strict
user@CE1# set mpls path path1 10.255.10.5 loose
user@CE1# set mpls path path1 10.36.1.1 strict
```

13. Enable MPLS on all the interfaces of Router CE1, excluding the management interface.

```
[edit protocols]
user@CE1# set mpls interface all
user@CE1# set mpls interface fxp0.0 disable
```

14. Configure a traffic engineering link, and assign addresses for the local and remote end of the link.

```
[edit protocols]
user@CE1# set link-management te-link link10 local-address 10.35.1.1
user@CE1# set link-management te-link link10 remote-address 10.35.1.2
```

15. Enable setting up of Layer 2 VLAN LSP on the link10 traffic engineering link.

```
[edit protocols]
user@CE1# set link-management te-link link10 ethernet-vlan
```

16. Configure the Router CE1 interface as the member interface of the link10 traffic engineering link.

```
[edit protocols]
user@CE1# set link-management te-link link10 interface ge-0/0/0
```

17. Configure Router PE1 as the Link Management Protocol (LMP) peer for Router CE1, and configure the peer attributes.

```
[edit protocols]
user@CE1# set link-management peer PE1 address 10.255.10.2
user@CE1# set link-management peer PE1 control-channel gre.0
user@CE1# set link-management peer PE1 te-link link10
```

Results

From configuration mode, confirm your configuration by entering the `show interfaces`, `show routing-options`, and `show protocols` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@CE1# show interfaces
ge-0/0/0 {
    vlan-tagging;
    unit 1 {
        vlan-id 1;
        family inet {
            address 1.1.1.1/30;
        }
        family mpls;
    }
    unit 10 {
        vlan-id 10;
        family inet {
            address 10.10.10.1/24;
```

```
        }
        family mpls;
    }
}
gre {
    unit 0 {
        tunnel {
            source 1.1.1.1;
            destination 1.1.1.2;
        }
        family inet {
            address 10.35.100.25/30;
        }
    }
}
lo0 {
    unit 0 {
        family inet {
            address 10.255.10.1/32;
        }
    }
}
```

```

        te-link link10;
    }
}
```

Configuring the Server Router

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the CLI User Guide.

To configure Router PE1:

NOTE: Repeat this procedure for Router PE2 in the server-layer network, after modifying the appropriate interface names, addresses, and any other parameters for the router.

1. Configure the interface connecting Router PE1 to Router CE1.

```
[edit interfaces]
user@PE1# set ge-0/0/0 vlan-tagging
user@PE1# set ge-0/0/0 encapsulation flexible-ethernet-services
```

2. Configure the control VLAN for the ge-0/0/0 interface.

```
[edit interfaces]
user@PE1# set ge-0/0/0 unit 1 vlan-id 1
user@PE1# ge-0/0/0 unit 1 family inet address 1.1.1.2/30
user@PE1# set ge-0/0/0 unit 1 family mpls
```

3. Configure the LSP VLAN on the ge-0/0/0 interface.

```
[edit interfaces]
user@PE1# set ge-0/0/0 unit 10 encapsulation vlan-ccc
user@PE1# set ge-0/0/0 unit 10 vlan-id 10
```

4. Configure the interface connecting Router PE1 to the core routers (Router P1 and Router P2).

```
[edit interfaces]
user@PE1# set ge-0/0/1 unit 0 family inet address 70.70.70.1/30
user@PE1# set ge-0/0/1 unit 0 family mpls
user@PE1# set ge-0/0/2 unit 0 family inet address 20.20.20.1/30
user@PE1# set ge-0/0/2 unit 0 family mpls
```

5. Configure the GRE tunnel as the controlling interface for Router PE1.

```
[edit interfaces]
user@PE1# set gre unit 0 tunnel source 1.1.1.2
```

```
user@PE1# set gre unit 0 tunnel destination 1.1.1.1
user@PE1# set gre unit 0 family inet address 10.35.100.26/30
```

6. Configure the loopback interface of Router PE1.

```
[edit interfaces]
user@PE1# set lo0 unit 0 family inet address 10.255.10.2/32
```

7. Configure the loopback address of Router PE1 as its router ID.

```
[edit routing-options]
user@PE1# set router-id 10.255.10.2
```

8. Configure an associated bidirectional LSP, and enable unidirectional reverse LSP setup for single-sided provisioned forward LSP.

```
[edit protocols]
user@PE1# set rsvp associated-bidirectional-lsp single-sided-provisioning
```

9. Enable RSVP on all the interfaces of Router PE1, excluding the management interface.

```
[edit protocols]
user@PE1# set rsvp interface all
user@PE1# set rsvp interface fxp0.0 disable
```

10. Configure the RSVP peer interface for Router PE1, and enable dynamic setup of bidirectional packet LSP for transporting nonpacket GMPLS LSP.

```
[edit protocols]
user@PE1# set rsvp peer-interface CE1 dynamic-bidirectional-transport
```

11. Enable MPLS on all the interfaces of Router PE1, excluding the management interface.

```
[edit protocols]
user@PE1# set mpls interface all
user@PE1# set mpls interface fxp0.0 disable
```

12. Configure OSPF with traffic engineering capabilities.

```
[edit protocols]
user@PE1# set ospf traffic-engineering
```

13. Enable OSPF area 0 on all the interfaces of Router PE1, excluding the management interface.

```
[edit protocols]
user@PE1# set ospf area 0.0.0.0 interface all
user@PE1# set ospf area 0.0.0.0 interface fxp0.0 disable
```

14. Configure a traffic engineering link, and assign addresses for the local and remote end of the link.

```
[edit protocols]
user@PE1# set link-management te-link link1 local-address 10.35.1.2
user@PE1# set link-management te-link link1 remote-address 10.35.1.1
```

15. Enable setting up of a Layer 2 VLAN LSP for a specific range of VLANs on the link1 traffic engineering link.

```
[edit protocols]
user@PE1# set link-management te-link link1 ethernet-vlan vlan-id-range 1-1000
```

16. Configure the Router PE1 interface as the member interface of the link1 traffic engineering link.

```
[edit protocols]
user@CE1# set link-management te-link link1 interface ge-0/0/0
```

17. Configure Router CE1 as the LMP peer for Router PE1, and configure the peer attributes.

```
[edit protocols]
user@CE1# set link-management peer CE1 address 10.255.10.1
user@CE1# set link-management peer CE1 control-channel gre.0
user@CE1# set link-management peer CE1 te-link link1
```

Results

From configuration mode, confirm your configuration by entering the `show interfaces`, `show routing-options`, and `show protocols` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1# show interfaces
ge-0/0/0 {
    vlan-tagging;
    encapsulation flexible-ethernet-services;
    unit 1 {
        vlan-id 1;
        family inet {
            address 1.1.1.2/30;
        }
        family mpls;
    }
    unit 10 {
        encapsulation vlan-ccc;
        vlan-id 10;
    }
}

    }
}
```

Verification

IN THIS SECTION

- Verifying the Traffic Engineering Link Status on the Client Routers | **1923**
- Verifying the RSVP Session Status on the Client Routers | **1925**
- Verifying the LSP Status on the Server Router | **1926**
- Verifying the CCC Entries in the MPLS Routing Table of the Server Routers | **1927**
- Verifying End-to-End Connectivity | **1928**

Confirm that the configuration is working properly.

Verifying the Traffic Engineering Link Status on the Client Routers

Purpose

Verify the status of the traffic engineering link configured between Router CE1 and Router CE2.

Action

From operational mode, run the **show link-management** and the **show link-management te-link detail** commands.

```
user@CE1> show link-management
Peer name: PE1, System identifier: 50740
 State: Up, Control address: 10.255.10.2
 Hello interval: 150, Hello dead interval: 500

10.36.1.2, Encoding: Ethernet, Switching: EVPL, Minimum bandwidth: 0bps,
  Maximum bandwidth: 1000Mbps, Total bandwidth: 1000Mbps, Available bandwidth: 900Mbps
    Name                            State Local ID  Remote ID      Bandwidth Used  LSP-name
    ge-0/0/0                        Up       54183          0       1000Mbps  Yes  CE1-to-CE2
```

Meaning

The Link Management Protocol (LMP) peering has been established between the client routers, and the traffic engineering link is up on both Routers CE1 and CE2.

Verifying the RSVP Session Status on the Client Routers

Purpose

Verify the status of the RSVP sessions between Router CE1 and Router CE2.

Action

From operational mode, run the **show rsvp session** command.

```
user@CE1> show rsvp session
Ingress RSVP: 1 sessions
To              From            State   Rt Style Labelin Labelout LSPname
10.255.10.6     10.255.10.1     Up       0  1 FF       -       10 CE1-to-CE2 Bidir
Total 1 displayed, Up 1, Down 0

Egress RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0

Transit RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

```
user@CE2> show rsvp session
Ingress RSVP: 0 sessions
```

```
Total 0 displayed, Up 0, Down 0

Egress RSVP: 1 sessions
To              From            State   Rt Style Labelin Labelout LSPname
10.255.10.6     10.255.10.1     Up       0  1 FF      10        - CE1-to-CE2 Bidir
Total 1 displayed, Up 1, Down 0

Transit RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Meaning

The RSVP sessions are established between the ingress router, Router CE1, and the egress router, Router CE2.

Verifying the LSP Status on the Server Router

Purpose

Verify the status of the MPLS LSP on Router PE1.

Action

From operational mode, run the **show mpls lsp** command.

```
user@PE1> show mpls lsp
Ingress LSP: 1 sessions
To              From            State Rt P     ActivePath       LSPname
10.255.10.5     10.255.10.2     Up     0 *                      vlan:0:10:8176:10.255.10.2-
>10.255.10.5 Assoc-Bidir
Total 1 displayed, Up 1, Down 0

Egress LSP: 1 sessions
To              From            State   Rt Style Labelin Labelout LSPname
10.255.10.2     10.255.10.5     Up       0  1 FF       3        - vlan:0:10:8176:10.255.10.2-
>10.255.10.5:rev
Total 1 displayed, Up 1, Down 0

Transit LSP: 1 sessions
To              From            State   Rt Style Labelin Labelout LSPname
```

```
10.255.10.6     10.255.10.1     Up       0  1 FF      10   299808 CE1-to-CE2 Bidir
Total 1 displayed, Up 1, Down 0
```

Meaning

The CE1-to-CE2 LSP is established, and the output displays the LSP attributes.

Verifying the CCC Entries in the MPLS Routing Table of the Server Routers

Purpose

Verify the circuit cross-connect (CCC) interface entries in the MPLS routing table.

Action

From operational mode, run the **show route table mpls.0** and the **show route forwarding-table ccc *ccc-interface*** commands.

```
user@PE1> show route table mpls.0
mpls.0: 6 destinations, 6 routes (6 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

0                  *[MPLS/0] 1d 22:14:51, metric 1
                      Receive
1                  *[MPLS/0] 1d 22:14:51, metric 1
                      Receive
2                  *[MPLS/0] 1d 22:14:51, metric 1
                      Receive
13                 *[MPLS/0] 1d 22:14:51, metric 1
                      Receive
299824             *[RSVP/7/1] 17:32:07, metric 1
                    > via ge-0/0/0.10, Pop
ge-0/0/0.10        *[RSVP/7/1] 17:32:07, metric 1
                    > to 20.20.20.2 via ge-0/0/2.0, label-switched-path CE1-to-CE2
```

```
user@PE1> show route forwarding-table ccc ge-0/0/0.10
Routing table: default.mpls
MPLS:
Destination        Type RtRef Next hop           Type Index    NhRef Netif
```

```
ge-0/0/0.10  (CCC) user     0 20.20.20.2       Push 299808, Push 299872(top)      581     2
ge-0/0/2.0

Routing table: __mpls-oam__.mpls
MPLS:
Destination        Type RtRef Next hop           Type Index    NhRef Netif
default            perm     0                    dscd      534     1
```

Meaning

The output displays the CCC interface that is the client-router-facing interface and the next-hop details for that interface.

Verifying End-to-End Connectivity

Purpose

Verify the connectivity between Router CE1 and the remote client router, Router CE2.

Action

From operational mode, run the **ping** command.

```
user@CE1> ping 10.10.10.2
PING 10.10.10.2 (10.10.10.2): 56 data bytes
64 bytes from 10.10.10.2: icmp_seq=0 ttl=64 time=15.113 ms
64 bytes from 10.10.10.2: icmp_seq=1 ttl=64 time=13.353 ms
64 bytes from 10.10.10.2: icmp_seq=2 ttl=64 time=13.769 ms
64 bytes from 10.10.10.2: icmp_seq=3 ttl=64 time=10.341 ms
64 bytes from 10.10.10.2: icmp_seq=4 ttl=64 time=12.597 ms
^C
--- 10.10.10.2 ping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
round-trip min/avg/max/stddev = 10.341/13.035/15.113/1.575 ms
```

Meaning

The ping from Router CE1 to Router CE2 is successful.

Understanding Ethernet-over-MPLS (L2 Circuit)

IN THIS SECTION

- Ethernet-over-MPLS in Data Centers | **1931**

Ethernet-over-MPLS allows sending Layer 2 (L2) Ethernet frames transparently over MPLS. Ethernet-over-MPLS uses a tunneling mechanism for Ethernet traffic through an MPLS-enabled Layer 3 core. It encapsulates Ethernet protocol data units (PDUs) inside MPLS packets and forwards the packets, using label stacking, across the MPLS network This technology has applications in service provider, enterprise and data center environments. For disaster recovery purposes, data centers are hosted in multiple sites that are geographically distant and interconnected using a WAN network.

NOTE: A Layer 2 circuit is similar to a circuit cross-connect (CCC), except that multiple Layer 2 circuits can be transported over a single label-switched path (LSP) tunnel between two provider edge (PE) routers. In contrast, each CCC requires a dedicated LSP.

Ethernet-over-MPLS in Data Centers

For disaster recovery purposes, data centers are hosted in multiple sites that are geographically distant and interconnected using a WAN network. These data centers require L2 connectivity between them for the following reasons:

- To replicate the storage over Fiber Channel IP (FCIP). FCIP works only on the same broadcast domain.
- To run a dynamic routing protocol between the sites.
- To support High Availability clusters that interconnect the nodes hosted in the various data centers.

Configuring Ethernet over MPLS (Layer 2 Circuit) | 1932

Configuring Ethernet over MPLS (Layer 2 Circuit)

IN THIS SECTION

- Configuring the Local PE Switch for Port-Based Layer 2 Circuit (Pseudo-wire) | 1933
- Configuring the Remote PE Switch for Port-Based Layer 2 Circuit (Pseudo-wire) | 1934
- Configuring the Local PE Switch for VLAN-Based Layer 2 Circuit | 1935
- Configuring the Remote PE Switch for VLAN-Based Layer 2 Circuit | 1936

To implement Ethernet over MPLS, you must configure a Layer 2 circuit on the provider edge (PE) switches. No special configuration is required on the customer edge (CE) switches. The provider switches require MPLS and LDP to be configured on the interfaces that will be receiving and transmitting MPLS packets.

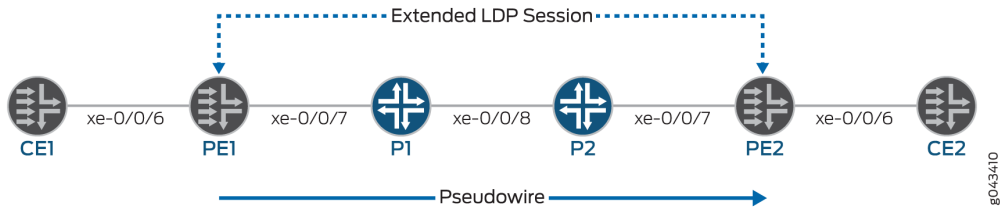
NOTE: A Layer 2 circuit is similar to a circuit cross-connect (CCC), except that multiple Layer 2 circuits can be transported over a single label-switched path (LSP) tunnel between two PE switches. In contrast, each CCC requires a dedicated LSP.

This topic describes how to configure the PE switches to support Ethernet over MPLS. You must configure interfaces and protocols on both the local PE (PE1) and the remote PE (PE2) switches. The interface configuration varies depending upon whether the Layer 2 circuit is port-based or VLAN-based.

Starting in Junos OS Release 20.3R1, support for Layer 2 circuit to provide Layer 2 VPN and VPWS with LDP signaling.

Figure 123 on page 1933 shows an example of a Layer 2 circuit configuration.

Figure 123: Ethernet over MPLS Layer 2 Circuit



NOTE: This topic refers to the local PE switch as PE1 and the remote PE switch as PE2. It also uses interface names rather than variables to help clarify the connections between the switches. The loopback addresses of the switches are configured as follows:

- PE1: 127.1.1.1
- PE2: 127.1.1.2

NOTE: On QFX Series and EX4600 switches, the Layer 2 circuit CE facing interface does not support AE interfaces.

Configuring the Local PE Switch for Port-Based Layer 2 Circuit (Pseudo-wire)

CAUTION: Configure MPLS networks with an MTU (maximum transmission unit) that is at least 12 bytes larger than the largest frame size that will be transported by the LSPs. If the size of a encapsulated packet on the ingress LSR exceeds the LSP MTU, that packet is dropped. If an egress LSR receives a packet on a VC LSP with a length (after the label stack and sequencing control word have been popped) that exceeds the MTU of the destination layer 2 interface, that packet is also dropped.

To configure the local PE switch (PE1) for a port-based layer 2 circuit (pseudo-wire):

1. Configure an access CE-facing interface for Ethernet encapsulation:

```
[edit interfaces]
user@switch# set xe-0/0/6 encapsulation ethernet-ccc
```

2. Configure the Layer 2 circuit from PE1 to PE2:

```
[edit protocols]
user@switch#set l2circuit neighbor 127.1.1.1 interface xe-0/0/6 virtual-circuit-id 1
```

3. Configure the label switched path from PE1 to PE2:

```
[edit protocols]
user@switch#set mpls label-switched-path PE1-to-PE2 to 127.1.1.1
```

4. Configure the protocols on the core and loopback interfaces:

```
[edit protocols]
user@switch#set mpls interface xe-0/0/7
user@switch#set ldp interface lo0.0
```

Configuring the Remote PE Switch for Port-Based Layer 2 Circuit (Pseudo-wire)

To configure the remote PE switch (PE2) for a port-based layer 2 circuit:

1. Configure an access CE-facing interface for Ethernet encapsulation:

```
[edit interfaces]
user@switch# set xe-0/0/6 encapsulation ethernet-ccc
```

2. Configure the Layer 2 circuit from PE2 to PE1:

```
[edit protocols]
user@switch#set l2circuit neighbor 127.1.1.2 interface xe-0/0/6 virtual-circuit-id 1
```

3. Configure the label switched path from PE2 to PE1:

```
[edit protocols]
user@switch#set mpls label-switched-path PE2-to-PE1 to 127.1.1.2
```

4. Configure the protocols on the core and loopback interfaces:

```
[edit protocols]
user@switch#set mpls interface xe-0/0/7
user@switch#set ldp interface lo0.0
```

Configuring the Local PE Switch for VLAN-Based Layer 2 Circuit

To configure the local PE switch (PE1) for a VLAN-based layer 2 circuit:

1. Configure an access CE-facing interface for VLAN encapsulation:

```
[edit interfaces]
user@switch# set xe-0/0/6 encapsulation vlan-ccc
```

2. Configure the logical unit of the CE-facing interface for VLAN encapsulation:

```
[edit interfaces]
user@switch# set xe-0/0/6 unit 0 encapsulation vlan-ccc
```

3. Configure the logical unit of the CE-facing interface to belong to family ccc:

```
[edit interfaces]
user@switch# set xe-0/0/6 unit 0 family ccc
```

4. Configure the same interface for VLAN tagging:

```
[edit interfaces]
user@switch# set xe-0/0/6 vlan-tagging
```

5. Configure the VLAN ID of the interface:

```
[edit interfaces]
user@switch# set xe-0/0/6 unit 0 vlan-id 600
```

6. Configure the Layer 2 circuit from PE1 to PE2:

```
[edit protocols]
user@switch#set l2circuit neighbor 127.1.1.1 interface xe-0/0/6 virtual-circuit-id 1
```

7. Configure the label switched path from PE1 to PE2:

```
[edit protocols]
user@switch#set mpls label-switched-path PE1-to-PE2 to 127.1.1.1
```

8. Configure the protocols on the core and loopback interfaces:

```
[edit protocols]
user@switch#set mpls interface xe-0/0/7
user@switch#set ldp interface lo0.0
```

Configuring the Remote PE Switch for VLAN-Based Layer 2 Circuit

To configure the remote PE switch (PE2) for a VLAN-based layer 2 circuit:

1. Configure an access CE-facing interface for VLAN encapsulation:

```
[edit interfaces]
user@switch# set xe-0/0/6 encapsulation vlan-ccc
```

2. Configure the logical unit of the CE-facing interface for VLAN encapsulation:

```
[edit interfaces]
user@switch# set xe-0/0/6 unit 0 encapsulation vlan-ccc
```

3. Configure the logical unit of the CE-facing interface to belong to family ccc:

```
[edit interfaces]
user@switch# set xe-0/0/6 unit 0 family ccc
```

4. Configure the same interface for VLAN tagging:

```
[edit interfaces]
user@switch# set xe-0/0/6 vlan-tagging
```

5. Configure the VLAN ID of the interface:

```
[edit interfaces]
user@switch# set xe-0/0/6 unit 0 vlan-id 600
```

6. Configure the Layer 2 circuit from PE2 to PE1:

```
[edit protocols]
user@switch#set l2circuit neighbor 127.1.1.2 interface xe-0/0/6 virtual-circuit-id 1
```

7. Configure the label switched path from PE2 to PE1:

```
[edit protocols]
user@switch#set mpls label-switched-path PE2-to-PE1 to 127.1.1.2
```

8. Configure the protocols on the core and loopback interfaces:

```
[edit protocols]
user@switch#set mpls interface xe-0/0/7
user@switch#set ldp interface lo0.0
```

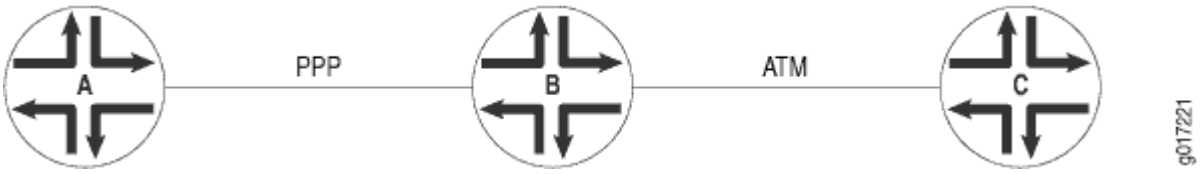
TCC and Layer 2.5 Switching Overview

Translational cross-connect (TCC) allows you to forward traffic between a variety of Layer 2 protocols or circuits. It is similar to its predecessor, CCC. However, while CCC requires the same Layer 2 encapsulations on both sides of a router (such as Point-to-Point Protocol [PPP] or Frame Relay-to-Frame Relay), TCC lets you connect different types of Layer 2 protocols interchangeably. With TCC, combinations such as PPP-to-ATM and Ethernet-to-Frame Relay cross-connections are possible. Also, TCC can be used to create Layer 2.5 VPNs and Layer 2.5 circuits.

Consider a sample topology (Figure 124 on page 1939) in which you can configure a full-duplex Layer 2.5 translational cross-connect between Router A and Router C, using a Juniper Networks router, Router B, as the TCC interface. In this topology, Router B strips all PPP encapsulation data from frames arriving from Router A and adds ATM encapsulation data before the frames are sent to Router C. All Layer 2 negotiations are terminated at the interconnecting router (Router B).

Figure 124: Sample Translation Cross-Connect Topology



TCC functionality is different from standard Layer 2 switching. TCC only swaps Layer 2 headers. No other processing, such as header checksums, time-to-live (TTL) decrementing, or protocol handling, is performed. Currently, TCC is supported in IPv4, ISO, and MPLS.

Ethernet TCC is supported on interfaces that carry IPv4 traffic only. For 8-port, 12-port, and 48-port Fast Ethernet PICs, TCC and extended VLAN CCC are not supported. For 4-port Gigabit Ethernet PICs, extended VLAN CCC and extended VLAN TCC are not supported.

Configuring VLAN TCC Encapsulation

VLAN TCC encapsulation allows circuits to have different media on either side of the forwarding path. VLAN TCC encapsulation supports TPID 0x8100 only. You must include configuration statements at the logical and physical interface hierarchy levels.

Starting in Junos OS Release 20.1R1, aggregated Ethernet interfaces support VLAN translational cross-connect (TCC) encapsulation. For configuring VLAN TCC encapsulation, you must have the member links of aggregated Ethernet with VLAN TCC encapsulation supported hardware.

NOTE: MX series routers does not perform any external commit check for member links of aggregated interfaces for the VLAN TCC encapsulation supported hardware.

To configure VLAN TCC encapsulation, include the `encapsulation` statement and specify the `vlan-tcc` option:

```
[edit interfaces interface-name unit logical-unit-number]
encapsulation vlan-tcc;
```

You can include this statement at the following hierarchy levels:

- `[edit interfaces interface-name unit logical-unit-number ]`
- `[edit logical-systems logical-system-name interfaces interface-name unit logical-unit-number]`

Additionally, configure the logical interface by including the `proxy` and `remote` statements:

```
proxy {
    inet-address;
}
remote {
    (inet-address | mac-address);
}
```

You can include these statements at the following hierarchy levels:

- `[edit interfaces interface-name unit logical-unit-number family tcc]`
- `[edit logical-systems logical-system-name interfaces interface-name unit logical-unit-number family tcc]`

The proxy address is the IP address of the non-Ethernet TCC neighbor for which the TCC router is acting as a proxy.

The remote address is the IP or MAC address of the remote router. The `remote` statement provides ARP capability from the TCC switching router to the Ethernet neighbor. The MAC address is the physical Layer 2 address of the Ethernet neighbor.

When VLAN TCC encapsulation is configured on the logical interface, you also must specify flexible Ethernet services on the physical interface. To specify flexible Ethernet services, include the `encapsulation`

statement at the `[edit interfaces interface-name]` hierarchy level and specify the `flexible-ethernet-services` option:

```
[edit interfaces interface-name]
encapsulation flexible-ethernet-services;
```

Extended VLAN TCC encapsulation supports TPIDs 0x8100 and 0x9901. Extended VLAN TCC is specified at the physical interface level. When configured, all units on that interface must use VLAN TCC encapsulation, and no explicit configuration is needed on logical interfaces.

One-port Gigabit Ethernet, 2-port Gigabit Ethernet, and 4-port Fast Ethernet PICs with VLAN tagging enabled can use VLAN TCC encapsulation. To configure the encapsulation on a physical interface, include the `encapsulation` statement at the `[edit interfaces interface-name]` hierarchy level and specify the `extended-vlan-tcc` option:

```
[edit interfaces interface-name]
encapsulation extended-vlan-tcc;
```

For VLAN TCC encapsulation, all VLAN IDs from 1 through 1024 are valid. VLAN ID 0 is reserved for tagging the priority of frames.

Extended VLAN TCC is not supported on 4-port Gigabit Ethernet PICs.

Configuring TCC Interface Switching

To configure a full-duplex Layer 2.5 translation cross-connect between two routers (A and C), you can configure a Juniper Networks router (Router B) as the TCC interface. Ethernet TCC encapsulation provides an Ethernet wide area circuit for interconnecting IP traffic. Consider the topology in Figure 125 on page 1941 where the Router A-to-Router B circuit is PPP, and the Router B-to-Router C circuit accepts packets carrying standard TPID values.

Figure 125: Sample Topology of Layer 2.5 Translational Cross-Connect

If traffic flows from Router A to Router C, the Junos OS strips all PPP encapsulation data from incoming packets and adds Ethernet encapsulation data before forwarding the packets. If traffic flows from Router C to Router A, the Junos OS strips all Ethernet encapsulation data from incoming packets and adds PPP encapsulation data before forwarding the packets.

To configure the router as the translational cross-connect interface:

1. In the configuration mode, at the [edit] hierarchy level, first configure the interface that is connected to Router A.

```
[edit]
user@host# edit interfaces interface-name
```

2. (Optional) Specify the description of the interface. For example, you could specify the interface name on Router A that is connected to this interface.

```
[edit interfaces interface-name]
user@host# set description description
```

3. Specify the encapsulation. If the Router A to Router B circuit is PPP, then specify ppp-tcc as the encapsulation. If the Router A to Router B circuit is frame relay, specify frame-relay-tcc.

```
[edit interfaces interface-name]
user@host# set encapsulation encapsulation-type
```

4. In the configuration mode, at the [edit] hierarchy level, first configure the interface that is connected to Router C.

```
[edit]
user@host# edit interfaces interface-name
```

5. (Optional) Specify the description of this interface. For example, you could specify the interface name on Router C that is connected to this interface.

```
[edit interfaces interface-name]
user@host# set description description
```

6. Specify the encapsulation. If the Router B to Router C circuit is Ethernet, then specify ethernet-tcc as the encapsulation. If the Router B to Router C circuit is ATM, specify atm-tcc-vc-mux.

```
[edit interfaces interface-name]
user@host# set encapsulation encapsulation-type
```

7. Specify the IP address or MAC address of the remote router to provide address resolution protocol (ARP) for the TCC router's Ethernet-based neighbor using the remote statement. You must specify the

statement at the [edit interfaces interface-name unit unit-number family tcc] hierarchy level. You can a specify the MAC address of the remote router instead of the IP address. The MAC address is the physical Layer 2 address of the Ethernet neighbor.

```
[edit interfaces interface-name]
user@host# set unit 0 family family remote inet-address ip-address
```

8. Specify the IP address of the non-Ethernet TCC neighbor for which the TCC router is acting as a proxy using the proxy statement. You must specify the statement at the [edit interfaces interface-name unit unit-number family tcc] hierarchy level.

```
[edit interfaces interface-name]
user@host# set unit 0 family family proxy inet-address ip-address
```

To verify the TCC connection, use the show connections command on TCC router.

CCC Overview

Circuit cross-connect (CCC) allows you to configure transparent connections between two circuits, where a circuit can be a Frame Relay data-link connection identifier (DLCI), an Asynchronous Transfer Mode (ATM) virtual circuit (VC), a Point-to-Point Protocol (PPP) interface, a Cisco High-Level Data Link Control (HDLC) interface, or an MPLS label-switched path (LSP). Using CCC, packets from the source circuit are delivered to the destination circuit with, at most, the Layer 2 address being changed. No other processing—such as header checksums, time-to-live (TTL) decrementing, or protocol processing—is done.

NOTE: The QFX10000 Series switches do not support ATM virtual circuits.

CCC circuits fall into two categories: logical interfaces, which include DLCIs, VCs, virtual local area network (VLAN) IDs, PPP and Cisco HDLC interfaces, and LSPs. The two circuit categories provide three types of cross-connect:

- Layer 2 switching—Cross-connects between logical interfaces provide what is essentially Layer 2 switching. The interfaces that you connect must be of the same type.
- MPLS tunneling—Cross-connects between interfaces and LSPs allow you to connect two distant interface circuits of the same type by creating MPLS tunnels that use LSPs as the conduit.
- LSP stitching—Cross-connects between LSPs provide a way to “stitch” together two label-switched paths, including paths that fall in two different traffic engineering database areas.

For Layer 2 switching and MPLS tunneling, the cross-connect is bidirectional, so packets received on the first interface are transmitted out the second interface, and those received on the second interface are transmitted out the first. For LSP stitching, the cross-connect is unidirectional.

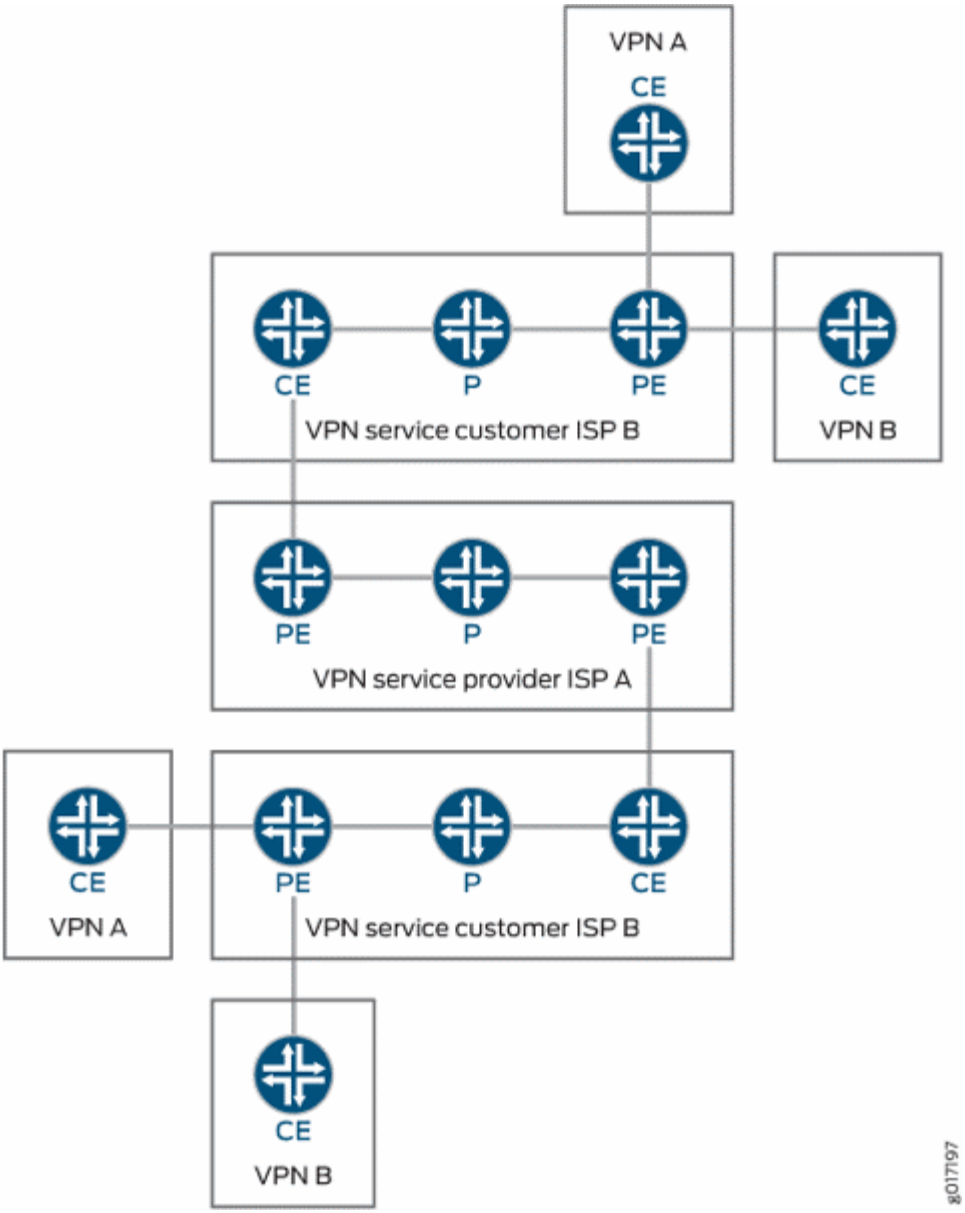
- Internet Service Provider as the Customer | **1945**
- VPN Service Provider as the Customer | **1946**

The customer of a VPN service provider might be a service provider for the end customer. The following are the two main types of carrier-of-carriers VPNs (as described in RFC 4364:

- "Internet Service Provider as the Customer" on page 1945—The VPN customer is an ISP that uses the VPN service provider's network to connect its geographically disparate regional networks. The customer does not have to configure MPLS within its regional networks.
- "VPN Service Provider as the Customer" on page 1946—The VPN customer is itself a VPN service provider offering VPN service to its customers. The carrier-of-carriers VPN service customer relies on the backbone VPN service provider for inter-site connectivity. The customer VPN service provider is required to run MPLS within its regional networks.

Figure 126 on page 1945 illustrates the network architecture used for a carrier-of-carriers VPN service.

Figure 126: Carrier-of-Carriers VPN Architecture



This topic covers the following:

Internet Service Provider as the Customer

In this type of carrier-of-carriers VPN configuration, ISP A configures its network to provide Internet service to ISP B. ISP B provides the connection to the customer wanting Internet service, but the actual Internet service is provided by ISP A.

This type of carrier-of-carriers VPN configuration has the following characteristics:

- The carrier-of-carriers VPN service customer (ISP B) does not need to configure MPLS on its network.
- The carrier-of-carriers VPN service provider (ISP A) must configure MPLS on its network.
- MPLS must also be configured on the CE routers and PE routers connected together in the carrier-of-carriers VPN service customer's and carrier-of-carriers VPN service provider's networks.

VPN Service Provider as the Customer

A VPN service provider can have customers that are themselves VPN service providers. In this type of configuration, also called a hierarchical or recursive VPN, the customer VPN service provider's VPN-IPv4 routes are considered external routes, and the backbone VPN service provider does not import them into its VRF table. The backbone VPN service provider imports only the customer VPN service provider's internal routes into its VRF table.

The similarities and differences between interprovider and carrier-of-carriers VPNs are shown in Table 32 on page 1946.

Table 32: Comparison of Interprovider and Carrier-of-Carriers VPNs

Feature	ISP Customer	VPN Service Provider Customer
Customer edge device	AS border router	PE router
IBGP sessions	Carry IPv4 routes	Carry external VPN-IPv4 routes with associated labels
Forwarding within the customer network	MPLS is optional	MPLS is required

Support for VPN service as the customer is supported on QFX10000 switches starting with Junos OS Release 17.1R1.

Understanding Interprovider and Carrier-of-Carriers VPNs

All interprovider and carrier-of-carriers VPNs share the following characteristics:

- Each interprovider or carrier-of-carriers VPN customer must distinguish between internal and external customer routes.
- Internal customer routes must be maintained by the VPN service provider in its PE routers.

- External customer routes are carried only by the customer's routing platforms, not by the VPN service provider's routing platforms.

The key difference between interprovider and carrier-of-carriers VPNs is whether the customer sites belong to the same AS or to separate ASs:

- *Interprovider VPNs*—The customer sites belong to different ASs. You need to configure EBGP to exchange the customer's external routes.
- *Understanding Carrier-of-Carriers VPNs*—The customer sites belong to the same AS. You need to configure IBGP to exchange the customer's external routes.

In general, each service provider in a VPN hierarchy is required to maintain its own internal routes in its P routers, and the internal routes of its customers in its PE routers. By recursively applying this rule, it is possible to create a hierarchy of VPNs.

The following are definitions of the types of PE routers specific to interprovider and carrier-of-carriers VPNs:

- The AS border router is located at the AS border and handles traffic leaving and entering the AS.
- The end PE router is the PE router in the customer VPN; it is connected to the CE router at the end customer's site.

Configuring BGP to Gather Interprovider and Carrier-of-Carriers VPNs Statistics

You can configure BGP to gather traffic statistics for interprovider and carrier-of-carriers VPNs.

To configure BGP to gather traffic statistics for interprovider and carrier-of-carriers VPNs, include the `traffic-statistics` statement:

```
traffic-statistics {
    file filename <world-readable | no-world-readable>;
    interval seconds;
}
```

For a list of the hierarchy levels at which you can include this statement, see the summary section for this statement.

NOTE: Traffic statistics for interprovider and carrier-of-carriers VPNs are available only for IPv4. IPv6 is not supported.

If you do not specify a filename, the statistics are not written to a file. However, if you have included the `traffic-statistics` statement in the BGP configuration, the statistics are still available and can be accessed by means of the `show bgp group traffic-statistics` *`group-name`* command.

To account for traffic from each customer separately, separate labels must be advertised for the same prefix to the peer routers in different groups. To enable separate traffic accounting, you need to include the `per-group-label` statement in the configuration for each BGP group. By including this statement, statistics are collected and displayed that account for traffic sent by the peers of the specified BGP group.

If you configure the statement at the `[edit protocols bgp family inet]` hierarchy level, rather than configuring it for a specific BGP group, then the traffic statistics are shared with all BGP groups configured with the `traffic-statistics` statement but not configured with the `per-group-label` statement.

To account for traffic from each customer separately, include the `per-group-label` statement in the configuration for each BGP group:

```
per-group-label;
```

For a list of the hierarchy levels at which you can include this statement, see the summary section for this statement.

The following shows a sample of the output to the traffic statistics file:

```
Dec 19 10:39:54 Statistics for BGP group ext2 (Index 1) NLRI inet-labeled-unicast
Dec 19 10:39:54  FEC               Packets         Bytes   EgressAS   FECLabel

```

Configuring an MPLS-Based VLAN CCC Using a Layer 2 Circuit

You can configure an 802.1Q VLAN as an MPLS-based Layer 2 circuit on the switch to interconnect multiple customer sites with Layer 2 technology.

This topic describes configuring provider edge (PE) switches in an MPLS network using a circuit cross-connect (CCC) on a tagged VLAN interface (802.1Q VLAN) rather than a simple interface.

NOTE: You do not need to make any changes to existing provider switches in your MPLS network to support this type of configuration. For information on configuring provider switches, see "Configuring MPLS on Provider Switches" on page 77.

NOTE: You can send any kind of traffic over a CCC, including nonstandard bridge protocol data units (BPDUs) generated by other vendors' equipment.

NOTE: If you configure a physical interface as VLAN-tagged and with the vlan-ccc encapsulation, you cannot configure the associated logical interfaces with the inet family. Doing so could cause the logical interfaces to drop packets.

To configure a PE switch with a VLAN CCC and an MPLS-based Layer 2 circuit:

1. Configure OSPF (or IS-IS) on the loopback (or switch address) and core interfaces:

```
[edit protocols]
user@switch# set ospf area 0.0.0.0 interface lo0.0
user@switch# set ospf area 0.0.0.0 interface interface-name
user@switch# set ospf area 0.0.0.0 interface interface-name
user@switch# set ospf area 0.0.0.0 interface interface-name
```

2. Enable traffic engineering for the routing protocol:

```
[edit protocols]
user@switch# set ospf traffic-engineering
```

3. Configure an IP address for the loopback interface and for the core interfaces:

```
[edit]
user@switch# set interfaces lo0 unit logical-unit-number family inet address address
user@switch# set interfaces interface-name unit logical-unit-number family inet address
address
user@switch# set interfaces interface-name unit logical-unit-number family inet address
address
```

```
user@switch# set interfaces interface-name unit logical-unit-number family inet address
address
```

4. Enable the MPLS protocol with CSPF disabled:

> **NOTE**: CSPF is a shortest-path-first algorithm that has been modified to take into account specific restrictions when the shortest path across the network is calculated. You need to disable CSPF for link protection to function properly on interarea paths.

```
[edit protocols]
user@switch# set mpls no-cspf
```

5. Configure the customer edge interface as a Layer 2 circuit from the local PE switch to the other PE switch:

```
[edit protocols]
user@switch# set l2circuit neighbor address interface interface-name virtual-circuit-id
identifier
```

> **TIP**: Use the switch address of the other switch as the neighbor address.

6. Configure MPLS on the core interfaces:

```
[edit protocols]
user@switch# set mpls interface interface-name
user@switch# set mpls interface interface-name
user@switch# set mpls interface interface-name
```

7. Configure LDP on the loopback interface and the core interfaces:

```
[edit protocols]
user@switch# set ldp interface lo0.0
user@switch# set ldp interface interface-name
user@switch# set ldp interface interface-name
user@switch# set ldp interface interface-name
```

8. Configure `family mpls` on the logical units of the core interfaces:

```
[edit]
user@switch# set interfaces interface-name unit logical-unit-number family mpls
user@switch# set interfaces interface-name unit logical-unit-number family mpls
user@switch# set interfaces interface-name unit logical-unit-number family mpls
```

> **NOTE**: You can enable `family mpls` on either individual interfaces or aggregated Ethernet interfaces. You cannot enable it on tagged VLAN interfaces.

9. Enable VLAN tagging on the customer edge interface of the local PE switch:

```
[edit]
user@switch# set interfaces interface-name vlan-tagging
```

10. Configure the customer edge interface to use VLAN CCC encapsulation:

```
[edit]
user@switch# set interfaces interface-name encapsulation vlan-ccc
```

11. Configure the logical unit of the customer edge interface with a VLAN ID:

> **NOTE**: The VLAN ID cannot be configured on logical interface unit `0`. The logical unit number must be `1` or higher.
>
> The same VLAN ID must be used when configuring the customer edge interface on the other PE switch.

```
[edit ]
user@switch# set interfaces interface-name logical-unit-number vlan-idvlan-id
```

When you have completed configuring one PE switch, follow the same procedures to configure the other PE switch.

> **NOTE**: For EX Series switches, you must use the same type of switch for the other PE switch.

VLAN CCC Encapsulation on Transport Side of Pseudowire Client Logical Interfaces Overview

IN THIS SECTION

- Pseudowire Configuration from Access Node | 1952
- Pseudowire Configuration from Aggregation Node | 1953

Currently, Junos OS does not allow the same VLAN ID to be configured on more than one logical interface under the same pseudowire client physical interface. To support `vlan-ccc` encapsulation on transport pseudowire service (PS) interface on the provider edge (PE) device, this restriction is removed and you can configure the same VLAN ID on more than one logical interface.

The primary reason to configure `vlan-ccc` on the transport PS interface is interoperability with the existing access and aggregate devices in the network. Currently, Junos OS supports `ethernet-ccc` encapsulation on the transport PS interface. Typically, while establishing a pseudowire connection, the access device initiates a VLAN-based pseudowire (also known as VLAN-tagged mode), and a PE router signals the Ethernet mode VLAN back to the access device. For this type of pseudowire connection to be established, you can use the `ignore-encapsulation-mismatch` statement. However, the Junos OS device (access device) might not support the `ignore-encapsulation-mismatch` statement and, as a result, the pseudowire connection is not formed. When the `ignore-encapsulation-mismatch` statement is not supported on the access device, you can configure `vlan-ccc` between the nodes to form a pseudowire connection.

The forwarding data path is not changed with the new `vlan-ccc` encapsulation on the transport PS interface and the behavior similar to that when the `ethernet-ccc` encapsulation is configured on the transport PS interface. The transport PS interface either encapsulates or de-encapsulate the outer Layer 2 header and MPLS headers on the transmitted or received packets on the WAN port. Inner Ethernet or VLAN headers of the packet are handled on pseudowire client service logical interfaces. You must configure pseudowire client service logical interfaces with appropriate VLAN IDs or VLAN tags.

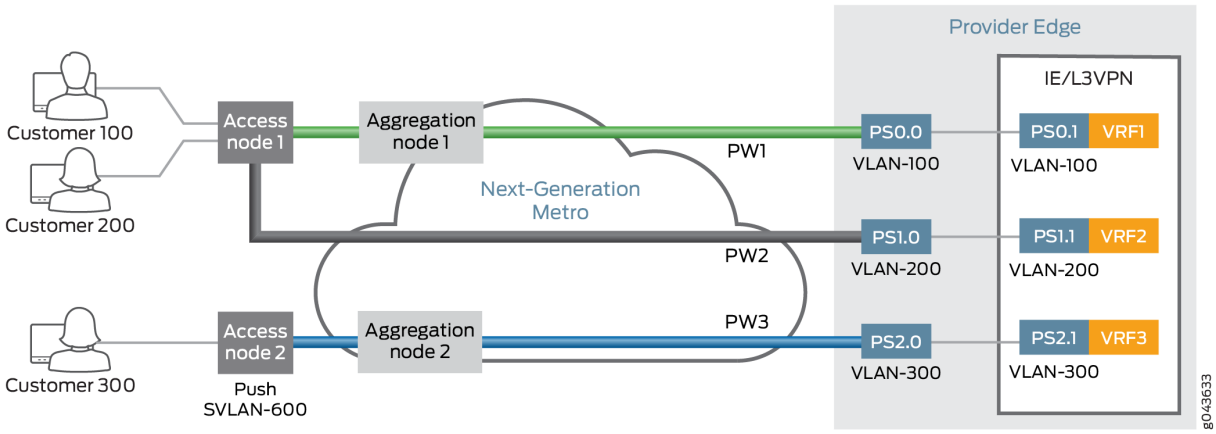
The following sections provides details, along with a sample configuration, about pseudowire configuration from both access and aggregation nodes.

Pseudowire Configuration from Access Node

These pseudowires are set up using VLANs from the access node for customer devices attached to the Layer 2 circuit configured on access and PE routers with customer VLANs (C-VLANs). The ingress traffic (from the access node side) on the PE router is single VLAN tagged (inner Ethernet header), and thus the service logical interfaces must be configured with the same VLAN IDs corresponding to the C-VLAN IDs attached to the access node.

Figure 127 on page 1953 provides the details of a transport PS interface from an access node (access node).

Figure 127: Pseudowire Client Transport Logical Interface from Access Node



The following example shows the configuration of a pseudowire client logical interface configuration on a PE router from an access node:

```
interfaces {
    ps0 {
        anchor-point lt-3;
        unit 0 {
            encapsulation VLAN-ccc;
            VLAN ID 100;
        }
        unit 1 {
            VLAN ID 100;
            family inet;
        }
    }
}
```

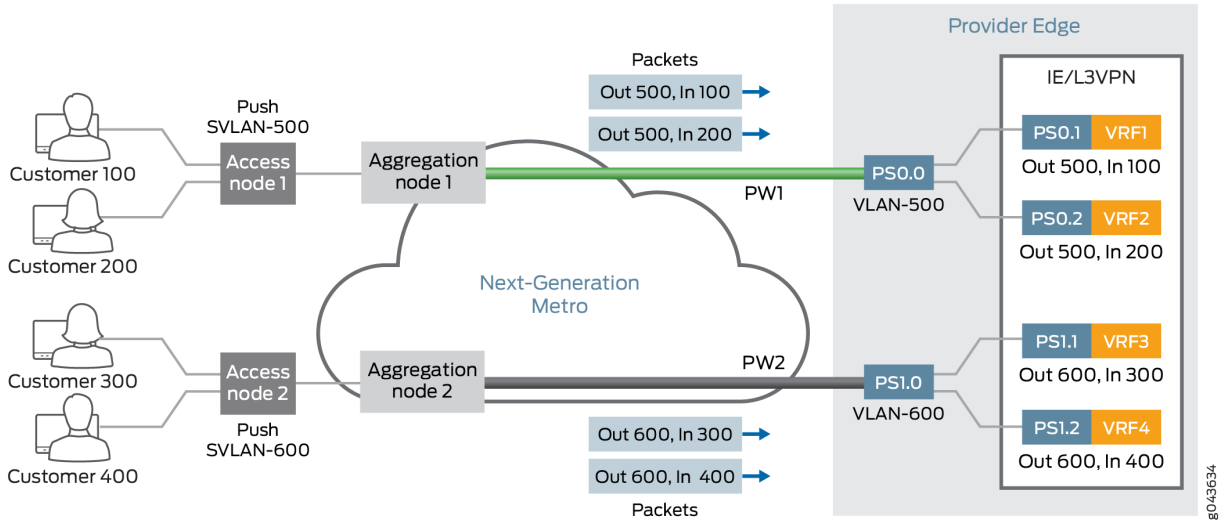
Pseudowire Configuration from Aggregation Node

In this case, the aggregation node processes a stacked VLAN (also known as Q-in-Q). The pseudowire originates from aggregation node and terminates on a PE router. The aggregation node pushes the service VLAN (S-VLAN) tag, and the PE router is expected to operate on two VLAN tags—the outer VLAN tag corresponds to an S-VLAN and the inner VLAN tag corresponds to a C-VLAN. The VLAN ID

configured on the transport PS interface at the PE router must match the VLAN tag of the S-VLAN. On the pseudowire client service logical interface, the outer VLAN tag must be configured to match the S-VLAN and the inner VLAN tag must be configured to match the C-VLAN.

Figure 128 on page 1954 provides the details of a transport PS interface from an aggregation node.

Figure 128: Pseudowire Client Transport Logical Interface from Aggregation Node



The following example shows the configuration of a pseudowire client logical interface configuration on a PE router from an aggregation node:

```
interfaces {
    ps0 {
        anchor-point lt-3;
        unit 0 {
            encapsulation VLAN-ccc;
            VLAN ID 500;
        }
        unit 1 {
            VLAN tags  {
                outer 500;
                inner 100;
            }
        }
        unit 2 {
            VLAN tags  {
                outer 500;
```

```
                inner 200;
            }
        }
    }
}
```

Transmitting Nonstandard BPDUs

CCC protocol (and Layer 2 Circuit and Layer 2 VPN) configurations can transmit nonstandard bridge protocol data units (BPDUs) generated by other vendors' equipment. This is the default behavior on all supported PICs and requires no additional configuration.

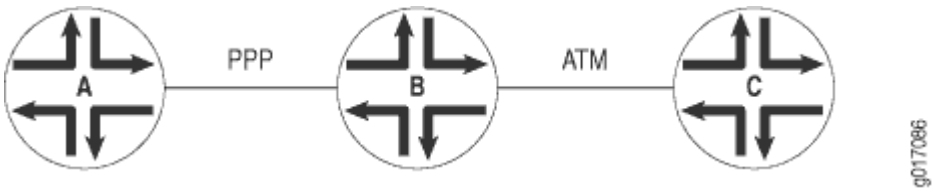
The following PICs are supported on M320 and T Series routers:

- 1-port Gigabit Ethernet PIC
- 2-port Gigabit Ethernet PIC
- 4-port Gigabit Ethernet PIC
- 10-port Gigabit Ethernet PIC

TCC Overview

Translational cross-connect (TCC) is a switching concept that enables you to establish interconnections between a variety of Layer 2 protocols or circuits. It is similar to CCC. However, whereas CCC requires the same Layer 2 encapsulations on each side of a Juniper Networks router (such as PPP-to-PPP or Frame Relay-to-Frame Relay), TCC enables you to connect different types of Layer 2 protocols interchangeably. When you use TCC, combinations such as PPP-to-ATM (see Figure 129 on page 1955) and Ethernet-to-Frame Relay connections are possible.

Figure 129: TCC Example



The Layer 2 circuits and encapsulation types that can be interconnected by TCC are:

- Ethernet
- Extended VLANs

- PPP
- HDLC
- ATM
- Frame Relay

TCC works by removing the Layer 2 header when frames enter the router and adding a different Layer 2 header on the frames before they leave the router. In Figure 129 on page 1955, the PPP encapsulation is stripped from the frames arriving at Router B, and the ATM encapsulation is added before the frames are sent to Router C.

Note that all control traffic is terminated at the interconnecting router (Router B). Examples of traffic controllers include the Link Control Protocol (LCP) and the Network Control Protocol (NCP) for PPP, keepalives for HDLC, and Local Management Interface (LMI) for Frame Relay.

TCC functionality is different from standard Layer 2 switching. TCC only swaps Layer 2 headers. No other processing, such as header checksums, TTL decrementing, or protocol handling is performed. TCC is supported for IPv4 only.

Address Resolution Protocol (APR) packet policing on TCC Ethernet interfaces is effective for releases 10.4 and onwards.

You can configure TCC for interface switching and for Layer 2 VPNs. For more information about using TCC for virtual private networks (VPNs), see the Junos OS VPNs Library for Routing Devices.

Configuring Layer 2 Switching Cross-Connects Using CCC

IN THIS SECTION

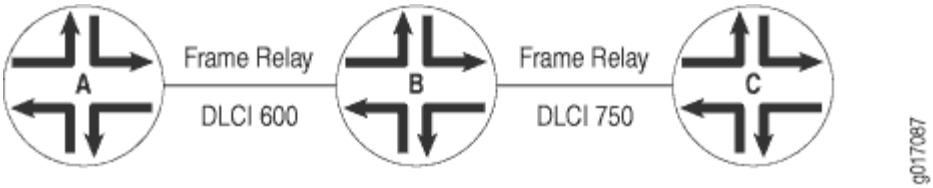
- Configuring the CCC Encapsulation for Layer 2 Switching Cross-Connects | **1957**
- Configuring the CCC Connection for Layer 2 Switching Cross-Connects | **1962**
- Configuring MPLS for Layer 2 Switching Cross-Connects | **1963**
- Example: Configuring a Layer 2 Switching Cross-Connect | **1964**
- Configuring Layer 2 Switching Cross-Connect on ACX5440 | **1966**

Layer 2 switching cross-connects join logical interfaces to form what is essentially Layer 2 switching. The interfaces that you connect must be of the same type.

Figure 130 on page 1957 illustrates a Layer 2 switching cross-connect. In this topology, Router A and Router C have Frame Relay connections to Router B, which is a Juniper Networks router. Circuit cross-connect (CCC) allows you to configure Router B to act as a Frame Relay (Layer 2) switch.

To configure Router B to act as a Frame Relay switch, you configure a circuit from Router A to Router C that passes through Router B, effectively configuring Router B as a Frame Relay switch with respect to these routers. This configuration allows Router B to transparently switch packets (frames) between Router A and Router C without regard to the packets' contents or the Layer 3 protocols. The only processing that Router B performs is to translate DLCI 600 to 750.

Figure 130: Layer 2 Switching Cross-Connect



If the Router A–to–Router B and Router B–to–Router C circuits were PPP, for example, the Link Control Protocol and Network Control Protocol exchanges occur between Router A and Router C. These messages are handled transparently by Router B, allowing Router A and Router C to use various PPP options (such as header or address compression and authentication) that Router B might not support. Similarly, Router A and Router C exchange keepalives, providing circuit-to-circuit connectivity status.

You can configure Layer 2 switching cross-connects on PPP, Cisco HDLC, Frame Relay, Ethernet, and ATM circuits. In a single cross-connect, only like interfaces can be connected.

To configure Layer 2 switching cross-connects, you must configure the following on the router that is acting as the switch (Router B in Figure 130 on page 1957):

Configuring the CCC Encapsulation for Layer 2 Switching Cross-Connects

To configure Layer 2 switching cross-connects, configure the CCC encapsulation on the router that is acting as the switch (Router B in Figure 130 on page 1957).

> **NOTE**: You cannot configure families on CCC interfaces; that is, you cannot include the `family` statement at the `[edit interfaces` *`interface-name`* `unit` *`logical-unit-number`*`]` hierarchy level.

For instructions for configuring the encapsulation for Layer 2 switching cross-connects, see the following sections:

Configuring ATM Encapsulation for Layer 2 Switching Cross-Connects

For ATM circuits, specify the encapsulation when configuring the virtual circuit (VC). Configure each VC as a circuit or a regular logical interface by including the following statements:

```
at-fpc/pic/port {
    atm-options {
        vpi vpi-identifier maximum-vcs maximum-vcs;
    }
    unit logical-unit-number {
        encapsulation encapsulation-type;
        point-to-point; # Default interface type
        vci vpi-identifier.vci-identifier;
    }
}
```

You can include these statements at the following hierarchy levels:

- [edit interfaces]
- [edit logical-systems *logical-system-name* interfaces]

Configuring Ethernet Encapsulation for Layer 2 Switching Cross-Connects

For Ethernet circuits, specify `ethernet-ccc` in the `encapsulation` statement. This statement configures the entire physical device. For these circuits to work, you must also configure a logical interface (unit 0).

Ethernet interfaces with standard Tag Protocol Identifier (TPID) tagging can use Ethernet CCC encapsulation. On M Series Multiservice Edge Routers, except the M320, one-port Gigabit Ethernet, two-port Gigabit Ethernet, four-port Gigabit Ethernet, and four-port Fast Ethernet PICs can use Ethernet CCC encapsulation. On T Series Core Routers and M320 routers, one-port Gigabit Ethernet and two-port Gigabit Ethernet PICs installed in FPC2 can use Ethernet CCC encapsulation. When you use this encapsulation type, you can configure the `ccc` family only.

```
fe-fpc/pic/port {
    encapsulation ethernet-ccc;
    unit 0;
}
```

You can include these statements at the following hierarchy levels:

- [edit interfaces]

- [edit logical-systems *logical-system-name* interfaces]

Configuring Ethernet VLAN Encapsulation for Layer 2 Switching Cross-Connects

An Ethernet virtual LAN (VLAN) circuit can be configured using either the vlan-ccc or extended-vlan-ccc encapsulation. If you configure the extended-vlan-ccc encapsulation on the physical interface, you cannot configure the inet family on the logical interfaces. Only the ccc family is allowed. If you configure the vlan-ccc encapsulation on the physical interface, both the inet and ccc families are supported on the logical interfaces. Ethernet interfaces in VLAN mode can have multiple logical interfaces.

For encapsulation type vlan-ccc, VLAN IDs from 512 through 4094 are reserved for CCC VLANs. For the extended-vlan-ccc encapsulation type, all VLAN IDs 1 and higher are valid. VLAN ID 0 is reserved for tagging the priority of frames.

NOTE: Some vendors use the proprietary TPIDs 0x9100 and 0x9901 to encapsulate a VLAN-tagged packet into a VLAN-CCC tunnel to interconnect a geographically separated metro Ethernet network. By configuring the extended-vlan-ccc encapsulation type, a Juniper Networks router can accept all three TPIDs (0x8100, 0x9100, and 0x9901).

Configure an Ethernet VLAN circuit with the vlan-ccc encapsulation as follows:

```
interfaces {
    type-fpc/pic/port {
        vlan-tagging;
        encapsulation vlan-ccc;
        unit logical-unit-number {
            encapsulation vlan-ccc;
            vlan-id vlan-id;
        }
    }
}
```

You can configure these statements at the following hierarchy levels:

- [edit interfaces]
- [edit logical-systems *logical-system-name* interfaces]

Configure an Ethernet VLAN circuit with the extended-vlan-ccc encapsulation statement as follows:

```
interfaces {
    type-fpc/pic/port {
        vlan-tagging;
        encapsulation extended-vlan-ccc;
        unit logical-unit-number {
            vlan-id vlan-id;
            family ccc;
        }
    }
}
```

You can configure these statements at the following hierarchy levels:

- [edit interfaces]
- [edit logical-systems *logical-system-name* interfaces]

Whether you configure the encapsulation as vlan-ccc or extended-vlan-ccc, you must enable VLAN tagging by including the vlan-tagging statement.

Configuring Aggregated Ethernet Encapsulation for Layer 2 Switching Cross-Connects

You can configure aggregated Ethernet interfaces for CCC connections and for Layer 2 virtual private networks (VPNs).

Aggregated Ethernet interfaces configured with VLAN tagging can be configured with multiple logical interfaces. The only encapsulation available for aggregated Ethernet logical interfaces is vlan-ccc. When you configure the vlan-id statement, you are limited to VLAN IDs 512 through 4094.

Aggregated Ethernet interfaces configured without VLAN tagging can be configured only with the ethernet-ccc encapsulation. All untagged Ethernet packets received are forwarded based on the CCC parameters.

To configure aggregated Ethernet interfaces for CCC connections, include the ae0 statement at the [edit interfaces] hierarchy level:

```
[edit interfaces]
ae0 {
    encapsulation (ethernet-ccc | extended-vlan-ccc | vlan-ccc);
    vlan-tagging;
    aggregated-ether-options {
```

```
        minimum-links links;
        link-speed speed;
    }
    unit logical-unit-number {
        encapsulation vlan-ccc;
        vlan-id identifier;
        family ccc;
    }
}
```

Be aware of the following limitations when configuring CCC connections over aggregated Ethernet interfaces:

- If you configured load balancing between child links, be aware that a different hash key is used to distribute packets among the child links. Standard aggregated interfaces have family inet configured. An IP version 4 (IPv4) hash key (based on the Layer 3 information) is used to distribute packets among the child links. A CCC connection over an aggregated Ethernet interface has family ccc configured instead. Instead of an IPv4 hash key, an MPLS hash key (based on the destination media access control [MAC] address) is used to distributed packets among the child links.
- The extended-vlan-ccc encapsulation is not supported on the 12-port Fast Ethernet PIC and the 48-port Fast Ethernet PIC.
- The Junos OS does not support the Link Aggregation Control Protocol (LACP) when an aggregated interface is configured as a VLAN (with vlan-ccc encapsulation). LACP can be configured only when the aggregated interface is configured with the ethernet-ccc encapsulation.

For more information about how to configure aggregated Ethernet interfaces, see the Junos OS Network Interfaces Library for Routing Devices.

Configuring Frame Relay Encapsulation for Layer 2 Switching Cross-Connects

For Frame Relay circuits, specify the encapsulation when configuring the DLCI. Configure each DLCI as a circuit or a regular logical interface. The DLCI for regular interfaces must be from 1 through 511. For CCC interfaces, it must be from 512 through 4094.

```
interfaces {
    type-fpc/pic/port {
        unit logical-unit-number {
            dlci dlci-identifier;
            encapsulation encapsulation-type;
            point-to-point; # Default interface type
        }
```

```
    }
}
```

You can configure these statements at the following hierarchy levels:

- [edit interfaces]
- [edit logical-systems *logical-system-name* interfaces]

Configuring PPP and Cisco HDLC Encapsulation for Layer 2 Switching Cross-Connects

For PPP and Cisco HDLC circuits, specify the encapsulation in the encapsulation statement. This statement configures the entire physical device. For these circuits to work, you must configure a logical interface (unit 0).

```
interfaces type-fpc/pic/port {
    encapsulation encapsulation-type;
    unit 0;
}
```

You can configure these statements at the following hierarchy levels:

- [edit interfaces *type-fpc/pic/port*]
- [edit logical-systems *logical-system-name* interfaces *type-fpc/pic/port*]

Configuring the CCC Connection for Layer 2 Switching Cross-Connects

To configure Layer 2 switching cross-connects, define the connection between the two circuits by including the interface-switch statement. You configure this connection on the router that is acting as the switch (Router B in Figure 130 on page 1957). The connection joins the interface that comes from the circuit's source to the interface that leads to the circuit's destination. When you specify the interface names, include the logical portion of the name, which corresponds to the logical unit number. The cross-connect is bidirectional, so packets received on the first interface are transmitted out the second interface, and those received on the second interface are transmitted out the first.

```
interface-switch connection-name {
    interface interface-name.unit-number;
    interface interface-name.unit-number;
}
```

You can include this statement at the following hierarchy levels:

- [edit protocols connections]
- [edit logical-systems *logical-system-name* protocols connections]

Configuring MPLS for Layer 2 Switching Cross-Connects

For Layer 2 switching cross-connects to work, you must enable MPLS on the router by including at least the following statements. This minimum configuration enables MPLS on a logical interface for the switching cross-connect.

Include the `family mpls` statement:

```
family mpls;
```

You can configure this statement at the following hierarchy levels:

- [edit interfaces *interface-name* unit *logical-unit-number*]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]

You can then specify this logical interface in the MPLS protocol configuration:

```
mpls {
    interface interface-name; # Required to enable MPLS on the interface
}
```

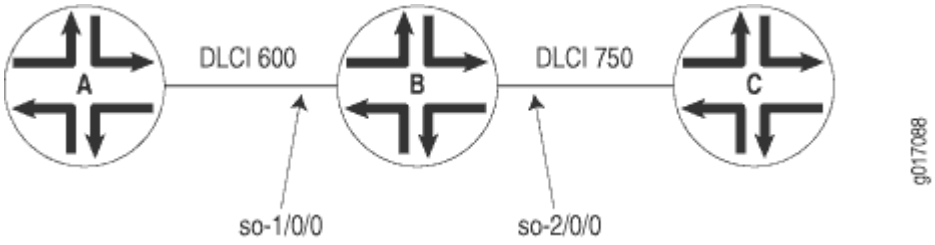
You can configure these statements at the following hierarchy levels:

- [edit protocols]
- [edit logical-systems *logical-system-name* protocols]

Example: Configuring a Layer 2 Switching Cross-Connect

Configure a full-duplex Layer 2 switching cross-connect between Router A and Router C, using a Juniper Networks router, Router B, as the virtual switch. See the topology in Figure 131 on page 1964 and Figure 132 on page 1965.

Figure 131: Topology of a Frame Relay Layer 2 Switching Cross-Connect



```
[edit]
interfaces {
    so-1/0/0 {
        encapsulation frame-relay-ccc;
        unit 1 {
            point-to-point;
            encapsulation frame-relay-ccc;
            dlci 600;
        }
    }
    so-2/0/0 {
        encapsulation frame-relay-ccc;
        unit 2 {
            point-to-point;
            encapsulation frame-relay-ccc;
            dlci 750;
        }
    }
}
protocols {
    connections {
        interface-switch router-a-to-router-c {
            interface so-1/0/0.1;
            interface so-2/0/0.2;
        }
    }
```

```
    mpls {
        interface all;
    }
}
```

        vlan-tagging;
        encapsulation vlan-ccc;
        unit 0 {
            encapsulation vlan-ccc;
            vlan-id 600;
        }
    }
    ge-2/2/0 {
        vlan-tagging;
        encapsulation vlan-ccc;
        unit 0 {
            encapsulation vlan-ccc;
            vlan-id 600;
        }
        unit 1 {
            family inet {
                vlan-id 1;
                address 10.9.200.1/24;
            }
        }
    }
}
protocols {
```

```
    mpls {
        interface all;
    }
    connections {
        interface-switch layer2-sw {
            interface ge-2/1/0.0;
            interface ge-2/2/0.0;
        }
    }
}
```

Configuring Layer 2 Switching Cross-Connect on ACX5440

Starting in Junos OS Release 19.3R1, you can leverage the hardware support available for cross-connects on the ACX5448 device with the Layer 2 local switching functionality using certain models. With this support, you can provide the EVP and Ethernet Virtual Private Line (EVPL) services..

Local-switching with the following forwarding models are supported:

- VLAN-CCC (logical interface-level local-switching) without any map.
- VLAN-CCC (logical interface-level local-switching) with the following vlan-maps:
  - Push 0x8100.pushVLAN (QinQ type)
  - Swap 0x8100.swapVLAN
- Aggregated Ethernet (AE) static interfaces.
- AE interfaces with LACP, load-balance all active mode.
- Local-switching end-interface support for AE or LAG interface (one non-AE interface and other AE interface).
- Local-switching both interface as AE or LAG interfaces.

To enable Layer 2 local switching on the ACX5448 device, you can use the existing configuration statements for Layer 2 circuits. For example,

```
[edit protocols l2circuit]
local-switching {
    interface interface1 {
        end-interface interface3;
        ignore-encapsulation-mismatch;
        ignore-mtu-mismatch;
```

```
    }
}
```

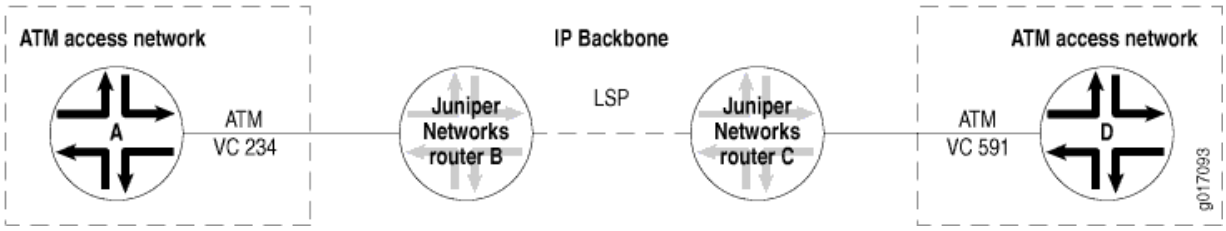
Configuring MPLS LSP Tunnel Cross-Connects Using CCC

IN THIS SECTION

- Configuring the CCC Encapsulation for LSP Tunnel Cross-Connects | **1968**
- Configuring the CCC Connection for LSP Tunnel Cross-Connects | **1970**
- Example: Configuring an LSP Tunnel Cross-Connect | **1971**

MPLS tunnel cross-connects between interfaces and LSPs allow you to connect two distant interface circuits of the same type by creating MPLS tunnels that use LSPs as the conduit. The topology in Figure 133 on page 1967 illustrates an MPLS LSP tunnel cross-connect. In this topology, two separate networks, in this case ATM access networks, are connected through an IP backbone. CCC allows you to establish an LSP tunnel between the two domains. With LSP tunneling, you tunnel the ATM traffic from one network across a SONET backbone to the second network by using an MPLS LSP.

Figure 133: MPLS Tunnel Cross-Connect



When traffic from Router A (VC 234) reaches Router B, it is encapsulated and placed into an LSP, which is sent through the backbone to Router C. At Router C, the label is removed, and the packets are placed onto the ATM permanent virtual circuit (PVC) (VC 591) and sent to Router D. Similarly, traffic from Router D (VC 591) is sent over an LSP to Router B, then placed on VC 234 to Router A.

You can configure LSP tunnel cross-connect on PPP, Cisco HDLC, Frame Relay, and ATM circuits. In a single cross-connect, only like interfaces can be connected.

When you use MPLS tunnel cross-connects to support IS-IS, you must ensure that the LSP's maximum transmission unit (MTU) can, at a minimum, accommodate a 1492-octet IS-IS protocol data unit (PDU) in addition to the link-level overhead associated with the technology being connected.

For the tunnel cross-connects to work, the IS-IS frame size on the edge routers (Routers A and D in Figure 134 on page 1971) must be smaller than the LSP's MTU.

NOTE: Frame size values do not include the frame check sequence (FCS) or delimiting flags.

To determine the LSP MTU required to support IS-IS, use the following calculation:

```
IS-IS MTU (minimum 1492, default 1497) + frame overhead + 4 (MPLS shim header) = Minimum LSP MTU
```

The framing overhead varies based on the encapsulation being used. The following lists the IS-IS encapsulation overhead values for various encapsulations:

- ATM
  - AAL5 multiplex—8 bytes (RFC 1483)
  - VC multiplex—0 bytes
- Frame Relay
  - Multiprotocol—2 bytes (RFCs 1490 and 2427)
  - VC multiplex—0 bytes
- HDLC—4 bytes
- PPP—4 bytes
- VLAN—21 bytes (802.3/LLC)

For IS-IS to work over VLAN-CCC, the LSP's MTU must be at least 1513 bytes (or 1518 for 1497-byte PDUs). If you increase the size of a Fast Ethernet MTU above the default of 1500 bytes, you might need to explicitly configure jumbo frames on intervening equipment.

To modify the MTU, include the `mtu` statement when configuring the logical interface family at the `[edit interfaces` *`interface-name`* `unit` *`logical-unit-number`* `encapsulation` *`family`*`]` hierarchy level. For more information about setting the MTU, see the Junos OS Network Interfaces Library for Routing Devices.

To configure an LSP tunnel cross-connect, you must configure the following on the interdomain router (Router B in Figure 134 on page 1971):

Configuring the CCC Encapsulation for LSP Tunnel Cross-Connects

To configure LSP tunnel cross-connects, you must configure the CCC encapsulation on the ingress and egress routers (Router B and Router C, respectively, in Figure 134 on page 1971).

NOTE: You cannot configure families on CCC interfaces; that is, you cannot include the `family` statement at the [`edit interfaces` *interface-name* `unit` *logical-unit-number*] hierarchy level.

For PPP or Cisco HDLC circuits, include the `encapsulation` statement to configure the entire physical device. For these circuits to work, you must configure logical unit 0 on the interface.

```
type-fpc/pic/port {
    encapsulation (ppp-ccc | cisco-hdlc-ccc);
    unit 0;
}
```

You can include these statements at the following hierarchy levels:

- [edit interfaces]
- [edit logical-systems *logical-system-name* interfaces]

For ATM circuits, specify the encapsulation when configuring the VC by including the following statements. For each VC, you configure whether it is a circuit or a regular logical interface.

```
at-fpc/pic/port {
    atm-options {
        vpi vpi-identifier maximum-vcs maximum-vcs;
    }
    unit logical-unit-number {
        point-to-point; # Default interface type
        encapsulation atm-ccc-vc-mux;
        vci vpi-identifier.vci-identifier;
    }
}
```

You can include these statements at the following hierarchy levels:

- [edit interfaces]
- [edit logical-systems *logical-system-name* interfaces]

For Frame Relay circuits, include the following statements to specify the encapsulation when configuring the DLCI. For each DLCI, you configure whether it is a circuit or a regular logical interface. The DLCI for

regular interfaces must be in the range 1 through 511. For CCC interfaces, it must be in the range 512 through 1022.

```
type-fpc/pic/port {
    encapsulation frame-relay-ccc;
    unit logical-unit-number {
        point-to-point; # default interface type
        encapsulation frame-relay-ccc;
        dlci dlci-identifier;
    }
}
```

You can include these statements at the following hierarchy levels:

- [edit interfaces]
- [edit logical-systems *logical-system-name* interfaces]

For more information about the encapsulation statement, see the Junos OS Network Interfaces Library for Routing Devices.

Configuring the CCC Connection for LSP Tunnel Cross-Connects

To configure LSP tunnel cross-connects, include the remote-interface-switch statement to define the connection between the two circuits on the ingress and egress routers (Router B and Router C, respectively, in Figure 134 on page 1971). The connection joins the interface or LSP that comes from the circuit's source to the interface or LSP that leads to the circuit's destination. When you specify the interface name, include the logical portion of the name, which corresponds to the logical unit number. For the cross-connect to be bidirectional, you must configure cross-connects on two routers.

```
remote-interface-switch connection-name {
    interface interface-name.unit-number;
    transmit-lsp label-switched-path;
    receive-lsp label-switched-path;
}
```

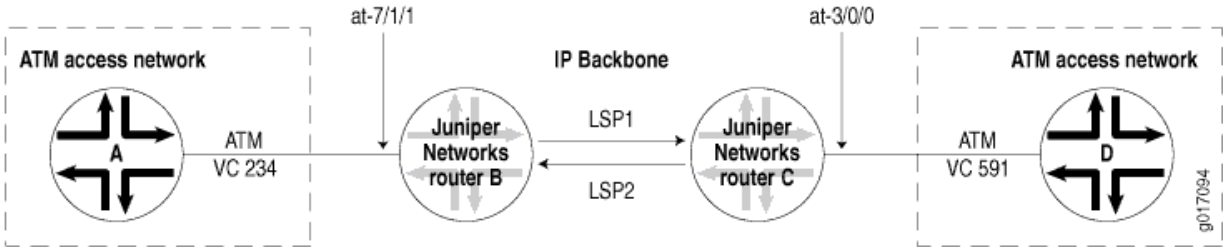
You can include these statements at the following hierarchy levels:

- [edit protocols connections]
- [edit logical-systems *logical-system-name* protocols connections]

Example: Configuring an LSP Tunnel Cross-Connect

Configure a full-duplex MPLS LSP tunnel cross-connect from Router A to Router D, passing through Router B and Router C. See the topology in Figure 134 on page 1971.

Figure 134: Example Topology of MPLS LSP Tunnel Cross-Connect



On Router B:

```
[edit]
interfaces {
    at-7/1/1 {
        atm-options {
            vpi 1 maximum-vcs 600;
        }
        unit 1 {
            point-to-point; # default interface type
            encapsulation atm-ccc-vc-mux;
            vci 1.234;
        }
    }
}
protocols {
    connections {
        remote-interface-switch router-b-to-router-c {
            interface at-7/1/1.1;
            transmit-lsp lsp1;
            receive-lsp lsp2;
        }
    }
}
```

On Router C:

```
[edit]
interfaces {
    at-3/0/0 {
        atm-options {
            vpi 2 maximum-vcs 600;
        }
        unit 2 {
            point-to-point; # default interface type
            encapsulation atm-ccc-vc-mux;
            vci 2.591;
        }
    }
}
protocols {
    connections {
        remote-interface-switch router-b-to-router-c {
            interface at-3/0/0.2;
            transmit-lsp lsp2;
            receive-lsp lsp1;
        }
    }
}
```

Configuring TCC

IN THIS SECTION

- Configuring the Encapsulation for Layer 2 Switching TCCs | **1973**
- Configuring the Connection for Layer 2 Switching TCCs | **1977**
- Configuring MPLS for Layer 2 Switching TCCs | **1978**

This section describes how to configure translational cross-connect (TCC).

To configure TCC, you must perform the following tasks on the router that is acting as the switch:

Configuring the Encapsulation for Layer 2 Switching TCCs

To configure a Layer 2 switching TCC, specify the TCC encapsulation on the desired interfaces of the router that is acting as the switch.

> **NOTE**: You cannot configure standard protocol families on TCC or CCC interfaces. Only the CCC family is allowed on CCC interfaces, and only the TCC family is allowed on TCC interfaces.
>
> For Ethernet circuits and Ethernet extended VLAN circuits, you must also configure the Address Resolution Protocol (ARP). See "Configuring ARP for Ethernet and Ethernet Extended VLAN Encapsulations" on page 1976.

Configuring PPP and Cisco HDLC Encapsulation for Layer 2 Switching TCCs

For PPP and Cisco HDLC circuits, configure the encapsulation type for the entire physical device by specifying the appropriate value for the `encapsulation` statement. For these circuits to work, you must also configure the logical interface `unit 0`.

```
encapsulation (ppp-tcc | cisco-hdlc-tcc);
unit 0{...}
```

You can include these statements at the following hierarchy levels:

- `[edit interfaces` *`interface-name`*`]`
- `[edit logical-systems` *`logical-system-name`* `interfaces` *`interface-name`*`]`

Configuring ATM Encapsulation for Layer 2 Switching TCCs

For ATM circuits, configure the encapsulation type by specifying the appropriate value for the `encapsulation` statement in the virtual circuit (VC) configuration. Specify whether each VC is a circuit or a regular logical interface.

```
atm-options {
    vpi vpi-identifier maximum-vcs maximum-vcs;
}
unit logical-unit-number {
    encapsulation (atm-tcc-vc-mux | atm-tcc-snap);
    point-to-point;
```

```
    vci vpi-identifier.vci-identifier;
}
```

You can include these statements at the following hierarchy levels:

- [edit interfaces at-*fpc*/*pic*/*port*]
- [edit logical-systems *logical-system-name* interfaces at-*fpc*/*pic*/*port*]

Configuring Frame Relay Encapsulation for Layer 2 Switching TCCs

For Frame Relay circuits, configure the encapsulation type by specifying the value `frame-relay-tcc` for the `encapsulation` statement when configuring the data-link connection identifier (DLCI). You configure each DLCI as a circuit or a regular logical interface. The DLCI for regular interfaces must be in the range from 1 through 511, but for TCC and CCC interfaces it must be in the range from 512 through 1022.

```
encapsulation frame-relay-tcc;
unit logical-unit-number {
    dlci dlci-identifier;
    encapsulation frame-relay-tcc;
    point-to-point;
}
```

You can include these statements at the following hierarchy levels:

- [edit interfaces *interface-name*]
- [edit logical-systems *logical-system-name* interfaces *interface-name*]

Configuring Ethernet Encapsulation for Layer 2 Switching TCCs

For Ethernet TCC circuits, configuring the encapsulation type for the entire physical device by specifying the value `ethernet-tcc` for the `encapsulation` statement.

You must also specify static values for a remote address and a proxy address at the [edit interfaces *interface-name* unit *unit-number* family tcc] or [edit logical-systems *logical-system-name* interfaces *interface-name* unit *unit-number* family tcc] hierarchy level.

The remote address is associated with the TCC switching router's Ethernet neighbor; in the `remote` statement you must specify both the IP address and the media access control (MAC) address of the Ethernet neighbor. The proxy address is associated with the TCC router's other neighbor connected by the unlike link; in the `proxy` statement you must specify the IP address of the non-Ethernet neighbor.

You can configure Ethernet TCC encapsulation for the interfaces on 1-port Gigabit Ethernet, 2-port Gigabit Ethernet, 4-port Fast Ethernet, and 4-port Gigabit Ethernet PICs.

```
encapsulation ethernet-tcc;
unit logical-unit-number {
    family tcc {
        proxy {
            inet-address ip-address;
        }
        remote {
            inet-address ip-address;
            mac-address mac-address;
        }
    }
}
```

You can include these statements at the following hierarchy levels:

- `[edit interfaces (fe | ge)-fpc/pic/port]`
- `[edit logical-systems logical-system-name interfaces (fe | ge)-fpc/pic/port]`

NOTE: For Ethernet circuits, you must also configure the Address Resolution Protocol (ARP). See "Configuring ARP for Ethernet and Ethernet Extended VLAN Encapsulations" on page 1976.

Configuring Ethernet Extended VLAN Encapsulation for Layer 2 Switching TCCs

For Ethernet extended VLAN circuits, configure the encapsulation type for the entire physical device by specifying the value `extended-vlan-tcc` for the `encapsulation` statement.

You must also enable VLAN tagging. Ethernet interfaces in VLAN mode can have multiple logical interfaces. With encapsulation type `extended-vlan-tcc`, all VLAN IDs from 0 through 4094 are valid, up to a maximum of 1024 VLANs. As with Ethernet circuits, you must also specify a proxy address and a remote address at the `[edit interfaces interface-name unit logical-unit-number family tcc]` or `[edit logical-systems logical-system-name interfaces interface-name unit unit-number family tcc]` hierarchy level (see "Configuring Ethernet Encapsulation for Layer 2 Switching TCCs" on page 1974).

```
encapsulation extended-vlan-tcc;
vlan-tagging;
unit logical-unit-number {
```

```
    vlan-id identifier;
    family tcc;
    proxy {
        inet-address ip-address;
    }
    remote {
        inet-address ip-address;
        mac-address mac-address;
    }
}
```

You can configure these statements at the following hierarchy levels:

- [edit interfaces *interface-name*]
- [edit logical-systems *logical-system-name* interfaces *interface-name*]

NOTE: For Ethernet extended VLAN circuits, you must also configure the Address Resolution Protocol (ARP). See "Configuring ARP for Ethernet and Ethernet Extended VLAN Encapsulations" on page 1976.

Configuring ARP for Ethernet and Ethernet Extended VLAN Encapsulations

For Ethernet and Ethernet extended VLAN circuits with TCC encapsulation, you must also configure ARP. Because TCC simply removes one Layer 2 header and adds another, the default form of dynamic ARP is not supported; you must configure static ARP.

Because remote and proxy addresses are specified on the router performing TCC switching, you must apply the static ARP statement to the Ethernet-type interfaces of the routers that connect to the TCC-switched router. The arp statement must specify the IP address and the MAC address of the remotely connected neighbor by use of the unlike Layer 2 protocol on the far side of the TCC switching router.

```
arp ip-address mac mac-address;
```

You can include this statement at the following hierarchy levels:

- [edit interfaces *interface-name* unit *logical-unit-number* family inet address *ip-address*]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number* family inet address *ip-address*]

Configuring the Connection for Layer 2 Switching TCCs

You must configure the connection between the two circuits of the Layer 2 switching TCC on the router acting as the switch. The connection joins the interface coming from the circuit's source to the interface leading to the circuit's destination. When you specify the interface names, include the logical portion of the name, which corresponds to the logical unit number. The cross-connect is bidirectional, so packets received on the first interface are transmitted from the second interface, and those received on the second interface are transmitted from the first.

To configure a connection for a local interface switch, include the following statements:

```
interface-switch connection-name {
    interface interface-name.unit-number;
}
lsp-switch connection-name {
    transmit-lsp lsp-number;
    receive-lsp lsp-number;
}
```

You can include these statements at the following hierarchy levels:

- `[edit protocols connections]`
- `[edit logical-systems logical-system-name protocols connections]`

To configure a connection for a remote interface switch, include the following statements:

```
remote-interface-switch connection-name {
    interface interface-name.unit-number;
    interface interface-name.unit-number;
    transmit-lsp lsp-number;
    receive-lsp lsp-number;
}
```

You can include these statements at the following hierarchy levels:

- `[edit protocols connections]`
- `[edit logical-systems logical-system-name protocols connections]`

Configuring MPLS for Layer 2 Switching TCCs

For a Layer 2 switching TCC to work, you must enable MPLS on the router by including at least the following statements. This minimum configuration enables MPLS on a logical interface for the switching cross-connect.

Include the `family mpls` statement:

```
family mpls;
```

You can configure this statement at the following hierarchy levels:

- `[edit interfaces` *`interface-name`* `unit` *`logical-unit-number`*`]`
- `[edit logical-systems` *`logical-system-name`* `interfaces` *`interface-name`* `unit` *`logical-unit-number`*`]`

You can then specify this logical interface in the MPLS protocol configuration:

```
mpls {
    interface interface-name; # Required to enable MPLS on the interface
}
```

You can configure these statements at the following hierarchy levels:

- `[edit protocols]`
- `[edit logical-systems` *`logical-system-name`* `protocols]`

NOTE: MPLS LSP link protection does not support TCC.

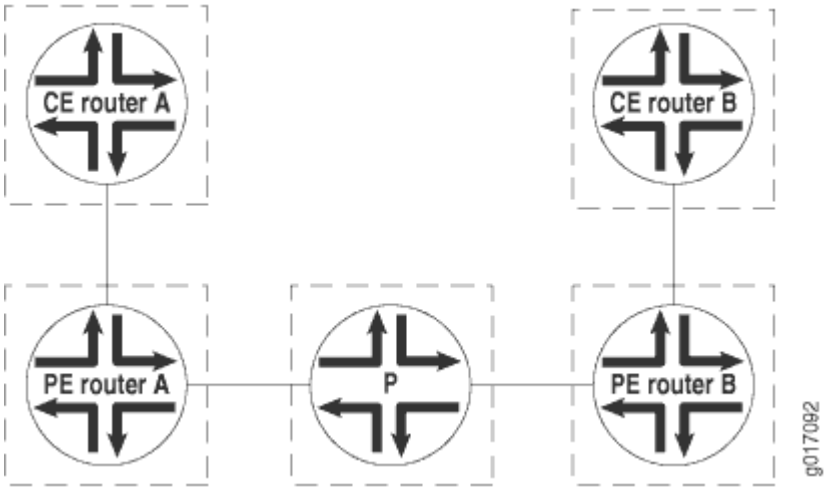
CCC and TCC Graceful Restart

CCC and TCC graceful restart allows Layer 2 connections between customer edge (CE) routers to restart gracefully. These Layer 2 connections are configured with the `remote-interface-switch` or `lsp-switch` statements. Because these CCC and TCC connections have an implicit dependency on RSVP LSPs, graceful restart for CCC and TCC uses the RSVP graceful restart capabilities.

RSVP graceful restart must be enabled on the PE routers and P routers to enable graceful restart for CCC and TCC. Also, because RSVP is used as the signaling protocol for signaling label information, the neighboring router must use helper mode to assist with the RSVP restart procedures.

Figure 135 on page 1979 illustrates how graceful restart might work on a CCC connection between two CE routers.

Figure 135: Remote Interface Switch Connecting Two CE Routers Using CCC



PE Router A is the ingress for the transmit LSP from PE Router A to PE Router B and the egress for the receive LSP from PE Router B to PE Router A. With RSVP graceful restart enabled on all the PE and P routers, the following occurs when PE router A restarts:

- PE Router A preserves the forwarding state associated with the CCC routes (those from CCC to MPLS and from MPLS to CCC).
- Traffic flows without disruption from CE router to CE router.
- After the restart, PE Router A preserves the label for the LSP for which PE Router A is the egress (the receive LSP, for example). The transmit LSP from PE Router A to PE Router B can derive new label mappings, but should not cause any traffic disruption.

Configuring CCC and TCC Graceful Restart

To enable CCC and TCC graceful restart, include the `graceful-restart` statement:

```
graceful-restart;
```

You can include this statement at the following hierarchy levels:

- `[edit routing-options]`
- `[edit logical-systems` *`logical-system-name`* `routing-options]`

Configuring an MPLS-Based VLAN CCC Using the Connection Method (CLI Procedure)

You can configure an 802.1Q VLAN as an MPLS-based connection using EX8200 and EX4500 switches to interconnect multiple customer sites with Layer 2 technology.

This topic describes configuring provider edge (PE) switches in an MPLS network using a circuit cross-connect (CCC) on a tagged VLAN interface (802.1Q VLAN) rather than a simple interface.

NOTE: You do not need to make any changes to existing provider switches in your MPLS network to support this type of configuration. For information on configuring provider switches, see "Configuring MPLS on EX8200 and EX4500 Provider Switches" on page 94.

NOTE: You can send any kind of traffic over a CCC, including nonstandard bridge protocol data units (BPDUs) generated by other vendors' equipment.

NOTE: If you configure a physical interface as VLAN-tagged and with the vlan-ccc encapsulation, you cannot configure the associated logical interfaces with the inet family. Doing so could cause the logical interfaces to drop packets.

To configure a PE switch with a VLAN CCC and an MPLS-based connections:

1. Configure OSPF (or IS-IS) on the loopback (or switch address) and core interfaces:

```
[edit protocols]
user@switch# set ospf area 0.0.0.0 interface lo0.0
user@switch# set ospf area 0.0.0.0 interface interface-name
user@switch# set ospf area 0.0.0.0 interface interface-name
user@switch# set ospf area 0.0.0.0 interface interface-name
```

2. Enable traffic engineering for the routing protocol:

```
[edit protocols]
user@switch# set ospf traffic-engineering
```

3. Configure an IP address for the loopback interface and for the core interfaces:

```
[edit]
user@switch# set interfaces lo0 unit logical-unit-number family inet address address
user@switch# set interfaces interface-name unit logical-unit-number family inet address
address
user@switch# set interfaces interface-name unit logical-unit-number family inet address
address
user@switch# set interfaces interface-name unit logical-unit-number family inet address
address
```

4. Enable the MPLS protocol with **cspf** disabled:

> **NOTE**: CSPF is a shortest-path-first algorithm that has been modified to take into account specific restrictions when the shortest path across the network is calculated. You need to disable CSPF for link protection to function properly on interarea paths.

```
[edit protocols]
user@switch# set mpls no-cspf
```

5. Enable VLAN tagging on the customer edge interface of the local PE switch:

```
[edit]
user@switch# set interfaces interface-name vlan-tagging
```

6. Configure the customer edge interface to use encapsulation **vlan-ccc**:

```
[edit]
user@switch# set interfaces interface-name encapsulation vlan-ccc
```

7. Configure the logical unit of the customer edge interface with a VLAN ID:

> **NOTE**: The VLAN ID cannot be configured on logical interface unit **0**.

The same VLAN ID must be used when configuring the customer edge interface on the other PE switch.

```
[edit ]
user@switch# set interfaces interface-name logical-unit-numberrbhadran vlan-id
```

8. Define the label switched path (LSP):

```
[edit protocols]
user@switch# set mpls label-switched-path lsp-name from address
user@switch# set mpls label-switched-path lsp-name to address
```

TIP: You will need to use the specified LSP name again when configuring the CCC.

9. Configure the connection between the two circuits in the CCC connection

```
[edit protocols]
user@switch# set connections remote-interface-switch interface-switch interface local-
interface
user@switch# set connections remote-interface-switch interface-switch transmit-lsp
destination-lsp
user@switch# set connections remote-interface-switch interface-switch receive-lsp source-lsp
```

Configuring CCC Switching for Point-to-Multipoint LSPs

IN THIS SECTION

- Configuring the Point-to-Multipoint LSP Switch on Ingress PE Routers | **1983**
- Configuring Local Receivers on a Point-to-Multipoint CCC LSP Switch on Ingress PE Routers | **1984**
- Configuring the Point-to-Multipoint LSP Switch on Egress PE Routers | **1984**

You can configure circuit cross-connect (CCC) between two circuits to switch traffic from interfaces to point-to-multipoint LSPs. This feature is useful for handling multicast or broadcast traffic (for example, a digital video stream).

To configure CCC switching for point-to-multipoint LSPs, you do the following:

- On the ingress provider edge (PE) router, you configure CCC to switch traffic from an incoming interface to a point-to-multipoint LSP.
- On the egress PE, you configure CCC to switch traffic from an incoming point-to-multipoint LSP to an outgoing interface.

The CCC connection for point-to-multipoint LSPs is unidirectional.

For more information about point-to-multipoint LSPs, see "Point-to-Multipoint LSPs Overview" on page 755.

To configure a CCC connection for a point-to-multipoint LSP, complete the steps in the following sections:

Configuring the Point-to-Multipoint LSP Switch on Ingress PE Routers

To configure the ingress PE router with a CCC switch for a point-to-multipoint LSP, include the `p2mp-transmit-switch` statement:

```
p2mp-transmit-switch switch-name {
    input-interface input-interface-name.unit-number;
    transmit-p2mp-lsp transmitting-lsp;
}
```

You can include the `p2mp-transmit-switch` statement at the following hierarchy levels:

- `[edit protocols connections]`
- `[edit logical-systems logical-system-name protocols connections]`

switch-name specifies the name of the ingress CCC switch.

`input-interface` *input-interface-name.unit-number* specifies the name of the ingress interface.

`transmit-p2mp-lsp` *transmitting-lsp* specifies the name of the transmitting point-to-multipoint LSP.

Configuring Local Receivers on a Point-to-Multipoint CCC LSP Switch on Ingress PE Routers

In addition to configuring an incoming CCC interface to a point-to-multipoint LSP on an ingress PE router, you can also configure CCC to switch traffic on an incoming CCC interface to one or more outgoing CCC interfaces by configuring output interfaces as local receivers.

To configure output interfaces, include the `output-interface` statement at the `[edit protocols connections p2mp-transmit-switch` *`p2mp-transmit-switch-name`*`]` hierarchy level.

```
[edit protocols connections]
p2mp-transmit-switch pc-ccc {
    input-interface fe-1/3/1.0;
    transmit-p2mp-lsp myp2mp;
    output-interface [fe-1/3/2.0 fe-1/3/3.0];
}
```

You can configure one or more output interfaces as local receivers on the ingress PE router using this statement.

Use the `show connections p2mp-transmit-switch (extensive | history | status)`, `show route ccc` *`<interface-name>`* `(detail | extensive)`, and `show route forwarding-table ccc` *`<interface-name>`* `(detail | extensive)` commands to view details of the local receiving interfaces on the ingress PE router.

Configuring the Point-to-Multipoint LSP Switch on Egress PE Routers

To configure the CCC switch for a point-to-multipoint LSP on the egress PE router, include the `p2mp-receive-switch` statement.

```
p2mp-receive-switch switch-name {
    output-interface [ output-interface-name.unit-number ];
    receive-p2mp-lsp receptive-lsp;
}
```

You can include this statement at the following hierarchy levels:

- `[edit protocols connections]`
- `[edit logical-systems` *`logical-system-name`* `protocols connections]`

`switch-name` specifies the name of the egress CCC switch.

`output-interface [` *`output-interface-name.unit-number`* `]` specifies the name of one or more egress interfaces.

`receive-p2mp-lsp` *`receptive-lsp`* specifies the name of the receptive point-to-multipoint LSP.

Configuring an MPLS-Based VLAN CCC Using a Layer 2 VPN (CLI Procedure)

You can configure an 802.1Q VLAN as an MPLS-based Layer 2 virtual private network (VPN) using EX8200 and EX4500 switches to interconnect multiple customer sites with Layer 2 technology.

This topic describes configuring provider edge (PE) switches in an MPLS network using a circuit cross-connect (CCC) on a tagged VLAN interface (802.1Q VLAN) rather than a simple interface.

NOTE: You do not need to make any changes to existing provider switches in your MPLS network to support this type of configuration. For information on configuring provider switches, see "Configuring MPLS on EX8200 and EX4500 Provider Switches" on page 94.

NOTE: You can send any kind of traffic over a CCC, including nonstandard bridge protocol data units (BPDUs) generated by other vendors' equipment.

NOTE: If you configure a physical interface as VLAN-tagged and with the vlan-ccc encapsulation, you cannot configure the associated logical interfaces with the inet family. Doing so could cause the logical interfaces to drop packets.

To configure a PE switch with a VLAN CCC and an MPLS-based Layer 2 VPN:

1. Configure OSPF (or IS-IS) on the loopback (or switch address) and core interfaces:

```
[edit protocols]
user@switch# set ospf area 0.0.0.0 interface lo0.0
user@switch# set ospf area 0.0.0.0 interface interface-name
user@switch# set ospf area 0.0.0.0 interface interface-name
user@switch# set ospf area 0.0.0.0 interface interface-name
```

2. Enable traffic engineering for the routing protocol:

```
[edit protocols]
user@switch# set ospf traffic-engineering
```

3. Configure an IP address for the loopback interface and for the core interfaces:

```
[edit]
user@switch# set interfaces lo0 unit logical-unit-number family inet address address
user@switch# set interfaces interface-name unit logical-unit-number family inet address
address
user@switch# set interfaces interface-name unit logical-unit-number family inet address
address
user@switch# set interfaces interface-name unit logical-unit-number family inet address
address
```

4. Enable the MPLS protocol with **cspf** disabled:

> **NOTE**: CSPF is a shortest-path-first algorithm that has been modified to take into account specific restrictions when the shortest path across the network is calculated. You need to disable CSPF for link protection to function properly on interarea paths.

```
[edit protocols]
user@switch# set mpls no-cspf
```

5. Define the label switched path (LSP):

```
[edit protocols]
user@switch# set mpls label-switched-path lsp_name to address
```

> **TIP**: You will need to use the specified LSP name again when configuring the CCC.

6. Configure MPLS on the core interfaces:

```
[edit protocols]
user@switch# set mpls interface interface-name
user@switch# set mpls interface interface-name
user@switch# set mpls interface interface-name
```

7. Configure RSVP on the loopback interface and the core interfaces:

```
[edit protocols]
user@switch# set rsvp interface lo0.0
user@switch# set rsvp interface interface-name
user@switch# set rsvp interface interface-name
user@switch# set rsvp interface interface-name
```

8. Configure **family mpls** on the logical units of the core interfaces:

```
[edit]
user@switch# set interfaces interface-name unit logical-unit-number family mpls
user@switch# set interfaces interface-name unit logical-unit-number family mpls
user@switch# set interfaces interface-name unit logical-unit-number family
mpls
```

> **NOTE**: You can enable **family mpls** on either individual interfaces or aggregated Ethernet interfaces. You cannot enable it on tagged VLAN interfaces.

9. Enable VLAN tagging on the customer edge interface of the local PE switch:

```
[edit]
user@switch# set interfaces interface-name vlan-tagging
```

10. Configure the customer edge interface to use encapsulation **vlan-ccc**:

```
[edit]
user@switch# set interfaces interface-name encapsulation vlan-ccc
```

11. Configure the logical unit of the customer edge interface with a VLAN ID:

> **NOTE**: The VLAN ID cannot be configured on logical interface unit **0**. The logical unit number must be **1** or higher.

The same VLAN ID must be used when configuring the customer edge interface on the other PE switch.

```
[edit ]
user@switch# set interfaces interface-name logical-unit-numbervlan-id vlan-id
```

12. Configure BGP, specifying the loopback address as the local address and enabling **family l2vpn signaling**:

```
[edit protocols bgp]
user@switchPE1# set local-address address family l2vpn signaling
```

13. Configure the BGP group, specifying the group name and type:

```
[edit protocols bgp]
user@switchPE1# set group ibgp type internal
```

14. Configure the BGP neighbor, specifying the loopback address of the remote PE switch as the neighbor's address:

```
[edit protocols bgp]
user@switchPE1# set neighbor address
```

15. Configure the routing instance, specifying the routing-instance name and using **l2vpn** as the instance type:

```
[edit routing-instances]
user@switchPE1# set routing-instance-name instance-type l2vpn
```

16. Configure the routing instance to apply to the customer edge interface:

```
[edit routing-instances]
user@switchPE1# set routing-instance-name interface interface-name
```

17. Configure the routing instance to use a route distinguisher:

```
[edit routing-instances]
user@switchPE1# set routing-instance-name route-distinguisher address
```

18. Configure the VPN routing and forwarding (VRF) target of the routing instance:

```
[edit routing-instances]
user@switchPE1# set routing-instance-name vrf-target community
```

NOTE: You can create more complex policies by explicitly configuring VRF import and export policies using the import and export options. See the *Junos OS VPNs Configuration Guide*.

19. Configure the protocols and encapsulation type used by the routing instance:

```
[edit routing-instances]
user@switchPE1# set routing-instance-name protocols l2vpn encapsulation-type ethernet-vlan
```

20. Apply the routing instance to a customer edge interface and specify a description for it:

```
[edit routing-instances]
user@switchPE1# set routing-instance-name protocols interface interface-name description
description
```

21. Configure the routing-instance protocols site:

```
[edit routing-instances]
user@switchPE1# set routing-instance-name protocols l2vpn site site-name site-identifier
identifier remote-site-id identifier
```

NOTE: The remote site ID (configured with the `remote-site-id` statement) corresponds to the site ID (configured with the `site-identifier` statement) configured on the other PE switch.

When you have completed configuring one PE switch, follow the same procedures to configure the other PE switch.

NOTE: You must use the same type of switch for the other PE switch. You cannot use an EX8200 as one PE switch and use an EX3200 or EX4200 as the other PE switch.

Understanding Ethernet-over-MPLS (L2 Circuit)

IN THIS SECTION

- Ethernet-over-MPLS in Data Centers | **1990**

Ethernet-over-MPLS allows sending Layer 2 (L2) Ethernet frames transparently over MPLS. Ethernet-over-MPLS uses a tunneling mechanism for Ethernet traffic through an MPLS-enabled Layer 3 core. It encapsulates Ethernet protocol data units (PDUs) inside MPLS packets and forwards the packets, using label stacking, across the MPLS network This technology has applications in service provider, enterprise and data center environments. For disaster recovery purposes, data centers are hosted in multiple sites that are geographically distant and interconnected using a WAN network.

NOTE: A Layer 2 circuit is similar to a circuit cross-connect (CCC), except that multiple Layer 2 circuits can be transported over a single label-switched path (LSP) tunnel between two provider edge (PE) routers. In contrast, each CCC requires a dedicated LSP.

Ethernet-over-MPLS in Data Centers

For disaster recovery purposes, data centers are hosted in multiple sites that are geographically distant and interconnected using a WAN network. These data centers require L2 connectivity between them for the following reasons:

- To replicate the storage over Fiber Channel IP (FCIP). FCIP works only on the same broadcast domain.
- To run a dynamic routing protocol between the sites.
- To support High Availability clusters that interconnect the nodes hosted in the various data centers.

Configuring Ethernet over MPLS (Layer 2 Circuit)

IN THIS SECTION

- Configuring the Local PE Switch for Port-Based Layer 2 Circuit (Pseudo-wire) | 1992
- Configuring the Remote PE Switch for Port-Based Layer 2 Circuit (Pseudo-wire) | 1993
- Configuring the Local PE Switch for VLAN-Based Layer 2 Circuit | 1994
- Configuring the Remote PE Switch for VLAN-Based Layer 2 Circuit | 1995

To implement Ethernet over MPLS, you must configure a Layer 2 circuit on the provider edge (PE) switches. No special configuration is required on the customer edge (CE) switches. The provider switches require MPLS and LDP to be configured on the interfaces that will be receiving and transmitting MPLS packets.

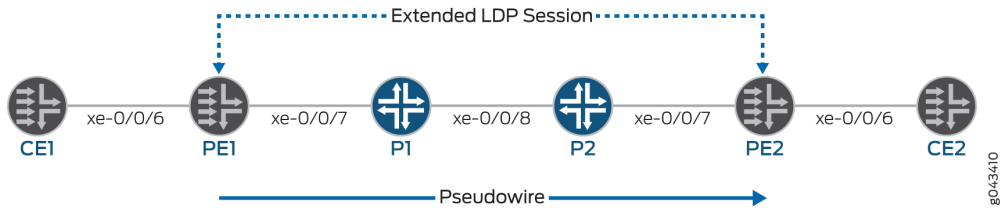
NOTE: A Layer 2 circuit is similar to a circuit cross-connect (CCC), except that multiple Layer 2 circuits can be transported over a single label-switched path (LSP) tunnel between two PE switches. In contrast, each CCC requires a dedicated LSP.

This topic describes how to configure the PE switches to support Ethernet over MPLS. You must configure interfaces and protocols on both the local PE (PE1) and the remote PE (PE2) switches. The interface configuration varies depending upon whether the Layer 2 circuit is port-based or VLAN-based.

Starting in Junos OS Release 20.3R1, support for Layer 2 circuit to provide Layer 2 VPN and VPWS with LDP signaling.

Figure 136 on page 1992 shows an example of a Layer 2 circuit configuration.

Figure 136: Ethernet over MPLS Layer 2 Circuit



NOTE: This topic refers to the local PE switch as PE1 and the remote PE switch as PE2. It also uses interface names rather than variables to help clarify the connections between the switches. The loopback addresses of the switches are configured as follows:

- PE1: 127.1.1.1
- PE2: 127.1.1.2

NOTE: On QFX Series and EX4600 switches, the Layer 2 circuit CE facing interface does not support AE interfaces.

Configuring the Local PE Switch for Port-Based Layer 2 Circuit (Pseudo-wire)

CAUTION: Configure MPLS networks with an MTU (maximum transmission unit) that is at least 12 bytes larger than the largest frame size that will be transported by the LSPs. If the size of a encapsulated packet on the ingress LSR exceeds the LSP MTU, that packet is dropped. If an egress LSR receives a packet on a VC LSP with a length (after the label stack and sequencing control word have been popped) that exceeds the MTU of the destination layer 2 interface, that packet is also dropped.

To configure the local PE switch (PE1) for a port-based layer 2 circuit (pseudo-wire):

1. Configure an access CE-facing interface for Ethernet encapsulation:

```
[edit interfaces]
user@switch# set xe-0/0/6 encapsulation ethernet-ccc
```

2. Configure the Layer 2 circuit from PE1 to PE2:

```
[edit protocols]
user@switch#set l2circuit neighbor 127.1.1.1 interface xe-0/0/6 virtual-circuit-id 1
```

3. Configure the label switched path from PE1 to PE2:

```
[edit protocols]
user@switch#set mpls label-switched-path PE1-to-PE2 to 127.1.1.1
```

4. Configure the protocols on the core and loopback interfaces:

```
[edit protocols]
user@switch#set mpls interface xe-0/0/7
user@switch#set ldp interface lo0.0
```

Configuring the Remote PE Switch for Port-Based Layer 2 Circuit (Pseudo-wire)

To configure the remote PE switch (PE2) for a port-based layer 2 circuit:

1. Configure an access CE-facing interface for Ethernet encapsulation:

```
[edit interfaces]
user@switch# set xe-0/0/6 encapsulation ethernet-ccc
```

2. Configure the Layer 2 circuit from PE2 to PE1:

```
[edit protocols]
user@switch#set l2circuit neighbor 127.1.1.2 interface xe-0/0/6 virtual-circuit-id 1
```

3. Configure the label switched path from PE2 to PE1:

```
[edit protocols]
user@switch#set mpls label-switched-path PE2-to-PE1 to 127.1.1.2
```

4. Configure the protocols on the core and loopback interfaces:

```
[edit protocols]
user@switch#set mpls interface xe-0/0/7
user@switch#set ldp interface lo0.0
```

Configuring the Local PE Switch for VLAN-Based Layer 2 Circuit

To configure the local PE switch (PE1) for a VLAN-based layer 2 circuit:

1. Configure an access CE-facing interface for VLAN encapsulation:

```
[edit interfaces]
user@switch# set xe-0/0/6 encapsulation vlan-ccc
```

2. Configure the logical unit of the CE-facing interface for VLAN encapsulation:

```
[edit interfaces]
user@switch# set xe-0/0/6 unit 0 encapsulation vlan-ccc
```

3. Configure the logical unit of the CE-facing interface to belong to family ccc:

```
[edit interfaces]
user@switch# set xe-0/0/6 unit 0 family ccc
```

4. Configure the same interface for VLAN tagging:

```
[edit interfaces]
user@switch# set xe-0/0/6 vlan-tagging
```

5. Configure the VLAN ID of the interface:

```
[edit interfaces]
user@switch# set xe-0/0/6 unit 0 vlan-id 600
```

6. Configure the Layer 2 circuit from PE1 to PE2:

```
[edit protocols]
user@switch#set l2circuit neighbor 127.1.1.1 interface xe-0/0/6 virtual-circuit-id 1
```

7. Configure the label switched path from PE1 to PE2:

```
[edit protocols]
user@switch#set mpls label-switched-path PE1-to-PE2 to 127.1.1.1
```

8. Configure the protocols on the core and loopback interfaces:

```
[edit protocols]
user@switch#set mpls interface xe-0/0/7
user@switch#set ldp interface lo0.0
```

Configuring the Remote PE Switch for VLAN-Based Layer 2 Circuit

To configure the remote PE switch (PE2) for a VLAN-based layer 2 circuit:

1. Configure an access CE-facing interface for VLAN encapsulation:

```
[edit interfaces]
user@switch# set xe-0/0/6 encapsulation vlan-ccc
```

2. Configure the logical unit of the CE-facing interface for VLAN encapsulation:

```
[edit interfaces]
user@switch# set xe-0/0/6 unit 0 encapsulation vlan-ccc
```

3. Configure the logical unit of the CE-facing interface to belong to family ccc:

```
[edit interfaces]
user@switch# set xe-0/0/6 unit 0 family ccc
```

4. Configure the same interface for VLAN tagging:

```
[edit interfaces]
user@switch# set xe-0/0/6 vlan-tagging
```

5. Configure the VLAN ID of the interface:

```
[edit interfaces]
user@switch# set xe-0/0/6 unit 0 vlan-id 600
```

6. Configure the Layer 2 circuit from PE2 to PE1:

```
[edit protocols]
user@switch#set l2circuit neighbor 127.1.1.2 interface xe-0/0/6 virtual-circuit-id 1
```

7. Configure the label switched path from PE2 to PE1:

```
[edit protocols]
user@switch#set mpls label-switched-path PE2-to-PE1 to 127.1.1.2
```

8. Configure the protocols on the core and loopback interfaces:

```
[edit protocols]
user@switch#set mpls interface xe-0/0/7
user@switch#set ldp interface lo0.0
```

Release History Table

Release	Description
20.3R1	Starting in Junos OS Release 20.3R1, support for Layer 2 circuit to provide Layer 2 VPN and VPWS with LDP signaling.
20.1R1	Starting in Junos OS Release 20.1R1, aggregated Ethernet interfaces support VLAN translational cross-connect (TCC) encapsulation.
19.3R1	Starting in Junos OS Release 19.3R1, you can leverage the hardware support available for cross-connects on the ACX5448 device with the Layer 2 local switching functionality using certain models. With this support, you can provide the EVP and Ethernet Virtual Private Line (EVPL) services.

17.1R1	Support for VPN service as the customer is supported on QFX10000 switches starting with Junos OS Release 17.1R1.

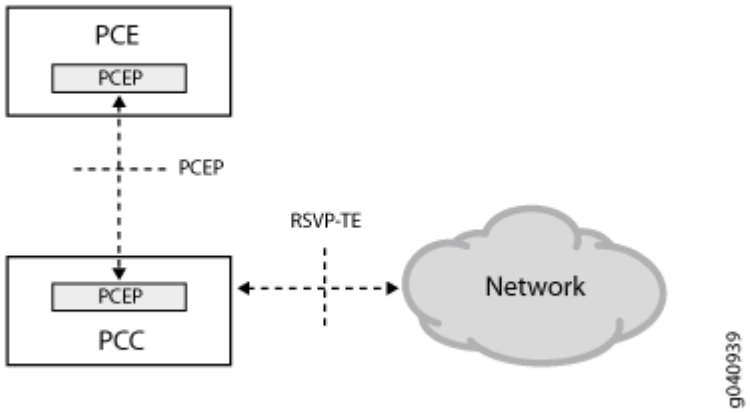
PCEP Overview

A Path Computation Element (PCE) is an entity (component, application, or network node) that is capable of computing a network path or route based on a network graph and applying computational constraints. A Path Computation Client (PCC) is any client application requesting a path computation to be performed by a PCE. The Path Computation Element Protocol (PCEP) enables communications between a PCC and a PCE, or between two PCEs (defined in RFC 5440).

PCEP is a TCP-based protocol defined by the IETF PCE Working Group, and defines a set of messages and objects used to manage PCEP sessions and to request and send paths for multidomain traffic engineered LSPs (TE LSPs). It provides a mechanism for a PCE to perform path computation for a PCC's external LSPs. The PCEP interactions include LSP status reports sent by the PCC to the PCE, and PCE updates for the external LSPs.

Figure 137 on page 2000 illustrates the role of PCEP in the client-side implementation of a stateful PCE architecture in an MPLS RSVP-TE enabled network.

Figure 137: PCEP Session



A TCP-based PCEP session connects a PCC to an external PCE. The PCC initiates the PCEP session and stays connected to the PCE for the duration of the PCEP session. During the PCEP session, the PCC requests LSP parameters from the stateful PCE. On receiving one or more LSP parameters from the PCE, the PCC re-signals the TE LSP. When the PCEP session is terminated, the underlying TCP connection is closed immediately, and the PCC attempts to re-establish the PCEP session.

Thus, the PCEP functions include:

- LSP tunnel state synchronization between a PCC and a stateful PCE—When an active stateful PCE connection is detected, a PCC tries to delegate all LSPs to this PCE in a procedure called LSP state synchronization. PCEP enables synchronization of the PCC LSP state to the PCE.
- Delegation of control over LSP tunnels to a stateful PCE—An active stateful PCE controls one or more LSP attributes for computing paths, such as bandwidth, path (ERO), and priority (setup and hold). PCEP enables such delegation of LSPs for path computation.
- Stateful PCE control of timing and sequence of path computations within and across PCEP sessions– An active stateful PCE modifies one or more LSP attributes, such as bandwidth, path (ERO), and priority (setup and hold). PCEP communicates these new LSP attributes from the PCE to the PCC, after which the PCC re-signals the LSP in the specified path.

Understanding MPLS RSVP-TE

Traffic engineering (TE) deals with performance optimization of operational networks, mainly mapping traffic flows onto an existing physical topology. Traffic engineering provides the ability to move traffic flow away from the shortest path selected by the interior gateway protocol (IGP) and onto a potentially less congested physical path across a network.

For traffic engineering in large, dense networks, MPLS capabilities can be implemented because they potentially provide most of the functionality available from an overlay model, in an integrated manner, and at a lower cost than the currently competing alternatives. The primary reason for implementing MPLS traffic engineering is to control paths along which traffic flows through a network. The main advantage of implementing MPLS traffic engineering is that it provides a combination of the traffic engineering capabilities of ATM, along with the class-of-service (CoS) differentiation of IP.

In an MPLS network, data plane information is forwarded using label switching. A packet arriving on a provider edge (PE) router from the customer edge (CE) router has labels applied to it, and it is then forwarded to the egress PE router. The labels are removed at the egress router and it is then forwarded out to the appropriate destination as an IP packet. The label-switching routers (LSRs) in the MPLS domain use label distribution protocols to communicate the meaning of labels used to forward traffic between and through the LSRs. RSVP-TE is one such label distribution protocol that enables an LSR peer to learn about the label mappings of other peers.

When both MPLS and RSVP are enabled on a router, MPLS becomes a client of RSVP. The primary purpose of the Junos OS RSVP software is to support dynamic signaling within label-switched paths (LSPs). RSVP reserves resources, such as for IP unicast and multicast flows, and requests quality-of-service (QoS) parameters for applications. The protocol is extended in MPLS traffic engineering to enable RSVP to set up LSPs that can be used for traffic engineering in MPLS networks.

When MPLS and RSVP are combined, labels are associated with RSVP flows. Once an LSP is established, the traffic through the path is defined by the label applied at the ingress node of the LSP. The mapping of label to traffic is accomplished using different criteria. The set of packets that are assigned the same label value by a specific node belong to the same forwarding equivalence class (FEC), and effectively define the RSVP flow. When traffic is mapped onto an LSP in this way, the LSP is called an LSP tunnel.

LSP tunnels are a way to establish unidirectional label-switched paths. RSVP-TE builds on the RSVP core protocol by defining new objects and modifying existing objects used in the PATH and RESV objects for LSP establishment. The new objects—LABEL-REQUEST object (LRO), RECORD-ROUTE object (RRO), LABEL object, and EXPLICIT-ROUTE object (ERO)—are optional with respect to the RSVP protocol, except for the LRO and LABEL objects, which are both mandatory for establishing LSP tunnels.

In general, RSVP-TE establishes a label-switched path that ensures frame delivery from ingress to egress router. However, with the new traffic engineering capabilities, the following functions are supported in an MPLS domain:

- Possibility to establish a label-switched path using either a full or partial explicit route (RFC 3209).

- Constraint-based LSP establishment over links that fulfill requirements, such as bandwidth and link properties.
- Endpoint control, which is associated with establishing and managing LSP tunnels at the ingress and egress routers.
- Link management, which manages link resources to do resource-aware routing of traffic engineering LSPs and to program MPLS labels.
- MPLS fast reroute (FRR), which manages the LSPs that need protection and assigns backup tunnel information to these LSPs.

Current MPLS RSVP-TE Limitations

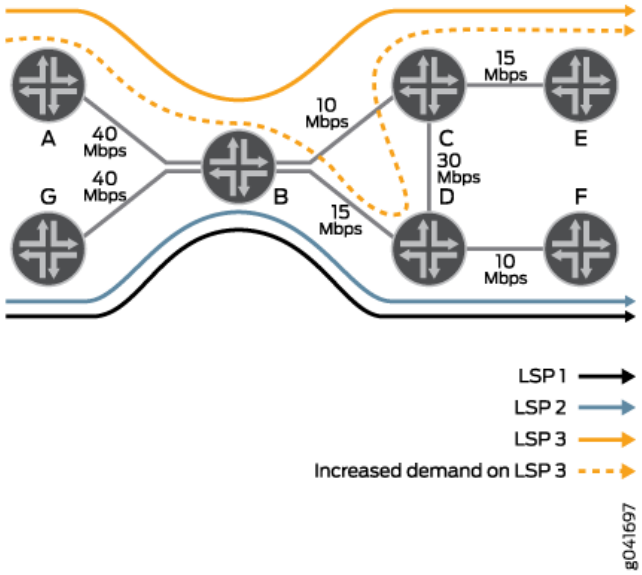
Although the RSVP extensions for traffic engineering enable better network utilization and meet requirements of classes of traffic, today's MPLS RSVP-TE protocol suite has several issues inherent to its distributed nature. This causes a number of issues during contention for bisection capacity, especially within an LSP priority class where a subset of LSPs share common setup and hold priority values. The limitations of RSVP-TE include:

- Lack of visibility of individual per-LSP, per-device bandwidth demands—The ingress routers in an MPLS RSVP-TE network establish LSPs without having a global view of the bandwidth demand on the network. Information about network resource utilization is only available as total reserved capacity by traffic class on a per interface basis. Individual LSP state is available locally on each label edge router (LER) for its own LSPs only. As a result, a number of issues related to demand pattern arise, particularly within a common setup and hold priority.
- Asynchronous and independent nature of RSVP signaling—In RSVP-TE, the constraints for path establishment are controlled by an administrator. As such, bandwidth reserved for an LSP tunnel is set by the administrator and does not automatically imply any limit on the traffic sent over the tunnel. Therefore, bandwidth available on a traffic engineering link is the bandwidth configured for the link, excluding the sum of all reservations made on the link. Thus, the unsignaled demands on an LSP tunnel lead to service degradation of the LSP requiring excess bandwidth, as well as the other LSPs that comply with the bandwidth requirements of the traffic engineering link.
- LSPs established based on dynamic or explicit path options in the order of preference—The ingress routers in an MPLS RSVP-TE network establish LSPs for demands based on the order of arrival. Because the ingress routers do not have a global view of the bandwidth demand on the network, using the order of preference to establish LSPs can cause traffic to be dropped or LSPs not being established at all when there is an excess of bandwidth demand.

As an example, Figure 138 on page 2004 is configured with MPLS RSVP-TE, in which A and G are the label edge routers (LERs). These ingress routers establish LSPs independently based on the order of

demands and have no knowledge or control over each other's LSPs. Routers B, C, and D are intermediate or transit routers that connect to the egress routers E and F.

Figure 138: Example MPLS Traffic Engineering



The ingress routers establish LSPs based on the order in which the demands arrive. If Router G receives two demands of capacity 5 each for G-F, then G signals two LSPs – LSP1 and LSP2 – through G-B-D-F. In the same way, when Router A receives the third demand of capacity 10 for A-E, then it signals an LSP, LSP3, through A-B-C-E. However, if the demand on the A-E LSP increases from 10 to 15, Router A cannot signal LSP3 using the same (A-B-C-E) path, because the B-C link has a lower capacity.

Router A should have signaled the increased demand on LSP3 using the A-B-D-C-E path. Since LSP1 and LSP2 have utilized the B-D link based on the order of demands received, LSP3 is not signaled.

Thus, although adequate max-flow bandwidth is available for all the LSPs, LSP3 is subject to potentially prolonged service degradation. This is due to Router A's lack of global demand visibility and the lack of systemic coordination in demand placement by the ingress routers A and G.

Use of an External Path Computing Entity

As a solution to the current limitations found in the MPLS RSVP-TE path computation, an external path computing entity with a global view of per-LSP, per-device demand in the network independent of available capacity is required.

Currently, only online and real-time constraint-based routing path computation is provided in an MPLS RSVP-TE network. Each router performs constraint-based routing calculations independent of the other

routers in the network. These calculations are based on currently available topology information—information that is usually recent, but not completely accurate. LSP placements are locally optimized, based on current network status. The MPLS RSVP-TE tunnels are set up using the CLI. An operator configures the TE LSP, which is then signaled by the ingress router.

In addition to the existing traffic engineering capabilities, the MPLS RSVP-TE functionality is extended to include an external path computing entity, called the Path Computation Element (PCE). The PCE computes the path for the TE LSPs of ingress routers that have been configured for external control. The ingress router that connects to a PCE is called a Path Computation Client (PCC). The PCC is configured with the Path Computation Client Protocol (PCEP) to facilitate external path computing by a PCE.

For more information, see "Components of External Path Computing" on page 2005.

To enable external path computing for a PCC's TE LSPs, include the `lsp-external-controller` *`pccd`* statement at the `[edit mpls]` and `[edit mpls lsp` *`lsp-name`*`]` hierarchy levels.

Components of External Path Computing

The components that make up an external path computing system are:

Path Computation Element

A Path Computation Element (PCE) can be any entity (component, application, or network node) that is capable of computing a network path or route based on a network graph and applying computational constraints. However, a PCE can compute the path for only those TE LSPs of a PCC that have been configured for external control.

A PCE can either be stateful or stateless.

- Stateful PCE—A stateful PCE maintains strict synchronization between the PCE and network states (in terms of topology and resource information), along with the set of computed paths and reserved resources in use in the network. In other words, a stateful PCE utilizes information from the traffic engineering database as well as information about existing paths (for example, TE LSPs) in the network when processing new requests from the PCC.

  A stateful PCE is of two types:

  - Passive stateful PCE—Maintains synchronization with the PCC and learns the PCC LSP states to better optimize path calculations, but does not have control over them.
  - Active stateful PCE—Actively modifies the PCC LSPs, in addition to learning about the PCC LSP states.

> **NOTE**: In a redundant configuration with main and backup active stateful PCEs, the backup active stateful PCE cannot modify the attributes of delegated LSPs until it becomes the main PCE at the time of a failover. There is no preempting of PCEs in the case of a switchover. The main PCE is backed by a backup PCE, and when the main PCE goes down, the backup PCE assumes the role of the main PCE and remains the main PCE even after the PCE that was previously the main PCE is operational again.

A stateful PCE provides the following functions:

- Offers offline LSP path computation.
- Triggers LSP re-route when there is a need to re-optimize the network.
- Changes LSP bandwidth when there is an increase in bandwidth demand from an application.
- Modifies other LSP attributes on the router, such as ERO, setup priority, and hold priority.

A PCE has a global view of the bandwidth demand in the network and maintains a traffic-engineered database to perform path computations. It performs statistics collection from all the routers in the MPLS domain using SNMP and NETCONF. This provides a mechanism for offline control of the PCC's TE LSPs. Although an offline LSP path computation system can be embedded in a network controller, the PCE acts like a full-fledged network controller that provides control over the PCC's TE LSPs, in addition to computing paths.

Although a stateful PCE allows for optimal path computation and increased path computation success, it requires reliable state synchronization mechanisms, with potentially significant control plane overhead and the maintenance of a large amount of data in terms of states, as in the case of a full mesh of TE LSPs.

- Stateless PCE—A stateless PCE does not remember any computed path, and each set of requests is processed independently of each other (RFC 5440).

Path Computation Client

A Path Computation Client (PCC) is any client application requesting a path computation to be performed by a PCE.

A PCC can connect to a maximum of 10 PCEs at one time. The PCC to PCE connection can be a configured static route or a TCP connection that establishes reachability. The PCC assigns each connected PCE a priority number. It sends a message to all the connected PCEs with information about its current LSPs, in a process called LSP state synchronization. For the TE LSPs that have external control enabled, the PCC delegates those LSPs to the main PCE. The PCC elects, as the main PCE, a PCE with the lowest priority number, or the PCE that it connects to first in the absence of a priority number.

The PCC re-signals an LSP based on the computed path it receives from a PCE. When the PCEP session with the main PCE is terminated, the PCC elects a new main PCE, and all delegated LSPs to the previously main PCE are delegated to the newly available main PCE.

Path Computation Element Protocol

The Path Computation Element Protocol (PCEP) is used for communication between PCC and PCE (as well as between two PCEs) (RFC 5440). PCEP is a TCP-based protocol defined by the IETF PCE Working Group, and defines a set of messages and objects used to manage PCEP sessions and to request and send paths for multidomain TE LSPs. The PCEP interactions include PCC messages, as well as notifications of specific states related to the use of a PCE in the context of MPLS RSVP-TE. When PCEP is used for PCE-to-PCE communication, the requesting PCE assumes the role of a PCC.

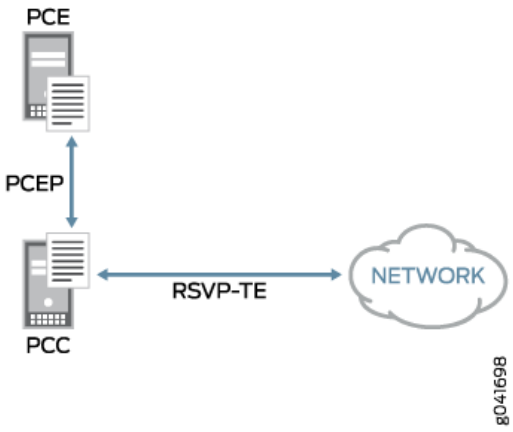
Thus, the PCEP functions include:

- LSP tunnel state synchronization between PCC and a stateful PCE.
- Delegation of control over LSP tunnels to a stateful PCE.

Interaction Between a PCE and a PCC Using PCEP

Figure 139 on page 2007 illustrates the relationship between a PCE, PCC, and the role of PCEP in the context of MPLS RSVP-TE.

Figure 139: PCC and RSVP-TE



The PCE to PCC communication is enabled by the TCP-based PCEP. The PCC initiates the PCEP session and stays connected to a PCE for the duration of the PCEP session.

NOTE: Starting with Junos OS Release 16.1, you can secure a PCEP session using TCP-MD5 authentication as per RFC 5440. To enable the MD5 security mechanism for a PCEP session, it is recommended that you define and bind the MD5 authentication key at the `[edit protocols pcep pce pce-id]` hierarchy level for a PCEP session. You can, however, also use a predefined keychain from the `[edit security authentication-key-chains key-chain]` hierarchy level to secure a PCEP session. In this case, you should bind the predefined keychain into the PCEP session at the `[edit protocols pcep pce pce-id]` hierarchy level.

The PCE and PCC use the same key to verify the authenticity of each segment sent on the TCP connection of the PCEP session, thereby securing the PCEP communication between the devices, which might be subject to attacks and can disrupt services on the network.

For more information on securing PCEP sessions using MD5 authentication, see "TCP-MD5 Authentication for PCEP Sessions" on page 2018.

Once the PCEP session is established, the PCC performs the following tasks:

1. LSP state synchronization—The PCC sends information about all the LSPs (local and external) to all connected PCEs. For external LSPs, the PCC sends information about any configuration change, RRO change, state change, and so on, to the PCE.

   For PCE-initiated LSPs, there is no LSP configuration present on the PCC. The PCE initiating the LSP sends the LSP parameters to the PCC that has indicated its capability of supporting PCE-initiated LSPs.

   NOTE: Support for PCE-initiated LSPs is provided in Junos OS Release 13.3 and later releases.

2. LSP delegation—After the LSP state information is synchronized, the PCC then delegates the external LSPs to one PCE, which is the main active stateful PCE. Only the main PCE can set parameters for the external LSP. The parameters that the main PCE modifies include bandwidth, path (ERO), and priority (setup and hold). The parameters specified in the local configuration are overridden by the parameters that are set by the main PCE.

   NOTE: When the PCEP session with the main PCE is terminated, the PCC elects a new main PCE, and all delegated LSPs to the previously main PCE are delegated to the newly available main PCE.

In the case of PCE-initiated LSPs, the PCC creates the LSP using the parameters received from the PCE. The PCC assigns the PCE-initiated LSP a unique LSP-ID, and automatically delegates the LSP to the PCE. A PCC cannot revoke the delegation for the PCE-initiated LSPs for an active PCEP session.

When a PCEP session terminates, the PCC starts two timers without immediately deleting the PCE-initiated LSPs – **delegation cleanup timeout** and **lsp cleanup timer** – to avoid disruption of services. During this time, an active stateful PCE can acquire control of the LSPs provisioned by the failed PCE, by sending a create request for the LSP.

Control over PCE-initiated LSPs reverts to the PCC at the expiration of the **delegation cleanup timeout**. When the **delegation cleanup timeout** expires, and no other PCE has acquired control over the LSP from the failed PCE, the PCC takes local control of the non-delegated PCE-initiated LSP. Later, when the original or a new active stateful PCE wishes to acquire control of the locally controlled PCE-initiated LSPs, the PCC delegates these LSPs to the PCE and the **lsp cleanup timer** timer is stopped.

A PCE may return the delegation of the PCE-initiated LSP to the PCC to allow LSP transfer between PCEs. This triggers the **lsp cleanup timer** for the PCE-initiated LSP. The PCC waits for the LSP cleanup timer to expire before removing the non-delegated PCE-initiated LSPs from the failed PCE.

When the **lsp cleanup timer** expires, and no other PCE has acquired control over the LSPs from the failed PCE, the PCC deletes all the LSPs provisioned by the failed PCE.

> **NOTE**: In compliance with *draft-ietf-pce-stateful-pce-09*, revoking of PCE-initiated LSP delegations by a PCC happens in a make-before-break fashion before the LSPs are redelegated to an alternate PCE. Starting in Junos OS Release 18.1R1, the `lsp-cleanup-timer` must be greater than or equal to the `delegation-cleanup-timeout` for the PCC to revoke the LSP delegations. If not, the redelegation timeout interval for the PCC can be set to infinity, where the LSP delegations to that PCE remain intact until specific action is taken by the PCC to change the parameters set by the PCE.

3. LSP signaling—On receiving one or more LSP parameters from the main active stateful PCE, the PCC re-signals the TE LSP based on the PCE provided path. If the PCC fails to set up the LSP, it notifies the PCE of the setup failure and waits for the main PCE to provide new parameters for that LSP, and then re-signals it.

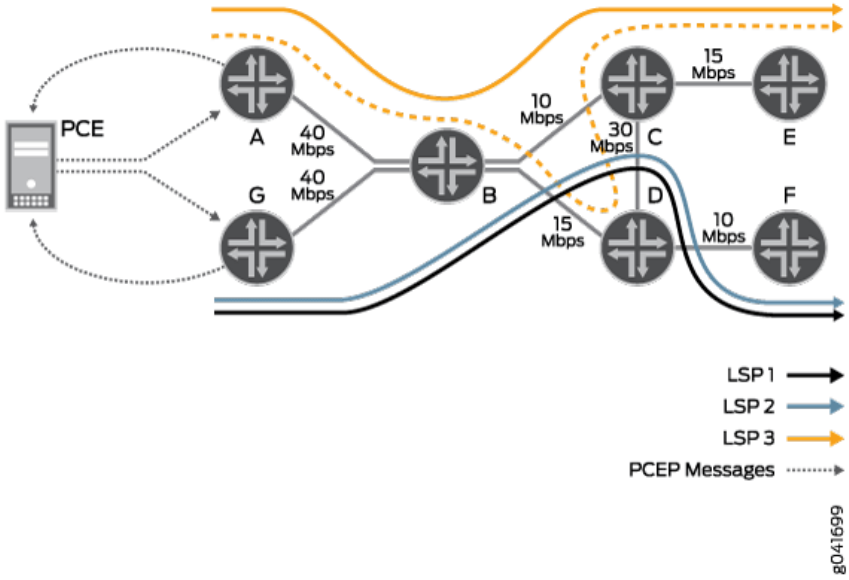
   When the PCE specifies a path that is incomplete or has loose hops where only the path endpoints are specified, the PCC does not perform local constraint-based routing to find out the complete set of hops. Instead, the PCC provides RSVP with the PCE provided path, as it is, for signaling, and the path gets set up using IGP hop-by-hop routing.

Considering the topology used in Figure 138 on page 2004, Figure 140 on page 2010 illustrates the partial client-side PCE implementation in the MPLS RSVP-TE enabled network. The ingress routers A

and G are the PCCs that are configured to connect to the external stateful PCE through a TCP connection.

The PCE has a global view of the bandwidth demand in the network and performs external path computations after looking up the traffic engineering database. The active stateful PCE then modifies one or more LSP attributes and sends an update to the PCC. The PCC uses the parameters it receives from the PCE to re-signal the LSP.

Figure 140: Example PCE for MPLS RSVP-TE



This way, the stateful PCE provides a cooperative operation of distributed functionality used to address specific challenges of a shortest interdomain constrained path computation. It eliminates congestion scenarios in which traffic streams are inefficiently mapped onto available resources, causing overutilization of some subsets of network resources, while other resources remain underutilized.

LSP Behavior with External Computing

LSP Types

In a client-side PCE implementation, there are three types of TE LSPs:

- CLI-controlled LSPs—The LSPs that do not have the `lsp-external-controller` *pccd* statement configured are called CLI-controlled LSPs. Although these LSPs are under local control, the PCC updates the connected PCEs with information about the CLI-controlled LSPs during the initial LSP synchronization process. After the initial LSP synchronization, the PCC informs the PCE of any new and deleted LSPs as well.

- PCE-controlled LSPs—The LSPs that have the `lsp-external-controller` *pccd* statement configured are called PCE-controlled LSPs. The PCC delegates the PCC-initiated LSPs to the main PCE for external path computation.

  The PCC informs the PCE about the configured parameters of a PCE-controlled LSP, such as bandwidth, ERO, and priorities. It also informs the PCE about the actual values used for these parameters to set up the LSP including the RRO, when available.

  The PCC sends such LSP status reports to the PCE only when a reconfiguration has occurred or when there is a change in the ERO, RRO, or status of the PCE-controlled LSPs under external control.

  There are two types of parameters that come from the CLI configuration of an LSP for a PCE:

  - Parameters that are not overridden by a PCE, and that are applied immediately.
  - Parameters that are overridden by a PCE. These parameters include bandwidth, path, and priority (setup and hold values). When the control mode switches from external to local, the CLI-configured values for these parameters are applied at the next opportunity to re-signal the LSP. The values are not applied immediately.

- Externally-provisioned LSPs (or PCE-initiated LSPs)—The LSPs that have the `lsp-provisioning` statement configured are called PCE-initiated LSPs. A PCE-initiated LSP is dynamically created by an external PCE; as a result, there is no LSP configuration present on the PCC. The PCC creates the PCE-initiated LSP using the parameters provided by the PCE, and automatically delegates the LSP to the PCE.

  NOTE: Support for PCE-initiated LSPs is provided in Junos OS Release 13.3 and later releases.

The CLI-controlled LSPs, PCE-controlled LSPs, and PCE-initiated LSPs can coexist on a PCC.

The CLI-controlled LSPs and PCE-controlled LSPs can coexist on a PCC.

LSP Control Mode

In a client-side PCE implementation, there are two types of control modes for a PCC-controlled LSP:

- External—By default, all PCE-controlled LSPs are under external control. When an LSP is under external control, the PCC uses the PCE-provided parameters to set up the LSP.
- Local—A PCE-controlled LSP can come under local control. When the LSP switches from external control to local control, path computation is done using the CLI-configured parameters and constraint-based routing. Such a switchover happens only when there is a trigger to re-signal the LSP.

Until then, the PCC uses the PCE-provided parameters to signal the PCE-controlled LSP, although the LSP remains under local control.

A PCE-controlled LSP switches to local control from its default external control mode in cases such as no connectivity to a PCE or when a PCE returns delegation of LSPs back to the PCC.

For more information about CLI-controlled LSPs and PCE-controlled LSPs, see "LSP Types" on page 2010.

Configuration Statements Supported for External Computing

Table 33 on page 2012 lists the MPLS and existing LSP configuration statements that apply to a PCE-controlled LSP.

Table 33: Applicability of MPLS and Existing LSP Configurations to a PCE-Controlled LSP

Support for PCE-Controlled LSP	Applicable LSP Configuration Statements	Applicable MPLS Configuration Statements
These configuration statements can be configured along with the PCE configuration. However, they take effect only when the local configuration is in use. During PCE control, these configuration statements remain inactive.	• admin-group • auto-bandwidth • hop-limit • least-fill • most-fill • random	• admin-group • admin-groups • admin-group-extended • hop-limit • no-cspf • smart-optimize-timer
These configuration statements can be configured along with the PCE configuration, but are overridden by the PCE-controlled LSP attributes. However, when the local configuration is in use, the configured values for these configuration statements are applied. **NOTE**: Changes to the local configuration using the CLI while the LSP is under the control of a stateful PCE do not have any effect on the LSP. These changes come into effect only when the local configuration is applied.	• bandwidth • primary • priority	• priority

Table 33: Applicability of MPLS and Existing LSP Configurations to a PCE-Controlled LSP *(Continued)*

Support for PCE-Controlled LSP	Applicable LSP Configuration Statements	Applicable MPLS Configuration Statements
These configuration statements cannot be configured along with the PCE configuration.	• p2mp • template	• p2mp-lsp-next-hop

The rest of the LSP configuration statements are applicable in the same way as for existing LSPs. On configuring any of the above configuration statements for a PCE-controlled LSP, an MPLS log message is generated to indicate when the configured parameters take effect.

PCE-Controlled LSP Protection

The protection paths, including fast reroute and bypass LSPs, are locally computed by the PCC using constraint-based routing. A stateful PCE specifies the primary path (ERO) only. A PCE can also trigger a non-standby secondary path, even if the local configuration does not have a non-standby secondary path for LSP protection.

PCE-Controlled LSP ERO

For PCE-controlled LSPs (PCC-delegated LSPs and PCE-initated LSPs), only a full-blown Explicit Route Object (ERO) object has to be sent from the PCE to the PCC; otherwise the PCC rejects the PCUpdate or PCCreate message for that PCEP session.

Starting in Junos OS Release 17.2, in addition to `external cspf`, two new path computation types are introduced for the PCE-controlled LSPs: `local cspf` and `no cspf`.

- `local cspf`—A PCC uses the `local cspf` computation type only when the PCE sends in a Juniper Vendor TLV (enterprise number: 0x0a4c) of type 5.
- `no cspf`—Neither the PCE nor the PCC performs a constrained path calculation. The endpoints and constraints are given to the RSVP module for setting up the LSP with the IGP path.

  A PCC uses `no cspf` computation type in the following cases:

  - When the PCE sends `local cspf` TLV, and when the Junos OS configuration or matching template for this LSP included `no-cspf` in the PCC-delegated LSP.
  - When the PCE sends `local cspf` TLV, and when the Junos OS configuration template for this LSP included `no-cspf` in the PCE-initiated LSP.

- When the PCE does not send `local cspf` TLV with an empty ERO or loose ERO (with loose bit set in the ERO object).

With these new computation types, a PCC can accept an ERO object either as a loose ERO, or as an empty ERO. An external path computing entity that is not capable of computing a path can modify parameters such as bandwidth and color, based on the analytics. In such cases, an empty ERO object or loose ERO is used and the path to be taken is decided by the PCC.

PCE-Controlled Point-to-Multipoint RSVP-TE LSPs

After a PCEP session is established between a PCE and a PCC, the PCC reports all the LSPs in the system to the PCE for LSP state synchronization. This includes PCC-controlled, PCE-delegated, and PCE-initiated point-to-point LSPs. Starting with Junos OS Release 15.1F6 and 16.1R1, this capability is extended to report point-to-multipoint LSPs as well. For a PCE, the point-to-multipoint LSP is similar to that of RSVP point-to-multipoint LSP, where the point-to-multipoint LSP is treated as collection of point-to-point LSPs grouped under a point-to-multipoint identifier.

By default, PCE control of point-to-multipoint LSPs is not supported on a PCC. To add this capability, include the `p2mp-lsp-report-capability` statement at the `[edit protocols pcep pce` *`pce-name`*`]` or `[edit protocols pcep pce-group` *`group-id`*`]` hierarchy levels. After the point-to-multipoint report capability is configured on a PCC, the PCC advertises this capability to the PCE. If the PCE advertises the same point-to-multipoint report capability in return, then the PCC reports the complete point-to-multipoint LSP tree to the PCE for LSP state synchronization.

A PCC with the point-to-multipoint TE LSP capability supports reporting of point-to-multipoint TE LSPs for stateful PCEs, point-to-multipoint update, and LSP database supporting point-to-multipoint LSP name as key. However, the following features and functions are not supported for Junos OS Release 15.1F6 and 16.1:

- Static point-to-multipoint LSPs
- PCE-delegated and PCE-initiated point-to-multipoint LSPs
- Auto-bandwidth
- TE++
- PCE request and reply message
- Creation of point-to-multipoint LSPs using templates
- Configuring forward entry on the PCE-initiated point-to-multipoint LSPs
- Configuring forward entry on the router pointing to a provisioned LSP.

PCE-Initiated Point-to-Point LSPs

Starting with Junos OS Release 16.1, the PCEP functionality is extended to allow a stateful PCE to initiate and provision traffic engineering LSPs through a PCC. Earlier, the LSPs were configured on the PCC and the PCC delegated control over the external LSPs to a PCE. The ownership of the LSP state was maintained by the PCC. With the introduction of the PCE-initiated LSPs, a PCE can initiate and provision a traffic engineering point-to-point LSP dynamically without the need for a locally configured LSP on the PCC. On receiving a PCCreate message from a PCE, the PCC creates the PCE-initiated LSP and automatically delegates the LSP to the PCE.

By default, a PCC rejects the request for provisioning PCE-initiated point-to-point LSPs from a PCE. To enable support of PCE-initated LSPs on the PCC, include the lsp-provisioning statement at the [edit protocols pcep pce *pce-id*] or [edit protocols pcep pce-group *group-id*] hierarchy levels.

A PCC indicates its capability of supporting PCE-initiated point-to-point LSPs while establishing the Path Computation Element Protocol (PCEP) session with the PCE. A PCE selects a PCC with this capability to initiate an LSP. The PCE provides the PCC with the PCE-initiated LSP parameters. On receiving the PCE-initiated point-to-point LSP parameters, the PCC sets up the LSP, assigns an LSP ID, and automatically delegates the LSP to the PCE.

When the PCE initiating the LSP does not provide the PCE-initiated point-to-point LSP parameters, the PCC uses the default parameters. An optional LSP template may also be configured to specify values for the PCE-initiated point-to-point LSP when the LSP parameters are not provided by the PCE. To configure an LSP template for PCE-initiated point-to-point LSPs on the PCC, include the "label-switched-path-template" on page 3059 statement at the [edit protocols mpls lsp-external-controller *lsp-external-controller*] hierarchy level.

When a PCEP session terminates, the PCC starts two timers without immediately deleting the PCE-initiatedLSPs—delegation cleanup timeout and lsp cleanup timer—to avoid disruption of services. During this time, an active stateful PCE can acquire control of the LSPs provisioned by the failed PCE.

A PCE may return the delegation of the PCE-initiated point-to-point LSP to the PCC to allow LSP transfer between PCEs. Control over PCE-initiated LSPs reverts to the PCC at the expiration of the delegation cleanup timeout. When the delegation cleanup timeout expires, and no other PCE has acquired control over the LSP from the failed PCE, the PCC takes local control of the non-delegated PCE-initiated LSP. Later, when the original or a new active stateful PCE wishes to acquire control of the locally controlled PCE-initiated point-to-point LSPs, the PCC delegates these LSPs to the PCE and the LSP cleanup timer is stopped.

The PCC waits for the LSP cleanup timer to expire before deleting the non-delegated PCE-initiated point-to-point LSPs from the failed PCE. When the LSP cleanup timer expires, and no other PCE has acquired control over the LSPs from the failed PCE, the PCC deletes all the LSPs provisioned by the failed PCE.

Starting in Junos OS Release 21.1R1, we support nonstop active routing (NSR) for PCE-initiated RSVP-based point-to-point and point-to-multipoint LSPs. Only the primary Routing Engine maintains the PCEP session with the controller. It synchronizes all RSVP LSPs initiated by PCEs, including multicast flow specifications for any PCE-initiated P2MP LSPs, with the backup Routing Engine. During a switchover, the PCEP session goes down and re-establishes when the backup Routing Engine becomes the primary Routing Engine. This reduces traffic loss for the traffic carried over PCE-initiated RSVP LSPs during Routing Engine switchovers. This feature is enabled when NSR is configured.

PCE-Initiated Bypass LSP

Understanding PCE-Initiated Bypass LSPs

There can be traffic outages at the time of a link or node failure because the backup protection paths in the network do not have sufficient bandwidth to handle traffic. In such networks, although a PCE may be used to compute all the paths, to optimize network performance, the local protection paths also need to be controlled through the PCE.

Junos OS Release 19.2R1 and later releases provide partial support for the Internet draft draft-cbrt-pce-stateful-local-protection-01 (expires December 2018), *PCEP Extensions for RSVP-TE Local-Protection with PCE-Stateful*, where the PCEP functionality is extended to allow a stateful PCE to initiate, provision, and manage bypass LSPs for a protected interface. Multiple bypass LSPs with bandwidth reservation can be initiated by the PCE to protect a link or node. The bandwidth on the bypass LSP is expected to be smaller than the total bandwidth of the primary LSPs that it might protect.

The existing bypass selection mechanism, that prefers manual bypass LSPs (if available) over dynamic bypass LSPs, is extended to prefer PCE-provisioned bypass LSPs (if available) over dynamic bypass LSPs. The PCE-provisioned bypass LSPs have a higher preference over dynamic bypass LSPs, but are less preferred over manual bypass LSPs.

The set of operations that are used to perform on any operational bypass LSPs, such as `clear rsvp session`, can also be performed on the PCE-initiated bypass LSPs. You can use commands, such as `show path-computation-client status extensive` and `show path-computation-client lsp` to view PCE-initiated bypass LSP statistics.

With the support of PCE-initiated bypass LSP, you can:

- Create a RSVP bypass LSP through PCEP from an external controller, where the bypass LSP:
  - can be for link or node protection.
  - must have a non-zero bandwidth.
  - must have a specified strict ERO.
- Update the bandwidth and ERO for an existing PCE-created bypass LSP.

- Oversubscribe the bypass LSP bandwidth for admission control of primary LSPs. This must be a per-bypass parameter, and should allow updating the subscription per bypass LSP.

Benefits of PCE-Initiated Bypass LSP

The PCE-initiated bypass LSPs provide the following benefits:

- Better control over traffic after a failure and more deterministic path computation of protection paths.
- Meet complex constraints and diversity requirements, such as maintaining diverse paths for LSPs, as well as their local protection paths.
- Ensure links are not overloaded during failure events.

Behavior of PCE-Initiated Bypass LSPs During PCEP Session Failure

At the time of a PCEP session failure, the PCE-initiated bypass LSPs become orphan until the expiration of the state timeout timer. The PCE-initiated bypass LSPs get cleaned up on the expiration of the state timeout timer. To obtain control of a PCE-initiated bypass LSP (after PCEP session fails), a PCE (either the primary PCE, or any secondary PCE) sends a PCInitiate message before the expiration of the state timeout timer.

PCE-Initiated Point-to-Multipoint LSPs

With the introduction of point-to-multipoint PCE-initiated LSPs, a PCE can initiate and provision a point-to-multipoint LSP dynamically without the need for local LSP configuration on the PCC. This enables the PCE to control the timing and sequence of the point-to-multipoint path computations within and across Path Computation Element Protocol (PCEP) sessions, thereby creating a dynamic network that is centrally controlled and deployed.

For more information, see "Understanding Path Computation Element Protocol for MPLS RSVP-TE with Support for PCE-Initiated Point-to-Multipoint LSPs" on page 2076.

SRv6 LSP in PCEP

Segment routing can be applied to both MPLS and IPv6 forwarding plane. The Path Computation Element (PCE) computes SR paths for both MPLS and IPv6 forwarding plane. Segment routing for PCEP supports SR LSPs such as PCE-initiated, locally created, and delegated SR LSPs in IPv6 forwarding plane.

Benefits of SRv6 LSPs in PCEP

- Allows you to create PCE initiated SRv6 LSPs.

- Delegate the SRv6 LSPs created on the router to the controller.
- Report the LSPs which are locally created on the router to the controller.
- SRv6 network programming provides the flexibility to leverage segment routing without deploying MPLS.

PCEP supports creation, updation, and deletion of PCE initiated colored and uncolored SRv6 LSPs. When PCE initiated SRv6 LSP co-exists along with a static SRv6 LSP for the same IP or color-based IP, then the static SRv6 TE LSP contributing route is preferred over PCE initiated SRv6 TE LSP contributing route.

To configure a PCEP session to be SRv6 capable, you need to enable the `srv6-capability` configuration statement at the [edit protocols pcep pce pce-id] or at the [`edit protocols pcep pce-group pce-id`] hierarchy levels. If the `srv6-capability` configuration statement is enabled, then you must also enable srv6 configuration statement at the [`edit protocols source-packet-routing`] hierarchy level otherwise during commit and error will be displayed.

To configure SRv6 for SR-TE, you need to add the srv6 configuration statement at the [edit protocols source-packet-routing] hierarchy level.

[See Understanding SR-TE Policy for SRv6 Tunnel for more information.

To configure the maximum segment list depth for SRv6 LSP, you need to enable the `maximum-srv6-segment-list-depth` configuration statement at the [`edit protocols pcep`] hierarchy level.

Auto-Bandwidth and PCE-Controlled LSP

Starting in Junos OS Release 14.2R4, support of auto-bandwidth is provided for PCE-controlled LSPs. In earlier releases, the auto-bandwidth option did not apply to PCE-controlled LSPs, although LSPs under the control of auto-bandwdith and constraint-based routing could coexist with PCE-controlled LSPs. The statistics collection for auto-bandwidth was taking effect only when the control mode of a PCE-controlled LSP changes from external to local. This was happening in cases such as no connectivity to a PCE or when a PCE returns delegation of LSPs back to the PCC.

TCP-MD5 Authentication for PCEP Sessions

A stateful PCE server automates the creation of traffic engineering paths across the network, increasing network utilization and enabling a customized programmable networking experience with the use of PCEP communication with a PCC. A PCC sends LSP reports to a PCE server, and the PCE updates or provisions LSPs back to the PCC. The data sent over a PCEP session is crucial for a PCE server to perform external path computing. As a result, an attack on the PCEP communication can disrupt network services. If altered PCEP messages are sent to a PCC, inappropriate LSPs can be set up. Similarly, if altered PCEP messages are sent to a PCE, an incorrect view of the network is learned by the PCE.

Considering the significance of the PCEP communication between a PCE and PCC in executing the PCE functionalities effectively, Junos OS Release 16.1 introduces the feature of securing a PCEP session using TCP-MD5 authentication as per RFC 5440. This feature protects the communication between a PCE and PCC over a PCEP session, which might be subject to an attack, and can disrupt network services.

To enable the MD5 security mechanism for a PCEP session, it is recommended that you define and bind the MD5 authentication key at the `[edit protocols pcep pce pce-id]` hierarchy level for a PCEP session. You can, however, also use a predefined keychain from the `[edit security authentication-key-chains key-chain]` hierarchy level to secure a PCEP session. In this case, you should bind the predefined keychain into the PCEP session at the `[edit protocols pcep pce pce-id]` hierarchy level.

The following configuration is executed on the PCC to establish a secure PCEP session with a PCE:

- Using MD5 authentication key:

```
[edit protocols pcep pce pce-id]
user@PCC# set authentication-key key
```

- Using predefined authentication keychain:

```
[edit protocols pcep pce pce-id]
user@PCC# set authentication-key-chain key-chain
user@PCC# set authentication-algorithm md5
```

For secure PCEP sessions to be established successfully, the MD5 authentication should be configured with the pre-shared authentication key on both the PCE server and the PCC. The PCE and PCC use the same key to verify the authenticity of each segment sent on the TCP connection of the PCEP session.

NOTE:

- Junos OS Release 16.1 supports only TCP-MD5 authentication for PCEP sessions, without extending support for TLS and TCP-AO, such as protection against eavesdropping, tampering, and message forgery.
- Initial application of security mechanism to a PCEP session causes the session to reset.
- If MD5 is misconfigured or not configured on one side of the PCEP session, the session does not get established. Verify that the configurations on the PCC and PCE are matching.

- This feature does not provide support for any session authentication mechanism.
- To view the authentication keychain used by the PCEP session, use the `show path-computation-client status` and `show protocols pcep` command outputs.
- Use the `show system statistics tcp | match auth` command to view the number of packets that get dropped by TCP because of authentication errors.
- Operation of the keychain can be verified by using the `show security keychain detail` command output.

Impact of Client-Side PCE Implementation on Network Performance

The maintenance of a stateful database can be non-trivial. In a single centralized PCE environment, a stateful PCE simply needs to remember all the TE LSPs that the PCE has computed, the TE LSPs that were actually set up (if this can be known), and when the TE LSPs were torn down. However, these requirements cause substantial control protocol overhead in terms of state, network usage and processing, and optimizing links globally across the network. Thus, the concerns of a stateful PCE implementation include:

- Any reliable synchronization mechanism results in significant control plane overhead. PCEs might synchronize state by communicating with each other, but when TE LSPs are set up using distributed computation performed among several PCEs, the problems of synchronization and race condition avoidance become larger and more complex.
- Out-of-band traffic engineering database synchronization can be complex with multiple PCEs set up in a distributed PCE computation model, and can be prone to race conditions, scalability concerns, and so on.
- Path calculations incorporating total network state is highly complex, even if the PCE has detailed information on all paths, priorities, and layers.

In spite of the above concerns, the partial client-side implementation of the stateful PCE is extremely effective in large traffic engineering systems. It provides rapid convergence and significant benefits in terms of optimal resource usage, by providing the requirement for global visibility of a TE LSP state and for ordered control of path reservations across devices within the system being controlled.

Example: Configuring the Path Computation Element Protocol for MPLS RSVP-TE

IN THIS SECTION

- Requirements | 2021
- Overview | 2022
- Configuration | 2025
- Verification | 2032

This example shows how to enable external path computing by a Path Computation Element (PCE) for traffic engineered label-switched paths (TE LSPs) on a Path Computation Client (PCC). It also shows how to configure the Path Computation Element Protocol (PCEP) on the PCC to enable PCE to PCC communication.

Requirements

This example uses the following hardware and software components:

- Three routers that can be a combination of ACX Series routers, M Series Multiservice Edge Routers, MX Series 5G Universal Routing Platforms, T Series Core Routers, or PTX Series Transport Router, one of which is configured as a PCC.
- A TCP connection to an external stateful PCE from the PCC.
- Junos OS Release 12.3 or later running on the PCC along with the JSDN add-on package.

NOTE: The JSDN add-on package is required to be installed along with the core Junos OS installation package.

Before you begin:

1. Configure the device interfaces.
2. Configure MPLS and RSVP-TE.
3. Configure IS-IS or any other IGP protocol.

Overview

IN THIS SECTION

- Topology | **2024**

Starting with Junos OS Release 12.3, the MPLS RSVP-TE functionality is extended to provide a partial client-side implementation of the stateful PCE architecture (draft-ietf-pce-stateful-pce) on a PCC.

NOTE: The partial client-side implementation of the stateful PCE architecture is based on version 2 of Internet draft draft-ietf-pce-stateful-pce. Starting with Junos OS Release 16.1, this implementation is upgraded to support version 7, as defined in Internet draft draft-ietf-pce-stateful-pce-07. Releases prior to 16.1 support the older version of the PCE draft, causing interoperability issues between a PCC running a previous release and a stateful PCE server that adheres to Internet draft draft-ietf-pce-stateful-pce-07.

To enable external path computing by a PCE, include the `lsp-external-controller` statement on the PCC at the `[edit mpls]` and `[edit mpls lsp` *`lsp-name`*`]` hierarchy levels.

```
lsp-external-controller pccd;
```

An LSP configured with the `lsp-external-controller` statement is referred to as a PCE-controlled LSP and is under the external control of a PCE by default. An active stateful PCE can override the parameters set from the CLI, such as bandwidth, path (ERO), and priority, for such PCE-controlled LSPs of the PCC.

To enable PCE to PCC communication, configure PCEP on the PCC at the `[edit protocols]` hierarchy level.

```
pcep { ... }
```

When configuring PCEP on a PCC, be aware of the following considerations:

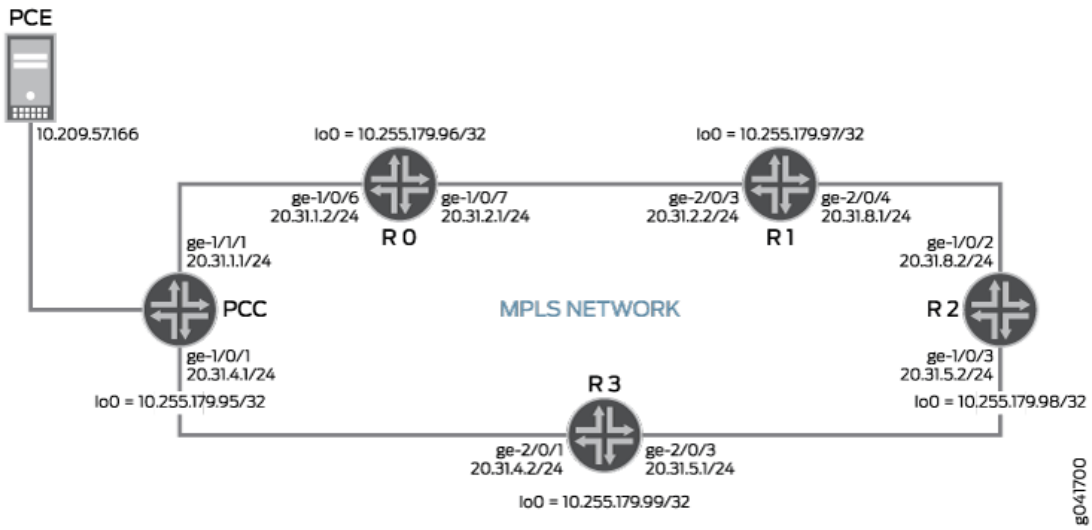
- The JSDN add-on package is required to be installed along with the core Junos OS installation package.

- Junos OS Release 12.3 supports only stateful PCEs.

- A PCC can connect to a maximum of 10 stateful PCEs. At any given point in time, there can be only one main PCE (the PCE with the lowest priority value, or the PCE that connects to the PCC first in the absence of a PCE priority) to which the PCC delegates LSPs for path computation.
- For Junos OS Release 12.3, the PCC always initiates the PCEP sessions. PCEP sessions initiated by remote PCEs are not accepted by the PCC.
- Existing LSP features, such as LSP protection and make-before-break, work for PCE-controlled LSPs.
- The auto-bandwidth option is turned off for PCE-controlled LSPs, although LSPs under the control of auto-bandwdith and constraint-based routing can coexist with PCE-controlled LSPs.
- PCE-controlled LSPs can be referred to by other CLI configurations, such as lsp-nexthop to routes, forwarding adjacencies, CCC connections, and logical tunnels.
- PCE-controlled LSPs do not support GRES.
- PCE-controlled LSPs under logical-systems are not supported.
- PCE-controlled LSPs cannot be point-to-multipoint LSPs.
- Bidirectional LSPs are not supported.
- PCE-controlled LSPs cannot have secondary paths without a primary path.
- PCE-controlled LSPs depend on external path computation, which impacts overall setup time, reroutes, and make-before-break features.
- Setup time and convergence time (reroute, MBB) for exisiting LSPs is the same as in previous releases, in the absence of PCE-controlled LSPs. However, a small impact is seen in the presence of PCE-controlled LSPs.
- ERO computation time is expected to be significantly higher than local-CSPF.

Topology

Figure 141: Configuring PCEP for MPLS RSVP-TE



In this example, PCC is the ingress router that connects to the external active stateful PCE.

The external LSPs of Router PCC are computed as follows:

1. Router PCC receives the LSP tunnel configuration that was set up using the CLI. Assuming that the received configuration is enabled with external path computing, Router PCC becomes aware that some of the LSP attributes – bandwidth, path, and priority – are under the control of the stateful PCE and delegates the LSP to the PCE.

   In this example, the external LSP is called `PCC-to-R2` and it is being set up from Router PCC to Router R2 . The CLI-configured ERO for `PCC-to-R2` is PCC-R0-R1-R2. The bandwidth for `PCC-to-R2` is 10m, and both the setup and hold priority values are 4.

2. Router PCC tries to retrieve the PCE-controlled LSP attributes. To do this, Router PCC sends out a PCRpt message to the stateful PCE stating that the LSP has been configured. The PCRpt message communicates the status of the LSP and contains the local configuration parameters of the LSP.

3. The stateful PCE modifies one or more of the delegated LSP attributes and sends the new LSP parameters to Router PCC through the PCUpd message.

4. On receiving the new LSP parameters, Router PCC sets up a new LSP and re-signals it using the PCE-provided path.

   In this example, the PCE-provided ERO for `PCC-to-R2` is PCC-R3-R2. The bandwidth for `PCC-to-R2` is 8m, and both the setup and hold priority values are 3.

5. Router PCC sends a PCRpt with the new RRO to the stateful PCE.

Configuration

Procedure

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure Router PCC:

> **NOTE**: Repeat this procedure for every Juniper Networks ingress router in the MPLS domain, after modifying the appropriate interface names, addresses, and any other parameters for each router.

1. Configure the interfaces.

   To enable MPLS, include the protocol family on the interface so that the interface does not discard incoming MPLS traffic.

```
[edit interfaces]
user@PCC# set ge-1/0/1 unit 0 family inet address 20.31.4.1/24
user@PCC# set ge-1/0/1 unit 0 family iso
user@PCC# set ge-1/0/1 unit 0 family mpls
user@PCC# set ge-1/1/1 unit 0 family inet address 20.31.1.1/24
user@PCC# set ge-1/1/1 unit 0 family iso
user@PCC# set ge-1/1/1 unit 0 family mpls
user@PCC# set lo0 unit 0 family inet address 10.255.179.95/32
```

2. Enable RSVP on all interfaces of Router PCC, excluding the management interface.

```
[edit protocols]
user@PCC# set rsvp interface all
user@PCC# set rsvp interface fxp0.0 disable
```

3. Configure the label-switched path (LSP) from Router PCC to Router R2 and enable external control of LSPs by the PCE.

```
[edit protocols]
user@PCC# set mpls lsp-external-controller pccd
user@PCC# set mpls label-switched-path PCC-to-R2 to 10.255.179.98/32
```

```
user@PCC# set mpls label-switched-path PCC-to-R2 bandwidth 10m
user@PCC# set protocols mpls label-switched-path PCC-to-R2 priority 4 4
user@PCC# set protocols mpls label-switched-path PCC-to-R2 primary to-R2-path
user@PCC# set protocols mpls label-switched-path PCC-to-R2 lsp-external-controller pccd
```

4. Configure the LSP from Router PCC to Router R2, which has local control and is overridden by the PCE-provided LSP parameters.

```
[edit protocols]
user@PCC# set mpls path to-R2-path 20.31.1.2/30 strict
user@PCC# set mpls path to-R2-path 20.31.2.2/30 strict
```

5. Enable MPLS on all interfaces of Router PCC, excluding the management interface.

```
[edit protocols]
user@PCC# set mpls interface all
user@PCC# set mpls interface fxp0.0 disable
```

6. Configure IS-IS on all interfaces of Router PCC, excluding the management interface.

```
[edit protocols]
user@PCC# set isis level 1 disable
user@PCC# set isis interface all
user@PCC# set isis interface fxp0.0 disable
user@PCC# set isis interface lo0.0
```

7. Define the PCE that Router PCC connects to, and configure the IP address of the PCE.

```
[edit protocols]
user@PCC# set pcep pce pce1 destination-ipv4-address 10.209.57.166
```

8. Configure the destination port for Router PCC that connects to a PCE using the TCP-based PCEP.

```
[edit protocols]
user@PCC# set pcep pce pce1 destination-port 4189
```

9. Configure the PCE type.

```
[edit protocols]
user@PCC# set pcep pce pce1 pce-type active
user@PCC# set pcep pce pce1 pce-type stateful
```

Results

From configuration mode, confirm your configuration by entering the `show interfaces` and `show protocols` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PCC# show interfaces
ge-1/0/1 {
    unit 0 {
        family inet {
            address 20.31.4.1/24;
        }
        family iso;
        family mpls;
    }
}
ge-1/1/1 {
    unit 0 {
        family inet {
            address 20.31.1.1/24;
        }
        family iso;
        family mpls;
    }
}
lo0 {
    unit 0 {
        family inet {
            address 10.255.179.95/32;
        }
```

```
    }
}
```

```
user@PCC# show protocols
rsvp {
    interface all;
    interface fxp0.0 {
        disable;
    }
}
mpls {
    lsp-external-controller pccd;
    label-switched-path PCC-to-R2 {
        to 10.255.179.98;
        bandwidth 10m;
        priority 4 4;
        primary to-R2-path;
        lsp-external-controller pccd;
    }
    path to-R2-path {
        20.31.1.2 strict;
        20.31.2.2 strict;
    }
    interface all;
    interface fxp0.0 {
        disable;
    }
}
isis {
    level 1 disable;
    interface all;
    interface fxp0.0 {
        disable;
    }
    interface lo0.0;
}
pcep {
    pce pce1 {
        destination-ipv4-address 10.209.57.166;
        destination-port 4189;
        pce-type active stateful;
```

```
    }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

IN THIS SECTION

- Verifying the PCEP Session Status | **2032**
- Verifying the PCE-Controlled LSP Status When LSP Control Is External | **2033**
- Verifying the PCE-Controlled LSP Status When LSP Control Is Local | **2035**

Confirm that the configuration is working properly.

Verifying the PCEP Session Status

Purpose

Verify the PCEP session status between the PCE and Router PCC when the PCE status is up.

Action

From operational mode, run the **show path-computation-client active-pce** command.

```
user@PCC> show path-computation-client active-pce
PCE pce1
General
    IP address              : 10.209.57.166
    Priority                : 0
    PCE status              : PCE_STATE_UP
    Session type            : PCE_TYPE_STATEFULACTIVE
    PCE-mastership          : main

Counters
    PCReqs              Total: 0           last 5min: 0           last hour: 0
    PCReps              Total: 0           last 5min: 0           last hour: 0
```

```
    PCRpts              Total: 5           last 5min: 5           last hour: 5
    PCUpdates           Total: 1           last 5min: 1           last hour: 1

Timers
    Local            Keepalive timer:        30 [s]   Dead timer:       120 [s]
    Remote           Keepalive timer:        30 [s]   Dead timer:       120 [s]

Errors
    PCErr-recv
    PCErr-sent
    PCE-PCC-NTFS
    PCC-PCE-NTFS
```

Meaning

The output displays information about the current active stateful PCE that Router PCC is connected to. The **PCE status** output field indicates the current status of the PCEP session between the PCE and Router PCC.

For **pce1**, the status of the PCEP session is **PCE_STATE_UP**, which indicates that the PCEP session has been established between the PCEP peers.

The statistics of **PCRpts** indicate the number of messages sent by Router PCC to the PCE to report the current status of LSPs. The **PCUpdates** statistics indicate the number of messages received by Router PCC from the PCE. The **PCUpdates** messages include the PCE modified parameters for the PCE-controlled LSPs.

Verifying the PCE-Controlled LSP Status When LSP Control Is External

Purpose

Verify the status of the PCE-controlled LSP from Router PCC to Router R2 when the LSP is under external control.

Action

From operational mode, run the **show mpls lsp name PCC-to-R2 extensive** command.

```
user@PCC> show mpls lsp name PCC-to-R2 extensive
Ingress LSP: 1 sessions

10.255.179.98
```

```
  From: 10.255.183.59, State: Up, ActiveRoute: 0, LSPname: PCC-to-R2

Meaning

In the output, the **LSPtype** and **LSP Control Status** output fields show that the LSP is externally controlled. The output also shows a log of the PCEP messages sent between Router PCC and the PCE.

The PCEP session between the PCE and Router PCC is up, and Router PCC receives the following PCE-controlled LSP parameters:

- ERO (path)—20.31.4.2 and 20.31.5.2
- Bandwidth—8Mbps
- Priorities—3 3 (setup and hold values)

Verifying the PCE-Controlled LSP Status When LSP Control Is Local

Meaning

In the output, the **LSP Control Status** output field shows that the LSP is under local control. Although the PCE-controlled LSP is under local control, Router PCC continues to use the PCE-provided parameters, until the next opportunity to re-signal the LSP.

The output now displays the LSP parameters that were configured using the CLI along with the PCE-provided parameters used to establish the LSP as the actual values in use.

- Bandwidth—10Mbps (ActualBandwidth: 8Mbps)
- Priorities—4 4 (ActualPriorities 3 3)

On the trigger to re-signal the LSP, Router PCC uses the local configuration parameters to establish the PCE-controlled LSP.

```

The **Computed ERO** is 20.31.1.2, 20.31.2.2, and 20.31.8.2. The PCE-controlled LSP is established using the local configuration parameters.

Example: Configuring Path Computation Element Protocol for MPLS RSVP-TE with Support of PCE-Initiated Point-to-Point LSPs

IN THIS SECTION

- Requirements | 2039
- Overview | 2039
- Configuration | 2042
- Verification | 2047

This example shows how to configure the Path Computation Client (PCC) with the capability of supporting Path Computation Element (PCE)-initiated traffic-engineered point-to-point label-switched paths (LSPs).

Requirements

This example uses the following hardware and software components:

- Three routers that can be a combination of ACX Series, M Series, MX Series, or T Series routers.
- A TCP connection to two external stateful PCEs from the ingress router (PCC).
- Junos OS Release 16.1 or later running on the PCC.

Before you begin:

- Configure the device interfaces.
- Configure MPLS and RSVP-TE (RSVP-Traffic Engineering).
- Configure OSPF or any other IGP protocol.

Overview

IN THIS SECTION

- Topology | 2041

Starting with Junos OS Release 16.1, the PCEP functionality is extended to allow a stateful PCE to initiate and provision traffic engineering LSPs through a PCC. Earlier, the LSPs were configured on the PCC and the PCC delegated control over the external LSPs to a PCE. The ownership of the LSP state was maintained by the PCC. With the introduction of the PCE-initiated LSPs, a PCE can initiate and provision a traffic engineering point-to-point LSP dynamically without the need for a locally configured LSP on the PCC. On receiving a PCCreate message from a PCE, the PCC creates the PCE-initiated LSP and automatically delegates the LSP to the PCE.

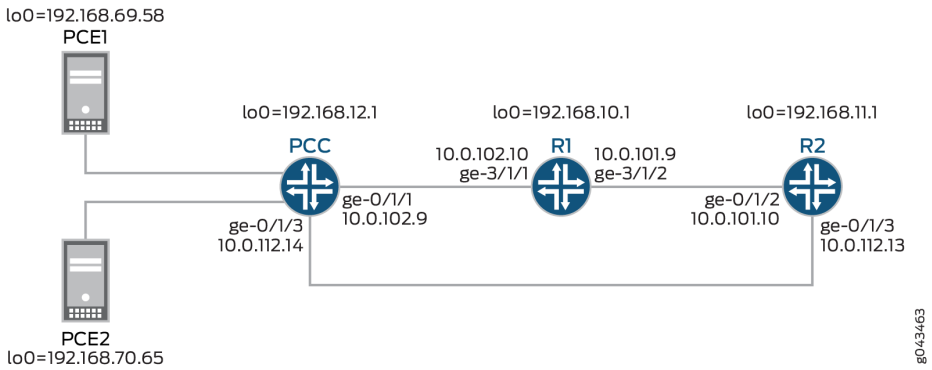
When configuring the support of PCE-initiated point-to-point LSPs for a PCC, be aware of the following considerations:

- Junos OS Release 13.3 supports only stateful PCEs.
- For Junos OS Release 13.3, the PCC always initiates the PCEP sessions. PCEP sessions initiated by remote PCEs are not accepted by the PCC.
- Existing LSP features, such as LSP protection and make-before-break, work for PCE-initiated LSPs.
- PCE-initiated LSPs do not support graceful Routing Engine switchover (GRES).
- PCE-initiated LSPs under logical systems are not supported.
- PCE-initiated LSPs cannot be point-to-multipoint LSPs.
- Bidirectional LSPs are not supported.
- RSVP-TE for unnumbered links is not supported. PCE-initiated LSPs support only numbered links.
- The PCE initiating a segment routing LSP can use the binding segment ID (SID) labels associated with non-colored segment routing LSPs to provision the PCE-initiated segment routing LSP paths.

  Starting in Junos OS Release 18.2R1, statically configured non-colored segment routing LSPs on the ingress device are reported to a PCE through a PCEP session. These non-colored segment routing LSPs may have binding SID labels associated with them. With this feature, the PCE can use this binding SID label in the label stack to provision PCE-initiated segment routing LSP paths.

Topology

Figure 142: Example PCE-Initated Point-to-Point LSP for MPLS RSVP-TE



In this example, PCC is the ingress router that connects to two external stateful PCEs: PCE1 and PCE2.

When there is a new demand, the active stateful PCE dynamically initiates an LSP to meet the requirement. Since PCC is configured with the capability of supporting the PCE-initiated LSP, path computation on PCC is performed as follows:

1. A PCE sends a PCCreate message to the PCC to initiate and provision an LSP. The PCC sets up the PCE-initiated LSP using the parameters received from the PCE, and automatically delegates the PCE-initiated LSP to the PCE that initiated it.

   In this example, PCE1 is the active stateful PCE that initiates and provisions the PCE-initiated LSP on PCC. On receiving the PCE-initiated LSP parameters, PCC sets up the LSP and automatically delegates the PCE-initiated LSP to PCE1.

2. When the PCEP session between PCC and PCE1 is terminated, PCC starts two timers for the PCE1-initiated LSP: delgation cleanup timeout and the LSP cleanup timer. During this time, PCE1 or PCE2 can acquire control of the PCE-initiated LSP.

3. If PCE2 acquires control over the PCE-initiated LSP before the expiration of the LSP cleanup timer, PCC delegates the PCE-initiated LSP to PCE2, and the LSP cleanup timer and the delegation cleanup timeout are stopped.

4. If the delegation cleanup timeout expired, and neither PCE1 nor PCE2 acquired control over the PCE-initiated LSP, PCC takes local control of the non-delegated PCE-initiated LSP until the expiration of the LSP cleanup timer.

5. After the expiration of the LSP cleanup timer, PCC deletes the PCE-initiated LSP provisioned by PCE1.

Configuration

IN THIS SECTION

- CLI Quick Configuration | 2042
- Procedure | 2044
- Results | 2046

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the `[edit]` hierarchy level.

PCC

Procedure

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure the PCC router:

> **NOTE**: Repeat this procedure for every Juniper Networks ingress router in the MPLS domain, after modifying the appropriate interface names, addresses, and any other parameters for each router.

1. Configure the interfaces.

   To enable MPLS, include the protocol family on the interface so that the interface does not discard incoming MPLS traffic.

```
[edit interfaces]
user@PCC# set ge-0/1/1 unit 0 family inet address 10.0.102.9/24
user@PCC# set ge-0/1/1 unit 0 family iso
user@PCC# set ge-0/1/1 unit 0 family mpls
user@PCC# set ge-0/1/3 unit 0 family inet address 10.0.112.14/24
user@PCC# set ge-0/1/3 unit 0 family iso
user@PCC# set ge-0/1/3 unit 0 family mpls
user@PCC# set lo0 unit 0 family inet address 192.168.12.1/32
```

2. Enable RSVP on all interfaces of the PCC, excluding the management interface.

```
[edit protocols]
user@PCC# set rsvp interface all
user@PCC# set rsvp interface fxp0.0 disable
```

3. Enable external control of LSPs by the PCEs.

```
[edit protocols]
user@PCC# set mpls lsp-external-controller pccd
```

4. Enable MPLS on all interfaces of the PCC, excluding the management interface.

```
[edit protocols]
user@PCC# set mpls interface all
user@PCC# set mpls interface fxp0.0 disable
```

5. Configure OSPF on all interfaces of the PCC, excluding the management interface.

```
[edit protocols]
user@PCC# set ospf traffic-engineering
user@PCC# set ospf area 0.0.0.0 interface all
user@PCC# set ospf area 0.0.0.0 interface fxp0.0 disable
user@PCC# set ospf interface lo0.0
```

6. Define the PCE group and enable support of PCE-initiated LSPs for the PCE group.

```
[edit protocols]
user@PCC# set protocols pcep pce-group PCEGROUP pce-type active
user@PCC# set protocols pcep pce-group PCEGROUP pce-type stateful
user@PCC# set protocols pcep pce-group PCEGROUP lsp-provisioning
user@PCC# set protocols pcep pce-group PCEGROUP lsp-cleanup-timer 30
```

7. Define the PCEs that connect to the PCC.

```
[edit protocols]
user@PCC# set pcep pce PCE1 destination-ipv4-address 192.168.69.58
user@PCC# set pcep pce PCE1 destination-port 4189
user@PCC# set pcep pce PCE1 pce-group PCEGROUP
user@PCC# set pcep pce PCE2 destination-ipv4-address 192.168.70.65
user@PCC# set pcep pce PCE2 destination-port 4189
user@PCC# set pcep pce PCE2 pce-group PCEGROUP
```

Results

From configuration mode, confirm your configuration by entering the `show interfaces` and `show protocols` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PCC# show interfaces
ge-0/1/1 {
    unit 0 {
        family inet {
            address 10.0.102.9/24;
        }
        family iso;
        family mpls;
    }
}
ge-0/1/3 {
    unit 0 {
        family inet {
            address 10.0.112.14/24;
        }
        family iso;
        family mpls;
    }
}
lo0 {
    unit 0 {
        family inet {
            address 192.168.12.1/32;
        }
    }
}
```

```
user@PCC# show protocols
rsvp {
    interface all;
    }
    interface fxp0.0 {
        disable;
    }
}
```

```
mpls {
    lsp-external-controller pccd;
    interface all;
    interface fxp0.0 {
        disable;
    }
}
ospf {
    traffic-engineering;
    area 0.0.0.0 {
        interface all;
        interface fxp0.0 {
            disable;
        }
    }
}
pce-group PCEGROUP {
    pce-type active stateful;
    lsp-provisioning;
    lsp-cleanup-timer 30;
}
pce PCE1 {
    destination-ipv4-address 192.168.69.58;
    destination-port 4189;
    pce-group PCEGROUP;
}
pce PCE2 {
    destination-ipv4-address 192.168.70.65;
    destination-port 4189;
    pce-group PCEGROUP;
}
```

If you are done configuring the device, enter `commit` from configuration mode.

Verification

IN THIS SECTION

- Verifying PCC Status | **2048**
- Verifying PCE1 Status | **2049**

- Verifying the PCE-Initiated LSP Status When the LSP Is Externally Provisioned | **2050**

Confirm that the configuration is working properly.

Verifying PCC Status

Purpose

Verify the PCEP session status and LSP summary between the PCC and the connected PCEs.

Action

From operational mode, run the `show path-computation-client status` command.

```
user@PCC# show path-computation-client status
Session              Type                       Provisioning   Status
  PCE1               Stateful Active            On             Up
  PCE2               Stateful Active            On             Up

LSP Summary
  Total number of LSPs        : 1
  Static LSPs                 : 0
  Externally controlled LSPs  : 0
  Externally provisioned LSPs : 1/16000 (current/limit)
  Orphaned LSPs               : 0

PCE1 (main)
  Delegated              : 1
  Externally provisioned : 1
PCE2
  Delegated              : 0
  Externally provisioned : 0
```

Meaning

The output displays the status of the PCEP session between the active stateful PCEs and the PCC. It also displays information about the different types of LSPs on the PCC, and the number of LSPs provisioned by the connected PCEs and delegated to them.

PCE1 is the main active PCE and has one PCE-initiated LSP that has been automatically delegated to it by the PCC.

Verifying PCE1 Status

Purpose

Verify the status of the main active stateful PCE.

Action

From operational mode, run the `show path-computation-client active-pce detail` command.

```
user@PCC# show path-computation-client active-pce
PCE PCE1
-----------------------------------------
General
    IP address               : 192.168.69.58
    Priority                 : 0
    PCE status               : PCE_STATE_UP
    Session type             : PCE_TYPE_STATEFULACTIVE
    LSP provisioning allowed : On
    LSP cleanup timer        : 30 [s]
    PCE-mastership           : main
    Max unknown messages     : 5
    Keepalives received      : 0
    Keepalives sent          : 0
    Dead timer               : 0 [s]
    Elapsed as main current  : 1 [s]
    Elapsed as main total    : 446380 [s]
    Unknown msgs/min rate    : 0
    Session failures         : 2198
    Corrupted messages       : 0
    Delegation timeout set   : 30
    Delegation timeout in    : 0 [s]
    Delegation failures      : 0
```

```
    Connection down          : 167092 [s]

Counters
    PCReqs              Total: 0           last 5min: 0           last hour: 0
    PCReps              Total: 0           last 5min: 0           last hour: 0
    PCRpts              Total: 5           last 5min: 5           last hour: 5
    PCUpdates           Total: 0           last 5min: 0           last hour: 0
    PCCreates           Total: 1           last 5min: 1           last hour: 1

Timers
    Local  Keepalive timer:   30 [s]  Dead timer:  120 [s]  LSP cleanup timer:   30 [s]
    Remote Keepalive timer:    0 [s]  Dead timer:    0 [s]  LSP cleanup timer:    - [s]

Errors
    PCErr-recv
    PCErr-sent
    PCE-PCC-NTFS
    PCC-PCE-NTFS
```

Meaning

The output displays information about the current active stateful PCE to which the PCC is connected. The `PCE status` output field indicates the current status of the PCEP session between a PCE and PCC.

For PCE1, the status of the PCEP session is `PCE_STATE_UP`, which indicates that the PCEP session has been established with the PCC.

Verifying the PCE-Initiated LSP Status When the LSP Is Externally Provisioned

Purpose

Verify the status of the PCE-initiated LSP.

Action

From operational mode, run the `show mpls lsp externally-provisioned detail` command.

```
user@PCC# show mpls lsp externally-provisioned detail
Ingress LSP: 1 sessions

10.0.101.10
```

```
  From: 10.0.102.9, State: Up, ActiveRoute: 0, LSPname: lsp15
  ActivePath: path1 (primary)
  Link protection desired
  LSPtype: Externally Provisioned, Penultimate hop popping
  LSP Control Status: Externally controlled
  LoadBalance: Random
  Encoding type: Packet, Switching type: Packet, GPID: IPv4
 *Primary   path1            State: Up
    Priorities: 7 0
    Bandwidth: 8Mbps
    Computed ERO (S [L] denotes strict [loose] hops): (CSPF metric: 3)
 10.0.102.10 S 10.0.101.9 S
    Received RRO (ProtectionFlag 1=Available 2=InUse 4=B/W 8=Node
10=SoftPreempt 20=Node-ID):
 10.0.102.10 S 10.0.101.9 S
```

Meaning

In the output, the `LSPtype` output field shows that the LSP is externally provisioned.

The PCEP session between PCC and PCE1 is up, and the PCC receives the following PCE-initiated LSP parameters:

- ERO (path)—10.0.102.10 and 10.0.101.9
- Bandwidth—8 Mbps
- Priority—7 0 (setup and hold values)

Configuring Path Computation Element Protocol for MPLS RSVP-TE with Support of PCE-Initiated Point-to-Point LSPs

You can configure a Path Computation Client (PCC) with the capability of supporting dynamically created label switched paths (LSPs) from a centralized external path computing entity. A stateful Path Computaiton Element (PCE) can be used to perform external path computation and generate dynamic LSPs when there is an increase in demand.

A PCC creates the PCE-initiated point-to-point LSP using the PCE-provided LSP parameters, or parameters from a pre-configured LSP template when the PCE does not provision the LSP, and automatically delegates the PCE-initiated point-to-point LSP to the respective PCE. As a result, for PCE-initiated LSPs, there is no need for a locally configured LSP on the PCC.

A CLI-controlled LSP, PCE-controlled LSP, and PCE-initiated LSP can coexist with each other on a PCC.

Before you begin:

- Configure the device interfaces.
- Configure MPLS and RSVP-TE.
- Configure OSPF or any other IGP protocol.

To configure PCC to support PCE-initiated point-to-point LSPs, complete the following tasks:

1. In configuration mode, go to the following hierarchy level:

```
[edit]
user@PCC# edit protocols pcep
```

2. Specify the number of messages per minute that the PCC can receive at maximum.

```
[edit protocols pcep]
user@PCC# set message-rate-limit messages-per-minute
```

3. Specify the number of externally provisioned label switched paths (LSPs) over all connected PCEs that the PCC can accept at maximum.

```
[edit protocols pcep]
user@PCC# set max-provisioned-lsps max-count
```

4. Specify the unique user defined ID for the connected PCE to configure the PCE parameters.

```
[edit protocols pcep]
user@PCC# edit pce pce-id
```

5. Specify the amount of time (in seconds) that the PCC must wait before returning control of LSPs to the routing protocol process after a PCEP session is disconnected.

```
[edit protocols pcep pce pce-id]
user@PCC# set delegation-cleanup-timeout seconds
```

6. Specify the IPv4 address of the PCE to connect with.

```
[edit protocols pcep pce pce-id]
user@PCC# set destination-ipv4-address ipv4-address
```

7. Specify the TCP port number that the PCE is using

```
[edit protocols pcep pce pce-id]
user@PCC# set destination-port port-number
```

The value can range from 1 through 65535 and the default value is 4189.

8. Specify the amount of time (in seconds) that the PCC must wait before deleting any non-delegated PCE-initiated LSPs from the failed PCE after a PCEP session terminates.

```
[edit protocols pcep pce pce-id]
user@PCC# set lsp-cleanup-timer seconds
```

9. Configure the PCC to accept SPs that are externally provisioned by connected PCEs. By default, the PCC rejects PCE-initiated LSPs.

```
[edit protocols pcep pce pce-id]
user@PCC# set lsp-provisioning
```

10. Specify the number of unknown messages per minute that the PCC can receive at maximum after which the PCEP session is closed.

```
[edit protocols pcep pce pce-id]
user@PCC# set max-unknown-messages messages-per-minute
```

The value can range from 1 through 16384, and the default value is 0 (disabled or no limit).

11. Specify the number of unknown requests per minute that the PCC can receive at maximum after which the PCEP session is terminated.

```
[edit protocols pcep pce pce-id]
user@PCC# set max-unknown-requests requests-per-minute
```

The value can range from 0 through 16384, and the default value is 5. A value of 0 disables this statement.

12. Configure the PCE type.

```
[edit protocols pcep pce pce-id]
user@PCC# set pce-type active stateful
```

13. Specify the amount of time (in seconds) that the PCC must wait for a reply before resending a request.

```
[edit protocols pcep pce pce-id]
user@PCC# set request-timer seconds
```

The value can range from 0 through 65535 seconds.

14. Verify and commit the configuration.

```
user@PCC# show
user@PCC# commit
```

Sample Output

```
[edit]
user@PCC# edit protocols pcep

[edit protocols pcep]
user@PCC# set message-rate-limit 50

[edit protocols pcep]
user@PCC# set max-provisioned-lsps 16000

[edit protocols pcep]
user@PCC# edit pce PCE

[edit protocols pcep pce PCE]
user@PCC# set delegation-cleanup-timeout 20

[edit protocols pcep pce PCE]
user@PCC# set destination-ipv4-address 192.168.69.58

[edit protocols pcep pce PCE]
user@PCC# set destination-port 4189

[edit protocols pcep pce PCE]
user@PCC# set lsp-cleanup-timer 50

[edit protocols pcep pce PCE]
user@PCC# set lsp-provisioning
```

```
[edit protocols pcep pce PCE]
user@PCC# set max-unknown-messages 5

[edit protocols pcep pce PCE]
user@PCC# set max-unknown-requests 5

[edit protocols pcep pce PCE]
user@PCC# set request-timer 50

[edit protocols pcep pce PCE]
user@PCC# up

[edit protocols pcep]
user@PCC# show
message-rate-limit 50;
max-provisioned-lsps 16000;
pce PCE {
    destination-ipv4-address 192.168.69.58;
    destination-port 4189;
    lsp-provisioning;

Example: Configuring Path Computation Element Protocol for MPLS RSVP-TE with Support for PCE-Controlled Point-to-Multipoint LSPs

IN THIS SECTION

- Requirements | **2056**
- Overview | **2056**
- Configuration | **2058**

- Verification | 2072

This example shows how to configure the Path Computation Client (PCC) with the capability of reporting point-to-multipoint traffic engineered label-switched paths (TE LSPs) to a Path Computation Element (PCE).

Requirements

This example uses the following hardware and software components:

- Three routers that can be a combination of ACX Series, M Series, MX Series, or T Series routers.
- One virtual machine configured with Virtual Route Reflector (VRR) feature.
- A TCP connection to an external stateful PCE from the VRR.
- Junos OS Release 16.1 or later running on the PCC.

Before you begin:

- Configure the device interfaces.
- Configure MPLS and RSVP-TE.
- Configure OSPF or any other IGP protocol.

Overview

IN THIS SECTION

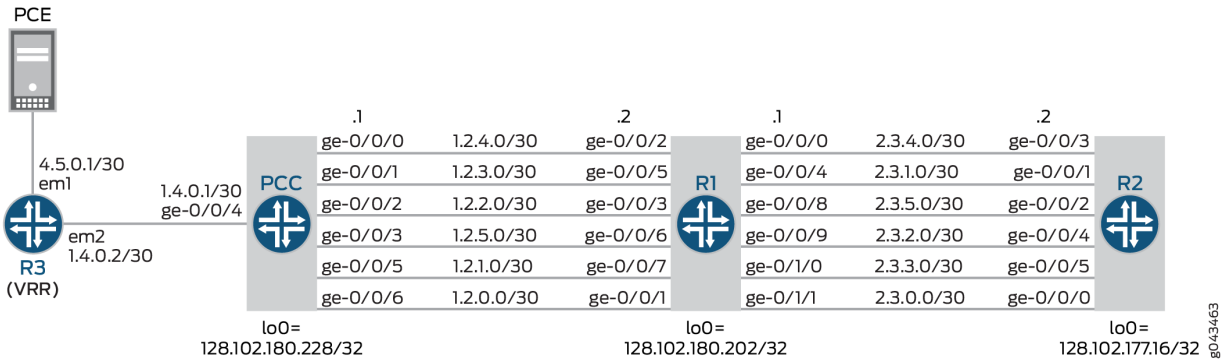
- Topology | 2057

After a PCEP session is established between a PCE and a PCC, the PCC reports all the LSPs in the system to the PCE for LSP state synchronization. This includes PCC-controlled, PCE-delegated, and PCE-initiated point-to-point LSPs. Starting with Junos OS Release 15.1F6 and 16.1R1, this capability is extended to report point-to-multipoint LSPs as well.

By default, PCE control of point-to-multipoint LSPs is not supported on a PCC. To add this capability, include the `p2mp-lsp-report-capability` statement at the `[edit protocols pcep pce pce-name]` or `[edit protocols pcep pce-group group-id]` hierarchy levels.

Topology

Figure 143: Example PCE-Controlled Point-to-Multipoint LSPs



In this example, PCC is the ingress router, Router R1 is the transit router, and Router R2 is the egress router. PCC is connected to a Virtual Route Reflector (VRR) that is connected to a PCE. There are many point-to-multipoint interfaces between PCC, Router R1, and Router R2.

The reporting of point-to-multipoint LSPs is executed as follows:

1. If Router PCC is configured with point-to-point and point-to-multipoint LSPs without the support for point-to-multipoint reporting capability, only the point-to-point LSPs are reported to the connected PCE. By default, a PCC does not support point-to-multipoint LSP reporting capability.
2. When Router PCC is configured with point-to-multipoint LSP reporting capability, PCC first advertises this capability to PCE through a report message.
3. By default, a PCE provides support for point-to-multipoint LSP capability. On receiving the PCC's advertisement for point-to-multipoint LSP capability, the PCE in return advertises its capability to the PCC.
4. On receiving the PCE's advertisement of the point-to-multipoint capability, PCC reports all branches of point-to-multipoint LSPs to the PCE using the update message.
5. Once all the LSPs are reported to the PCE, LSP state is synchronized between the PCE and PCC.

Configuration

IN THIS SECTION

- CLI Quick Configuration | 2058
- Procedure | 2063
- Results | 2067

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the `[edit]` hierarchy level.

PCC

```
set interfaces ge-0/0/0 unit 0 family inet address 1.2.4.1/30
set interfaces ge-0/0/0 unit 0 family mpls
set interfaces ge-0/0/1 unit 0 family inet address 1.2.3.1/30

Procedure

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure the PCC router:

1. Configure the interfaces of Router PCC. To enable MPLS, include the protocol family on the interface so that the interface does not discard incoming MPLS traffic.

```
[edit interfaces]
user@PCC# set ge-0/0/0 unit 0 family inet address 1.2.4.1/30
user@PCC# set ge-0/0/0 unit 0 family mpls
user@PCC# set ge-0/0/1 unit 0 family inet address 1.2.3.1/30
user@PCC# set ge-0/0/1 unit 0 family mpls
user@PCC# set ge-0/0/2 unit 0 family inet address 1.2.2.1/30
user@PCC# set ge-0/0/2 unit 0 family mpls
user@PCC# set ge-0/0/3 unit 0 family inet address 1.2.5.1/30
user@PCC# set ge-0/0/3 unit 0 family mpls
user@PCC# set ge-0/0/4 unit 0 family inet address 1.4.0.1/30
user@PCC# set ge-0/0/4 unit 0 family mpls
user@PCC# set ge-0/0/5 unit 0 family inet address 1.2.1.1/30
user@PCC# set ge-0/0/5 unit 0 family mpls
user@PCC# set ge-0/0/6 unit 0 family inet address 1.2.0.1/30
user@PCC# set ge-0/0/6 unit 0 family mpls
```

2. Configure the autonomous system number for Router PCC.

```
[edit routing-options]
user@PCC# set autonomous-system 100
```

3. Enable RSVP on all interfaces of Router PCC, excluding the management interface.

```
[edit protocols]
user@PCC# set rsvp interface all
user@PCC# set rsvp interface fxp0.0 disable
```

4. Enable MPLS on all the interfaces of Router PCC, excluding the management interface.

```
[edit protocols]
user@PCC# set mpls interface all
user@PCC# set mpls interface fxp0.0 disable
```

5. Configure a dynamic LSP and disable automatic path computation for the LSP.

```
[edit protocols]
user@PCC# set mpls label-switched-path lsp_template_no_cspf template
user@PCC# set mpls label-switched-path lsp_template_no_cspf no-cspf
```

6. Configure point-to-multipoint LSPs and define external path computing entity for the LSP.

```
[edit protocols]
user@PCC# set mpls label-switched-path lsp1-pcc to 128.102.177.16
user@PCC# set mpls label-switched-path lsp2-pcc to 128.102.177.16
user@PCC# set mpls label-switched-path lsp2-pcc lsp-external-controller pccd
```

7. Enable external path computing for the MPLS LSPs and assign a template for externally provisioned LSPs.

```
[edit protocols]
user@PCC# set mpls lsp-external-controller pccd pce-controlled-lsp pcc_delegated_no_cspf_*
label-switched-path-template lsp_template_no_cspf
user@PCC# set mpls lsp-external-controller pccd pce-controlled-lsp
pce_initiated_no_ero_no_cspf_* label-switched-path-template lsp_template_no_cspf
user@PCC# set mpls lsp-external-controller pccd pce-controlled-lsp
pce_initiated_loose_ero_no_cspf_* label-switched-path-template lsp_template_no_cspf
```

8. Configure the LSPs that have local control and are overridden by the PCE-provided LSP parameters.

```
[edit protocols]
user@PCC# set mpls path loose-path 1.2.3.2 loose
user@PCC# set mpls path strict-path 1.2.3.2 strict
user@PCC# set mpls path strict-path 2.3.3.2 strict
user@PCC# set mpls path path-B
user@PCC# set mpls path path-C
```

9. Configure MPLS administrative group policies for constrained-path LSP computation.

```
[edit protocols]
user@PCC# set mpls admin-groups violet 1
user@PCC# set mpls admin-groups indigo 2
user@PCC# set mpls admin-groups blue 3
user@PCC# set mpls admin-groups green 4
user@PCC# set mpls admin-groups yellow 5
user@PCC# set mpls admin-groups orange 6
```

10. Assign the configured administrative group policies to Router PCC interfaces.

```
[edit protocols]
user@PCC# set mpls interface ge-0/0/6.0 admin-group violet
user@PCC# set mpls interface ge-0/0/5.0 admin-group indigo
user@PCC# set mpls interface ge-0/0/2.0 admin-group blue
user@PCC# set mpls interface ge-0/0/1.0 admin-group green
user@PCC# set mpls interface ge-0/0/0.0 admin-group yellow
user@PCC# set mpls interface ge-0/0/3.0 admin-group orange
```

11. Configure a traffic engineering database (TED) import policy.

```
[edit protocols]
user@PCC# set mpls traffic-engineering database import policy TE
```

12. Configure a BGP internal group.

```
[edit protocols]
user@PCC# set bgp group northstar type internal
```

```
user@PCC# set bgp group northstar local-address 128.102.180.228
user@PCC# set bgp group northstar neighbor 128.102.180.215
```

13. Configure traffic engineering for BGP and assign the export policy.

```
[edit protocols]
user@PCC# set bgp group northstar family traffic-engineering unicast
user@PCC# set bgp group northstar export TE
```

14. Configure OSPF area 0 on all the point-to-multipoint interfaces of Router PCC.

```
[edit protocols]
user@PCC# set ospf area 0.0.0.0 interface lo0.0
user@PCC# set ospf area 0.0.0.0 interface ge-0/0/6.0
user@PCC# set ospf area 0.0.0.0 interface ge-0/0/5.0
user@PCC# set ospf area 0.0.0.0 interface ge-0/0/2.0
user@PCC# set ospf area 0.0.0.0 interface ge-0/0/1.0
user@PCC# set ospf area 0.0.0.0 interface ge-0/0/0.0
user@PCC# set ospf area 0.0.0.0 interface ge-0/0/3.0
```

15. Configure OSPF area 0 on the point-to-point interface of Router PCC.

```
[edit protocols]
user@PCC# set ospf area 0.0.0.0 interface ge-0/0/4.0 interface-type p2p
```

16. Enable traffic engineering for OSPF.

```
[edit protocols]
user@PCC# set ospf traffic-engineering
```

17. Define the PCE that Router PCC connects to, and configure the the PCE parameters.

```
[edit protocols]
user@PCC# set pcep pce pce1 local-address 10.102.180.228
user@PCC# set pcep pce pce1 destination-ipv4-address 10.102.180.246
user@PCC# set pcep pce pce1 destination-port 4189
user@PCC# set pcep pce pce1 pce-type active
user@PCC# set pcep pce pce1 pce-type stateful
```

```
user@PCC# set pcep pce pce1 lsp-provisioning
user@PCC# set pcep pce pce1 lsp-cleanup-timer 0
user@PCC# set pcep pce pce1 delegation-cleanup-timeout 60
```

18. Configure Router PCC to enable point-to-multipoint LSP capability for external path computing.

```
[edit protocols]
set pcep pce pce1 p2mp-lsp-report-capability
```

19. Configure the traffic engineering policy.

```
[edit policy-options]
user@PCC# set policy-statement TE term 1 from family traffic-engineering
user@PCC# set policy-statement TE term 1 then accept
```

Results

From configuration mode, confirm your configuration by entering the `show interfaces` and `show protocols` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PCC# show interfaces
ge-0/0/0 {
    unit 0 {
        family inet {
            address 1.2.4.1/30;
        }
        family mpls;
    }
}
ge-0/0/1 {
    unit 0 {
        family inet {
            address 1.2.3.1/30;
        }
        family mpls;
    }
}
ge-0/0/2 {
```

```

Verification

IN THIS SECTION

- Verifying LSP Configuration on the PCC | **2072**
- Verifying PCE Configuration on the PCC | **2075**

Confirm that the configuration is working properly.

Verifying LSP Configuration on the PCC

Purpose

Verify the LSP type and running state of the point-to-multipoint LSP.

Action

From operational mode, run the `show mpls lsp extensive` command.

```
user@PCC> show mpls lsp extensive
Ingress LSP: 2 sessions

128.102.177.16
  From: 128.102.180.228, State: Up, ActiveRoute: 0, LSPname: lsp1-pcc
  ActivePath:  (primary)
  LSPtype: Static Configured, Penultimate hop popping
  LoadBalance: Random
  Encoding type: Packet, Switching type: Packet, GPID: IPv4
 *Primary                    State: Up
    Priorities: 7 0

Understanding Path Computation Element Protocol for MPLS RSVP-TE with Support for PCE-Initiated Point-to-Multipoint LSPs

IN THIS SECTION

- Benefits of PCE-Initiated Point-to-Multipoint LSPs | **2077**
- Signaling of PCE-Initiated Point-to-Multipoint LSPs | **2077**
- Behavior of PCE-Initiated Point-to-Multipoint LSPs After PCEP Session Failure | **2077**
- Configuring PCE-Initiated Point-to-Multipoint LSP Capability | **2077**
- Supported and Unsupported Features for PCE-Initiated Point-to-Multipoint LSPs | **2078**
- Mapping PCE-initiated Point-To-Multipoint LSPs to MVPN | **2079**

With the introduction of point-to-multipoint PCE-initiated LSPs, a PCE can initiate and provision a point-to-multipoint LSP dynamically without the need for local LSP configuration on the PCC. This enables the PCE to control the timing and sequence of the point-to-multipoint path computations within and across Path Computation Element Protocol (PCEP) sessions, thereby creating a dynamic network that is centrally controlled and deployed.

Benefits of PCE-Initiated Point-to-Multipoint LSPs

Meets the requirements of point-to-multipoint traffic engineering LSP placement in response to application demands through dynamic creation and tear down of point-to-multipoint LSPs, thereby creating a dynamic network that is centrally controlled and deployed.

Signaling of PCE-Initiated Point-to-Multipoint LSPs

The signaling of PCE-initiated point-to-multipoint LSPs is as follows:

- **When a new branch is added (Grafting)**—Only the new branch sub-LSP is signaled and does not result in re-signaling of the entire point-to-multipoint tree.

  If any topology changes occurred before provisioning of the new sub-LSP, then the Path Computation Server (PCS) re-computes the entire point-to-multipoint tree and updates the point-to-multipoint LSP using a PC update message.

- **When a branch is deleted (Pruning)**—The deleted branch sub-LSP is torn down and does not result in re-signaling of the entire point-to-multipoint tree.

- **When a branch sub-LSP parameter is changed**—Change in sub-LSP parameters, such as Explicit Route Object (ERO), bandwidth, or priority, can happen either because of optimization, or on user request. If there is a re-signaling request for a sub-LSP, the entire point-to-multipoint tree is re-signaled, and then the switchover to the new instance happens once the new instances of all the branches are up.

- **When a branch sub-LSP path fails**—An error is reported to the PCS for the failed branch sub-LSP. On receiving the new ERO from the PCS, the entire point-to-multipoint tree is re-signaled along with the failed branch sub-LSP, and the switchover to the new instance happens in a make-before-break (MBB) fashion.

Behavior of PCE-Initiated Point-to-Multipoint LSPs After PCEP Session Failure

When a PCEP session fails, the PCE-initiated point-to-multipoint LSPs are orphaned until the expiration of the `state timeout` timer. After the `state timeout` timer expires, the PCE-initiated LSPs are cleaned up.

To obtain control of a PCE-initiated point-to-multipoint LSP after a PCEP session failure, the primary or secondary PCE sends a `PCInitiate` message before the `state timeout` timer expires.

Configuring PCE-Initiated Point-to-Multipoint LSP Capability

By default, the creation and provisioning of point-to-multipoint LSPs by a PCE is not supported on a PCC. To enable this capability, include the `p2mp-lsp-init-capability` and `p2mp-lsp-update-capability` statements at the `[edit protocols pcep pce` *`pce-name`*`]` or `[edit protocols pcep pce-group group-id]` hierarchy levels.

The p2mp-lsp-init-capability statement provides the capability to provision point-to-multipoint RSVP-TE LSPs by a PCE. The p2mp-lsp-update-capability statement provides the capability to update point-to-multipoint RSVP-TE LSP parameters by a PCE.

Supported and Unsupported Features for PCE-Initiated Point-to-Multipoint LSPs

The following features are supported with PCE-initiated point-to-multipoint LSPs:

- Partial compliance with the Internet draft draft-ietf-pce-stateful-pce-p2mp (expires October 2018), *Path Computation Element (PCE) Protocol Extensions for Stateful PCE usage for Point-to-Multipoint Traffic Engineering Label Switched Paths*.
- Starting in Junos OS Release 21.1R1, we support nonstop active routing (NSR) for PCE-initiated RSVP-based point-to-multipoint LSPs. Only the primary Routing Engine maintains the PCEP session with the controller. It synchronizes all RSVP LSPs initiated by PCEs, including multicast flow specifications for any PCE-initiated P2MP LSPs, with the backup Routing Engine. During a switchover, the PCEP session goes down and re-establishes when the backup Routing Engine becomes the primary Routing Engine. This reduces traffic loss for the traffic carried over PCE-initiated RSVP LSPs during Routing Engine switchovers. This feature is enabled when NSR is configured.

The following features are not supported with PCE-initiated point-to-multipoint LSPs:

- Delegation of point-to-multipoint locally controlled LSP.
- LSP control delegation.
- Interior gateway protocol (IGP) extension for PCE discovery within an IGP routing domain.
- Request/response messaging.
- Direct movement of branch sub-LSP from one point-to-multipoint tree to another.

  The same can be achieved by deleting a branch sub-LSP from the first point-to-multipoint tree and re-adding it to another after the PCReport message indicates LSP removal from the device.
- IPv6 is not supported.
- SERO based signalling is not supported.
- Empty-ERO feature is not supported.
- Link protection is not supported.

Mapping PCE-initiated Point-To-Multipoint LSPs to MVPN

You can associate a single or range of MVPN multicast flows (S,G) to a dynamically created PCE-initiated point-to-multipoint label-switched path (LSP). You can specify only selective types of flows for this feature to work. This includes:

- Route distinguisher (RD) which is mapped to the MVPN routing-instance.
- (S,G) which is the source of a multicast packet and destination multicast group address. This is used to filter incoming traffic for mapping it to the tunnel.
- Point-to-multipoint LSP that is used to send traffic that matches the above-mentioned flow specification.

For more details, see Internet draft draft-ietf-pce-pcep-flowspec-05 (expires February 16, 2020) *PCEP Extension for Flow Specification*.

The current implementation of this feature does not implement the following sections of the draft:

- Section 3.1.2—Advertising PCE capabilties in IGP
- Section 3.2—PCReq and PCRep message
- Section 7—Most of the flow specifications, except route distinguThe current implementation of this feature does not supporisher and IPv4 multicast flow specifications, are not supported.

To enable the mapping of PCE-initiated point-to-multipoint LSPs to MVPN:

- Include the `pce_traffic_steering` statement at the `[edit protocols pcep pce` *`pce-id`*`]` hierarchy level to indicate the support for flow specification capability (also called traffic steering) by the PCC.
- Include the `external-controller` statement at the `[edit routing-instances` *`routing-instance-name`* `provider-tunnel]` hierarchy level.

  The presence of `external-controller` in the provider-tunnel configuration for MVPN indicates that the point-to-multipoint LSP and (S,G) for this MVPN instance can be provided by the external controller. This enables the external controller to dynamically configure (S,G) and point-to-multipoint LSP for MVPN.

Take the following into consideration for mapping of PCE-initiated point-to-multipoint LSPs to MVPN:

- If you do not enable the `external-controller` *`pccd`* statement for a particular MVPN instance, then the PCCD process does not configure (S,G) dynamically.
- If you disable the `external-controller` *`pccd`* configuration from the CLI, then the dynamically learned multicast flows (S,G) for that particular MVPN instance is deleted and reported to the external controller.

- When (S,G) is already configured from the CLI, the PCC cannot configure (S,G) dynamically as local configuration has a higher priority.
- If any particular (S,G) is learned from the external controller dynamically and then you configure the same (S,G) for the same MVPN instance, then the dynamically learned (S,G) is deleted and reported to the external controller through the PCC.
- If the routing protocol process reboots, then the PCCD process reconfigures all the (S,G) again.
- If the PCCD process reboots, then MVPN reports all PCCD configured (S,G) to the external controller.
- If user enables `external-controller` *pccd* for a particular MVPN instance, then MVPN requests the PCCD process to configure (S,G), if any present.
- If there are major configuration changes to a particular MPVN instance, then MVPN requests the PCCD process to reconfigure all (S,G) for that particular MVPN instance.
- All flow specifications associated with any PCE-initiated point-to-multipoint LSP must have the same RD. During PC initiation if all flow specifications do not have the same RD, then the PC initiate message is dropped with an error.
- You can associate a point-to-multipoint LSP only with selective type of flow specifications, otherwise the PC initiate message is dropped with an error.
- During PC update if all flow specifications do not have same the RD either due to a new flow specification addition, or due to existing flow specification update, then the PCC drops the update message.
- During PC update if all flow specifications do not meet the selective condition either due to new flow specification addition, or due to existing flow specifications update, then the PCC drops the update message.
- Behavior for mapping of PCE-initiated point-to-multipoint LSP with MVPN routing-instance and mapping of static (locally configured) point-to-multipoint LSP with MVPN instance is the same at user level.
- A flow specification ID can be associated with only one point-to-multipoint LSP. To associate the same RD and (S,G) to multiple point-to-multipoint LSPs, you can add multiple flow specifications with different IDs and same RD & (S,G).
- For PCEP-mapped dynamic (S,G), the threshold value is always the default value of *0*.
- There is no limit on the number of flow specifications mapped to a single PCE-initiated point-to-multipoint LSP.
- The current implementation of this feature does not support:

- Reporting of forwarding states that are associated with the point-to-multipoint LSP.
- Inclusive provider tunnel dynamic configuration
- Mapping for MVPN ingress replication tunnel
- Programmable routing protocol process (prpd)
- Reporting of CLI configured point-to-multipoint LSP which is mapped to MVPN multicast flows (S,G).

Configuring Nonstop Active Routing

Enable Segment Routing for the Path Computation Element Protocol

SUMMARY

You can enable segment routing or Source Packet Routing in Networking (SPRING) traffic-engineering (SR-TE) with the Path Computation Element Protocol (PCEP) for traffic steering. With this support, the advantages of segment routing are extended to the label-switched paths (LSPs) that are externally controlled by a Path Computation Element (PCE).

IN THIS SECTION

- Segment Routing for the Path Computation Element Protocol Overview | **2081**
- Example: Configure Segment Routing for the Path Computation Element Protocol | **2089**

Segment Routing for the Path Computation Element Protocol Overview

IN THIS SECTION

- Benefits of Segment Routing for PCEP | **2082**
- Segment Routing for Traffic Engineering | **2082**
- Junos OS Implementation of Segment Routing for PCEP | **2083**
- Segment Routing for PCEP Limitations and Unsupported Features | **2088**

Benefits of Segment Routing for PCEP

- Setting up of LSPs through an external controller provides a global view of per-LSP and per-device bandwidth demand on the network, enabling online and real-time constraint-based path computation.

  The advantages of segment routing are extended to the LSPs initiated by an external controller, also known as a Path Computation Element (PCE), augmenting the benefits of external path computing in an MPLS network.

- A Path Computation Client (PCC, which is an ingress MX Series router) with delegation capability can take back control of the delegated segment routing LSPs from the PCE when the PCEP session goes down; the LSPs would otherwise be deleted from the PCC. You can thus ensure LSP data protection by averting a situation where packets are silently discarded or dropped (also known as a null route condition).

Segment Routing for Traffic Engineering

Segment routing can operate over an IPv4 or IPv6 data plane, and supports equal-cost multipath (ECMP). With the IGP extensions built into it, segment routing integrates with the rich multiservice capabilities of MPLS, including Layer 3 VPN, Virtual Private Wire Service (VPWS), Virtual Private LAN Service (VPLS), and Ethernet VPN (EVPN).

Some of the high-level components of the segment routing–traffic engineering (SR–TE) solution include:

- Use of an IGP for advertising link characteristics. This functionality is similar to RSVP-TE.
- Use of Constrained Shortest Path First (CSPF) on the ingress device or the PCE.
- Use of an IGP for advertising labels for links.

  In SR-TE functionality:

  1. The ingress device constructs an LSP by stacking the labels of the links that it wants to traverse.
  2. The per-link IGP advertisement is combined with label stacking to create source-routed LSPs on the ingress device, so the transit devices are not aware of the end-to-end LSPs.
  3. LSPs are created between edge nodes without placing any per-LSP memory requirements on the transit devices. (Creation of such LSPs is enabled as there is no per-LSP signaling in SR-TE.)
  4. Per-neighbor labels are stacked, which results in the management of a large number of labels, leading to control plane scaling.

Junos OS Implementation of Segment Routing for PCEP

Junos OS implements segment routing for PCEP for two types of LSPs—PCE-initiated LSPs and PCE-delegated LSPs.

PCE-Initiated Segment Routing LSPs

The PCE-initiated segment routing LSPs are those LSPs that the PCE creates for the adjacency and node segments

The PCE performs the following functions:

1. Computes the path of the segment routing LSP.
2. Provisions the LSP on the Path Computation Client (PCC) using PCEP segment routing extensions.
3. Parses the PCEP segment routing extensions.
4. Creates a tunnel route on the PCC that has its own preference value and is made available in the inet.3 routing table to resolve IP traffic and services like any other tunnel route.

The PCC performs the following functions:

1. Selects the outgoing interface based on the first network access identifier (NAI) in the source Explicit Route Object (S-ERO).

   Junos OS supports S-EROs that contain the first hop as a strict hop; Junos OS doesn't support selection of the outgoing interface on the PCC based on a loose-hop node segment ID (SID). However, the remaining hops can be loose. No specific processing is done for the S-EROs that are beyond the first hop, other than to simply use the label for next-hop creation.

2. Rejects the S-ERO if:

   - The S-ERO does not have labels in it.
   - The S-ERO carries more than six hops.

   The PCC creates an equal-cost multipath (ECMP) route when there are multiple LSPs to the same destination with the same metric.

3. Waits for the PCE to process any event that leads to a change in the segment routing LSP after it is provisioned—for example, if the label is changed or withdrawn, or if one of the interfaces traversed by the LSP goes down.

When the PCEP session goes down, the PCE-initiated segment routing LSP:

1. Remains up for 300 seconds.

2. Is deleted from the PCC after 300 seconds.

For more details, see Internet drafts draft-ietf-pce-lsp-setup-type-03.txt (expires December 25, 2015), *Conveying path setup type in PCEP messages*; and draft-ietf-pce-segment-routing-06.txt (expires February 10, 2016), *PCEP Extensions for Segment Routing*.

PCE-Delegated Segment Routing LSPs

The PCE-delegated segment routing LSPs are those LSPs that the PCC configures locally and then delegates to a PCE controller.

NOTE: Junos OS Release 20.1R1 supports:

- PCE delegation capability only for noncolored segment routing LSPs with IPv4 destinations.
- Delegation and reporting of only the first segment of a segment list to an external controller. Multiple segments are not supported for PCE delegation.

The PCC can delegate a segment routing LSP to an external controller (the PCE) in the following ways:

- **Initial delegation**—The local LSPs are yet to be configured on the PCC, and the delegation of the LSP happens at the time the LSP is configured.
- **Delegation of existing LSP**—The local LSPs are configured on the PCC, and the delegation of the LSP happens after the source-routing path is configured. That is, the delegation capability is enabled on existing segment routing LSPs.

After delegating a segment routing LSP, the PCE controls the delegated LSPs and can modify the LSP attributes for path computation. The LSP control reverts to the PCC when the PCEP session between the PCC and the PCE goes down. The PCE-delegated LSPs have an advantage over PCE-initiated LSPs in case the PCEP session goes down. In the case of PCE-initiated LSPs, when the PCEP session is down, the LSPs are deleted from the PCC. However, in the case of PCE-delegated LSPs, when the PCEP session goes down, the PCC takes back control of the delegated LSPs from the PCE. As a result, with PCE-delegated LSPs, we avert a situation where packets are silently discarded (also known as a null route condition) when the session goes down.

The following types of segment routing LSPs support the PCE-delegation capability:

- **Static LSPs**—Statically configured source-routing paths that have the entire label stack statically configured.
- **Auto-translated LSPs**—Statically configured source-routing paths that are automatically translated.
- **Computed LSPs**—Statically configured source-routing paths that are computed with distributed Constrained Shortest Path First (CSPF).

- **Dynamic LSPs**—Dynamically created tunnels triggered through the Dynamic Tunnel Module that have last-hop ERO resolution.

Depending on the source of the segment routing LSP, you can configure the delegation capability on the PCC. To enable delegation of segment routing LSPs, include the `lsp-external-controller` *pccd* statement at the appropriate level under the `[edit protocols source-packet-routing]` hierarchy.

Table 2 shows a mapping of the LSP source to the corresponding configuration hierarchy level at which the delegation capability is enabled.

NOTE: You must include the `lsp-external-controller` *pccd* statement at the `[edit protocols source-packet-routing]` and `[edit protocols mpls]` hierarchy levels before configuring the delegation capability on the PCC.

Table 34: Mapping of Segment Routing LSP Source with Configuration Hierarchy

Source of Segment Routing LSP	Configuration Hierarchy
• Auto-translated LSPs • Static LSPs	Primary segment list at `[edit protocols source-packet-routing source-routing-path` *lsp-name* `primary` *path-name*`]`
Computed LSPs (distributed CSPF)	Primary segment list of the source-routing path at: • `[edit protocols source-packet-routing source-routing-path` *lsp-name* `primary` *path-name* `compute` *profile-name*`]` • `[edit protocols source-packet-routing source-routing-path` *lsp-name* `primary` *path-name*`]`
Dynamic LSPs	Primary segment list of the source-routing path template at: • `[edit protocols source-packet-routing source-routing-path-template` *template-name* `primary` *primary-segment-list-name*`]` • `[edit protocols source-packet-routing source-routing-path-template` *template-name*`]`

You can view the control status of the SR-TE LSPs from the "show spring-traffic-engineering" on page 3599 command output.

Table 3 displays the PCEP interaction when the `lsp-external-controller` statement is configured for a source-routing path.

Table 35: PCEP Interaction LSP Delegation

lsp-external-controller Configuration Hierarchy	source-routing-path Delegation State	PCEP Interaction Between PCC and PCE
Primary segment list of source-routing path	Initial delegation	1. A PCReport message is sent to the PCE for delegation. The PCReport contains only constraints and path details (such as ERO). 2. PCE calculates the path for LSP and reports path to be in the down state. 3. No route is programmed by the local LSP until the controller computes the ERO and notifies the result to the PCC through PCUpdate. The same behavior is seen when the routing protocol process (rpd) restarts or a Routing Engine switchover happens.

Table 35: PCEP Interaction LSP Delegation *(Continued)*

lsp-external-controller Configuration Hierarchy	source-routing-path Delegation State	PCEP Interaction Between PCC and PCE
Primary segment list of source-routing path	Delegation of existing path	1. A PCReport is sent to the PCE for delegation. The PCReport contains only constraints and path details (such as ERO). 2. A corresponding primary segment is delegated to the PCE. 3. PCE calculates the path for the LSP. 4. The primary segment continues to contribute to the route as determined by the local configuration or computation until a PCUpdate is received from the PCE. • If Seamless BFD (S-BFD) is not configured for the primary segment, then there is no further update to the route and the LSP state is also not monitored and reported to the PCE. The LSP state at this point is reported as up or down depending on whether path computation had succeeded at that point. • If S-BFD is configured for the primary segment, then the state of the primary segment is tracked and reported to the PCE. If BFD detects the primary segment to be down, the corresponding primary path is removed from the route. The same route that was previously calculated is reprogrammed if that path is up now. 5. If a PCUpdate message is received from the PCE, SR-TE uses the received parameter to set up the path for which the PCReport message was sent. The programmed path then includes only the segment list received from the PCE, and all the other segment lists that were previously programmed are removed. This reprogramming of the route happens in a make-before-break fashion.

Table 35: PCEP Interaction LSP Delegation *(Continued)*

lsp-external-controller Configuration Hierarchy	source-routing-path Delegation State	PCEP Interaction Between PCC and PCE
Primary segment of source-routing path	Delegation is not configured or has been deleted.	The segment list from the PCE (if available) is no longer used and the computation result from the local configuration is used. When the local result for the segment list is available, the corresponding segment list is used to program the route in a make-before-break fashion.
Segment list of source-routing path	Delegation is enabled after LSP is configured.	Delegation functionality is triggered for the primary segment list under the source-routing path.
Segment list of source-routing path	Delegation is not configured or has been deleted.	Delegation functionality is removed from the primary segment list under the source-routing path.
Primary segment list of source-routing path template	Delegation is enabled after LSP is configured.	• Under the source-routing path template—Delegation functionality is triggered for the entire source-routing path. Template configurations can be applied only to the Dynamic Tunnel Module. • Under the primary path in the source-routing path template—Delegation functionality is triggered for that particular primary path according to the configuration.
Primary segment list of source-routing path template	Delegation is not configured or has been deleted.	Delegation functionality is removed from all the source-routing paths and primary paths that match the template configuration.

Segment Routing for PCEP Limitations and Unsupported Features

The support of segment routing for PCEP does not add to the performance burden on the system. However, it has the following limitations:

- An SR-TE LSP is not locally protected on the PCC. When the LSP is more than six hops, no service is provided on the LSP other than to carry plain IP traffic.

- Graceful Routing Engine switchover (GRES) and unified in-service software upgrade (unified ISSU) are not supported.
- Nonstop active routing (NSR) is not supported.
- IPv6 is not supported.
- PCE-delegated LSPs do not support the following:
  - Colored SR-TE LSPs
  - IPv6 LSPs
  - Secondary segment list of the source-routing path. Only one path of the segment list can be delegated.
  - Multisegment standard. Only the first segment of the segment list is delegated and reported to the controller.

Example: Configure Segment Routing for the Path Computation Element Protocol

IN THIS SECTION

- Requirements | **2089**
- Overview | **2090**
- Configuration | **2092**
- Verification | **2101**

This example shows how to configure segment routing or Source Packet Routing in Networking (SPRING) traffic-engineering (SR-TE) for the Path Computation Element Protocol (PCEP). In the configuration, we leverage the advantages of segment routing with the benefits of external path computing for efficient traffic engineering.

Requirements

This example uses the following hardware and software components:

- Four MX Series 5G Universal Routing Platforms, where the ingress MX Series router is the Path Computation Client (PCC).
- A TCP connection from the PCC to an external stateful Path Computation Element (PCE).
- Junos OS Release 17.2 or later running on the PCC for the implementation of PCE-initiated LSPs.

For PCE-delegation functionality, you must run Junos OS Release 20.1R1 or a later release.

Before you begin:

- Configure the device interfaces.
- Configure MPLS.
- Configure IS-IS.

Overview

IN THIS SECTION

Topology | **2091**

The Junos OS implementation of segment routing for PCEP includes PCE-initiated and PCE-delegated SR-TE LSPs.

- The implementation of PCE-initiated LSPs is introduced in Junos OS Release 17.2R1, where the traffic-engineering capabilities of segment routing are supported in PCEP sessions for LSPs initiated by a PCE. The PCE creates the LSPs for the adjacency and node segments. Tunnel routes are created in the inet.3 routing table of the PCC corresponding to the PCE-initiated SR-TE LSPs.
- The implementation of PCE-delegated LSPs is introduced in Junos OS Release 20.1R1, where the locally configured IPv4 noncolored segment routing LSPs on the PCC can be delegated to a PCE controller. The PCE then controls the LSP and can modify LSP attributes for path computation.

The PCE-delegated LSPs have an advantage over PCE-initiated LSPs at the time the PCEP session goes down. In the case of PCE-initiated LSPs, when the PCEP session is down, the LSPs are deleted from the PCC. However, in the case of PCE-delegated LSPs, when the PCEP session goes down, the PCC takes back control of the delegated LSPs from the PCE. As a result, with PCE-delegated LSPs, we avert a situation where packets are silently discarded (also known as a null route condition) when the PCEP session goes down.

To enable segment routing for PCEP:

For PCE-initiated segment routing LSPs:

1. Enable external path computing for MPLS by including the `lsp-external-controller` statement at the `[edit protocols mpls]` hierarchy level.

   This configuration is required for PCEP with RSVP-TE extensions as well. You cannot disable PCEP with RSVP-TE when segment routing for PCEP is enabled.

2. Enable external path computing for SR-TE by including the `lsp-external-controller` *`pccd`* statement at the `[edit protocols spring-traffic-engineering]` hierarchy level.

3. Enable segment routing for the PCE by including the `spring-capability` statement at the `[edit protocols pcep pce` *`pce-name`*`]` hierarchy level.

4. Optionally, configure the maximum SID depth for the PCE by including the `max-sid-depth` *`number`* statement at the `[edit protocols pcep pce` *`pce-name`*`]` hierarchy level.

   The maximum SID depth is the number of SIDs supported by a node or a link on a node. When not configured, a default maximum SID value of 5 is applied.

5. Optionally, configure the preference value for segment routing by including the `preference` *`preference-value`* at the `[edit protocol spring-te]` hierarchy level.

   The preference value indicates the order in which a path is selected as the active path form among candidate paths, where a higher value has a higher preference. When not configured, a default preference value of 8 is applied.

6. Optionally, configure segment routing logging for troubleshooting purpose by including the `traceoptions` statement at the `[edit protocols spring-te]` hierarchy level.

For PCE-delegation of segment routing LSPs, in addition to the aforementioned steps, do the following:

1. Define a segment list with label parameters. This creates a segment routing LSP locally on the PCC.

2. Enable delegation capability of the locally configured LSP on the PCC by including the `lsp-external-controller` *`pccd`* statement at any of the following hierarchies depending on the segment routing LSP source:

   - For statically configured source-routing paths that are computed with distributed CSPF—`[edit protocols source-packet-routing source-routing-path` *`lsp-name`* `primary` *`path-name`* `compute` *`profile-name`*`]` and `[edit protocols source-packet-routing source-routing-path` *`lsp-name`* `primary` *`path-name`*`]` hierarchy levels.

   - For statically configured source-routing paths that have the entire label stack statically configured and source-routing paths that are automatically translated—`[edit protocols source-packet-routing source-routing-path` *`lsp-name`* `primary` *`path-name`*`]` hierarchy level.

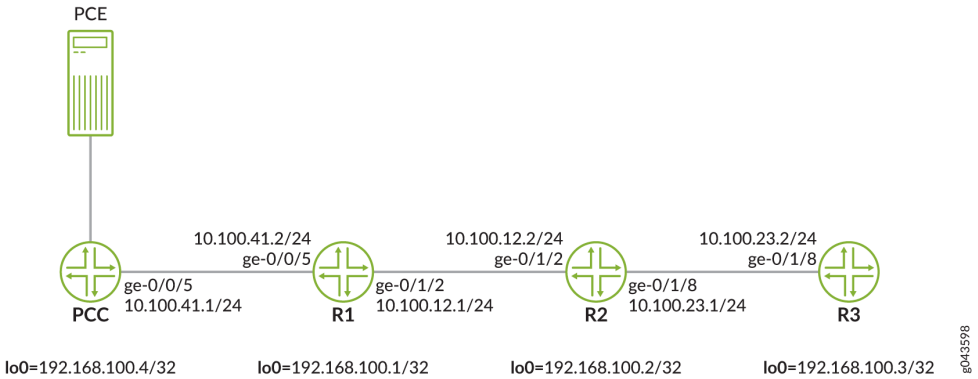
   - For dynamically created tunnels triggered through the Dynamic Tunnel Module that have last-hop ERO resolution—`[edit protocols source-packet-routing source-routing-path-template` *`template-name`* `primary` *`primary-segment-list-name`*`]` and `[edit protocols source-packet-routing source-routing-path-template` *`template-name`*`]` hierarchy levels.

Topology

Figure 144 on page 2092 illustrates a sample network topology that has a PCEP session running between the PCE and the PCC (the ingress MX Series router). Routers R1, R2, and R3 are the other MX

Series routers in the network. In this example, we configure segment routing for PCEP on the PCC. We also configure a static route on the PCC to Router R3 to verify the use of SR-TE tunnel routes when routing traffic for the static route.

Figure 144: Segment Routing for PCEP



Configuration

IN THIS SECTION

- CLI Quick Configuration | **2092**
- Procedure | **2095**
- Results | **2099**

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the `[edit]` hierarchy level, and then enter `commit` from configuration mode.

Although we present the configuration of all the devices (PCC and the three routers) in this section, the Step-by-Step procedure documents only the configuration of the PCC.

Procedure

Step-by-Step Procedure

In this example, we configure only the PCC.

The following steps require that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the CLI User Guide.

To configure the PCC:

1. Configure the interfaces of the PCC.

```
[edit interfaces]
user@PCC# set ge-0/0/5 unit 0 family inet address 10.100.41.1/24
user@PCC# set ge-0/0/5 unit 0 family iso
user@PCC# set ge-0/0/5 unit 0 family mpls
user@PCC# set lo0 unit 0 family inet address 192.168.100.4/32 primary
user@PCC# set lo0 unit 0 family iso address 49.0011.0110.0000.0101.00
user@PCC# set lo0 unit 0 family mpls
```

2. Configure the router ID and assign an autonomous system number for the PCC.

```
[edit routing-options]
user@PCC# set router-id 192.168.100.4
user@PCC# set autonomous-system 64496
```

3. Configure a static route from the PCC to Router R3.

   The static route is created for verification purpose only and does not affect the feature functionality.

```
[edit routing-options]
user@PCC# set static route 100.1.1.1/32 next-hop 192.168.100.3
```

4. Configure RSVP on all the interfaces of the PCC, excluding the management interface.

```
[edit protocols]
user@PCC# set rsvp interface fxp0.0 disable
user@PCC# set rsvp interface all
```

5. Configure MPLS on all the interfaces of the PCC, excluding the management interface.

```
[edit protocols]
user@PCC# set mpls interface all
user@PCC# set mpls interface fxp0.0 disable
```

6. Enable external path computing capability for MPLS.

```
[edit protocols]
user@PCC# set mpls lsp-external-controller pccd
```

7. Configure IS-IS level 2 on all the interfaces of the PCC, excluding the management and loopback interfaces.

```
[edit protocols]
user@PCC# set isis level 1 disable
user@PCC# set isis level 2 wide-metrics-only
user@PCC# set isis interface all point-to-point
user@PCC# set isis interface all level 2 metric 10
user@PCC# set isis interface fxp0.0 disable
user@PCC# set isis interface lo0.0 passive
```

8. Configure segment routing global block (SRGB) attributes for segment routing.

```
[edit protocols]
user@PCC# set isis source-packet-routing srgb start-label 800000
user@PCC# set isis source-packet-routing srgb index-range 4000
user@PCC# set isis source-packet-routing node-segment ipv4-index 101
user@PCC# set isis source-packet-routing node-segment ipv6-index 11
```

9. Enable external path computing capability for SR-TE.

```
[edit protocols]
user@PCC# set spring-traffic-engineering lsp-external-controller pccd
```

10. Configure the PCE parameters and enable provisioning of the LSP by the PCE and the segment routing capability.

```
[edit protocols]
user@PCC# set pcep pce pce1 local-address 192.168.100.4
user@PCC# set pcep pce pce1 destination-ipv4-address 10.102.180.232
user@PCC# set pcep pce pce1 destination-port 4189
```

```
user@PCC# set pcep pce pce1 pce-type active
user@PCC# set pcep pce pce1 pce-type stateful
```

11. Enable provisioning of segment routing LSPs by the PCE.

```
[edit protocols]
user@PCC# set pcep pce pce1 lsp-provisioning
```

12. Enable segment routing capability for the PCE.

```
[edit protocols]
user@PCC# set pcep pce pce1 spring-capability
```

13. Define the static segment list `static_seg_list_1` parameters.

```
[edit protocols]
user@PCC# set source-packet-routing segment-list static_seg_list_1 hop1 label 800102
user@PCC# set source-packet-routing segment-list static_seg_list_1 hop2 label 800103
```

14. Configure a static segment routing LSP from the PCC to Router R3 for PCE delegation.

```
[edit protocols]
user@PCC# set source-packet-routing source-routing-path static_srte_lsp_1 to 192.168.100.3
```

15. Enable delegation capability for the `static_srte_lsp_1` source-routing path.

```
[edit protocols]
user@PCC# set source-packet-routing source-routing-path static_srte_lsp_1 primary
static_seg_list_1 lsp-external-controller pccd
```

By completing Steps 13, 14, and 15, you enable the PCC to delegate the segment routing LSPs to the PCE.

16. Commit the configuration.

Results

From configuration mode, confirm your configuration by entering the `show interfaces`, `show routing-options`, and `show protocols` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PCC# show interfaces
ge-0/0/5 {
    unit 0 {
        family inet {
            address 10.100.41.1/24;
        }
        family iso;
        family mpls;
    }
}
lo0 {
    unit 0 {
        family inet {
            address 192.168.100.4/32 {
                primary;
            }
        }
        family iso {
            address 49.0011.0110.0000.0101.00;
        }
        family mpls;
    }
}
```

```
user@PCC# show routing-options
static {
    route 100.1.1.1/32 next-hop 192.168.100.3;
}
router-id 192.168.100.4;
autonomous-system 64496;
```

```
user@PCC# show protocols
rsvp {
```

```
    interface fxp0.0 {
        disable;
    }
    interface all;
}
mpls {
    lsp-external-controller pccd;
    interface all;
    interface fxp0.0 {
        disable;
    }
}
isis {
    source-packet-routing {
        srgb start-label 800000 index-range 4000;
        node-segment {
            ipv4-index 101;
            ipv6-index 11;
        }
    }
    level 1 disable;
    level 2 wide-metrics-only;
    interface all {
        point-to-point;
        level 2 metric 10;
    }
    interface fxp0.0 {
        disable;
    }
    interface lo0.0 {
        passive;
    }
}
spring-traffic-engineering {
    lsp-external-controller pccd;
}
source-packet-routing {
    segment-list static_seg_list_1 {
        hop1 label 800102
        hop1 label 800102
    }
    source-routing-path static_srte_lsp_1 {
        to 192.168.100.3;
```

```
        primary {
            static_seg_list_1 {
                lsp-external-controller pccd;
            }
        }
    }
}
pcep {
    pce pce1 {
        local-address 192.168.100.4;
        destination-ipv4-address 10.102.180.232;
        destination-port 4189;
        pce-type active stateful;
        lsp-provisioning;
        spring-capability;
    }
}
```

If you are done configuring the device (the PCC), enter `commit` from configuration mode.

Verification

IN THIS SECTION

- Verify IS-IS Adjacency and Labels | **2101**
- Verify the Traffic Engineering Database | **2111**
- Verify SR-TE LSPs | **2115**
- Verify Tunnel Route Creation | **2118**
- Verify Forwarding Table Entries | **2120**
- Verify the Use of Tunnel Routes for Static Route Forwarding | **2122**

Confirm that the configuration is working properly.

Verify IS-IS Adjacency and Labels

Purpose

Verify the IS-IS adjacency on the PCC. Take note of the SRGB label range, adjacency and node segment values, and SPRING capability output fields.

Action

From operational mode, run the `show isis adjacency extensive`, `show isis database extensive`, and `show isis overview` commands.

```
user@PCC> show isis adjacency extensive
R1
  Interface: ge-0/0/5.0, Level: 2, State: Up, Expires in 25 secs

    Source Packet Routing is enabled
```

Meaning

The IS-IS adjacency between the PCC and PCE and that between the PCC and Router R1 are up and operational. The output also displays the label assignments for the adjacent and node segments.

Verify the Traffic Engineering Database

Purpose

Verify the traffic engineering database entries on the PCC.

Action

From operational mode, run the `show ted database extensive` command.

```
user@PCC# show ted database extensive

```

Meaning

The traffic engineering database includes entries advertised from Routers R1, R2, and R3, which the PCE uses for external path computing for the PCC.

Verify SR-TE LSPs

Purpose

Verify the creation of SR-TE LSPs on the PCC.

Action

From operational mode, run the `show path-computation-client lsp`, `show spring-traffic-engineering lsp detail`, and `show route protocol spring-te` commands.

```
user@PCC> show path-computation-client lsp

  Name                              Status            PLSP-Id  LSP-Type       Controller

iso.0: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)

mpls.0: 12 destinations, 12 routes (12 active, 0 holddown, 0 hidden)

inet6.0: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
```

Meaning

The outputs show that two SR-TE LSPs—`adj_sid_lsp` and `node_sid_lsp`—have been created by the PCE for the adjacency and node segments, respectively.

The segment routing LSP, `static_srte_lsp_1`, is enabled with the delegation capability. The `Delegation info` field shows the control and routing status of PCE-delegated LSPs. `Externally controlled` signifies that the PCE has control over the LSPs. `Externally routed` signifies that the PCE has provided the ERO for the source-routing path.

Verify Tunnel Route Creation

Purpose

Verify the tunnel routes created for the SR-TE LSPs that are included in the inet.3 routing table on the PCC.

Action

From operation mode, run the `show route table inet.3 extensive` command.

```
user@PCC> show route table inet.3 extensive
inet.3: 3 destinations, 4 routes (3 active, 0 holddown, 0 hidden)

Meaning

Tunnel routes have been created for the PCE-controlled LSP destination with SR-TE as the protocol label.

Verify Forwarding Table Entries

Purpose

Verify that the SR-TE LSP destination to Router R3 is installed in the forwarding table of the PCC.

Action

From operation mode, run the `show route forwarding-table destination` *ip-address* `extensive` command.

```
user@PCC> show route forwarding-table destination 192.168.100.3 extensive
Routing table: default.inet [Index 0]
Internet:
Enabled protocols: Bridging,

Destination:  192.168.100.3/32
  Route type: user
  Route reference: 0                   Route interface-index: 0
  Multicast RPF nh index: 0
  P2mpidx: 0
  Flags: sent to PFE, rt nh decoupled
  Nexthop: 10.100.41.2
  Next-hop type: unicast               Index: 581      Reference: 14
  Next-hop interface: ge-0/0/5.0

Routing table: __pfe_private__.inet [Index 3]
Internet:

```

```
Routing table: __master.anon__.inet [Index 6]
Internet:
Enabled protocols: Bridging, Dual VLAN,

Destination:  default
  Route type: permanent
  Route reference: 0                    Route interface-index: 0
  Multicast RPF nh index: 0
  P2mpidx: 0
  Flags: sent to PFE
  Next-hop type: reject                 Index: 545      Reference: 1
```

Meaning

The SR-TE LSP destination IP address to Router R3 is installed as a forwarding entry.

Verify the Use of Tunnel Routes for Static Route Forwarding

Purpose

Verify that the static route is taking the tunnel route created for the SR-TE LSPs.

Action

From operational mode, run the `show route` *ip-address* and `show route forwarding-table destination` *ip-address* commands.

```
user@PCC> show route 100.1.1.1
inet.0: 17 destinations, 17 routes (17 active, 0 holddown, 0 hidden)

The segment routing architecture enables the ingress devices in a core network to steer traffic through explicit paths. You can configure these paths using segment lists to define the paths that the incoming traffic should take. The incoming traffic may be labeled or IP traffic, causing the forwarding operation at the ingress device to be either a label swap, or a destination-based lookup.

Source packet routing or segment routing is a control-plane architecture that enables an ingress router to steer a packet through a specific set of nodes and links in the network without relying on the intermediate nodes in the network to determine the actual path it should take.

Introduction to Segment Routing LSPs

Segment routing leverages the source routing paradigm. A device steers a packet through an ordered list of instructions, called segments. A segment can represent any instruction, topological or service-based. A segment can have a local semantic to a segment routing node or to a global node within a segment routing domain. Segment routing enforces a flow through any topological path and service chain while maintaining per-flow state only at the ingress device to the segment routing domain. Segment routing can be directly applied to the MPLS architecture with no change on the forwarding plane. A segment is encoded as an MPLS label. An ordered list of segments is encoded as a stack of labels. The segment to process is on the top of the stack. Upon completion of a segment, the related label is popped from the stack.

Segment routing LSPs can either be dynamic or static in nature.

Dynamic segment routing LSPs—When a segment routing LSP is created either by an external controller and downloaded to an ingress device through Path Computation Element Protocol (PCEP) extensions, or from a BGP segment routing policy through BGP segment routing extensions, the LSP is dynamically provisioned. The segment list of the dynamic segment routing LSP is contained in the PCEP Explicit Route Object (ERO), or the BGP segment routing policy of the LSP.

Static segment routing LSPs—When a segment routing LSP is created on the ingress device through local configuration, the LSP is statically provisioned.

A static segment routing LSP can further be classified as colored and non-colored LSPs based on the configuration of the `color` statement at the `[edit protocols source-packet-routing source-routing-path` *`lsp-name`*`]` hierarchy level.

For example:

```
[edit protocols]
    source-packet-routing {
    source-routing-path lsp_name {
        to destination_address;
        color color_value;
        binding-sid binding-label;
        primary segment_list_1_name weight weight;
        ...
        primary segment_list_n_name weight weight;
        secondary segment_list_n_name;
        sr-preference sr_preference_value;
    }
}
```

Here, each primary and secondary statement refers to a segment list.

```
[edit protocols]
source-packet-routing {
    segment-list segment_list_name {
        hop_1_name label sid_label;
        ...
        hop_n_name label sid_label;
    }
}
```

Benefits of using Segment Routing LSPs

- Static segment routing does not rely on per LSP forwarding state on transit routers. Hence, removing the need of provisioning and maintaining per LSP forwarding state in the core.
- Provide higher scalability to MPLS networks.

Colored Static Segment Routing LSP

A static segment routing LSP configured with the `color` statement is called a colored LSP.

Understanding Colored Static Segment Routing LSPs

Similar to a BGP segment routing policy, the ingress route of the colored LSP is installed in the `inetcolor.0` or `inet6color.0` routing tables, with `destincation-ip-address, color` as key for mapping IP traffic.

A static colored segment routing LSP may have a binding SID, for which a route is installed in the `mpls.0` routing table. This binding SID label is used to map labeled traffic to the segment routing LSP. The gateways of the route are derived from the segment list configurations under the primary and secondary paths.

Segment List of Colored Segment Routing LSPs

The colored static segment routing LSPs already provde support for first hop label mode of resolving an LSP. However, first hop IP mode is not supported for colored segment routing LSPs. Starting in Junos OS Release 19.1R1, a commit check feature is introduced to ensure that all the segment lists contributing to the colored routes have the minimum label present for all hops. If this requirement is not met, the commit is blocked.

Non-Colored Static Segment Routing LSP

A static segment routing LSP that is configured without the `color` statement is a non-colored LSP. Similar to PCEP segment routing tunnels, the ingress route is installed in the `inet.3` or `inet6.3` routing tables.

Junos OS supports non-colored static segment routing LSPs on ingress routers. You can provision non-colored static segment routing LSP by configuring one source routed path and one or more segment lists. These segment lists can be used by multiple non-colored segment routing LSPs.

Understanding Non-Colored Segment Routing LSPs

The non-colored segment routing LSP has a unique name and a destination IP address. An ingress route to the destination is installed in the inet.3 routing table with a default preference of 8 and a metric of 1. This route allows non-colored services to be mapped to the segment routing LSP pertaining to the

destination. In case the non-colored segment routing LSP does not require an ingress route then the ingress route can be disabled. A non-colored segment routing LSP uses binding SID label to achieve segment routing LSP stitching. This label that can be used to model the segment routing LSP as a segment that may be further used to construct other segment routing LSPs in a hierarchical manner. The transit of the binding SID label, by default, has a preference of 8 and a metric of 1.

Starting in Junos OS Release 18.2R1, statically configured non-colored segment routing LSPs on the ingress device are reported to the Path Computation Element (PCE) through a Path Computation Element Protocol (PCEP) session. These non-colored segment routing LSPs may have binding service identifier (SID) labels associated with them. With this feature, the PCE can use this binding SID label in the label stack to provision PCE-initiated segment routing LSP paths.

A non-colored segment routing LSP can have a maximum of 8 primary paths. If there are multiple operational primary paths then the packet forwarding engine (PFE) distributes traffic over the paths based on the load balancing factors like the weight configured on the path. This is equal cost multi path (ECMP) if none of the paths have a weight configured on them or weighted ECMP if at least one of the paths has a non-zero weight configured on the paths. In both the cases, when one or some of the paths fail, the PFE rebalances the traffic over the remaining paths that automatically leads to achieving path protection. A non-colored segment routing LSP can have a secondary path for dedicated path protection. Upon failure of a primary path, the PFE rebalances the traffic to the remaining functional primary paths. Otherwise, the PFE switches the traffic to the backup path, hence achieving path protection. A non-colored segment routing LSP may specify a metric at `[edit protocols source-packet-routing source-routing-path` *`lsp-name`*`]` for its ingress and binding-SID routes. Multiple non-colored segment routing LSPs have the same destination address that contribute to the next hop of the ingress route.

Multiple non-colored segment routing LSPs have the same destination address that contribute to the next hop of the ingress route. Each path ,either primary or secondary, of each segment routing LSP is considered as a gateway candidate, if the path is functional and the segment routing LSP has the best preference of all these segment routing LSPs. However, the maximum number of gateways that the next-hop can hold cannot exceed the RPD multi-path limit, which is 128 by default. Extra paths are pruned, firstly secondary paths and then primary paths. A given segment list may be referred multiple times as primary or secondary paths by these segment routing LSPs. In this case, there are multiple gateways, each having a unique segment routing LSP tunnel ID. These gateways are distinct, although they have identical outgoing label stack and interface. A non-colored segment routing LSP and a colored segment routing LSP may also have the same destination address. However, they correspond to different destination addresses for ingress routes, as the colored segment routing LSP's destination address is constructed with both its destination address and color.

NOTE: In the case where a static non-colored segment routing LSP and a PCEP-created segment routing LSP co-exist and have the same to address that contributes to the same ingress route, if

they also have the same preference. Otherwise, the segment routing LSP with the best preference is installed for the route.

Segment List of Non-Colored Segment Routing LSPs

A segment list consists of a list of hops. These hops are based on the SID label or an IP address. The number of SID labels in the segment list should not exceed the maximum segment list limit. Maximum segment-list binding to a LSP tunnel is increased from 8 to 128, with maximum 1000 tunnels per system. A maximum of 128 primary paths are supported per static segment routing LSP. You can configure the maximum segment list limit at the `[edit protocols source-packet-routing]` hierarchy level.

Prior to Junos OS Release 19.1R1, for a non-colored static segment routing LSP to be usable, the first hop of the segment list had to be an IP address of an outgoing interface and the second to *n*th hops could be SID labels. Starting in Junos OS Release 19.1R1, this requirement does not apply, as the first hop of the non-colored static LSPs now provides support for SID labels, in addition to IP addresses. With the first hop label support, MPLS fast reroute (FRR) and weighted equal-cost multipath is enabled for resolving the static non-colored segment routing LSPs, similar to colored static LSPs.

For the first-hop label mode to take effect, you must include the `inherit-label-nexthops` statement globally or individually for a segment list, and the first hop of the segment list must include both IP address and label. If the first hop includes only IP address, the `inherit-label-nexthops` statement does not have any effect.

You can configure `inherit-label-nexthops` at any one of the following hierarchies. The `inherit-label-nexthops` statement takes effect only if the segment list first hop includes both IP address and label.

- **Segment list level**—At the `[edit protocols source-packet-routing segment-list` *`segment-list-name`*`]` hierarchy level.
- **Globally**—At the `[edit protocols source-packet-routing]` hierarchy level.

When the `inherit-label-nexthops` statement is configured globally, it takes precedence over the segment-list level configuration, and the `inherit-label-nexthops` configuration is applied to all the segment lists. When the `inherit-label-nexthops` statement is not configured globally, only segment lists with both labels and IP address present in the first hop, and configured with `inherit-label-nexthops` statement are resolved using SID labels.

For dynamic non-colored static LSPs, that is the PCEP-driven segment routing LSPs, the `inherit-label-nexthops` statement must be enabled globally, as the segment-level configuration is not applied.

Table 4 describes the mode of segment routing LSP resolution based on the first hop specification.

Table 36: Non-Colored Static LSP Resolution Based on First Hop Specification

First Hop Specification	Mode of LSP Resolution

IP address only
 	
For example:
 	
`segment-list path-1 {`
`  hop-1 ip-address 172.0.12.2;`
`  hop-2 label 1000012;`
`  hop-3 label 1000013;`
`  hop-4 label 1000014;`
`}`
	The segment list is resolved using the IP address.

SID only
 	
For example:
 	
`segment-list path-2 {`
`  hop-1 label 1000011;`
`  hop-2 label 1000012;`
`  hop-3 label 1000013;`
`  hop-4 label 1000014;`
`}`
	The segment list is resolved using SID labels.

IP address and SID (without the `inherit-label-nexthops` configuration)
 	
For example:
 	
`segment-list path-3 {`
`  hop1 {`
`  label 801006;`
`  ip-address 172.24.1.2;`
`  }`
`  hop-2 label 1000012;`
`  hop-3 label 1000013;`
`  hop-4 label 1000014;`
`}`
	By default, the segment list is resolved using IP address.

Table 36: Non-Colored Static LSP Resolution Based on First Hop Specification *(Continued)*

First Hop Specification	Mode of LSP Resolution

IP address and SID (with the `inherit-label-nexthops` configuration)
 	
For example:
 	
`segment-list path-3 {`
`  **inherit-label-nexthops**;`
`  hop1 {`
`  **label 801006**;`
`  **ip-address 172.24.1.2**;`
`  }`
`  hop-2 label 1000012;`
`  hop-3 label 1000013;`
`  hop-4 label 1000014;`
`}`
	The segment list is resolved using SID labels.

You can use the `show route` *ip-address* `protocol spring-te active-path table inet.3` command to view the non-colored segment routing traffic-engineered LSPs having multiple segment lists installed in the inet.3 routing table.

For example:

```
user@host> show route 7.7.7.7 protocol spring-te active-path table inet.3
inet.3: 42 destinations, 59 routes (41 active, 0 holddown, 1 hidden)
+ = Active Route, - = Last Active, * = Both

7.7.7.7/32         *[SPRING-TE/8] 00:01:25, metric 1, metric2 0
                    > to 11.1.1.2 via et-0/0/0.1, Push 801007
                      to 21.1.1.2 via et-0/0/2.1, Push 801007
                      to 11.102.1.2 via et-0/0/0.2, Push 801007, Push 801002(top)
                      to 21.202.1.2 via et-0/0/2.2, Push 801007, Push 801005(top)
                      to 11.103.1.2 via et-0/0/0.3, Push 801007, Push 801003(top)
                      to 21.203.1.2 via et-0/0/2.3, Push 801007, Push 801006(top)
                      to 11.104.1.2 via et-0/0/0.4, Push 801007, Push 801003, Push 801002(top)
                      to 21.204.1.2 via et-0/0/2.4, Push 801007, Push 801006, Push 801005(top)
```

NOTE: The first hop type of segment lists of a static segment routing LSP can cause a commit to fail, if:

- Different segment lists of a tunnel have different first hop resolution types. This is applicable to both colored and non-colored static segment routing LSPs. However, this does not apply for PCEP-driven LSPs; a system log message is generated for the mismatch in the first hop resolution type at the time of computing the path.

  For example:

  ```
  segment-list path-1 {
      hop-1 ip-address 172.0.12.2;
      hop-2 label 1000012;
      hop-3 label 1000013;
      hop-4 label 1000014;
  }
  segment-list path-2 {
      hop-1 label 1000011;
      hop-2 label 1000012;
      hop-3 label 1000013;
      hop-4 label 1000014;
  }
  source-routing-path lsp1 {
      to 172.10.10.1;
      primary {
          path-1;
          path-2;
      }
  }
  ```

  The commit of tunnel *lsp1* fails, as path-1 is of IP addressmode and path-2 is of label mode.

- The binding SID is enabled for the static non-colored LSP whose segment list type is SID label.

  For example:

  ```
  segment-list path-3 {
      hop-1 label 1000011;
      hop-2 label 1000012;
  ```

```
        hop-3 label 1000013;
        hop-4 label 1000014;
    }
    source-routing-path lsp1 {
        to 172.10.10.1;
        binding-sid 333;
        primary {
            path-3;
        }
    }
```

Configuring binding SID over label segment list is supported only for colored static LSPs and not for no-colored static LSPs.

Static Segment Routing LSP Provisioning

Segment provisioning is performed on per-router basis. For a given segment on a router, a unique service identifier (SID) label is allocated from a desired label pool which may be from the dynamic label pool for an adjacency SID label or from the segment routing global block (SRGB) for a prefix SID or node SID. The adjacency SID label can be dynamically allocated, which is the default behavior, or be allocated from a local static label pool (SRLB). A route for the SID label is then installed in the mpls.0 table.

Junos OS allows static segment routing LSPs by configuring the `segment` statement at the `[edit protocols mpls static-label-switched-path` *`static-label-switched-path`*`]` hierarchy level. A static segment LSP is identified by a unique SID label that falls under Junos OS static label pool. You can configure the Junos OS static label pool by configuring the `static-label-range` *`static-label-range`* statement at the `[edit protocols mpls label-range]` hierarchy level.

Static Segment Routing LSP Limitations

- Junos OS currently has a limitation that the next hop cannot be built to push more than the maximum segment list depth labels. So, a segment list with more than the maximum SID labels (excluding the SID label of the first hop which is used to resolve forwarding next-hop) is not usable for colored or non-colored segment routing LSPs. Also, the actual number allowed for a given segment routing LSP may be even lower than the maximum limit, if an MPLS service is on the segment routing LSP or the segment routing LSP is on a link or a node protection path. In all cases, the total number of service labels, SID labels, and link or node protection labels must not exceed the maximum segment list depth. You can configure the maximum segment list limit at `[edit protocols source-packet-routing]` hierarchy level. Multiple non-colored segment routing LSPs with less than or equal to the maximum SID labels can be stitched together to construct a longer segment routing LSP. This is called segment routing LSP stitching. It can be achieved using binding-SID label.

- The segment routing LSP stitching is actually performed at path level. If a non-colored segment routing LSP has multiple paths that is multiple segment lists, each path can be independently stitched to another non-colored segment routing LSP at a stitching point. A non-colored segment routing LSP which is dedicated to stitching may disable ingress route installation by configuring `no-ingress` statement at `[edit protocols source-packet-routing source-routing-path lsp-name]` hierarchy level.
- A maximum of 128 primary paths and 1 secondary path are supported per non-colored static segment routing LSP. If there is a violation in configuration, commit check fails with an error.
- Maximum segment-list binding to a LSP tunnel is increased from 8 to 128, with maximum 1000 tunnels per system. A maximum of 128 primary paths are supported per static segment routing LSP. As a limitation, the maximum sensor support for LSP path is 32000 only.
- If any segment-list is configured with more labels than the maximum segment list depth, the configuration commit check fails with an error.

Dynamic Creation of Segment Routing LSPs

In segment routing networks that have each provider edge (PE) device connected to every other PE device, a large amount of configuration is required for setting up the segment routing label-switched paths (LSPs), although only a few segment routing traffic-engineered (SR-TE) paths may be used. You can enable BGP-trigerred dynamic creation of these LSPs to reduce the amount of configuration in such deployments.

Configuring Dynamic Segment Routing LSP Template

To configure the template for enabling dynamic creation of segment routing LSPs, you must include the "spring-te" on page 2717 statement at the `[edit routing-options dynamic-tunnels]` hierarchy.

- The following is a sample configuration for color dynamic segment routing LSP template:

```
[edit routing-options]
dynamic-tunnels {
    <dynamic-tunnel-name> {
        spring-te {
            source-routing-path-template {
                <template-name1> color [c1 c2];
                <template-name2> color [c3];
                <template-name3> color-any;
            }
            destination-networks {
                <dest1>;
                <dest2>;
```

```
            }
        }
    }
}
```

- The following is a sample configuration for non-color dynamic segment routing LSP template:

```
dynamic-tunnels {
    <dynamic-tunnel-name> {
        spring-te {
            source-routing-path-template {
                <template-name1>;
            }
            destination-networks {
                <dest1>;
                <dest2>;
            }
        }
    }
}
```

Resolving Dynamic Segment Routing LSPs

Resolving Colored Dynamic Segment Routing LSP

When the BGP prefixes are assigned with color community, they initially get resolved over the catch-all-route-for-that–particular-color policy, and in turn, the SR-TE template on which the BGP prefix should be resolved onto is identified. The destinations SID is then derived from the BGP payload prefix next-hop attribute. For example, if the next hop of the BGP payload prefix is an IP address that belongs to Device A, then the node-SID of Device A is taken and a corresponding label is prepared and pushed to the bottom of the stack. The BGP payload prefix is resolved in a color-only mode, where the node-SID of Device A is at the bottom of the final label stack, and the SR-TE path labels are on top.

The final LSP template name is a combination of prefix, color, and tunnel name; for example, `<prefix>:<color>:dt-srte-<tunnel-name>`. The color in the LSP name is displayed in hexadecimal format, and the format of the tunnel name is similar to that o RSVP-triggered tunnel LSP names.

To successfully resolve a colored destination network, the color should have a valid template mapping, either to a specific color, or through the `color-any` template. Without a valid mapping, the tunnel is not created and the BGP route requesting for resolution remains unresolved.

Resolving Uncolored Dynamic Segment Routing LSPs

The catch-all routes for non-colored LSPs are added to the inet.3 routing table. The non-colored tunnel destination must be configured in a different `spring-te` configuration with only one template name in the mapping list. This template name is used for all the tunnel routes matching any of the destination networks configured under the same `spring-te` configuration. These tunnels are similar to RSVP tunnels in functionality.

The final LSP template name is a combination of prefix and tunnel name; for example, `<prefix>:dt-srte-<tunnel-name>`.

Dynamic Segment Routing LSP Sample Configuration

The dynamic segment routing LSP template always carries a partial path. The last hop node SID is derived automatically at the tunnel creation time depending on the protocol next-hop address (PNH) node SID. The same template can be used by multiple tunnels to different destinations. In such cases, the partial path remains the same, and only the last hop changes depending on the PNH. Dynamic segment routing LSP templates are not common to a single tunnel, as a result a full path cannot be carried on it. You can use a segment list if a full path is to be used.

Colored Dynamic Segment Routing LSPs

Sample configuration for colored dynamic segment routing LSPs:

```
protocols source-packet-routing {
    source-routing-path-template sr_lsp1 {
        primary sr_sl1
        primary sr_sl2 weight 2
        sr-preference 180;
    }
}
dynamic-tunnels tunnel1 {
    spring-te {
        source-routing-path-template {
            sr_lsp1 color [ 123 124 125 ];
            sr_lsp2 color-any
        }
        destination-networks {
            22.33.44.0/24;
        }
```

```
    }
}
```

For the above-mentioned sample configuration, the route entries are as follows:

1. **inetcolor.0 tunnel route**: 22.33.44.0-0/24 --> RT_NH_TUNNEL
2. **inetcolor6.0 tunnel route**: ffff::22.33.44.0-0/120 --> RT_NH_TUNNEL
3. **BGP prefix to tunnel mapping**:

   R1(prefix) -> 22.33.44.55-101(PNH) LSP tunnel name = 22.33.44.55:65:dt-srte-tunnel1

   R1(prefix) -> ffff::22.33.44.55-101(PNH) LSP tunnel name = 22.33.44.55:65:dt-srte-tunnel1

   R1(prefix) -> ffff::22.33.44.55-124(PNH) LSP tunnel name = 22.33.44.55:7c:dt-srte-tunnel1

4. **inetcolor.0 tunnel route**:

   22.33.44.55-101/64 --> <next-hop>

   22.33.44.55-124/64 --> <next-hop>

5. **inetcolor6.0 tunnel route:**

   ffff::22.33.44.55-101/160 --> <next-hop>

   ffff::22.33.44.55-124/160 --> <next-hop>

Non-Colored Dynamic Segment Routing LSPs

Sample configuration for non-colored dynamic segment routing LSPs:

```
protocols source-packet-routing {
    source-routing-path-template sr_lsp1 {
        primary sr_sl1
        primary sr_sl2 weight 2
        sr-preference 180;
    }
}
dynamic-tunnels {
    tunnel1 {
        spring-te {
            source-routing-path-template {
                sr_lsp1 color [ 101 ];
            }
```

```
            destination-networks {
                22.33.44.0/24;
            }
        }
    }
    tunnel2 {
        spring-te {
            source-routing-path-template {
                sr_lsp1;
            }
            destination-networks {
                22.33.44.0/24;
            }
        }
    }
}
```

For the above-mentioned sample configuration, the route entries are as follows:

1. **inet.3 tunnel route**: 22.33.44.0/24 --> RT_NH_TUNNEL
2. **inet6.3 tunnel route**: ffff::22.33.44.0/120 --> RT_NH_TUNNEL
3. **BGP prefix to tunnel mapping**:

   R1(prefix) -> 22.33.44.55(PNH) LSP template name = LSP1 --- 22.33.44.55:dt-srte-tunnel2

   R1(prefix) -> ffff::22.33.44.55(PNH) LSP template name = LSP1 --- 22.33.44.55:dt-srte-tunnel2
4. **inet.3 tunnel route**: 22.33.44.55/32 --> <next-hop>
5. **inet6.3 tunnel route**: ffff::22.33.44.55/128 --> <next-hop>

Unresolved Dynamic Segment Routing LSP

Sample configuration for unresolved dynamic segment routing LSPs:

```
protocols source-packet-routing {
    source-routing-path-template sr_lsp1 {
        primary sr_sl1
        primary sr_sl2 weight 2
        sr-preference 180;
    }
}
```

```
dynamic-tunnels tunnel1 {
    spring-te {
        source-routing-path-template {
            sr_lsp1 color [120 121 122 123];
        }
        destination-networks {
            22.33.44.0/24;
            1.1.1.0/24;
        }
    }
}
```

For the above-mentioned sample configuration, the route entries are as follows:

1. **inetcolor.0 tunnel route**: 22.33.44.0 - 0/24 --> RT_NH_TUNNEL 1.1.1.0 - 0 /24 --> RT_NH_TUNNEL
2. **inetcolor6.0 tunnel route**: ffff::22.33.44.0 - 0/120 --> RT_NH_TUNNEL ffff::1.1.1.0 - 0 /24 --> RT_NH_TUNNEL
3. **BGP prefix to tunnel mapping**: R1(prefix) -> 22.33.44.55-124(PNH) Tunnel will not be created. (Template not found for the color).

Considerations for Configuring Dynamic Creation of Segment Routing LSPs

When configuring the dynamic creation of segment routing LSPs, take the following into consideration:

- A template can be assigned with a color object. When the dynamic tunnel `spring-te` configuration includes a template with a color object, you must configure all other templates with color objects as well. All destinations are assumed to be colored within that configuration.
- A template can have a list of colors defined on it, or can be configured with the `color-any` option. Both these options can coexist in the same `spring-te` configuration. In such cases, templates assigned with specific colors have a higher preference.
- In a `spring-te` configuration, only one template can be defined with the `color-any` option.
- The color-to-template mapping is done on a one-to-one basis. One color cannot map to multiple templates.
- The template name should be configured in the `spring-te` statement under the `[edit protocols]` hierarchy, and should have the `primary` option enabled.
- Colored and non-colored destinations cannot co-exist in the same `spring-te` configuration.
- You cannot configure same destination networks, with or without color, under different `spring-te` configuration statements.

- In non-colored `spring-te` configuration, only one template can be configured without color object.

Services Supported over Dynamic Segment Routing LSPs

The following services are supported over colored dynamic segment routing LSPs:

- Layer 3 VPN
- BGP EVPN
- Export policy services

The following services are supported over non-colored dynamic segment routing LSPs:

- Layer 3 VPN
- Layer 2 VPN
- Multipath configurations

Behavior With Multiple Tunnel Sources in Segment Routing

When two sources download routes to the same destination from segment routing (for example static and dynamic sourced tunnels), then the segment routing preference is used for choosing the active route entry. A higher value has greater preference. In case the preference remains the same, then the tunnel source is used to determine the route entry.

Dynamic Segment Routing LSPs Limitations

The dynamic SR-TE LSPs do not support the following features and functionalities:

- IPv6 segment routing tunnels.
- Static tunnels.
- 6PE is not supported.
- Distributed CSPF.
- sBFD and LDP tunnelling is not supported for dynamic SR-TE LSPs and in a template.
- Install and B-SID routes in a template.

Color-Based Mapping of VPN Services

You can specify color as a protocol next hop constraint (in addition to the IPv4 or IPv6 address) for resolving transport tunnels over static colored and BGP segment routing traffic-engineered (SRTE) LSPs. This is called the color-IP protocol next hop resolution, where you are required to configure a resolution-map and apply to the VPN services. With this feature, you can enable color-based traffic steering of Layer 2 and Layer 3 VPN services.

Junos OS supports colored SRTE LSPs associated with a single color. The color-based mapping of VPN services feature is supported on static colored LSPs and BGP SRTE LSPs.

VPN Service Coloring

In general, a VPN service may be assigned a color on the egress router where the VPN NLRI is advertised, or on an ingress router where the VPN NLRI is received and processed.

You can assign a color to the VPN services at different levels:

- Per routing instance.
- Per BGP group.
- Per BGP neighbor.
- Per prefix.

Once you assign a color, the color is attached to a VPN service in the form of BGP color extended community.

You can assign multiple colors to a VPN service, referred to as multi-color VPN services. In such cases, the last color attached is considered as the color of the VPN service, and all other colors are ignored.

Multiple colors are assigned by egress and/or ingress devices through multiple policies in the following order:

- BGP export policy on the egress device.
- BGP import policy on the ingress device.
- VRF import policy on the ingress device.

The two modes of VPN service coloring are:

Egress Color Assignment

In this mode, the egress device (that is, the advertiser of the VPN NLRI) is responsible for coloring the VPN service. To enable this mode, you can define a routing policy, and apply it in the VPN service's

routing-instance `vrf-export`, group export, or group neighbor export at the `[edit protocols bgp]` hierarchy level. The VPN NLRI is advertised by BGP with the specified color extended community.

For example:

```
[edit routing-options]
community red-comm {
    members color:0:50;
}
```

```
[edit policy-options]
policy-statement pol-color {
    term t1 {
        from {
            [any match conditions];
        }
        then {
            community add red-comm;
            accept;
        }
    }
}
```

```
[edit routing-instances]
vpn-X {
    ...
    vrf-export pol-color ...;
}
```

Or

NOTE: When you apply the routing policy as an export policy of a BGP group or BGP neighbor, you must include the `vpn-apply-export` statement at the BGP, BGP group, or BGP neighbor level in order for the policy to take an effect on the VPN NLRI.

```
[edit protocols bgp]
group PEs {
```

```
    ...
    neighbor PE-A {
        export pol-color ...;
        vpn-apply-export;
    }
}
```

The routing policies are applied to Layer 3 VPN prefix NLRIs, Layer 2 VPN NRLIs, and EVPN NLRIs. The color extended community is inherited by all the VPN routes, imported, and installed in the target VRFs on one or multiple ingress devices.

Ingress Color Assignment

In this mode, the ingress device (that is, the receiver of the VPN NLRI) is responsible for coloring the VPN service. To enable this mode, you can define a routing policy, and apply it to the VPN service's routing-instance `vrf-import`, group import, or group neighbor import at the `[edit protocols bgp]` hierarchy level. All the VPN routes matching the routing policy is attached with the specified color extended community.

For example:

```
[edit routing-options]
community red-comm {
    members color:0:50;
}
```

```
[edit policy-options]
policy-statement pol-color {
    term t1 {
        from {
            [any match conditions];
        }
        then {
            community add red-comm;
            accept;
        }
```

```
    }
}
```

```
[edit routing-instances]
vpn-Y {
    ...
    vrf-import pol-color ...;
}
```

Or

```
[edit protocols bgp]
group PEs {
    ...
    neighbor PE-B {
        import pol-color ...;
    }
}
```

Specifying VPN Service Mapping Mode

To specify flexible VPN service mapping modes, you must define a policy using the `resolution-map` statement, and refer the policy in a VPN service's routing-instance `vrf-import`, group import, or group neighbor import at the `[edit protocols bgp]` hierarchy level. All the VPN routes matching the routing policy are attached with the specified resolution-map.

For example:

```
[edit policy-options]
resolution-map map-A {
    <mode-1>;
    <mode-2>;
    ...
}
policy-statement pol-resolution {
    term t1 {
        from {
            [any match conditions];
        }
```

```
        then {
            resolution-map map-A;
            accept;
        }
    }
}
```

You can apply import policy to the VPN service's routing-instance.

```
[edit routing-instances]
vpn-Y {
    ...
    vrf-import pol-resolution ...;
}
```

You can also apply the import policy to a BGP group or BGP neighbor.

```
[edit protocols bgp]
group PEs {
    ...
    neighbor PE-B {
        import pol-resolution ...;
    }
}
```

NOTE: Each VPN service mapping mode should have a unique name defined in the resolution-map. Only a single entry of IP-color is supported in the resolution-map, where the VPN route(s) are resolved using a colored-IP protocol next hop in the form of `ip-address:color`.

Color-IP Protocol Next Hop Resolution

The protocol next hop resolution process is enhanced to support colored-IP protocol next hop resolution. For a colored VPN service, the protocol next hop resolution process takes a color and a resolution-map, builds a colored-IP protocol next hop in the form of *IP-address:color*, and resolves the protocol next hop in the inet6color.0 routing table.

You must configure a policy to support multipath resolution of colored Layer 2 VPN, Layer 3 VPN, or EVPN services over colored LSPs. The policy must then be applied with the relevant RIB table as the resolver import policy.

For example:

```
[edit policy-options]
policy-statement mpath {
    then multipath-resolve;
}
```

```
[edit routing-options]
resolution {
    rib bgp.l3vpn.0 {
        inetcolor-import mpath;
    }
}

resolution {
    rib bgp.l3vpn-inet6.0 {
        inet6color-import mpath;
    }
}

resolution {
    rib bgp.l2vpn.0 {
        inetcolor-import mpath;
    }
}

resolution {
    rib mpls.0 {
        inetcolor-import mpath;
    }
}

resolution {
    rib bgp.evpn.0 {
        inetcolor-import mpath;
    }
}
```

Fallback to IP Protocol Next Hop Resolution

If a colored VPN service does not have a resolution-map applied to it, the VPN service ignores its color and falls back to the IP protocol next hop resolution. Conversely, if a non-colored VPN service has a resolution-map applied to it, the resolution-map is ignored, and the VPN service uses the IP protocol next hop resolution.

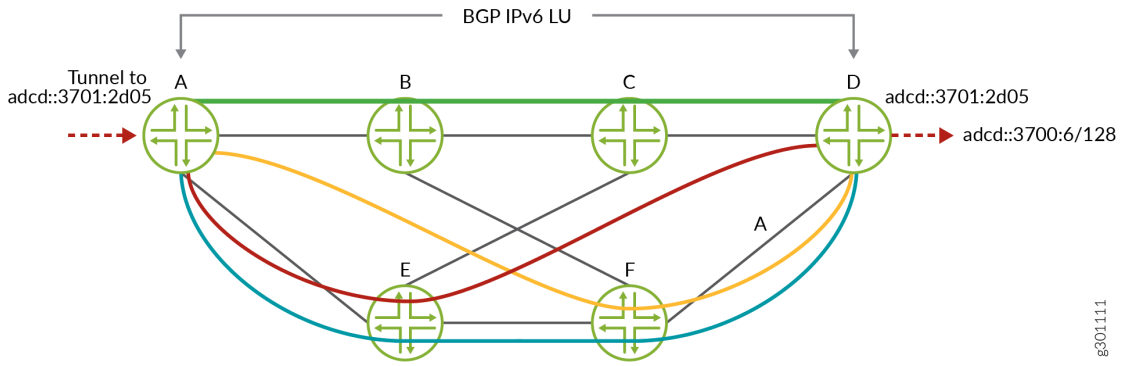
The fallback is a simple process from colored SRTE LSPs to LDP LSPs, by using a RIB group for LDP to install routes in inet{6}color.0 routing tables. A longest prefix match for a colored-IP protocol next hop ensures that if a colored SRTE LSP route does not exist, an LDP route with a matching IP address should be returned.

BGP Labeled Unicast Color-based Mapping over SR-TE

Starting in Junos OS Release 20.2R1, BGP Labeled Unicast (BGP-LU) can resolve IPv4 or IPv6 routes over segment routing–traffic engineering (SR-TE) for both IPv4 and IPv6 address families. BGP-LU supports mapping a BGP community color and defining a `resolution map` for SR-TE. A colored protocol next hop is constructed and it is resolved on a colored SR-TE tunnel in the `inetcolor.0` or `inet6color.0` table. BGP uses `inet.3` and `inet6.3` tables for non-color based mapping. This enables you to advertise BGP-LU IPv6 and IPv4 prefixes with an IPv6 next-hop address in IPv6-only networks where routers do not have any IPv4 addresses configured. With this feature, Currently we support BGP IPv6 LU over SR-TE with IS-IS underlay.

In *Figure 9*, the controller configures 4 colored tunnels in an IPv6 core network configured with SR-TE. Each colored tunnel takes a different path to the destination router D depending on the defined resolution map. The controller configures a colored SR-TE tunnel to abcd:3701:2d05 interface in router D . BGP imports policies to assign a color and resolution map to the received prefix abcd::3700:6/128. Based on the assigned community color, BGP-LU resolves the colored next hop for BGP IPv6 LU prefix according to the assigned resolution map policy.

Figure 145: BGP IPv6 LU over colored IPv6 SR-TE



BGP-LU supports the following scenarios:

- BGP IPv4 LU over colored BGP IPv4 SR-TE, with ISIS/OSPF IPv4 SR extensions.
- BGP IPv4 LU over static colored and non-colored IPv4 SR-TE, with ISIS/OSPF IPv4 SR extensions.
- BGP IPv6 LU over colored BGP IPv6 SR-TE, with ISIS IPv6 SR extensions.
- BGP IPv6 LU over static colored and non-colored IPv6 SR-TE, with ISIS IPv6 SR extensions.
- IPv6 Layer 3 VPN services with IPv6 local address and IPv6 neighbor address.
- IPv6 Layer 3 VPN services over BGP IPv6 SR-TE, with ISIS IPv6 SR extensions.
- IPv6 Layer 3 VPN services over static-colored and non-colored IPv6 SR-TE, with ISIS IPv6 SR extensions.

Supported and Unsupported Features for Color-Based Mapping of VPN Services

The following features and functionality are supported with color-based mapping of VPN services:

- BGP Layer 2 VPN (Kompella Layer 2 VPN)
- BGP EVPN
- Resolution-map with a single IP-color option.
- Colored IPv4 and IPv6 protocol next hop resolution.
- Routing information base (also known as routing table) group based fallback to LDP LSP in inetcolor.0 routing table.
- Colored SRTE LSP.
- Virtual platforms.
- 64-bit Junos OS.
- Logical systems.
- BGP labeled unicast.

The following features and functionality are not supported with color-based mapping of VPN services:

- Colored MPLS LSPs, such as RSVP, LDP, BGP-LU, static.
- Layer 2 circuit
- FEC-129 BGP auto-discovered and LDP-signaled Layer 2 VPN.

- VPLS
- MVPN
- IPv4 and IPv6 using resolution-map.

Tunnel Templates for PCE-Initiated Segment Routing LSPs

You can configure a tunnel template for PCE-initiated segment routing LSPs to pass down two additional parameters for these LSPs - Bidirectional forwarding detection (BFD) and LDP tunneling.

When a PCE-Initiated segment routing LSP is being created, the LSP is checked against policy statements (if any) and if there is a match, the policy applies the configured template for that LSP. The template configuration is inherited only if it is not provided by the LSP source (PCEP); for example, metric.

To configure a template:

1. Include the "source-routing-path-template" on page 2712 statement at the `[edit protocols source-packet-routing]` hierarchy level. You can configure the additional BFD and LDP tunneling parameters here.
2. Include the source-routing-path-template-map statement at the `[edit protocols source-packet-routing]` hierarchy level to list the policy statements against which the PCE-initiated LSP should be checked.
3. Define a policy to list the LSPs on which the template should be applied.

   The `from` statement can include either the LSP name or LSP regular expression using the `lsp` and `lsp-regex` match conditions. These options are mutually exclusive, so you can specify only one option at a given point in time.

   The `then` statement must include the `sr-te-template` option with an accept action. This applies the template to the PCE-initiated LSP.

Take the following into consideration when configuring a template for PCE-initiated LSPs:

- Template configuration is not applicable to staticalyy configured segment routing LSPs, or any other client's segment routing LSP.
- PCEP-provided configuration has precedence over template configuration.
- PCEP LSP does not inherit template segment-list configuration.

Example: Configuring Static Segment Routing Label Switched Path

IN THIS SECTION

- Requirements | 2149
- Overview | 2149
- Configuration | 2150
- Verification | 2164

This example shows how to configure static segment routing label switched paths (LSPs) in MPLS networks. This configuration helps to bring higher scalability to MPLS networks.

Requirements

This example uses the following hardware and software components:

- Seven MX Series 5G Universal Routing Platforms
- Junos OS Release 18.1 or later running on all the routers

Before you begin, be sure you configure the device interfaces.

Overview

IN THIS SECTION

- Topology | 2150

Junos OS a set of explicit segment routing paths are configured on the ingress router of a non-colored static segment routing tunnel by configuring the `segment-list` statement at the `[edit protocols source-packet-routing]` hierarchy level. You can configure segment routing tunnel by configuring the `source-routing-path` statement at `[edit protocols source-packet-routing]` hierarchy level. The segment routing tunnel has a destination address and one or more primary paths and optionally secondary paths that refer to the segment list. Each segment list consists of a sequence of hops. For non-colored static segment routing tunnel, the first hop of the segment list specifies an immediate next hop IP address and the second to Nth hop specifies the segment identifies (SID) labels corresponding to the link or node which the path traverses. The route to the destination of the segment routing tunnel is installed in inet.3 table.

Topology

In this example, configure layer 3 VPN on the provider edge routers PE1 and PE5. Configure the MPLS protocol on all the routers. The segment routing tunnel is configured from router PE1 to router PE5 with a primary path configured on router PE1 and router PE5 . Router PE1 is also configured with secondary path for path protection. The transit routers PE2 to PE4 are configured with adjacency SID labels with label pop and an outgoing interface.

Configuring Device PE1

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the CLI User Guide.

To configure Device PE1:

1. Configure the interfaces.

```
[edit interfaces]
set ge-0/0/0 unit 0 family inet address 10.10.12.1/24
set ge-0/0/0 unit 0 family mpls maximum-labels 5
set ge-0/0/1 unit 0 family inet address 10.10.13.1/24
set ge-0/0/1 unit 0 family mpls maximum-labels 5
set ge-0/0/5 unit 0 family inet address 10.10.17.1/24
```

2. Configure autonomous system number and options to control packet forwarding routing options.

```
[edit routing-options]
set autonomous-system 65000
set forwarding-table export load-balance-policy
set forwarding-table chained-composite-next-hop ingress l3vpn
```

3. Configure the interfaces with the MPLS protocol and configure the MPLS label range.

```
[edit protocols mpls]
set interface ge-0/0/0.0
set interface ge-0/0/1.0
set label-range static-label-range 1000000 1000999
```

4. Configure the type of peer group, local address, protocol family for NLRIs in updates, and IP address of a neighbor for the peer group.

```
[edit protocols bgp]
set group pe type internal
set group pe local-address 192.168.147.211
set group pe family inet-vpn unicast
set group pe neighbor 192.168.146.181
```

5. Configure the protocol area interfaces.

```
[edit protocols ospf]
set area 0.0.0.0 interface ge-0/0/0.0
```

```
set area 0.0.0.0 interface lo0.0
set area 0.0.0.0 interface ge-0/0/1.0
```

6. Configure the IPv4 address and labels of primary and secondary paths for source routing-traffic engineering (TE) policies of protocol source packet routing (SPRING).

```
[edit protocols source-packet-routing segment-list]
set sl-15-primary hop-1 ip-address 10.10.13.3
set sl-15-primary hop-2 label 1000134
set sl-15-primary hop-3 label 1000145
set sl-15-backup hop-1 ip-address 10.10.12.2
set sl-15-backup hop-2 label 1000123
set sl-15-backup hop-3 label 1000134
set sl-15-backup hop-4 label 1000145
```

7. Configure destination IPv4 address, binding SID label, primary, and secondary source routing path for protocol SPRING.

```
[edit protocols source-packet-routing source-routing-path]
set lsp-15 to 192.168.146.181
set lsp-15 binding-sid 1000999
set lsp-15 primary sl-15-primary
set lsp-15 secondary sl-15-backup
```

8. Configure policy options.

```
[edit policy-options policy-statement]
set VPN-A-export term a from protocol ospf
set VPN-A-export term a from protocol direct
set VPN-A-export term a then community add VPN-A
set VPN-A-export term a then accept
set VPN-A-export term b then reject
set VPN-A-import term a from protocol bgp
set VPN-A-import term a from community VPN-A
set VPN-A-import term a then accept
set VPN-A-import term b then reject
set bgp-to-ospf from protocol bgp
set bgp-to-ospf from route-filter 10.10.0.0/16 orlonger
```

```
set bgp-to-ospf then accept
set load-balance-policy then load-balance per-packet
```

9. Configure BGP community information.

```
[edit policy-options]
set community VPN-A members target:65000:1
```

10. Configure routing instance VRF1 with instance type, interface, router distinguisher, VRF import, export and table label. Configure export policy and interface of area for protocol OSPF.

```
[edit routing-instances VRF1]
set instance-type vrf
set interface ge-0/0/5.0
set route-distinguisher 192.168.147.211:1
set vrf-import VPN-A-import
set vrf-export VPN-A-export
set vrf-table-label
set protocols ospf export bgp-to-ospf
set protocols ospf area 0.0.0.0 interface ge-0/0/5.0
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show policy-options**, **show protocols**, **show routing-options**, and **show routing-instances** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1# show interfaces
    ge-0/0/0 {

}
```

Configuring Device PE2

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the CLI User Guide.

1. Configure the interfaces.

```
[edit interfaces]
set ge-0/0/0 unit 0 family inet address 10.10.12.2/24
set ge-0/0/0 unit 0 family mpls
set ge-0/0/1 unit 0 family inet address 10.10.23.2/24
set ge-0/0/1 unit 0 family mpls
```

2. Configure the static LSP for protocol MPLS.

```
[edit protocols mpls static-label-switched-path]
set adj-23 segment 1000123
set adj-23 segment next-hop 10.10.23.3
set adj-23 segment pop
set adj-21 segment 1000221
set adj-21 segment next-hop 10.10.12.1
set adj-21 segment pop
```

3. Configure interfaces and static label range for protocol MPLS.

```
[edit protocols mpls]
set interface ge-0/0/0.0
set interface ge-0/0/1.0
set label-range static-label-range 1000000 1000999
```

4. Configure interfaces for protocol OSPF.

```
[edit protocols ospf area 0.0.0.0]
set interface ge-0/0/0.0
set interface ge-0/0/1.0
```

Results

From configuration mode on router PE2, confirm your configuration by entering the **show interfaces** and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE2# show interfaces
ge-0/0/0 {
    unit 0 {
        family inet {
            address 55.1.12.2/24;
        }
        family mpls;
    }
}
ge-0/0/1 {
```

```
    unit 0 {
        family inet {
            address 55.1.23.2/24;
        }
        family mpls;
    }
}
```

```
user@PE2# show protocols
mpls {
    static-label-switched-path adj-23 {
        segment {
            1000123;
            next-hop 55.1.23.3;
            pop;
        }
    }
    static-label-switched-path adj-21 {
        segment {
            1000221;
            next-hop 55.1.12.1;
            pop;
        }
    }
    interface ge-0/0/0.0;
    interface ge-0/0/1.0;
    label-range {
        static-label-range 1000000 1000999;
    }
}
ospf {
    area 0.0.0.0 {
        interface ge-0/0/0.0;
        interface ge-0/0/1.0;
    }
}
```

Verification

IN THIS SECTION

- Verifying Route Entry of Routing Table inet.3 of Router PE1 | **2164**
- Verifying Route Table Entries of Routing Table mpls.0 of Router PE1 | **2165**
- Verifying SPRING Traffic Engineered LSP of Router PE1 | **2165**
- Verifying SPRING Traffic Engineered LSPs on the Ingress Router of Router PE1 | **2166**
- Verifying the Routing Table Entries of Routing Table mpls.0 of Router PE2 | **2167**
- Verifying the Status of Static MPLS LSP Segments of Router PE2 | **2168**

Confirm that the configuration is working properly.

Verifying Route Entry of Routing Table inet.3 of Router PE1

Purpose

Verify the route entry of routing table inet.3 of router PE1.

Action

From operational mode, enter the `show route table inet.3` command.

```
user@PE1> show route table inet.3
inet.3: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192.168.146.181/32   *[SPRING-TE/8] 03:09:26, metric 1
                    > to 10.10.13.3 via ge-0/0/1.0, Push 1000145, Push 1000134(top)
                      to 10.10.12.2 via ge-0/0/0.0, Push 1000145, Push 1000134, Push 1000123(top)
```

Meaning

The output displays the ingress routes of segment routing tunnels.

Verifying Route Table Entries of Routing Table mpls.0 of Router PE1

Purpose

Verify the route entries of routing table mpls.0

Action

From operational mode, enter the `show route table mpls.0` command.

```
user@PE1> show route table mpls.0
mpls.0: 6 destinations, 6 routes (6 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

0                  *[MPLS/0] 03:25:52, metric 1
                      Receive
1                  *[MPLS/0] 03:25:52, metric 1
                      Receive
2                  *[MPLS/0] 03:25:52, metric 1
                      Receive
13                 *[MPLS/0] 03:25:52, metric 1
                      Receive
16                 *[VPN/0] 03:25:52
                    > via lsi.0 (VRF1), Pop
1000999            *[SPRING-TE/8] 03:04:03, metric 1
                    > to 10.10.13.3 via ge-0/0/1.0, Swap 1000145, Push 1000134(top)
                      to 10.10.12.2 via ge-0/0/0.0, Swap 1000145, Push 1000134, Push 1000123(top)
```

Meaning

The output displays the SID labels of segment routing tunnels.

Verifying SPRING Traffic Engineered LSP of Router PE1

Purpose

Verify SPRING traffic engineered LSPs on the ingress routers.

Action

From operational mode, enter the `show spring-traffic-engineering overview` command.

```
user@PE1> show spring-traffic-engineering overview
Overview of SPRING-TE:
  Route preference: 8
  Number of LSPs: 1 (Up: 1, Down: 0)
  External controllers:
            < Not configured >
```

Meaning

The output displays the overview of SPRING traffic engineered LSPs on the ingress router.

Verifying SPRING Traffic Engineered LSPs on the Ingress Router of Router PE1

Purpose

Verify SPRING traffic engineered LSPs on the ingress router.

Action

From operational mode, enter the `show spring-traffic-engineering lsp detail` command.

```
user@PE1# show spring-traffic-engineering lsp detail
Name: lsp-15
To: 192.168.146.181
State: Up
  Path: sl-15-primary
  Outgoing interface: ge-0/0/1.0
  BFD status: N/A (Up: 0, Down: 0)
  SR-ERO hop count: 3
    Hop 1 (Strict):
      NAI: IPv4 Adjacency ID, 0.0.0.0 -> 10.10.13.3
      SID type: None
    Hop 2 (Strict):
      NAI: None
      SID type: 20-bit label, Value: 1000134
```

```
    Hop 3 (Strict):
      NAI: None
      SID type: 20-bit label, Value: 1000145
  Path: sl-15-backup
  Outgoing interface: ge-0/0/0.0
  BFD status: N/A (Up: 0, Down: 0)
  SR-ERO hop count: 4
    Hop 1 (Strict):
      NAI: IPv4 Adjacency ID, 0.0.0.0 -> 10.10.12.2
      SID type: None
    Hop 2 (Strict):
      NAI: None
      SID type: 20-bit label, Value: 1000123
    Hop 3 (Strict):
      NAI: None
      SID type: 20-bit label, Value: 1000134
    Hop 4 (Strict):
      NAI: None
      SID type: 20-bit label, Value: 1000145

Total displayed LSPs: 1 (Up: 1, Down: 0)
```

Meaning

The output displays details of SPRING traffic engineered LSPs on the ingress router

Verifying the Routing Table Entries of Routing Table mpls.0 of Router PE2

Purpose

Verify the routing table entries of routing table mpls.0 of router PE2.

Action

From operational mode, enter the `show route table mpls.0` command.

```
user@PE2> show route table mpls.0
mpls.0: 8 destinations, 8 routes (8 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
```

```
0                  *[MPLS/0] 03:22:29, metric 1
                      Receive
1                  *[MPLS/0] 03:22:29, metric 1
                      Receive
2                  *[MPLS/0] 03:22:29, metric 1
                      Receive
13                 *[MPLS/0] 03:22:29, metric 1
                      Receive
1000123            *[MPLS/6] 03:22:29, metric 1
                       > to 10.10.23.3 via ge-0/0/1.0, Pop
1000123(S=0)       *[MPLS/6] 03:22:29, metric 1
                       > to 10.10.23.3 via ge-0/0/1.0, Pop
1000221            *[MPLS/6] 03:22:29, metric 1
                       > to 10.10.12.1 via ge-0/0/0.0, Pop
1000221(S=0)       *[MPLS/6] 03:22:29, metric 1
                       > to 10.10.12.1 via ge-0/0/0.0, Pop
```

Verifying the Status of Static MPLS LSP Segments of Router PE2

Purpose

Verify the status of MPLS LSP segments of router PE2.

Action

From operational mode, enter the `show mpls static-lsp` command.

```
user@PE2> show mpls static-lsp
Ingress LSPs:
Total 0, displayed 0, Up 0, Down 0

Transit LSPs:
Total 0, displayed 0, Up 0, Down 0

Bypass LSPs:
Total 0, displayed 0, Up 0, Down 0

Segment LSPs:
LSPname                             SID-label       State
adj-21                              1000221         Up
```

```
adj-23                              1000123         Up
Total 2, displayed 2, Up 2, Down 0
```

Meaning

The output displays the status of static MPLS LSP segments of router PE2.

Enabling Distributed CSPF for Segment Routing LSPs

Prior to Junos OS Release 19.2R1S1, for traffic engineering of segment routing paths, you could either explicitly configure static paths, or use computed paths from an external controller. With the distributed Constrained Shortest Path First (CSPF) for segment routing LSP feature, you can compute a segment routing LSP locally on the ingress device according to the constraints you have configured. With this feature, the LSPs are optimized based on the configured constraints and metric type (traffic-engineering or IGP). The LSPs are computed to utilize the available ECMP paths to the destination with segment routing label stack compression enabled or disabled.

Distributed CSPF Computation Constraints

Segment routing LSP paths are computed when all the configured constraints are met.

The distributed CSPF computation feature supports the following subset of constraints specified in the Internet draft, draft-ietf-spring-segment-routing-policy-03.txt, *Segment Routing Policy for Traffic Engineering*:

- Inclusion and exclusion of administrative groups.
- Inclusion of loose or strict hop IP addresses.

NOTE: You can specify only router IDs in the loose or strict hop constraints. Labels and other IP addresses cannot be specified as loose or strict hop constraints in Junos OS Release 19.2R1-S1.

- Maximum number of segment IDs (SIDs) in the segment list.
- Maximum number of segment lists per candidate segment routing path.

The distributed CSPF computation feature for segment routing LSPs does not support the following types of constraints and deployment scenarios:

- IPV6 addresses.
- Inter domain segment routing traffic engineering (SRTE) LSPs.
- Unnumbered interfaces.
- Multiple protocols routing protocols such as, OSPF, ISIS, and BGP-LS, enabled at the same time.
- Computation with prefixes or anycast addresses as destinations.
- Including and excluding interface IP addresses as constraints.

Distributed CSPF Computation Algorithm

The distributed CSPF computation feature for segment routing LSPs uses the label stack compression algorithm with CSPF.

Label Stack Compression Enabled

A compressed label stack represents a set of paths from a source to a destination. It generally consists of node SIDs and adjacency SIDs. When label stack compression is enabled, the result of the computation is a set of paths that maximize ECMP to the destination, with minimum number of SIDs in the stack, while conforming to constraints.

Label Stack Compression Disabled

The multipath CSPF computation with label stack compression disabled finds up to *N* segment lists to destination, where:

- The cost of all segment lists is equal to and the same as the shortest traffic-engineering metric to reach the destination.
- Each segment list is comprised of adjacency SIDs.

- The value of *N* is the maximum number of segment lists allowed for the candidate path by configuration.
- No two segment lists are identical.
- Each segment list satisfies all the configured constraints.

Distributed CSPF Computation Database

The database used for SRTE computation has all links, nodes, prefixes and their characteristics irrespective of whether traffic-engineering is enabled in those advertising nodes. In other words, it is the union of the traffic-engineering database (TED) and the IGP link state database of all domains that the computing node has learnt from.

Configuring Distributed CSPF Computation Constraints

You can use a compute profile to logically group the computation constraints. These compute profiles are referenced by the segment routing paths for computing the primary and secondary segment routing LSPs.

To configure a compute profile, include the "compute-profile" on page 2433 statement at the `[edit protocols source-packet-routing]` hierarchy level.

The configuration for the supported computation constraints include:

- **Administrative groups**

  You can configure "admin-groups" on page 2398 under the `[edit protocols mpls]` hierarchy level. Junos OS applies the administrative group configuration to the segment routing traffic-engineering (SRTE) interfaces.

  To configure the computation constraints you can specify three categories for a set of administrative groups. The computation constraint configuration can be common to all candidate segment routing paths, or it can be under individual candidate paths.

  - `include-any`—Specifies that any link with at least one of the configured administrative groups in the list is acceptable for the path to traverse.
  - `include-all`—Specifies that any link with all of the configured administrative groups in the list is acceptable for the path to traverse.
  - `exclude`—Specifies that any link which does not have any of the configured administrative groups in the list is acceptable for the path to traverse.

- **Explicit path**

You can specify a series of router IDs in the compute profile as a constraint for computing the SRTE candidate paths. Each hop has to be an IPv4 address and can be of type strict or loose. If the type of a hop is not configured, strict is used. You must include the `compute` option under the *segment-list* statement when specifying the explicit path constraint.

- **Maximum number of segment lists (ECMP paths)**

  You can associate a candidate path with a number of dynamic segment-lists. The paths are ECMP paths, where each segment-list translates into a next hop gateway with active weight. These paths are a result of path computation with or without compression.

  You can configure this attribute using the `maximum-computed-segment-lists` *`maximum-computed-segment-lists`* option under the "compute-profile" on page 2433 configuration statement. This configuration determines the maximum number of such segment lists computed for a given primary and secondary LSP.

- **Maximum segment list depth**

  The maximum segment list depth computation parameter ensures that amongst the ECMP paths that satisfy all other constraints such as administrative group, only the paths that have segment lists less than or equal to the maximum segment list depth are used. When you configure this parameter as a constraint under the compute-profile, it overrides the `maximum-segment-list-depth` configuration under the `[edit protocols source-packet-routing]` hierarchy level, if present.

  You can configure this attribute using the `maximum-segment-list-depth` *`maximum-segment-list-depth`* option under the "compute-profile" on page 2433 configuration statement.

- **Protected or unprotected adjacency SIDs**

  You can configure protected or unprotected adjacency SID as a constraint under the "compute-profile" on page 2433 to avoid links with the specified SID type.

- **Metric type**

  You can specify the type of metric on the link to be used for computation. By default, SR-TE LSPs use traffic-engineering metrics of the links for computation. The traffic-engineering metric for links is advertised by traffic-engineering extensions of IGP protocols. However, you may also choose to use the IGP-metric for computation by using the metric-type configuration in the compute profile.

  You can configure this attribute using the `metric-type (`*`igp | te`*`)` option under the "compute-profile" on page 2433 configuration statement.

Distributed CSPF Computation

The SRTE candidate paths are computed locally such that they satisfy the configured constraints. When label stack compression is disabled, the multi-path CSPF computation result is a set of adjacency SID

stacks. When label stack compression is enabled, the result is a set of compressed label stacks (composed of adjacent SIDs and node SIDs).

When secondary paths are computed, the links, nodes and SRLGs taken by the primary paths are not avoided for computation. For more information on primary and secondary paths, see "Configuring Primary and Secondary LSPs" on page 663.

For any LSPs with unsuccessful computation result, the computation is retried as traffic-engineering database (TED) changes.

Interaction Between Distributed CSPF Computation and SRTE Features

Weights Associated With Paths of an SRTE Policy

You can configure weights against computed and static SRTE paths, which contribute to the next hops of the route. However, a single path that has computation enabled can result in multiple segment lists. These computed segment lists are treated as ECMP amongst themselves. You can assign hierarchical ECMP weights to these segments, considering the weights assigned to each of the configured primaries.

BFD Liveliness Detection

You can configure BFD liveliness detection for the computed primary or secondary paths. Every computed primary or secondary path can result in multiple segment lists, as a result, the BFD parameters configured against the segment lists are applied to all the computed segment lists. If all the active primary paths go down, the pre-programmed secondary path (if provided) becomes active.

inherit-label-nexthops

You are not required to explicitly enable the `inherit-label-nexthops` configuration under the `[edit protocols source-packet-routing segment-list segment-list-name]` hierarchy for the computed primary or secondary paths, as it is a default behavior.

Auto-Translate Feature

You can configure the auto-translate feature on the segment lists, and the primary or secondary paths with the auto-translate feature reference these segment lists. On the other hand, the primary or secondary on which compute feature is enabled cannot reference any segment list. As a result, you cannot enable both the compute feature and the auto-translate feature for a given primary or secondary path. However, you could have an LSP configured with a primary path with compute type and another with auto-translate type.

Distributed CSPF Computation Sample Configurations

Example 1

In Example 1,

- The non-computed primary path references a configured segment-list. In this example, the configured segment list *static_sl1* is referenced, and it also serves as the name for this primary path.
- A computed primary should have a name configured, and this name should not reference any configured segment list. In this example, *compute_segment1* is not a configured segment list.
- The *compute_profile_red* compute-profile is applied to the primary path with the name *compute_segment1*.
- The *compute_profile_red* compute-profile includes a segment list of type `compute`, which is used to specify the explicit path constraint for the computation.

```
[edit protocols source-packet-routing]
segment-list static_sl1{
    hop1 label 80000
}
segment-list exp_path1 {
    hop1 ip-address 10.1.1.1 loose
    hop2 ip-address 2.2.2.2
    compute
}
compute-profile compute_profile_red {
    include-any red
    segment-list exp_path1
    maximum-segment-list-depth 5
}
```

The weights for computed path next-hops and static next-hops are 2 and 3, respectively. Assuming the next-hops for computed paths are *comp_nh1*, *comp_nh2*, and *comp_nh3*, and the next-hop for static path is *static_nh*, the weights are applied as follows:

Next-Hop	Weight
comp_nh1	2

(Continued)

Next-Hop	Weight
comp_nh2	2
comp_nh3	2
static_nh	9

Example 2

In Example 2, both the primary and secondary paths can be of compute type and can have their own compute-profiles.

```
[edit protocols source-packet-routing]
compute-profile compute_profile_green{
    include-any green
    maximum-segment-list-depth 5
}
compute-profile compute_profile_red{
    include-any red
    maximum-segment-list-depth 8
}
```

Example 3

In Example 3, when compute is mentioned under a primary or secondary path, it results in local computation of a path to the destination without any constraints or other parameters for the computation.

```
[edit protocols source-packet-routing]
source-routing-path srte_colored_policy1 {
    to 5.5.5.5
    color 5
    binding-sid 10001
    primary {
        compute_segment1 {
```

```
            compute
        }
    }
}
```

Example: Configuring CoS-Based Forwarding and Policy-Based Routing For SR-TE LSPs

SUMMARY

CoS-based forwarding (CBF) and policy-based routing (PBR, also known as filter-based forwarding) can be enabled for non-colored segment routing-traffic engineered (SR–TE) LSPs to steer selective traffic over an explicit SR-TE path, providing you the benefit of servicing traffic based on class-of-service or a policy.

IN THIS SECTION

- CoS-Based Forwarding and Policy-Based Routing For SR-TE LSPs Overview | **2176**
- Configure CoS-Based Forwarding and Policy-Based Routing for SR-TE LSPs | **2177**

CoS-Based Forwarding and Policy-Based Routing For SR-TE LSPs Overview

IN THIS SECTION

- Benefits of CoS-Based Forwarding (CBF) and Policy-Based Routing (PBR) For SR-TE LSPs | **2176**
- Segment Routing Path Sources Supporting CBF and PBR | **2176**
- Considerations for Configuring CBF and PBR for SR-TE LSPs | **2177**

Benefits of CoS-Based Forwarding (CBF) and Policy-Based Routing (PBR) For SR-TE LSPs

With CBF and PBR you can:

- Use combinations of segment routing-traffic engineering (SR-TE) paths to steer service traffic in the core.
- Choose the supporting services to resolve over the selected SR-TE paths.

Segment Routing Path Sources Supporting CBF and PBR

The following segment routing path sources support CoS-based forwarding and policy-based routing:

- **Static SR–TE paths**—Statically configured source-routing paths that have the entire label stack statically configured.
- **PCEP**—Dynamically provisioning source-routing paths created on a controller, and downloaded to an ingress router in an ERO either through PCEP segment routing extensions, or in a BGP segment routing policy through BGP segment routing extensions.
- **Dynamic LSPs**—Dynamically created tunnels triggered through the Dynamic Tunnel Module that have last-hop ERO resolution.
- **Auto-translated paths**—Statically configured source-routing paths that are automatically translated.

Considerations for Configuring CBF and PBR for SR-TE LSPs

Remember:

- CBF and PBR is enabled only on non-colored SR-TE LSPs that are either statically or dynamically configured.
- Both CBF and PBR configurations for SR-TE LSPs can co-exist on a device; the order of configuration decides the type in which the routes are forwarded.
- For PBR, if the first-hop of the SR-TE LSP is a label, then you must include the `resolution preserve-nexthop-hiearchy` statement at the `[edit routing-options]` hierarchy level.
- The class-based forwarding of routes for CBF is visible only in the forwarding table and not on the routes.
- The policy-based forwarding of routes for PBR is done on the routes and is seen in the `show route` command output.

Configure CoS-Based Forwarding and Policy-Based Routing for SR-TE LSPs

SUMMARY

CoS-based forwarding (CBF) and policy-based routing (PBR, also known as filter-based forwarding FBF) can be used to steer selective traffic using an explicit segment routing-traffic engineered (SR-TE) label-swtiched path (LSP). Only non-colored segment routing LSPs that have the next hop configured as first hop label or IP address support CBF and PBR .

Before You Begin

- You must be running Junos OS Release 20.1 and later releases to enable CBF and PBR for non-colored SR-TE LSPs.
- Configure the device interfaces and ensure the devices are connected to the network.
- Define segment lists and configure SR-TE LSPs and their associated parameters.

To configure an SR-TE LSP, do the following:

1. Define the segment list with label parameters.

```
[edit protocol]
user@host# set source-packet-routing segment-list segment-list-name hop-name ip-address ip-address
user@host# set source-packet-routing segment-list segment-list-name hop-name label number
```

For example:

```
[edit protocol]
user@host# set source-packet-routing segment-list sr1 hop1 ip-address 11.1.1.2
user@host# set source-packet-routing segment-list sr1 hop2 label 801002
user@host# set source-packet-routing segment-list sr1 hop3 label 801003
user@host# set source-packet-routing segment-list sr1 hop4 label 801007
user@host# set source-packet-routing segment-list sr1 hop1 ip-address 11.1.1.2
user@host# set source-packet-routing segment-list sr1 hop2 label 801002
user@host# set source-packet-routing segment-list sr1 hop3 label 801003
user@host# set source-packet-routing segment-list sr1 hop4 label 801007
user@host# set source-packet-routing segment-list sr2 hop1 ip-address 11.11.1.2
user@host# set source-packet-routing segment-list sr2 hop2 label 801002
user@host# set source-packet-routing segment-list sr2 hop3 label 801003
user@host# set source-packet-routing segment-list sr2 hop4 label 801007
user@host# set source-packet-routing segment-list sr3 hop1 ip-address 11.12.1.2
user@host# set source-packet-routing segment-list sr3 hop2 label 801002
user@host# set source-packet-routing segment-list sr3 hop3 label 801003
user@host# set source-packet-routing segment-list sr3 hop4 label 801007
user@host# set source-packet-routing segment-list sr4 hop1 ip-address 11.13.1.2
user@host# set source-packet-routing segment-list sr4 hop2 label 801002
user@host# set source-packet-routing segment-list sr4 hop3 label 801003
user@host# set source-packet-routing segment-list sr4 hop4 label 801007
```

2. Configure the source-routing path for the SR-TE LSPs and specify the preference value and primary segment for the path.

```
[edit protocols]
user@host# set source-packet-routing source-routing-path source-routing-path-name to
destination-ip-address
user@host# set source-packet-routing source-routing-path source-routing-path-name preference
preference
user@host# set source-packet-routing source-routing-path source-routing-path-name primary
primary-segment
```

For example:

```
[edit protocols]
user@host# set source-packet-routing source-routing-path srtelsp1 to 7.7.7.7
user@host# set source-packet-routing source-routing-path srtelsp1 preference 1
user@host# set source-packet-routing source-routing-path srtelsp1 primary sr1
user@host# set source-packet-routing source-routing-path srtelsp2 to 7.7.7.7
user@host# set source-packet-routing source-routing-path srtelsp2 preference 1
user@host# set source-packet-routing source-routing-path srtelsp2 primary sr2
user@host# set source-packet-routing source-routing-path srtelsp3 to 7.7.7.7
user@host# set source-packet-routing source-routing-path srtelsp3 preference 1
user@host# set source-packet-routing source-routing-path srtelsp3 primary sr3
user@host# set source-packet-routing source-routing-path srtelsp4 to 7.7.7.7
user@host# set source-packet-routing source-routing-path srtelsp4 preference 1
user@host# set source-packet-routing source-routing-path srtelsp4 primary sr4
```

You can now configure CBF and PBR for the configured SR-TE LSPs.

To configure CBF, do the following

1. Define Differentiated Services Code Point (DSCP) classifiers to handle incoming IPv4 packets, forwarding classes, and option values.

```
[edit class-of-service]
user@host# set classifiers dscpclassifier-name forwarding-class forwarding-class-name loss-
priority level code-points [ aliases ] [ 6 bit-patterns ]
```

For example:

```
[edit class-of-service]
user@host# set classifiers dscp mydscp forwarding-class af11 loss-priority low code-points
001010
user@host# set classifiers dscp mydscp forwarding-class af11 loss-priority medium-high code-
points 001100
user@host# set classifiers dscp mydscp forwarding-class af11 loss-priority high code-points
001110
user@host# set classifiers dscp mydscp forwarding-class af21 loss-priority low code-points
010010
user@host# set classifiers dscp mydscp forwarding-class af21 loss-priority medium-high code-
points 010100
user@host# set classifiers dscp mydscp forwarding-class af21 loss-priority high code-points
010110
user@host# set classifiers dscp mydscp forwarding-class af31 loss-priority low code-points
011010
user@host# set classifiers dscp mydscp forwarding-class af31 loss-priority medium-high code-
points 011100
user@host# set classifiers dscp mydscp forwarding-class af31 loss-priority high code-points
011110
user@host# set classifiers dscp mydscp forwarding-class af41 loss-priority low code-points
100010
user@host# set classifiers dscp mydscp forwarding-class af41 loss-priority medium-high code-
points 100100
user@host# set classifiers dscp mydscp forwarding-class af41 loss-priority high code-points
100110
```

2. Define forwarding classes (FCs) for grouping packets for transmission, and assign packets to output queues.

```
[edit class-of-service]
user@host# set forwarding-classes queue queue-numner class-name
```

For example:

```
[edit class-of-service]
user@host# set forwarding-classes queue 0 af11
user@host# set forwarding-classes queue 1 af21
```

```
user@host# set forwarding-classes queue 2 af31
user@host# set forwarding-classes queue 3 af41
```

3. Assign the configured classifiers to the device interfaces.

```
[edit class-of-service]
user@host# set interfaces interface-name unit unit classifiers dscp classifier-name
```

For example:

```
[edit class-of-service]
user@host# set interfaces ge-0/0/8 unit 1 classifiers dscp mydscp
user@host# set interfaces ge-0/0/8 unit 2 classifiers dscp mydscp
```

4. Define CoS-based forwarding policy options with LSP next-hop as the SR-TE LSP.

```
[edit class-of-service]
user@host# set forwarding-policy next-hop-map map-name forwarding-classes class-name lsp-next-
hop source-routing-path-name
```

For example:

```
[edit class-of-service]
user@host# set forwarding-policy next-hop-map my_cbf forwarding-class af11 lsp-next-hop
srtelsp1
user@host# set forwarding-policy next-hop-map my_cbf forwarding-class af21 lsp-next-hop
srtelsp2
user@host# set forwarding-policy next-hop-map my_cbf forwarding-class af41 lsp-next-hop
srtelsp3
user@host# set forwarding-policy next-hop-map my_cbf forwarding-class af31 lsp-next-hop
srtelsp4
```

5. Discard traffic that does not meet any forwarding class in the next-hop map.

```
[edit class-of-service]
user@host# set forwarding-policy next-hop-map map-name forwarding-class-default discard
```

For example:

```
[edit class-of-service]
user@host# set forwarding-policy next-hop-map my_cbf forwarding-class-default discard
```

6. Configure a policy statement that specifies that routes matching the route filter are subject to the CoS next-hop mapping specified by map-name.

```
[edit policy-options]
user@host# set policy-statement policy-name from route-filter destination-prefix match-type
<actions>
user@host# set policy-statement policy-name then cos-next-hop-map map-name
```

For example:

```
[edit policy-options]
user@host# set policy-statement cbf from route-filter 4.0.0.1/16 orlonger
user@host# set policy-statement cbf then cos-next-hop-map my_cbf
```

7. Apply the policy to routes being exported from the routing table into the forwarding table. This enables CBF for SR-TE LSPs.

```
[edit routing-options]
user@host# set forwarding-table export policy-name
```

For example:

```
[edit routing-options]
user@host# set forwarding-table export cbf
```

8. Commit the configuration.

```
user@host# commit
```

Verify CBF Configuration

You can verify the CBF configuration using the `show route forwarding-table destination` *ip-address* `vpn` *vpn-name* `extensive` command.

```
user@host> show route forwarding-table destination 4.0.0.1 vpn vpn1 extensive
Routing table: vpn1.inet [Index 8]
Internet:
Destination:  4.0.0.1/32
  Route type: user
  Route reference: 0
  Multicast RPF nh index: 0
  P2mpidx: 0

Flags: sent to PFE
Next-hop type: indirect
Next-hop type: indexed
Route type: idx:0
Nexthop: 11.1.1.2
Next-hop type: Push 296, Push 801007, Push 801003, Push 801002(top) Index: 807

Reference: 1

Route interface-index: 0

Index: 1048579  Reference: 10001
Index: 837      Reference: 2
Load Balance Label: None
Next-hop interface: ge-0/0/1.1
Route type: idx:1
Nexthop: 11.11.1.2
Next-hop type: Push 296, Push 801007, Push 801003, Push 801002(top) Index: 809
```

For CBF, the class-based forwarding of routes is visible only in the forwarding table, unlike PBR, where the filtered routes are visible in the `show route` command output.

To configure PBR, do the following

1. Configure a policy statement which specifies that routes matching the protocol and route filter are subject to the LSP next-hop, or are load balanced as equal-cost multipath (ECMP) in the forwarding table.

```
[edit policy-options]
user@host# set policy-statement policy-name from protocol protocol-name
```

```
user@host# set policy-statement policy-name from route-filter destination-prefix match-type
<actions>
user@host# set policy-statement policy-name then install-nexthop lsp lsp-name
user@host# set policy-statement policy-name then load-balance per-packet
```

For example:

```
[edit policy-options]
user@host# set policy-statement pbr term 1 from protocol bgp
user@host# set policy-statement pbr term 1 from route-filter 4.0.0.1/32 exact
user@host# set policy-statement pbr term 1 then install-nexthop lsp srtelsp1
user@host# set policy-statement pbr term 1 then load-balance per-packet
user@host# set policy-statement pbr term 1 then reject
```

2. Configure the device to perform custom route resolution on protocol next hops of routes.

> **NOTE**: The `resolution preserve-nexthop-hierarchy` statement is mandatory for PBR to work when the first-hop of the SR-TE LSP is a label.

```
[edit routing-options]
user@host# set resolution preserve-nexthop-hierarchy
```

3. Apply the policy to routes being exported from the routing table into the forwarding table. This enables PBR for SR-TE LSPs.

```
[edit routing-options]
user@host# set forwarding-table export policy-name
```

For example:

```
[edit routing-options]
user@host# set forwarding-table export pbr
```

4. Commit the configuration.

```
user@host# commit
```

Verify PBR Configuration

You can verify the PBR configuration using the `show route` *`destination-prefix`* command.

```
user@host> show route 4.0.0.1
vpn1.inet.0: 10003 destinations, 10003 routes (10003 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

4.0.0.1/32         *[BGP/170] 00:24:12, localpref 100, from 7.7.7.7
                      AS path: 10 I, validation-state: unverified
                       to 11.1.1.2 via ge-0/0/1.1, Push 50983, Push 801007, Push 801003, Push
801002(top)
                     >  to 11.11.1.2 via ge-0/0/1.2, Push 50983, Push 801007, Push 801003, Push
801002(top)
                       to 11.12.1.2 via ge-0/0/1.3, Push 50983, Push 801007, Push 801003, Push
801002(top)
                       to 11.13.1.2 via ge-0/0/1.4, Push 50983, Push 801007, Push 801003, Push
801002(top)
```

```
user@host> show route 4.0.0.1 expanded-nh extensive
vpn1.inet.0: 10003 destinations, 10003 routes (10003 active, 0 holddown, 0 hidden)
4.0.0.1/32 (1 entry, 1 announced)
Installed-nexthop:
Indr (0xc7aaa54) 7.7.7.7 Push 50983 Session-ID: 0x16f
  Krt_inh (0xc745a84) Index:1048579 PNH: 7.7.7.7
    Chain (0xc7aa798) Index:823 Push 50983
      Router (0xc417034) 11.1.1.2 Push 801007, Push 801003, Push 801002(top) via ge-0/0/1.1
```

The output displays all next-hops for the destination prefix, 4.0.0.1. The `expanded-nh extensive` options displays the filtered next-hops under the `Krt_inh` output field.

```
user@host> show route 4.0.0.2
vpn1.inet.0: 10003 destinations, 10003 routes (10003 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

4.0.0.2/32         *[BGP/170] 00:30:14, localpref 100, from 7.7.7.7
                      AS path: 10 I, validation-state: unverified
                       to 11.1.1.2 via ge-0/0/1.1, Push 569, Push 801007, Push 801003, Push
801002(top)
                     >  to 11.11.1.2 via ge-0/0/1.2, Push 569, Push 801007, Push 801003, Push
```

```
801002(top)
                      to 11.12.1.2 via ge-0/0/1.3, Push 569, Push 801007, Push 801003, Push
801002(top)
                      to 11.17.1.2 via ge-0/0/1.8, Push 569, Push 801007, Push 801003, Push
801002(top)
```

```
user@host> show route 7.7.7.7 protocol spring-te
inet.0: 10082 destinations, 10119 routes (10082 active, 0 holddown, 0 hidden)

inet.3: 25 destinations, 77 routes (25 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

7.7.7.7/32         *[SPRING-TE/1] 00:00:32, metric 1, metric2 4
                    >  to 11.1.1.2 via ge-0/0/1.1, Push 801007, Push 801003, Push 801002(top)
                       to 11.11.1.2 via ge-0/0/1.2, Push 801007, Push 801003, Push 801002(top)
                       to 11.12.1.2 via ge-0/0/1.3, Push 801007, Push 801003, Push 801002(top)
                       to 11.17.1.2 via ge-0/0/1.8, Push 801007, Push 801003, Push 801002(top)
```

For PBR the `show route` command output does the policy-based filtering of routes.

Release History Table

Release	Description
21.R1	Starting in Junos OS Release 21.1R1, Junos OS supports nonstop active routing (NSR) for PCE-initiated RSVP-based point-to-point and point-to-multipoint LSPs.
21.R1	Starting in Junos OS Release 21.1R1, Junos OS supports nonstop active routing (NSR) for PCE-initiated RSVP-based point-to-multipoint LSPs.
20.2R1	Starting in Junos OS Release 20.2R1, BGP Labeled Unicast (BGP-LU) can resolve IPv4 or IPv6 routes over segment routing–traffic engineering (SR-TE) for both IPv4 and IPv6 address families.
19.4R1	You can associate a single or range of MVPN multicast flows (S,G) to a dynamically created PCE-initiated point-to-multipoint label-switched path (LSP).
19.4R1	You can configure a tunnel template for PCE-initiated segment routing LSPs to pass down two additional parameters for these LSPs - Bidirectional forwarding detection (BFD) and LDP tunneling.
19.1R1	Starting in Junos OS Release 19.1R1, a commit check feature is introduced to ensure that all the segment lists contributing to the colored routes have the minimum label present for all hops.

19.1R1	Starting in Junos OS Release 19.1R1, this requirement does not apply, as the first hop of the non-colored static LSPs now provides support for SID labels, in addition to IP addresses. With the first hop label support, MPLS fast reroute (FRR) and weighted equal-cost multipath is enabled for resolving the static non-colored segment routing LSPs, similar to colored static LSPs.
18.2R1	Starting in Junos OS Release 18.2R1, statically configured non-colored segment routing LSPs on the ingress device are reported to the Path Computation Element (PCE) through a Path Computation Element Protocol (PCEP) session.
17.2R1	Starting in Junos OS Release 17.2, in addition to external cspf, two new path computation types are introduced for the PCE-controlled LSPs: local cspf and no cspf.
16.1	Starting with Junos OS Release 16.1, you can secure a PCEP session using TCP-MD5 authentication as per RFC 5440.
16.1	Junos OS Release 16.1 introduces the feature of securing a PCEP session using TCP-MD5 authentication as per RFC 5440.
14.2R4	Starting in Junos OS Release 14.2R4, support of auto-bandwidth is provided for PCE-controlled LSPs.

Verify MPLS Interfaces

IN THIS SECTION

- Purpose | **2190**
- Action | **2190**
- Meaning | **2192**

Purpose

If the MPLS protocol is not configured correctly on the routers in your network, the interfaces are not able to perform MPLS switching.

NOTE: For a labeled route to be resolved over an interface, `family mpls` must be configured at the `[edit interfaces]` hierarchy level for the route to be successfully resolved. When the interface is not configured with `family mpls`, labelled routes do not get resolved.

Action

To verify MPLS interfaces, enter the following Junos OS command-line interface (CLI) operational mode command:

```
user@host>                          show mpls interface
```

Sample Output 1

command-name

The following sample output is for all routers in the network shown in MPLS Network Topology.

```
user@R1> show mpls interface
Interface        State       Administrative groups
so-0/0/0.0       Up          <none>
so-0/0/1.0       Up          <none>
so-0/0/2.0       Up          <none>

user@R2> show mpls interface
Interface        State       Administrative groups
so-0/0/0.0       Up          <none>
so-0/0/1.0       Up          <none>
so-0/0/2.0       Up          <none>
so-0/0/3.0       Up          <none>

user@R3> show mpls interface
Interface        State       Administrative groups
so-0/0/0.0       Up          <none>
so-0/0/1.0       Up          <none>
so-0/0/2.0       Up          <none>
so-0/0/3.0       Up          <none>

user@R4> show mpls interface
Interface        State       Administrative groups
so-0/0/0.0       Up          <none>
so-0/0/1.0       Up          <none>
so-0/0/2.0       Up          <none>
so-0/0/3.0       Up          <none>

user@R5> show mpls interface
Interface        State       Administrative groups
so-0/0/0.0       Up          <none>
so-0/0/1.0       Up          <none>
so-0/0/2.0       Up          <none>

user@R6> show mpls interface
Interface        State       Administrative groups
so-0/0/0.0       Up          <none>
```

```
so-0/0/1.0       Up         <none>
so-0/0/2.0       Up         <none>
so-0/0/3.0       Up         <none>
```

Sample Output 2

command-name

```
user@R6>  show mpls interface
Interface        State       Administrative groups
so-0/0/0.0       Up         <none>
so-0/0/1.0       Up         <none>
so-0/0/3.0       Up         <none>       # so-0/0/2.0 is missing
```

Sample Output 3

command-name

```
user@host> show mpls interface
MPLS not configured
```

Meaning

Sample Output 1 shows that all MPLS interfaces on all routers in the network are enabled (**Up**) and can perform MPLS switching. If you fail to configure the correct interface at the [**edit protocols mpls**] hierarchy level or include the `family mpls` statement at the [**edit interfaces** *type-fpc/pic/port* **unit** *number*] hierarchy level, the interface cannot perform MPLS switching, and does not appear in the output for the `show mpls interface` command.

Administrative groups are not configured on any of the interfaces shown in the example network in MPLS Network Topology. However, if they were, the output would indicate which affinity class bits are enabled on the router.

Sample Output 2 shows that interface **so-0/0/2.0** is missing and therefore might be incorrectly configured. For example, the interface might not be included at the [**edit protocols mpls**] hierarchy level, or the `family mpls` statement might not be included at the [**edit interfaces** *type-fpc/pic/port* **unit** *number*] hierarchy level. If the interface is configured correctly, RSVP might not have signaled over this interface

yet. For more information on determining which interface is incorrectly configured, see "Verify Protocol Families" on page 2193.

Sample Output 3 shows that the MPLS protocol is not configured at the [**edit protocols mpls**] hierarchy level.

Verify Protocol Families

IN THIS SECTION

- Purpose | **2193**
- Action | **2193**
- Meaning | **2197**

Purpose

If a logical interface does not have MPLS enabled, it cannot perform MPLS switching. This step allows you to quickly determine which interfaces are configured with MPLS and other protocol families.

Action

To verify the protocol families configured on the routers in your network, enter the following Junos OS CLI operational mode command:

```
user@host>                          show interfaces terse
```

Sample Output 1

command-name

```
user@R1> show interfaces terse
Interface               Admin Link Proto Local                 Remote
so-0/0/0                up    up
so-0/0/0.0              up    up   inet  10.1.12.1/30
                                    iso
                                    mpls
so-0/0/1                up    up
```

```
so-0/0/1.0              up    up   inet  10.1.15.1/30
                                   iso
                                   mpls
so-0/0/2                up    up
so-0/0/2.0              up    up   inet  10.1.13.1/30
                                   iso
                                   mpls
so-0/0/3                up    down

user@R2> show interfaces terse
Interface               Admin Link Proto Local                 Remote
so-0/0/0                up    up

```

Meaning

Sample Output 1 shows the interface, the administrative status of the link (**Admin**), the data link layer status of the link (**Link**), the protocol families configured on the interface (**Proto**), and the local and remote addresses on the interface.

All interfaces on all routes in the network shown in MPLS Network Topology are administratively enabled and functioning at the data link layer with MPLS and IS-IS, and have an **inet** address. All are configured with an IPv4 protocol family (**inet**), and have the IS-IS (**iso**) and MPLS (**mpls**) protocol families configured at the [**edit interfaces** *type-fpc/pic/port* **unit** *number*] hierarchy level.

Sample Output 2 shows that interface **so-0/0/2.0** on **R6** does not have the `mpls` statement included at the [**edit interfaces** *type-fpc/pic/port* **unit** *number*] hierarchy level.

Verify the MPLS Configuration

IN THIS SECTION

- Purpose | **2197**
- Action | **2198**
- Meaning | **2200**

Purpose

After you have checked the transit and ingress routers, use the `traceroute` command to verify the BGP next hop, and used the `ping` command to verify the active path, you can check for problems with the MPLS configuration at the `[edit protocols mpls]` and `[edit interfaces]` hierarchy levels.

NOTE: For a labeled route to be resolved over an interface, `family mpls` must be configured at the `[edit interfaces]` hierarchy level for the route to be successfully resolved. When the interface is not configured with `family mpls`, labelled routes do not get resolved.

Action

To verify the MPLS configuration, enter the following commands from the ingress, transit, and egress routers:

```
user@host>              show configuration protocols mpls
user@host>              show configuration interfaces
```

Sample Output 1

command-name

```
user@R1> show configuration protocols mpls
label-switched-path R1-to-R6 {
    to 10.0.0.6;
}
inactive: interface so-0/0/0.0;
inactive: interface so-0/0/1.0;
interface so-0/0/2.0;
interface fxp0.0 {
    disable;
}

user@R3> show configuration protocols mpls
interface fxp0.0 {
    disable;
}
inactive: interface so-0/0/0.0;
inactive: interface so-0/0/1.0;
interface so-0/0/2.0;
interface so-0/0/3.0;

user@R6> show configuration protocols mpls
label-switched-path R6-to-R1 {
    to 10.0.0.1;
}
inactive: interface so-0/0/0.0;
inactive: interface so-0/0/1.0;
inactive: interface so-0/0/2.0;
inactive: interface so-0/0/3.0; <<< Incorrectly configured
```

Sample Output 2

command-name

```
user@R6> show configuration interfaces
so-0/0/0 {
    unit 0 {
        family inet {
            address 10.1.56.2/30;
        }
        family iso;
        family mpls;
    }
}
so-0/0/1 {
    unit 0 {
        family inet {
            address 10.1.46.2/30;
        }
        family iso;
        family mpls;
    }
}
so-0/0/2 {
    unit 0 {
        family inet {
            address 10.1.26.2/30;
        }
        family iso;
        family mpls;
    }
}
so-0/0/3 {
    unit 0 {
        family inet {
            address 10.1.36.2/30;
        }
        family iso;
        family mpls;
    }
}
fxp0 {
```

```
    unit 0 {
        family inet {
            address 192.168.70.148/21;
        }
    }
}
lo0 {
    unit 0 {
        family inet {
            address 10.0.0.6/32;
            address 127.0.0.1/32;
        }
        family iso {
            address 49.0003.1000.0000.0006.00;
        }
    }
}
```

Meaning

Sample Output 1 from the ingress, transit, and egress routers shows that the configuration of interfaces on egress router **R6** is incorrect. Interface **so-0/0/3.0** is included as inactive at the [**edit protocols mpls**] hierarchy level, when it should be active because it is the interface through which the LSP travels.

Sample Output 2 shows that interfaces are correctly configured for MPLS on egress router **R6**. The interfaces are also correctly configured on the ingress and transit routers (not shown).

Checking the MPLS Layer

IN THIS SECTION

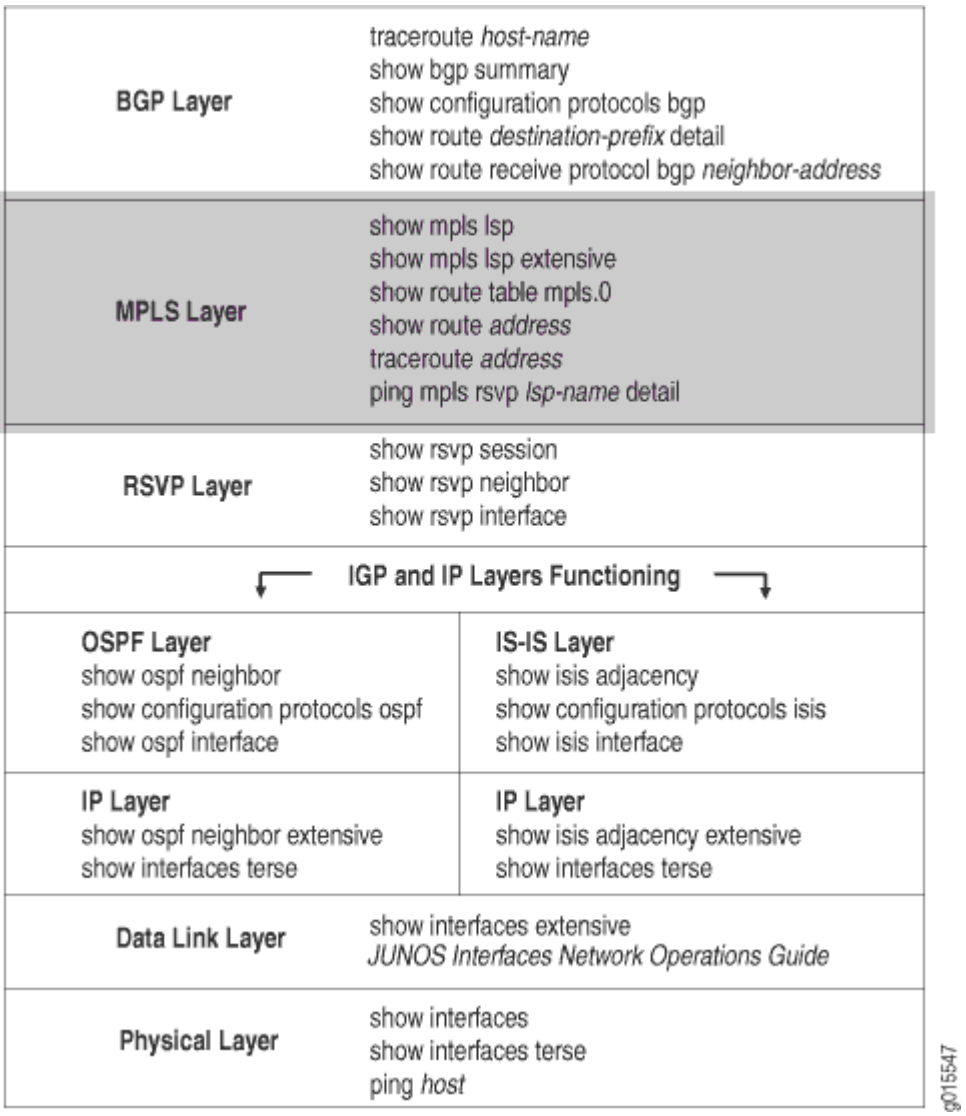
- Verify the LSP | **2203**
- Verify the LSP Route on the Transit Router | **2207**
- Verify the LSP Route on the Ingress Router | **2209**
- Verify MPLS Labels with the traceroute Command | **2211**
- Verify MPLS Labels with the ping Command | **2213**
- Take Appropriate Action | **2215**
- Verify the LSP Again | **2217**

Purpose

After you have configured the label-switched path (LSP), issued the `show mpls lsp` command, and determined that there is an error, you might find that the error is not in the physical, data link, Internet Protocol (IP), interior gateway protocol (IGP), or Resource Reservation Protocol (RSVP) layers. Continue investigating the problem at the MPLS layer of the network.

Figure 147 on page 2201 illustrates the MPLS layer of the layered MPLS model.

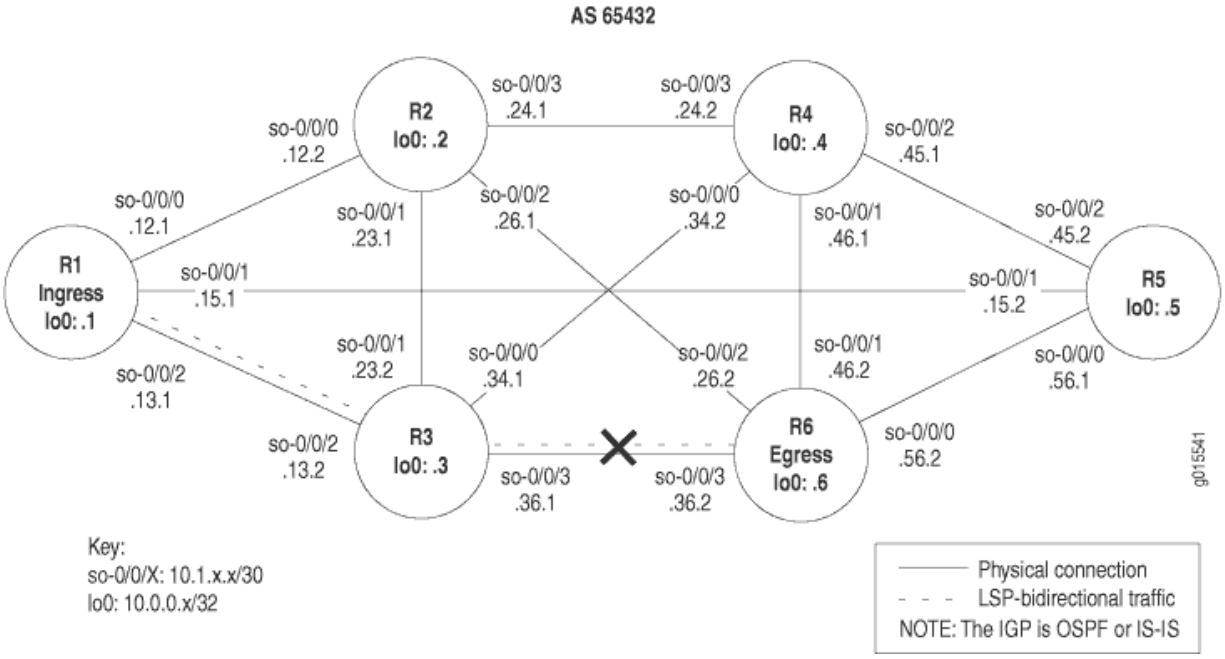
Figure 147: Checking the MPLS Layer



With the MPLS layer, you check whether the LSP is up and functioning correctly. If the network is not functioning at this layer, the LSP does not work as configured.

Figure 148 on page 2202 illustrates the MPLS network used in this topic.

Figure 148: MPLS Network Broken at the MPLS Layer



The network shown in Figure 148 on page 2202 is a fully meshed configuration where every directly connected interface can receive and send packets to every other similar interface. The LSP in this network is configured to run from ingress router **R1**, through transit router **R3**, to egress router **R6**. In addition, a reverse LSP is configured to run from **R6** through **R3** to **R1**, creating bidirectional traffic.

However, in this example, the reverse LSP is down without a path from **R6** to **R1**.

The cross shown in Figure 148 on page 2202 indicates where the LSP is broken. Some possible reasons the LSP is broken might include an incorrectly configured MPLS protocol, or interfaces that are incorrectly configured for MPLS.

In the network shown in Figure 148 on page 2202, a configuration error on egress router **R6** prevents the LSP from traversing the network as expected.

To check the MPLS layer, follow these steps:

Verify the LSP

IN THIS SECTION

- Purpose | 2203
- Action | 2203
- Meaning | 2207

Purpose

Typically, you use the `show mpls lsp extensive` command to verify the LSP. However for quick verification of the LSP state, use the `show mpls lsp` command. If the LSP is down, use the **extensive** option (`show mpls lsp extensive`) as a follow-up. If your network has numerous LSPs, you might consider specifying the name of the LSP, using the **name** option (`show mpls lsp name` ***name*** or `show mpls lsp name` ***name*** **extensive).**

Action

To verify that the LSP is up, enter some or all of the following commands from the ingress router:

```
user@host> show mpls lsp
user@host> show mpls lsp extensive
user@host> show mpls lsp name name
user@host> show mpls lsp name name extensive
```

Sample Output 1

command-name

```

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Meaning

Sample Output 1 shows a brief description of the state of the LSP for the ingress, transit, and egress routers. Output from ingress router **R1** and egress router **R6** shows that both LSPs are down, **R1-to-R6** and **R6-toR1**. With the configured LSPs on **R1** and **R6**, we would expect egress LSP sessions on both **R1** and **R6**. In addition, transit router **R3** has no transit sessions.

Sample Output 2 shows all information about the LSPs, including all past state history and the reason why an LSP failed. Output from **R1** and **R6** indicates that there is no route to the destination because the Constrained Shortest Path First (CSPF) algorithm failed.

Sample Outputs 3 and 4 show examples of the output for the `show mpls lsp name` command with the **extensive** option. In this instance, the output is very similar to the `show mpls lsp` command because only one LSP is configured in the example network in "MPLS Network Broken at the MPLS Layer" on page 2189. However, in a large network with many LSPs configured, the results would be quite different between the two commands.

Verify the LSP Route on the Transit Router

IN THIS SECTION

- Purpose | **2207**
- Action | **2207**
- Meaning | **2209**

Purpose

If the LSP is up, the LSP route should appear in the **mpls.0** routing table. MPLS maintains an MPLS path routing table (**mpls.0**), which contains a list of the next label-switched router in each LSP. This routing table is used on transit routers to route packets to the next router along an LSP. If routes are not present in the output for the transit router, check the MPLS protocol configuration on the ingress and egress routers.

Action

To verify the LSP route on the transit router, enter the following command from the transit router:

```
user@host> show route table mpls.0
```

Sample Output 1

command-name

```
user@R3> show route table mpls.0
mpls.0: 3 destinations, 3 routes (3 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
0                  *[MPLS/0] 16w2d 21:52:40, metric 1
                      Receive
1                  *[MPLS/0] 16w2d 21:52:40, metric 1
                      Receive
2                  *[MPLS/0] 16w2d 21:52:40, metric 1
                      Receive
```

Sample Output 2

command-name

```
user@R3> show route table mpls.0
mpls.0: 7 destinations, 7 routes (7 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
0                  *[MPLS/0] 16w2d 22:26:08, metric 1
                      Receive
1                  *[MPLS/0] 16w2d 22:26:08, metric 1
                      Receive
2                  *[MPLS/0] 16w2d 22:26:08, metric 1
                      Receive
100864             *[RSVP/7] 00:07:23, metric 1
                    > via so-0/0/2.0, label-switched-path R6-to-R1
100864(S=0)        *[RSVP/7] 00:07:23, metric 1
                    > via so-0/0/2.0, label-switched-path R6-to-R1
100880             *[RSVP/7] 00:07:01, metric 1
                    > via so-0/0/3.0, label-switched-path R1-to-R6
100880(S=0)        *[RSVP/7] 00:07:01, metric 1
                    > via so-0/0/3.0, label-switched-path R1-to-R6
```

Meaning

Sample Output 1 from transit router **R3** shows three route entries in the form of MPLS label entries. These MPLS labels are reserved MPLS labels defined in RFC 3032, and are always present in the **mpls.0** routing table, regardless of the state of the LSP. The incoming labels assigned by RSVP to the upstream neighbor are missing from the output, indicating that the LSP is down. For more information on MPLS label entries, see Checklist for Verifying LSP Use.

In contrast, Sample Output 2 shows the MPLS labels and routes for a correctly configured LSP. The three reserved MPLS labels are present, and the four other entries represent the incoming labels assigned by RSVP to the upstream neighbor. These four entries represent two routes. There are two entries per route because the stack values in the MPLS header may be different. For each route, the second entry **100864 (S=0)** and **100880 (S=0)** indicates that the stack depth is not 1, and additional label values are included in the packet. In contrast, the first entry, **100864** and **100880** has an inferred S=1 value which indicates a stack depth of 1 and makes each label the last label in that particular packet. The dual entries indicate that this is the penultimate router. For more information on MPLS label stacking, see RFC 3032, *MPLS Label Stack Encoding.*

Verify the LSP Route on the Ingress Router

IN THIS SECTION

- Purpose | **2209**
- Action | **2209**
- Meaning | **2211**

Purpose

Check whether the LSP route is included in the active entries in the **inet.3** routing table for the specified address.

Action

To verify the LSP route, enter the following command from the ingress router:

```
user@host>              show route destination
```

Sample Output 1

command-name

```
user@R1> show route 10.0.0.6
inet.0 : 27 destinations, 27 routes (27 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
10.0.0.6/32        *[IS-IS/18] 6d 01:41:37, metric 20
                      to 10.1.12.2 via so-0/0/0.0
                    > to 10.1.15.2 via so-0/0/1.0
                      to 10.1.13.2 via so-0/0/2.0

user@R6> show route 10.0.0.1

inet.0 : 28 destinations, 28 routes (28 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
10.0.0.1/32        *[IS-IS/18] 5d 01:01:38, metric 20
                      to 10.1.56.1 via so-0/0/0.0
                    > to 10.1.26.1 via so-0/0/2.0
                      to 10.1.36.1 via so-0/0/3.0
```

Sample Output 2

command-name

```
user@R1> show route 10.0.0.6
inet.0: 28 destinations, 28 routes (27 active, 0 holddown, 1 hidden)
+ = Active Route, - = Last Active, * = Both

10.0.0.6/32        *[IS-IS/18] 6d 02:13:42, metric 20
                      to 10.1.12.2 via so-0/0/0.0
                    > to 10.1.15.2 via so-0/0/1.0
                      to 10.1.13.2 via so-0/0/2.0

inet.3 : 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.0.0.6/32        *[RSVP/7] 00:08:07, metric 20

inet.3 : 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.0.0.1/32        *[RSVP/7] 00:10:39, metric 20
                    >  via so-0/0/3.0, label-switched-path R6-to-R1
```

Meaning

Sample Output 1 shows entries in the **inet.0** routing table only. The **inet.3** routing table is missing from the output because the LSP is not working. The **inet.0** routing table is used by interior gateway protocols (IGPs) and Border Gateway Protocol (BGP) to store routing information. In this case, the IGP is Intermediate System-to-Intermediate System (IS-IS). For more information on the **inet.0** routing table, see the *Junos MPLS Applications Configuration Guide*.

If the LSP was working, we would expect to see entries that include the LSP in the **inet.3** routing table. The **inet.3** routing table is used on ingress routers to route BGP packets to the destination egress router. BGP uses the **inet.3** routing table on the ingress router to help resolve next-hop addresses. BGP is configured in the example network shown in "MPLS Network Broken at the MPLS Layer" on page 2189.

Sample Output 2 shows output you should receive when the LSP is up. The output shows both the **inet.0** and **inet.3** routing tables, indicating that LSPs **R1-to-R6** and **R6-to-R1** are available.

Verify MPLS Labels with the traceroute Command

IN THIS SECTION

- Purpose | 2212
- Action | 2212
- Meaning | 2213

Purpose

Display the route packets take to a BGP destination where the BGP next hop for that route is the LSP egress address. By default, BGP uses the **inet.0** and the **inet.3** routing tables to resolve the next-hop address. When the next-hop address of the BGP route is not the router ID of the egress router, traffic is mapped to IGP routes, not to the LSP. Use the `traceroute` command as a debugging tool to determine whether the LSP is being used to forward traffic.

Action

To verify MPLS labels, enter the following command from the ingress router:

```
user@host> traceroute hostname
```

Sample Output 1

command-name

```
user@R1> traceroute 100.100.6.1
traceroute to 100.100.6.1 (100.100.6.1), 30 hops max, 40 byte packets
 1  10.1.12.2 (10.1.12.2)  0.627 ms  0.561 ms  0.520 ms
 2  10.1.26.2 (10.1.26.2)  0.570 ms !N  0.558 ms !N  4.879 ms !N

user@R6> traceroute 100.100.1.1
traceroute to 100.100.1.1 (100.100.1.1), 30 hops max, 40 byte packets
 1  10.1.26.1 (10.1.26.1)  0.630 ms  0.545 ms  0.488 ms
 2  10.1.12.1 (10.1.12.1)  0.551 ms !N  0.557 ms !N  0.526 ms !N
```

Sample Output 2

command-name

```
user@R1> traceroute 100.100.6.1
 to 100.100.6.1 (100.100.6.1), 30 hops max, 40 byte packets
 1  10.1.13.2 (10.1.13.2)  0.866 ms  0.746 ms  0.724 ms
      MPLS Label=100912 CoS=0 TTL=1 S=1
 2  10.1.36.2 (10.1.36.2)  0.577 ms !N  0.597 ms !N  0.546 ms !N
```

```
user@R6> traceroute 100.100.1.1
traceroute to 100.100.1.1 (100.100.1.1), 30 hops max, 40 byte packets
 1  10.1.36.1 (10.1.36.1)  0.802 ms  0.716 ms  0.688 ms
      MPLS Label=100896 CoS=0 TTL=1 S=1
 2  10.1.13.1 (10.1.13.1)  0.570 ms !N  0.568 ms !N  0.546 ms !N
```

Meaning

Sample Output 1 shows that BGP traffic is not using the LSP, consequently MPLS labels do not appear in the output. Instead of using the LSP, BGP traffic is using the IGP (IS-IS, in the example network in "MPLS Network Broken at the MPLS Layer" on page 2189) to reach the BGP next-hop LSP egress address. The Junos OS default behavior uses LSPs for BGP traffic when the BGP next hop equals the LSP egress address.

Sample Output 2 is an example of output for a correctly configured LSP. The output shows MPLS labels, indicating that BGP traffic is using the LSP to reach the BGP next hop.

Verify MPLS Labels with the ping Command

IN THIS SECTION

- Purpose | **2213**
- Action | **2213**
- Meaning | **2215**

Purpose

When you ping a specific LSP, you check that echo requests are sent over the LSP as MPLS packets.

Action

To verify MPLS labels, enter the following command from the ingress router to ping the egress router:

```
user@host> ping mpls rsvp lsp-name detail
```

For example:

```
user@R1> ping mpls rsvp R1-to-R6 detail
```

Sample Output 1

command-name

```
user@R1> ping mpls rsvp R1-to-R6 detail
LSP R1-to-R6 - LSP has no active path, exiting.

user@R6> ping mpls rsvp R6-to-R1 detail
LSP R6-to-R1 - LSP has no active path, exiting.
```

Sample Output 2

command-name

```
user@R1> traceroute 10.0.0.6
traceroute to 10.0.0.6 (10.0.0.6), 30 hops max, 40 byte packets
 1  10.1.15.2 (10.1.15.2)  0.708 ms  0.613 ms  0.576 ms
 2  10.0.0.6 (10.0.0.6)  0.763 ms  0.708 ms  0.700 ms

user@R1> ping mpls rsvp R1-to-R6 detail
Request for seq 1, to interface 69, label 100880
Reply for seq 1, return code: Egress-ok
Request for seq 2, to interface 69, label 100880
Reply for seq 2, return code: Egress-ok
Request for seq 3, to interface 69, label 100880
Reply for seq 3, return code: Egress-ok
Request for seq 4, to interface 69, label 100880
Reply for seq 4, return code: Egress-ok
Request for seq 5, to interface 69, label 100880
Reply for seq 5, return code: Egress-ok

--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
```

```
user@R6> ping mpls rsvp R6-to-R1 detail
Request for seq 1, to interface 70, label 100864
Reply for seq 1, return code: Egress-ok
Request for seq 2, to interface 70, label 100864
Reply for seq 2, return code: Egress-ok
Request for seq 3, to interface 70, label 100864
Reply for seq 3, return code: Egress-ok
Request for seq 4, to interface 70, label 100864
Reply for seq 4, return code: Egress-ok
Request for seq 5, to interface 70, label 100864
Reply for seq 5, return code: Egress-ok

--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
```

Meaning

Sample Output 1 shows that the LSP does not have an active path to forward echo requests, indicating that the LSP is down.

Sample Output 2 is an example of output you should receive when the LSP is up and forwarding packets.

Take Appropriate Action

IN THIS SECTION

- Problem | 2215
- Solution | 2216

Problem

Description

Depending on the error you encountered in your investigation, you must take the appropriate action to correct the problem. In this example, an interface is incorrectly configured at the [**edit protocols mpls**] hierarchy level on egress router **R6.**

Solution

To correct the error in this example, follow these steps:

1. Activate the interface in the MPLS protocol configuration on egress router **R6**:

```
user@R6> edit
user@R6# edit protocols mpls
[edit protocols mpls]
user@R6# show
user@R6# activate interface so-0/0/3.0
```

2. Verify and commit the configuration:

```
[edit protocols mpls]
user@R6# show
user@R6# commit
```

Sample Output

```
user@R6> edit
Entering configuration mode

[edit]
user@R6# edit protocols mpls

[edit protocols mpls]
user@R6# show
label-switched-path R6-to-R1 {
    to 10.0.0.1;
}
inactive: interface so-0/0/0.0;
inactive: interface so-0/0/1.0;
inactive: interface so-0/0/2.0;
inactive: interface so-0/0/3.0; <<< Incorrectly configured interface

[edit protocols mpls]
user@R6#  activate interface so-0/0/3

[edit protocols mpls]
```

```
user@R6# show
label-switched-path R6-to-R1 {
    to 10.0.0.1;
}
inactive: interface so-0/0/0.0;
inactive: interface so-0/0/1.0;
inactive: interface so-0/0/2.0;
interface so-0/0/3.0; <<< Correctly configured interface

[edit protocols mpls]
user@R6# commit
commit complete
```

Meaning

The sample output shows that the incorrectly configured interface **so-0/0/3.0** on egress router **R6** is now activated at the [**edit protocols mpls**] hierarchy level. The LSP can now come up.

Verify the LSP Again

IN THIS SECTION

- Purpose | **2217**
- Action | **2217**
- Meaning | **2221**

Purpose

After taking the appropriate action to correct the error, the LSP needs to be checked again to confirm that the problem in the BGP layer has been resolved.

Action

To verify the LSP again, enter the following command from the ingress, transit, and egress routers:

```
user@host>              show mpls lsp extensive
```

Sample Output

command-name

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

```

Meaning

Sample Output 1 from ingress router **R1** shows that LSP **R1-to-R6** has an active route to **R6** and the state is up.

Sample Output 2 from transit router **R3** shows that there are two transit LSP sessions, one from **R1** to **R6** and the other from **R6** to **R1**. Both LSPs are up.

Sample Output 3 from egress router **R6** shows that the LSP is up and the active route is the primary route. The LSP is now traversing the network along the expected path, from **R1** through **R3** to **R6**, and the reverse LSP, from **R6** through **R3** to **R1**.

Verify That Node-Link Protection Is Up

IN THIS SECTION

- Purpose | **2221**
- Action | **2221**
- Meaning | **2222**

Purpose

After you configure node-link protection, you must check that bypass paths are up. You can also check the number of LSPs protected by the bypass paths. In the network shown in "Node-Link Protection" on page 351, two bypass paths should be up: one next-hop bypass path protecting the link between **R1** and **R2** (or next-hop **10.0.12.14**), and a next-next-hop bypass path avoiding **R2**.

Action

To verify node-link protection (many-to-one backup), enter the following Junos OS CLI operational mode commands on the ingress router. You can also issue the commands on transit routers and other routers used in the bypass path for slightly different information.

```
show mpls lsp
show mpls lsp extensive
```

```
show rsvp interface
show rsvp interface extensive
show rsvp session detail
```

Sample Output

command-name

```
user@R1> show mpls lsp
Ingress LSP: 1 sessions
To              From            State Rt ActivePath       P     LSPname

192.168.6.1     192.168.0.1      Up        0  1 FF  100448        3  r0-to-t6
Total 2 displayed, Up 2, Down 0
```

Meaning

Sample output from **R1** for the `show mpls lsp` command shows a brief description of the state of configured and active LSPs for which **R1** is the ingress, transit, and egress router. All LSPs are up. **R1** is the ingress router for **lsp2-r1-to-r5**, and the egress router for return LSP **r5-to-r1**. Two LSPs transit **R1**, **lsp1-r6-to-r0** and the return LSP **r0-to-t6**. For more detailed information about the LSP, include the **extensive** option when you issue the `show mpls lsp` command.

Sample Output

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

Meaning

Sample output from **R1** for the `show mpls lsp extensive` command shows detailed information about all LSPs for which **R1** is the ingress, egress, or transit router, including all past state history and the reason why an LSP failed. All LSPs are up. The main two LSPs **lsp2-r1-to-r5** and **lsp1-r6-to-r0** have node-link protection as indicated by the **Node/Link protection desired** field in the ingress and transit sections of the output. In the ingress section of the output, the **Link-protection Up** field shows that **lsp2-r1-to-r5** has link protection up. In the transit section of the output, the **Type: Node/Link protected LSP** field shows that **lsp1-r6-to-r0** has node-link protection up, and in case of failure will use the bypass **LSP Bypass->10.0.12.14->10.0.24.2.**

Sample Output

```
user@R1> show rsvp interface
RSVP interface: 4 active
                  Active Subscr- Static      Available   Reserved    Highwater
Interface   State resv   iption  BW          BW          BW          mark

```

Meaning

Sample output from **R1** for the `show rsvp interface` command shows four interfaces enabled with RSVP (**Up**). Interface **fe-0/1/0.0** has two active RSVP reservations (**Active resv**) that might indicate sessions for the two main LSPs, **lsp1-r6-to-r0** and **lsp2-r1-to-r5.** Interface **fe-0/1/0.0** is the connecting interface between R1 and R2, and both LSPs are configured with a strict path through **fe-0/1/0.0**. For more detailed information about what is happening on interface **fe-0/1/0.0**, issue the `show rsvp interface extensive` command.

Sample Output

```
user@R1> show rsvp interface extensive

```

Meaning

Sample output from **R1** for the `show rsvp interface extensive` command shows more detailed information about the activity on all RSVP interfaces (**3**). However, only output for **fe-0/1/0.0** is shown. Protection is enabled (**Protection: On**), with two bypass paths (**Bypass: 2**) protecting two LSPs (**Protected LSP: 2**). All LSPs are protected, as indicated by the **Unprotected LSP: 0** field. The first bypass **Bypass->10.0.12.14**is a link protection bypass path (**Type: LP**), protecting the link between **R1** and **R2 fe-0/1/0.0.** The second bypass path **10.0.12.14->10.0.24.2** is a node-link protected LSP, avoiding **R2** in case of node failure.

Sample Output

Meaning

Sample output from **R1** shows detailed information about the RSVP sessions active on **R1**. All sessions are up, with two ingress sessions, one egress session, and two transit sessions.

Within the ingress section, the first session is a bypass path, as indicated by the **Type: Bypass LSP** field; and the second session is a protected LSP (**lsp2-r1-to-r5)** originating on **R1**, as indicated by the **Type: Node/Link protected LSP** field.

Conclusion

Multiprotocol Label Switching (MPLS) label-switched path (LSP) link protection and node-link protection are facility-based methods used to reduce the amount of time needed to reroute LSP traffic. These protection methods are often compared to fast reroute—the other Junos OS LSP protection method.

While fast reroute protects LSPs on a one-to-one basis, link protection and node-link protection protect multiple LSPs by using a single, logical bypass LSP. Link protection provides robust backup support for a link, node-link protection bypasses a node or a link, and both types of protection are designed to interoperate with other vendor equipment. Such functionality makes link protection and node-link protection excellent choices for scalability, redundancy, and performance in MPLS-enabled networks.

Related Information

For additional information about MPLS fast reroute and MPLS protection methods, see the following:

Verify That Link Protection Is Up

IN THIS SECTION

- Purpose | **2229**
- Action | **2230**
- Meaning | **2231**

Purpose

When you verify link protection, you must check that the bypass LSP is up. You can also check the number of LSPs protected by the bypass. In the network shown in Many-to-One or Link Protection, a bypass path should be up to protect the link between **R1** and **R2**, or next-hop **10.0.12.14**, and the two LSPs traversing the link, **lsp2-r1-to-r5** and **lsp1-r6-to-r0**.

Action

To verify link protection (many-to-one backup), enter the following Junos OS CLI operational mode commands on the ingress router:

```
user@host> show mpls lsp extensive
user@host> show rsvp session detail
user@host> show rsvp interface
```

Sample Output

command-name

```
user@R1> show mpls lsp extensive | no-more
Ingress LSP: 1 sessions

Meaning

The sample output from ingress router **R1** shows that **lsp2-r1-to-r5** and **lsp1-r6-to-r0** have link protection up, and both LSPs are using the bypass path, **10.0.12.14**. However, the `show mpls lsp` command does not list the bypass path. For information about the bypass path, use the `show rsvp session` command.

```

Meaning

The sample output from ingress router **R1** shows the ingress, egress, and transit LSPs for **R1**. Some information is similar to that found in the `show mpls lsp` command. However, because link protection is an RSVP feature, information about bypass paths is provided. The bypass path appears as a separate RSVP ingress session for the protected interface, as indicated by the **Type** field.

The bypass path name is automatically generated. By default, the name appears as **Bypass > *interface-address***, where the interface address is the next downstream router's interface (**10.0.12.14**). The explicit route **10.0.17.14 10.0.27.1** for the session shows **R7** as the transit node and **R2** as the egress node.

Within the ingress RSVP section of the output, the LSP originating at **R1** (**lsp2-r1-to-r5)** is shown requesting link protection. Since a bypass path is in place to protect the downstream link, **lsp2-r1-to-r5** is associated with the bypass, as indicated by the **Link protected LSP** field.

The egress section of the output shows the return LSP **r5-to-r1**, which is not protected.

The transit section of the output shows link protection requested by **lsp1-r6-to-r0.** Since a bypass path is in place to protect the downstream link, **lsp1-r6-to-r0** is associated with the bypass, as indicated by the **Link protected LSP** field. Also included in the transit section of the output is the return LSP **r0-to-r6**, which is not protected.

Sample Output

```
user@R1> show rsvp interface
RSVP interface: 4 active
                  Active Subscr- Static      Available   Reserved    Highwater
Interface   State resv   iption  BW          BW          BW          mark
fe-0/1/0.0  Up          2    100%  100Mbps     100Mbps     0bps        35Mbps
fe-0/1/1.0  Up          1    100%  100Mbps     100Mbps     0bps        0bps
fe-0/1/2.0  Up          0    100%  100Mbps     100Mbps     0bps        0bps
so-0/0/3.0  Up          1    100%  155.52Mbps  155.52Mbps  0bps        0bps
```

Meaning

The sample output from ingress router **R1** shows the number of LSPs going through the interfaces configured on **R1**. The **Active resv** field shows the number of LSPs for each interface. For example, interface **fe-0/1/0.0** between **R1** and **R2** has two active reservations, **lsp1-r6-to-r0** and **lsp2-r1-to-r5**; interface **fe-0/1/1.0** between **R1** and **R7** has one, the bypass (**10.0.12.14**); interface **fe-0/1/2.0** between **R6** and **R1** has no LSP reservations; and interface **so-0/0/3.0** between **R6** and **R1** has one LSP reservation, **lsp1-r6-to-r0**.

Verify One-to-One Backup

IN THIS SECTION

- Purpose | 2235
- Action | 2235
- Meaning | 2236

Purpose

You can verify that one-to-one backup is established by examining the ingress router and the other routers in the network.

Action

To verify one-to-one backup, enter the following Junos OS CLI operational mode commands:

```
user@host> show mpls lsp ingress extensive
user@host> show rsvp session
```

Sample Output

command-name

The following sample output is from the ingress router **R1** :

```
user@R1> show mpls lsp ingress extensive
Ingress LSP: 1 sessions

192.168.5.1
  From: 192.168.1.1, State: Up, ActiveRoute: 0, LSPname: r1-to-r5
  ActivePath: via-r2 (primary)
   FastReroute desired
  LoadBalance: Random
  Encoding type: Packet, Switching type: Packet, GPID: IPv4
 *Primary   via-r2          State: Up
    SmartOptimizeTimer: 180
```

```

  Created: Thu May 11 14:50:52 2006
Total 1 displayed, Up 1, Down 0
```

Meaning

The sample output from **R1** shows that the **FastReroute desired** object was included in the Path messages for the LSP, allowing **R1** to select the active path for the LSP and establish a detour path to avoid **R2**.

In line 8, **Fast-reroute Detour Up** shows that the detour is operational. Lines 6 and 7 indicate that transit routers **R2** and **R4** have established their detour paths.

R2, **10.0.12.14**, includes **(flag=9)**, indicating that node protection is available for the downstream node and link. **R4**, **10.0.24.2**, includes **(flag=1)**, indicating that link protection is available for the next downstream link. In this case, **R4** can protect only the downstream link because the node is the egress router **R5**, which cannot be protected. For more information about flags, see the *Junos User Guide*.

The output for the `show mpls lsp extensive` command does not show the actual path of the detour. To see the actual links used by the detour paths, you must use the `show rsvp session ingress detail` command.

Sample Output

The following sample output is from the ingress router **R1** in the network shown in One-to-One Backup Detours.

```
user@R1> show rsvp session ingress detail
Ingress RSVP: 1 sessions

192.168.5.1
  From: 192.168.1.1,  LSPstate: Up,  ActiveRoute: 0

```

Meaning

The sample output from **R1** shows the RSVP session of the main LSP. The detour path is established, **Detour is Up**. The physical path of the detour is displayed in **Detour Explct route**. The detour path uses **R7** and **R9** as transit routers to reach **R5**, the egress router.

Sample Output

The following sample output is from the first transit router R2 in the network shown in One-to-One Backup Detours:

```
user@R2> show rsvp session transit detail
Transit RSVP: 1 sessions

192.168.5.1
```

```

    Detour Label out: 100736
Total 1 displayed, Up 1, Down 0
```

Meaning

The sample output from **R2** shows the detour is established (**Detour is Up**) and avoids **R4**, and the link connecting **R4** and **R5** (**10.0.45.2**). The detour path is through **R7** (**10.0.27.2**) and **R9** (**10.0.79.2**) to **R5** (**10.0.59.1**), which is different from the explicit route for the detour from **R1**. **R1** has the detour passing through the **10.0.17.14** link on **R7**, while **R1** is using the **10.0.27.2** link. Both detours merge at **R9** through the **10.0.79.2** link to **R5** (**10.0.59.1**).

Sample Output

The following sample output is from the second transit router R4 in the network shown in One-to-One Backup Detours:

```
user@R4> show rsvp session transit detail
Transit RSVP: 1 sessions
```

```
192.168.5.1

    Detour Label out: 100352
Total 1 displayed, Up 1, Down 0
```

Meaning

The sample output from **R4** shows the detour is established (**Detour is Up**) and avoids the link connecting **R4** and **R5** (**10.0.45.2**). The detour path is through R9 (**10.0.49.2**) to **R5** (**10.0.59.1**). Some of the information is similar to that found in the output for **R1** and **R2**. However, the explicit route for the detour is different, going through the link connecting **R4** and **R9** (**so-0/0/3** or **10.0.49.2.**

Sample Output

The following sample output is from **R7**, which is used in the detour path in the network shown in One-to-One Backup Detours:

```
user@R7> show rsvp session transit detail
Transit RSVP: 1 sessions, 1 detours

192.168.5.1

     Label in: 100752, Label out: 100368
Total 1 displayed, Up 1, Down 0
```

Meaning

The sample output from **R7** shows the same information as for a regular transit router used in the primary path of the LSP: the ingress address (**192.168.1.1**), the egress address (**192.168.5.1**), and the name of the LSP (**r1-to-r5**). Two detour paths are displayed; the first to avoid **R4** (**192.168.4.1**) and the second to avoid **R2** (**192.168.2.1**). Because **R7** is used as a transit router by **R2** and **R4**, **R7** can merge the detour paths together as indicated by the identical **Label out** value (**100368**) for both detour paths. Whether **R7** receives traffic from **R4** with a label value of **100736** or from **R2** with a label value of **100752**, **R7** forwards the packet to **R5** with a label value of **100368**.

Sample Output

The following sample output is from R9, which is a router used in the detour path in the network shown in One-to-One Backup Detours:

```
user@R9> show rsvp session transit detail
Transit RSVP: 1 sessions, 1 detours

192.168.5.1

      Explct route: 10.0.59.1
     Record route: 10.0.12.13 10.0.27.1 10.0.79.1 <self> 10.0.59.1
      Label in: 100368,  Label out: 3
Total 1 displayed, Up 1, Down 0
```

Meaning

The sample output from **R9** shows that **R9** is the penultimate router for the detour path, the explicit route includes only the egress link address (**10.0.59.1**), and the **Label out** value (**3**) indicates that **R9** has performed penultimate-hop label popping. Also, the detour branch from **10.0.27.1** does not include path information because **R7** has merged the detour paths from **R2** and **R4**. Notice that the **Label out** value in the detour branch from **10.0.17.13** is **100368**, the same value as the **Label out** value on **R7**.

Sample Output

The following sample output is from the egress router R5 in the network shown in One-to-One Backup Detours:

```
user@R5> show rsvp session egress detail
Egress RSVP: 1 sessions, 1 detours

192.168.5.1

```

Meaning

The sample output from **R5** shows the main LSP in the **Record route** field and the detours through the network.

Verify That the Primary Path Is Operational

IN THIS SECTION

- Purpose | **2244**
- Action | **2244**
- Meaning | **2245**

Purpose

Primary paths must always be used in the network if they are available, therefore an LSP always moves back to the primary path after a failure, unless the configuration is adjusted. For more information on adjusting the configuration to prevent a failed primary path from reestablishing, see "Preventing Use of a Path That Previously Failed" on page 357.

Action

To verify that the primary path is operational, enter the following Junos OS command-line interface (CLI) operational mode commands:

```
user@host> show mpls lsp extensive ingress
user@host> show rsvp interface
```

Sample Output 1

command-name

```
user@R1> show mpls lsp extensive ingress
Ingress LSP: 1 sessions

192.168.5.1
  From: 192.168.1.1, State: Up, ActiveRoute: 0, LSPname: r1-to-r5
   ActivePath: via-r2 (primary)
  LoadBalance: Random
  Encoding type: Packet, Switching type: Packet, GPID: IPv4
 *Primary   via-r2          State: Up
     Priorities: 6 6
     Bandwidth: 35Mbps
    SmartOptimizeTimer: 180
     Computed ERO (S [L] denotes strict [loose] hops): (CSPF metric: 11)
 10.0.12.14 S 10.0.24.2 S
     Received RRO  (ProtectionFlag 1=Available 2=InUse 4=B/W 8=Node 10=SoftPreempt):
           10.0.12.14 10.0.24.2
    5 Apr 29 14:40:43 Selected as active path
    4 Apr 29 14:40:43 Record Route:  10.0.12.14 10.0.24.2
    3 Apr 29 14:40:43 Up
    2 Apr 29 14:40:43 Originate Call
    1 Apr 29 14:40:43 CSPF: computation result accepted
```

```
  Standby   via-r7           State: Dn
    SmartOptimizeTimer: 180
        No computed ERO.
  Created: Sat Apr 29 14:40:43 2006
Total 1 displayed, Up 1, Down 0
```

Sample Output 2

command-name

```
user@R1> show rsvp interface
RSVP interface: 3 active
                 Active Subscr- Static      Available   Reserved    Highwater
Interface   State resv   iption  BW          BW          BW          mark
fe-0/1/0.0  Up         2   100%   100Mbps      100Mbps     0bps        0bps
fe-0/1/1.0  Up         1   100%   100Mbps      100Mbps     0bps        0bps
so-0/0/3.0  Up         1   100%   155.52Mbps   155.52Mbps  0bps        0bps
```

Meaning

Sample output 1 shows that the LSP is operational and is using the primary path (**via-r2**) with **R2** (**10.0.12.14**) and **R4** (**10.0.24.2**) as transit routers. The priority values are the same for setup and hold, **6 6**. Priority 0 is the highest (best) priority and 7 is the lowest (worst) priority. The Junos OS default for setup and hold priority is 7:0. Unless some LSPs are more important than others, preserving the default is a good practice. Configuring a setup priority that is better than the hold priority is not allowed, resulting in a failed commit in order to avoid preemption loops.

Verify That the Secondary Path Is Established

IN THIS SECTION

- Purpose | **2246**
- Action | **2246**
- Meaning | **2248**

Purpose

When the secondary path is configured with the `standby` statement, the secondary path should be *up* but *not active*; it will become active if the primary path fails. A secondary path configured without the `standby` statement will not come up unless the primary path fails. To test that the secondary path is correctly configured and would come up if the primary path were to fail, you must deactivate a link or node critical to the primary path, then issue the `show mpls lsp` *`lsp-path-name`* `extensive` command.

Action

To verify that the secondary path is established, enter the following Junos OS CLI operational mode command:

Sample Output

```
user@R1> show mpls lsp extensive
```

Sample Output

command-name

The following sample output shows a correctly configured secondary path before and after it comes up. In the example, interface **fe-0/1/0** on **R2** is deactivated, which brings down the primary path **via-r2**. The ingress router **R1** switches traffic to the secondary path **via-r7**.

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

192.168.5.1
  From: 192.168.1.1, State: Up, ActiveRoute: 0, LSPname: r1-to-r5

Total 1 displayed, Up 1, Down 0
```

Meaning

The sample output from egress router **R1** shows a correctly configured standby secondary path in a down state because the primary path is still up. Upon deactivation of an interface (**interface fe-0/1/0** on **R2**) critical to the primary path, the primary path **via-r2** goes down and the standby secondary path **via-r7** comes up, allowing **R1** to switch traffic to the standby secondary path.

Verifying the Physical Layer

IN THIS SECTION

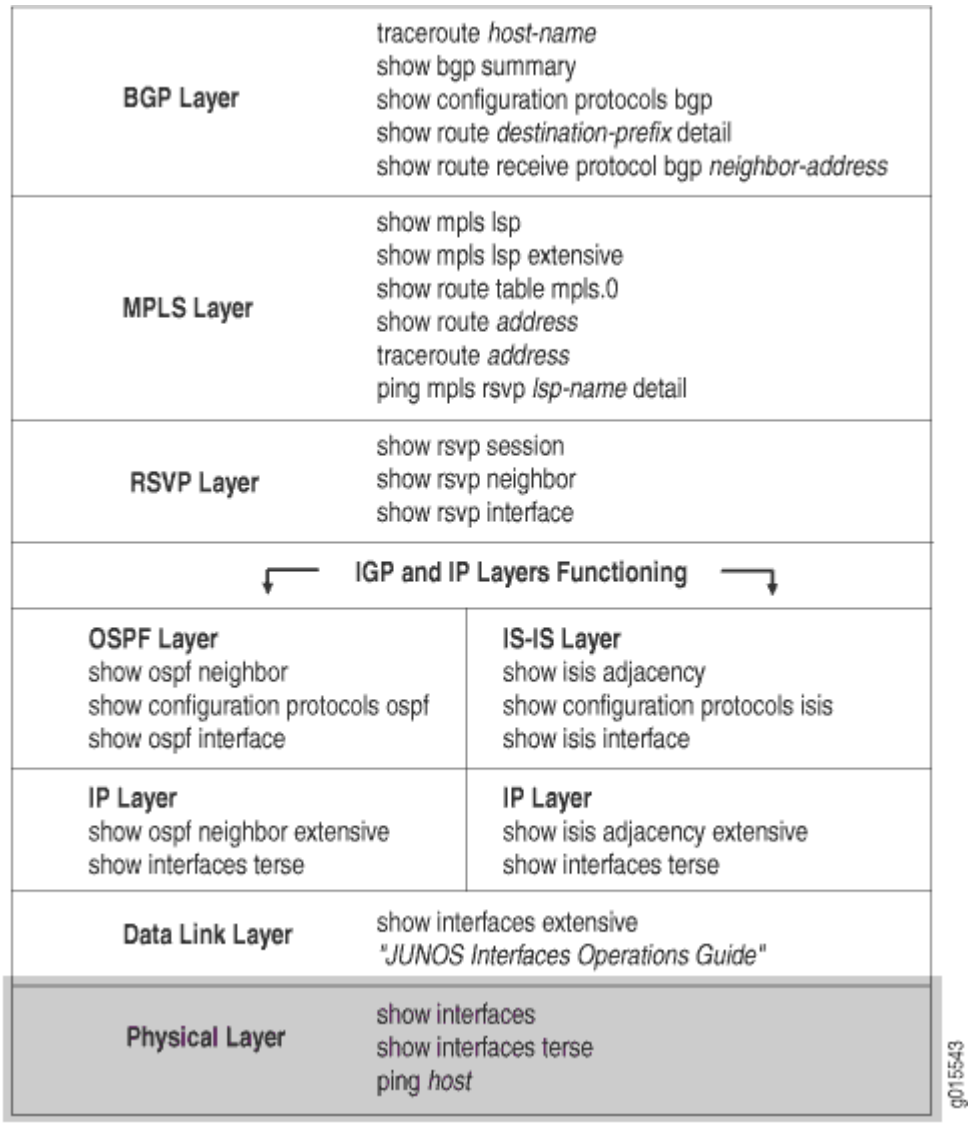
- Verify the LSP | **2251**
- Verify Router Connection | **2253**
- Verify Interfaces | **2254**
- Take Appropriate Action | **2256**
- Verify the LSP Again | **2257**

Purpose

After you have configured the LSP, issued the `show mpls lsp extensive` command, and determined that there is an error, you can start investigating the problem at the physical layer of the network.

Figure 149 on page 2249 illustrates the physical layer of the layered MPLS model.

Figure 149: Verifying the Physical Layer

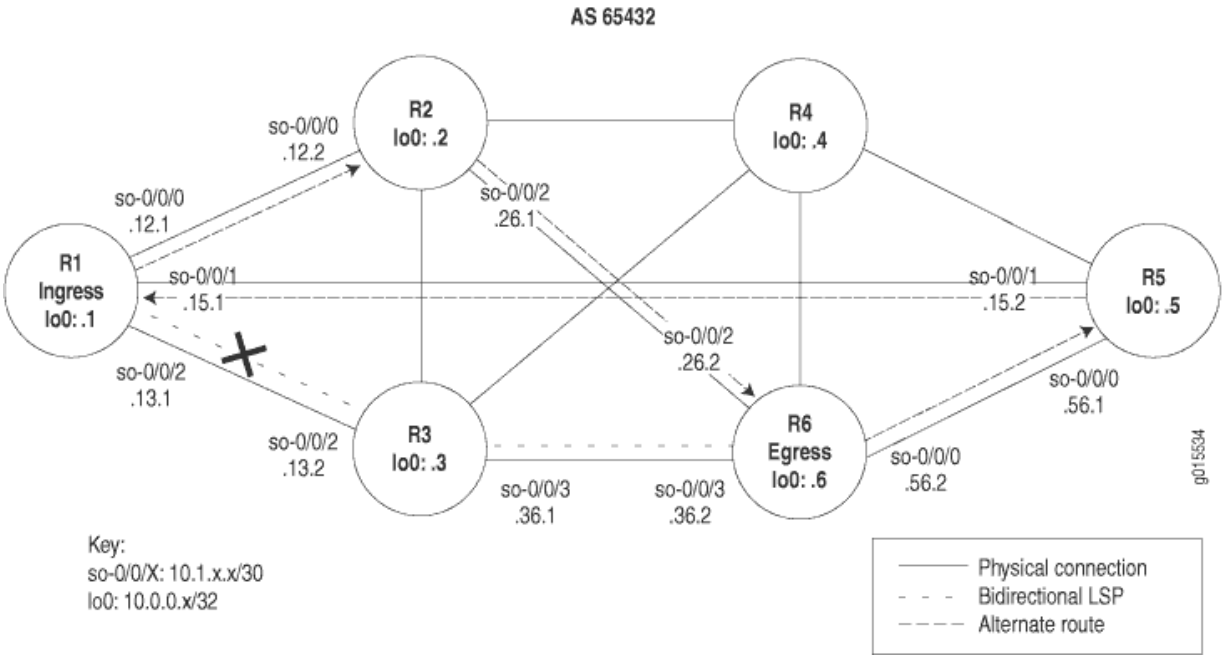


With this layer, you must ensure that the routers are connected, and that the interfaces are up and configured correctly on the ingress, egress, and transit routers.

If the network is not functioning at this layer, the label-switched path (LSP) does not work as configured.

Figure 150 on page 2250 illustrates the MPLS network and the problem described in this topic.

Figure 150: MPLS Network Broken at the Physical Layer



The network shown in Figure 150 on page 2250 is a fully meshed configuration where every directly connected interface can receive and send packets to every other similar interface. The LSP in this network is configured to run from ingress router **R1**, through transit router **R3**, to egress router **R6**. In addition, a reverse LSP is configured to run from **R6** through **R3** to **R1**, creating bidirectional traffic.

However, in this example, traffic does not use the configured LSP. Instead traffic uses the alternate route from **R1** through **R2** to **R6**, and in the reverse direction, from **R6** through **R5 to R1**.

When you become aware of a situation where an alternate route is used rather than the configured LSP, verify that the physical layer is functioning correctly. You might find that routers are not connected, or that interfaces are not up and configured correctly on the ingress, egress, or transit routers.

The cross shown in Figure 150 on page 2250 indicates where the LSP is broken because of a configuration error on ingress router **R1**.

To check the physical layer, follow these steps:

Verify the LSP

IN THIS SECTION

- Purpose | 2251
- Action | 2251
- Meaning | 2253

Purpose

Typically, you use the `show mpls lsp extensive` command to verify the LSP. However, for quick verification of the LSP state, use the `show mpls lsp` command. If the LSP is down, use the **extensive** option (`show mpls lsp extensive`) as a follow-up. If your network has numerous LSPs, you might consider specifying the name of the LSP, using the **name** option (`show mpls lsp name` ***name*** or `show mpls lsp name` ***name*** **extensive).**

Action

To determine whether the LSP is up, enter the following command from the ingress router:

```
user@ingress-router> show mpls lsp extensive
```

Sample Output

command-name

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

10.0.0.6
  From: 10.0.0.1, State: Up, ActiveRoute: 1, LSPname: R1-to-R6

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Meaning

The sample output from ingress router **R1** shows that the LSP is using an alternate path rather than the configured path. The configured path for the LSP is **R1** through **R3** to **R6,** and for the reverse LSP, **R6** through **R3** to **R1**. The alternate path used by the LSP is **R1** through **R2** to **R6,** and for the reverse LSP, **R6 t**hrough **R5** to **R1**.

Verify Router Connection

IN THIS SECTION

- Purpose | **2253**
- Action | **2253**
- Meaning | **2254**

Purpose

Confirm that the appropriate ingress, transit, and egress routers are functioning by examining whether the packets have been received and transmitted with 0% packet loss.

Action

To determine that the routers are connected, enter the following command from the ingress and transit routers:

```
user@host>              ping host
```

Sample Output

command-name

```
user@R1> ping 10.0.0.3 count 3
PING 10.0.0.3 (10.0.0.3): 56 data bytes
64 bytes from 10.0.0.3: icmp_seq=0 ttl=254 time=0.859 ms
64 bytes from 10.0.0.3: icmp_seq=1 ttl=254 time=0.746 ms
64 bytes from 10.0.0.3: icmp_seq=2 ttl=254 time=0.776 ms
```

```
--- 10.0.0.3 ping statistics ---
3 packets transmitted, 3 packets received, 0% packet loss
round-trip min/avg/max/stddev = 0.746/0.794/0.859/0.048 ms

user@R3>  ping 10.0.0.6 count 3
PING 10.0.0.6 (10.0.0.6): 56 data bytes
64 bytes from 10.0.0.6: icmp_seq=0 ttl=255 time=0.968 ms
64 bytes from 10.0.0.6: icmp_seq=1 ttl=255 time=3.221 ms
64 bytes from 10.0.0.6: icmp_seq=2 ttl=255 time=0.749 ms

--- 10.0.0.6 ping statistics ---
3 packets transmitted, 3 packets received, 0% packet loss
round-trip min/avg/max/stddev = 0.749/1.646/3.221/1.117 ms
```

Meaning

The sample output shows that ingress router **R1** is receiving packets from transit router **R3**, and that the transit router is receiving packets from the egress router. Therefore, the routers in the LSP are connected.

Verify Interfaces

IN THIS SECTION

- Purpose | **2254**
- Action | **2255**
- Meaning | **2255**

Purpose

Confirm that the interfaces are configured correctly with the `family mpls` statement.

Action

To determine that the relevant interfaces are up and configured correctly, enter the following commands from the ingress, transit, and egress routers:

```
user@host> show interfaces terse
user@host> show configuration interfaces type-fpc/pic/port
```

Sample Output

command-name

```
user@R1> show interfaces so* terse
Interface               Admin Link Proto Local                 Remote
so-0/0/0                up    up
so-0/0/0.0              up    up   inet  10.1.12.1/30
                                  iso
                                  mpls
so-0/0/1                up    up
so-0/0/1.0              up    up   inet  10.1.15.1/30
                                  iso
                                  mpls
so-0/0/2                up    up
so-0/0/2.0              up    up   inet  10.1.13.1/30
                                  iso   <<< family mpls is missing
so-0/0/3                up    down

user@R1>  show configuration interfaces so-0/0/2
unit 0 {
    family inet {
        address 10.1.13.1/30;
    }
    family iso; <<<  family mpls is missing
}
```

Meaning

The sample output shows that interface **so-0/0/2.0** on the ingress router does not have the `family mpls` statement configured at the [**edit interfaces *type-fpc/pic/port***] hierarchy level, indicating that the

interface is incorrectly configured to support the LSP. The LSP is configured correctly at the [**edit protocols mpls**] hierarchy level.

The output from the transit and egress routers (not shown) shows that the interfaces on those routers are configured correctly.

Take Appropriate Action

IN THIS SECTION

- Problem | 2256
- Solution | 2256

Problem

Description

Depending on the error you encountered in your investigation, you must take the appropriate action to correct the problem. In the example below, the `family mpls` statement, which was missing, is included in the configuration of ingress router **R1**.

Solution

To correct the error in this example, enter the following commands:

```
[edit interfaces                type-fpc/pic/port]
user@R1# set family mpls
user@R1# show
user@R1# commit
```

Sample Output

```
[edit interfaces so-0/0/2 unit 0]
user@R1# set family mpls

[edit interfaces so-0/0/2 unit 0]
user@R1# show
```

```
family inet {
    address 10.1.13.1/30;
}
family iso;
family mpls;

[edit interfaces so-0/0/2 unit 0]
user@R1# commit
commit complete
```

Meaning

The sample output from ingress router **R1** shows that the `family mpls` statement is configured correctly for interface **so-0/0/2.0**, and that the LSP is now functioning as originally configured.

Verify the LSP Again

IN THIS SECTION

- Purpose | 2257
- Action | 2257
- Meaning | 2259

Purpose

After taking the appropriate action to correct the error, the LSP needs to be checked again to confirm that the problem in the physical layer has been resolved.

Action

To verify that the LSP is up and traversing the network as expected, enter the following command:

```
user@host> show mpls lsp extensive
```

Sample Output 1

command-name

```
user@R1> show mpls lsp extensive

```

Meaning

Sample Output 1 from ingress router **R1** shows that the LSP is now traversing the network along the expected path, from **R1** through **R3** to **R6**, and the reverse LSP, from **R6** through **R3** to **R1**.

Sample Output 2 from ingress router **R1** shows that the LSP is forced to take the intended path because MPLS is deactivated on **R1** interfaces **so-0/0/0.0** and **so-0/0/1.0**. If these interfaces were not deactivated, even though the configuration is now correct, the LSP would still traverse the network through the alternate path.

Checking the Data Link Layer

IN THIS SECTION

- Verify the LSP | **2262**
- Verify Interfaces | **2264**

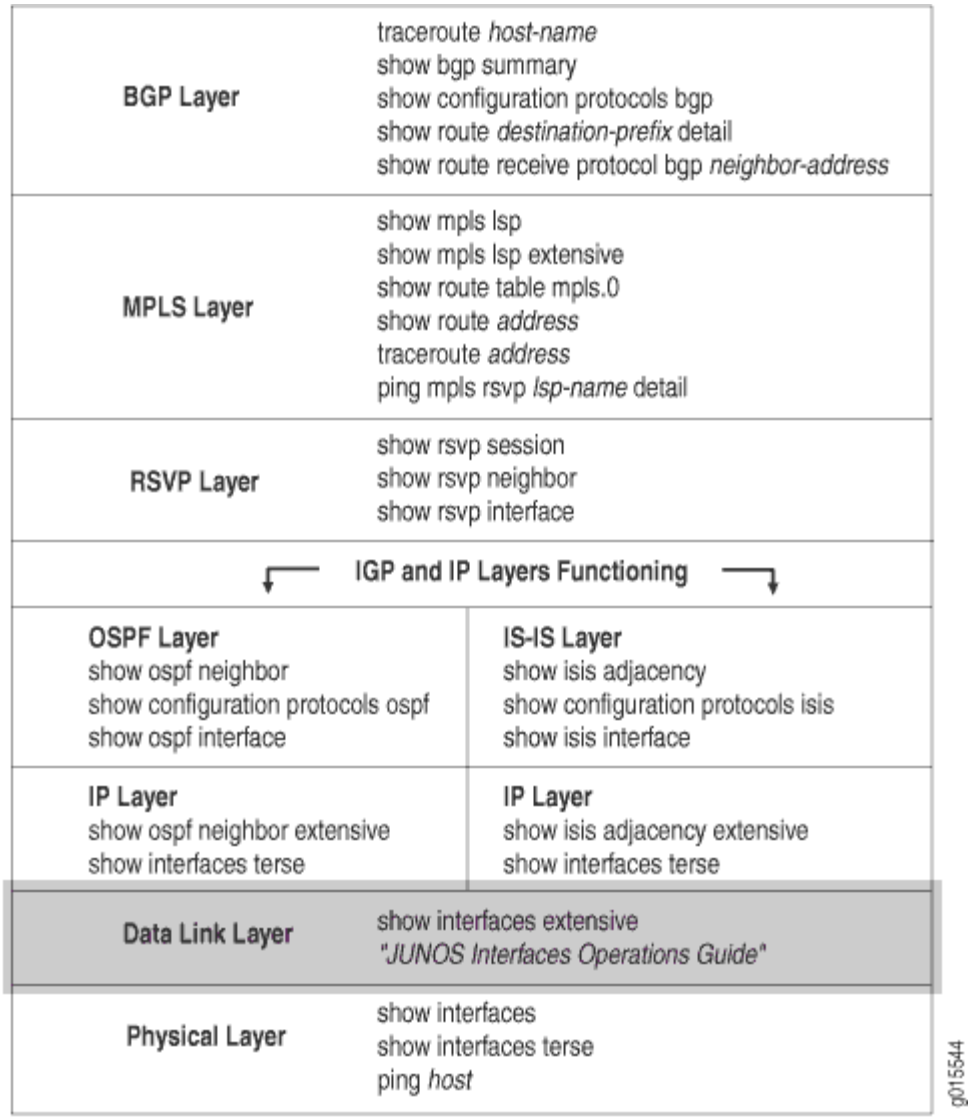
Take Appropriate Action | **2269**
Verify the LSP Again | **2271**

Purpose

After you have configured the label-switched path (LSP), issued the `show mpls lsp extensive` command, and determined that there is an error, you might find that the error is not in the physical layer. Continue investigating the problem at the data link layer of the network.

Figure 151 on page 2261 illustrates the data link layer of the layered MPLS model.

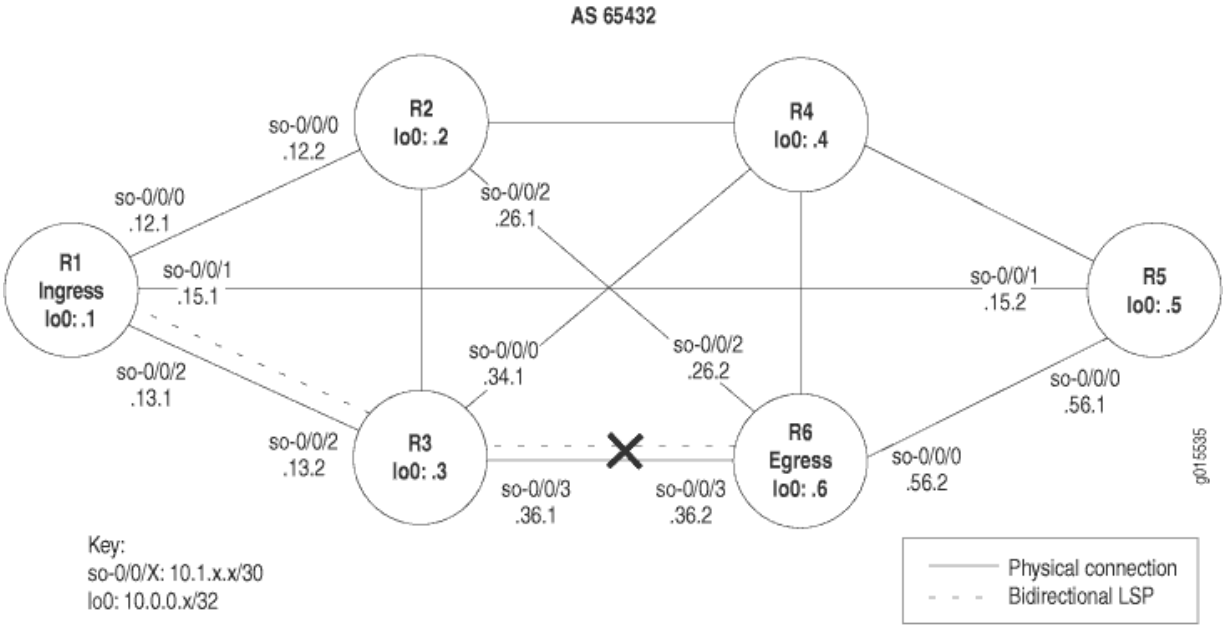
Figure 151: Checking the Data Link Layer



With this layer, you must check the encapsulation mode, for example, Point-to-Point Protocol (PPP) or Cisco High-Level Data Link Control (HDLC); PPP options, for example, header encapsulation; frame check sequence (FCS) size; and whether keepalive frames are enabled or disabled. Also, check the ingress, egress, and transit routers.

Figure 152 on page 2262 illustrates the MPLS network used in this topic.

Figure 152: MPLS Network Broken at the Data Link Layer



The network shown in Figure 152 on page 2262 is a fully meshed configuration where every directly connected interface can receive and send packets to every other similar interface. The LSP in this network is configured to run from ingress router **R1**, through transit router **R3**, to egress router **R6**. In addition, a reverse LSP is configured to run from **R6** through **R3** to **R1**, creating bidirectional traffic.

However, in this example, the LSP is down without a path in either direction, from **R1** to **R6** or from **R6** to **R1**.

When you verify that the data link layer is not functioning correctly, you might find a mismatch with PPP or Cisco HDLC encapsulation, PPP options, or keepalive frames.

The cross shown in Figure 152 on page 2262 indicates where the LSP is broken because of a configuration error on ingress router **R1** that prevents the LSP from traversing the network as expected.

To check the data link layer, follow these steps:

Verify the LSP

IN THIS SECTION

Purpose | 2263

Action | 2263
Meaning | 2264

Purpose

Typically, you use the `show mpls lsp extensive` command to verify the LSP. However for quick verification of the LSP state, use the `show mpls lsp` command. If the LSP is down, use the **extensive** option (`show mpls lsp extensive`) as a follow-up. If your network has numerous LSPs, you might consider specifying the name of the LSP, using the **name** option (`show mpls lsp name` ***name*** or `show mpls lsp name` ***name*** **extensive).**

Action

To determine whether the LSP is up, enter the following command from the ingress router:

```
user@host> show mpls lsp extensive
```

Sample Output 1

command-name

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

10.0.0.6
  From: 10.0.0.1 , State: Dn, ActiveRoute: 0,  LSPname: R1-to-R6

Total 1 displayed, Up 0, Down 1

Egress LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Meaning

The sample output from ingress router **R1** shows the LSPs within which it participates. The ingress LSP is down, without a path from **R1** to **R6.** Because a reverse LSP is configured in the network shown in "MPLS Network Broken at the Data Link Layer" on page 2189, we would expect an egress LSP session to be up. However, **R1** does not have any egress LSPs, indicating that the LSP from **R6** to **R1** is not functioning.

Verify Interfaces

IN THIS SECTION

- Purpose | **2264**
- Action | **2265**
- Meaning | **2269**

Purpose

From your network topology, determine the adjacent interfaces through which the LSP is meant to traverse, and examine the output for the encapsulation type, PPP options, FCS size, and whether keepalive frames are enabled or disabled

NOTE: Before you proceed with this step, check the physical layer to ensure that the problem is not in the physical layer.

Action

To verify the functioning of adjacent interfaces, enter the following commands from the relevant routers:

```
user@host> show interfaces type-fpc/pic/port extensive
user@host> show interfaces type-fpc/pic/port
```

Sample Output 1

command-name

```
user@R6> show interfaces so-0/0/3 extensive

    Flags: None
    Addresses, Flags: Is-Preferred Is-Primary
      Destination: 10.1.36.0/30, Local: 10.1.36.1, Broadcast: 10.1.36.3
  Protocol iso, MTU: 4470
    Flags: None
  Protocol mpls, MTU: 4458
    Flags: None
```

Meaning

Sample Output 1 from egress router **R6** shows that there are no SONET alarms or defects (**none**), the states are all **OK**, and the path trace shows the distant end (**R3 so-0.0.0**), indicating that the physical link is up. However, the logical link is down, and the link-level type is Cisco HDLC.

Sample Output 2 from transit router **R3** shows that the link-level type is PPP, indicating that the encapsulation types are mismatched, resulting in the LSP going down.

Take Appropriate Action

IN THIS SECTION

- Problem | 2269
- Solution | 2270

Problem

Description

Depending on the error you encountered in your investigation, you must take the appropriate action to correct the problem. In the example below, the encapsulation types are mismatched.

Solution

To correct the error in this example, enter the following commands:

```
[edit interfaces so-0/0/3]
user@R1# show
user@R1# delete encapsulation
user@R1# show
user@R1# commit
```

Sampel Output

```
[edit interfaces so-0/0/3]
user@R6# show
encapsulation cisco-hdlc;
unit 0 {
    family inet {
        address 10.1.36.2/30;
    }
    family iso;
    family mpls;
}

[edit interfaces so-0/0/3]
user@R6# delete encapsulation

[edit interfaces so-0/0/3]
user@R6# show
unit 0 {
    family inet {
        address 10.1.36.2/30;
    }
    family iso;
    family mpls;
}

[edit interfaces so-0/0/3]
user@R6# commit
commit complete
```

Meaning

The sample output from egress router **R6** shows that the Cisco HDLC was incorrectly configured on interface **so-0/0/3** which prevented the LSP from using the intended path. The problem was corrected when the `encapsulation` statement was deleted and the configuration committed.

Verify the LSP Again

IN THIS SECTION

- Purpose | **2271**
- Action | **2271**
- Meaning | **2276**

Purpose

After taking the appropriate action to correct the error, the LSP needs to be checked again to confirm that the problem in the data link layer has been resolved.

Action

From the ingress, egress, and transit routers, verify that the LSP is up and traversing the network as expected:

```
user@host>  show mpls lsp extensive
```

Sample Output 1

command-name

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

Meaning

Sample Outputs 1 and 2 from ingress router **R1** and egress router **R6,** respectively, show that the LSP is now traversing the network along the expected path, from **R1** through **R3** to **R6**, and the reverse LSP, from **R6** through **R3** to **R1**.

Sample Output 3 from transit router **R3** shows that there are two transit LSP sessions, one from **R1** to **R6** and the other from **R6** to **R1**.

Sample Output 4 shows the interfaces that were deactivated on the ingress, egress, and transit routers, forcing the LSP to take the intended path. If these interfaces were not deactivated, even though the configuration is now correct, the LSP would still traverse the network through the alternate path.

Verifying the IP and IGP Layers

IN THIS SECTION

- Problem | **2276**
- Solution | **2277**

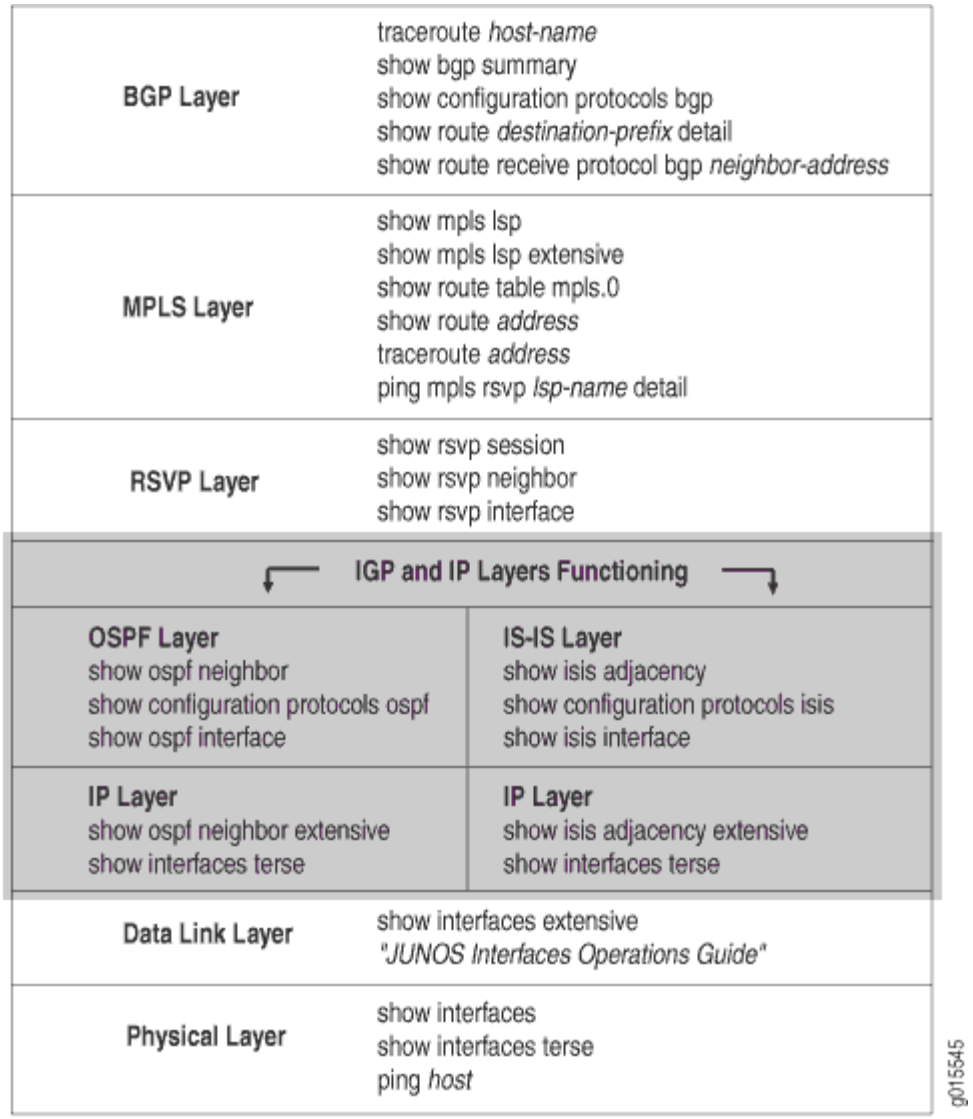
Problem

Description

After you have configured the label-switched path (LSP), issued the `show mpls lsp extensive` command, and determined that there is an error, you might find that the error is not in the physical or data link layers. Continue investigating the problem at the IP and IGP layers of the network.

Figure 153 on page 2277 illustrates the IP and IGP layers of the layered MPLS model.

Figure 153: IP and IGP Layers



Solution

At the IP and IGP layers, you must check the following:

- Interfaces have correct IP addressing, and the IGP neighbors or adjacencies are established.
- Open Shortest Path First (OSPF) or Intermediate System-to-Intermediate System (IS-IS) protocols are configured and running correctly.

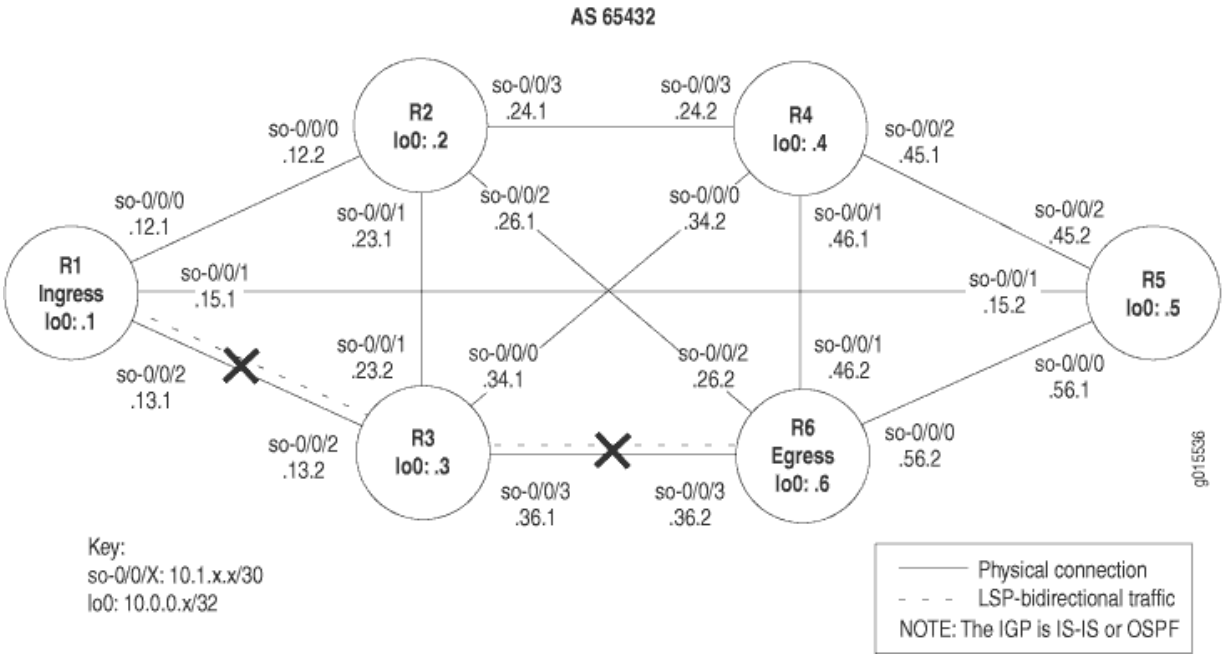
- If the OSPF protocol is configured, check the IP layer first, then the OSPF configuration, making sure that the protocol, interfaces, and traffic engineering are configured correctly.
- If the IS-IS protocol is configured, it doesn't matter whether you check IS-IS or IP first because both protocols are independent of each other. Verify that IS-IS adjacencies are up, and that the interfaces and IS-IS protocol are configured correctly.

> **NOTE**: The IS-IS protocol has traffic engineering enabled by default.

If the network is not functioning at the IP or IGP layers, the LSP does not work as configured.

Figure 154 on page 2278 illustrates the MPLS network used in this topic.

Figure 154: MPLS Network Broken at the IP and IGP Layers



The network shown in Figure 154 on page 2278 is a fully meshed configuration where every directly connected interface can receive and send packets to every other similar interface. The LSP in this network is configured to run from ingress router **R1**, through transit router **R3**, to egress router **R6**. In addition, a reverse LSP is configured to run from **R6**, through **R3**, to **R1**, creating bidirectional traffic. The crosses in Figure 154 on page 2278 indicate where the LSP is not working because of the following problems at the IP and IGP layer:

- An IP address is configured incorrectly on the ingress router (**R1**).

- The OSPF protocol is configured with a router ID (RID) but without the loopback (**lo0**) interface, and traffic engineering is missing from the transit router (**R3**).
- Levels in the IS-IS network are mismatched.

Verifying the IP Layer

IN THIS SECTION

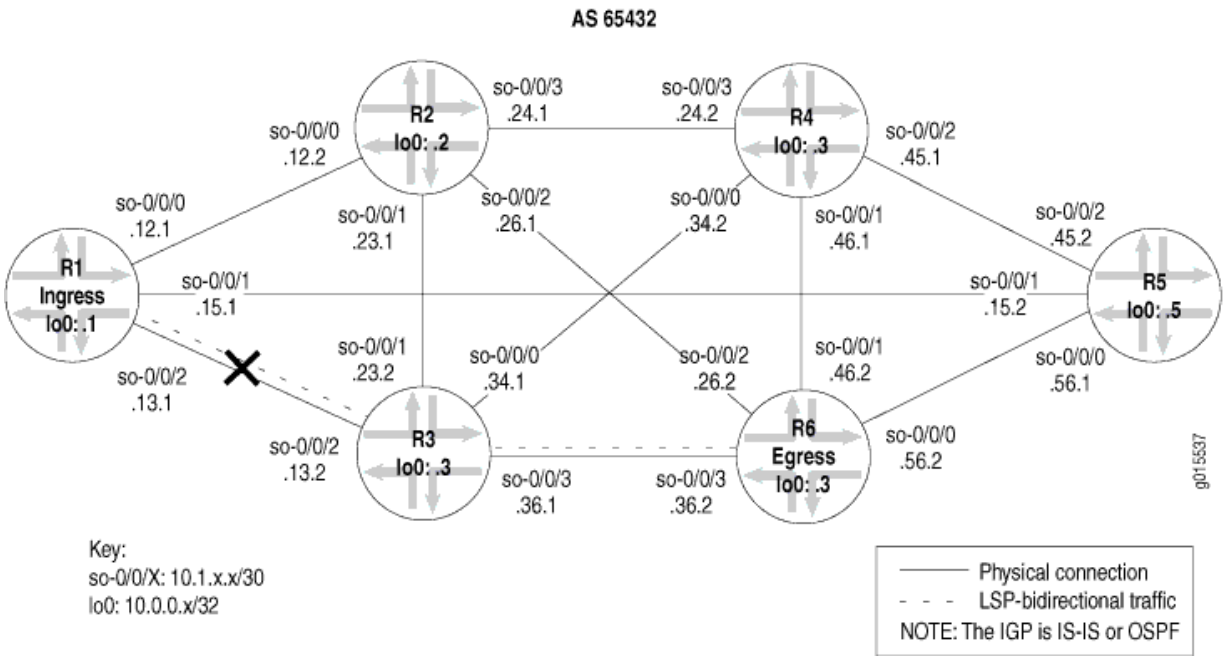
- Verify the LSP | **2280**
- Verify IP Addressing | **2282**
- Verify Neighbors or Adjacencies at the IP Layer | **2284**
- Take Appropriate Action | **2289**
- Verify the LSP Again | **2291**

Purpose

You can check the IP layer before or after you check the interior gateway protocol (IGP) layer, depending on whether you have OSPF or IS-IS configured as the IGP. If your MPLS network is configured with OSPF as the IGP, you must first verify the IP layer, checking that the interfaces have correct IP addressing and that the OSPF neighbors are established before you check the OSPF layer.

If you have IS-IS configured as the IGP in your MPLS network, you can verify either the IP layer or the IS-IS protocol layer first. The order in which you check the IP or IS-IS layer does not affect the results.

Figure 155: MPLS Network Broken at the IP Layer



The cross in Figure 155 on page 2280 indicates where the LSP is broken because of the incorrect configuration of an IP address on ingress router **R1**.

Verify the LSP

IN THIS SECTION

- Purpose | **2280**
- Action | **2281**
- Meaning | **2282**

Purpose

After configuring the LSP, you must verify that the LSP is up. LSPs can be ingress, transit, or egress. Use the `show mpls lsp` command for quick verification of the LSP state, with the **extensive** option (`show mpls lsp extensive`) as a follow-up if the LSP is down. If your network has numerous LSPs, you might consider

specifying the name of the LSP, using the **name** option (`show mpls lsp name` ***name*** or `show mpls lsp name` ***name*** **extensive)**.

Action

To verify that the LSP is up, enter the following command from the ingress router:

```
user@host> show mpls lsp extensive
```

Sample Output 1

command-name

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

   37 Oct 14 18:43:43 Up
   [...Output truncated...]
  Created: Thu Oct 14 16:04:33 2004
Total 1 displayed, Up 0,  Down 1

Egress LSP: 0 sessions
Total 0 displayed , Up 0, Down 0
```

```
Transit LSP: 0 sessions
Total 0 displayed , Up 0, Down 0
```

Meaning

The sample output from ingress router **R1** shows that an MPLS label allocation failure occurred and the Constrained Shortest Path First (CSPF) algorithm failed, resulting in no route to destination **10.0.0.6** on **R6**.

Verify IP Addressing

IN THIS SECTION

- Purpose | **2282**
- Action | **2282**
- Meaning | **2284**

Purpose

When you investigate the IP layer, you verify that interfaces have correct IP addressing, and that OSPF neighbors or IS-IS adjacencies are established. In this example, an IP address is configured incorrectly on the ingress router (**R1**).

Action

To verify IP addressing, enter the following command from the ingress, transit, and egress routers:

```
user@host> show interfaces terse
```

Sample Output

command-name

```
user@R1> show interfaces terse
Interface               Admin Link Proto Local                 Remote
so-0/0/0                up    up
```

```

```

Meaning

The sample output shows that the IP addresses for interface **so-0/0/2.0** on **R1** and interface **so-0/0/2.0** on **R3** are identical. Interface IP addresses within a network must be unique for the interface to be identified correctly.

Verify Neighbors or Adjacencies at the IP Layer

IN THIS SECTION

- Purpose | **2284**
- Action | **2285**
- Meaning | **2289**

Purpose

If the IP addressing is configured incorrectly then the OSPF neighbors or IS-IS adjacencies both need to be checked to determine if one or both of them are established.

Action

To verify neighbors (OSPF) or adjacencies (IS-IS), enter the following commands from the ingress, transit, and egress routers:

```
user@host> show ospf neighbor extensive
user@host> show isis adjacency extensive
```

Sample Output 1

command-name

```
user@R1> show ospf neighbor extensive

Meaning

Sample Output 1 from the ingress, transit, and egress routers shows that **R1** and **R3** are not established OSPF neighbors. Considering that the two interfaces **so-0/0/2.0** (**R1** and **R3**) are configured with identical IP addresses, you would expect this. The OSPF protocol routes IP packets based solely on the destination IP address contained in the IP packet header. Therefore, identical IP addresses in the autonomous system (AS) result in neighbors not establishing.

Sample Output 2 from the ingress, transit, and egress routers shows that **R1** and **R3** have established an IS-IS adjacency despite the identical IP addresses configured on interfaces **so-0/0/2.0** on **R1** and **R3**. The IS-IS protocol behaves differently from the OSPF protocol because it does not rely on IP to establish an adjacency. However, if the LSP is not up, it is still useful to check the IP subnet addressing in case there is a mistake in that layer. Correcting the addressing error might bring the LSP back up.

Take Appropriate Action

IN THIS SECTION

- Problem | **2289**
- Solution | **2290**

Problem

Description

Depending on the error you encountered in your investigation, you must take the appropriate action to correct the problem. In this example, the IP address of an interface on transit router **R2** is incorrectly configured.

Solution

To correct the error in this example, enter the following commands:

```
[edit interfaces                          so-0/0/2]
user@R1# show
user@R1#              rename unit 0 family inet address 10.1.13.2/30 to address
10.1.13.1/30
user@R1# show
user@R1# commit
```

Sample Output

```
[edit interfaces so-0/0/2]
user@R1# show
unit 0 {
    family inet {
        address 10.1.13.2/30;  <<< Incorrect IP address
    }
    family iso;
    family mpls;
}

[edit interfaces so-0/0/2]
user@R1# rename unit 0 family inet address 10.1.13.2/30 to address 10.1.13.1/30

[edit interfaces so-0/0/2]
user@R1# show
unit 0 {
    family inet {
        address 10.1.13.1/30;  <<< Correct IP address.
    }
    family iso;
    family mpls;
}

[edit interfaces so-0/0/2]
user@R1# commit
commit complete
```

Meaning

The sample output shows that interface **so-0/0/2** on ingress router **R1** is now configured with the correct IP address. This correction results in unique subnet IP addresses for all interfaces in the MPLS network in "MPLS Network Broken at the IP and IGP Layers" on page 2189, and the possibility that the LSP might come up.

Verify the LSP Again

IN THIS SECTION

- Purpose | **2291**
- Action | **2291**
- Meaning | **2295**

Purpose

After taking the appropriate action to correct the error, the LSP needs to be checked again to confirm that the problem in the OSPF protocol has been resolved.

Action

To verify the LSP again, enter the following command on the ingress, transit, and egress routers:

```
user@host> show mpls lsp extensive
```

Sample Output 1

```

Meaning

Sample Output 1 from ingress router **R1** shows that LSP **R1-to-R6** has an active route to **R6** and the state is up. The output shows that the egress LSP session **R6-to-R1** received and sent a recovery label.

Sample Output 2 from transit router **R3** shows that there are two transit LSP sessions, one from **R1** to **R6** and the other from **R6** to **R1.** Both LSPs are up.

Sample Output 3 from egress router **R6** shows that the LSP is up and the active route is the primary route. The LSP is now traversing the network along the expected path, from **R1** through **R3** to **R6**, and the reverse LSP, from **R6** through **R3** to **R1**.

Verify the LSP Again

IN THIS SECTION

- Purpose | **2295**
- Action | **2296**
- Meaning | **2299**

Purpose

After taking the appropriate action to correct the error, the LSP needs to be checked again to confirm that the problem in the IS-IS protocol has been resolved.

Action

To verify that the LSP is up and traversing the network as expected, enter the following command from the ingress, egress, and transit routers:

```
user@host>              show mpls lsp extensive
```

Sample Output

command-name

```
user@R1> show mpls lsp extensive

Total 0 displayed, Up 0, Down 0
```

Meaning

The sample output from ingress router **R1** and egress router **R6** shows that the LSP is now traversing the network along the expected path, from **R1** through **R3** to **R6**, and the reverse LSP, from **R6** through **R3** to **R1**. In addition, the sample output from transit router **R3** shows that there are two transit LSP sessions, one from **R1** to **R6**, and the other from **R6** to **R1**.

Checking the RSVP Layer

IN THIS SECTION

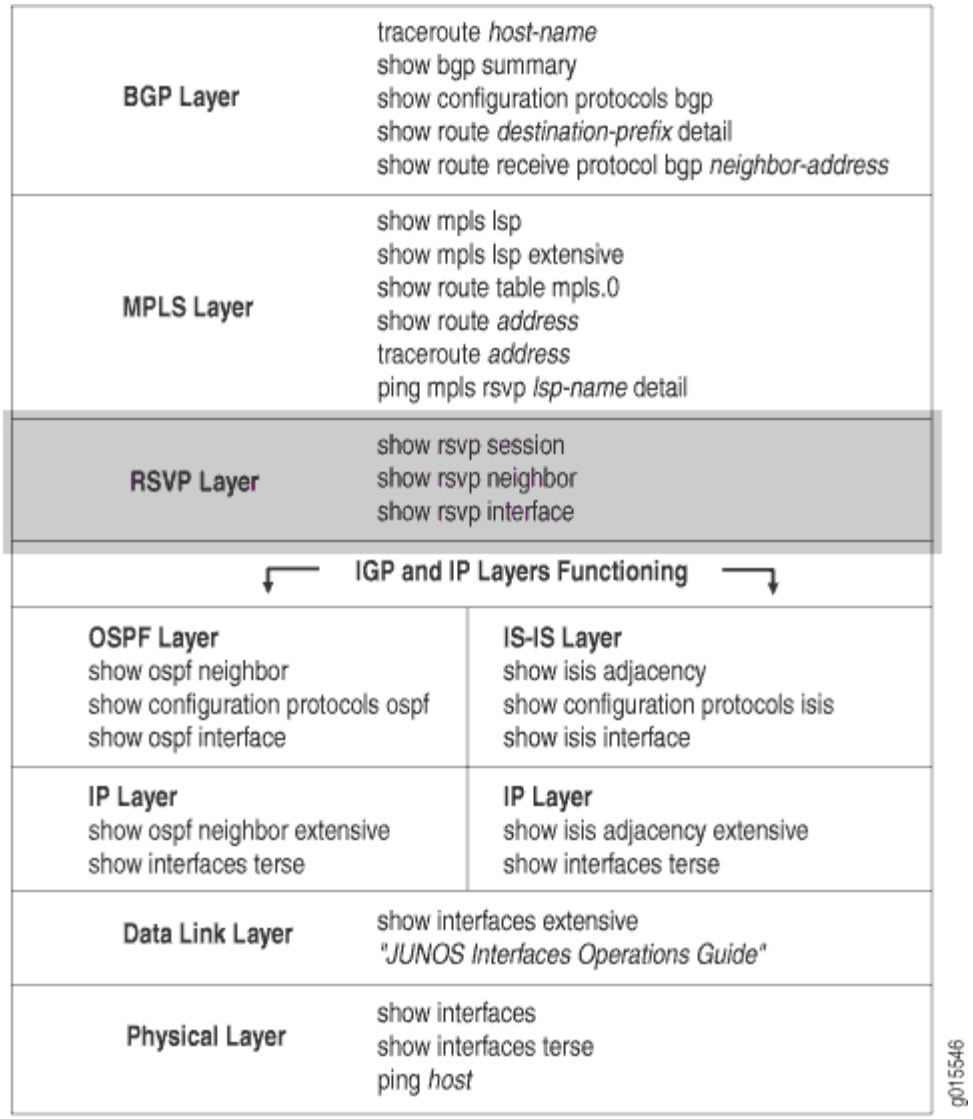
- Verify the LSP | **2302**
- Verify RSVP Sessions | **2304**
- Verify RSVP Neighbors | **2307**
- Verify RSVP Interfaces | **2309**
- Verify the RSVP Protocol Configuration | **2311**
- Take Appropriate Action | **2312**
- Verify the LSP Again | **2314**

Purpose

After you have configured the label-switched path (LSP), issued the `show mpls lsp extensive` command, and determined that there is an error, you might find that the error is not in the physical, data link, or Internet Protocol (IP) and interior gateway protocol (IGP) layers. Continue investigating the problem at the RSVP layer of the network.

Figure 156 on page 2300 illustrates the RSVP layer of the layered MPLS model.

Figure 156: Checking the RSVP Layer

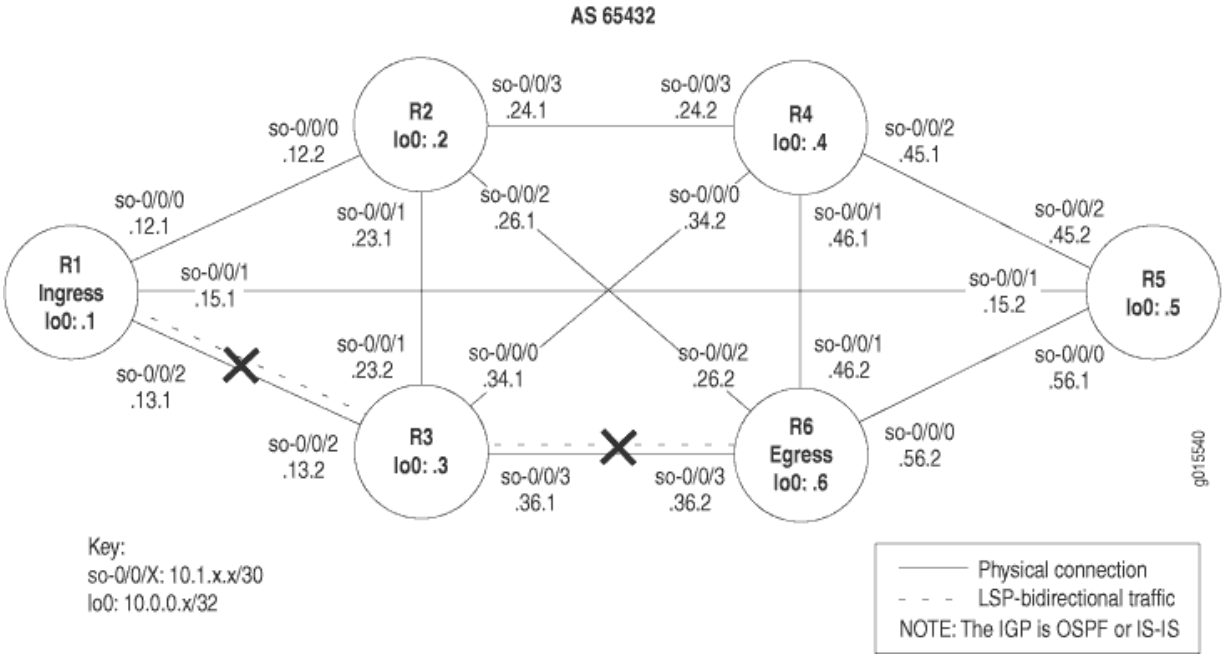


With this layer, you check that dynamic RSVP signaling is occurring as expected, neighbors are connected, and interfaces are configured correctly for RSVP. Check the ingress, egress, and transit routers.

If the network is not functioning at this layer, the LSP does not work as configured.

Figure 157 on page 2301 illustrates the MPLS network used in this topic.

Figure 157: MPLS Network Broken at the RSVP Layer



The network shown in Figure 157 on page 2301 is a fully meshed configuration where every directly connected interface can receive and send packets to every other similar interface. The LSP in this network is configured to run from ingress router **R1**, through transit router **R3**, to egress router **R6**. In addition, a reverse LSP is configured to run from **R6** through **R3** to **R1**, creating bidirectional traffic.

However, in this example, the LSP is down without a path in either direction, from **R1** to **R6** or from **R6** to **R1**.

The crosses shown in Figure 157 on page 2301 indicate where the LSP is broken. Some possible reasons the LSP is broken might include that dynamic RSVP signaling is not occurring as expected, neighbors are not connected, or interfaces are incorrectly configured for RSVP.

In the network in Figure 157 on page 2301, a configuration error on transit router **R3** prevents the LSP from traversing the network as expected.

To check the RSVP layer, follow these steps:

Verify the LSP

IN THIS SECTION

- Purpose | 2302
- Action | 2302
- Meaning | 2304

Purpose

Typically, you use the `show mpls lsp extensive` command to verify the LSP. However for quick verification of the LSP state, use the `show mpls lsp` command. If the LSP is down, use the **extensive** option (`show mpls lsp extensive`) as a follow-up. If your network has numerous LSPs, you might consider specifying the name of the LSP, using the **name** option (`show mpls lsp name` ***name*** or `show mpls lsp name` ***name*** **extensive).**

Action

To determine whether the LSP is up, enter the following command from the ingress router:

```
user@host>              show mpls lsp extensive
```

Sample Output 1

command-name

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

10.0.0.6
  From: 10.0.0.1, State: Dn, ActiveRoute: 0,  LSPname: R1-to-R6

Total 1 displayed, Up 0,  Down 1

Egress LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Meaning

The sample output shows that the LSP is down in both directions, from **R1** to **R6**, and from **R6** to **R1**. The output from **R1** shows that **R1** is using a no-cspf LSP since it tried to originate the call without being able to reach the destination. The output from **R6** shows that the Constrained Shortest Path First (CSPF) algorithm failed, resulting in no route to destination **10.0.0.1**.

Verify RSVP Sessions

IN THIS SECTION

- Purpose | **2304**
- Action | **2304**
- Meaning | **2306**

Purpose

When an RSVP session is successfully created, the LSP is set up along the paths created by the RSVP session. If the RSVP session is unsuccessful, the LSP does not work as configured.

Action

To verify currently active RSVP sessions, enter the following command from the ingress, transit, and egress routers:

```
user@host>              show rsvp session
```

Sample Output 1

command-name

```
user@R1> show rsvp session
Ingress RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0

Egress RSVP: 0 sessions
```

```
Total 0 displayed, Up 0, Down 0

Ingress RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0

Egress RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0

Transit RSVP:  2 sessions
To              From            State Rt Style Labelin Labelout LSPname
10.0.0.1        10.0.0.6        Up     1 1 FF  100784        3  R6-to-R1
10.0.0.6        10.0.0.1        Up     1 1 FF  100768        3  R1-to-R6
Total 2 displayed,  Up 2 , Down 0

user@R6> show rsvp session
Ingress RSVP: 1 sessions
To              From            State Rt Style Labelin Labelout LSPname
10.0.0.1        10.0.0.6        Up     1 1 FF       -   100784  R6-to-R1
Total 1 displayed,  Up 1 , Down 0

Egress RSVP: 1 sessions
To              From            State Rt Style Labelin Labelout LSPname
10.0.0.6        10.0.0.1        Up     0 1 FF       3        -  R1-to-R6
Total 1 displayed,  Up 1 , Down 0

Transit RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Meaning

Sample Output 1 from all routers shows that no RSVP sessions were successfully created, even though the LSP **R6-to-R1** is configured.

In contrast to Sample Output 1and to illustrate correct output, Sample Output 2 shows the output from the ingress, transit, and egress routers when the RSVP configuration is correct, and the LSP is traversing the network as configured. **R1** and **R6** both show an ingress and egress RSVP session, with the LSP **R1-to-R6**, and the reverse LSP **R6-to-R1**. Transit router **R3** shows two transit RSVP sessions.

Verify RSVP Neighbors

IN THIS SECTION

- Purpose | 2307
- Action | 2307
- Meaning | 2308

Purpose

Display a list of RSVP neighbors that were learned dynamically when exchanging RSVP packets. Once a neighbor is learned, it is never removed from the list of RSVP neighbors unless the RSVP configuration is removed from the router.

Action

To verify RSVP neighbors, enter the following command from the ingress, transit, and egress routers:

```
user@host>              show rsvp neighbor
```

Sample Output 1

command-name

```
user@R1> show rsvp neighbor
RSVP neighbor: 1 learned
Address            Idle Up/Dn LastChange HelloInt HelloTx/Rx MsgRcvd
10.1.13.2            10   1/0         9:22        9    64/64   32

user@R3> show rsvp neighbor
RSVP neighbor: 2 learned
Address            Idle Up/Dn LastChange HelloInt HelloTx/Rx MsgRcvd
10.1.13.1             0  1/0       28:20        9   190/190  41
10.1.36.2         16:50   1/1        15:37        9   105/78   38

user@R6> show rsvp neighbor
```

```
RSVP neighbor: 1 learned
Address            Idle Up/Dn LastChange HelloInt HelloTx/Rx MsgRcvd
10.1.36.1         17:30   1/1        16:15        9   104/78   39
```

Sample Output 2

command-name

```
user@R3> show rsvp neighbor
RSVP neighbor: 2 learned
Address            Idle Up/Dn LastChange HelloInt HelloTx/Rx MsgRcvd
10.1.13.1             5   1/0         9:14        9    63/63   33
10.1.36.2             5   1/0         9:05        9    62/62   32

user@R6> show rsvp neighbor
RSVP neighbor: 1 learned
Address            Idle Up/Dn LastChange HelloInt HelloTx/Rx MsgRcvd
10.1.36.1             5   1/0        8:54        9    61/61   32
```

Meaning

Sample Output 1 shows that **R1** and **R6** have one RSVP neighbor each, **R3**. However, the values in the **Up/Dn** field are different. **R1** has a value of **1/0** and **R6** has a value of **1/1**, indicating that **R1** is an active neighbor with **R3**, but **R6** is not. When the up count is one more than the down count, the neighbor is active; if the values are equal, the neighbor is down. The values for **R6** are equal, **1/1**, indicating that the neighbor **R3** is down.

Transit router **R3** knows about two neighbors, **R1** and **R6**. The **Up/Dn** field indicates that **R1** is an active neighbor and **R6** is down. At this point it is not possible to determine if the problem resides with **R3** or **R6**, because both neighbors are not active.

In contrast to Sample Output 1 and to illustrate correct output, Sample Output 2 shows the correct neighbor relationship between transit router **R3** and egress router **R6**. The **Up/Dn** field shows the up count to be one more than the down count, **1/0**, indicating that the neighbors are active.

Verify RSVP Interfaces

IN THIS SECTION

- Purpose | 2309
- Action | 2309
- Meaning | 2311

Purpose

Display the status of each interface on which RSVP is enabled to determine where the configuration error occurred.

Action

To verify the status of RSVP interfaces, enter the following command from the ingress, transit, and egress routers:

```
user@host>              show rsvp interface
```

Sample Output 1

command-name

```
user@R1> show rsvp interface

                  Active Subscr- Static      Available   Reserved    Highwater
Interface   State resv   iption  BW          BW          BW          mark
so-0/0/0.0  Up         0   100%  155.52Mbps  155.52Mbps  0bps        0bps
so-0/0/1.0  Up         0   100%  155.52Mbps  155.52Mbps  0bps        0bps
so-0/0/2.0  Up          1    100%  155.52Mbps  155.52Mbps  0bps        0bps
so-0/0/3.0  Up          1    100%  155.52Mbps  155.52Mbps  0bps        0bps

user@R6> show rsvp interface
RSVP interface: 4 active
                  Active Subscr- Static      Available   Reserved    Highwater
Interface   State resv   iption  BW          BW          BW          mark
so-0/0/0.0  Up         0   100%  155.52Mbps  155.52Mbps  0bps        0bps
so-0/0/1.0  Up         0   100%  155.52Mbps  155.52Mbps  0bps        0bps
```

```
so-0/0/2.0  Up         0   100%  155.52Mbps  155.52Mbps  0bps        0bps
so-0/0/3.0  Up          1    100%  155.52Mbps  155.52Mbps  0bps        0bps
```

Meaning

Sample Output 1 shows that even though each router has interfaces that are up and have RSVP active, there are no reservations (**Active resv**) on any of the routers. In this example, we would expect at least one reservation on the ingress and egress routers, and two reservations on the transit router.

In addition, interface **so-0/0/3** on transit router **R3** is not included in the configuration. The inclusion of this interface is critical to the success of the LSP.

In contrast to Sample Output 1 and to illustrate correct output, Sample Output 2 shows the relevant interfaces with active reservations.

Verify the RSVP Protocol Configuration

IN THIS SECTION

- Purpose | **2311**
- Action | **2311**
- Meaning | **2312**

Purpose

After you have checked RSVP sessions, interfaces, neighbors, and determined that there might be a configuration error, verify the RSVP protocol configuration.

Action

To verify the RSVP configuration, enter the following command from the ingress, transit, and egress routers:

```
user@host>              show configuration protocols rsvp
```

Sample Output

command-name

```
user@R1> show configuration protocols rsvp
interface so-0/0/0.0;
interface so-0/0/1.0;
interface so-0/0/2.0;
interface fxp0.0 {
    disable;
}

user@R3> show configuration protocols rsvp
interface so-0/0/0.0;
interface so-0/0/1.0;
interface so-0/0/2.0; <<< Missing interface so-0/0/3.0
interface fxp0.0 {
    disable;
}

user@R6> show configuration protocols rsvp
interface so-0/0/0.0;
interface so-0/0/1.0;
interface so-0/0/2.0;
interface so-0/0/3.0;
interface fxp0.0 {
    disable;
}
```

Meaning

The sample output shows that **R3** has interface **so-0/0/3.0** missing from the RSVP protocol configuration. This interface is critical for the correct functioning of the LSP.

Take Appropriate Action

IN THIS SECTION

Problem | 2313

- Solution | 2313

Problem

Description

Depending on the error you encountered in your investigation, you must take the appropriate action to correct the problem. In this example, an interface is missing from the configuration of router R3.

Solution

To correct the error in this example, follow these steps:

1. Include the missing interface in the configuration of transit router R3:

```
user@R3> edit
user@R3#                    edit protocols rsvp
[edit protocols rsvp]
user@R3# show
user@R3#                    set interface so-0/0/3.0
```

2. Verify and commit the configuration:

```
[edit protocols rsvp]
user@R3# show
user@R3# commit
```

Sample Output

```
user@R3> edit
Entering configuration mode

[edit]
user@R3# edit protocols rsvp

[edit protocols rsvp]
```

```
user@R3# show
interface so-0/0/0.0;
interface so-0/0/1.0;
interface so-0/0/2.0; <<< Missing interface so-0/0/3.0
interface fxp0.0 {
    disable;
}
[edit protocols rsvp]
user@R3# set interface so-0/0/3.0

[edit protocols rsvp]
user@R3# show
interface so-0/0/0.0;
interface so-0/0/1.0;
interface so-0/0/2.0;
interface fxp0.0 {
    disable;
}
interface so-0/0/3.0; <<< Interface now included in the configuration

[edit protocols rsvp]
user@R3# commit
commit complete
```

Meaning

The sample output shows that the missing interface **so-0/0/3.0** on transit router **R3** is now correctly included at the [**edit protocols rsvp**] hierarchy level. This results in the possibility that the LSP might come up.

Verify the LSP Again

IN THIS SECTION

- Purpose | **2315**
- Action | **2315**
- Meaning | **2318**

Purpose

After taking the appropriate action to correct the error, the LSP needs to be checked again to confirm that the problem in the MPLS layer has been resolved.

Action

To verify the LSP again, enter the following command on the ingress, transit, and egress routers:

```
user@host>              show mpls lsp extensive
```

Sample Output 1

command-name

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

10.0.0.6

```

Meaning

Sample Output 1 from ingress router **R1** shows that LSP **R1-to-R6** has an active route to **R6** and the state is up.

Sample Output 2 from transit router **R3** shows that there are two transit LSP sessions, one from **R1** to **R6** and the other from **R6** to **R1**. Both LSPs are up.

Sample Output 3 from egress router **R6** shows that the LSP is up and the active route is the primary route. The LSP is now traversing the network along the expected path, from **R1** through **R3** to **R6**, and the reverse LSP, from **R6** through **R3** to **R1**.

Determining LSP Statistics

IN THIS SECTION

- Purpose | 2319
- Action | 2319
- Meaning | 2320

Purpose

Display detailed information about RSVP objects to assist the diagnosis of an LSP problem.

Action

To verify RSVP objects, enter the following Junos OS CLI operational mode command:

```
user@host>                      show rsvp session detail
```

Sample Output

command-name

```
user@R1> show rsvp session detail
Ingress RSVP: 1 sessions

Total 1 displayed, Up 1, Down 0

Transit RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Meaning

The sample output shows that there is one ingress and one egress RSVP session. The ingress session has a source address of **10.0.0.1** (**R1**), and the session is up, with one active route. The LSP name is **R1-to-R6** and it is the primary path for the LSP.

The recovery label (**100064**) is sent by a graceful restart router to its neighbor to recover a forwarding state. It is probably the old label that the router advertised before it went down.

This session is using the fixed filter (**FF**) reservation style (**Resv style**). Since this is an ingress router, there is no inbound label. The outbound label (provided by the next downstream router) is **100064**.

The **Time Left** field provides the number of seconds remaining in the RSVP session, and the **Tspec** object provides information about the controlled load rate (**rate**) and maximum burst size (**peak**), an infinite value (**Infbps**) for the guaranteed delivery option, and the indication that packets smaller than 20 bytes are treated as 20 bytes, while packets larger than 1500 bytes are treated as 1500 bytes.

The port number is the IPv4 tunnel ID, while the sender/receiver port number is the LSP ID. The IPv4 tunnel ID is unique for the life of the LSP, while the sender/receiver LSP ID can change, for example, with an SE style reservation.

The **PATH rcvfrom** field includes the source of the path message. Since this is the ingress router, the local client originated the path message.

The **PATH sentto** field includes the path message destination (**10.1.13.2**) and outgoing interface (**so-0/0/2.0**). The **RESV rcvfrom** field includes both the source of the Resv message received (**10.1.13.2**) and the incoming interface (**so-0/0/2.0**).

The RSVP explicit route and the route record values are identical: **10.1.13.2** and **10.1.36.2**. In most cases, the explicit route and the record route values are identical. Differences indicate that some path rerouting has occurred, typically during Fast-Reroute.

The **Total** fields indicate the total number of ingress, egress, and transit RSVP sessions, with the total being equal to the sum of the up and down sessions. In this example, there is one ingress session, one egress session, and no transit RSVP sessions.

Verifying LSP Use in Your Network

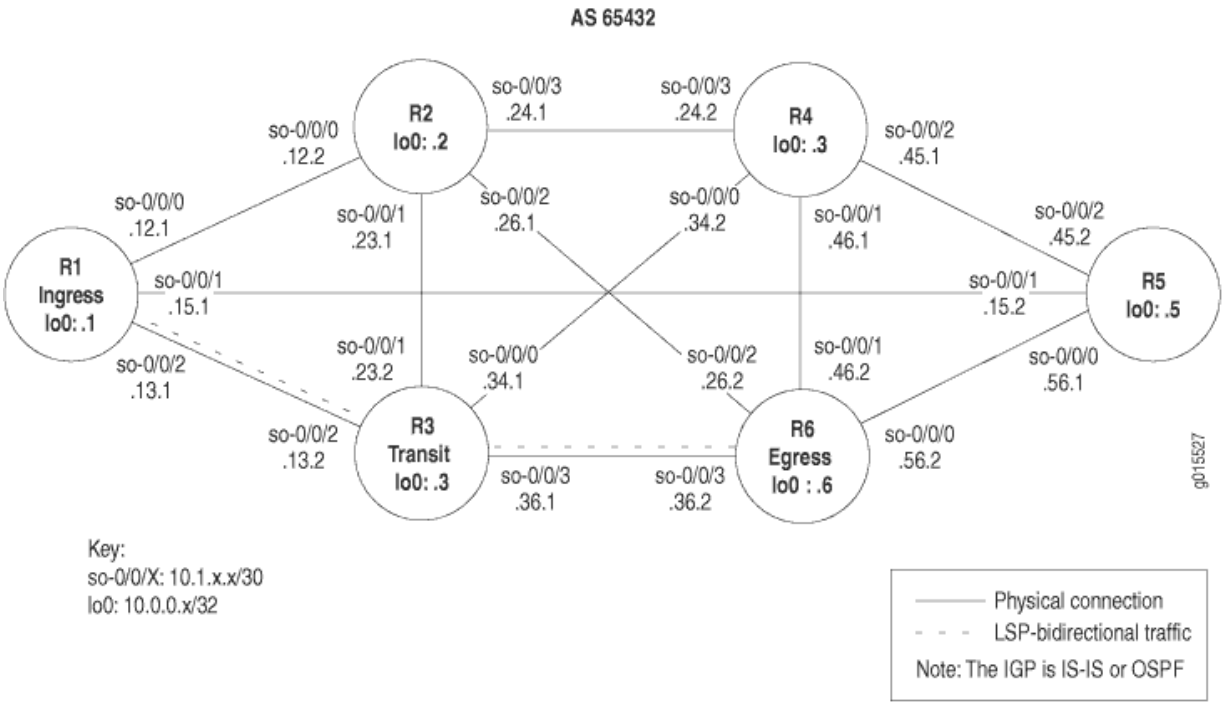
IN THIS SECTION

- Verifying an LSP on the Ingress Router | **2323**
- Verifying an LSP on a Transit Router | **2324**

Purpose

When you verify the valid use of an LSP on the ingress and transit routers in your network, you can determine if there is a problem with Multiprotocol Label Switching (MPLS) in your network. Figure 158 on page 2322 describes the example network used in this topic.

Figure 158: MPLS Topology for Verifying LSP Use



The MPLS network in Figure 158 on page 2322 illustrates a router-only network with SONET interfaces that consist of the following components:

- A full-mesh interior Border Gateway Protocol (IBGP) topology, using AS 65432
- MPLS and Resource Reservation Protocol (RSVP) enabled on all routers
- A **send-statics** policy on routers R1 and R6 that allows a new route to be advertised into the network
- An LSP between routers R1 and R6

The network shown in Figure 158 on page 2322 is a Border Gateway Protocol (BGP) full-mesh network. Since route reflectors and confederations are not used to propagate BGP learned routes, each router must have a BGP session with every other router running BGP.

To verify LSP use in your network, follow these steps:

Verifying an LSP on the Ingress Router

IN THIS SECTION

- Purpose | 2323
- Action | 2323
- Meaning | 2324

Purpose

You can verify the availability of an LSP when it is up by examining the **inet.3** routing table on the ingress router. The **inet.3** routing table contains the host address of each LSP's egress router. This routing table is used on ingress routers to route BGP packets to the destination egress router. BGP uses the **inet.3** routing table on the ingress router to help resolve next-hop addresses.

Action

To verify an LSP on an ingress router, enter the following Junos OS command-line interface (CLI) operational mode command:

```
user@host> show route table inet.3
```

Sample Output

command-name

```
user@R1> show route table inet.3
inet.3: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.0.0.6/32        *[RSVP/7] 4w0d 22:40:57, metric 20
                    > via so-0/0/2.0, label-switched-path R1-to-R6
```

Meaning

The sample output shows the **inet.3** routing table. By default, only BGP and MPLS virtual private networks (VPNs) can use the **inet.3** route table to resolve next-hop information. One destination is listed in the route table, **10.0.0.6**. This destination (**10.0.0.6**) is signaled by RSVP, and is the current active path, as indicated by the asterisk (*****). The protocol preference for this route is **7**, and the metric associated with it is **20**. The label-switched path is **R1-to-R6**, through interface **so-0/0/2.0**, which is the physical next-hop transit interface.

Typically, the penultimate router in the LSP either pops the packet's label or changes the label to a value of 0. If the penultimate router pops the top label and an IPv4 packet is underneath, the egress router routes the IPv4 packet, consulting the IP routing table **inet.0** to determine how to forward the packet. If another type of label (such as one created by Label Distribution Protocol (LDP) tunneling or VPNs, but not IPv4) is underneath the top label, the egress router does not examine the **inet.0** routing table. Instead, it examines the **mpls.0** routing table for forwarding decisions.

If the penultimate router changes the packet's label to a value of 0, the egress router strips off the 0 label, indicating that an IPv4 packet follows. The packet is examined by the **inet.0** routing table for forwarding decisions.

When a transit or egress router receives an MPLS packet, information in the MPLS forwarding table is used to determine the next transit router in the LSP or whether this router is the egress router.

When BGP resolves a next-hop prefix, it examines both the **inet.0** and **inet.3** routing tables, seeking the next hop with the lowest preference; for example, RSVP preference 7 is preferred over OSPF preference 10. The RSVP signaled LSP is used to reach the BGP next hop. This is the default when the BGP next hop equals the LSP egress address. Once the BGP next hop is resolved through an LSP, the BGP traffic uses the LSP to forward BGP transit traffic.

Verifying an LSP on a Transit Router

IN THIS SECTION

- Purpose | **2325**
- Action | **2325**
- Meaning | **2325**

Purpose

You can verify the availability of an LSP when it is up by examining the **mpls.0** routing table on a transit router. MPLS maintains the **mpls.0** routing table, which contains a list of the next label-switched router in each LSP. This routing table is used on transit routers to route packets to the next router along an LSP.

Action

To verify an LSP on a transit router, enter the following Junos OS CLI operational mode command:

```
user@host> show route table mpls.0
```

Sample Output

command-name

```
user@R3> show route table mpls.0
mpls.0: 5 destinations, 5 routes (5 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

0                  *[MPLS/0] 7w3d 22:20:56, metric 1
                    Receive
1                  *[MPLS/0] 7w3d 22:20:56, metric 1
                    Receive
2                  *[MPLS/0] 7w3d 22:20:56, metric 1
                    Receive
100064             *[RSVP/7] 2w1d 04:17:36, metric 1
                    > via so-0/0/3.0, label-switched-path R1-to-R6
100064 (S=0)        *[RSVP/7] 2w1d 04:17:36, metric 1
                   > via so-0/0/3.0, label-switched-path R1-to-R6
```

Meaning

The sample output from transit router **R3** shows route entries in the form of MPLS label entries, indicating that there is only one active route, even though there are five active entries.

The first three MPLS labels are reserved MPLS labels defined in RFC 3032. Packets received with these label values are sent to the Routing Engine for processing. Label 0 is the IPv4 explicit null label. Label 1 is the MPLS equivalent of the IP Router Alert label and Label 2 is the IPv6 explicit null label.

The two entries with the **100064** label are for the same LSP, **R1-to-R6.** There are two entries because the stack values in the MPLS header may be different. The second entry, **100064 (S=0)**, indicates that the stack depth is not 1 and additional label values are included in the packet. In contrast, the first entry of **100064** has an inferred S=1 which indicates a stack depth of 1 and makes it the last label in the packet. The dual entry indicates that this is the penultimate router. For more information on MPLS label stacking, see RFC 3032, *MPLS Label Stack Encoding.*

The incoming label is the MPLS header of the MPLS packet, and is assigned by RSVP to the upstream neighbor. Juniper Networks routers dynamically assign labels for RSVP traffic-engineered LSPs in the range from 100,000 through 1,048,575.

The router assigns labels starting at label 100,000, in increments of 16. The sequence of label assignments is 100,000, 100,016, 100,032, 100,048, and so on. At the end of the assigned labels, the label numbers start over at 100001, incrementing in units of 16. Juniper Networks reserves labels for various purposes. *Table 1* lists the various label range allocations for incoming labels.

Table 37: MPLS Label Range Allocations

Incoming Label	Status
0 through **15**	Reserved by IETF
16 through **1023**	Reserved for static LSP assignment
1024 through **9999**	Reserved for internal use (for example, CCC labels)
10,000 through **99,999**	Reserved for static LSP assignment
100,000 through **1,048,575**	Reserved for dynamic label assignment

Verify That Load Balancing Is Working

IN THIS SECTION

- Purpose | **2327**
- Action | **2327**
- Meaning | **2328**

Purpose

After configuring load balancing, check that traffic is load-balanced equally across paths. In this section, the command output reflects the load-balancing configuration of the example network shown in "Load-Balancing Network Topology" on page 233. The `clear` commands are used to reset LSP and interface counters to zero so that the values reflect the operation of the load-balancing configuration.

Action

To verify load balancing across interfaces and LSPs, use the following command on the ingress router:

```
user@host# show configuration
```

To verify load balancing across interfaces and LSPs, use the following commands on a transit router:

```
user@host# show route
user@host# show route forwarding-table
user@host# show mpls lsp statistics
user@host# monitor interface traffic
user@host# clear mpls lsp statistics
user@host# clear interface statistics
```

Sample Output

command-name

The following sample output is for the configuration on ingress router **R1**:

```
user@R1> show configuration | no-more
[...Output truncated...]
routing-options {
    [...Output truncated...]
     forwarding-table {
        export lbpp;
    }
}
[...Output truncated...]
policy-options {
     policy-statement lbpp {
        then {
```

```
            load-balance per-packet;
        }
    }
}
```

Meaning

The sample output for the `show configuration` command on ingress router **R1** shows that load balancing is correctly configured with the **lbpp** policy statement. Also, the **lbpp** policy is exported into the forwarding table at the `[edit routing-options]` hierarchy level.

Sample Output

The following sample output is from transit router R2:

```
user@R2> show route 192.168.0.1 terse

inet.0: 25 destinations, 27 routes (25 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
A Destination        P Prf   Metric 1   Metric 2  Next hop        AS path
* 192.168.0.1/32     O  10          3             so-0/0/1.0
                                                 >so-0/0/2.0
[...Output truncated...]
```

Meaning

The sample output for the `show route` command issued on transit router **R2** shows the two equal-cost paths (**so-0/0/1** and **so-0/0/2)** through the network to the loopback address to **R0** (**192.168.0.1**). Even though the right angle bracket (>) usually indicates the active route, in this instance it does not, as shown in the following four sample outputs.

Sample Output

The following sample output is from transit router R2:

```
user@R2> monitor interface traffic

R2                                Seconds: 65                 Time: 11:41:14
```

```
Interface    Link  Input packets        (pps)     Output packets        (pps)
 so-0/0/0      Up              0          (0)                 0          (0)
 so-0/0/1      Up            126          (0)            164659       (2128)
 so-0/0/2      Up          85219       (1004)            164598       (2128)
 so-0/0/3      Up              0          (0)                 0          (0)
 fe-0/1/0      Up         328954       (4265)             85475       (1094)
 fe-0/1/1      Up              0          (0)                 0          (0)
 fe-0/1/2      Up              0          (0)                 0          (0)
 fe-0/1/3      Up              0          (0)                 0          (0)
[...Output truncated...]
```

Meaning

The sample output for the `monitor interface traffic` command issued on transit router **R2** shows that output traffic is evenly distributed across the two interfaces **so-0/0/1** and **so-0/0/2**.

Sample Output

The following sample output is from transit router R2:

```
user@R2> show mpls lsp statistics
Ingress LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

Egress LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

Transit LSP: 5 sessions

```

Meaning

The sample output for the `show mpls lsp statistics` command issued on transit router **R2** shows that output traffic is evenly distributed across the four LSPs configured on ingress router **R6**.

Sample Output

The following sample output is from transit router R2:

```
user@R2> show route forwarding-table destination 10.0.90.14
Routing table: inet
Internet:
Destination        Type RtRef Next hop           Type Index NhRef Netif
10.0.90.12/30      user     0                     ulst 262144     6
                                                  ucst   345     5 so-0/0/1.0
                                                  ucst   339     2 so-0/0/2.0
```

Meaning

The sample output for the `show route forwarding-table destination` command issued on transit router **R2** shows **ulst** in the **Type** field, which indicates that load balancing is working. The two unicast (**ucst)** entries in the **Type** field are the two next hops for the LSPs.

Sample Output

The following sample output is from transit router R2:

```
user@R2> show route forwarding-table | find mpls
Routing table: mpls
MPLS:
Destination        Type RtRef Next hop           Type Index NhRef Netif
default            perm     0                    dscd    38     1
0                  user     0                    recv    37     3
1                  user     0                    recv    37     3
2                  user     0                    recv    37     3
100112             user     0                   Swap 100032       so-0/0/1.0
100128             user     0                   Swap 100048       so-0/0/1.0
100144             user     0 10.0.12.13        Swap 100096       fe-0/1/0.0
100160             user     0                   Swap 100112       so-0/0/2.0
100176             user     0                   Swap 100128       so-0/0/2.0
```

Meaning

The sample output for the `show route forwarding-table | find mpls` command issued on transit router R2 shows the MPLS routing table that contains the labels received and used by this router to forward packets to the next-hop router. This routing table is used mostly on transit routers to route packets to the next router along an LSP. The first three labels in the **Destination** column (Label 0, Label 1, and Label 2) are automatically entered by MPLS when the protocol is enabled. These labels are reserved MPLS labels defined in RFC 3032. Label 0 is the IPv4 explicit null label. Label 1 is the MPLS equivalent of the IP Router Alert label, and Label 2 is the IPv6 explicit null label.

The remaining five labels in the **Destination** column are nonreserved labels that the router uses to forward traffic, and the last column **Netif**, shows the interfaces used to send the labeled traffic. For nonreserved labels, the second **Type** column shows the operation performed on matching packets. In this example, all non-reserved packets are swapped for outgoing packet labels. For example, packets with the label **100112** have their label swapped for **100032** before they are pushed out of interface **so-0/0/1.0**.

Verify the Operation of Uneven Bandwidth Load Balancing

IN THIS SECTION

- Purpose | 2331
- Action | 2331
- Meaning | 2333

Purpose

When a router is performing unequal-cost load balancing between LSPs paths, the `show route detail` command displays a balance field associated with each next hop being used.

Action

To verify that an RSVP LSP is unevenly load-balanced, use the following Junos OS CLI operational mode commands:

```
user@host> show route protocol rsvp detail
user@host> show mpls lsp statistics
```

Sample Output

command-name

```
user@R1> show route protocol rsvp detail

inet.0: 25 destinations, 25 routes (25 active, 0 holddown, 0 hidden)
10.0.90.14/32 (1 entry, 1 announced)

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Meaning

The sample output from ingress router **R1** shows that traffic is distributed according to the LSP bandwidth configuration, as indicated by the **Balance: xx%** field. For example, **lsp1** has 10 Mbps of bandwidth configured, as reflected in the **Balance: 10%** field.

Use the traceroute Command to Verify MPLS Labels

IN THIS SECTION

Purpose | 2334

Action | 2334
Meaning | 2335

Purpose

You can use the `traceroute` command to verify that packets are being sent over the LSP.

Action

To verify MPLS labels, enter the following Junos OS CLI operational mode command, where ***host-name*** is the IP address or the name of the remote host:

```
user@host> traceroute host-name
```

Sample Output 1

command-name

```
user@R1> traceroute 100.100.6.1
traceroute to 100.100.6.1 (100.100.6.1), 30 hops max, 40 byte packets
 1  10.1.12.2 (10.1.12.2)  0.861 ms  0.718 ms  0.679 ms
      MPLS Label=100048 CoS=0 TTL=1 S=1
 2  10.1.24.2 (10.1.24.2)  0.822 ms  0.731 ms  0.708 ms
      MPLS Label=100016 CoS=0 TTL=1 S=1
 3  10.1.46.2 (10.1.46.2)  0.571 ms !N  0.547 ms !N  0.532 ms !N
```

Sample Output 2

command-name

```
user@R1> traceroute 10.0.0.6
traceroute to 10.0.0.6 (10.0.0.6), 30 hops max, 40 byte packets
 1  10.1.13.2 (10.1.13.2)  0.605 ms  0.548 ms  0.503 ms
 2  10.0.0.6 (10.0.0.6)  0.761 ms  0.676 ms  0.675 ms
```

Meaning

Sample Output 1 shows that MPLS labels are used to forward packets through the network. Included in the output is a label value (**MPLS Label=100048**), the time-to-live value (**TTL=1**), and the stack bit value (**S=1**).

The **MPLS Label** field is used to identify the packet to a particular LSP. It is a 20-bit field, with a maximum value of (2^^20-1), or approximately 1,000,000.

The TTL value contains a limit on the number of hops that this MPLS packet can travel through the network (1). It is decremented at each hop, and if the TTL value drops below one, the packet is discarded.

The bottom of the stack bit value (**S=1**) indicates that is the last label in the stack and that this MPLS packet has one label associated with it. The MPLS implementation in the Junos OS supports a stacking depth of 3 on the M-series routers and up to 5 on the T-series platforms. For more information on MPLS label stacking, see RFC 3032, *MPLS Label Stack Encoding.*

MPLS labels appear in Sample Output 1 because the `traceroute` command is issued to a BGP destination where the BGP next hop for that route is the LSP egress address. The Junos OS default behavior uses LSPs for BGP traffic when the BGP next hop equals the LSP egress address.

Sample Output 2 shows that MPLS labels do not appear in the output for the `traceroute` command. If the BGP next hop does not equal the LSP egress address or the destination is an IGP route, the BGP traffic does not use the LSP. Instead of using the LSP, the BGP traffic is using the IGP (IS-IS, in this case) to reach the egress address (**R6**).

Troubleshooting GMPLS and GRE Tunnel

IN THIS SECTION

- Problem | **2335**
- Solution | **2348**

Problem

Description

The logical control channel for GMPLS must be a point-to-point link and must have some form of IP reachability. On broadcast interfaces or when there are multiple hops between control channel peers,

use a GRE tunnel for the control channel. For more detailed information on GMPLS and GRE tunnels see the *Junos MPLS Applications Configuration Guide* and the *Junos User Guide*.

A tunnel PIC is *not* required to configure a GRE tunnel for the GMPLS control channel. Instead, use the software-based **gre** interface, rather than the hardware-based **gr-*fpc/pic/port*** interface.

CAUTION: Due to restrictions to the software-based **gre** interface, the GMPLS control channel is the only supported use of the software-based **gre** interface. Any other use is expressly unsupported and might cause an application failure.

The following example shows a basic **gre** interface configuration. In this case, the tunnel source is the loopback address of the local router and the destination address is the loopback destination of the remote router. Traffic that has a next hop of the tunnel destination will use the tunnel. The tunnel is not automatically used by all the traffic passing through the interface. Only traffic with the tunnel destination as the next hop uses the tunnel.

Sample Output

```
user@R1> show configuration interfaces
[...Output truncated...]
gre {
    unit 0 {
        tunnel {
            source 10.0.12.13;
            destination 10.0.12.14;
        }
        family inet {
            address 10.35.1.6/30;
        }
        family mpls;
    }
}
```

Sample Output

The following sample output for the show interfaces command shows the encapsulation type and header, the maximum speed, packets through the logical interface, the destination, and logical address.

```
user@R1> show interfaces gre
Physical interface: gre, Enabled, Physical link is Up
  Interface index: 10, SNMP ifIndex: 8
   Type: GRE, Link-level type: GRE,  MTU: Unlimited, Speed: Unlimited
  Device flags   : Present Running
  Interface flags: Point-To-Point SNMP-Traps
    Input packets : 0
    Output packets: 0

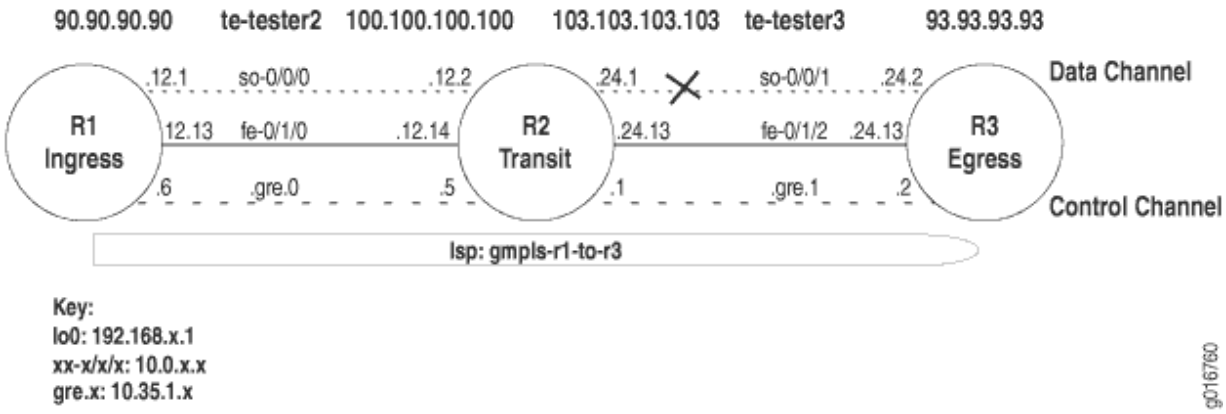
  Logical interface gre.0 (Index 70) (SNMP ifIndex 47)
    Flags: Point-To-Point SNMP-Traps 0x4000
     IP-Header 10.0.12.14:10.0.12.13:47:df:64:0000000000000000
     Encapsulation: GRE-NULL
    Input packets : 171734
    Output packets: 194560
    Protocol inet, MTU: 1476
      Flags: None
      Addresses, Flags: Is-Preferred Is-Primary
         Destination: 10.35.1.4/30, Local: 10.35.1.6, Broadcast: 10.35.1.7
    Protocol mpls, MTU: 1464
      Flags: None
```

The following are various requirements when you configure a GMPLS LSP using a GRE tunnel:

- The data channel must start and end on the same type of interface.
- The control channel can be a GRE tunnel that starts and ends on the same or different interface type.
- The GRE tunnel must be configured indirectly with the **peer-interface** *peer-name* statement at the `[edit protocol ospf]` hierarchy level.
- The GRE interface must be disabled at the `[edit protocols ospf]` and `[edit protocols rsvp]` hierarchy levels.
- Data and control channels must be defined correctly in the LMP configuration .
- It is optional to disable Constrained Shortest Path First (CSPF) with the `no-cspf` statement.

This case focuses on the incorrect configuration of the endpoints of the GRE tunnel. However, you can use a similar process and commands to diagnose other GRE tunnel problems. Figure 159 on page 2338 illustrates a network topology with MPLS tunneled through a GRE interface.

Figure 159: GMPLS Network Topology



The MPLS network topology in Figure 159 on page 2338 shows Juniper Networks routers configured with a GRE tunnel that consists of the following components:

- A strict GMPLS LSP path from the ingress router to the egress router.
- On the ingress router, CSPF disabled with the `no-cspf` statement at the [**edit protocol mpls label-switched-path** *lsp-name*] hierarchy level.
- Traffic-engineering links and control channels within the `peer` statement at the [**edit protocols link-management**] hierarchy level on all routers.
- OSPF and OSPF traffic engineering configured on all routers.
- A reference to the **peer-interface** in both OSPF and RSVP on all routers.
- A switching-type problem between **R2** and **R3**.

Symptom

The LSP in the network shown in Figure 159 on page 2338 is down, as indicated by the output from the `show mpls lsp` and `show rsvp session` commands, which display very similar information. The `show mpls lsp` command shows all LSPs configured on the router, as well as all transit and egress LSPs. The `show rsvp session` command displays summary information about RSVP sessions. You can use either command to verify the state of the LSP. In this case, LSP **gmpls-r1-to-r3** is down (**Dn**).

Sample Output

```
user@R1> show mpls lsp
Ingress LSP: 1 sessions
To              From            State Rt ActivePath       P     LSPname
192.168.4.1     192.168.1.1     Dn     0 -                      gmpls-r1-to-r3
Bidir

Total 1 displayed, Up 0, Down 1

Egress RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0

Transit RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Cause

The cause of the problem with the GMPLS LSP is the configuration of different interface types at both ends of the GMPLS data channel.

Troubleshooting Commands

The Junos OS includes commands that are useful when troubleshooting a problem. This topic provides a brief description of each command, followed by sample output, and a discussion of the output in relation to the problem.

You can use the following commands when troubleshooting a GMPLS problem:

```
user@host> show mpls lsp extensive
user@host> show rsvp session detail
user@host> show link-management peer
user@host> show link-management te-link
user@host> show configuration protocols mpls
user@host> monitor start filename
user@host> show log filename
```

Sample Output

Use the show mpls lsp extensive command on transit router R1 to display detailed information about all LSPs transiting, terminating, and configured on the router.

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

192.168.4.1
  From: 192.168.1.1, State: Dn, ActiveRoute: 0, LSPname: gmpls-r1-to-r3

Egress LSP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

```
Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Meaning

The sample output for the `show mpls lsp extensive` command shows an error message (**MPLS label allocation failure)** in the log section of the output. This LSP event indicates that the MPLS protocol or the `family mpls` statement were not configured properly. When the LSP event is preceded by an IP address, the address is typically the router that has the MPLS configuration error. In this case, it appears that the router with the **lo0** address of **192.168.4.1** (**R3**) has an MPLS configuration error.

Sample Output

Use the show rsvp session detail command to display detailed information about RSVP sessions.

```
user@R1> show rsvp session detail
Ingress RSVP: 1 sessions

```

Meaning

The sample output for the `show rsvp session detail` command shows that LSP **gmpls-r1-to-r3** is down (**LSPstate: Dn**). The route record is incomplete, indicating a problem with the explicit route **100.100.100.100 93.93.93.93**. The address **100.100.100.100** is the data channel on **R2 so-0/0/0**, and the address **93.93.93.93** is the data channel on **R3**.

Sample Output

Use the show link-management peer command to display MPLS peer link information.

```
user@R1> show link-management peer
Peer name: tester2, System identifier: 48428
  State: Up, Control address:  10.35.1.5
   Control-channel                  State
   gre.0                             Active
  TE links:
   tester2

user@R2> show link-management peer
Peer name: tester2, System identifier: 48428
 State: Up, Control address: 10.35.1.6
   Control-channel                  State
   gre.0                             Active
  TE links:
   te-tester2

Peer name: tester3 , System identifier: 48429
  State: Up , Control address: 10.35.1.2
   Control-channel                  State
   gre.1                             Active
  TE links:
   te-tester3

user@R3> show link-management peer
Peer name: tester3, System identifier: 48429
  State: Up, Control address: 10.35.1.1
   Control-channel                  State
```

```
   gre.0                              Active
  TE links:
   te-tester3
```

Meaning

The sample output from all routers in the example network in Figure 159 on page 2338 for the `show link-management peer` command shows that all control channels are up and active. A detailed analysis of the output shows the following information:

- Name of the peer, **tester2** or **tester3**, which is the same on neighboring routers for ease of troubleshooting.
- Internal identifier for the peer, **48428** for **tester2** and **48429** for **tester3**. The internal identifier is a range of values from 0 through 64,000.
- The state of the peer, which can be up or down. In this case, all peers are up.
- The address to which a control channel is established, for example, **10.35.1.5.**
- The state of the control channel, which can be up, down, or active.
- The traffic-engineered links that are managed by their peer, indicating that control channel **gre.0** is managed by **tester3**.

Sample Output

Use the show link-management te-link command to display the resources used to set up Multiprotocol Label Switching (MPLS) traffic-engineered forwarding paths.

```
user@R1> show link-management te-link
TE link name:  tester2, State: Up
  Local identifier: 2005, Remote identifier: 21253, Local address: 90.90.90.90, Remote address:
100.100.100.100,
  Encoding: SDH/SONET, Switching: PSC-1, Minimum bandwidth: 155.52Mbps, Maximum bandwidth:
155.52Mbps, Total bandwidth: 155.52Mbps,
  Available bandwidth: 0bps
    Name        State Local ID  Remote ID      Bandwidth  Used   LSP-name
     so-0/0/0    Up       21253      21253      155.52Mbps   Yes   gmpls-r1-to-r3

user@R2> show link-management te-link
 TE link name:  te-tester2, State: Up
```

```
  Local identifier: 7002, Remote identifier: 22292, Local address: 100.100.100.100, Remote
address: 90.90.90.90,

Remote address: 103.103.103.103,
  Encoding: SDH/SONET, Switching: PSC-1, Minimum bandwidth: 0bps, Maximum bandwidth: 0bps, Total
bandwidth: 0bps,
  Available bandwidth: 0bps
    Name        State Local ID  Remote ID      Bandwidth Used  LSP-name
    so-0/0/1    Dn       21252      21252     155.52Mbps    No
```

Meaning

The sample output for the `show link-management te-link` command issued on the three routers in the network in Figure 159 on page 2338 shows the resources allocated to the traffic-engineered links **te-tester2** and **te-tester3**. The resources are the SONET interfaces **so-0/0/0** and **so-0/0/1.** On **R1** and **R2,** the SONET interfaces are used for the LSP **gmpls-r1-to-r3**, as indicated by **Yes** in the **Used** field.However, the SONET interface **so-0/0/1** on **R3** is down (**Dn**) and is not used for the LSP (**Used No**). Further investigation is required to discover why the SONET interface on **R3** is down.

Sample Outut

Use the show log *filename* command to display the contents of the specified log file. In this case, the log file rsvp.log is configured at the [edit protocols rsvp traceoptions] hierarchy level. When the log file is configured, you must issue the monitor start *filename* command to begin logging messages to the file.

```
user@R1> show configuration protocols rsvp
traceoptions {
    file rsvp.log size 3m world-readable;
    flag state detail;
    flag error detail;
    flag packets detail;
}

user@R1> monitor start rsvp.log
```

NOTE: The **find Error** option entered after the pipe **(|)** searches the output for an instance of the term *Error*.

Sample Output

```
user@R3>
show log rsvp.log | find Error

```

Meaning

The sample output from the egress router **R3** for the `show log rsvp.log` command is a snippet taken from the log file. The snippet shows a Link Management Protocol (LMP) resource request for the LSP **gmpls-r1-to-r3.** The request has problems with the encoding type (SDH/SONET), indicating a possible error with the SONET interface connecting **R2** and **R3**. Further investigation of the configuration of the LMP on **R2** and **R3** is required.

Sample Output

Use the show configuration *statement-path* command to display a specific configuration hierarchy; in this instance, link-management.

```
user@R2> show configuration protocols link-management
te-link te-tester2 {
    local-address 100.100.100.100;
    remote-address 90.90.90.90;
    remote-id 22292;
    interface so-0/0/0 {
        local-address 100.100.100.100;
        remote-address 90.90.90.90;
        remote-id 21253;
    }
}
te-link te-tester3  {
    local-address 103.103.103.103;
    remote-address 93.93.93.93;
    remote-id 21254;
     interface so-0/0/1  {
        local-address 103.103.103.103;
        remote-address 93.93.93.93;
        remote-id 21252;
    }
```

```
}
peer tester2 {
    address 10.35.1.6;
    control-channel gre.0;
    te-link te-tester2;
}
peer tester3 {
    address 10.35.1.2;
    control-channel gre.1;
    te-link te-tester3;
}

user@R3> show configuration protocols link-management
te-link te-tester3  {
    local-address 93.93.93.93;
    remote-address 103.103.103.103;
    remote-id 21254;
    }
     interface at-0/3/1 {
        local-address 93.93.93.93;
        remote-address 103.103.103.103;
        remote-id 21252;
    }
}
peer tester3 {
    address 10.35.1.1;
    control-channel gre.0;
    te-link te-tester3;
}
```

Meaning

The sample output from transit router **R2** and ingress router **R3** for the `show configuration protocols link-management` command shows that the interface type on the two routers is different. The resource allocated to **te-tester3** on transit router **R2** is a SONET interface, while the resource allocated to **te-tester3** on egress router **R3** is an ATM interface. The interface type on each end of the data or control channels must be of the same type. In this case, both ends should be SONET or ATM.

Solution

Solution

The solution to the problem of different interface or encapsulation types at either end of the GMPLS LSP is to make sure that the interface type is the same at both ends. In this case, the ATM interface was deleted from the link-management configuration on **R3**, and a SONET interface was configured instead.

The following commands illustrate the correct configuration and commands to verify that the GMPLS LSP is up and using the data channel:

```
user@R3> show configuration protocols link-management
user@R3> show mpls lsp
user@R3> show link-management te-link
```

Sample Output

```
user@R3> show configuration protocols link-management
te-link te-tester3 {
    local-address 93.93.93.93;
    remote-address 103.103.103.103;
    remote-id 21254;
     interface so-0/0/1 { # SONET interface replaces the incorrect ATM interface
        local-address 93.93.93.93;
        remote-address 103.103.103.103;
        remote-id 21252;
    }
}
peer tester3 {
    address 10.35.1.1;
    control-channel gre.0;
    te-link te-tester3;
}

user@R3> show mpls lsp
Ingress LSP: 0 sessions

user@R3> show link-management te-link
 TE link name: te-tester3, State: Up
  Local identifier: 7003, Remote identifier: 21254, Local address: 93.93.93.93, Remote address:
103.103.103.103,
  Encoding: SDH/SONET, Switching: PSC-1, Minimum bandwidth: 155.52Mbps, Maximum bandwidth:
155.52Mbps, Total bandwidth: 155.52Mbps,
  Available bandwidth: 0bps
    Name        State Local ID  Remote ID      Bandwidth Used  LSP-name
     so-0/0/1    Up       21252      21252     155.52Mbps  Yes  gmpls-r1-to-r3
```

Meaning

The sample output for the `show protocols link-management`, `show mpls lsp`, and `show link-management te-link` commands from ingress router **R3** show that the problem is solved. LMP is correctly configured, and the LSP **gmpls-r1-to-r3** is up and using the data channel **so-0/0/1**.

Conclusion

In conclusion, both ends of a GMPLS data channel must be the same encapsulation or interface type. This case illustrates the correct configuration of the data channel. The principles are the same for the control channel.

Router Configurations

Output that shows the configurations of the ingress router in the network. The **no-more** option entered after the pipe **(|)** prevents the output from being paginated if the output is longer than the length of the terminal screen.

Sample Output

The following sample output is for ingress router R1:

```
user@R1>  show configuration | no-more
[...Output truncated...]
interfaces {
```

```
    so-0/0/0 {
        unit 0 {
            family inet {
                address 10.0.12.1/32 {
                    destination 10.0.12.2;
                }
            }

Determining LSP Status

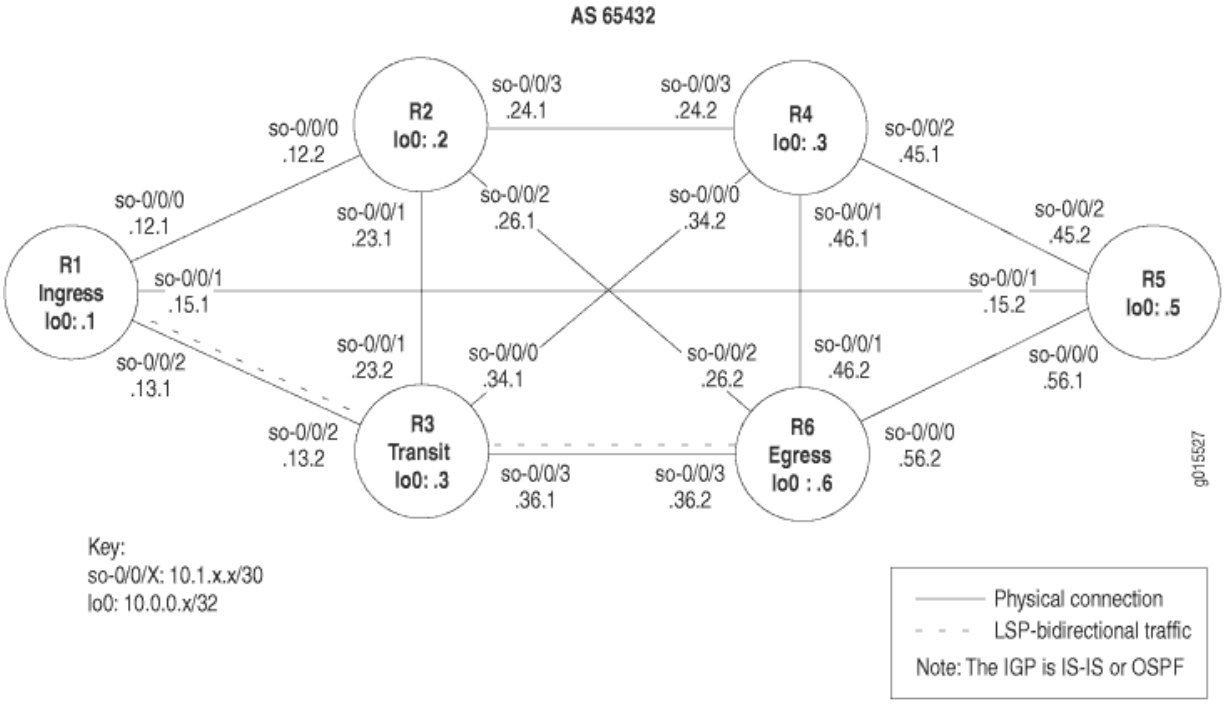
IN THIS SECTION

- Check the Status of the LSP | **2361**
- Display Extensive Status About the LSP | **2363**

Display detailed information about Resource Reservation Protocol (RSVP) objects and the label-switched path (LSP) history to pinpoint a problem with the LSP.

Figure 160 on page 2361 illustrates the network topology used in this topic.

Figure 160: MPLS Network Topology



To determine the LSP state, follow these steps:

Check the Status of the LSP

IN THIS SECTION

- Purpose | 2361
- Action | 2362
- Meaning | 2362

Purpose

Display the status of the label-switched pathe (LSP).

Action

To determine the LSP status, on the ingress router, enter the following Junos OS command-line interface (CLI) operational mode command:

```
user@host>              show mpls lsp
```

Sample Output

command-name

```
user@R1> show mpls lsp
Ingress LSP: 1 sessions
To              From            State Rt ActivePath       P     LSPname
10.0.0.6        10.0.0.1        Up     1                  *     R1-to-R6
Total 1 displayed, Up 1, Down 0

Egress LSP: 1 sessions
To              From            State Rt  Style   Labelin  Labelout LSPname
10.0.0.1        10.0.0.6         Up     0 1  FF        3         -  R6-to-R1
Total 1 displayed, Up 1, Down 0

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Meaning

The sample output is from the ingress router (**R1**), and shows ingress, egress, and transit LSP information. Ingress information is for the sessions that originate from this router, egress information is for sessions that terminate on this router, and transit information is for sessions that transit through this router.

There is one ingress route from **R1** (**10.0.0.1**) to **R6** (**10.0.0.6**). This route is currently up, and is an active route installed in the routing table (**Rt**). The LSP **R1-to-R6** is the primary path (**P**) as opposed to the secondary path, and is indicated by an asterisk (*****). The route to **R6** does not contain a named path (**ActivePath**).

There is one egress LSP from **R6** to **R1**. The **State** is up, with no routes installed in the routing table. RSVP reservation style (**Style**) consists of two parts. The first is the number of active reservations (**1**). The second is the reservation style, which is **FF** (fixed filter). The reservation style can be **FF**, **SE** (shared

explicit), or **WF** (wildcard filter). There are three incoming labels (**Labelin**) and no labels going out (**Labelout**) for this LSP.

There are no transit LSPs.

For more information on checking the LSP state, see Checklist for Working with the Layered MPLS Troubleshooting Model.

Display Extensive Status About the LSP

IN THIS SECTION

- Purpose | 2363
- Action | 2363
- Meaning | 2366

Purpose

Display extensive information about LSPs, including all past state history and the reasons why an LSP might have failed.

Action

To display extensive information about LSPs, on the ingress router, enter the following Junos OS CLI operational mode command:

```
user@host>                          show mpls lsp extensive
```

Sample Output

command-name

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

10.0.0.6

Meaning

The sample output is from the ingress router (**R1**), and shows ingress, egress, and transit LSP information in detail, including all past state history and the reasons why an LSP failed. Ingress information is for sessions that originate from this router, egress information is for sessions that terminate on this router, and transit information is for sessions that transit through this router.

There is one ingress route from **R1** (**10.0.0.1**) to **R6** (**10.0.0.6**). This route is currently up (**State**), with one route actively using the LSP, **R1-to-R6**. The LSP active path is the primary path. Even if the LSP does not contain a **primary** or **secondary** keyword, the router still treats the LSP as a primary LSP, indicating that if the LSP fails, the router will attempt to signal inactive LSPs at 30-second intervals, by default.

Load balancing is **Random**, which is the default, indicating that when selecting the physical path for an LSP, the router randomly selects among equal-cost paths that have an equal hop count. Other options that you can configure are **Least-fill** and **Most-fill**. **Least-fill** places the LSP over the least utilized link of the equal-cost paths with equal hop count. **Most-fill** places the LSP over the most utilized link of the equal-cost paths sharing an equal hop count. Utilization is based on the percentage of available bandwidth.

The **Encoding type** field shows Generalized MPLS (GMPLS) signaling parameters (**Packet)**, indicating IPv4. The **Switching type** is **Packet**, and the Generalized Payload Identifier (**GPID**) is IPv4.

The primary path is the active path, as indicated by an asterisk (*). The state of the LSP is **Up**.

The Explicit Route Object (**ERO**) includes the Constrained Shortest Path First (CSPF) cost (**20**) for the physical path that the LSP follows. The presence of the CSPF metric indicates that this is a CSPF LSP. The absence of the CSPF metric indicates a no-CSPF LSP.

The field **10.1.13.2 S** indicates the actual ERO. The RSVP signaling messages went to **10.1.13.2** strictly (as a next hop) and finished at **10.1.36.2** strictly. All ERO addresses are strict hops when the LSP is a CSPF LSP. Loose hops can only display in a no-CSPF LSP.

The received Record Route Object (**RRO**) has the following protection flags:

- **0x01**—Local protection available. The link downstream of this node is protected by a local repair mechanism. This flag can only be set if the Local protection flag was set in the SESSION_ATTRIBUTE object of the corresponding path message.
- **0x02**—Local protection in use. A local repair mechanism is in use to maintain this tunnel (usually because of an outage of the link it was routed over previously).
- **0x04**— Bandwidth protection. The downstream router has a backup path providing the same bandwidth guarantee as the protected LSP for the protected section.
- **0x08**—Node protection. The downstream router has a backup path providing protection against link and node failure on the corresponding path section. If the downstream router can set up only a link-

protection backup path, the “Local protection available” bit is set but the “Node protection” bit is cleared.

- **0x10**—Preemption pending. The preempting node sets this flag if a pending preemption is in progress for the traffic engineered LSP. This indicates to the ingress label edge router (LER) of this LSP that it should be rerouted.

For more information on protection flags, see the *Junos Routing Protocols and Policies Command Reference.*

The field **10.1.13.2.10.1.36.2** is the actual received record route (**RRO**). Note that the addresses in the **RRO** field match those in the **ERO** field. This is the normal case for CSPF LSPs. If the RRO and ERO addresses do not match for a CSPF LSP, the LSP has to reroute or detour.

The lines numbered 91 through 42 contain the 49 most recent entries to the history log. Each line is time stamped. The most recent entries have the largest log history number and are at the top of the log, indicating that line 91 is the most recent history log entry. When you read the log, start with the oldest entry (**42**) to the most recent (**91**).

The history log was started on July 10, and displays the following sequence of activities: an LSP was selected as active, was found to be down, MPLS label allocation failed several times, was deleted several times, was preempted because of an ResvTear, was deselected as active, and was cleared. In the end, the router computed a CSPF ERO, signaled the call, the LSP came up with the listed RRO (line 90), and was listed as active.

For more information on error messages, see the *Junos MPLS Network Operations Guide Log Reference.*

The total number of ingress LSPs displayed is **1**, with **1** up and **0** down. The number in the **Up** field plus the number in the **Down** field should equal the total.

There is one egress LSP session from **R6** to **R1**. The **State** is up, with no routes installed in the routing table. RSVP reservation style (**Style**) consists of two parts. The first is the number of active reservations (**1**). The second is the reservation style, which is **FF** (fixed filter). The reservation style can be **FF**, **SE** (shared explicit), or **WF** (wildcard filter). There are three incoming labels (**Labelin**) and no labels going out (**Labelout**) for this LSP.

There are no transit LSPs.

For more information on checking the LSP state, see Checklist for Working with the Layered MPLS Troubleshooting Model.

Checking That RSVP Path Messages Are Sent and Received

IN THIS SECTION

- Purpose | 2368
- Action | 2368
- Meaning | 2369

Purpose

The presence or absence of various RSVP messages can help determine if there is a problem with Multiprotocol Label Switching (MPLS) in your network. For example, if path messages occur in the output without Resv messages, it might indicate that label-switched paths (LSPs) are not being created.

Action

To check that RSVP Path messages are sent and received, enter the following Junos OS command-line interface (CLI) operational mode command:

```
user@host> show rsvp statistics
```

Sample Output

command-name

```
user@R1> show rsvp statistics
  PacketType              Total                 Last 5 seconds
                    Sent      Received        Sent      Received
 Path            114523         80185           1             0
  PathErr             5             10          0             0
   PathTear           12              6            0             0
  Resv FF          80515         111476           0             0
  Resv WF              0              0          0             0
  Resv SE              0              0          0             0
  ResvErr              0              0          0             0
   ResvTear            0              5          0             0
  ResvConf             0              0          0             0
```

```
Ack                  0            0          0            0
SRefresh             0            0          0            0
Hello           915851       915881          0            0
EndtoEnd RSVP        0            0          0            0

Errors                          Total           Last 5 seconds
Rcv pkt bad length                0                       0
Rcv pkt unknown type              0                       0
Rcv pkt bad version               0                       0
Rcv pkt auth fail                 0                       0
Rcv pkt bad checksum              0                       0
Rcv pkt bad format                0                       0
Memory allocation fail            0                       0
No path information               0                       0
Resv style conflict               0                       0
Port conflict                     0                       0
Resv no interface                 0                       0
PathErr to client                15                       0
ResvErr to client                 0                       0
Path timeout                      0                       0
Resv timeout                      0                       0
Message out-of-order              0                       0
Unknown ack msg                   0                       0
Recv nack                         0                       0
Recv duplicated msg-id            0                       0
No TE-link to recv Hop            0                       0
```

Meaning

The sample output shows RSVP messages sent and received. The total number of RSVP Path messages is 11,4532 sent and 80,185 received. Within the last 5 seconds, no messages have been sent or received.

A total of 5 **PathErr** messages were sent and 10 received. When path errors occur (usually because of parameter problems in a path message), the router sends a unicast PathErr message to the sender that issued the path message. In this case, **R1** sent at least 10 path messages with an error, as indicated by the 10 PathErr messages that **R1** has received. The downstream router sent **R1** five path messages with an error, as indicated by the five PathErr messages that **R1** has sent. PathErr messages transmit in the opposite direction to path messages.

A total of 12 **PathTear** messages were sent and 6 received, none in the last 5 seconds. In contrast to PathErr messages, PathTear messages travel in the same direction as path messages. Since path

messages are both sent and received, PathTear messages are also sent and received. However, if only path messages are sent, then only the PathTear messages that are sent appear in the output.

A total of 80,515 reservation (**Resv**) messages with the fixed filter (**FF**) reservation style were sent and 111,476 received, none in the last 5 seconds. An **FF** reservation style indicates that within each session, each receiver establishes its own reservation with each upstream sender, and that all selected senders are listed. No messages for the wildcard filter (**WF**) or shared explicit (**SE**) reservation styles are sent or received. For more information on RSVP reservation styles, see the *Junos MPLS Applications Configuration Guide*.

Other RSVP message types are not sent or received. For information on the ResvErr, ResvTear, and Resvconf message types, see the *Junos MPLS Applications Configuration Guide*.

Ack and summary refresh (SRefresh) messages do not appear in the output. Ack and summary refresh messages are defined in RFC 2961 and are part of the RSVP extensions. Ack messages are used to reduce the amount of RSVP control traffic in the network.

A total of 915,851 hello messages were sent and 915,881 received, with none transmitted or received in the last 5 seconds. The RSVP hello interval is 9 seconds. If more than one hello message is sent or received in the last 5 seconds, it implies that more than one interface supports RSVP.

EndtoEnd RSVP messages are legacy RSVP messages that are not used for RSVP traffic engineering. These counters increment only when RSVP forwards legacy RSVP messages issued by a virtual private network (VPN) customer for transit across the backbone to the other site(s) in the VPN. They are called end-to-end messages because they are intended for the opposite side of the network and only have meaning at the two ends of the provider network.

The **Errors** section of the output shows statistics about RSVP packets with errors. A total of 15 **PathErr to client** packets were sent to the Routing Engine. The total combines the sent and received **PathErr** packets.

Description

Define router clusters or groups, similar to the sequence of real-hop constraints (strict or loose), as a sequence of abstract hops for setting up a label-switched path (LSP).

An abstract hop is a logical combination of the existing traffic engineering constraints, such as administrative groups, extended administrative groups, and Shared Risk Link Groups (SRLGs), along with the ordering property of real hops. As a result, when a sequence of abstract hops is used in a path constraint, ordering is achieved among the groups of routers that meet a logical combination of link or node attributes called constituent attributes. A path can use a combination of real and abstract hops as constraints.

Options

abstract-hop-name Name of the abstract hop that is a logical combination of the existing traffic engineering constraints, such as administrative groups, extended administrative groups, and SRLGs, along with the ordering property of real hops.

constituent-list ***constituent-list-name*** Name of the predefined constituent list to be included in defining the abstract hop. A constituent list enables you to define a set of constituent attributes that is identified with a user-defined name.

include-any-list Satisfy any one of the attributes specified in the constituent list.

include-all-list Satisfy all of the attributes specified in the constituent list.

exclude-all-list Satisfy none of the attributes specified in the constituent list.

exclude-any-list Fail to satisfy any one of the attributes specified in the constituent list.

operators Specify the operation between constituent lists when more than one constituent list is included in the abstract hop definition.

AND Satisfy all the constituent lists referenced in the abstract hop definition for the attached node to be a member of the abstract hop.

OR Satisy at least one of the constituent lists referenced in the abstract hop definition for the attached node to be a member of the abstract hop.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 17.1.

secondary) path-name],
[edit protocols mpls label-switched-path lsp-name],
[edit protocols mpls label-switched-path lsp-name (primary | secondary) path-name]
```

Description

During reroute, do not double-count bandwidth on links shared by the old and new paths. Including this statement causes RSVP to use shared explicit (SE) reservation styles and assists in smooth transition during rerouting.

Default

The configured object is disabled.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

adjust-threshold percent;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name auto-
bandwidth],
[edit protocols mpls label-switched-path lsp-name auto-bandwidth]
```

Description

Specify in percentage how sensitive the automatic bandwidth adjustment for a label-switched path (LSP) is to changes in bandwidth utilization.

To specify the changes in the automatic bandwidth adjustment for a LSP in absolute value, use the "adjust-threshold-absolute" on page 2386 statement instead.

Options

percent—Bandwidth demand for the current bandwidth adjustment interval is determined and compared to the LSP's current bandwidth allocation. If the percentage difference in bandwidth is greater than or equal to the percentage specified by this statement, the LSP's bandwidth is adjusted to the current bandwidth demand.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

bandwidth  ],
[edit protocols mpls label-switched-path name auto-bandwidth  ],
[edit routing-instances name protocols mpls label-switched-path name auto-bandwidth  ]
```

Description

Specify in bits per second how sensitive the automatic bandwidth adjustment for a label-switched path (LSP) is to changes in the average LSP utilization.

The `adjust-threshold-absolute` statement works in conjunction with the "adjust-threshold" on page 2384statement, which specifies the change in automatic bandwidth adjustment for an LSP as a percentage.

By triggering automatic bandwidth LSP resignaling based on absolute change in bandwidth instead of percentage bandwidth change, LSP resignaling can be optimized for both big and small LSPs at the same time.

Options

bps Change in average LSP utilization to trigger automatic bandwidth adjustment in bits per second.

- **Default:** 0 bps

[edit routing-options]
```

Description

Enables you to configure extended administrative groups, represented by a 32-bit value, expanding the number of administrative groups supported in the network beyond just 32. In MPLS traffic engineering, a link can be configured with a set of administrative groups (also known as colors or resource classes). Administrative groups are carried in IGPs (OSPFv2 and IS-IS) as a 32-bit value assigned to each link. By default, Juniper Networks routers interpret this 32-bit value as a bit mask with each bit representing a

group. This normally limits each network to a total of 32 distinct administrative groups (value range 0 through 31).

The extended administrative groups configuration accepts a set of interfaces with a corresponding set of extended administrative group names. It converts the names into a set of 32-bit values and propagates this information into the IGP. The extended administrative group values are global and must be identically configured on all the supported routers participating in the network. The domain-wide extended administrative groups database, learned from other routers through IGP flooding, is used by CSPF for path computation.

Options

maximum *maximum-number*	The range of configurable values is between 32 and 4,294,967,295. The range maximum must be greater than the range minimum.
minimum *minimum-number*	The range of configurable values is between 32 and 4,294,967,295. The range maximum must be greater than the range minimum.

protection context-identifier context-id],
[edit protocols mpls egress-protection context-identifier context-id],
[edit protocols mpls label-switched-path lsp-name egress-protection context-identifier context-
id]
```

Description

Configure the method for the interior gateway protocol (IGP) to advertise egress protection availability.

Egress protection availability is advertised in the IGP. Label protocols along with CSPF use this information to do egress protection.

Options

stub-alias Context identifier has an alias.

In the alias method, the LSP end-point address has an explicit backup egress node where the backup node can be learned or configured on the penultimate hop node (PHN) of a protected LSP. With this model, the PHN of a protected LSP sets up the bypass LSP tunnel to back up the egress node by avoiding the primary egress node. This model requires a Junos OS upgrade in core nodes, but is flexible enough to support all traffic engineering constraints.

stub-proxy Context-identifier has a stub proxy node.

A stub node is one that only appears at the end of an AS path, which means it does not provide transit service. In this mode, known as the virtual or proxy mode, the LSP end-point address is represented as a node with bidirectional links, with the LSP's primary egress node and backup egress node. With this representation, the penultimate hop of the LSP primary egress point can behave like a PLR in setting up a bypass tunnel to back up the egress by avoiding the primary egress node. This model has the advantage that you do not need to upgrade Junos OS on core nodes and thereby helps operators to deploy this technology.

```

Description

Enable the automatic policing of all the MPLS LSPs on the router or logical system.

Options

`class all`—Apply the same policer action to all the class types (`ct0`, `ct1`, `ct2`, and `ct3`).

`class ct`*number*—Specific class type (`ct0`, `ct1`, `ct2`, or `ct3`) to which to apply a policer action.

Policer actions—You can specify the following policer actions:

- **Default:** no action
- `drop`—Drop all packets.
- `loss-priority-high`—Set the packet loss priority (PLP) to high.
- `loss-priority-low`—Set the PLP to low.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced for QFX10000 Series switches in release 15.1X53-D40.

Statement introduced for MX240, MX480, MX960, MX2010, and MX2020 routers with MPC10E and MPC11E line cards in Junos OS 20.2R1.

bandwidth (Fast Reroute, Signaled, and Multiclass LSPs)

IN THIS SECTION

- Syntax | 2418
- Hierarchy Level | 2418
- Description | 2419
- Options | 2419
- Required Privilege Level | 2419
- Release Information | 2420

Syntax

```
bandwidth bps {
    ct0 bps;
    ct1 bps;
    ct2 bps;
    ct3 bps;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name],
```

```
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name fast-
reroute],
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name (primary |
secondary) path-name],
[edit protocols mpls],
[edit protocols mpls label-switched-path lsp-name],
[edit protocols mpls label-switched-path lsp-name fast-reroute],
[edit protocols mpls label-switched-path lsp-name (primary | secondary) path-name]
```

Description

When configuring an LSP, specify the traffic rate associated with the LSP.

When configuring fast reroute, allocate bandwidth for the reroute path. By default, no bandwidth is reserved for the rerouted path. The fast reroute bandwidth does not need to be identical to that allocated for the LSP itself.

When configuring a multiclass LSP, use the `ct`*number bandwidth* statements to specify the bandwidth to be allocated for each class type.

Options

bps—Bandwidth, in bits per second. You can specify this as an integer value. You can also use the abbreviations `k` (for a thousand), `m` (for a million), or `g` (for a billion).

- **Range:** Any positive integer
- **Default:** 0 (no bandwidth is reserved)

> **NOTE**: On the ACX Series, *bps* is the only supported option.

`ct`*number bps*—Bandwidth for the specified class type, in bits per second. You can specify this as an integer value. If you do so, count your zeros carefully, or you can use the abbreviations `k` (for a thousand), `m` (for a million), or `g` (for a billion [also called a thousand million]).

- **Range:** Any positive integer
- **Default:** 0 (no bandwidth is reserved)

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

- Release Information | 2423

Syntax

```
bandwidth-model {
    extended-mam;
    mam;
    rdm;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls diffserv-te],
[edit protocols mpls diffserv-te]
```

Description

Configure the bandwidth model for differentiated services. Note that you cannot configure both bandwidth models at the same time.

Options

`extended-mam`—The extended maximum allocation model (MAM) is a bandwidth model based on MAM.

`mam`—The MAM is defined in RFC 4125, *Maximum Allocation Bandwidth Constraints Model for Diffserv-aware MPLS Traffic Engineering*.

`rdm`—The Russian dolls bandwidth allocation model (RDM) is defined in RFC 4127, *Russian Dolls Bandwidth Constraints Model for Diffserv-aware MPLS Traffic Engineering*. RDM makes efficient use of bandwidth by allowing the class types to share bandwidth.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name fast-reroute],
[edit protocols mpls label-switched-path lsp-name fast-reroute]
```

Description

Configure the percentage of bandwidth to reserve for the detour path in case the primary path for a traffic engineered LSP or a multiclass LSP fails. The percentage configured indicates the percentage of the protected path's bandwidth that is reserved for the detour path.

Options

percentage—The percentage of the protected path's bandwidth that is reserved for the detour path.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

bfd-liveness-detection (Protocols MPLS)

IN THIS SECTION

- Syntax | 2425
- Hierarchy Level | 2425
- Description | 2425
- Options | 2426
- Required Privilege Level | 2426
- Release Information | 2426

Syntax

```
bfd-liveness-detection {
    failure-action {
        make-before-break teardown-timeout seconds;
        teardown;
    }
    minimum-interval milliseconds;
    minimum-receive-interval milliseconds;
    minimum-transmit-interval milliseconds;
    multiplier detection-time-multiplier;
}
```

Hierarchy Level

```
[edit protocols mpls label-switched-path lsp-name oam],
[edit protocols mpls oam]
```

Description

Enable Bidirectional Forwarding Detection (BFD) for all of the MPLS LSPs or for just a specific LSP.

Options

`minimum-interval`—Minimum transmit and receive interval.

- **Range:** 50 through 255,000 milliseconds
- **Default:** 50

`minimum-receive-interval`—Minimum receive interval.

- **Range:** 50 through 255,000 milliseconds
- **Default:** 50

`minimum-transmit-interval`—Minimum transmit interval.

- **Range:** 50 through 255,000 milliseconds
- **Default:** 50

`multiplier`—Detection time multiplier.

- **Range:** 1 through 255
- **Default:** 3

The `failure-action` statement is explained separately.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 7.6.

`failure-action` option added in Junos OS Release 8.5.

bfd-liveness-detection (Source Packet Routing Template)

IN THIS SECTION

- Syntax | 2427
- Hierarchy Level | 2427
- Description | 2427
- Options | 2428
- Required Privilege Level | 2428
- Release Information | 2428

Syntax

```
bfd-liveness-detection {
    minimum-interval milliseconds;
    multiplier multiplier;
    no-router-alert-option;
    sbfd;
}
```

Hierarchy Level

```
[edit protocols source-packet-routing source-routing-path-template]
```

Description

Configure Bidirectional forwarding detection (BFD) options for PCE-initiated segment routing LSP template.

NOTE: The BFD configuration is applied at the top level and not individually per segment list. As a result, each path of the PCE-initiated LSP inherits the same BFD configuration.

Options

minimum-interval Specify in milliseconds the minimum transmit and receive interval.

- **Range:** 1 through 255000 milliseconds

multiplier Specify the detection time multiplier.

- **Default:** 3
- **Range:** 1 through 255

no-router-alert-option Do not set the router alert option in the IP header.

The remaining statements are explained separately. See CLI Explorer.

[edit protocols mpls label-switched-path lsp-name (primary | secondary) path-name],
[edit logical-systems logical-system-name protocols mpls static-label-switched-path lsp-name
ingress]
```

Description

Class-of-service (CoS) value given to all packets in the LSP.

The CoS value might affect the scheduling or queuing algorithm of traffic traveling along an LSP.

Options

cos-value—CoS value. A higher value typically corresponds to a higher level of service.

- **Range:** 0 through 7
- **Default:** If you do not specify a CoS value, the IP precedence bits from the packet's IP header are used as the packet's CoS value.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

- Description | 2434
- Options | 2434
- Required Privilege Level | 2435
- Release Information | 2435

Syntax

```
compute-profile name {
    protected {
        mandatory;
    }
    unprotected {
        mandatory;
    }
```

```
    admin-group include-any [ include-any ... ]include-all [ include-all ... ]exclude
[ exclude ... ];
    compute-segment-list compute-segment-list;
    maximum-computed-segment-lists maximum-computed-segment-lists;
    maximum-segment-list-depth maximum-segment-list-depth;
    metric-type {
        (igp | te | delay);
    }
    no-label-stack-compression;
}
```

Hierarchy Level

```
[edit protocols source-packet-routing]
```

Description

Configure the compute profile for dynamically computed paths. You can use a compute profile to logically group the computation constraints. These compute profiles are referenced by the segment routing paths for computing the primary and secondary segment routing LSPs.

Options

name Name of the computation-profile.

protected Choose protected labels if available.

- Values:
  - mandatory—Mandatorily choose protected labels.

unprotected Choose unprotected labels if available.

- Values:
  - mandatory—Mandatorily choose unprotected labels.

compute-segment-list Name of the compute type segment list.

maximum-computed-segment-lists Maximum number of segment-lists (ECMP paths) to be computed.

- **Range:** 1 through 128

maximum-segment-list-depth Maximum depth of computed path.

- **Range:** 1 through 16

metric-type Specify the metric type used for computation.

- Values:
  - igp—Interior gateway protocol metric.
  - te—Traffic-engineering metric.
  - delay—Compute delay metrics.

    For metric-type delay, you can assign the following metric types:
    - minimum—Minimum delay metric value from TED for cumulative lowest latency path calculation. The minimum delay metric is enabled by default.
    - average—Average delay metric value from TED for cumulative lowest latency path calculation.
    - maximum—Maximum delay metric value from TED for cumulative lowest latency path calculation.
    - delay-variation-threshold <value>—Link delay variation threshold (1..16777215). Any link exceeding the delay variation threshold would be excluded from path calculation. The delay variation threshold is independent of whether you are doing optimization for minimum, maximum, or average.

no-label-stack-compression Provide fully expanded path, using adjacency segment identifiers.

The remaining statements are explained separately. See CLI Explorer.

Statement introduced in Junos OS Release 20.3R1 and Junos OS Evolved Release 20.3R1 on all platforms.

Description

The statement enables you to delay the CSPF by configured number of seconds, on receiving bandwidth unavailable PathErr on PSB2. If the configured value is zero, then the CSPF starts immediately for PSB2, when bandwidth-unavailable PathErr is received. If the statement is not configured, the default exponential back-off occurs.

Options

seconds—CSPF delay time in seconds.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

- Options | 2459
- Required Privilege Level | 2460
- Release Information | 2460

Syntax

```
dual-transport {
    inet-lsr-id inet-lsr-id;
    inet6-lsr-id inet6-lsr-id;
}
```

Hierarchy Level

```
[edit protocols ldp]
```

Description

Configure to allow Junos LDP to establish the TCP connection over IPv4 with IPv4 neighbors, and over IPv6 with IPv6 neighbors as a single-stack LSR. `inet-lsr-id` and `inet6-lsr-id` are the two LSR IDs that have to be configured to establish an LDP session over IPv4 and IPv6 TCP transport. These two IDs should be non-zero and must be configured with different values.

Options

inet-lsr-id *inet-lsr-id* Configure the LSR ID to establish an LDP session over IPv4 TCP transport.

inet6-lsr-id *inet6-lsr-id* Configure the LSR ID to establish an LDP session over IPv6 TCP transport.

Required Privilege Level

dynamic (Source Packet Routing)

IN THIS SECTION

- Syntax | **2461**
- Hierarchy Level | **2461**
- Description | **2461**
- Options | **2462**
- Required Privilege Level | **2462**
- Release Information | **2462**

Syntax

```
dynamic {
    protected {
        mandatory;
    }
    unprotected {
        mandatory;
    }
}
```

Hierarchy Level

```
[edit protocols source-packet-routing segment-list]
```

Description

Enable dynamic computation of segment routing label-switched paths (LSPs) based on tunnel destination and translation service to fetch the corresponding segment identifiers (SIDs).

NOTE:

When the dynamic statement is enabled, all the next hops must have an IP address assigned as a minimum configuration. In the case of segment-lists, if a next hop has both IP address and label configured, then the configured label is retained.

NOTE:

- Because translation service use IGP instance of traffic-engineered database (TED), you must include the `igp-topology` statement at the `[edit protocols isis traffic-engineering]` hierarchy level for successful translation.
- The `auto-translation` and `dynamic` statements are mutually exclusive, and only either of them can be configured under a segment-list.

Options

protected (Optional) Ensures a protected adjacency SID is used for the links of the LSP.

unprotected (Optional) Ensures an unprotected adjacency SID is used for the links of the LSP.

mandatory (Optional) Enabled translation to fail if the specified type of adjacency SID cannot be found for a link. This option does not have effect on node SIDs.

Required Privilege Level

routing

options],
[edit logical-systems logical-system-name routing-options],
[edit routing-instances routing-instance-name routing-options],
[edit routing-options]
```

Description

Configure a dynamic tunnel between two PE routers.

NOTE: ACX Series routers do not support the `gre` statement.

Configure dynamic IPv4-over-IPv6 tunnels and define their attributes to forward IPv4 traffic over an IPv6-only network. IPv4 traffic is tunneled from customer premises equipment to IPv4-over-IPv6 gateways. You must also configure `extended-nexthop` option at `[edit protocols bgp family inet unicast]` hierarchy level to allow BGP to route IPv4 address families over an IPv6 session.

Options

bgp-signal Enable the creation of a tunnel signaled by BGP.

gre Enable dynamic generic routing encapsulation type tunnel mode for IPv4.

- Values:
  - `next-hop-based-tunnel`—Enable next hop base dynamic-tunnel for steering IPv4 traffic with IPv6 next hop address.

ipip Enable dynamic IP in IP encapsulation type tunnel mode for IPv4

- Values:
  - `full-resolved-next-hop-based-tunnel`—Enable fully resolved next hop base dynamic-tunnel for steering IPv4 traffic with IPv6 next hop address.

source-address Specify the source address of the tunnel.

tunnel-name Name of the dynamic tunnel.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

`bgp-signal` option introduced in Junos OS Release 17.4R1.

egress-chaining

IN THIS SECTION

- Syntax | 2465
- Hierarchy Level | 2465
- Description | 2465
- Options | 2466
- Required Privilege Level | 2466
- Release Information | 2466

Syntax

```
egress-chaining {
    spring-te;
}
```

Hierarchy Level

```
[edit routing-options forwarding-table],
```

Description

Enable egress chaining for devices that support a maximum of two labels push at the ingress. You can configure egress chaining to implement more than two labels push using a composite next hop at the

egress and pass a pointer from the ingress to the egress about the location of its label stack. Route pointing to this next hop chain can be IPv4, IPV6, or an MPLS label (binding segment ID).

NOTE:

- Label push at the egress should ensure that they are pushed ahead of any other labels programmed at the egress.
- Egress chaining is possible for one chain only. Any more composite next hops after egress chaining are flattened into forwarding next hops.
- Junos OS release 20.4R1 supports only a single egress chain.

Options

spring-te Enable egress chaining for segment routing traffic-engineered (SPRING-TE) routes.

When you configure the `spring-te`, you set the egress chain flag in the SPRING-TE route's next hop. This enables installation of a composite next hop in the egress Packet Forwarding Engine (PFE).

NOTE: Ensure that you do not resolve the SPRING-TE route further over another composite next hop when the `spring-te` option is enabled.

Required Privilege Level

routing

Release Information

Statement introduced in Junos OS Release 20.4R1.

Syntax

```
entropy-label {
    ingress-policy ingress-policy-name;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp],
```

Description

Assists the transit router in load-balancing MPLS traffic across ECMP paths or Link Aggregation groups by introducing the entropy label to the MPLS label stack. The entropy label allows routers to load balance MPLS traffic by using a hash-input without the need to perform deep packet inspection. Deep packet inspection requires more of the router's processing power and is not a capability shared by all routers.

Options

The other statements are explained separately.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 14.1.

- Description | 2474
- Options | 2475
- Required Privilege Level | 2475
- Release Information | 2475

Syntax

```
entropy-label {
    import policy-name;
    no-next-hop-validation;
}
```

Hierarchy Level

```
[edit logical-systems logical-system name protocols bgp family inet labeled-unicast],
[edit logical-systems logical-system name protocols bgp group group-name family inet labeled-
unicast],
[edit logical-systems logical-system name protocols bgp group group-name neighbor address
labeled-unicast],
[edit protocols bgp family inet labeled-unicast],
[edit protocols bgp group group-name family inet labeled-unicast],
[edit protocols bgp group group-name neighbor address labeled-unicast]
```

Description

Insert the entropy label into the BGP labeled unicast LSP packets, which assists the transit router in load-balancing BGP traffic across equal-cost multipaths or link aggregation groups. The ingress label edge router inspects the flow information of a packet and maps it to an entropy label, which is inserted

into the BGP label stack. LSRs in the core use this entropy label as the key to hash the packet and direct it to the correct path.

Options

`import` *`policy-name`*	(Optional) Specify a policy that lists the routes that allow the use of entropy labels.
`no-next-hop-validation`	(Optional) Do not validate the next-hop field in the entropy label capability attribute against the route next hop.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Syntax

```
ether-pseudowire {
    zero-control-word;
}
```

Hierarchy Level

```
[edit forwarding-options enhanced-hash-key family mpls]
```

Description

Load-balance IP over Ethernet pseudowire. Presence of zero-control-word in the payload indicates an Ethernet frame.

zero-control-word Precedes Ethernet packet to indicate the start Ethernet farme in an MPLS ether-pseudowire payload.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 16.1 for the MX Series.

exclude (for Administrative Groups)

IN THIS SECTION

- Syntax | **2478**
- Hierarchy Level | **2478**
- Description | **2479**
- Options | **2479**
- Required Privilege Level | **2479**
- Release Information | **2479**

Syntax

```
exclude [ group-names ];
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name admin-group],
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name (primary |
secondary) path-name admin-group],
```

```
[edit protocols mpls label-switched-path lsp-name admin-group],
[edit protocols mpls label-switched-path lsp-name (primary | secondary) path-name admin-group]
```

Description

Define the administrative groups to exclude for an LSP or for a path's primary and secondary paths.

Options

group-names—Names of one or more groups defined with the "admin-groups" on page 2398 statement.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

protection],
[edit protocols rsvp interface interface-name link-protection bypass destination],
[edit logical-systems logical-system-name protocols rsvp interface interface-name link-
protection bypass destination]
```

Description

Exclude Shared Risk Link Group (SRLG) links for the secondary path for critical links where it is imperative to keep the secondary and primary label-switched paths completely disjoint from any common SRLG.

When specified, the Constrained Shortest Path First (CSPF) algorithm excludes any link belonging to the set of SRLGs in the primary path. When not specified and if a link belongs to the set of SRLGs in the primary path, CSPF adds the SRLG cost to the metric, but still accepts the link for computing the path.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 11.4.

[edit class-of-service classifiers],
[edit class-of-service code-point-aliases],
[edit class-of-service interfaces interface-name unit logical-unit-number rewrite-rules],
[edit class-of-service rewrite-rules]
```

Description

Define the experimental bits (EXP) code point mapping that is applied to MPLS packets. You can define an exp classifier only on EX3200 switches, EX4200 and EX8200 standalone switches, and EX8200 Virtual Chassis. You can bind an exp rewrite rule on EX8200 standalone switches and EX8200 Virtual Chassis.

EX Series switches support only one EXP code mapping on the switch (either default or custom). It is applied globally and implicitly to all the MPLS-enabled interfaces on the switch. You cannot bind it or disable it on individual interfaces.

Options

classifier-name—Name of the classifier.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 10.1.

Syntax

```
expand-loose-hop;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],
[edit protocols mpls]
```

Description

Allow an LSP to traverse multiple OSPF areas within a service provider's network.

Allows a point-to-multipoint LSP to span multiple domains in a network. Effectively, this allows you to configure one or more sub-LSPs (branches) in separate network domains. Examples of such domains include OSPF areas and autonomous systems (ASs). A sub-LSP of an inter-domain point-to-multipoint

LSP can be intra-area, inter-area, or inter-AS, depending on the location of the egress node (leaf) with respect to the ingress node (source). Only OSPF areas are supported for inter-domain point-to-multipoint LSPs. IS-IS levels are not supported.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 7.6.

Point-to-multipoint LSP support introduced in Junos OS Release 11.2.

liveness-detection],
[edit protocols mpls label-switched-path lsp-name oam bfd-liveness-detection],
[edit protocols mpls oam bfd-liveness-detection]
```

Description

Configure route and next-hop properties in the event of a Bidirectional Forwarding Detection (BFD) protocol session failure event on an RSVP label-switched path (LSP). The failure event could be an existing BFD session that has gone down or a BFD session that never came up. RSVP adds back the route or next hop when the relevant BFD session comes back up.

Options

`make-before-break`—When a BFD session fails for an RSVP LSP, an attempt is made to signal a new LSP path before tearing down the old LSP path.

`teardown`—When a BFD session fails for an RSVP LSP, the associated LSP path is taken down and resignaled immediately.

`teardown-timeout` *seconds*—When you configure the `make-before-break` option, you can specify a time in seconds for the `teardown-timeout` option. At the end of the time specified, the associated RSVP LSP is automatically torn down and resignaled.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.4.

                source-msb;
                source-lsb;
                destination-msb;
                destination-lsb;
            }
        }
    }
}
```

Hierarchy Level

```
[edit forwarding-options hash-key]
```

Description

For aggregated Ethernet and SONET/SDH interfaces only, configure load balancing based on MPLS labels and payload. Only the IPv4 protocol is supported.

Options

`family mpls`—(Aggregated Ethernet interfaces, aggregated SONET/SDH interfaces, and multiple equal-cost MPLS next hops only) Incorporate MPLS label and payload information into the hash key for per-flow load balancing. Only the IPv4 protocol is supported.

- `all-labels`—(PTX Series Packet Transport Routers only) Up to eight MPLS labels are included in the hash key to identify the uniqueness of a flow in the Packet Forwarding Engine. This is the default setting.
- `label-1`—(M120, M320, MX Series, and T Series routers only) Include the first MPLS label into the hash key. This is used for a one-label packet for per-flow load balancing IPv4 VPLS traffic based on IP information and MPLS labels.
- `label-2`—(M120, M320, MX Series, and T Series routers only) Include the second MPLS label into the hash key. This is used for a two-label packet for per-flow load balancing IPv4 VPLS traffic based on IP information and MPLS labels. To use the second MPLS label in the hash key, include both the `label-1`

and label-2 statements at the [edit forwarding-options hash-key family mpls] hierarchy level. By default, the router provides hashing on the first and second labels. If both labels are specified, the entire first label and the first 16 bits of the second label are hashed.

- label-3—(M120, M320, MX Series, and T Series routers only) Include the third MPLS label into the hash key. To use the third MPLS label, include the label-1, label-2, and label-3 statements at the [edit forwarding-options hash-key family mpls] hierarchy level.
- no-labels—Include no MPLS labels into the hash key.
- no-label-1-exp—(M120, M320, MX Series, and T Series routers only) The EXP bit of the first label is not used in the hash calculation to avoid reordering complications.
- payload—Incorporate bits from the IP payload into the hash key for per-flow load balancing Layer 2 information based on MPLS labels.
  - disable—(PTX Series Packet Transport Routers only) Exclude IP payload from the hash key.
  - ether-pseudowire—(M120, M320, MX Series, and T Series routers only) Load-balance IPv4 traffic over Layer 2 Ethernet pseudowires.
  - zero-control-word—(M Series, MX Series, and PTX Series) Precedes Ethernet packet to indicate the start of an Ethernet frame in an MPLS ether-pseudowire payload.
  - ip—Include the IP address of the IPv4 or IPv6 payload into the hash key for per-flow load balancing Layer 2 information based on MPLS labels. For the PTX Series Packet Transport Routers, this is the default setting with both Layer 3 and Layer 4 IP information included in the hash key.
    - disable—(PTX Series Packet Transport Routers only) Exclude IP payload from the hash key.
    - layer-3-only—Include only Layer 3 IP information from the IP payload data into the hash key for per-flow load balancing Layer 2 information based on MPLS labels.
    - port-data—(M120, M320, MX Series, and T Series routers only) Include the source and destination port field information into the hash key. By default, the most significant byte and least significant byte of the source and destination port fields are hashed. To select specific bytes to be hashed, include one or more of the source-msb, source-lsb, destination-msb, and destination-lsb options at the [edit forwarding-options hash-key family mpls payload ip port-data] hierarchy level. To prevent all four bytes from being hashed, include the layer-3-only statement at the [edit forwarding-options hash-key family mpls payload ip] hierarchy level.
      - destination-lsb—Include the least-significant byte of the destination port.
      - destination-msb—Include the most-significant byte of the destination port.
      - source-lsb—Include the least-significant byte of the source port.

- source-msb—Include the most-significant byte of the source port.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

no-label-1-exp option introduced in Junos OS Release 8.0.

label-3 and no-labels options introduced in Junos OS Release 8.1.

ether-pseudowire statement introduced in Junos OS Release 9.1 (M320 and T Series routers only); support extended to M120 and MX Series routers in Junos OS Release 9.4.

all-labels and payload ip disable options introduced in Junos OS Release 12.1X48R2. (PTX Series Packet Transport Routers only).

zero-control-word option introduced in Junos OS Release 16.1 for the M Series, MX Series, and PTX Series.

[edit logical-systems logical-system-name routing-instances routing-instance-name routing-
options],
[edit routing-options],
[edit routing-instances routing-instance-name routing-options]
```

Description

Specify a backup path in case the primary path becomes unusable.

You specify one or more objects with common characteristics within a group. All objects are treated as /32 host addresses. The objects can be a LAN interface, a router ID, or a point-to-point link. Sequence is insignificant.

Changing the fate-sharing database does not affect existing established LSPs until the next CSPF reoptimization. The fate-sharing database does affect fast-reroute detour path computations.

Options

`cost` *value*—Cost assigned to the group.

- **Range:** 1 through 65,535
- **Default:** 1

`from` *address*—Address of the router or address of the LAN/NBMA interface. For example, an Ethernet network with four hosts in the same fate-sharing group would require you to list all four of the separate `from` addresses in the group.

`group` *group-name*—Each fate-sharing group must have a name, which can have a maximum of 32 characters, including letters, numbers, periods (.), and hyphens (-). You can define up to 512 groups.

`to` *address*—(Optional) Address of egress router. For point-to-point link objects, you must specify both a `from` and a `to` address.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

fib-next-hop-split

IN THIS SECTION

- Syntax | 2498
- Hierarchy Level | 2498
- Description | 2499
- Options | 2499
- Required Privilege Level | 2499
- Release Information | 2499

Syntax

```
fib-next-hop-split {
    labeled-isis;
}
```

Hierarchy Level

```
[edit routing-options forwarding-table],
```

Description

You must configure the `fib-next-hop-split` statement in conjunction with the "egress-chaining" on page 2465 and "transit" on page 3334 statements to enable route resolution over labeled IS-IS routes using flattened router next hops. Configuring the `fib-next-hop-split` statement alone does not have any effect.

When you configure the `no-labeled-isis` statement at the `[edit routing-options forwarding-table chained-composite-next-hop transit]` hierarchy level, the labeled IS-IS routes are flattened to ensure that the segment routing traffic-engineering (SPRING-TE) routes are not resolved any further over another composite next hop.

Options

labeled-isis Create composite-chained next hops for labeled IS-IS routes.

In addition to enabling `fib-next-hop-split`, you can also configure "egress-chaining" on page 2465 to reduce the number of chained next hops present in a route that involves resolution over multiple routes with labels.

Required Privilege Level

routing

Release Information

Statement introduced in Junos OS Release 20.4R1.

gpid (ethernet | hdlc | ipv4 | pos-scrambling-crc-16 | pos-no-scrambling-crc-16 | pos-scrambling-crc-32 | pos-no-scrambling-crc-32 | ppp);
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name lsp-attributes],
[edit protocols mpls label-switched-path lsp-name lsp-attributes]
```

Description

Specify the type of payload carried by the LSP. It can be any of the following:

- `ethernet`—Ethernet (GPID value: 33)
- `hdlc`—High-level Data Link Control (HDLC) (GPID value: 44)
- `ipv4`—IP version 4 (GPID value: 0x0800)
- `pos-no-scrambling-crc-16`—for interoperability with other vendors' equipment (GPID value: 29)
- `pos-no-scrambling-crc-32`—for interoperability with other vendors' equipment (GPID value: 30)
- `pos-scrambling-crc-16`—for interoperability with other vendors' equipment (GPID value: 31)
- `pos-scrambling-crc-32`—for interoperability with other vendors' equipment (GPID value: 32)
- `ppp`—Point-to-Point Protocol (PPP) (GPID value: 50)

Default

`ipv4`

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

`pos-scrambling-crc-16`, `pos-no-scrambling-crc-16`, `pos-scrambling-crc-32`, and `pos-no-scrambling-crc-32` options added in Junos OS Release 8.0.

gre (Routing Options)

IN THIS SECTION

- Syntax | **2507**
- Hierarchy Level | **2507**
- Description | **2508**
- Options | **2508**
- Required Privilege Level | **2508**
- Release Information | **2508**

Syntax

```
gre;
next-hop-based-tunnel;
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-options dynamic-tunnels tunnel-name],
[edit routing-options dynamic-tunnels tunnel-name]
```

Description

Enable generic routing encapsulation (GRE) type for IPv4 to automatically establish label-switched paths (LSPs) for any new provider edge (PE) router added to a full mesh of LSPs.

Options

next-hop-based-tunnel Create a tunnel composite next hop for every dynamic GRE tunnel configured. The tunnel composite next hop includes the dynamic tunnel's encapsulation data and a VPN label (when chained composite next hop is not enabled). When this option is not configured, the default interface-based tunnel mode is enabled. By configuring this option, a device can scale up to 32,000 IP tunnels, which is otherwise restricted to the system limit on the number of interfaces supported.

At a given point in time, either the next-hop-based dynamic tunnel or the default interface-based dynamic GRE tunnel can exist on a device. A switchover from one tunnel mode to another deletes the existing tunnels and creates new tunnels in the new tunnel mode. As a result, a tunnel mode switchover can impact network performance.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 10.1.

`next-hop-based-tunnel` option introduced in Junos OS Release 16.2.

[edit protocols rsvp interface interface-name link-protection],
[edit protocols rsvp interface interface-name link-protection bypass bypass-name]
```

Description

Specify the maximum number of routers that an LSP can traverse. This limit can be applied to any of the following:

- LSPs—The configured hop limit includes the ingress and egress routers. You can specify a hop limit for an LSP and for both primary and secondary paths.
- Fast reroute detour—Specify the number of additional routers a fast reroute detour can traverse relative to the protected LSP. For example, if an LSP traverses 4 routers, any detour for the LSP can be no more than 10 router hops, including the ingress and egress routers.
- Link protection bypass—Specify the maximum number of routers that a link protection bypass can traverse.

Options

number—Maximum number of hops.

- **Range:** 2 through 255 (for an LSP or for a link protection bypass); 0 through 255 (for fast reroute)
- **Default:** 255 (for an LSP or for a link protection bypass); 6 (for fast reroute)

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

import (MPLS Traffic Engineering Database)

IN THIS SECTION

- Syntax | 2511
- Hierarchy Level | 2511
- Description | 2511
- Options | 2512
- Required Privilege Level | 2512
- Release Information | 2512

Syntax

```
import {
    bgp-ls-identifier domain-identifier;
    identifier identifier;
    ipv6;
    policy policy-name;
    igp-topology{
        bgp-link-state;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls traffic-engineering database],
[edit protocols mpls traffic-engineering database]
```

Description

Configure the traffic engineering database import parameters.

Options

bgp-ls-identifier *domain-identifier*
BGP-TE domain identifier.

identifier *identifier*
BGP-TE identifier.

- **Range:** 2 through 18446744073709551615

ipv6
Enable import of IPv6 addresses into the traffic engineering database (TED).

policy *policy-name*
Name of the import policy.

igp-topology
Download IGP topology information into the traffic engineering database (TED). In Junos OS, the IGPs install topology information into a database called the traffic engineering database. The traffic engineering database contains the aggregated topology information. The IGP routes are installed by the traffic engineering database on behalf of the corresponding IGP into a user-visible routing table called lsdist.0, subject to route policies.

bgp-link-state
Export IGP topology information into BGP-Link State (BGP-LS) from the lsdist.0 routing table. The lsdist.0 routing table stores the network topology information from the traffic engineering database. The BGP-LS reads IGP entries from lsdist.0 and advertises the information to BGP peers.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 14.2.

`ipv6` option introduced in Junos OS Release 20.4R1.

ip-tunnel-rpf-check

IN THIS SECTION

- Syntax | 2513
- Hierarchy Level | 2513
- Description | 2513
- Options | 2514
- Required Privilege Level | 2514
- Release Information | 2514

Syntax

```
ip-tunnel-rpf-check {
    mode (strict | loose);
    fail-filter filter-name;
}
```

Hierarchy Level

```
[edit routing-instances routing-instance-name routing-options forwarding-table]
```

Description

Configure the system to enable anti-spoofing protection for next-hop-based dynamic tunnels, where reverse path forwarding checks are placed to ensure that the tunnel traffic is received from a legitimate source through designated IP tunnel, where the source is reachable on the same tunnel on which the packet was received.

When a packet comes from a nondesignated source, the reverse path forwarding check fails in the strict mode, and passes in the loose mode. When a packet comes from a nonexistent source, the reverse path forwarding check fails.

By default, the reverse path forwarding check is in strict mode, where the packets are not forwarded if the source of the packet is from a nondesignated tunnel.

Options

mode (*strict* | *loose*)

(Optional) Specify the mode of the reverse path forwarding check to enable anti-spoofing protection for next-hop-based dynamic tunnels.

In the strict mode (default), the reverse path forwarding check fails when the packet is received from a nondesignated tunnel source. The check passes only for packets from designated tunnels.

In the loose mode, the reverse path forwarding check passes even if the packet is received from a nondesignated tunnel source.

When the packet is from a nonexistent tunnel source, the reverse path forwarding check fails in both the strict and loose modes.

- **Default:** If you omit the mode statement, the default behavior is strict mode.

fail-filter *filter-name*

(Optional) Attach a filter to the Layer 3 VPN to log packets that failed the reverse path forwarding check.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 17.1.

install (Protocols MPLS)

IN THIS SECTION

- Syntax | **2529**
- Hierarchy Level | **2529**
- Description | **2530**
- Options | **2531**
- Required Privilege Level | **2531**
- Release Information | **2531**

Syntax

```
install {
    destination-prefix <active>;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name],
[edit logical-systems logical-system-name protocols mpls static-label-switched-path lsp-name
ingress],
[edit protocols mpls label-switched-path lsp-name],
[edit protocols mpls static-label-switched-path lsp-name ingress]
[edit protocols source-packet-routing source-routing-path lsp-name]
```

Description

Associate one or more prefixes with an LSP. When the LSP is up, all the prefixes are installed as entries into the inet.3 or inet6.3 routing table.

The support of the `install` statement at the `[edit protocols source-packet-routing source-routing-path` *`lsp-name`*`]` is applicable for both colored and non-colored segment routing LSPs.

For static colored LSPs, when the install prefix is configured, a route similar to the tunnel ingress route is installed in the `inetcolor.0` or `inet6color.0` routing table.

On the other hand, for static non-colored LSPs, when the install prefix is configured, a route similar to the tunnel `to` route is installed in `inet.3` or `inet6.3` routing table.

You can use the *show route table* command to view the `install` routes for both colored and non-colored segment routing traffic-engineered LSPs.

NOTE: Take the following into consideration when configuring the `install` *`destination-prefix`* statement at the `[edit protocols source-packet-routing source-routing-path` *`lsp-name`*`]` hierarchy level:

- The install prefixes should be unique in a tunnel, and should not be the same as the tunnel `to` address. A commit check is done to ensure that the prefixes are unique.
- If two install prefixes are same across two different tunnels, then the gateways of the both tunnels are considered only if the segment lists are of the same resolution type. If the first hop resolution types vary, the route is not installed. In such cases, a system log message is generated to record the error.

For example:

```
[edit protocols source-packet-routing]
segment-list path-1 {
    hop-1 ip-address 172.0.12.2;
    hop-2 label 1000012;
    hop-3 label 1000013;
    hop-4 label 1000014;
}
source-routing-path lsp1 {
    to 10.10.10.1;
    install 20.20.20.2;
    install 30.30.30.3;
    primary {
        path-1;
```

```
    }
}
```

The `inet.3` routing table has two additional routes (to 20.20.20.2 and 30.30.30.3) with next hops derived from the same segment list path-1 with same attributes as the `to` address route.

Options

active (Optional) Install the route into the inet.0 or inet6.0 routing table. This allows you to issue a `ping` or `traceroute` command on this address.

> **NOTE**: The `install` *`destination-prefix`* `active` statement is not supported on static LSPs. When the `install` *`destination-prefix`* `active` statement is configured for a static LSP, the MPLS routes do not get installed into the inet.0 routing table.

destination-prefix IPv4 or IPv6 address to associate with the LSP.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Support at the `[edit protocols source-packet-routing source-routing-path` *`lsp-name`*`]` hierarchy level introduced in Junos OS Release 19.1R1.

}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],
[edit protocols mpls]
```

Description

Enable MPLS on one or more interfaces.

Options

interface-name—Name of the interface on which to configure MPLS. To configure all interfaces, specify `all`. For details about specifying interfaces, see the Junos OS Network Interfaces Library for Routing Devices.

`srlg` *srlg-name*—Name of the SRLG to associate with an interface.

The remaining options are explained separately.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

ip-tunnel-rpf-check

IN THIS SECTION

- Syntax | 2538
- Hierarchy Level | 2538
- Description | 2538
- Options | 2539
- Required Privilege Level | 2539
- Release Information | 2539

Syntax

```
ip-tunnel-rpf-check {
    mode (strict | loose);
    fail-filter filter-name;
}
```

Hierarchy Level

```
[edit routing-instances routing-instance-name routing-options forwarding-table]
```

Description

Configure the system to enable anti-spoofing protection for next-hop-based dynamic tunnels, where reverse path forwarding checks are placed to ensure that the tunnel traffic is received from a legitimate source through designated IP tunnel, where the source is reachable on the same tunnel on which the packet was received.

When a packet comes from a nondesignated source, the reverse path forwarding check fails in the strict mode, and passes in the loose mode. When a packet comes from a nonexistent source, the reverse path forwarding check fails.

By default, the reverse path forwarding check is in strict mode, where the packets are not forwarded if the source of the packet is from a nondesignated tunnel.

Options

mode (*strict* | *loose*)

(Optional) Specify the mode of the reverse path forwarding check to enable anti-spoofing protection for next-hop-based dynamic tunnels.

In the strict mode (default), the reverse path forwarding check fails when the packet is received from a nondesignated tunnel source. The check passes only for packets from designated tunnels.

In the loose mode, the reverse path forwarding check passes even if the packet is received from a nondesignated tunnel source.

When the packet is from a nonexistent tunnel source, the reverse path forwarding check fails in both the strict and loose modes.

- **Default:** If you omit the mode statement, the default behavior is strict mode.

fail-filter *filter-name*

(Optional) Attach a filter to the Layer 3 VPN to log packets that failed the reverse path forwarding check.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 17.1.

```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],
[edit protocols mpls]
```

Description

Configure an LSP to use in dynamic MPLS. When configuring an LSP, you must specify the address of the egress router in the `to` statement. All remaining statements are optional.

Options

lsp-name	Name that identifies the LSP. The name can be up to 64 characters and can contain letters, digits, periods, and hyphens. To include other characters, enclose the name in quotation marks. The name must be unique within the ingress router.
cross-credibility-cspf	Enable path computation across credibility levels. The constraint path computation is run across multi-protocol links and nodes, instead of a credibility-by-credibility basis.
link-protection	Enable protection for LSP from link faults only.
no-self-ping	Disable self-ping for the LSP.

> **NOTE**: Starting in Junos OS 17.4, you can override the behavior of self-ping running by default using `no-self-ping` statement.

`self-ping-duration` *seconds*

Specify the duration (in seconds) for which to run the self-ping mechanism unless the ping succeeds sooner.

LSP self-ping for an LSP starts at the ingress label edge router (LER), once a Resv message for that LSP has been received. The configured self-ping time indicates the duration for which the self-ping mechanism runs once the LSP instance is signaled to be `UP`.

By default, self-ping is enabled. The LSP types like CCC, P2MP, VLAN-based , and non-default instances do not support self-ping .

The self-ping mechanism runs until the self-ping probe is received back (at which point the traffic is immediately switched to it) , or until the configured self-ping duration for the LSP is over (at which point traffic is switched over).

When LSP self-ping-duration is enabled, the LSP behavior reverts back to a timer-based mechanism similar to the `optimize-switchover-delay`, where a specific amount of time is provided for all the downstream nodes to install the forwarding path before switchover. When LSP self-ping-duration is not enabled, the default behavior is to wait for an infinite amount of time for the self-ping to succeed before switching the traffic.

- **Range:** 1 through 65535 seconds

> **NOTE**: Starting in Junos OS 17.4R1, the default time-out duration for which the self-ping runs on an LSP instance is reduced from 65535 (runs until success) to 1800 seconds. You can also configure the self ping duration value between 1 to 65535 (runs until success) seconds.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

`cross-credibility-cspf` option introduced in Junos OS Release 14.2.

`self-ping-duration` and `no-self-ping` options introduced in Junos OS Release 16.1.

- Required Privilege Level | 2556
- Release Information | 2557

Syntax

```
log-updown {
    no-trap {
        mpls-lsp-traps;
        rfc3812-traps;
    }
    (syslog | no-syslog);
    trap;
    trap-path-down;
    trap-path-up;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],
[edit protocols mpls]
```

Description

Log a message or send an SNMP trap whenever an LSP makes a transition from up to down, or vice versa, and whenever an LSP switches from one active path to another. Only the ingress router performs these operations.

NOTE: System log messages for LSPs are generated by default. To disable the default logging of messages for LSPs, configure the `no-syslog` option under the `log-updown` statement.

Default

There is no default behavior for this statement. If you do not specify the options, the configuration cannot be committed.

Options

`no-syslog`—Do not log a message to the system log file.

`no-trap`—Do not send an SNMP trap.

`syslog`—Log a message to the system log file.

`trap`—Send an SNMP trap.

`trap-path-down`—Send an SNMP trap when an LSP path goes down.

`trap-path-up`—Send an SNMP trap when an LSP path comes up.

The `no-trap` statement is explained separately.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.
The `mpls-lsp-traps` and `rfc-3812-traps` options added in Junos OS Release 9.0.

lsp-attributes

IN THIS SECTION

- Syntax | 2564
- Hierarchy Level | 2564
- Description | 2564
- Required Privilege Level | 2564
- Release Information | 2564

Syntax

```
lsp-attributes {
    encoding-type (ethernet | packet | pdh | sonet-sdh);
    gpid (ethernet | hdlc | ipv4 | pos-scrambling-crc-16 | pos-no-scrambling-crc-16 | pos-
scrambling-crc-32 | pos-no-scrambling-crc-32 | ppp);
    signal-bandwidth type;
    switching-type (fiber | lambda | psc-1 | tdm);
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name],
[edit protocols mpls label-switched-path lsp-name]
```

Description

Define the parameters signaled during LSP setup. These usually determine the nature of the resource (label) allocated for the LSP.

The remaining statements are explained separately.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

`pos-scrambling-crc-16`, `pos-no-scrambling-crc-16`, `pos-scrambling-crc-32`, and `pos-no-scrambling-crc-32` options added in Junos OS Release 8.0.

RELATED DOCUMENTATION

lsping-channel-type

IN THIS SECTION

- Syntax | 2565
- Hierarchy Level | 2565
- Description | 2565
- Options | 2566
- Required Privilege Level | 2566
- Release Information | 2566

Syntax

```
lsping-channle-type {
    ipv4;
    on-demand-cv;
}
```

Hierarchy Level

```
[edit protocols mpls label-switched-path  lsp-name oam mpls-tp-mode]
[edit protocols mpls oam mpls-tp-mode]
```

Description

Specify the control-channel types for MPLS-TP mode. By default, LSPING (0x0008) is used, and the GACH-TLV is used along with this channel type.

As per RFC 7026, GACH-TLV is deprecated for ipv4 and on-demand-cv channel types.

Options

ipv4	Channel type 0x0021. This channel type uses the IP/UDP encapsulation and provides interoperability support with other vendor devices using IP addressing.
on-demand-cv	Channel type 0x0025. This is a new pseudowire channel type and is used for on-demand CV without IP/UDP encapsulation, where IP addressing is not available or non-IP encapsulation is preferred.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 16.1.

maximum-helper-recovery-time

IN THIS SECTION

- Syntax | 2571
- Hierarchy Level | 2571
- Description | 2571
- Options | 2571
- Required Privilege Level | 2572
- Release Information | 2572

Syntax

```
maximum-helper-recovery-time seconds;
```

Hierarchy Level

```
[edit protocols rsvp graceful-restart],
[edit logical-systems logical-system-name protocols rsvp graceful-restart]
```

Description

Specify the length of time the router or switch retains the state of its Resource Reservation Protocol (RSVP) neighbors while they undergo a graceful restart.

Options

seconds—Legnth of time that the router retains the state of its Resource Reservation Protocol (RSVP) neighbors while they undergo a graceful restart.

- **Range:** 1 through 3600
- **Default:** 180

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Syntax

```
maximum-helper-restart-time seconds;
```

Hierarchy Level

```
[edit protocols rsvp graceful-restart],
[edit logical-systems logical-system-name protocols rsvp graceful-restart]
```

Description

Specify the length of time the router or switch waits after it discovers that a neighboring router has gone down before it declares the neighbor down. This value is applied to all RSVP neighbor routers and should be based on the time that the slowest RSVP neighbor requires for restart.

Options

seconds—The time the router or switch waits after it discovers that a neighboring router has gone down before it declares the neighbor down.

- **Range:** 1 through 1800
- **Default:** 60

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 8.3.

metric (Protocols MPLS)

IN THIS SECTION

- Syntax | 2579
- Hierarchy Level | 2580
- Description | 2580
- Options | 2580
- Required Privilege Level | 2580
- Release Information | 2580

Syntax

```
metric metric;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name],
[edit logical-systems logical-system-name protocols mpls static-label-switched-path lsp-name
ingress],
[edit protocols mpls label-switched-path lsp-name],
[edit protocols mpls static-label-switched-path lsp-name ingress]
```

Description

Compare against another LSP or against an IGP route. To disable dynamic metric tracking, assign a fixed metric value to an LSP. If no metric is assigned, the LSP metric is dynamic and automatically tracks underlying IGP metrics.

Options

metric—LSP metric value.

- **Default:** No metric assigned (dynamic)
- **Range:** 1 through 16,777,215

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

minimum-bandwidth

IN THIS SECTION

- Syntax | 2581
- Hierarchy Level | 2581
- Description | 2581
- Options | 2582
- Required Privilege Level | 2582
- Release Information | 2582

Syntax

```
minimum-bandwidth bps;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name auto-
bandwidth],
[edit protocols mpls label-switched-path lsp-name auto-bandwidth]
```

Description

Set the minimum bandwidth in bps for an LSP with automatic bandwidth allocation enabled.

NOTE: For a label-swtiched path (LSP) that has both `bandwidth` and `minimum-bandwidth` for autobandwidth configured under the `[edit protocols mpls label-switched-path lsp-name]` hierarchy level, the LSP bandwidth is adjusted differently.

The LSP is initiated with the bandwidth value configured under the `bandwidth` statement at the `[edit protocols mpls label-switched-path lsp-name]` hierarchy level. At the expiry of the `adjust-interval` timer, the LSP bandwidth gets adjusted based on the traffic flow.

If the bandwidth to be signaled is less than the value configured under the `minimum-bandwidth` statement at the `[edit protocols mpls label-switched-path lsp-name autobandwidth]` hierarchy level, then the LSP is signaled only using the minimum bandwidth.

If the bandwidth to be signaled is greater than the value configured under the `maximum-bandwidth` statement at the `[edit protocols mpls label-switched-path lsp-name autobandwidth]` hierarchy level, then the LSP is signaled only using the maximum bandwidth.

Options

bps—Miniminum bandwidth for the LSP.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

```
[edit protocols mpls label-switched-path lsp-name oam],
[edit protocols mpls oam]
```

Description

Enable GAL or G-Ach OAM operation without IP encapsulation on a label-switched path (LSP).

Include this statement at the `[edit protocols mpls oam]` hierarchy level to enable GAL or G-Ach OAM operation without IP encapsulation on all LSPs in the MPLS network. Include this statement at the `[edit protocols mpls label-switched-path lsp-name oam]` hierarchy level to enable GAL and G-Ach OAM operation without IP encapsulation on a specific LSP.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.1.

`lsping-channel-type` statement introduced in Junos OS Release 16.1.

```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols l2circuit],
[edit protocols l2circuit]
```

Description

Each Layer 2 circuit is represented by the logical interface connecting the local provider edge (PE) router or switch to the local customer edge (CE) router or switch. All the Layer 2 circuits using a particular remote PE router or switch designated for remote CE routers or switches are listed under the `neighbor` statement (neighbor designates the PE router or switch). Each neighbor is identified by its IP address and is usually the end-point destination for the LSP tunnel (transporting the Layer 2 circuit).

Options

address—IP address of a neighboring router or switch.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

no-bfd-triggered-local-repair

IN THIS SECTION

- Syntax | 2596
- Hierarchy Level | 2596
- Description | 2596
- Default | 2596

Required Privilege Level | 2596
Release Information | 2597

Syntax

```
no-bfd-triggered-local-repair;
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-options],
[edit routing-options]
```

Description

Disable Bidirectional Forwarding Detection (BFD) sessions to trigger fast reroute (FRR) using MPLS-FRR and loop-free alternates (LFAs). When this statement is configured, no BFD-triggered local repair is supported. However, logical interface down-based local repair is in force.

When using this statement to disable local repair, you also must restart routing to ensure proper behavior. To restart routing, include the **graceful-restart** command for the interior gateway protocol (IGP) used in your configuration. For example, if your IGP is OSPF, include the **graceful-restart** statement at the [edit protocols ospf] hierarchy level.

Default

BFD-triggered local repair is the default behavior. The loss of a neighbor results in BFD local repair for all next hops that derive themselves from the base next hop with which the BFD session is established.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.2.

```
[edit logical-systems logical-system-name protocols mpls],
[edit logical-systems logical-system-name protocols mplslabel-switched-path lsp-name],
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name (primary |
secondary) path-name],
[edit protocols mpls],
```

```
[edit protocols mpls label-switched-path lsp-name],
[edit protocols mpls label-switched-path lsp-name (primary | secondary) path-name]
```

Description

Disable constrained-path LSP computation.

An explicit-path LSP is completely configured through operator action. Once configured, it is initiated only along the explicitly specified path.

A constrained-path LSP relies on an ingress router to compute the complete path. The ingress router takes into account the following information during the computation:

- Interior gateway protocol (IGP) topology database
- Link utilization information from extensions in the IGP link-state database
- Administrative group information from extensions in the IGP link-state database
- LSP requirements, including bandwidth, hop count, and administrative group

Constrained-path LSPs can generally avoid link failures and congested links. They also permit recomputation (therefore, a new path) during topology changes or unsuccessful setup.

Default

Constrained-path LSP computation enabled.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

- Release Information | 2600

Syntax

```
no-decrement-ttl;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name],
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name (primary |
secondary) path-name],
[edit protocols mpls],
[edit protocols mpls label-switched-path lsp-name],
[edit protocols mpls label-switched-path lsp-name (primary | secondary) path-name]
```

Description

Disable normal time-to-live (TTL) decrementing, which decrements the TTL field in the IP header by 1. This statement decrements the IP TTL by 1 before encapsulating the IP packet within an MPLS packet. When the penultimate router pops off the top label, it does not use the standard write-back procedure of writing the MPLS TTL into the IP TTL field. Therefore, the IP packet is decremented by 1. The ultimate router then decrements the packet by one more for a total cloud appearance of 2, thus hiding the network topology.

Default

Normal TTL decrementing enabled; the TTL field value is decremented by 1 as the packet passes through each label-switched router in the LSP.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Evolved Release 20.1R1 on PTX10008.

graceful-restart (Enabling Globally)

IN THIS SECTION

- Syntax | 2601
- Hierarchy Level | 2601
- Description | 2601
- Default | 2602
- Options | 2602
- Required Privilege Level | 2602
- Release Information | 2602

Syntax

```
graceful-restart {
    disable;
    helper-disable;
    maximum-helper-recovery-time seconds;
    maximum-helper-restart-time seconds;
    notify-duration seconds;
    recovery-time seconds;
    restart-duration seconds;
    stale-routes-time seconds;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-options],
[edit logical-systems logical-system-name routing-instances routing-instance-name routing-
options],
[edit routing-options],
[edit routing-instances routing-instance-name routing-options]
```

Description

You configure the graceful restart routing option globally to enable the feature, but not to enable graceful restart for all routing protocols in a routing instance. To enable graceful restart globally, include the graceful-restart statement under the `[edit routing options]` hierarchy level. This enables graceful restart globally for all routing protocols. You can, optionally, modify the global settings at the individual protocol level.

NOTE:

- For VPNs, the `graceful-restart` statement allows a router whose VPN control plane is undergoing a restart to continue to forward traffic while recovering its state from neighboring routers.
- For BGP, if you configure graceful restart after a BGP session has been established, the BGP session restarts and the peers negotiate graceful restart capabilities.

- LDP sessions flap when `graceful-restart` configurations change.

Default

Graceful restart is disabled by default.

Options

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

no-mcast-replication

IN THIS SECTION

- Syntax | 2607
- Hierarchy Level | 2607
- Description | 2608
- Default | 2608
- Required Privilege Level | 2608
- Release Information | 2608

Syntax

```
no-mcast-replication;
```

Hierarchy Level

```
[edit chassis fpc slot-number pic pic-number],
[edit chassis lcc number fpc slot-number pic pic-number]
```

Description

For point-to-multipoint LSPs configured on T Series routers, protect the Packet Forwarding Engine (PFE) from bandwidth saturation. When a PFE does not need to replicate traffic, the PFE's bandwidth is less likely to become saturated. When you include the `no-mcast-replication` statement, the PFE is forced to be a leaf node in the binary tree. Leaf nodes, unlike branch nodes, do not replicate traffic in the process of forwarding traffic. Because leaf nodes have no children, they do not need to replicate traffic, and thus are less likely to become saturated with traffic.

Default

If you omit the `no-mcast-replication` statement, the PFE can become a branch node or a leaf node. When the PFE becomes a branch node, the PFE must replicate traffic.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 11.3.

no-propagate-ttl

IN THIS SECTION

- Syntax | 2609
- Hierarchy Level | 2609
- Description | 2609
- Default | 2609

Required Privilege Level | 2609
Release Information | 2609

Syntax

```
no-propagate-ttl;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],
[edit protocols mpls]
```

Description

Disable normal time-to-live (TTL) decrementing. You configure this statement once per router, and it affects all RSVP-signaled or LDP-signaled LSPs. When this router acts as an ingress router for an LSP, it pushes an MPLS header with a TTL value of 255, regardless of the IP packet TTL. When the router acts as the penultimate router, it pops the MPLS header without writing the MPLS TTL into the IP packet.

When you add the `no-propagate-ttl` statement to the configuration or delete it from the configuration, the effect takes place immediately. There is no need to clear existing RSVP LSPs or LDP sessions.

Default

Normal TTL decrementing enabled; the TTL field value is decremented by 1 as the packet passes through each label-switched router in the LSP.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Evolved Release 20.1R1 on PTX10008.

    normalization-retry-limits number;
    normalize-interval seconds;
}
```

Hierarchy Level

```
[edit protocols mpls container-label-switched-path lsp-name splitting-merging]
```

Description

Perform normailzation.

Options

failover-normalization

Enable the ingress router to pro-actively normalize or re-distribute traffic when a link or node failure happens on a member LSP. A member LSP can go down between two scheduled normalization events because of a link-failure or pre-emption.

- **Default:** Disabled

no-incremental-normalize

Disables automatic switchover by the ingress router to a new instance of the container LSP until the desired demand is satisfied, although the given number of LSPs can be successfully signaled such that the new aggregate bandwidth value exceeds the old aggregate bandwidth value.

- **Default:** False (disabled)

normalization-retry-duration *seconds*

Specifies the duration before which the ingress router performs a normalization reattempt when the previous normalization has not been successful. Normalization is done until a sufficient number of LSPs come up with an aggregate bandwidth that is more than the current aggregate or desired bandwidth.

- **Default:** 30 seconds

`normalization-retry-limits number` Specifies the maximum number of times the ingress router performs normalization reattempts until a sufficient number of LSPs come up successfully with new bandwidth values.

- **Default:** 1

`normalize-interval seconds` Specifies the duration between two normalization events.

- **Range:** 21600 seconds through 6 hours
- **Default:** 21600 seconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit protocols mpls label-switched-path lsp-name primary path-name]
```

Description

Enable Operation, Administration, and Maintenance (OAM) for RSVP-signaled LSPs.

Options

`lsp-ping-interval` *seconds*—Specify the duration of the LSP ping interval in seconds. To issue a ping on an RSVP-signaled LSP, use the `ping mpls rsvp` command.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 7.6.
