YEAR 2000 NOTICE

Juniper Networks hardware and software products are Year 2000 compliant. Junos OS has no known time-related limitations through the year 2038. However, the NTP application is known to have some difficulty in the year 2036.

END USER LICENSE AGREEMENT

The Juniper Networks product that is the subject of this technical documentation consists of (or is intended for use with) Juniper Networks software. Use of such software is subject to the terms and conditions of the End User License Agreement ("EULA") posted at https://support.juniper.net/support/eula/. By downloading, installing or using such software, you agree to the terms and conditions of that EULA.

Table of Contents

About This Guide | xlvi

1 **Overview**

Understanding MPLS | 2

MPLS Overview | 2

- MPLS Overview | 2
- TTL Processing on Incoming MPLS Packets | 7
- Link-Layer Support in MPLS | 11
- MPLS Overview for ACX Series Universal Metro Routers | 11
- MPLS for EX Series Switches Overview | 12
- MPLS Feature Support on QFX Series and EX4600 Switches | 14
- MPLS Limitations on QFX Series and EX4600 Switches | 31

Supported Standards | 37

Supported MPLS Standards | 37

- Supported MPLS Standards | 37
- Supported RSVP Standards | 41
- Supported LDP Standards | 42
- DiffServ-Aware Traffic Engineering Standards | 43
- Supported GMPLS Standards | 43
- Supported PCEP Standards | 44

2 **MPLS Configuration**

Configuring MPLS | 47

Basic MPLS Configuration | 47

- MPLS Configuration Overview | 47
- MPLS Configuration Guidelines | 48
- Configuring MPLS | 49
- Example: Enabling MPLS | 49
  - Requirements | 50
  - Overview | 50
  - Configuration | 50
  - Verification | 52

Example: Configuring MPLS on EX8200 and EX4500 Switches | 53

Requirements | 54

Overview and Topology | 54

Configuring the Local PE Switch | 60

Configuring the Remote PE Switch | 64

Configuring the Provider Switch | 68

Verification | 72

MPLS on Provider and Provider Edge Devices Configuration | 77

Configuring MPLS on Provider Switches | 77

Configuring MPLS on Provider Edge Switches | 79

Configuring the Ingress PE Switch | 79

Configuring the Egress PE Switch | 81

Configuring MPLS on Provider Edge Switches Using IP-Over-MPLS | 84

Configuring the Ingress PE Switch | 84

Configuring the Egress PE Switch | 87

Configuring MPLS on Provider Edge EX8200 and EX4500 Switches Using Circuit Cross-Connect | 90

Configuring MPLS on EX8200 and EX4500 Provider Switches | 94

Configuring MPLS Tunnels | 97

IPv6-over-Ipv4 Tunnels | 97

Configuring IPv6 Tunneling for MPLS | 97

Example: Tunneling IPv6 Traffic over MPLS IPv4 Networks | 99

Requirements | 99

Overview | 99

Configuration | 102

Verification | 110

Next-Hop-Based Dynamic Tunnels | 111

Example: Configuring Next-Hop-Based MPLS-Over-UDP Dynamic Tunnels | 112

Requirements | 112

Overview | 113

Configuration | 117

Verification | 124

Troubleshooting | 129

Anti-Spoofing Protection for Next-Hop-Based Dynamic Tunnels Overview | 130

Example: Configuring Anti-Spoofing Protection for Next-Hop-Based Dynamic Tunnels | **133**

Requirements | **133**

Overview | **134**

Configuration | **136**

Verification | **144**

Next-Hop-Based Dynamic Tunnel Localization Overview | **147**

Overview of Next-Hop-Based Dynamic Tunneling Using IP-Over-IP Encapsulation | **153**

Example: Configuring Next-Hop-Based IP-Over-IP Dynamic Tunnels | **155**

Requirements | **155**

Overview | **156**

Configuring IP-over-IP Dynamic Tunnels with a Protocol Next Hop | **157**

Example: Configure an IPoIP Tunnel in an MPLS Environment with LDP tunnel, Resolved Through inetcolor.0 Using Static Configuration | **173**

Example: Configure an IPoIP Tunnel with LDP tunnel in an MPLS Cloud, Resolved through inetcolor.0 Using BGP Signaling | **187**

Verification | **193**

3 **MPLS Traffic**

Managing MPLS Traffic | 198

Bidirectional Forwarding Detection (BFD) for MPLS | **198**

Configuring Bidirectional Forwarding Detection for MPLS (CLI Procedure) | **198**

Configuring BFD on Provider Edge and Provider Switches for an LDP-Based LSP | **199**

Configuring BFD on Provider Edge and Provider Switches for an RSVP-Based LSP | **202**

BFD-Triggered Local Repair for Rapid Convergence | **203**

Understanding BFD-Triggered Local Protection | **204**

Configuring BFD for MPLS IPv4 LSPs | **206**

Firewall Filters for MPLS | **210**

Configuring MPLS Firewall Filters and Policers on Routers | **210**

Overview of MPLS Firewall Filters on Loopback Interface | **220**

Configuring MPLS Firewall Filters and Policers on Switches | **221**

Configuring an MPLS Firewall Filter | **221**

Applying an MPLS Firewall Filter to an MPLS Interface | **222**

Applying an MPLS Firewall Filter to a Loopback Interface | **222**

Configuring Policers for LSPs | **223**

System Log Messages and SNMP Traps for MPLS | **224**

Load Balancing MPLS Traffic | 226

Configuring Load Balancing Based on MPLS Labels | 227

Example: Load-Balanced MPLS Network | 233

Router Configurations for the Load-Balanced MPLS Network | 234

Configuring Load Balancing Based on MPLS Labels on ACX Series Routers | 249

MPLS Encapsulated Payload Load-balancing Overview | 253

Configuring MPLS Encapsulated Payload for Load Balancing | 254

Policy-Based Multipath Routes Overview | 255

Understanding IP-Based Filtering and Selective Port Mirroring of MPLS Traffic | 261

Shared Risk Link Groups for MPLS | 267

SRLG Overview | 267

Example: Configuring SRLG | 268

Requirements | 269

Overview | 269

Configuration | 270

Verification | 278

Example: Excluding SRLG Links Completely for the Secondary LSP | 281

Requirements | 282

Overview | 282

Configuration | 283

Verification | 288

Example: Configuring SRLG with Link Protection | 290

Requirements | 290

Overview | 290

Configuration | 291

Verification | 318

Example: Configuring SRLG with Link Protection with the exclude-srlg Option | 320

Requirements | 320

Overview | 320

Configuration | 321

Verification | 348

Protecting MPLS Traffic | 350

Node and Path Protection for MPLS LSPs | 350

MPLS and Traffic Protection | 350

Node-Link Protection Overview | 351

Path Protection Overview | 353

Configuring Path Protection in an MPLS Network (CLI Procedure) | 354

Configuring the Primary Path | 355

Configuring the Secondary Path | 356

Configuring the Revert Timer | 357

Preventing Use of a Path That Previously Failed | 357

Configuring MPLS Inter-AS Link-Node Protection with Labeled BGP | 358

Understanding MPLS Inter-AS Link Protection | 358

Example: Configuring MPLS Inter-AS Link-Node Protection | 360

Configuring Egress Protection Service Mirroring for BGP Signaled Layer 2 Services | 379

Example: Configuring MPLS Egress Protection Service Mirroring for BGP Signaled Layer 2 Services | 385

Requirements | 385

Overview | 385

Configuration | 387

Verification | 404

Example: Configuring Layer 3 VPN Egress Protection with PLR as Protector | 409

Requirements | 409

Overview | 409

Configuration | 410

Verification | 434

Understanding MPLS and Path Protection on EX Series Switches | 445

Verifying Path Protection in an MPLS Network | 445

Verifying the Primary Path | 446

Verifying the RSVP-Enabled Interfaces | 447

Verifying a Secondary Path | 448

Link Protection for MPLS LSPs | 450

Link Protection | 450

Multiple Bypass LSPs for Link Protection | 451

Node Protection | 452

Fast Reroute, Node Protection, and Link Protection | 453

Configuring Link Protection on Interfaces Used by LSPs | 458

Configuring Node Protection or Link Protection for LSPs | 467

Configuring Inter-AS Node and Link Protection | 468

Measuring MPLS Traffic | 469

Gather Statistics on MPLS Sessions | **469**

Configuring MPLS to Gather Statistics | **469**

On-Demand Packet Loss and Delay Measurement for UHP LSPs Overview | **471**

Example: Configuring On-Demand Loss and Delay Measurement | **478**

Requirements | **478**

Overview | **479**

Configuration | **480**

Verification | **486**

Example: Configuring Pro-active Loss and Delay Measurements for Bidirectional MPLS LSPs | **492**

Requirements | **492**

Overview | **493**

Configuration | **494**

Verification | **500**

Configuring On-Demand Loss and Delay Measurement | **502**

Configuring Pro-Active Loss and Delay Measurements | **503**

4 **MPLS LSPs**

Understanding MPLS LSPs | 507

LSP Overview | **507**

How a Packet Travels Along an LSP | **507**

Types of LSPs | **508**

Scope of LSPs | **508**

LSP Labels | **509**

MPLS Label Overview | **509**

MPLS Label Allocation | **509**

Operations on MPLS Labels | **511**

Understanding MPLS Label Operations | **511**

Understanding MPLS Label Manager | **515**

Special MPLS Labels | **515**

Entropy Label Support in Mixed Mode Overview | **516**

Abstract Hops for MPLS LSPs Overview | **516**

Example: Configuring Abstract Hops for MPLS LSPs | **530**

Requirements | **530**

Overview | **531**

Configuration | **533**

Verification | **550**

Configuring the Maximum Number of MPLS Labels | **552**

Configuring MPLS to Pop the Label on the Ultimate-Hop Router | **554**

Advertising Explicit Null Labels to BGP Peers | **555**

Understanding MPLS Label Operations on EX Series Switches | **556**

LSP Routes | **560**

MPLS and Routing Tables | **560**

Fast Reroute Overview | **562**

Configuring Fast Reroute | **565**

Detour Merging Process | **566**

Detour Computations | **567**

Fast Reroute Path Optimization | **568**

Configuring the Optimization Interval for Fast Reroute Paths | **568**

Adding LSP-Related Routes to the inet.3 or inet6.3 Routing Table | **568**

LSP Computation | **570**

Constrained-Path LSP Computation | **570**

How CSPF Selects a Path | **572**

CSPF Path Selection Tie-Breaking | **573**

Computing CSPF Paths Offline | **574**

Configuring CSPF Tie Breaking | **574**

Disabling Constrained-Path LSP Computation | **575**

LSP Routers | **576**

Routers in an LSP | **576**

Configuring the Ingress and Egress Router Addresses for LSPs | **577**

Configuring the Ingress Router for MPLS-Signaled LSPs | **579**

Configuring the Intermediate and Egress Routers for MPLS-Signaled LSPs | **585**

Configuring the Connection Between Ingress and Egress Routers | **585**

Pinging LSPs | **586**

Configuring MPLS LSPs | 589

Basic LSP Configuration | **589**

Configuring LSP Metrics | **590**

Configuring a Text Description for LSPs | **592**

Configuring MPLS Soft Preemption | **594**

Configuring Priority and Preemption for LSPs | **595**

Configuring Administrative Groups for LSPs | **596**

Configuring Extended Administrative Groups for LSPs | **599**

Configuring Preference Values for LSPs | **601**

Disabling Path Route Recording by LSPs | **601**

Achieving a Make-Before-Break, Hitless Switchover for LSPs | **602**

- Specifying the Amount of Time the Router Waits to Switch Over to New Paths | **603**
- Specifying the Amount of Time to Delay the Tear Down of Old Paths | **603**
- Achieving a Hitless, MBB Switchover Without Artificial Delays | **604**

Optimizing Signaled LSPs | **605**

Configuring the Smart Optimize Timer for LSPs | **608**

Limiting the Number of Hops in LSPs | **610**

Configuring the Bandwidth Value for LSPs | **610**

Automatic Bandwidth Allocation for LSPs | **610**

Configuring Automatic Bandwidth Allocation for LSPs | **611**

Configuring Optimized Auto-bandwidth Adjustments for MPLS LSPs | **612**

Configuring Reporting of Automatic Bandwidth Allocation Statistics for LSPs | **616**

Configuring an LSP Across ASs | **620**

Damping Advertisement of LSP State Changes | **622**

Configuring Corouted Bidirectional LSPs | **622**

Configuring the Entropy Label for LSPs | **625**

Example: Configuring an Entropy Label for a BGP Labeled Unicast LSP | **627**

- Requirements | **627**
- Overview | **628**
- Configuration | **629**
- Verification | **648**

Configuring Ultimate-Hop Popping for LSPs | **652**

Configuring Explicit-Path LSPs | **656**

Example: Configuring an Explicit-Path LSP | **657**

LSP Bandwidth Oversubscription Overview | **658**

LSP Size Oversubscription | **659**

LSP Link Size Oversubscription | **659**

Class Type Oversubscription and Local Oversubscription Multipliers | **659**

Configuring the Bandwidth Subscription Percentage for LSPs | **660**

Primary, Secondary, and Static LSP Configuration | **663**

Configuring Primary and Secondary LSPs | **663**

Configuring Hot Standby of Secondary Paths for LSPs | **666**

Configuring Static LSPs | **667**

Configuring Static Label Switched Paths for MPLS (CLI Procedure) | **677**

Configuring the Ingress PE Switch | **678**

Configuring the Provider and the Egress PE Switch | **679**

Configuring Static Label Switched Paths for MPLS | **680**

Configuring the Ingress PE Switch | **681**

Configuring the Provider and the Egress PE Switch | **682**

Adaptive LSP Configuration | **683**

Container LSP Configuration | **684**

Dynamic Bandwidth Management Using Container LSP Overview | **684**

Example: Configuring Dynamic Bandwidth Management Using Container LSP | **716**

Requirements | **717**

Overview | **717**

Configuration | **718**

Verification | **730**

Configuring Dynamic Bandwidth Management Using Container LSP | **748**

Multiclass LSP Configuration | **753**

Multiclass LSP Overview | **753**

Multiclass LSPs | **753**

Establishing a Multiclass LSP on the Differentiated Services Domain | **754**

Point-to-Multipoint LSP Configuration | **754**

Point-to-Multipoint LSPs Overview | **755**

Understanding Point-to-Multipoint LSPs | **757**

Point-to-Multipoint LSP Configuration Overview | **759**

Example: Configuring a Collection of Paths to Create an RSVP-Signaled Point-to-Multipoint LSP | **759**

Requirements | **759**

Overview | **760**

Configuration | **761**

Verification | **785**

Configuring Primary and Branch LSPs for Point-to-Multipoint LSPs | **787**

Configuring Inter-Domain Point-to-Multipoint LSPs | **789**

Configuring Link Protection for Point-to-Multipoint LSPs | **790**

Configuring Graceful Restart for Point-to-Multipoint LSPs | **791**

Configuring a Multicast RPF Check Policy for Point-to-Multipoint LSPs | **792**

Configuring Ingress PE Router Redundancy for Point-to-Multipoint LSPs | **793**

Configuring a Service to Correlate Point-to-Multipoint sub-LSPs with FPCs | **794**

Enabling Point-to-Point LSPs to Monitor Egress PE Routers | **798**

Preserving Point-to-Multipoint LSP Functioning with Different Junos OS Releases | **799**

Re-merge Behavior on Point-to-Multipoint LSP Overview | **799**

Pop-and-Forward LSP Configuration | **802**

Segment Routing LSP Configuration | **809**

Enabling Distributed CSPF for Segment Routing LSPs | **810**

Static Segment Routing Label Switched Path | **817**

Understanding Static Segment Routing LSP in MPLS Networks | **817**

Example: Configuring Static Segment Routing Label Switched Path | **843**

Routing Engine-based S-BFD for Segment-Routing Traffic Engineering with First-Hop Label Resolution | **863**

Understanding RE-based S-BFD for Segment-Routing Traffic Engineering with First-Hop Label Resolution | **863**

Configuring RE-based S-BFD for Segment-Routing Traffic Engineering with First-Hop Label Resolution | **865**

Example | **868**

Verify That LSPs Are Configured for Static Segment-Routing Tunnels and That S-BFD Session Status Is Visible | **869**

Verify the Segment-Routing Tunnel Route with a Primary Next Hop and a Secondary Next Hop | **871**

Verify the S-BFD Session of the Primary Path | **872**

Configuring Static Adjacency Segment Identifier for Aggregate Ethernet Member Links Using Single-Hop Static LSP | **873**

Computing Delay Optimized Intradomain and Interdomain Segment Routing Paths | **875**

Express Segment LSP Configuration | **880**

Establish End-to-End Segment Routing Path Using Express Segments | **881**

Example: Inter-domain SR-TE Connectivity Using Express Segments Through RSVP-TE Underlay | **891**

Requirements | **891**

Overview | **891**

Configuration | **896**

Verification | **987**

Example: Inter-domain SR-TE Connectivity Using Express Segments Through SR-TE Underlay | **1004**

Requirements | **1004**

Overview | **1004**

Configuration | **1009**

Verification | **1155**

5 **MPLS Signalling Protocols**

RSVP | 1181

RSVP Overview | **1181**

RSVP Overview | **1182**

RSVP Operation Overview | **1182**

Understanding the RSVP Signaling Protocol | **1183**

RSVP-TE protocol extensions for FRR | **1186**

Junos OS RSVP Protocol Implementation | **1188**

RSVP Authentication | **1189**

RSVP and IGP Hello Packets and Timers | **1189**

RSVP Message Types | **1190**

Understanding RSVP Automatic Mesh | **1192**

RSVP Reservation Styles | **1193**

RSVP Refresh Reduction | **1194**

MTU Signaling in RSVP | **1194**

How the Correct MTU Is Signaled in RSVP | **1195**

Determining an Outgoing MTU Value | **1196**

MTU Signaling in RSVP Limitations | **1196**

RSVP Configuration | **1197**

Minimum RSVP Configuration | **1198**

Configuring RSVP and MPLS | **1199**

Configuring RSVP Interfaces | **1201**

Configuring RSVP Node-ID Hellos | **1207**

Example: Configuring RSVP-Signaled LSPs | **1208**

Requirements | **1208**

Overview and Topology | **1208**

Configuration | **1209**

Verification | **1212**

Example: Configuring RSVP Automatic Mesh | **1214**

Requirements | **1215**

Overview | **1215**

Configuration | **1216**

Verification | **1218**

Configuring Hello Acknowledgments for Nonsession RSVP Neighbors | **1219**

Switching LSPs Away from a Network Node | **1220**

Configuring RSVP Setup Protection | **1221**

Configuring Load Balancing Across RSVP LSPs | **1222**

Configuring RSVP Automatic Mesh | **1223**

Configuring Timers for RSVP Refresh Messages | **1224**

Preempting RSVP Sessions | **1225**

Configuring MTU Signaling in RSVP | **1226**

Configuring Ultimate-Hop Popping for LSPs | **1227**

Configuring RSVP to Pop the Label on the Ultimate-Hop Router | **1231**

Enabling Ultimate-Hop Popping on Point-to-Multipoint LSPs | **1232**

Tracing RSVP Protocol Traffic | **1233**

RSVP Graceful Restart | **1236**

RSVP Graceful Restart Terminology | **1237**

Restart time (in milliseconds) | **1237**

Recovery time (in milliseconds) | **1237**

RSVP Graceful Restart Operation | **1238**

Processing the Restart Cap Object | **1239**

Configuring RSVP Graceful Restart | **1239**

RSVP LSP Tunnels Overview | **1241**

Example: RSVP LSP Tunnel Configuration | **1244**

Configuring Link Management Protocol Peers | **1269**

Configuring Link Management Protocol Traffic Engineering Links | **1270**

Configuring Peer Interfaces in OSPF and RSVP | **1270**

Defining Label-Switched Paths for the FA-LSP | **1271**

Establishing FA-LSP Path Information | **1271**

Option: Tearing Down RSVP LSPs Gracefully | **1272**

LDP | 1274

LDP Overview | **1274**

LDP Introduction | **1275**

Understanding the LDP Signaling Protocol | **1275**

Example: Configuring LDP-Signaled LSPs | **1276**

- Requirements | **1276**
- Overview | **1276**
- Configuration | **1277**

Junos OS LDP Protocol Implementation | **1280**

LDP Operation | **1280**

LDP Message Types | **1280**

Tunneling LDP LSPs in RSVP LSPs | **1282**

Tunneling LDP LSPs in RSVP LSPs Overview | **1282**

Tunneling LDP over SR-TE | **1283**

Example: Tunneling LDP over SR-TE | **1286**

- Requirements | **1287**
- Overview | **1287**
- Configuration | **1288**
- Verification | **1309**

Label Operations | **1317**

LDP Session Protection | **1319**

LDP Native IPv6 Support Overview | **1319**

Longest Match Support for LDP Overview | **1320**

LDP Configuration | **1320**

Minimum LDP Configuration | **1322**

Enabling and Disabling LDP | **1322**

Configuring the LDP Timer for Hello Messages | **1323**

Configuring the Delay Before LDP Neighbors Are Considered Down | **1324**

Enabling Strict Targeted Hello Messages for LDP | **1326**

Configuring the Interval for LDP Keepalive Messages | **1327**

Configuring the LDP Keepalive Timeout | **1327**

Configuring Longest Match for LDP | **1327**

Example: Configuring Longest Match for LDP | **1328**

- Requirements | **1328**
- Overview | **1329**
- Configuration | **1330**
- Verification | **1337**

Configuring LDP Route Preferences | **1349**

LDP Graceful Restart | **1349**

Configuring LDP Graceful Restart | **1350**

Filtering Inbound LDP Label Bindings | **1353**

Filtering Outbound LDP Label Bindings | **1356**

Specifying the Transport Address Used by LDP | **1359**

Control Transport Address Used for Targeted-LDP Session | **1359**

Configuring the Prefixes Advertised into LDP from the Routing Table | **1362**

Configuring FEC Deaggregation | **1363**

Configuring Policers for LDP FECs | **1364**

Configuring LDP IPv4 FEC Filtering | **1365**

Configuring BFD for LDP LSPs | **1366**

Configuring ECMP-Aware BFD for LDP LSPs | **1369**

Configuring a Failure Action for the BFD Session on an LDP LSP | **1370**

Configuring the Holddown Interval for the BFD Session | **1371**

Configuring LDP Link Protection | **1371**

Example: Configuring LDP Link Protection | **1373**

- LDP Link Protection Overview | **1374**
- Example: Configuring LDP Link Protection | **1396**

Understanding Multicast-Only Fast Reroute | **1408**

Configuring Multicast-Only Fast Reroute | **1417**

Example: Configuring Multicast-Only Fast Reroute in a Multipoint LDP Domain | **1420**

- Requirements | **1421**
- Overview | **1421**
- CLI Quick Configuration | **1422**
- Configuration | **1431**
- Verification | **1438**

Example: Configuring LDP Downstream on Demand | **1443**

- Requirements | **1443**
- Overview | **1443**
- Configuration | **1444**
- Verification | **1448**

Configuring LDP Native IPv6 Support | **1450**

Example: Configuring LDP Native IPv6 Support | **1451**

- Requirements | **1451**
- Overview | **1452**

Configuration | **1452**

Example: Configuring Multipoint LDP In-Band Signaling for Point-to-Multipoint LSPs | **1470**

Understanding Multipoint LDP Inband Signaling for Point-to-Multipoint LSPs | **1471**

Example: Configuring Multipoint LDP In-Band Signaling for Point-to-Multipoint LSPs | **1482**

LDP Mapping Server for Interoperability of Segment Routing with LDP Overview | **1509**

Configuring Miscellaneous LDP Properties | **1514**

Configuring LDP LSP Traceroute | **1522**

Collecting LDP Statistics | **1523**

Tracing LDP Protocol Traffic | **1526**

Example: Configuring Multiple-Instance LDP | **1530**

Example: Tunneling LDP over SR-TE | **1557**

Requirements | **1557**

Overview | **1558**

Configuration | **1559**

Verification | **1579**

6 **MPLS Traffic Engineering**

Configuring MPLS Traffic Engineering | 1589

MPLS Traffic Engineering Configuration | **1589**

MPLS and Traffic Engineering | **1590**

MPLS Traffic Engineering and Signaling Protocols Overview | **1590**

Traffic Engineering Capabilities | **1591**

Components of Traffic Engineering | **1591**

Configuring Traffic Engineering for LSPs | **1592**

Enabling Interarea Traffic Engineering | **1595**

Enabling Inter-AS Traffic Engineering for LSPs | **1596**

Packet Forwarding Component | **1599**

Offline Path Planning and Analysis | **1602**

Flexible LSP Calculation and Configuration | **1602**

Link-State Distribution Using BGP Overview | **1603**

Example: Configuring Link State Distribution Using BGP | **1618**

Requirements | **1618**

Overview | **1619**

Configuration | **1620**

Verification | **1635**

Configuring Link State Distribution Using BGP | **1642**

BGP Classful Transport Planes Overview | **1646**

BGP Classful Transport (BGP-CT) with Underlying Colored SR-TE Tunnels Overview | **1654**

Improving Traffic Engineering Database Accuracy with RSVP PathErr Messages | **1655**

MPLS Traffic Engineering Configuration | **1658**

MPLS and Traffic Engineering | **1659**

MPLS Traffic Engineering and Signaling Protocols Overview | **1659**

Traffic Engineering Capabilities | **1660**

Components of Traffic Engineering | **1661**

Configuring Traffic Engineering for LSPs | **1661**

Enabling Interarea Traffic Engineering | **1665**

Enabling Inter-AS Traffic Engineering for LSPs | **1665**

Packet Forwarding Component | **1668**

Offline Path Planning and Analysis | **1671**

Flexible LSP Calculation and Configuration | **1672**

Link-State Distribution Using BGP Overview | **1673**

Example: Configuring Link State Distribution Using BGP | **1688**

Requirements | **1688**

Overview | **1689**

Configuration | **1690**

Verification | **1705**

Configuring Link State Distribution Using BGP | **1712**

BGP Classful Transport Planes Overview | **1715**

BGP Classful Transport (BGP-CT) with Underlying Colored SR-TE Tunnels Overview | **1724**

Improving Traffic Engineering Database Accuracy with RSVP PathErr Messages | **1725**

DiffServ-Aware Traffic Engineering Configuration | **1728**

DiffServ-Aware Traffic Engineering Introduction | **1728**

DiffServ-Aware Traffic Engineering Terminology | **1729**

Bandwidth model | **1729**

CAC | **1729**

Class type | **1730**

Differentiated Services | **1730**

Differentiated Services domain | **1730**

DiffServ-aware traffic engineering | **1730**

Multiclass LSP | **1730**

MAM | **1730**

RDM | **1730**

Traffic engineering class | **1730**

Traffic engineering class map | **1731**

DiffServ-Aware Traffic Engineering Features | **1731**

Configuring Link Down Notification for Optics Options Alarm or Warning | **1732**

DiffServ-Aware Traffic Engineered LSPs Overview | **1732**

DiffServ-Aware Traffic Engineered LSPs Operation | **1733**

Configuring Routers for DiffServ-Aware Traffic Engineering | **1733**

Configuring LSPs for DiffServ-Aware Traffic Engineering | **1738**

7 **MPLS Transport Profile**

Operation, Administration, and Maintenance (OAM) for MPLS | 1744

MPLS OAM Configuration | **1744**

Configuring the MPLS Transport Profile for OAM | **1744**

MPLS Transport Profile Overview | **1744**

Example: Configuring the MPLS Transport Profile for OAM | **1745**

Configuring OAM Ingress Policies for LDP | **1762**

Tracing MPLS and LSP Packets and Operations | **1763**

MPLS Pseudowires | 1765

MPLS Pseudowires Configuration | **1765**

Ethernet Pseudowire Overview | **1765**

Example: Ethernet Pseudowire Base Configuration | **1766**

Requirements | **1766**

Overview of an Ethernet Pseudowire Base Configuration | **1766**

Configuring an Ethernet Pseudowire | **1767**

Pseudowire Overview for ACX Series Universal Metro Routers | **1770**

Understanding Multisegment Pseudowire for FEC 129 | **1771**

Example: Configuring a Multisegment Pseudowire | **1777**

Requirements | **1777**

Overview | **1778**

Configuration | **1784**

Verification | **1812**

Troubleshooting | **1823**

MPLS Stitching For Virtual Machine Connection | **1826**

TDM Pseudowires Overview | **1828**

Example: TDM Pseudowire Base Configuration | **1828**

Requirements | **1829**

Overview of a TDM Pseudowire Base Configuration | **1829**

Configuring an TDM Pseudowire | **1829**

Configuring Load Balancing for Ethernet Pseudowires | **1833**

Configuring Load Balancing Based on MAC Addresses | **1835**

Class-of-Service (CoS) for MPLS | 1837

MPLS Class-of-Service Configuration | **1837**

Configuring Class of Service for MPLS LSPs | **1838**

Configuring MPLS Rewrite Rules | **1841**

Configuring CoS Bits for an MPLS Network | **1843**

Configuring CoS on an MPLS Provider Edge Switch Using IP Over MPLS | **1844**

Configuring CoS | **1844**

Configuring an LSP Policer | **1845**

Configuring CoS on an MPLS Provider Edge Switch Using Circuit Cross-Connect | **1846**

Configuring CoS | **1847**

Configuring an LSP Policer | **1848**

Configuring CoS on Provider Switches of an MPLS Network | **1849**

Understanding Using CoS with MPLS Networks on EX Series Switches | **1850**

Example: Combining CoS with MPLS on EX Series Switches | **1855**

Requirements | **1855**

Overview and Topology | **1856**

Configuring the Local PE Switch | **1859**

Configuring the Remote PE Switch | **1863**

Configuring the Provider Switch | **1864**

Verification | **1866**

Understanding CoS MPLS EXP Classifiers and Rewrite Rules | **1873**

Configuring Rewrite Rules for MPLS EXP Classifiers | **1876**

Configuring CoS Bits for an MPLS Network | **1877**

Configuring a Global MPLS EXP Classifier | **1878**

Generalized MPLS (GMPLS) | 1880

GMPLS Configuration | **1880**

Introduction to GMPLS | **1880**

GMPLS Terms and Acronyms | **1882**

Generalized MPLS (GMPLS) | **1882**
Forwarding adjacency | **1882**
GMPLS label | **1882**
GMPLS LSP types | **1882**
Link Management Protocol | **1883**
Traffic engineering link | **1883**
GMPLS Operation | **1883**
GMPLS and OSPF | **1884**
GMPLS and CSPF | **1884**
GMPLS Features | **1884**
Configuring MPLS Paths for GMPLS | **1885**
Tracing LMP Traffic | **1886**
Configuring MPLS LSPs for GMPLS | **1887**
Gracefully Tearing Down GMPLS LSPs | **1890**
GMPLS RSVP-TE VLAN LSP Signaling Overview | **1892**
Example: Configuring GMPLS RSVP-TE VLAN LSP Signaling | **1899**
Requirements | **1899**
Overview | **1900**
Configuration | **1907**
Verification | **1923**

8 **MPLS VPNs and Circuits**

Ethernet over MPLS (L2 Circuit) | 1931

Understanding Ethernet-over-MPLS (L2 Circuit) | **1931**

Configuring Ethernet over MPLS (Layer 2 Circuit) | **1932**
Configuring the Local PE Switch for Port-Based Layer 2 Circuit (Pseudo-wire) | **1933**
Configuring the Remote PE Switch for Port-Based Layer 2 Circuit (Pseudo-wire) | **1934**
Configuring the Local PE Switch for VLAN-Based Layer 2 Circuit | **1935**
Configuring the Remote PE Switch for VLAN-Based Layer 2 Circuit | **1936**

CCC, TCC, and Layer 2.5 Switching | 1938

CCC, TCC, and Ethernet Over MPLS Configuration | **1938**
TCC and Layer 2.5 Switching Overview | **1939**
Configuring VLAN TCC Encapsulation | **1939**
Configuring TCC Interface Switching | **1941**
CCC Overview | **1943**

Understanding Carrier-of-Carriers VPNs | **1944**

Understanding Interprovider and Carrier-of-Carriers VPNs | **1946**

Configuring BGP to Gather Interprovider and Carrier-of-Carriers VPNs Statistics | **1947**

Configuring an MPLS-Based VLAN CCC Using a Layer 2 Circuit | **1948**

VLAN CCC Encapsulation on Transport Side of Pseudowire Client Logical Interfaces Overview | **1952**

Transmitting Nonstandard BPDUs | **1955**

TCC Overview | **1955**

Configuring Layer 2 Switching Cross-Connects Using CCC | **1956**

Configuring MPLS LSP Tunnel Cross-Connects Using CCC | **1967**

Configuring TCC | **1972**

CCC and TCC Graceful Restart | **1978**

Configuring CCC and TCC Graceful Restart | **1979**

Configuring an MPLS-Based VLAN CCC Using the Connection Method (CLI Procedure) | **1980**

Configuring CCC Switching for Point-to-Multipoint LSPs | **1982**

Configuring an MPLS-Based VLAN CCC Using a Layer 2 VPN (CLI Procedure) | **1985**

Understanding Ethernet-over-MPLS (L2 Circuit) | **1990**

Configuring Ethernet over MPLS (Layer 2 Circuit) | **1991**

- Configuring the Local PE Switch for Port-Based Layer 2 Circuit (Pseudo-wire) | **1992**
- Configuring the Remote PE Switch for Port-Based Layer 2 Circuit (Pseudo-wire) | **1993**
- Configuring the Local PE Switch for VLAN-Based Layer 2 Circuit | **1994**
- Configuring the Remote PE Switch for VLAN-Based Layer 2 Circuit | **1995**

9 **MPLS for Software Defined Networking (SDN)**

Path Computatoin Element Protocol (PCEP) | 1999

PCEP Configuration | **1999**

PCEP Overview | **2000**

Support of the Path Computation Element Protocol for RSVP-TE Overview | **2001**

Example: Configuring the Path Computation Element Protocol for MPLS RSVP-TE | **2021**

- Requirements | **2021**
- Overview | **2022**
- Configuration | **2025**
- Verification | **2032**

Example: Configuring Path Computation Element Protocol for MPLS RSVP-TE with Support of PCE-Initiated Point-to-Point LSPs | **2039**

- Requirements | **2039**
- Overview | **2039**

Configuration | **2042**

Verification | **2047**

Configuring Path Computation Element Protocol for MPLS RSVP-TE with Support of PCE-Initiated Point-to-Point LSPs | **2051**

Example: Configuring Path Computation Element Protocol for MPLS RSVP-TE with Support for PCE-Controlled Point-to-Multipoint LSPs | **2055**

Requirements | **2056**

Overview | **2056**

Configuration | **2058**

Verification | **2072**

Understanding Path Computation Element Protocol for MPLS RSVP-TE with Support for PCE-Initiated Point-to-Multipoint LSPs | **2076**

Enable Segment Routing for the Path Computation Element Protocol | **2081**

Segment Routing for the Path Computation Element Protocol Overview | **2081**

Example: Configure Segment Routing for the Path Computation Element Protocol | **2089**

Static Segment Routing Label Switched Path | **2123**

Understanding Static Segment Routing LSP in MPLS Networks | **2124**

Example: Configuring Static Segment Routing Label Switched Path | **2149**

Enabling Distributed CSPF for Segment Routing LSPs | **2169**

Example: Configuring CoS-Based Forwarding and Policy-Based Routing For SR-TE LSPs | **2176**

CoS-Based Forwarding and Policy-Based Routing For SR-TE LSPs Overview | **2176**

Configure CoS-Based Forwarding and Policy-Based Routing for SR-TE LSPs | **2177**

10 **MPLS Troubleshooting**

Troubleshooting MPLS | 2189

Troubleshooting MPLS | **2189**

Verify MPLS Interfaces | **2190**

Verify Protocol Families | **2193**

Verify the MPLS Configuration | **2197**

Checking the MPLS Layer | **2200**

Verify the LSP | **2203**

Verify the LSP Route on the Transit Router | **2207**

Verify the LSP Route on the Ingress Router | **2209**

Verify MPLS Labels with the traceroute Command | **2211**

Verify MPLS Labels with the ping Command | **2213**

Take Appropriate Action | **2215**

Verify the LSP Again | **2217**

Verify That Node-Link Protection Is Up | **2221**

Verify That Link Protection Is Up | **2229**

Verify One-to-One Backup | **2235**

Verify That the Primary Path Is Operational | **2243**

Verify That the Secondary Path Is Established | **2245**

Verifying the Physical Layer | **2248**

- Verify the LSP | **2251**
- Verify Router Connection | **2253**
- Verify Interfaces | **2254**
- Take Appropriate Action | **2256**
- Verify the LSP Again | **2257**

Checking the Data Link Layer | **2259**

- Verify the LSP | **2262**
- Verify Interfaces | **2264**
- Take Appropriate Action | **2269**
- Verify the LSP Again | **2271**

Verifying the IP and IGP Layers | **2276**

Verifying the IP Layer | **2279**

- Verify the LSP | **2280**
- Verify IP Addressing | **2282**
- Verify Neighbors or Adjacencies at the IP Layer | **2284**
- Take Appropriate Action | **2289**
- Verify the LSP Again | **2291**

Verify the LSP Again | **2295**

Checking the RSVP Layer | **2299**

- Verify the LSP | **2302**
- Verify RSVP Sessions | **2304**
- Verify RSVP Neighbors | **2307**
- Verify RSVP Interfaces | **2309**
- Verify the RSVP Protocol Configuration | **2311**
- Take Appropriate Action | **2312**
- Verify the LSP Again | **2314**

Determining LSP Statistics | **2319**

Verifying LSP Use in Your Network | **2321**

- Verifying an LSP on the Ingress Router | **2323**
- Verifying an LSP on a Transit Router | **2324**

Verify That Load Balancing Is Working | **2326**

Verify the Operation of Uneven Bandwidth Load Balancing | **2331**

Use the traceroute Command to Verify MPLS Labels | **2333**

Troubleshooting GMPLS and GRE Tunnel | **2335**

Determining LSP Status | **2360**

- Check the Status of the LSP | **2361**
- Display Extensive Status About the LSP | **2363**

Checking That RSVP Path Messages Are Sent and Received | **2368**

11 **Configuration Statements**

Multiprotocol Label Switching (MPLS) is a protocol that uses labels to route packets instead of using IP addresses. In a traditional network, each switch performs an IP routing lookup, determines a next-hop based on its routing table, and then forwards a packet to that next-hop. With MPLS, only the first device does a routing lookup, and, instead of finding the next-hop, finds the ultimate destination along with a path to that destination. The path of an MPLS packet is called a label-switched path (LSP).

MPLS applies one or more labels to a packet so it can follow the LSP to the destination. Each switch pops off its label and sends the packet to the next switch label in the sequence.

The Junos OS includes everything you need to configure MPLS. You do not need to install any additional programs or protocols. MPLS is supported on switches with a subset of the commands supported on routers. The Junos MPLS-configured switches can interact with each other and with Junos MPLS-configured routers.

MPLS has the following advantages over conventional packet forwarding:

- Packets arriving on different ports can be assigned different labels.
- A packet arriving at a particular provider edge (PE) switch can be assigned a label that is different from that of the same packet entering the network at a different PE switch. As a result, forwarding decisions that depend on the ingress PE switch can be easily made.
- Sometimes it is desirable to force a packet to follow a particular route that is explicitly chosen at or before the time the packet enters the network, rather than letting it follow the route chosen by the normal dynamic routing algorithm as the packet travels through the network. In MPLS, a label can be used to represent the route so that the packet need not carry the identity of the explicit route.

This topic describes:

Why Use MPLS?

MPLS reduces the use of the forwarding table by using labels instead of the forwarding table. The size of forwarding tables on a switch are limited by silicon and using exact matching for forwarding to destination devices is cheaper than buying more sophisticated hardware. In addition, MPLS allows you to control where and how traffic is routed on your network – this is called traffic engineering.

Some reasons to use MPLS instead of another switching solution are:

- MPLS can connect different technologies that would not otherwise be compatible---service providers have this compatibility issue when connecting clients with different autonomous systems

in their networks. In addition, MPLS has a feature called Fast Reroute that provides alternate backups for paths – this prevents network degradation in case of a switch failure.

- • Other IP-based encapsulations such as Generic Route Encapsulation (GRE) or Virtual Extensible Local Area Networks (VXLAN) support only two levels of hierarchy, one for the transport tunnel and one piece of metadata. Using virtual servers means that you need multiple hierarchy levels. For example, one label is needed for top-of-rack (ToR), one label for the egress port that identifies the server, and one for the virtual server.

Why Not Use MPLS?

There are no protocols to auto-discover MPLS enabled nodes. MPLS protocol just exchanges label values for an LSP. They do not create the LSPs.

You must build the MPLS mesh, switch by switch. We recommend using scripts for this repetitive process.

MPLS hides suboptimal topologies from BGP where multiple exits may exist for the same route.

Large LSPs are limited by the circuits they traverse. You can work around this by creating multiple, parallel LSPs.

How Do I Configure MPLS?

There are three types of switches you must set up for MPLS:

- Label Edge Router/Switch (LER) or ingress node to the MPLS network. This switch encapsulates the packets.
- Label Switching Routers/Switches (LSR). One or more switches that transfer MPLS packets in the MPLS network.
- Egress router/switch is the final MPLS device that removes the last label before packets leave the MPLS network.

Service providers (SP) use the term provider router (P) for a backbone router/switch doing label switching only. The customer-facing router at the SP is called a provider edge router (PE). Each customer needs a customer edge router (CE) to communicate with the PE. Customer facing routers typically can terminate IP addresses, L3VPNs, L2VPNs/ pseudowires, and VPLS before packets are transferred to the CE.

Configure the MPLS LER (Ingress) Switch and the Egress Switch

To configure MPLS, you must first create one or more named paths on the ingress and egress routers. For each path, you can specify some or all transit routers in the path, or you can leave it empty. See

"Configuring the Ingress and Egress Router Addresses for LSPs" on page 577 and "Configuring the Connection Between Ingress and Egress Routers" on page 585.

Configure LSRs for MPLS

Configure one or more MPLS LSRs by following these steps:

1. Configure interfaces on each switch to transmit and receive MPLS packets using the usual interface command with MPLS appended. For example:

```
[edit interfaces ge-0/0/0 unit 0] family mpls;
```

2. Add those same interfaces under [edit protocols mpls]. For example:

```
[edit protocols mpls]
interface ge-0/0/0;
```

3. Configure the interfaces on each switch to handle MPLS labels with a protocol. For example, for LDP:

```
[edit protocols ldp]
Interface ge-0/0/0.0;
```

   To watch a demo of these configurations, see https://www.youtube.com/watch?v=xegWBCUJ4tE.

What Does the MPLS Protocol Do?

Multiprotocol Label Switching (MPLS) is an Internet Engineering Task Force (IETF)-specified framework that provides for the designation, routing, forwarding and switching of traffic flows through the network. In addition, MPLS:

- Specifies mechanisms to manage traffic flows of various granularities, such as flows between different hardware, machines, or even flows between different applications.
- Remains independent of the layer-2 and layer-3 protocols.
- Provides a means to map IP addresses to simple, fixed-length labels used by different packet-forwarding and packet-switching technologies.
- Interfaces to existing routing protocols, such as Resource ReSerVation Protocol (RSVP) and Open Shortest PathFirst (OSPF).

- Supports IP, ATM, and Frame Relay layer-2 protocols.
- Uses these additional technologies:
    - FRR: MPLS Fast Reroute improves convergence during a failure by mapping out alternate LSPs in advance.
    - Link Protection/ Next-hop backup: A bypass LSP is created for every possible link failure.
    - Node Protection/ Next-hop backup: A bypass LSP is created for every possible switch (node) failure.
    - VPLS: Creates Ethernet multipoint switching service over MPLS and emulates functions of an L2 switch.
    - L3VPN: IP-based VPN customers get individual virtual routing domains.

How Does MPLS Interface to Other Protocols?

Some of the protocols that work with MPLS are:

- RSVP-TE: Resource Reservation Protocol - Traffic Engineering reserves bandwidth for LSPs.
- LDP: Label Distribution Protocol is the defacto protocol used for distribution of MPLS packets and is usually configured to tunnel inside RSVP-TE.
- IGP: Interior Gateway Protocol is a routing protocol. Edge routers (PE-routers) run BGP between themselves to exchange external (customer) prefixes. Edge and core (P) routers run IGP (usually OSPF or IS-IS) to find optimum path toward BGP next hops. P- and PE-routers use LDP to exchange labels for known IP prefixes (including BGP next hops). LDP indirectly builds end-to-end LSPs across the network core.
- BGP: Border Gateway Protocol (BGP) allows policy-based routing to take place, using TCP as its transport protocol on port 179 to establish connections. The Junos OS routing protocol software includes BGP version 4. You do not configure BGP---configuring interfaces with MPLS and LDP/ RSVP establishes the labels and the ability to transmit packets. BGP automatically determines the routes packets take.
- OSPF and ISIS: These protocols are used for routing between the MPLS PE and CE. Open Shortest Path First (OSPF) is perhaps the most widely used interior gateway protocol (IGP) in large enterprise networks. IS-IS, another link-state dynamic routing protocol, is more common in large service provider networks. Assuming you're running L3VPN to your customers, on the SP edge between the PE and the CE you can run any protocol that your platform supports as a VRF aware instance.

If I Have Used Cisco MPLS, What Do I Need to Know?

Cisco Networks and Juniper Networks use different MPLS terminology.

What Cisco Calls:	Juniper Calls:
affinities	admin-groups
autoroute announce	TE shortcuts
forwarding adjacency	LSP-advertise
tunnel	LSP
make-before-break	adaptive
application-window	adjust-interval
shared risk link groups	fate-sharing

TTL Processing on Incoming MPLS Packets

The flow chart on Figure 1 on page 10 illustrates TTL processing on incoming MPLS packets. On a transit LSR or an egress LER, MPLS pops one or more labels and can push one or more labels. The incoming TTL of the packet is determined by the configured TTL processing tunnel model.

When all of the following conditions are met, the incoming TTL is set to the TTL value found in the immediate inner header:

- The outer label is popped as opposed to being swapped
- The TTL processing model is configured to pipe
- The inner header is MPLS or IP

If any of those conditions is not met, then the incoming TTL is set to the TTL value found in the outermost label. In all cases, the TTL values of any further inner labels are ignored.

When an IP packet is exposed after MPLS pops all the labels that should be popped, MPLS passes the packet to IP for further processing, including TTL checking. When the uniform tunnel model for TTL processing is in effect, MPLS sets the TTL value of the IP packet to the incoming TTL value that was just

set. In other words, the TTL value is copied from the outermost label to the IP packet. When the pipe model for TTL processing is in effect, the TTL value in the IP header is left unchanged.

If an IP packet is not exposed by the label popping, then MPLS performs the TTL validation. If the incoming TTL is less than 2, the packet is dropped. If innermost packet is IP, an ICMP packet is built and

sent. If the TTL does not expire and the packet needs to be sent out, the outgoing TTL is determined by the rules for outgoing MPLS packets.

Link-Layer Support in MPLS

MPLS supports the following link-layer protocols, which are all supported in the Junos OS MPLS implementation:

- Point-to-Point Protocol (PPP)—Protocol ID 0x0281, Network Control Protocol (NCP) protocol ID 0x8281.
- Ethernet/Cisco High-level Data Link Control (HDLC)—Ethernet type 0x8847.
- Asynchronous Transfer Mode (ATM)—Subnetwork attachment point encoded (SNAP-encoded) Ethernet type 0x8847. Support is included for both point-to-point mode or nonbroadcast multiaccess (NBMA) mode. Support is not included for encoding MPLS labels as part of ATM virtual path identifier/virtual circuit identifier (VPI/VCI).
- Frame Relay—SNAP-encoded, Ethernet type 0x8847. Support is not included for encoding MPLS labels as part of Frame Relay data-link connection identifier (DLCI).
- Generic routing encapsulation (GRE) tunnel—Ethernet type 0x8847.

MPLS Overview for ACX Series Universal Metro Routers

Multiprotocol Label Switching (MPLS) provides a mechanism for engineering network traffic patterns that is independent of routing tables by assigning short labels to network packets, which describe how to forward them through the network. MPLS is independent of any routing protocol and can be used for unicast packets. On the ACX Series routers, the following MPLS features are supported:

- The configuration of a *label-switching router* (LSR) for processing of label-switched packets and forwarding of packets based on their labels.
- The configuration of an ingress label edge router (LER) where IP packets are encapsulated within MPLS packets and forwarded to the MPLS domain, and as an egress LER where MPLS packets are decapsulated and the IP packets contained within the MPLS packets are forwarded using information in the IP forwarding table. Configuring MPLS on the LER is the same as configuring an LSR.
- Uniform and pipe mode configuration providing different types of visibility in the MPLS network. Uniform mode makes all the nodes that a label-switched path (LSP) traverses visible to nodes outside the LSP tunnel. Uniform mode is the default. Pipe mode makes only the LSP ingress and egress points visible to nodes outside the LSP tunnel. Pipe mode acts like a circuit and must be enabled with the global `no-propagate-ttl` statement at the [**edit protocols mpls**] hierarchy level on each router that is in the path of the LSP. The `no-propagate-ttl` statement disables time-to-live (TTL) propagation at the

router level and affects all RSVP-signalled or LDP-signalled LSPs. Only the global configuration of TTL propagation is supported.

- Exception packet handling of IP packets not processed by the normal packet flow through the Packet Forwarding Engine. The following types of exception packet handling are supported:
  - Router alert
  - Time-to-live (TTL) expiry value
  - Virtual circuit connection verification (VCCV)
- LSP hot standby for secondary paths configuration to maintain a path in a hot-standby state enabling swift cut over to the secondary path when downstream routers on the current active path indicate connectivity problems.
- Redundancy for a label-switched path (LSP) path with the configuration of fast reroute.
- Configuration of link protection to ensure that traffic traversing a specific interface from one router to another can continue to reach its destination in the event that this interface fails.

MPLS for EX Series Switches Overview

IN THIS SECTION

- Benefits of MPLS | **13**
- Additional Benefits of MPLS and Traffic Engineering | **13**

You can configure Junos OS MPLS on Juniper Networks EX Series Ethernet Switches to increase transport efficiency in the network. MPLS services can be used to connect various sites to a backbone network and to ensure better performance for low-latency applications such as voice over IP (VoIP) and other business-critical functions.

NOTE: MPLS configurations on EX Series switches are compatible with configurations on other Juniper Networks devices that support MPLS and MPLS-based circuit cross-connect (CCC). MPLS features available on the switches depend upon which switch you are using. For information about the software features on the EX Series switches, see Feature Explorer.

NOTE: MPLS configurations on the switches do not support:

- Q-in-Q tunneling

This topic describes:

Benefits of MPLS

MPLS has the following advantages over conventional packet forwarding:

- Packets arriving on different ports can be assigned different labels.
- A packet arriving at a particular provider edge (PE) switch can be assigned a label that is different from that of the same packet entering the network at a different PE switch. As a result, forwarding decisions that depend on the ingress PE switch can be easily made.
- Sometimes it is desirable to force a packet to follow a particular route that is explicitly chosen at or before the time the packet enters the network, rather than letting it follow the route chosen by the normal dynamic routing algorithm as the packet travels through the network. In MPLS, a label can be used to represent the route so that the packet need not carry the identity of the explicit route.

Additional Benefits of MPLS and Traffic Engineering

MPLS is the packet-forwarding component of the Junos OS traffic engineering architecture. Traffic engineering provides the capabilities to do the following:

- Route primary paths around known bottlenecks or points of congestion in the network.
- Provide precise control over how traffic is rerouted when the primary path is faced with single or multiple failures.
- Provide efficient use of available aggregate bandwidth and long-haul fiber by ensuring that certain subsets of the network are not overutilized while other subsets of the network along potential alternate paths are underutilized.
- Maximize operational efficiency.
- Enhance the traffic-oriented performance characteristics of the network by minimizing packet loss, minimizing prolonged periods of congestion, and maximizing throughput.
- Enhance statistically bound performance characteristics of the network (such as loss ratio, delay variation, and transfer delay) required to support a multiservice Internet.

MPLS Feature Support on QFX Series and EX4600 Switches

IN THIS SECTION

- Supported Features | 14

This topic describes the MPLS features that are supported on the QFX Series, EX4600, EX4650 switches. Be sure to check for any exceptions to this support in "MPLS Limitations on QFX Series and EX4600 Switches" on page 31. Configuring unsupported statements on the switch does not affect its operation.

NOTE: EX4600 and EX4650 switches use the same chipset as QFX5100 switches—this is why EX Series switches are included here along with QFX Series switches. Other EX Series switches also support MPLS but with a different feature set.

Supported Features

The tables in this section lists the MPLS features that are supported on the QFX Series, EX4600, EX4650 switches, and the Junos OS release in which they were introduced. Table 1 on page 14 lists the features for QFX10000 switches. Table 2 on page 20 lists the features for QFX3500, QFX5100, QFX5120, QFX5110, QFX5200, QFX5210 switches.Table 3 on page 28 lists the features for EX4600 and EX4650 switches.

Table 1: QFX10000 MPLS Features

Feature	QFX10002	QFX10008	QFX10016
QFX10000 standalone switch as an MPLS provider edge (PE) switch or provider switch	15.1X53-D10	15.1X53-D30	15.1X53-D60

Table 1: QFX10000 MPLS Features *(Continued)*

Feature	QFX10002	QFX10008	QFX10016

Label-switching router (LSR)	15.1X53-D10	15.1X53-D30	15.1X53-D60
BGP MPLS Ethernet VPN (EVPN)	17.4R1	17.4R1	17.4R1
BGP route reflectors	15.1X53-D10	15.1X53-D30	15.1X53-D60
Automatic bandwidth and dynamic label-switched path (LSP) count sizing	15.1X53-D60	15.1X53-D60, 17.2R1	15.1X53-D60, 17.2R1
BGP labeled unicast	15.1X53-D10	15.1X53-D30	15.1X53-D60
BGP link state distribution	17.1R1	17.1R1	17.1R1
Carrier-of-carriers and interprovider Layer 3 VPNs	17.1R1	17.1R1	17.1R1
Entropy labels	17.2R1	17.2R1	17.2R1

Table 1: QFX10000 MPLS Features *(Continued)*

Feature	QFX10002	QFX10008	QFX10016
Ethernet-over-MPLS (L2 circuit)	15.1X53-D60	15.1X53-D60	15.1X53-D60
Fast reroute, one-to-one local protection and many-to-one local protection	15.1X53-D10	15.1X53-D30	15.1X53-D60
Fast reroute using detours and secondary LSP	15.1X53-D10	15.1X53-D30	15.1X53-D60
Flexible Ethernet services	17.3R1	17.3R1	17.3R1
Firewall filters	15.1X53-D30	15.1X53-D30	15.1X53-D60
RSVP graceful restart for OSPF	15.1X53-D10	15.1X53-D30	15.1X53-D60
IP-over-MPLS LSPs, both static and dynamic links	15.1X53-D10	15.1X53-D30	15.1X53-D60
IPv6 tunneling over an IPv4 network (6PE)	15.1X53-D10	15.1X53-D30	15.1X53-D60

Table 1: QFX10000 MPLS Features *(Continued)*

Feature	QFX10002	QFX10008	QFX10016
LDP tunneling over RSVP	15.1X53-D10	15.1X53-D30	15.1X53-D60
L2 Circuit on aggregated interfaces	17.3R1	17.3R1	17.3R1
L3VPNs for both IPv4 and IPv6	15.1X53-D10	15.1X53-D30	15.1X53-D60
MPLS over integrated bridging and routing (IRB) interfaces	15.1X53-D10	15.1X53-D30	15.1X53-D60
MPLS over UDP	18.3R1	18.3R1	18.3R1
MTU signaling in RSVP	15.1X53-D10	15.1X53-D30	15.1X53-D60
Operation, Administration, and Maintenance (OAM) including ping, traceroute and Bidirectional Forwarding Detection (BFD)	15.1X53-D10	15.1X53-D30	15.1X53-D60
OSPF TE	15.1X53-D10	15.1X53-D30	15.1X53-D60

Table 1: QFX10000 MPLS Features *(Continued)*

Feature	QFX10002	QFX10008	QFX10016
OSPFv2 as an interior gateway protocol (IGP)	15.1X53-D10	15.1X53-D30	15.1X53-D60
Path Computation Element Protocol for RSVP-TE	16.3R1	16.3R1	16.3R1
Pseudowire-over-aggregated Ethernet interfaces (core-facing interface)	15.1X53-D60 (supported only on network-to-network (NNI) interfaces)	15.1X53-D60 (supported only on NNI interfaces)	15.1X53-D60 (supported only on NNI interfaces)
RSVP support, including bandwidth allocation and traffic engineering	15.1X53-D10	15.1X53-D30	15.1X53-D60
RSVP fast reroute (FRR), including link-protection, node-link-protection, fast reroute using detours, and secondary LSP	15.1X53-D10	15.1X53-D30	15.1X53-D60

Table 1: QFX10000 MPLS Features *(Continued)*

Feature	QFX10002	QFX10008	QFX10016
SNMP MIB support	15.1X53-D10	15.1X54-D30	15.1X53-D60
Static and dynamic LSPs	15.1X53-D10	15.1X53-D30	15.1X53-D60
Traffic engineering extensions (OSPF-TE, IS-IS-TE)	15.1X53-D10	15.1X53-D30	15.1X53-D60
Traffic engineering (TE) Automatic bandwidth allocation and RSVP bandwidth Dynamic bandwidth management using ingress LSP splitting and merging	15.1X53-D10	15.1X53-D30	15.1X53-D60
Virtual routing and forwarding (VRF) label support	15.1X53-D10	15.1X53-D30	15.1X53-D60

Table 2: QFX3500, QFX5100, QFX5110, QFX5120, QFX5200, QFX5210 MPLS Features

Feature	QFX3500	QFX5100	QFX5110	QFX5120	QFX5200	QFX5210
QFX Series standalone switches as MPLS provider edge (PE) switches or provider switches	12.2X50-D10	13.2X51-D15 VC/VCF (14.1X53-D30)	15.1X53-D210	18.3R1	15.1X53-D30	18.1R1
Label edge router (LER)	12.2X50-D10	13.2X51-D15 VC/VCF (14.1X53-D30)	15.1X53-D210	18.3R1	15.1X53-D30	18.1R1

Feature	EX4600	EX4650
IPv6 tunneling over an MPLS IPv4 network (6PE)	14.1X53-D15	18.3R1
IPv6 over an MPLS core network	Not supported	Not supported
LDP tunneling over RSVP	14.1X53-D15	18.3R1
Layer 3 VPNs for both IPv4 and IPv6	14.1X53-D15	18.3R1
Loop-free alternate (LFA)	Not supported	Not supported
MPLS over integrated bridging and routing (IRB) interfaces	Not supported	18.3R1
MTU signaling in RSVP	14.1X53-D15	18.3R1
Operation, Administration, and Maintenance (OAM) including MPLS ping, traceroute, and BFD	14.1X53-D15	18.3R1
OSPF TE	14.1X53-D15	18.3R1
OSPFv2 as an interior gateway protocol	13.2X51-D25	18.3R1
Path Computation Element Protocol for RSVP-TE	Not supported	18.3R1
Pseudowire-over-aggregated Ethernet interfaces (core-facing interface)	14.1X53-D15	18.3R1

Table 3: EX4600 and EX4650 MPLS Features *(Continued)*

Feature	EX4600	EX4650
RSVP automatic bandwidth	14.1X53-D15	18.3R1
RSVP fast reroute (FRR), including link-protection, node-link-protection, fast reroute using detours, and secondary LSP	14.1X53-D15	18.3R1
RSVP-TE extensions (IS-IS and OSPF)	14.1X53-D15	18.3R1
SNMP MIB support	14.1X53-D15	18.3R1
Static and dynamic LSPs	14.1X53-D15	18.3R1
Traffic engineering (TE)automatic bandwidth allocation on LSPs	14.1X53-D15	18.3R1
Virtual routing and forwarding (VRF) label support	14.1X53-D15	18.3R1
VRF support in IRB Interfaces in a Layer 3 VPN	Not supported	18.3R1

MPLS Limitations on QFX Series and EX4600 Switches

IN THIS SECTION

- MPLS Limitations on QFX10000 Switches | **32**
- MPLS Limitations on EX4600, EX4650, QFX5100, QFX5110, QFX5120, QFX5200, and QFX5210 Switches | **33**
- MPLS Limitations on QFX5100 Virtual Chassis and Virtual Chassis Fabric Switches | **35**
- MPLS Limitations on QFX3500 Switches | **35**

MPLS is a fully implemented protocol on routers, while switches support a subset of the MPLS features. The limitations of each switch are listed in a separate section here, although many of the limitations are duplicates that apply to more than one switch.

MPLS Limitations on QFX10000 Switches

- Configuring an MPLS firewall filter on a switch that is deployed as an egress provider edge (PE) switch has no effect.
- Configuring the `revert-timer` statement at the `[edit protocols mpls]` hierarchy level has no effect.
- These LDP features are not supported on the QFX10000 switches:
  - LDP multipoint
  - LDP link protection
  - LDP Bidirectional Forwarding Detection (BFD)
  - LDP Operation Administration and Management (OAM)
  - LDP multicast-only fast reroute (MoFRR)
- Pseudowire-over-aggregated Ethernet interfaces on UNI are not supported.
- MPLS-over-UDP tunnels are not supported on the following:
  - MPLS TTL propagation
  - IP fragmentation at the tunnel start point
  - CoS rewrite rules and priority propagation for RSVP LSP labels (ingress tunnels only)
  - Plain IPv6
  - Multicast traffic
  - Firewall filters on tunnel start and endpoints
  - CoS tunnel endpoints

> **NOTE**: MPLS-over-UDP tunnels are created only if corresponding RSVP-TE, LDP, or BGP-LU tunnels are not available for the destination route.

MPLS Limitations on EX4600, EX4650, QFX5100, QFX5110, QFX5120, QFX5200, and QFX5210 Switches

- MPLS support differs on the various switches. EX4600 switches support only basic MPLS functionality while the QFX5100, QFX5110, QFX5120, QFX5200, and QFX5210 switches support some of the more advanced features. See "MPLS Feature Support on QFX Series and EX4600 Switches" on page 14 for details.

- On a QFX5100 switch, configuring integrated bridging and routing (IRB) interfaces on the MPLS core is implemented on the switch by using TCAM rules. This is the result of a chip limitation on the switch, which only allows for a limited amount of TCAM space. There is 1K TCAM space is allocated for IRB. If multiple IRBs exist, make sure that you have enough available TCAM space on the switch. To check the TCAM space, see TCAM Filter Space Allocation and Verification in QFX Devices from Junos OS 12.2x50-D20 Onward.

- (QFX5100, QFX5110, QFX5120, QFX5200, QFX5210, EX4600) When VLAN bridge encapsulation is enabled on a CE connected interface, the switch drops packets if both flexible Ethernet services and VLAN CCC encapsulations are configured on the same logical interface. Only one can be configured, not both. For example:

  `set interfaces xe-0/0/18 encapsulation flexible-ethernet-services`, or `set interfaces xe-0/0/18 encapsulation vlan-ccc`.

- Layer 2 circuits on aggregated Ethernet (AE) interfaces are not supported on QFX5100, QFX5110, QFX5120, QFX5200, and QFX5210 switches.

- Layer 2 circuit local switching is not supported on the EX4600, EX4650, and QFX5100 switches.

- The QFX5100, QFX5110, QFX5120, QFX5200, and QFX5210 switches do not depend on the VRF match for loopback filters configured at different routing instances. Loopback filters per routing instance (such as lo0.100, lo0.103, lo0.105) are not supported and may cause unpredictable behavior. We recommend that you only apply the loopback filter (lo0.0) to the master routing instance

- On EX4600 and EX4650 switches, when loopback filters with both accept and deny terms for the same IP address are configured and if RSVP packets have that IP address in either source IP or destination IP, then those RSVP packets will be dropped even if accept terms have higher priority than deny terms. As per design, if the switch receives an RSVP packet with IP OPTION, the packet is copied to the CPU and then the original packet is dropped. Because RSVP packets are marked for drop, the accept term will not process these packets and the deny term will drop the packets.

- On a link-protected, fast reroute Layer 2 circuit, you might see a traffic convergence delay of 200 to 300 milliseconds.

- If you configure the BGP labeled unicast address family (using the `labeled-unicast` statement at the `[edit protocols bgp family inet]` hierarchy level) on a QFX Series switch or on an EX4600 switch

deployed as a route reflector for BGP labeled routes, path selection will occur at the route reflector, and a single best path will be advertised. This will result in loss of BGP multipath informaton.

- Although fast reroute (FRR) on regular interfaces is supported, the `include-all` and `include-any` options for FRR are not supported. See "Fast Reroute Overview" on page 562.
- FRR is not supported on MPLS over IRB interfaces.
- MPLS-based circuit cross-connects (CCC) are not supported—only circuit-based pseudowires are supported.
- Configuring link aggregation groups (LAGs) on user-to-network interface (UNI) ports for L2 circuits is not supported.
- MTU signaling in RSVP and discovery is supported in the control plane. However, this cannot be enforced in the data plane.
- With L2 circuit-based pseudowires, if multiple equal-cost RSVP LSPs are available to reach an L2 circuit neighbor, one LSP is randomly used for forwarding. Use this feature to specify LSPs for specific L2 circuit traffic to load-share the traffic in the MPLS core.
- Configuring an MPLS firewall filter on a switch that is deployed as an egress provider edge (PE) switch has no effect.
- Firewall filters and policers on `family mpls` are only supported on QFX5100 switches that act as pure label-switching routers (LSRs) in an MPLS network. A pure LSR is a transit router that switches paths solely on the incoming label's instructions. Firewall filters and policers on `family mpls` are not supported on QFX5100 ingress and egress provider edge (PE) switches. This includes switches that perform penultimate hop popping (PHP).
- Configuring the `revert-timer` statement at the `[edit protocols mpls]` hierarchy level has no effect.
- These are the hardware limitations for EX4600, EX4650, QFX5100, QFX5110, QFX5120, QFX5200, and QFX5210 switches:
  - Push of a maximum of three labels is supported in the MPLS edge switch if label swap is not done.
  - Push of a maximum of two labels is supported in the MPLS edge switch if label swap is done.
  - Pop at line rate is supported for a maximum of two labels.
  - Global label space is supported but interface-specific label space is not supported.
  - MPLS ECMP on PHY node with BOS=1 is not supported for single labels.
  - QFX Series switches with Broadcom chips do not support separate next hops for the same label with different S bits (S-0 and S-1). This includes the QFX3500, QFX3600, EX4600, QFX5100, and QFX5200 switches.

    - On EX4600, EX4650, QFX5100, QFX5110, QFX5120, QFX5200, and QFX5210 switches, the MPLS MTU command can cause unexpected behavior—this is due to SDK chipset limitations on this platform.

- These LDP features are not supported on the EX4600, EX4650, QFX5100, QFX5110, QFX5120, QFX5200, and QFX5210 switches:
    - LDP multipoint
    - LDP link protection
    - LDP Bidirectional Forwarding Detection (BFD)
    - LDP Operation Administration and Management (OAM)
    - LDP multicast-only fast reroute (MoFRR)
- Configuring unit with `family mpls` and unit with `encapsulation vlan-bridge` on the same physical interface is not supported on EX4600, EX4650, QFX5100, QFX5110, or QFX5120.

MPLS Limitations on QFX5100 Virtual Chassis and Virtual Chassis Fabric Switches

The following MPLS features are not supported by the QFX5100 VC and QFX5100 VCF switches:

- Next-hop LSP
- BFD including BFD triggered FRR
- L2 VPN based on BGP (See RFC 6624)
- VPLS
- Extended VLAN CCC
- Pseudowire protection using Ethernet OAM
- Local switching of pseudo-wire
- Pseudowire fault detection based on VCCV
- QFX Series switches with Broadcom chipsets do not support separate next hops for the same label with different S bits (S-0 and S-1). This includes QFX3500, QFX3600, EX4600, QFX5100, and QFX5200 switches.

MPLS Limitations on QFX3500 Switches

- If you configure the BGP labeled unicast address family (using the `labeled-unicast` statement at the `[edit protocols bgp family inet]` hierarchy level) on a QFX Series switch or on an EX4600 switch deployed as a route reflector for BGP labeled routes, path selection will occur at the route reflector, and a single best path will be advertised. This will result in loss of BGP multipath information.
- Although fast reroute is supported, the `include-all` and `include-any` options for fast reroute are not supported. See "Fast Reroute Overview" on page 562 for details.
- MPLS-based circuit cross-connects (CCC) are not supported—only circuit-based pseudowires are supported.
- MTU signaling in RSVP and discovery is supported in the control plane. However, this cannot be enforced in the data plane.
- With Layer 2 (L2) circuit-based pseudowires, if multiple equal-cost RSVP label-switched paths (LSPs) are available to reach a L2 circuit neighbor, one LSP is randomly used for forwarding. Use this feature to specify LSPs for specific L2 circuit traffic to load-share the traffic in the MPLS core.
- Configuring an MPLS firewall filter on a switch that is deployed as an egress provider edge (PE) switch has no effect.
- Configuring the `revert-timer` statement at the `[edit protocols mpls]` hierarchy level has no effect.

CHAPTER 2

Supported Standards

IN THIS CHAPTER

- Supported MPLS Standards | 37

Supported MPLS Standards

IN THIS SECTION

- Supported MPLS Standards | 37
- Supported RSVP Standards | 41
- Supported LDP Standards | 42
- DiffServ-Aware Traffic Engineering Standards | 43
- Supported GMPLS Standards | 43
- Supported PCEP Standards | 44

Supported MPLS Standards

Junos OS substantially supports the following RFCs and Internet drafts, which define standards for MPLS and traffic engineering.

- RFC 2858, *Multiprotocol Extensions for BGP-4*
- RFC 3031, *Multiprotocol Label Switching Architecture*
- RFC 3032, *MPLS Label Stack Encoding*
- RFC 3140, *Per Hop Behavior Identification Codes*
- RFC 3270, *Multi-Protocol Label Switching (MPLS) Support of Differentiated Services*

Only E-LSPs are supported.

- RFC 3443, *Time To Live (TTL) Processing in Multi-Protocol Label Switching (MPLS) Networks*
- RFC 3478, *Graceful Restart Mechanism for Label Distribution Protocol*
- RFC 3906, *Calculating Interior Gateway Protocol (IGP) Routes Over Traffic Engineering Tunnels*
- RFC 4090, *Fast Reroute Extensions to RSVP-TE for LSP Tunnels*

  Node protection in facility backup is not supported.
- RFC 4124, *Protocol Extensions for Support of Diffserv-aware MPLS Traffic Engineering*
- RFC 4182, *Removing a Restriction on the use of MPLS Explicit NULL*
- RFC 4364, *BGP/MPLS IP Virtual Private Networks (VPNs)*
- RFC 4379, *Detecting Multi-Protocol Label Switched (MPLS) Data Plane Failures*
- RFC 4385, *Pseudowire Emulation Edge-to-Edge (PWE3) Control Word for Use over an MPLS PSN*.

  Supported on MX Series routers with the Channelized OC3/STM1 (Multi-Rate) Circuit Emulation MIC with SFP.
- RFC 4875, *Extensions to RSVP-TE for Point-to-Multipoint TE LSPs*
- RFC 4950, *ICMP Extensions for Multiprotocol Label Switching*
- RFC 5317, *Joint Working Team (JWT) Report on MPLS Architectural Considerations for a Transport Profile*
- RFC 5586, *MPLS Generic Associated Channel*
- RFC 5654, *Requirements of an MPLS Transport Profile*

  The following capabilities are supported in the Junos OS implementation of MPLS Transport Profile (MPLS-TP):

  - MPLS-TP OAM can send and receive packets with GAL and G-Ach, without IP encapsulation.
  - Two unidirectional RSVP LSPs between a pair of routers can be associated with each other to create an associated bidirectional LSP for binding a path for the GAL and G-Ach OAM messages. A single Bidirectional Forwarding Detection (BFD) session is established for the associated bidirectional LSP.
- RFC 5712, *MPLS Traffic Engineering Soft Preemption*
- RFC 5718, *An In-Band Data Communication Network For the MPLS Transport Profile*

- RFC 5860, *Requirements for Operations, Administration, and Maintenance (OAM) in MPLS Transport Networks*
- RFC 5884, *Bidirectional Forwarding Detection (BFD) for MPLS Label Switched Paths (LSPs)*
- RFC 5921, *A Framework for MPLS in Transport Networks*
- RFC 5950, *Network Management Framework for MPLS-based Transport Networks*
- RFC 5951, *Network Management Requirements for MPLS-based Transport Networks*
- RFC 5960, *MPLS Transport Profile Data Plane Architecture*
- RFC 6215, *MPLS Transport Profile User-to-Network and Network-to-Network Interfaces*
- RFC 6291, *Guidelines for the Use of the "OAM" Acronym in the IETF.*
- RFC 6370, *MPLS Transport Profile (MPLS-TP) Identifiers*
- RFC 6371, *Operations, Administration, and Maintenance Framework for MPLS-Based Transport Networks*.
- RFC 6372, *MPLS Transport Profile (MPLS-TP) Survivability Framework*
- RFC 6373, *MPLS-TP Control Plane Framework*
- RFC 6388, *Label Distribution Protocol Extensions for Point-to-Multipoint and Multipoint-to-Multipoint Label Switched Paths*

  Only Point-to-Multipoint LSPs are supported.
- RFC 6424, *Mechanism for Performing Label Switched Path Ping (LSP Ping) over MPLS Tunnels*
- RFC 6425, *Detecting Data-Plane Failures in Point-to-Multipoint MPLS - Extensions to LSP Ping*
- RFC 6426, *MPLS On-Demand Connectivity Verification and Route Tracing*
- RFC 6428, *Proactive Connectivity Verification, Continuity Check, and Remote Defect Indication for the MPLS Transport Profile*
- RFC 6510, *Resource Reservation Protocol (RSVP) Message Formats for Label Switched Path (LSP) Attributes Objects*
- RFC 7746, *Label Switched Path (LSP) Self-Ping*
- Internet draft draft-ietf-mpls-rsvp-te-no-php-oob-mapping-01.txt, *Non PHP behavior and Out-of-Band Mapping for RSVP-TE LSPs*

The following RFCs and Internet drafts do not define standards, but provide information about MPLS, traffic engineering, and related technologies. The IETF classifies them variously as “Experimental,” “Historic,” or “Informational.”

- RFC 2547, *BGP/MPLS VPNs*
- RFC 2702, *Requirements for Traffic Engineering Over MPLS*
- RFC 2917, *A Core MPLS IP VPN Architecture*
- RFC 3063, *MPLS Loop Prevention Mechanism*
- RFC 3208, *PGM Reliable Transport Protocol Specification*

  Only the network element is supported.
- RFC 3469, *Framework for Multi-Protocol Label Switching (MPLS)-based Recovery*
- RFC 3564, *Requirements for Support of Differentiated Services-aware MPLS Traffic Engineering*
- RFC 4125, *Maximum Allocation Bandwidth Constraints Model for Diffserv-aware MPLS Traffic Engineering*
- RFC 4127, *Russian Dolls Bandwidth Constraints Model for Diffserv-aware MPLS Traffic Engineering*
- Internet draft draft-martini-l2circuit-encap-mpls-11.txt, *Encapsulation Methods for Transport of Layer 2 Frames Over IP and MPLS Networks*

  Junos OS differs from the Internet draft in the following ways:

  - A packet with a sequence number of 0 is treated as out of sequence.
  - Any packet that does not have the next incremental sequence number is considered out of sequence.
  - When out-of-sequence packets arrive, the expected sequence number for the neighbor is set to the sequence number in the Layer 2 circuit control word.
- Internet draft draft-martini-l2circuit-trans-mpls-19.txt, *Transport of Layer 2 Frames Over MPLS*
- Internet draft draft-raggarwa-mpls-p2mp-te-02.txt, *Establishing Point to Multipoint MPLS TE LSPs*

  The features discussed in the indicated sections of the draft are not supported:

  - Nonadjacent signaling for branch LSPs (section 7.1)
  - Make-before-break and fast reroute (section 9)
  - LSP hierarchy using point-to-point LSPs (section 10)

Supported RSVP Standards

Junos OS substantially supports the following RFCs and Internet drafts, which define standards for RSVP.

- RFC 2205, *Resource ReSerVation Protocol (RSVP)—Version 1 Functional Specification*
- RFC 2210, *The Use of RSVP with IETF Integrated Services*
- RFC 2211, *Specification of the Controlled-Load Network Element Service*
- RFC 2212, *Specification of Guaranteed Quality of Service*
- RFC 2215, *General Characterization Parameters for Integrated Service Network Elements*
- RFC 2745, *RSVP Diagnostic Messages*
- RFC 2747, *RSVP Cryptographic Authentication* (updated by RFC 3097)
- RFC 2750, *RSVP Extensions for Policy Control* (RFC is not supported. Fully compliant with devices that support this RFC).
- RFC 2961, *RSVP Refresh Overhead Reduction Extensions*
- RFC 3097, *RSVP Cryptographic Authentication—Updated Message Type Value*
- RFC 3209, *RSVP-TE: Extensions to RSVP for LSP Tunnels*

  The Null Service Object for maximum transmission unit (MTU) signaling in RSVP is not supported.
- RFC 3473, *Generalized Multi-Protocol Label Switching (GMPLS) Signaling Resource ReserVation Protocol-Traffic Engineering (RSVP-TE) Extensions*

  Only Section 9, “Fault Handling,” is supported.
- RFC 3477, *Signalling Unnumbered Links in Resource ReSerVation Protocol - Traffic Engineering (RSVP-TE)*
- RFC 4090, *Fast Reroute Extensions to RSVP-TE for LSP Tunnels*
- RFC 4203, *OSPF Extensions in Support of Generalized Multi-Protocol Label Switching (GMPLS)*

  (OSPF extensions can carry traffic engineering information over unnumbered links.)
- RFC 4558, *Node-ID Based Resource Reservation Protocol (RSVP) Hello: A Clarification Statement*
- RFC 4561, *Definition of a Record Route Object (RRO) Node-Id Sub-Object*

  The RRO node ID subobject is for use in inter-AS link and node protection configurations.

- RFC 4875, *Extensions to RSVP-TE for Point-to-Multipoint TE LSPs*
- RFC 5420, *Encoding of Attributes for MPLS LSP Establishment Using Resource Reservation Protocol Traffic Engineering (RSVP-TE)*

  Only the LSP_ATTRIBUTES object is supported.
- RFC 7570, *Label Switched Path (LSP) Attribute in the Explicit Route Object (ERO)*
- RFC 8370, *Techniques to Improve the Scalability of RSVP-TE Deployments*
- draft-ietf-mpls-ri-rsvp-frr-05, *Refresh Interval Independent FRR Facility Protection*
- draft-ietf-mpls-rsvp-shared-labels-09, *Signaling RSVP-TE tunnels on a shared MPLS forwarding plane*

The following RFCs do not define standards, but provide information about RSVP and related technologies. The IETF classifies them variously as “Experimental” or “Informational.”

- RFC 2209, *Resource ReSerVation Protocol (RSVP)—Version 1 Message Processing Rules*
- RFC 2216, *Network Element Service Specification Template*
- RFC 4125, *Maximum Allocation Bandwidth Constraints Model for Diffserv-aware MPLS Traffic Engineering*
- RFC 4127, *Russian Dolls Bandwidth Constraints Model for Diffserv-aware MPLS Traffic Engineering*

Supported LDP Standards

Junos OS substantially supports the following RFCs and Internet drafts, which define standards for LDP.

- RFC 3212, *Constraint-Based LSP Setup using LDP*
- RFC 3478, *Graceful Restart Mechanism for Label Distribution Protocol*
- Internet draft draft-napierala-mpls-targeted-mldp-01.txt, *Using LDP Multipoint Extensions on Targeted LDP Sessions*

The following RFCs do not define standards, but provide information about LDP. The IETF classifies them as “Informational.”

- RFC 3215, *LDP State Machine*
- RFC 5036, *LDP Specification*

  For the following features described in the indicated sections of the RFC, Junos OS supports one of the possible modes but not the others:

  - Label distribution control (section 2.6.1): Ordered mode is supported, but not Independent mode.

  - Label retention (section 2.6.2): Liberal mode is supported, but not Conservative mode.
  - Label advertisement (section 2.6.3): Both Downstream Unsolicited mode and Downstream on Demand mode are supported.
- RFC 5283, *LDP Extension for Inter-Area Label Switched Paths (LSPs)*
- RFC 5443, *LDP IGP Synchronization*
- RFC 5561, *LDP Capabilities*
- RFC 6826, *Multipoint LDP In-Band Signaling for Point-to-Multipoint and Multipoint-to-Multipoint Label Switched Paths*

  Junos OS support limited to point-to-multipoint extensions for LDP.

DiffServ-Aware Traffic Engineering Standards

The following RFCs provide information on DiffServ-aware traffic engineering and multiclass LSPs:

- RFC 3270, *Multi-Protocol Label Switching (MPLS) Support of Differentiated Services*
- RFC 3564, *Requirements for Support of Differentiated Services-aware MPLS Traffic Engineering*
- RFC 4124, *Protocol Extensions for Support of Differentiated-Service-Aware MPLS Traffic Engineering*
- RFC 4125, *Maximum Allocation Bandwidth Constraints Model for Diff-Serv-aware MPLS Traffic Engineering*
- RFC 4127, *Russian Dolls Bandwidth Constraints Model for Diff-Serv-aware MPLS*

These RFCs are available on the IETF website at http://www.ietf.org/.

Supported GMPLS Standards

Junos OS substantially supports the following RFCs and Internet drafts, which define standards for Generalized MPLS (GMPLS).

- RFC 3471, *Generalized Multi-Protocol Label Switching (GMPLS) Signaling Functional Description*

  Only the following features are supported:

  - Bidirectional LSPs (upstream label only)
  - Control channel separation
  - Generalized label (suggested label only)
  - Generalized label request (bandwidth encoding only)

- RFC 3473, *Generalized Multi-Protocol Label Switching (GMPLS) Signaling Resource ReserVation Protocol-Traffic Engineering (RSVP-TE) Extensions*

  Only Section 9, "Fault Handling," is supported.

- RFC 4202, *Routing Extensions in Support of Generalized Multi-Protocol Label Switching*

  Only interface switching is supported.

- RFC 4206, *Label Switched Paths (LSP) Hierarchy with Generalized Multi-Protocol Label Switching (GMPLS) Traffic Engineering (TE)*

- Internet draft draft-ietf-ccamp-gmpls-rsvp-te-ason-02.txt, *Generalized MPLS (GMPLS) RSVP-TE Signalling in support of Automatically Switched Optical Network (ASON)* (expires January 2005)

- Internet draft draft-ietf-ccamp-gmpls-sonet-sdh-08.txt, *Generalized Multi-Protocol Label Switching Extensions for SONET and SDH Control*

  Only S,U,K,L,M-format labels and SONET traffic parameters are supported.

- Internet draft draft-ietf-ccamp-lmp-10.txt, *Link Management Protocol (LMP)*

- Internet draft draft-ietf-ccamp-ospf-gmpls-extensions-12.txt, *OSPF Extensions in Support of Generalized Multi-Protocol Label Switching*

  The following sub-TLV types for the Link type, link, value (TLV) are not supported:

  - Link Local/Remote Identifiers (type 11)
  - Link Protection Type (type 14)
  - Shared Risk Link Group (SRLG) (type 16)

  The features described in Section 2 of the draft, "Implications on Graceful Restart," are also not supported.

  The Interface Switching Capability Descriptor (type 15) sub-TLV type is implemented, but only for packet switching.

- Internet draft draft-ietf-mpls-bundle-04.txt, *Link Bundling in MPLS Traffic Engineering*

Supported PCEP Standards

Junos OS substantially supports the following RFCs and Internet drafts, which define standards for PCEP.

- RFC 5440, *Path Computation Element (PCE) Communication Protocol (PCEP)—Stateful PCE*

- RFC 8231, *Path Computation Element Communication Protocol (PCEP)—Extensions for Stateful PCE*

- RFC 8281, *Path Computation Element Communication Protocol (PCEP)—Extensions PCE-Initiated LSP Setup in a Stateful PCE Model*
- Internet draft-ietf-pce-stateful-pce-07.txt, *PCEP Extensions for Stateful PCE*
- Internet draft-crabbe-pce-pce-initiated-lsp-03.txt, *PCEP Extensions for PCE-initiated LSP Setup in a Stateful PCE Model*
- Internet draft-ietf-pce-segment-routing-06.txt, *PCEP Extensions for Segment Routing*
- Internet draft-ietf-pce-stateful-pce-p2mp-02.txt, *Path Computation Element (PCE) Protocol Extensions for Stateful PCE usage for Point-to-Multipoint Traffic Engineering Label Switched Paths*
- Internet draft draft-cbrt-pce-stateful-local-protection-01, *PCEP Extensions for RSVP-TE Local-Protection with PCE-Stateful* (excluding support for bypass LSP mapping)
- Internet draft draft-ietf-pce-pcep-flowspec-05, *PCEP Extension for Flow Specification*

  The current implementation of this feature does not implement the following sections of the draft:

  - Section 3.1.2—Advertising PCE capabilties in IGP
  - Section 3.2—PCReq and PCRep message
  - Section 7—Most of the flow specifications, except route distinguisher and IPv4 Multicast Flow specifications, are not supported.

Basic MPLS Configuration

IN THIS SECTION

- MPLS Configuration Overview | 47
- MPLS Configuration Guidelines | 48
- Configuring MPLS | 49
- Example: Enabling MPLS | 49
- Example: Configuring MPLS on EX8200 and EX4500 Switches | 53

MPLS Configuration Overview

When you first install Junos OS on your device, MPLS is disabled by default. You must explicitly configure your device to allow MPLS traffic to pass through. Complete the following steps for all devices in your MPLS network that are running Junos OS.

To enable MPLS:

1. Delete all configured security services from the device. If you do not complete this step, you will get a commit failure. See Example: Deleting Security Services.
2. Enable MPLS on the device. See "Example: Enabling MPLS" on page 49.
3. Commit the configuration.
4. Reboot the device.

5. Configure MPLS features such as traffic engineering, VPNs, and VPLS. See:

   - "MPLS Traffic Engineering and Signaling Protocols Overview" on page 1590
   - MPLS VPN Overview
   - CLNS Overview
   - VPLS Overview

> **CAUTION**: When packet forwarding mode is changed to MPLS, all flow-based security features are deactivated, and the device performs packet-based processing only. Flow-based services such as security policies, zones, NAT, ALGs, chassis clustering, screens, firewall authentication, and IPsec VPNs are unavailable on the device. However, MPLS can be enabled in flow-based packet forwarding mode for selected traffic using firewall filters.

MPLS Configuration Guidelines

When configuring MPLS on QFX Series devices or on EX4600, note that the number of IP prefixes supported depends on the specific platform being used. See the scale specifications in the data sheet of your device for additional information.

- We recommend the following:
  - If your ingress provider edge (PE) switch needs to support more than 8000 external IP prefixes, use a larger capacity device as an ingress PE switch.
  - If you use a switch as a route reflector for BGP labeled routes, use it as a dedicated route reflector (that is, the switch must not participate in managing data traffic).
  - If you use a switch as a PE switch or as a route reflector for BGP labeled routes, configure routing policies on the PE switch and the route reflector to filter external IP routes from the routing table.

    The configuration example for a routing policy named fib_policy (at the `[edit policy-options` and `[edit routing-options` hierarchy levels) to filter BGP labeled routes from the inet.0 routing table is given below:

```
user@switch# show policy-options
policy-statement fib_policy {
    from {
        protocol bgp;
        rib inet.0;
    }
```

```
    then reject;
}
```

```
user@switch# show routing-options
forwarding-table {
    export fib_policy;
}
```

- Packet fragmentation using the `allow-fragmentation` statement at the `[edit protocols mpls path-mtu]` hierarchy level is not supported on QFX Series devices or on the EX4600 switch. Therefore, you must ensure that the maximum transmission unit (MTU) values configured on every MPLS interface is sufficient to handle MPLS packets. The packets whose size exceeds the MTU value of an interface will be dropped.

Configuring MPLS

You must also configure MPLS for a Layer 2 cross-connect to work. The following is a minimal MPLS configuration:

```
[edit]
interfaces {
                                    interface-name              {
        unit                logical-unit-number;
    }
}
protocols {
    mpls {
        interface all;
    }
}
```

Example: Enabling MPLS

IN THIS SECTION

- Requirements | 50
- Overview | 50

Configuration | 50
Verification | 52

This example shows how to enable MPLS for packet-based processing. It also shows how to enable the MPLS family and MPLS process on all of the transit interfaces in the network.

NOTE: When MPLS is enabled, all flow-based security features are deactivated and the device performs packet-based processing. Flow-based services such as security policies, zones, NAT, ALGs, chassis clustering, screens, firewall authentication, IP packets, and IPsec VPNs are unavailable on the device.

Before changing from flow mode to packet mode, you must remove all security policies remaining under flow mode. To prevent management connection loss, you must bind the management interface to zones and enable host-inbound traffic to prevent the device from losing connectivity.

For information about configuring zones, see Security Policies User Guide for Security Devices.

Requirements

Before you begin, delete all configured security services. See Example: Deleting Security Services.

Overview

The instructions in this topic describe how to enable MPLS on the device. You must enable MPLS on the device before including a device running Junos OS in an MPLS network.

Configuration

IN THIS SECTION

Procedure | 51

Procedure

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the `[edit]` hierarchy level, and then enter `commit` from configuration mode.

```
set security forwarding-options family mpls mode packet-based
set interfaces ge-1/0/0 unit 0 family mpls
set protocols mpls ge-1/0/0 unit 0
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To enable MPLS:

1. Enable MPLS for packet-based processing.

```
[edit security forwarding-options]
user@host# set family mpls mode packet-based
```

2. Enable the MPLS family on each transit interface that you want to include in the MPLS network.

```
[edit interfaces]
user@host# set interfaces ge-1/0/0 unit 0 family mpls
```

3. Enable the MPLS process on all of the transit interfaces in the MPLS network.

```
[edit protocols mpls]
user@host# set interface ge-1/0/0 unit 0
```

Results

From configuration mode, confirm your configuration by entering the `show security forwarding-options` command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

NOTE: If you enable MPLS for packet-based processing by using the command `set security forward-option family mpls mode packet`, the mode will not change immediately and the system will display the following messages:

warning: Reboot may required when try reset flow inet mode

warning: Reboot may required when try reset mpls flow mode please check security flow status for detail.

You need to reboot your device for the configuration to take effect.

CAUTION: If you disable MPLS and switch back to using the security services (flow-based processing), the mode will not change immediately and the system will display warning messages instructing you to restart your device. You must reboot your device for the configuration to take effect. This will also result in management sessions being reset and transit traffic getting interrupted.

```
[edit]
user@host# show security forwarding-options
family {
    mpls {
        mode packet-based;
    }
}
```

If you are done configuring the device, enter `commit` from configuration mode.

Verification

IN THIS SECTION

Verifying MPLS Is Enabled at the Protocols Level | 53

- Verifying MPLS Is Enabled at the Interfaces Level | 53

Confirm that the configuration is working properly.

Verifying MPLS Is Enabled at the Protocols Level

Purpose

Verify that MPLS is enabled at the protocols level.

Action

From operational mode, enter the **show protocols** command.

Verifying MPLS Is Enabled at the Interfaces Level

Purpose

Verify that MPLS is enabled at the interfaces level.

Action

From operational mode, enter the **show interfaces** command.

Example: Configuring MPLS on EX8200 and EX4500 Switches

IN THIS SECTION

- Requirements | 54
- Overview and Topology | 54
- Configuring the Local PE Switch | 60
- Configuring the Remote PE Switch | 64
- Configuring the Provider Switch | 68
- Verification | 72

You can configure MPLS on switches to increase transport efficiency in your network. MPLS services can be used to connect various sites to a backbone network and to ensure better performance for low-latency applications such as voice over IP (VoIP) and other business-critical functions.

To implement MPLS on the switches, you must configure two provider edge (PE) switches—an ingress PE switch and an egress PE switch— and at least one provider (transit) switch. You can configure the customer edge (CE) interfaces on the PE switches of the MPLS network as either circuit cross-connect (CCC) or IP (**family inet**) interfaces.

This example shows how to configure an MPLS tunnel using a simple interface as a CCC:

NOTE: This example shows how to configure MPLS using a simple interface as a CCC. For information on configuring a tagged VLAN interface as a CCC, see "Configuring an MPLS-Based VLAN CCC Using a Layer 2 VPN (CLI Procedure)" on page 1985 or "Configuring an MPLS-Based VLAN CCC Using a Layer 2 Circuit" on page 1948.

Requirements

This example uses the following hardware and software components:

- Junos OS Release 10.1 or later for switches
- Three EX Series switches

Before you begin configuring MPLS, ensure that you have configured the routing protocol (OSPF or IS-IS) on the core interface and the loopback interface on all the switches. This example includes the configuration of OSPF on all the switches. For information on configuring IS-IS as the routing protocol, see the *Junos OS Routing Protocols Configuration Guide*.

Overview and Topology

This example includes an ingress or local PE switch, an egress or remote PE switch, and one provider switch. It includes CCCs that tie the customer edge interface of the local PE switch (PE-1) to the customer edge interface of the remote PE switch (PE-2). It also describes how to configure the core interfaces of the PE switches and the provider switch to support the transmission of the MPLS packets. In this example, the core interfaces that connect the local PE switch and the provider switch are individual interfaces, while the core interfaces that connect the remote PE switch and the provider switch are aggregated Ethernet interfaces.

NOTE:

- Core interfaces cannot be tagged VLAN interfaces.
- Core interfaces can be aggregated Ethernet interfaces. This example includes a LAG between the provider switch and the remote PE switch because this type of configuration is another option you can implement. For information on configuring LAGs, see Configuring Aggregated Ethernet Links (CLI Procedure).

Figure 2 on page 55 shows the topology used in this example.

Figure 2: Configuring MPLS on EX Series Switches

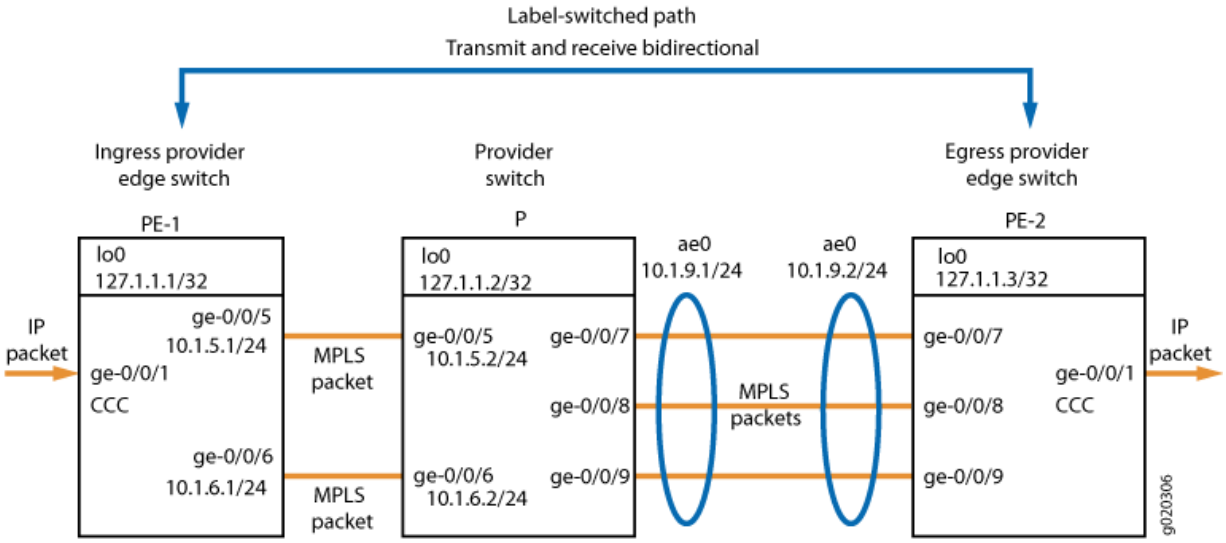

Table 4 on page 55 shows the MPLS configuration components used for the ingress PE switch in this example.

Table 4: Components of the Ingress PE Switch in the Topology for MPLS with Interface-Based CCC

Property	Settings	Description
Local PE switch hardware	EX Series switch	PE-1
Loopback address	**lo0 127.1.1.1/32**	Identifies PE-1 for interswitch communications.

Table 4: Components of the Ingress PE Switch in the Topology for MPLS with Interface-Based CCC *(Continued)*

Property	Settings	Description
Routing protocol	**ospf traffic-engineering**	Indicates that this switch is using OSPF as the routing protocol and that traffic engineering is enabled.
MPLS protocol and definition of label-switched path	**mpls** **label-switched-path lsp_to_pe2_ge1 to 127.1.13**	Indicates that this PE switch is using the MPLS protocol with the specified LSP to reach the other PE switch (specified by the loopback address). The statement must also specify the core interfaces to be used for MPLS traffic.
RSVP	**rsvp**	Indicates that this switch is using RSVP. The statement must specify the loopback address and the core interfaces that will be used for the RSVP session.
Interface family	**family inet** **family mpls** **family ccc**	The logical units of the core interfaces are configured to belong to both **family inet** and **family mpls**. The logical unit of the customer edge interface is configured to belong to **family ccc**.
Customer edge interface	**ge-0/0/1**	Interface that connects this network to devices outside the network.
Core interfaces	**ge-0/0/5.0** and **ge-0/0/6.0** with IP addresses **10.1.5.1/24** and **10.1.6.1/24**	Interfaces that connect to other switches within the MPLS network.

Table 4: Components of the Ingress PE Switch in the Topology for MPLS with Interface-Based CCC *(Continued)*

Property	Settings	Description
CCC definition	**connections** **remote-interface-switch ge-1-to-pe2** **interface ge-0/0/1.0** **transmit-lsp lsp_to_pe2_ge1** **receive-lsp lsp_to_pe1_ge1**	Associates the circuit cross-connect (CCC), **ge-0/0/1**, with the LSPs that have been defined on the local and remote PE switches.

Table 5 on page 57 shows the MPLS configuration components used for the egress PE switch in this example.

Table 5: Components of the Egress PE Switch in the Topology for MPLS with Interface-Based CCC

Property	Settings	Description
Remote PE switch hardware	EX Series switch	PE-2
Loopback address	**lo0 127.1.1.3/32**	Identifies PE-2 for interswitch communications.
Routing protocol	**ospf traffic-engineering**	Indicates that this switch is using OSPF as the routing protocol and that traffic engineering is enabled.
MPLS protocol and definition of label-switched path	**mpls** **label-switched-path lsp_to_pe1_ge1** **to 127.1.1.1**	Indicates that this PE switch is using the MPLS protocol with the specified label-switched path (LSP) to reach the other PE switch. The statement must also specify the core interfaces to be used for MPLS traffic.

Table 5: Components of the Egress PE Switch in the Topology for MPLS with Interface-Based CCC *(Continued)*

Property	Settings	Description
RSVP	**rsvp**	Indicates that this switch is using RSVP. The statement must specify the loopback address and the core interfaces that will be used for the RSVP session.
Interface family	**family inet** **family mpls** **family ccc**	The logical unit of the core interface is configured to belong to both **family inet** and **family mpls**. The logical unit of the customer edge interface is configured to belong to **family ccc**.
Customer edge interface	**ge-0/0/1**	Interface that connects this network to devices outside the network.
Core interface	**ae0** with IP address **10.1.9.2/24**	Aggregated Ethernet interface on PE-2 that connects to aggregated Ethernet interface **ae0** of the provider switch and belongs to **family mpls**.
CCC definition	**connections remote-interface-switch ge-1-to-pe1** **interface ge-0/0/1.0** **transmit-lsp lsp_to_pe1_ge1;** **receive-lsp lsp_to_pe2_ge1;**	Associates the CCC, **ge-0/0/1**, with the LSPs that have been defined on the local and remote PE switches.

Table 6 on page 59 shows the MPLS configuration components used for the provider switch in this example.

Table 6: Components of the Provider Switch in the Topology for MPLS with Interface-Based CCC

Property	Settings	Description
Provider switch hardware	EX Series switch	Transit switch within the MPLS network configuration.
Loopback address	**lo0 127.1.1.2/32**	Identifies provider switch for interswitch communications.
Routing protocol	**ospf traffic-engineering**	Indicates that this switch is using OSPF as the routing protocol and that traffic engineering is enabled.
MPLS protocol	**mpls**	Indicates that this switch is using the MPLS protocol. The statement must specify the core interfaces that will be used for MPLS traffic.
RSVP	**rsvp**	Indicates that this switch is using RSVP. The statement must specify the loopback and the core interfaces that will be used for the RSVP session.
Interface family	**family inet** **family mpls**	The logical units for the loopback interface and the core interfaces belong to **family inet**. The logical units of the core interfaces are also configured to belong to **family mpls**.
Core interfaces	**ge-0/0/5.0** and **ge-0/0/6.0** with IP addresses **10.1.5.1/24** and **10.1.6.1/24** and **ae0** with IP address **10.1.9.1/24**	Interfaces that connect the provider switch (P) to PE-1. Aggregated Ethernet interface on P that connects to aggregated Ethernet interface **ae0** of PE-2.

Configuring the Local PE Switch

IN THIS SECTION

- Procedure | 60

Procedure

CLI Quick Configuration

To quickly configure the local ingress PE switch, copy the following commands and paste them into the switch terminal window of PE-1:

```
[edit]
                        set protocols ospf traffic-engineering
                        set protocols ospf area 0.0.0.0 interface lo0.0
                        set protocols ospf area 0.0.0.0 interface ge-0/0/5.0
                        set protocols ospf area 0.0.0.0 interface ge-0/0/6.0
                        set protocols mpls label-switched-path lsp_to_pe2_ge1 to 127.1.1.3
                        set protocols mpls interface ge-0/0/5.0
                        set protocols mpls interface ge-0/0/6.0
                        set protocols rsvp interface lo0.0
                        set protocols rsvp interface ge-0/0/5.0
                        set protocols rsvp interface ge-0/0/6.0
                        set interfaces lo0 unit 0 family inet address 127.1.1.1/32
                        set interfaces ge-0/0/5 unit 0 family inet address 10.1.5.1/24
                        set interfaces ge-0/0/6 unit 0 family inet address 10.1.6.1/24
                        set interfaces ge-0/0/5 unit 0 family mpls
                        set interfaces ge-0/0/6 unit 0 family mpls
                        set interfaces ge-0/0/1 unit 0 family ccc
                        set protocols connections remote-interface-switch ge-1-to-pe2 interface
ge-0/0/1.0
                        set protocols connections remote-interface-switch ge-1-to-pe2 transmit-
lsp lsp_to_pe2_ge1
                        set protocols connections remote-interface-switch ge-1-to-pe2 receive-
lsp lsp_to_pe1_ge1
```

Step-by-Step Procedure

To configure the local ingress PE switch:

1. Configure OSPF with traffic engineering enabled:

```
[edit protocols]
user@switchPE-1# set ospf traffic-
engineering
```

2. Configure OSPF on the loopback address and the core interfaces:

```
[edit protocols]
user@switchPE-1# set ospf area 0.0.0.0 interface lo0.0
user@switchPE-1# set ospf area 0.0.0.0 interface ge-0/0/5.0
user@switchPE-1# set ospf area 0.0.0.0 interface ge-0/0/6.0
```

3. Configure MPLS on this PE switch (PE-1) with a label-switched path (LSP) to the other PE switch (PE-2):

```
[edit protocols]
user@switchPE-1# set mpls                                    label-switched-path lsp_to_pe2_ge1
to 127.1.1.3
```

4. Configure MPLS on the core interfaces:

```
[edit protocols]
user@switchPE-1# set mpls interface ge-0/0/5.0
user@switchPE-1# set mpls interface ge-0/0/6.0
```

5. Configure RSVP on the loopback interface and the core interfaces:

```
[edit protocols]
user@switchPE-1# set rsvp interface lo0.0
user@switchPE-1# set rsvp interface ge-0/0/5.0
```

```
user@switchPE-1# set rsvp interface ge-0/0/6.0
```

6. Configure IP addresses for the loopback interface and the core interfaces:

```
[edit]
user@switchPE-1# set interfaces lo0 unit 0 family inet address 127.1.1.1/32
user@switchPE-1# set interfaces ge-0/0/5 unit 0 family inet address 10.1.5.1/24
user@switchPE-1# set interfaces ge-0/0/6 unit 0 family inet address
10.1.6.1/24
```

7. Configure **family mpls** on the logical unit of the core interface addresses:

```
[edit]
user@switchPE-1# set interfaces ge-0/0/5 unit 0 family mpls
user@switchPE-1# set interfaces ge-0/0/6 unit 0 family mpls
```

8. Configure the logical unit of the customer edge interface as a CCC:

```
[edit interfaces ge-0/0/1 unit 0]
-user@PE-1# set family ccc
```

9. Configure the interface-based CCC from PE-1 to PE-2:

> **NOTE**: You can also configure a tagged VLAN interface as a CCC. See "Configuring an MPLS-Based VLAN CCC Using a Layer 2 VPN (CLI Procedure)" on page 1985 or "Configuring an MPLS-Based VLAN CCC Using a Layer 2 Circuit" on page 1948.

```
[edit protocols]
user@PE-1# set connections                                    remote-interface-switch ge-1-to-
pe2 interface ge-0/0/1.0
user@PE-1# set connections remote-interface-switch ge-1-to-pe2 transmit-lsp lsp_to_pe2_ge1
user@PE-1# set connections remote-interface-switch ge-1-to-pe2 receive-lsp
lsp_to_pe1_ge1
```

Results

Display the results of the configuration:

```
user@switchPE-1>                                show
configuration
```

            interface ge-0/0/6.0;
        }
    }
    connections {
        remote-interface-switch ge-1-to-pe2 {
            interface ge-0/0/1.0;
            transmit-lsp lsp_to_pe2_ge1;
            receive-lsp lsp_to_pe1_ge1;
        }
    }
```

Configuring the Remote PE Switch

IN THIS SECTION

- Procedure | 65

Procedure

CLI Quick Configuration

To quickly configure the remote PE switch, copy the following commands and paste them into the switch terminal window of PE-2:

```
[edit]
                        set protocols ospf traffic-engineering
                        set protocols ospf area 0.0.0.0 interface lo0.0
                        set protocols ospf area 0.0.0.0 interface ae0
                        set protocols mpls label-switched-path lsp_to_pe1_ge1 to 127.1.1.1
                        set protocols mpls interface ae0
                        set protocols rsvp interface lo0.0
                        set protocols rsvp interface ae0
                        set interfaces lo0 unit 0 family inet address 127.1.1.3/32
                        set interfaces ae0 unit 0 family inet address 10.1.9.2/24
                        set interfaces ae0 unit 0 family mpls
                        set interfaces ge-0/0/1 unit 0 family ccc
                        set protocols connections remote-interface-switch ge-1-to-pe1 interface
ge-0/0/1.0
                        set protocols connections remote-interface-switch ge-1-to-pe1 transmit-
lsp lsp_to_pe1_ge1
                        set protocols connections remote-interface-switch ge-1-to-pe1 receive-
lsp lsp_to_pe2_ge1
```

Step-by-Step Procedure

To configure the remote PE switch (PE-2):

1. Configure OSPF with traffic engineering enabled:

```
[edit protocols]
user@switchPE-2# set ospf traffic-engineering
```

2. Configure OSPF on the loopback interface and the core interface:

```
[edit protocols]
user@switchPE-2# set ospf area 0.0.0.0 interface lo0.0
```

```
user@switchPE-2# set ospf area 0.0.0.0 interface ae0
```

3. Configure MPLS on this switch (PE-2) with a label-switched path (LSP) to the other PE switch (PE-1):

```
[edit protocols]
user@switchPE-2# set mpls label-switched-path lsp_to_pe1_ge1 to 127.1.1.1
```

4. Configure MPLS on the core interface:

```
[edit protocols]
user@switchPE-2# set mpls interface ae0
```

5. Configure RSVP on the loopback interface and the core interface:

```
[edit protocols]
ser@switchPE-2# set rsvp interface lo0.0
user@switchPE-2# set rsvp interface ae0
```

6. Configure IP addresses for the loopback interface and the core interface:

```
[edit]
user@switchPE-2# set interfaces lo0 unit 0 family inet address 127.1.1.3/32
user@switchPE-2# set interfaces ae0 unit 0 family inet address
10.1.9.2/24
```

7. Configure **family mpls** on the logical unit of the core interface:

```
[edit]
user@switchPE-2# set interfaces ae0 unit 0 family mpls
```

8. Configure the logical unit of the customer edge interface as a CCC:

```
[edit interfaces ge-0/0/1 unit 0]
user@PE-2# set family ccc
```

9. Configure the interface-based CCC from PE-2 to PE-1:

```
[edit protocols]
user@PE-2# set connections remote-interface-switch ge-1-to-pe1 interface ge-0/0/1.0
user@PE-2# set connections remote-interface-switch ge-1-to-pe1 transmit-lsp lsp_to_pe1_ge1
user@PE-2# set connections remote-interface-switch ge-1-to-pe1 receive-lsp
lsp_to_pe2_ge1
```

Results

Display the results of the configuration:

```
user@switchPE-2>                                show
configuration
```

```
interfaces {
    ge-0/0/1 {
        unit 0 {
            family ccc;
        }
    }
    ae0 {
        unit 0 {
            family inet {
                address 10.1.9.2/24;

            to 127.1.1.1;
        }
        interface ae0.0;
    }
    ospf {
        traffic-engineering;
        area 0.0.0.0 {
            interface ae0.0;
        }
    }
    connections {
        remote-interface-switch ge-1-to-pe1 {
            interface ge-0/0/1.0;
            transmit-lsp lsp_to_pe1_ge1;
            receive-lsp lsp_to_pe2_ge1;
        }
    }
}
```

Configuring the Provider Switch

IN THIS SECTION

- Procedure | 69

Procedure

CLI Quick Configuration

To quickly configure the provider switch, copy the following commands and paste them into the switch terminal window:

```
[edit]
                    set  protocols ospf traffic-engineering
                    set protocols ospf area 0.0.0.0 interface lo0.0
                    set protocols ospf area 0.0.0.0  interface ge-0/0/5.0
                    set protocols ospf area 0.0.0.0  interface ge-0/0/6.0
                    set protocols ospf area 0.0.0.0  interface ae0
                    set protocols mpls interface ge-0/0/5.0
                    set protocols mpls interface ge-0/0/6.0
                    set protocols mpls interface ae0
                    set protocols rsvp interface lo0.0
                    set protocols rsvp interface ge-0/0/5.0
                    set protocols rsvp interface ge-0/0/6.0
                    set protocols rsvp interface ae0
                    set interfaces lo0 unit 0 family inet address 127.1.1.2/32
                    set interfaces ge-0/0/5 unit 0 family inet address 10.1.5.1/24
                    set interfaces ge-0/0/6 unit 0 family inet address 10.1.6.1/24
                    set interfaces ae0 unit 0 family inet address 10.1.9.1/24
                    set interfaces ge-0/0/5 unit 0 family mpls
                    set interfaces ge-0/0/6 unit 0 family mpls
                    set interfaces ae0 unit 0 family mpls
```

Step-by-Step Procedure

To configure the provider switch:

1. Configure OSPF with traffic engineering enabled:

```
[edit protocols]
user@switchP# set ospf traffic-engineering
```

2. Configure OSPF on the loopback interface and the core interfaces:

```
[edit protocols]
user@switchP# set ospf area 0.0.0.0 interface lo0.0
user@switchP# set ospf area 0.0.0.0 interface ge-0/0/5
user@switchP# set ospf area 0.0.0.0 interface ge-0/0/6
user@switchP# set ospf area 0.0.0.0 interface ae0
```

3. Configure MPLS on the core interfaces on the switch:

```
[edit protocols]
user@switchP# set mpls interface ge-0/0/5
user@switchP# set mpls interface ge-0/0/6
user@switchP# set mpls interface ae0
```

4. Configure RSVP on the loopback interface and the core interfaces:

```
[edit protocols]
user@switchP# set rsvp interface lo0.0
user@switchP# set rsvp interface ge-0/0/5
user@switchP# set rsvp interface ge-0/0/6
user@switchP# set rsvp interface ae0
```

5. Configure IP addresses for the loopback interface and the core interfaces:

```
[edit]
user@switchP# set interfaces lo0 unit 0 family inet address 127.1.1.2/32
user@switchP# set interfaces ge-0/0/5 unit 0 family inet address 10.1.5.1/24
user@switchP# set interfaces ge-0/0/6 unit 0 family inet address 10.1.6.1/24
user@switchP# set interfaces ae0 unit 0 family inet address 10.1.9.1/24
```

6. Configure **family mpls** on the logical unit of the core interface addresses:

```
[edit]
user@switchP# set interfaces ge-0/0/5 unit 0 family mpls
```

```
user@switchP# set interfaces ge-0/0/6 unit 0 family mpls
user@switchP# set interfaces ae0 unit 0 family mpls
```

Results

Display the results of the configuration:

```
user@switchP>                                   show
configuration
```

```
interfaces {
    ge-0/0/5 {
        unit 0 {
            family inet {
                address 10.1.5.1/24;
            }
            family mpls;
            }
        }
    ge-0/0/6 {
        unit 0 {
            family inet {
                address 10.1.6.1/24;
            }
            family mpls;
            }
        }
    }
    ae0 {
        unit 0 {
            family inet {
                address 10.1.9.1/24;
            }
            family mpls;
        }
    }
    lo0 {
        unit 0 {
            family inet {
                address 127.1.1.2/32;
```

```
            }
        }
    }
protocols {
    rsvp {
        interface lo0.0;
        interface ge-0/0/5.0;
        interface ge-0/0/6.0;
        interface ae0.0;
    }
    mpls {
        interface ge-0/0/5.0;
        interface ge-0/0/6.0;
        interface ae0.0;
    }
    ospf {
        traffic-engineering;
        area 0.0.0.0 {
            interface lo0.0;
            interface ge-0/0/5.0;
            interface ge-0/0/6.0;
            interface ae0.0;
        }
    }
```

Verification

IN THIS SECTION

- Verifying the Physical Layer on the Switches | **73**
- Verifying the Routing Protocol | **74**
- Verifying the Core Interfaces Being Used for MPLS Traffic | **74**
- Verifying the Status of the RSVP Sessions | **75**
- Verifying the Assignment of Interfaces for MPLS Label Operations | **75**
- Verifying the Status of the CCC | **76**

To confirm that the configuration is working properly, perform these tasks:

Verifying the Physical Layer on the Switches

Purpose

Verify that the interfaces are up. Perform this verification task on each of the switches.

Action

```
user@switchPE-1> show interfaces terse

Interface               Admin Link Proto    Local                 Remote
ge-0/0/0                up    up
ge-0/0/0.0              up    up  eth-switch
ge-0/0/1                up    up
ge-0/0/1.0              up    up  ccc
ge-0/0/2                up    up
ge-0/0/2.0              up    up  eth-switch
ge-0/0/3                up    up
ge-0/0/3.0              up    up eth-switch
ge-0/0/4                up    up
ge-0/0/4.0              up    up eth-switch
ge-0/0/5                up    up
ge-0/0/5.0              up    up inet     10.1.5.1/24
                              mpls
ge-0/0/6                up    up
ge-0/0/6.0              up    up inet     10.1.6.1/24
                              mpls
```

Meaning

The `show interfaces terse` command displays status information about the Gigabit Ethernet interfaces on the switch. This output verifies that the interfaces are **up**. The output for the protocol family (**Proto** column) shows that interface **ge-0/0/1.0** is configured as a circuit cross-connect. The output for the protocol family of the core interfaces (**ge-0/0/5.0** and **ge-0/0/6.0**) shows that these interfaces are configured as both **inet** and **mpls**. The **Local** column for the core interfaces shows the IP address configured for these interfaces.

Verifying the Routing Protocol

Purpose

Verify the state of the configured routing protocol. Perform this verification task on each of the switches. The state must be **Full**.

Action

```
user@switchPE-1> show ospf neighbor

Address          Interface              State     ID               Pri  Dead
127.1.1.2          ge-0/0/5              Full     10.10.10.10      128    39
```

Meaning

The `show ospf neighbor` command displays the status of the routing protocol. This output shows that the state is **Full**, meaning that the routing protocol is operating correctly—that is, hello packets are being exchanged between directly connected neighbors.

Verifying the Core Interfaces Being Used for MPLS Traffic

Purpose

Verify that the state of the MPLS interface is **Up**. Perform this verification task on each of the switches.

Action

```
user@switchPE-1>                              show mpls
interface

Interface        State       Administrative groups
ge-0/0/5            Up          <none>
ge-0/0/6            Up          <none>
```

Meaning

The `show mpls interface` command displays the status of the core interfaces that have been configured to belong to **family mpls**. This output shows that the interface configured to belong to **family mpls** is **Up**.

Verifying the Status of the RSVP Sessions

Purpose

Verify the status of the RSVP sessions. Perform this verification task on each of the switches.

Action

```
user@switchPE-1>   show rsvp session

Ingress RSVP: 1 sessions
To              From            State   Rt Style Labelin Labelout LSPname
127.1.13         127.1.1.1         Up       0  1 FF       -   300064 lsp_to_pe2_ge1
Total 1 displayed, Up 1, Down 0

Egress RSVP: 1 sessions
To              From            State   Rt Style Labelin Labelout LSPname
127.1.1.1        127.1.1.3         Up       0  1 FF       299968     lsp_to_pe1_ge1
Total 1 displayed, Up 1, Down 0

Transit RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Meaning

This output confirms that the RSVP sessions are **Up**.

Verifying the Assignment of Interfaces for MPLS Label Operations

Purpose

Verify which interface is being used as the beginning of the CCC and which interface is being used to push the MPLS packet to the next hop. Perform this task only on the PE switches.

Action

```
user@switchPE-1>                              show route forwarding-table family
mpls
MPLS:
Destination        Type RtRef Next hop           Type Index NhRef Netif
```

```
default            perm     0                    dscd    50     1
0                  user     0                    recv    49     3
1                  user     0                    recv    49     3
2                  user     0                    recv    49     3
299776             user     0                   Pop     541     2     ge-0/0/1.0
ge-0/0/1.0  (CCC)  user     0 2.0.0.1           Push 299792   540 2   ge-0/0/5.0
```

Meaning

This output shows that the CCC has been set up on interface **ge-0/0/1.0**. The switch receives ingress traffic on **ge-0/0/1.0** and pushes label **299792** onto the packet, which goes out through interface **ge-0/0/5.0**. The output also shows when the switch receives an MPLS packet with label 29976, it pops the label and sends the packet out through interface **ge-0/0/1.0**

After you have checked the local PE switch, run the same command on the remote PE switch.

Verifying the Status of the CCC

Purpose

Verify the status of the CCC. Perform this task only on the PE switches.

Action

```
user@switchPE-1>                              show
connections

CCC and TCC connections [Link Monitoring On]
Legend for status (St)              Legend for connection types
UN -- uninitialized                 if-sw:  interface switching
NP -- not present                   rmt-if: remote interface switching
WE -- wrong encapsulation           lsp-sw: LSP switching
DS -- disabled                      tx-p2mp-sw: transmit P2MP switching
Dn -- down                          rx-p2mp-sw: receive P2MP switching
-> -- only outbound conn is up
 <- -- only inbound  conn is up      Legend for circuit types
Up -- operational                   intf -- interface
RmtDn -- remote CCC down            tlsp -- transmit LSP
Restart -- restarting               rlsp -- receive LSP
```

```
Connection/Circuit              Type        St      Time last up     # Up trans
ge1-to-pe2                      rmt-if      Up      Feb 17 05:00:09  1
  ge-0/0/1.0                     intf       Up
  lsp_to_pe1_ge1                   tlsp     Up
  lsp_to_pe2_ge1                   rlsp     Up
```

Meaning

The `show connections` command displays the status of the CCC connections. This output verifies that the CCC interface and its associated transmit and receive LSPs are **Up**. After you have checked the local PE switch, run the same command on the remote PE switch.

- Configuring MPLS on EX8200 and EX4500 Provider Switches | 94

Configuring MPLS on Provider Switches

To implement MPLS, you must configure at least one provider switch as a transit switch for the MPLS packets.

MPLS requires the configuration of an interior gateway protocol (OSPF) and a signaling protocol (RSVP) on the core interfaces and the loopback interface of all the switches. This procedure includes the configuration of OSPF on the provider switch.

To configure the provider switch, complete the following tasks:

1. Configure OSPF on the loopback and core interfaces:

   NOTE: You can use the switch address as an alternative to the loopback interface.

```
[edit protocols ospf]
user@switch# set area 0.0.0.0 interface lo0.0
user@switch# set area 0.0.0.0 interface xe-0/0/5.0
user@switch# set area 0.0.0.0 interface xe-0/0/6.0
user@switch# set area 0.0.0.0 interface ae0
```

2. Configure MPLS on the core interfaces:

```
[edit protocols mpls]
user@switch# set interface xe-0/0/5.0
user@switch# set interface xe-0/0/6.0
user@switch# set interface ae0
```

3. Configure RSVP on the loopback interface and the core interfaces:

```
[edit protocols rsvp]
user@switch# set interface lo0.0
user@switch# set interface xe-0/0/5.0
user@switch# set interface xe-0/0/6.0
user@switch# set interface ae0
```

4. Configure an IP address for the loopback interface and the core interfaces:

```
[edit interfaces]
user@switch# set lo0 unit 0 family inet address 127.1.1.1/32
user@switch# set xe-0/0/5 unit 0 family inet address 10.1.5.1/24
user@switch# set xe-0/0/6 unit 0 family inet address 10.1.6.1/24
user@switch# set ae0 unit 0 family inet address 10.1.9.2/24
```

5. Configure `family mpls` on the logical units of the core interfaces, thereby identifying the interfaces that will be used for forwarding MPLS packets:

```
[edit interfaces]
user@switch# set xe-0/0/5 unit 0 family mpls
user@switch# set xe-0/0/6 unit 0 family mpls
user@switch# set ae0 unit 0 family mpls
```

Configuring MPLS on Provider Edge Switches

IN THIS SECTION

- Configuring the Ingress PE Switch | 79
- Configuring the Egress PE Switch | 81

To implement MPLS, you must configure two provider edge (PE) switches—an ingress PE switch and an egress PE switch—and at least one provider switch. You can configure the customer edge (CE) interfaces on the PE switches of the MPLS network using IP over MPLS.

This topic describes how to configure an ingress PE switch and an egress PE switch using IP over MPLS:

Configuring the Ingress PE Switch

To configure the ingress PE switch:

1. Configure an IP address for the loopback interface and the core interfaces:

```
[edit interfaces]
user@switch# set lo0 unit 0 family inet address 192.168.10.1/32
user@switch# set xe-0/0/5 unit 0 family inet address 10.1.5.1/24
user@switch# set xe-0/0/6 unit 0 family inet address 10.1.6.1/24
```

NOTE: You cannot use routed VLAN interfaces (RVIs) or Layer 3 subinterfaces as core interfaces.

2. Configure OSPF on the loopback interface and the core interfaces:

NOTE: You can use the switch address as an alternative to the loopback interface.

```
[edit protocols ospf]
user@switch# set area 0.0.0.0 interface lo0.0
user@switch# set area 0.0.0.0 interface xe-0/0/5.0
user@switch# set area 0.0.0.0 interface xe-0/0/6.0
```

3. Configure OSPF traffic engineering:

```
[edit protocols ospf]
user@switch# set traffic-engineering
```

4. Configure RSVP on the loopback interface and the core interfaces:

```
[edit protocols rsvp]
user@switch# set interface lo0.0
user@switch# set interface xe-0/0/5.0
user@switch# set interface xe-0/0/6.0
```

5. Configure MPLS traffic engineering.

```
[edit protocols mpls]
user@switch# set traffic-engineering
```

6. Configure MPLS on the core interfaces:

```
[edit protocols mpls]
user@switch# set interface xe-0/0/5.0
user@switch# set interface xe-0/0/6.0
```

7. Configure `family mpls` on the logical units of the core interfaces, thereby identifying the interfaces that will be used for forwarding MPLS packets:

```
[edit interfaces]
user@switch# set xe-0/0/5 unit 0 family mpls
user@switch# set xe-0/0/6 unit 0 family mpls
```

8. Configure a customer edge interface as a Layer 3 routed interface, specifying an IP address:

```
[edit interfaces]
user@switch# set xe-0/0/3 unit 0 family inet address 121.100.10.1/16
```

9. Configure this Layer 3 customer edge interface for the routing protocol:

```
[edit]
user@switch# set protocols ospf area 0.0.0 interface xe-0/0/3.0
```

10. Configure an LSP on the ingress PE switch (192.168.10.1) to send IP packets over MPLS to the egress PE switch (192.168.12.1):

```
[edit protocols mpls]
user@switch# set label-switched-path lsp_1 to 192.168.12.1
```

11. Disable constrained-path LSP computation for this LSP:

```
[edit protocols mpls]
user@switch# set label-switched-path lsp_1 no-cspf
```

12. Configure a static route from the ingress PE switch to the egress PE switch, thereby indicating to the routing protocol that the packets will be forwarded over the MPLS LSP that has been set up to that destination:

```
[edit routing-options]
user@switch# set static route 2.2.2.0/24 next-hop 192.168.10.1
user@switch# set static route 2.2.2.0/24 resolve
```

Configuring the Egress PE Switch

To configure the egress PE switch:

1. Configure an IP address for the loopback interface and the core interfaces:

```
[edit interfaces]
user@switch# set lo0 unit 0 family inet address 192.168.12.1/32
user@switch# set xe-0/0/5 unit 0 family inet address 10.1.20.1/24
user@switch# set xe-0/0/6 unit 0 family inet address 10.1.21.1/24
```

NOTE: You cannot use routed VLAN interfaces (RVIs) or Layer 3 subinterfaces as core interfaces.

2. Configure OSPF on the loopback interface and the core interfaces:

NOTE: You can use the switch address as an alternative to the loopback interface.

```
[edit protocols ospf]
user@switch# set area 0.0.0.0 interface lo0.0
user@switch# set area 0.0.0.0 interface xe-0/0/5.0
user@switch# set area 0.0.0.0 interface xe-0/0/6.0
```

3. Configure RSVP on the loopback interface and the core interfaces:

```
[edit protocols rsvp]
user@switch# set rsvp interface lo0.0
user@switch# set rsvp interface xe-0/0/5.0
user@switch# set rsvp interface xe-0/0/6.0
```

4. Configure MPLS on the core interfaces:

```
[edit protocols mpls]
user@switch# set interface xe-0/0/5.0
user@switch# set interface xe-0/0/6.0
```

5. Configure `family mpls` on the logical units of the core interfaces, thereby identifying the interfaces that will be used for forwarding MPLS packets:

```
[edit interfaces]
user@switch# set xe-0/0/5 unit 0 family mpls
user@switch# set xe-0/0/6 unit 0 family mpls
```

6. Configure a customer edge interface as a Layer 3 routed interface, specifying an IP address:

```
[edit interfaces]
user@switch# set xe-0/0/3 unit 0 family inet address 2.2.2.1/16
```

7. Configure this Layer 3 customer edge interface for the routing protocol:

```
[edit]
user@switch# set protocols ospf area 0.0.0 interface xe-0/0/3
```

8. Configure an LSP on the egress PE switch (192.168.12.1) to send IP packets over MPLS to the ingress PE switch (192.168.10.1):

```
[edit protocols mpls]
user@switch# set label-switched-path lsp_2 to 192.168.10.1
```

9. Disable constrained-path LSP computation for this LSP:

```
[edit protocols mpls]
user@switch# set label-switched-path lsp_2 no-cspf
```

10. Configure a static route from the ingress PE switch to the egress PE switch, thereby indicating to the routing protocol that the packets will be forwarded over the MPLS LSP that has been set up to that destination:

```
[edit routing-options]
user@switch# set static route 121.121.121.0/24 next-hop 192.168.12.1
user@switch# set static route 121.121.121.0/24 resolve
```

Configuring MPLS on Provider Edge Switches Using IP-Over-MPLS

IN THIS SECTION

- Configuring the Ingress PE Switch | 84
- Configuring the Egress PE Switch | 87

You can configure MPLS on EX Series switches to increase transport efficiency in your network. MPLS services can be used to connect various sites to a backbone network or to ensure better performance for low-latency applications such as VoIP and other business-critical functions.

To implement MPLS on switches, you must configure two provider edge (PE) switches—an ingress PE switch and an egress PE switch—and at least one provider switch. You can configure customer edge (CE) interfaces on the PE switches of the MPLS network by using either IP over MPLS or MPLS over circuit cross-connect (CCC).

The main differences between configuring IP over MPLS and configuring MPLS over CCC are that for IP over MLPS you configure the customer edge interfaces to belong to `family inet` (rather than `family ccc`) and you configure a static route for the label-switched path (LSP). The configuration of the provider switch is the same regardless of whether you have used IP over MPLS or MPLS over CCC. See "Configuring MPLS on EX8200 and EX4500 Provider Switches" on page 94.

This topic describes how to configure an ingress PE switch and an egress PE switch using IP over MPLS:

Configuring the Ingress PE Switch

To configure the ingress PE switch:

1. Configure an IP address for the loopback interface and for the core interfaces:

```
[edit]
user@switch# set interfaces lo0 unit 0 family inet address 100.100.100.100/32
user@switch# set interfaces ge-0/0/5 unit 0 family inet address 10.1.5.1/24
user@switch# set interfaces ge-0/0/6 unit 0 family inet address
10.1.6.1/24
```

2. Configure OSPF on the loopback and core interfaces:

```
[edit protocols]
user@switch# set ospf area 0.0.0.0 interface lo0.0
user@switch# set ospf area 0.0.0.0 interface ge-0/0/5.0
user@switch# set ospf area 0.0.0.0 interface ge-0/0/6.0
```

NOTE: If you want to use routed VLAN interfaces (RVIs) or Layer 3 subinterfaces as the core interfaces, replace ge-0/0/5.0 and ge-0/0/6 each with an RVI name (for example, vlan.*logical-interface-number*) or a subinterface name (for example, *interface-name.logical-unit-number*).

RVIs function as logical routers, eliminating the need to have both a switch and a router. Layer 3 subinterfaces allow you to route traffic among multiple VLANs along a single trunk line that connects an EX Series switch to a Layer 2 switch.

3. Enable traffic engineering for the routing protocol:

```
[edit protocols]
user@switch# set ospf traffic-engineering
```

4. Configure RSVP on the loopback interface and the core interfaces:

```
[edit protocols]
user@switch# set rsvp interface lo0.0
user@switch# set rsvp interface ge-0/0/5.0
user@switch# set rsvp interface ge-0/0/6.0
```

5. Configure MPLS traffic engineering:

```
[edit protocols]
user@switch# set protocols mpls traffic-engineering bgp-igp
```

6. Configure MPLS on the core interfaces:

```
[edit protocols]
user@switch# set mpls interface ge-0/0/5.0
user@switch# set mpls interface ge-0/0/6.0
```

7. Configure `family mpls` on the logical units of the core interfaces, thereby identifying the interfaces that will be used for forwarding MPLS packets:

```
[edit]
user@switch# set interfaces ge-0/0/5 unit 0 family mpls
user@switch# set interfaces ge-0/0/6 unit 0 family mpls
```

8. Configure a customer edge interface as a Layer 3 routed interface, specifying an IP address:

```
[edit]
user@switch# set interfaces ge-2/0/3 unit 0 family inet
121.121.121.1/16
```

9. Configure this Layer 3 customer edge interface for the routing protocol:

```
[edit]
user@switch# set protocols ospf area 0.0.0 interface
ge-2/0/3.0
```

10. Configure an LSP on the ingress PE switch (`100.100.100.100`) to send IP packets over MPLS to the egress PE switch (`208.208.208.208`):

```
[edit protocols mpls]
user@switch# set label-switched-path ip_lspjavae_29 from 100.100.100.100
user@switch# set label-switched-path ip_lspjavae_29 to 208.208.208.208
```

11. Disable constrained-path LSP computation for this LSP:

```
[edit protocols mpls]
user@switch# set label-switched-path ip_lspjavae_29 no-cspf
```

12. Configure a static route from the ingress PE switch to the egress PE switch, thereby indicating to the routing protocol that the packets will be forwarded over the MPLS LSP that has been set up to that destination:

> **NOTE**: Do not configure a static route if you are using this procedure to configure an MPLS-based Layer 3 VPN.

```
[edit]
user@switch# set routing-options static route 2.2.2.0/24 next-hop 100.100.100.100
user@switch# set routing-options static route 2.2.2.0/24 resolve
```

Configuring the Egress PE Switch

To configure the egress PE switch:

1. Configure an IP address for the loopback interface and for the core interfaces:

```
[edit]
user@switch# set interfaces lo0 unit 0 family inet address 208.208.208.208/32
user@switch# set interfaces ge-0/0/5 unit 0 family inet address 10.1.20.1/24
user@switch# set interfaces ge-0/0/6 unit 0 family inet address 10.1.21.1/24
```

2. Configure OSPF on the loopback interface (or switch address) and core interfaces:

```
[edit protocols]
user@switch# set ospf area 0.0.0.0 interface lo0.0
user@switch# set ospf area 0.0.0.0 interface ge-0/0/5.0
user@switch# set ospf area 0.0.0.0 interface ge-0/0/6.0
```

> **NOTE**: If you want to use routed VLAN interfaces (RVIs) or Layer 3 subinterfaces as the core interfaces, replace ge-0/0/5.0 and ge-0/0/6 each with an RVI name (for example, vlan.*logical-interface-number*) or a subinterface name (for example, *interface-name.logical-unit-number*).

RVIs function as logical routers, eliminating the need to have both a switch and a router. Layer 3 subinterfaces allow you to route traffic among multiple VLANs along a single trunk line that connects an EX Series switch to a Layer 2 switch.

3. Enable traffic engineering for the routing protocol:

```
[edit protocols]
user@switch# set ospf traffic-engineering
```

4. Configure RSVP on the loopback interface and the core interfaces:

```
[edit protocols]
user@switch# set rsvp interface lo0.0
user@switch# set rsvp interface ge-0/0/5.0
user@switch# set rsvp interface ge-0/0/6.0
```

5. Configure MPLS traffic engineering on both BGP and IGP destinations:

```
[edit protocols]
user@switch# set protocols mpls traffic-engineering bgp-igp
```

6. Configure MPLS on the core interfaces:

```
[edit protocols]
user@switch# set mpls interface ge-0/0/5.0
user@switch# set mpls interface ge-0/0/6.0
```

7. Configure `family mpls` on the logical units of the core interfaces, thereby identifying the interfaces that will be used for forwarding MPLS packets:

```
[edit]
user@switch# set interfaces ge-0/0/5 unit 0 family mpls
user@switch# set interfaces ge-0/0/6 unit 0 family mpls
```

8. Configure a customer edge interface as a Layer 3 routed interface, specifying an IP address:

```
[edit]
user@switch# set interfaces ge-2/0/3 unit 0 family inet address
2.2.2.1/16
```

9. Configure this Layer 3 customer edge interface for the routing protocol:

```
[edit]
user@switch# set protocols ospf area 0.0.0 interface ge-2/0/3
```

10. Configure an LSP on the egress PE switch (208.208.208.208) to send IP packets over MPLS to the ingress PE switch (100.100.100.100):

```
[edit protocols mpls]
user@switch# set label-switched-path ip_lsp29_javae from 208.208.208.208
user@switch# set label-switched-path ip_lsp29_javae to 100.100.100.100
```

11. Disable constrained-path LSP computation for this LSP:

```
[edit protocols mpls]
user@switch# set label-switched-path ip_lsp29_javae no-cspf
```

12. Configure a static route from the ingress PE switch to the egress PE switch, thereby indicating to the routing protocol that the packets will be forwarded over the MPLS LSP that has been set up to that destination:

NOTE: Do not configure a static route if you are using this procedure to configure an MPLS-based Layer 3 VPN.

```
[edit]
user@switch# set routing-options static route 121.121.121.0/24 next-hop 208.208.208.208
user@switch# set routing-options static route 121.121.121.0/24 resolve
```

Configuring MPLS on Provider Edge EX8200 and EX4500 Switches Using Circuit Cross-Connect

Junos OS MPLS for EX8200 and EX4500 switches supports Layer 2 protocols and Layer 2 virtual private networks (VPNs). You can configure MPLS on switches to increase transport efficiency in your network. MPLS services can be used to connect various sites to a backbone network and to ensure better performance for low-latency applications such as VoIP and other business-critical functions.

This topic describes configuring provider edge (PE) switches in an MPLS network using a circuit cross-connect (CCC). The customer edge interface can be either a simple interface or a tagged VLAN interface.

> **NOTE**: If you are configuring a CCC on a tagged VLAN interface, you do not specify **family ccc**. See Configuring an MPLS-Based VLAN CCC Using a Layer 2 VPN and Configuring an MPLS-Based VLAN CCC Using a Layer 2 Circuit.

> **NOTE**: If you are going through this procedure in preparation for configuring an MPLS-based Layer 2 VPN, you do not need to configure the association of the label-switched path (LSP) with the customer edge interface. The BGP signaling automates the connections, so manual configuration of the **connections** is not required.

The following guidelines apply to CCC configurations:

- When an interface is configured to belong to **family ccc**, it cannot belong to any other family.
- You can send any kind of traffic over a CCC, including nonstandard bridge protocol data units (BPDUs) generated by other vendors' equipment.
- If you are configuring a CCC on a tagged VLAN interface, you must explicitly enable VLAN tagging and specify a VLAN ID. The VLAN ID cannot be configured on logical interface unit **0**. The logical unit number must be **1** or higher. See Configuring an MPLS-Based VLAN CCC Using a Layer 2 VPN and Configuring an MPLS-Based VLAN CCC Using a Layer 2 Circuit.

This procedure shows how to set up two CCCs:

- If you are configuring a CCC on a simple interface (**ge-0/0/1**), you do not need to enable VLAN tagging or specify a VLAN ID, so you skip those steps.
- If you are configuring a CCC on a tagged VLAN interface (**ge-0/0/2**), include all the steps in this procedure.

To configure a PE switch with a CCC:

1. Configure OSPF (or IS-IS) on the loopback (or switch address) and core interfaces:

```
[edit protocols]
user@switch# set ospf area 0.0.0.0 interface lo0.0
user@switch# set ospf area 0.0.0.0 interface ge-0/0/5.0
user@switch# set ospf area 0.0.0.0 interface ge-0/0/6.0
user@switch# set ospf area 0.0.0.0 interface ae0
```

2. Enable traffic engineering for the routing protocol:

```
[edit protocols]
user@switch# set ospf traffic-engineering
```

3. Configure an IP address for the loopback interface and for the core interfaces:

```
[edit]
user@switch# set interfaces lo0 unit 0 family inet address 127.1.1.1/32
user@switch# set interfaces ge-0/0/5 unit 0 family inet address 10.1.5.1/24
user@switch# set interfaces ge-0/0/6 unit 0 family inet address 10.1.6.1/24
user@switch# set interfaces ae0 unit 0 family inet address
10.1.9.1/24
```

4. Enable MPLS and define the LSP:

```
[edit protocols]
user@switch# set mpls                                label-switched-path lsp_to_pe2_ge1 to
127.1.1.3
```

TIP: **lsp_to_pe2_ge1** is the LSP name. You will need to use the specified name again when configuring the CCC.

5. Configure MPLS on the core interfaces:

```
[edit protocols]
user@switch# set mpls interface ge-0/0/5.0
```

```
user@switch# set mpls interface ge-0/0/6.0
user@switch# set mpls interface ae0
```

6. Configure RSVP on the loopback interface and the core interfaces:

```
[edit protocols]
user@switch# set rsvp interface lo0.0
user@switch# set rsvp interface ge-0/0/5.0
user@switch# set rsvp interface ge-0/0/6.0
user@switch# set rsvp interface ae0
```

7. Configure **family mpls** on the logical units of the core interfaces:

```
[edit]
user@switch# set interfaces ge-0/0/5 unit 0 family mpls
user@switch# set interfaces ge-0/0/6 unit 0 family mpls
user@switch# set interfaces ae0 unit 0 family mpls
```

NOTE: You can enable **family mpls** on either individual interfaces or aggregated Ethernet interfaces. You cannot enable it on tagged VLAN interfaces.

8. If you are configuring a CCC on a tagged VLAN interface, enable VLAN tagging on the customer edge interface **ge-0/0/2** of the local PE switch:

```
[edit interfaces ge-0/0/2]
user@switch# set vlan-tagging
```

If you are configuring a CCC on a simple interface (**ge-0/0/1**), omit this step.

9. If you are configuring a CCC on a tagged VLAN interface, configure the logical unit of the customer edge interface with a VLAN ID:

```
[edit interfaces ge-0/0/2 unit 1]
user@switch# set vlan-id 100
```

If you are configuring a CCC on a simple interface (**ge-0/0/1**), omit this step.

10. Configure the logical unit of the customer edge interface to belong to **family ccc**:

- On a simple interface:

```
[edit interfaces ge-0/0/1 unit 0]
user@switch# set family ccc
```

- On a tagged VLAN interface:

```
[edit interfaces ge-0/0/2 unit 1]
user@switch# set family ccc
```

11. Associate the CCC interface with two LSPs, one for transmitting MPLS packets and the other for receiving MPLS packets:

> **NOTE**: If you are configuring a Layer 2 VPN, omit this step. The BGP signaling automates the connections, so manual configuration of the **connections** is not required.

- On a simple interface:

```
[edit protocols]
user@switch# set connections                                remote-interface-switch
ge-1-to-pe2 interface ge-0/0/1.0
user@switch# set connections remote-interface-switch ge-1-to-pe2 transmit-lsp
lsp_to_pe2_ge1
user@switch# set connections remote-interface-switch ge-1-to-pe2 receive-lsp
lsp_to_pe1_ge1
```

- On a tagged VLAN interface:

```
[edit protocols]
user@switch# set connections remote-interface-switch ge-1-to-pe2 interface ge-0/0/2.1
user@switch# set connections remote-interface-switch ge-1-to-pe2 transmit-lsp
lsp_to_pe2_ge1
user@switch# set connections remote-interface-switch ge-1-to-pe2 receive-lsp
lsp_to_pe1_ge1
```

> **TIP**: The **transmit-lsp** option specifies the LSP name that was configured on PE-1 (the local PE switch) by the `label-switched-path` statement within the `[edit protocols mpls]` hierarchy. The **receive-lsp** option specifies the LSP name that was configured on PE-2 (the remote PE switch) by the `label-switched-path` statement within the `[edit protocols mpls]` hierarchy.

When you have completed configuring one PE switch, follow the same procedures to configure the other PE switch.

Configuring MPLS on EX8200 and EX4500 Provider Switches

You can configure MPLS on EX8200 and EX4500 switches to increase transport efficiency in your network. MPLS services can be used to connect various sites to a backbone network and to ensure better performance for low-latency applications such as VoIP and other business-critical functions.

To implement MPLS on EX Series switches, you must configure at least one provider switch as a transit switch for the MPLS packets. The configuration of all the provider switches remains the same regardless of whether the provider edge (PE) switches are using circuit cross-connect (CCC) or using MPLS over IP for the customer edge interfaces. Likewise, you do not need to change the configuration of the provider switches if you implement an MPLS-based Layer 2 VPN, Layer 3 VPN, or a Layer 2 circuit configuration.

MPLS requires the configuration of a routing protocol (OSPF or IS-IS) on the core interfaces and the loopback interface of all the switches. This procedure includes the configuration of OSPF on the provider switch. For information on configuring IS-IS as the routing protocol, see *Junos OS Routing Protocols Configuration Guide*.

To configure the provider switch, complete the following tasks:

1. Enable the routing protocol (OSPF or IS-IS) on the loopback interface and on the core interfaces:

> **NOTE**: You can use the switch address as an alternative to the loopback interface.

```
[edit protocols]
user@switch# set ospf area 0.0.0.0  interface lo0.0
user@switch# set ospf area 0.0.0.0  interface ge-0/0/5.0
user@switch# set ospf area 0.0.0.0 interface ge-0/0/6.0
user@switch# set ospf area 0.0.0.0  interface ae0
```

2. Enable traffic engineering for the routing protocol (traffic engineering must be explicitly enabled for OSPF):

```
[edit protocols]
user@switch# set ospf traffic-engineering
```

3. Enable MPLS within the **protocols** stanza and apply it to the core interfaces:

```
[edit protocols]
user@switch# set mpls interface ge-0/0/5.0
user@switch# set mpls interface ge-0/0/6.0
user@switch# set mpls interface ae0
```

4. Configure RSVP on the loopback interface and the core interfaces:

```
[edit protocols]
user@switch# set rsvp interface lo0.0
user@switch# set rsvp interface ge-0/0/5.0
user@switch# set rsvp interface ge-0/0/6.0
user@switch# set rsvp interface ae0
```

5. Configure an IP address for the loopback interface and for the core interfaces:

```
[edit]
user@switch# set interfaces lo0 unit 0 family inet address 127.1.1.1/32
user@switch# set interfaces ge-0/0/5 unit 0 family inet address 10.1.5.1/24
user@switch# set interfaces ge-0/0/6 unit 0 family inet address 10.1.6.1/24
user@switch# set interfaces ae0 unit 0 family inet address 10.1.9.2/24
```

6. Configure **family mpls** on the logical units of the core interfaces:

```
[edit]
user@switch# set interfaces ge-0/0/5 unit 0 family mpls
user@switch# set interfaces ge-0/0/6 unit 0 family mpls
user@switch# set interfaces ae0 unit 0 family mpls
```

NOTE: You can enable **family mpls** on either individual interfaces or aggregated Ethernet interfaces. You cannot enable it on tagged VLAN interfaces.

Configuring IPv6 Tunneling for MPLS

You can configure the IPv6 tunneling for MPLS to tunnel IPv6 traffic over an MPLS-based IPv4 network. This configuration allows you to interconnect a number of smaller IPv6 networks over an IPv4-based network core, giving you the ability to provide IPv6 service without having to upgrade the switches in your core network. BGP is configured to exchange routes between the IPv6 networks, and data is tunneled between these IPv6 networks by means of IPv4-based MPLS.

To configure IPv6 tunneling for MPLS on your EX Series switch:

1. Configure IPv4 and IPv6 IP addresses for all the core interfaces:

```
[edit]
user@switch# set interfaces interface-name unit logical-unit-number family inet address
address
```

2. Configure the number assigned to you by the Network Information Center (NIC) as the autonomous system (AS) number

```
[edit routing-options]
user@switch# set autonomous-system number
```

3. Advertise label 0 to the egress router of the LSP:

```
[edit protocols]
user@switch# set mpls explicit-null
```

4. Configure the LSP to allow IPv6 routes to be resolved over an MPLS network by converting all routes stored in the inet3 routing table to IPv4-mapped IPv6 addresses and then copying them into the inet6.3 routing table:

```
[edit protocols]
user@switch# set mpls ipv6-tunneling
```

5. Set the local AS number:

```
[edit protocols bgp]
user@switch# set local-as local-autonomous-system-number
```

6. Configure the default import and export policies:

```
[edit protocols bgp]
user@switch# set local-address address
user@switch# set import default-import
user@switch# set family inet6 labeled-unicast explicit-null
user@switch# set export default-export
```

7. Configure a BGP group that recognizes only the specified BGP systems as peers. Define a group name, group type, local end of a BGP session, and a neighbor (peer). To configure multiple BGP peers, include multiple neighbor statements:

```
[edit protocols bgp]
user@switch# set group group-name type internal
user@switch# set group group-name local-address address-of-the-local-end-of-a-bgp-session
user@switch# set group group-name family inet6 labeled-unicast explicit-null
```

```
user@switch# set group group-name peer-as peer-autonomous-system-number
user@switch# set group group-name neighbor address family inet6 labeled-unicast explicit-null
```

8. Configure routing options to accept the default import and export policies:

```
[edit policy-options]
user@switch# set policy-statement default-import then accept
user@switch# set policy-statement default-export then accept
```

Example: Tunneling IPv6 Traffic over MPLS IPv4 Networks

IN THIS SECTION

- Requirements | 99
- Overview | 99
- Configuration | 102
- Verification | 110

This example shows how to configure the Junos OS to tunnel IPv6 over an MPLS-based IPv4 network. External BGP (EBGP) is used between the customer edge (CE) and provider edge (PE) devices. The remote CE devices have different AS numbers for loop detection.

Requirements

No special configuration beyond device initialization is required before you configure this example.

Overview

Detailed information about the Juniper Networks implementation of IPv6 over MPLS is described in the following Internet drafts:

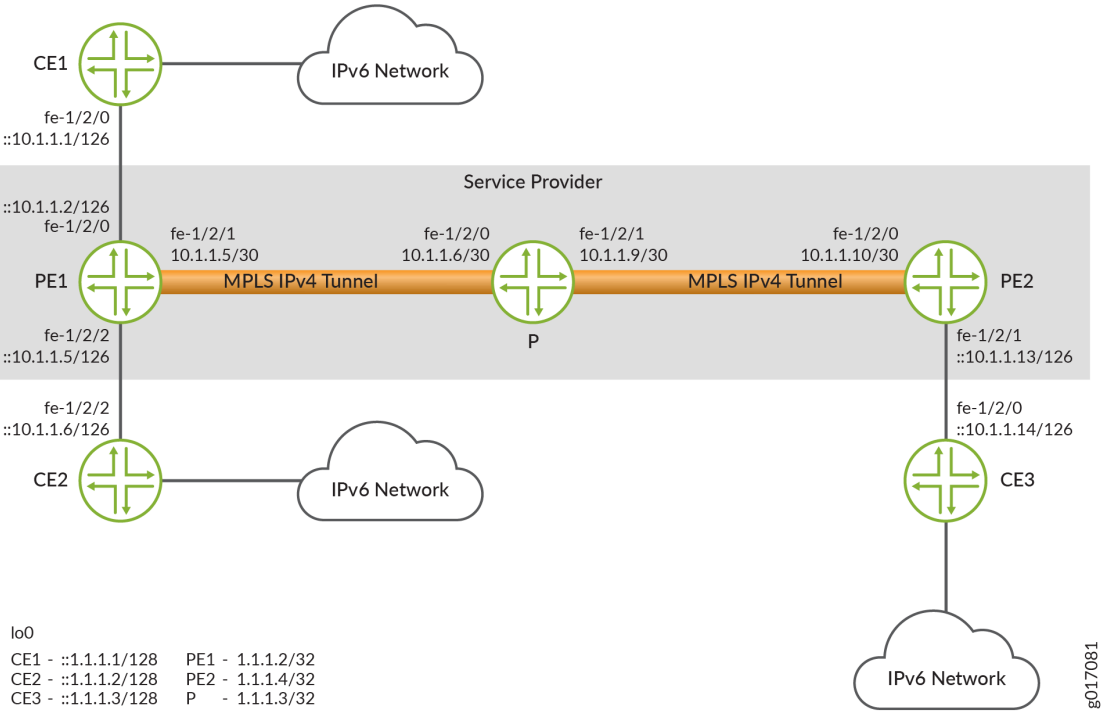
- Internet draft draft-ietf-l3vpn-bgp-ipv6-07.txt, *BGP-MPLS IP VPN extension for IPv6 VPN* (expires January 2006)
- Internet draft draft-ooms-v6ops-bgp-tunnel-06.txt, *Connecting IPv6 Islands over IPv4 MPLS using IPv6 Provider Edge Routers* (expires July 2006)

These Internet drafts are available on the IETF website at http://www.ietf.org/.

This example shows you how to interconnect a two IPv6 networks over an IPv4-based network core, giving you the ability to provide IPv6 service without having to upgrade the routers in your core network. Multiprotocol Border Gateway Protocol (MP-BGP) is configured to exchange routes between the IPv6 networks, and data is tunneled between these IPv6 networks by means of IPv4-based MPLS.

In Figure 3 on page 100, Routers PE1 and PE2 are dual-stack BGP routers, meaning they have both IPv4 and IPv6 stacks. The PE routers link the IPv6 networks through the customer edge (CE) routers to the IPv4 core network. The CE routers and the PE routers connect through a link layer that can carry IPv6 traffic. The PE routers use IPv6 on the CE router-facing interfaces and use IPv4 and MPLS on the core-facing interfaces. Note that one of the connected IPv6 networks could be the global IPv6 Internet.

Figure 3: IPv6 Networks Linked by MPLS IPv4 Tunnels



The two PE routers are linked through an MP-BGP session using IPv4 addresses. They use the session to exchange IPv6 routes with an IPv6 (value 2) address family indicator (AFI) and a subsequent AFI (SAFI) (value 4). Each PE router sets the next hop for the IPv6 routes advertised on this session to its own IPv4 address. Because MP-BGP requires the BGP next hop to correspond to the same address family as the network layer reachability information (NLRI), this IPv4 address needs to be embedded within an IPv6 format.

The PE routers can learn the IPv6 routes from the CE routers connected to them using routing protocols Routing Information Protocol next generation (RIPng) or MP-BGP, or through static configuration. Note that if BGP is used as the PE-router-to-CE-router protocol, the MP-BGP session between the PE router

and CE router could occur over an IPv4 or IPv6 Transmission Control Protocol (TCP) session. Also, the BGP routes exchanged on that session would have SAFI unicast. You must configure an export policy to pass routes between IBGP and EBGP, and between BGP and any other protocol.

The PE routers have MPLS LSPs routed to each others' IPv4 addresses. IPv4 provides signaling for the LSPs by means of either LDP or RSVP. These LSPs are used to resolve the next-hop addresses of the IPv6 routes learned from MP-BGP. The next hops use IPv4-mapped IPv6 addresses, while the LSPs use IPv4 addresses.

The PE routers always advertise IPv6 routes to each other using a label value of 2, the explicit null label for IPv6 as defined in RFC 3032, *MPLS Label Stack Encoding*. As a consequence, each of the forwarding next hops for the IPv6 routes learned from remote PE routers normally push two labels. The inner label is 2 (this label could be different if the advertising PE router is not a Juniper Networks routing platform), and the outer label is the LSP label. If the LSP is a single-hop LSP, then only Label 2 is pushed.

It is also possible for the PE routers to exchange plain IPv6 routes using SAFI unicast. However, there is one major advantage in exchanging labeled IPv6 routes. The penultimate-hop router for an MPLS LSP can pop the outer label and then send the packet with the inner label as an MPLS packet. Without the inner label, the penultimate-hop router would need to discover whether the packet is an IPv4 or IPv6 packet to set the protocol field in the Layer 2 header correctly.

When the PE1 router in Figure 3 on page 100 receives an IPv6 packet from the CE1 router, it performs a lookup in the IPv6 forwarding table. If the destination matches a prefix learned from the CE2 router, then no labels need to be pushed and the packet is simply sent to the CE2 router. If the destination matches a prefix that was learned from the PE2 router, then the PE1 router pushes two labels onto the packet and sends it to the provider router. The inner label is 2 and the outer label is the LSP label for the PE2 router.

Each provider router in the service provider's network handles the packet as it would any MPLS packet, swapping labels as it passes from provider router to provider router. The penultimate-hop provider router for the LSP pops the outer label and sends the packet to the PE2 router. When the PE2 router receives the packet, it recognizes the IPv6 explicit null label on the packet (Label 2). It pops this label and treats it as an IPv6 packet, performing a lookup in the IPv6 forwarding table and forwarding the packet to the CE3 router.

This example includes the following settings:

- In addition to configuring the `family inet6` statement on all the CE router–facing interfaces, you must also configure the statement on all the core-facing interfaces running MPLS. Both configurations are necessary because the router must be able to process any IPv6 packets it receives on these interfaces. You should not see any regular IPv6 traffic arrive on these interfaces, but you will receive MPLS packets tagged with Label 2. Even though Label 2 MPLS packets are sent in IPv4, these packets are treated as native IPv6 packets.

- You enable IPv6 tunneling by including the `ipv6-tunneling` statement in the configuration for the PE routers. This statement allows IPv6 routes to be resolved over an MPLS network by converting all

routes stored in the inet.3 routing table to IPv4-mapped IPv6 addresses and then copying them into the inet6.3 routing table. This routing table can be used to resolve next hops for both inet6 and inet6-vpn routes.

> **NOTE**: BGP automatically runs its import policy even when copying routes from a primary routing table group to a secondary routing table group. If IPv4 labeled routes arrive from a BGP session (for example, when you have configured the `labeled-unicast` statement at the `[edit protocols bgp family inet]` hierarchy level on the PE router), the BGP neighbor's import policy also accepts IPv6 routes, since the neighbor's import policy is run while doing the copy operation to the inet6.3 routing table.

- When you configure MP-BGP to carry IPv6 traffic, the IPv4 MPLS label is removed at the destination PE router. The remaining IPv6 packet without a label can then be forwarded to the IPv6 network. To enable this, include the `explicit-null` statement in the BGP configuration.

Configuration

IN THIS SECTION

- CLI Quick Configuration | **102**
- Configuring Device PE1 | **105**

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the `[edit]` hierarchy level.

Device PE1

```
set interfaces fe-1/2/0 unit 2 family inet6 address ::10.1.1.2/126
set interfaces fe-1/2/0 unit 2 family mpls
set interfaces fe-1/2/1 unit 5 family inet address 10.1.1.5/30
set interfaces fe-1/2/1 unit 5 family inet6
set interfaces fe-1/2/1 unit 5 family mpls
set interfaces lo0 unit 2 family inet address 1.1.1.2/32
set protocols mpls ipv6-tunneling
```

```
set protocols mpls interface fe-1/2/0.2
set protocols mpls interface fe-1/2/1.5
set protocols bgp group toCE1 type external
set protocols bgp group toCE1 local-address ::10.1.1.2
set protocols bgp group toCE1 family inet6 unicast
set protocols bgp group toCE1 export send-bgp6
set protocols bgp group toCE1 peer-as 1
set protocols bgp group toCE1 neighbor ::10.1.1.1
set protocols bgp group toPE2 type internal
set protocols bgp group toPE2 local-address 1.1.1.2
set protocols bgp group toPE2 family inet6 labeled-unicast explicit-null
set protocols bgp group toPE2 export next-hop-self
set protocols bgp group toPE2 export send-v6
set protocols bgp group toPE2 neighbor 1.1.1.4
set protocols ospf area 0.0.0.0 interface fe-1/2/1.5
set protocols ospf area 0.0.0.0 interface lo0.2 passive
set protocols ldp interface fe-1/2/1.5
set policy-options policy-statement next-hop-self then next-hop self
set policy-options policy-statement send-bgp6 from family inet6
set policy-options policy-statement send-bgp6 from protocol bgp
set policy-options policy-statement send-bgp6 then accept
set policy-options policy-statement send-v6 from family inet6
set policy-options policy-statement send-v6 from protocol bgp
set policy-options policy-statement send-v6 from protocol direct
set policy-options policy-statement send-v6 then accept
set routing-options router-id 1.1.1.2
set routing-options autonomous-system 2
```

Device PE2

```

Configuring Device PE1

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the Junos OS CLI User Guide.

To configure Device PE1:

1. Configure the interfaces.

```
[edit interfaces]
user@PE1# set fe-1/2/0 unit 2 family inet6 address ::10.1.1.2/126
user@PE1# set fe-1/2/0 unit 2 family mpls
user@PE1# set fe-1/2/1 unit 5 family inet address 10.1.1.5/30
user@PE1# set fe-1/2/1 unit 5 family inet6
user@PE1# set fe-1/2/1 unit 5 family mpls
user@PE1# set lo0 unit 2 family inet address 1.1.1.2/32
```

2. Configure MPLS on the interfaces.

```
[edit protocols mpls]
user@PE1# set ipv6-tunneling
user@PE1# set interface fe-1/2/0.2
user@PE1# set interface fe-1/2/1.5
```

3. Configure BGP.

```
[edit protocols bgp]
user@PE1# set group toCE1 type external
user@PE1# set group toCE1 local-address ::10.1.1.2
user@PE1# set group toCE1 family inet6 unicast
user@PE1# set group toCE1 export send-bgp6
user@PE1# set group toCE1 peer-as 1
user@PE1# set group toCE1 neighbor ::10.1.1.1
user@PE1# set group toPE2 type internal
user@PE1# set group toPE2 local-address 1.1.1.2
user@PE1# set group toPE2 family inet6 labeled-unicast explicit-null
user@PE1# set group toPE2 export next-hop-self
user@PE1# set group toPE2 export send-v6
user@PE1# set group toPE2 neighbor 1.1.1.4
```

4. Configure OSPF

```
[edit protocols ospf area 0.0.0.0]
user@PE1# set interface fe-1/2/1.5
user@PE1# set interface lo0.2 passive
```

5. Configure a signaling protocol.

```
[edit protocols]
user@PE1# set ldp interface fe-1/2/1.5
```

6. Configure the routing policies.

```
[edit policy-options]
user@PE1# set policy-statement next-hop-self then next-hop self
user@PE1# set policy-statement send-bgp6 from family inet6
user@PE1# set policy-statement send-bgp6 from protocol bgp
user@PE1# set policy-statement send-bgp6 then accept
user@PE1# set policy-statement send-v6 from family inet6
user@PE1# set policy-statement send-v6 from protocol bgp
user@PE1# set policy-statement send-v6 from protocol direct
user@PE1# set policy-statement send-v6 then accept
```

7. Configure the router ID and the autonomous system (AS) number.

```
[edit routing-options]
user@PE1# set router-id 1.1.1.2
user@PE1# set autonomous-system 2
```

Results

From configuration mode, confirm your configuration by entering the `show interfaces`, `show policy-options`, `show protocols`, and `show routing-options` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R1# show interfaces
fe-1/2/0 {
    unit 2 {
        family inet6 {
            address ::10.1.1.2/126;
        }
        family mpls;
    }
}
```

```
fe-1/2/1 {
    unit 5 {
        family inet {
            address 10.1.1.5/30;
        }
        family inet6;
        family mpls;
    }
}
lo0 {
    unit 2 {
        family inet {
            address 1.1.1.2/32;
        }
    }
}
```

```
user@R1# show policy-options
policy-statement next-hop-self {
    then {
        next-hop self;
    }
}
policy-statement send-bgp6 {
    from {
        family inet6;
        protocol bgp;
    }
    then accept;
}
policy-statement send-v6 {
    from {
        family inet6;
        protocol [ bgp direct ];
    }
    then accept;
}
```

```
user@R1# show protocols
mpls {
```

```
    ipv6-tunneling;
    interface fe-1/2/0.2;
    interface fe-1/2/1.5;
}
bgp {
    group toCE1 {
        type external;
        local-address ::10.1.1.2;
        family inet6 {
            unicast;
        }
        export send-bgp6;
        peer-as 1;
        neighbor ::10.1.1.1;
    }
    group toPE2 {
        type internal;
        local-address 1.1.1.2;
        family inet6 {
            labeled-unicast {
                explicit-null;
            }
        }
        export [ next-hop-self send-v6 ];
        neighbor 1.1.1.4;
    }
}
ospf {
    area 0.0.0.0 {
        interface fe-1/2/1.5;
        interface lo0.2 {
            passive;
        }
    }
}
ldp {
```

```
    interface fe-1/2/1.5;
}
```

```
user@R1# show routing-options
router-id 1.1.1.2;
autonomous-system 2;
```

If you are done configuring the device, enter `commit` from configuration mode.
Configure the other devices in the topology, as shown in "CLI Quick Configuration" on page 102.

Verification

IN THIS SECTION

- Verifying That the CE Devices Have Connectivity | **110**

Confirm that the configuration is working properly.

Verifying That the CE Devices Have Connectivity

Purpose

Make sure that the tunnel is operating.

Action

From operational mode, enter the `ping` command.

```
user@CE1> ping ::10.1.1.14
PING6(56=40+8+8 bytes) ::10.1.1.1 --> ::10.1.1.14
16 bytes from ::10.1.1.14, icmp_seq=0 hlim=61 time=10.687 ms
```

```
16 bytes from ::10.1.1.14, icmp_seq=1 hlim=61 time=9.239 ms
16 bytes from ::10.1.1.14, icmp_seq=2 hlim=61 time=1.842 ms
```

```
user@CE3> ping ::10.1.1.1
PING6(56=40+8+8 bytes) ::10.1.1.14 --> ::10.1.1.1
16 bytes from ::10.1.1.1, icmp_seq=0 hlim=61 time=1.484 ms
16 bytes from ::10.1.1.1, icmp_seq=1 hlim=61 time=1.338 ms
16 bytes from ::10.1.1.1, icmp_seq=2 hlim=61 time=1.351 ms
```

Meaning

The IPv6 CE devices can communicate over the core IPv4 network.

Example: Configuring Next-Hop-Based MPLS-Over-UDP Dynamic Tunnels

IN THIS SECTION

- Requirements | 112
- Overview | 113
- Configuration | 117
- Verification | 124
- Troubleshooting | 129

This example shows how to configure a dynamic MPLS-over-UDP tunnel that includes a tunnel composite next hop. The MPLS-over-UDP feature provides a scaling advantage on the number of IP tunnels supported on a device.

Starting in Junos OS Release 18.3R1, MPLS-over-UDP tunnels are supported on PTX Series routers and QFX Series switches. For every dynamic tunnel configured on a PTX router or a QFX switch, a tunnel composite next hop, an indirect next hop, and a forwarding next hop is created to resolve the tunnel destination route. You can also use policy control to resolve the dynamic tunnel over select prefixes by including the forwarding-rib configuration statement at the `[edit routing-options dynamic-tunnels]` hierarchy level.

Requirements

This example uses the following hardware and software components:

- Five MX Series routers with MPCs and MICs.
- Junos OS Release 16.2 or later running on the provider edge (PE) routers.

Before you begin:

1. Configure the device interfaces, including the loopback interface.
2. Configure the router ID and autonmous system number for the device.
3. Establish an internal BGP (IBGP) session with the remote PE device.
4. Establish OSPF peering among the devices.

Overview

IN THIS SECTION

- Topology | 116

Starting with Junos OS Release 16.2, a dynamic UDP tunnel supports the creation of a tunnel composite next hop for every UDP tunnel configured. These next-hop-based dynamic UDP tunnels are referred to as MPLS-over-UDP tunnels. The tunnel composite next hop are enabled by default for the MPLS-over-UDP tunnels.

MPLS-over-UDP tunnels can be bidirectional or unidirectional in nature.

- Bidirectional—When the PE devices are connected over MPLS-over-UDP tunnels in both directions, it is called a bidirectional MPLS-over-UDP tunnel.
- Unidirectional—When two PE devices are connected over MPLS-over-UDP tunnel in one direction, and over MPLS/IGP in the other direction, it is called an unidirectional MPLS-over-UDP tunnel.

  Unidirectional MPLS-over-UDP tunnels are used in migration scenarios, or in cases where two PE devices provide connectivity to each other over two disjoint networks. Because reverse direction tunnel does not exist for unidirectional MPLS-over-UDP tunnels, you must configure a filter-based MPLS-over-UDP decapsulation on the remote PE device for forwarding the traffic.

Starting in Junos OS Release 18.2R1, on PTX series routers and QFX10000 with unidirectional MPLS-over-UDP tunnels, you must configure the remote PE device with an input filter for MPLS-over-UDP packets, and an action for decapsulating the IP and UDP headers for forwarding the packets in the reverse tunnel direction.

For example, on the remote PE device, Device PE2, the following configuration is required for unidirectional MPLS-over-UDP tunnels:

PE2

```
[edit firewall filter]
user@host# set Decap_Filter term udp_decap from protocol udp
user@host# set Decap_Filter term udp_decap from destination-port 6635
user@host# set Decap_Filter term udp_decap then count UDP_PKTS
user@host# set Decap_Filter term udp_decap then decapsulate mpls-in-udp
user@host# set Decap_Filter term def then count def_pkt
user@host# set Decap_Filter term def then accept
```

In the above sample configuration, *Decap_Filter* is the name of the firewall filter used for MPLS-over-UDP decapsulation. The term *udp_decap* is the input filter for accepting UDP packets on the core-facing interface of Device PE2, and then decapsulate the MPLS-over-UDP packets to MPLS-over-IP packets for forwarding.

You can use the existing firewall operational mode commands, such as `show firewall filter` to view the filter-based MPLS-over-UDP decapsulation.

For example:

```
user@host >show firewall filter Decap_Filter
Filter: Decap_Filter
Counters:
Name                                                Bytes              Packets
UDP_PKTS                                            16744                  149
def_pkt                                             13049                  136
```

NOTE: For unidirectional MPLS-over-UDP tunnels:

- Only IPv4 address is supported as the outer header. Filter-based MPLS-over-UDP decapsulation does not support IPv6 address in the outer header.
- Only the default routing instance is supported after decapsulation.

Starting in Junos OS Release 17.1, on MX Series routers with MPCs and MICs, the scaling limit of MPLS-over-UDP tunnels is increased.

Starting in Junos Release 19.2R1, on MX Series routers with MPCs and MICs, carrier supporting carrier (CSC) architecture can be deployed with MPLS-over-UDP tunnels carrying MPLS traffic over dynamic IPv4 UDP tunnels that are established between supporting carrier's PE devices. With this enhancement, the scaling advantage that the MPLS-over-UDP tunnels provided is further increased. The CSC support with MPLS-over-UDP tunnel is not supported for IPv6 UDP tunnel.

The existing dynamic tunnel feature requires complete static configuration. Currently, the tunnel information received from peer devices in advertised routes is ignored. Starting in Junos OS Release 17.4R1, on MX Series routers, the next-hop-based dynamic MPLS-over-UDP tunnels are signaled using BGP encapsulation extended community. BGP export policy is used to specify the tunnel types, advertise the sender side tunnel information, and parse and convey the receiver side tunnel information. A tunnel is created according to the received type tunnel community.

Multiple tunnel encapsulations are supported by BGP. On receiving multiple capability, the next-hop-based dynamic tunnel is created based on the configured BGP policy and tunnel preference. The tunnel preference should be consistent across both the tunnel ends for the tunnel to be set up. By default,

MPLS-over-UDP tunnel is preferred over GRE tunnels. If dynamic tunnel configuration exists, it takes precedence over received tunnel community.

When configuring a next-hop-based dynamic MPLS-over-UDP tunnel, be aware of the following considerations:

- An IBGP session must be configured between the PE devices.
- A switchover between the next-hop-based dynamic tunnel encapsulations (UDP and GRE) is allowed, and this can impact network performance in terms of the supported IP tunnel scaling values in each mode.
- Having both GRE and UDP next-hop-based dynamic tunnel encapsulation types for the same tunnel destination leads to a commit failure.
- For unidirectional MPLS-over-UDP tunnels, you must explicitly configure filter-based MPLS-over-UDP decapsulation on the remote PE device for the packets to be forwarded.
- Graceful Routing Engine switchover (GRES) is supported with MPLS-over-UDP, and the MPLS-over-UDP tunnel type flags are unified ISSU and NSR compliant.
- MPLS-over-UDP tunnels are supported on virtual MX (vMX) in Lite mode.
- MPLS-over-UDP tunnels support dynamic GRE tunnel creation based upon new IPv4-mapped-IPv6 next hops.
- MPLS-over-UDP tunnel are supported in interoperability with contrail, wherein the MPLS-over-UDP tunnels are created from the contrail vRouter to an MX gateway. To enable this, the following community is required to be advertised in the route from the MX Series router to the contrail vRouter:

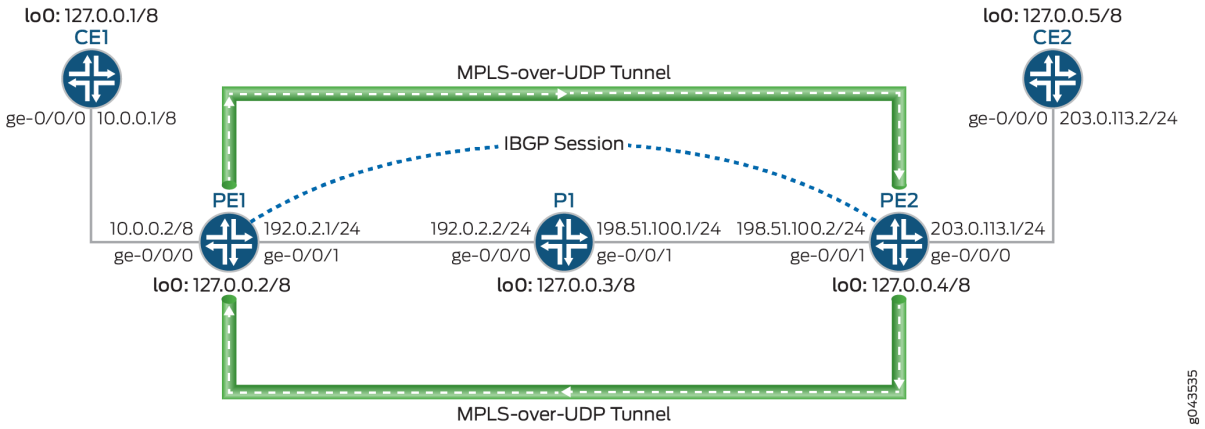
  ```
  [edit policy-options community]
  udp members 0x030c:64512:13;
  ```

  At a given point in time, only one tunnel type is supported on the contrail vRouter—next-hop-based dynamic GRE tunnels, MPLS-over-UDP tunnels, or VXLAN.
- The following features are not supported with the next-hop-based dynamic MPLS-over-UDP tunnel configuration:
  - RSVP automatic mesh
  - Plain IPV6 GRE and UDP tunnel configuration
  - Logical systems

Topology

Figure 4 on page 116 illustrates a Layer 3 VPN scenario over dynamic MPLS-over-UDP tunnels. The customer edge (CE) devices, CE1 and CE2, connect to provider edge (PE) devices, PE1 and PE2, respectively. The PE devices are connected to a provider device (Device P1), and an internal BGP (IBGP) session interconnects the two PE devices. A dynamic next-hop-based bidirectional MPL-over-UDP tunnel is configured between the PE devices.

Figure 4: Dynamic MPLS-over-UDP Tunnels



The MPLS-over-UDP tunnel is handled as follows:

1. After a MPLS-over-UDP tunnel is configured, a tunnel destination mask route with a tunnel composite next hop is created for the tunnel in the inet.3 routing table. This IP tunnel route is withdrawn only when the dynamic tunnel configuration is deleted.

   The tunnel composite next-hop attributes include the following:

   - When Layer 3 VPN composite next hop is disabled—Source and destination address, encapsulation string, and VPN label.
   - When Layer 3 VPN composite next hop and per-prefix VPN label allocation are enabled—Source address, destination address, and encapsulation string.
   - When Layer 3 VPN composite next hop is enabled and per-prefix VPN label allocation is disabled —Source address, destination address, and encapsulation string. The route in this case is added to the other virtual routing and forwarding instance table with a secondary route.

2. The PE devices are interconnected using an IBGP session. The IBGP route next hop to a remote BGP neighbor is the protocol next hop, which is resolved using the tunnel mask route with the tunnel next hop.

3. After the protocol next hop is resolved over the tunnel composite next hop, indirect next hops with forwarding next hops are created.

4. The tunnel composite next hop is used to forward the next hops of the indirect next hops.

Configuration

```

Procedure

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the CLI User Guide.

To configure Device PE1:

1. Configure the device interfaces including the loopback interface of the device.

```
[edit interfaces]
user@PE1# set ge-0/0/0 unit 0 family inet address 10.0.0.2/8
user@PE1# set ge-0/0/1 unit 0 family inet address 192.0.2.1/24
user@PE1# set ge-0/0/1 unit 0 family mpls
user@PE1# set lo0 unit 0 family inet address 127.0.0.2/8
```

2. Configure a static route for routes from Device PE1 with Device P1 as the next-hop destination.

```
[edit routing-options]
user@PE1# set static route 33.0.0.0/8 next-hop 192.0.2.2
```

3. Configure the router-ID and autonomous system number for Device PE1.

```
[edit routing-options]
user@PE1# set router-id 127.0.0.2
user@PE1# set autonomous-system 100
```

4. (PTX Series only) Configure policy control to resolve the MPLS-over-UDP dynamic tunnel route over select prefixes.

```
[edit routing-options dynamic-tunnels]
user@PTX-PE1# set forwarding-rib inet.0 inet-import dynamic-tunnel-fwd-route-import
```

5. (PTX Series only) Configure the inet-import policy for resolving dynamic tunnel destination routes over .

```
[edit policy-options]
user@PTX-PE1# set policy-statement dynamic-tunnel-fwd-route-import term 1 from route-filter
127.0.0.0/8 exact
user@PTX-PE1# set policy-statement dynamic-tunnel-fwd-route-import term 1 then accept
user@PTX-PE1# set policy-options policy-statement dynamic-tunnel-fwd-route-import then
reject
```

6. Configure IBGP peering between the PE devices.

```
[edit protocols]
user@PE1# set bgp group IBGP type internal
user@PE1# set bgp group IBGP local-address 127.0.0.2
user@PE1# set bgp group IBGP family inet-vpn unicast
user@PE1# set bgp group IBGP neighbor 127.0.0.4
```

7. Configure OSPF on all the interfaces of Device PE1, excluding the management interface.

```
[edit protocols]
user@PE1# set ospf area 0.0.0.0 interface ge-0/0/1.0
user@PE1# set ospf area 0.0.0.0 interface lo0.0 passive
```

8. Enable next-hop-based dynamic GRE tunnel configuration on Device PE1.

NOTE: This step is required only for illustrating the implementation difference between next-hop-based dynamic GRE tunnels and MPLS-over-UDP tunnels.

```
[edit routing-options]
user@PE1# set dynamic-tunnels gre next-hop-based-tunnel
```

9. Configure the MPLS-over-UDP tunnel parameters from Device PE1 to Device PE2.

```
[edit routing-options]
user@PE1# set dynamic-tunnels udp-dyn-tunnel-to-pe2 source-address 127.0.0.2
user@PE1# set dynamic-tunnels udp-dyn-tunnel-to-pe2 udp
user@PE1# set dynamic-tunnels udp-dyn-tunnel-to-pe2 destination-networks 127.0.0.0/8
```

10. Configure a VRF routing instance on Device PE1 and other routing instance parameters.

```
[edit routing-instances]
user@PE1# set MPLS-over-UDP-PE1 instance-type vrf
user@PE1# set MPLS-over-UDP-PE1 interface ge-0/0/0.0
user@PE1# set MPLS-over-UDP-PE1 route-distinguisher 127.0.0.2:1
user@PE1# set MPLS-over-UDP-PE1 vrf-target target:600:1
```

11. Enable BGP in the routing instance configuration for peering with Device CE1.

```
[edit routing-instances]
user@PE1# set MPLS-over-UDP-PE1 protocols bgp group pe1-ce1 peer-as 200
user@PE1# set MPLS-over-UDP-PE1 protocols bgp group pe1-ce1 neighbor 10.0.0.1 as-override
```

Results

From configuration mode, confirm your configuration by entering the `show interfaces`, `show routing-options`, `show protocols`, and `show routing-instances` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1# show interfaces
ge-0/0/0 {
    unit 0 {
        family inet {
            address 10.0.0.2/8;
        }
    }
}
ge-0/0/1 {
    unit 0 {
        family inet {
            address 192.0.2.1/24;
        }
        family mpls;
    }
}
lo0 {
    unit 0 {
        family inet {
            address 127.0.0.2/8;
        }
    }
}
```

```
user@PE1# show routing-options
static {
    route 33.0.0.0/8 next-hop 192.0.2.2;
```

```
}
router-id 127.0.0.2;
autonomous-system 100;
forwarding-table {
    export pplb;
}
dynamic-tunnels {
    gre next-hop-based-tunnel;
    udp-dyn-tunnel-to-pe2 {
        source-address 127.0.0.2;
        udp;
        destination-networks {
            127.0.0.0/8;
        }
    }
}
```

```
user@PE1# show protocols
bgp {
    group IBGP {
        type internal;
        local-address 127.0.0.2;
        family inet-vpn {
            unicast;
        }
        neighbor 127.0.0.4;
    }
}
ospf {
    area 0.0.0.0 {
        interface ge-0/0/1.0;
        interface lo0.0 {
            passive;
        }
    }
}
```

```
user@PE1# show routing-instances
MPLS-over-UDP-PE1 {
    instance-type vrf;
```

```
    interface ge-0/0/0.0;
    route-distinguisher 127.0.0.2:1;
    vrf-target target:600:1;
    protocols {
        bgp {
            group pe1-ce1 {
                peer-as 200;
                neighbor 10.0.0.1 {
                    as-override;
                }
            }
        }
    }
}
```

If you are done configuring the device, enter `commit` from configuration mode.

Verification

IN THIS SECTION

- Verifying the Connection Between PE Devices | **124**
- Verify the Dynamic Tunnel Routes on Device PE1 | **125**
- Verify the Dynamic Tunnel Routes on Device PE2 | **127**
- Verifying That the Routes Have the Expected Indirect-Next-Hop Flag | **128**

Confirm that the configuration is working properly.

Verifying the Connection Between PE Devices

Purpose

Verify the BGP peering status between Device PE1 and Device PE2, and the BGP routes received from Device PE2.

Action

From operational mode, run the **show bgp summary** and **show route receive-protocol bgp *ip-address* table bgp.l3vpn.0** commands.

```
user@PE1> show bgp summary
Groups: 2 Peers: 2 Down peers: 0
Table          Tot Paths  Act Paths Suppressed    History Damp State    Pending
bgp.l3vpn.0
                      2          2          0          0          0          0
Peer                     AS      InPkt     OutPkt    OutQ   Flaps Last Up/Dwn State|#Active/
Received/Accepted/Damped...
127.0.0.4             100        139        136       0       0       58:23 Establ
  bgp.l3vpn.0: 2/2/2/0
  MPLS-over-UDP-PE1.inet.0: 2/2/2/0
10.0.0.1               200        135        136       0       0       58:53 Establ
  MPLS-over-UDP-PE1.inet.0: 1/1/1/0
```

```
user@PE1> show route receive-protocol bgp 127.0.0.4 table bgp.l3vpn.0
bgp.l3vpn.0: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)
  Prefix                  Nexthop              MED     Lclpref    AS path
  127.0.0.4:1:127.0.0.5/8
*                         127.0.0.4                 100        200 I
  127.0.0.4:1:200.1.1.0/24
*                         127.0.0.4                 100        I
```

Meaning

- In the first output, the BGP session state is `Establ`, which means that the session is up and the PE devices are peered.
- In the second output, Device PE1 has learned two BGP routes from Device PE2.

Verify the Dynamic Tunnel Routes on Device PE1

Purpose

Verify the routes in the inet.3 routing table and the dynamic tunnel database information on Device PE1.

Action

From operational mode, run the **show route table inet.3**, **show dynamic-tunnels database terse**, **show dynamic-tunnels database**, and **show dynamic-tunnels database summary** commands.

```
user@PE1> show route table inet.3
inet.3: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

127.0.0.0/8      *[Tunnel/300] 00:21:18
                      Tunnel
127.0.0.4/8     *[Tunnel/300] 00:21:18
                      Tunnel Composite
```

```
user@PE1> show dynamic-tunnels database terse
Table: inet.3

Destination-network: 127.0.0.0/8
Destination         Source          Next-hop                 Type        Status
127.0.0.4/8      127.0.0.2     0xb395b10 nhid 613        udp         Up
```

```
user@PE1> show dynamic-tunnels database
Table: inet.3

Destination-network: 55.0.0.0/8

Destination-network: 55.66.0.0/16

Destination-network: 55.66.77.0/24
Tunnel to: 127.0.0.4/8
  Reference count: 2
  Next-hop type: UDP
    Source address: 127.0.0.2 Tunnel Id: 2
    Next hop: tunnel-composite, 0xb395b10, nhid 613
      VPN Label: Push 299776 Reference count: 3
```

```
      Traffic Statistics: Packets 0, Bytes 0
      State: Up
```

```
user@PE1> show dynamic-tunnels database summary
Dynamic Tunnels,  Total 1 displayed
GRE Tunnel:
Active Tunnel Mode, Next Hop Base
  IFL Based,  Total 0 displayed, Up 0, Down 0
  Nexthop Based,  Total 0 displayed, Up 0, Down 0
RSVP Tunnel:
  Total 0 displayed
UDP Tunnel:
  Total 1 displayed, Up 1, Down 0
```

Meaning

- In the first output, because Device PE1 is configured with the MPLS-over-UDP tunnel, a tunnel composite route is created for the inet.3 routing table route entry.
- In the remaining outputs, the MPLS-over-UDP tunnel is displayed with the tunnel encapsulation type, tunnel next hop parameters, and tunnel status.

Verify the Dynamic Tunnel Routes on Device PE2

Purpose

Verify the routes in the inet.3 routing table and the dynamic tunnel database information on Device PE2.

Action

From operational mode, run the **show route table inet.3**, and the **show dynamic-tunnels database terse** commands.

```
user@PE2> show route table inet.3
inet.3: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

127.0.0.0/8      *[Tunnel/300] 00:39:31
                      Tunnel
```

```
127.0.0.2/8     *[Tunnel/300] 00:24:53
                      Tunnel Composite
```

```
user@PE1> show dynamic-tunnels database terse
Table: inet.3

Destination-network: 127.0.0.0/8
Destination         Source          Next-hop                Type        Status
127.0.0.2/8      127.0.0.4     0xb395450 nhid 615        udp         Up
```

Meaning

The outputs show the MPLS-over-UDP tunnel creation and the next-hop ID assigned as the next-hop interface, similar to Device PE1.

Verifying That the Routes Have the Expected Indirect-Next-Hop Flag

Purpose

Verify that Device PE1 and Device PE2 are configured to maintain the indirect next hop to forwarding next-hop binding on the Packet Forwarding Engine forwarding table.

Action

From operational mode, run the **show krt indirect-next-hop** command on Device PE1 and Device PE2.

```
user@PE1> show krt indirect-next-hop
Indirect Nexthop:
Index: 1048574 Protocol next-hop address: 127.0.0.4

         IGP Actual Route handle(hex) : 0x0            IGP Actual rt_entry protocol : Any
```

Meaning

The outputs show that a next-hop-based dynamic MPLS-over-UDP tunnel is created between the PE devices.

Troubleshooting

IN THIS SECTION

- Troubleshooting Commands | 130

To troubleshoot the next-hop-based dynamic tunnels, see:

Troubleshooting Commands

Problem

The next-hop-based dynamic MPLS-over-UDP tunnel configuration is not taking effect.

Solution

To troubleshoot the next-hop-based MPLS-over-UDP tunnel configuration, use the following `traceroute` commands at the `[edit routing-options dynamic-tunnels]` statement hierarchy:

- `traceoptions file` *`file-name`*
- `traceoptions file size` *`file-size`*
- `traceoptions flag all`

For example:

```
[edit routing-options dynamic-tunnels]
traceoptions {
    file udp_dyn_pe1.wri size 4294967295;
    flag all;
}
```

Anti-Spoofing Protection for Next-Hop-Based Dynamic Tunnels Overview

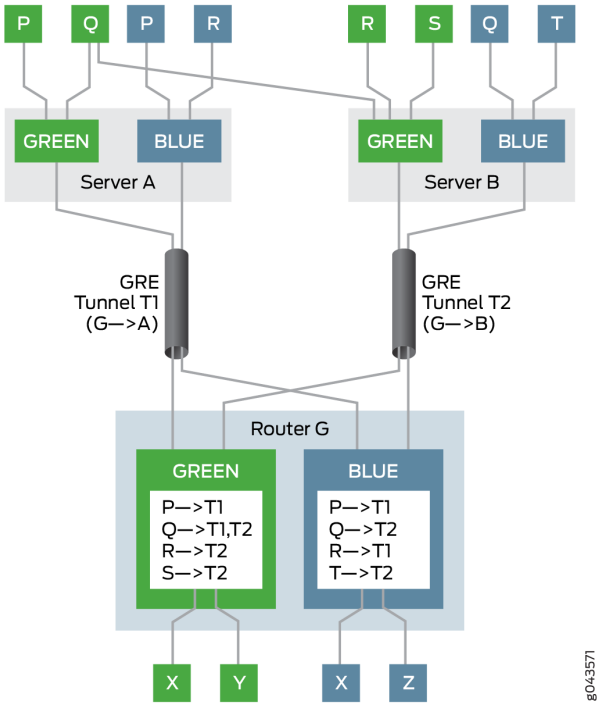
With the rise in deployment of high-scale IP tunnels in data centers, there is a need to add security measures that allow users to limit malicious traffic from compromised virtual machines (VMs). One possible attack is the injecting of traffic into an arbitrary customer VPN from a compromised server through the gateway router. In such cases, anti-spoofing checks on IP tunnels ensure that only legitimate sources are injecting traffic into data centers from their designated IP tunnels.

Next-hop-based dynamic IP tunnels create a tunnel composite next hop for every dynamic tunnel created on the device. Because next-hop-based dynamic tunnels remove the dependency on physical interfaces for every new dynamic tunnel configured, configuring next-hop-based dynamic tunnels provides a scaling advantage over the number of dynamic tunnels that can be created on a device. Starting in Junos OS Release 17.1, anti-spoofing capabilities for next-hop-based dynamic IP tunnels is provided for next-hop-based dynamic tunnels. With this enhancement, a security measure is implemented to prevent injecting of traffic into an arbitrary customer VPN from a compromised server through the gateway router.

Anti-spoofing is implemented using reverse path forwarding checks in the Packet Forwarding Engine. The checks are implemented for the traffic coming through the tunnel to the routing instance. Currently, when the gateway router receives traffic from a tunnel, only the destination lookup us done and the packet is forwarded accordingly. When anti-spoofing protection is enabled, the gateway router also does a source address lookup of the encapsulation packet IP header in the VPN, in addition to the tunnel destination lookup. This ensures that legitimate sources are injecting traffic through their designated IP tunnels. As a result, anti-spoofing protection ensures that the tunnel traffic is received from a legitimate source on the designated tunnels.

Figure 5 on page 131 illustrates a sample topology with the requirements for anti-spoofing protection.

Figure 5: Anti-Spoofing Protection for Next-Hop-Based Dynamic Tunnels



In this example, the gateway router is Router G. Router G has two VPNs—Green and Blue. The two servers, Server A and Server B, can reach the Green and Blue VPNs on Router G through the next-hop-based dynamic tunnels T1 and T2, respectively. Several hosts and virtual machines (P, Q, R, S, and T) connected to the servers can reach the VPNs through the gateway router, Router G. Router G has the virtual routing and forwarding (VRF) tables for Green and Blue VPNs, each populated with the reachability information for the virtual machines in those VPNs.

For example, in VPN Green, Router G uses tunnel T1 to reach host P, tunnel T2 to reach hosts R and S, and load balancing is done between tunnels T1 and T2 to reach the multihomed host Q. In VPN Blue, Router G uses tunnel T1 to reach hosts P and R, and tunnel T2 to reach hosts Q and T.

The check passes for reverse path forwarding when:

- A packet comes from a legitimate source on its designated tunnel.

  Host P in VPN Green sends a packet to host X using tunnel T1. Because Router G can reach host P through tunnel T1, it allows the packet to pass and forwards the packet to host X.

- A packet comes from a multihomed source on its designated tunnels.

  Host Q in VPN Green is multihomed on servers A and B, and can reach Router G through tunnels T1 and T2. Host Q sends a packet to host Y using tunnel T1, and a packet to host X using tunnel T2. Because Router G can reach host Q through tunnels T1 and T2, it allows the packets to pass and forwards them to hosts Y and X, respectively.

Layer 3 VPNs do not have anti-spoofing protection enabled by default. To enable anti-spoofing for next-hop-based dynamic tunnels, include the `ip-tunnel-rpf-check` statement at the `[edit routing-instances` *`routing-instance-name`* `routing-options forwarding-table]` hierarchy level. The reverse path forwarding check is applied to the VRF routing instance only. The default mode is set to `strict`, where the packet that comes from a source on a nondesignated tunnel does not pass the check. The `ip-tunnel-rpf-check` mode can be set as `loose`, where the reverse path forwarding check fails when the packet comes from a nonexistent source. An optional firewall filter can be configured under the `ip-tunnel-rpf-check` statement to count and log the packets that failed the reverse path forwarding check.

The following sample output shows an anti-spoofing configuration:

```
[edit routing-instances routing-instance-name routing-options forwarding-table]
ip-tunnel-rpf-check {
    mode loose;
    fail-filter filter-name;
}
```

Take the following guidelines under consideration when configuring anti-spoofing protection for next-hop-based dynamic tunnels:

- Anti-spoofing protection can be enabled for IPv4 tunnels and IPv4 data traffic only. The anti-spoofing capabilities are not supported on IPv6 tunnels and IPv6 data traffic.
- Anti-spoofing for next-hop-based dynamic tunnels can detect and prevent a compromised virtual machine (inner source reverse path forwarding check) but not a compromised server that is label-spoofing.
- The next-hop-based IP tunnels can originate and terminate on an inet.0 routing table.

- Anti-spoofing protection is effective when the VRF routing instance has label-switched interfaces (LSIs) (using the `vrf-table-label`), or virtual tunnel (VT) interfaces. With `per-next-hop` label on the VRF routing instance, anti-spoofing protection is not supported.
- The `rpf fail-filter` is applicable only to the inner IP packet.
- Enabling anti-spoofing checks does not affect the scaling limit of the next-hop-based dynamic tunnels on a device.
- The system resource utilization with anti-spoofing protection enabled for the VRF routing instance is slightly higher than the utilization of next-hop-based dynamic tunnels without the anti-spoofing protection enabled.
- Anti-spoofing protection requires additional source IP address checks, which has minimal impact on network performance.
- Graceful Routing Engine switchover (GRES) and in-service software upgrade (ISSU) are supported with anti-spoofing protection.

Example: Configuring Anti-Spoofing Protection for Next-Hop-Based Dynamic Tunnels

IN THIS SECTION

- Requirements | 133
- Overview | 134
- Configuration | 136
- Verification | 144

This example shows how to configure reverse path forwarding checks for the virtual routing and forwarding (VRF) routing instance to enable anti-spoofing protection for next-hop-based dynamic tunnels. The checks ensure that legitimate sources are injecting traffic through their designated IP tunnels.

Requirements

This example uses the following hardware and software components:

- Three MX Series Routers with MICs, each connected to a host device.
- Junos OS Release 17.1 or later running on one or all the routers.

Before you begin:

- Enable tunnel services configuration on the Flexible PIC Concentrator.
- Configure the router interfaces.
- Configure the router-ID and assign an autonomous system number for the router.
- Establish an internal BGP (IBGP) session with the tunnel endpoints.
- Configure RSVP on all the routers.
- Configure OSPF or any other interior gateway protocol on all the routers.
- Configure two dynamic next-hop-based IP tunnels between the two routers.
- Configure a VRF routing instance for every router-to-host connection.

Overview

IN THIS SECTION

Topology | 134

Starting in Junos OS Release 17.1, anti-spoofing capabilities are added to next-hop-based dynamic IP tunnels, where checks are implemented for the traffic coming through the tunnel to the routing instance using reverse path forwarding in the Packet Forwarding Engine.

Currently, when the gateway router receives traffic from a tunnel, only the destination address lookup is done before forwarding. With anti-spoofing protection, the gateway router does a source address lookup of the encapsulation packet IP header in the VPN to ensure that legitimate sources are injecting traffic through their designated IP tunnels. This is called the strict mode and is the default behavior of anti-spoofing protection. To pass traffic from nondesignated tunnels, the reverse path forwarding check is enabled in the lose mode. For traffic received from nonexistent sources, the reverse path forwarding check fails for both the strict and loose modes.

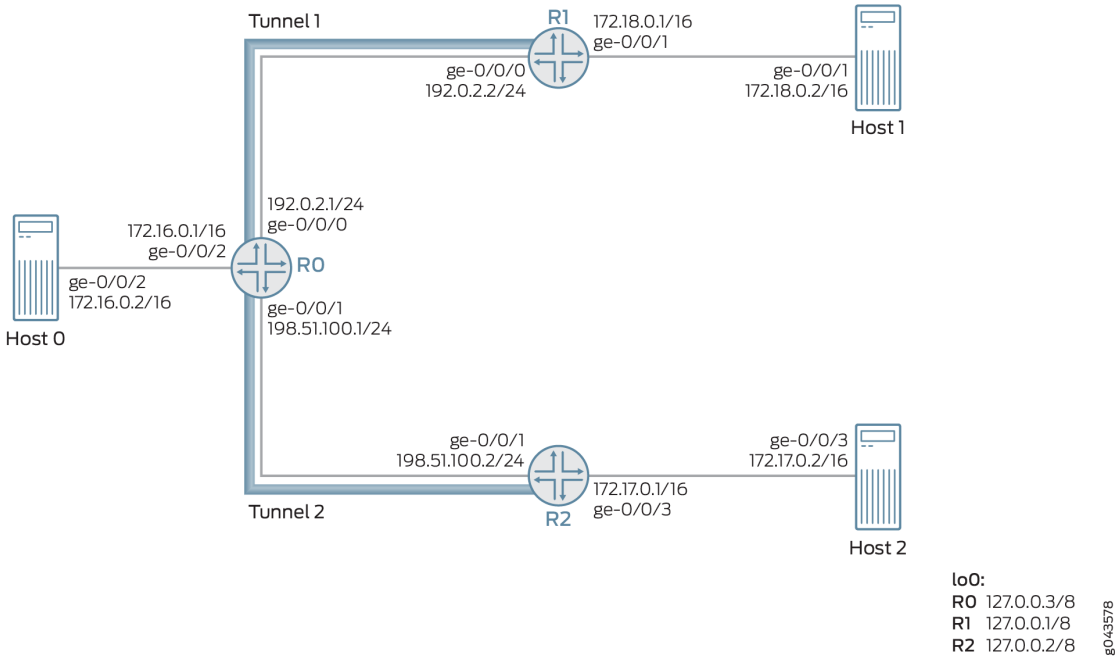
Anti-spoofing is supported on VRF routing instances. To enable anti-spoofing for dynamic tunnels, include the `ip-tunnel-rpf-check` statement at the `[edit routing-instances routing-instance-name routing-options forwarding-table]` hierarchy level.

Topology

Figure 6 on page 135 illustrates a sample network topology enabled with anti-spoofing protection. Routers R0, R1 and R2 are each connected to hosts Host0, Host1, and Host2, respectively. Two generic

routing encapsulation (GRE) next-hop-based dynamic tunnels, Tunnel 1 and Tunnel 2 – connect Router R0 with Routers R1 and R2, respectively. The VRF routing instance is running between each router and its connected host devices.

Figure 6: Anti-Spoofing Protection for Next-Hop-Based Dynamic Tunnels



Taking as an example, three packets (Packets A, B, and C) are received on Router 0 from Router R2 through the next-hop-based dynamic GRE tunnel (Tunnel 2). The source IP address of these packets are 172.17.0.2 (Packet A), 172.18.0.2 (Packet B), and 172.20.0.2 (Packet C).

The source IP address of Packets A and B belong to Host 2 and Host 1, respectively. Packet C is a nonexistent source tunnel. The designated tunnel in this example is Tunnel 2, and the nondesignated tunnel is Tunnel 1. Therefore, the packets are processed as follows:

- **Packet A**—Because the source is coming from a designated tunnel (Tunnel 2), Packet A passes the reverse path forwarding check and is processed for forwarding through Tunnel 2.
- **Packet B**—Because the source is coming from Tunnel 1, which is a nondesinated tunnel, by default, Packet B fails the reverse path forwarding check in the strict mode. If loose mode is enabled, Packet B is allowed for forwarding.
- **Packet C**—Because the source is a nonexistent tunnel source, Packet C fails the reverse path forwarding check, and the packet is not forwarded.

Configuration

IN THIS SECTION

- CLI Quick Configuration | 136
- Procedure | 138
- Results | 141

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the `[edit]` hierarchy level, and then enter `commit` from configuration mode.

Router R0

```
set interfaces ge-0/0/0 unit 0 family inet address 192.0.2.1/24

Procedure

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the CLI User Guide.

To configure Router R0:

1. Configure Router R0's interfaces, including the loopback interface.

```
[edit interfaces]
user@R0# set ge-0/0/0 unit 0 family inet address 192.0.2.1/24
user@R0# set ge-0/0/1 unit 0 family inet address 198.51.100.1/24
user@R0# set ge-0/0/2 vlan-tagging
user@R0# set ge-0/0/2 unit 0 vlan-id 1
user@R0# set ge-0/0/2 unit 0 family inet address 172.16.0.1/16
user@R0# set lo0 unit 0 family inet address 10.1.1.1/32
```

2. Assign the router ID and autonomous system number for Router R0.

```
[edit routing-options]
user@R0# set router-id 10.1.1.1
user@R0# set autonomous-system 100
```

3. Configure IBGP peering between the routers.

```
[edit protocols]
user@R0# set bgp group IBGP type internal
user@R0# set bgp group IBGP local-address 10.1.1.1
user@R0# set bgp group IBGP family inet-vpn unicast
user@R0# set bgp group IBGP neighbor 20.1.1.1
user@R0# set bgp group IBGP neighbor 30.1.1.1
```

4. Configure OSPF on all the interfaces of Router R0, excluding the management interface.

```
[edit protocols]
user@R0# set ospf traffic-engineering
user@R0# set ospf area 0.0.0.0 interface lo0.0 passive
user@R0# set ospf area 0.0.0.0 interface all
```

5. Configure RSVP on all the interfaces of Router R0, excluding the management interface.

```
[edit protocols]
user@R0# set rsvp interface all
user@R0# set rsvp interface fxp0.0 disable
```

6. Enable next-hop-based dynamic GRE tunnel configuration on Router R0.

```
[edit routing-options]
user@R0# set dynamic-tunnels gre next-hop-based-tunnel
```

7. Configure the dynamic GRE tunnel parameters from Router R0 to Router R1.

```
[edit routing-options]
user@R0# set dynamic-tunnels T1 source-address 192.0.2.1
user@R0# set dynamic-tunnels T1 gre
user@R0# set dynamic-tunnels T1 destination-networks 192.0.2.0/24
```

8. Configure the dynamic GRE tunnel parameters from Router R0 to Router R2.

```
[edit routing-options]
user@R0# set dynamic-tunnels T2 source-address 198.51.100.1
user@R0# set dynamic-tunnels T2 gre
user@R0# set dynamic-tunnels T2 destination-networks 198.51.100.0/24
```

9. Configure a virtual routing and forwarding (VRF) routing instance on Router R0, and assign the interface connecting to Host 1 to the VRF instance.

```
[edit routing-instances]
user@R0# set VPN1 instance-type vrf
user@R0# set VPN1 route-distinguisher 100:100
user@R0# set VPN1 vrf-target target:100:1
user@R0# set VPN1 vrf-table-label
user@R0# set VPN1 interface ge-0/0/2.0
```

10. Configure an external BGP session with Host 1 for the VRF routing instance.

```
[edit routing-instances]
user@R0# set VPN1 protocols bgp group External type external
user@R0# set VPN1 protocols bgp group External family inet unicast
user@R0# set VPN1 protocols bgp group External peer-as 200
user@R0# set VPN1 protocols bgp group External neighbor 172.16.0.1
```

11. Configure anti-spoofing protection for the VRF routing instance on Router R0. This enables reverse path forwarding check for the next-hop-based dynamic tunnels, T1 and T2, on Router 0.

```
[edit routing-instances]
user@R0# set VPN1 routing-options forwarding-table ip-tunnel-rpf-check mode strict
```

Results

From configuration mode, confirm your configuration by entering the `show interfaces`, `show routing-options`, `show protocols`, and `show routing-options` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R0# show interfaces
ge-0/0/0 {
    unit 0 {
        family inet {
            address 192.0.2.1/24;
        }
    }
}
ge-0/0/1 {
    unit 0 {
        family inet {
            address 198.51.100.1/24;
        }
    }
}
ge-0/0/2 {
    vlan-tagging;
    unit 0 {
        vlan-id 1;
        family inet {
            address 172.16.0.1/16;
        }
    }
}
lo0 {
    unit 0 {
        family inet {
            address 10.1.1.1/32;
        }
```

```
    }
}
```

```
user@R0# show routing-options
router-id 10.1.1.1;
autonomous-system 100;
dynamic-tunnels {
    gre next-hop-based-tunnel;
    T1 {
        source-address 192.0.2.1;
        gre;
        destination-networks {
            192.0.2.0/24;
        }
    }
    T2 {
        source-address 198.51.100.1;
        gre;
        destination-networks {
            198.51.100.0/24;
        }
    }
}
```

```
user@R0# show protocols
rsvp {
    interface all;
    interface fxp0.0 {
        disable;
    }
}

            group External {
                type external;
                family inet {
                    unicast;
                }
                peer-as 200;
                neighbor 172.16.0.1;
            }
        }
    }
}
```

Verification

IN THIS SECTION

- Verifying Basic Configuration | 144
- Verifying Dynamic Tunnel Configuration | 145
- Verifying Anti-Spoofing Protection Configuration | 146

Confirm that the configuration is working properly.

Verifying Basic Configuration

Purpose

Verify the OSPF and BGP peering status between the Router R0 and Routers R1 and R2.

Action

From operational mode, run the **show ospf neighbor** and **show bgp summary**commands.

```
user@R0> show ospf neighbor
Address          Interface              State     ID               Pri  Dead
192.0.2.2        ge-0/0/0.0             Full      20.1.1.1         128    32
198.51.100.2     ge-0/0/1.0             Full      30.1.1.1         128    32

user@R0> show bgp summary
Groups: 2 Peers: 3 Down peers: 1
Table          Tot Paths  Act Paths Suppressed    History Damp State    Pending
bgp.l3vpn.0
                       0          0          0          0          0          0
Peer                     AS      InPkt     OutPkt    OutQ   Flaps Last Up/Dwn State|#Active/
Received/Accepted/Damped...
20.1.1.1                100        182        178       0       0     1:20:27 Establ
  bgp.l3vpn.0: 0/0/0/0
30.1.1.1                100        230        225       0       0     1:41:51 Establ
  bgp.l3vpn.0: 0/0/0/0
172.16.0.1              200          0          0       0       0     1:42:08 Establ
```

Meaning

The OSPF and BGP sessions are up and running between the Routers R0, R1, and R2.

Verifying Dynamic Tunnel Configuration

Purpose

Verify the status of the next-hop-based dynamic GRE tunnels between the Router R0 and Routers R1 and R2.

Action

From operational mode, run the **show route table inet.3**, and the **show dynamic-tunnels database terse** commands.

```
user@R0> show route table inet.3

inet.3: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192.0.2.0/24       *[Tunnel/300] 01:47:57
                       Tunnel
192.0.2.2/24       *[Tunnel/300] 01:47:57
                       Tunnel Composite

198.51.100.0/24    *[Tunnel/300] 01:47:57
                       Tunnel
198.51.100.2/24    *[Tunnel/300] 01:47:57
                       Tunnel Composite
```

```
user@R0> show dynamic-tunnels database terse
Table: inet.3

Destination-network: 192.0.2.0/24
Destination             Source             Next-hop                      Type         Status
192.0.2.2/24      192.0.2.1     0xb395e70 nhid 612         gre       Up

Destination-network: 198.51.100.0/24
Destination             Source                     Next-hop                     Type
```

```
Status
198.51.100.2      198.51.100.1     0xb395e70 nhid 612         gre       Up
```

Meaning

The two next-hop-based dynamic GRE tunnels, Tunnel 1 and Tunnel 2, are up.

Verifying Anti-Spoofing Protection Configuration

Purpose

Verify that the reverse path forwarding check has been enabled on the VRF routing instance on Router R0.

Action

From the operational mode, run the **show krt table VPN1.inet.0 detail**.

```
user@R0> show krt table VPN1.inet.0 detail
KRT tables:
VPN1.inet.0                  : GF: 1 krt-index: 8     ID: 0 kernel-id: 8
        flags: (null)
        tunnel rpf config data : enable, strict, filter [0], 0x2
        tunnel rpf tlv data : enable, strict, filter [0], 0x4
        unicast reverse path: disabled
        fast-reroute-priority: 0
        Permanent NextHops
          Multicast        : 0 Broadcast : 0
          Receive          : 0   Discard   : 0
          Multicast Discard: 0   Reject    : 0
          Local            : 0   Deny      : 0
          Table            : 0
```

Meaning

The configured reverse path forwarding check is enabled on the VRF routing instance in the strict mode.

Next-Hop-Based Dynamic Tunnel Localization Overview

IN THIS SECTION

- Benefits of Next-Hop-Based Dynamic Tunnel Localization | **147**
- Use Cases for Next-Hop-Based Dynamic Tunnel Localization | **147**
- Traffic Handling with Localization of Next-Hop-Based Dynamic Tunnels | **148**
- Configuring Next-Hop-Based Dynamic Tunnels Localization | **148**
- Troubleshooting Localized Next-Hop-Based Dynamic Tunnels | **151**
- Unsupported Features for Next-Hop-Based Dynamic Tunnels Localization | **153**

Next-hop-based dynamic tunnels include generic routing encapsulation (GRE) tunnels and MPLS-over-UDP tunnels. These tunnels provide a scaling advantage over the interface-based tunnels. However, unlike the interface-based tunnels, the next-hop-based dynamic tunnels are anchorless in nature, where the forwarding information of the tunnels is distributed to the Packet Forwarding Engines (PFEs) on every line card on the device. This limits the maximum number of tunnels supported on the device to the tunnel capacity of a single line card. With the support for localization, you can configure next-hop-based dynamic tunnel localization to create the forwarding information only on the PFE of a line card that is designated as the anchor PFE. The PFEs on the other line cards on the device have state forwarding information to steer the packets to the anchor PFE. This provides a scaling advantage by increasing the maximum number of tunnels supported on a device.

Benefits of Next-Hop-Based Dynamic Tunnel Localization

Provides a scaling advantage by increasing the maximum number of tunnels supported on a device.

Use Cases for Next-Hop-Based Dynamic Tunnel Localization

- The IPsec gateway devices that host a number of MS-MPC are used to terminate IPSec tunnels and are required to support moderate load. This support is affected with the use of next-hop-based dynamic tunnels when the scaling limit of the device is reached. With the localization of next-hop-based dynamic tunnels, the maximum number of the tunnels supported is increased, allowing the device to accommodate more tunnels at the cost of an extra fabric hop.
- For Internet or VPN gateway devices, such as a virtual public cloud data center, there is a need for the gateway devices to communicate with a large number of servers. The data center servers are reachable through next-hop-based dynamic tunnels. The anchorless property of the dynamic tunnels limits the overall scaling numbers of the device. The gateway devices host multiple MPCs, with

increased traffic demands. With the localization of the next-hop-based dynamic tunnels, the tunnels can be spread across the MPCs, thereby facilitating an increase in the tunnel scaling numbers.

Traffic Handling with Localization of Next-Hop-Based Dynamic Tunnels

With support for localization, the next-hop-based dynamic tunnel state is localized to an anchor Packet Forwarding Engine, and the other Packet Forwarding Engine has the tunnel state for steering traffic to the tunnel anchor.

Figure 7 on page 148 illustrates the forwarding path of next-hop-based dynamic tunnels without localization.

Figure 7: Forwarding Path of Next-Hop-Based Dynamic Tunnels Without Localization

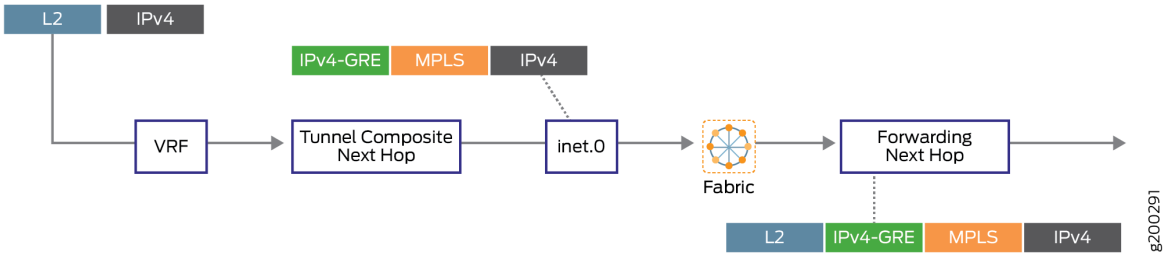

Figure 8 on page 148 illustrates the forwarding path of next-hop-based dynamic tunnels with localization.

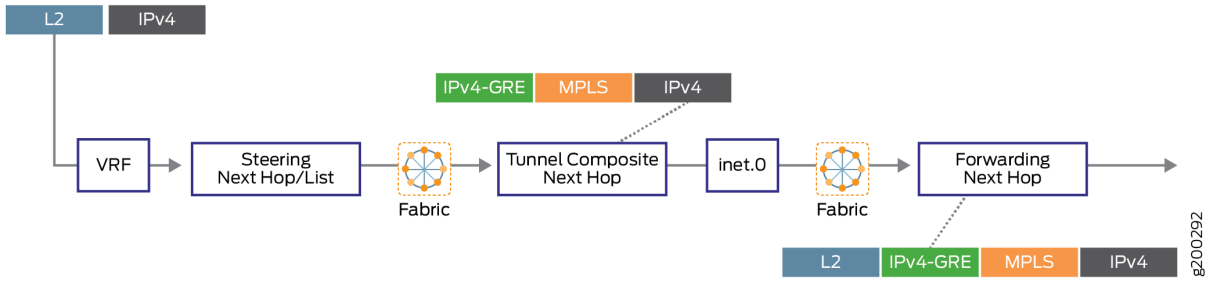
Figure 8: Forwarding Path of Next-Hop-Based Dynamic Tunnels With Localization



Configuring Next-Hop-Based Dynamic Tunnels Localization

Localization support can be configured for newly created next-hop-based dynamic tunnels, or for existing non-local dynamic tunnels.

Configuring Localization for New Next-Hop-Based Dynamic Tunnels

The localization of next-hop-based dynamic tunnels uses a policy-based approach to specify prefix groups. In other words, route policies are used to apply the localization properties to the next-hop-based dynamic tunnels. Dynamic tunnel attribute profiles are created and configured under routing options for association with the prefix group using the policy.

1. Creating dynamic tunnel profiles.

   The dynamic tunnel profile specifies the tunnel type and the anchor Packet Forwarding Engine information. Multiple dynamic tunnel profiles can be created for localization of the dynamic tunnels. The values for the dynamic tunnel type can be GRE, UDP, or BGP-SIGNAL.

   Although BGP-SIGNAL is not a valid tunnel type, on assigning BGP-SIGNAL as the tunnel type, the tunnels created from the BGP-signalled attributes are localized. When using BGP-SIGNAL, the tunnel type is decided based on the type advertised by BGP in its TLV. BGP-SIGNAL tunnels are always next-hop-based tunnels. The GRE tunnels created dynamically by BGP-SIGNAL are always next-hop-based, even if the user has manually configured tunnels created by GRE to use IFLs.

   The anchor Packet Forwarding Engine value is the line card of the anchor Packet Forwarding Engine, for example, pfe-x/y/0. This information can be viewed from the `show interfaces terse` *pfe** command output.

   Sample Configuration:

```
[edit routing-options]
dynamic-tunnels {
    dynamic-tunnel-attributes attribute-1 {
        dynamic-tunnel-type <GRE | UDP | BGP-SIGNAL>;
        dynamic-tunnel-anchor-pfe pfe-1/0/0;
    }
}
```

2. Associating dynamic tunnel profile to prefix list.

   Configuring a policy with `dynamic-tunnel-attributes` as the action associates the dynamic tunnel to the prefix list. The policy `from` action allows the creation of tunnel with specified attributes for any matching condition, such as a prefix range, community, or source address of BGP routes, and so on.

   Sample configuration:

```
[edit policy-options]
policy-statement policy-name {
    term term {
```

```
        from {
            <route-filter | next-hop | community>>;
        }
        then {
            dynamic-tunnel-attributes <attribute-name>;
        }
    }
}
```

3. Including the tunnel policy under the forwarding table export policy.

   After the policy is configured, it is included in the forwarding table export policy for the parsing of the policy.

   Using the export-policy, the tunnel attributes get associated with the route. Whenever a route from BGP is queued for resolution, the forwarding table export policy is evaluated, and the tunnel attributes are obtained from the policy module based on the applied filters. The obtained tunnel attributes are then attached to the next hop in form of a tunnel composite next hop. The corresponding anchor forwarding structures, based on the Packet Forwarding Engine name and tunnel type, are created and sent to the forwarding table before a tunnel composite next hop is sent. However, if none of the attributes map to the tunnel composite next hop, then the forwarding structure is created on every Packet Forwarding Engine, similar to the non-localized dynamic tunnels.

   Sample configuration:

```
[edit routing-options]
forwarding-table {
    export  dynamic-tunnel;
}
```

Configuring Localization for Existing Next-Hop-Based Dynamic Tunnels

CAUTION: Making on the fly changes to dynamic tunnel attributes can result in an FPC crash due to high memory utilization. Hence, we recommend deactivating the dynamic-tunnels configuration before configuring localization.

To update tunnel attributes for existing next-hop-based dynamic tunnels, the following should be performed:

1. Deactivate `dynamic-tunnels` configuration under the `[edit routing-options]` hierarchy level.

Sample configuration:

```
[edit routing-options]
user@host# deactivate dynamic-tunnels
user@host# commit
```

2. Change tunnel attributes as required.

3. Activate `dynamic-tunnels` configuration under the `[edit routing-options]` hierarchy level.

   Sample configuration:

```
[edit routing-options]
user@host# activate dynamic-tunnels
user@host# commit
```

To configure localization for existing non-local next-hop-based dynamic tunnels:

> ⚠ **CAUTION**: Making on the fly changes to configure localization for existing non-local next-hop-based dynamic tunnels can result in an FPC crash due to high memory utilization. Hence, we recommend deactivating the dynamic-tunnels configuration before configuring localization.

1. Deactivate the `dynamic-tunnels` configuration at the `[edit routing-options]` hierarchy level.

2. Create tunnel-attributes profile and add policy for localizing the dynamic tunnels, similar to new next-hop-based dynamic tunnels.

3. Activate the `dynamic-tunnels` configuration.

Troubleshooting Localized Next-Hop-Based Dynamic Tunnels

With localization of next-hop-based dynamic tunnels, the tunnel composite next hops are associated with anchor Packet Forwarding Engine IDs. The following traceroute configuration statements at the `[edit routing-options]` hierarchy level help in troubleshooting the localized dynamic tunnels:

- `dynamic-tunnels traceoptions flag all`—Tracking creation and deletion of tunnel in DTM.
- `resolution traceoptions flag tunnel`—Tracking resolver operations on BGP route.
- `forwarding-table traceoptions flag all`—Tracking tunnels sent to the kernel.
- `traceoptions flag all`—Tracking of route learning process.

The following commands can be used to check if a route is using a localized next-hop-based dynamic tunnel:

1. **show route *prefix* extensive**—To obtain the indirect next hop.

   For example:

```
user@host> show route 1.2.3.4 extensive
MPLS-over-UDP-PE1.inet.0: 24 destinations, 26 routes (24 active, 0 holddown, 0 hidden)
1.2.3.4/32 (1 entry, 1 announced)
TSI:
KRT in-kernel 1.2.3.4/32 -> {indirect(1048577)}
Page 0 idx 1, (group pe1-ce1 type External) Type 1 val 0xb209a78 (adv_entry)
   Advertised metrics:
     Nexthop: Self
     AS path: [100] I
     Communities: target:600:1 encapsulation:mpls-in-udp(0xd)
```

2. **show krt indirect-next-hop index *indirect-next-hop* detail**—To check for anchor Packet Forwarding Engine field in the detailed output of the indirect next hop.

   For example:

```
user@host> show krt indirect-next-hop index 1048577 detail
Indirect Nexthop detail:
Index: 1048577 Protocol next-hop address: 1.1.1.6
  RIB Table: bgp.l3vpn.0               Label: Push 299808
  Policy Version: 2                    References: 11
  Locks: 3                             0xb227980
  Flags: 0x0
  INH Session ID: 0x0
  Ref RIB Table: unknown
  Export policy detail:
     (Dynamic tunnel hash : 309985522)
        Tunnel type: UDP, Reference count: 4, nhid: 1016
        Destination address: 1.1.1.6, Source address: 1.1.1.2
        Anchored-PFE: pfe-1/0/0
        VPN Label: Push 299808, TTL action: prop-ttl
      IGP FRR Interesting proto count : 11
      Chain IGP FRR Node Num          : 1
         IGP Resolver node(hex)       : 0xc838b94
```

```
          IGP Route handle(hex)        : 0xb1d7674      IGP rt_entry protocol        : Tunnel
          IGP Actual Route handle(hex) : 0x0            IGP Actual rt_entry protocol : Any
```

Unsupported Features for Next-Hop-Based Dynamic Tunnels Localization

Junos OS does not support the following functionality with localization for next-hop-based dynamic tunnels:

- Chained composite next hops at the `[edit routing-options forwarding-table chained-composite-next-hop ingress l3vpn]` hierarchy level.
- Anchor Packet Forwarding Engine resiliency.

  There is no resiliency support for next-hop-based dynamic tunnels with localization. After localization of the next-hop-based dynamic tunnels, the anchor Packer Forwarding Engine becomes the single entity for processing any given tunnel on the device. Although anchor Packer Forwarding Engine resiliency is not supported, for gateway devices, redundancy at the gateway device ensures that when the Packer Forwarding Engine to which the tunnel composite next hop is delegated goes down, the traffic must be rerouted to the redundant gateway device. The routing protocol process monitors the state of the Packer Forwarding Engine, and withdraws BGP advertisement of all the routes pointing to the tunnel composite next hops anchored on that Packer Forwarding Engine.

  Only the anchored Packet Forwarding Engine has the full-fledged tunnel composite next hop and all the other Packet Forwarding Engines have only steering entries to forward traffic to the anchor Packet Forwarding Engine. These steering entries are not withdrawn, when an anchor FPC goes down.
- Localization of next-hop-based dynamic tunnels is not supported on logical systems.
- IPv6 is not supported with localization of next-hop-based dynamic tunnels.
- With localization, the `show dynamic-tunnels database summary` command does not display accurate tunnels summary when the state of the anchor Packet Forwarding Engine line card is not up. As a workaround, use the `show dynamic-tunnels database` and `show dynamic-tunnels database terse` command output.

Overview of Next-Hop-Based Dynamic Tunneling Using IP-Over-IP Encapsulation

SUMMARY

IN THIS SECTION

Benefits | 154

What is IP-over-IP Dynamic Next Hop-based Tunneling? | 154

IP-over-IP Tunnel Stitching | 155

Benefits

IP-over-IP tunneling provides the following benefits:

- **Alternative to MPLS over UDP**—Can be used as an alternative to MPLS-over-UDP tunneling to provide IP service wherein there is a dedicated device per service.
- **Ability to steer specific traffic**—Enables smooth migration when MPLS and IP networks co-exist because routes can be filtered to steer specific traffic over IP tunnels as opposed to MPLS tunnels.
- **Ability to support tunnels at increasing scale**—Dynamic tunnel creation using BGP control plane can facilitate tunnel creation at scale.

What is IP-over-IP Dynamic Next Hop-based Tunneling?

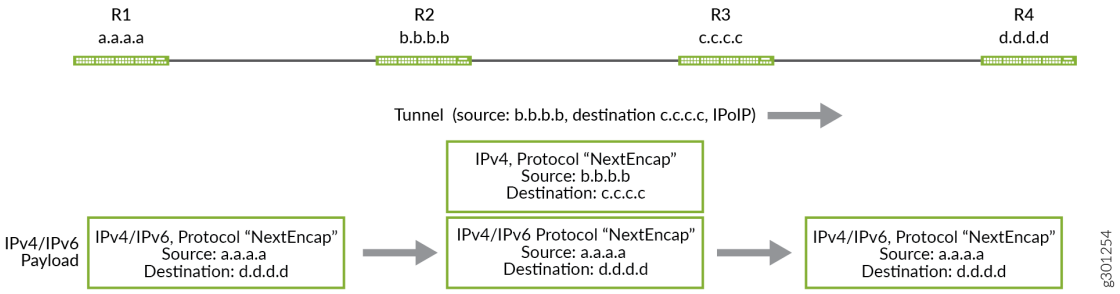
An IP network contains edge devices and core devices. To achieve higher scale and reliability among these devices, you need to logically isolate the core network from the external network that the edge devices interact with, by using an overlay encapsulation.

Starting in Junos OS Release 20.3R1, we support an IP-over-IP encapsulation to facilitate IP overlay construction over IP transport network. IP over IP relies on a next hop-based infrastructure to support a higher scale. The feature supports IPv4 encapsulation of IPv6 and IPv4 payload. Among the other overlay encapsulations supported, IP-over-IP encapsulation is the only kind that allows:

- transit devices to parse the inner payload and use inner packet fields for hash computation
- customer edge devices to route traffic into and out of the tunnel without any throughput reduction

On MX Series routers, routing protocol daemon (RPD) sends the encapsulation header with tunnel composite nexthop and the Packet Forwarding Engine (PFE) finds the tunnel destination address and forwards the packet. On PTX Series routers and QFX10000 switches, RPD sends fully resolved next hop-based tunnel to the Packet Forwarding Engine. BGP protocol is used to distribute routes and signal dynamic tunnels.

The following illustration depicts how IPv4 or IPv6 traffic are sent from R-1 to R-5 through an IP over IP tunnel established between R-2 and R-4:



IP-over-IP Tunnel Stitching

In Junos OS Release 21.3R1, we introduce IP-over-IP tunnel stitching on MX240, MX480, MX960, PTX1000, PTX10008, PTX10016, and QFX10002. You can use this feature to terminate an IP-over-IP tunnel on a device and initiate another tunnel on the same device. When a device receives the IP-over-IP packet, it de-encapsulates the outer packet header and inner packet lookup occurs. The inner IP packet header then points to another tunnel on the same device, where the same device encapsulates the packet again with another IP-over-IP header.

Example: Configuring Next-Hop-Based IP-Over-IP Dynamic Tunnels

SUMMARY

Learn how to configure next hop-based tunnels by using IP-over-IP encapsulation.

Requirements

This example uses the following hardware and software components:

- 4 MX Series routers and 1 PTX Series router.
- Junos OS Release 20.3R1 or later version.

Overview

IN THIS SECTION

Topology | 156

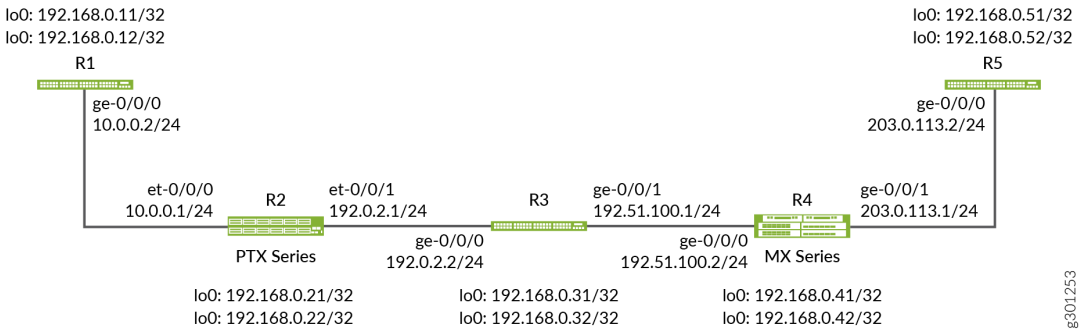
Starting in Junos OS Release 20.3R1, we support an IP-over-IP encapsulation to facilitate IP overlay construction over IP transport network. This example shows the establishment of unicast IP-over-IP tunnels between devices with a protocol next hop (PNH) through static configuration and a BGP protocol configuration.

To explain the difference in behavior between MX and PTX1000/PTX10000/QFX10000 devices, we have included a PTX Series router (R2) for this example. An IBGP is also configured between R2 and R4, which are connected over IP core, to exchange routes and signal dynamic tunnels.

Topology

Figure 1 illustrates an IP-over-IP scenario with 5 devices. In this topology, R1 is connected to R2 and R5 is connected to R4. R2 is a PTX Series device. R2 and R4 are connected to an R3 device in the center.

In this example, we are attempting to exchange routes from R1 to R5 and vice versa through IP-over-IP dynamic tunnels established between the R2 and R4 devices. Routes generated from R1 are exported to R2 and routes from R5 are exported to R4, by using an IS-IS export policy. You can configure a unicast IPIP tunnel *Tunnel-01* from R2 to R4 and another tunnel *Tunnel-02* from R4 to R2. Route prefixes that are generated within the network masks from the configured destination-networks of the peer device are used for creating the tunnel and traffic flows in the opposite direction of the routes in the tunnel..



Configuring IP-over-IP Dynamic Tunnels with a Protocol Next Hop

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the `[edit]` hierarchy level, and then enter commit from configuration mode.

```

Configuring IP-IP dynamic tunnels with a Protocol Next Hop

Step-by-Step Procedure

1. Enter configuration mode on R1 and R5 devices.
2. Configure basic device requirements such as VLAN, family iso, device interfaces, and loopback addresses. Routes are generated on the loopback addresses.

R1

```
[edit]
user@R1# set interfaces ge-0/0/0 vlan-tagging
user@R1# set interfaces ge-0/0/0 unit 0 description "Connection Between R-01 and R-02"
user@R1# set interfaces ge-0/0/0 unit 0 vlan-id 1
user@R1# set interfaces ge-0/0/0 unit 0 family inet address 10.0.0.2/24
user@R1# set interfaces ge-0/0/0 unit 0 family iso
user@R1# set interfaces lo0 unit 0 description "Router ID for R_01"
```

```
user@R1# set interfaces lo0 unit 0 family inet address 192.168.0.11/32
user@R1# set interfaces lo0 unit 0 family inet address 192.168.0.12/32
user@R1# set interfaces lo0 unit 0 family iso address 49.0001.1720.1600.1010.00
```

R5

```
[edit]
user@R5# set interfaces ge-0/0/0 vlan-tagging
user@R5# set interfaces ge-0/0/0 unit 0 description "Connection Between R_05 and R_05"
user@R5# set interfaces ge-0/0/0 unit 0 vlan-id 1
user@R5# set interfaces ge-0/0/0 unit 0 family inet address 203.0.113.2/24
user@R5# set interfaces ge-0/0/0 unit 0 family iso
user@R5# set interfaces lo0 unit 0 description "Router ID for R_05"
user@R5# set interfaces lo0 unit 0 family inet address 192.168.0.51/32
user@R5# set interfaces lo0 unit 0 family inet address 192.168.0.52/32
user@R5# set interfaces lo0 unit 0 family iso address 49.0001.1720.1600.1011.00
```

3. Configure router-ID and autonomous system (AS) number to assign IP addresses to the routers and to enable BGP.

R1

```
user@R1# set routing-options router-id 192.168.0.11
user@R1# set routing-options autonomous-system 64496
```

R5

```
user@R5# set routing-options router-id 192.168.0.51
user@R5# set routing-options autonomous-system 64496
```

4. Configure IS-IS protocols to enable IGP. Routes are exported from R1 to R2 and R5 to R4 devices by using IS-IS protocol.

R1

```
user@R1# set protocols isis interface ge-0/0/0.0
user@R1# set protocols isis interface lo0.0
```

R5

```
user@R5# set protocols isis interface ge-0/0/0.0
user@R5# set protocols isis interface lo0.0
```

5. Enter `commit` on R1 and R5 devices from the configuration mode.

6. Enter configuration mode on R2 and R4 to configure them.

7. Configure basic device requirements such as VLAN, family iso, MPLS, router interfaces, and loopback addresses on R2 and R4.

R2

```

user@R2# set interfaces lo0 unit 0 family inet address 192.168.0.21/32
user@R2# set interfaces lo0 unit 0 family inet address 192.168.0.22/32
user@R2# set interfaces lo0 unit 0 family iso address 49.0001.1720.1600.1030.00
```

R4

```
[edit]
user@R4# set interfaces ge-0/0/0 vlan-tagging
user@R4# set interfaces ge-0/0/0 unit 0 description "Connection Between R_04 and R_05"
user@R4# set interfaces ge-0/0/0 unit 0 vlan-id 1
```

```
user@R4# set interfaces ge-0/0/0 unit 0 family inet address 203.0.113.1/24
user@R4# set interfaces ge-0/0/0 unit 0 family iso
user@R4# set interfaces ge-0/0/1 unit 0 description "Connection Between R_04 and R_03"
user@R4# set interfaces ge-0/0/1 unit 0 family inet address 192.51.100.2/24
user@R4# set interfaces ge-0/0/1 unit 0 family mpls
user@R4# set interfaces lo0 unit 0 description "Router-ID for R_04"
user@R4# set interfaces lo0 unit 0 family inet address 192.168.0.41/32
user@R4# set interfaces lo0 unit 0 family inet address 192.168.0.42/32
user@R4# set interfaces lo0 unit 0 family iso address 49.0001.1720.1600.1041.00
```

8. Configure an IBGP between R2 and R4.

R2

```
user@R2# set protocols bgp group iBGP type internal
user@R2# set protocols bgp group iBGP local-address 192.168.0.21
user@R2# set protocols bgp group iBGP family inet unicast
user@R2# set protocols bgp group iBGP export export-isis
user@R2# set protocols bgp group iBGP neighbor 192.168.0.41
```

R4

```
user@R4# set protocols bgp group iBGP type internal
user@R4# set protocols bgp group iBGP local-address 192.168.0.41
user@R4# set protocols bgp group iBGP family inet unicast
user@R4# set protocols bgp group iBGP export export-isis
user@R4# set protocols bgp group iBGP neighbor 192.168.0.21
```

9. Configure an IS-IS export policy on R2 and R4 with BGP export to export routes from R1 to R2 and R5 to R4.

R2

```
[edit]
user@R2# set protocols isis export export-bgp
user@R2# set protocols isis interface et-0/0/0:0.0
user@R2# set protocols isis interface lo0.0
```

R4

```
[edit]
user@R4# set protocols isis export export-bgp
```

```
user@R4# set protocols isis interface ge-0/0/0.0
user@R4# set protocols isis interface lo0.0
```

10. Configure OSPF protocol between R2 and R4 for reachability.

R2

```
[edit]
user@R2# set protocols ospf area 0.0.0.0 interface et-0/0/1:0.0
user@R2# set protocols ospf area 0.0.0.0 interface 192.168.0.21
```

R4

```
[edit]
user@R4# set protocols ospf area 0.0.0.0 interface ge-0/0/1.0
user@R4# set protocols ospf area 0.0.0.0 interface 192.168.0.41
```

11. Configure a unicast IP-IP dynamic tunnel *Tunnel-01* from R2 to R4 and *Tunnel-02* from R4 to R2.

R2

```
[edit]
user@R2# set routing-options forwarding-table export plb
user@R2# set routing-options resolution rib inet.0 resolution-ribs inet.3
user@R2# set routing-options dynamic-tunnels Tunnel-01 source-address 192.168.0.21
user@R2# set routing-options dynamic-tunnels Tunnel-01 ipip
user@R2# set routing-options dynamic-tunnels Tunnel-01 destination-networks 192.168.0.0/24 preference
100
```

R4

```
[edit]
user@R4# set routing-options forwarding-table export pplb
user@R4# set routing-options resolution rib inet.0 resolution-ribs inet.3
user@R4# set routing-options dynamic-tunnels Tunnel-02 source-address 192.168.0.41
user@R4# set routing-options dynamic-tunnels Tunnel-02 ipip
user@R4# set routing-options dynamic-tunnels Tunnel-02 destination-networks 192.168.0.0/24 preference
100
```

12. Configure BGP and IS-IS export policy terms on R2 and policy statement to forward routes from BGP and RIB inet.0 to a fully resolved next hop (on R2-PTX device).

R2

```
[edit]
user@R2# set policy-options policy-statement export-bgp term t1 from protocol bgp
user@R2# set policy-options policy-statement export-bgp term t1 then accept
user@R2# set policy-options policy-statement export-isis term t1 from protocol isis
user@R2# set policy-options policy-statement export-isis term t1 then next-hop self
user@R2# set policy-options policy-statement export-isis term t1 then accept
user@R2# set policy-options policy-statement plb term t1 from protocol bgp
user@R2# set policy-options policy-statement plb term t1 from rib inet.0
user@R2# set policy-options policy-statement plb term t1 then install-to-fib
```

R4

```
user@R4# set policy-options policy-statement export-bgp term t1 from protocol bgp
user@R4# set policy-options policy-statement export-bgp term t1 then accept
user@R4# set policy-options policy-statement export-isis term t1 from protocol isis
user@R4# set policy-options policy-statement export-isis term t1 then next-hop self
user@R4# set policy-options policy-statement export-isis term t1 then accept
user@R4# set policy-options policy-statement pplb term 1 then load-balance per-packet
user@R4# set policy-options policy-statement pplb term 1 then accept
```

13. Enter `commit` from the configuration mode on R2 and R4 devices.

14. Configure VLAN device interfaces, loopback addresses, family mpls, router-ID, and autonomous system (AS) numbers.

R3

```
[edit]
user@R3# set interfaces ge-0/0/0 unit 0 description "Connection Between R_03 and R_02"
user@R3# set interfaces ge-0/0/0 unit 0 family inet address 192.0.2.2/24
user@R3# set interfaces ge-0/0/0 unit 0 family mpls
user@R3# set interfaces ge-0/0/1 unit 0 description "Connection Between R_03 and R_04"
user@R3# set interfaces ge-0/0/1 unit 0 family inet address 192.51.100.1/24
user@R3# set interfaces ge-0/0/1 unit 0 family mpls
user@R3# set interfaces lo0 unit 0 description "Router ID for R_03"
user@R3# set interfaces lo0 unit 0 family inet address 192.168.0.31/32
user@R3# set interfaces lo0 unit 0 family inet address 192.168.0.32/32
```

```
user@R3# set routing-options router-id 192.168.0.31
user@R3# set routing-options autonomous-system 64496
```

15. Configure OSPF protocols on R3 to R2 and R4 devices for reachability.

```
R3
[edit]
user@R3# set protocols ospf area 0.0.0.0 interface ge-0/0/0.0
user@R3# set protocols ospf area 0.0.0.0 interface ge-0/0/1.0
user@R3# set protocols ospf area 0.0.0.0 interface lo0.0 passive
```

16. Enter `commit` from configuration mode on R3 device.

Results

Verify your configuration by checking the below configurations from devices as follows:

Here's how you can verify configurations on R2 device:

`user@R2# show interfaces`

```
interfaces {
    et-0/0/0:0 {
        description "Connection Between R-01 and R-02";
        vlan-tagging;
            unit 0 {
                vlan-id 1;
                    family inet {
                        address 10.0.0.1/24;
                    }
                family iso;
                family mpls;
                }
            }
    }
    et-0/0/1:0 {
        description "Connection Between R-02 and R-03 Link 01";
            unit 0 {
                 family inet {
                     address 192.0.2.1/24;
                }
```

```
                family mpls;
            }
    }
    lo0 {
        unit 0 {
            description "Router ID for R_02";
            family inet {
                address 192.168.0.21/32;
                address 192.168.0.22/32;
            }
            family iso {
                address 49.0001.1720.1600.1030.00;
            }
        }
    }
```

user@R2# show routing-options

```
routing-options {
    router-id 192.168.0.21;
    autonomous-system 64496;
        forwarding-table {
            export plb;
        }
        resolution {
            rib inet.0 {
                resolution-ribs inet.3;
            }
        }
        dynamic-tunnels {
            Tunnel-01 {
                source-address 192.168.0.21;
                ipip;
                destination-networks {
                    192.168.0.0/24 preference 100;
                }
            }
        }
{
```

user@R2# show protocols

```
protocols {
    bgp {
        group iBGP {
            type internal;
                local-address 192.168.0.21;
                family inet {
                    unicast;
                }
                export export-isis;
            neighbor 192.168.0.41;
        }
        isis {
            export export-bgp;
            interface et-0/0/0:0.0;
            interface lo0.0;
        }
        ospf {
            area 0.0.0.0 {
                interface et-0/0/1:0.0;
                interface 192.168.0.21;
        }
    }
}
```

user@R2# show policy-options

```
policy-options {
    policy-statement export-bgp {
        term t1 {
            from protocol bgp;
            then accept;
        }
    }
    policy-statement export-isis {
        term t1 {
            from protocol isis;
                then {
                    next-hop self;
                    accept;
```

```
                }
            }
        }
        policy-statement plb {
            term t1 {
                from {
                    protocol bgp;
                    rib inet.0;
                }
                then install-to-fib;
            }
            term t3 {
                then {
                    load-balance per-packet;
                }
            }
        }
}
```

Verification

IN THIS SECTION

- Verify Dynamic Tunnel Database | **169**
- Verify Route Table in inet.3 | **171**
- Verify BGP Routes Received and Advertised through Tunnel | **172**

Verify Dynamic Tunnel Database

Purpose

To verify the dynamic tunnel database information, use the `show dynamic-tunnels database` operational mode command.

Action

```
user@R2> show dynamic-tunnels database
*- Signal Tunnels #- PFE-down
Table: inet.3
```

```
Destination-network: 192.168.0.0/24

Tunnel to: 192.168.0.41/32
  Reference count: 3
  Next-hop type: IPoIP (extended-attr)
    Source address: 192.168.0.21
    Next hop: chain tunnel-composite, 0xcb42910, nhid 573
      Reference count: 4
      Ingress Route: [OSPF] 192.168.0.41/32, via metric 2
      Traffic Statistics: Packets 0, Bytes 0
      State: Up
  Aggregate Traffic Statistics:
    Tunnel Encapsulation: Dest 192.168.0.41, Src 192.168.0.21, IPoIP, Tunnel-Id 1
    Traffic Statistics: Packets 0, Bytes 0
```

```
user@R4> show dynamic-tunnels database
*- Signal Tunnels #- PFE-down
Table: inet.3

Destination-network: 192.168.0.0/24

Tunnel to: 192.168.0.21/32
  Reference count: 3
  Next-hop type: IPoIP (extended-attr)
    Source address: 192.168.0.41
    Next hop: tunnel-composite, 0xccd7670, nhid 593
      Reference count: 4
      Ingress Route: [OSPF] 192.168.0.21/32, via metric 2
      Traffic Statistics: Packets 0, Bytes 0
      State: Up
  Aggregate Traffic Statistics:
    Tunnel Encapsulation: Dest 192.168.0.21, Src 192.168.0.41, IPoIP, Tunnel-Id 1
    Traffic Statistics: Packets 0, Bytes 0
```

Meaning

The output indicates that an IPoIP tunnel is established with a tunnel encapsulation between R2 (`192.168.0.21` source) and R4 (`192.168.0.41` destination) on R2 device and another IPoIP tunnel is

established a tunnel encapsulation between R4 (192.168.0.41 source) and R2 (192.168.0.21 destination) on R4 device.

Verify Route Table in inet.3

Purpose

To verify routes generated on inet.3 table, use the show route table inet.3 operational mode command.

Action

```
user@R2> show route table inet.3
inet.3: 11 destinations, 11 routes (11 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.0.0.0/24         *[Direct/0] 01:11:55
                     > via et-0/0/0:0.0
10.0.0.1/32         *[Local/0] 01:11:55
                       Local via et-0/0/0:0.0
10.205.128.0/18     *[Direct/0] 01:12:48
                     > via em0.0
10.205.171.44/32    *[Local/0] 01:12:48
                       Local via em0.0
128.205.171.44/32   *[Direct/0] 01:12:48
                     > via lo0.0
192.0.2.0/24        *[Direct/0] 01:11:55
                     > via et-0/0/1:0.0
192.0.2.1/32        *[Local/0] 01:11:55
                       Local via et-0/0/1:0.0
192.168.0.0/24      *[Tunnel/305] 01:11:55
                       Tunnel
192.168.0.21/32     *[Direct/0] 01:11:54
                     > via lo0.0
192.168.0.22/32     *[Direct/0] 01:11:54
                     > via lo0.0
192.168.0.41/32     *[Tunnel/305] 01:06:28, metric 2
                       Tunnel Composite, IPoIP (src 192.168.0.21 dest 192.168.0.41)
```

```
user@R4> show route table inet.3
inet.3: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)
```

```
+ = Active Route, - = Last Active, * = Both

192.168.0.0/24     *[Tunnel/100] 4d 20:06:00
                       Tunnel
192.168.0.21/32    *[Tunnel/100] 4d 19:59:58, metric 2
                       Tunnel Composite, IPoIP (src 192.168.0.41 dest 192.168.0.21)
```

Meaning

The output indicates that R2 has received route `192.168.0.41/32` from R4 through the IPIP tunnel.

Verify BGP Routes Received and Advertised through Tunnel

Purpose

To verify BGP route prefixes received and advertised on R2 with BGP peer `192.168.0.41`, use the `show route receive-protocol bgp` *peer* and `show route advertising-protocol bgp` *peer* operational mode commands.

Action

```
user@R2> show route receive-protocol bgp 192.168.0.41
inet.0: 52 destinations, 52 routes (52 active, 0 holddown, 0 hidden)
  Prefix                  Nexthop              MED     Lclpref    AS path
* 128.205.171.125/32      192.168.0.41         10      100        I
* 192.168.0.51/32         192.168.0.41         10      100        I
* 192.168.0.52/32         192.168.0.41         10      100        I

inet.2: 9 destinations, 9 routes (9 active, 0 holddown, 0 hidden)

inet.3: 11 destinations, 11 routes (11 active, 0 holddown, 0 hidden)

iso.0: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)
```

```
user@R2> show route advertising-protocol bgp 192.168.0.41
inet.0: 52 destinations, 52 routes (52 active, 0 holddown, 0 hidden)
  Prefix                  Nexthop              MED     Lclpref    AS path
* 128.205.171.66/32       Self                 10      100        I
```

```
* 192.168.0.11/32         Self                10      100        I
* 192.168.0.12/32         Self                10      100        I
```

```
user@R4> show route advertising-protocol bgp 192.168.0.21
inet.0: 53 destinations, 53 routes (53 active, 0 holddown, 0 hidden)
  Prefix                  Nexthop              MED     Lclpref    AS path
* 128.205.171.125/32      Self                10      100        I
* 192.168.0.51/32         Self                10      100        I
* 192.168.0.52/32         Self                10      100        I
```

```
user@R4> show route receive-protocol bgp 192.168.0.21
inet.0: 18 destinations, 18 routes (18 active, 0 holddown, 0 hidden)
  Prefix                  Nexthop              MED     Lclpref    AS path
* 192.168.0.11/32         192.168.0.21         10      100        I

inet.3: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)

iso.0: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)

inet6.0: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
```

Meaning

The output indicates that R2 is receiving routes from R5 by using BGP, and R2 is advertising or sending routes from R1.

Example: Configure an IPoIP Tunnel in an MPLS Environment with LDP tunnel, Resolved Through inetcolor.0 Using Static Configuration

IN THIS SECTION

- Verification | **181**

By default, MPLS has a higher preference than IP. For example, with MPLS and LDP configured among R2, R3, and R4, wherein R2 is reachable with R4 through LDP, routes from R2 will get resolved over LDP, instead of IP-over-IP, because of the higher preference.

If you prefer to have a particular route to resolve over the IP-over-IP instead of LDP, you can do so by creating an inetcolor table, where IP-over-IP has a higher preference and setting BGP to resolve that route over inetcolor table instead of inet3 table. The following example shows you how to do so by using static configuration.

CLI Quick Configuration

R2

```
[edit]
user@R2# set protocols mpls interface et-0/0/1:0.0
user@R2# set protocols ldp interface et-0/0/1:0.0
user@R2# set protocols bgp group iBGP import ipip-tunnel-color
user@R2# set protocols bgp group iBGP family inet unicast extended-nexthop-color
user@R2# set routing-options dynamic-tunnels Tunnel-01 destination-networks 192.168.0.0/24 preference 100

192.168.0.21
user@R4# set policy-options policy-statement set-dynamic-tunnel-ep term t1 then accept
```

Procedure

Step-by-Step Procedure

1. Configure MPLS and LDP protocols between R2 and R3 and R3 and R4.

R2

```
user@R2# set protocols mpls interface et-0/0/1:0.0
user@R2# set protocols ldp interface et-0/0/1:0.0
```

R3

```
user@R3# set protocols mpls interface ge-0/0/1.0
user@R3# set protocols mpls interface ge-0/0/1.0
```

```
user@R3# set protocols ldp interface ge-0/0/1.0
user@R3# set protocols ldp interface ge-0/0/1.0
```

R4

```
user@R4# set protocols mpls interface ge-0/0/1.0
user@R4# set protocols ldp interface ge-0/0/1.0
```

2. Configure BGP protocols to enable BGP to import IPIP tunnel color and extended next-hop.

R2

```
user@R2# set protocols bgp group iBGP import ipip-tunnel-color
user@R2# set protocols bgp group iBGP family inet unicast extended-nexthop-color
```

R4

```
user@R4# set protocols bgp group iBGP import ipip-tunnel-color
user@R4# set protocols bgp group iBGP family inet unicast extended-nexthop-color
```

3. Configure routing-options to enable these destination networks to add the color attribute *100*, to create dynamic-tunnels using this attribute.

R2

```
user@R2# set routing-options dynamic-tunnels Tunnel-01 destination-networks 192.168.0.0/24 colors 100
```

R4

```
user@R4# set routing-options dynamic-tunnels Tunnel-02 destination-networks 192.168.0.0/24 colors 100
```

4. Configure preference to assign a preference value.

R2

```
user@R2# set routing-options dynamic-tunnels Tunnel-01 destination-networks 192.168.0.0/24 preference
100
```

R4

```
user@R4# set routing-options dynamic-tunnels Tunnel-02 destination-networks 192.168.0.0/24 preference
100
```

5. Configure policy-options to assign color red and IPIP to the chosen route filter. It is through policy-options that you can set router filters to select the routes you wish to resolve over IP-over-IP, add color and ipip to it.

R2

```
user@R2# set policy-options policy-statement ipip-tunnel-color term term-01 from route-filter
192.168.0.51/32 exact
user@R2# set policy-options policy-statement ipip-tunnel-color term term-01 then community add red
user@R2# set policy-options policy-statement ipip-tunnel-color term term-01 then community add ipip
user@R2# set policy-options policy-statement ipip-tunnel-color term term-01 then accept
```

R4

```
user@R4# set policy-options policy-statement ipip-tunnel-color term term-01 from route-filter
192.168.0.11/32 exact
user@R4# set policy-options policy-statement ipip-tunnel-color term term-01 then community add red
user@R4# set policy-options policy-statement ipip-tunnel-color term term-01 then community add ipip
user@R4# set policy-options policy-statement ipip-tunnel-color term term-01 then accept
```

6. Configure policy-options of community to assign encapsulation to the `ipip community` and add attributes to the `community red`.

```
R2
user@R2# set policy-options community ipip members encapsulation:0L:7
user@R2# set policy-options community red members color:0:100
```

```
R4
user@R4# set policy-options community ipip members encapsulation:0L:7
user@R4# set policy-options community red members color:0:100
```

7. Configure routing-options and policy-options to set a dynamic tunnel from R2 to R4 and R4 to R2, with the tunnel end points `192.168.0.41` and `192.168.0.21`.

```
R2
user@R2# set routing-options dynamic-tunnels Tunnel-01 destination-networks 192.168.0.0/24 dyn-tunnel-attribute-policy set-dynamic-tunnel-ep
user@R2# set policy-options policy-statement set-dynamic-tunnel-ep term t1 from route-filter 192.168.0.41/32 exact
user@R2# set policy-options policy-statement set-dynamic-tunnel-ep term t1 then tunnel-end-point-address 192.168.0.41
user@R2# set policy-options policy-statement set-dynamic-tunnel-ep term t1 then accept
```

```
R4
user@R4# set routing-options dynamic-tunnels Tunnel-02 destination-networks 192.168.0.0/24 dyn-tunnel-attribute-policy set-dynamic-tunnel-ep
user@R4# set policy-options policy-statement set-dynamic-tunnel-ep term t1 from route-filter 192.168.0.21/32 exact
user@R4# set policy-options policy-statement set-dynamic-tunnel-ep term t1 then tunnel-end-point-address 192.168.0.21
user@R4# set policy-options policy-statement set-dynamic-tunnel-ep term t1 then accept
```

8. Enter `commit` on R2, R3, and R4 from the configuration mode.

Results

Verify configurations set for scenario 2 from the configuration mode. Here's how you can check the configurations on R2:

user@R2# show protocols

```
mpls {
    interface et-0/0/1:0.0;
{
bgp {
    group iBGP {
        type internal;
            local-address 192.168.0.21;
            import ipip-tunnel-color;
        {
        family inet {
            unicast {
                extended-nexthop-color;
            }
        {
        export export-isis;
        neighbor 192.168.0.41;
    {

        tunnel-end-point-address 192.168.0.41;
        accept;
    {
{
```

user@R2# show policy-options community ipip

```
members encapsulation:0L:7;
```

user@R2# show policy-options community red

```
members color:0:100;
```

Verification

IN THIS SECTION

- Verify Route Resolution | **181**
- Verify Dynamic Tunnel Database | **183**
- Verify Route Next-Hops | **184**

Verify Route Resolution

Purpose

To verify the route resolution of routes in both inet.3 and inetcolor.0 tables, use the `show route table inet.3` and `show route table inetcolor.0` operational mode commands.

Action

```
user@R2> show route table inet.3
inet.3: 12 destinations, 13 routes (12 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.0.0.0/24        *[Direct/0] 5d 10:41:36
                    > via et-0/0/0:0.0
10.0.0.1/32        *[Local/0] 5d 10:41:36
                      Local via et-0/0/0:0.0
10.205.128.0/18    *[Direct/0] 5d 10:42:30
                    > via em0.0
10.205.176.131/32  *[Local/0] 5d 10:42:30
                      Local via em0.0
128.205.176.131/32 *[Direct/0] 5d 10:42:30
                    > via lo0.0
192.0.2.0/24       *[Direct/0] 5d 10:41:36
                    > via et-0/0/1:0.0
192.0.2.1/32       *[Local/0] 5d 10:41:36
                      Local via et-0/0/1:0.0
192.168.0.0/24     *[Tunnel/305] 14:12:14
                      Tunnel
192.168.0.21/32    *[Direct/0] 5d 10:41:36
                    > via lo0.0
```

```
192.168.0.22/32    *[Direct/0] 5d 10:41:36
                    > via lo0.0
192.168.0.31/32    *[LDP/9] 5d 10:36:12, metric 1
                    > to 192.0.2.2 via et-0/0/1:0.0
192.168.0.41/32    *[LDP/9] 5d 10:36:12, metric 1
                    > to 192.0.2.2 via et-0/0/1:0.0, Push 299792
                    [Tunnel/305] 14:12:14, metric 2
                      Tunnel Composite, IPoIP (src 192.168.0.21 dest 192.168.0.41)
```

```
user@R2> show route table inetcolor.0
inetcolor.0: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192.168.0.0-0<c>/24
                   *[Tunnel/305] 14:21:02
                      Tunnel
192.168.0.41-100<c>/64
                   *[Tunnel/305] 14:21:02, metric 2
                      Tunnel Composite, IPoIP (src 192.168.0.21 dest 192.168.0.41-100<c>)
```

```
user@R4> show route table inet.3
inet.3: 3 destinations, 4 routes (3 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192.168.0.0/24     *[Tunnel/305] 14:08:27
                      Tunnel
192.168.0.21/32    *[LDP/9] 5d 10:37:41, metric 1
                    > to 192.51.100.1 via ge-0/0/1.0, Push 299776
                    [Tunnel/305] 14:08:27, metric 2
                      Tunnel Composite, IPoIP (src 192.168.0.41 dest 192.168.0.21)
192.168.0.31/32    *[LDP/9] 5d 10:37:41, metric 1
                    > to 192.51.100.1 via ge-0/0/1.0
```

```
user@R4> show route table inetcolor.0
inetcolor.0: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192.168.0.0-0<c>/24
                   *[Tunnel/305] 14:13:43
```

```
                    Tunnel
192.168.0.21-100<c>/64
                  *[Tunnel/305] 14:13:43, metric 2
                    Tunnel Composite, IPoIP (src 192.168.0.41 dest 192.168.0.21-100<c>)
```

Meaning

The R2 output indicates that on inet.3 table, the route `192.168.0.41` is getting resolved by LDP because of higher preference than IP-over-IP. On the other hand, in the newly created inetcolor.0 table, the route `192.168.0.41` is getting resolved through IP-over-IP tunnel with <c> attached.

The R4 output indicates that on inet.3 table, the route `192.168.0.21` is getting resolved by LDP because of higher preference, but on inetcolor.0 table, the route `192.168.0.21` is getting resolved through IP-over-IP tunnel with <c> attached.

Verify Dynamic Tunnel Database

Purpose

To verify the IP-over-IP dynamic tunnel created by routes in the inetcolor.0 table, use the `show dynamic-tunnels database terse` operational mode command.

Action

```
user@R2>show dynamic-tunnels database terse
*- Signal Tunnels #- PFE-down
Table: inet.3

Destination-network: 192.168.0.0/24

*- Signal Tunnels #- PFE-down
Table: inetcolor.0

Destination-network: 192.168.0.0-0<c>/24
Destination                     Source          Next-hop                Type       Status
192.168.0.41-100<c>/64          192.168.0.21    0xcb42820 nhid 579      IPoIP      Up (chain-
nexthop, via metric 2, tunnel-endpoint 192.168.0.41)
```

```
user@R4> show dynamic-tunnels database terse
*- Signal Tunnels #- PFE-down
```

```
Table: inet.3

Destination-network: 192.168.0.0/24

*- Signal Tunnels #- PFE-down
Table: inetcolor.0

Destination-network: 192.168.0.0-0<c>/24
Destination                    Source          Next-hop                Type       Status
192.168.0.21-100<c>/64         192.168.0.41    0xccd8b10 nhid 600      IPoIP      Up (via
metric 2, tunnel-endpoint 192.168.0.21)
```

Meaning

The R2 output indicates that the route `192.168.0.41` has created a next-hop-based dynamic tunnel.

The R4 output indicates that the route `192.168.0.21` has created a next-hop-based dynamic tunnel.

Verify Route Next-Hops

Purpose

To verify all next-hops of the route that is set to resolve through IP-over-IP, us e the `show route 192.168.0.51/32 extensive expanded-nh` operational mode command.

Action

```
user@R2>show route 192.168.0.51/32 extensive expanded-nh
inet.0: 53 destinations, 53 routes (53 active, 0 holddown, 0 hidden)
192.168.0.51/32 (1 entry, 1 announced)

address: 192.168.0.41
```

Meaning

The R2 output indicates the expanded next hop of `192.168.0.51/32` route. As R2 is a PTX Series router, it sends a protocol next hop and a composite next hop with a fully resolved tunnel.

The R4 output indicates the expanded next hop of `192.168.0.11/32` route. As R4 is an MX Series router, it sends a protocol next hop and an indirect next hop.

Example: Configure an IPoIP Tunnel with LDP tunnel in an MPLS Cloud, Resolved through inetcolor.0 Using BGP Signaling

IN THIS SECTION

- CLI Quick Configuration | **188**
- Procedure | **189**
- Results | **191**

In an MPLS environment with LDP enabled, BGP routes get resolved through LDP on inet.3 table because MPLS has higher preference than IP.

If you still prefer to have your routes resolved through IP-over-IP in the MPLS environment, you can do so by creating an inetcolor.0 table that assigns higher preference for IP-over-IP and resolve chosen routes through IP-over-IP. To enable this feature by using BGP, the route resolution is performed on the remote end device of the tunnel and with the export policy configured on the remote device, routes are received and advertised through BGP signaling. This example shows how to configure this by using the BGP protocol configuration.

NOTE: If you are following this example after configuring IP-over-IP tunnel with LDP using static configuration, retain the MPLS and LDP configurations on R2, R3, and R4 devices and delete the remaining static configurations statements.

If you are following this example after configuring IP-over-IP dynamic tunnels with a protocol next hop, then set the MPLS and LDP configurations on R2, R3, and R4 devices before configuring the following statements. Remember to apply the `export-tunnel-route` policy before applying the `export-isis` policy from the first example.

CLI Quick Configuration

R2

```
user@R2# set routing-options dynamic-tunnels Tunnel-01 source-address 192.168.0.21
user@R2# set routing-options dynamic-tunnels Tunnel-01 destination-networks 192.168.0.0/24 preference 100
user@R2# set routing-options dynamic-tunnels Tunnel-01 destination-networks 192.168.0.0/24 colors 100
user@R2# set routing-options dynamic-tunnels Tunnel-01 bgp-signal
user@R2# set routing-options resolution
user@R2# set policy-options policy-statement export-tunnel-route term t1 from route-filter 192.168.0.11/32
exact
user@R2# set policy-options policy-statement export-tunnel-route term t1 then tunnel-attribute set tunnle-
attr-02
user@R2# set policy-options policy-statement export-tunnel-route term t1 then next-hop self
user@R2# set policy-options policy-statement export-tunnel-route term t1 then accept
user@R2# set policy-options tunnel-attribute tunnle-attr-02 tunnel-type ipip
user@R2# set policy-options tunnel-attribute tunnle-attr-02 tunnel-color 100
user@R2# set policy-options tunnel-attribute tunnle-attr-02 remote-end-point 192.168.0.41
user@R2# set protocols bgp group iBGP export export-tunnel-route
user@R2# set protocols bgp group iBGP family inet unicast extended-nexthop-tunnel
```

R4

```
user@R4# set routing-options dynamic-tunnels Tunnel-02 bgp-signal
user@R4# set routing-options dynamic-tunnels Tunnel-02 source-address 192.168.0.41
user@R4# set routing-options dynamic-tunnels Tunnel-02 destination-networks 192.168.0.0/24 preference 100
user@R4# set routing-options dynamic-tunnels Tunnel-02 destination-networks 192.168.0.0/24 colors 100
user@R4# set policy-options policy-statement export-tunnel-route term t1 from route-filter 192.168.0.51/32
exact
user@R4# set policy-options policy-statement export-tunnel-route term t1 then tunnel-attribute set tunnle-
attr-01
user@R4# set policy-options policy-statement export-tunnel-route term t1 then next-hop self
user@R4# set policy-options policy-statement export-tunnel-route term t1 then accept
user@R4# set policy-options tunnel-attribute tunnle-attr-01 tunnel-type ipip
user@R4# set policy-options tunnel-attribute tunnle-attr-01 tunnel-color 100
user@R4# set policy-options tunnel-attribute tunnle-attr-01 remote-end-point 192.168.0.21
user@R4# set protocols bgp group iBGP family inet unicast extended-nexthop-tunnel
user@R4# set protocols bgp group iBGP export export-tunnel-route
```

Procedure

Step-by-Step Procedure

1. Enter configuration mode on R2 and R4 devices.
2. Configure BGP protocols on R2 and R4 to enable nexthop tunnel and export routes from the remote end device.

R2

```
user@R2# set protocols bgp group iBGP family inet unicast extended-nexthop-tunnel
user@R2# set protocols bgp group iBGP export export-tunnel-route
```

R4

```
user@R4# set protocols bgp group iBGP family inet unicast extended-nexthop-tunnel
user@R4# set protocols bgp group iBGP export export-tunnel-route
```

3. Configure routing options on R2 to create a tunnel from R2 to R4 and R4 to create a tunnel between R4 to R2, with color value and preference set to 100.

```
R2
user@R2# set routing-options dynamic-tunnels Tunnel-01 source-address 192.168.0.21
user@R2# set routing-options dynamic-tunnels Tunnel-01 destination-networks 192.168.0.0/24 preference
100
user@R2# set routing-options dynamic-tunnels Tunnel-01 destination-networks 192.168.0.0/24 colors 100
user@R2# set routing-options dynamic-tunnels Tunnel-01 bgp-signal
user@R2# set routing-options resolution
```

```
R4
user@R4# set routing-options dynamic-tunnels Tunnel-02 source-address 192.168.0.41
user@R4# set routing-options dynamic-tunnels Tunnel-02 destination-networks 192.168.0.0/24 preference
100
user@R4# set routing-options dynamic-tunnels Tunnel-02 destination-networks 192.168.0.0/24 colors 100
user@R4# set routing-options dynamic-tunnels Tunnel-02 bgp-signal
```

4. Configure policy statement to export routes on R2 and R4 with an export filter and add tunnel attributes.

```
R2
user@R2# set policy-options policy-statement export-tunnel-route term t1 from route-filter
192.168.0.11/32 exact
user@R2# set policy-options policy-statement export-tunnel-route term t1 then tunnel-attribute set
tunnle-attr-02
user@R2# set policy-options policy-statement export-tunnel-route term t1 then next-hop self
user@R2# set policy-options policy-statement export-tunnel-route term t1 then accept
```

```
R4
user@R4# set policy-options policy-statement export-tunnel-route term t1 from route-filter
192.168.0.51/32 exact
user@R4# set policy-options policy-statement export-tunnel-route term t1 then tunnel-attribute set
tunnle-attr-01
user@R4# set policy-options policy-statement export-tunnel-route term t1 then next-hop self
user@R4# set policy-options policy-statement export-tunnel-route term t1 then accept
```

5. Configure policy options to assign to add tunnel color, tunnel type, and a remote end point on R2 and R4.

```
R2
user@R2# set policy-options tunnel-attribute tunnle-attr-02 tunnel-type ipip
user@R2# set policy-options tunnel-attribute tunnle-attr-02 tunnel-color 100
user@R2# set policy-options tunnel-attribute tunnle-attr-02 remote-end-point 192.168.0.41
```

```
R4
user@R4# set policy-options tunnel-attribute tunnle-attr-01 tunnel-type ipip
user@R4# set policy-options tunnel-attribute tunnle-attr-01 tunnel-color 100
user@R4# set policy-options tunnel-attribute tunnle-attr-01 remote-end-point 192.168.0.21
```

6. Enter `commit` from the configuration mode.

Results

You can check your configurations by using the following show commands from the configuration mode. Here's how you can check the configurations on R2 device:

```
user@R2# show routing-options
```

```
router-id 192.168.0.21;
autonomous-system 64496;
forwarding-table {
    export plb;
    {
resolution;
dynamic-tunnels {
    Tunnel-01 {
        source-address 192.168.0.21;
        bgp-signal;
        destination-networks {
            192.168.0.0/24
                preference 100;
                    colors 100;
                {
        {
```

```
    {
{
```

user@R2# show policy-options policy-statement export-tunnel-route

```
term t1 {
    from {
        route-filter 192.168.0.11/32 exact;
    {
    then {
        tunnel-attribute set tunnle-attr-02;
            next-hop self;
        accept;
    {
}
```

user@R2# show policy-options tunnel-attribute tunnle-attr-02

```
tunnel-type ipip;
    tunnel-color 100;
remote-end-point 192.168.0.41;
```

user@R2# show protocols bgp group iBGP

```
type internal;
local-address 192.168.0.21;
family inet {
    unicast {
        extended-nexthop-tunnel;
    {
{
export [ export-tunnel-route export-isis ];
neighbor 192.168.0.41;
```

Verification

IN THIS SECTION

- Verify BGP Routes | 193
- Verify Received Routes | 194
- Verify Advertised Routes | 195

Verify BGP Routes

Purpose

Verify routes sent by using BGP protocol.

Action

R2

```
user@R2> show route protocol bgp
inet.0: 22 destinations, 22 routes (22 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192.168.0.51/32    *[BGP/170] 00:16:42, MED 10, localpref 100, from 192.168.0.41
                      AS path: I, validation-state: unverified
                    >  via Tunnel Composite, IPoIP (src 192.168.0.21 dest 192.168.0.41-100&lt;c>
tunnel-endpoint 192.168.0.21)
192.168.0.52/32    *[BGP/170] 00:39:38, MED 10, localpref 100, from 192.168.0.41
                      AS path: I, validation-state: unverified
                    >  to 192.0.2.2 via et-0/0/1:0.0, Push 299792
```

R4

```
user@R4> show route protocol bgp
inet.0: 22 destinations, 22 routes (22 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192.168.0.11/32    *[BGP/170] 00:19:44, MED 10, localpref 100, from 192.168.0.21
```

```
                    AS path: I, validation-state: unverified
                  >  via Tunnel Composite, IPoIP (src 192.168.0.41 dest 192.168.0.21-100&lt;c>
tunnel-endpoint 192.168.0.41)
192.168.0.12/32    *[BGP/170] 00:42:15, MED 10, localpref 100, from 192.168.0.21
                    AS path: I, validation-state: unverified
                  >  to 192.51.100.1 via ge-0/0/1.0, Push 299776
```

Meaning

The output shows the routes from BGP.

Verify Received Routes

Purpose

Verify the routes received through BGP by using the following operational mode commands.

Action

R2

```
user@R2>  show route receive-protocol bgp 192.168.0.41 192.168.0.51 extensive
inet.0: 22 destinations, 22 routes (22 active, 0 holddown, 0 hidden)
* 192.168.0.51/32 (1 entry, 1 announced)
     Accepted
     Nexthop: 192.168.0.41
     MED: 10
     Localpref: 100
     AS path: I
     Tunnel type: ipip, Tunnel color: 100, Remote end point: 192.168.0.21

inet.3: 3 destinations, 3 routes (3 active, 0 holddown, 0 hidden)
```

R4

```
user@R4> show route receive-protocol bgp 192.168.0.21 192.168.0.11 extensive
inet.0: 22 destinations, 22 routes (22 active, 0 holddown, 0 hidden)
* 192.168.0.11/32 (1 entry, 1 announced)
     Accepted
     Nexthop: 192.168.0.21
```

```
      MED: 10
      Localpref: 100
      AS path: I
      Tunnel type: ipip, Tunnel color: 100, Remote end point: 192.168.0.41

inet.3: 3 destinations, 3 routes (3 active, 0 holddown, 0 hidden)
```

Meaning

The R2 and R4 output indicates the routes received on the devices.

Verify Advertised Routes

Purpose

Verify the routes advertised through BGP by using the following operational mode commands.

Action

R2

```
user@R2> show route advertising-protocol bgp 192.168.0.41 192.168.0.11 extensive
inet.0: 22 destinations, 22 routes (22 active, 0 holddown, 0 hidden)
* 192.168.0.11/32 (1 entry, 1 announced)
BGP group iBGP type Internal
      Nexthop: Self
      Flags: Nexthop Change
      MED: 10
      Localpref: 100
      AS path: [64496] I
      Tunnel type: ipip, Tunnel color: 100, Remote end point: 192.168.0.41
```

R4

```
user@R4> show route advertising-protocol bgp 192.168.0.21 192.168.0.51 extensive
inet.0: 22 destinations, 22 routes (22 active, 0 holddown, 0 hidden)
* 192.168.0.51/32 (1 entry, 1 announced)
BGP group iBGP type Internal
      Nexthop: Self
      Flags: Nexthop Change
```

```
MED: 10
Localpref: 100
AS path: [64496] I
Tunnel type: ipip, Tunnel color: 100, Remote end point: 192.168.0.21
```

Meaning

The R2 and R4 output indicates the routes being advertised.

Release History Table

Release	Description
19.2R1	Starting in Junos Release 19.2R1, on MX Series routers with MPCs and MICs, carrier supporting carrier (CSC) architecture can be deployed with MPLS-over-UDP tunnels carrying MPLS traffic over dynamic IPv4 UDP tunnels that are established between supporting carrier's PE devices.
18.3R1	Starting in Junos OS Release 18.3R1, MPLS-over-UDP tunnels are supported on PTX Series routers and QFX Series switches.
18.2R1	Starting in Junos OS Release 18.2R1, on PTX series routers and QFX10000 with unidirectional MPLS-over-UDP tunnels, you must configure the remote PE device with an input filter for MPLS-over-UDP packets, and an action for decapsulating the IP and UDP headers for forwarding the packets in the reverse tunnel direction.
17.4R1	Starting in Junos OS Release 17.4R1, on MX Series routers, the next-hop-based dynamic MPLS-over-UDP tunnels are signaled using BGP encapsulation extended community.
17.1R1	Starting in Junos OS Release 17.1, on MX Series routers with MPCs and MICs, the scaling limit of MPLS-over-UDP tunnels is increased.

- Configuring BFD on Provider Edge and Provider Switches for an RSVP-Based LSP | **202**

You can configure the Bidirectional Forwarding Detection (BFD) protocol on EX8200 standalone switches and EX8200 Virtual Chassis to detect failures in the MPLS label-switch path (LSP). The BFD protocol is a simple hello mechanism that detects failures in a network. Hello packets are sent at a specified, regular interval. A neighbor failure is detected when the routing device stops receiving a reply from the neighbor after a specified interval. BFD works with a wide variety of network environments and topologies. The failure detection timers for BFD have shorter time limits than those of the failure detection mechanisms for static routes, and thus provide faster detection. These timers are also adaptive. For example, a timer can adapt to a higher value if an adjacency fails, or a neighbor can negotiate a higher value than the one configured.

This topic describes configuring the provider edge (PE) switches and the provider switches to support for LDP-based LSPs and RSVP-based LSPs.

This topic includes:

Configuring BFD on Provider Edge and Provider Switches for an LDP-Based LSP

You can enable BFD for the LDP-based LSPs or RSVP-based LSPs associated with a specific forwarding equivalence class (FEC). Alternatively, you can configure an Operation Administration and Maintenance (OAM) ingress policy to enable BFD on a range of FEC addresses.

Before you configure BFD for an LDP-based based LSP, you must configure the basic components for an MPLS network:

- Configure two PE switches. See "Configuring MPLS on Provider Edge Switches Using IP-Over-MPLS" on page 84.
- Configure one or more provider switches. See "Configuring MPLS on EX8200 and EX4500 Provider Switches" on page 94.

To configure BFD on PE and provider switches:

1. Define an OAM policy:

```
[edit]
user@switch# set protocols ldp oam ingress-policy policy-name
```

2. Specify the FEC on which you want to enable OAM:

```
[edit]
user@switch# set protocols ldp oam fec address
```

3. Specify the minimum transmit and receive interval for the BFD configuration:

NOTE: If you configure the `minimum-interval` statement, you do not need to configure the `minimum-receive-interval` statement or the `minimum-transmit-interval` statement.

```
[edit]
user@switch# set protocols ldp oam bfd-liveness-detection minimum-interval time
```

or

```
[edit]
user@switch# set protocols ldp oam bfd-liveness-detection minimum-receive-interval time
user@switch# set protocols ldp oam bfd-liveness-detection minimum-transmit-interval time
```

4. Specify the detection time multiplier. The negotiated transmit interval multiplied by this value gives the detection time for the receiving system in Asynchronous mode:

```
[edit]
user@switch# set protocols ldp oam bfd-liveness-detection multiplier multiplier
```

5. Specify the minimum transmit interval (or the minimum receive interval).

```
[edit]
user@switch# set protocols ldp oam bfd-liveness-detection transmit-interval minimum-
interval time
```

6. Specify a threshold for detecting the adaptation of the detection time:

```
[edit]
user@switch# set protocols ldp oam bfd-liveness-detection detection-time threshold time
```

7. Configure route and next-hop action in the event of a BFD session failure event on the LDP-based LSP:

```
[edit]
user@switch# set protocols ldp oam bfd-liveness-detection failure-action action
```

NOTE: When a BFD session goes down, you can configure the Junos OS to resignal the LSP path or to simply disable the LSP path. You can configure a standby LSP path to handle traffic while the primary LSP path is unavailable. The switch can automatically recover from LSP failures that can be detected by BFD. By default, if a BFD session fails, the event is simply logged.

8. Specify how long the BFD session must be up before adding the route or next hop. Specifying a time of 0 seconds causes the route or next hop to be added as soon as the BFD session comes back up.

```
[edit]
user@switch# set protocols ldp oam bfd-liveness-detection holddown-interval time
```

9. Enable tracing of FECs for LDP-based LSPs and specify a source address for sending probes. Then, specify a wait interval, after which to send the probe packet.

```
[edit]
user@switch# set protocols ldp oam periodic-traceroute source address
user@switch# set protocols ldp oam periodic-traceroute wait time
```

10. Specify the duration of the LSP ping interval in seconds:

```
[edit]
user@switch# set protocols ldp oam lsp-ping-interval time
```

11. Specify the action to be taken for the OAM policy:

```
[edit]
user@switch# set policy-options policy-statement policy-name then accept
```

12. Apply the BFD configurations at the MPLS hierarchy level for the configuration to inherit the statements in the configuration group:

```
[edit]
user@switch# set apply-groups MPLS
```

Configuring BFD on Provider Edge and Provider Switches for an RSVP-Based LSP

When BFD is configured for an RSVP-based LSP on the ingress switch, it is enabled on the primary path and on all standby secondary paths for that LSP. You can enable BFD for all LSPs on a switch or for specific LSPs. If you configure BFD for a specific LSP, whatever values configured globally for BFD are overridden on that LSP. The BFD sessions originate only at the ingress switch and terminate at the egress switch.

Before you configure BFD for an RSVP-based LSP, you must configure the basic components for an MPLS network:

- Configure two PE switches. See "Configuring MPLS on Provider Edge Switches Using IP-Over-MPLS" on page 84.
- Configure one or more provider switches. See "Configuring MPLS on EX8200 and EX4500 Provider Switches" on page 94.

To configure BFD on PE and provider switches:

1. Specify the minimum transmit and receive interval for the BFD configuration:

   NOTE: If you configure the `minimum-interval` statement, you do not need to configure the `minimum-receive-interval` statement or the `minimum-transmit-interval` statement.

   ```
   [edit]
   user@switch# set protocols mpls label-switched-path lsp-name oam bfd-liveness-detection
   minimum-interval time
   ```

   or

   ```
   [edit]
   user@switch# set protocols mpls label-switched-path lsp-name oam bfd-liveness-detection
   minimum-receive-interval time
   user@switch# set protocols mpls label-switched-path lsp-name oam bfd-liveness-detection
   minimum-transmit-interval time
   ```

2. Specify the detection time multiplier. The negotiated transmit interval multiplied by this value gives the detection time for the receiving system in Asynchronous mode:

```
[edit]
user@switch# set protocols mpls label-switched-path lsp-name oam bfd-liveness-detection
multiplier multiplier
```

3. Specify the minimum transmit interval (or the minimum receive interval):

```
[edit]
user@switch# set protocols mpls label-switched-path lsp-name oam bfd-liveness-detection
transmit-interval minimum-interval time
```

4. Configure route and next-hop actions in the event of a BFD session failure event on the RSVP-based LSP:

```
[edit]
user@switch# set protocols mpls label-switched-path lsp-name oam bfd-liveness-detection
failure-action action
```

NOTE: When a BFD session goes down, you can configure the Junos OS to resignal the LSP path or to simply disable the LSP path. You can configure a standby LSP path to handle traffic while the primary LSP path is unavailable. The switch can automatically recover from LSP failures that can be detected by BFD. By default, if a BFD session fails, the event is simply logged if you do not specifically configure a failure action.

BFD-Triggered Local Repair for Rapid Convergence

Understanding BFD-Triggered Local Protection

IN THIS SECTION

- Purpose of BFD-Triggered Local Repair | 204
- Configuring BFD-Triggered Local Repair | 205
- Disabling BFD-Triggered Local Repair | 205

The time it takes for a network to converge following a link or node failure can vary dramatically based on a number of factors, including network size, the protocols used, and network design. However, while each particular convergence event is different, the process of convergence is essentially consistent. The failure is detected, the failure is reported (flooded) in the network, an alternate path is found for traffic, and the forwarding plane is updated to pass traffic on a new path.

This overview discusses how Bidirectional Forwarding Detection (BFD)-triggered local repair contributes to a quicker restoration time for rapid convergence in an MPLS network.

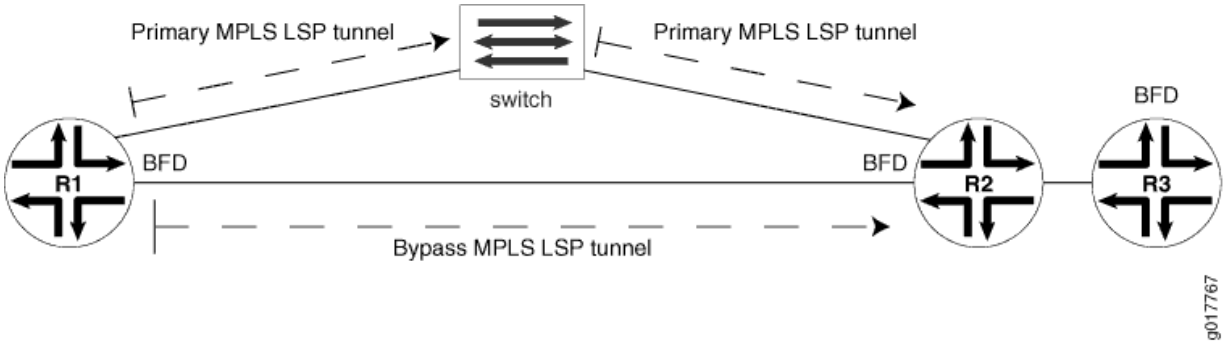
Purpose of BFD-Triggered Local Repair

In Junos OS, general MPLS traffic protection for RSVP-signaled label-switched path (LSP) failures is provided by several complementary mechanisms. These protection mechanisms include local protection (fast reroute, link protection, and node-link protection) and path protection (primary and secondary paths). Local protection in conjunction with path protection can provide minimum packet loss for an LSP, and control the way the LSP is rerouted after a failure. Traditionally, both types of protection rely on fast detection of connectivity failure at the physical level. However, for transmission media without fast physical level detection, Junos OS supports BFD and MPLS ping for fast failure detection.

With links between routers, when a route goes down, the routing protocol process recalculates the next best path. When MPLS fast reroute (FRR) is enabled, ifl messages are flooded to all Flexible PIC Concentrators (FPCs). The edge FPC enables the bypass MPLS LSP tunnel. Lastly, all routes are repaired and sent through the bypass MPLS LSP tunnel. The amount of time it takes to repair all routes is proportional to the number of routes.

This repair scenario becomes more difficult when a switch lies between two links. See *Figure 1*.

Figure 9: Topology with BFD-Triggered Local Repair



When a link goes down at the remote end, the failure is not detected at the local end until the interior gateway protocol (IGP) goes down. To wait for the routing protocol process to recalculate the next best path takes too much time.

With BFD-triggered local repair enabled, the Packet Forwarding Engine completes the repair first, using the bypass MPLS LSP tunnel (that is preconfigured and installed), then informs the routing protocol process to recalculate a new route. By doing this, when the primary MPLS LSP tunnel goes down, the FPC can intermittently and immediately divert traffic to the FPC with the bypass MPLS LSP tunnel.

Using local repair in this way achieves a faster restoration time of less than 50 ms.

Configuring BFD-Triggered Local Repair

BFD-triggered local repair is not configurable, but is part of the default configuration.

BFD-triggered local repair works within the legacy Junos OS features MPLS-FRR, BFD for IGP, and loop-free alternates (LFAs).

Disabling BFD-Triggered Local Repair

By default, BFD-triggered local repair is enabled for all routing interfaces. If desired, you can disable BFD-triggered local repair at the [**edit routing-options**] hierarchy level.

To explicitly disable BFD-triggered local repair:

1. Include the `no-bfd-triggered-local-repair` statement at the [edit routing-options] hierarchy level:

```
user@host# set no-bfd-triggered-local-repair
```

2. (Optional) Verify your configuration settings before committing them by using the `show routing-options` command.

```
user@host# run show routing-options
```

Confirm your configuration by issuing the **show routing-options** command.

```
user@host# show routing-options
...
    no-bfd-triggered-local-repair;
}
```

NOTE: When you disable this feature, you must also restart routing by including the **graceful-restart** statement for the IGP. For example, for OSPF, this is accomplished by including the **graceful-restart** statement at the `[edit protocols ospf]` hierarchy level.

Configuring BFD for MPLS IPv4 LSPs

IN THIS SECTION

- Configuring BFD for RSVP-Signaled LSPs | **207**
- Configuring a Failure Action for the BFD Session on an RSVP LSP | **209**

You can configure Bidirectional Forwarding Detection (BFD) protocol on MPLS IPv4 LSPs as outlined in the Internet draft draft-ietf-bfd-mpls-02.txt, *BFD for MPLS LSPs*. BFD is used as a periodic Operation, Administration, and Maintenance (OAM) feature for LSPs to detect LSP data plane faults. You can configure BFD for LSPs that use either LDP or RSVP as the signaling protocol.

NOTE: BFD for MPLS IPv4 LSP is based on the Routing Engine and is not distributed. As a result, the minimum supported BFD timer interval is (100 ms * 3) per one LSP session, and for scaled LSP sessions, the minimum supported BFD timer interval is (300 ms * 3). As you increase the number of LSP sessions with BFD, you must also increase (scale) the interval timers to support the network.

For Routing Engine switchover instances with nonstop active routing (NSR) support, the minimum supported BFD timer interval is (2.5 seconds * 3).

You can also use the LSP `ping` commands to detect LSP data plane faults. However, BFD has a couple of benefits: it requires less computer processing than LSP `ping` commands and can quickly detect faults in large numbers of LSPs (LSP `ping` commands must be issued for each LSP individually). On the other hand, BFD cannot be used to verify the control plane against the data plane at the egress LSR, which is possible when an LSP `ping` echo request is associated with a forwarding equivalence class (FEC).

The BFD failure detection timers are adaptive and can be adjusted to be more or less aggressive. For example, the timers can adapt to a higher value if the adjacency fails, or a neighbor can negotiate a higher value for a timer than the configured value. The timers adapt to a higher value when a BFD session flap occurs more than three times in a span of 15 seconds. A back-off algorithm increases the receive (Rx) interval by two if the local BFD instance is the reason for the session flap. The transmission (Tx) interval is increased by two if the remote BFD instance is the reason for the session flap. You can use the `clear bfd adaptation` command to return BFD interval timers to their configured values. The `clear bfd adaptation` command is hitless, meaning that the command does not affect traffic flow on the routing device.

Starting from Junos OS Release 13.2R4, 13.3R2, and 14.1, you can set the time interval between LSP ping messages and the number of LSP ping responses, respectively, after which the Bidirectional Forwarding Detection (BFD) session is brought down. To so do, you configure the `lsp-ping-interval` statement and the `lsp-ping-multiplier` statement at the `[edit protocols mpls oam]` hierarchy level.

For configuration instructions for LDP-signaled LSPs, see "Configuring BFD for LDP LSPs" on page 1366. For configuration instructions for RSVP-signaled LSPs, see the following section.

Configuring BFD for RSVP-Signaled LSPs

BFD for RSVP supports unicast IPv4 LSPs. When BFD is configured for an RSVP LSP on the ingress router, it is enabled on the primary path and on all standby secondary paths for that LSP. The source IP address for outgoing BFD packets from the egress side of an MPLS BFD session is based on the outgoing interface IP address. You can enable BFD for all LSPs on a router or for specific LSPs. If you configure BFD for a specific LSP, whatever values configured globally for BFD are overridden. The BFD sessions originate only at the ingress router and terminate at the egress router.

An error is logged whenever a BFD session for a path fails. The following example shows how BFD for RSVP LSP log messages might appear:

```
RPD_MPLS_PATH_BFD_UP: MPLS BFD session for path path1 up on LSP R0_to_R3
RPD_MPLS_PATH_BFD_DOWN: MPLS BFD session for path path1 down on LSP R0_to_R3
```

You can configure BFD for all of the RSVP LSPs on the router, a specific LSP, or the primary path of a specific LSP. To configure BFD for RSVP LSPs, include the `oam` and `bfd-liveness-detection` statements.

```
oam {
    bfd-liveness-detection {
        failure-action {
            make-before-break teardown-timeout seconds;
            teardown;
        }
        failure-action teardown;
        minimum-interval milliseconds;
        minimum-receive-interval milliseconds;
        minimum-transmit-interval milliseconds;
        multiplier detection-time-multiplier;
    }
    lsp-ping-interval time-interval;
    lsp-ping-multiplier multiplier;
}
```

You can configure this statement at the following hierarchy levels:

- `[edit protocols mpls]`
- `[edit protocols mpls label-switched-path lsp-name]`
- `[edit protocols mpls label-switched-path lsp-name primary path-name]`

The `bfd-liveness-detection` statement includes the following options:

- `minimum-interval`—Specifies the minimum transmit and receive interval.
- `minimum-receive-interval`—Specifies the minimum receive interval. The range is from 1 through 255,000 milliseconds.
- `minimum-transmit-interval`—Specifies the minimum transmit interval. The range is from 1 through 255,000 milliseconds.
- `lsp-ping-multiplier`—Specifies the detection time multiplier. The range is from 1 through 255.

NOTE: To avoid triggering false negatives, configure a BFD fault detection time that is longer than the fast reroute time.

You can also configure the `lsp-ping-interval` option to adjust the time interval between LSP pings. The LSP ping command for RSVP-signaled LSPs is `ping mpls rsvp`. For more information on the `ping mpls rsvp` command, see the CLI Explorer.

Configuring a Failure Action for the BFD Session on an RSVP LSP

When the BFD session for an RSVP LSP goes down, the LSP is torn down and resignaled. Traffic can be switched to a standby LSP, or you can simply tear down the LSP path. Any actions performed are logged.

When a BFD session for an RSVP LSP path goes down, you can configure the Junos OS to resignal the LSP path or to simply disable the LSP path. A standby LSP path could be configured to handle traffic while the primary LSP path is unavailable. The router can automatically recover from LSP failures that can be detected by BFD. By default, if a BFD session fails, the event is simply logged.

To enable the Junos OS to tear down an RSVP LSP path in the event of a BFD event, include the `failure-action` statement:

```
failure-action {
    make-before-break teardown-timeout seconds;
    teardown;
}
```

For a list of the hierarchy levels at which you can include this statement, see the statement summary section for this statement.

You can configure either the `teardown` or `make-before-break` options:

- `teardown`—Causes the LSP path to be taken down and resignaled immediately.
- `make-before-break`—Causes the Junos OS to attempt to signal a new LSP path before tearing down the old LSP path. You can also configure the `teardown-timeout` option to automatically tear down the LSP after the time period specified if the attempt to resignal the LSP fails within the `teardown-timeout` interval. If you specify a value of 0 for the `teardown-timeout` interval, the LSP is taken down and resignaled immediately (the same behavior as when you configure the `teardown` option).

To configure a failure action for all of the RSVP LSPs, include the `failure-action` statement at the `[edit protocols mpls oam bfd-liveness-detection]` hierarchy level. To configure a failure action for a specific RSVP LSP, include the `failure-action` statement at the `[edit protocols mpls label-switched-path` *`lsp-name`* `oam bfd-liveness-detection]` hierarchy level.

To configure a failure action for a specific primary path, include the `failure-action` statement at the `[edit protocols mpls label-switched path` *`lsp-name`* `primary` *`path-name`* `oam bfd-liveness-detection]` hierarchy level. To configure a failure action for a specific secondary LSP path, include the `failure-action` statement at the `[edit protocols mpls label-switched-path` *`lsp-name`* `secondary` *`path-name`* `oam bfd-liveness-detection]` hierarchy level.

Release History Table

Release	Description
13.2R4	Starting from Junos OS Release 13.2R4, 13.3R2, and 14.1, you can set the time interval between LSP ping messages and the number of LSP ping responses, respectively, after which the Bidirectional Forwarding Detection (BFD) session is brought down.

Configuring MPLS Firewall Filters and Policers on Routers

IN THIS SECTION

- Configuring MPLS Firewall Filters | 211
- Examples: Configuring MPLS Firewall Filters | 212
- Configuring Policers for LSPs | 213
- Example: Configuring an LSP Policer | 215
- Configuring Automatic Policers | 216
- Writing Different DSCP and EXP Values in MPLS-Tagged IP Packets | 219

You can configure an MPLS firewall filter to count packets based on the EXP bits for the top-level MPLS label in a packet. You can also configure policers for MPLS LSPs.

The following sections discuss MPLS firewall filters and policers:

Configuring MPLS Firewall Filters

You can configure an MPLS firewall filter to count packets based on the EXP bits for the top-level MPLS label in a packet. You can then apply this filter to a specific interface. You can also configure a policer for the MPLS filter to police (that is, rate-limit) the traffic on the interface to which the filter is attached. You cannot apply MPLS firewall filters to Ethernet (fxp0) or loopback (lo0) interfaces.

You can configure the following match criteria attributes for MPLS filters at the `[edit firewall family mpls filter filter-name term term-name from]` hierarchy level:

- `exp`
- `exp-except`

These attributes can accept EXP bits in the range 0 through 7. You can configure the following choices:

- A single EXP bit—for example, `exp 3;`
- Several EXP bits—for example, `exp 0, 4;`
- A range of EXP bits—for example, `exp [0-5];`

If you do not specify a match criterion (that is, you do not configure the `from` statement and use only the `then` statement with the `count` action keyword), all the MPLS packets passing through the interface on which the filter is applied will be counted.

You also can configure any of the following action keywords at the `[edit firewall family mpls filter filter-name term term-name then]` hierarchy level:

- `count`
- `accept`
- `discard`
- `next`
- `policer`

For more information about how to configure firewall filters, see the Routing Policies, Firewall Filters, and Traffic Policers User Guide. For more information about how to configure interfaces, see the Junos OS Network Interfaces Library for Routing Devices and the Junos OS Services Interfaces Library for Routing Devices.

Examples: Configuring MPLS Firewall Filters

The following examples illustrate how you might configure an MPLS firewall filter and then apply the filter to an interface. This filter is configured to count MPLS packets with EXP bits set to either 0 or 4.

The following shows a configuration for an MPLS firewall filter:

```
[edit firewall]
family mpls {
    filter expf {
        term expt0 {
            from {
                exp 0,4;
            }
            then {
                count counter0;
                accept;
            }
        }
    }
}
```

The following shows how to apply the MPLS firewall filter to an interface:

```
[edit interfaces]
so-0/0/0 {
    mtu 4474;
    encapsulation ppp;
    sonet-options {
        fcs 32;
    }
    unit 0 {
        point-to-point;
        family mpls {
            filter {
                input expf;
                output expf;
            }
        }
    }
}
```

The MPLS firewall filter is applied to the input and output of an interface (see the `input` and `output` statements in the preceding example).

Configuring Policers for LSPs

MPLS LSP policing allows you to control the amount of traffic forwarded through a particular LSP. Policing helps to ensure that the amount of traffic forwarded through an LSP never exceeds the requested bandwidth allocation. LSP policing is supported on regular LSPs, LSPs configured with DiffServ-aware traffic engineering, and multiclass LSPs. You can configure multiple policers for each multiclass LSP. For regular LSPs, each LSP policer is applied to all of the traffic traversing the LSP. The policer's bandwidth limitations become effective as soon as the total sum of traffic traversing the LSP exceeds the configured limit.

NOTE: The PTX10003 router only supports regular LSPs.

You configure the multiclass LSP and DiffServ-aware traffic engineering LSP policers in a filter. The filter can be configured to distinguish between the different class types and apply the relevant policer to each class type. The policers distinguish between class types based on the EXP bits.

You configure LSP policers under the `family any` filter. The `family any` filter is used because the policer is applied to traffic entering the LSP. This traffic might be from different families: IPv6, MPLS, and so on. You do not need to know what sort of traffic is entering the LSP, as long as the match conditions apply to all types of traffic.

You can configure only those match conditions that apply across all types of traffic. The following are the supported match conditions for LSP policers:

- `forwarding-class`
- `packet-length`
- `interface`
- `interface-set`

To enable a policer on an LSP, first you need to configure a policing filter and then include it in the LSP configuration. For information about how to configure policers, see the Routing Policies, Firewall Filters, and Traffic Policers User Guide.

To configure a policer for an LSP, specify a filter by including the `filter` option to the `policing` statement:

```
policing {
    filter filter-name;
}
```

You can include the `policing` statement at the following hierarchy levels:

- `[edit protocols mpls label-switched-path lsp-name]`
- `[edit protocols mpls static-label-switched-path lsp-name]`
- `[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name]`
- `[edit logical-systems logical-system-name protocols mpls static-label-switched-path lsp-name]`

LSP Policer Limitations

When configuring MPLS LSP policers, be aware of the following limitations:

- LSP policers are supported for packet LSPs only.
- LSP policers are supported for unicast next hops only. Multicast next hops are not supported.
- LSP policers are not supported on aggregated interfaces.
- The LSP policer runs before any output filters.
- Traffic sourced from the Routing Engine (for example, ping traffic) does not take the same forwarding path as transit traffic. This type of traffic cannot be policed.
- LSP policers work on all T Series routers and on M Series routers that have the Internet Processor II application-specific integrated circuit (ASIC).

NOTE: Starting with Junos OS Release 12.2R2, on T Series routers only, you can configure an LSP policer for a specific LSP to be shared across different protocol family types. To do so, you must configure the *logical-interface-policer* statement at the `[edit firewall policer policer-name]` hierarchy level.

Example: Configuring an LSP Policer

The following example shows how you can configure a policing filter for an LSP:

```
[edit firewall]
policer police-ct1 {
    if-exceeding {
        bandwidth-limit 50m;
        burst-size-limit 1500;
    }
    then {
        discard;
    }
}
policer police-ct0 {
    if-exceeding {
        bandwidth-limit 200m;
        burst-size-limit 1500;
    }
    then {
        discard;
    }
}
family any {
    filter bar {
        term discard-ct0 {
            then {
                policer police-ct0;
                accept;
            }
        }
    }
    term discard-ct1 {
        then {
            policer police-ct1;
            accept;
        }
    }
}
```

Configuring Automatic Policers

Automatic policing of LSPs allows you to provide strict service guarantees for network traffic. Such guarantees are especially useful in the context of Differentiated Services for traffic engineered LSPs, providing better emulation for ATM wires over an MPLS network. For more information about Differentiated Services for LSPs, see DiffServ-Aware Traffic Engineering Introduction.

Differentiated Services for traffic engineered LSPs allow you to provide differential treatment to MPLS traffic based on the EXP bits. To ensure these traffic guarantees, it is insufficient to simply mark the traffic appropriately. If traffic follows a congested path, the requirements might not be met.

LSPs are guaranteed to be established along paths where enough resources are available to meet the requirements. However, even if the LSPs are established along such paths and are marked properly, these requirements cannot be guaranteed unless you ensure that no more traffic is sent to an LSP than there is bandwidth available.

It is possible to police LSP traffic by manually configuring an appropriate filter and applying it to the LSP in the configuration. However, for large deployments it is cumbersome to configure thousands of different filters. Configuration groups cannot solve this problem either, since different LSPs might have different bandwidth requirements, requiring different filters. To police traffic for numerous LSPs, it is best to configure automatic policers.

When you configure automatic policers for LSPs, a policer is applied to all of the LSPs configured on the router. However, you can disable automatic policing on specific LSPs.

NOTE: When you configure automatic policers for DiffServ-aware traffic engineering LSP, GRES is not supported.

NOTE: You cannot configure automatic policing for LSPs carrying CCC traffic.

The following sections describe how to configure automatic policers for LSPs:

Configuring Automatic Policers for LSPs

To configure automatic policers for standard LSPs (neither DiffServ-aware traffic engineered LSPs nor multiclass LSPs), include the `auto-policing` statement with either the `class all` *`policer-action`* option or the `class ct0` *`policer-action`* option:

```
auto-policing {
    class all policer-action;
```

```
    class ct0 policer-action;
}
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls]
- [edit logical-systems *logical-system-name* protocols mpls]

You can configure the following policer actions for automatic policers:

- drop—Drop all packets.
- loss-priority-high—Set the packet loss priority (PLP) to high.
- loss-priority-low—Set the PLP to low.

These policer actions are applicable to all types of LSPs. The default policer action is to do nothing.

Automatic policers for LSPs police traffic based on the amount of bandwidth configured for the LSPs. You configure the bandwidth for an LSP using the bandwidth statement at the [edit protocols mpls label-switched-path *lsp-path-name*] hierarchy level. If you have enabled automatic policers on a router, change the bandwidth configured for an LSP, and commit the revised configuration, the change does not take affect on the active LSPs. To force the LSPs to use the new bandwidth allocation, issue a clear mpls lsp command.

NOTE: You cannot configure automatic policers for LSPs that traverse aggregated interfaces or Multilink Point-to-Point Protocol (MLPPP) interfaces.

Configuring Automatic Policers for DiffServ-Aware Traffic Engineering LSPs

To configure automatic policers for DiffServ-aware traffic engineering LSPs and for multiclass LSPs, include the auto-policing statement:

```
auto-policing {
    class all policer-action;
    class ctnumber policer-action;
}
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls]

- [edit logical-systems *logical-system-name* protocols mpls]

You include either the class all *policer-action* statement or a class ct*number policer-action* statement for each of one or more classes (you can configure a different policer action for each class). For a list of the actions that you can substitute for the *policer-action* variable, see "Configuring Automatic Policers for LSPs" on page 216. The default policer action is to do nothing.

NOTE: You cannot configure automatic policers for LSPs that traverse aggregated interfaces or MLPPP interfaces.

Configuring Automatic Policers for Point-to-Multipoint LSPs

You can configure automatic policers for point-to-multipoint LSPs by including the auto-policing statement with either the class all *policer-action* option or the class ct0 *policer-action* option. You only need to configure the auto-policing statement on the primary point-to-multipoint LSP (for more information on primary point-to-multipoint LSPs, see Configuring the Primary Point-to-Multipoint LSP). No additional configuration is required on the subLSPs for the point-to-multipoint LSP. Point-to-multipoint automatic policing is applied to all branches of the point-to-multipoint LSP. In addition, automatic policing is applied to any local VRF interfaces that have the same forwarding entry as a point-to-multipoint branch. Feature parity for automatic policers for MPLS point-to-multipoint LSPs on the Junos Trio chipset is supported in Junos OS Releases 11.1R2, 11.2R2, and 11.4.

The automatic policer configuration for point-to-multipoint LSPs is identical to the automatic policer configuration for standard LSPs. For more information, see "Configuring Automatic Policers for LSPs" on page 216.

Disabling Automatic Policing on an LSP

When you enable automatic policing, all of the LSPs on the router or logical system are affected. To disable automatic policing on a specific LSP on a router where you have enabled automatic policing, include the policing statement with the no-auto-policing option:

```
policing no-auto-policing;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls label-switched-path *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name*]

Example: Configuring Automatic Policing for an LSP

Configure automatic policing for a multiclass LSP, specifying different actions for class types `ct0`, `ct1`, `ct2`, and `ct3`.

```
[edit protocols mpls]
diffserv-te {
    bandwidth-model extended-mam;
}
auto-policing {
    class ct1 loss-priority-low;
    class ct0 loss-priority-high;
    class ct2 drop;
    class ct3 loss-priority-low;
}
traffic-engineering bgp-igp;
label-switched-path sample-lsp {
    to 3.3.3.3;
    bandwidth {
        ct0 11;
        ct1 1;
        ct2 1;
        ct3 1;
    }
}
interface fxp0.0 {
    disable;
}
interface t1-0/5/3.0;
interface t1-0/5/4.0;
```

Writing Different DSCP and EXP Values in MPLS-Tagged IP Packets

You can selectively set the DiffServ code point (DSCP) field of MPLS-tagged IPv4 and IPv6 packets to 0 without affecting output queue assignment, and continue to set the MPLS EXP field according to the configured rewrite table, which is based on forwarding classes. You can accomplish this by configuring a firewall filter for the MPLS-tagged packets.

Overview of MPLS Firewall Filters on Loopback Interface

IN THIS SECTION

- Benefits of Adding MPLS Firewall Filters on the Loopback Interface | **220**
- Guidelines and Limitations | **220**

Although all interfaces are important, the loopback interface might be the most important because it is the link to the Routing Engine, which runs and manages all the routing protocols. The loopback interface is a gateway for all the control traffic that enters the Routing Engine of the switch. You can control this traffic by configuring a firewall filter on the loopback interface (lo0) on `family mpls`. Loopback firewall filters affect only traffic destined for the Routing Engine CPU. You can apply a loopback firewall filter only in the *ingress* direction (packets entering the interface). Starting with Junos OS Release 19.2R1, you can apply an MPLS firewall filter to a loopback interface on a label switch router (LSR) on QFX5100, QFX5110, QFX5200, and QFX5210 switches.

When you configure an MPLS firewall filter, you define filtering criteria (*terms, with match conditions*) for the packets and an *action* for the switch to take if the packets match the filtering criteria. Because you apply the filter to a loopback interface, you must explicitly specify the time to live (TTL) match condition under `family mpls` and set its TTL value to 1 (`ttl=1`). The TTL is an 8-bit (IPv4) header field that signifies the remaining time an IP packet has left before its life ends and is dropped. You can also match packets with other MPLS qualifiers such as `label`, `exp`, Layer 4 `source port`, and Layer 4 `destination port`. For more information, see *Firewall Filter Match Conditions for MPLS Traffic*.

Benefits of Adding MPLS Firewall Filters on the Loopback Interface

- Protects the Routing Engine by ensuring that it accepts traffic only from trusted networks.
- Helps protect the Routing Engine from denial-of-service attacks.
- Gives you the flexibility to match packets on the source port and destination port. For example, if you run a traceroute, you can selectively filter traffic by choosing either TCP or UDP.

Guidelines and Limitations

- You can apply a loopback firewall filter only in the *ingress* direction
- Only MPLS fields `label`, `exp`, `ttl=1` and Layer 4 fields `tcp` and `udp` port numbers are supported.
- Only `accept`, `discard`, and `count` actions are supported.

- You must explicitly specify `ttl=1` under `family mpls` to match on TLL packets.
- Filters applied on the loopback interface cannot be matched on the destination port (inner payload) of an IPv6 packet.
- You cannot apply a filter on packets that have more than two MPLS labels.
- You cannot specify a port range for TCP or UDP match conditions.
- Only 255 firewall terms are supported.

Configuring MPLS Firewall Filters and Policers on Switches

IN THIS SECTION

- Configuring an MPLS Firewall Filter | **221**
- Applying an MPLS Firewall Filter to an MPLS Interface | **222**
- Applying an MPLS Firewall Filter to a Loopback Interface | **222**
- Configuring Policers for LSPs | **223**

You can configure firewall filters to filter MPLS traffic. To use an MPLS firewall filter, you must first configure the filter and then apply it to an interface you have configured for forwarding MPLS traffic. You can also configure a policer for the MPLS filter to police (that is, rate-limit) the traffic on the interface to which the filter is attached.

When you configure an MPLS firewall filter, you define the filtering criteria (terms, with match conditions) and an action for the switch to take if the packets match the filtering criteria.

NOTE: You can only configure MPLS filters in the ingress direction. Egress MPLS firewall filters are not supported.

Configuring an MPLS Firewall Filter

To configure an MPLS firewall filter:

1. Configure the filter name, term name, and at least one match condition—for example, match on MPLS packets with EXP bits set to either 0 or 4:

```
[edit firewall family mpls]
user@switch# set filter ingress-exp-filter term term-one from exp 0,4
```

2. In each firewall filter term, specify the actions to take if the packet matches all the conditions in that term—for example, count MPLS packets with EXP bits set to either 0 or 4:

```
[edit firewall family mpls filter ingress-exp-filter term term-one then]
user@switch# set count counter0
user@switch# set accept
```

3. When you are finished, follow the steps below to apply the filter to an interface.

Applying an MPLS Firewall Filter to an MPLS Interface

To apply the MPLS firewall filter to an interface you have configured for forwarding MPLS traffic (using the `family mpls` statement at the `[edit interfaces interface-name unit unit-number]` hierarchy level):

NOTE: You can apply firewall filters only to filter MPLS packets that enter an interface.

1. Apply the firewall filter to an MPLS interface—for example, apply the firewall filter to interface xe-0/0/5:

```
[edit interfaces]
user@switch# set xe-0/0/5 unit 0 family mpls filter input ingress-exp-filter
```

2. Review your configuration and issue the `commit` command:

```
[edit interfaces]
user@switch# commit
commit complete
```

Applying an MPLS Firewall Filter to a Loopback Interface

To apply an MPLS firewall filter to a loopback interface (lo0):

1. First, specify the packet format by using the *packet-format-match* command. You must restart the PFE every time you configure this command.
2. Configure the firewall filter match conditions and actions as described in "Configuring MPLS Firewall Filters and Policers on Switches" on page 221. You must explicitly set the TTL match condition to (`ttl=1`). You can also match packets with other MPLS qualifiers such as `label`, `exp`, and Layer 4 `source port`, and `destination port`.
3. Apply the filter to the loopback interface as an input filter.

```
[edit interfaces]
user@switch# set lo0 unit 0 family mpls filter input ingress-exp-filter
```

4. Review your configuration and issue the `commit` command:

```
[edit interfaces]
user@switch# commit
commit complete
```

The following is an example configuration.

```
set groups lo_mpls_filter interfaces lo0 unit 0 family mpls filter input mpls_lo
set groups lo_mpls_filter firewall family mpls filter mpls_lo term mpls_lo_term from ttl 1
set groups lo_mpls_filter firewall family mpls filter mpls_lo term mpls_lo_term from ip-version ipv4
protocol udp source-port 10
set groups lo_mpls_filter firewall family mpls filter mpls_lo term mpls_lo_term from ip-version ipv4
protocol udp destination-port 11
set groups lo_mpls_filter firewall family mpls filter mpls_lo term mpls_lo_term then count c1
set groups lo_mpls_filter firewall family mpls filter mpls_lo term mpls_lo_term then accept
```

Configuring Policers for LSPs

Starting with Junos OS 13.2X51-D15, you can send traffic matched by an MPLS filter to a two-color policer or three-color policer. MPLS LSP policing allows you to control the amount of traffic forwarded through a particular LSP. Policing helps to ensure that the amount of traffic forwarded through an LSP never exceeds the requested bandwidth allocation. LSP policing is supported on regular LSPs, LSPs configured with DiffServ-aware traffic engineering, and multiclass LSPs. You can configure multiple policers for each multiclass LSP. For regular LSPs, each LSP policer is applied to all of the traffic traversing the LSP. The policer's bandwidth limitations become effective as soon as the total sum of traffic traversing the LSP exceeds the configured limit.

You configure the multiclass LSP and DiffServ-aware traffic engineering LSP policers in a filter. The filter can be configured to distinguish between the different class types and apply the relevant policer to each class type. The policers distinguish between class types based on the EXP bits.

You configure LSP policers under the `family any` filter. The `family any` filter is used because the policer is applied to traffic entering the LSP. This traffic might be from different families: IPv6, MPLS, and so on. You do not need to know what sort of traffic is entering the LSP, as long as the match conditions apply to all types of traffic.

When configuring MPLS LSP policers, be aware of the following limitations:

- LSP policers are supported for packet LSPs only.
- LSP policers are supported for unicast next hops only. Multicast next hops are not supported.
- The LSP policer runs before any output filters.
- Traffic sourced from the Routing Engine (for example, ping traffic) does not take the same forwarding path as transit traffic. This type of traffic cannot be policed.

Release History Table

Release	Description
19.2R1	Starting with Junos OS Release 19.2R1, you can apply an MPLS firewall filter to a loopback interface on a label switch router (LSR) on QFX5100, QFX5110, QFX5200, and QFX5210 switches.

System Log Messages and SNMP Traps for MPLS

Whenever an LSP makes a transition from up to down, or down to up, and whenever an LSP switches from one active path to another, the ingress router generates a system log message and sends an SNMP trap. The following shows a sample system log message:

```
RPD_MPLS_LSP_UP: MPLS LSP sheep1 up on primary(any) Route  192.168.1.1 192.168.1.2 192.168.1.3
RPD_MPLS_LSP_CHANGE: MPLS LSP sheep1 change on primary(any) Route  192.168.1.1 192.168.1.2
192.168.1.3
RPD_MPLS_LSP_DOWN: MPLS LSP sheep1 down on primary(any)
```

For information about the MPLS SNMP traps and the proprietary MPLS MIBs, see the Junos OS Network Management Administration Guide for Routing Devices.

System log messages for LSPs are generated by default. To disable the default logging of messages for LSPs, configure the `no-syslog` option under the `log-updown` statement:

```
log-updown {
    no-syslog;
}
```

To generate SNMP traps for LSPs, include the `trap` option to the `log-updown` statement:

```
log-updown {
    trap;
}
```

To generate SNMP traps whenever an LSP path goes down, include the `trap-path-down` option to the `log-updown` statement:

```
log-updown {
    trap-path-down;
}
```

To generate SNMP traps whenever an LSP path comes up, include the `trap-path-up` option to the `log-updown` statement:

```
log-updown {
    trap-path-up;
}
```

To disable the generation of system log messages, include the `no-syslog` option to the `log-updown` statement:

```
log-updown {
    no-syslog;
}
```

To disable the generation of SNMP traps, include the `no-trap` statement:

```
no-trap {
    mpls-lsp-traps;
```

```
    rfc3812-traps;
}
```

You can include this statement at the following hierarchy levels:

- `[edit protocols mpls log-updown]`
- `[edit logical-systems` *`logical-system-name`* `protocols mpls log-updown]`

For scalability reasons, only the ingress router generates SNMP traps. By default, MPLS issues traps for all configured LSPs. If you have many LSPs, the number of traps can become quite large. To disable the generation of SNMP traps, configure the `no-trap` statement.

The `no-trap` statement also includes the following options which allow you to block certain categories of MPLS SNMP traps:

- `mpls-lsp-traps`—Blocks the MPLS LSP traps defined in the **jnx-mpls.mib**, but allows the **rfc3812.mib** traps.
- `rfc-3812-traps`—Blocks the traps defined in the **rfc3812.mib**, but allows the MPLS LSP traps defined in the **jnx-mpls.mib**.

Load Balancing MPLS Traffic

Configuring Load Balancing Based on MPLS Labels

Load balancing occurs on a per-packet basis for MPLS flows on supported platforms. Entropy, or random distribution, is essential for the uniform distribution of packets to their next hops. By default, when load balancing is used to help distribute traffic, Junos OS employs a hash algorithm to select a next-hop address to install into the forwarding table. Whenever the set of next hops for a destination changes, the next-hop address is reselected by means of the hash algorithm. You can configure how the hash algorithm is used to load-balance traffic across a set of equal-cost label switched paths (LSPs).

To ensure entropy for VPLS & VPWS traffic, Junos OS can create a hash based on data from the IP header and as many as three MPLS labels (the so-called top labels).

In some cases, as the number of network feature that use labels grows (such as MPLS Fast Reroute, and RFC 3107, RSVP and VPN) data in the top three labels can become static and thus not a sufficient source for entropy. Load balancing can become skewed as a result, or the incidence of out-of-order packet delivery may rise. For these cases, labels from the bottom of the label stack can be used (see Table 1, below for qualifications). Top labels and bottom labels cannot be used at the same time.

NOTE: MPC cards do not support the regular hash key configuration. For the MPC-based hash key configuration to be effective, you need an *enhanced-hash-key* configuration.

Load balancing is used to evenly distribute traffic when the following conditions apply:

- There are multiple equal-cost next hops over different interfaces to the same destination.
- There is a single next hop over an aggregated interface.

An LSP tends to load-balance its placement by randomly selecting one of the equal-cost next hops and using it exclusively. The random selection is made independently at each transit router, which compares Interior Gateway Protocol (IGP) metrics alone. No consideration is given to bandwidth or congestion levels.

This feature applies to aggregated Ethernet and aggregated SONET/SDH interfaces as well as multiple equal-cost MPLS next hops. In addition, on the T Series, MX Series, M120, and M320 routers only, you can configure load balancing for IPv4 traffic over Layer 2 Ethernet pseudowires. You can also configure load balancing for Ethernet pseudowires based on IP information. The option to include IP information in the hash key provides support for Ethernet circuit cross-connect (CCC) connections.

To load-balance based on the MPLS label information, configure the `family mpls` statement:

```
[edit forwarding-options hash-key]
family mpls {
    all-labels;
    bottom-label-1;
```

```
    bottom-label-2;
    bottom-label-3;
    label-1;
    label-2;
    label-3;
    no-labels;
    no-label-1-exp;
    payload {
        ether-pseudowire;
        ip {
            disable;
            layer-3-only;
            port-data {
                destination-lsb;
                destination-msb;
                source-lsb;
                source-msb;
            }
        }
    }
}
```

You can include this statement at the following hierarchy levels:

- `[edit forwarding-options hash-key]`

Table 7 on page 228 provides detailed information about all of the possible MPLS LSP load-balancing options.

Table 7: MPLS LSP Load Balancing Options

Statement	Supported Platforms	MPLS LSP Load Balancing Options
`all-labels`	MX Series and PTX Series	Prior to Junos OS Release 19.1R1, up to eight MPLS labels were included in the hash key to identify the uniqueness of a flow in the Packet Forwarding Engine. On PTX Series routers, this value is set by default. Starting in Junos OS Release 19.1R1, for MX Series routers with MPC and MIC interfaces, up to sixteen incoming MPLS labels are included in the hash key.

Table 7: MPLS LSP Load Balancing Options *(Continued)*

Statement	Supported Platforms	MPLS LSP Load Balancing Options
`bottom-label-1`	MX Series with DPC (I-Chip). Not supported on M10i, M7i, and M120.	Uses the bottom-most label for calculating the hash key, for example if the top labels do not provide sufficient variable for the required level of entropy.
`bottom-label-2`	MX Series with DPC (I-Chip). Not supported on M10i, M7i, and M120.	Uses the second label from the bottom for calculating the hash key, for example if the top labels do not provide sufficient variable for the required level of entropy.
`bottom-label-3`	MX Series with DPC (I-Chip). Not supported on M10i, M7i, and M120.	Uses the third label from the bottom for calculating the hash key, for example if the top labels do not provide sufficient variable for the required level of entropy.
`label-1`	M Series, MX Series, T Series	Include the first label in the hash key. Use this option for single label packets.
`label-2`	M Series, MX Series, T Series	Include the second label in the hash key. You must also configure the `label-1` option. The entire first label and the first 16 bits of the second label are used in the hash key.
`label-3`	M Series, MX Series, T Series	Include the third label in the hash key. You must also configure the `label-1` option and the `label-2` option.
`no-labels`	All	Excludes MPLS labels from the hash key.

Table 7: MPLS LSP Load Balancing Options *(Continued)*

Statement	Supported Platforms	MPLS LSP Load Balancing Options
`no-label-1-exp`	M Series, MX Series, T Series	Excludes the EXP bit of the top label from the hash key. You must also configure the `label-1` option. For Layer 2 VPNs, the router could encounter a packet reordering problem. When a burst of traffic pushes the customer traffic bandwidth to exceed its limits, the traffic might be affected in mid flow. Packets might be reordered as a result. By excluding the EXP bit from the hash key, you can avoid this reordering problem.
`payload`	All	Allows you to configure which parts of the IP packet payload to include in the hash key. For the PTX Series Packet Transport Router, this value is set by default.
`disable`	PTX Series	Exclude IP payload from the hash key.
`ether-pseudowire`	M120, M320, MX Series, T Series	Load-balance IPv4 traffic over Layer 2 Ethernet pseudowires.
`ip`	All	Include the IPv4 or IPv6 address in the hash key. You must also configure either `label-1` or `no-labels`.
`layer-3-only`	All	Include only the Layer 3 IP information in the hash key. Excludes all of the `port-data` bytes from the hash key.
`port-data`	M Series, MX Series, T Series	Include the source and destination port field information. By default, the most significant byte and least significant byte of the source and destination port fields are used in the hash key. To select specific bytes to use in the hash key, include one or more of the `source-msb`, `source-lsb`, `destination-msb`, and `destination-lsb` options at the `[edit forwarding-options hash-key family mpls payload ip port-data]` hierarchy level. To prevent all four bytes from being hashed, include the `layer-3-only` statement at the `[edit forwarding-options hash-key family mpls payload ip]` hierarchy level.

Table 7: MPLS LSP Load Balancing Options *(Continued)*

Statement	Supported Platforms	MPLS LSP Load Balancing Options
`destination-lsb`	M Series, MX Series, T Series	Include the least significant byte of the destination port in the hash key. Can be combined with any of the other `port-data` options.
`destination-msb`	M Series, MX Series, T Series	Include the most significant byte of the destination port in the hash key. Can be combined with any of the other `port-data` options.
`source-lsb`	M Series, MX Series, T Series	Include the least significant byte of the source port in the hash key. Can be combined with any of the other `port-data` options.
`source-msb`	M Series, MX Series, T Series	Include the most significant byte of the source port in the hash key. Can be combined with any of the other `port-data` options.

The following examples illustrate ways in which you can configure MPLS LSP load balancing:

- To include the IP address as well as the first label in the hash key:
  - For M Series, MX Series, and T Series routers, configure the `label-1` statement and the `ip` option for the `payload` statement at the `[edit forwarding-options hash-key family mpls]` hierarchy level:

```
[edit forwarding-options hash-key family mpls]
label-1;
payload {
    ip;
}
```

  - For PTX Series Packet Transport Routers, the `all-labels` and `ip payload` options are configured by default, so no configuration is necessary.

- (M320 and T Series routers only) To include the IP address as well as both the first and second labels in the hash key, configure the `label-1` and `label-2` options and the `ip` option for the `payload` statement at the `[edit forwarding-options hash-key family mpls]` hierarchy level:

```
[edit forwarding-options hash-key family mpls]
label-1;
label-2;
payload {
    ip;
}
```

> **NOTE**: You can include this combination of statements on M320 and T Series routers only. If you include them on an M Series Multiservice Edge Router, only the first MPLS label and the IP payload are used in the hash key.

- For T Series routers, ensure proper load balancing by including the `label-1`, `label-2`, and `label-3` options at the `[edit forwarding-options hash-key family mpls]` hierarchy level:

```
[edit forwarding-options hash-key family mpls]
label-1;
label-2;
label-3;
```

- (M Series, MX Series, and T Series routers only) For Layer 2 VPNs, the router could encounter a packet reordering problem. When a burst of traffic pushes the customer traffic bandwidth to exceed its limits, the traffic might be affected in mid flow. Packets might be reordered as a result. By excluding the EXP bit from the hash key, you can avoid this reordering problem. To exclude the EXP bit of the first label from the hash calculations, include the `no-label-1-exp` statement at the `[edit forwarding-options hash-key family mpls]` hierarchy level:

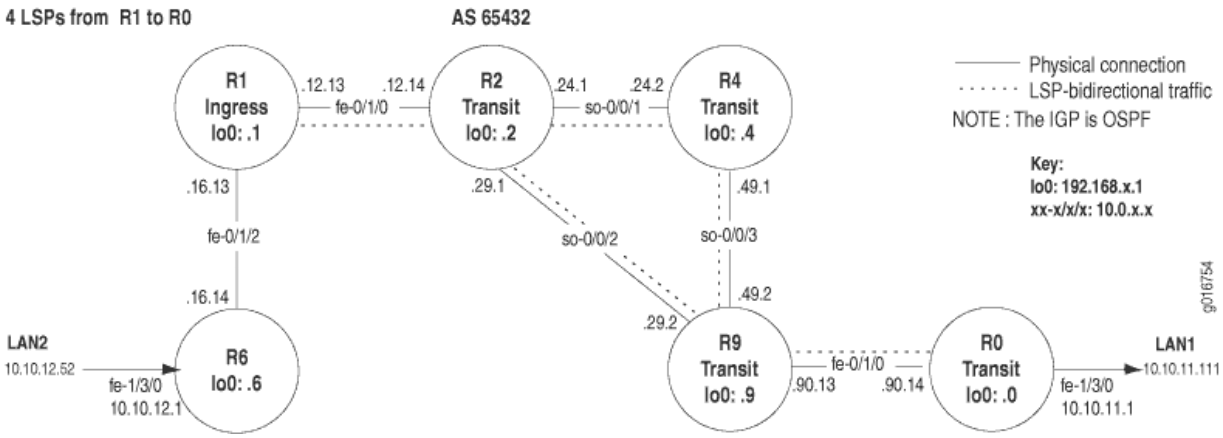
```
[edit forwarding-options hash-key family mpls]
label-1;
no-label-1-exp;
payload {
    ip;
}
```

Example: Load-Balanced MPLS Network

When you configure several RSVP LSPs to the same egress router, the LSP with the lowest metric is selected and carries all traffic. If all of the LSPs have the same metric, one of the LSPs is selected at random and all traffic is forwarded over it. To distribute traffic equally across all LSPs, you can configure load balancing on the ingress or transit routers, depending on the type of load balancing configured.

Figure 10 on page 233 illustrates an MPLS network with four LSPs configured to the same egress router (**R0**). Load balancing is configured on ingress router **R1**. The example network uses Open Shortest Path First (OSPF) as the interior gateway protocol (IGP) with OSPF area **0.0.0.0**. An IGP is required for the Constrained Shortest Path First (CSPF) LSP, which is the default for the Junos OS. In addition, the example network uses a policy to create BGP traffic.

Figure 10: Load-Balancing Network Topology



The network shown in Figure 10 on page 233 consists of the following components:

- A full-mesh interior BGP (IBGP) topology, using AS 65432
- MPLS and RSVP enabled on all routers
- A send-statics policy on routers **R1** and **R0** that allows a new route to be advertised into the network
- Four unidirectional LSPs between **R1** and **R0**, and one reverse direction LSP between **R0** and **R1**, which allows for bidirectional traffic
- Load balancing configured on ingress router **R1**

The network shown in Figure 10 on page 233 is a BGP full-mesh network. Since route reflectors and confederations are not used to propagate BGP learned routes, each router must have a BGP session with every other router running BGP.

Router Configurations for the Load-Balanced MPLS Network

IN THIS SECTION

- Purpose | 234
- Action | 234
- Sample Output 1 | 234
- Sample Output 2 | 236
- Sample Output 3 | 239
- Sample Output 4 | 242
- Sample Output 5 | 244
- Sample Output 6 | 246
- Meaning | 248

Purpose

The configurations in this topic are for the six load-balanced routers in the example network illustrated in "Load-Balancing Network Topology" on page 233.

Action

To display the configuration of a router, use the following Junos OS CLI operational mode command:

```
user@host> show configuration | no-more
```

Sample Output 1

The following configuration output is for edge router **R6**.

```
user@R6> show configuration | no-more
[...Output truncated...]
interfaces {
    fe-0/1/2 {
        unit 0 {
            family inet {
```

```
                address 10.0.16.14/30;
            }
             family mpls;  #MPLS enabled on relevant interfaces
        }
    }
    fe-1/3/0 {
        unit 0 {
            family inet {
                address 10.10.12.1/24;
            }
        }
    }
    fxp0 {
        unit 0 {
            family inet {
                address 192.168.70.148/21;
            }
        }
    }
    lo0 {
        unit 0 {
            family inet {
                address 192.168.6.1/32;
            }
        }
    }
}
routing-options {

    }
}
```

Meaning

Sample Outputs 1 through 6 show the base interfaces, routing options, protocols, and policy options configurations for all six routers in the example network illustrated in "Example: Load-Balanced MPLS Network" on page 233.

All routers in the network have MPLS, RSVP, and BGP enabled. OSPF is configured as the IGP, and relevant interfaces have basic IP information and MPLS support.

In addition, all routers have the router ID (RID) configured manually at the `[edit routing-options]` hierarchy level to avoid duplicate RID problems. The `passive` statement is included in the OSPF configuration to ensure that protocols are not run over the loopback (**lo0**) interface and that the loopback (**lo0**) interface is advertised correctly throughout the network.

Sample Outputs 1, 3, 4, and 5 for **R6**, **R2**, **R4**, and **R9** show the base configuration for transit label-switched routers. The base configuration includes all interfaces enabled for MPLS, the RID manually configured, and the relevant protocols (RSVP, MPLS, BGP, and OSPF).

Sample Output 2 from ingress router **R1** shows the base configuration plus four LSPs (**lsp1** through **lsp4**) configured to **R0**. The four LSPs are configured with different primary paths that specify a loose hop through **R4** for **lsp1** and **lsp4**, and through **R2** for **lsp2** and **lsp3**.

To create traffic, **R1** has a static route (**100.100.1.0/24**) configured at the `[edit routing-options static route]` hierarchy level. The prefix is included in the send-statics policy at the `[edit policy-options send statics]` hierarchy level so the routes can become BGP routes.

In addition, on the ingress router **R1**, load balancing is configured using the **per-packet** option, and the policy is exported at the `[edit routing-options forwarding-table]` hierarchy level.

Sample Output 6 from egress router **R0** shows one LSP (**r0-r6**) to **R6** used to create bidirectional traffic. OSPF requires bidirectional LSP reachability before it will advertise the LSP into the IGP. Although the LSP is advertised into the IGP, no hello messages or routing updates occur over the LSP—only user traffic is sent over the LSP. The router uses its local copy of the IGP database to verify bidirectional reachability.

In addition, **R0** has a static route (**100.100.10.0/24**) configured at the `[edit routing-options static route]` hierarchy level. The prefix is included in the send-statics policy at the `[edit policy-options send statics]` hierarchy level so the routes can become BGP routes.

Configuring Load Balancing Based on MPLS Labels on ACX Series Routers

Table 8 on page 251 provides detailed information about all of the possible MPLS LSP load-balancing options.

ACX Series routers can load-balance on a per-packet basis in MPLS. Load balancing can be performed on information in both the IP header and on up to three MPLS labels, providing a more uniform distribution of MPLS traffic to next hops. This feature is enabled on supported platforms by default and requires no configuration.

Load balancing is used to evenly distribute traffic when there is a single next hop over an aggregated interface or a LAG bundle. Load balancing using MPLS labels is supported only for LAG interfaces and not for equal-cost multipath (ECMP) links.

By default, when load balancing is used to help distribute traffic, Junos OS employs a hash algorithm to select a next-hop address to install into the forwarding table. Whenever the set of next hops for a destination changes in any way, the next-hop address is reselected by means of the hash algorithm. You can configure how the hash algorithm is used to load-balance traffic across interfaces in an aggregated Ethernet (ae) interface.

An LSP tends to load-balance its placement by randomly selecting one of the interfaces in an `ae-` interface bundle and using it exclusively. The random selection is made independently at each transit router, which compares Interior Gateway Protocol (IGP) metrics alone. No consideration is given to bandwidth or congestion levels.

To load-balance based on the MPLS label information, configure the `family mpls` statement:

```
[edit forwarding-options hash-key]
family mpls {
```

```
    all-labels;
    label-1;
    label-2;
    label-3;
    no-labels;
    payload {
        ether-pseudowire;
        ip {
            layer-3-only;
            port-data {
                destination-lsb;
                destination-msb;
                source-lsb;
                source-msb;
            }
        }
    }
}
```

You can include this statement at the `[edit forwarding-options hash-key]` hierarchy level.

NOTE: When you configure payload ip (`user@host#` **set forwarding-options hash-key family mpls payload ip**), configuring `layer-3-only` and `port-data` is mandatory.

Load balancing functionality, without proper hash-keys configuration, may result in an unpredictable behavior.

For Layer 2 VPN/pseudowire tunnel termination, upto two labels are used for hashing and payload MAC destination and source addresses can be optionally selected. These controls can be used to support ether-pseudowire knob in family mpls under hash-key configuration shown above. However, since ACX2000 and ACX4000 also support TDM pseudowires, the ether-pseudowire knobs needs to be used only when TDM pseudowires are not being used.

For Layer 3 VPN tunnel termination, upto two labels are used for hasing and payload IP source and destination addresses and Layer 4 source and destination ports can be optionally selected. These controls can be used for supporting ip port-data knobs in family mpls under hash-key configuration shown above. However, since Layer 4 port MSB and LSB cannot be individually selected, one of destination-lsb or destination-msb knobs or one of source-lsb or source-msb knobs would select Layer 4 destination or source ports, respectively.

For LSR case, upto three labels are used for hashing. If a BOS is seen when parsing the first three labels, BCM examines the first nibble of payload - if the nibble is 4, the payload is treated as IPv4 and if the first nibble is 6, the payload is treated as IPv6 and in such cases payload source and destination IP

addresses can be speculatively used for hashing. These controls can be used for supporting ip port-data knobs in family mpls under hash-key configuration. However, Layer 4 ports cannot be used for hashing in LSR case, and only layer-3-only knob is applicable. BCM does not claim support for hashing on fields beyond the three MPLS labels. Load Balancing for a single pseudowire session does not take place in case of LSR as all the traffic specific to that session will carry the same set of MPLS labels.

Load balancing on LSR AE interfaces can be achieved for a higher number of MPLS sessions, that is minimum of 10 sessions. This is applicable for CCC/VPLS/L3VPN. In case of Layer 3 VPN, the traffic may not be equally distributed across the member links as the layer 3 addresses also get accounted for (along with the labels) for the hash input function.

For LER scenarios, in case of ACX5048 and ACX5096, hashing based on Layer 3 and Layer 4 fields is possible by configuring the payload option under the “family mpls” hierarchy. Hashing on the LER is not be based on Labels. For Layer 3 service, it is mandatory to mention the payload as “layer-3-only” and specify “port-data” in case of Layer 4 service. You can also mention the label count while configuring hash-keys on LER routers.

NOTE: LER and LSR load balancing behavior is applicable for CCC/VPLS/Layer 3 VPN and other IP MPLS scenarios.

This feature applies to aggregated Ethernet and aggregated SONET/SDH interfaces. In addition, you can configure load balancing for IPv4 traffic over Layer 2 Ethernet pseudowires. You can also configure load balancing for Ethernet pseudowires based on IP information. The option to include IP information in the hash key provides support for Ethernet circuit cross-connect (CCC) connections.

Table 8: MPLS LSP Load Balancing Options

Statement	MPLS LSP Load Balancing Options
`label-1`	Include the first label in the hash key. Use this option for single label packets.
`label-2`	Include the second label in the hash key. You must also configure the `label-1` option. The entire first label and the first 16 bits of the second label are used in the hash key.
`label-3`	Include the third label in the hash key. You must also configure the `label-1` option and the `label-2` option.
`no-labels`	Excludes MPLS labels from the hash key.

Table 8: MPLS LSP Load Balancing Options *(Continued)*

Statement	MPLS LSP Load Balancing Options
payload	Allows you to configure which parts of the IP packet payload to include in the hash key. For the PTX Series Packet Transport Switch, this value is set by default.
disable	Exclude IP payload from the hash key.
ether-pseudowire	Load-balance IPv4 traffic over Layer 2 Ethernet pseudowires.
ip	Include the IPv4 or IPv6 address in the hash key. You must also configure either label-l or no-labels.
layer-3-only	Include only the Layer 3 IP information in the hash key. Excludes all of the port-data bytes from the hash key.
port-data	Include the source and destination port field information. By default, the most significant byte and least significant byte of the source and destination port fields are used in the hash key. To select specific bytes to use in the hash key, include one or more of the source-msb, source-lsb, destination-msb, and destination-lsb options at the [edit forwarding-options hash-key family mpls payload ip port-data] hierarchy level. To prevent all four bytes from being hashed, include the layer-3-only statement at the [edit forwarding-options hash-key family mpls payload ip] hierarchy level.
destination-lsb	Include the least significant byte of the destination port in the hash key. Can be combined with any of the other port-data options.
destination-msb	Include the most significant byte of the destination port in the hash key. Can be combined with any of the other port-data options.
source-lsb	Include the least significant byte of the source port in the hash key. Can be combined with any of the other port-data options.
source-msb	Include the most significant byte of the source port in the hash key. Can be combined with any of the other port-data options.

To include the IP address as well as the first label in the hash key, configure the `label-1` statement and the `ip` option for the `payload` statement at the `[edit forwarding-options hash-key family mpls]` hierarchy level:

```
[edit forwarding-options hash-key family mpls]
label-1;
payload {
    ip;
}
```

To include the IP address as well as both the first and second labels in the hash key, configure the `label-1` and `label-2` options and the `ip` option for the `payload` statement at the `[edit forwarding-options hash-key family mpls]` hierarchy level:

```
[edit forwarding-options hash-key family mpls]
label-1;
label-2;
payload {
    ip;
}
```

Ensure proper load balancing by including the `label-1`, `label-2`, and `label-3` options at the `[edit forwarding-options hash-key family mpls]` hierarchy level:

```
[edit forwarding-options hash-key family mpls]
label-1;
label-2;
label-3;
```

MPLS Encapsulated Payload Load-balancing Overview

Routers can load-balance on a per-packet basis in MPLS. Load balancing can be performed on the information in both the IP header and on up to three MPLS labels, providing a more uniform distribution of MPLS traffic to next hops.

Load balancing is used to evenly distribute traffic when the following conditions apply:

- There are multiple equal-cost next hops over different interfaces to the same destination.
- There is a single next hop over an aggregated interface.

By default, when load balancing is used to help distribute traffic, a hash algorithm is used to select a next-hop address to install into the forwarding table. Whenever the set of next hops for a destination changes in any way, the next-hop address is reselected by means of the hash algorithm.

In case of multiple transport layer networks such as Ethernet over MPLS or Ethernet pseudowire, the hash algorithm needs to look beyond the outer header of the payload and into the inner headers to generate an even distribution. To determine the inner encapsulation, the PFE relies on the presence of certain codes or numbers at fixed payload offets; for example the presence of payload type 0X800 or the presence of protocol number 4 for an IPv4 packet. In Junos OS, you can configure `zero-control-word` option to indicate the start of an Ethernet frame in an MPLS ether-pseudowire payload. On seeing this control word, which is four bytes having a numerical value of all zeros, the hash generator assumes the start of an Ethernet frame at the end of the control word in an MPLS ether-pseudowire packet.

NOTE: For DPC I-chip-based cards, configure the `zero-control-word` option at the `[edit forwarding-options hash-key family mpls ether-pseudowire]` hierarchy level; and for MPC cards, configure the `zero-control-word` option at the `[edit forwarding-options enhanced-hash-key family mpls ether-pseudowire]` hierarchy level.

Configuring MPLS Encapsulated Payload for Load Balancing

By default, when load balancing is used to help distribute traffic, a hash algorithm is used to select a next-hop address to install into the forwarding table. Whenever the set of next hops for a destination changes in any way, the next-hop address is reselected by means of the hash algorithm. Configure the `zero-control-word` option to indicate the start of an Ethernet frame in an MPLS ether-pseudowire payload. On seeing this control word, four bytes having a numerical value of all zeros, the hash generator assumes the start of the Ethernet frame at the end of the control word in an MPLS ether-pseudowire packet.

Before you begin to configure MPLS encapsulated payload for load balancing, configure routing and signaling protocols.

To configure MPLS encapsulated payload for load balancing:

Configure the `zero-control-word` option to indicate the start of an Ethernet frame in an MPLS ether-pseudowire payload.

- For DPC I-chip-based cards, configure the `zero-control-word` option at the `[edit forwarding-options hash-key family mpls ether-pseudowire]` hierarchy level.

```
[edit forwarding-options hash-key family mpls ether-pseudowire]
user@host# set zero-control-word
```

- For MPC cards, configure the `zero-control-word` option at the `[edit forwarding-options enhanced-hash-key family mpls ether-pseudowire]` hierarchy level.

```
[edit forwarding-options enhanced-hash-key family mpls ether-pseudowire]
user@host# set zero-control-word
```

Policy-Based Multipath Routes Overview

Segment routing networks can have multiple transport protocols in the core. You can combine segment routing SR-TE LDP or RSVP routes and SR-TE IP routes and install a multipath route in the routing information base (also known as routing table). You can then steer selective service traffic using the mutlipath route through policy configuration.

Understanding Policy-Based Multipath Routes

There are different transport protocols in a network, such as IGP, labelled IGP, RSVP, LDP, and segment routing traffic-engineering (SR-TE) protocols, that are used to resolve service traffic. However, you could not use a combination of the transport protocols to resolve the service traffic. With the introduction of the policy-based multipath feature, you can combine segment routing traffic-engineered (SR-TE) LDP or RSVP routes and SR-TE IP routes to create a multipath route that is installed in the routing information base. You can resolve BGP service routes over the mutlipath route through policy configuration and steer traffic differently for different prefixes.

A multipath route has combined next hops of route entries that are used for load balancing. All the supporting routes of the multipath route entry must be in same routing information base. When the supporting routes are under different routing information base, you can use the `rib-group` configuration statement to add route entries to a particular routing information base.

You can configure a multipath route using a policy to select the list of routes whose next hops is to be combined together. When you include the `policy-multipath` statement along with the `policy` statement at the `[edit routing-options rib routing-table-name]` hierarchy level, a policy-based multipath route is created.

The policy-based multipath feature is supported for both IP and IPv6 protocols, and can be configured under the `[edit routing-instances]` hierarchy level.

For example:

```
[edit routing-options]
user@host# set rib inet.3 policy-multipath policy example-policy

[edit policy-options]
user@host# set policy-statement example-policy from example-conditions
user@host# set policy-options policy-statement example-policy then accept
```

The configured policy is applied to each route entry for a given prefix. The multipath route is created only when more than one route (including active route) passes the policy. Any action commands configured in the policy, such as apply, is evaluated using the active route. For non-active routes, the policy is applied to check if the routes can participate in the multipath route or not. Multipath routes inherit all attributes of the active route. These attributes can be modified using the multipath policy configuration.

Benefits of Policy-Based Multipath Routes

- Provides flexibility to combine core network protocols to steer selective traffic.
- Optimizes network performance with weighted equal-cost multipath using multipath routes.

Policy-Based Multipath Routes for Route Resolution

You can combine segment routing traffic-engineered (SR-TE) LDP or RSVP routes and SR-TE IP routes and install a multipath route in the routing information base. The policy-based multipath routes are not active entries in the routing information base. When a multipath route is generated by configuration of policy, it is used for resolving protocol next hops instead of active routes. A multipath route next hop is created by merging gateways of next hops of each constituent route.

Take the following into consideration when configuring policy-based multipath routes for route resolution:

- If the member route of a multipath route points to a next hop other than the router next hop or an indirect next hop with forwarding next hop to the router next hop, such next hops are ignored.

- If the constituent routes point to indirect next hop, then gateways from the forwarding-next hop are merged and the indirect next hop is ignored.
- If total number of gateways exceeds the `maximum-ecmp` supported on the device, then only the `maximum-ecmp` gateways are retained and all other gateways are ignored.
- Gateways with lower weights are given preference. When one of the member route has unilist of indirect next hops and each of the next hop is pointing to a forwarding next hop, there can be weight values both at the indirect next hop and at forwarding next hop. In such cases, weight value of gateways is updated to reflect the combined effect of weights at both levels.

Sample Route Resolution Using Policy-Based Multipath Routes

Taking as an example, let us assume there are segment routing traffic-engineered LSPs, label IS-IS routes, and LDP LSPs for a destination 1.1.1.1/32, as displayed in the output below:

```
1.1.1.1/32         *[SPRING-TE/8] 00:00:58, metric 1, metric2 30
                    > to 13.1.1.2 via ge-0/0/1.1, Push 33333, Push 801005, Push 801006(top)
                    [L-ISIS/14] 1w0d 00:15:57, metric 10
                    > to 12.1.1.1 via ge-0/0/0.1
                      to 12.22.1.1 via ge-0/0/0.2
                      to 12.23.1.1 via ge-0/0/0.3
                      to 12.24.1.1 via ge-0/0/0.4
                      to 12.25.1.1 via ge-0/0/0.5
                      to 13.1.1.2 via ge-0/0/1.1, Push 801001, Push 801005(top)
                    [LDP/19] 1w0d 00:09:27, metric 1
                    > to 12.1.1.1 via ge-0/0/0.1
                      to 12.22.1.1 via ge-0/0/0.2
                      to 12.23.1.1 via ge-0/0/0.3
                      to 12.24.1.1 via ge-0/0/0.4
                      to 12.25.1.1 via ge-0/0/0.5
                      to 13.1.1.2 via ge-0/0/1.1, Push 801001, Push 801005(top)
```

Here, segment routing LSP is the active route entry to the 1.1.1.1 destination, and by default, only this route is used to resolve any services resolving over 1.1.1.1.

When there is a requirement to use more than one protocols for resolving service routes, you can achieve this by configuring "policy-multipath" on page 2642 to combine the protocols. For instance, if segment routing and LDP paths are required for service resolution, you must configure `policy-multipath` combining the segement routing and LDP routes for prefix 1.1.1.1.

For example:

```
[edit policy-options]
user@host# set rib inet.3 policy-multipath policy example-policy
user@host# set policy-statement abc term 1 from protocol spring-te
user@host# set policy-statement abc term 1 from protocol ldp
user@host# set policy-statement abc term 1 from route-filter 1.1.1.1/32 exact
user@host# set policy-statement abc term 1 then accept
```

With this configuration, you create a policy-based multipath route for prefix 1.1.1.1/32 that uses constituent route entries of segment routing and LDP protocols.

You can view the multipath route using the `show route` command output, as follows:

```
1.1.1.1/32         *[SPRING-TE/8] 00:10:28, metric 1, metric2 30
                    > to 13.1.1.2 via ge-0/0/1.1, Push 33333, Push 801005, Push 801006(top)
                    [L-ISIS/14] 1w0d 00:25:27, metric 10
                    > to 12.1.1.1 via ge-0/0/0.1
                      to 12.22.1.1 via ge-0/0/0.2
                      to 12.23.1.1 via ge-0/0/0.3
                      to 12.24.1.1 via ge-0/0/0.4
                      to 12.25.1.1 via ge-0/0/0.5
                      to 13.1.1.2 via ge-0/0/1.1, Push 801001, Push 801005(top)
                    [LDP/19] 1w0d 00:18:57, metric 1
                    > to 12.1.1.1 via ge-0/0/0.1
                      to 12.22.1.1 via ge-0/0/0.2
                      to 12.23.1.1 via ge-0/0/0.3
                      to 12.24.1.1 via ge-0/0/0.4
                      to 12.25.1.1 via ge-0/0/0.5
                      to 13.1.1.2 via ge-0/0/1.1, Push 801001, Push 801005(top)
                    [Multipath/8] 00:03:13, metric 1, metric2 30
                    > to 12.1.1.1 via ge-0/0/0.1
                      to 12.22.1.1 via ge-0/0/0.2
                      to 12.23.1.1 via ge-0/0/0.3
                      to 12.24.1.1 via ge-0/0/0.4
                      to 12.25.1.1 via ge-0/0/0.5
                      to 13.1.1.2 via ge-0/0/1.1, Push 33333, Push 801005, Push 801006(top)
                      to 13.1.1.2 via ge-0/0/1.1, Push 801001, Push 801005(top)
```

You can see form the command output that the multipath route combines next hops of segment routing and LDP paths. The multipath route it is not active, and by default, the route preference and metric is the same as that of active route.

NOTE: You can use the following combinations for the poilcy-based multipath route: However we cannot create multipath of LDP/L-ISIS as active-route is not part of multipath.

- Segment routing traffic-engineered LSPs and LDP LSPs.
- Segment routing traffic-engineered LSPs, and label IS-IS paths.
- Segment routing traffic-engineered LSPs, LDP LSPs, and label IS-IS paths.

However, you cannot create multipath route of LDP and label IS-IS, as the active route is not part of the multipath route.

With the same configuration, assuming that there is a static route 1.2.3.4/32 configured with a protocol next hop of 1.1.1.1, this route is resolved using the multipath route over both segment routing traffic-engineered LSPs and LDP LSPs.

For example:

```
1.2.3.4/32         *[Static/5] 00:00:12, metric2 1
                      to 12.1.1.1 via ge-0/0/0.1
                    > to 12.22.1.1 via ge-0/0/0.2
                      to 12.23.1.1 via ge-0/0/0.3
                      to 12.24.1.1 via ge-0/0/0.4
                      to 12.25.1.1 via ge-0/0/0.5
                      to 13.1.1.2 via ge-0/0/1.1, Push 33333, Push 801005, Push 801006(top)
                      to 13.1.1.2 via ge-0/0/1.1, Push 801001, Push 801005(top)
```

Enhancement to Class-of-Service (CoS) Forwarding-Policy

For class-of-service-based forwarding, you must use the `forwarding-policy next-hop-map` configuration statement.

Prior to Junos OS Release 19.1R1, the match conditions supported under class-of-service-based forwarding included:

- **next-hop**—Match next hop based on outgoing interface or next hop address.
- **lsp-next-hop**—Match named LSPs using regular expression of LSP name.
- **non-lsp-next-hop**—Match all LSPs without an LSP name.

With the policy-based multipath route feature, you can also match all next hops without a label for certain prefixes. To do this, you must enable the `non-labelled-next-hop` option at the `[edit class-of-service forwarding-policy next-hop-map` *`map-name`* `forwarding-class` *`forwarding-class-name`* hierarchy level.

For example:

```
[edit]
class-of-service {
    forwarding-policy {
        next-hop-map abc {
            forwarding-class best-effort {
                                non-labelled-next-hop;
            }
        }
    }
}
```

Enhancements to Policy Match Protocol

Prior to Junos OS Release 19.1R1, when you used a policy to match protocol using the `from protocol` statement at the `[edit policy-options policy-statement` *`statement-name`*`]` hierarchy level, all protocol routes (labeled and unlabeled) were matched. With the policy-based multipath route feature, you can match labeled protocol routes specifically.

The options for matching labeled protocols) are:

- **l-isis**—Match labeled IS-IS routes. The `isis` option matches IS-IS routes, excluding label IS-IS routes.
- **l-ospf**—Match labled OSPF routes. The `ospf` option matches all OSPF routes, including OSPFv2, OSPFv3 and label OSPF.

For example:

```
[edit]
policy-options {
    policy-statement abc {
        from protocol [ l-ospf l-isis ];
    }
}
```

Impact of Configuring Policy-Based Multipath Route on Network Performance

When you configure policy-based multipath route, a change of route in the routing information base results in the evaluation of the policy to check if a multipath route needs to be created. Because this feature requires that member routes must be in the same routing information base, the `rib-group` statement is used to merge routes from different routing information base. Configuring the `rib-group` statement at the application level increases number of routes in the system.

When there are a number of routes in the routing information base, constant change of routes leads to reevaluation of the multipath policy. This could impact network performance. It is recommended to configure the policy-based multipath route feature only when required.

Understanding IP-Based Filtering and Selective Port Mirroring of MPLS Traffic

IN THIS SECTION

- IP-Based Filtering of MPLS Traffic | **261**
- Selective Port Mirroring of MPLS Traffic | **262**
- Sample Configurations | **263**

In an MPLS packet, the IP header comes immediately after the MPLS header. The IP-based filtering feature provides a deep inspection mechanism, where a maximum of upto eight MPLS labels of the inner payload can be inspected to enable filtering of MPLS traffic based on IP parameters. The filtered MPLS traffic can also be port mirrored to a monitoring device to offer network-based services in the core MPLS network.

IP-Based Filtering of MPLS Traffic

Prior to Junos OS Release 18.4R1, filtering based on IP parameters was not supported for MPLS family filter. With the introduction of the IP-based filtering feature, you can apply inbound and outbound filters for MPLS-tagged IPv4 and IPv6 packets based on IP parameters, such as source and destination addresses, Layer 4 protocol type, and source and destination ports.

The IP-based filtering feature enables you to filter MPLS packets at the ingress of an interface, where the filtering is done using match conditions on the inner payload of the MPLS packet. The selective MPLS traffic can then be port mirrored to a remote monitoring device using logical tunnels.

To support IP-based filtering, additional match conditions are added that allow MPLS packets to be deep inspected to parse the inner payload with Layer 3 and Layer 4 headers before the appropriate filters are applied.

NOTE: The IP-based filtering feature is supported only for MPLS-tagged IPv4 and IPv6 packets. In other words, the MPLS filters match IP parameters only when the IP payload comes immediately after the MPLS labels.

In other scenarios, where the MPLS payload includes pseudowires, protocols other than inet and inet6, or other encapsulations like Layer 2 VPN or VPLS, the IP-based filtering feature is not supported.

The following match conditions are added for the IP-based filtering of MPLS traffic:

- IPv4 source address
- IPv4 destination address
- IPv6 source address
- IPv6 destination address
- Protocol
- Source port
- Destination port
- Source IPv4 prefix list
- Destination IPv4 prefix list
- Source IPv6 prefix list
- Destination IPv6 prefix list

NOTE: The following match combinations are supported for the IP-based filtering of MPLS traffic:

- Source and destination address match conditions with IPv4 and IPv6 prefix lists.
- Source and destination port address and protocol types match conditions with IPv4 and IPv6 prefix lists.

Selective Port Mirroring of MPLS Traffic

Port mirroring is the capability of mirroring a packet to a configured destination, in addition to the normal processing and forwarding of the packets. Port mirroring is applied as an action for a firewall

filter, which is applied at the ingress or egress of any interface. Similarly, the selective port mirroring feature provides the capability to mirror MPLS traffic, which is filtered based on IP parameters, to a mirrored destination using logical tunnels.

To enable selective port mirroring, additional actions are configured at the `[edit firewall family mpls filter filter-name term term-name then]` hierarchy level, in addition to the existing `counter`, `accept`, and `discard` actions:

- `port-mirror`
- `port-mirror-instance`

Port Mirroring

The `port-mirror` action enables port mirroring globally on the device, which applies to all Packet Forwarding Engines (PFEs) and associated interfaces.

For MPLS family filter, the `port-mirror` action is enabled for global port mirroring.

Port Mirroring Instance

The `port-mirror-instance` action enables you to customize each instance with different properties for input sampling and port mirroring output destinations, instead of having to use a single system-wide configuration for port mirroring.

You can configure only two port mirroring instances per Flexible PIC Concentrator (FPC) by including the `instance port-mirror-instance-name` statement at the `[edit forwarding-options port-mirror]` hierarchy level. You can then associate individual port mirroring instances with an FPC, PIC, or (Forwarding Engine Board (FEB) depending on the device hardware.

For MPLS family filter, the `port-mirror-instance` action is enabled only for the port-mirroring instance.

NOTE: For both `port-mirror` and `port-mirror-instance` actions, the output interface must be enabled with Layer 2 family and not family MPLS (Layer 3) for the selective port mirroring feature to work.

Sample Configurations

IP-Based Filtering Configuration

```
[edit firewall family mpls filter mpls-filter]
term ipv4-term {
    from {
        ip-version {
```

```
            ipv4 {
                source-address {
                    10.10.10.10/24;
                }
                destination-address {
                    20.20.20.20/24;
                }
                protocol tcp {
                    source-port 100;
                    destination-port 200;
                }
                soure-prefix-list ipv4-source-users;
                destination-prefix-list ipv4-destination-users;
            }
        }
        exp 1;
        }
        then port-mirror;
        then accept;
    then count;
}
term ipv6-term {
    from {
        ip-version {
            ipv6 {
                source-address {
                    2000::1/128;
                }
                destination-address {
                    3000::1/128;
                }
                protocol tcp {
                    source-port 100;
                    destination-port 200;
                }
                source-prefix-list ipv6-source-users;
                destination-prefix-list ipv6-destination-users;
            }
        }
        exp 1;
    }
    then port-mirror-instance port-mirror-instance1;
    then accept;
```

```
    then count;
}
```

```
[edit policy-options]
prefix-list ipv4-source-users {
    172.16.1.16/28;
    172.16.2.16/28;
}
prefix-list ipv6-source-users {
    2001::1/128;
    3001::1/128;
}
```

```
[edit interfaces]
xe-0/0/1 {
    unit 0 {
        family inet {
            address 100.100.100.1/30;
        }
        family mpls {
            filter {
                input mpls-filter;
            }
        }
    }
}
```

Selective Port Mirroring Configuration

```
[edit forwarding-options]
port-mirroring {
    input {
        rate 2;
        run-length 4;
        maximum-packet-length 500;
    }
    family any {
        output {
```

```
            interface xe-2/0/2.0;
        }
    }
}
```

```
[edit forwarding-options]
port-mirroring {
    instance {
        port-mirror-instance1 {
            input {
                rate 3;
                run-length 5;
                maximum-packet-length 500;
            }
            family any {
                output {
                    interface xe-2/0/2.0;
                }
            }
        }
    }
}
```

NOTE: The output interface `xe-2/0/2.0` is configured for Layer 2 family and not family MPLS. For both `port-mirror` and `port-mirror-instance` actions, the output interface must be enabled with Layer 2 family and not family MPLS (Layer 3) for the selective port mirroring feature to work.

Mirrored Destination Configuration

```
[edit interfaces]
xe-2/0/2 {
    vlan-tagging;
    encapsulation extended-vlan-bridge;
    unit 0 {
        vlan-id 600;
```

```
    }
}
```

```
[edit bridge-domains]
bd {
    domain-type bridge;
    interface xe-2/0/2.0;
}
```

Release History Table

Release	Description
19.1R1	Starting in Junos OS Release 19.1R1, for MX Series routers with MPC and MIC interfaces, up to sixteen incoming MPLS labels are included in the hash key.

SRLG Overview

In MPLS traffic engineering, a Shared Risk Link Group (SRLG) is a set of links sharing a common resource, which affects all links in the set if the common resource fails. These links share the same risk of failure

and are therefore considered to belong to the same SRLG. For example, links sharing a common fiber are said to be in the same SRLG because a fault with the fiber might cause all links in the group to fail.

An SRLG is represented by a 32-bit number unique within an IGP (OSPFv2 and IS-IS) domain. A link might belong to multiple SRLGs. The SRLG of a path in a label-switched path (LSP) is the set of SRLGs for all the links in the path. When computing the secondary path for an LSP, it is preferable to find a path such that the secondary and primary paths do not have any links in common in case the SRLGs for the primary and secondary paths are disjoint. This ensures that a single point of failure on a particular link does not bring down both the primary and secondary paths in the LSP.

When the SRLG is configured, the device uses the Constrained Shortest Path First (CSPF) algorithm and tries to keep the links used for the primary and secondary paths mutually exclusive. If the primary path goes down, the CSPF algorithm computes the secondary path by trying to avoid links that share any SRLG with the primary path. In addition, when computing the path for a bypass LSP, CSPF tries to avoid links that share any SRLG with the protected links.

When the SRLG is not configured, CSPF only takes into account the costs of the links when computing the secondary path.

Any change in link SRLG information triggers the IGP to send LSP updates for the new link SRLG information. CSPF recomputes the paths during the next round of reoptimization.

Junos OS Release 11.4 and later supports SRLG based on the following RFCs:

- RFC 4203, *OSPF Extensions in Support of Generalized Multi-Protocol Label Switching (GMPLS)*.
- RFC 5307, *IS-IS Extensions in Support of Generalized Multi-Protocol Label Switching (GMPLS)*.

NOTE: Currently, the “Fate Sharing” feature continues to be supported with the SRLG feature.

Example: Configuring SRLG

IN THIS SECTION

- Requirements | **269**
- Overview | **269**
- Configuration | **270**
- Verification | **278**

This example shows how to configure Shared Risk Link Groups (SRLGs) on a device.

Requirements

This example uses the following hardware and software components:

- Seven routers that can be a combination of M Series, MX Series, or T Series routers
- Junos OS Release 11.4 or later running on all the devices

Overview

IN THIS SECTION

Topology | 270

Junos OS Release 11.4 and later support SRLG configuration in an IGP (OSPFv2 and IS-IS) domain. In this example, you configure SRLG and associate it with the MPLS interface on a device.

The device uses the SRLG cost parameter for the Constrained Shortest Path First (CSPF) algorithm and tries to keep the links used for the primary and secondary paths mutually exclusive by avoiding links that share any SRLG with the primary path.

To configure the SRLG, you first define the SRLG parameters at the `[edit routing-options srlg srlg-name]` hierarchy level and then associate the SRLG with an MPLS interface at the `[edit mpls interface interface-name]` hierarchy level.

The `srlg srlg-name` statement has the following options:

- `srlg-cost`—Include a cost for the SRLG ranging from 1 through 65535. The cost of the SRLG determines the level of impact this SRLG has on the CSPF algorithm for path computations. The higher the cost, the less likely it is for a secondary path to share the same SRLG as the primary path. By default, the `srlg-cost` is 1.
- `srlg-value`—Include a group ID for the SRLG ranging from 1 through 4294967295.

In this example:

- PE1 is the ingress router and PE2 is the egress router.
- P1, P2, and P3, P4, and P5 are transit routers.
  - P1 has direct primary path connections to both the PE1 ingress and PE2 egress routers.
  - P2 has direct secondary path connections to PE1 and PE2.

- P3 has a direct secondary path connection to PE1, and an indirect secondary path through P4 and P5 to PE2.
- P4 has indirect secondary paths to PE1 through P3 and to PE2 through P5.
- P5 has an indirect path through P4 and P3 to PE1 and a direct secondary path to PE2.

OSPF is configured on all the routers as the interior gateway protocol (IGP). SRLG is configured on all seven routers. The primary path includes SRLG `srlg-a`. For the standby secondary path, the link P2>PE2 belongs to SRLG `srlg-a`. The effective link metric, with the added `srlg-cost` of 10, becomes 11. Therefore, the computed secondary path is PE1>P3>P4>P5>PE2 with a CSPF link metric of 4.

set protocols rsvp interface ge-0/0/3.0
set protocols mpls interface ge-0/0/1.0
set protocols mpls interface ge-0/0/2.0
set protocols mpls interface ge-0/0/3.0
set protocols ospf traffic-engineering
set protocols ospf area 0.0.0.0 interface ge-0/0/1.0
set protocols ospf area 0.0.0.0 interface ge-0/0/2.0
set protocols ospf area 0.0.0.0 interface ge-0/0/3.0
set protocols ospf area 0.0.0.0 interface lo0.0
```

Procedure

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the Junos OS CLI User Guide.

To configure the ingress router PE1:

1. Configure the device interfaces.

```
[edit interfaces]
user@PE1# set ge-0/0/1 unit 0 family inet address 192.168.12.1/24
user@PE1# set ge-0/0/1 unit 0 family mpls
user@PE1# set ge-0/0/2 unit 0 family inet address 192.168.13.1/24
user@PE1# set ge-0/0/2 unit 0 family mpls
user@PE1# set ge-0/0/3 unit 0 family inet address 192.168.14.1/24
user@PE1# set ge-0/0/3 unit 0 family mpls
user@PE1# set lo0 unit 0 family inet address 10.255.0.1/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@PE1# set traffic-engineering
user@PE1# set area 0.0.0.0 interface ge-0/0/1.0
user@PE1# set area 0.0.0.0 interface ge-0/0/2.0
user@PE1# set area 0.0.0.0 interface ge-0/0/3.0
user@PE1# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@PE1# set srlg srlg-a srlg-value 101
user@PE1# set srlg srlg-a srlg-cost 10
```

4. Configure MPLS and the LSPs.

```
[edit protocols mpls]
user@PE1# set interface ge-0/0/1.0
user@PE1# set interface ge-0/0/2.0
user@PE1# set interface ge-0/0/3.0
user@PE1# set optimize-timer 120
user@PE1# set label-switched-path pe1-pe2 to 10.255.0.7
user@PE1# set label-switched-path pe1-pe2 primary via-p1
user@PE1# set label-switched-path pe1-pe2 secondary path2 standby
user@PE1# set path via-p1 10.255.0.2 strict
user@PE1# set path path2
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@PE1# set interface ge-0/0/1.0
user@PE1# set interface ge-0/0/2.0
user@PE1# set interface ge-0/0/3.0
```

Results

From configuration mode, confirm your configuration by entering the `show interfaces`, `show protocols ospf`, `show routing-options`, `show protocols mpls`, and `show protocols rsvp` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1# show interfaces
interfaces {
    ge-0/0/1 {
        unit 0 {
            family inet {
                address 192.168.12.1/24;
            }
            family mpls;
        }
    }
    ge-0/0/2 {
        unit 0 {
            family inet {
                address 192.168.13.1/24;
            }
            family mpls;
        }
    }
    ge-0/0/3 {
        unit 0 {
            family inet {
                address 192.168.14.1/24;
            }
            family mpls;
        }
    }
    lo0 {
```

```
        unit 0 {
            family inet {
                address 10.255.0.1/32;
            }
        }
    }
}
```

```
user@PE1# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
    interface ge-0/0/1.0;;
    interface ge-0/0/2.0;
    interface ge-0/0/3.0;
    interface lo0.0;
}
```

```
user@PE1# show protocols mpls
optimize-timer 120;
label-switched-path pe1-pe2 {
    to 10.255.0.7;
    primary via-p1;
    secondary path2 {
        standby;
    }
}
path via-p1 {
    10.255.0.2 strict;
}
path path2;
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;
```

```
user@PE1# show protocols rsvp
interface ge-0/0/1.0;
```

```
interface ge-0/0/2.0;
interface ge-0/0/3.0;
```

```
user@PE1# show routing-options
routing-options {
    srlg {
        srlg-a {
            srlg-value 101;
            srlg-cost 10;
        }
    }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

NOTE: Repeat this procedure for every Juniper Networks router in the IGP domain, after modifying the appropriate interface names, addresses, and any other parameters for each router.

Verification

IN THIS SECTION

- Verifying SRLG Definitions | **278**
- Verify TE-Link SRLG | **279**
- Verify Standby Secondary Path | **280**

Confirm that the configuration is working properly.

Verifying SRLG Definitions

Purpose

Verify SRLG-to-value mappings and SRLG cost.

Action

```
user@PE1> show mpls srlg

SRLG             Value      Cost
srlg-a             101        10
```

Verify TE-Link SRLG

Purpose

Verify the traffic engineering link SRLG association.

Action

```
user@PE1> show ted link detail
...
10.255.0.2->192.168.27.7-1, Local: 192.168.27.2, Remote: 0.0.0.0
  Local interface index: 0, Remote interface index: 0
  LocalPath: 1, Metric: 1, StaticBW: 1000Mbps, AvailBW: 1000Mbps
      Color: 0 <none>
  SRLGs: srlg-a
  localBW [0] 0bps  [1] 0bps  [2] 0bps  [3] 0bps
  localBW [4] 0bps  [5] 0bps  [6] 0bps  [7] 0bps

...
10.255.0.3->192.168.37.7-1, Local: 192.168.37.3, Remote: 0.0.0.0
  Local interface index: 0, Remote interface index: 0
  LocalPath: 0, Metric: 1, StaticBW: 1000Mbps, AvailBW: 1000Mbps
      Color: 0 <none>
  SRLGs: srlg-a
  localBW [0] 0bps  [1] 0bps  [2] 0bps  [3] 0bps
  localBW [4] 0bps  [5] 0bps  [6] 0bps  [7] 0bps

...
```

Meaning

Links P1-PE2 and P2-PE2 are associated with SRLG `srlg-a`.

Verify Standby Secondary Path

Purpose

Check the SRLG link cost and its impact on the CSPF computation of the standby secondary path link.

Action

```
user@PE1> show mpls lsp ingress extensive
Ingress LSP: 1 sessions

Total 1 displayed, Up 1, Down 0
```

Meaning

Check the standby secondary path. The effective link cost for P2>PE2 is 11 (with the added `srlg-cost` of 10). CSPF computes the secondary path as PE1>P3>P4>P5>PE2 with a CSPF link metric of 4.

Example: Excluding SRLG Links Completely for the Secondary LSP

IN THIS SECTION

- Requirements | **282**
- Overview | **282**
- Configuration | **283**
- Verification | **288**

This example shows how to configure the `exclude-srlg` option to exclude Shared Risk Link Group (SRLG) links for the secondary label-switched path (LSP).

Requirements

This example uses the following hardware and software components:

- M Series, MX Series, or T Series devices
- Junos OS Release 11.4 or later running on all the devices

Overview

IN THIS SECTION

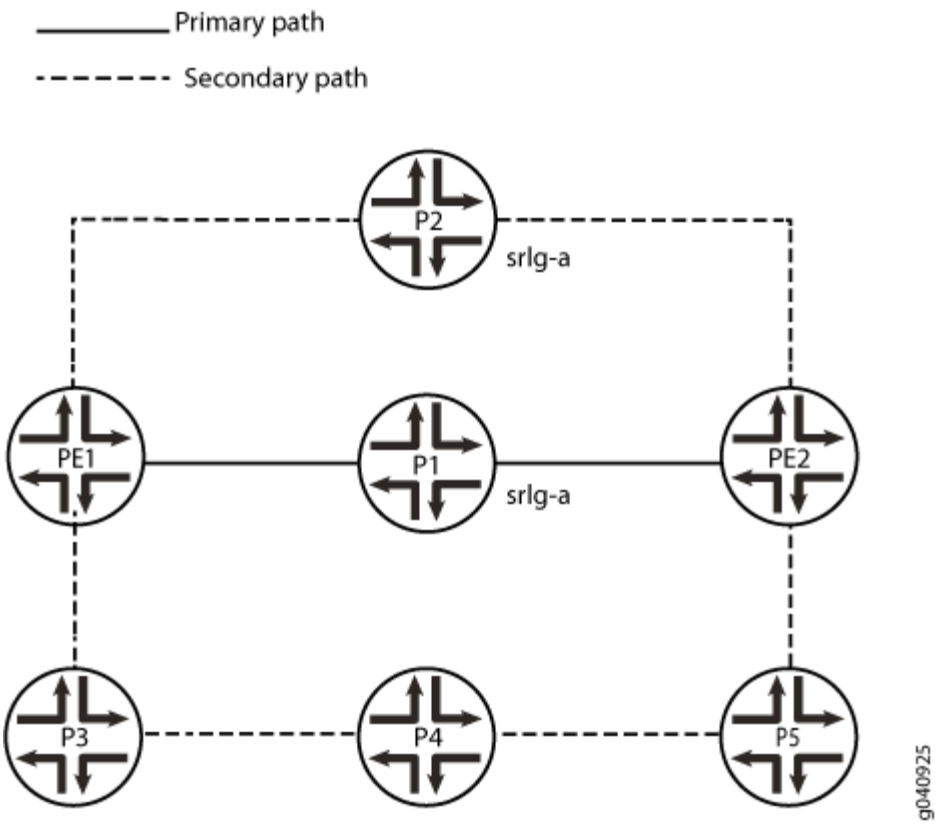
- Topology | **283**

For critical links where it is imperative to keep the secondary and primary paths completely disjoint from any common SRLG, you can optionally configure the `exclude-srlg` statement at the `[edit protocols mpls]` or `[edit protocols mpls label-switched-path` *`path-name`*`]` hierarchy levels. For logical systems, you configure the `exclude-srlg` statement at the `edit logical-systems protocols mpls[edit logical-systems` *`logical-system-name`* `protocols mpls label-switched-path` *`path-name`*`]` hierarchy level.

If `exclude-srlg` is configured, the Constrained Shortest Path First (CSPF) algorithm excludes any link belonging to the set of SRLGs in the primary path. If `exclude-srlg` is not configured, and if a link belongs to the set of SRLGs in the primary path, CSPF adds the SRLG cost to the metric, but still accepts the link for computing the path.

In this example, PE1 is the ingress router and PE2 is the egress router. P1, P2, and P3, P4, and P5 are transit routers. OSPF is configured on all the routers as the interior gateway protocol (IGP). SRLG is configured on all seven routers. The primary path includes SRLG `srlg-a`. For the standby secondary path, the link P2>PE2 belongs to SRLG `srlg-a`. Because `exclude-srlg` is configured, CSPF rejects link P2>PE2 as the link belongs to the SRLG `srlg-a`. Therefore, the computed standby secondary path is PE1>P3>P4>P5>PE2.

Topology



Configuration

IN THIS SECTION

- CLI Quick Configuration | **283**
- Procedure | **284**

CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the `[edit]` hierarchy level.

Router PE1

```
set interfaces ge-0/0/1 unit 0 family inet address 192.168.12.1/24
set interfaces ge-0/0/1 unit 0 family mpls
set interfaces ge-0/0/2 unit 0 family inet address 192.168.13.1/24
set interfaces ge-0/0/2 unit 0 family mpls
set interfaces ge-0/0/3 unit 0 family inet address 192.168.14.1/24
set interfaces ge-0/0/3 unit 0 family mpls
set interfaces lo0 unit 0 family inet address 10.255.0.1/32
set routing-options srlg srlg-a srlg-value 101
set protocols rsvp interface ge-0/0/1.0
set protocols rsvp interface ge-0/0/2.0
set protocols rsvp interface ge-0/0/3.0
set protocols mpls optimize-timer 120
set protocols mpls exclude-srlg
set protocols mpls label-switched-path pe1-pe2 to 10.255.0.7
set protocols mpls label-switched-path pe1-pe2 primary via-p1
set protocols mpls label-switched-path pe1-pe2 secondary path2 standby
set protocols mpls path via-p1 10.255.0.2 strict
set protocols mpls path path2
set protocols mpls interface ge-0/0/1.0
set protocols mpls interface ge-0/0/2.0
set protocols mpls interface ge-0/0/3.0
set protocols ospf traffic-engineering
set protocols ospf area 0.0.0.0 interface ge-0/0/1.0
set protocols ospf area 0.0.0.0 interface ge-0/0/2.0
set protocols ospf area 0.0.0.0 interface ge-0/0/3.0
set protocols ospf area 0.0.0.0 interface lo0.0
```

Procedure

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the Junos OS CLI User Guide.

1. Configure the device interfaces.

```
[edit interfaces]
user@PE1# set ge-0/0/1 unit 0 family inet address 192.168.12.1/24
user@PE1# set ge-0/0/1 unit 0 family mpls
```

```
user@PE1# set ge-0/0/2 unit 0 family inet address 192.168.13.1/24
user@PE1# set ge-0/0/2 unit 0 family mpls
user@PE1# set ge-0/0/3 unit 0 family inet address 192.168.14.1/24
user@PE1# set ge-0/0/3 unit 0 family mpls
user@PE1# set lo0 unit 0 family inet address 10.255.0.1/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@PE1# set traffic-engineering
user@PE1# set area 0.0.0.0 interface ge-0/0/1.0
user@PE1# set area 0.0.0.0 interface ge-0/0/2.0
user@PE1# set area 0.0.0.0 interface ge-0/0/3.0
user@PE1# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@PE1# set routing-options srlg srlg-a srlg-value 101
```

4. Configure MPLS and the LSPs.

```
[edit protocols mpls]
user@PE1# set interface ge-0/0/1.0
user@PE1# set interface ge-0/0/2.0
user@PE1# set interface ge-0/0/3.0
user@PE1# set optimize-timer 120
user@PE1# set exclude-srlg
user@PE1# set label-switched-path pe1-pe2 to 10.255.0.7
user@PE1# set label-switched-path pe1-pe2 primary via-p1
user@PE1# set label-switched-path pe1-pe2 secondary path2 standby
user@PE1# set path via-p1 10.255.0.2 strict
user@PE1# set path path2
```

5. Configure the `exclude-srlg` statement to forcibly keep the links for the secondary path completely disjoint from the primary LSP path.

```
user@PE1 set protocols mpls exclude-srlg
```

6. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@PE1# set interface ge-0/0/1.0
user@PE1# set interface ge-0/0/2.0
user@PE1# set interface ge-0/0/3.0
```

Results

From configuration mode, confirm your configuration by entering the `show interfaces`, `show protocols ospf`, `show routing-options`, `show protocols mpls`, and `show protocols rsvp` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1# show interfaces
interfaces {
    ge-0/0/1 {
        unit 0 {
            family inet {
                address 192.168.12.1/24;
            }
            family mpls;
        }
    }
    ge-0/0/2 {
        unit 0 {
            family inet {
                address 192.168.13.1/24;
            }
            family mpls;
        }
    }
    ge-0/0/3 {
        unit 0 {
            family inet {
                address 192.168.14.1/24;
            }
            family mpls;
        }
    }
    lo0 {
```

```
        unit 0 {
            family inet {
                address 10.255.0.1/32;
            }
        }
    }
}
```

```
user@PE1# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
    interface ge-0/0/1.0;;
    interface ge-0/0/2.0;
    interface ge-0/0/3.0;
    interface lo0.0;
}
```

```
user@PE1# show protocols mpls
optimize-timer 120;
label-switched-path pe1-pe2 {
    to 10.255.0.7;
    primary via-p1;
    secondary path2 {
        standby;
    }
}
path via-p1 {
    10.255.0.2 strict;
}
path path2;
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;
```

```
user@PE1# show protocols rsvp
interface ge-0/0/1.0;
```

```
interface ge-0/0/2.0;
interface ge-0/0/3.0;
```

```
user@PE1# show routing-options
routing-options {
    srlg {
        srlg-a srlg-value 101;
    }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

NOTE: Repeat this procedure for every Juniper Networks router in the IGP domain, after modifying the appropriate interface names, addresses, and any other parameters for each router.

Verification

IN THIS SECTION

- Verifying the Secondary Path Link for the LSP | 288

Confirm that the configuration is working properly.

Verifying the Secondary Path Link for the LSP

Purpose

Verify that the link for the secondary path is completely disjoint from the primary path.

Action

```
user@PE1> show mpls lsp detail
Ingress LSP: 1 sessions

10.255.0.7
```

```
  From: 10.255.0.1, State: Up, ActiveRoute: 0, LSPname: pe1-pe2
  ActivePath: via-p1 (primary)
  LSPtype: Static Configured
  LoadBalance: Random
  Encoding type: Packet, Switching type: Packet, GPID: IPv4
 *Primary   via-p1           State: Up
    Priorities: 7 0
    OptimizeTimer: 120
    SmartOptimizeTimer: 180
    SRLG: srlg-a
    Reoptimization in 77 second(s).
    Computed ERO (S [L] denotes strict [loose] hops): (CSPF metric: 2)
 192.168.12.2 S 192.168.27.7 S
    Received RRO (ProtectionFlag 1=Available 2=InUse 4=B/W 8=Node 10=SoftPreempt 20=Node-ID):
          192.168.12.2 192.168.27.7
  Standby   path2            State: Up
    Priorities: 7 0
    OptimizeTimer: 120
    SmartOptimizeTimer: 180
    Reoptimization in 106 second(s).
    Computed ERO (S [L] denotes strict [loose] hops): (CSPF metric: 4)
 192.168.14.4 S 192.168.45.5 S 192.168.56.6 S 192.168.67.7 S
    Received RRO (ProtectionFlag 1=Available 2=InUse 4=B/W 8=Node 10=SoftPreempt 20=Node-ID):
          192.168.14.4 192.168.45.5 192.168.56.6 192.168.67.7
Total 1 displayed, Up 1, Down 0

Link P1->PE2: SRLG srlg-a
Link P2->PE2: SRLG srlg-a

Primary path:      PE1-P1-PE2       (CSPF metric: 2)
Standby secondary: PE1-P3-P4-P5-PE2 (CSPF metric: 4)
```

Meaning

Primary path includes SRLG `srlg-a`. For the standby secondary path, the link P2>PE2 belongs to SRLG `srlg-a`. CSPF rejects link P2>PE2 because the link belongs to the SRLG `srlg-a`.

Example: Configuring SRLG with Link Protection

IN THIS SECTION

- Requirements | 290
- Overview | 290
- Configuration | 291
- Verification | 318

This example shows how to configure SRLG with link protection without the `exclude-srlg` option.

Requirements

This example uses the following hardware and software components:

- M Series, MX Series, or T Series devices
- Junos OS Release 11.4 or later running on all the devices

Overview

IN THIS SECTION

- Topology | 291

In this example, PE1 is the ingress router and PE2 is the egress router. P1, P2, and P3, P4, and P5 are transit routers. OSPF is configured on all the routers as the interior gateway protocol (IGP). SRLG is configured on all seven routers. The link P1>PE2 (primary path) and the link P2>PE2 belong to SRLG srlg-a.

You configure link protection for the interface P1>PE2 by including the `link-protection` statement.

When SRLG srlg-a is configured on the link P1>PE2 and P2>PE2, the bypass takes the longer path P1>P4>P5>PE2, not selecting the link P2>PE2 because of the added SRLG cost for srlg-a.

Configuring Device PE1

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the Junos OS CLI User Guide.

To configure the ingress router PE1:

1. Configure the device interfaces.

```
[edit interfaces]
user@PE1# set ge-0/0/1 unit 0 family inet address 192.168.12.1/24
user@PE1# set ge-0/0/1 unit 0 family mpls
user@PE1# set ge-0/0/2 unit 0 family inet address 192.168.13.1/24
user@PE1# set ge-0/0/2 unit 0 family mpls
user@PE1# set ge-0/0/3 unit 0 family inet address 192.168.14.1/24
user@PE1# set ge-0/0/3 unit 0 family mpls
user@PE1# set lo0 unit 0 family inet address 10.255.0.1/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@PE1# set traffic-engineering
user@PE1# set area 0.0.0.0 interface ge-0/0/1.0
user@PE1# set area 0.0.0.0 interface ge-0/0/2.0
user@PE1# set area 0.0.0.0 interface ge-0/0/3.0
user@PE1# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@PE1# set srlg srlg-a srlg-value 101
user@PE1# set srlg srlg-a srlg-cost 10
```

4. Configure MPLS and the LSPs and configure link protection for the `pe1-pe2` LSP.

```
[edit protocols mpls]
user@PE1# set interface ge-0/0/1.0
user@PE1# set interface ge-0/0/2.0
user@PE1# set interface ge-0/0/3.0
user@PE1# set optimize-timer 120
user@PE1# set label-switched-path pe1-pe2 to 10.255.0.7
user@PE1# set protocols mpls label-switched-path pe1-pe2 link-protection
user@PE1# set label-switched-path pe1-pe2 primary via-p1
user@PE1# set label-switched-path pe1-pe2 secondary path2 standby
user@PE1# set path via-p1 10.255.0.2 strict
user@PE1# set path path2
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@PE1# set interface ge-0/0/1.0
user@PE1# set interface ge-0/0/2.0
user@PE1# set interface ge-0/0/3.0
```

Results

From configuration mode, confirm your configuration by entering the `show interfaces`, `show protocols ospf`, `show routing-options`, `show protocols mpls`, and `show protocols rsvp` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1# show interfaces
ge-0/0/1 {
    unit 0 {
        family inet {
            address 192.168.12.1/24;
        }
        family mpls;
    }
}
ge-0/0/2 {
    unit 0 {
        family inet {
```

```
            address 192.168.13.1/24;
        }
        family mpls;
    }
}
ge-0/0/3 {
    unit 0 {
        family inet {
            address 192.168.14.1/24;
        }
        family mpls;
    }
}
lo0 {
    unit 0 {
        family inet {
            address 10.255.0.1/32;
        }
    }
}
}
```

```
user@PE1# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
    interface ge-0/0/1.0;
    interface ge-0/0/2.0;
    interface ge-0/0/3.0;
    interface lo0.0;
}
```

```
user@PE1# show protocols mpls
optimize-timer 120;
label-switched-path pe1-pe2 {
    to 10.255.0.7;
    link-protection;
    primary via-p1;
    secondary path2 {
        standby;
    }
```

```
}
path via-p1 {
    10.255.0.2 strict;
}
path path2;
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;
```

```
user@PE1# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;
```

```
user@PE1# show routing-options
srlg {
    srlg-a {
        srlg-value 101;
        srlg-cost 10;
    }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring Device P1

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the Junos OS CLI User Guide.

To configure device P1:

1. Configure the device interfaces.

```
[edit interfaces]
user@P1# set ge-0/0/1 unit 0 family inet address 192.168.12.2/24
user@P1# set ge-0/0/1 unit 0 family mpls
user@P1# set ge-0/0/2 unit 0 family inet address 192.168.27.2/24
user@P1# set ge-0/0/2 unit 0 family mpls
```

```
user@P1# set ge-0/0/3 unit 0 family inet address 192.168.23.2/24
user@P1# set ge-0/0/3 unit 0 family mpls
user@P1# set ge-0/0/4 unit 0 family inet address 192.168.25.2/24
user@P1# set ge-0/0/4 unit 0 family mpls
user@P1# set lo0 unit 0 family inet address 10.255.0.2/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@P1# set traffic-engineering
user@P1# set area 0.0.0.0 interface ge-0/0/1.0
user@P1# set area 0.0.0.0 interface ge-0/0/2.0
user@P1# set area 0.0.0.0 interface ge-0/0/3.0
user@P1# set area 0.0.0.0 interface ge-0/0/4.0
user@P1# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@P1# set srlg srlg-a srlg-value 101
user@P1# set srlg srlg-a srlg-cost 10
```

4. Configure MPLS on the interfaces and associate the SRLG `srlg-a` with interface **ge-0/0/2.0** for the P1>PE2 link.

```
[edit protocols mpls]
user@P1# set interface ge-0/0/1.0
user@P1# set interface ge-0/0/2.0 srlg srlg-a
user@P1# set interface ge-0/0/3.0
user@P1# set interface ge-0/0/4.0
```

5. Enable RSVP on the interfaces and configure `link-protection` for interface `ge-0/0/2.0`.

```
[edit protocols rsvp]
user@P1# set interface ge-0/0/1.0
user@P1# set interface ge-0/0/2.0 link-protection
user@P1# set interface ge-0/0/3.0
user@P1# set interface ge-0/0/4.0
```

Results

From configuration mode, confirm your configuration by entering the `show interfaces`, `show protocols ospf`, `show protocols mpls`, `show protocols rsvp`, and `show routing-options` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@P1# show interfaces
ge-0/0/1 {
    unit 0 {
        family inet {
            address 192.168.12.2/24;
        }
        family mpls;
    }
}
ge-0/0/2 {
    unit 0 {
        family inet {
            address 192.168.27.2/24;
        }
        family mpls;
    }
}
ge-0/0/3 {
    unit 0 {
        family inet {
            address 192.168.23.2/24;
        }
        family mpls;
    }
}
ge-0/0/4 {
    unit 0 {
        family inet {
            address 192.168.25.2/24;
        }
        family mpls;
    }
}
lo0 {
    unit 0 {
        family inet {
```

```
            address 10.255.0.2/32;
        }
    }
}
```

```
user@P1# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
    interface ge-0/0/1.0;
    interface ge-0/0/2.0;
    interface ge-0/0/3.0;
    interface ge-0/0/4.0;
    interface lo0.0;
}
```

```
user@P1# show protocols mpls
interface ge-0/0/1.0;
interface ge-0/0/2.0 {
    srlg srlg-a;
}
interface ge-0/0/3.0;
interface ge-0/0/4.0;
```

```
user@P1# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0 {
    link-protection;
}
interface ge-0/0/3.0;
interface ge-0/0/4.0;
```

```
user@P1# show routing-options

    srlg-a {
        srlg-value 101;
        srlg-cost 10;
```

```
    }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring Device P2

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the Junos OS CLI User Guide.

To configure P2:

1. Configure the device interfaces.

```
[edit interfaces]
user@P2# set ge-0/0/1 unit 0 family inet address 192.168.13.3/24
user@P2# set ge-0/0/1 unit 0 family mpls
user@P2# set ge-0/0/2 unit 0 family inet address 192.168.37.3/24
user@P2# set ge-0/0/2 unit 0 family mpls
user@P2# set ge-0/0/3 unit 0 family inet address 192.168.23.3/24
user@P2# set ge-0/0/3 unit 0 family mpls
user@P2# set lo0 unit 0 family inet address 10.255.0.3/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@P2# set traffic-engineering
user@P2# set area 0.0.0.0 interface ge-0/0/1.0
user@P2# set area 0.0.0.0 interface ge-0/0/2.0
user@P2# set area 0.0.0.0 interface ge-0/0/3.0
user@P2# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@P2# set srlg srlg-a srlg-value 101
user@P2# set srlg srlg-a srlg-cost 10
```

4. Configure MPLS on the interfaces and associate the SRLG `srlg-a` with interface **ge-0/0/2.0** for the P2>PE2 link.

```
[edit protocols mpls]
user@P2# set interface ge-0/0/1.0
user@P2# set interface ge-0/0/2.0 srlg srlg-a
user@P2# set interface ge-0/0/3.0
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@P2# set interface ge-0/0/1.0
user@P2# set interface ge-0/0/2.0
user@P2# set interface ge-0/0/3.0
```

Results

From configuration mode, confirm your configuration by entering the `show interfaces`, `show protocols ospf`, `show protocols mpls`, `show protocols rsvp`, and `show routing-options` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@P2# show interfaces
ge-0/0/1 {
    unit 0 {
        family inet {
            address 192.168.13.3/24;
        }
        family mpls;
    }
}
ge-0/0/2 {
    unit 0 {
        family inet {
            address 192.168.37.3/24;
        }
        family mpls;
    }
}
ge-0/0/3 {
```

```
    unit 0 {
        family inet {
            address 192.168.23.3/24;
        }
        family mpls;
    }
}
lo0 {
    unit 0 {
        family inet {
            address 10.255.0.3/32;
        }
    }
}
}
```

```
user@P2# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
    interface ge-0/0/1.0;
    interface ge-0/0/2.0;
    interface ge-0/0/3.0;
    interface lo0.0;
}
```

```
user@P2# show protocols mpls
interface ge-0/0/1.0;
interface ge-0/0/2.0 {
    srlg srlg-a;
}
interface ge-0/0/3.0;
}
```

```
user@P2# show protocols rsvp
interface ge-0/0/1.0;
```

```
interface ge-0/0/2.0;
interface ge-0/0/3.0;
```

```
user@P2# show routing-options
srlg {
    srlg-a {
        srlg-value 101;
        srlg-cost 10;
    }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring Device P3

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the Junos OS CLI User Guide.

To configure P3:

1. Configure the device interfaces.

```
[edit interfaces]
user@P3# set ge-0/0/1 unit 0 family inet address 192.168.14.4/24
user@P3# set ge-0/0/1 unit 0 family mpls
user@P3# set ge-0/0/2 unit 0 family inet address 192.168.45.4/24
user@P3# set ge-0/0/2 unit 0 family mpls
user@P3# set lo0 unit 0 family inet address 10.255.0.4/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@P3# set traffic-engineering
user@P3# set area 0.0.0.0 interface ge-0/0/1.0
user@P3# set area 0.0.0.0 interface ge-0/0/2.0
user@P3# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@P3# set srlg srlg-a srlg-value 101
user@P3# set srlg srlg-a srlg-cost 10
```

4. Configure MPLS on the interfaces.

```
[edit protocols mpls]
user@P3# set interface ge-0/0/1.0
user@P3# set interface ge-0/0/2.0
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@P3# set interface ge-0/0/1.0
user@P3# set interface ge-0/0/2.0
```

Results

From configuration mode, confirm your configuration by entering the `show interfaces`, `show protocols ospf`, `show protocols mpls`, `show protocols rsvp`, and `show routing-options` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@P3# show interfaces
interfaces {
    ge-0/0/1 {
        unit 0 {
            family inet {
                address 192.168.14.4/24;
            }
            family mpls;
        }
    }
    ge-0/0/2 {
        unit 0 {
            family inet {
                address 192.168.45.4/24;
```

```
            }
            family mpls;
        }
    }
    lo0 {
        unit 0 {
            family inet {
                address 10.255.0.4/32;
            }
        }
    }
}
```

```
user@P3# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
    interface ge-0/0/1.0;
    interface ge-0/0/2.0;
    interface lo0.0;
}
```

```
user@P3# show protocols mpls
interface ge-0/0/1.0;
interface ge-0/0/2.0;
```

```
user@P3# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0;
```

```
user@P3# show routing-options
srlg {
    srlg-a {
        srlg-value 101;
        srlg-cost 10;
    }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring Device P4

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the Junos OS CLI User Guide.

To configure P4:

1. Configure the device interfaces.

```
[edit interfaces]
user@P4# set ge-0/0/1 unit 0 family inet address 192.168.45.5/24
user@P4# set ge-0/0/1 unit 0 family mpls
user@P4# set ge-0/0/2 unit 0 family inet address 192.168.56.5/24
user@P4# set ge-0/0/2 unit 0 family mpls
user@P4# set ge-0/0/3 unit 0 family inet address 192.168.25.5/24
user@P4# set ge-0/0/3 unit 0 family mpls
user@P4# set lo0 unit 0 family inet address 10.255.0.5/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@P4# set traffic-engineering
user@P4# set area 0.0.0.0 interface ge-0/0/1.0
user@P4# set area 0.0.0.0 interface ge-0/0/2.0
user@P4# set area 0.0.0.0 interface ge-0/0/3.0
user@P4# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@P4# set srlg srlg-a srlg-value 101
user@P4# set srlg srlg-a srlg-cost 10
```

4. Configure MPLS on the interfaces.

```
[edit protocols mpls]
user@P4# set interface ge-0/0/1.0
user@P4# set interface ge-0/0/2.0
user@P4# set interface ge-0/0/3.0
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@P4# set interface ge-0/0/1.0
user@P4# set interface ge-0/0/2.0
user@P4# set interface ge-0/0/3.0
```

Results

From configuration mode, confirm your configuration by entering the `show interfaces`, `show protocols ospf`, `show protocols mpls`, `show protocols rsvp`, and `show routing-options` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@P4# show interfaces
ge-0/0/1 {
    unit 0 {
        family inet {
            address 192.168.45.5/24;
        }
        family mpls;
    }
}
ge-0/0/2 {
    unit 0 {
        family inet {
            address 192.168.56.5/24;
        }
        family mpls;
    }
}
ge-0/0/3 {
    unit 0 {
```

```
        family inet {
            address 192.168.25.5/24;
        }
        family mpls;
    }
}
lo0 {
    unit 0 {
        family inet {
            address 10.255.0.5/32;
        }
    }
}
```

```
user@P4# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
    interface ge-0/0/1.0;
    interface ge-0/0/2.0;
    interface ge-0/0/3.0;
    interface lo0.0;
}
```

```
user@P4# show protocols mpls
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;
```

```
user@P4# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;
```

```
user@P4# show routing-options
srlg {
    srlg-a {
        srlg-value 101;
```

```
        srlg-cost 10;
    }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring Device P5

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the Junos OS CLI User Guide.

To configure P5:

1. Configure the device interfaces.

```
[edit interfaces]
user@P5# set ge-0/0/1 unit 0 family inet address 192.168.56.6/24
user@P5# set ge-0/0/1 unit 0 family mpls
user@P5# set ge-0/0/2 unit 0 family inet address 192.168.67.6/24
user@P5# set ge-0/0/2 unit 0 family mpls
user@P5# set lo0 unit 0 family inet address 10.255.0.6/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@P5# set traffic-engineering
user@P5# set area 0.0.0.0 interface ge-0/0/1.0
user@P5# set area 0.0.0.0 interface ge-0/0/2.0
user@P5# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@P5# set srlg srlg-a srlg-value 101
user@P5# set srlg srlg-a srlg-cost 10
```

4. Configure MPLS on the interfaces.

```
[edit protocols mpls]
user@P5# set interface ge-0/0/1.0
user@P5# set interface ge-0/0/2.0
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@P5# set interface ge-0/0/1.0
user@P5# set interface ge-0/0/2.0
```

Results

From configuration mode, confirm your configuration by entering the `show interfaces`, `show protocols ospf`, `show protocols mpls`, `show protocols rsvp`, and `show routing-options` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@P5# show interfaces
ge-0/0/1 {
    unit 0 {
        family inet {
            address 192.168.56.6/24;
        }
        family mpls;
    }
}
ge-0/0/2 {
    unit 0 {
        family inet {
            address 192.168.67.6/24;
        }
        family mpls;
    }
}
lo0 {
    unit 0 {
        family inet {
            address 10.255.0.6/32;
```

```
        }
    }
}
```

```
user@P5# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
    interface ge-0/0/1.0;
    interface ge-0/0/2.0;
    interface lo0.0;
}
```

```
user@P5# show protocols mpls
interface ge-0/0/1.0;
interface ge-0/0/2.0;
```

```
user@P5# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0;
```

```
user@P5# show routing-options
srlg {
    srlg-a {
        srlg-value 101;
        srlg-cost 10;
    }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring Device PE2

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the Junos OS CLI User Guide.

To configure PE2:

1. Configure the device interfaces.

```
[edit interfaces]
user@PE2# set ge-0/0/1 unit 0 family inet address 192.168.27.7/24
user@PE2# set ge-0/0/1 unit 0 family mpls
user@PE2# set ge-0/0/2 unit 0 family inet address 192.168.37.7/24
user@PE2# set ge-0/0/2 unit 0 family mpls
user@PE2# set ge-0/0/3 unit 0 family inet address 192.168.67.7/24
user@PE2# set ge-0/0/3 unit 0 family mpls
user@PE2# set lo0 unit 0 family inet address 10.255.0.7/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@PE2# set traffic-engineering
user@PE2# set area 0.0.0.0 interface ge-0/0/1.0
user@PE2# set area 0.0.0.0 interface ge-0/0/2.0
user@PE2# set area 0.0.0.0 interface ge-0/0/3.0
user@PE2# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@PE2# set srlg srlg-a srlg-value 101
user@PE2# set srlg srlg-a srlg-cost 10
```

4. Configure MPLS on the interfaces.

```
[edit protocols mpls]
user@PE2# set interface ge-0/0/1.0
user@PE2# set interface ge-0/0/2.0
user@PE2# set interface ge-0/0/3.0
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@PE2# set interface ge-0/0/1.0
user@PE2# set interface ge-0/0/2.0
user@PE2# set interface ge-0/0/3.0
```

Results

From configuration mode, confirm your configuration by entering the `show interfaces`, `show protocols ospf`, `show protocols mpls`, `show protocols rsvp`, and `show routing-options` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE2# show interfaces
interfaces {
    ge-0/0/1 {
        unit 0 {
            family inet {
                address 192.168.27.7/24;
            }
            family mpls;
        }
    }
    ge-0/0/2 {
        unit 0 {
            family inet {
                address 192.168.37.7/24;
            }
            family mpls;
        }
    }
    ge-0/0/3 {
        unit 0 {
            family inet {
                address 192.168.67.7/24;
            }
            family mpls;
        }
    }
    lo0 {
```

```
        unit 0 {
            family inet {
                address 10.255.0.7/32;
            }
        }
    }
}
```

```
user@PE2# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
    interface ge-0/0/1.0;
    interface ge-0/0/2.0;
    interface ge-0/0/3.0;
    interface lo0.0;
}
```

```
user@PE2# show protocols mpls
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;
```

```
user@PE2# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;
```

```
user@PE2# show routing-options
srlg {
    srlg-a {
        srlg-value 101;
        srlg-cost 10;
    }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

IN THIS SECTION

- Verifying the SRLG Cost Is Added to the TE Link | 318

Confirm that the configuration is working properly.

Verifying the SRLG Cost Is Added to the TE Link

Purpose

Verify that the SRLG cost is added to the TE link if it belongs to the SRLG of the protected link. Issue the `show ted link detail` and `show rsvp session extensive bypass` commands on device P1.

Action

```
user@P1> show ted link detail

...
10.255.0.2->192.168.27.7-1, Local: 192.168.27.2, Remote: 0.0.0.0
  Local interface index: 0, Remote interface index: 0
  LocalPath: 0, Metric: 1, StaticBW: 1000Mbps, AvailBW: 1000Mbps
      Color: 0 <none>
  SRLGs: srlg-a
  localBW [0] 0bps  [1] 0bps  [2] 0bps  [3] 0bps
  localBW [4] 0bps  [5] 0bps  [6] 0bps  [7] 0bps
[...]
10.255.0.3->192.168.37.7-1, Local: 192.168.37.3, Remote: 0.0.0.0
  Local interface index: 0, Remote interface index: 0
  LocalPath: 0, Metric: 1, StaticBW: 1000Mbps, AvailBW: 1000Mbps
      Color: 0 <none>
  SRLGs: srlg-a
  localBW [0] 0bps  [1] 0bps  [2] 0bps  [3] 0bps
```

```
  localBW [4] 0bps  [5] 0bps  [6] 0bps  [7] 0bps
...
```

```
user@P1> show rsvp session extensive bypass

Ingress RSVP: 1 sessions

Total 1 displayed, Up 1, Down 0
```

Meaning

The shortest path for the bypass protecting the link P1->PE2 would have been P1->P2->PE2. Because the links P1>PE2 and P2>PE2 both belong to SRLG `srlg-a`, the SRLG cost of 10 for `srlg-a` is added to the metric for the link P2>PE2. This makes the metric for the link P2>PE2 too high to be selected for the shortest path. Therefore, the CSPF result for the computed path for the bypass becomes P1>P4>P5>PE2.

Example: Configuring SRLG with Link Protection with the exclude-srlg Option

IN THIS SECTION

- Requirements | 320
- Overview | 320
- Configuration | 321
- Verification | 348

This example shows how to configure SRLG with link protection with the `exclude-srlg` option.

Requirements

This example uses the following hardware and software components:

- M Series, MX Series, or T Series devices
- Junos OS Release 11.4 or later running on all the devices

Overview

IN THIS SECTION

- Topology | 321

In this example, PE1 is the ingress router and PE2 is the egress router. P1, P2, and P3, P4, and P5 are transit routers. OSPF is configured on all the routers as the interior gateway protocol (IGP). SRLG is configured on all seven routers. The link P1>PE2 (primary path) and the link P2>PE2 belong to SRLG `srlg-a`.

You configure link protection for the interface P1>PE2 by including the `link-protection` statement along with the `exclude-srlg` option. This makes the bypass LSP and the protected link completely disjoint in any SRLG.

When SRLG `srlg-a` is configured on the link P1>PE2 and P2>PE2, the link P2>PE2 is rejected for CSPF consideration due to the `exclude-srlg` configuration. Therefore, the computed path for the bypass becomes P1>P4>P5>PE2.

Configuring Device PE1

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the Junos OS CLI User Guide.

To configure the ingress router PE1:

1. Configure the device interfaces.

```
[edit interfaces]
user@PE1# set ge-0/0/1 unit 0 family inet address 192.168.12.1/24
user@PE1# set ge-0/0/1 unit 0 family mpls
user@PE1# set ge-0/0/2 unit 0 family inet address 192.168.13.1/24
user@PE1# set ge-0/0/2 unit 0 family mpls
user@PE1# set ge-0/0/3 unit 0 family inet address 192.168.14.1/24
user@PE1# set ge-0/0/3 unit 0 family mpls
user@PE1# set lo0 unit 0 family inet address 10.255.0.1/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@PE1# set traffic-engineering
user@PE1# set area 0.0.0.0 interface ge-0/0/1.0
user@PE1# set area 0.0.0.0 interface ge-0/0/2.0
user@PE1# set area 0.0.0.0 interface ge-0/0/3.0
user@PE1# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@PE1# set routing-options srlg srlg-a srlg-value 101
user@PE1# set routing-options srlg srlg-a srlg-cost 10
```

4. Configure MPLS and the LSPs and configure link protection for the `pe1-pe2` LSP.

```
[edit protocols mpls]
user@PE1# set interface ge-0/0/1.0
user@PE1# set interface ge-0/0/2.0
```

```
user@PE1# set interface ge-0/0/3.0
user@PE1# set optimize-timer 120
user@PE1# set label-switched-path pe1-pe2 to 10.255.0.7
user@PE1# set protocols mpls label-switched-path pe1-pe2 link-protection
user@PE1# set label-switched-path pe1-pe2 primary via-p1
user@PE1# set label-switched-path pe1-pe2 secondary path2 standby
user@PE1# set path via-p1 10.255.0.2 strict
user@PE1# set path path2
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@PE1# set interface ge-0/0/1.0
user@PE1# set interface ge-0/0/2.0
user@PE1# set interface ge-0/0/3.0
```

Results

From configuration mode, confirm your configuration by entering the `show interfaces`, `show protocols ospf`, `show routing-options`, `show protocols mpls`, and `show protocols rsvp` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1# show interfaces
ge-0/0/1 {
    unit 0 {
        family inet {
            address 192.168.12.1/24;
        }
        family mpls;
    }
}
ge-0/0/2 {
    unit 0 {
        family inet {
            address 192.168.13.1/24;
        }
        family mpls;
    }
}
ge-0/0/3 {
```

```
    unit 0 {
        family inet {
            address 192.168.14.1/24;
        }
        family mpls;
    }
}
lo0 {
    unit 0 {
        family inet {
            address 10.255.0.1/32;
        }
    }
}
}
```

```
user@PE1# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
    interface ge-0/0/1.0;
    interface ge-0/0/2.0;
    interface ge-0/0/3.0;
    interface lo0.0;
}
```

```
user@PE1# show protocols mpls
optimize-timer 120;
label-switched-path pe1-pe2 {
    to 10.255.0.7;
    link-protection;
    primary via-p1;
    secondary path2 {
        standby;
    }
}
path via-p1 {
    10.255.0.2 strict;
}
path path2;
interface ge-0/0/1.0;
```

```
interface ge-0/0/2.0;
interface ge-0/0/3.0;
```

```
user@PE1# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;
```

```
user@PE1# show routing-options
srlg {
    srlg-a {
        srlg-value 101;
        srlg-cost 10;
    }
}
```

If you are done configuring the device, enter `commit` from configuration mode.

Configuring Device P1

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the Junos OS CLI User Guide.

To configure device P1:

1. Configure the device interfaces.

```
[edit interfaces]
user@P1# set ge-0/0/1 unit 0 family inet address 192.168.12.2/24
user@P1# set ge-0/0/1 unit 0 family mpls
user@P1# set ge-0/0/2 unit 0 family inet address 192.168.27.2/24
user@P1# set ge-0/0/2 unit 0 family mpls
user@P1# set ge-0/0/3 unit 0 family inet address 192.168.23.2/24
user@P1# set ge-0/0/3 unit 0 family mpls
user@P1# set ge-0/0/4 unit 0 family inet address 192.168.25.2/24
user@P1# set ge-0/0/4 unit 0 family mpls
user@P1# set lo0 unit 0 family inet address 10.255.0.2/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@P1# set traffic-engineering
user@P1# set area 0.0.0.0 interface ge-0/0/1.0
user@P1# set area 0.0.0.0 interface ge-0/0/2.0
user@P1# set area 0.0.0.0 interface ge-0/0/3.0
user@P1# set area 0.0.0.0 interface ge-0/0/4.0
user@P1# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@P1# set routing-options srlg srlg-a srlg-value 101
user@P1# set routing-options srlg srlg-a srlg-cost 10
```

4. Configure MPLS on the interfaces and associate the SRLG with interface **ge-0/0/2.0** for the P1>PE2 link.

```
[edit protocols mpls]
user@P1# set interface ge-0/0/1.0
user@P1# set interface ge-0/0/2.0 srlg srlg-a
user@P1# set interface ge-0/0/3.0
user@P1# set interface ge-0/0/4.0
```

5. Enable RSVP on the interfaces and include the `link-protection` statement with the `exclude-srlg` option for interface `ge-0/0/2.0`.

```
[edit protocols rsvp]
user@P1# set interface ge-0/0/1.0
user@P1# set interface ge-0/0/2.0 link-protection exclude-srlg
user@P1# set interface ge-0/0/3.0
user@P1# set interface ge-0/0/4.0
```

Results

From configuration mode, confirm your configuration by entering the `show interfaces`, `show protocols ospf`, `show protocols mpls`, `show protocols rsvp`, and `show routing-options` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@P1# show interfaces
ge-0/0/1 {
    unit 0 {
        family inet {
            address 192.168.12.2/24;
        }
        family mpls;
    }
}
ge-0/0/2 {
    unit 0 {
        family inet {
            address 192.168.27.2/24;
        }
        family mpls;
    }
}
ge-0/0/3 {
    unit 0 {
        family inet {
            address 192.168.23.2/24;
        }
        family mpls;
    }
}
ge-0/0/4 {
    unit 0 {
        family inet {
            address 192.168.25.2/24;
        }
        family mpls;
    }
}
lo0 {
    unit 0 {
        family inet {
```

```
            address 10.255.0.2/32;
        }
    }
}
```

```
user@P1# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
    interface ge-0/0/1.0;
    interface ge-0/0/2.0;
    interface ge-0/0/3.0;
    interface ge-0/0/4.0;
    interface lo0.0;
}
```

```
user@P1# show protocols mpls
interface ge-0/0/1.0;
interface ge-0/0/2.0 {
    srlg srlg-a;
}
interface ge-0/0/3.0;
interface ge-0/0/4.0;
```

```
user@P1# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0 {
    link-protection {
        exclude-srlg;
    }
interface ge-0/0/3.0;
interface ge-0/0/4.0;
}
```

```
user@P1# show routing-options
srlg {
    srlg-a {
        srlg-value 101;
```

```
        srlg-cost 10;
    }
}
```

If you are done configuring the device, enter `commit` from configuration mode.

Configuring Device P2

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the Junos OS CLI User Guide.

To configure P2:

1. Configure the device interfaces.

```
[edit interfaces]
user@P2# set ge-0/0/1 unit 0 family inet address 192.168.13.3/24
user@P2# set ge-0/0/1 unit 0 family mpls
user@P2# set ge-0/0/2 unit 0 family inet address 192.168.37.3/24
user@P2# set ge-0/0/2 unit 0 family mpls
user@P2# set ge-0/0/3 unit 0 family inet address 192.168.23.3/24
user@P2# set ge-0/0/3 unit 0 family mpls
user@P2# set lo0 unit 0 family inet address 10.255.0.3/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@P2# set traffic-engineering
user@P2# set area 0.0.0.0 interface ge-0/0/1.0
user@P2# set area 0.0.0.0 interface ge-0/0/2.0
user@P2# set area 0.0.0.0 interface ge-0/0/3.0
user@P2# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@P2# set routing-options srlg srlg-a srlg-value 101
user@P2# set routing-options srlg srlg-a srlg-cost 10
```

4. Configure MPLS on the interfaces and associate the SRLG with interface **ge-0/0/2.0** for the P2>PE2 link.

```
[edit protocols mpls]
user@P2# set interface ge-0/0/1.0
user@P2# set interface ge-0/0/2.0 srlg srlg-a
user@P2# set interface ge-0/0/3.0
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@P2# set interface ge-0/0/1.0
user@P2# set interface ge-0/0/2.0
user@P2# set interface ge-0/0/3.0
```

Results

From configuration mode, confirm your configuration by entering the `show interfaces`, `show protocols ospf`, `show protocols mpls`, `show protocols rsvp`, and `show routing-options` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@P2# show interfaces
ge-0/0/1 {
    unit 0 {
        family inet {
            address 192.168.13.3/24;
        }
        family mpls;
    }
}
ge-0/0/2 {
    unit 0 {
        family inet {
            address 192.168.37.3/24;
        }
        family mpls;
    }
}
ge-0/0/3 {
```

```
    unit 0 {
        family inet {
            address 192.168.23.3/24;
        }
        family mpls;
    }
}
lo0 {
    unit 0 {
        family inet {
            address 10.255.0.3/32;
        }
    }
}
}
```

```
user@P2# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
    interface ge-0/0/1.0;
    interface ge-0/0/2.0;
    interface ge-0/0/3.0;
    interface lo0.0;
}
```

```
user@P2# show protocols mpls
interface ge-0/0/1.0;
interface ge-0/0/2.0 {
    srlg srlg-a;
}
interface ge-0/0/3.0;
}
```

```
user@P2# show protocols rsvp
interface ge-0/0/1.0;
```

```
interface ge-0/0/2.0;
interface ge-0/0/3.0;
```

```
user@P2# show routing-options
srlg {
    srlg-a {
        srlg-value 101;
        srlg-cost 10;
    }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring Device P3

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the Junos OS CLI User Guide.

To configure P3:

1. Configure the device interfaces.

```
[edit interfaces]
user@P3# set ge-0/0/1 unit 0 family inet address 192.168.14.4/24
user@P3# set ge-0/0/1 unit 0 family mpls
user@P3# set ge-0/0/2 unit 0 family inet address 192.168.45.4/24
user@P3# set ge-0/0/2 unit 0 family mpls
user@P3# set lo0 unit 0 family inet address 10.255.0.4/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@P3# set traffic-engineering
user@P3# set area 0.0.0.0 interface ge-0/0/1.0
user@P3# set area 0.0.0.0 interface ge-0/0/2.0
user@P3# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@P3# set routing-options srlg srlg-a srlg-value 101
user@P3# set routing-options srlg srlg-a srlg-cost 10
```

4. Configure MPLS on the interfaces.

```
[edit protocols mpls]
user@P3# set interface ge-0/0/1.0
user@P3# set interface ge-0/0/2.0
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@P3# set interface ge-0/0/1.0
user@P3# set interface ge-0/0/2.0
```

Results

From configuration mode, confirm your configuration by entering the `show interfaces`, `show protocols ospf`, `show protocols mpls`, `show protocols rsvp`, and `show routing-options` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@P3# show interfaces
interfaces {
    ge-0/0/1 {
        unit 0 {
            family inet {
                address 192.168.14.4/24;
            }
            family mpls;
        }
    }
    ge-0/0/2 {
        unit 0 {
            family inet {
                address 192.168.45.4/24;
```

```
            }
            family mpls;
        }
    }
    lo0 {
        unit 0 {
            family inet {
                address 10.255.0.4/32;
            }
        }
    }
}
```

```
user@P3# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
    interface ge-0/0/1.0;
    interface ge-0/0/2.0;
    interface lo0.0;
}
```

```
user@P3# show protocols mpls
interface ge-0/0/1.0;
interface ge-0/0/2.0;
```

```
user@P3# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0;
```

```
user@P3# show routing-options
srlg {
    srlg-a {
        srlg-value 101;
        srlg-cost 10;
    }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring Device P4

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the Junos OS CLI User Guide.

To configure P4:

1. Configure the device interfaces.

```
[edit interfaces]
user@P4# set ge-0/0/1 unit 0 family inet address 192.168.45.5/24
user@P4# set ge-0/0/1 unit 0 family mpls
user@P4# set ge-0/0/2 unit 0 family inet address 192.168.56.5/24
user@P4# set ge-0/0/2 unit 0 family mpls
user@P4# set ge-0/0/3 unit 0 family inet address 192.168.25.5/24
user@P4# set ge-0/0/3 unit 0 family mpls
user@P4# set lo0 unit 0 family inet address 10.255.0.5/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@P4# set traffic-engineering
user@P4# set area 0.0.0.0 interface ge-0/0/1.0
user@P4# set area 0.0.0.0 interface ge-0/0/2.0
user@P4# set area 0.0.0.0 interface ge-0/0/3.0
user@P4# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@P4# set routing-options srlg srlg-a srlg-value 101
user@P4# set routing-options srlg srlg-a srlg-cost 10
```

4. Configure MPLS on the interfaces.

```
[edit protocols mpls]
user@P4# set interface ge-0/0/1.0
user@P4# set interface ge-0/0/2.0
user@P4# set interface ge-0/0/3.0
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@P4# set interface ge-0/0/1.0
user@P4# set interface ge-0/0/2.0
user@P4# set interface ge-0/0/3.0
```

Results

From configuration mode, confirm your configuration by entering the `show interfaces`, `show protocols ospf`, `show protocols mpls`, `show protocols rsvp`, and `show routing-options` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@P4# show interfaces
ge-0/0/1 {
    unit 0 {
        family inet {
            address 192.168.45.5/24;
        }
        family mpls;
    }
}
ge-0/0/2 {
    unit 0 {
        family inet {
            address 192.168.56.5/24;
        }
        family mpls;
    }
}
ge-0/0/3 {
    unit 0 {
```

```
        family inet {
            address 192.168.25.5/24;
        }
        family mpls;
    }
}
lo0 {
    unit 0 {
        family inet {
            address 10.255.0.5/32;
        }
    }
}
```

```
user@P4# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
    interface ge-0/0/1.0;
    interface ge-0/0/2.0;
    interface ge-0/0/3.0;
    interface lo0.0;
}
```

```
user@P4# show protocols mpls
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;
```

```
user@P4# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;
```

```
user@P4# show routing-options
srlg {
    srlg-a {
        srlg-value 101;
```

```
        srlg-cost 10;
    }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring Device P5

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the Junos OS CLI User Guide.

To configure P5:

1. Configure the device interfaces.

```
[edit interfaces]
user@P5# set ge-0/0/1 unit 0 family inet address 192.168.56.6/24
user@P5# set ge-0/0/1 unit 0 family mpls
user@P5# set ge-0/0/2 unit 0 family inet address 192.168.67.6/24
user@P5# set ge-0/0/2 unit 0 family mpls
user@P5# set lo0 unit 0 family inet address 10.255.0.6/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@P5# set traffic-engineering
user@P5# set area 0.0.0.0 interface ge-0/0/1.0
user@P5# set area 0.0.0.0 interface ge-0/0/2.0
user@P5# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@P5# set routing-options srlg srlg-a srlg-value 101
user@P5# set routing-options srlg srlg-a srlg-cost 10
```

4. Configure MPLS on the interfaces.

```
[edit protocols mpls]
user@P5# set interface ge-0/0/1.0
user@P5# set interface ge-0/0/2.0
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@P5# set interface ge-0/0/1.0
user@P5# set interface ge-0/0/2.0
```

Results

From configuration mode, confirm your configuration by entering the `show interfaces`, `show protocols ospf`, `show protocols mpls`, `show protocols rsvp`, and `show routing-options` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@P5# show interfaces
ge-0/0/1 {
    unit 0 {
        family inet {
            address 192.168.56.6/24;
        }
        family mpls;
    }
}
ge-0/0/2 {
    unit 0 {
        family inet {
            address 192.168.67.6/24;
        }
        family mpls;
    }
}
lo0 {
    unit 0 {
        family inet {
            address 10.255.0.6/32;
```

```
        }
    }
}
```

```
user@P5# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
    interface ge-0/0/1.0;
    interface ge-0/0/2.0;
    interface lo0.0;
}
```

```
user@P5# show protocols mpls
interface ge-0/0/1.0;
interface ge-0/0/2.0;
```

```
user@P5# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0;
```

```
user@P5# show routing-options
srlg {
    srlg-a {
        srlg-value 101;
        srlg-cost 10;
    }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring Device PE2

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the Junos OS CLI User Guide.

To configure PE2:

1. Configure the device interfaces.

```
[edit interfaces]
user@PE2# set ge-0/0/1 unit 0 family inet address 192.168.27.7/24
user@PE2# set ge-0/0/1 unit 0 family mpls
user@PE2# set ge-0/0/2 unit 0 family inet address 192.168.37.7/24
user@PE2# set ge-0/0/2 unit 0 family mpls
user@PE2# set ge-0/0/3 unit 0 family inet address 192.168.67.7/24
user@PE2# set ge-0/0/3 unit 0 family mpls
user@PE2# set lo0 unit 0 family inet address 10.255.0.7/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@PE2# set traffic-engineering
user@PE2# set area 0.0.0.0 interface ge-0/0/1.0
user@PE2# set area 0.0.0.0 interface ge-0/0/2.0
user@PE2# set area 0.0.0.0 interface ge-0/0/3.0
user@PE2# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@PE2# set routing-options srlg srlg-a srlg-value 101
user@PE2# set routing-options srlg srlg-a srlg-cost 10
```

4. Configure MPLS on the interfaces.

```
[edit protocols mpls]
user@PE2# set interface ge-0/0/1.0
user@PE2# set interface ge-0/0/2.0
user@PE2# set interface ge-0/0/3.0
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@PE2# set interface ge-0/0/1.0
user@PE2# set interface ge-0/0/2.0
user@PE2# set interface ge-0/0/3.0
```

Results

From configuration mode, confirm your configuration by entering the `show interfaces`, `show protocols ospf`, `show protocols mpls`, `show protocols rsvp`, and `show routing-options` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE2# show interfaces
interfaces {
    ge-0/0/1 {
        unit 0 {
            family inet {
                address 192.168.27.7/24;
            }
            family mpls;
        }
    }
    ge-0/0/2 {
        unit 0 {
            family inet {
                address 192.168.37.7/24;
            }
            family mpls;
        }
    }
    ge-0/0/3 {
        unit 0 {
            family inet {
                address 192.168.67.7/24;
            }
            family mpls;
        }
    }
    lo0 {
```

```
        unit 0 {
            family inet {
                address 10.255.0.7/32;
            }
        }
    }
}
```

```
user@PE2# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
    interface ge-0/0/1.0;
    interface ge-0/0/2.0;
    interface ge-0/0/3.0;
    interface lo0.0;
}
```

```
user@PE2# show protocols mpls
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;
```

```
user@PE2# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;
```

```
user@PE2# show routing-options
srlg {
    srlg-a {
        srlg-value 101;
        srlg-cost 10;
    }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

IN THIS SECTION

- Verifying the SRLG Cost Is Added to the TE Link | 348

Confirm that the configuration is working properly.

Verifying the SRLG Cost Is Added to the TE Link

Purpose

Verify that the TE link is excluded if it belongs to the SRLG of the protected link when `link-protection` is configured with `exclude-srlg`. Issue the `show ted link detail` and `show rsvp session extensive bypass` commands on device P1.

Action

```
user@P1> show ted link detail

...
10.255.0.2->192.168.27.7-1, Local: 192.168.27.2, Remote: 0.0.0.0

  PATH sentto: 192.168.25.5 (ge-0/0/4.0) 63 pkts
  RESV rcvfrom: 192.168.25.5 (ge-0/0/4.0) 63 pkts
  Explct route: 192.168.25.5 192.168.56.6 192.168.67.7
  Record route: <self> 192.168.25.5 192.168.56.6 192.168.67.7
Total 1 displayed, Up 1, Down 0
```

Meaning

The shortest path for the bypass protecting the link P1>PE2 would have been P1>P2>PE2. Because the links P1>PE2 and P2>PE2 both belong to SRLG `srlg-a`, the link P2>PE2 is rejected for CSPF consideration due to the `exclude-srlg` constraint. Therefore, the computed path for the bypass becomes P1>P4>P5>PE2.

MPLS and Traffic Protection

Typically, when an LSP fails, the router immediately upstream from the failure signals the outage to the ingress router. The ingress router calculates a new path to the egress router, establishes the new LSP, and then directs the traffic from the failed path to the new path. This rerouting process can be time-

consuming and prone to failure. For example, the outage signals to the ingress router might get lost, or the new path might take too long to come up, resulting in significant packet drops. The Junos OS provides several complementary mechanisms for protecting against LSP failures:

- Standby secondary paths—You can configure primary and secondary paths. You configure secondary paths with the `standby` statement. To activate traffic protection, you need to configure these standby paths only on the ingress router. If the primary path fails, the ingress router immediately reroutes traffic from the failed path to the standby path, thereby eliminating the need to calculate a new route and signal a new path. For information about configuring standby LSPs, see "Configuring Hot Standby of Secondary Paths for LSPs" on page 666.

- Fast reroute—You configure fast reroute on an LSP to minimize the effect of a failure in the LSP. Fast reroute enables a router upstream from the failure to route around the failure quickly to the router downstream of the failure. The upstream router then signals the outage to the ingress router, thereby maintaining connectivity before a new LSP is established. For a detailed overview of fast reroute, see "Fast Reroute Overview" on page 562. For information about configuring fast reroute, see "Configuring Fast Reroute" on page 565.

- Link protection—You can configure link protection to help ensure that traffic traversing a specific interface from one router to another can continue to reach its destination in the event that this interface fails. When link protection is configured for an interface and configured for an LSP that traverses this interface, a bypass LSP is created that handles this traffic if the interface fails. The bypass LSP uses a different interface and path to reach the same destination. For information about configuring link protection, see "Configuring Link Protection on Interfaces Used by LSPs" on page 458.

When standby secondary path, and fast reroute or link protection are configured on an LSP, full traffic protection is enabled. When a failure occurs in an LSP, the router upstream from the failure routes traffic around the failure and notifies the ingress router of the failure. This rerouting keeps the traffic flowing while waiting for the notification to be processed at the ingress router. After receiving the failure notification, the ingress router immediately reroutes the traffic from the patched primary path to the more optimal standby path.

Fast reroute and link protection provide a similar type of traffic protection. Both features provide a quick transfer service and employ a similar design. Fast reroute and link protection are both described in RFC 4090, *Fast Reroute Extensions to RSVP-TE for LSP Tunnels*. However, you need to configure only one or the other. Although you can configure both, there is little, if any, benefit in doing so.

Node-Link Protection Overview

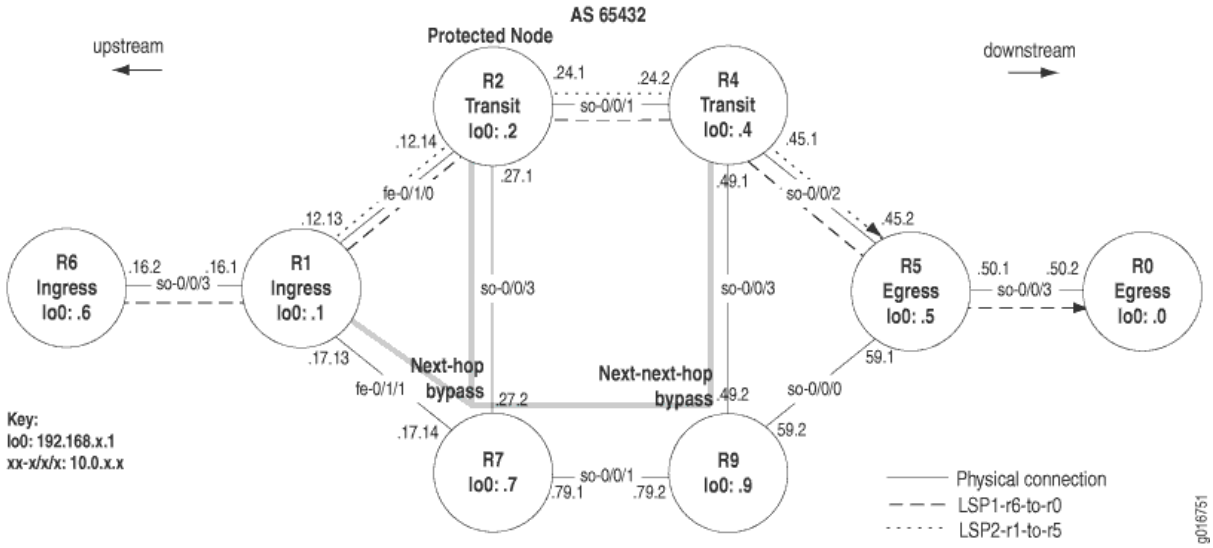
Node-link protection (many-to-one or facility backup) extends the capabilities of link protection and provides slightly different protection from fast reroute. While link protection is useful for selecting an alternate path to the same router when a specific link fails, and fast reroute protects interfaces or nodes along the entire path of an LSP, node-link protection establishes a bypass path that avoids a particular node in the LSP path.

When you enable node-link protection for an LSP, you must also enable link protection on all RSVP interfaces in the path. Once enabled, the following types of bypass paths are established:

- Next-hop bypass LSP—Provides an alternate route for an LSP to reach a neighboring router. This type of bypass path is established when you enable either node-link protection or link protection.
- Next-next-hop bypass LSP—Provides an alternate route for an LSP through a neighboring router en route to the destination router. This type of bypass path is established exclusively when node-link protection is configured.

Figure 11 on page 352 illustrates the example MPLS network topology used in this topic. The example network uses OSPF as the interior gateway protocol (IGP) and a policy to create traffic.

Figure 11: Node-Link Protection



The MPLS network in Figure 11 on page 352 illustrates a router-only network that consists of unidirectional LSPs between **R1** and **R5**, (**lsp2-r1-to-r5**) and between **R6** and **R0** (**lsp1-r6-to-r0**). Both LSPs have strict paths configured that go through interface **fe-0/1/0**.

In the network shown in Figure 11 on page 352, both types of bypass paths are preestablished around the protected node (**R2**)**.** A next-hop bypass path avoids interface **fe-0/1/0** by going through **R7**, and a next-next-hop bypass path avoids **R2** altogether by going through **R7** and **R9** to **R4**. Both bypass paths are shared by all protected LSPs traversing the failed link or node (many LSPs protected by one bypass path).

Node-link protection (many-to-one or facility backup) allows a router immediately upstream from a node failure to use an alternate node to forward traffic to its downstream neighbor. This is accomplished by preestablishing a bypass path that is shared by all protected LSPs traversing the failed link.

When an outage occurs, the router immediately upstream from the outage switches protected traffic to the bypass node, and then signals the failure to the ingress router. Like fast reroute, node-link protection provides local repair, restoring connectivity faster than the ingress router can establish a standby secondary path or signal a new primary LSP.

Node-link protection is appropriate in the following situations:

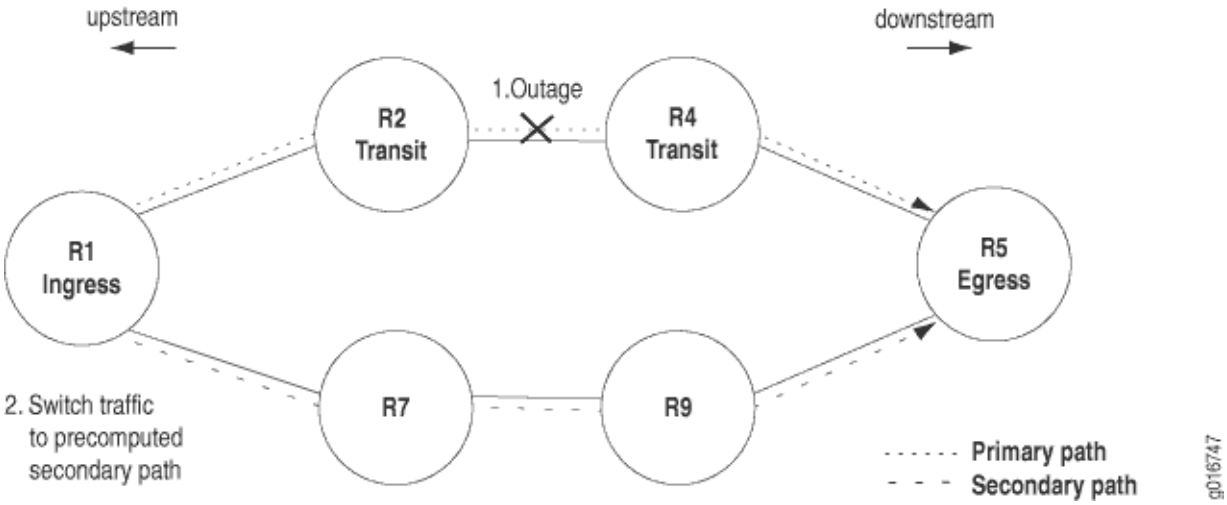
- Protection of the downstream link and node is required.
- The number of LSPs to be protected is large.
- Satisfying path selection criteria (priority, bandwidth, and link coloring) for bypass paths is less critical.
- Control at the granularity of individual LSPs is not required.

Path Protection Overview

The main advantages of path protection are control over where the traffic goes after a failure and minimum packet loss when combined with fast reroute (one-to-one backup or link protection). Path protection is the configuration, within a label-switched path (LSP), of two types of paths: a primary path, used in normal operations, and a secondary path used when the primary fails, as shown in Figure 12 on page 353.

In Figure 12 on page 353, an MPLS network consisting of eight routers has a primary path between **R1** and **R5** which is protected by the secondary path between **R1** and **R5**. When a failure is detected, such as an interface down event, an Resource Reservation Protocol (RSVP) error message is sent to the ingress router which switches traffic to the secondary path, maintaining traffic flow.

Figure 12: Path Protection



If the secondary path is pre-signaled or on standby, recovery time from a failure is faster than if the secondary path is not pre-signaled. When the secondary path is not pre-signaled a call-setup delay occurs during which the new physical path for the LSP is established, extending the recovery time. If the failure in the primary path is corrected, and after a few minutes of hold time, the ingress router switches traffic back from the secondary path to the primary path.

Because path protection is provided by the ingress router for the entire path, there can be some disadvantages, for example, double-booking of resources and unnecessary protection of links. By protecting a single resource at a time, local protection can remedy these disadvantages.

Configuring Path Protection in an MPLS Network (CLI Procedure)

IN THIS SECTION

- Configuring the Primary Path | **355**
- Configuring the Secondary Path | **356**
- Configuring the Revert Timer | **357**

The Junos OS implementation of MPLS on EX Series switches provides path protection as a mechanism for protecting against label switched path (LSP) failures. Path protection reduces the time required to recalculate a route in case of a failure within the MPLS tunnel. You configure path protection on the ingress provider edge switch in your MPLS network. You do not configure the egress provider edge switch or the provider switches for path protection. You can explicitly specify which provider switches are used for the primary and secondary paths, or you can let the software calculate the paths automatically.

Before you configure path protection, be sure you have:

- Configured an ingress provider edge switch and an egress provider edge switch. See "Configuring MPLS on Provider Edge Switches Using IP-Over-MPLS" on page 84 or "Configuring MPLS on Provider Edge EX8200 and EX4500 Switches Using Circuit Cross-Connect" on page 90.
- Configured at least one provider (transit) switch. See "Configuring MPLS on EX8200 and EX4500 Provider Switches" on page 94.
- Verified the configuration of your MPLS network.

To configure path protection, complete the following tasks on the ingress provider edge switch:

Configuring the Primary Path

The `primary` statement creates the primary path, which is the LSP's preferred path. The `secondary` statement creates an alternative path if the primary path can no longer reach the egress provider edge switch.

In the tasks described in this topic, the ***lsp-name*** has already been configured on the ingress provider edge switch as **lsp_to_240** and the loopback interface address on the remote provider edge switch has already been configured as **127.0.0.8**.

When the software switches from the primary to a secondary path, it continuously attempts to revert to the primary path, switching back to it when it is again reachable but no sooner than the time specified in the `revert-timer` statement.

You can configure zero primary paths or one primary path. If you do not configure a primary path, the first secondary path (if a secondary path has been configured) is selected as the path. If you do not specify any named paths, or if the path that you specify is empty, the software makes all routing decisions necessary for the packets to reach the egress provider edge switch.

To configure a primary path:

1. Create the primary path for the LSP:

```
[edit protocols mpls                          label-switched-path lsp_to_240 to 127.0.0.8]
user@switch# set primary primary_path_lsp_to_240
```

2. Configure an explicit route for the primary path by specifying the IP address of the loopback interface or the switch IP address or hostname of each switch used in the MPLS tunnel. You can specify the link types as either **strict** or **loose** in each `path` statement. If the link type is **strict**, the LSP must go to the next address specified in the `path` statement without traversing other switches. If the link type is **loose**, the LSP can traverse through other switches before reaching this switch. This configuration uses the default **strict** designation for the paths.

> **NOTE**: You can enable path protection without specifying which provider switches are used. If you do not list the specific provider switches to be used for the MPLS tunnel, the switch calculates the route.

TIP: Do not include the ingress provider edge switch in these statements. List the IP address of the loopback interface or switch address or hostname of all other switch hops in sequence, ending with the egress provider edge switch.

```
[edit protocols mpls label-switched-path lsp_to_240 to 127.0.0.8]
user@switch# set path primary_path_lsp_to_240 127.0.0.2
user@switch# set path primary_path_lsp_to_240 127.0.0.3
user@switch# set path primary_path_lsp_to_240 127.0.0.8
```

Configuring the Secondary Path

You can configure zero or more secondary paths. All secondary paths are equal, and the software tries them in the order that they are listed in the configuration. The software does not attempt to switch among secondary paths. If the first secondary path in the configuration is not available, the next one is tried, as so on. To create a set of equal paths, specify secondary paths without specifying a primary path. If you do not specify any named paths, or if the path that you specify is empty, the software makes all routing decisions necessary to reach the egress provider edge switch.

To configure the secondary path:

1. Create a secondary path for the LSP:

```
[edit protocols mpls label-switched-path lsp_to_240 to 127.0.0.8]
user@switch# set secondary secondary_path_lsp_to_240
standby
```

2. Configure an explicit route for the secondary path by specifying the IP address of the loopback interface or the switch IP address or hostname of each switch used in the MPLS tunnel. You can specify the link types as either **strict** or **loose** in each `path` statement. This configuration uses the default **strict** designation for the paths.

TIP: Do not include the ingress provider edge switch in these statements. List the IP address of the loopback interface or switch address or hostname of all other switch hops in sequence, ending with the egress provider edge switch.

```
[edit protocols mpls label-switched-path lsp_to_240 to 127.0.0.8]
user@switch# set path secondary_path_lsp_to_240 127.0.0.4
user@switch# set path primary_path_lsp_to_240 127.0.0.8
```

Configuring the Revert Timer

For LSPs configured with both primary and secondary paths, you can optionally configure a revert timer. If the primary path goes down and traffic is switched to the secondary path, the revert timer specifies the amount of time (in seconds) that the LSP must wait before it can revert traffic back to the primary path. If the primary path experiences any connectivity problems or stability problems during this time, the timer is restarted.

TIP: If you do not explicitly configure the revert timer, it is set by default to 60 seconds.

To configure the revert timer for LSPs configured with primary and secondary paths:

- For all LSPs on the switch:

```
[edit protocols mpls]
user@switch#  set revert-timer 120
```

- For a specific LSP on the switch:

```
[edit protocols mpls label-switched-path]
user@switch#  set lsp_to_240 revert-timer 120
```

Preventing Use of a Path That Previously Failed

If you configure an alternate path through the network in case the active path fails, you may not want traffic to revert back to the failed path, even if it is no longer failing. When you configure a primary path, the traffic switches over to the secondary path during a failure, and reverts back to the primary path when it returns.

At times, switching traffic back to a primary path that has previously failed may not be a particularly sound idea. In this case, only configure secondary paths, resulting in the next configured secondary path establishing when the first secondary path fails. Later, if the first secondary path becomes operational, the Junos OS will not revert to it, but will continue using the second secondary path.

Configuring MPLS Inter-AS Link-Node Protection with Labeled BGP

Understanding MPLS Inter-AS Link Protection

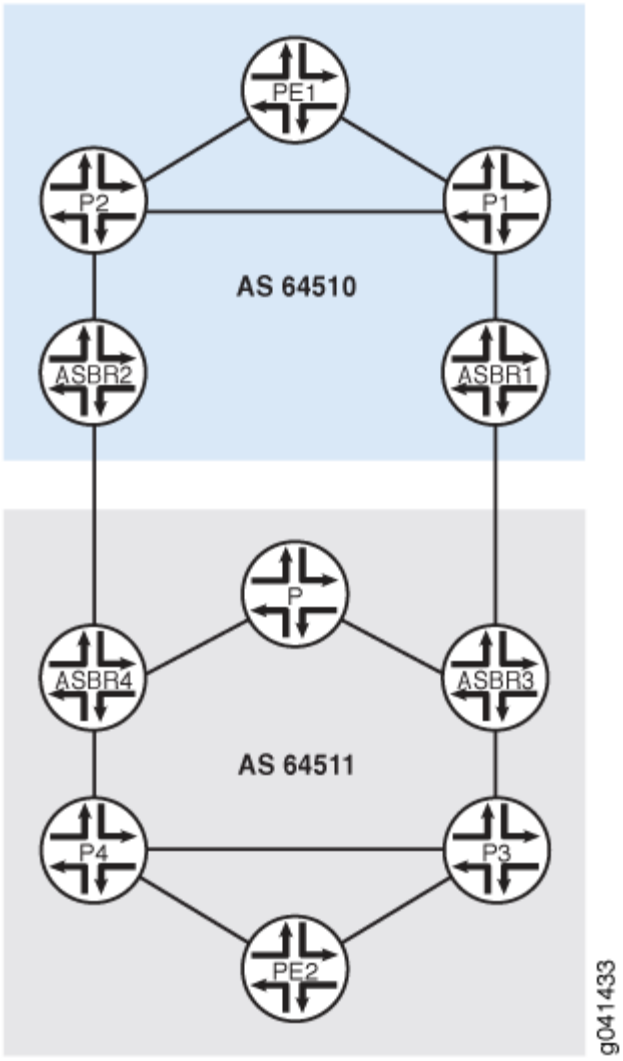
Link protection is essential in an MPLS network to ensure traffic restoration in case of an interface failure. The ingress router chooses an alternate link through another interface to send traffic to its destination.

In *Figure 3*, autonomous system border routers (ASBRs) run external BGP (EBGP) to ASBRs in another autonomous system (AS) to exchange labels for /32 IPv4 routes. Inside the ASs, internal BGP (IBGP) propagates the routes to provider edge (PE) devices. If the link from Device ASBR3 to Device ASBR1 goes down, until Device ASBR3 reinstalls the new next hop, all traffic going toward AS 64510 from AS 64511 through the ASBR3-ASBR1 link is dropped. A fast traffic restoration can be achieved if Device ASBR3 preprograms a backup path either through Device ASBR4 or through a direct path to Device ASBR2 if one exists (not shown in the diagram). This assumes that Device ASBR3 learns a loop-free MPLS path for routes that need to protected either through IBGP or EBGP.

This solution does not handle a failure on Device ASBR3 for traffic going toward AS 64511 from AS 64510 through the ASBR3-ASBR1 link. This solution is limited to downstream inter-AS link-node protection with labeled BGP. This solution does not support service restoration between provider (P) and ASBR routers when there is an ASBR failure. For example, this solution does not handle a failure on the P3-ASBR3 link.

This supported functionality is similar to BGP multipath, except only one next hop is used for active forwarding, and a second path is in protected mode.

Figure 13: MPLS Inter-AS Link-Node Protection Conceptual Topology



In an MPLS inter-AS environment, link protection can be enabled when `labeled-unicast` is used to send traffic between ASs. Hence, MPLS inter-AS link protection is configured on the link between two routers in different ASs.

To configure link protection on an interface, use the `protection` statement at the `[edit protocols bgp group` *`group-name`* `family inet labeled-unicast]` hierarchy level:

```
protocols {
    bgp {
```

```
        group test1 {
            type external;
            local-address 192.168.1.2;
            family inet {
                labeled-unicast {
                    protection;
                }
            }
        }
    }
}
```

NOTE: MPLS inter-AS link protection is supported only with *labeled-unicast* and external peers in a master routing instance.

The link on which protection is configured is known as the protection path. A protection path is selected only after the best path selection and is not selected in the following cases:

- The best path is a non-BGP path.
- Multiple next hops are active, as in BGP multipath.

This example shows how to configure tail-end protection in an inter-AS deployment with Layer 3 VPNs.

Requirements

No special configuration beyond device initialization is required before configuring this example.

Overview

IN THIS SECTION

- Topology | **362**

In Figure 14 on page 362. autonomous system border routers (ASBRs) run external BGP (EBGP) to ASBRs in another autonomous system (AS) to exchange labels for /32 IPv4 routes. Inside the ASs, internal BGP (IBGP) propagates the routes to provider edge (PE) devices.

If the link from Device ASBR3 to Device ASBR1 goes down, until ASBR3 reinstalls the new next hop, all traffic going toward AS 64510 from AS 64511 through the ASBR3-ASBR1 link is dropped.

This example shows how to achieve fast traffic restoration by configuring Device ASBR3 to preprogram a backup path through Device ASBR2.

NOTE: This solution does not handle the Device P3 to Device ASBR3 failure. Nor does it handle a failure on Device ASBR3 for traffic going toward AS 645111 from AS 64510 through the ASBR3-ASBR1 link. This traffic is dropped.

Procedure

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the Junos OS CLI User Guide.

To configure the EBGP scenario:

1. Configure the router interfaces.

```
[edit interfaces]
user@ASBR3# set fe-1/2/0 unit 0 description to-ASBR1
user@ASBR3# set fe-1/2/0 unit 0 family inet address 21.21.21.2/30
user@ASBR3# set fe-1/2/0 unit 0 family mpls
user@ASBR3# set fe-1/2/2 unit 0 description to-P3
user@ASBR3# set fe-1/2/2 unit 0 family inet address 22.22.22.1/30
user@ASBR3# set fe-1/2/2 unit 0 family mpls
user@ASBR3# set fe-1/2/1 unit 0 description to-ASBR2
user@ASBR3# set fe-1/2/1 unit 0 family inet address 26.26.26.2/30
user@ASBR3# set fe-1/2/1 unit 0 family mpls
user@ASBR3# set lo0 unit 0 family inet address 5.5.5.5/32
```

2. Configure an interior gateway protocol (IGP), such as OSPF or IS-IS.

```
[edit protocols ospf]
user@ASBR3# set traffic-engineering
[edit protocols ospf area 0.0.0.0]
user@ASBR3# set interface fe-1/2/2.0
```

```
user@ASBR3# set interface lo0.0 passive
user@ASBR3# set interface fe-1/2/1.0
```

3. Configure the autonomous system (AS) number.

```
[edit routing-options]
user@ASBR3# set autonomous-system 64511
```

4. Configure the routing policy.

```
[edit policy-options policy-statement To-ASBR1]
user@ASBR3# set term 1 from route-filter 7.7.7.7/32 exact
user@ASBR3# set term 1 then accept
user@ASBR3# set term 2 then reject
[edit policy-options policy-statement To-ASBR2]
user@ASBR3# set term 1 from route-filter 7.7.7.7/32 exact
user@ASBR3# set term 1 then accept
user@ASBR3# set term 2 then reject
[edit policy-options policy-statement next-hop-self]
user@ASBR3# set then next-hop self
```

5. Configure the EBGP sessions.

```
[edit protocols bgp group To-ASBR1]
user@ASBR3# set type external
user@ASBR3# set family inet labeled-unicast protection
user@ASBR3# set family inet labeled-unicast per-prefix-label
user@ASBR3# set export To-ASBR1
user@ASBR3# set neighbor 21.21.21.1 peer-as 64510
[edit protocols bgp group To-ASBR2]
user@ASBR3# set type external
user@ASBR3# set family inet labeled-unicast protection
user@ASBR3# set family inet labeled-unicast per-prefix-label
user@ASBR3# set export To-ASBR2
user@ASBR3# set neighbor 26.26.26.1 peer-as 64510
```

6. Configure the IBGP sessions.

```
[edit protocols bgp group To-PE2]
user@ASBR3# set type internal
user@ASBR3# set local-address 5.5.5.5
user@ASBR3# set family inet unicast
user@ASBR3# set export next-hop-self
user@ASBR3# set neighbor 7.7.7.7 family inet labeled-unicast
```

7. Configure MPLS.

```
[edit protocols mpls]
user@ASBR3# set traffic-engineering bgp-igp-both-ribs
user@ASBR3# set label-switched-path To_PE2 to 7.7.7.7
user@ASBR3# set interface lo0.0
user@ASBR3# set interface fe-1/2/0.0
user@ASBR3# set interface fe-1/2/2.0
user@ASBR3# set interface fe-1/2/1.0
```

8. Configure a signaling protocol.

```
[edit protocols rsvp]
user@ASBR3# set interface fe-1/2/2.0
user@ASBR3# set interface lo0.0
user@ASBR3# set interface fe-1/2/0.0
user@ASBR3# set interface fe-1/2/1.0
```

Results

From configuration mode, confirm your configuration by entering the `show interfaces`, `show protocols`, `show policy-options`, and `show routing-options`, commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@ASBR3# show interfaces

  Output Queue[0]: 0
```

Meaning

The output shows that the `Protection` option is enabled for the EBGP peers, Device ASBR1 and Device ASBR2.

This is also shown with the `NLRI configured with protection: inet-labeled-unicast` screen output.

Checking the Routes

Purpose

Make sure that the backup path is installed in the routing table.

Action

```
user@ASBR3> show route 2.2.2.2
inet.0: 12 destinations, 14 routes (12 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

2.2.2.2/32         *[BGP/170] 01:36:25, MED 2, localpref 100
                      AS path: 64510 I, validation-state: unverified
                    > to 21.21.21.1 via fe-1/2/0.0, Push 299824
                      to 26.26.26.1 via fe-1/2/1.0, Push 299808
                    [BGP/170] 01:36:25, MED 2, localpref 100
                      AS path: 64510 I, validation-state: unverified
                    > to 26.26.26.1 via fe-1/2/1.0, Push 299808
```

Meaning

The `show route` command displays active as well as backup paths to Device PE1.

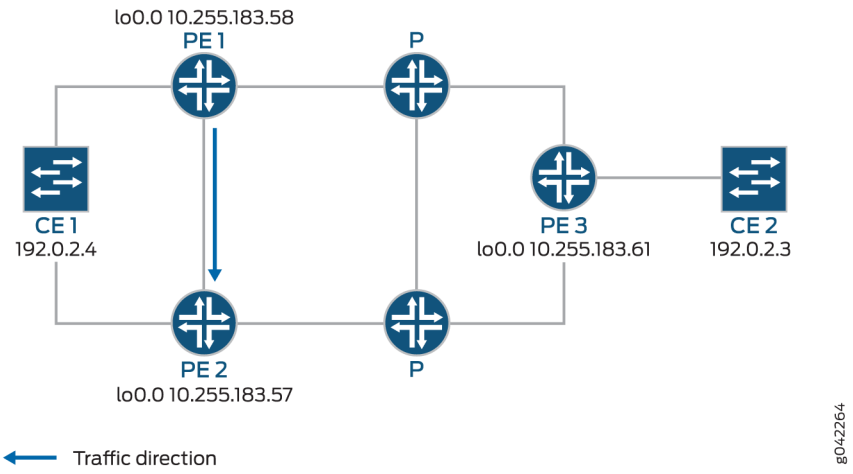
Configuring Egress Protection Service Mirroring for BGP Signaled Layer 2 Services

Starting in Junos OS Release 14.2, Junos OS supports the restoration of egress traffic when there is a link or node failure in the egress PE node. If there is a link or node failure in the core network, a protection mechanism such as MPLS fast reroute can be triggered on the transport LSPs between the PE routers to repair the connection within tens of milliseconds. An egress protection LSP addresses the problem of a node-link failure at the edge of the network (for example, a failure of a PE router).

Figure 1 shows a simplified topology of the use case that explains this feature.

Figure 15: Egress Protection LSP Configured from Router PE1 to Router PE2



CE1 is multihomed to PE1 and PE2. There are two paths connecting CE1 and CE2. The working path is CE2-PE3-P-PE1-CE1, via pseudowire PW21. The protecting path is CE2-PE3-P-PE2-CE1, via pseudowire PW22 Traffic is flowing through the working path under normal circumstances. When the end-to-end OAM between CE1 and CE2 detects failure on the working path, traffic will be switched from the working path to the protecting path. The end-to-end failure detection and recovery relies on control plane hence should be relatively slow. To achieve faster protection, local repair mechanisms similar to those used by MPLS fast reroute should be used. In Figure 1 above, if link or node failed in the core network (like link failure on P-PE1, P-PE3, or node failure on P), the MPLS fast reroute will happen on the transport LSPs between PE1 and PE3. The failure could be locally repaired within tens of milliseconds. However, if link or node failure happens at the edge (like link failure on PE3-CE2 or node failure on PE3), there is no local repair currently so we have to rely on the CE1-CE2 end-to-end protection to repair the failure.

- Device CE2—Traffic origin
- Router PE3—Ingress PE router
- Router PE1— (Primary) Egress PE router
- Router PE2—Protector PE router
- Device CE1—Traffic destination

When the link between CE1– PE1 goes downs, PE1 will briefly redirect that traffic towards CE1, to PE2. PE2 forwards it to CE1 until ingress router PE3 recalculates to forward the traffic to PE2.

Initially the traffic direction was; CE2 – PE3 – P – PE1 – CE1.

When the link between CE1– PE1 goes down, the traffic will be; CE2 – PE3 – P – PE1 – PE2 –CE1. PE3 then recalculates the path; CE2 – PE3 – P – PE2 – CE1.

1. Configure RSVP on PE1, PE2, and PE3.

```
[edit protocols]
user@PE1# set interface all
user@PE2# set interface all
user@PE3# set interface all
```

2. Configure MPLS.

```
[edit protocols mpls]
user@PE1# set interface all
user@PE2# set interface all
user@PE3# set interface all
```

3. Set PE1 as `primary` and PE2 as `protector` nodes.

```
[edit protocols mpls]
user@PE1# set egress-protection context-identifier address primary
user@PE2# set egress-protection context-identifier address protector
```

4. Enable `egress-protection` on PE1 and PE2.

```
[edit protocols bgp]
user@PE1# set group ibgp family l2vpn egress-protection
user@PE2# set group ibgp family l2vpn egress-protection
```

5. Configure LDP and ISIS on PE1, PE2, and PE3.

```
[edit protocols ldp]
user@PE1# set interface all
```

```
user@PE2# set interface all
user@PE3# set interface all
```

```
[edit protocols isis]
user@PE1# set interface all point-to-point
user@PE2# set interface all point-to-point
user@PE3# set interface all point-to-point
```

6. Configure a load balancing policy at PE1, PE2, and PE3.

```
[edit]
user@PE1# set policy-options policy-statement lb then load-balance per-packet
user@PE2# set policy-options policy-statement lb then load-balance per-packet
user@PE3# set policy-options policy-statement lb then load-balance per-packet
```

7. Configure the routing options at PE1, PE2, and PE3, to export routes based on the load balancing policy.

```
[edit]
user@PE1# set routing-options traceoptions file ro.log
user@PE1# set routing-options traceoptions flag normal
user@PE1# set routing-options traceoptions flag route
user@PE1# set routing-options autonomous-system 100
user@PE1# set routing-options forwarding-table export lb
```

```
[edit]
user@PE2# set routing-options traceoptions file ro.log
user@PE2# set routing-options traceoptions flag normal
user@PE2# set routing-options traceoptions flag route
user@PE2# set routing-options autonomous-system 100
user@PE2# set routing-options forwarding-table export lb
```

```
[edit]
user@PE3# set routing-options traceoptions file ro.log
user@PE3# set routing-options traceoptions flag normal
user@PE3# set routing-options traceoptions flag route
```

```
user@PE3# set routing-options autonomous-system 100
user@PE3# set routing-options forwarding-table export lb
```

8. Configure BGP at PE1 to advertise nrli from the routing instance with context-ID as next-hop.

```
[edit]
user@PE1# set routing-instances foo egress-protection context-identifier context-identifier
```

9. Configure l2vpn at PE1, PE2, and PE3

   At PE1:

```
[edit routing-instances]
foo {
    instance-type l2vpn;
    egress-protection {
        context-identifier {
            198.51.100.0;
        }
    }
    interface ge-2/0/2.0;
    route-distinguisher 10.255.183.58:1;
    vrf-target target:9000:1;
    protocols {
        l2vpn {
            encapsulation-type ethernet-vlan;
            site foo {
                site-identifier 1;
                multi-homing;
                site-preference primary;
                interface ge-2/0/2.0 {
                    remote-site-id 2;
                }
            }
        }
    }
}
```

   At PE2:

```
[edit routing-instances]
foo {
```

```
    instance-type l2vpn;
    egress-protection {
        protector;
    }
    interface ge-2/0/2.0;
    route-distinguisher 10.255.183.57:1;
    vrf-target target:9000:1;
    protocols {
        l2vpn {
            encapsulation-type ethernet-vlan;
            site foo{
                site-identifier 1;
                multi-homing;
                site-preference backup;
                interface ge-2/0/2.0 {
                    remote-site-id 2;
                }
            }
        }
    }
}
```

At PE3:

```
[edit routing-instances]
foo {
    instance-type l2vpn;
    interface ge-2/1/2.0;
    route-distinguisher 10.255.183.61:1;
    vrf-target target:9000:1;
    protocols {
        l2vpn {
            encapsulation-type ethernet-vlan;
            site foo {
                site-identifier 2;
                interface ge-2/1/2.0;
            }
        }
    }
}
```

Example: Configuring MPLS Egress Protection Service Mirroring for BGP Signaled Layer 2 Services

IN THIS SECTION

- Requirements | 385
- Overview | 385
- Configuration | 387
- Verification | 404

Starting in Junos OS Release 14.2, Junos OS supports the restoration of egress traffic when there is a link or node failure in the egress PE node. If there is a link or node failure in the core network, a protection mechanism such as MPLS fast reroute can be triggered on the transport LSPs between the PE routers to repair the connection within tens of milliseconds. An egress protection LSP addresses the problem of a node-link failure at the edge of the network (for example, a failure of a PE router).

This example shows how to configure link protection for BGP signaled Layer 2 services.

Requirements

MX Series Routers running Junos OS Release 14.2 or later.

Overview

IN THIS SECTION

- Topology | 386

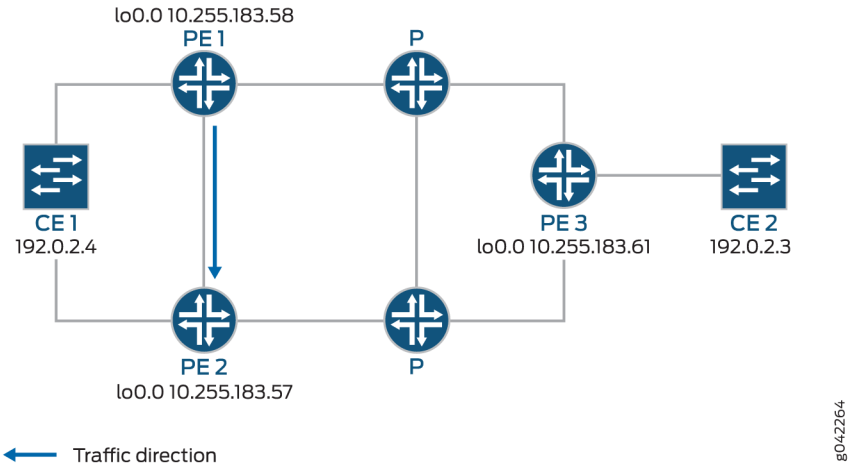
If there is a link or node failure in the core network, a protection mechanism such as MPLS fast reroute can be triggered on the transport LSPs between the PE routers to repair the connection within tens of milliseconds. An egress protection LSP addresses the problem of a node-link failure at the edge of the network (for example, a failure of a PE router).

This example includes the following configuration concepts and statements that are unique to the configuration of an egress protection LSP:

- `context-identifier`—Specifies an IPv4 or IPv6 address used to define the pair of PE routers participating in the egress protection LSP. It is assigned to each ordered pair of primary PE and the protector to facilitate protection establishment. This address is globally unique, or unique in the address space of the network where the primary PE and the protector reside.
- `egress-protection`—Configures the protector information for the protected Layer 2 circuit and configures the protector Layer 2 circuit at the `[edit protocols mpls]` hierarchy level. Configures an LSP as an egress protection LSP at the `[edit protocols mpls]` hierarchy level.
- `protector`—Configures the creation of standby pseudowires on the backup PE for link or node protection for the instance.

Topology

Figure 16: Egress Protection LSP Configured from Router PE1 to Router PE2



In the event of a failure of the egress PE Router PE1, traffic is switched to the egress protection LSP configured between Router PE1 and Router PE2 (the protector PE router):

- Device CE2—Traffic origin
- Router PE3—Ingress PE router
- Router PE1— (Primary) Egress PE router
- Router PE2—Protector PE router
- Device CE1—Traffic destination

When the link between CE1– PE1 goes downs, PE1 will briefly redirect that traffic toward CE1, to PE2. PE2 forwards it to CE1 until ingress router PE3 recalculates to forward the traffic to PE2.

Initially the traffic direction was: CE2 – PE3 – P – PE1 – CE1.

When the link between CE1– PE1 goes down, the traffic will be: CE2 – PE3 – P – PE1 – PE2 –CE1. PE3 then recalculates the path: CE2 – PE3 – P – PE2 – CE1.

This example shows how to configure routers PE1, PE2, and PE3.

Configuration

IN THIS SECTION

- CLI Quick Configuration | 387
- Step-by-Step Procedure | 390
- Results | 397

CLI Quick Configuration

To quickly configure an egress protection LSP, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configurations, copy and then paste the commands into the CLI and enter `commit` from configuration mode.

PE1

```
set protocols rsvp interface all
set protocols rsvp interface fxp0.0 disable
set protocols mpls interface all

Step-by-Step Procedure

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure an egress protection LSP for router PE1:

1. Configure RSVP.

```
[edit protocols rsvp]
user@PE1# set interface all
user@PE1# set interface fxp0.0 disable
```

2. Configure MPLS to use the egress protection LSP to protect against a link failure to Device CE1.

```
[edit protocols mpls]
user@PE1# set interface all
user@PE1# set interface fxp0.0 disable
```

```
user@PE1# set egress-protection context-identifier 198.51.100.3 primary
user@PE1# set egress-protection context-identifier 198.51.100.3 advertise-mode stub-alias
user@PE1# set egress-protection traceoptions file ep size 100m
user@PE1# set egress-protection traceoptions flag all
```

3. Configure BGP.

```
[edit protocols bgp]
user@PE1# set traceoptions file bgp.log world-readable
user@PE1# set group ibgp type internal
user@PE1# set group ibgp local-address 10.255.183.58
user@PE1# set group ibgp family inet unicast
user@PE1# set group ibgp family l2vpn signaling egress-protection
user@PE1# set group ibgp neighbor 192.0.2.3
user@PE1# set group ibgp neighbor 192.0.2.4
```

4. Configure IS-IS.

```
[edit protocols isis]
user@PE1# set traceoptions file isis-edge size 10m world-readable
user@PE1# set traceoptions flag error
user@PE1# set level 1 disable
user@PE1# set level 2 wide-metrics-only
user@PE1# set interface all point-to-point
user@PE1# set interface all level 2 metric 10
user@PE1# set interface fxp0.0 disable
```

5. Configure LDP.

```
[edit protocols ldp]
user@PE1# set interface all
user@PE1# set interface fxp0.0 disable
```

6. Configure a load-balancing policy.

```
[edit]
user@PE1# set policy-options policy-statement lb then load-balance per-packet
```

7. Configure the routing options to export routes based on the load-balancing policy.

```
[edit routing-options]
user@PE1# set traceoptions file ro.log
user@PE1# set traceoptions flag all
user@PE1# set autonomous-system 100
user@PE1# set forwarding-table export lb
```

8. Configure BGP to advertise nrli from the routing instance with context-ID as next-hop.

```
[edit routing-instances]
user@PE1# set foo instance-type l2vpn
user@PE1# set foo egress-protection context-identifier 198.51.100.3
user@PE1# set foo interface ge-2/0/2.0
user@PE1# set foo route-distinguisher 10.255.183.58:1
user@PE1# set foo vrf-target target:9000:1
```

9. Configure l2vpn instance to use the egress LSP configured.

```
[edit routing-instances]
user@PE1# set foo protocols l2vpn encapsulation-type ethernet-vlan
user@PE1# set foo protocols l2vpn site foo site-identifier 1
user@PE1# set foo protocols l2vpn site foo site-preference primary
user@PE1# set foo protocols l2vpn site foo interface ge-2/0/2.0 remote-site-id 2
```

10. If you are done configuring the device, enter `commit` from configuration mode.

Step-by-Step Procedure

To configure an egress protection LSP for Router PE2:

1. Configure RSVP.

```
[edit protocols rsvp]
user@PE2# set interface all
user@PE2# set interface fxp0.0 disable
```

2. Configure MPLS and the LSP that acts as the egress protection LSP.

```
[edit protocols mpls]
user@PE2# set interface all
user@PE2# set interface fxp0.0 disable
user@PE2# set egress-protection context-identifier 198.51.100.3 protector
user@PE2# set egress-protection context-identifier 198.51.100.3 advertise-mode stub-alias
user@PE2# set egress-protection traceoptions file ep size 100m
user@PE2# set egress-protection traceoptions flag all
```

3. Configure BGP.

```
[edit protocols bgp]
user@PE2# set traceoptions file bgp.log world-readable
user@PE2# set group ibgp type internal
user@PE2# set group ibgp local-address 10.255.183.57
user@PE2# set group ibgp family inet unicast
user@PE2# set group ibgp family l2vpn signaling
user@PE2# set group ibgp family l2vpn egress-protection
user@PE2# set group ibgp neighbor 192.0.2.3
user@PE2# set group ibgp neighbor 192.0.2.4
```

4. Configure IS-IS.

```
[edit protocols isis]
user@PE2# set traceoptions file isis-edge size 10m world-readable
user@PE2# set traceoptions flag error
user@PE2# set level 1 disable
user@PE2# set level 2 wide-metrics-only
user@PE2# set interface all point-to-point
user@PE2# set interface all level 2 metric 10
user@PE2# set interface fxp0.0 disable
```

5. Configure LDP.

```
[edit protocols ldp]
user@PE2# set interface all
user@PE2# set interface fxp0.0 disable
```

6. Configure a load-balancing policy.

```
[edit]
user@PE2# set policy-options policy-statement lb then load-balance per-packet
```

7. Configure the routing options to export routes based on the load-balancing policy.

```
[edit routing-options]
user@PE2# set traceoptions file ro.log
user@PE2# set traceoptions flag all
user@PE2# set autonomous-system 100
user@PE2# set forwarding-table export lb
```

8. Configure BGP to advertise nrli from the routing instance with context-ID as next-hop.

```
[edit routing-instances]
user@PE2# set foo instance-type l2vpn
user@PE2# set foo egress-protection protector
user@PE2# set foo interface ge-2/0/2.0
user@PE2# set foo route-distinguisher 10.255.183.57:1
user@PE2# set foo vrf-target target:9000:1
```

9. Configure l2vpn instance to use the egress LSP configured.

```
[edit routing-instances]
user@PE2# set foo protocols l2vpn encapsulation-type ethernet-vlan
user@PE2# set foo protocols l2vpn site foo hot-standby
user@PE2# set foo protocols l2vpn site foo site-identifier 1
user@PE2# set foo protocols l2vpn site foo site-preference backup
user@PE2# set foo protocols l2vpn site foo interface ge-2/0/2.0 remote-site-id 2
```

10. If you are done configuring the device, enter `commit` from configuration mode.

Step-by-Step Procedure

To configure an egress protection LSP for Router PE3:

1. Configure RSVP.

```
[edit protocols rsvp]
user@PE3# set interface all
user@PE3# set interface fxp0.0 disable
```

2. Configure MPLS.

```
[edit protocols mpls]
user@PE3# set interface all
user@PE3# set interface fxp0.0 disable
```

3. Configure BGP.

```
[edit protocols bgp]
user@PE3# set traceoptions file bgp.log world-readable
user@PE3# set group ibgp type internal
user@PE3# set group ibgp local-address 10.255.183.61
user@PE3# set group ibgp family inet unicast
user@PE3# set group ibgp family l2vpn signaling
user@PE3# set group ibgp neighbor 192.0.2.3
user@PE3# set group ibgp neighbor 192.0.2.4
```

4. Configure IS-IS.

```
[edit protocols isis]
user@PE3# set traceoptions file isis-edge size 10m world-readable
user@PE3# set traceoptions flag error
user@PE3# set level 1 disable
user@PE3# set level 2 wide-metrics-only
user@PE3# set protocols isis interface all point-to-point
[edit protocols isis]
user@PE3# set protocols isis interface all level 2 metric 10
[edit protocols isis]
user@PE3# set protocols isis interface fxp0.0 disable
```

5. Configure LDP.

```
[edit protocols ldp]
user@PE3# set interface all
user@PE3# set interface fxp0.0 disable
```

6. Configure a load-balancing policy.

```
[edit]
user@PE3# set policy-options policy-statement lb then load-balance per-packet
```

7. Configure the routing options to export routes based on the load-balancing policy.

```
[edit routing-options]
user@PE3# set traceoptions file ro.log
user@PE3# set traceoptions flag normal
user@PE3# set traceoptions flag route
user@PE3# set autonomous-system 100
user@PE3# set forwarding-table export lb
```

8. Configure BGP to advertise nlri from the routing instance with context-ID as next-hop.

```
[edit]
user@PE3# set routing-instances foo instance-type l2vpn
user@PE3# set routing-instances foo interface ge-2/1/2.0
user@PE3# set routing-instances foo route-distinguisher 10.255.183.61:1
user@PE3# set routing-instances foo vrf-target target:9000:1
```

9. Configure l2vpn to specify the interface that connects to the site and the remote interface to which you want the specified interface to connect.

```
[edit routing-instances]
user@PE3# set foo protocols l2vpn encapsulation-type ethernet-vlan
user@PE3# set foo protocols l2vpn site foo site-identifier 2
user@PE3# set foo protocols l2vpn site foo interface ge-2/1/2.0 remote-site-id 1
```

10. If you are done configuring the device, enter `commit` from configuration.

Results

From configuration mode, confirm your configuration on Router PE1 by entering the **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

                interface ge-2/1/2.0 {
                    remote-site-id 1;
                }
            }
        }
    }
}
```

Verification

IN THIS SECTION

- Verifying the L2VPN Configuration | **405**
- Verifying the Routing Instance Details | **406**
- Verifying the IS-IS Configuration | **407**
- Verifying the MPLS Configuration | **407**

Confirm that the configuration is working properly.

Verifying the L2VPN Configuration

Purpose

Verify that LSP is protected by the connection protection logic.

Action

From operational mode, run the `show l2vpn connections extensive` command.

```
user@PE2> show l2vpn connections extensive
```

```
Layer-2 VPN connections:
Legend for connection status (St)
EI -- encapsulation invalid      NC -- interface encapsulation not CCC/TCC/VPLS
EM -- encapsulation mismatch     WE -- interface and instance encaps not same
VC-Dn -- Virtual circuit down    NP -- interface hardware not present
CM -- control-word mismatch      -> -- only outbound connection is up
CN -- circuit not provisioned    <- -- only inbound connection is up
OR -- out of range               Up -- operational
OL -- no outgoing label          Dn -- down
LD -- local site signaled down   CF -- call admission control failure
RD -- remote site signaled down  SC -- local and remote site ID collision
LN -- local site not designated  LM -- local site ID not minimum designated
RN -- remote site not designated RM -- remote site ID not minimum designated
XX -- unknown connection status  IL -- no incoming label
MM -- MTU mismatch               MI -- Mesh-Group ID not available
BK -- Backup connection          ST -- Standby connection
PF -- Profile parse failure      PB -- Profile busy
RS -- remote site standby        SN -- Static Neighbor
LB -- Local site not best-site   RB -- Remote site not best-site
VM -- VLAN ID mismatch
Legend for interface status
Up -- operational
Dn -- down
Instance: foo
Local site: foo (1)
```

```
  connection-site           Type  St  Time last up          # Up trans
   2                         rmt   Up  Aug  3 00:08:14 2001           1
     Local circuit: ge-2/0/2.0, Status: Up
     Remote PE: 192.0.2.3
     Incoming label: 32769, Outgoing label: 32768
     Egress Protection: Yes
       Time                  Event            Interface/Lbl/PE
       Aug  3 00:08:14 2001  PE route up
       Aug  3 00:08:14 2001  Out lbl Update              32768
       Aug  3 00:08:14 2001  In lbl Update               32769
       Aug  3 00:08:14 2001  ckt0 up                 fe-0/0/0.0
```

Meaning

The `Egress Protection: Yes` output shows that the given PVC is protected by connection protection logic.

Verifying the Routing Instance Details

Purpose

Verify the routing instance information and the context identifier configured on the primary, which is used as the next-hop address in case of node-link failure.

Action

From operational mode, run the `show route foo detail` command.

```
user@PE2> show route foo detail
```

```
foo:
  Router ID: 0.0.0.0
  Type: l2vpn non-forwarding State: Active
  Interfaces:
    lt-1/2/0.56
  Route-distinguisher: 10.255.255.11:1
  Vrf-import: [ __vrf-import-foo-internal__ ]
  Vrf-export: [ __vrf-export-foo-internal__ ]
  Vrf-import-target: [ target:100:200 ]
  Vrf-export-target: [ target:100:200 ]
```

```
  Fast-reroute-priority: low
  Vrf-edge-protection-id:  198.51.100.3
  Tables:
    foo.l2vpn.0           : 5 routes (3 active, 0 holddown, 0 hidden)
    foo.l2id.0            : 6 routes (2 active, 0 holddown, 0 hidden)
```

Meaning

The context-id is set to `198.51.100.3` and the `Vrf-import: [ __vrf-import-foo-internal__]` in the output mentions the policy used for rewriting the next-hop address.

Verifying the IS-IS Configuration

Purpose

Verify the IS-IS context identifier information.

Action

From operational mode, run the `show isis context-identifier detail` command.

```
user@PE2> show isis context-identifier detail
```

```
IS-IS context database:
Context               L  Owner     Role       Primary      Metric
198.51.100.3             2  MPLS      Protector  pro17-b-lr-R1 0
  Advertiser pro17-b, Router ID 10.255.107.49, Level 2, tlv protector
  Advertiser pro17-b-lr-R1, Router ID 10.255.255.11, Metric 1, Level 2, tlv prefix
```

Meaning

Router PE2 is the protector and the configured context identifier is in use for the MPLS protocol.

Verifying the MPLS Configuration

Purpose

Verify the context identifier details on the primary and protector PEs.

Action

From operational mode, run the `show mpls context-identifier detail` command.

```
user@PE1> show mpls context-identifier detail
```

```
ID: 198.51.100.3
  Type: primary, Metric: 1, Mode: alias

Total 1, Primary 1, Protector 0
```

```
user@PE2> show mpls context-identifier detail
```

```
ID: 198.51.100.3
  Type: protector, Metric: 16777215, Mode: alias
  Context table: __198.51.100.3__.mpls.0, Label out: 299968
```

```
user@PE2> show mpls egress-protection detail
```

```
Instance                Type      Protection-Type
foo                   local-l2vpn Protector
  Route Target 100:200
```

Meaning

Context-id is `198.51.100.3`, advertise-mode is `alias`, the MPLS table created for egress protection is `__198.51.100.3__.mpls.0`, and the egress instance name is `foo`, which is of type `local-l2vpn`.

Example: Configuring Layer 3 VPN Egress Protection with PLR as Protector

IN THIS SECTION

- Requirements | 409
- Overview | 409
- Configuration | 410
- Verification | 434

This example shows how to configure fast service restoration at the egress of a Layer 3 VPN when the customer is multihomed to the service provider.

Starting in Junos OS Release 15.1, the enhanced point of local repair (PLR) functionality addresses a special scenario of egress node protection, where the PLR and the protector are co-located as one router. In this case, there is no need to have a bypass LSP reroute traffic during local repair. Instead, the PLR or the protector can send the traffic directly to the target CE (in Co-located protector model where the PLR or the protector is also the backup PE that is directly connected to the CE) or to the backup PE (in Centralized protector model where the backup PE is a separate router).

Requirements

No special configuration beyond device initialization is required before configuring this example.

This example requires Junos OS Release 15.1 or later.

Overview

IN THIS SECTION

- Topology | 410

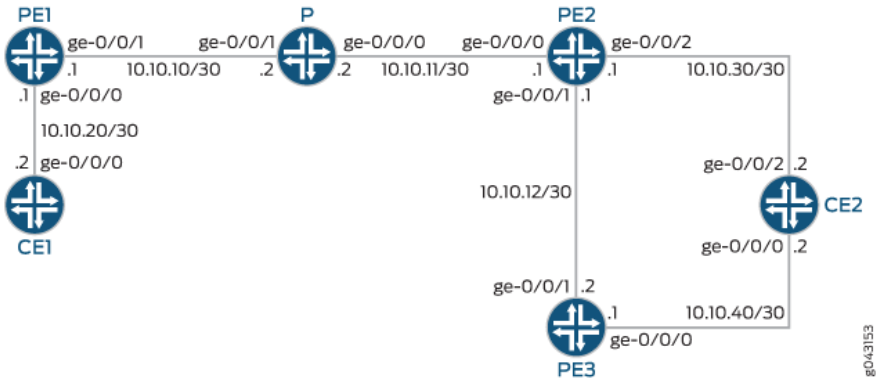
As a special scenario of egress node protection, if a router is both a Protector and a PLR, it installs backup next hops to protect the transport LSP. In particular, it does not need a bypass LSP for local repair.

In the Co-located protector model, the PLR or the Protector is directly connected to the CE via a backup AC, while in the Centralized protector model, the PLR or the protector has an MPLS tunnel to the backup PE. In either case, the PLR or the Protector will install a backup next hop with a label followed by a lookup in a `context label` table, i.e. `__context__.mpls.0`. When the egress node fails, the PLR or the Protector will switch traffic to this backup next hop in PFE. The outer label (the transport LSP label) of packets is popped, and the inner label (the layer 3 VPN label allocated by the egress node) is looked up in `__context__.mpls.0`, which results in forwarding the packets directly to the CE (in Collocated protector model) or the backup PE (in Centralized protector model).

Topology

Figure 17 on page 410 shows the sample network.

Figure 17: Co-located PLR and protector in collocated protector model



Configuration

```

Configuring Device CE1

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the Junos OS CLI User Guide.

1. Configure interfaces.

```
[edit interfaces]
user@CE1# set ge-0/0/0 unit 0 family inet address 10.10.20.2/30
user@CE1# set lo0 unit 0 family inet address 10.255.162.87/32
```

Configuring Device PE1

Step-by-Step Procedure

1. Configure the interfaces.

```
[edit interfaces]
user@PE1# set ge-0/0/0 unit 0 family inet address 10.10.20.1/30
user@PE1# set ge-0/0/1 unit 0 family inet address 10.10.10.1/30
user@PE1# set ge-0/0/1 unit 0 family iso
user@PE1# set ge-0/0/1 unit 0 family inet6
user@PE1# set ge-0/0/1 unit 0 family mpls
user@PE1# set lo0 unit 0 family inet address 127.0.0.1/32
user@PE1# set lo0 unit 0 family inet address 10.255.162.84/32 primary
user@PE1# set lo0 unit 0 family iso address 47.0005.80ff.f800.0000.0108.0001.0102.5516.2084.00
user@PE1# set lo0 unit 0 family inet6 address abcd::10:255:162:84/128 primary
```

2. Configure the autonomous system (AS) number.

```
[edit routing-options]
user@PE1# set autonomous-system 65000
user@PE1# set forwarding-table export pplb
```

3. Configure RSVP.

```
[edit protocols rsvp]
user@PE1# set interface all link-protection
user@PE1# set interface fxp0.0 disable
```

4. Enable MPLS.

```
[edit protocols mpls]
user@PE1# set interface all
user@PE1# set interface fxp0.0 disable
```

5. Configure BGP.

```
[edit protocols bgp]
user@PE1# set group vpn type internal
user@PE1# set group vpn local-address 10.255.162.84
user@PE1# set group vpn family inet-vpn unicast
user@PE1# set group vpn neighbor 10.255.162.91
user@PE1# set group vpn neighbor 10.255.162.89
user@PE1# set vpn-apply-export
```

6. Enable IS-IS.

```
[edit protocols isis]
user@PE1# set interface all
user@PE1# set interface fxp0.0 disable
user@PE1# set interface lo0.0 passive
```

7. (Optional) Configure OSPF

```
[edit protocols ospf]
user@PE1# set area 0.0.0.0 interface all
user@PE1# set area 0.0.0.0 interface fxp0.0 disable
user@PE1# set area 0.0.0.0 interface lo0.0 passive
user@PE1# set traffic-engineering
```

8. Configure the routing instance.

```
[edit routing-instances]
user@PE1# set vpn instance-type vrf
user@PE1# set vpn interface ge-1/0/0.0
user@PE1# set vpn route-distinguisher 100:100
user@PE1# set vpn vrf-import vpn-imp
```

```
user@PE1# set vpn vrf-export vpn-exp
user@PE1# set vpn vrf-table-label
user@PE1# set vpn protocols bgp group vpn type external
user@PE1# set vpn protocols bgp group vpn family inet unicast
user@PE1# set vpn protocols bgp group vpn family inet6 unicast
user@PE1# set vpn protocols bgp group vpn peer-as 65001
user@PE1# set vpn protocols bgp group vpn as-override
user@PE1# set vpn protocols bgp group vpn neighbor 10.10.20.2
```

9. Configure the routing policy.

```
[edit]
user@PE1# set policy-options policy-statement vpn-exp term 1 from protocol direct
user@PE1# set policy-options policy-statement vpn-exp term 1 from route filter 10.10.20.0/24
exact
user@PE1# set policy-options policy-statement vpn-exp term 1 then community add vpn
user@PE1# set policy-options policy-statement vpn-exp term 1 then accept
user@PE1# set policy-options policy-statement vpn-imp term 1 from community vpn
user@PE1# set policy-options policy-statement vpn-imp term 1 then accept
user@PE1# set policy-options policy-statement vpn-imp term 2 then reject
user@PE1# set policy-options community vpn members traget:1:1
```

Configuring Device P

Step-by-Step Procedure

1. Configure the device interfaces.

```
[edit interfaces]
user@P# set ge-0/0/0 unit 0 family inet address 10.10.11.2/30
user@P# set ge-0/0/0 unit 0 family inet6
user@P# set ge-0/0/0 unit 0 family iso
user@P# set ge-0/0/0 unit 0 family mpls
user@P# set ge-0/0/1 unit 0 family inet address 10.10.10.2/30
user@P# set ge-0/0/1 unit 0 family inet6
user@P# set ge-0/0/1 unit 0 family iso
user@P# set ge-0/0/1 unit 0 family mpls
user@P# set lo0 unit 0 family inet address 127.0.0.1/32
user@P# set lo0 unit 0 family inet address 10.255.162.86/32 primary
```

```
user@P# set lo0 unit 0 family inet6 address abcd::10:255:162:86/128 primary
user@P# set lo0 unit 0 family iso address 47.0005.80ff.f800.0000.0108.0001.0102.5516.2086.00
```

2. Enable IS-IS.

```
[edit protocols isis]
user@P# set interface all
user@P# set interface fxp0.0 disable
```

3. Enable MPLS.

```
[edit protocols mpls ]
user@P# set interface all
user@P# set interface fxp0.0 disable
```

4. Configure RSVP.

```
[edit protocols rsvp]
user@P# set interface all link-protection
user@P# set interface fxp0.0 disable
```

5. (Optional) Configure OSPF.

```
[edit protocols ospf]
user@P# set area 0.0.0.0 interface all
user@P# set area 0.0.0.0 interface fxp0.0 disable
user@P# set area 0.0.0.0 interface lo0.0 passive
user@P# set traffic-engineering
```

Configuring Device PE2

Step-by-Step Procedure

1. Configure the interfaces.

```
[edit interfaces]
user@PE2# set ge-0/0/0 unit 0 family inet address 10.10.11.1/30
```

```
user@PE2# set ge-0/0/0 unit 0 family iso
user@PE2# set ge-0/0/0 unit 0 family inet6
user@PE2# set ge-0/0/0 unit 0 family mpls
user@PE2# set ge-0/0/1 unit 0 family inet address 10.10.12.1/30
user@PE2# set ge-0/0/1 unit 0 family iso
user@PE2# set ge-0/0/1 unit 0 family inet6
user@PE2# set ge-0/0/1 unit 0 family mpls
user@PE2# set ge-0/0/2 unit 0 family inet address 10.10.30.1/30
user@PE2# set lo0 unit 0 family inet address 127.0.0.1/32
user@PE2# set lo0 unit 0 family inet address 10.255.162.91/32 primary
user@PE2# set lo0 unit 0 family iso address 47.0005.80ff.f800.0000.0108.0001.0102.5516.2091.00
user@PE2# set lo0 unit 0 family inet6 address abcd::10:255:162:91/128 primary
```

2. Configure autonomous number(AS).

```
[edit routing-options]
user@PE2# set autonomous-system 65000
user@PE2# set forwarding-table export pplb
```

3. Configure RSVP.

```
[edit protocols rsvp]
user@PE2# set interface all link-protection
user@PE2# set interface fxp0.0 disable
```

4. Configure MPLS.

```
[edit protocols mpls]
user@PE2# set label-switched-path to_PE1 to 10.255.162.84
user@PE2# set interface all
user@PE2# set interface fxp0.0 disable
user@PE2# set egress-protection context-identifier 1.1.1.1 protector
user@PE2# set egress-protection context-identifier 1.1.1.1 advertise-mode stub-alias
```

5. Configure BGP.

```
[edit protocols bgp]
user@PE2# set group vpn family inet-vpn unicast egress-protection
user@PE2# set group vpn local-address 10.255.162.91
```

```
user@PE2# set group vpn neighbor 10.255.162.84
user@PE2# set group vpn neighbor 10.255.162.89
user@PE2# set group vpn type internal
user@PE2# set vpn-apply-export
```

6. Configure IS-IS.

```
[edit protocols isis]
user@PE2# set interface all
user@PE2# set interface fxp0.0 disable
user@PE2# set interface lo0.0 passive
user@PE2# set level 2 disable
user@PE2# set traceoptions file isis.log
user@PE2# set traceoptions flag all detail
```

7. (Optional) Configure OSPF.

```
[edit protocols ospf]
user@PE2# set area 0.0.0.0 interface all
user@PE2# set area 0.0.0.0 interface fxp0.0 disable
user@PE2# set area 0.0.0.0 interface lo0.0 passive
user@PE2# set traffic-engineering
```

8. Configure the routing policy.

```
[edit policy-options]
user@PE2# set community vpn members target:1:1
user@PE2# set policy-statement pplb term 1 then load-balance per-packet
user@PE2# set policy-statement vpn-exp term 1 from protocol bgp
user@PE2# set policy-statement vpn-exp term 1 then community add vpn
user@PE2# set policy-statement vpn-exp term 1 then accept
user@PE2# set policy-statement vpn-imp term 1 from community vpn
user@PE2# set policy-statement vpn-imp term 1 then accept
user@PE2# set policy-statement vpn-imp term 2 then reject
```

9. Configure the routing instance.

```
[edit routing-instances]
user@PE2# set vpn instance-type vrf
```

```
user@PE2# set vpn interface ge-3/2/4.0
user@PE2# set vpn route-distinguisher 100:100
user@PE2# set vpn vrf-import vpn-imp
user@PE2# set vpn vrf-export vpn-exp
user@PE2# set vpn vrf-table-label
user@PE2# set vpn protocols bgp group vpn type external
user@PE2# set vpn protocols bgp group vpn family inet unicast
user@PE2# set vpn protocols bgp group vpn family inet6 unicast
user@PE2# set vpn protocols bgp group vpn peer-as 65001
user@PE2# set vpn protocols bgp group vpn as-override
user@PE2# set vpn protocols bgp group vpn neighbor 10.10.30.2
```

Configuring Device PE3

Step-by-Step Procedure

1. Configure the interfaces.

```
[edit interfaces]
user@PE3# set ge-0/0/0 unit 0 family inet address 10.10.40.1/30
user@PE3# set ge-0/0/1 unit 0 family inet address 10.10.12.2/30
user@PE3# set ge-0/0/1 unit 0 family iso
user@PE3# set ge-0/0/1 unit 0 family inet6
user@PE3# set ge-0/0/1 unit 0 family mpls
user@PE3# set lo0 unit 0 family inet address 127.0.0.1/32
user@PE3# set lo0 unit 0 family inet address 10.255.162.89/32 primary
user@PE3# set lo0 unit 0 family iso address 47.0005.80ff.f800.0000.0108.0001.0102.5516.2089.00
user@PE3# set lo0 unit 0 family inet6 address abcd::10:255:162:89/128 primary
```

2. Configure the autonomous number (AS).

```
[edit routing-options]
user@PE3# set autonomous-system 65000
user@PE3# set forwarding-table export pplb
```

3. Configure RSVP.

```
[edit protocols rsvp]
user@PE3# set interface all link-protection
user@PE3# set interface fxp0.0 disable
```

4. Configure MPLS.

```
[edit protocols mpls]
user@PE3# set interface all
user@PE3# set interface fxp0.0 disable
user@PE3# set egress-protection context-identifier 1.1.1.1 primary
user@PE3# set egress-protection context-identifier 1.1.1.1 advertise-mode stub-alias
user@PE3# set label-switched-path to_PE2 to 10.255.162.91
user@PE3# set label-switched-path to_PE1 to 10.255.162.84
```

5. Configure BGP.

```
[edit protocols bgp]
user@PE3# set group vpn type internal
user@PE3# set group vpn local-address 10.255.162.89
user@PE3# set group vpn family inet-vpn unicast
user@PE3# set group vpn neighbor 10.255.162.84 local-preference 300
user@PE3# set group vpn neighbor 10.255.162.91
user@PE3# set vpn-apply-export
```

6. Configure IS-IS.

```
[edit protocols isis]
user@PE3# set interface all
user@PE3# set interface fxp0.0 disable
user@PE3# set interface lo0.0 passive
user@PE3# set level 2 disable
```

7. (Optional) Configure OSPF.

```
[edit protocols ospf]
user@PE3# set area 0.0.0.0 interface all
```

```
user@PE3# set area 0.0.0.0 interface fxp0.0 disable
user@PE3# set area 0.0.0.0 interface lo0.0 passive
user@PE3# set traffic-engineering
```

8. Configure the routing instance.

```
[edit routing-instances]
user@PE3# set vpn egress-protection context-identifier 1.1.1.1
user@PE3# set vpn instance-type vrf
user@PE3# set vpn interface ge-1/1/0.0
user@PE3# set vpn protocols bgp group vpn type external
user@PE3# set vpn protocols bgp group vpn family inet unicast
user@PE3# set vpn protocols bgp group vpn family inet6 unicast
user@PE3# set vpn protocols bgp group vpn peer-as 65001
user@PE3# set vpn protocols bgp group vpn as-override
user@PE3# set vpn protocols bgp group vpn neighbor 10.10.40.2
user@PE3# set vpn route-distinguisher 100:100
user@PE3# set vpn vrf-export vpn-exp
user@PE3# set vpn vrf-import vpn-imp
user@PE3# set vpn vrf-table-label
```

Configuring Device CE2

Step-by-Step Procedure

1. Configure the interfaces.

```
[edit interfaces]
user@CE2# set ge-0/0/0 unit 0 family inet address 10.10.40.2/30
user@CE2# set ge-0/0/2 unit 0 family inet address 10.10.30.2/30
user@CE2# set lo0 unit 0 family inet address 127.0.0.1/32
user@CE2# set lo0 unit 0 family inet address 10.255.162.88/32 primary
user@CE2# set lo0 unit 0 family iso address 47.0005.80ff.f800.0000.0108.0001.0102.5516.2088.00
user@CE2# set lo0 unit 0 family inet6 address abcd::10:255:162:88/128 primary
```

Results

From configuration mode, confirm your configuration by entering the `show interfaces` and `show protocols` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

Device CE1

```
user@CE1# show interfaces
ge-0/0/0 {
    unit 0 {
        family inet {
            address 10.10.20.2/30;
        }
    }
}
```

Device PE1

```
user@PE1# show interfaces
ge-0/0/0 {
    unit 0 {
        family inet {
            address 10.10.20.1/30;
        }
    }
}
ge-0/0/1 {
    unit 0 {
        family inet {
            address 10.10.10.1/30;
        }
        family iso;
        family inet6;
        family mpls;
    }
}
lo0 {
    unit 0 {
        family inet {
            address 127.0.0.1/32;
            address 10.255.162.84/32 {
```

```
                primary;
            }
        }
        family iso {
            address 47.0005.80ff.f800.0000.0108.0001.0102.5516.2084.00;
        }
        family inet6 {
            address abcd::10:255:162:84/128 {
                primary;
            }
        }
    }
}
```

```

```

Verification

IN THIS SECTION

- Verifying the Routing Instance | 434
- Checking the Context Identifier Route | 442

Verifying the Routing Instance

Purpose

Check the routes in the routing table.

Action

```
user@PE1> show route 10.10.50  table vpn.inet.0
vpn.inet.0: 6 destinations, 7 routes (6 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.10.50.0/24      *[BGP/170] 00:01:26, localpref 100, from 10.255.162.96
```

```
                      AS path: 65001 I, validation-state: unverified
                    > to 10.10.10.2 via ge-2/0/2.0, Push 16, Push 300064(top)
                    [BGP/170] 00:06:22, localpref 50, from 10.255.162.91

Understanding MPLS and Path Protection on EX Series Switches

Junos OS MPLS for Juniper Networks EX Series Ethernet Switches provides path protection to protect your MPLS network from label switched path (LSP) failures.

By default, an LSP routes itself hop-by-hop from the ingress provider edge switch through the provider switches toward the egress provider edge switch. The LSP generally follows the shortest path as dictated by the local routing table, usually taking the same path as destination-based, best-effort traffic. These paths are “soft” in nature because they automatically reroute themselves whenever a change occurs in a routing table or in the status of a node or link.

Typically, when an LSP fails, the switch immediately upstream from the failure signals the outage to the ingress provider edge switch. The ingress provider edge switch calculates a new path to the egress provider edge switch, establishes the new LSP, and then directs traffic from the failed path to the new path. This rerouting process can be time-consuming and prone to failure. For example, the outage signals to the ingress switch might get lost or the new path might take too long to come up, resulting in significant packet drops.

You can configure path protection by configuring primary and secondary paths on the ingress switch. If the primary path fails, the ingress switch immediately reroutes traffic from the failed path to the standby path, eliminating the need for the ingress switch to calculate a new route and signal a new path. For information about configuring standby LSPs, see "Configuring Path Protection in an MPLS Network (CLI Procedure)" on page 354.

Verifying Path Protection in an MPLS Network

IN THIS SECTION

- Verifying the Primary Path | **446**
- Verifying the RSVP-Enabled Interfaces | **447**
- Verifying a Secondary Path | **448**

To verify that path protection is working correctly on EX Series switches, perform the following tasks:

Verifying the Primary Path

IN THIS SECTION

- Purpose | 446
- Action | 446
- Meaning | 447

Purpose

Verify that the primary path is operational.

Action

```
user@switch> show mpls lsp extensive ingress

Ingress LSP: 2 sessions

127.1.8.8
  From: 127.1.9.9, State: Up, ActiveRoute: 0, LSPname: lsp_to_240

    1 Mar 11 23:45:48.095 CSPF failed: no route toward 10.5.5.5[2 times]
  Created: Wed Mar 11 23:44:37 2009
 [Output truncated]
```

Meaning

As indicated by the **ActivePath** in the output, the LSP **primary_path_lsp_to_240** is active.

Verifying the RSVP-Enabled Interfaces

IN THIS SECTION

- Purpose | **447**
- Action | **447**
- Meaning | **448**

Purpose

Verify the status of Resource Reservation Protocol (RSVP)-enabled interfaces and packet statistics.

Action

```
user@switch> show rsvp interfaces
```

```
RSVP interface: 1 active
                  Active Subscr- Static      Available   Reserved    Highwater
Interface   State resv   iption  BW          BW          BW          mark
ge-0/0/20.0 Up         2   100%  1000Mbps    1000Mbps    0bps        0bps
```

Meaning

This output verifies that RSVP is enabled and operational on interface **ge-0/0/20.0**.

Verifying a Secondary Path

IN THIS SECTION

- Purpose | **448**
- Action | **448**
- Meaning | **449**

Purpose

Verify that a secondary path is established.

Action

Deactivate a switch that is critical to the primary path and then issue the following command:

```
user@switch> show mpls lsp extensive

Ingress LSP: 1 sessions

127.0.0.8
  From: 127.0.0.1, State: Up, ActiveRoute: 0, LSPname: lsp_to_240
  ActivePath: secondary_path_lsp_to_240 (secondary)

 [Output truncated]
```

Meaning

As indicated by the **ActivePath** in the output, the LSP **secondary_path_lsp_to_240** is active.

Release History Table

Release	Description
15.1	Starting in Junos OS Release 15.1, the enhanced point of local repair (PLR) functionality addresses a special scenario of egress node protection, where the PLR and the protector are co-located as one router. In this case, there is no need to have a bypass LSP reroute traffic during local repair.
14.2	Starting in Junos OS Release 14.2, Junos OS supports the restoration of egress traffic when there is a link or node failure in the egress PE node.
14.2	Starting in Junos OS Release 14.2, Junos OS supports the restoration of egress traffic when there is a link or node failure in the egress PE node.

Link Protection

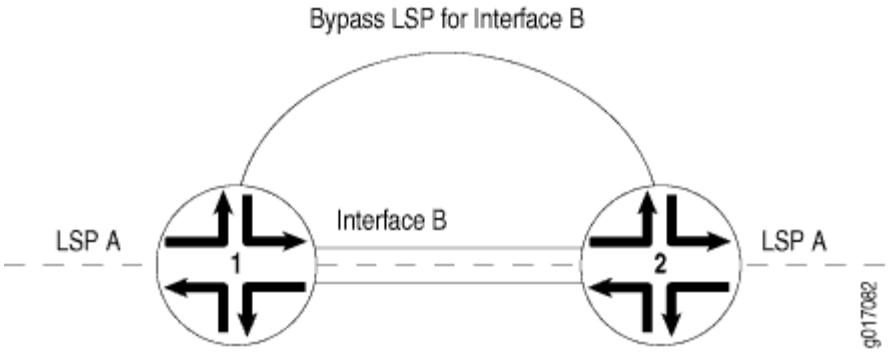
Link protection helps to ensure that traffic going over a specific interface to a neighboring router or switch can continue to reach this router (switch) if that interface fails. When link protection is configured for an interface and an LSP that traverses this interface, a bypass LSP is created that will handle this

traffic if the interface fails. The bypass LSP uses a different interface and path to reach the same destination. The path used can be configured explicitly, or you can rely on CSPF. The RSVP metric for the bypass LSP is set in the range of 20,000 through 29,999 (this value is not user configurable).

If a link-protected interface fails, traffic is quickly switched to the bypass LSP. Note that a bypass LSP cannot share the same egress interface with the LSPs it monitors.

In Figure 18 on page 451, link protection is enabled on Interface B between Router 1 and Router 2. It is also enabled on LSP A, an LSP that traverses the link between Router 1 and Router 2. If the link between Router 1 and Router 2 fails, traffic from LSP A is quickly switched to the bypass LSP generated by link protection.

Figure 18: Link Protection Creating a Bypass LSP for the Protected Interface



Although LSPs traversing an interface can be configured to take advantage of link protection, it is important to note that it is specifically the interface that benefits from link protection. If link protection is enabled on an interface but not on a particular LSP traversing that interface, then if the interface fails, that LSP will also fail.

NOTE: Link protection does not work on unnumbered interfaces.

To protect traffic over the entire route taken by an LSP, you should configure fast reroute. For more information, see "Configuring Fast Reroute" on page 565.

Multiple Bypass LSPs for Link Protection

By default, link protection relies on a single bypass LSP to provide path protection for an interface. However, you can also specify multiple bypass LSPs to provide link protection for an interface. You can individually configure each of these bypass LSPs or create a single configuration for all of the bypass LSPs. If you do not configure the bypass LSPs individually, they all share the same path and bandwidth constraints.

The following algorithm describes how and when an additional bypass LSP is activated for an LSP:

1. If any currently active bypass can satisfy the requirements of the LSP (bandwidth, link protection, or node-link protection), the traffic is directed to that bypass.

2. If no active bypass LSP is available, scan through the manual bypass LSPs in first-in, first-out (FIFO) order, skipping those that are already active (each manual bypass can only be activated once). The first inactive manual bypass that can satisfy the requirements is activated and traffic is directed to that bypass.

3. If no manual bypass LSPs are available and if the `max-bypasses` statement activates multiple bypass LSPs for link protection, determine whether an automatically configured bypass LSP can satisfy the requirements. If an automatically configured bypass LSP is available and if the total number of active automatically configured bypass LSPs does not exceed the maximum bypass LSP limit (configured with the `max-bypasses` statement), activate another bypass LSP.

For information about how to configure multiple bypass LSPs for link protection, see "Configuring Bypass LSPs" on page 458.

Node Protection

Node protection extends the capabilities of link protection. Link protection helps to ensure that traffic going over a specific interface to a neighboring router can continue to reach this router if that interface fails. Node protection ensures that traffic from an LSP traversing a neighboring router can continue to reach its destination even if the neighboring router fails.

When you enable node protection for an LSP, you must also enable link protection. Once enabled, node protection and link protection establish the following types of bypass LSPs:

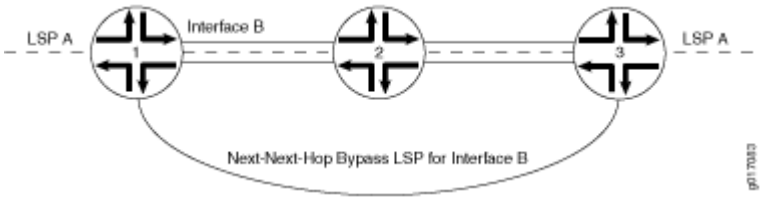
- Next-hop bypass LSP—Provides an alternate route for an LSP to reach a neighboring router. This type of bypass LSP is established when you enable either node protection or link protection.

- Next-next-hop bypass LSP—Provides an alternate route for an LSP to get around a neighboring router en route to the destination router. This type of bypass LSP is established exclusively when node protection is configured. If a next-next-hop bypass LSP cannot be created, an attempt is made to signal a next-hop bypass LSP.

In Figure 19 on page 453, node protection is enabled on Interface B on Router 1. Node protection is also enabled on LSP A, an LSP that traverses the link transiting Router 1, Router 2, and Router 3. If Router 2

suffers a hardware or software failure, traffic from LSP A is switched to the next-next-hop bypass LSP generated by node protection.

Figure 19: Node Protection Creating a Next-Next-Hop Bypass LSP



The time needed by node protection to switch traffic to a next-next-hop bypass LSP can be significantly longer than the time needed by link protection to switch traffic to a next-hop bypass LSP. Link protection relies on a hardware mechanism to detect a link failure, allowing it to quickly switch traffic to a next-hop bypass LSP.

Node failures are often due to software problems on the node router. Node protection relies on the receipt of hello messages from a neighboring router to determine whether it is still functioning. The time it takes node protection to divert traffic partly depends on how often the node router sends hello messages and how long it takes the node-protected router to react to having not received a hello message. However, once the failure is detected, traffic can be quickly diverted to the next-next-hop bypass LSP.

NOTE: Node protection provides traffic protection in the event of an error or interruption of the physical link between two routers. It does not provide protection in the event of control plane errors. The following provides an example of a control plane error:

- A transit router changes the label of a packet due to a control plane error.
- When the ingress router receives the packet, it considers the label change to be a catastrophic event and deletes both the primary LSP and the associated bypass LSP.

Fast Reroute, Node Protection, and Link Protection

IN THIS SECTION

- LSP Protection Overview | 454
- LSP Protection Types Comparison | 454
- One-to-One Backup Implementation | 455

Facility Backup Implementation | 457

This document discusses the following sections:

LSP Protection Overview

RSVP-TE extensions establish backup label-switched path (LSP) tunnels for local repair of LSP tunnels. These mechanisms enable immediate re-direction of traffic onto backup LSP tunnels, in the event of a failure.

RFC 4090, *Fast Reroute Extensions to RSVP-TE for LSP Tunnels*, describes two different types of traffic protection for RSVP-signaled LSPs:

- One-to-one backup—In this method, detour LSPs for each protected LSP is created at each potential point of local repair.
- Facility backup—In this method, a bypass tunnel is created to protect a set of LSPs that have similar backup constraints at a potential failure point, by taking advantage of the MPLS label stacking.

The one-to-one backup and the facility backup methods protect links and nodes during network failure, and can co-exist in a mixed network.

LSP Protection Types Comparison

In the Junos OS, the one-to-one backup of traffic protection is provided by fast reroute. Each LSP requires a protecting LSP to be signaled at each hop except the egress router. This method of LSP protection cannot be shared.

In the facillity backup method, the LSP traffic protection is provided on the node and link. Unlike fast reroute, this protecting LSP can be shared by other LSPs.

Table 9 on page 454 summarizes the traffic protection types.

Table 9: One-to-One Backup Compared with Facility Backup

Comparison	One-to-One Backup	Facility Backup
Name of the protecting LSP	Detour LSP	Bypass LSP
Sharing of the protecting LSP	Cannot be shared	Can be shared by multiple LSPs

Table 9: One-to-One Backup Compared with Facility Backup *(Continued)*

Comparison	One-to-One Backup	Facility Backup
Junos configuration statements	`fast-reroute`	`node-link-protection` and `link-protection`

One-to-One Backup Implementation

In the one-to-one backup method, the points of local repair maintain separate backup paths for each LSP passing through a facility. The backup path terminates by merging back with the primary path at a node called the merge point. In this approach, the merge point can be any node downstream from the protected facility.

In the one-to-one backup method, an LSP is established that intersects the original LSP downstream of the point of link or node failure. A separate backup LSP is established for each LSP that is backed up.

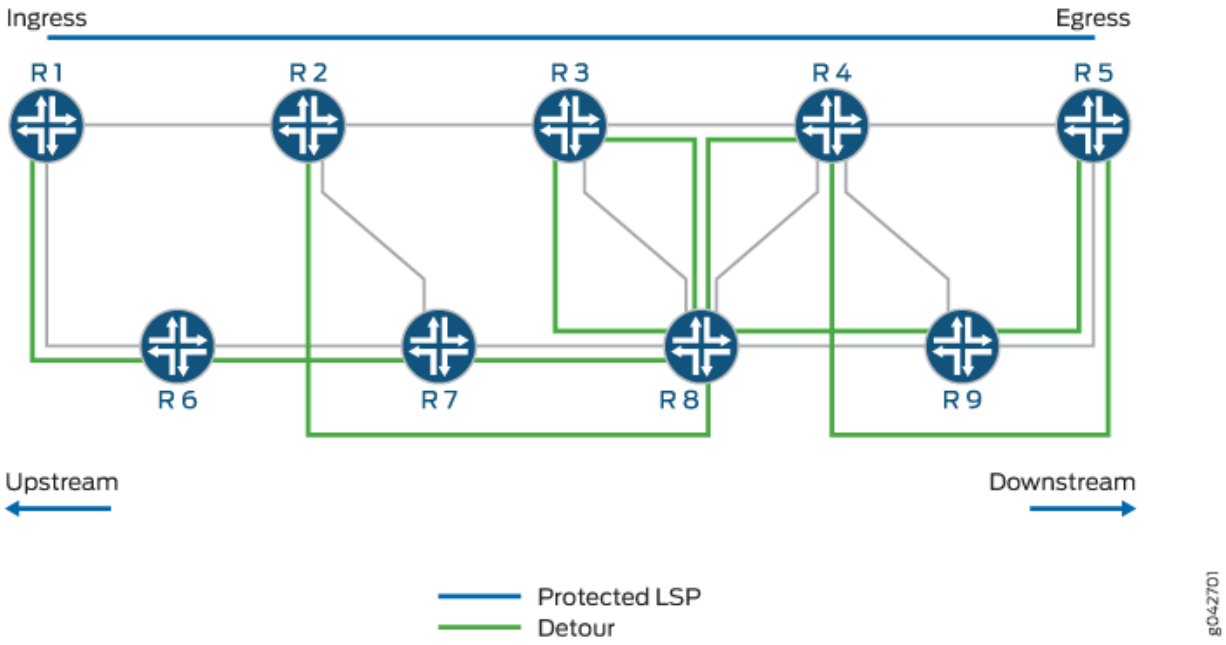
One-to-one backup is appropriate under the following circumstances:

- Protection of a small number of LSPs relative to the total number of LSPs.
- Path selection criteria, such as bandwidth, priority, and link coloring for detour paths is critical.
- Control of individual LSPs is important.

In Figure 20 on page 456, Routers R1 and R5 are the ingress and egress routers, respectively. A protected LSP is established between the two routers transiting Routers R2, R3, and R4. Router R2 provides user traffic protection by creating a partial backup LSP that merges with the protected LSP at

Router R4. This partial one-to-one backup LSP is called a detour. Detours are always calculated to avoid the immediate downstream link and node, providing against both link and node failure.

Figure 20: One-to-One Backup



In the example, the protected LSP is `R1-R2-R3-R4-R5`, and the following detours are established:

- Router R1—`R1-R6-R7-R8-R3`
- Router R2—`R2-R7-R8-R4`
- Router R3—`R3-R8-R9-R5`
- Router R4—`R4-R9-R5`

To protect an LSP that traverses `N` nodes fully, there can be as many as (`N - 1`) detours. The point of local repair sends periodic refresh messages to maintain each backup path, as a result maintaining state information for backup paths protecting individual LSPs is a significant resource burden for the point of local repair. To minimize the number of LSPs in the network, it is desirable to merge a detour back to its protected LSP, when feasible. When a detour LSP intersects its protected LSP at an LSR with the same outgoing interface, it is merged.

Facility Backup Implementation

In the facility backup approach, a point of local repair maintains a single backup path to protect a set of primary LSPs traversing the point of local repair, the facility, and the merge point. The facility backup is based on interface rather than on LSP. While fast reroute protects interfaces or nodes along the entire path of a LSP, the facility backup protection can be applied on interfaces as needed. As a result, fewer states need to be maintained and refreshed which results in a scalable solution. The facility backup method is also called many-to-one backup.

The facility backup method takes advantage of the MPLS label stack. Instead of creating a separate LSP for every backed-up LSP, a single LSP is created that serves to back up a set of LSPs. Such an LSP tunnel is called a bypass tunnel. In this method, a router immediately upstream from a link failure uses an alternate interface to forward traffic to its downstream neighbor, and the merge point should be the node immediately downstream to the facility. This is accomplished by preestablishing a bypass path that is shared by all protected LSPs traversing the failed link. A single bypass path can safeguard a set of protected LSPs. When an outage occurs, the router immediately upstream from the link outage switches protected traffic to the bypass link, then signals the link failure to the ingress router.

The bypass tunnel must intersect the path of the original LSP(s) somewhere downstream of the point of local repair. This constrains the set of LSPs being backed up through that bypass tunnel to those that pass through some common downstream nodes. All LSPs that pass through the point of local repair and through this common node, and that do not also use the facilities involved in the bypass tunnel are candidates for this set of LSPs.

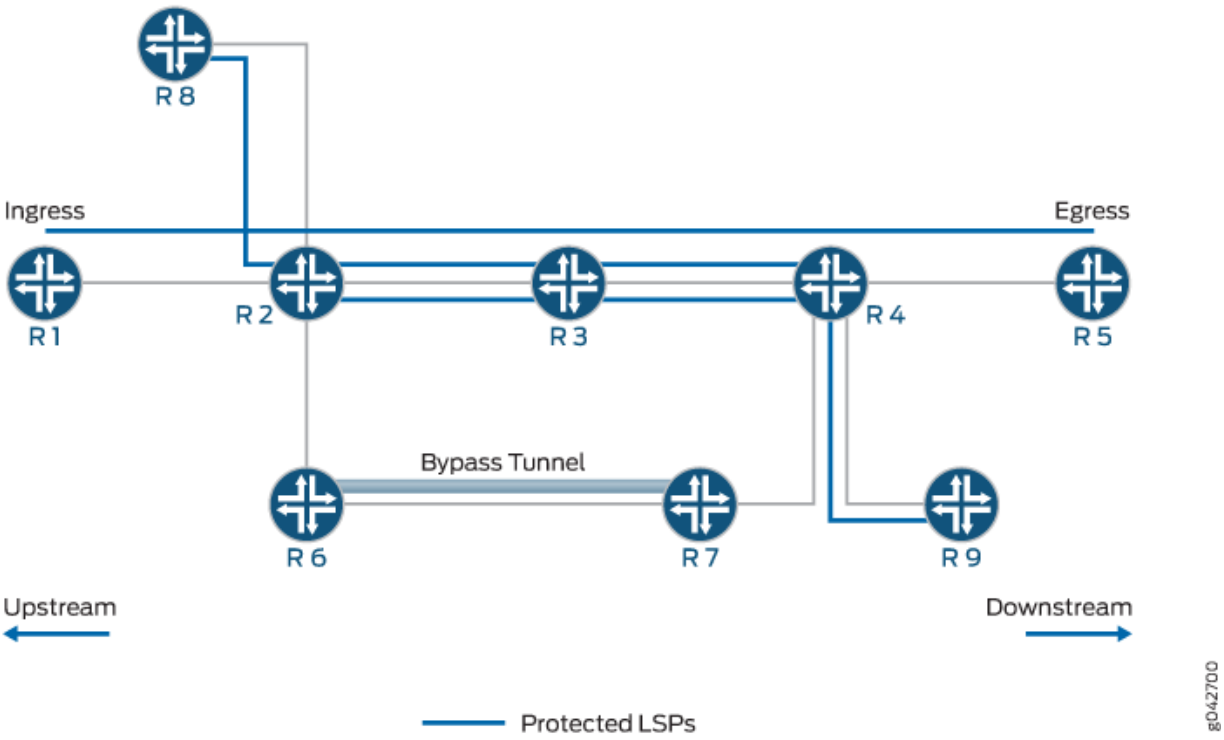
The facility backup method is appropriate in the following situations:

- The number of LSPs to be protected is large.
- Satisfying path selection criteria (priority, bandwidth, and link coloring) for bypass paths is less critical.
- Control at the granularity of individual LSPs is not required.

In Figure 21 on page 458, Routers R1 and R5 are the ingress and egress routers, respectively. Router R2 has established a bypass tunnel that protects against the failure of Router R2-R3 link and Router R3

node. A bypass tunnel is established between Routers R6 and R7. There are three different protected LSPs that are using the same bypass tunnel for protection.

Figure 21: Facility Backup



The facility backup method provides a scalability improvement, wherein the same bypass tunnel is also used to protect LSPs from any of RoutersR1, R2, or R8 to any of Routers R4, R5, or R9.

Configuring Link Protection on Interfaces Used by LSPs

IN THIS SECTION

- Configuring Bypass LSPs | **460**
- Configuring Administrative Groups for Bypass LSPs | **461**
- Configuring the Bandwidth for Bypass LSPs | **462**
- Configuring Class of Service for Bypass LSPs | **462**
- Configuring the Hop Limit for Bypass LSPs | **463**

- Configuring the Maximum Number of Bypass LSPs | **463**
- Disabling CSPF for Bypass LSPs | **464**
- Disabling Node Protection for Bypass LSPs | **464**
- Configuring the Optimization Interval for Bypass LSPs | **465**
- Configuring an Explicit Path for Bypass LSPs | **465**
- Configuring the Amount of Bandwidth Subscribed for Bypass LSPs | **466**
- Configuring Priority and Preemption for Bypass LSPs | **466**

When you configure node protection or link protection on a router for LSPs as described in "Configuring Node Protection or Link Protection for LSPs" on page 467, you also must configure the `link-protection` statement on the RSVP interfaces used by the LSPs.

To configure link protection on the interfaces used by the LSPs, include the "link-protection" on page 2550 statement:

```
link-protection {
    disable;
    admin-group
        exclude group-names;
        include-all group-names;
        include-any group-names;
    }
    bandwidth bps;
    bypass bypass-name {
        bandwidth bps;
        description text;
        hop-limit number;
        no-cspf;
        path address <strict | loose>;
        priority setup-priority reservation-priority;
        to address;
    }
    class-of-service cos-value;
    hop-limit number;
    max-bypasses number;
    no-cspf;
    no-node-protection;
    optimize-timer seconds;
```

```
    path address <strict | loose>;
    priority setup-priority reservation-priority;
    subscription percent {
        ct0 percent;
        ct1 percent;
        ct2 percent;
        ct3 percent;
    }
}
```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp interface *interface-name*]
- [edit logical-systems *logical-system-name* protocols rsvp interface *interface-name*]

All the statements under link-protection are optional.

The following sections describe how to configure link protection:

Configuring Bypass LSPs

You can configure specific bandwidth and path constraints for a bypass LSP. Each manual bypass LSP on a router should have a unique “to” IP address. You can also individually configure each bypass LSP generated when you enable multiple bypass LSPs. If you do not configure the bypass LSPs individually, they all share the same path and bandwidth constraints (if any).

If you specify the bandwidth, hop-limit, and path statements for the bypass LSP, these values take precedence over the values configured at the [edit protocols rsvp interface *interface-name* link-protection] hierarchy level. The other attributes (subscription, no-node-protection, and optimize-timer) are inherited from the general constraints.

To configure a bypass LSP, specify a name for the bypass LSP using the bypass statement. The name can be up to 64 characters in length.

```
bypass bypass-name {
    bandwidth bps;
    description text;
    class-of-service cos-value;
    hop-limit number;
    no-cspf;
    path address <strict | loose>;
    priority setup-priority reservation-priority;
```

```
    to address;
}
```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp interface *interface-name* link-protection]
- [edit logical-systems *logical-system-name* protocols rsvp interface *interface-name* link-protection]

Configuring the Next-Hop or Next-Next-Hop Node Address for Bypass LSPs

If you configure a bypass LSP, you must also configure the to statement. The to statement specifies the address for the interface of the immediate next-hop node (for link protection) or the next-next-hop node (for node-link protection). The address specified determines whether this is a link protection bypass or a node-link protection bypass. On multiaccess networks (for example, a LAN), this address is also used to specify which next-hop node is being protected.

Configuring Administrative Groups for Bypass LSPs

Administrative groups, also known as link coloring or resource class, are manually assigned attributes that describe the “color” of links, such that links with the same color conceptually belong to the same class. You can use administrative groups to implement a variety of policy-based LSP setups. You can configure administrative groups for bypass LSPs. For more information about configuring administrative groups, see "Configuring Administrative Groups for LSPs" on page 596.

To configure administrative groups for bypass LSPs, include the admin-group statement:

```
admin-group {
    exclude group-names;
    include-all group-names;
    include-any group-names;
}
```

To configure an administrative group for all of the bypass LSPs, include the admin-group statement at the following hierarchy levels:

- [edit protocols rsvp interface *interface-name* link-protection]
- [edit logical-systems *logical-system-name* protocols rsvp interface *interface-name* link-protection]

To configure an administrative groups for a specific bypass LSP, include the admin-group statement at the following hierarchy levels:

- [edit protocols rsvp interface *interface-name* link-protection bypass *bypass-name*]

- [edit logical-systems *logical-system-name* protocols rsvp interface *interface-name* link-protection bypass *bypass-name*]

Configuring the Bandwidth for Bypass LSPs

You can specify the amount of bandwidth allocated for automatically generated bypass LSPs or you can individually specify the amount of bandwidth allocated for each LSP.

If you have enabled multiple bypass LSPs, this statement is required.

To specify the bandwidth allocation, include the bandwidth statement:

```
bandwidth bps;
```

For automatically generated bypass LSPs, include the bandwidth statement at the following hierarchy levels:

- [edit protocols rsvp interface *interface-name* link-protection]
- [edit logical-systems *logical-system-name* protocols rsvp interface *interface-name* link-protection]

For individually configured bypass LSPs, include the bandwidth statement at the following hierarchy levels:

- [edit protocols rsvp interface *interface-name* link-protection bypass *bypass-name*]
- [edit logical-systems *logical-system-name* protocols rsvp interface *interface-name* link-protection bypass *bypass-name*]

Configuring Class of Service for Bypass LSPs

You can specify the class-of-service value for bypass LSPs by including the class-of-service statement:

```
class-of-service cos-value;
```

To apply a class-of-service value to all the automatically generated bypass LSPs, include the class-of-service statement at the following hierarchy levels:

- [edit protocols rsvp interface *interface-name* link-protection]
- [edit logical-systems *logical-system-name* protocols rsvp interface *interface-name* link-protection]

To configure a class-of-service value for a specific bypass LSPs, include the class-of-service statement at the following hierarchy levels:

- [edit protocols rsvp interface *interface-name* link-protection bypass *bypass-name*]

- [edit logical-systems *logical-system-name* protocols rsvp interface *interface-name* link-protection bypass *bypass-name*]

Configuring the Hop Limit for Bypass LSPs

You can specify the maximum number of hops a bypass can traverse. By default, each bypass can traverse a maximum of 255 hops (the ingress and egress routers count as one hop each, so the minimum hop limit is two).

To configure the hop limit for bypass LSPs, include the hop-limit statement:

```
hop-limit number;
```

For automatically generated bypass LSPs, include the hop-limit statement at the following hierarchy levels:

- [edit protocols rsvp interface *interface-name* link-protection]
- [edit logical-systems *logical-system-name* protocols rsvp interface *interface-name* link-protection]

For individually configured bypass LSPs, include the hop-limit statement at the following hierarchy levels:

- [edit protocols rsvp interface *interface-name* link-protection bypass *bypass-name*]
- [edit logical-systems *logical-system-name* protocols rsvp interface *interface-name* link-protection bypass *bypass-name*]

Configuring the Maximum Number of Bypass LSPs

You can specify the maximum number of dynamic bypass LSPs permitted for protecting an interface using the max-bypasses statement at the [edit protocols rsvp interface *interface-name* link-protection] hierarchy level. When this statement is configured, multiple bypasses for link protection are enabled. Call admission control (CAC) is also enabled.

By default, this option is disabled and only one bypass is enabled for each interface. You can configure a value of between 0 through 99 for the max-bypasses statement. Configuring a value of 0 prevents the creation of any dynamic bypass LSPs for the interface. If you configure a value of 0 for the max-bypasses statement, you need to configure one or more static bypass LSPs to enable link protection on the interface.

If you configure the max-bypasses statement, you must also configure the bandwidth statement (discussed in "Configuring the Bandwidth for Bypass LSPs" on page 462).

To configure the maximum number of bypass LSPs for a protected interface, include the max-bypasses statement:

```
max-bypasses number;
```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp interface *interface-name* link-protection]
- [edit logical-systems *logical-system-name* protocols rsvp interface *interface-name* link-protection]

Disabling CSPF for Bypass LSPs

Under certain circumstances, you might need to disable CSPF computation for bypass LSPs and use the configured Explicit Route Object (ERO) if available. For example, a bypass LSP might need to traverse multiple OSPF areas or IS-IS levels, preventing the CSPF computation from working. To ensure that link and node protection function properly in this case, you have to disable CSPF computation for the bypass LSP.

You can disable CSPF computation for all bypass LSPs or for specific bypass LSPs.

To disable CSPF computation for bypass LSPs, include the no-cspf statement:

```
no-cspf;
```

For a list of hierarchy levels where you can include this statement, see the statement summary for this statement.

Disabling Node Protection for Bypass LSPs

You can disable node protection on the RSVP interface. Link protection remains active. When this option is configured, the router can only initiate a next-hop bypass, not a next-next-hop bypass.

To disable node protection for bypass LSPs, include the no-node-protection statement:

```
no-node-protection;
```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp interface *interface-name* link-protection]
- [edit logical-systems *logical-system-name* protocols rsvp interface *interface-name* link-protection]

Configuring the Optimization Interval for Bypass LSPs

You can configure an optimization interval for bypass LSPs using the `optimize-timer` statement. At the end of this interval, an optimization process is initiated that attempts to either minimize the number of bypasses currently in use, minimize the total amount of bandwidth reserved for all of the bypasses, or both. You can configure an optimization interval from 1 through 65,535 seconds. A default value of 0 disables bypass LSP optimization.

When you configure the `optimize-timer` statement, bypass LSPs are reoptimized automatically when you configure or change the configuration of any of the following:

- Administrative group for a bypass LSP—The configuration for an administrative group has been changed on a link along the path used by the bypass LSP. Configure an administrative group using the `admin-group` statement at the `[edit protocols rsvp interface` *`interface-name`* `link-protection]` hierarchy level.
- Fate sharing group—The configuration for a fate sharing group has been changed. Configure a fate sharing group using the `group` statement at the `[edit routing-options fate-sharing]` hierarchy level.
- IS-IS overload—The configuration for IS-IS overload has been changed on a router along the path used by the bypass LSP. Configure IS-IS overload using the `overload` statement at the `[edit protocols isis]` hierarchy level.
- IGP metric—The IGP metric has been changed on a link along the path used by the bypass LSP.

To configure the optimization interval for bypass LSPs, include the `optimize-timer` statement:

```
optimize-timer seconds;
```

You can include this statement at the following hierarchy levels:

- `[edit protocols rsvp interface` *`interface-name`* `link-protection]`
- `[edit logical-systems` *`logical-system-name`* `protocols rsvp interface` *`interface-name`* `link-protection]`

Configuring an Explicit Path for Bypass LSPs

By default, when you establish a bypass LSP to an adjacent neighbor, CSPF is used to discover the least-cost path. The `path` statement allows you to configure an explicit path (a sequence of strict or loose routes), giving you control over where and how the bypass LSP is established. To configure an explicit path, include the `path` statement:

```
path address <strict | loose>;
```

For automatically generated bypass LSPs, include the `path` statement at the following hierarchy levels:

- [edit protocols rsvp interface *interface-name* link-protection]
- [edit logical-systems *logical-system-name* protocols rsvp interface *interface-name* link-protection]

For individually configured bypass LSPs, include the path statement at the following hierarchy levels:

- [edit protocols rsvp interface *interface-name* link-protection bypass *bypass-name*]
- [edit logical-systems *logical-system-name* protocols rsvp interface *interface-name* link-protection bypass *bypass-name*]

Configuring the Amount of Bandwidth Subscribed for Bypass LSPs

You can configure the amount of bandwidth subscribed to bypass LSPs. You can configure the bandwidth subscription for the whole bypass LSP or for each class type that might traverse the bypass LSP. You can configure any value between 1 percent and 65,535 percent. By configuring a value less than 100 percent, you are undersubscribing the bypass LSPs. By configuring a value greater than 100 percent, you are oversubscribing the bypass LSPs.

The ability to oversubscribe the bandwidth for the bypass LSPs makes it possible to more efficiently use network resources. You can configure the bandwidth for the bypass LSPs based on the average network load as opposed to the peak load.

To configure the amount of bandwidth subscribed for bypass LSPs, include the subscription statement:

```
subscription percentage {
    ct0 percentage;
    ct1 percentage;
    ct2 percentage;
    ct3 percentage;
}
```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp interface *interface-name* link-protection]
- [edit logical-systems *logical-system-name* protocols rsvp interface *interface-name* link-protection]

Configuring Priority and Preemption for Bypass LSPs

When there is insufficient bandwidth to establish a more important LSP, you might want to tear down a less important existing LSP to release the bandwidth. You do this by preempting the existing LSP.

For more detailed information on configuring setup priority and reservation priority for LSPs, see "Configuring Priority and Preemption for LSPs" on page 595.

To configure the bypass LSP's priority and preemption properties, include the `priority` statement:

```
priority setup-priority reservation-priority;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Configuring Node Protection or Link Protection for LSPs

When you configure node protection or link protection on a router or switch, bypass LSPs are created to the next-hop or next-next-hop routers (switches) for the LSPs traversing the router (switch). You must configure node protection or link protection for each LSP that you want protected. To extend protection along the entire path used by an LSP, you must configure protection on each router that the LSP traverses.

You can configure node protection or link protection for both static and dynamic LSPs.

To configure node protection on a router for a specified LSP, include the `node-link-protection` statement:

```
node-link-protection;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls label-switched-path *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name*]

To configure link protection on a router for a specified LSP, include the "link-protection" on page 2550 statement:

```
link-protection;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls label-switched-path *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name*]

NOTE: To complete the configuration of node or link protection, you must also configure link protection on all unidirectional RSVP interfaces that the LSPs traverse, as described in "Configuring Link Protection on Interfaces Used by LSPs" on page 458.

Configuring Inter-AS Node and Link Protection

To interoperate with other vendors' equipment, the Junos OS supports the record route object (RRO) node ID subobject for use in inter-AS link and node protection configurations. The RRO node ID subobject is defined in RFC 4561, *Definition of a Record Route Object (RRO) Node-Id Sub-Object*. This functionality is enabled by default in Junos OS Release 9.4 and later.

If you have Juniper Networks routers running Junos OS Release 9.4 and later releases in the same MPLS-TE network as routers running Junos OS Release 8.4 and earlier releases, you might need to disable the RRO node ID subobject by configuring the `no-node-id-subobject` statement:

```
no-node-id-subobject;
```

You can include this statement at the following hierarchy levels:

- `[edit protocols rsvp]`
- `[edit logical-systems logical-system-name protocols rsvp]`

- Configuring On-Demand Loss and Delay Measurement | 502
- Configuring Pro-Active Loss and Delay Measurements | 503

Configuring MPLS to Gather Statistics

You can configure MPLS so that it periodically gathers traffic statistics about all MPLS sessions, including transit sessions, by configuring the `statistics` statement. You must configure the `statistics` statement if you want to collect MPLS traffic statistics using SNMP polling of MPLS Management Information Bases (MIBs).

To enable or disable MPLS statistics collection, include the `statistics` statement:

```
statistics {
    auto-bandwidth (MPLS Statistics);
    file filename <files number> <size size> <world-readable | no-world-readable>;
    interval seconds;
```

```
    no-transit-statistics;
    transit-statistics-polling;
}
```

You can configure these statements at the following hierarchy levels:

- `[edit protocols mpls]`
- `[edit logical-systems` *`logical-system-name`* `protocols mpls]`

The default interval is 300 seconds.

If you configure the `file` option, the statistics are placed in a file, with one entry per LSP. During the specified interval, the following information is recorded in this file:

- The number of packets, number of bytes, packets per second, and bytes per second transmitted by each LSP. Feature parity for the display of packet and byte statistics for sub-LSPs of a point-to-multipoint LSP on the Junos Trio chipset is supported in Junos OS Releases 11.1R2, 11.2R2, and 11.4.
- The percent of bandwidth transmitted over a given LSP in relation to the bandwidth percentage configured for that LSP. If no bandwidth is configured for an LSP, 0 percent is recorded in the percentage column.

At the end of each periodic report, a summary shows the current time, total number of sessions, number of sessions read, number of sessions ignored, and read errors, if any. Ignored sessions are typically those not in the up state or those with a reserved (0 through 15) incoming label (typically the egress point of an LSP). The reason for a read error appears on the same line as the entry for the LSP on which the error occurred. Gathering statistics is an unreliable process; occasional read errors might affect their accuracy. Sample output follows:

```
lsp6                    0 pkt              0 Byte      0 pps        0 Bps    0
lsp5                    0 pkt              0 Byte      0 pps        0 Bps    0
lsp6.1              34845 pkt        2926980 Byte   1049 pps    88179 Bps  132
lsp5.1                  0 pkt              0 Byte      0 pps        0 Bps    0
lsp4                    0 pkt              0 Byte      0 pps        0 Bps    0
Dec  7 17:28:38 Total 6 sessions: 5 success, 0 fail, 1 ignored
```

On-Demand Packet Loss and Delay Measurement for UHP LSPs Overview

IN THIS SECTION

This topic describes methods for measuring packet loss, delay, and throughput for point-to-point ultimate hop popping (UHP) label-switched paths (LSPs) in MPLS networks to enable monitoring of network performance.

Importance of Measuring Packet Loss and Delay

The rise of bandwidth-consuming applications, such as IPTV and mobile video, coupled with the pressure to minimize the cost per bit and maximize the value per bit, is forcing carriers to transition their transport networks from circuit-based technologies to packet-based technologies. MPLS is a widely successful, connection-oriented packet transport technology that is ideally suited for packet-based transport networks.

With the emergence of new applications on data networks, it is becoming increasingly important for service providers to accurately predict the impact of new application rollouts. Understanding and modelling network performance in the network is especially relevant for deployment of new-world applications to ensure successful implementations. In packet networks, packet loss and delay are two of the most fundamental measures of performance. Their role is even more central when it comes to end-to-end measurements.

The traffic belonging to most of the end-to-end user applications is either loss sensitive (file transfer), delay sensitive (voice or video applications), or both (interactive computing applications). The service-level agreements (SLAs) of service providers depend on the ability to measure and monitor these network performance metrics, as the SLAs are directly or indirectly dependent on the loss and delay the customer traffic experiences in the service provider network.

To ensure compliance to the SLA, service providers need tools to measure and monitor the performance metrics for packet loss, one-way delay and two-way delay, and related metrics, such as delay variation

and channel throughput. This measurement capability provides service providers with greater visibility into the performance characteristics of their networks, thereby facilitating planning, troubleshooting, and network performance evaluation.

Defining Packet Loss, Delay, and Throughput

In packet networks, packet loss and delay are two of the most fundamental measures of performance.

- **Loss**—Packet loss is the failure of one or more transmitted packets to arrive at their destination. Packet loss refers to the packets of data that are dropped by the network to manage congestion.

  Data applications are very tolerant to packet loss, as they are generally not time sensitive and can retransmit the packets that were dropped. However, in video conference environments and pure audio communications, such as VoIP, packet loss can create jitter.

- **Delay**—Packet delay (also called latency) is the amount of time it takes for a packet of data to get from one designated point to another, depending on the speed of the transmission medium, such as copper wire, optical fiber, or radio waves, and the delays in transmission by devices along the way, such as routers and modems.

  A low latency indicates a high network efficiency.

- **Throughput**—Packet delay measures the amount of time between the start of an action and its completion, whereas throughput is the total number of such actions that occur in a given amount of time.

Packet Loss and Delay Measurement Mechanisms

Packet delay and loss are two fundamental measures of network performance. Junos OS provides an on-demand mechanism to measure packet loss and delay over associated bidirectional MPLS ultimate hop popping (UHP) label-switched paths (LSPs).

The on-demand delay and packet loss measurement mechanism is initiated using the following CLI commands:

- `monitor mpls loss rsvp`—Performs an on-demand loss measurement for associated bidirectional UHP LSPs.

- `monitor mpls delay rsvp`—Performs an on-demand delay measurement for associated bidirectional UHP LSPs.

- `monitor mpls loss-delay rsvp`—Performs an on-demand combined loss and delay measurement for associated bidirectional UHP LSPs.

For initiating the delay and packet loss measuring mechanism, the desired parameters for measurement, such as the type of measurement and LSP name, need to be entered. On receiving the parameters, a summary of the performance monitoring data is displayed and the mechanism is terminated.

Packet Loss and Delay Metrics

The following performance metrics are measured using the on-demand packet loss and delay mechanisms:

- Loss measurement (packet and octet)
- Throughput measurement (packet and octet)
- Two-way channel delay
- Round-trip delay
- Inter-packet delay variation (IPDV)

The `monitor mpls loss rsvp` command performs the loss and throughput measurement, and the `monitor mpls delay rsvp` command performs the two-way channel delay, round-trip delay, and IPDV measurements. The `monitor mpls loss-delay rsvp` command performs a combined loss and delay measurement and measures all of the above-mentioned performance metrics simultaneously.

Packet Loss and Delay Measurement Concepts

The following concepts help to better understand the functionality of packet loss and delay:

- **Querier**—A querier is the ingress provider edge (PE) router, which originates the query message for loss or delay measurement.
- **Responder**—A responder is the egress PE router, which receives and responds to the query messages from a querier.
- **Associated bidirectional LSP**—An associated bidirectional LSP consists of two unidirectional LSPs that are tied together (or associated with each other) through configuration on both of the LSP end points.

  The on-demand loss and delay measurement can be carried out only on associated bidirectional UHP LSPs.
- **Generic associated channel (G-Ach)**—The performance monitoring messages for the on-demand loss and delay measurement flow over the MPLS G-Ach. This type of channel supports only in-band responses, and does not provide support for out-of-band or no-response modes.
- **Measurement point (MP)**—MP is the location at which a condition is described for the measurement.

The MP for packet loss on the transmit side is between the switching fabric and the transmit interface. The counter value is stamped in the loss measurement message in the hardware before it is queued for transmission.

The MP for packet loss on the receive side is between the receive interface and the switching fabric. The MP is distributed on the receive side. Furthermore, when the transmit interface is an aggregate interface, the MP is distributed as well.

- **Query rate**—Query rate is the interval between two queries sent for loss and delay measurement.

  Because the loss and delay measurement messages originate from the Routing Engine, a high query rate for multiple channels puts a heavy burden on the Routing Engine. The minimum query interval supported is 1 second.

  The query rate should be high for 32-bit counters, because the counters might wrap quickly when data traffic rate is very high. The query rate can be low when 64-bit counters are in use at all the four measurement point locations involved in loss measurement. Junos OS supports only 64-bit counters.

- **Traffic class**—By default, loss measurement is supported for the whole channel. Junos OS also supports traffic class scoped packet loss measurement, where counters that maintain data traffic statistics per traffic class have to be created.

  Per traffic class counters are not created by default. To configure traffic class scoped loss measurement, include the `traffic-class-statistics` statement at the `[edit protocols mpls statistics]` hierarchy level.

  When `traffic-class-statistics` is configured, control packets flowing over the G-Ach are not counted in the transmit and receive counters.

  > **NOTE**: Enabling and disabling of traffic class statistics results in the resetting of all counters (aggregate counter and per-class counters) for the LSPs.

- **Loss measurement mode**—Junos OS supports the direct-mode of on-demand loss measurement, and does not provide support for the inferred-mode.

  Direct loss measurement requires data traffic statistics to be maintained at the ingress and egress of two unidirectional LSPs of the associated bidirectional LSP. When an MX Series router is using only MPCs and MICs, counters to maintain data traffic statistics are created by default at the ingress of all types of LSPs and egress of UHP LSPs.

  However, the direct-mode of loss measurement is not fully accurate due to the following reasons:

  - Parallel forwarding nature of the hardware.

- Presence of equal cost multipath (ECMP) in the network, such as aggregated Ethernet interfaces, which can result in re-ordering of data packets relative to the loss measurement messages.
- Control packets that do not flow over G-Ach are not counted at the LSP ingress, but are counted at the LSP egress.
- Data traffic re-ordering relative to the loss measurement message when a Diffserv is implemented in the MPLS network and loss measurement scope is the complete channel and not traffic class scoped.

  To overcome this limitation, perform traffic class scoped loss measurement when a Diffserv is implemented.

> **NOTE**: Direct mode loss measurement is vulnerable to disruption when the ingress or egress interface associated with the LSP changes.

- **Loss measurement synchronization**—The synchronization conditions specified in section 2.9.8 of RFC 6374 do not hold true in the absolute sense. However, as the loss measurement counters are stamped in hardware, the errors introduced due to not satisfying the synchronization conditions are relatively small. These errors need to be quantified.

  When the transmit or receive interface of the LSP is an aggregate interface, more errors are introduced as compared to when the interfaces are non-aggregate interfaces. In any case, the loss measurement counters are stamped in hardware, and the error needs to be quantified.

- **Delay measurement accuracy**—When the transmit and receive interfaces reside on different Packet Forwarding Engines, the clock must be synchronized on these Packet Forwarding Engines for two-way delay measurements. This condition holds true for the platform on which the on-demand delay measurement feature is implemented.

  When there are aggregate interfaces or ECMP, the delay is measured for only one of the potential paths.

  When a combined loss and delay message is used for delay calculation, the accuracy of delay is lower compared to when the delay measurement message is used in some cases, such as when the transmit or receive interface is an aggregate interface.

  Delay measurement is always performed on a per-traffic-class basis, and the accuracy of the measurement needs to be quantified after testing.

- **Timestamp format**—Junos OS supports only the IEEE 1588 Precision Time Protocol (PTP) [IEEE1588] format for recording delay measurement messages. Network Time Format (NTP) is not supported.

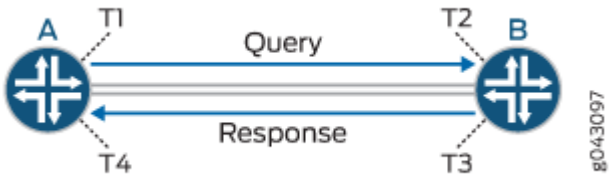
- **Operations, administration, and maintenance (OAM)**—To indicate that all the OAM messages for MPLS LSPs flow over the MPLS G-Ach, and to enable the MPLS performance monitoring messages

to be carried over the MPLS G-Ach, the `oam mpls-tp-mode` statement must be included at the `[edit protocols mpls label-switched-path lsp-name]` hierarchy level.

Packet Loss and Delay Measurement Functionality

Figure 22 on page 476 illustrates the basic methods used for the bidirectional measurement of packet loss and delay. A bidirectional channel exists between the two routers, Router A and Router B. The temporal reference points – T1, T2, T3, and T4 – are associated with a measurement operation that takes place at Router A. The operation consists of Router A sending a query message to Router B, and Router B sending back a response. Each reference point indicates the point of time at which either the query or the response message is transmitted or received over the channel.

Figure 22: Basic Bidirectional Measurement



In Figure 22 on page 476, Router A can arrange to measure the packet loss over the channel in the forward and reverse directions by sending loss measurement query messages to Router B. Each of the forward and reverse messages contain the count of packets transmitted prior to time T1 over the channel to Router B (A_TxP).

When the message reaches Router B, two values are appended to the message and the message is reflected back to Router A. The two values are the count of packets received prior to time T2 over the channel from Router A (B_RxP) and the count of packets transmitted prior to time T3 over the channel to Router A (B_TxP).

When the response reaches Router A, a fourth value is appended to the message – the count of packets received prior to time T4 over the channel from Router B (A_RxP).

These four counter values – (A_TxP), (B_RxP), (B_TxP), and (A_RxP) – enable Router A to compute the desired loss statistics. Because the transmit count at Router A and the receive count at Router B (and vice versa) might not be synchronized at the time of the first message, and to limit the effects of counter wrap, the loss is computed in the form of a delta between the messages.

The transmit loss (A_TxLoss[n-1,n]) and receive loss (A_RxLoss[n-1,n]) within the measurement interval marked by the messages LM[n-1] and LM[n] are computed by Router A as follows:

1. A_TxLoss[n-1,n] = (A_TxP[n] - A_TxP[n-1]) - (B_RxP[n] - B_RxP[n-1])

2. A_RxLoss[n-1,n] = (B_TxP[n] - B_TxP[n-1]) - (A_RxP[n] - A_RxP[n-1])

The arithmetic is modulo the counter size.

To measure at Router A the delay over the channel to Router B, a delay measurement query message is sent from Router A to Router B containing a timestamp recording the instant at which it is transmitted. In Figure 22 on page 476, the timestamp is recorded in T1.

When the message reaches Router B, a timestamp is added, recording the instant at which it is received (T2). The message can now be reflected from Router B to Router A, with Router B adding its transmit timestamp (T3) and Router A adding its receive timestamp (T4).

These four timestamps – T1, T2, T3, and T4 – enable Router A to compute the one-way delay in each direction, as well as the two-way delay for the channel. The one-way delay computations require that the clocks of Routers A and B be synchronized.

At this point, Router A can compute the two-way channel delay and round-trip delay associated with the channel as follows:

1. Two-way channel delay = (T4 - T1) - (T3 - T2)
2. Round-trip delay = T4 - T1

Packet Loss and Delay Features

Supported Features of Packet Loss and Delay

Junos OS supports the following features with on-demand loss and delay measurement:

- Performance monitoring for associated bidirectional MPLS point-to-point UHP LSPs only
- Loss measurement
- Throughput measurement
- Two-way delay measurement (channel delay and round-trip delay)
- Inter-packet delay variation (IPDV)
- Direct-mode loss measurement
- Aggregated Ethernet and aggregated SONET interfaces
- Multichassis support
- 64-bit compatible

Unsupported Features of Packet Loss and Delay

Junos OS does not support the following on-demand loss and delay measurement functionality:

- Loss and delay measurement for pseudowires (section 2.9.1 of RFC 6374)
- Unidirectional measurement (section 2.6 of RFC 6374)
- Dyadic measurement (section 2.7 of RFC 6374)
- Loss and delay measurement in loopback mode (section 2.8 of RFC 6374)
- Loss and delay measurement to an intermediate node from an LSP endpoint (section 2.9.5 of RFC 6374)
- External post-processing (section 2.9.7 of RFC 6374)
- Inferred-mode loss measurement (section 2.9.8 of RFC 6374)
- Pro-active mode
- Logical systems
- SNMP

Example: Configuring On-Demand Loss and Delay Measurement

IN THIS SECTION

- Requirements | **478**
- Overview | **479**
- Configuration | **480**
- Verification | **486**

This example shows how to enable on-demand loss and delay measurement for point-to-point ultimate hop popping (UHP) label-switched paths (LSPs) in MPLS networks to monitor network performance.

Requirements

This example uses the following hardware and software components:

- Two MX Series 5G Universal Routing Platforms that contain MPC/MICs only
- Junos OS Release 14.2 or later running on all the routers

Before you begin:

1. Configure the device interfaces.
2. Configure the autonomous system numbers and router IDs for the devices.
3. Configure the following protocols:
   - RSVP
   - MPLS
   - OSPF

Overview

IN THIS SECTION

- Topology | **480**

Starting with Junos OS Release 14.2, an on-demand tool to monitor and measure packet loss, packet delay, or both for associated bidirectional MPLS ultimate hop popping (UHP) point-to-point label-switched paths (LSPs) is introduced. The tool can be enabled using the following CLI commands – `monitor mpls loss rsvp`, `monitor mpls delay rsvp`, and `monitor mpls loss-delay rsvp`.

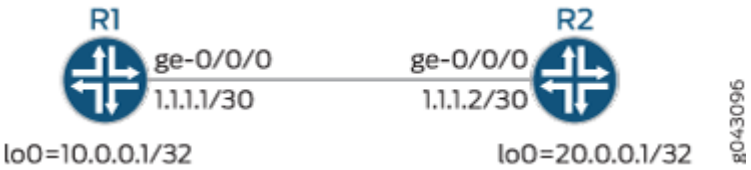
These commands provide an on-demand summary of performance metrics for direct mode packet loss, two-way packet delay, and related metrics, such as inter-packet delay variation and channel throughput measurement.

This functionality provides real-time visibility into network performance, thereby facilitating network performance planning, troubleshooting, and evaluation.

Topology

Figure 23 on page 480 illustrates the on-demand loss and delay measurement using a simple two-router topology.

Figure 23: Configuring On-Demand Loss and Delay Measurement



In this example, an associated bidirectional LSP is configured between Routers R1 and R2, for which the performance metrics is measured.

Configuration

IN THIS SECTION

- CLI Quick Configuration | 480
- Procedure | 482
- Results | 484

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the `[edit]` hierarchy level, and then enter `commit` from configuration mode.

R1

```
set chassis fpc 0 pic 3 tunnel-services bandwidth 1g
set chassis network-services enhanced-ip
set interfaces ge-0/0/0 unit 0 family inet address 1.1.1.1/30
set interfaces ge-0/0/0 unit 0 family mpls
set interfaces lo0 unit 0 family inet address 10.0.0.1/32
set interfaces lo0 unit 0 family mpls
set routing-options router-id 10.0.0.1
```

```
set protocols rsvp interface ge-0/0/0.0
set protocols rsvp interface lo0.0
set protocols rsvp interface fxp0.0 disable
set protocols mpls statistics traffic-class-statistics
set protocols mpls label-switched-path R1-R2 to 20.0.0.1
set protocols mpls label-switched-path R1-R2 oam mpls-tp-mode
set protocols mpls label-switched-path R1-R2 ultimate-hop-popping
set protocols mpls label-switched-path R1-R2 associate-lsp R2-R1
set protocols mpls interface ge-0/0/0.0
set protocols mpls interface lo0.0
set protocols mpls interface fxp0.0 disable
set protocols ospf traffic-engineering
set protocols ospf area 0.0.0.0 interface ge-0/0/0.0
set protocols ospf area 0.0.0.0 interface lo0.0
set protocols ospf area 0.0.0.0 interface fxp0.0 disable
```

R2

```
set chassis fpc 0 pic 3 tunnel-services bandwidth 1g
set chassis network-services enhanced-ip
set interfaces ge-0/0/0 unit 0 family inet address 1.1.1.2/30
set interfaces ge-0/0/0 unit 0 family mpls
set interfaces lo0 unit 0 family inet address 20.0.0.1/32
set interfaces lo0 unit 0 family mpls
set routing-options router-id 20.0.0.1
set protocols rsvp interface ge-0/0/0.0
set protocols rsvp interface lo0.0
set protocols rsvp interface fxp0.0 disable
set protocols mpls statistics traffic-class-statistics
set protocols mpls label-switched-path R2-R1 to 10.0.0.1
set protocols mpls label-switched-path R2-R1 oam mpls-tp-mode
set protocols mpls label-switched-path R2-R1 ultimate-hop-popping
set protocols mpls label-switched-path R2-R1 associate-lsp R1-R2
set protocols mpls interface ge-0/0/0.0
set protocols mpls interface lo0.0
set protocols mpls interface fxp0.0 disable
set protocols ospf traffic-engineering
set protocols ospf area 0.0.0.0 interface ge-0/0/0.0
set protocols ospf area 0.0.0.0 interface lo0.0
set protocols ospf area 0.0.0.0.interface fxp0.0 disable
```

Procedure

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the CLI User Guide.

To configure Router R1:

1. Enable the chassis with tunnel services and enhanced IP network services configuration.

```
[edit chassis]
user@R1# set fpc 0 pic 3 tunnel-services bandwidth 1g
user@R1# set network-services enhanced-ip
```

2. Configure the interfaces for Router R1.

```
[edit interfaces]
user@R1# set ge-0/0/0 unit 0 family inet address 1.1.1.1/30
user@R1# set ge-0/0/0 unit 0 family mpls
user@R1# set lo0 unit 0 family inet address 10.0.0.1/32
user@R1# set lo0 unit 0 family mpls
```

3. Configure the router ID for Router R1.

```
[edit routing-options]
user@R1# set router-id 10.0.0.1
```

4. Enable RSVP on all the interfaces of Router R1, excluding the management interface.

```
[edit protocols]
user@R1# set rsvp interface ge-0/0/0.0
user@R1# set rsvp interface lo0.0
user@R1# set rsvp interface fxp0.0 disable
```

5. Enable MPLS on all the interfaces of Router R1, excluding the management interface.

```
[edit protocols]
user@R1# set mpls interface ge-0/0/0.0
user@R1# set mpls interface lo0.0
user@R1# set mpls interface fxp0.0 disable
```

6. Configure an associated bidirectional LSP to Router R2.

```
[edit protocols]
user@R1# set mpls label-switched-path R1-R2 to 20.0.0.1
user@R1# set mpls label-switched-path R1-R2 oam mpls-tp-mode
user@R1# set mpls label-switched-path R1-R2 ultimate-hop-popping
user@R1# set mpls label-switched-path R1-R2 associate-lsp R2-R1
```

7. Create traffic classes for maintaining data traffic statistics per traffic class.

   This enables traffic class scoped loss measurement.

```
[edit protocols]
user@R1# set mpls statistics traffic-class-statistics
```

8. Configure OSPF with traffic engineering capabilities, and enable OSPF on all the interfaces of Router R1, excluding the management interface.

```
[edit protocols]
user@R1# set ospf traffic-engineering
user@R1# set ospf area 0.0.0.0 interface ge-0/0/0.0
user@R1# set ospf area 0.0.0.0 interface lo0.0
user@R1# set ospf interface fxp0.0 disable
```

Results

From configuration mode, confirm your configuration by entering the `show chassis`, `show interfaces`, `show routing-options`, and `show protocols` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R1# show chassis
fpc 0 {
    pic 3 {
        tunnel-services {
            bandwidth 1g;
        }
    }
}
network-services enhanced-ip;
```

```
user@R1# show interfaces
ge-0/0/0 {
    unit 0 {
        family inet {
            address 1.1.1.1/30;
        }
        family mpls;
    }
}
lo0 {
    unit 0 {
        family inet {
            address 10.0.0.1/32;
        }
        family mpls;
```

```
    }
}
```

```
user@R1# show routing-options
router-id 10.0.0.1;
```

```
user@R1# show protocols
rsvp {
    interface ge-0/0/0.0;
    interface lo0.0;
    interface fxp0.0 {
        disable;
    }
}
mpls {
    statistics {
        traffic-class-statistics;
    }
    label-switched-path R1-R2 {
        to 20.0.0.1;
        oam mpls-tp-mode;
        ultimate-hop-popping;
        associate-lsp R2-R1;
    }
    interface ge-0/0/0.0;
    interface lo0.0;
    interface fxp0.0 {
        disable;
    }
}
ospf {
    traffic-engineering;
    area 0.0.0.0 {
        interface ge-0/0/0.0;
        interface lo0.0;
        interface fxp0.0 {
            disable;
        }
```

```
    }
}
```

Verification

IN THIS SECTION

- Verifying the LSP Status | **486**
- Verifying Packet Loss Measurement | **487**
- Verifying Packet Delay Measurement | **488**
- Verifying Packet Loss-Delay Measurement | **490**

Confirm that the configuration is working properly.

Verifying the LSP Status

Purpose

Verify that the associated bidirectional LSP between Routers R1 and R2 is up.

Action

From operational mode, run the `show mpls lsp` command.

```
user@R1> show mpls lsp
Ingress LSP: 1 sessions
To              From            State Rt P     ActivePath       LSPname
20.0.0.1        10.0.0.1        Up     0 *                      R1-R2 Assoc-Bidir
Total 1 displayed, Up 1, Down 0

Egress LSP: 1 sessions
To              From            State   Rt Style Labelin Labelout LSPname
10.0.0.1        20.0.0.1        Up       0  1 FF  299776        - R2-R1 Assoc-Bidir
Total 1 displayed, Up 1, Down 0
```

```
Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Meaning

The associated bidirectional LSP R1-R2 is up and active.

Verifying Packet Loss Measurement

Purpose

Verify the on-demand loss measurement result.

Action

From operational mode, run the `monitor mpls loss rsvp R1-R2 count 2 detail` command.

```
user@R1> monitor mpls loss rsvp R1-R2 count 2 detail
(0)

```

Meaning

The packet delay measurement for two counts is displayed.

Verifying Packet Loss-Delay Measurement

Purpose

Verify the on-demand loss and delay measurement result.

Action

From operational mode, run the `monitor mpls loss-delay rsvp R1-R2 count 2 detail` command.

```
user@R1> monitor mpls loss-delay rsvp R1-R2 count 2 detail
(0)
Response code                          : Success
Forward transmit count                 : 142049
Forward receive count                  : 142049

Meaning

The packet loss and delay measurement for two counts is displayed.

Example: Configuring Pro-active Loss and Delay Measurements for Bidirectional MPLS LSPs

IN THIS SECTION

- Requirements | 492
- Overview | 493
- Configuration | 494
- Verification | 500

This example shows how to configure pro-active loss and delay measurements for point-to-point ultimate-hop popping label-switched paths (LSPs) in MPLS networks to monitor network performance.

Requirements

This example uses the following hardware and software components:

- Two MX Series 5G Universal Routing Platforms that contain MPC/MICs only
- Junos OS Release 15.1 or later running on all the routers

Before you begin:

1. Configure the device interfaces.
2. Configure the autonomous system numbers and router IDs for the devices.
3. Configure the following protocols:
   a. MPLS
   b. OSPF

c. RSVP

Overview

IN THIS SECTION

- Topology | 493

Starting with Junos OS Release 15.1, a pro-active tool to monitor and measure packet loss, packet delay, or both for associated bidirectional MPLS ultimate-hop popping point-to-point label-switched paths (LSPs) is introduced.

This feature provides the following performance metrics:

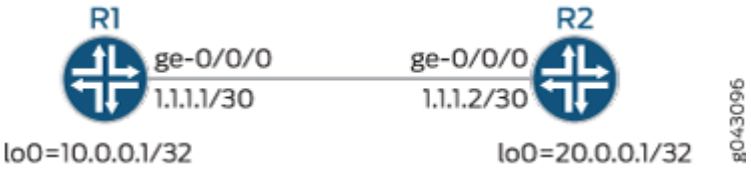
- Inter-packet delay variation (IPDV)
- Loss measurement
- Round-trip delay (RTT)
- Throughput measurement
- Two-way channel delay

This functionality provides real-time visibility into network performance, thereby facilitating network performance planning, troubleshooting, and evaluation.

Topology

Figure 24 on page 493 illustrates the pro-active loss and delay measurements using a simple two-router topology.

Figure 24: Configuring Pro-Active Loss and Delay Measurements



In this example, an associated bidirectional LSP is configured between Routers R1 and R2, for which the performance metrics are measured.

Configuration

IN THIS SECTION

- CLI Quick Configuration | 494
- Procedure | 496
- Results | 498

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the `[edit]` hierarchy level, and then enter `commit` from configuration mode.

R1

```
set chassis network-services enhanced-ip
set interfaces ge-0/0/0 unit 0 family inet address 1.1.1.1/30
set interfaces ge-0/0/0 unit 0 family mpls
set interfaces lo0 unit 0 family inet address 10.0.0.1/32

```
set protocols rsvp interface fxp0.0 disable
set routing-options router-id 20.0.0.1
```

Procedure

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the CLI User Guide.

To configure Router R1:

1. Enable the enhanced IP network services configuration.

```
[edit chassis]
user@R1# set network-services enhanced-ip
```

2. Configure the interfaces for Router R1.

```
[edit interfaces]
user@R1# set ge-0/0/0 unit 0 family inet address 1.1.1.1/30
user@R1# set ge-0/0/0 unit 0 family mpls
user@R1# set lo0 unit 0 family inet address 10.0.0.1/32
user@R1# set lo0 unit 0 family mpls
```

3. Configure the router ID for Router R1.

```
[edit routing-options]
user@R1# set router-id 10.0.0.1
```

4. Enable RSVP on all the interfaces of Router R1, excluding the management interface.

```
[edit protocols]
user@R1# set rsvp interface ge-0/0/0.0
user@R1# set rsvp interface lo0.0
user@R1# set rsvp interface fxp0.0 disable
```

5. Enable MPLS on all the interfaces of Router R1, excluding the management interface.

```
[edit protocols]
user@R1# set mpls interface ge-0/0/0.0
user@R1# set mpls interface lo0.0
user@R1# set mpls interface fxp0.0 disable
```

6. Configure an associated bidirectional LSP to Router R2.

```
[edit protocols]
user@R1# set mpls label-switched-path R1-R2 to 20.0.0.1
user@R1# set mpls label-switched-path R1-R2 install 20.10.30.0/24 active
user@R1# set mpls label-switched-path R1-R2 oam mpls-tp-mode
user@R1# set mpls label-switched-path R1-R2 ultimate-hop-popping
user@R1# set mpls label-switched-path R1-R2 associate-lsp R2-R1
```

7. Create traffic classes for maintaining data traffic statistics per traffic class.

   This enables traffic class scoped loss and delay measurement.

```
[edit protocols]
user@R1# set mpls statistics traffic-class-statistics
```

8. Configure performance monitoring at the querier side.

```
[edit protocols]
user@R1# set mpls label-switched-path R1-R2 oam performance-monitoring querier delay
traffic-class tc-0 query-interval 1000
user@R1# set mpls label-switched-path R1-R2 oam performance-monitoring querier loss traffic-
class none query-interval 1000
user@R1# set mpls label-switched-path R1-R2 oam performance-monitoring querier loss-delay
traffic-class tc-0 query-interval 1000
```

9. Configure performance monitoring at the responder side.

```
[edit protocols]
user@R1# set mpls label-switched-path R1-R2 oam performance-monitoring responder delay min-
query-interval 1000
```

```
user@R1# set mpls label-switched-path R1-R2 oam performance-monitoring responder loss min-
query-interval 1000
```

10. Configure OSPF with traffic engineering capabilities, and enable OSPF on all the interfaces of Router R1, excluding the management interface.

```
[edit protocols]
user@R1# set ospf traffic-engineering
user@R1# set ospf area 0.0.0.0 interface ge-0/0/0.0
user@R1# set ospf area 0.0.0.0 interface lo0.0
user@R1# set ospf interface fxp0.0 disable
```

Results

From configuration mode, confirm your configuration by entering the `show chassis`, `show interfaces`, `show routing-options`, and `show protocols` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R1# show chassis
network-services enhanced-ip;
```

```
user@R1# show interfaces
ge-0/0/0 {
    unit 0 {
        family inet {
            address 1.1.1.1/30;
        }
        family mpls;
    }
}
lo0 {
    unit 0 {
        family inet {
            address 10.0.0.1/32;
        }
        family mpls;
```

```
    }
}
```

```
user@R1# show routing-options
router-id 10.0.0.1;
```

```
user@R1# show protocols
rsvp {
    interface ge-0/0/0.0;
    interface lo0.0;
    interface fxp0.0 {
        disable;
    }
}
mpls {
    label-switched-path R1-R2 {
        to 20.0.0.1;
        install 20.10.30.0/24  active;
        oam {
            mpls-tp-mode;
            performance-monitoring {
                querier {
                    loss {
                        traffic-class none {
                            query-interval 1000;
                        }
                    }
                    delay {
                        traffic-class tc-0 {
                            query-interval 1000;
                        }
                    }
                    loss-delay {
                        traffic-class none {
                            query-interval 1000;
                        }
                    }
                }
                responder {
                    loss {
```

```
                        min-query-interval 1000;
                    }
                    delay {
                        min-query-interval 1000;
                    }
                }
            }
        }
        ultimate-hop-popping;
        associate-lsp R2-R1;
    }
}
ospf {
    traffic-engineering;
    area 0.0.0.0 {
        interface ge-0/0/0.0;
        interface lo0.0;
        interface fxp0.0 {
            disable;
        }
    }
}
```

Verification

IN THIS SECTION

- Verifying Loss and Delay Measurement | 500

Verifying Loss and Delay Measurement

Purpose

Verify the loss and delay measurement.

Action

From operational mode, run the `show performance-monitoring mpls lsp` command.

```
user@R1> show performance-monitoring mpls lsp
Session Total: 3 Up: 3 Down: 0
  LSP name:R1-R2, PM State:Up

```

Meaning

The packet loss and delay measurement metrics for LSP are displayed.

Configuring On-Demand Loss and Delay Measurement

You can configure an on-demand loss and delay measurement for point-to-point ultimate hop popping (UHP) label-switched paths (LSPs) in MPLS networks to monitor network performance. The `monitor mpls loss rsvp`, `monitor mpls delay rsvp`, and `monitor mpls loss-delay rsvp` CLI commands provide an on-demand summary of performance metrics for direct mode packet loss, two-way packet delay, and related metrics, such as inter-packet delay variation and channel throughput measurement.

This functionality provides real-time visibility into network performance, thereby facilitating network performance planning, troubleshooting, and evaluation.

Before you begin:

1. Configure the device interfaces.
2. Configure the device router ID.
3. Configure the following protocols:
   - RSVP
   - OSPF

     Enable traffic engineering capabilities.
   - MPLS

To configure the PE device:

1. Enable the chassis with tunnel services and enhanced IP network services configuration.

```
[edit chassis]
user@R1# set fpc fpc-slot pic pic-slot tunnel-services bandwidth bandwidth
user@R1# set network-services enhanced-ip
```

2. Configure an associated bidirectional LSP to the remote router.

```
[edit protocols]
user@R1# set mpls label-switched-path lsp-name to remote-router-ip-address
user@R1# set mpls label-switched-path lsp-name oam mpls-tp-mode
user@R1# set mpls label-switched-path lsp-name ultimate-hop-popping
user@R1# set mpls label-switched-path lsp-name associate-lsp lsp-name
```

3. Create traffic classes for maintaining data traffic statistics per traffic class.

   This enables traffic class scoped loss measurement.

```
[edit protocols]
user@R1# set mpls statistics traffic-class-statistics
```

Configuring Pro-Active Loss and Delay Measurements

You can configure pro-active loss and delay measurements for point-to-point ultimate-hop popping label-switched paths (LSPs) in MPLS networks to monitor network performance. The `show performance-monitoring mpls lsp` CLI command provides a summary of performance metrics for direct mode packet loss, two-way packet delay, and related metrics, such as inter-packet delay variation and channel throughput measurement.

This functionality provides real-time visibility into network performance, thereby facilitating network performance planning, troubleshooting, and evaluation.

This feature provides the following performance metrics:

- Inter-packet delay variation (IPDV)
- Loss measurement
- Round-trip delay (RTT)
- Throughput measurement
- Two-way channel delay

Before you begin:

1. Configure the device interfaces.
2. Configure the autonomous system numbers and router IDs for the devices.
3. Configure the following protocols:
   - MPLS
   - OSPF
   - RSVP

To configure pro-active loss and delay measurements on the PE device:

1. Configure an associated bidirectional LSP to Router R2.

```
[edit protocols]
user@host# set mpls label-switched-path lsp-name to remote-router-ip-address
user@host# set mpls label-switched-path lsp-name install destination-prefix/prefix-length
active
user@host# set mpls label-switched-path lsp-name oam mpls-tp-mode
user@host# set mpls label-switched-path lsp-name ultimate-hop-popping
user@host# set mpls label-switched-path lsp-name associate-lsp remote-lsp-name
```

2. Create traffic classes for maintaining data traffic statistics per traffic class.

   This enables traffic class scoped loss and delay measurements.

```
[edit protocols]
user@host# set mpls statistics traffic-class-statistics
```

3. Configure performance monitoring at the querier side.

```
[edit protocols]
user@host# set mpls label-switched-path lsp-name oam performance-monitoring querier delay
traffic-class tc-value query-interval milliseconds
user@host# set mpls label-switched-path lsp-name oam performance-monitoring querier loss
traffic-class tc-value query-interval milliseconds
user@host# set mpls label-switched-path lsp-name oam performance-monitoring querier loss-
delay traffic-class tc-value query-interval milliseconds
```

4. Configure performance monitoring at the responder side.

```
[edit protocols]
user@host# set mpls label-switched-path lsp-name oam performance-monitoring responder delay
min-query-interval milliseconds
user@host# set mpls label-switched-path lsp-name oam performance-monitoring responder loss
min-query-interval milliseconds
```

How a Packet Travels Along an LSP

When an IP packet enters an LSP, the ingress router examines the packet and assigns it a label based on its destination, placing the label in the packet's header. The label transforms the packet from one that is forwarded based on its IP routing information to one that is forwarded based on information associated with the label.

The packet is then forwarded to the next router in the LSP. This router and all subsequent routers in the LSP do not examine any of the IP routing information in the labeled packet. Rather, they use the label to look up information in their label forwarding table. They then replace the old label with a new label and forward the packet to the next router in the path.

When the packet reaches the egress router, the label is removed, and the packet again becomes a native IP packet and is again forwarded based on its IP routing information.

Types of LSPs

There are three types of LSPs:

- Static LSPs—For static paths, you must manually assign labels on all routers involved (ingress, transit, and egress). No signaling protocol is needed. This procedure is similar to configuring static routes on individual routers. Like static routes, there is no error reporting, liveliness detection, or statistics reporting.
- LDP-signaled LSPs—See "LDP Introduction" on page 1275.
- RSVP-signaled LSPs—For signaled paths, RSVP is used to set up the path and dynamically assign labels. (RSVP signaling messages are used to set up signaled paths.) You configure only the ingress router. The transit and egress routers accept signaling information from the ingress router, and they set up and maintain the LSP cooperatively. Any errors encountered while establishing an LSP are reported to the ingress router for diagnostics. For signaled LSPs to work, a version of RSVP that supports tunnel extensions must be enabled on all routers.

There are two types of RSVP-signaled LSPs:

- Explicit-path LSPs—All intermediate hops of the LSP are manually configured. The intermediate hops can be strict, loose, or any combination of the two. Explicit path LSPs provide you with complete control over how the path is set up. They are similar to static LSPs but require much less configuration.
- Constrained-path LSPs—The intermediate hops of the LSP are automatically computed by the software. The computation takes into account information provided by the topology information from the IS-IS or OSPF link-state routing protocol, the current network resource utilization determined by RSVP, and the resource requirements and constraints of the LSP. For signaled constrained-path LSPs to work, either the IS-IS or OSPF protocol and the IS-IS or OSPF traffic engineering extensions must be enabled on all routers.

Scope of LSPs

For constrained-path LSPs, the LSP computation is confined to one IGP domain, and cannot cross any AS boundary. This prevents an AS from extending its IGP into another AS.

Explicit-path LSPs, however, can cross as many AS boundaries as necessary. Because intermediate hops are manually specified, the LSP does not depend on the IGP topology or a local forwarding table.

MPLS Label Overview

Packets traveling along an LSP are identified by a label—a 20-bit, unsigned integer in the range 0 through 1,048,575. For push labels on ingress routers, no labels in this range are restricted. For incoming labels on the transit static LSP, the label value is restricted to 1,000,000 through 1,048,575.

On MX Series, PTX Series, and T Series routers, the value for entropy and flow labels is restricted to 16 through 1,048,575.

MPLS Label Allocation

In the Junos OS, label values are allocated per router or switch—the rest of this explanation uses router to cover both. The display output shows only the label (for example, `01024`). Labels for multicast packets are independent of those for unicast packets. Currently, the Junos OS does not support multicast labels.

Labels are assigned by downstream routers relative to the flow of packets. A router receiving labeled packets (the next-hop router) is responsible for assigning incoming labels. A received packet containing a label that is unrecognized (unassigned) is dropped. For unrecognized labels, the router does not attempt to unwrap the label to analyze the network layer header, nor does it generate an Internet Control Message Protocol (ICMP) destination unreachable message.

A packet can carry a number of labels, organized as a last-in, first-out stack. This is referred to as a *label stack*. At a particular router, the decision about how to forward a labeled packet is based exclusively on the label at the top of the stack.

Figure 25 on page 510 shows the encoding of a single label. The encoding appears after data link layer headers, but before any network layer header.

Figure 25: Label Encoding

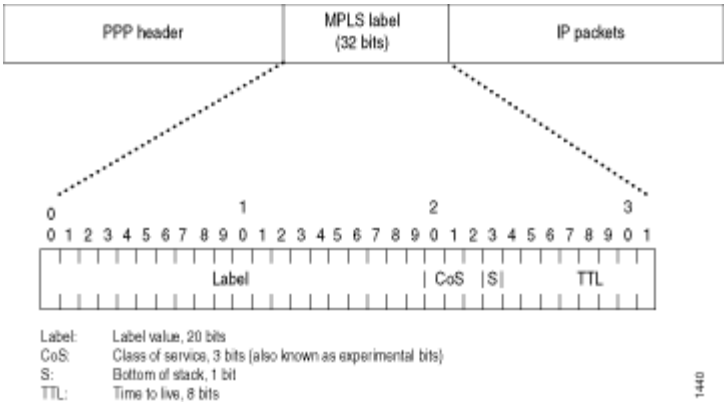

Figure 26 on page 510 illustrates the purpose of the class-of-service bits (also known as the EXP or experimental bits). Bits 20 and 21 specify the queue number. Bit 22 is the packet loss priority (PLP) bit used to specify the random early detection (RED) drop profile. For more information about *class of service* and the class-of-service bits, see "Configuring Class of Service for MPLS LSPs" on page 1838.

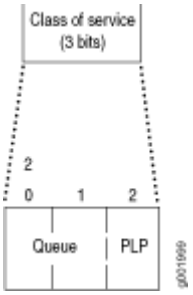
Figure 26: Class-of-Service Bits



Operations on MPLS Labels

The router supports the following label operations:

- Push—Add a new label to the top of the packet. For IPv4 packets, the new label is the first label. The time-to-live (TTL) and s bits are derived from the IP packet header. The MPLS *class of service* (CoS) is derived from the queue number. If the push operation is performed on an existing MPLS packet, you will have a packet with two or more labels. This is called label stacking. The top label must have its s bit set to 0, and might derive CoS and TTL from lower levels. The new top label in a label stack always initializes its TTL to 255, regardless of the TTL value of lower labels.
- Pop—Remove the label from the beginning of the packet. Once the label is removed, the TTL is copied from the label into the IP packet header, and the underlying IP packet is forwarded as a native IP packet. In the case of multiple labels in a packet (label stacking), removal of the top label yields another MPLS packet. The new top label might derive CoS and TTL from a previous top label. The popped TTL value from the previous top label is not written back to the new top label.
- Swap—Replace the label at the top of the label stack with a new label. The S and CoS bits are copied from the previous label, and the TTL value is copied and decremented (unless the `no-decrement-ttl` or `no-propagate-ttl` statement is configured). A transit router supports a label stack of any depth.
- Multiple Push—Add multiple labels (up to three) on top of existing packets. This operation is equivalent to pushing multiple times.
- Swap and Push—Replace the existing top of the label stack with a new label, and then push another new label on top.

Understanding MPLS Label Operations

- Reserved Labels | **513**
- MPLS Label Operations | **513**
- Penultimate-Hop Popping and Ultimate-Hop Popping | **514**

In the traditional packet-forwarding paradigm, as a packet travels from one switch to the next, an independent forwarding decision is made at each hop. The IP network header is analyzed and the next hop is chosen based on this analysis and on the information in the routing table. In an MPLS environment, the analysis of the packet header is made only once, when a packet enters the MPLS tunnel (that is, the path used for MPLS traffic).

When an IP packet enters a label-switched path (LSP), the ingress provider edge (PE) switch examines the packet and assigns it a label based on its destination, placing the label in the packet's header. The label transforms the packet from one that is forwarded based on its IP routing information to one that is forwarded based on information associated with the label. The packet is then forwarded to the next provider switch in the LSP. This switch and all subsequent switches in the LSP do not examine any of the IP routing information in the labeled packet. Rather, they use the label to look up information in their label forwarding table. They then replace the old label with a new label and forward the packet to the next switch in the path. When the packet reaches the egress PE switch, the label is removed, and the packet again becomes a native IP packet and is forwarded based on its IP routing information.

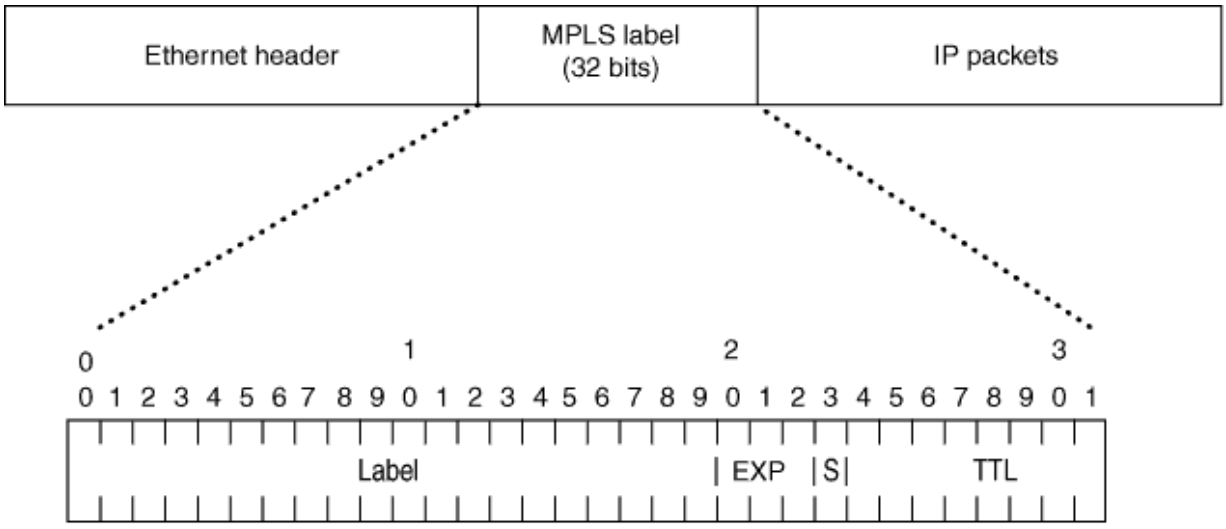
This topic describes:

MPLS Label-Switched Paths and MPLS Labels

When a packet enters the MPLS network, it is assigned to an LSP. Each LSP is identified by a label, which is a short (20-bit), fixed-length value at the front of the MPLS label (32 bits). Labels are used as lookup indexes for the label forwarding table. For each label, this table stores forwarding information. Because no additional parsing or lookup is done on the encapsulated packet, MPLS supports the transmission of any other protocols within the packet payload.

Figure 27 on page 512 shows the encoding of a single label. The encoding appears after data link layer headers, but before any network layer header.

Figure 27: Label Encoding



Reserved Labels

Labels range from 0 through 1,048,575. Labels 0 through 999,999 are for internal use.

Some of the reserved labels (in the range 0 through 15) have well-defined meanings. The following reserved labels are used by QFX Series and EX4600 devices:

- 0, IPv4 Explicit Null label—This value is valid only when it is the sole label entry (no label stacking). It indicates that the label must be popped on receipt. Forwarding continues based on the IP version 4 (IPv4) packet.
- 1, Router Alert label—When a packet is received with a top label value of 1, it is delivered to the local software module for processing.
- 3, Implicit Null label—This label is used in the signaling protocol (RSVP) only to request label popping by the downstream switch. It never actually appears in the encapsulation. Labels with a value of 3 must not be used in the data packet as real labels. No payload type (IPv4 or IPv6) is implied with this label.

MPLS Label Operations

QFX Series and EX4600 devices support the following MPLS label operations:

- Push
- Pop
- Swap

NOTE: There is a limit with regard to the number of labels that QFX and EX4600 devices can affix (push operations) to the label stack or remove (pop operations) from the label stack.

- For Push operations—As many as three labels are supported.
- For Pop operations—As many as three labels are supported.

The push operation affixes a new label to the top of the IP packet. For IPv4 packets, the new label is the first label. The time to live (TTL) field value in the packet header is derived from the IP packet header. The push operation cannot be applied to a packet that already has an MPLS label.

The pop operation removes a label from the beginning of the packet. Once the label is removed, the TTL is copied from the label into the IP packet header, and the underlying IP packet is forwarded as a native IP packet

The swap operation removes an existing MPLS label from an IP packet and replaces it with a new MPLS label, based on the following:

- Incoming interface
- Label
- Label forwarding table

Figure 28 on page 514 shows an IP packet without a label arriving on the customer edge interface (ge-0/0/1) of the ingress PE switch. The ingress PE switch examines the packet and identifies that packet's destination as the egress PE switch. The ingress PE switch applies label 100 to the packet and sends the MPLS packet to its outgoing MPLS core interface (ge-0/0/5). The MPLS packet is transmitted on the MPLS tunnel through the provider switch, where it arrives at interface ge-0/0/5 with label 100. The provider switch swaps label 100 with label 200 and forwards the MPLS packet through its core interface (ge-0/0/7) to the next hop on the tunnel, which is the egress PE switch. The egress PE switch receives the MPLS packet through its core interface (ge-0/0/7), removes the MPLS label, and sends the IP packet out of its customer edge interface (ge-0/0/1) to a destination that is beyond the tunnel.

Figure 28: MPLS Label Swapping

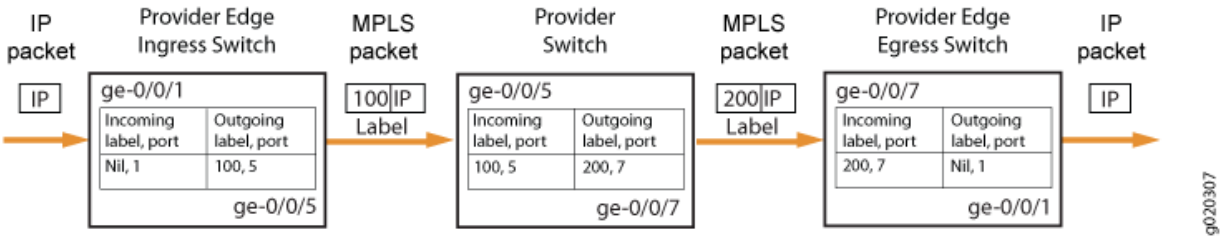


Figure 28 on page 514 shows the path of a packet as it passes in one direction from the ingress PE switch to the egress PE switch. However, the MPLS configuration also allows traffic to travel in the reverse direction. Thus, each PE switch operates as both an ingress switch and an egress switch.

Penultimate-Hop Popping and Ultimate-Hop Popping

The switches enable penultimate-hop popping (PHP) by default with IP over MPLS configurations. With PHP, the penultimate provider switch is responsible for popping the MPLS label and forwarding the traffic to the egress PE switch. The egress PE switch then performs an IP route lookup and forwards the traffic. This reduces the processing load on the egress PE switch, because it is not responsible for popping the MPLS label.

- The default advertised label is label 3 (Implicit Null label). If label 3 is advertised, the penultimate-hop switch removes the label and sends the packet to the egress PE switch.
- If ultimate-hop popping is enabled, label 0 (IPv4 Explicit Null label) is advertised and the egress PE switch of the LSP removes the label.

Understanding MPLS Label Manager

MPLS label manager is used to manage different label types such as LSI, dynamic, block, and static, which are supported on platforms using Modular Port Concentrators (MPCs) equipped with Junos Trio chipsets. These line cards provide more flexibility and scalability, when the `enhanced-ip` command is configured on the device.

The existing behavior of `label-space` command is retained, which is *not recommended*. To provide additional functionality such as multiple ranges for each type of label, `label-range` command is introduced under the `[edit protocols mpls label usage]` hierarchy, which is independent of `label-space` configuration. You can choose either style if only one range is needed for each type of label.

The following features are optimized with the `enhanced-ip` command configured on the device:

- Allows you to define the system wide global label pool to be used by segment-routing global block (SRGB) through IS-IS routing protocol.
- Increases the `vrf-table-label` space to at least 16,000, if the platform can support the scale.
- Allows you to specify the label value to be used by static VRF table label.
- Allows you to specify the label value range to be used by supported label application types.
- Allows you to change dynamically the SRGB and label type ranges.

Special MPLS Labels

Some of the reserved labels (in the 0 through 15 range) have well-defined meanings. For more complete details, see RFC 3032, *MPLS Label Stack Encoding*.

- 0, IPv4 Explicit Null label—This value is legal only when it is the sole label entry (no label stacking). It indicates that the label must be popped upon receipt. Forwarding continues based on the IP version 4 (IPv4) packet.
- 1, Router Alert label—When a packet is received with a top label value of 1, it is delivered to the local software module for processing.
- 2, IPv6 Explicit Null label—This value is legal only when it is the sole label entry (no label stacking). It indicates that the label must be popped on receipt. Forwarding continues based on the IP version 6 (IPv6) packet.
- 3, Implicit Null label—This label is used in the control protocol (LDP or RSVP) only to request label popping by the downstream router. It never actually appears in the encapsulation. Labels with a value of 3 should not be used in the data packet as real labels. No payload type (IPv4 or IPv6) is implied with this label.
- 4 through 6—Unassigned.

- 7, Entropy label indicator—This label is used when an Entropy label is in the label stack and precedes the Entropy label.
- 8 through 15—Unassigned.

Special labels are commonly used between the egress and penultimate routers of an LSP. If the LSP is configured to carry IPv4 packets only, the egress router might signal the penultimate router to use 0 as a final-hop label. If the LSP is configured to carry IPv6 packets only, the egress router might signal the penultimate router to use 2 as a final-hop label.

The egress router might simply signal the penultimate router to use 3 as the final label, which is a request to perform penultimate-hop label popping. The egress router will not process a labeled packet; rather, it receives the payload (IPv4, IPv6, or others) directly, reducing one MPLS lookup at egress.

For label-stacked packets, the egress router receives an MPLS label packet with its top label already popped by the penultimate router. The egress router cannot receive label-stacked packets that use label 0 or 2. It typically requests label 3 from the penultimate router.

Entropy Label Support in Mixed Mode Overview

Starting with Junos OS Release 14.2, entropy label is supported in mixed mode chassis where the entropy label can be configured without enhanced-ip configuration. The entropy label helps transit routers load-balance MPLS traffic across ECMP paths or link aggregation groups. The entropy label introduces a load-balancing label to be used by routers to load balance traffic rather than relying on deep packet inspection, reducing the packet processing requirements in the forwarding plane at the expense of increased label stack depth. Junos OS supports the entropy label only for MX Series routers with MPCs or MICs and can be enabled with enhanced-ip mode. But, this leads to a packet drop if the core-facing interface has an entropy label configured on the MPC or MIC and the other end of this core-facing connection has a DPC line card. In order to avoid this, the entropy label is now supported in mixed mode where the entropy label can be configured without enhanced-ip configuration. This allows MX Series router DPCs to support a pop out entropy label. However, this does not support a flow label.

Abstract Hops for MPLS LSPs Overview

IN THIS SECTION

- Understanding Abstract Hops | **517**
- Benefits of Using Abstract Hops | **518**
- Junos OS Implementation of Abstract Hops | **520**

An abstract hop is a logical combination of the existing traffic engineering constraints, such as administrative groups, extended administrative groups, and Shared Risk Link Groups (SRLGs), which results in a user-defined group or cluster of routers that can be sequenced and used as constraints for setting up an MPLS label-switched path (LSP). Abstract hops overcome the limitations of existing path constraint specifications and provide several benefits to the traffic engineering capabilities of MPLS.

Understanding Abstract Hops

The path constraint for setting up of an MPLS LSP can be specified as either individual routers in the form of real hops or as a set of routers by way of administrative group or color specification. When a path constraint uses real hops (strict or loose), the LSP is set up along a specified sequence of routers (for example, R1, R2, … R*n*). When a path constraint uses an administrative group or color specification, a group of routers that meet the specified criteria is used to set up the LSP without picking a specific router, and unlike real-hop constraint, there is no sequence among the different groups of routers used in the constraint.

The drawback of real-hop constraint is that in a failure scenario, if any of the router hops goes down or the bandwidth utilization of the attached interface gets saturated, the path goes down (or relies on local or end-to-end protection). Although other alternative routers might be available to recover or set up the LSP, the LSP remains down until the operator configures another router hop sequence as the path constraint to bring the path up again or to disengage the protection path.

The administrative group or color specification constraint overcomes this limitation of a real-hop constraint to a certain extent. Here, when one of the routers in the group goes down or has its link capacity saturated, setting up of the LSP is not affected. This is because the next hop router to be used in the path constraint is not picked beforehand, and the LSP is set up along other routers that have the same administrative group or color without operator intervention. However, the drawback with router group constraints is that a sequence cannot be specified among the hop constraints.

Abstract hops overcome these drawbacks by creating user-defined router groups, where each member router meets a user-defined constraint. The user-defined constraint is a logical combination of the existing traffic engineering constraints, such as administrative groups, extended administrative groups, and Shared Risk Link Groups (SRLGs). Ordering is achieved among the router groups by specifying a sequence of abstract hops used in a path constraint. As a result, abstract hops combine the ordering property of real-hop constraint specification and the resilience that comes with the other traffic engineering constraints.

A path can use a combination of real and abstract hops as constraints. When using abstract hops, instead of specifying a sequence of routers (R1, R2, … R*n*) as with real hops, you specify an ordered set of router groups or abstract hops (G1, G2, … G*n*) as the path constraint. Each specified router group, G*i* for example, consists of some user-defined set of routers—R1, R2, R*j*, … R*n*. When one of the routers in the group goes down, say Router R*j* in group G*i*, another router, say Router R*k*, from the same group G*i* is picked up by path computation to replace the router that went down (that is, Router R*j*). This is

because the path constraint is sequenced and has to go through a sequence of abstract hops, instead of a sequence of individual routers.

Benefits of Using Abstract Hops

Abstract hops are user-defined router groups. Similar to real-hop constraints that use a sequence of individual routers, a sequence of abstract hops can be used for setting up a label-switched path (LSP). The use of abstract hops provides resiliency to sequenced path constraints. The other benefits of using abstract hops include:

Specifying a Sequence of Constraint Combinations

Currently, it is possible to specify a path that can go through links that satisfy multiple attributes. Such a path constraint is called a compound constraint combination; for example, a constraint (Ci) that includes low latency links of green color and also excludes SRLG north.

However, there is no support for specifying a path with a sequence of compound constraint combinations. For example, a sequenced constraint (C1, C2, Ci, ...Cn) that includes low latency green links, no latency blue links, and then low latency red links.

The need for such a sequenced compound constraint combination arises when there is a requirement to establish paths through a sequence of geographical regions with a different link affinity (attributes) requirement in each region. Abstract hops meet this requirement by allowing computing nodes to map each constraint combination (Ci, for example) with the user-defined group of routers—that is, the abstract hops.

Avoiding New Network Configuration on Transit Nodes

With current path constraint specification capabilities, it is possible to include or exclude links of certain attributes along an entire path; for example, excluding SRLG west from a path. However, there is no support to either conditionally exclude or include attributes, or to apply different exclude or include attributes in different parts of the path; for example, excluding SRLG west only when traversing red links.

As a workaround, a new administrative group can be created to identify all such red links that do not have SRLG west, and configure all the relevant links appropriately with that administrative group. The drawback of this approach is that configuration changes are required throughout the network to reflect the new administrative group membership.

Instead, by using abstract hops, the configuration changes can be contained on the ingress router only. At the ingress router, the constraint combination is mapped to the abstract hop, thereby meeting the aforementioned requirement without the need for any new configuration on the transit nodes.

Combining Centralized and Distributed Path Computation Paradigms

Traffic engineering of MPLS paths can be achieved by distributed computing or with a centralized controller for computing paths. A combination of both the computation types is called the hybrid computation paradigm. The key feature of the hybrid computation approach is the ability of the centralized controller—referred to as a Path Computation Element (PCE)—to loosely specify the path computation directives, per path, to the ingress router—referred to as a Path Computation Client (PCC)—and the ability of the ingress router to use it as input for path computation.

A sequence of abstract hops serves the purpose of acting as the guideline from the centralized controller. Abstract hops provide the flexibility to the controller to weave into the path constraint and attributes. This also enables the controller to build in the element of sequence in the constraint. The controller does not have to specify each hop the path needs to take, leaving room for the ingress router to act within the limits of the guideline or directive.

Table 10 on page 519 lists the key features of the hybrid computation paradigm and provides a comparison of this approach with the current path computation methods.

Table 10: Hybrid Computation for Abstract Hops

Features	Distributed Constrained Shortest Path First	Centralized Constrained Shortest Path First	Hybrid Constrained Shortest Path First
React to frequent changes in a large network	Yes		Yes
Sophisticated path computation with global view		Yes	Yes
Incorporation of business logic in path computation		Yes	Yes
Resilience (no single point of failure)	Yes		Yes
Predictability		Yes	Yes
React to network load in (close to) real time	Yes		Yes

Field tested (versus early adoption)	Yes		Yes

Junos OS Implementation of Abstract Hops

The order-aware abstract hops feature is introduced in Junos OS Release 17.1. The following sections describe the implementation of abstract hops in Junos OS:

Defining Abstract Hops

An abstract hop is a group of routers that users can define to be used in setting up a label-switched path (LSP). The user can control which routers to include in the group by defining a logical combination of heterogeneous link attributes or constraints called constituent attributes. The routers with links that satisfy the defined constituent attributes make it to the group of routers representing the abstract hop.

The mapping of constituent attributes with the abstract hop is local to the computing node or the ingress of the LSP being setup. As a result, abstract hops do not have associated interior gateway protocol updates or signaling protocol extensions, and implementing abstract hops in a network does not require new configuration on the transit nodes.

A constituent list enables defining of a set of constituent traffic engineering attributes, that is identified by a user-defined name. Constituent lists are used in an abstract hop definition by using any of the following configuration statements:

- **include-any-list**—Link satisfies the constituent-list if any of the specified constituent attributes are true for the link.
- **include-all-list**—Link satisfies the constituent-list if all the specified constituent attributes are true for the link.
- **exclude-all-list**—Link satisfies the constituent-list if none of the specified constituent attributes are true for the link.
- **exclude-any-list**—Link satisfies the constituent-list if at least one of the specified constituent attributes is not true for the link.

An abstract hop is defined as a logical combination of constituent-list references that can belong to any of the aforementioned categories. To achieve this, logical operators `AND` and `OR` are included in the abstract hop definition, and applied to the constituent list.

- **OR**—At least one of the constituent-list references in the abstract hop definition must be satisfied by a link for the attached node to be part of the abstract hop.
- **AND**—All of the constituent-list references in the abstract hop definition must be satisfied by a link for the attached node to be part of the abstract hop.

Sample Abstract Hop Definition

Taking as an example, the definition of abstract hops hopA is as follows:

Abstract hops hopA must include all routers whose emanating links satisfy the logical combination of the following link attributes, respectively:

- **hopA**—((administrative group red && Srlg south) || (administrative group green || Srlg north)), where:
  - *administrative group red* and *Srlg south* belong to include-all constituent list (listA1, in this example).
  - *administrative group green* and *Srlg north* belong to include-any constituent list (listA2, in this example).
  - //is the OR operator.

The configuration for abstract hops hopA is as follows:

- **hopA configuration**

```
[edit protocols mpls]
Constituent-list listA1 {
    administrative-group red;
    Srlg south;
}
Constituent-list listA2 {
    administrative-group green;
    Srlg north;
}
Abstract-hop hopA{
    Operator OR;
    Constituent-list listA1 include-all-list;
    Constituent-list listA2 include-any-list;
}
```

Verifying Abstract Hop Configuration

The `show mpls abstract hop membership` *<abstract hop name>* command is used to view members of an abstract hop. The command output provides the abstract hop to traffic engineering database node mapping.

```
user@host> show mpls abstract-hop-membership
Abstract hop: hop1A
   Credibility: 0
```

```
Address: 128.102.165.105
Address: 128.102.166.237
Address: 128.102.168.0
Address: 128.102.173.123

Abstract hop: hopB
   Credibility: 0
Address: 128.102.160.211
Address: 128.102.165.5
Address: 128.102.166.237
Address: 128.102.172.157
Address: 128.102.172.196
```

Here, the output field `Credibility` indicates the credibility associated with interior gateway protocol in use.

The output of the `show ted database extensive local` command provides the view captured in traffic engineering database. A keyword `local` is added to indicate that the output would include any local instrumentation. The command output shows the abstract hop as an attribute of links that satisfy the associated logical combination of link attributes.

```

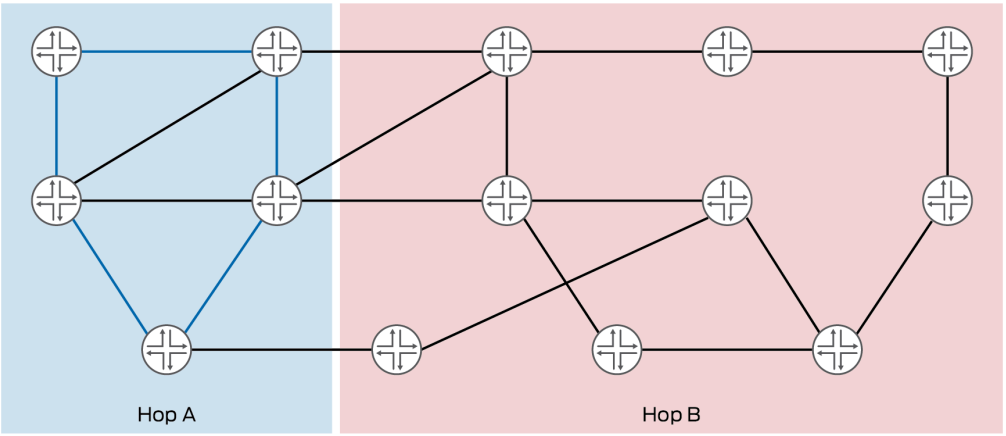
Abstract hop hopA is for low latency AND SRLG west, and abstract hop hopB is for excluding SRLG west. Figure 29 on page 523 displays the ingress view of these abstract hops.

Figure 29: Ingress View of Abstract Hops



Using Abstract Hops in Path Constraint

The user associates a unique identifier with each abstract hop definition. This identifier is used for referring to the abstract hop in the path constraint. A sequence of abstract hops can be specified as the path constraint, similar to how real IP hops are used. The path constraint could also be a sequence of abstract hops interleaved by real IP hops.

Using abstract hops or real hops in a path constraint requires more than one Constrained Shortest Path First pass to the destination, typically one pass per hop. When real hops are provided as the path constraint, the constraint computation involves as many passes as the number of hops in the path constraint, where each pass ends on reaching a hop in the constraint list. The starting point for each pass is the destination of the previous pass, with the first pass using the ingress router as the start.

Alternatively, when path constraint uses strict or loose abstract hops, constraint computation comprises passes where each pass processes the subsequent abstract hop in the constraint list. In such a case, more than one node qualifies to be the destination for the pass. The set of nodes is called the viable router set for the pass.

An abstract hop traverses member nodes by using the following:

- Links that satisfy the logical combination of defined constituent attributes
- Any kind of links

The means of abstract hops traversing the member nodes is controlled by the use of the abstract hop qualifiers—strict, loose, and loose-link—in defining the path constraint. Taking for example, abstract hop hopA is processed differently with different qualifiers:

- **Strict**—After the last processed hop in the constraint list, the path traverses only links or nodes having membership of abstract hop hopA, before reaching a node with hopA's membership that is a feasible starting point for processing the next abstract hop.
- **Loose**—After the last processed hop in the constraint list, the path can traverse any real nodes that do not have abstract hop membership of hopA, before reaching a node with abstract hop membership hopA, which is a feasible starting point for processing the next abstract hop.
- **Loose-link**—After the last processed hop in the constraint list, the path can traverse any real nodes that do not have abstract hop membership of hopA, before reaching a node with abstract hop membership hopA, which is a feasible starting point for processing the next abstract hop. But the path should have traversed at least one link of abstract hop hopA membership in the course of the same.

  In other words, the abstract hop of type loose-link is said to be processed only if any of the viable routers in the constraint is reachable through a link of associated abstract hop membership.

Sample Abstract Hops Specification

Table 11 on page 525 provides sample use case for using abstract hops in path constraints.

Table 11: Using Abstract Hops in Path Constraints

Purpose of Path Constraint	Abstract Hop Qualifier	Configuration	Viable Router Set	Affinity

Traverse nodes that are members of hopA taking only links that satisfy hopA.	Strict	`[edit protocols mpls]`
		`Path path_hopA_s {`
		`  hopA abstract strict;`
		`}`
			All members of abstract hopA. That is, A1, A2…A*n*.	hopA (pick only links that satisfy abstract hopA).

Traverse nodes that are members of hopA but not necessarily links that satisfy hopA	Loose	`[edit protocols mpls]`
		`Path path_hopA_l {`
		`  hopA abstract loose;`
		`}`
			All members of abstract hopA. That is, A1, A2…A*n*.	None (any kind of links).

Traverse nodes that are members of hopA by taking at least one link that satisfies hopA.	Loose-link
	
	NOTE: The loose-link qualifier is viewed as loose followed by strict for the same abstract hop. In other words, hopA loose-link is the same as hopA loose and hopA strict.
		`[edit protocols mpls]`
		`Path path_hopA_ll {`
		`  hopA abstract loose-link;`
		`}`
			In this case, there are two computation passes associated with hopA in the path constraint. The viable router set for both passes is:
			
			All members of abstract hopA. That is, A1, A2…A*n*.
			
			NOTE: During path computation, a router is traversed only once.
				In this case, there are two computation passes associated with hopA in the path constraint. The affinity for the two passes is:
				
				• Pass 1—None (any kind of links).
				
				• Pass 2—hopA (pick only links that satisfy abstract hopA).

Table 11: Using Abstract Hops in Path Constraints *(Continued)*

Purpose of Path Constraint	Abstract Hop Qualifier	Configuration	Viable Router Set	Affinity

Traverse nodes that are members of hopA, taking only links that satisfy hopA, followed by nodes that are members of hopB taking only links that satisfy hopB.	Strict	`[edit protocols mpls]`
		`Path path_hopA_hopB_s {`
		`  hopA abstract strict;`
		`  hopB abstract strict;`
		`}`
			• hopA—Intersection of member set of hopA and hopB.
			NOTE: When an abstract hop is followed by a strict abstract hop, the intersection of the two member sets is considered as viable router set.
			• hopB—All members of abstract hopB. That is, B1, B2… B*n*.
				• hopA—hopA (pick only links that satisfy abstract hopA).
				• hopB—hopB (pick only links that satisfy abstract hopB).

Traverse nodes that are members of hopA taking only links that satisfy hopA, followed by nodes that are members of hopB taking any kind of links.	Strict and loose	`[edit protocols mpls]`
		`Path path_hopA_s_hopB_l {`
		`  hopA abstract strict;`
		`  hopB abstract loose;`
		`}`
			• hopA—All members of abstract hopA. That is, A1, A2… A*n*.
			• hopB—All members of abstract hopB. That is, B1, B2… B*n*.
				• hopA—hopA (pick only links that satisfy abstract hopA).
				• hopB—None (pick any links).

Table 11: Using Abstract Hops in Path Constraints *(Continued)*

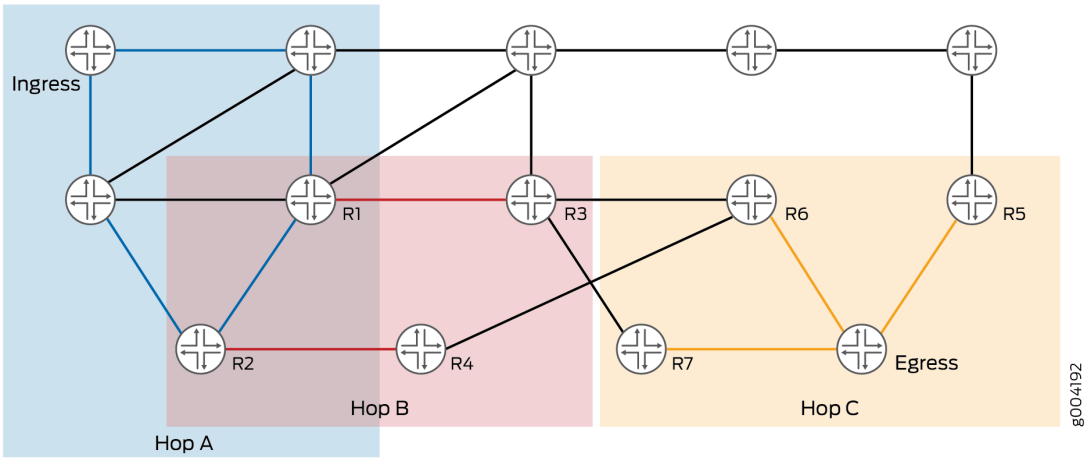
Purpose of Path Constraint	Abstract Hop Qualifier	Configuration	Viable Router Set	Affinity

Traverse nodes that are members of hopA by taking any kinds of links, followed by nodes that are members of hopB taking any kind of links.	Loose	`[edit protocols mpls]`
		`Path path_hopA_l_hopB_l {`
		`  hopA abstract loose;`
		`  hopB abstract loose;`
		`}`
			• hopA—All members of abstract hopA. That is, A1, A2… A*n*.
			• hopB—All members of abstract hopB. That is, B1, B2… B*n*.
				None (pick any links).

Traverse nodes that are members of hopA by taking any kinds of links, followed by nodes that are members of hopB taking only links that satisfy hopB.	Loose and strict	`[edit protocols mpls]`
		`Path path_hopA_l_hopB_s {`
		`  hopA abstract loose;`
		`  hopB abstract strict;`
		`}`
			• hopA—Intersection of the members of hopA and hopB.
			When an abstract hop is followed by a strict abstract hop, the intersection of the two member sets is considered as viable router set.
			• hopB—All members of abstract hopB. That is, B1, B2… B*n*.
				• hopA—None (pick any links).
				• hopB—hopB (pick only links that satisfy abstract hopB).

Figure 30 on page 528 displays path constraints for abstract hops hopA, hopB, and hopC with loose, strict, and loose abstract hop qualifiers, respectively.

Figure 30: Sample Path Constraints for Abstract Hops



The Constrained Shortest Path First passes for the abstract hops are as follows:

- Pass 1 associated with hopA
  - Viable routers—Routers R1 and R2 (intersection of hopA and hopB, as hopB is a strict abstract hop).
  - Affinity—None (as hopA is loose).
- Pass 2 associated with hopB
  - Viable routers—Routers R1, R2, R3, and R4
  - Affinity—Pick only hopB-compliant links (as hopB is a strict abstract hop).
- Pass 3 associated with hopC
  - Viable routers—Routers R5, R6, R7, and the egress router.
  - Affinity—None (as hopC is a loose abstract hop).

Path Computation and Backtracking

In each Constrained Shortest Path First pass, when the nearest router from a viable router set is reached using links satisfying the affinity figured for the pass, the abstract hop associated with the pass is said to be processed. The viable router thus reached serves as the start for the next constraint pass. If any

constraint pass fails, and it is not the one with the ingress router as start router, then the pass is backtracked to the previous pass and the process is repeated.

Sample Backtracking

When a Constrained Shortest Path First pass p (other than the first one) fails, the exit router of the previous pass (p – 1) that served as start for the current pass p is disqualified in the viable router set of the previous pass (p – 1). Then the previous pass (p – 1) is re-executed to find the next best exit router or destination for the pass p – 1 from the viable router set.

The router thus determined serves as the new start router for the pass p. This procedure is repeated as long as there are failures and there are viable routers that are not explored.

The `show mpls lsp abstract-hop-computation name` *`lsp-name`* command provides the various computation passes involved per LSP and the qualifying exit routers for each pass. The command output also gives the affinity per pass, and shows the current start router chosen for the pass. For each viable router, the state of backtracking is displayed, where it can be either valid or disqualified.

```

```

```
CSPF pass no: 2 Start address of the pass: 128.102.172.196
Destination: 128.102.172.157, , State: VALID
```

The output field `Credibility` indicates the credibility associated with the interior gateway protocol in use.

Example: Configuring Abstract Hops for MPLS LSPs

IN THIS SECTION

- Requirements | **530**
- Overview | **531**
- Configuration | **533**
- Verification | **550**

This example shows how to configure abstract hops for MPLS label-switched paths (LSPs). Abstract hops combine the key features of existing traffic engineering constraints that enables the user to specify an order-aware and resilient path constraint for MPLS LSPs.

Requirements

This example uses the following hardware and software components:

- Six devices that can be a combination of M Series Multiservice Edge Routers, MX Series 5G Universal Routing Platforms, T Series Core Routers, and PTX Series Packet Transport Routers.
- Junos OS Release 17.1 or later running on all the devices.

Before you begin:

- Configure the device interfaces.
- Configure the device router ID and assign an autonomous system (AS) number.
- Configure RSVP on all the devices.
- Configure OSPF or any other interior gateway protocol on all the devices.
- Configure administrative groups, extended administrative groups, and Shared Risk Link Groups (SRLGs) on all the devices.

Overview

IN THIS SECTION

- Topology | 532

Junos OS Release 17.1 introduces abstract hops, which are user-defined router clusters or groups. Similar to the sequence of real-hop constraints (strict or loose), a sequence of abstract hops can be used for setting up a label-switched path (LSP). A path can use a combination of real and abstract hops as constraints.

An abstract hop is a logical combination of the existing traffic engineering constraints, such as administrative groups, extended administrative groups, and SRLGs, along with the ordering property of real hops. As a result, when a sequence of abstract hops is used in a path constraint, ordering is achieved among the groups of routers that meet a logical combination of link or node attributes called constituent attributes.

To configure abstract hops:

- Create constituent lists with constituent traffic engineering attributes by including the `constituent-list` *`list-name`* statement at the `[edit protocols mpls]` hierarchy level.
- Include the constituent lists in the abstract hop definition at the `[edit protocols mpls abstract-hop` *`abstract-hop-name`*`]` hierarchy level.
- Define path constraints that use abstract hops at the `[edit protocols mpls path` *`path-name`*`]` hierarchy level.

Take the following guidelines under consideration when configuring abstract hops for MPLS LSPs:

- Abstract hops are supported only in the master routing instance of a device.
- IPv6 destinations are not supported in abstract hop constraints (only IPv4 destinations work).
- Abstract hops can be strict or loose constraints.
- Abstract hops support in Junos OS Release 17.1 is provided only for intra-area MPLS LSPs and not for inter-domain, or inter-area LSPs.
- Abstract hop constraints is enabled for regular point-to-point LSPs only. Other types of MPLS LSPs, such as point-to-multipoint LSPs, externally controlled bidirectional LSPs, dynamic container LSPs, RSVP automesh LSPs, and inter-area LSPs are not supported with abstract hops configuration.
- Abstract hops do not enable computation of overall shortest path for LSPs.

- An abstract hop must not be referred to more than once in the same path constraint.
- Abstract hop constraint specifications do not affect the support for Graceful Routing Engine switchover (GRES), unified in-service software upgrade (ISSU), and nonstop routing (NSR).
- Abstract hop constraint specifications do not affect overall network performance. However, the time taken for constrained shortest path first computation increases with abstract hop configuration. The setup time for an abstract hop LSP is more than the time taken to set up an LSP without abstract hop configuration.

Topology

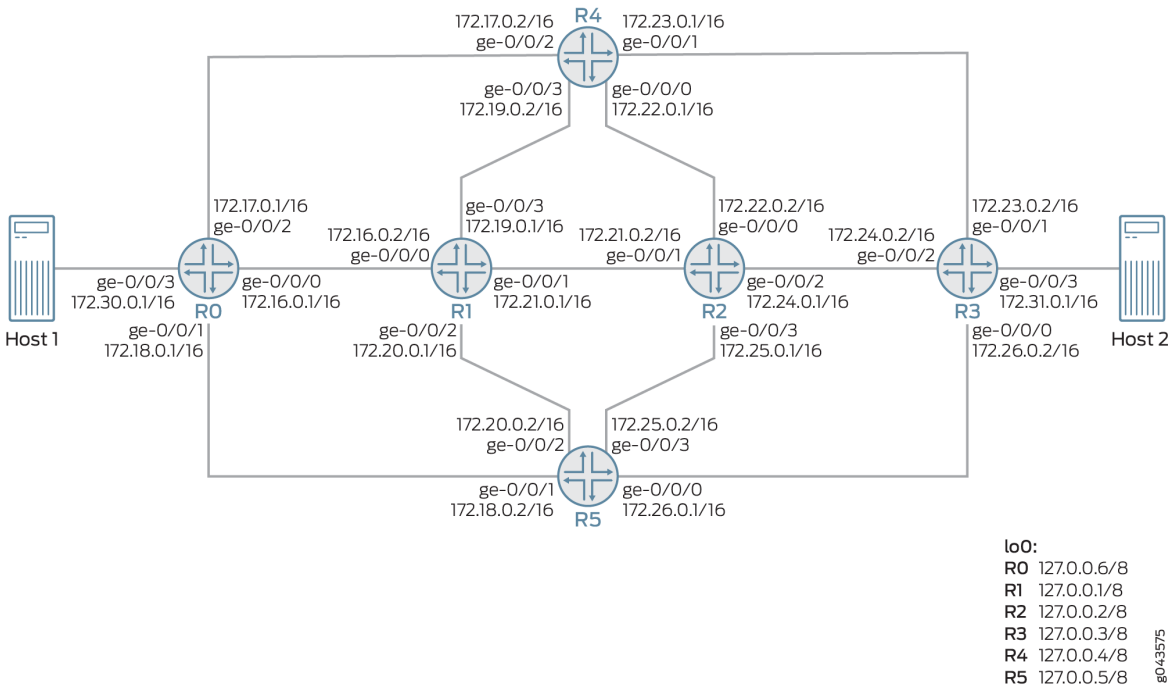
Figure 31 on page 533 illustrates a sample network topology configured with abstract hops. Devices R0 and R3 are each connected to hosts (Host 1 and Host 2). Devices R4 and R5 are each connected to Devices R0, R1, R2, and R3. Devices R1 and R2 are also directly connected to each other.

Devices R0 and R3 are configured under the same autonomous system—AS 64496. An MPLS LSP is configured from Device R0 through Device R3 with one primary path and two secondary paths (standby and nonstandby secondary paths).

Four constituent lists—c1, c2, c3, and c4—are created using three SRLGs (g1, g2, and g3), three administrative groups (green, blue, and red), and one extended administrative group (gold). Three abstract hops (ah1, ah2, and ah3) are defined using the configured constituent lists, and are specified as path constraints. Abstract hop ah1 is specified as constraint for the primary path, while abstract hops

ah2 and ah3 are specified as constraints for the secondary standby path and the secondary nonstandby path, respectively.

Figure 31: Configuring Abstract Hop Path Constraint



Configuration

IN THIS SECTION

- CLI Quick Configuration | 533
- Procedure | 540

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the `[edit]` hierarchy level, and then enter `commit` from configuration mode.

Procedure

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the CLI User Guide.

To configure Device R0:

1. Enable enhanced IP network services on Device R0.

```
[edit chassis]
user@R0# set network-services ip
```

2. Configure the interfaces on Device R0, including the loopback interface.

```
[edit interfaces]
user@R0# set ge-0/0/0 unit 0 family inet address 172.16.0.1/16
user@R0# set ge-0/0/0 unit 0 family mpls
user@R0# set ge-0/0/1 unit 0 family inet address 172.18.0.1/16
user@R0# set ge-0/0/1 unit 0 family mpls
user@R0# set ge-0/0/2 unit 0 family inet address 172.17.0.1/16
user@R0# set ge-0/0/2 unit 0 family mpls
user@R0# set ge-0/0/3 unit 0 family inet address 172.30.0.1/16
user@R0# set lo0 unit 0 family inet address 127.0.0.6/8
```

3. Assign the router ID and autonomous system number for Device R0.

```
[edit routing-options]
user@R0# set router-id 127.0.0.6
user@R0# set autonomous-system 64496
```

4. Configure the SRLG definitions.

```
[edit routing-options]
user@R0# set srlg g1 srlg-value 100
user@R0# set srlg g1 srlg-cost 1000
user@R0# set srlg g2 srlg-value 200
user@R0# set srlg g2 srlg-cost 2000
user@R0# set srlg g3 srlg-value 300
user@R0# set srlg g3 srlg-cost 3000
```

5. Configure the extended administrative group definitions.

```
[edit routing-options]
user@R0# set administrative-groups-extended-range minimum 50000
user@R0# set administrative-groups-extended-range maximum 60000
user@R0# set administrative-groups-extended gold group-value 50000
```

6. Configure the administrative group definitions.

```
[edit protocols]
user@R0# set mpls administrative-groups green 0
user@R0# set mpls administrative-groups blue 1
user@R0# set mpls administrative-groups red 2
```

7. Configure MPLS on all the interfaces of Device R0, excluding the management interface.

```
[edit protocols]
user@R0# set mpls interface all
user@R0# set mpls interface fxp0.0 disable
```

8. Assign the interfaces of Device R0 with the configured traffic engineering attributes.

```
[edit protocols]
user@R0# set mpls interface ge-0/0/0.0 srlg g1
user@R0# set mpls interface ge-0/0/0.0 administrative-group green
user@R0# set mpls interface ge-0/0/0.0 administrative-group-extended gold
user@R0# set mpls interface ge-0/0/2.0 srlg g2
user@R0# set mpls interface ge-0/0/2.0 administrative-group red
user@R0# set mpls interface ge-0/0/2.0 administrative-group-extended gold
user@R0# set mpls interface ge-0/0/1.0 srlg g3
user@R0# set mpls interface ge-0/0/1.0 administrative-group blue
user@R0# set mpls interface ge-0/0/1.0 administrative-group-extended gold
```

9. Configure an LSP connecting Device R0 with Device R3, and assign primary and secondary path attributes to the LSP.

```
[edit protocols]
user@R0# set mpls label-switched-path R0-R31 to 127.0.0.3
user@R0# set mpls label-switched-path R0-R31 primary prim
user@R0# set mpls label-switched-path R0-R31 secondary stdby standby
user@R0# set mpls label-switched-path R0-R31 secondary nonstdby
```

10. Define the primary and secondary paths for the R0-R31 LSP.

```
[edit protocols]
user@R0# set mpls path path_primary 172.16.0.2 strict
user@R0# set mpls path path_primary 172.21.0.2 strict
user@R0# set mpls path path_primary 172.24.0.2 strict
user@R0# set mpls path path_ter_nonstdby 172.18.0.1 strict
user@R0# set mpls path path_ter_nonstdby 172.26.0.2 strict
user@R0# set mpls path path_sec_stdby 172.17.0.2 strict
user@R0# set mpls path path_sec_stdby 172.23.0.2 strict
```

11. Create constituent lists with constituent traffic engineering attributes for abstract-hop definitions.

```
[edit protocols]
user@R0# set mpls constituent-list c1 srlg g1
user@R0# set mpls constituent-list c1 administrative-group green
user@R0# set mpls constituent-list c2 administrative-group green
user@R0# set mpls constituent-list c2 administrative-group-extended gold
user@R0# set mpls constituent-list c3 srlg g2
user@R0# set mpls constituent-list c3 administrative-group red
user@R0# set mpls constituent-list c3 administrative-group-extended gold
user@R0# set mpls constituent-list c4 srlg g3
user@R0# set mpls constituent-list c4 administrative-group blue
user@R0# set mpls constituent-list c4 administrative-group-extended gold
```

12. Define abstract hops by assigning the configured constituent lists and respective operators.

```
[edit protocols]
user@R0# set mpls abstract-hop ah1 operator AND
user@R0# set mpls abstract-hop ah1 constituent-list c1 include-all-list
user@R0# set mpls abstract-hop ah1 constituent-list c2 include-all-list
user@R0# set mpls abstract-hop ah2 operator AND
user@R0# set mpls abstract-hop ah2 constituent-list c3 include-all-list
user@R0# set mpls abstract-hop ah3 operator AND
user@R0# set mpls abstract-hop ah3 constituent-list c4 include-all-list
```

13. Define constraints for the configured paths by including abstract hop definitions.

```
[edit protocols]
user@R0# set mpls path prim ah1 abstract
user@R0# set mpls path prim ah1 strict
user@R0# set mpls path stdby ah2 abstract
user@R0# set mpls path stdby ah2 strict
user@R0# set mpls path nonstdby ah3 abstract
user@R0# set mpls path nonstdby ah3 strict
```

14. Configure RSVP on Device R0. Enable RSVP on all the interfaces of Device R0, excluding the management interface and interface connecting to Host1, and assign bandwidth values.

```
[edit protocols]
user@R0# set rsvp interface all aggregate
user@R0# set rsvp interface fxp0.0 disable
user@R0# set rsvp interface ge-0/0/0.0 bandwidth 80m
user@R0# set rsvp interface ge-0/0/2.0 bandwidth 200m
user@R0# set rsvp interface ge-0/0/1.0 bandwidth 500m
```

15. Configure OSPF on all the interfaces of Device R0, excluding the management interface, and assign traffic engineering capabilities.

```
[edit protocols]
user@R0# set ospf traffic-engineering
user@R0# set ospf area 0.0.0.0 interface all
user@R0# set ospf area 0.0.0.0 interface fxp0.0 disable
```

16. Configure a policy on Device R0 to enable load balancing on a per-packet basis.

```
[edit policy-options]
user@R0# set forwarding-table export test
```

17. Export the load-balancing policy to the forwarding table.

```
[edit policy-options]
user@R0# set policy-statement test then load-balance per-packet
```

Results

From configuration mode, confirm your configuration by entering the `show chassis`, `show interfaces`, `show routing-options`, `show protocols`, and `show policy-options` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R0# show chassis
network-services ip;
```

```
user@R0# show interfaces
ge-0/0/0 {
    unit 0 {
        family inet {
            address 172.16.0.1/16;
        }
        family mpls;
    }
}
ge-0/0/1 {
    unit 0 {
        family inet {
            address 172.18.0.1/16;
        }
        family mpls;
    }
}
ge-0/0/2 {
    unit 0 {
        family inet {
            address 172.17.0.1/16;

Verification

IN THIS SECTION

- Verifying Abstract Hop Configuration | 550
- Verifying Abstract Hop Path Computation | 551

Confirm that the configuration is working properly.

Verifying Abstract Hop Configuration

Purpose

Verify the members of the abstract hop definition on Device R0 by issuing the `show mpls abstract-hop-membership` command, which displays the abstract hop membership tables.

Action

From operational mode, run the **show mpls abstract-hop-membership** command.

```
user@R0> show mpls abstract-hop-membership
Abstract hop: ah1
   Credibility: 0
Address: 127.0.0.6
Address: 127.0.0.1
Address: 127.0.0.2
Address: 127.0.0.3

Abstract hop: ah2
   Credibility: 0
Address: 127.0.0.6
Address: 127.0.0.3
Address: 127.0.0.4

Abstract hop: ah3
   Credibility: 0
Address: 127.0.0.6
```

```
Address: 127.0.0.3
Address: 127.0.0.5
```

Meaning

The `show mpls abstract-hop-membership` command output provides the abstract hop to traffic engineering database node mapping. The `Credibility` field displays the credibility value associated with the interior gateway protocol in use (OSPF).

Verifying Abstract Hop Path Computation

Purpose

Verify the abstract computation preprocessing for LSPs on Device R0 by issuing the `show mpls lsp abstract-computation` command.

Action

From operational mode, run the **show mpls lsp abstract-computation** command.

```
user@R0> show mpls lsp abstract-computation
Path computation using abstract hops for LSP: R0-R31
   Path type: Primary, Path name: prim

   Credibility: 0, Total no of CSPF passes: 2
     CSPF pass no: 0
      Start address of the pass: 127.0.0.6
       Destination: 127.0.0.1, State: VALID
       Destination: 127.0.0.2, State: VALID
       Destination: 127.0.0.3, State: VALID
       Affinity: ah1
     CSPF pass no: 1
      Start address of the pass: 127.0.0.1
       Destination: 127.0.0.3, State: VALID
   Path type: Secondary, Path name: nonstdby
   Path type: Standby, Path name: stdby

   Credibility: 0, Total no of CSPF passes: 2
     CSPF pass no: 0
      Start address of the pass: 127.0.0.6
       Destination: 127.0.0.3, State: VALID
```

```
        Destination: 127.0.0.4, State: VALID
        Affinity: ah2
      CSPF pass no: 1
       Start address of the pass: 127.0.0.4
        Destination: 127.0.0.3, State: VALID
```

Meaning

The `show mpls lsp abstract-hop-computation` command output provides the various computation passes involved per LSP, and the qualifying exit devces for each pass. The command output also gives the affinity per pass, and shows the current start device chosen for the pass. For each viable router (device), the state of backtracking is displayed, where it can either be valid or disqualified.

The `Credibility` field indicates the credibility value associated with the interior gateway protocol in use (OSPF).

Configuring the Maximum Number of MPLS Labels

For interfaces that you configure for MPLS applications, you can set the maximum number of labels upon which MPLS can operate.

By default, the maximum number of labels is three. You can change the maximum to four labels or five labels for applications that require four or five labels.

Starting in Junos OS Release 19.1R1, the maximum number of labels that can be pushed by the egress Packet Forwarding Engine (PFE) can be leveraged, wherein the number of labels that can be pushed for an MPLS next hop is the number of labels the device is capable of pushing, or the "maximum-labels" on page 2574 configured under `family mpls` of the outgoing interface, whichever is smaller. This support is enabled on MX Series routers with MPC and MIC interfaces, and PTX Series routers with third-generation FPCs.

The increased label push capability is useful for features, such as segment routing traffic-engineering LSPs and RSVP-TE pop-and-forward LSPs. All existing functionality of applications using MPLS next hops continue to work with the increased label push capability. This includes:

- All OAM utilities, such as lsping, traceroute, and BFD for MPLS LSPs.
- Monitoring utilities, such as lspmon, and LM DM for MPLS LSPs.

The `show route table` and `show route forwarding-table` command outputs are enhanced to display up to 16 labels per next hop component.

For example:

```
user@host> show route table inet.3

inet.3: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

11.0.0.17/32       *[SPRING-TE/8] 00:02:16, metric 1

```

NOTE: When the maximum number of MPLS labels of an interface is modified, the MPLS interface is bounced. All LDP and RSVP sessions on that interface are restarted, resulting in all LSPs over that interface to flap.

For example, suppose you configure a two-tier carrier-of-carriers VPN service for customers who provide VPN service. A carrier-of-carrier VPN is a two-tiered relationship between a provider carrier (Tier 1 ISP) and a customer carrier (Tier 2 ISP). In a carrier-of-carrier VPN, the provider carrier provides a VPN backbone network for the customer carrier. The customer carrier in turn provides Layer 3 VPN service to its end customers. The customer carrier sends labeled traffic to the provider carrier to deliver it to the next hop on the other side of the provider carrier's network. This scenario requires a three-label stack: one label for the provider carrier VPN, another label for the customer carrier VPN, and a third label for the transport route.

If you add fast reroute service, the PE routers in the provider carrier's network must be configured to support a fourth label (the reroute label). If the customer carrier is using LDP as its signaling protocol and the provider carrier is using RSVP, the provider carrier must support LDP over RSVP tunnel service. This additional service requires an additional label, for a total of five labels.

To the customer carrier, the router it uses to connect to the provider carrier's VPN is a PE router. However, the provider carrier views this device as a CE router.

Table 12 on page 554 summarizes the label requirements.

Table 12: Sample Scenarios for Using 3, 4, or 5 MPLS Labels

Number of Labels Required	Scenarios
3	Carrier-of-carriers VPN or a VPN with two labels and fast reroute
4	Combination of carrier-of-carriers and fast reroute
5	Carrier-of-carriers with fast reroute and the customer carrier running LDP, with the provider carrier running RSVP

To configure and monitor the maximum number of labels:

1. Specify the maximum on the logical interface. Apply this configuration to the carrier's PE routers.

```
[edit interfaces ge-0/1/3 unit 0 family mpls]
user@switch# set maximum-labels maximum-limit
```

2. Verify the configuration.

```
[edit system]
user@switch# show interfaces ge-0/1/3.0
Logical interface ge-0/1/3.0 (Index 77) (SNMP ifIndex 507)
    Flags: SNMP-Traps Encapsulation: ENET2
    Input packets : 0
    Output packets: 0
    Protocol mpls, MTU: 1480, Maximum labels: 8
      Flags: Is-Primary
```

The command output includes the `Maximum labels: 5` field under the logical interface unit 0.

Configuring MPLS to Pop the Label on the Ultimate-Hop Router

You can control the label value advertised on the egress router of a label-switched path (LSP). The default advertised label is label 3 (Implicit Null Label). If label 3 is advertised, the penultimate-hop router removes the label and sends the packet to the egress router. By enabling ultimate-hop popping, label 0 (IPv4 Explicit Null Label) is advertised. Ultimate-hop popping ensures that any packets traversing an MPLS network include a label.

NOTE: Juniper Networks routers queue packets based on the incoming label. Routers from other vendors might queue packets differently. Keep this in mind when working with networks containing routers from multiple vendors.

To configure MPLS to pop the label on the ultimate-hop router, include the `explicit-null` statement:

```
explicit-null;
```

You can configure this statement at the following hierarchy levels:

- `[edit protocols mpls]`
- `[edit logical-systems` *`logical-system-name`* `protocols mpls]`

Advertising Explicit Null Labels to BGP Peers

For the IPv4 (`inet`) family only, BGP peers in a routing group can send an explicit NULL label for a set of connected routes (direct and loopback routes) for the inet labeled-unicast and inet6 labeled-unicast NLRI. By default, peers advertise label 3 (implicit NULL). If the `explicit-null` statement is enabled, peers advertise label 0 (explicit NULL). The explicit NULL labels ensures that labels are always present on packets traversing an MPLS network. If the implicit NULL label is used. the penultimate hop router removes the label and sends the packet as a plain IP packet to the egress router. This might cause issues in queuing the packet properly on the penultimate hop router if the penultimate hop is another vendor's router. Some other vendors queue packets based on the CoS bits in the outgoing label rather than the incoming label.

To advertise an explicit null label, include the following statements in the configuration:

```
family inet {
    labeled-unicast {
        aggregate-label {
            community community-name:
        }
        explicit-null {
            connected-only;
        }
    }
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

The `connected-only` statement is required to advertise explicit null labels.

To verify that the explicit NULL label is being advertised for connected routes, use the `show route advertising-protocol bgp` *`neighbor-address`* command.

Understanding MPLS Label Operations on EX Series Switches

- MPLS Label-Switched Paths and MPLS Labels on the Switches | **556**
- Reserved Labels | **557**
- MPLS Label Operations on the Switches | **558**
- Penultimate-Hop Popping and Ultimate-Hop Popping | **559**

In the traditional packet-forwarding paradigm, as a packet travels from one switch to the next, an independent forwarding decision is made at each hop. The IP network header is analyzed and the next hop is chosen based on this analysis and on the information in the routing table. In an MPLS environment, the analysis of the packet header is made only once, when a packet enters the MPLS tunnel (that is, the path used for MPLS traffic).

When an IP packet enters a label-switched path (LSP), the ingress provider edge (PE) switch examines the packet and assigns it a label based on its destination, placing the label in the packet's header. The label transforms the packet from one that is forwarded based on its IP routing information to one that is forwarded based on information associated with the label. The packet is then forwarded to the next provider switch in the LSP. This switch and all subsequent switches in the LSP do not examine any of the IP routing information in the labeled packet. Rather, they use the label to look up information in their label forwarding table. They then replace the old label with a new label and forward the packet to the next switch in the path. When the packet reaches the egress PE switch, the label is removed, and the packet again becomes a native IP packet and is again forwarded based on its IP routing information.

This topic describes:

MPLS Label-Switched Paths and MPLS Labels on the Switches

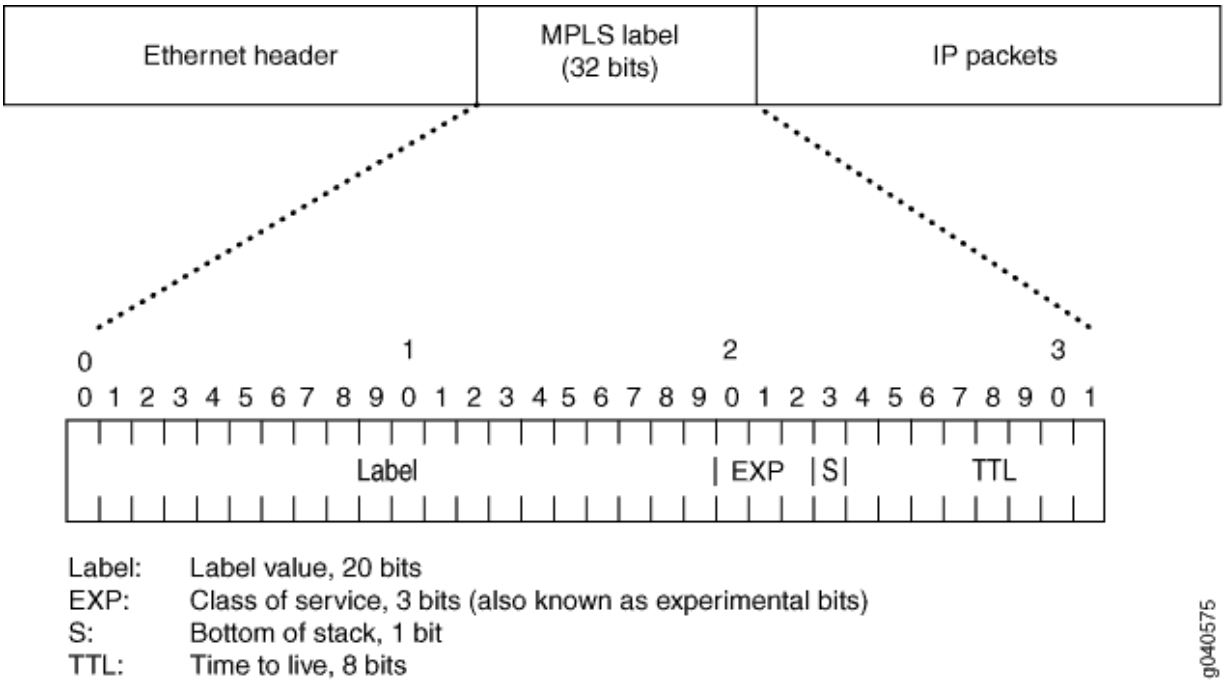
When a packet enters the MPLS network, it is assigned to an LSP. Each LSP is identified by a label, which is a short (20-bit), fixed-length value at the front of the MPLS label (32 bits). Labels are used as lookup indexes for the label forwarding table. For each label, this table stores forwarding information.

Because no additional parsing or lookup is done on the encapsulated packet, MPLS supports the transmission of any other protocols within the packet payload.

NOTE: The implementation of MPLS on Juniper Networks EX3200 and EX4200 Ethernet Switches supports only single-label packets. However, MPLS on Juniper Networks EX8200 Ethernet Switches supports packets with as many as three labels.

Figure 32 on page 557 shows the encoding of a single label. The encoding appears after data link layer headers, but before any network layer header.

Figure 32: Label Encoding



Reserved Labels

Labels range from 0 through 1,048,575. Labels 0 through 999,999 are for internal use.

Some of the reserved labels (in the range 0 through 15) have well-defined meanings. The following reserved labels are used by the switches:

- 0, IPv4 Explicit Null label—This value is valid only when it is the sole label entry (no label stacking). It indicates that the label must be popped on receipt. Forwarding continues based on the IP version 4 (IPv4) packet.

- 1, Router Alert label—When a packet is received with a top label value of 1, it is delivered to the local software module for processing.
- 2, IPv6 Explicit Null label—This value is legal only when it is the sole label entry (no label stacking). It indicates that the label must be popped on receipt.
- 3, Implicit Null label—This label is used in the signaling protocol (RSVP) only to request label popping by the downstream switch. It never actually appears in the encapsulation. Labels with a value of 3 must not be used in the data packet as real labels. No payload type (IPv4 or IPv6) is implied with this label.

MPLS Label Operations on the Switches

EX Series switches support the following label operations:

- Push
- Pop
- Swap

The push operation affixes a new label to the top of the IP packet. For IPv4 packets, the new label is the first label. The time to live (TTL) field value in the packet header is derived from the IP packet header. The push operation cannot be applied to a packet that already has an MPLS label.

The pop operation removes a label from the beginning of the packet. Once the label is removed, the TTL is copied from the label into the IP packet header, and the underlying IP packet is forwarded as a native IP packet

The swap operation removes an existing MPLS label from an IP packet and replaces it with a new MPLS label, based on the following:

- Incoming interface
- Label
- Label forwarding table

Figure 33 on page 559 shows an IP packet without a label arriving on the customer edge interface (**ge-0/0/1**) of the ingress PE switch. The ingress PE switch examines the packet and identifies that packet's destination as the egress PE switch. The ingress PE switch applies label 100 to the packet and sends the MPLS packet to its outgoing MPLS core interface (**ge-0/0/5**). The MPLS packet is transmitted on the MPLS tunnel through the provider switch, where it arrives at interface **ge-0/0/5** with label 100. The provider switch swaps label 100 to label 200 and forwards the MPLS packet through its core interface (**ge-0/0/7**) to the next hop on the tunnel, which is the egress PE switch. The egress PE switch

receives the MPLS packet through its core interface (**ge-0/0/7**), removes the MPLS label, and sends the IP packet out of its customer edge interface (**ge-0/0/1**) to a destination that is beyond the tunnel.

Figure 33: MPLS Label Swapping

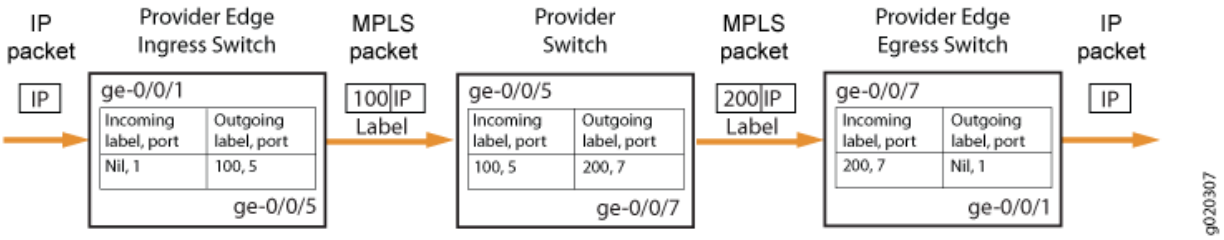


Figure 33 on page 559 shows the path of a packet as it passes in one direction from the ingress PE switch to the egress PE switch. However, the MPLS configuration also allows traffic to travel in the reverse direction. Thus, each PE switch operates as both an ingress switch and an egress switch.

Penultimate-Hop Popping and Ultimate-Hop Popping

The switches enable penultimate-hop popping (PHP) by default with IP over MPLS configurations. With PHP, the penultimate provider switch is responsible for popping the MPLS label and forwarding the traffic to the egress PE switch. The egress PE switch then performs an IP route lookup and forwards the traffic. This reduces the processing load on the egress PE switch, because it is not responsible for popping the MPLS label.

On EX8200 switches, you can choose to use either the default, PHP, or to configure ultimate-hop popping.

- The default advertised label is label 3 (Implicit Null label). If label 3 is advertised, the penultimate-hop switch removes the label and sends the packet to the egress PE switch.
- If ultimate-hop popping is enabled, label 0 (IPv4 Explicit Null label) is advertised and the egress PE switch of the LSP removes the label.

Release History Table

Release	Description
19.1R1	Starting in Junos OS Release 19.1R1, the maximum number of labels that can be pushed by the egress Packet Forwarding Engine (PFE) can be leveraged, wherein the number of labels that can be pushed for an MPLS next hop is the number of labels the device is capable of pushing, or the maximum-labels configured under family mpls of the outgoing interface, whichever is smaller. This support is enabled on MX Series routers with MPC and MIC interfaces, and PTX Series routers with third-generation FPCs.

14.2	Starting with Junos OS Release 14.2, entropy label is supported in mixed mode chassis where the entropy label can be configured without enhanced-ip configuration.

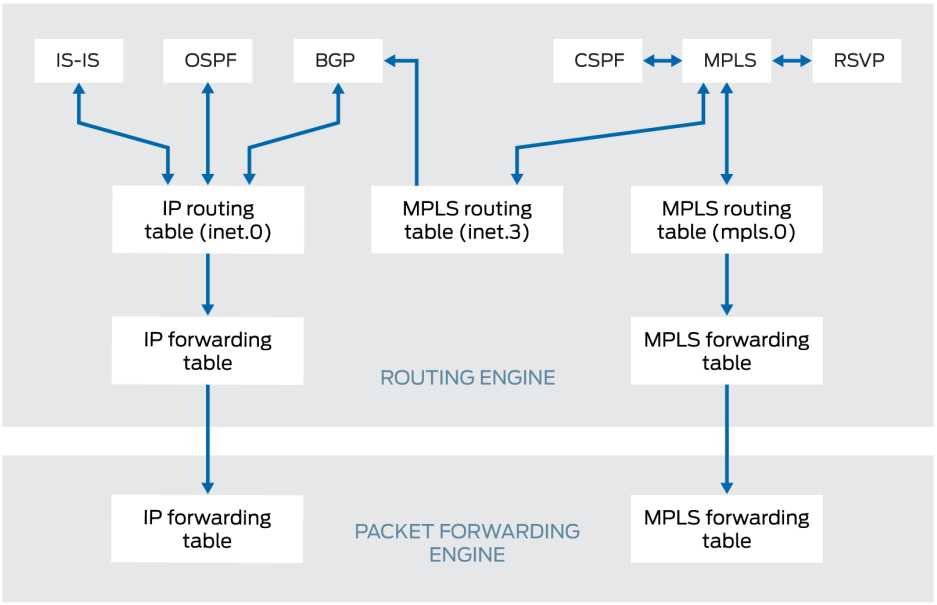
MPLS and Routing Tables

The IGPs and BGP store their routing information in the inet.0 routing table, the main IP routing table. If the `traffic-engineering bgp` command is configured, thereby allowing only BGP to use MPLS paths for forwarding traffic, MPLS path information is stored in a separate routing table, inet.3. Only BGP accesses the inet.3 routing table. BGP uses both inet.0 and inet.3 to resolve next-hop addresses. If the `traffic-engineering bgp-igp` command is configured, thereby allowing the IGPs to use MPLS paths for

forwarding traffic, MPLS path information is stored in the inet.0 routing table. (Figure 34 on page 561 and Figure 35 on page 562 illustrate the routing tables in the two traffic engineering configurations.)

Figure 34: Routing and Forwarding Tables, traffic-engineering bgp



The inet.3 routing table contains the host address of each LSP's egress router. This routing table is used on ingress routers to route packets to the destination egress router. BGP uses the inet.3 routing table on the ingress router to help in resolving next-hop addresses.

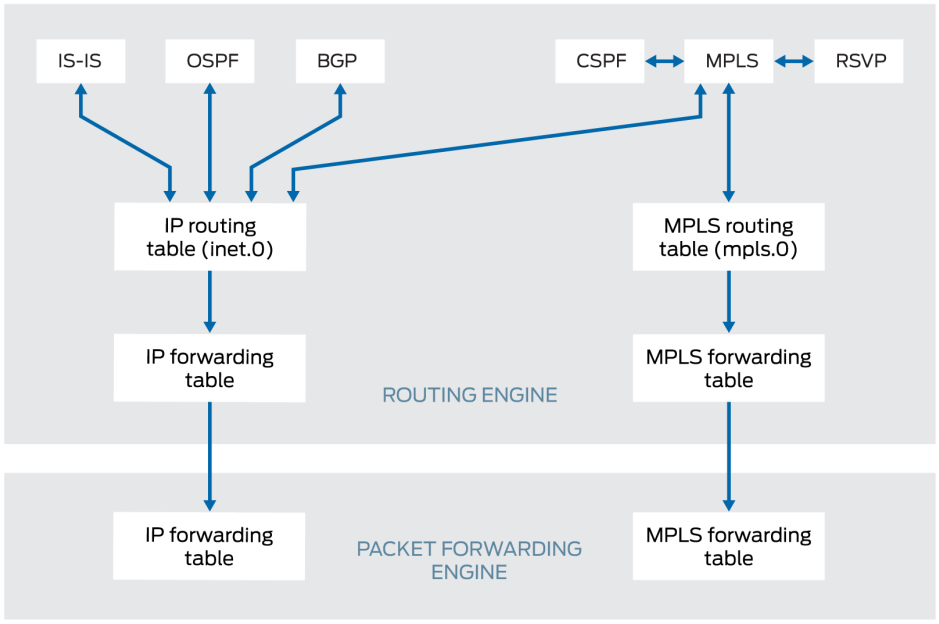
MPLS also maintains an MPLS path routing table (mpls.0), which contains a list of the next label-switched router in each LSP. This routing table is used on transit routers to route packets to the next router along an LSP.

Typically, the egress router in an LSP does not consult the mpls.0 routing table. (This router does not need to consult mpls.0 because the penultimate router in the LSP either changes the packet's label to a value of 0 or pops the label.) In either case, the egress router forwards it as an IPv4 packet, consulting the IP routing table, inet.0, to determine how to forward the packet.

When a transit or egress router receives an MPLS packet, information in the MPLS forwarding table is used to determine the next transit router in the LSP or to determine that this router is the egress router.

When BGP resolves a next-hop prefix, it examines both the inet.0 and inet.3 routing tables, seeking the next hop with the lowest preference. If it finds a next-hop entry with an equal preference in both routing tables, BGP prefers the entry in the inet.3 routing table.

Figure 35: Routing and Forwarding Tables, traffic-engineering bgp-igp



Generally, BGP selects next-hop entries in the inet.3 routing table because their preferences are always lower than OSPF and IS-IS next-hop preferences. When you configure LSPs, you can override the default preference for MPLS LSPs, which might alter the next-hop selection process.

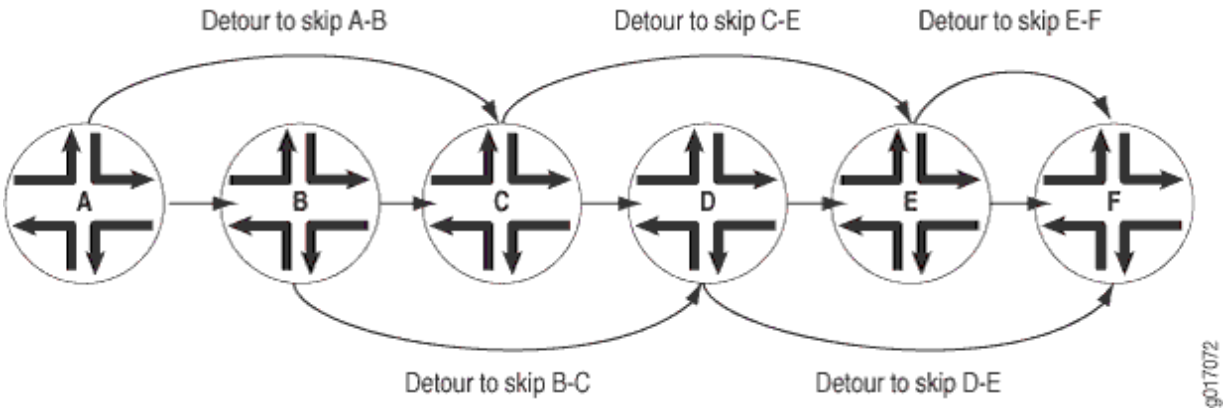
When BGP selects a next-hop entry from the inet.3 routing table, it installs that LSP into the forwarding table in the Packet Forwarding Engine, which causes packets destined for that next hop to enter and travel along the LSP. If the LSP is removed or fails, the path is removed from the inet.3 routing table and from the forwarding table, and BGP reverts to using a next hop from the inet.0 routing table.

Fast Reroute Overview

Fast reroute provides redundancy for an LSP path. When you enable fast reroute, detours are precomputed and preestablished along the LSP. In case of a network failure on the current LSP path, traffic is quickly routed to one of the detours. Figure 36 on page 563 illustrates an LSP from Router A to Router F, showing the established detours. Each detour is established by an upstream node to avoid the link toward the immediate downstream node and the immediate downstream node itself. Each detour might traverse through one or more label-switched routers (or switches) that are not shown in the figure.

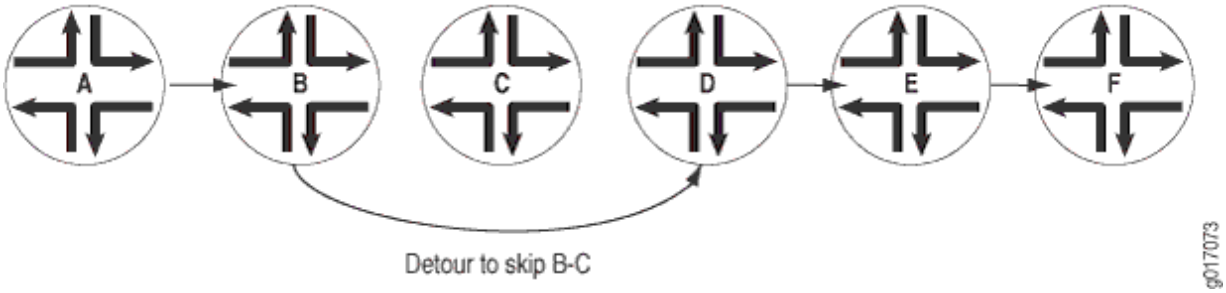
Fast reroute protects traffic against any single point of failure between the ingress and egress routers (or switches). If there is a failure in a scaled fast reroute scenario, the devices lose reachability to all the peers that were connected through the failed link. This leads to traffic interruption, as the BGP session among the devices goes down. If there are multiple failures along an LSP, fast reroute itself might fail. Also, fast reroute does not protect against failure of the ingress or egress routers.

Figure 36: Detours Established for an LSP Using Fast Reroute



If a node detects that a downstream link has failed (using a link-layer-specific liveness detection mechanism) or that a downstream node has failed (for example, using the RSVP neighbor hello protocol), the node quickly switches the traffic to the detour and, at the same time, signals the ingress router about the link or node failure. Figure 37 on page 563 illustrates the detour taken when the link between Router B and Router C fails.

Figure 37: Detour After the Link from Router B to Router C Fails



If the network topology is not rich enough (there are not enough routers with sufficient links to other routers), some of the detours might not succeed. For example, the detour from Router A to Router C in Figure 36 on page 563 cannot traverse link A-B and Router B. If such a path is not possible, the detour does not occur.

Note that after the node switches traffic to the detour, it might switch the traffic again to a newly calculated detour soon after. This is because the initial detour route might not be the best route. To make rerouting as fast as possible, the node switches traffic onto the initial detour without first verifying that the detour is valid. Once the switch is made, the node recomputes the detour. If the node determines that the initial detour is still valid, traffic continues to flow over this detour. If the node determines that the initial detour is no longer valid, it again switches the traffic to a newly computed detour.

NOTE: If you issue `show` commands after the node has switched traffic to the initial detour, the node might indicate that the traffic is still flowing over the original LSP. This situation is temporary and should correct itself quickly.

The time required for a fast-rerouting detour to take effect depends on two independent time intervals:

- Amount of time to detect that there is a link or node failure—This interval depends greatly on the link layer in use and the nature of the failure. For example, failure detection on an SONET/SDH link typically is much faster than on a Gigabit Ethernet link, and both are much faster than detection of a router failure.
- Amount of time required to splice the traffic onto the detour—This operation is performed by the Packet Forwarding Engine, which requires little time to splice traffic onto the detour. The time needed can vary depending on the number of LSPs being switched to detours.

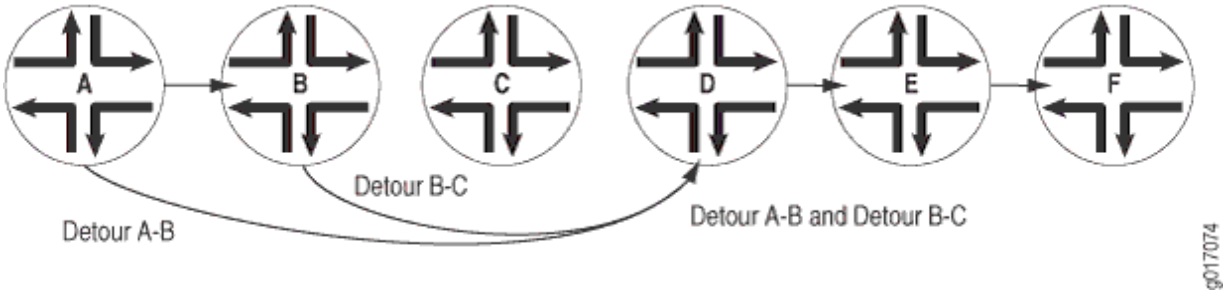
Fast reroute is a short-term patch to reduce packet loss. Because detour computation might not reserve adequate bandwidth, the detours might introduce congestion on the alternate links. The ingress router is the only router that is fully aware of LSP policy constraints and, therefore, is the only router able to come up with adequate long-term alternate paths.

Detours are created by use of RSVP and, like all RSVP sessions, they require extra state and overhead in the network. For this reason, each node establishes at most one detour for each LSP that has fast reroute enabled. Creating more than one detour for each LSP increases the overhead, but serves no practical purpose.

To reduce network overhead further, each detour attempts to merge back into the LSP as soon as possible after the failed node or link. If you can consider an LSP that travels through n router nodes, it is possible to create $n - 1$ detours. For instance, in Figure 38 on page 565, the detour tries to merge back into the LSP at Router D instead of at Router E or Router F. Merging back into the LSP makes the detour

scalability problem more manageable. If topology limitations prevent the detour from quickly merging back into the LSP, detours merge with other detours automatically.

Figure 38: Detours Merging into Other Detours



Configuring Fast Reroute

Fast reroute provides a mechanism for automatically rerouting traffic on an LSP if a node or link in an LSP fails, thus reducing the loss of packets traveling over the LSP.

To configure fast reroute on an LSP, include the `fast-reroute` statement on the ingress router (or switch):

```
fast-reroute {
    (bandwidth bps | bandwidth-percent percentage);
    (exclude [ group-names ] | no-exclude );
    hop-limit number;
    (include-all [ group-names ] | no-include-all);
    (include-any [ group-names ] | no-include-any);
}
```

You can include this statement at the following hierarchy levels:

- `[edit protocols mpls label-switched-path lsp-name]`
- `[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name]`

You do not need to configure fast reroute on the LSP's transit and egress routers (or switches). Once fast reroute is enabled, the ingress router (or switch) signals all the downstream routers (or switches) that fast reroute is enabled on the LSP, and each downstream router does its best to set up detours for the LSP. If a downstream router does not support fast reroute, it ignores the request to set up detours and continues to support the LSP. A router that does not support fast reroute will cause some of the detours to fail, but otherwise has no impact on the LSP.

NOTE: To enable PFE fast reroute, configure a routing policy statement with the `load-balance per-packet` statement at the `[edit policy-options policy-statement` *`policy-name`* `then]` hierarchy level on each of the routers where traffic might be rerouted. See also "Configuring Load Balancing Across RSVP LSPs" on page 1222.

By default, no bandwidth is reserved for the rerouted path. To allocate bandwidth for the rerouted path, include either the `bandwidth` statement or the `bandwidth-percent` statement. You can only include one of these statements at a time. If you do not include either the `bandwidth` statement or the `bandwidth-percent` statement, the default setting is to not reserve bandwidth for the detour path.

When you include the `bandwidth` statement, you can specify the specific amount of bandwidth (in bits per second [bps]) you want to reserve for the detour path. The bandwidth does not need to be identical to that allocated for the LSP.

When you specify a bandwidth percent using the `bandwidth-percent` statement, the detour path bandwidth is computed by multiplying the bandwidth percentage by the bandwidth configured for the main traffic-engineered LSP. For information about how to configure the bandwidth for a traffic-engineered LSP, see "Configuring Traffic-Engineered LSPs" on page 1738.

Hop-limit constraints define how many more routers a detour is allowed to traverse compared with the LSP itself. By default, the hop limit is set to 6. For example, if an LSP traverses 4 routers, any detour for the LSP can be up to 10 (that is, 4 + 6) router hops, including the ingress and egress routers.

By default, a detour inherits the same administrative (coloring) group constraints as its parent LSP when CSPF is determining the alternate path. Administrative groups, also known as link coloring or resource class, are manually assigned attributes that describe the “color” of links, such that links with the same color conceptually belong to the same class. If you specify the `include-any` statement when configuring the parent LSP, all links traversed by the alternate session must have at least one color found in the list of groups. If you specify the `include-all` statement when configuring the parent LSP, all links traversed by the alternate session must have all of the colors found in the list of groups. If you specify the `exclude` statement when configuring the parent LSP, none of the links must have a color found in the list of groups. For more information about administrative group constraints, see "Configuring Administrative Groups for LSPs" on page 596.

Detour Merging Process

This section describes the process used by a router to determine which LSP to select when the router receives path messages from different interfaces with identical Session and Sender Template objects. When this occurs, the router needs to merge the path states.

The router employs the following process to determine when and how to merge path states:

- When all the path messages do not include a fast reroute or a detour object, or when the router is the egress of the LSP, no merging is required. The messages are processed according to RSVP traffic engineering.
- Otherwise, the router *must* record the path state in addition to the incoming interface. If the path messages do not share the same outgoing interface and next-hop router, the router considers them to be independent LSPs and does not merge them.
- For all the path messages that share the same outgoing interface and next-hop router, the router uses the following process to select the final LSP:
    - If only one LSP originates from this node, select it as the final LSP.
    - If only one LSP contains a fast reroute object, select it as the final LSP.
    - If there are several LSPs and some of them have a detour object, eliminate those containing a detour object from the final LSP selection process.
    - If several final LSP candidates remain (that is, there are still both detour and protected LSPs), select the LSPs with fast reroute objects.
    - If none of the LSPs have fast reroute objects, select the ones without detour objects. If all the LSPs have detour objects, select them all.
    - Of the remaining LSP candidates, eliminate from consideration those that traverse nodes that other LSPs avoid.
    - If several candidate LSPs still remain, select the one with the shortest explicit route object (ERO) path length. If more than one LSP has the same path length, select one randomly.
- Once the final LSP has been identified, the router must transmit only the path messages that correspond to this LSP. All other LSPs are considered merged at this node.

Detour Computations

Computing and setting up detours is done independently at each node. On a node, if an LSP has fast reroute enabled and if a downstream link or node can be identified, the router performs a Constrained Shortest Path First (CSPF) computation using the information in the local traffic engineering database. For this reason, detours rely on your IGP supporting traffic engineering extensions. Without the traffic engineering database, detours cannot be established.

CSPF initially attempts to find a path that skips the next downstream node. Attempting to find this path provides protection against downstream failures in either nodes or links. If a node-skipping path is not available, CSPF attempts to find a path on an alternate link to the next downstream node. Attempting to find an alternate link provides protection against downstream failures in links only. Detour computations might not succeed the first time. If a computation fails, the router recomputes detours approximately

once every refresh interval until the computation succeeds. The RSVP metric for each detour is set to a value in the range from 10,000 through 19,999.

Fast Reroute Path Optimization

A fast reroute protection path is nondeterministic. The actual protection path of a particular node depends on the history of the LSP and the network topology when the fast reroute path was computed. The lack of deterministic behavior can lead to operational difficulties and poorly optimized paths after multiple link flaps in a network. Even in a small network, after a few link flaps fast reroute paths can traverse an arbitrarily large number of nodes and can remain in that state indefinitely. This is inefficient and makes the network less predictable.

Fast reroute optimization addresses this deficiency. It provides a global path optimization timer, allowing you to optimize all LSPs that have fast reroute enabled and a detour path up and running. The timer value can be varied depending on the expected RE processing load.

The fast reroute optimization algorithm is based on the IGP metric only. As long as the new path's IGP metric is lower than the old path's, the CSPF result is accepted, even if the new path might be more congested (higher bandwidth utilization) or traverses more hops.

In conformance with RFC 4090, *Fast Reroute Extensions to RSVP-TE for LSP Tunnels*, when a new path is computed and accepted for fast reroute optimization, the existing detour is destroyed first and then the new detour is established. To prevent traffic loss, detours actively protecting traffic are not optimized.

Configuring the Optimization Interval for Fast Reroute Paths

You can enable path optimization for fast reroute by configuring the fast reroute optimize timer. The optimize timer triggers a periodic optimization process that recomputes the fast reroute detour LSPs to use network resources more efficiently.

To enable fast reroute path optimization, specify the number of seconds using the optimize-timer option for the `fast-reroute` statement:

```
fast-reroute seconds;
```

You can include this statement at the following hierarchy levels:

- `[edit protocols rsvp]`
- `[edit logical-systems logical-system-name protocols rsvp]`

Adding LSP-Related Routes to the inet.3 or inet6.3 Routing Table

By default, a host route toward the egress router is installed in the inet.3 or inet6.3 routing table. (The host route address is the one you configure in the `to` statement.) Installing the host route allows BGP to

perform next-hop resolution. It also prevents the host route from interfering with prefixes learned from dynamic routing protocols and stored in the inet.0 or inet6.0 routing table.

Unlike the routes in the inet.0 or inet6.0 table, routes in the inet.3 or inet6.3 table are not copied to the Packet Forwarding Engine, and hence they cause no changes in the system forwarding table directly. You cannot use the `ping` or `traceroute` command through these routes. The only use for inet.3 or inet6.3 is to permit BGP to perform next-hop resolution. To examine the inet.3 or inet6.3 table, use the `show route table inet.3` or `show route table inet6.3` command.

To inject additional routes into the inet.3 or inet6.3 routing table, include the `install` statement:

```
install {
    destination-prefix <active>;
}
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls label-switched-path *lsp-name*]
- [edit protocols mpls static-label-switched-path *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls static-label-switched-path *lsp-name*]

The specified routes are installed as aliases into the routing table when the LSP is established. Installing additional routes allows BGP to resolve next hops within the specified prefix and to direct additional traffic for these next hops to a particular LSP.

Including the `active` option with the `install` statement installs the specified prefix into the inet.0 or inet6.0 routing table, which is the primary forwarding table. The result is a route that is installed in the forwarding table any time the LSP is established, which means you can ping or trace the route. Use this option with care, because this type of prefix is very similar to a static route.

You use alias routes for routers that have multiple addresses being used as BGP next hops, or for routers that are not MPLS capable. In either of these cases, the LSP can be configured to another MPLS capable system within the local domain, which then acts as a “border” router. The LSP then terminates on the border router and, from that router, Layer 3 forwarding takes the packet to the true next-hop router.

In the case of an interconnect, the domain’s border router can act as the proxy router and can advertise the prefix for the interconnect if the border router is not setting the BGP next hop to itself.

In the case of a point of presence (POP) that has routers that do not support MPLS, one router (for example, a core router) that supports MPLS can act as a proxy for the entire POP and can inject a set of prefixes that cover the POP. Thus, all routers within the POP can advertise themselves as interior BGP

(IBGP) next hops, and traffic can follow the LSP to reach the core router. This means that normal IGP routing would prevail within the POP.

You cannot use the `ping` or `traceroute` commands on routes in the inet.3 or inet6.3 routing table.

For BGP next-hop resolution, it makes no difference whether a route is in inet.0/inet6.0 or inet.3/inet6.3; the route with the best match (longest mask) is chosen. Among multiple best-match routes, the one with the highest preference value is chosen.

> **NOTE**: The `install` *`destination-prefix`* `active` statement is not supported on static LSPs. When the `install` *`destination-prefix`* `active` statement is configured for a static LSP, the MPLS routes do not get installed into the inet.0 routing table.

Constrained-Path LSP Computation

The Constrained Shortest Path First (CSPF) algorithm is an advanced form of the shortest-path-first (SPF) algorithm used in OSPF and IS-IS route computations. CSPF is used in computing paths for LSPs that are subject to multiple constraints. When computing paths for LSPs, CSPF considers not only the

topology of the network, but also the attributes of the LSP and the links, and it attempts to minimize congestion by intelligently balancing the network load.

The constraints that CSPF considers include:

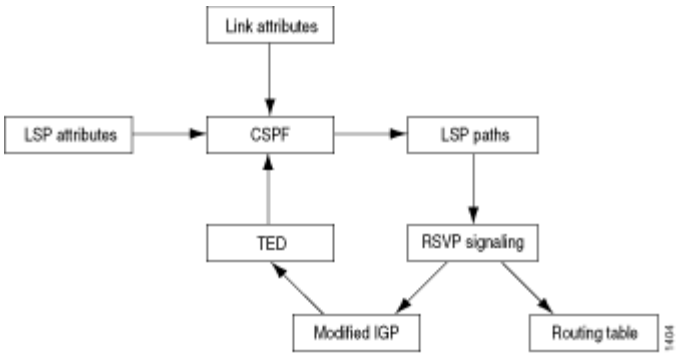
- LSP attributes
  - Administrative groups (that is, link color requirements)
  - Bandwidth requirements
  - Explicit route (strict or loose)
  - Hop limitations
  - Priority (setup and hold)
- Link attributes
  - Administrative groups (that is, link colors assigned to the link)
  - Reservable bandwidth of the links (static bandwidth minus the currently reserved bandwidth)

The data that CSPF considers comes from the following sources:

- Traffic engineering database—Provides CSPF with up-to-date topology information, the current reservable bandwidth of links, and the link colors. For the CSPF algorithm to perform its computations, a link-state IGP (such as OSPF or IS-IS) with special extensions is needed. For CSPF to be effective, the link-state IGP on all routers must support the special extensions. While building the topology database, the extended IGP must take into consideration the current LSPs and must flood the route information everywhere. Because changes in the reserved link bandwidth and link color cause database updates, an extended IGP tends to flood more frequently than a normal IGP. See Figure 39 on page 572 for a diagram of the relationships between these components.

- Currently active LSPs—Includes all the LSPs that should originate from the router and their current operational status (up, down, or timeout).

Figure 39: CSPF Computation Process



This section discusses the following topics:

- "How CSPF Selects a Path" on page 572
- "CSPF Path Selection Tie-Breaking" on page 573
- "Computing CSPF Paths Offline" on page 574

How CSPF Selects a Path

To select a path, CSPF follows certain rules. The rules are as follows:

1. Computes LSPs one at a time, beginning with the highest priority LSP (the one with the lowest setup priority value). Among LSPs of equal priority, CSPF services the LSPs in alphabetical order of the LSP names.
2. Prunes the traffic engineering database of all the links that are not full duplex and do not have sufficient reservable bandwidth.
3. If the LSP configuration includes the `include` statement, prunes all links that do not share any included colors.
4. If the LSP configuration includes the `exclude` statement, prunes all links that contain excluded colors. If the link does not have a color, it is accepted.
5. If several paths have equal cost, chooses the one whose last-hop address is the same as the LSP's destination.
6. If several equal cost paths remain, selects the one with the fewest number of hops.

7. If several equal-cost paths remain, applies the CSPF load-balancing rule configured on the LSP (least fill, most fill, or random).

CSPF finds the shortest path toward the LSP's egress router, taking into account explicit-path constraints. For example, if the path must pass through Router A, two separate SPFs are computed, one from the ingress router to Router A, the other from Router A to the egress router. All CSPF rules are applied to both computations.

CSPF Path Selection Tie-Breaking

If more than one path is still available after the CSPF rules ("How CSPF Selects a Path" on page 572) have been applied, a tie-breaking rule is applied to choose the path for the LSP. The rule used depends on the configuration. There are three tie-breaking rules:

- Random—One of the remaining paths is picked at random. This rule tends to place an equal number of LSPs on each link, regardless of the available bandwidth ratio. This is the default behavior.
- Least fill—The path with the largest minimum available bandwidth ratio is preferred. This rule tries to equalize the reservation on each link.
- Most fill—The path with the smallest minimum available bandwidth ratio is preferred. This rule tries to fill a link before moving on to alternative links.

The following definitions describe how a figure for minimum available bandwidth ratio is derived for the least fill and most fill rules:

- Reservable bandwidth = bandwidth of link x subscription factor of link
- Available bandwidth = reservable bandwidth – (sum of the bandwidths of the LSPs traversing the link)
- Available bandwidth ratio = available bandwidth/reservable bandwidth
- Minimum available bandwidth ratio (for a path) = the smallest available bandwidth ratio of the links in a path

NOTE: For the least fill or most fill behaviors to be used, the paths must have their bandwidth (specified using the `bandwidth` statement at the `[edit protocols mpls label-switched-path` *`lsp-name`*`]` hierarchy level) or minimum bandwidth (specified using the `minimum-bandwidth` statement at the `[edit protocols mpls label-switched-path` *`lsp-name`* `auto-bandwidth]` hierarchy level) configured to a value greater than 0. If the bandwidth or minimum bandwidth for the paths is either not configured or configured as 0, the minimum available bandwidth cannot be calculated and the random path selection behavior is used instead.

Computing CSPF Paths Offline

The Junos OS provides online, real-time CSPF computation only; each router performs CSPF calculations independent of the other routers in the network. These calculations are based on currently available topology information—information that is usually recent, but not completely accurate. LSP placements are locally optimized, based on current network status.

To optimize links globally across the network, you can use an offline tool to perform the CSPF calculations and determine the paths for the LSPs. You can create such a tool yourself, or you can modify an existing network design tool to perform these calculations. You should run the tool periodically (daily or weekly) and download the results into the router. An offline tool should take the following into account when performing the optimized calculations:

- All the LSP's requirements
- All link attributes
- Complete network topology

Configuring CSPF Tie Breaking

When selecting a path for an LSP, CSPF uses a tie-breaking process if there are several equal-cost paths. For information about how CSPF selects a path, see "How CSPF Selects a Path" on page 572.

You can configure one of the following statements (you can only configure one of these statements at a time) to alter the behavior of CSPF tie-breaking:

- By default, a random tie-breaking rule for CSPF is used to select a path from the set of equal-cost paths. However, you can also explicitly configure this behvior using the `random` statement:

```
random;
```

- To prefer the path with the least-utilized links, include the `least-fill` statement:

```
least-fill;
```

- To prefer the path with the most-utilized links, include the `most-fill` statement:

```
most-fill;
```

You can include each of these statements at the following hierarchy levels:

- `[edit protocols mpls label-switched-path` *`lsp-name`*`]`

- [edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name*]

Disabling Constrained-Path LSP Computation

If the IGP is a link-state protocol (such as IS-IS or OSPF) and supports extensions that allow the current bandwidth reservation on each router's link to be reported, constrained-path LSPs are computed by default.

The Junos implementations of IS-IS and OSPF include the extensions that support constrained-path LSP computation.

- IS-IS—These extensions are enabled by default. To disable this support, include the `disable` statement at the `[edit protocols isis traffic-engineering]` hierarchy level, as discussed in the Junos OS Routing Protocols Library for Routing Devices.
- OSPF—These extensions are disabled by default. To enable this support, include the `traffic-engineering` statement in the configurations of all routers running OSPF, as described in the Junos OS Routing Protocols Library for Routing Devices.

If IS-IS is enabled on a router or you enable OSPF traffic engineering extensions, MPLS performs the constrained-path LSP computation by default. For information about how constrained-path LSP computation works, see "Constrained-Path LSP Computation" on page 570.

Constrained-path LSPs have a greater chance of being established quickly and successfully for the following reasons:

- The LSP computation takes into account the current bandwidth reservation.
- Constrained-path LSPs reroute themselves away from node failures and congestion.

When constrained-path LSP computation is enabled, you can configure the LSP so that it is periodically reoptimized, as described in "Optimizing Signaled LSPs" on page 605.

When an LSP is being established or when an existing LSP fails, the constrained-path LSP computation is repeated periodically at the interval specified by the retry timer until the LSP is set up successfully. Once the LSP is set up, no recomputation is done. For more information about the retry timer, see "Configuring the Connection Between Ingress and Egress Routers" on page 585.

By default, constrained-path LSP computation is enabled. You might want to disable constrained-path LSP computation when all nodes do not support the necessary traffic engineering extensions. To disable constrained-path LSP computation, include the `no-cspf` statement:

```
no-cspf;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

If you disable constrained-path LSP computation on LSPs by configuring the `no-cspf` statement and then attempt to advertise other LSPs with lower metrics than the IGPs from this router in either IS-IS or OSPF, new LSPs cannot be established.

Routers in an LSP

Each router in an LSP performs one of the following functions:

- Ingress router—The router at the beginning of an LSP. This router encapsulates IP packets with an MPLS Layer 2 frame and forwards it to the next router in the path. Each LSP can have only one ingress router.
- Egress router—The router at the end of an LSP. This router removes the MPLS encapsulation, thus transforming it from an MPLS packet to an IP packet, and forwards the packet to its final destination using information in the IP forwarding table. Each LSP can have only one egress router. The ingress and egress routers in an LSP cannot be the same router.
- Transit router—Any intermediate router in the LSP between the ingress and egress routers. A transit router forwards received MPLS packets to the next router in the MPLS path. An LSP can contain zero or more transit routers, up to a maximum of 253 transit routers in a single LSP.

A single router can be part of multiple LSPs. It can be the ingress or egress router for one or more LSPs, and it also can be a transit router in one or more LSPs. The functions that each router supports depend on your network design.

Configuring the Ingress and Egress Router Addresses for LSPs

IN THIS SECTION

- Configuring the Ingress Router Address for LSPs | **577**
- Configuring the Egress Router Address for LSPs | **578**
- Preventing the Addition of Egress Router Addresses to Routing Tables | **578**

The following sections describe how to specify the addresses of an LSP's ingress and egress routers:

Configuring the Ingress Router Address for LSPs

The local router always is considered to be the ingress router, which is the beginning of the LSP. The software automatically determines the proper outgoing interface and IP address to use to reach the next router in an LSP.

By default, the router ID is chosen as the address of the ingress router. To override the automatic selection of the source address, specify a source address in the `from` statement:

```
from address;
```

You can include this statement at the following hierarchy levels:

- `[edit protocols mpls label-switched-path lsp-name]`
- `[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name]`

The outgoing interface used by the LSP is not affected by the source address that you configure.

Configuring the Egress Router Address for LSPs

When configuring an LSP, you must specify the address of the egress router by including the `to` statement:

```
to address;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls label-switched-path *lsp-name*]
- [edit protocols mpls static-label-switched-path *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls static-label-switched-path *lsp-name*]

When you are setting up a signaled LSP, the `to` statement is the only required statement. All other statements are optional.

After the LSP is established, the address of the egress router is installed as a host route in the routing table. This route can then be used by BGP to forward traffic.

To have the software send BGP traffic over an LSP, the address of the egress router is the same as the address of the BGP next hop. You can specify the egress router's address as any one of the router's interface addresses or as the BGP router ID. If you specify a different address, even if the address is on the same router, BGP traffic is not sent over the LSP.

To determine the address of the BGP next hop, use the `show route detail` command. To determine the destination address of an LSP, use the `show mpls lsp` command. To determine whether a route has gone through an LSP, use the `show route` or `show route forwarding-table` command. In the output of these last two commands, the `label-switched-path` or `push` keyword included with the route indicates it has passed through an LSP. Also, use the `traceroute` command to trace the actual path to which the route leads. This is another indication whether a route has passed through an LSP.

You also can manipulate the address of the BGP next hop by defining a BGP import policy filter that sets the route's next-hop address.

Preventing the Addition of Egress Router Addresses to Routing Tables

You must configure an address using the `to` statement for all LSPs. This address is always installed as a `/32` prefix in the inet.3 or inet.0 routing tables. You can prevent the egress router address configured using the `to` statement from being added to the inet.3 and inet.0 routing tables by including the `no-install-to-address` statement.

Some reasons not to install the `to` statement address in the inet.3 and inet.0 routing tables include the following:

- Allow Constrained Shortest Path First (CSPF) RSVP LSPs to be mapped to traffic intended for secondary loopback addresses. If you configure an RSVP tunnel, including the `no-install-to-address` statement, and then configure an `install pfx/ <active>` policy later, you can do the following:
  - Verify that the LSP was set up correctly without impacting traffic.
  - Map traffic to the LSP in incremental steps.
  - Map traffic to the destination loopback address (the BGP next hop) by removing the `no-install-to-address` statement once troubleshooting is complete.
- Prevent CCC connections from losing IP traffic. When an LSP determines that it does not belong to a connection, it installs the address specified with the `to` statement in the inet.3 routing table. IP traffic is then forwarded to the CCC remote endpoint, which can cause some types of PICs to fail.

To prevent the egress router address configured using the `to` statement from being added to the inet.3 and inet.0 routing tables, include the `no-install-to-address` statement:

```
no-install-to-address;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls label-switched-path *lsp-name*]
- [edit protocols mpls static-label-switched-path *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls static-label-switched-path *lsp-name*]

Configuring the Ingress Router for MPLS-Signaled LSPs

IN THIS SECTION

- Creating Named Paths | 580
- Configuring Alternate Backup Paths Using Fate Sharing | 582

MPLS-signaled label-switched paths (LSPs) run from a specific ingress router to a specific egress router. For basic MPLS-signaled LSP function, you must configure the ingress router, but do not have to configure any other routers.

To configure signaled LSPs, perform the following tasks on the ingress router:

Creating Named Paths

To configure signaled LSPs, you must first create one or more named paths on the ingress router. For each path, you can specify some or all transit routers in the path, or you can leave it empty.

Each pathname can contain up to 32 characters and can include letters, digits, periods, and hyphens. The name must be unique within the ingress router. Once a named path is created, you can use the named path with the `primary` or `secondary` statement to configure LSPs at the `[edit protocols mpls label-switched-path` *`label-path-name`*`]` hierarchy level. You can specify the same named path on any number of LSPs.

To determine whether an LSP is associated with the primary or secondary path in an RSVP session, issue the `show rsvp session detail` command.

To create an empty path, create a named path by including the following form of the `path` statement. This form of the `path` statement is empty, which means that any path between the ingress and egress routers is accepted. In actuality, the path used tends to be the same path as is followed by destination-based, best-effort traffic.

```
path path-name;
```

You can include this statement at the following hierarchy levels:

- `[edit protocols mpls]`
- `[edit logical-systems` *`logical-system-name`* `protocols mpls]`

To create a path in which you specify some or all transit routers in the path, include the following form of the `path` statement, specifying one address for each transit router:

```
path path-name {
    (address | hostname) <strict | loose>;
}
```

You can include this statement at the following hierarchy levels:

- `[edit protocols mpls]`
- `[edit logical-systems` *`logical-system-name`* `protocols mpls]`

In this form of the path statement, you specify one or more transit router addresses. Specifying the ingress or egress routers is optional. You can specify the address or hostname of each transit router, although you do not need to list each transit router if its type is loose. Specify the addresses in order, starting with the ingress router (optional) or the first transit router, and continuing sequentially along the path up to the egress router (optional) or the router immediately before the egress router. You need to specify only one address per router hop. If you specify more than one address for the same router, only the first address is used; the additional addresses are ignored and truncated.

For each router address, you specify the type, which can be one of the following:

- strict—(Default) The route taken from the previous router to this router is a direct path and cannot include any other routers. If *address* is an interface address, this router also ensures that the incoming interface is the one specified. Ensuring that the incoming interface is the one specified is important when there are parallel links between the previous router and this router. It also ensures that routing can be enforced on a per-link basis.

  For strict addresses, you must ensure that the router immediately preceding the router you are configuring has a direct connection to that router. The address can be a loopback interface address, in which case the incoming interface is not checked.

- loose—The route taken from the previous router to this router need not be a direct path, can include other routers, and can be received on any interface. The address can be any interface address or the address of the loopback interface.

Examples: Creating Named Paths

Configure a path, to-hastings, to specify the complete strict path from the ingress to the egress routers through 14.1.1.1, 13.1.1.1, 12.1.1.1, and 11.1.1.1, in that order. There cannot be any intermediate routers except the ones specified. However, there can be intermediate routers between 11.1.1.1 and the egress router because the egress router is not specifically listed in the path statement. To prevent intermediate routers before egress, configure the egress router as the last router, with a strict type.

```
[edit protocols mpls]
path to-hastings {
    14.1.1.1 strict;
    13.1.1.1 strict;
    12.1.1.1 strict;
    11.1.1.1 strict;
}
```

Create a path, `alt-hastings`, to allow any number of intermediate routers between routers `14.1.1.1` and `11.1.1.1`. In addition, intermediate routers are permitted between `11.1.1.1` and the egress router.

```
[edit protocols mpls]
path alt-hastings {
    14.1.1.1 strict;
    11.1.1.1 loose;
}
```

Configuring Alternate Backup Paths Using Fate Sharing

You can create a database of information that Constrained Shortest Path First (CSPF) uses to compute one or more backup paths in case the primary path becomes unstable. The database describes the relationships between elements of the network, such as routers and links. Because these network elements share the same fate, this relationship is called fate sharing.

You can configure backup paths that minimize the number of shared links and fiber paths with the primary paths as much as possible to ensure that, if a fiber is cut, the minimum amount of data is lost and a path still exists to the destination.

For a backup path to work optimally, it must not share links or physical fiber paths with the primary path. This ensures that a single point of failure will not affect the primary and backup paths at the same time.

The following sections describe how to configure fate sharing and how it affects CSPF, and provides a fate sharing configuration example:

Configuring Fate Sharing

To configure fate sharing, include the `fate-sharing` statement:

```
fate-sharing {
    group group-name {
        cost value;
        from address <to address>;
    }
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Each fate-sharing group must have a name, which can be up to 32 characters long and can contain letters, digits, periods (.) and hyphens (-). You can define up to 512 groups.

Fate-sharing groups contain three types of objects:

- Point-to-point links—Identified by the IP addresses at each end of the link. Unnumbered point-to-point links are typically identified by borrowing IP addresses from other interfaces. Order is not important; `from 1.2.3.4 to 1.2.3.5` and `from 1.2.3.5 to 1.2.3.4` have the same meaning.
- Non-point-to-point links—Include links on a LAN interface (such as Gigabit Ethernet interfaces) or nonbroadcast multiaccess (NBMA) interfaces (such as Asynchronous Transfer Mode [ATM] or Frame Relay). You identify these links by their individual interface address. For example, if the LAN interface `192.168.200.0/24` has four routers attached to it, each router link is individually identified:

  ```
  from 192.168.200.1;     # LAN interface of router 1
  from 192.168.200.2;     # LAN interface of router 2
  from 192.168.200.3;     # LAN interface of router 3
  from 192.168.200.4;     # LAN interface of router 4
  ```

  You can list the addresses in any order.
- A router node—Identified by its configured router ID.

All objects in a group share certain similarities. For example, you can define a group for all fibers that share the same fiber conduit, all optical channels that share the same fiber, all links that connect to the same LAN switch, all equipment that shares the same power source, and so on. All objects are treated as /32 host addresses.

For a group to be meaningful, it should contain at least two objects. You can configure groups with zero or one object; these groups are ignored during processing.

An object can be in any number of groups, and a group can contain any number of objects. Each group has a configurable cost attributed to it, which represents the level of impact this group has on CSPF computations. The higher the cost, the less likely a backup path will share with the primary path any objects in the group. The cost is directly comparable to traffic engineering metrics. By default, the cost is 1. Changing the fate-sharing database does not affect established LSPs until the next reoptimization of CSPF. The fate-sharing database does influence fast-reroute computations.

Implications for CSPF

When CSPF computes the primary paths of an LSP (or secondary paths when the primary path is not active), it ignores the fate-sharing information. You always want to find the best possible path (least IGP cost) for the primary path.

When CSPF computes a secondary path while the primary path (of the same LSP) is active, the following occurs:

1. CSPF identifies all fate-sharing groups that are associated with the primary path. CSPF does this by identifying all links and nodes that the primary path traverses and compiling group lists that contain at least one of the links or nodes. CSPF ignores the ingress and egress nodes in the search.
2. CSPF checks each link in the traffic engineering database against the compiled group list. If the link is a member of a group, the cost of the link is increased by the cost of the group. If a link is a member of multiple groups, all group costs are added together.
3. CSPF performs the check for every node in the traffic engineering database, except the ingress and egress node. Again, a node can belong to multiple groups, so costs are additive.
4. The router performs regular CSPF computation with the adjusted topology.

Implications for CSPF When Fate Sharing with Bypass LSPs

When fate sharing is enabled with link protection or link-node protection, CSPF operates as follows when calculating the bypass LSP path:

- CSPF identifies the fate-sharing groups that are associated with the primary LSP path. CSPF does this by identifying the immediate downstream link and immediate downstream nodes that the bypass is trying to protect. CSPF compiles group lists that contain the immediate downstream link and immediate downstream nodes.
- CSPF checks each link (from ingress to the immediate downstream node) in the traffic engineering database against the compiled group list. If the link is a member of a group, the cost of the link is increased by the cost of the group.
- CSPF identifies the downstream link that is not in the fate-shared path.

This calculation prevents bypasses from using the same physical link as the primary LSP path when viable alternatives are available.

Example: Configuring Fate Sharing

Configure fate-sharing groups `east` and `west`. Because `west` has no objects, it is ignored during processing.

```
[edit routing-options]
fate-sharing {
    group east {
        cost 20;           # Optional, default value is 1
        from 1.2.3.4 to 1.2.3.5; # A point-to-point link
```

```
        from 192.168.200.1;    # LAN interface
        from 192.168.200.2;     # LAN interface
        from 192.168.200.3;     # LAN interface
        from 192.168.200.4;   # LAN interface
        from 10.168.1.220;     # Router ID of a router node
        from 10.168.1.221;      # Router ID of a router node
    }
    group west {
        .....
    }
}
```

Configuring the Intermediate and Egress Routers for MPLS-Signaled LSPs

To configure signaled LSPs on all MPLS routers that should participate in MPLS, you need to enable MPLS and RSVP on these routers.

Configuring the Connection Between Ingress and Egress Routers

The ingress router might make many attempts to connect and reconnect to the egress router using the primary path. You can control how often the ingress router tries to establish a connection using the primary path and how long it waits between retry attempts.

The retry timer configures how long the ingress router waits before trying to connect again to the egress router using the primary path. The default retry time is 30 seconds. The time can be from 1 through 600 seconds. To modify this value, include the `retry-timer` statement:

```
retry-timer seconds;
```

You can configure this statement at the following hierarchy levels:

- `[edit protocols mpls label-switched-path lsp-name]`
- `[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name]`

By default, no limit is set to the number of times an ingress router attempts to establish or reestablish a connection to the egress router using the primary path. To limit the number of attempts, include the `retry-limit` statement:

```
retry-limit number;
```

You can configure this statement at the following hierarchy levels:

- [edit protocols mpls label-switched-path *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name*]

The limit can be a value up to 10,000. When the retry limit is exceeded, no more attempts are made to establish a path connection. At this point, intervention is required to restart the primary path.

If you set a retry limit, it is reset to 1 each time a successful primary path is created.

Pinging LSPs

IN THIS SECTION

- Pinging MPLS LSPs | **586**
- Pinging Point-to-Multipoint LSPs | **587**
- Pinging the Endpoint Address of MPLS LSPs | **587**
- Pinging CCC LSPs | **587**
- Pinging Layer 3 VPNs | **587**
- Support for LSP Ping and Traceroute Commands Based on RFC 4379 | **588**

The following sections describe how to use the ping mpls command to confirm LSP functioning.

Pinging MPLS LSPs

You can ping a specific LSP. Echo requests are sent over the LSP as MPLS packets. The payload is a User Datagram Protocol (UDP) packet forwarded to an address in the 127/8 range (127.0.0.1 by default, this address is configurable) and port 3503. The label and interface information for building and sending this information as an MPLS packet is the same as for standard LSP traffic.

When the echo request arrives at the egress node, the receiver checks the contents of the packet and sends a reply containing the correct return value, by using UDP. The router sending the echo request waits to receive an echo reply after a timeout of 2 seconds (you cannot configure this value).

You must configure MPLS at the [edit protocols mpls] hierarchy level on the remote router to be able to ping an LSP terminating there. You must configure MPLS even if you intend to ping only LDP forwarding equivalence classes (FECs).

To ping an MPLS LSP use the ping mpls <count *count*> <ldp <fec>> <rsvp <exp *forwarding-class*> <*lsp-name*>> command. To ping a secondary MPLS LSP, use the ping mpls <count *count*> <rsvp <*lsp-name*>> standby *path-name* command. For a detailed description of this command, see the CLI Explorer.

NOTE: The `ping mpls` command is not supported within routing instances.

NOTE: Self-ping is supported for the master instance and not supported for VLAN-based LSPs or LSPs used in CCC. The message is displayed for each LSP and reduces the readability of the configuration.

Pinging Point-to-Multipoint LSPs

To ping a point-to-multipoint LSP, use the `ping mpls rsvp` *`lsp-name`* `multipoint` or `ping mpls rsvp egress` *`address`* commands. The `ping mpls rsvp` *`lsp-name`* `multipoint` command returns a list of all of the egress router identifiers and the current status of the point-to-multipoint LSP egress routers. The `ping mpls rsvp` *`lsp-name`* `multipoint egress` *`address`* command returns the current status of the specified egress router.

Pinging the Endpoint Address of MPLS LSPs

To determine whether an LSP between two provider edge (PE) routers is up and running, you can ping the endpoint address of the LSP. To ping an MPLS LSP endpoint, use the `ping mpls lsp-end-point` *`address`* command. This command tells you what type of LSP (RSVP or LDP) terminates at the address specified and whether that LSP is up or down.

For a detailed description of this command, see the CLI Explorer.

Pinging CCC LSPs

You can ping a specific CCC LSP. The CCC LSP ping command is identical to the one used for MPLS LSPs. The command you use is `ping mpls <count` *`count`*`> <rsvp <`*`lsp-name`*`>>`. You can also ping a secondary standby CCC LSP by using the `ping mpls <count` *`count`*`> <rsvp <`*`lsp-name`*`>> standby` *`path-name`* command.

For a detailed description of this command, see the CLI Explorer.

Pinging Layer 3 VPNs

You can use a similar command, `ping mpls l3vpn` *`vpn-name`* `prefix` *`prefix`* `<count` *`count`*`>`, to ping a Layer 3 VPN. For more information about this command, see the Junos OS VPNs Library for Routing Devices and the CLI Explorer.

Support for LSP Ping and Traceroute Commands Based on RFC 4379

The Junos OS supports LSP `ping` and `traceroute` commands based on RFC 4379, *Detecting Multi-Protocol Label Switched (MPLS) Data Plane Failures*.

LSP `ping` and `traceroute` commands based on RFC 4379 attempt to trace the path taken by an LSP by relying on MPLS TTL expiration. An LSP can take multiple paths from ingress to egress. This occurs in particular with Equal Cost Multipath (ECMP). The LSP `traceroute` command can trace all possible paths to an LSP node.

Configuring LSP Metrics

IN THIS SECTION

- Configuring Dynamic LSP Metrics | **591**
- Configuring Static LSP Metrics | **591**

The LSP metric is used to indicate the ease or difficulty of sending traffic over a particular LSP. Lower LSP metric values (lower cost) increase the likelihood of an LSP being used. Conversely, high LSP metric values (higher cost) decrease the likelihood of an LSP being used.

The LSP metric can be specified dynamically by the router or explicitly by the user as described in the following sections:

Configuring Dynamic LSP Metrics

If no specific metric is configured, an LSP attempts to track the IGP metric toward the same destination (the `to` address of the LSP). IGP includes OSPF, IS-IS, Routing Information Protocol (RIP), and static routes. BGP and other RSVP or LDP routes are excluded.

For example, if the OSPF metric toward a router is 20, all LSPs toward that router automatically inherit metric 20. If the OSPF toward a router later changes to a different value, all LSP metrics change accordingly. If there are no IGP routes toward the router, the LSP raises its metric to 65,535.

Note that in this case, the LSP metric is completely determined by IGP; it bears no relationship to the actual path the LSP is currently traversing. If LSP reroutes (such as through reoptimization), its metric does not change, and thus it remains transparent to users. Dynamic metric is the default behavior; no configuration is required.

Configuring Static LSP Metrics

You can manually assign a fixed metric value to an LSP. Once configured with the `metric` statement, the LSP metric is fixed and cannot change:

```
metric number;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls label-switched-path *lsp-name*]
- [edit protocols mpls static-label-switched-path *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls static-label-switched-path *lsp-name*]

The LSP metric has several uses:

- When there are parallel LSPs with the same egress router, the metrics are compared to determine which LSP has the lowest metric value (the lowest cost) and therefore the preferred path to the destination. If the metrics are the same, the traffic is shared.

  Adjusting the metric values can force traffic to prefer some LSPs over others, regardless of the underlying IGP metric.

- When an IGP shortcut is enabled (see *Using Labeled-Switched Paths to Augment SPF to Compute IGP Shortcuts*), an IGP route might be installed in the routing table with an LSP as the next hop, if the LSP is on the shortest path to the destination. In this case, the LSP metric is added to the other IGP metrics to determine the total path metric. For example, if an LSP whose ingress router is X and egress router is Y is on the shortest path to destination Z, the LSP metric is added to the metric for the IGP route from Y to Z to determine the total cost of the path. If several LSPs are potential next hops, the total metrics of the paths are compared to determine which path is preferred (that is, has the lowest total metric). Or, IGP paths and LSPs leading to the same destination could be compared by means of the metric value to determine which path is preferred.

  By adjusting the LSP metric, you can force traffic to prefer LSPs, prefer the IGP path, or share the load among them.

- If router X and Y are BGP peers and if there is an LSP between them, the LSP metric represents the total cost to reach Y from X. If for any reason the LSP reroutes, the underlying path cost might change significantly, but X's cost to reach Y remains the same (the LSP metric), which allows X to report through a BGP multiple exit discriminator (MED) a stable metric to downstream neighbors. As long as Y remains reachable through the LSP, no changes are visible to downstream BGP neighbors.

It is possible to configure IS-IS to ignore the configured LSP metric by including the `ignore-lsp-metrics` statement at the `[edit protocols isis traffic-engineering shortcuts]` hierarchy level. This statement removes the mutual dependency between IS-IS and MPLS for path computation. For more information, see the Junos OS Routing Protocols Library for Routing Devices.

Configuring a Text Description for LSPs

You can provide a textual description for an LSP by enclosing any descriptive text that includes spaces within quotation marks (" "). The descriptive text you include is displayed in the detail output of the `show mpls lsp` or the `show mpls container-lsp` command.

Adding a text description for an LSP has no effect on the operation of the LSP. The LSP text description can be no more than 80 characters in length.

To provide a textual description for an LSP, include the `description` statement at any of the following hierarchy levels:

- `[edit protocols mpls label-switched-path` *`lsp-name`*`]`
- `[edit protocols mpls container-label-switched-path` *`lsp-name`*`]`
- `[edit protocols mpls static-label-switched-path` *`lsp-name`*`]`
- `[edit logical-systems` *`logical-system-name`* `protocols mpls label-switched-path` *`lsp-name`*`]`
- `[edit logical-systems` *`logical-system-name`* `protocols mpls static-label-switched-path` *`lsp-name`*`]`

Before you begin:

- Configure the device interfaces.
- Configure the device for network communication.
- Enable MPLS on the device interfaces.
- Configure an LSP in the MPLS domain.

To add a text description for an LSP:

1. Enter any text describing the LSP.

```
[edit protocols mpls lsp lsp-name]
user@host# set description text
```

For example:

```
[edit protocols mpls lsp LSP1]
user@host# set description “Connecting remote device”
```

2. Verify and commit the configuration.

For example:

```
[edit protocols mpls lsp]
user@host# set protocols mpls label-switched-path LSP1 to 1.1.1.1
user@host# set protocols mpls label-switched-path LSP1 description "Connecting remote device"
user@host# set protocols mpls interface ge-1/0/8.0
```

```
[edit]
user@host# commit
commit complete
```

3. View the description of an LSP using the `show mpls lsp detail` or `show mpls container-lsp detail` command, depending on the type of LSP configured.

```
user@host> show mpls lsp detail

Ingress LSP: 1 sessions
```

```
1.1.1.1
  From: 0.0.0.0, State: Up, ActiveRoute: 1, LSPname: LSP1
  Description: Connecting remote device
  ActivePath: (none)
  LSPtype: Static Configured, Penultimate hop popping
  LoadBalance: Random
  Encoding type: Packet, Switching type: Packet, GPID: IPv4

    Priorities: 7 0
    SmartOptimizeTimer: 180
        No computed ERO.
Total 1 displayed, Up 1, Down 0

Egress LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Configuring MPLS Soft Preemption

Soft preemption attempts to establish a new path for a preempted LSP before tearing down the original LSP. The default behavior is to tear down a preempted LSP first, signal a new path, and then reestablish the LSP over the new path. In the interval between when the path is taken down and the new LSP is established, any traffic attempting to use the LSP is lost. Soft preemption prevents this type of traffic loss. The trade-off is that during the time when an LSP is being soft preempted, two LSPs with their corresponding bandwidth requirements are used until the original path is torn down.

MPLS soft preemption is useful for network maintenance. For example, you can move all LSPs away from a particular interface, then take the interface down for maintenance without interrupting traffic. MPLS soft preemption is described in detail in RFC 5712, *MPLS Traffic Engineering Soft Preemption*.

Soft preemption is a property of the LSP and is disabled by default. You configure it at the ingress of an LSP by including the `soft-preemption` statement:

```
soft-preemption;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls label-switched-path *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name*]

You can also configure a timer for soft preemption. The timer designates the length of time the router should wait before initiating a hard preemption of the LSP. At the end of the time specified, the LSP is torn down and resignaled. The soft-preemption cleanup timer has a default value of 30 seconds; the range of permissible values is 0 through 180 seconds. A value of 0 means that soft preemption is disabled. The soft-preemption cleanup timer is global for all LSPs.

Configure the timer by including the `cleanup-timer` statement:

```
cleanup-timer seconds;
```

You can include this statement at the following hierarchy levels:

- `[edit protocols rsvp preemption soft-preemption]`
- `[edit logical-systems logical-system-name protocols rsvp preemption soft-preemption]`

NOTE: Soft preemption cannot be configured on LSPs for which fast reroute has been configured. The configuration fails to commit. However, you can enable soft preemption in conjunction with node and link protection.

NOTE: The counter value for *SoftPreemptionCnt* initializes with a value of 0 (zero), visible in the command `show rsvp interface detail` output.

Configuring Priority and Preemption for LSPs

When there is insufficient bandwidth to establish a more important LSP, you might want to tear down a less important existing LSP to free the bandwidth. You do this by preempting the existing LSP.

Whether an LSP can be preempted is determined by two properties associated with the LSP:

- Setup priority—Determines whether a new LSP that preempts an existing LSP can be established. For preemption to occur, the setup priority of the new LSP must be higher than that of the existing LSP. Also, the act of preempting the existing LSP must produce sufficient bandwidth to support the new LSP. That is, preemption occurs only if the new LSP can be set up successfully.
- Reservation priority—Determines the degree to which an LSP holds on to its session reservation after the LSP has been set up successfully. When the reservation priority is high, the existing LSP is less likely to give up its reservation, and hence it is unlikely that the LSP can be preempted.

You cannot configure an LSP with a high setup priority and a low reservation priority, because permanent preemption loops might result if two LSPs are allowed to preempt each other. You must configure the reservation priority to be higher than or equal to the setup priority.

The setup priority also defines the relative importance of LSPs on the same ingress router. When the software starts, when a new LSP is established, or during fault recovery, the setup priority determines the order in which LSPs are serviced. Higher-priority LSPs tend to be established first and hence enjoy more optimal path selection.

To configure the LSP's preemption properties, include the `priority` statement:

```
priority setup-priority reservation-priority;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Both *setup-priority* and *reservation-priority* can be a value from 0 through 7. The value 0 corresponds to the highest priority, and the value 7 to the lowest. By default, an LSP has a setup priority of 7 (that is, it cannot preempt any other LSPs) and a reservation priority of 0 (that is, other LSPs cannot preempt it). These defaults are such that preemption does not happen. When you are configuring these values, the setup priority should always be less than or equal to the hold priority.

Configuring Administrative Groups for LSPs

Administrative groups, also known as link coloring or resource class, are manually assigned attributes that describe the "color" of links, such that links with the same color conceptually belong to the same class. You can use administrative groups to implement a variety of policy-based LSP setups.

Administrative groups are meaningful only when constrained-path LSP computation is enabled.

You can assign up to 32 names and values (in the range 0 through 31), which define a series of names and their corresponding values. The administrative names and values must be identical across all routers within a single domain.

NOTE: The administrative value is distinct from the priority. You configure the priority for an LSP using the `priority` statement. See "Configuring Priority and Preemption for LSPs" on page 595.

To configure administrative groups, follow these steps:

1. Define multiple levels of service quality by including the `admin-groups` statement:

```
admin-groups {
    group-name group-value;
}
```

You can include this statement at the following hierarchy levels:

- `[edit protocols mpls]`
- `[edit logical-systems logical-system-name protocols mpls]`

The following configuration example illustrates how you might configure a set of administrative names and values for a domain:

```
[edit protocols mpls]
admin-groups {
    gold 1;
    silver 2;
    copper 3;
    best-effort 4;
}
```

2. Define the administrative groups to which an interface belongs. You can assign multiple groups to an interface. Include the `interface` statement:

```
interface interface-name {
    admin-group [ group-names ];
}
```

You can include this statement at the following hierarchy levels:

- `[edit protocols mpls]`
- `[edit logical-systems logical-system-name protocols mpls]`

If you do not include the `admin-group` statement, an interface does not belong to any group.

IGPs use the group information to build link-state packets, which are then flooded throughout the network, providing information to all nodes in the network. At any router, the IGP topology, as well as administrative groups of all the links, is available.

Changing the interface's administrative group affects only new LSPs. Existing LSPs on the interface are not preempted or recomputed to keep the network stable. If LSPs need to be removed because of a group change, issue the `clear rsvp session` command.

> **NOTE**: When configuring administrative groups and extended administrative groups together for a link, both the types of administrative groups must be configured on the interface.

3. Configure an administrative group constraint for each LSP or for each primary or secondary LSP path. Include the `label-switched-path` statement:

```
label-switched-path lsp-name {
    to address;
    ...
    admin-group {
        exclude [ group-names ];
        include-all [ group-names ];
        include-any [ group-names ];
    }
    primary path-name {
        admin-group {
            exclude [ group-names ];
            include-all [ group-names ];
            include-any [ group-names ];
        }
    }
    secondary path-name {
        admin-group {
            exclude [ group-names ];
            include-all [ group-names ];
            include-any [ group-names ];
        }
    }
}
```

You can include the `label-switched-path` statement at the following hierarchy levels:

- `[edit protocols mpls]`
- `[edit logical-systems logical-system-name protocols mpls]`

If you omit the `include-all`, `include-any`, or `exclude` statements, the path computation proceeds unchanged. The path computation is based on the constrained-path LSP computation. For

information about how the constrained-path LSP computation is calculated, see "How CSPF Selects a Path" on page 572.

> **NOTE**: Changing the LSP's administrative group causes an immediate recomputation of the route; therefore, the LSP might be rerouted.

Configuring Extended Administrative Groups for LSPs

In MPLS traffic engineering, a link can be configured with a set of administrative groups (also known as colors or resource classes). Administrative groups are carried in the interior gateway protocol (IGP) (OSPFv2 and IS-IS) as a 32-bit value assigned to each link. Juniper Networks routers normally interpret this 32-bit value as a bit mask with each bit representing a group, limiting each network to a total of 32 distinct administrative groups (value range 0 through 31).

You configure extended administrative groups, represented by a 32-bit value, expanding the number of administrative groups supported in the network beyond just 32. The original range of values available for administrative groups is still supported for backwards compatibility.

The extended administrative groups configuration accepts a set of interfaces with a corresponding set of extended administrative group names. It converts the names into a set of 32-bit values and propagates this information into the IGP. The extended administrative group values are global and must be identically configured on all the supported routers participating in the network. The domain-wide extended administrative groups database, learned from other routers through IGP flooding, is used by Constrained Shortest Path First (CSPF) for path computation.

The following procedure describes how to configure extended administrative groups:

1. Configure the `admin-groups-extended-range` statement:

```
admin-groups-extended-range {
    maximum maximum-number;
    mininum minimum-number;
}
```

You can include this statement at the following hierarchy levels:

- `[edit routing-options]`
- `[edit logical-systems logical-system-name routing-options]`

The `admin-groups-extended-range` statement includes the `minimum` and `maximum` options. The range maximum must be greater than the range minimum.

2. Configure the admin-groups-extended statement:

```
admin-groups-extended group-name {
    group-value group-identifier;
}
```

You can include this statement at the following hierarchy levels:

- [edit routing-options]
- [edit logical-systems *logical-system-name* routing-options]

The admin-groups-extended statement enables you to configure a group name and group value for the administrative group. The group value must be within the range of values configured using the admin-groups-extended-range statement.

3. The extended administrative groups for an MPLS interface consist of the set of extended administrative group names assigned for the interface. The interface extended administrative group names must be configured for the global extended administrative groups.

   To configure an extended administrative group for an MPLS interface, specify the administrative group name within the MPLS interface configuration using the admin-groups-extended statement:

```
admin-groups-extended group-name;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls interface *interface-name*]
- [edit logical-systems *logical-system-name* protocols mpls interface *interface-name*]

4. The LSP extended administrative groups define the set of include and exclude constraints for an LSP and for a path's primary and secondary paths. The extended administrative group names must be configured for the global extended administrative groups.

   To configure extended administrative groups for an LSP, include the admin-group-extended statement at an LSP hierarchy level:

```
admin-group-extended {
    apply-groups group-value;
    apply-groups-except group-value;
    exclude group-value;
    include-all  group-value;
    include-any  group-value;
}
```

The `admin-group-extended` statement includes the following options: `apply-groups`, `apply-groups-except`, `exclude`, `include-all`, and `include-any`. Each option enables you to configure one or more extended administrative groups.

For the list of the hierarchy levels at which you can configure this statement, see the statement summary for this statement.

5. To display the currently configured extended administrative groups, issue the `show mpls admin-groups-extended` command.

NOTE: When configuring administrative groups and extended administrative groups together for a link, both the types of administrative groups must be configured on the interface.

Configuring Preference Values for LSPs

As an option, you can configure multiple LSPs between the same pair of ingress and egress routers. This is useful for balancing the load among the LSPs because all LSPs, by default, have the same preference level. To prefer one LSP over another, set different preference levels for individual LSPs. The LSP with the lowest preference value is used. The default preference for RSVP LSPs is 7 and for LDP LSPs is 9. These preference values are lower (more preferred) than all learned routes except direct interface routes.

To change the default preference value, include the `preference` statement:

```
preference preference;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Disabling Path Route Recording by LSPs

The Junos implementation of RSVP supports the Record Route object, which allows an LSP to actively record the routers through which it transits. You can use this information for troubleshooting and to prevent routing loops. By default, path route information is recorded. To disable recording, include the `no-record` statement:

```
no-record;
```

For a list of hierarchy levels at which you can include the `record` and `no-record` statements, see the statement summary section for the statement.

Achieving a Make-Before-Break, Hitless Switchover for LSPs

IN THIS SECTION

- Specifying the Amount of Time the Router Waits to Switch Over to New Paths | **603**
- Specifying the Amount of Time to Delay the Tear Down of Old Paths | **603**
- Achieving a Hitless, MBB Switchover Without Artificial Delays | **604**

Adaptive label-switched paths (LSPs) might need to establish a new LSP instance and transfer traffic from an old LSP instance onto the new LSP instance before tearing down the old one. This type of configuration is referred to as a *make before break* (MBB).

RSVP-TE is a protocol used to establish LSPs in MPLS networks. The Junos OS implementation of RSVP-TE to achieve a hitless (no traffic loss) MBB switchover has relied on configuring the timer values in the following configuration statements:

- `optimize-switchover-delay`—Amount of time to wait before switching to the new LSP instance.
- `optimize-hold-dead-delay`—Amount of time to wait after switchover and before deletion of the old LSP instance.

Both the `optimize-switchover-delay` and `optimize-hold-dead-delay` statements apply to all LSPs that use the make-before-break behavior for LSP setup and teardown, not just for LSPs for which the `optimize-timer` statement has also been configured. The following MPLS features cause LSPs to be set up and torn down using make-before-break behavior:

- Adaptive LSPs
- Automatic bandwidth allocation
- BFD for LSPs
- Graceful Routing Engine switchover
- Link and node protection
- Nonstop active routing
- Optimized LSPs
- Point-to-multipoint (P2MP) LSPs
- Soft preemption

- Standby secondary paths

Both the optimize-switchover-delay and optimize-hold-dead-delay statements when configured add an artificial delay to the MBB process. The value of the optimize-switchover-delay statement varies with the size of the Explicit Route Objects (EROs). An ERO is an extension to RSVP that allows an RSVP PATH message to traverse an explicit sequence of routers that is independent of conventional shortest-path IP routing. The value of the optimize-switchover-delay statement also depends on the CPU load on each of the routers on the path. Customers set the optimize-switchover-delay statement by trial and error.

The value of the optimize-hold-dead-delay statement depends on how fast the ingress router moves all application prefixes to point to the new LSP. This is determined by the Packet Forwarding Engine load, which can vary from platform to platform. Customers have to set the optimize-hold-dead-delay statement by trial and error.

However, as of Release 15.1, Junos OS is able to achieve a hitless MBB switchover without configuring the artificial delays that such timer values introduce.

This topic summarizes the three methods of achieving a MBB switchover from an old LSP to a new LSP using Junos OS:

Specifying the Amount of Time the Router Waits to Switch Over to New Paths

To specify the amount of time the router waits to switch over LSP instances to newly optimized paths, use the optimize-switchover-delay statement. You only need to configure this statement on routers acting as the ingress for the affected LSPs (you do not need to configure this statement on transit or egress routers). The timer in this statement helps to ensure that the new optimized paths have been established before traffic is switched over from the old paths. This timer can only by enabled or disabled for all of the LSPs configured on the router.

To configure the amount of time the router waits to switch over LSP instances to newly optimized paths, specify the time in seconds by using the optimize-switchover-delay statement:

```
optimize-switchover-delay seconds;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls]
- [edit logical-systems *logical-system-name* protocols mpls]

Specifying the Amount of Time to Delay the Tear Down of Old Paths

To specify the amount of time to delay the tear down of old paths after the router has switched traffic to new optimized paths, use the optimize-hold-dead-delay statement. You only need to configure this

statement on routers acting as the ingress for the affected LSPs (you do not need to configure this statement on transit or egress routers). The timer in this statement helps to ensure that old paths are not torn down before all routes have been switched over to the new optimized paths. This timer can be enabled for specific LSPs or for all of the LSPs configured on the router.

To configure the amount of time in seconds to delay the tear down of old paths after the router has switched traffic to new optimized paths, use the `optimize-hold-dead-delay` statement:

```
optimize-hold-dead-delay seconds;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Achieving a Hitless, MBB Switchover Without Artificial Delays

As of Junos OS Release 15.1, there is another way to relinquish the old LSP instances after MBB switchover without relying on the arbitrary time intervals set up by the `optimize-switchover-delay` or `optimize-hold-dead-delay` statement. For example, if you use the `optimize-hold-dead-delay` statement, you configure a time you think it is safe to wait before tearing down the old LSP instance after MBB. However, some routes might still be in the process of shifting to the new instance. Tearing down the old LSP instance prematurely results in one of the transit nodes dropping the traffic for those routes that have not shifted to the new LSP instance.

To avoid traffic loss, instead of using the `optimize-switchover-delay` statement, you can use MPLS-OAM (lsp ping), which confirms that the LSP data plane is established end-to-end. Instead of using the `optimize-hold-dead-delay` statement, you can use a feedback mechanism from the rpd infrastructure that confirms that all prefixes referring to the old LSP have been switched over. The feedback mechanism is sourced from the Tag library and relies on the routing protocol process (rpd) infrastructure to determine when all the routes using the old LSP instance have fully shifted to the new LSP instance after MBB switchover.

The feedback mechanism is always in place, and it is optional. Configure the `optimize-adaptive-teardown` statement to have the feedback mechanism used during MBB switchover. This feature is not supported for RSVP point-to-multipoint (P2MP) LSP instances. Global configuration of the `optimize-adaptive-teardown` statement only affects the point-to-point LSPs that are configured in the system.

You only need to configure the `optimize-adaptive-teardown` statement on routers acting as the ingress for the affected LSPs (you do not need to configure this statement on transit or egress routers). This feedback mechanism ensures that old paths are not torn down before all routes have been switched

over to the new optimized paths. The global configuration of this configuration statement affects only the point-to-point LSPs that are configured in the system.

```
optimize-adaptive-teardown {
    p2p:
}
```

You can include this statement at the `[edit protocols mpls]` hierarchy level.

Optimizing Signaled LSPs

Once an LSP has been established, topology or resources changes might, over time, make the path suboptimal. A new path might have become available that is less congested, has a lower metric, and traverses fewer hops. You can configure the router to recompute paths periodically to determine whether a more optimal path has become available.

If reoptimization is enabled, an LSP can be rerouted through different paths by constrained-path recomputations. However, if reoptimization is disabled, the LSP has a fixed path and cannot take advantage of newly available network resources. The LSP is fixed until the next topology change breaks the LSP and forces a recomputation.

Reoptimization is not related to failover. A new path is always computed when topology failures occur that disrupt an established path.

Because of the potential system overhead involved, you need to carefully control the frequency of reoptimization. Network stability might suffer when reoptimization is enabled. By default, the `optimize-timer` statement is set to 0 (that is, it is disabled).

LSP optimization is meaningful only when constrained-path LSP computation is enabled, which is the default behavior. For more information about constrained-path LSP computation, see "Disabling Constrained-Path LSP Computation" on page 575. Also, LSP optimization is only applicable to ingress LSPs, so it is only necessary to configure the `optimize-timer` statement on the ingress router. The transit and egress routers require no specific configuration to support LSP optimization (other than to have MPLS enabled).

To enable path reoptimization, include the `optimize-timer` statement:

```
optimize-timer seconds;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Once you have configured the `optimize-timer` statement, the reoptimization timer continues its countdown to the configured value even if you delete the `optimize-timer` statement from the

configuration. The next optimization uses the new value. You can force the Junos OS to use a new value immediately by deleting the old value, committing the configuration, configuring the new value for the `optimize-timer` statement, and then committing the configuration again.

After reoptimization is run, the result is accepted only if it meets the following criteria:

1. The new path is not higher in IGP metric. (The metric for the old path is updated during computation, so if a recent link metric changed somewhere along the old path, it is accounted for.)
2. If the new path has the same IGP metric, it is not more hops away.
3. The new path does not cause preemption. (This is to reduce the ripple effect of preemption causing more preemption.)
4. The new path does not worsen congestion overall.

   The relative congestion of the new path is determined as follows:

   a. The percentage of available bandwidth on each link traversed by the new path is compared to that for the old path, starting from the most congested links.

   b. For each current (old) path, the software stores the four smallest values for bandwidth availability for the links traversed in ascending order.

   c. The software also stores the four smallest bandwidth availability values for the new path, corresponding to the links traversed in ascending order.

   d. If any of the four new available bandwidth values are smaller than any of the corresponding old bandwidth availability values, the new path has at least one link that is more congested than the link used by the old path. Because using the link would cause more congestion, traffic is not switched to this new path.

   e. If none of the four new available bandwidth values is smaller than the corresponding old bandwidth availability values, the new path is less congested than the old path.

When all the above conditions are met, then:

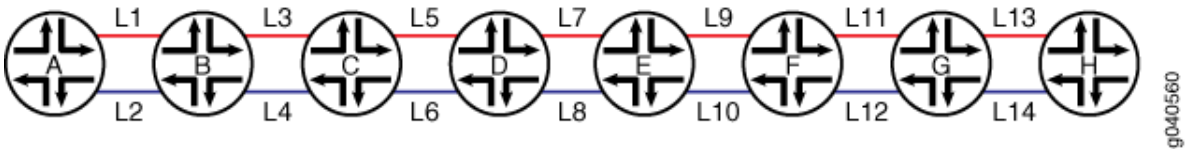
1. If the new path has a lower IGP metric, it is accepted.
2. If the new path has an equal IGP metric and lower hop count, it is accepted.
3. If you choose `least-fill` as a load balancing algorithm, LSPs are load balanced as follows:

   a. The LSP is moved to a new path that is utilized at least 10% less than the current path. This might reduce congestion on the current path by only a small amount. For example, if an LSP with 1 MB of bandwidth is moved off a path carrying a minimum of 200 MB, congestion on the original path is reduced by less than 1%.

   b. For `random` or `most-fill` algorithms, this rule does not apply.

The following example illustrates how the `least-fill` load balancing algorithm works.

Figure 40: least-fill Load Balancing Algorithm Example



As shown in Figure 40 on page 607, there are two potential paths for an LSP to traverse from router A to router H, the odd links from L1 through L13 and the even links from L2 through L14. Currently, the router is using the even links as the active path for the LSP. Each link between the same two routers (for example, router A and router B) has the same bandwidth:

- L1, L2 = 10GE
- L3, L4 = 1GE
- L5, L6 = 1GE
- L7, L8 = 1GE
- L9, L10 = 1GE
- L11, L12 = 10GE
- L13, L14 = 10GE

The 1GE links are more likely to be congested. In this example, the odd 1GE links have the following available bandwidth:

- L3 = 41%
- L5 = 56%
- L7 = 66%
- L9 = 71%

The even 1GE links have the following available bandwidth:

- L4 = 37%
- L6 = 52%
- L8 = 61%
- L10 = 70%

Based on this information, the router would calculate the difference in available bandwidth between the odd links and the even links as follows:

- L4 - L3 = 41% - 37% = 4%
- L6 - L5 = 56% - 52% = 4%
- L8 - L7 = 66% - 61% = 5%
- L10 - L9 = 71% - 70% = 1%

The total additional bandwidth available over the odd links is 14% (4% + 4% + 5% + 1%). Since 14% is greater than 10% (the least-fill algorithm minimum threshold), the LSP is moved to the new path over the odd links from the original path using the even links.

4. Otherwise, the new path is rejected.

You can disable the following reoptimization criteria (a subset of the criteria listed previously):

- If the new path has the same IGP metric, it is not more hops away.
- The new path does not cause preemption. (This is to reduce the ripple effect of preemption causing more preemption.)
- The new path does not worsen congestion overall.
- If the new path has an equal IGP metric and lower hop count, it is accepted.

To disable them, either issue the `clear mpls lsp optimize-aggressive` command or include the `optimize-aggressive` statement:

```
optimize-aggressive;
```

You can include this statement at the following hierarchy levels:

- `[edit protocols mpls]`
- `[edit logical-systems` *`logical-system-name`* `protocols mpls]`

Including the `optimize-aggressive` statement in the configuration causes the reoptimization procedure to be triggered more often. Paths are rerouted more frequently. It also limits the reoptimization algorithm to the IGP metric only.

Configuring the Smart Optimize Timer for LSPs

Because of network and router resource constraints, it is typically inadvisable to configure a short interval for the optimize timer. However, under certain circumstances, it might be desirable to reoptimize a path sooner than would normally be provided by the optimize timer.

For example, an LSP is traversing a preferred path that subsequently fails. The LSP is then switched to a less desirable path to reach the same destination. Even if the original path is quickly restored, it could take an excessively long time for the LSP to use it again, because it has to wait for the optimize timer to reoptimize the network paths. For such situations, you might want to configure the smart optimize timer.

When you enable the smart optimize timer, an LSP is switched back to its original path so long as the original path has been restored within 3 minutes of going down. Also, if the original path goes down again within 60 minutes, the smart optimize timer is disabled, and path optimization behaves as it normally does when the optimize timer alone is enabled. This prevents the router from using a flapping link.

The smart optimize timer is dependant on other MPLS features to function properly. For the scenario described here in which an LSP is switched to an alternate path in the event of a failure on the original path, it is assumed that you have configured one or more of the MPLS traffic protection features, including fast reroute, link protection, and standby secondary paths. These features help to ensure that traffic can reach its destination in the event of a failure.

At the least, you must configure a standby secondary path for the smart optimize timer feature to work properly. Fast reroute and link protection are more temporary solutions to a network outage. A secondary path ensures that there is a stable alternate path in the event the primary path fails. If you have not configured any sort of traffic protection for an LSP, the smart optimize timer by itself does not ensure that traffic can reach its destination. For more information about MPLS traffic protection, see "MPLS and Traffic Protection" on page 350.

When a primary path fails and the smart optimize timer switches traffic to the secondary path, the router might continue to use the secondary path even after the primary path has been restored. If the ingress router completes a CSPF calculation, it might determine that the secondary path is the better path.

This might be undesirable if the primary path should be the active path and the secondary path should be used as a backup only. Also, if the secondary path is being used as the active path (even though the primary path has been reestablished) and the secondary path fails, the smart optimize timer feature will not automatically switch traffic back to the primary path. However, you can enable protection for the secondary path by configuring node and link protection or an additional standby secondary path, in which case, the smart optimize timer can be effective.

Specify the time in seconds for the smart optimize timer using the `smart-optimize-timer` statement:

```
smart-optimize-timer seconds;
```

You can include this statement at the following hierarchy levels:

- `[edit protocols mpls]`

- [edit logical-systems *logical-system-name* protocols mpls]

Limiting the Number of Hops in LSPs

By default, each LSP can traverse a maximum of 255 hops, including the ingress and egress routers. To modify this value, include the hop-limit statement:

```
hop-limit number;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

The number of hops can be from 2 through 255. (A path with two hops consists of the ingress and egress routers only.)

Configuring the Bandwidth Value for LSPs

Each LSP has a bandwidth value. This value is included in the sender's Tspec field in RSVP path setup messages. You can specify a bandwidth value in bits per second. If you configure more bandwidth for an LSP, it should be able to carry a greater volume of traffic. The default bandwidth is 0 bits per second.

A nonzero bandwidth requires that transit and egress routers reserve capacity along the outbound links for the path. The RSVP reservation scheme is used to reserve this capacity. Any failure in bandwidth reservation (such as failures at RSVP policy control or admission control) might cause the LSP setup to fail. If there is insufficient bandwidth on the interfaces for the transit or egress routers, the LSP is not established.

To specify a bandwidth value for a signaled LSP, include the bandwidth statement:

```
bandwidth bps;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Automatic Bandwidth Allocation for LSPs

Automatic bandwidth allocation allows an MPLS tunnel to automatically adjust its bandwidth allocation based on the volume of traffic flowing through the tunnel. You can configure an LSP with minimal bandwidth; this feature can dynamically adjust the LSP's bandwidth allocation based on current traffic patterns. The bandwidth adjustments do not interrupt traffic flow through the tunnel.

You set a sampling interval on an LSP configured with automatic bandwidth allocation. The average bandwidth is monitored during this interval. At the end of the interval, an attempt is made to signal a new path for the LSP with the bandwidth allocation set to the maximum average value for the preceding

sampling interval. If the new path is successfully established and the original path is removed, the LSP is switched over to the new path. If a new path is not created, the LSP continues to use its current path until the end of the next sampling interval, when another attempt is made to establish a new path. Note that you can set minimum and maximum bandwidth values for the LSP.

During the automatic bandwidth allocation interval, the router might receive a steady increase in traffic (increasing bandwidth utilization) on an LSP, potentially causing congestion or packet loss. To prevent this, you can define a second trigger to prematurely expire the automatic bandwidth adjustment timer before the end of the current adjustment interval.

Configuring Automatic Bandwidth Allocation for LSPs

Automatic bandwidth allocation allows an MPLS tunnel to automatically adjust its bandwidth allocation based on the volume of traffic flowing through the tunnel. You can configure an LSP with minimal bandwidth, and this feature can dynamically adjust the LSP's bandwidth allocation based on current traffic patterns. The bandwidth adjustments do not interrupt traffic flow through the tunnel.

At the end of the automatic bandwidth allocation time interval, the current maximum average bandwidth usage is compared with the allocated bandwidth for the LSP. If the LSP needs more bandwidth, an attempt is made to set up a new path where bandwidth is equal to the current maximum average usage. If the attempt is successful, the LSP's traffic is routed through the new path and the old path is removed. If the attempt fails, the LSP continues to use its current path.

NOTE: In calculating the value for `Max AvgBW` (relative to the ingress LSP), the sample collected during make before break (MBB) is ignored to prevent inaccurate results. The first sample after a bandwidth adjustment, or after a change in the LSP ID (regardless of path change), is also ignored.

If you have configured link and node protection for the LSP and traffic has been switched to the bypass LSP, the automatic bandwidth allocation feature continues to operate and take bandwidth samples from the bypass LSP. For the first bandwidth adjustment cycle, the maximum average bandwidth usage taken from the original link and node-protected LSP is used to resignal the bypass LSP if more bandwidth is needed. (Link and node protection are not supported on QFX Series switches.)

If you have configured fast-reroute for the LSP, you might not be able to use this feature to adjust the bandwidth. Because the LSPs use a fixed filter (FF) reservation style, when a new path is signaled, the bandwidth might be double-counted. Double-counting can prevent a fast-reroute LSP from ever adjusting its bandwidth when automatic bandwidth allocation is enabled. (Fast reroute is not supported on QFX Series switches.)

To configure automatic bandwidth allocation, complete the steps in the following sections:

NOTE: On the QFX10000 switches, you can only configure automatic bandwidth allocation at the `edit protocols mpls` hierarchy level. Logical systems are not supported.

Configuring Optimized Auto-bandwidth Adjustments for MPLS LSPs

Auto-bandwidth functionality enables the RSVP-TE LSPs, either directly configured or automatically created using auto-mesh, to re-size based on the traffic rate. The traffic rate carried on each LSP is measured by periodically collecting samples of the traffic rate. The frequency of traffic statistics collection is controlled through the `adjust-interval` configuration statement. The minimum configurable value of `adjust-interval` is one second. The re-sizing of the LSPs is called adjustment and the frequency of adjustments is controlled through the `adjust-interval` statement.

Starting in Junos OS Release 20.4R1, the minimum `adjust-interval` for an `auto-bandwidth` adjustment is decreased to 150 seconds if the `adjust-threshold-overflow-limit` or `adjust-threshold-underflow-limit` statements cross the configured overflow or underflow threshold values.

However, the minimum `adjust-interval` for an `auto-bandwidth` adjustment is 300 seconds if no overflow or underflow sample is detected.

In releases earlier than Junos OS Release 20.4R1, the `adjust-interval` is 300 seconds under overflow or underflow conditions.

With the implementation of auto-bandwidth adjustment optimization, the `auto-bandwidth` decreases the bandwidth of the LSP faster. The ingress label edge router (LER) is able to resize within 150 seconds because of the reduction in `adjust-threshold-overflow-limit`, provided the tear down of an old LSP instance post make-before-break (MBB) is accomplished within 150 seconds.

The requirements for auto-bandwidth optmization are:

- Reduce the probability of LSP route change—This is to reduce the probability of LSP route change when an auto-bandwidth adjustment occurs.
- Reduce the probability of LSP reroute—This is to reduce the probability of the LSP reroute because of the higher priority LSPs that demand the same resource.

In order to fulfil these requirements, the auto-bandwidth adjustments optimization supports the following:

1. **In-place LSP Bandwidth Update**—Enables the ingress label edge router (LER) to re-use the LSP ID when performing bandwidth change on an intra-domain LSP.

NOTE: In-place LSP bandwidth update is not applicable for an inter-domain LSP.

In certain scenarios, the LSP route next hop carries the LSP bandwidth either directly or indirectly. Even though in-place LSP bandwidth update is supported in these scenarios, the performance improvement from the functionality is limited because of the LSP route change. That is, because of the change in the inet.3 route table after "auto-bandwidth (MPLS Tunnel)" on page 2411. For example, performance enhancement is limited when you configure either or both the statements:

- `auto-policing` configured under MPLS.
- The option `bandwidth` under the statement `load-balance` configured under RSVP.

NOTE: In-place LSP bandwidth update through LSP-ID re-use fails and the ingress LER immediately triggers MBB with a new LSP-ID if:

- `no-cspf` is configured for the LSP.
- LSP is controlled by the Path Computation Element (PCE).
- LSP optimization timer fires.
- `clear mpls lsp optimize-aggressive` command is executed.

2. **Per-priority Subscription**—In order to utilize the network resources more efficiently, per-priority subscription enables you to configure a lower RSVP subscription percentage for LSPs of lower priorities and higher RSVP subscription percentage for LSPs of higher priorities.

   For example, instead of setting RSVP subscription percentage as 90% for LSPs for all priorities, you can configure a lower RSVP subscription percentage (say 75%) for LSPs of lower priorities

NOTE: Per-priority subscription does not interoperate with Differentiated Services (DiffServ)-aware traffic engineering (TE). Differentiated Services (DiffServ)-aware traffic engineering offers more flexible and statistical sharing of TE link bandwidth than per-priority subscription.

To Configure In-place LSP Auto-bandwidth Resizing:

1. Configure the device interface to enable MPLS.

```
[edit]
user@host# set interfaces interface-name unit logical-unit-number family mpls
user@host# set protocols mpls interface et-0/0/0:1.0 unit 0 family mpls
```

2. Configure MPLS protocol on the interface.

```
[edit]
user@host# set protocols mpls interfaceinterface-name
user@host# set protocols mpls interface et-0/0/0:1.0
```

3. Configure MPLS and the LSPs and configure link protection for the LSP.

```
[edit]
user@host# set protocols mpls label-switched-path lsp-name to address
```

```
user@host# set protocols mpls label-switched-path lsp1 to 10.2.5.1
```

4. Configure `in-place-bandwidth-update` for the LSP to enable automatic bandwidth LSP resizing.

```
[edit]
user@host# set protocols mpls label-switched-path lsp-name in-place-lsp-bandwidth-update
```

```
user@host# set protocols mpls label-switched-path lsp1 in-place-lsp-bandwidth-update
```

5. Enter commit from the configuration mode.

Verification

From configuration mode, confirm your configuration by entering the, `show protocols show interfaces` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
interfaces {
    et-0/0/0:1 {
        unit 0 {
            family {
```

```
                    mpls;
                }
            }
        }
        }
protocols {
    mpls {
        label-switched-path lsp1 {
            to 10.2.5.1;
            in-place-lsp-bandwidth-update;
        }
    }
}
```

To Configure Per-priority Subscription:

1. Configure RSVP protocol on the interface.

```
[edit]
user@host# set protocols rsvp interfaceinterface-name
user@host# set protocols rsvp interface et-0/0/0:1.0
```

2. Configure the bandwidth subscription value for the interface. It can be a value from 0 through 65,000 percent. The default subscription value is 100 percent.

```
[edit]
user@host# set protocols rsvp interface interface-name subscription percentage
```

```
user@host# set protocols rsvp et-0/0/0:1.0 subscription 11
```

3. Configure the subscription priority over the interface.

```
[edit]
user@host# set protocols rsvp interface interface-name subscription percentage priority
```

```
user@host# set protocols rsvp et-0/0/0:1.0 subscription 11 priority 7
```

4. Configure the subscription percentage for the priority.

```
[edit]
user@host# set protocols rsvp interface interface-name subscription percentage priority
percentage
```

```
user@host# set protocols rsvp et-0/0/0:1.0 subscription 11 priority 7 percent 10
```

5. Enter commit from the configuration mode.

Verification

From configuration mode, confirm your configuration by entering the, `show protocols show interfaces` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
protocols {
    rsvp {
        interface et-0/0/0:1.0 {
            subscription 11{
            priority 7 {
            percent 10;
        }
    }
}
```

Configuring Reporting of Automatic Bandwidth Allocation Statistics for LSPs

Automatic bandwidth allocation allows an MPLS tunnel to automatically adjust its bandwidth allocation based on the volume of traffic flowing through the tunnel. You can configure the device to collect statistics related to automatic bandwidth allocation by completing the following steps:

1. To collect statistics related to automatic bandwidth allocation, configure the `auto-bandwidth` option for the `statistics` statement at the `[edit protocols mpls]` hierarchy level. These settings apply to all LSPs

configured on the router on which you have also configured the `auto-bandwidth` statement at the `[edit protocols mpls label-switched-path label-switched-path-name]` hierarchy level.

```
statistics {
    auto-bandwidth (MPLS Statistics);
    file filename <files number> <size size> <world-readable | no-world-readable>;
    interval seconds;
    no-transit-statistics;
    transit-statistics-polling;
}
```

2. Specify the *filename* for the files used to store the MPLS trace operation output using the `file` option. All files are placed in the directory **/var/log**. We recommend that you place MPLS tracing output in the file **mpls-log**.
3. Specify the maximum number of trace files using the `files number` option. When a trace file named ***trace-file*** reaches its maximum size, it is renamed ***trace-file*.0**, then ***trace-file*.1**, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.
4. Specify the interval for calculating the average bandwidth usage by configuring a time in seconds using the `interval` option. You can also set the adjustment interval on a specific LSP by configuring the `interval` option at the `[edit protocols mpls label-switch-path label-switched-path-name statistics]` hierarchy level.

   NOTE: To prevent unnecessary resignaling of LSPs, it is best to configure an LSP adjustment interval that is at least three times longer than the MPLS automatic bandwidth statistics interval. For example, if you configure a value of 30 seconds for the MPLS automatic bandwidth statistics interval (`interval` statement at the `[edit protocols mpls statistics]` hierarchy level), you should configure a value of at least 90 seconds for the LSP adjustment interval (`adjust-interval` statement at the `[edit protocols mpls label-switched-path label-switched-path-name auto-bandwidth]` hierarchy level).

5. To trace automatic bandwidth allocation, include the `autobw-state flag` for the MPLS `traceoptions` statement at the `[edit protocols mpls]` hierarchy level.

   The following configuration enables the MPLS traceoptions for automatic bandwidth allocation. The trace records are stored in a file called `auto-band-trace` (the filename is user configurable):

```
[edit protocols mpls]
traceoptions {
    file auto-band-trace size 10k files 10 world-readable;
```

```
    flag autobw-state;
}
```

6. Using the `show log` command, you can display the automatic bandwidth allocation statistics file generated when you configure the "auto-bandwidth (MPLS Statistics)" on page 2413 statement. The following shows sample log file output taken from an MPLS statistics file named `auto-band-stats` on a router configured with an LSP named `E-D`. The log file shows that LSP `E-D` is operating over its reserved bandwidth limit initially. Before `Oct 30 17:14:57`, the router triggered an automatic bandwidth adjustment (you might see two sessions for an LSP undergoing an automatic bandwidth adjustment). By `Oct 30 17:16:57`, the LSP has been reestablished at a higher bandwidth and is now shown using less than 100 percent of its `Reserved Bw` (reserved bandwidth).

```
user@host> show log auto-band-stats
E-D          (LSP ID 5, Tunnel ID 6741)          209 pkt          17094 Byte      1 pps
90 Bps Util 240.01% Reserved Bw       37 Bps

7. Issue the "show mpls lsp autobandwidth" on page 3247 command to display current information about automatic bandwidth allocation. The following shows sample output from the `show mpls lsp autobandwidth` command taken at about the same time as the log file shown previously:

```
user@host> show mpls lsp autobandwidth
Lspname               Last         Requested    Reserved     Highwater    AdjustTime
LastAdjust
                      BW           BW           BW           mark         Left
(sec)
E-D                   300bps      812.005bps  812bps      1.56801kbps 294 sec    Wed Oct 30
17:15:26 2013
```

8. Issue the `file show` command to display the MPLS trace file. You need to specify the file location and file name (the file is located in **/var/log/**. The following shows sample trace file output is taken from an MPLS trace file named `auto-band-trace.0.gz` on a router configured with an LSP named `E-D`. The trace file shows that LSP `E-D` is operating over its reserved bandwidth limit initially. At `Oct 30 17:15:26`, the router triggers an automatic bandwidth adjustment (you might see two sessions for an LSP undergoing an automatic bandwidth adjustment). By `Oct 30 17:15:57`, the LSP has been reestablished at a higher bandwidth and is now shown using less than 100 percent of its `Reserved Bw` (reserved bandwidth).

```
user@host> file show /var/log/auto-band-trace.0.gz

Configuring an LSP Across ASs

You can configure an LSP to traverse multiple areas in a network by including the `inter-domain` statement as a part of the LSP configuration. This statement allows the router to search for routes in the IGP

database. You need to configure this statement on routers that might be unable to locate a path using intra-domain CSPF (by looking in the traffic engineering database (TED)). When you configure inter-area LSPs, the `inter-domain` statement is required.

Before you begin:

- Configure the device interfaces with family MPLS.
- Configure the device router ID and autonomous system number.
- Enable MPLS and RSVP on the router and transit interfaces.
- Configure your IGP to support traffic engineering.
- Set up an LSP from the ingress to the egress router.

To configure an LSP across multiple ASs on the ingress label-switched router (LER):

1. Enable MPLS on all the interfaces (excluding the management interface).

```
[edit protocols]
user@LER# set mpls interface all
user@LER# set mpls interface fxp0.0 disable
```

2. Enable RSVP on all the interfaces (excluding the management interface).

```
[edit protocols]
user@LER# set rsvp interface all
user@LER# set rsvp interface fxp0.0 disable
```

3. Configure the inter-area LSP.

```
[edit protocols]
user@LER# set mpls label-switched-path inter-area-LSP-name to egress-LER-ip-address
user@LER# set mpls label-switched-path inter-area-LSP-name inter-domain
```

4. Verify and commit the configuration.

```
[edit protocols]
user@LER# set rsvp interface ge-0/0/0.0
user@LER# set rsvp interface lo0.0
user@LER# set rsvp interface fxp0.0 disable
user@LER# set mpls statistics traffic-class-statistics
```

```
user@LER# set mpls label-switched-path R1-R2 to 20.0.0.1
user@LER# set mpls label-switched-path R1-R2 inter-domain
user@LER# set mpls interface ge-0/0/0.0
user@LER# set mpls interface lo0.0
user@LER# set mpls interface fxp0.0 disable
user@LER# set ospf traffic-engineering
user@LER# set ospf area 0.0.0.0 interface ge-0/0/0.0
user@LER# set ospf area 0.0.0.0 interface lo0.0
```

Damping Advertisement of LSP State Changes

When an LSP changes from being up to being down, or from down to up, this transition takes effect immediately in the router software and hardware. However, when advertising LSPs into IS-IS and OSPF, you may want to damp LSP transitions, thereby not advertising the transition until a certain period of time has transpired (known as the hold time). In this case, if the LSP goes from up to down, the LSP is not advertised as being down until it has remained down for the hold-time period. Transitions from down to up are advertised into IS-IS and OSPF immediately. Note that LSP damping affects only the IS-IS and OSPF advertisements of the LSP; other routing software and hardware react immediately to LSP transitions.

To damp LSP transitions, include the `advertisement-hold-time` statement:

```
advertisement-hold-time seconds;
```

seconds can be a value from 0 through 65,535 seconds. The default is 5 seconds.

You can include this statement at the following hierarchy levels:

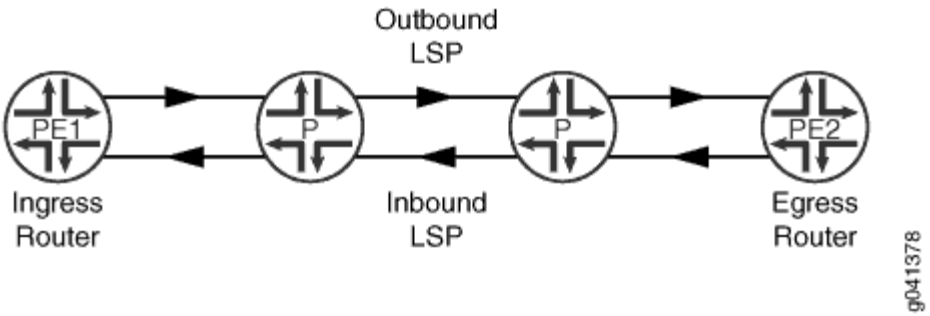
- `[edit protocols mpls]`
- `[edit logical-systems logical-system-name protocols mpls]`

Configuring Corouted Bidirectional LSPs

A corouted bidirectional packet LSP is a combination of two LSPs sharing the same path between a pair of ingress and egress nodes, as shown in Figure 41 on page 623. It is established using the GMPLS extensions to RSVP-TE. This type of LSP can be used to carry any of the standard types of MPLS-based traffic, including Layer 2 VPNs, Layer 2 circuits, and Layer 3 VPNs. You can configure a single BFD session for the bidirectional LSP (you do not need to configure a BFD session for each LSP in each direction). You can also configure a single standby bidirectional LSP to provide a backup for the primary bidirectional LSP. Corouted bidirectional LSPs are supported for both penultimate hop popping (PHP) and ultimate hop popping (UHP).

High availability is available for bidirectional LSPs. You can enable graceful restart and nonstop active routing. Graceful restart and nonstop active routing are supported when the restarting router is the ingress, egress, or transit router for the bidirectional LSP.

Figure 41: Corouted Bidirectional LSP



To configure a corouted bidirectional LSP:

1. In configuration mode, configure the ingress router for the LSP and include the `corouted-bidirectional` statement to specify that the LSP be established as a corouted bidirectional LSP.

   The path is computed using CSPF and initiated using RSVP signaling (just like a unidirectional RSVP signaled LSP). Both the path to the egress router and the reverse path from the egress router are created when this configuration is committed.

   ```
   [edit protocols mpls]
   user@PE1# set label-switched-path sample-lsp corouted-bidirectional
   ```

2. (Optional) For a reverse path, configure an LSP on the egress router and include the `corouted-bidirectional-passive` statement to associate the LSP with another LSP.

   No path computation or signaling is used for this LSP since it relies on the path computation and signaling provided by the ingress LSP. You cannot configure both the `corouted-bidirectional` statement and the `corouted-bidirectional-passive` statement on the same LSP.

   ```
   [edit protocols mpls]
   user@PE1# set label-switched-path sample-lsp-reverse-path corouted-bidirectional-passive
   ```

   This statement also makes it easier to debug corouted bidirectional LSPs. If you configure the `corouted-bidirectional-passive` statement (again, on the egress router), you can issue `ping mpls lsp-end-point`, `ping mpls ldp`, `ping mpls rsvp`, `traceroute mpls ldp`, and `traceroute mpls rsvp` commands to test the corouted bidirectional LSP from the egress router.

3. Use the `show mpls lsp extensive` and the `show rsvp session extensive` commands to display information about the bidirectional LSP.

   The following shows output for the `show rsvp session extensive` command when run on an ingress router with a bidirectional LSP configured:

```
user@PE1> show rsvp session extensive
Ingress RSVP: 2 sessions

Configuring the Entropy Label for LSPs

The insertion of entropy labels for an LSP enables transit routers to load-balance MPLS traffic across ECMP paths or Link Aggregation groups using just the MPLS label stack as a hash input without having to rely on deep packet inspection. Deep packet inspection requires more of the router's processing power and different routers have differing deep-packet inspection capabilities.

To configure the entropy label for an LSP, complete the following steps:

1. On the ingress router, include the `entropy-label` statement at the `[edit protocols mpls labeled-switched-path` *`labeled-switched-path-name`*`]` hierarchy level or at the `[edit protocols mpls static-labeled-switched-path` *`labeled-switched-path-name`* `ingress]` hierarchy level. The entropy label is added to the MPLS label stack and can be processed in the forwarding plane.

```
entropy-label;
```

NOTE: This is only applicable for RSVP and static LSPs.

2. On the ingress router, you can configure an ingress policy for LDP-signaled LSPs:

```
entropy-label {
    ingress-policy policy-name;
}
```

Configure the ingress policy at the `[edit policy-options]` hierarchy level:

```
policy-options {
    policy-statement policy-name {
        term term-name {
            from {
                prefix-list prefix-list-name;
            }
            then actions;
        }
    }
}
```

The following shows an example of an entropy label ingress policy.

```
policy-options {
    policy-statement entropy-policy {
        term no-insert-entropy-label {
            from {
                prefix-list no-entropy-label-fec;
            }
            then accept;
        }
    }
}
```

3. (Optional) By default, routers that support the pushing and popping of entropy labels are configured with the `load-balance-label-capability` statement at the `[edit forwarding-options]` hierarchy level to signal the labels on a per-LSP basis. If the peer router is not equipped to handle load-balancing labels, you can prevent the provider edge (PE) router from signaling the entropy label capability by configuring the `no-load-balance-label-capability` statement at the `[edit forwarding-options]` hierarchy level.

```
[edit forwarding-options]
user@PE no-load-balance-label-capability;
```

Transit routers require no configuration. The presence of the entropy label indicates to the transit router to load balance based solely on the MPLS label stack.

Penultimate hop routers pop the entropy label by default.

Example: Configuring an Entropy Label for a BGP Labeled Unicast LSP

IN THIS SECTION

- Requirements | 627
- Overview | 628
- Configuration | 629
- Verification | 648

This example shows how to configure an entropy label for a BGP labeled unicast to achieve end-to-end load balancing using entropy labels. When an IP packet has multiple paths to reach its destination, Junos OS uses certain fields of the packet headers to hash the packet to a deterministic path. This requires an entropy label, a special load-balancing label that can carry the flow information. LSRs in the core simply use the entropy label as the key to hash the packet to the correct path. An entropy label can be any label value between 16 to 1048575 (regular 20-bit label range). Since this range overlaps with the existing regular label range, a special label called entropy label indicator (ELI) is inserted before the entropy label. ELI is a special label assigned by IANA with the value of 7.

BGP labeled unicasts generally concatenate RSVP or LDP LSPs across multiple IGP areas or multiple autonomous systems. RSVP or LDP entropy labels are popped at the penultimate hop node, together with the RSVP or LDP label. This feature enables the use of entropy labels at the stitching points to bridge the gap between the penultimate hop node and the stitching point, in order to achieve end-to-end entropy label load balancing for BGP traffic.

Requirements

This example uses the following hardware and software components:

- Seven MX Series routers with MPCs
- Junos OS Release 15.1 or later running on all the devices

Before you configure an entropy label for BGP labeled unicast, make sure you:

1. Configure the device interfaces.
2. Configure OSPF or any other IGP protocol.
3. Configure BGP.
4. Configure RSVP.

5. Configure MPLS.

Overview

IN THIS SECTION

- Topology | 629

When BGP labeled unicasts concatenate RSVP or LDP LSPs across multiple IGP areas or multiple autonomous systems, RSVP or LDP entropy labels are popped at the penultimate hop node, together with the RSVP or LDP label. However, there are no entropy labels at the stitching points, that is, the routers between two areas. Therefore, the routers at the stitching points used the BGP labels to forward packets.

Beginning with Junos OS Release 15.1, you can configure an entropy label for BGP labeled unicast to achieve end-to-end entropy label load balancing. This feature enables the use of an entropy label at the stitching points in order to achieve end-to-end entropy label load balancing for BGP traffic. Junos OS allows the insertion of entropy labels at the BGP labeled unicast LSP ingress.

By default, routers that support entropy labels are configured with the `load-balance-label-capability` statement at the `[edit forwarding-options]` hierarchy level to signal the labels on a per-LSP basis. If the peer router is not equipped to handle load-balancing labels, you can prevent the signaling of entropy label capability by configuring the `no-load-balance-label-capability` at the `[edit forwarding-options]` hierarchy level.

```
[edit forwarding-options]
user@PE# no-load-balance-label-capability
```

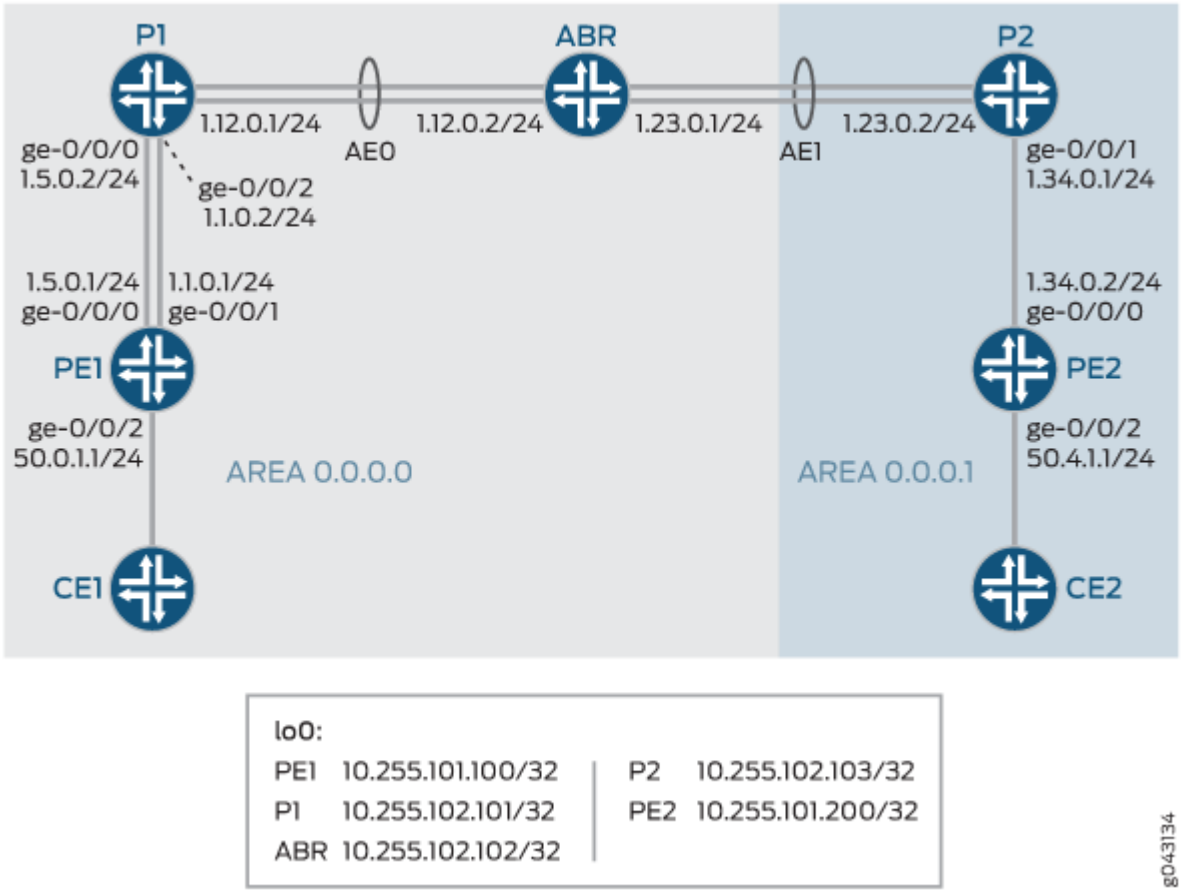
NOTE: You can explicitly disable advertising entropy label capability at egress for routes specified in the policy with the `no-entropy-label-capability` option at the `[edit policy-options` *`policy-statement policy name`* `then]` hierarchy level.

```
[edit policy-options policy-statement policy-name then]
user@PE# no-entropy-label-capability
```

Topology

In Figure 42 on page 629 , Router PE1 is the ingress router and Router PE2 is the egress router. Routers P1 and P2 are the transit routers. Router ABR is the area bridge router between Area 0 and Area 1. LAG is configured on the provider routers for load balancing the traffic. Entropy label capability for BGP labeled unicast is enabled on the ingress Router PE1.

Figure 42: Configuring an Entropy Label for BGP Labeled Unicast



Configuration

IN THIS SECTION

- Configuring Router PE1 | 635
- Configuring Router P1 | 639
- Configuring Router ABR | 642
- Results | 644

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter `commit` from configuration mode.

Router PE1

```

Configuring Router PE1

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the CLI User Guide.

To configure Router PE1:

NOTE: Repeat this procedure for Router PE2 after modifying the appropriate interface names, addresses, and other parameters.

1. Configure the interfaces with IPv4 and IPv6 addresses.

```
[edit interfaces]
user@PE1# set ge-0/0/0 unit 0 family inet address 1.5.0.1/24
user@PE1# set ge-0/0/0 unit 0 family iso
user@PE1# set ge-0/0/0 unit 0 family inet6 address 2000::1:5:0:1/120
user@PE1# set ge-0/0/0 unit 0 family mpls
user@PE1# set ge-0/0/1 unit 0 family inet address 1.1.0.1/24
user@PE1# set ge-0/0/1 unit 0 family iso
user@PE1# set ge-0/0/1 unit 0 family inet6 address 2000::1:1:0:1/120
user@PE1# set ge-0/0/1 unit 0 family mpls
user@PE1# set ge-0/0/2 unit 0 family inet address 50.0.1.1/24
user@PE1# set ge-0/0/2 unit 0 family inet6 address 2000::1:34:0:2/120
user@PE1# set ge-0/0/3 vlan-tagging
```

```
user@PE1# set ge-0/0/3 unit 0 vlan-id 520
user@PE1# set ge-0/0/3 unit 0 family inet address 1.0.0.2/16
```

2. Configure the loopback interface.

```
[edit interfaces]
user@PE1# set lo0 unit 0 family inet address 10.255.101.100/32 primary
```

3. Set the router ID and the autonomous system number.

```
[edit routing-options]
user@PE1# set router-id 10.255.101.100
user@PE1# set autonomous-system 1
```

4. Configure RSVP protocol for all interfaces.

```
[edit protocols]
user@PE1# set protocols rsvp interface all
```

5. Enable MPLS on all the interfaces of Router PE1 and specify the LSP.

```
[edit protocols]
user@PE1# set mpls icmp-tunneling
user@PE1# set mpls no-cspf
user@PE1# set mpls label-switched-path r0-r2 to 10.255.102.102
user@PE1# set mpls label-switched-path r0-r2 entropy-label
user@PE1# set mpls interface all
```

6. Configure IBGP on the internal routers.

```
[edit protocols]
user@PE1# set bgp group ibgp type internal
user@PE1# set bgp group ibgp local-address 10.255.101.100
```

7. Enable entropy label capability for BGP labeled unicast for internal BGP group ibgp.

```
user@PE1# set bgp group ibgp family inet labeled-unicast entropy-label
user@PE1# set bgp group ibgp neighbor 10.255.102.102 family inet labeled-unicast rib inet.3
user@PE1# set bgp group ibgp neighbor 10.255.101.200 family inet-vpn unicast
```

8. Enable the OSPF protocol on all the interfaces of the area border router (ABR).

```
[edit protocols]
user@PE1# set ospf traffic-engineering
user@PE1# set ospf area 0.0.0.0 interface all
user@PE1# set ospf area 0.0.0.0 interface fxp0.0 disable
user@PE1# set ospf area 0.0.0.0 interface lo0.0 passive
```

9. Define prefix lists to specify the routes with entropy label capability.

```
[edit policy-options ]
user@PE1# set policy-options prefix-list el-fec 10.255.101.200/32
user@PE1# set policy-options prefix-list el-fec-2 10.255.102.102/32
```

10. Define a policy EL to specify the routes with entropy label capability.

```
[edit policy-options ]
user@PE1# set policy-statement EL from prefix-list el-fec
user@PE1# set policy-statement EL then accept
```

11. Define another policy EL-2 to specify the routes with entropy label capability.

```
[edit policy-options ]
user@PE1# set policy-statement EL-2 from prefix-list el-fec-2
user@PE1# set policy-statement EL-2 then accept
```

12. Define a policy to export BGP routes to the OSPF routing table.

```
[edit policy-options ]
user@PE1# set policy-statement bgp-to-ospf from protocol bgp
user@PE1# set policy-statement bgp-to-ospf then accept
```

13. Define a policy to export OSPF routes to the BGP routing table.

```
[edit policy-options ]
user@PE1# set policy-statement ospf-to-bgp from protocol ospf
user@PE1# set policy-statement ospf-to-bgp then accept
```

14. Define a policy to export static routes to the BGP routing table.

```
[edit policy-options ]
user@PE1# set policy-statement stat-to-bgp from protocol static
user@PE1# set policy-statement stat-to-bgp then accept
```

15. Configure a VPN target for the VPN community.

```
[edit policy-options ]
user@PE1# set community VPN members target:100:1
```

16. Configure the Layer 3 VPN routing instance VPN-l3vpn.

```
[edit routing-instances]
user@PE1# set VPN-l3vpn instance-type vrf
```

17. Assign the interfaces for the VPN-l3vpn routing instance.

```
[edit routing-instances]
user@PE1# set VPN-l3vpn interface ge-0/0/2.0
user@PE1# set VPN-l3vpn interface ge-0/0/3.0
```

18. Configure the route distinguisher for the VPN-l3vpn routing instance.

```
[edit routing-instances]
user@PE1# set VPN-l3vpn route-distinguisher 100.100.100.100:100
```

19. Configure a VPN routing and forwarding (VRF) target for the VPN-l3vpn routing instance.

```
[edit routing-instances]
user@PE1# set VPN-l3vpn vrf-target target:100:1
```

20. Configure a static route to Device CE1 using the Layer 3 VPN protocol for the VPN-l3vpn routing instance.

```
[edit routing-instances]
user@PE1# set VPN-l3vpn routing-options static route 5.0.0.0/16 next-hop 1.0.0.1
```

21. Export the BGP routes to the OSPF routing table for the VPN-l3vpn routing instance.

```
[edit routing-instances]
user@PE1# set VPN-l3vpn protocols ospf export bgp-to-ospf
```

22. Assign the OSPF interface for the VPN-l3vpn routing instance.

```
[edit routing-instances]
user@PE1# set VPN-l3vpn protocols ospf area 0.0.0.0 interface ge-0/0/2.0
```

Configuring Router P1

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the CLI User Guide.

To configure Router P1:

NOTE: Repeat this procedure for Router P2 after modifying the appropriate interface names, addresses, and other parameters.

1. Configure the interfaces with IPv4 and IPv6 addresses.

```
[edit interfaces]
user@P1# set ge-0/0/0 unit 0 family inet address 1.5.0.2/24
user@P1# set ge-0/0/0 unit 0 family iso
user@P1# set ge-0/0/0 unit 0 family inet6 address 2000::1:5:0:2/120
user@P1# set ge-0/0/0 unit 0 family mpls
user@P1# set ge-0/0/2 unit 0 family inet address 1.1.0.2/24
user@P1# set ge-0/0/2 unit 0 family iso
user@P1# set ge-0/0/2 unit 0 family inet6 address 2000::1:1:0:2/120
user@P1# set ge-0/0/2 unit 0 family mpls
user@P1# set ge-0/0/1 gigether-options 802.3ad ae0
user@P1# set ge-0/0/3 gigether-options 802.3ad ae0
```

2. Configure link aggregation on the interfaces.

```
user@P1# set ae0 unit 0 family inet address 1.12.0.1/24
user@P1# set ae0 unit 0 family mpls
```

3. Configure the loopback interface.

```
[edit interfaces]
user@P1# set lo0 unit 0 family inet address 10.255.102.101/32 primary
```

4. Configure MPLS labels that the router uses for hashing the packets to its destination for load balancing.

```
[edit forwarding-options]
user@P1# set hash-key family mpls label-1
user@P1# set hash-key family mpls label-2
user@P1# set hash-key family mpls label-3
user@P1# set enhanced-hash-key family mpls no-payload
```

5. Set the router ID and the autonomous system number.

```
[edit routing-options]
user@P1# set router-id 10.255.102.101
user@P1# set autonomous-system 1
```

6. Enable per packet load balancing.

```
[edit routing-options]
user@P1# set forwarding-table export pplb
```

7. Configure the RSVP protocol for all interfaces.

```
[edit protocols]
user@P1# set protocols rsvp interface all
```

8. Enable MPLS on all the interfaces of Router P1 and specify the LSP.

```
[edit protocols]
user@P1# set protocols mpls icmp-tunneling
user@P1# set protocols mpls interface all
```

9. Enable the OSPF protocol on all the interfaces of Router P1 excluding the management interface.

```
[edit protocols]
user@P1# set protocols ospf traffic-engineering
user@P1# set protocols ospf area 0.0.0.0 interface lo0.0 passive
user@P1# set protocols ospf area 0.0.0.0 interface fxp0.0 disable
user@P1# set protocols ospf area 0.0.0.0 interface all
user@P1# set protocols ospf area 0.0.0.0 interface ge-0/0/3.0
user@P1# set protocols ospf area 0.0.0.0 interface ge-0/0/1.0
```

10. Define a policy for per packet load balancing.

```
[edit policy-options]]
user@P1# set policy-statement pplb then load-balance per-packet
```

Configuring Router ABR

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the CLI User Guide.

To configure Router ABR:

1. Configure the interfaces with IPv4 and IPv6 addresses.

```
[edit interfaces]
user@ABR# set ge-0/0/0 gigether-options 802.3ad ae0
user@ABR# set ge-0/0/1 gigether-options 802.3ad ae1
user@ABR# set ge-0/0/2 gigether-options 802.3ad ae0
user@ABR# set ge-0/0/3 gigether-options 802.3ad ae1
```

2. Configure the loopback interface.

```
[edit interfaces]
user@ABR# set lo0 unit 0 family inet address 10.255.102.102/32 primary
```

3. Configure link aggregation on the interfaces.

```
[edit interfaces]
user@ABR# set ae0 unit 0 family inet address 1.12.0.2/24
user@ABR# set ae0 unit 0 family mpls
user@ABR# set ae1 unit 0 family inet address 1.23.0.1/24
user@ABR# set ae1 unit 0 family mpls
```

4. Configure MPLS labels that the router uses for hashing the packets to its destination for load balancing.

```
[edit forwarding-options]
user@ABR# set hash-key family mpls label-1
user@ABR# set hash-key family mpls label-2
user@ABR# set hash-key family mpls label-3
user@ABR# set enhanced-hash-key family mpls no-payload
```

5. Set the router ID and the autonomous system number.

```
[edit routing-options]
user@ABR# set router-id 10.255.102.102
user@ABR# set autonomous-system 1
```

6. Enable per packet load balancing.

```
[edit routing-options]
user@ABR# set forwarding-table export pplb
```

7. Configure the RSVP protocol for all interfaces.

```
[edit protocols]
user@ABR# set protocols rsvp interface all
```

8. Enable MPLS on all the interfaces of Router P1 and specify the LSP.

```
[edit protocols]
user@ABR# set mpls icmp-tunneling
user@ABR# set mpls label-switched-path r2-r0 to 10.255.101.100
user@ABR# set mpls label-switched-path r2-r0 entropy-label
user@ABR# set mpls label-switched-path r2-r4 to 10.255.101.200
user@ABR# set mpls label-switched-path r2-r4 entropy-label
user@ABR# set mpls interface all
```

9. Configure IBGP on the internal routers.

```
[edit protocols ]
user@ABR# set bgp group ibgp type internal
user@ABR# set bgp group ibgp local-address 10.255.102.102
user@ABR# set bgp group ibgp family inet labeled-unicast rib inet.3
user@ABR# set bgp group ibgp neighbor 10.255.101.100 export send-inet3-R4
user@ABR# set bgp group ibgp neighbor 10.255.101.200 export send-inet3-R0
```

10. Enable the OSPF protocol on all the interfaces of ABR.

```
[edit protocols ]
user@ABR# set ospf traffic-engineering
user@ABR# set ospf area 0.0.0.0 interface lo0.0 passive
user@ABR# set ospf area 0.0.0.0 interface ge-0/0/2.0
user@ABR# set ospf area 0.0.0.0 interface ge-0/0/0.0
user@ABR# set ospf area 0.0.0.0 interface ae0.0
user@ABR# set ospf area 0.0.0.0 interface fxp0.0 disable
user@ABR# set ospf area 0.0.0.1 interface ge-0/0/3.0
user@ABR# set ospf area 0.0.0.1 interface ge-0/0/1.0
user@ABR# set ospf area 0.0.0.1 interface ae1.0
```

11. Define a policy to specify the routes with entropy label capability.

```
[edit policy-options ]
user@ABR# set policy-statement pplb then load-balance per-packet
user@ABR# set policy-statement send-inet3-R0 from route-filter 10.255.101.100/32 exact
user@ABR# set policy-statement send-inet3-R0 then accept
user@ABR# set policy-statement send-inet3-R4 from route-filter 10.255.101.200/32 exact
user@ABR# set policy-statement send-inet3-R4 then accept
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show routing-options**, **show forwarding options**, and **show policy-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

Verification

IN THIS SECTION

- Verifying That the Entropy Label Capability Is Being Advertised from Router PE2 | **648**
- Verifying That Router ABR Receives the Entropy Label Advertisement | **649**
- Verifying That the Entropy Label Flag Is Set | **651**

Confirm that the configuration is working properly.

Verifying That the Entropy Label Capability Is Being Advertised from Router PE2

Purpose

Verify that the entropy label capability path attribute is being advertised from the upstream Router PE2 at egress.

Action

From operational mode, run the **show route 10.255.101.200 advertising-protocol bgp 10.255.102.102** command on Router PE2.

```
user@PE2> show route 10.255.101.200 advertising-protocol bgp 10.255.102.102
```

```
inet.3: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)
* 10.255.101.200/32 (1 entry, 1 announced)
 BGP group ibgp type Internal
     Route Label: 299920
     Nexthop: Self
     Flags: Nexthop Change
     MED: 2
     Localpref: 4294967294
     AS path: [1] I
     Entropy label capable
```

Meaning

The output shows that the host PE2 with the IP address of 10.255.101.200 has the entropy label capability. The host is advertising the entropy label capability to its BGP neighbors.

Verifying That Router ABR Receives the Entropy Label Advertisement

Purpose

Verify that Router ABR receives the entropy label advertisement at ingress from Router PE2.

Action

From operational mode, run the **show route 10.255.101.200 receiving-protocol bgp 10.255.101.200** command on Router ABR.

```
user@ABR> show route 10.255.101.200 receiving-protocol bgp 10.255.101.200
inet.0: 63 destinations, 63 routes (63 active, 0 holddown, 0 hidden)

VPN-l3vpn.inet.0: 8 destinations, 8 routes (8 active, 0 holddown, 0 hidden)
```

Meaning

Router ABR receives the entropy label capability advertisement from its BGP neighbor PE2.

Verifying That the Entropy Label Flag Is Set

Purpose

Verify that the entropy label flag is set for the label elements at the ingress.

Action

From operational mode, run the **show route protocol bgp detail** command on Router PE1.

```
user@PE1> show route protocol bgp detail
inet.0: 64 destinations, 64 routes (64 active, 0 holddown, 0 hidden)

inet.3: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)

VPN-l3vpn.inet.0: 8 destinations, 8 routes (8 active, 0 holddown, 0 hidden)
```

Meaning

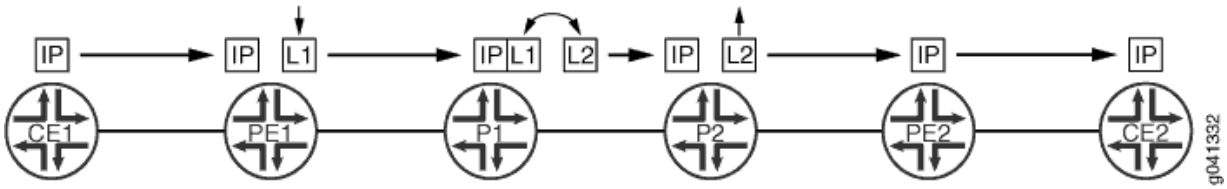
An entropy label is enabled on Router PE1. The output shows that the entropy label is being used for the BGP labeled unicast to achieve end-to-end load balancing.

Configuring Ultimate-Hop Popping for LSPs

By default, RSVP-signaled LSPs use penultimate-hop popping (*PHP*). Figure 43 on page 653 illustrates a penultimate-hop popping LSP between Router PE1 and Router PE2. Router CE1 forwards a packet to its next hop (Router PE1), which is also the LSP ingress. Router PE1 pushes label 1 on the packet and forwards the labeled packet to Router P1. Router P1 completes the standard MPLS label swapping operation, swapping label 1 for label 2, and forwards the packet to Router P2. Since Router P2 is the penultimate-hop router for the LSP to Router PE2, it first pops the label and then forwards the packet to

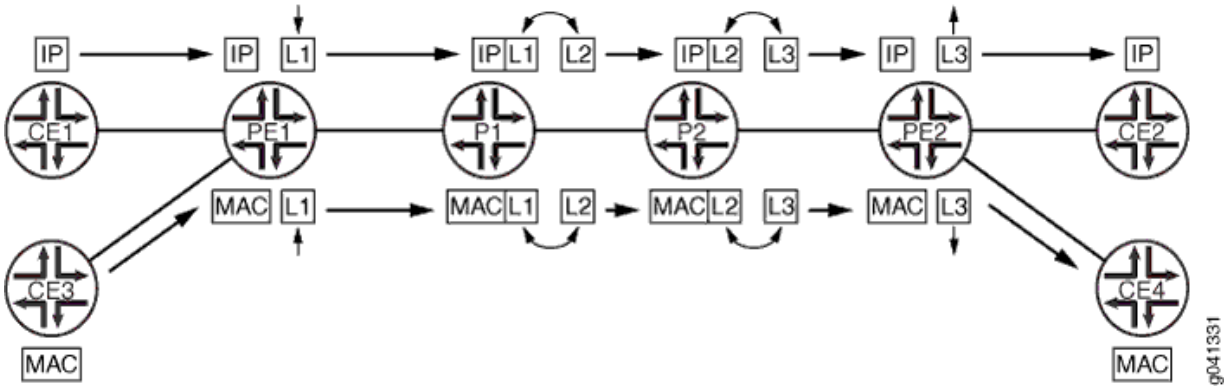
Router PE2. When Router PE2 receives it, the packet can have a service label, an explicit-null label, or just be a plain IP or VPLS packet. Router PE2 forwards the unlabeled packet to Router CE2.

Figure 43: Penultimate-Hop Popping for an LSP



You can also configure ultimate-hop popping (*UHP*) (as shown in Figure 44 on page 653) for RSVP-signaled LSPs. Some network applications can require that packets arrive at the egress router (Router PE2) with a non-null outer label. For an ultimate- hop popping LSP, the penultimate router (Router P2 in Figure 44 on page 653) performs the standard MPLS label swapping operation (in this example, label 2 for label 3) before forwarding the packet to egress Router PE2. Router PE2 pops the outer label and performs a second lookup of the packet address to determine the end destination. It then forwards the packet to the appropriate destination (either Router CE2 or Router CE4).

Figure 44: Ultimate-Hop Popping for an LSP



The following network applications require that you configure UHP LSPs:

- MPLS-TP for performance monitoring and in-band *OAM*
- Edge protection virtual circuits

The following features do not support the UHP behavior:

- LDP-signaled LSPs
- Static LSPs

- Point-to-multipoint LSPs
- CCC
- `traceroute` command

For more information about UHP behavior, see Internet draft draft-ietf-mpls-rsvp-te-no-php-oob-mapping-01.txt, *Non PHP behavior and Out-of-Band Mapping for RSVP-TE LSPs*.

For point-to-point RSVP-signaled LSPs, UHP behavior is signaled from the LSP ingress. Based on the ingress router configuration, RSVP can signal the UHP LSP with the non-PHP flag set. RSVP PATH messages carry the two flags in the LSP-ATTRIBUTES object. When the egress router receives the PATH message, it assigns a non-null label to the LSP. RSVP also creates and installs two routes in the mpls.0 routing table. S refers to the S bit of the MPLS label, which indicates whether or not the bottom of the label stack has been reached.

- Route S=0—Indicates that there are more labels in the stack. The next hop for this route points to the mpls.0 routing table, triggering a chained MPLS label lookup to discover the remaining MPLS labels in the stack.
- Route S=1—Indicates that there are no more labels. The next hop points to the inet.0 routing table if the platform supports chained and multi-family lookup. Alternatively, the label route can point to a *VT* interface to initiate IP forwarding.

If you enable UHP LSPs, MPLS applications such as Layer 3 VPNs, VPLS, Layer 2 VPNs, and Layer 2 circuits can use the UHP LSPs. The following explains how UHP LSPs affect the different types of MPLS applications:

- Layer 2 VPNs and Layer 2 circuits—A packet arrives at the PE router (egress of the UHP LSP) with two labels. The outer label (S=0) is the UHP label, and the inner label (S=1) is the *VC* label. A lookup based on the transport label results in a table handle for the mpls.0 routing table. There is an additional route in the mpls.0 routing table corresponding to the inner label. A lookup based on the inner label results in the CE router next hop.
- Layer 3 VPN—A packet arrives at the PE router (egress of the UHP LSP) with two labels. The outer label (S=0) is the UHP label, and the inner label is the VPN label (S=1). A lookup based on the transport label results in the table handle for the mpls.0 routing table. There are two cases in this scenario. By default, Layer 3 VPNs advertise the per-next hop label. A lookup based on the inner label results in the next hop toward the CE router. However, if you have configured the `vrf-table-label` statement for the Layer 3 VPN routing instance, the inner *LSI* label points to the VRF routing table. An IP lookup is also completed for the VRF routing table.

  NOTE: UHP for Layer 3 VPNs configured with the `vrf-table-label` statement is supported on MX Series 5G Universal Routing Platforms only.

- VPLS—A packet arrives at the PE router (egress of the UHP LSP) with two labels. The outer label is the transport label (S=0) and the inner label is the VPLS label (S=1). A lookup based on the transport label results in the table handle for the mpls.0 routing table. A lookup based on the inner label in mpls.0 routing table results in the LSI tunnel interface of the VPLS routing instance if tunnel-services is not configured (or a VT interface not available). MX 3D Series routers support chained lookup and multi-family lookup.

  NOTE: UHP for VPLS configured with the `no-tunnel-service` statement is supported on MX 3D Series routers only.

- IPv4 over MPLS—A packet arrives at the PE router (egress of the UHP LSP) with one label (S=1). A lookup based on this label returns a VT tunnel interface. Another IP lookup is completed on the VT interface to determine where to forward the packet. If the routing platform supports multi-family and chained lookups (for example, MX 3D routers and PTX Series Packet Transport Routers), lookup based on label route (S=1) points to the inet.0 routing table.

- IPv6 over MPLS—For IPv6 tunneling over MPLS, PE routers advertise IPv6 routes to each other with a label value of 2. This is the explicit null label for IPv6. As a result, the forwarding next hops for IPv6 routes that are learned from remote PE routers normally push two labels. The inner label is 2 (it could be different if the advertising PE router is from another vendor), and the router label is the LSP label. Packets arrive at the PE router (egress of the UHP LSP) with two labels. The outer label is the transport label (S=0), and the inner label is the IPv6 explicit-null label (label 2). Lookup based on the inner label in the mpls.0 routing table redirects back to the mpls.0 routing table. On MX 3D Series routers, the inner label (label 2) is stripped off and an IPv6 lookup is done using the inet6.0 routing table.

- Enabling both PHP and UHP LSPs—You can configure both PHP and UHP LSPs over the same network paths. You can separate PHP and UHP traffic by selecting forwarding LSP next hops using a regular expression with the `install-nexthop` statement. You can also separate traffic by simply naming the LSPs appropriately.

The following statements enable ultimate-hop popping for an LSP. You can enable this feature on a specific LSP or for all of the ingress LSPs configured on the router. Configure these statements on the router at the LSP ingress.

1. To enable ultimate-hop popping, include the `ultimate-hop-popping` statement:

   ```
   ultimate-hop-popping;
   ```

   Include this statement at the `[edit protocols mpls label-switched-path` *`label-switched-path-name`*`]` hierarchy level to enable ultimate-hop popping on a specific LSP. Include this statement at the `[edit protocols mpls]` hierarchy level to enable ultimate-hop popping on all of the ingress LSPs configured on the

router. You can also configure the `ultimate-hop-popping` statement under the equivalent `[edit logical-routers]` hierarchy levels.

> **NOTE**: When you enable ultimate-hop popping, RSVP attempts to resignal existing LSPs as ultimate-hop popping LSPs in a make-before-break fashion. If an egress router does not support ultimate-hop popping, the existing LSP is torn down (RSVP sends a *PathTear message* along an LSP's path, removing the path state and dependent reservation state and releasing the associated networking resources).
>
> If you disable ultimate-hop popping, RSVP resignals existing LSPs as penultimate-hop popping LSPs in a make-before-break fashion.

2. If you want to enable both ultimate-hop-popping and chained next hops on MX 3D Series routers only, you also need to configure the `enhanced-ip` option for the `network-services` statement:

```
network-services enhanced-ip;
```

   You configure this statement at the `[edit chassis]` hierarchy level. Once you have configured the `network-services` statement, you need to reboot the router to enable UHP behavior.

Configuring Explicit-Path LSPs

If you disable constrained-path label-switched path (LSP) computation, as described in "Disabling Constrained-Path LSP Computation" on page 575, you can configure LSPs manually or allow the LSPs to follow the IGP path.

When explicit-path LSPs are configured, the LSP is established along the path you specified. If the path is topologically not feasible, either because the network is partitioned or insufficient resources are available along some parts of the path, the LSP will fail. No alternative paths can be used. If the setup succeeds, the LSP stays on the defined path indefinitely.

To configure an explicit-path LSP, follow these steps:

1. Configure the path information in a named path, as described in "Creating Named Paths" on page 579. To configure complete path information, specify every router hop between the ingress and egress routers, preferably using the `strict` attribute. To configure incomplete path information, specify only a subset of router hops, using the `loose` attribute in places where the path is incomplete.

   For incomplete paths, the MPLS routers complete the path by querying the local routing table. This query is done on a hop-by-hop basis, and each router can figure out only enough information to reach the next explicit hop. It might be necessary to traverse a number of routers to reach the next (loose) explicit hop.

Configuring incomplete path information creates portions of the path that depend on the current routing table, and this portion of the path can reroute itself as the topology changes. Therefore, an explicit-path LSP that contains incomplete path information is not completely fixed. These types of LSPs have only a limited ability to repair themselves, and they tend to create loops or flaps depending on the contents of the local routing table.

2. To configure the LSP and point it to the named path, use either the `primary` or `secondary` statement, as described in "Configuring Primary and Secondary LSPs" on page 663.

3. Disable constrained-path LSP computation by including the `no-cspf` statement either as part of the LSP or as part of a `primary` or `secondary` statement. For more information, see "Disabling Constrained-Path LSP Computation" on page 575.

4. Configure any other LSP properties.

Using explicit-path LSPs has the following drawbacks:

- More configuration effort is required.
- Configured path information cannot take into account dynamic network bandwidth reservation, so the LSPs tend to fail when resources become depleted.
- When an explicit-path LSP fails, you might need to manually repair it.

Because of these limitations, we recommend that you use explicit-path LSPs only in controlled situations, such as to enforce an optimized LSP placement strategy resulting from computations with an offline simulation software package.

Example: Configuring an Explicit-Path LSP

On the ingress router, create an explicit-path LSP, and specify the transit routers between the ingress and egress routers. In this configuration, no constrained-path computation is performed. For the primary path, all intermediate hops are strictly specified so that its route cannot change. The secondary path must travel through router 14.1.1.1 first, then take whatever route is available to reach the destination. The remaining route taken by the secondary path is typically the shortest path computed by the IGP.

```
[edit]
interfaces {
    so-0/0/0 {
        unit 0 {
            family mpls;
        }
    }
}
protocols {
```

```
    rsvp {
        interface so-0/0/0;

            no-cspf;  # do not perform constrained-path computation
            primary to-hastings;
            secondary alt-hastings;
        }
        interface so-0/0/0;
    }
}
```

LSP Bandwidth Oversubscription Overview

LSPs are established with bandwidth reservations configured for the maximum amount of traffic you expect to traverse the LSP. Not all LSPs carry the maximum amount of traffic over their links at all times. For example, even if the bandwidth for link A has been completely reserved, actual bandwidth might still be available but not currently in use. This excess bandwidth can be used by allowing other LSPs to also use link A, oversubscribing the link. You can oversubscribe the bandwidth configured for individual class types or specify a single value for all of the class types using an interface.

You can use oversubscription to take advantage of the statistical nature of traffic patterns and to permit higher utilization of links.

The following examples describe how you might use bandwidth oversubscription and undersubscription:

- Use oversubscription on class types where peak periods of traffic do not coincide in time.
- Use oversubscription of class types carrying best-effort traffic. You take the risk of temporarily delaying or dropping traffic in exchange for making better utilization of network resources.

- Give different degrees of oversubscription or undersubscription of traffic for the different class types. For instance, you configure the subscription for classes of traffic as follows:
  - Best effort—`ct0 1000`
  - Voice—`ct3 1`

When you undersubscribe a class type for a multiclass LSP, the total demand of all RSVP sessions is always less than the actual capacity of the class type. You can use undersubscription to limit the utilization of a class type.

The bandwidth oversubscription calculation occurs on the local router only. Because no signaling or other interaction is required from other routers in the network, the feature can be enabled on individual routers without being enabled or available on other routers which might not support this feature. Neighboring routers do not need to know about the oversubscription calculation, they rely on the IGP.

The following sections describe the types of bandwidth oversubscription available in the Junos OS:

- "LSP Size Oversubscription" on page 659
- "LSP Link Size Oversubscription" on page 659
- "Class Type Oversubscription and Local Oversubscription Multipliers" on page 659

LSP Size Oversubscription

For LSP size oversubscription, you simply configure less bandwidth than the peak rate expected for the LSP. You also might need to adjust the configuration for automatic policers. Automatic policers manage the traffic assigned to an LSP, ensuring that it does not exceed the configured bandwidth values. LSP size oversubscription requires that the LSP can exceed its configured bandwidth allocation.

Policing is still possible. However, the policer must be manually configured to account for the maximum bandwidth planned for the LSP, rather than for the configured value.

LSP Link Size Oversubscription

You can increase the maximum reservable bandwidth on the link and use the inflated values for bandwidth accounting. Use the `subscription` statement to oversubscribe the link. The configured value is applied to all class type bandwidth allocations on the link. For more information about link size oversubscription, see "Configuring the Bandwidth Subscription Percentage for LSPs" on page 660.

Class Type Oversubscription and Local Oversubscription Multipliers

Local oversubscription multipliers (LOMs) allow different oversubscription values for different class types. LOMs are useful for networks where the oversubscription ratio needs to be configured differently on different links and where oversubscription values are required for different classes. You might use this feature to oversubscribe class types handling best-effort traffic, but use no oversubscription for

class types handling voice traffic. An LOM is calculated locally on the router. No information related to an LOM is signaled to other routers in the network.

An LOM is configurable on each link and for each class type. The per-class type LOM allows you to increase or decrease the oversubscription ratio. The per-class-type LOM is factored into all local bandwidth accounting for admission control and IGP advertisement of unreserved bandwidths.

The LOM calculation is tied to the bandwidth model (MAM, extended MAM, and Russian dolls) used, because the effect of oversubscription across class types must be accounted for accurately.

NOTE: All LOM calculations are performed by the Junos OS and require no user intervention. The formulas related to the oversubscription of class types are described in the following sections:

- Class Type Bandwidth and the LOM
- LOM Calculation for the MAM and Extended MAM Bandwidth Models
- LOM Calculation for the Russian Dolls Bandwidth Model
- Example: LOM Calculation

Configuring the Bandwidth Subscription Percentage for LSPs

IN THIS SECTION

- Constraints on Configuring Bandwidth Subscription | **661**

By default, RSVP allows all of a class type's bandwidth (100 percent) to be used for RSVP reservations. When you oversubscribe a class type for a multiclass LSP, the aggregate demand of all RSVP sessions is allowed to exceed the actual capacity of the class type.

If you want to oversubscribe or undersubscribe all of the class types on an interface using the same percentage bandwidth, configure the percentage using the `subscription` statement:

```
subscription percentage;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section.

To undersubscribe or oversubscribe the bandwidth for each class type, configure a percentage for each class type (ct0, ct1, ct2, and ct3) option for the subscription statement. When you oversubscribe a class type, an LOM is applied to calculate the actual bandwidth reserved. See "Class Type Oversubscription and Local Oversubscription Multipliers" on page 659 for more information.

```
subscription {
    ct0 percentage;
    ct1 percentage;
    ct2 percentage;
    ct3 percentage;
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section.

percentage is the percentage of class type bandwidth that RSVP allows to be used for reservations. It can be a value from 0 through 65,000 percent. If you specify a value greater than 100, you are oversubscribing the interface or class type.

The value you configure when you oversubscribe a class type is a percentage of the class type bandwidth that can actually be used. The default subscription value is 100 percent.

You can use the subscription statement to disable new RSVP sessions for one or more class types. If you configure a percentage of 0, no new sessions (including those with zero bandwidth requirements) are permitted for the class type.

Existing RSVP sessions are not affected by changing the subscription factor. To clear an existing session, issue the clear rsvp session command. For more information on the clear rsvp session command, see the CLI Explorer.

Constraints on Configuring Bandwidth Subscription

Be aware of the following issues when configuring bandwidth subscription:

- If you configure bandwidth constraints at the [edit class-of-service interface *interface-name*] hierarchy level, they override any bandwidth configuration you specify at the [edit protocols rsvp interface *interface-name* bandwidth] hierarchy level for Diffserv-TE. Also note that either of the CoS or RSVP bandwidth constraints can override the interface hardware bandwidth constraints.
- If you configure a bandwidth subscription value for a specific interface that differs from the value configured for all interfaces (by including different values for the subscription statement at the [edit protocols rsvp interface *interface-name*] and [edit protocols rsvp interface all] hierarchy levels), the interface-specific value is used for that interface.

- You can configure subscription for each class type only if you also configure a bandwidth model. If no bandwidth model is configured, the commit operation fails with the following error message:

```
user@host# commit check
[edit protocols rsvp interface all]
  'subscription'
RSVP: Must have a diffserv-te bandwidth model configured when configuring subscription per
traffic class.
error: configuration check-out failed
```

- You cannot include the `subscription` statement both in the configuration for a specific class type and the configuration for the entire interface. The commit operation fails with the following error message:

```
user@host# commit check
[edit protocols rsvp interface all]
  'subscription'
    RSVP: Cannot configure both link subscription and per traffic class subscription.
error: configuration check-out failed
```

Release History Table

Release	Description
14.1R9	Starting in Junos OS Release 14.1R9, 15.1R7, 16.1R5, 16.1X2, 16.2R3, and 17.2R2, all zero value bandwidth samples are considered as underflow samples, except for the zero value samples that arrive after an LSP comes up for the first time, and the zero value samples that arrive first after a Routing Engine switchover.

Configuring Primary and Secondary LSPs

IN THIS SECTION

- Configuring Primary and Secondary Paths for an LSP | 663
- Configuring the Revert Timer for LSPs | 664
- Specifying the Conditions for Path Selection | 665

By default, an LSP routes itself hop-by-hop toward the egress router. The LSP tends to follow the shortest path as dictated by the local routing table, usually taking the same path as destination-based, best-effort traffic. These paths are “soft” in nature because they automatically re-route themselves whenever a change occurs in a routing table or in the status of a node or link.

To configure the path so that it follows a particular route, create a named path using the `path` statement, as described in "Creating Named Paths" on page 579. Then apply the named path by including the `primary` or `secondary` statement. A named path can be referenced by any number of LSPs.

To configure primary and secondary paths for an LSP, complete the steps in the following sections:

Configuring Primary and Secondary Paths for an LSP

The `primary` statement creates the primary path, which is the LSP’s preferred path. The `secondary` statement creates an alternative path. If the primary path can no longer reach the egress router, the alternative path is used.

To configure primary and secondary paths, include the primary and secondary statements:

```
primary path-name {
    ...
}
secondary path-name {
    ...
}
```

You can include these statements at the following hierarchy levels:

- [edit protocols mpls label-switched-path *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name*]

When the software switches from the primary to a secondary path, it continuously attempts to revert to the primary path, switching back to it when it is again reachable but no sooner than the time specified in the revert-timer statement. (For more information, see "Configuring the Connection Between Ingress and Egress Routers" on page 585.)

You can configure zero or one primary path. If you do not configure a primary path, the first secondary path that is established is selected as the path.

You can configure zero or more secondary paths. All secondary paths are equal. The software does not attempt to switch among secondary paths. If the current secondary path is not available, the next one is tried in no particular order. To create a set of equal paths, specify secondary paths without specifying a primary path.

If you do not specify any named paths, or if the path that you specify is empty, the software makes all routing decisions necessary to reach the egress router.

Configuring the Revert Timer for LSPs

For LSPs configured with both primary and secondary paths, it is possible to configure the revert timer. If a primary path goes down and traffic is switched to the secondary path, the revert timer specifies the amount of time (in seconds) that the LSP must wait before it can revert traffic back to a primary path. If during this time, the primary path experiences any connectivity problems or stability problems, the timer is restarted. You can configure the revert timer for both static and dynamic LSPs.

The Junos OS also makes a determination as to which path is the preferred path. The preferred path is the path that has not encountered any difficulty in the last revert timer period. If both the primary and secondary paths have encountered difficulty, neither path is considered preferred. However, if one of the paths is dynamic and the other static, the dynamic path is selected as the preferred path.

If you have configured BFD on the LSP, Junos OS waits until the BFD session comes up on the primary path before starting the revert timer counter.

The range of values you can configure for the revert timer is 0 through 65,535 seconds. The default value is 60 seconds.

If you configure a value of 0 seconds, the traffic on the LSP, once switched from the primary path to the secondary path, remains on the secondary path permanently (until the network operator intervenes or until the secondary path goes down).

You can configure the revert timer for all LSPs on the router at the `[edit protocols mpls]` hierarchy level or for a specific LSP at the `[edit protocols mpls label-switched-path` *lsp-name*`]` hierarchy level.

To configure the revert timer, include the `revert-timer` statement:

```
revert-timer seconds;
```

For a list of hierarchy levels at which you can include this statement, see the summary section for this statement.

Specifying the Conditions for Path Selection

When you have configured both primary and secondary paths for an LSP, you may need to ensure that only a specific path is used.

The `select` statement is optional. If you do not include it, MPLS uses an automatic path selection algorithm.

The `manual` and `unconditional` options do the following:

- `manual`—The path is immediately selected for carrying traffic as long as it is up and stable. Traffic is sent to other working paths if the current path is down or degraded (receiving errors). This parameter overrides all other path attributes except the `select unconditional` statement.
- `unconditional`—The path is selected for carrying traffic unconditionally, regardless of whether the path is currently down or degraded (receiving errors). This parameter overrides all other path attributes.

  Because the `unconditional` option switches to a path without regard to its current status, be aware of the following potential consequences of specifying it:

  - If a path is not currently up when you enable the `unconditional` option, traffic can be disrupted. Ensure that the path is functional before specifying the `unconditional` option.
  - Once a path is selected because it has the `unconditional` option enabled, all other paths for the LSP are gradually cleared, including the primary and standby paths. No path can act as a standby to an unconditional path, so signaling those paths serves no purpose.

For a specific path, the manual and unconditional options are mutually exclusive. You can include the select statement with the manual option in the configuration of only one of an LSP's paths, and the select statement with the unconditional option in the configuration of only one other of its paths.

Enabling or disabling the manual and unconditional options for the select statement while LSPs and their paths are up does not disrupt traffic.

To specify that a path be selected for carrying traffic if it is up and stable for at least the revert timer window, include the select statement with the manual option:

```
select manual;
```

To specify that a path should always be selected for carrying traffic, even if it is currently down or degraded, include the select statement with the unconditional option:

```
select unconditional;
```

You can include the select statement at the following hierarchy levels:

- [edit protocols mpls label-switched-path *lsp-name* (primary | secondary) *path-name*]
- [edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name* (primary | secondary) *path-name*]

Configuring Hot Standby of Secondary Paths for LSPs

By default, secondary paths are set up only as needed. To have the system maintain a secondary path in a hot-standby state indefinitely, include the standby statement:

```
standby;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls label-switched-path *lsp-name* secondary]
- [edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name* secondary]

The hot-standby state is meaningful only on secondary paths. Maintaining a path in a hot-standby state enables swift cutover to the secondary path when downstream routers on the current active path indicate connectivity problems. Although it is possible to configure the standby statement at the [edit protocols mpls label-switched-path *lsp-name* primary *path-name*] hierarchy level, it has no effect on router behavior.

If you configure the standby statement at the following hierarchy levels, the hot-standby state is activated on all secondary paths configured beneath that hierarchy level:

- [edit protocols mpls]
- [edit protocols mpls label-switched-path *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls]
- [edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name*]

The hot-standby state has two advantages:

- It eliminates the call-setup delay during network topology changes. Call setup can suffer from significant delays when network failures trigger large numbers of LSP reroutes at the same time.
- A cutover to the secondary path can be made before RSVP learns that an LSP is down. There can be significant delays between the time the first failure is detected by protocol machinery (which can be an interface down, a neighbor becoming unreachable, a route becoming unreachable, or a transient routing loop being detected) and the time an LSP actually fails (which requires a timeout of soft state information between adjacent RSVP routers). When topology failures occur, hot-standby secondary paths can usually achieve the smallest cutover delays with minimal disruptions to user traffic.

When the primary path is considered to be stable again, traffic is automatically switched from the standby secondary path back to the primary path. The switch is performed no faster than twice the retry-timer interval and only if the primary path exhibits stability throughout the entire switch interval.

The drawback of the hot-standby state is that more state information must be maintained by all the routers along the path, which requires overhead from each of the routers.

NOTE: When viewed with inet.3, the same LSP may appear to be shown twice as the active route (both primary and secondary), even though traffic actually is being forwarded over the primary path LSP only. This is normal output, and reflects only that the secondary standby path is available.

Configuring Static LSPs

IN THIS SECTION

- Configuring the Ingress Router for Static LSPs | **668**
- Configuring the Intermediate (Transit) and Egress Routers for Static LSPs | **671**
- Configuring a Bypass LSP for the Static LSP | **675**

Configuring the Protection Revert Timer for Static LSPs | 675
Configuring Static Unicast Routes for Point-to-Multipoint LSPs | 675

To configure static LSPs, configure the ingress router and each router along the path up to and including the penultimate router.

To configure static MPLS, perform the following tasks:

Configuring the Ingress Router for Static LSPs

The ingress router checks the IP address in the incoming packet's destination address field and, if it finds a match in the routing table, applies the label associated with that address to the packets. The label has forwarding information associated with it, including the address of the next-hop router, and the route preference and CoS values.

To configure static LSPs on the ingress router, include the `ingress` statement:

```
ingress {
    bandwidth bps;
    class-of-service cos-value;
    description string;
    install {
        destination-prefix <active>;
    }
    link-protection bypass-name name;
    metric metric;
    next-hop (address | interface-name | address/interface-name);
    no-install-to-address;
    node-protection bypass-name name next-next-label label;
    policing {
        filter filter-name;
        no-auto-policing;
    }
    preference preference;
    push out-label;
    to address;
}
```

You can include these statements at the following hierarchy levels:

- [edit protocols mpls static-label-switched-path *static-lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls static-label-switched-path *static-lsp-name*]

When you configure a static LSP on the ingress router, the next-hop, push, and to statements are required; the other statements are optional.

The configuration for a static LSP on the ingress router includes the following:

- Criteria for analyzing an incoming packet:
  - The install statement creates an LSP that handles IPv4 packets. All static MPLS routes created using the install statement are installed in inet.3 routing table, and the creating protocol is identified as mpls. This process is no different from creating static IPv4 routes at the [edit routing-options static] hierarchy level.
  - In the to statement, you configure the IP destination address to check when incoming packets are analyzed. If the address matches, the specified outgoing label (push *out-label*) is assigned to the packet, and the packet enters an LSP. Manually assigned outgoing labels can have values from 0 through 1,048,575. This IP address is installed into inet.3 table (by default) by the mpls protocol.
- The next-hop statement, which supplies the IP address of the next hop to the destination. You can specify this as the IP address of the next hop, the interface name (for point-to-point interfaces only), or as *address*/*interface-name* to specify an IP address on an operational interface. When the next hop is on a directly attached interface, the route is installed in the routing table. You cannot configure a LAN or nonbroadcast multiaccess (NBMA) interface as a next-hop interface.
- Properties to apply to the LSP (all are optional):
  - Bandwidth reserved for this LSP (bandwidth *bps*)
  - Link protection and node protection to apply to the LSP (bypass *bypass-name*, link-protection bypass-name *name*, node-protection bypass-name next-next-label *label*)
  - Metric value to apply to the LSP (metric)
  - Class-of-service value to apply to the LSP (class-of-service)
  - Preference value to apply to the LSP (preference)
  - Traffic policing to apply to the LSP (policing)
  - Text description to apply to the LSP (description)
  - Install or no-install policy (install or no-install-to-address)

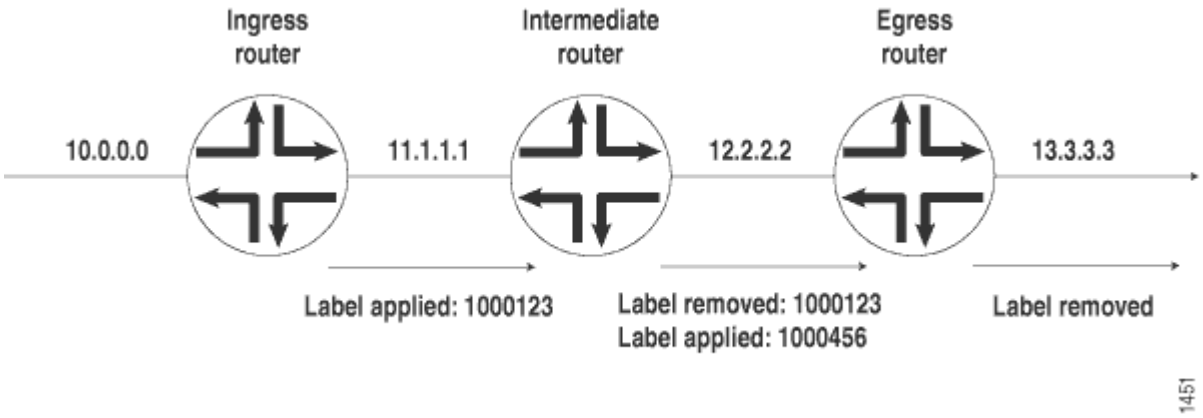
To determine whether a static ingress route is installed, use the command `show route table inet.3 protocol static`. Sample output follows. The `push` keyword denotes that a label is to be added in front of an IP packet.

```
10.0.0.0       *[Static/5] 00:01:48
> to 11.1.1.1 via so-0/0/0, push 1000123
```

Example: Configuring the Ingress Router

Configure the ingress router for a static LSP that consists of three routers (see Figure 45 on page 670).

Figure 45: Static MPLS Configuration



For packets addressed to `10.0.0.0`, assign label `1000123` and transmit them to the next-hop router at `11.1.1.1`:

```
[edit]
interfaces {
    so-0/0/0 {
        unit 0 {
            family mpls;
        }
    }
}
protocols {
    mpls {
        static-label-switched-path path1 {
            ingress {
```

```
                next-hop 11.1.1.1;
                to 10.0.0.0;
                push 1000123;
            }
        }
        interface so-0/0/0.0;
    }
}
routing-options {
    static {
        route 10.0.0.0/8 {
            static-lsp-next-hop path1;
        }
    }
```

To determine whether the static ingress route is installed, use the following command:

```
user@host> show route table inet.0 protocol static
```

Sample output follows. The `push 1000123` keyword identifies the route.

```
10.0.0.0/8       *[Static/5] 00:01:48
> to 11.1.1.1 via so-0/0/0.0, push 1000123
```

Configuring the Intermediate (Transit) and Egress Routers for Static LSPs

Intermediate (transit) and egress routers perform similar functions—they modify the label that has been applied to a packet. An intermediate router can change the label. An egress router removes the label (if the packet still contains a label) and continues forwarding the packet to its destination.

To configure static LSPs on intermediate and egress routers, include the `transit` statement:

```
static-label-switched-path lsp-name {
    transit incoming-label {
        bandwidth bps;
        description string;
        link-protection bypass-name name;
        next-hop (address | interface-name | address/interface-name);
        node-protection bypass-name name next-next-label label;
        pop;
```

```
        swap out-label;
    }
```

You can include these statements at the following hierarchy levels:

- [edit protocols mpls static-label-switched-path *static-lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls static-label-switched-path *static-lsp-name*]

For the transit statement configuration, the next-hop and pop | swap statements are required. The remaining statements are optional.

Each statement within the transit statement consists of the following parts:

- Packet label (specified in the transit statement)
- The next-hop statement, which supplies the IP address of the next hop to the destination. The address is specified as the IP address of the next hop, or the interface name (for point-to-point interfaces only), or *address* and *interface-name* to specify an IP address on an operational interface. When the specified next hop is on a directly attached interface, this route is installed in the routing table. You cannot configure a LAN or NBMA interface as a next-hop interface.
- Operation to perform on the labeled packet:
  - For egress routers, you generally just remove the packet's label altogether (PHP) and continue forwarding the packet to the next hop. However, if the previous router removed the label, the egress router examines the packet's IP header and forwards the packet toward its IP destination.
  - For intermediate (transit) routers only, exchange the label for another label (swap *out-label*). Manually assigned incoming labels can have values from 1,000,000 through 1,048,575. Manually assigned outgoing labels can have values from 0 through 1,048,575.
- Label properties to apply to the packet (all are optional):
  - Bandwidth reserved for this route (bandwidth *bps*).
  - Link-protection and node-protection to apply to the LSP (bypass *bypass-name*, link-protection bypass-name *name*, node-protection bypass-name next-next-label *label*).
  - Text description to apply to the LSP (specified in the description statement).

The routes are installed in the default MPLS routing table, mpls.0, and the creating protocol is identified as MPLS. To verify that a route is properly installed, use the command show route table mpls.0 protocol static. Sample output follows:

```
mpls.0: 8 destinations, 8 routes (8 active, 0 holddown, 0 hidden)
```

You can configure a revert timer for a static LSP transiting an intermediate router. After traffic has been switched to a bypass static LSP, it is typically switched back to the primary static LSP when it comes back up. There is a configurable delay in the time (called the revert timer) between when the primary static LSP comes up and when traffic is reverted back to it from the bypass static LSP. This delay is needed because when the primary LSP comes back up, it is not certain whether all of the interfaces on the downstream node of the primary path have come up yet. You can display the revert timer value for an interface using the `show mpls interface detail` command.

Example: Configuring an Intermediate Router

For packets labeled `1000123` arriving on interface `so-0/0/0`, assign the label `1000456`, and transmit them to the next-hop router at `12.2.2.2`:

```
[edit]
interfaces {
    so-0/0/0 {
        unit 0 {
            family mpls;
        }
    }
}
protocols {
    mpls {
        static-label-switched-path path1 {
            transit 1000123 {
                next-hop 12.2.2.2;
                swap 1000456;
            }
        }
        interface so-0/0/0.0;
    }
}
```

To determine whether the static intermediate route is installed, use the following command:

```
user@host> show route table mpls.0 protocol static
```

Sample output follows. The `swap 1000456` keyword identifies the route.

```
1000123       *[Static/5] 00:01:48
> to 12.2.2.2 via so-0/0/0, swap 1000456
```

Example: Configuring an Egress Router

For packets labeled `1000456` arriving on interface `so-0/0/0`, remove the label and transmit the packets to the next-hop router at `13.3.3.3`:

```
[edit]
interfaces {
    so-0/0/0 {
        unit 0 {
            family mpls;
        }
    }
}
protocols {
    mpls {
        static-label-switched-path path1 {
            transit 1000456 {
                next-hop 13.3.3.3;
                pop;
            }
        }
        interface so-0/0/0.0;
    }
}
```

To determine whether the static egress route is installed, use the following command:

```
user@host> show route table mpls.0 protocol static
```

Sample output follows. The `pop` keyword identifies the egress route.

```
1000456        *[Static/5] 00:01:48
> to 13.3.3.3 via so-0/0/0, pop
```

Configuring a Bypass LSP for the Static LSP

To enable a bypass LSP for the static LSP, configure the `bypass` statement:

```
bypass bypass-name {
    bandwidth bps;
    description string;
    next-hop (address | interface-name | address/interface-name);
    push out-label;
    to address;
}
```

Configuring the Protection Revert Timer for Static LSPs

For static LSPs configured with a bypass static LSP, it is possible to configure the protection revert timer. If a static LSP goes down and traffic is switched to the bypass LSP, the protection revert timer specifies the amount of time (in seconds) that the LSP must wait before it can revert back to the original static LSP.

The range of values you can configure for the protection revert timer is 0 through 65,535 seconds. The default value is 5 seconds.

If you configure a value of 0 seconds, the traffic on the LSP, once switched from the original static LSP to the bypass static LSP, remains on the bypass LSP permanently (until the network operator intervenes or until the bypass LSP goes down).

You can configure the protection revert timer for all dynamic LSPs on the router at the `[edit protocols mpls]` hierarchy level or for a specific LSP at the `[edit protocols mpls label-switched-path lsp-name]` hierarchy level.

To configure the protection revert timer for static LSPs include the `protection-revert-time` statement:

```
protection-revert-time seconds;
```

For a list of hierarchy levels at which you can include this statement, see the summary section for this statement.

Configuring Static Unicast Routes for Point-to-Multipoint LSPs

You can configure a static unicast IP route with a point-to-multipoint LSP as the next hop. For more information about point-to-multipoint LSPs, see "Point-to-Multipoint LSPs Overview" on page 755,

"Configuring Primary and Branch LSPs for Point-to-Multipoint LSPs" on page 787, and "Configuring CCC Switching for Point-to-Multipoint LSPs" on page 1982.

To configure a static unicast route for a point-to-multipoint LSP, complete the following steps:

1. On the ingress PE router, configure a static IP unicast route with the point-to-multipoint LSP name as the next hop by including the `p2mp-lsp-next-hop` statement:

   ```
   p2mp-lsp-next-hop point-to-multipoint-lsp-next-hop;
   ```

   You can include this statement at the following hierarchy levels:

   - `[edit routing-options static route route-name]`
   - `[edit logical-systems logical-system-name routing-options static route route-name]`

2. On the egress PE router, configure a static IP unicast route with the same destination address configured in Step "1" on page 676 (the address configured at the `[edit routing-options static route]` hierarchy level) by including the `next-hop` statement:

   ```
   next-hop address;
   ```

   You can include this statement at the following hierarchy levels:

   - `[edit routing-options static route route-name]`
   - `[edit logical-systems logical-system-name routing-options static route route-name]`

   NOTE: CCC and static routes cannot use the same point-to-multipoint LSP.

For more information on static routes, see the Junos OS Routing Protocols Library for Routing Devices.

The following `show route` command output displays a unicast static route pointing to a point-to-multipoint LSP on the ingress PE router where the LSP has two branch next hops:

```
user@host> show route 5.5.5.5 detail
inet.0: 29 destinations, 30 routes (28 active, 0 holddown, 1 hidden)
5.5.5.5/32 (1 entry, 1 announced)
        *Static Preference: 5
                Next hop type: Flood
                Next hop: via so-0/3/2.0 weight 1
                Label operation: Push 100000
```

```
Next hop: via t1-0/1/1.0 weight 1
Label operation: Push 100064
State: <Active Int Ext>
Local AS: 10458
Age: 2:41:15
Task: RT
Announcement bits (2): 0-KRT 3-BGP.0.0.0.0+179
AS path: I
```

Configuring Static Label Switched Paths for MPLS (CLI Procedure)

IN THIS SECTION

- Configuring the Ingress PE Switch | **678**
- Configuring the Provider and the Egress PE Switch | **679**

Configuring static label-switched paths (LSPs) for MPLS is similar to configuring static routes on individual switches. As with static routes, there is no error reporting, liveliness detection, or statistics reporting.

To configure static LSPs, configure the ingress switch and each provider switch along the path up to and including the egress switch.

For the ingress switch, configure which packets to tag (based on the packet's destination IP address), configure the next switch in the LSP, and the tag to apply to the packet. Manually assigned labels can have values from 0 through 1,048,575. Optionally, you can apply preference, class-of-service (CoS) values, node protection, and link protection to the packets.

For the transit switches in the path, configure the next switch in the path and the tag to apply to the packet. Manually assigned labels can have values from 1,000,000 through 1,048,575. Optionally, you can apply node protection and link protection to the packets.

For the egress switch, you generally just remove the label and continue forwarding the packet to the IP destination. However, if the previous switch removed the label, the egress switch examines the packet's IP header and forwards the packet toward its IP destination.

Before you configure an LSP, you must configure the basic components for an MPLS network:

- Configure two PE switches. See "Configuring MPLS on Provider Edge EX8200 and EX4500 Switches Using Circuit Cross-Connect" on page 90.

- Configure one or more provider switches. See "Configuring MPLS on EX8200 and EX4500 Provider Switches" on page 94.

This topic describes how to configure an ingress PE switch, one or more provider switches, and an egress PE switch for static LSP:

Configuring the Ingress PE Switch

To configure the ingress PE switch:

1. Configure an IP address for the core interfaces:

```
[edit]
user@switch# set interfaces interface-name unit logical-unit-number family inet address
address
user@switch# set interfaces interface-name unit logical-unit-number family inet address
address
```

2. Configure the name and the traffic rate associated with the LSP:

```
[edit]
user@switch# set protocols mpls static-label-switched-path lsp-name ingress bandwidth rate
```

3. Configure the next hop switch for the LSP:

```
[edit]
user@switch# set protocols mpls static-label-switched-path lsp-name ingress next-hop address-
of-next-hop
```

4. Enable link protection on the specified static LSP:

```
[edit]
user@switch# set protocols mpls static-label-switched-path lsp-name ingress link-protection
bypass-name name
```

5. Specify the address of the egress switch for the LSP:

```
[edit]
user@switch# set protocols mpls static-label-switched-path path1 ingress to address-of-egress-
switch
```

6. Configure the new label that you want to add to the top of the label stack:

```
[edit]
user@switch# set protocols mpls static-label-switched-path path1 ingress push out-label
```

7. Optionally, configure the next hop address and the egress router address that you want to bypass, for the static LSP:

```
[edit]
user@switch# set protocols mpls static-label-switched-path lsp-name by bypass next-hop
address-of-next-hop
user@switch# set protocols mpls static-label-switched-path lsp-name by bypass to address-of-
the-egress-switch
user@switch# set protocols mpls static-label-switched-path lsp-name bypass push out-label
```

Configuring the Provider and the Egress PE Switch

To configure a static LSP for MPLS on the provider and egress provider edge switch:

1. Configure a transit static LSP:

```
[edit]
user@switch# set protocols mpls static-label-switched-path path1 transit incoming-label
```

2. Configure the next hop switch for the LSP:

```
[edit]
user@switch# set protocols mpls static-label-switched-path lsp-name transit incoming-label
next-hop address-of-next-hop
```

3. Only for provider switches, remove the label at the top of the label stack and replace it with the specified label:

```
[edit]
user@switch# set protocols mpls static-label-switched-path lsp-name transit incoming-label
swap out-label
```

4. Only for the egress provider edge switch, remove the label at the top of the label stack:

NOTE: If there is another label in the stack, that label becomes the label at the top of the label stack. Otherwise, the packet is forwarded as a native protocol packet (typically, as an IP packet).

```
[edit]
user@switch# set protocols mpls static-label-switched-path lsp-name transit incoming-label pop
```

Configuring Static Label Switched Paths for MPLS

IN THIS SECTION

- Configuring the Ingress PE Switch | **681**
- Configuring the Provider and the Egress PE Switch | **682**

Configuring static label-switched paths (LSPs) for MPLS is similar to configuring static routes on individual switches. As with static routes, there is no error reporting, liveliness detection, or statistics reporting.

To configure static LSPs, configure the ingress PE switch and each provider switch along the path up to and including the egress PE switch.

For the ingress PE switch, configure which packets to tag (based on the packet's destination IP address), configure the next switch in the LSP, and the tag to apply to the packet. Manually assigned labels can have values from 0 through 1,048,575.

For the transit switches in the path, configure the next switch in the path and the tag to apply to the packet. Manually assigned labels can have values from 1,000,000 through 1,048,575.

The egress PE switch removes the label and forwards the packet to the IP destination. However, if the previous switch removed the label, the egress switch examines the packet's IP header and forwards the packet toward its IP destination.

Before you configure a static LSP, you must configure the basic components for an MPLS network:

- Configure two PE switches. See "Configuring MPLS on Provider Edge Switches" on page 79.

NOTE: Do not configure LSPs at the `[edit protocols mpls label-switched-path]` hierarchy level on the PE switches.

- Configure one or more provider switches. See "Configuring MPLS on Provider Switches" on page 77.

This topic describes how to configure an ingress PE switch, one or more provider switches, and an egress PE switch for static LSP:

Configuring the Ingress PE Switch

To configure the ingress PE switch:

1. Configure an IP address for every core interface:

```
[edit interfaces]
user@switch# set interface-name unit logical-unit-number family inet address address
```

NOTE: You cannot use routed VLAN interfaces (RVIs) or Layer 3 subinterfaces as core interfaces.

2. Configure the name associated with the static LSP:

```
[edit protocols mpls]
user@switch# set static-label-switched-path lsp-name
```

3. Configure the next hop switch for the LSP:

```
[edit protocols mpls]
user@switch# set static-label-switched-path lsp-name ingress next-hop address-of-next-hop
```

4. Specify the address of the egress switch for the LSP:

```
[edit protocols mpls]
user@switch# set static-label-switched-path lsp-name ingress to address-of-egress-switch
```

5. Configure the new label that you want to add to the top of the label stack:

```
[edit protocols mpls]
user@switch# set static-label-switched-path lsp-name ingress push out-label
```

Configuring the Provider and the Egress PE Switch

To configure a static LSP for MPLS on the provider and egress PE switch:

1. Configure a transit static LSP:

```
[edit protocols mpls]
user@switch# set static-label-switched-path lsp-name transit incoming-label
```

2. Configure the next hop switch for the LSP:

```
[edit protocols mpls]
user@switch# set static-label-switched-path lsp-name transit incoming-label next-hop address-
of-next-hop
```

3. Only for provider switches, remove the label at the top of the label stack and replace it with the specified label:

```
[edit protocols mpls]
user@switch# set static-label-switched-path lsp-name transit incoming-label swap out-label
```

4. Only for the egress PE switch, remove the label at the top of the label stack:

NOTE: If there is another label in the stack, that label becomes the label at the top of the label stack. Otherwise, the packet is forwarded as a native protocol packet (typically, as an IP packet).

```
[edit protocols mpls]
user@switch# set static-label-switched-path lsp-name transit incoming-label pop
```

RELATED DOCUMENTATION

MPLS Overview | 2

Adaptive LSP Configuration

An LSP occasionally might need to reroute itself for these reasons:

- The continuous reoptimization process is configured with the `optimize-timer` statement.
- The current path has connectivity problems.
- The LSP is preempted by another LSP configured with the `priority` statement and is forced to reroute.
- The explicit-path information for an active LSP is modified, or the LSP's bandwidth is increased.

You can configure an LSP to be *adaptive* when it is attempting to reroute itself. When it is adaptive, the LSP holds onto existing resources until the new path is successfully established and traffic has been cut over to the new LSP. To retain its resources, an adaptive LSP does the following:

- Maintains existing paths and allocated bandwidths—This ensures that the existing path is not torn down prematurely and allows the current traffic to continue flowing while the new path is being set up.
- Avoids double-counting for links that share the new and old paths—Double-counting occurs when an intermediate router does not recognize that the new and old paths belong to the same LSP and counts them as two separate LSPs, requiring separate bandwidth allocations. If some links are close to saturation, double-counting might cause the setup of the new path to fail.

By default, adaptive behavior is disabled. You can include the `adaptive` statement in two different hierarchy levels.

If you specify the `adaptive` statement at the LSP hierarchy levels, the adaptive behavior is enabled on all primary/secondary paths of the LSP. This means both the primary and secondary paths share the same bandwidth on common links.

To configure adaptive behavior for all LSP paths, include the `adaptive` statement in the LSP configuration:

```
adaptive;
```

You can include this statement at the following hierarchy levels:

- `[edit protocols mpls label-switched-path lsp-name]`
- `[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name]`

If you specify the `adaptive` statement at the `[edit protocols mpls label-switched-path lsp-name (primary | secondary) path-name]` hierarchy level, adaptive behavior is enabled only on the path on which it is specified. Bandwidth double-counting occurs between different paths. However, if you also have the `adaptive` statement configured at the `[edit protocols mpls label-switched-path lsp-name]` hierarchy level, it overrides the adaptive behavior of each individual path.

To configure adaptive behavior for either the primary or secondary level, include the `adaptive` statement:

```
adaptive;
```

You can include this statement at the following hierarchy levels:

- `[edit protocols mpls label-switched-path lsp-name (primary | secondary) path-name]`
- `[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name (primary | secondary) path-name]`

Container LSP Configuration

Configuration Statements Supported for Container LSPs | 709
Impact of Configuring Container LSPs on Network Performance | 714
Supported and Unsupported Features | 715

RSVP LSPs with the autobandwidth feature are increasingly deployed in networks to meet traffic engineering needs. However, the current traffic engineering solutions for point-to-point LSPs are inefficient in terms of network bandwidth utilization, mainly because the ingress routers originating the RSVP LSPs either try to fit the LSPs along a particular path without creating parallel LSPs, or do not interact with the other routers in the network and probe for additional available bandwidth.

This feature provides an ingress router with the capability of acquiring as much network bandwidth as possible by creating parallel LSPs dynamically.

Understanding RSVP Multipath Extensions

The RSVP multipath extensions proposed in the IETF [KOMPELLA-MLSP] allow the setup of traffic engineered multipath label-switched paths (container LSPs). The container LSPs, in addition to conforming to traffic engineering constraints, use multiple independent paths from a source to a destination, thereby facilitating load balancing of traffic. The multipath extensions require changes to the RSVP-TE protocol and allow for merging of labels at the downstream nodes (similar to LDP), which also helps in preserving forwarding resources.

The multipath extensions to RSVP provide the following benefits:

- Ease of configuration. Typically, multiple RSVP LSPs are configured for either load balancing or bin packing. With a container LSP, there is a single entity to provision, manage, and monitor LSPs. Changes in topology are handled easily and autonomously by the ingress LSP, by adding, changing, or removing member LSPs to rebalance traffic, while maintaining the same traffic engineering constraints.
- RSVP equal-cost multipath (ECMP) inherits the standard benefits of ECMP by absorbing traffic surges.
- Multipath traffic engineering allows for better and complete usage of network resources.
- Knowing the relationship among LSPs helps in computing diverse paths with constraint-based routing. It allows adjustment of member LSPs while other member LSPs continue to carry traffic.
- The intermediate routers have an opportunity to merge the labels of member LSPs. This reduces the number of labels that need to get added to the forwarding plane and in turn reduces the convergence time.

If the number of independent ECMP paths is huge, label merging overcomes the platform limitations on maximum (ECMP) next hops. With point-to-point RSVP LSPs that require link or node protection, the next hops are doubled as each LSP is programmed with both primary and backup next hops. RSVP multipath (or ECMP) obviates the need for backup next hops.

- When there is a link failure, the router upstream to the link failure can distribute traffic from the failed link to the remaining ECMP branches, obviating the need for bypass LSPs. The bypass LSP approach not only requires more state when signaling backup LSPs, but also suffers from scaling issues that result in merge-point timing out a protected path state block (PSB) before point of local repair (PLR) gets a chance to signal the backup LSP.

Junos OS RSVP Multipath Implementation

In order to deploy RSVP multipath (ECMP) in a network, all the nodes through which ECMP LSPs pass must understand RSVP ECMP protocol extensions. This can be a challenge, especially in a multivendor networks.

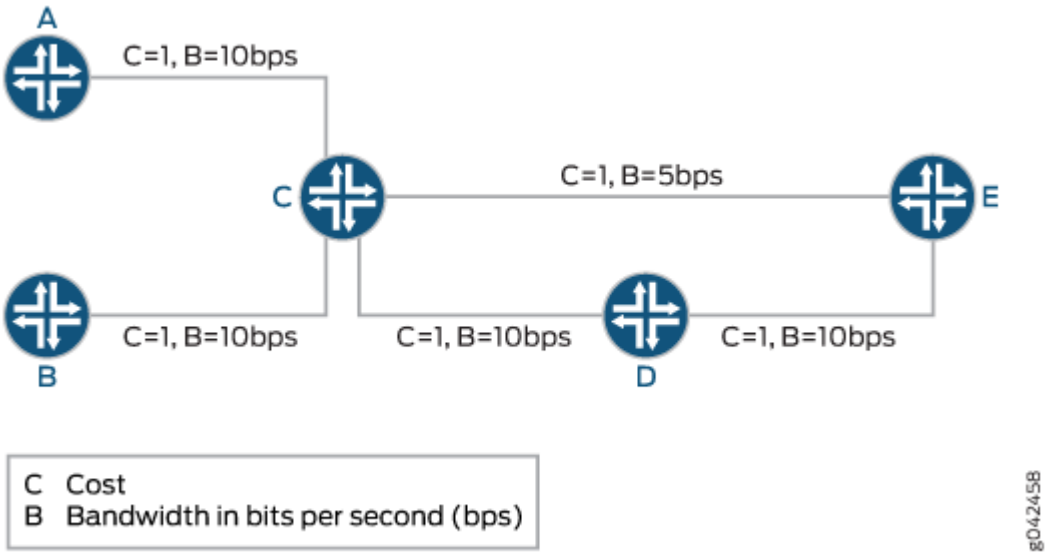
Junos OS implements the RSVP multipath extensions without the need for protocol extensions. A single container LSP, which has the characteristics of ECMP and RSVP TE, is provisioned. A container LSP consists of several member LSPs and is set up between the ingress and egress routing device. Each member LSP takes a different path to the same destination. The ingress routing device is configured with all the required parameters to compute the RSVP ECMP LSP. The parameters configured to compute a set of RSVP point-to-point LSPs can be used by the ingress routing device to compute the container LSP as well.

Current Traffic Engineering Challenges

The main challenge for traffic engineering is to cope with the dynamics of both topology and traffic demands. Mechanisms are needed that can handle traffic load dynamics in scenarios with sudden changes in traffic demand and dynamically distribute traffic to benefit form available resources.

Figure 46 on page 687 illustrates a sample network topology with all the LSPs having the same hold and setup priorities, and admission control restricted on the ingress router. All the links are annotated with a tuple (cost and capacity).

Figure 46: Sample Topology



Some of the traffic engineering problems seen in Figure 46 on page 687 are listed here:

- **Bin Packing**

  This problem arises because of a particular order in which LSPs are signaled. The ingress routers might not be able to signal some LSPs with required demands although bandwidth is available in the network, leading to under-utilization of link capacity.

  For example, the following LSPs arrive in the sequence mentioned in Table 13 on page 687.

  Table 13: LSP Sequence Order for Bin Packing

Time	Source	Destination	Demand	ERO
1	A	E	5	A-C-D-E
2	B	E	10	No ERO

The LSP originating at Router B is not routable as constraint-based routing fails to find a feasible path. However, if Router B is signaled first, both the LSPs are routable. Bin packing happens because of lack of visibility of individual per-LSP, per-device bandwidth demands at the ingress routing device.

Bin packing can also happen when there is no requirement for ordering of LSPs. For example, if there is an LSP with demand X and there are two different paths to the destination from the ingress router with available bandwidths Y1 and Y2, such that Y1 is less than X, Y2 is less than X, and Y1 plus Y2 is greater than or equal to X.

In this case, even though there are enough network resources in terms of available bandwidth to satisfy the aggregate LSP demand X, the LSP might not be signaled or re-optimized with the new demand. In Figure 46 on page 687, with container LSP support, the ingress B creates two LSPs each of size 5 when demand 10 is posed. One LSP is routed along B-C-E and another one along B-C-D-E.

- `Deadlock`

  Considering Figure 46 on page 687, the LSPs follow the sequence mentioned in Table 14 on page 688.

  Table 14: LSP Sequence Order for Deadlock

Time	Source	Destination	Demand	ERO	Event
1	A	E	2	A-C-D-E	Constraint-based routing with RSVP signaling
2	B	E	2	B-C-D-E	Constraint-based routing with RSVP signaling
3	A	E	2 to 20	A-C-D-E	Constraint-based routing fails, no RSVP signaling

  At time 3, the demand on LSP from A to E increases from 2 to 20. If autobandwidth is configured, the change does not get detected until the adjustment timer expires. In the absence of admission control at A, the increased traffic demand might cause traffic to drop on other LSPs that share common links with the mis-behaving LSP.

  This happens due to the following reasons:

  - Lack of global state at all the ingress routers
  - Signaling of mis-behaving demands
  - Tearing down of mis-behaving demands

  With container LSP configured, ingress A has more chances of splitting the load (even incrementally if not fully) across multiple LSPs. So, LSP from A is less likely to see prolonged traffic loss.

- **Latency Inflation**

  Latency inflation is caused by the autobandwidth and other LSPs parameters. Some of the other factors that contribute to latency inflation include:

  - LSP priority

    LSPs choose longer paths because shorter paths between data centers located in the same city can be congested. The bandwidth on the shorter paths can get exhausted by equal or higher priority LSPs. Due to periodic LSP optimization by autobandwidth, LSP can get rerouted to a higher delay path. When many LSPs undergo less than optimal path selection, they can potentially form a chain of dependencies. Modifing the LSP priorities dynamically is a workaround to the issue; however, dynamically adjusting LSP priorities to find shorter paths is a challenging task.

  - All or Nothing policy

    When the demand on an LSP increases and at least one of the links along the shorter path is close to its reservation limit, LSP optimization can force the LSP to move to a longer latency path. LSP has to traverse a long path even though the short path is capable of carrying most of the traffic.

  - Minimum and maximum bandwidth

    Minimum and maximum bandwidth specify the boundaries for LSP sizes. If minimum bandwidth is small, an LSP is more prone to autobandwidth adjustment because a small change in bandwidth is enough to cross the threshold limits. LSPs might reroute although bandwidth is available. On the other hand, if the minimum bandwidth is large, network bandwidth might be wasted. If the maximum bandwidth value is small, a large number of LSPs might be needed at the ingress router to accommodate the application demand. If the maximum bandwidth is large, the LSPs can grow larger in size. Such LSPs can suffer because of an all or nothing policy.

  - Autobandwidth adjustment threshold

    Bandwidth threshold dictates if LSPs need to be re-optimized and resized. If the value is small, LSPs are frequently re-optimized and rerouted. That might cause CPU spike because applications or protocols, such as BGP resolving over the LSPs, might keep the Routing Engine busy doing next-hop resolution. A large value might make an LSP immobile. With container LSP configured, an LSP is less likely to get subjected to one or no policy. An ingress router originates multiple LSPs, although not all LSPs potentially traverse high latency paths.

- **Predictability**

  Service providers often want predictable behavior in terms of how LSPs get signaled and routed. Currently, without any global coordination, it is difficult to set up the same set of LSPs in a predictable way. Consider the two different orderings in Table 15 on page 690 and Table 16 on page 690. The ERO that an LSP uses depends on its signaling time.

Table 15: LSP Sequence Order for Predictability

Time	Source	Destination	Demand	ERO
1	A	E	5	A-C-D-E
2	B	E	5	B-C-E

Table 16: LSP Sequence Order for Predictability

Time	Source	Destination	Demand	ERO
1	B	E	5	B-C-E
2	A	E	5	A-C-D-E

Container LSP does not directly help LSPs find predictable EROs. If LSPs are getting rerouted because of an all or no policy without container LSP configured, such LSPs might see less churn if container LSPs are configured, because smaller LSPs have better chances of finding a shorter or same path.

Using Container LSP as a Solution

A container LSP can be used as a solution to the challenges faced by the current traffic engineering features. Considering Figure 46 on page 687, when the demand X on a container LSP increases with the network capacity (max-flow) being more than the demand, the following approaches come into effect with a container LSP:

Accommodating the New Demand X

In the current implementation, autobandwidth attempts to re-signal an LSP with the new demand X and follows the all or nothing policy as mentioned earlier.

The container LSP approach computes several small (smaller than demand X) bandwidth LSPs such that the aggregate bandwidth is not less than X, and the ingress router performs this adjustment periodically. One of the triggers to create new LSPs or to delete old LSPs can be changed in aggregate bandwidth. The ingress router then load-balances the incoming traffic across the newly created LSPs.

Creating New LSPs to Meet Demand X

Although the number of new LSPs created can be a maximum of the allowed configurable limit, there is not much benefit from these LSPs once the number of LSPs exceeds the number of possible diverse paths or equal-cost multipaths (ECMPs). The benefit of creating the smaller LSPs is seen when an ingress router uses the newly created LSPs for load-balancing traffic. This, however, depends on the network topology and state.

Creating multiple parallel LSPs by all the ingress routers in the network can lead to scaling issues at the transit routers. Thus, the number of new LSPs to be created depends on the size of the individual LSPs and the given aggregate demand, X in this case.

Assigning Bandwidth to the New LSPs

In general, there can be a number of heuristics to allocate bandwidths to the newly created LSPs. An ingress router can solve an optimization problem in which it can maximize a given utility function. The output of an optimization problem is assigning optimal bandwidth values. However, to solve an optimization problem, the number of newly created LSPs has to be fixed. Therefore, it is complex to optimize the number and size of each LSP. Thus, to simplify the problem, the same amount of bandwidth is assumed for all the newly created LSPs, and then the number of required LSPs is computed.

Controlling the LSP Paths

The flexibility to control the LSP paths is expressed in terms of the configuration for point-to-point LSPs and container LSPs. Controlling the LSP paths using the configuration parameters can be applied under two different aspects:

- Topology—There are no topology constraints with this feature. Each member LSP is treated like a point-to-point LSP and is re-optimized individually. An ingress router does not try to compute equal IGP cost paths for all its LSPs, but instead it computes paths for all the LSPs using current traffic engineering database information. While computing a path, constraint-based routing adheres to any constraints specified through the configuration, although there is no change in the constraint-based routing method for path computation.

- When to create a new LSP—When to create a new LSP can be explicitly specified. By default, an ingress router periodically computes the aggregate traffic rate by adding up the traffic rate of all the individual LSPs. Looking at the aggregate bandwidth and configuration, the ingress router recomputes the number of LSPs and the bandwidths of the LSPs. The new LSPs are then signaled or the existing LSPs are re-signaled with the updated bandwidth. Instead of looking at the instantaneous aggregate rate, the ingress routers can compute an average (of aggregates) over some duration by removing outlier samples (of aggregates). Managing the LSPs that remain outstanding and active by considering aggregate bandwidth is more scalable than creating the new LSPs based on the usage of a particular LSP. The intervals and thresholds can be configured to track the aggregate

traffic and trigger adjustment. These dynamic LSPs co-exist and interoperate with per-LSP autobandwidth configuration.

Junos OS Container LSP Implementation

A container LSP is an ECMP TE LSP that acts like a container LSP consisting of one or more member LSPs. A point-to-point TE LSP is equivalent to a container LSP with a single member LSP. Member LSPs are added to the container LSP through a process called splitting, and removed from the container LSP through a process called merging.

Container LSP Terminology

The following terms are defined in the context of a container LSP:

- `Normalization`—An event occurring periodically when an action is taken to adjust the member LSPs, either to adjust their bandwidths, their number, or both. A normalization process is associated with a sampling process and periodically estimates aggregate utilization of a container LSP.
- `Nominal LSP`—The instance of a container LSP that is always present.
- `Supplementary LSP`—The instances or sub-LSPs of a container LSP, which are dynamically created or removed.

  Autobandwidth is run over each of the member LSPs, and each LSP is resized according to the traffic it carries and the autobandwidth configuration parameters. The aggregate demand on a container LSP is tracked by adding up the bandwidth across all the member LSPs.
- `Minimum signaling-bandwidth`—The minimum bandwidth with which a member LSP is signaled at the time of normalization or initialization. This could be different from the minimum-bandwidth defined under autobandwidth.
- `Maximum signaling-bandwidth` —The maximum bandwidth with which a member LSP is signaled at the time of normalization or initialization. This could be different from the maximum-bandwidth defined under autobandwidth.
- `Merging-bandwidth` —Specifies the lower bandwidth threshold on the aggregate bandwidth usage, such that if the aggregate usage falls below this value, the ingress router merges the member LSPs at the time of normalization.
- `Splitting-bandwidth` —Specifies the upper bandwidth threshold on the aggregate bandwidth usage, such that if the aggregate usage exceeds this value, the ingress router splits the member LSPs at the time of normalization.
- `Aggregate minimum-bandwidth` —Sum of merging-bandwidth of the current active member LSPs. This minimum bandwidth is different from the autobandwidth minimum-bandwidth.

- `Aggregate maximum-bandwidth`—Sum of the splitting-bandwidth of the current active member LSPs. This maximum bandwidth is different from the autobandwidth maximum-bandwidth.

LSP Splitting

Operational Overview

The LSP splitting mechanism enables an ingress router to create new member LSPs or to re-signal existing LSPs with different bandwidths within a container LSP when a demand X is placed on the container LSP. With LSP splitting enabled, an ingress router periodically creates a number of LSPs (by signaling new ones or re-signaling existing ones) to accommodate a new aggregate demand X. In the current implementation, an ingress router tries to find an LSP path satisfying a demand X and other constraints. If no path is found, either the LSP is not signaled or it remains up, but with the old reserved bandwidth.

Between two normalization events (splitting or merging), individual LSPs might get re-signaled with different bandwidths due to the autobandwidth adjustments. If a container LSP is not configured with autobandwidth, then the member LSPs are signaled with the static bandwidth value, if configured. There is no dynamic splitting in this case, as there is no dynamic estimation of aggregate bandwidth. The splitting adjustments with a specific bandwidth value can be manually triggered.

NOTE: Be aware of the following considerations for LSP splitting:

- After LSP splitting, the ingress router continues to inject one forwarding adjacency. Forwarding adjacencies are not supported in IGP for this feature.
- Between two normalization events, two LSPs might have different bandwidths subjected to autobandwidth constraints.
- After LSPs are split (or merged), make-before-break uses the fixed filter (FF) style sharing unless the `adaptive` option is configured. However, two different LSPs do not do the shared explicit (SE) style sharing for this feature.
- When LSPs are re-signaled with modified bandwidths, some of the LSPs might not get signaled successfully, leading to failover options.

Operational Constraints

LSP splitting has the following operational constraints:

- LSP bandwidth—Although there are a number of ways to allocate bandwidth values to the LSPs, the Junos OS implementation supports only an equal-bandwidth allocation policy when normalization is done, wherein all the member LSPs are signaled or re-signaled with equal bandwidth.

- Number of LSPs—If an ingress router is configured to have a minimum number of LSPs, it maintains the minimum number of LSPs even if the demand can be satisfied with less than the minimum number of LSPs. In case the ingress router is unable to do constraint-based routing for computations on the sufficient number of LSPs or signal sufficient number of LSPs, the ingress router resorts to a number of failback options.

  By default, an incremental approach is supported as a fallback option (unless configured differently), where an ingress router makes attempts to bring up the sufficient number of LSPs, such that the new aggregate bandwidth exceeds the old aggregate bandwidth (and is as close to the desired demand as possible). The ingress router then load-balances traffic using the LSPs. The LSPs that could not be brought up are removed by the ingress router.

Supported Criteria

When a container LSP signals a member LSP, the member LSP gets signaled with minimum-signaling-bandwidth. Since each member LSP is configured with autobandwidth, between two normalization events, each LSP can undergo autobandwidth adjustment multiple times. As the traffic demand increases, the ingress router creates additional supplementary LSPs . All member LSPs are used for ECMP, so they should roughly have the same reserved bandwidth after normalization.

For example, if there are K LSPs signaled after normalization, each LSP is signaled with equal bandwidth B. The total aggregate bandwidth reserved is B.K, where B satisfies the following condition:

- Minimum signaling-bandwidth is less than or equal to B, which is turn is less than or equal to the maximum signaling-bandwidth

  (minimum-signaling-bandwidth ≤ B ≤ maximum-signaling-bandwidth)

Until the next normalization event, each member LSP undergoes several autobandwidth adjustments. After any autobandwidth adjustment, if there are N LSPs with reserved bandwidths bi, where i=1,2,.., N, each bi should satisfy the following the condition:

- Minimum bandwidth is less than or equal to bi, which in turn is less than or equal to the maximum bandwidth

  (minimum-bandwidth ≤ bi ≤ maximum-bandwidth)

Both the above-mentioned conditions are applicable for per member LSP (nominal and supplementary), and essentially have the reserved bandwidth to exist within a range.

Splitting Triggers

Every time the normalization timer expires, the ingress router decides if LSP splitting is required. The ingress router works with the aggregate bandwidth instead of the individual LSP bandwidths. The following two variables are defined for aggregate bandwidth:

- Current-Aggr-Bw—Sum of reserved bandwidths of all current member LSPs.
- New-Aggr-Bw—Sum of traffic rates on all current member LSPs based on sampling.

Taking for example, if there are N member LSPs in the network at the time of normalization, the two approaches to trigger LSP splitting are as follows:

- Absolute trigger—LSP splitting is performed when New-Aggr-Bw is greater than Aggregate-maximum-bandwidth.

  (New-Aggr-Bw > Aggregate-maximum-bandwidth)

- Relative trigger—Under relative triggering, a dynamic calculation is performed. The Current-Aggr-Bw is compared with New-Aggr-Bw at the ingress routing device. LSP splitting is performed when the difference in bandwidth is greater than or equal to a calculated threshold amount. The following equation describes the desired state:

  ([1-a] x Current-Aggr-Bw < New-Aggr-Bw < [1+a] x Current-Aggr-Bw, where 0 </= a </= 1)

  NOTE: In the above condition, "a" is the adjustment threshold and its default value is 10 percent (that is, 0.10). You can configure the adjustment threshold using the splitting-merging-threshold statement at the [edit protocols mpls container-label-switched-path *lsp-name*] hierarchy level. The value is also displayed in the show mpls container-lsp extensive command output.

  When New-Aggr-Bw is greater than Current-Aggr-Bw multiplied by [1+a], thus exceeding the calculated threshold, the ingress routing device does not perform normalization. Instead because this is a relative triggering situation, LSP splitting is performed. However, when both LSP splitting and LSP merging are configured on the ingress router, LSP splitting is triggered on the ingress router when one of the two conditions is satisfied.

LSP Merging

Operational Overview

Junos OS supports two kinds of LSPs – CLI-configured LSPs and dynamically created LSPs. The CLI-configured LSPs are created manually and remain in the system until the configuration is modified. The dynamic LSPs are created dynamically by next generation MVPN, BGP virtual private LAN service (VPLS), or LDP, based on a template configuration, and are removed from the system when not used by any application for a certain duration. LSP merging follows a similar approach as dynamic LSPs.

LSP merging enables an ingress routing device to dynamically eliminate some member LSPs of the container LSP so less state information is maintained in the network. If an ingress router provisions several member LSPs between the ingress and egress routers, and there is an overall reduction in

aggregate bandwidth (resulting in some LSPs being under-utilized), the ingress router distributes the new traffic load among fewer LSPs.

Although there are a number of ways to merge the member LSPs, Junos OS supports only overall-merge when normalization is being performed. An ingress router considers the aggregate demand and the minimum (or maximum) number of LSPs and revises the number of LSPs that should be active at an ingress routing device. As a result, the following can take place periodically as the normalization timer fires:

- Re-signaling some of the existing LSPs with updated bandwidth
- Creating new LSPs
- Removing some of the existing LSPs

Operational Constraints

If a container LSP is not configured with autobandwidth, then the member LSPs are signaled with the static bandwidth value, if configured. LSP merging does not happen because there is no dynamic estimation of aggregate bandwidth. However, a manual trigger for splitting and adjusting with a specific bandwidth value can be configured.

NOTE:

- Nominal LSPs are never deleted as part of LSP merging.
- Before deleting an LSP, the LSP is made inactive, so that traffic shifts to other LSPs before removing the LSP. This is because RSVP sends PathTear before deleting routes and next hops from the Packet Forwarding Engine.
- When member LSPs are re-signaled with modified bandwidth, it might happen that some LSPs do not get signaled successfully.

Merging Triggers

Every time the normalization timer expires, the ingress router decides if LSP merging is required. The ingress router works with the aggregate bandwidth instead of the individual LSP bandwidths. The following two variables are defined for aggregate bandwidth:

- `Current-Aggr-Bw`—Sum of reserved bandwidths of all current member LSPs.
- `New-Aggr-Bw`—Sum of traffic rates on all current member LSPs based on sampling.

For example, if there are N member LSPs in the network at the time of normalization, the two approaches to trigger LSP merging are as follows:

- Absolute trigger—LSP merging is performed when `New-Aggr-Bw` is less than `Aggregate-minimum-bandwidth`.

  (`New-Aggr-Bw` < `Aggregate-minimum-bandwidth`)

- Relative trigger—The `Current-Aggr-Bw` is compared with `New-Aggr-Bw` at the ingress routing device. LSP merging is performed when the difference in the bandwidth amount is off by a threshold.

  ([1-a] x `Current-Aggr-Bw` < `New-Aggr-Bw` < [1+a] x `Current-Aggr-Bw`, where 0 </= a </= 1)

  > **NOTE**: In the above condition, "a" is the adjustment threshold and its default value is 10 percent (that is, 0.10). You can configure the adjustment threshold using the `splitting-merging-threshold` statement at the `[edit protocols mpls container-label-switched-path` *`lsp-name`*`]` hierarchy level. The value is also displayed in the `show mpls container-lsp extensive` command output.

  When the `New-Aggr-Bw` value is less than or equal to [1+a] multiplied by the `Current-Aggr-Bw` value, the ingress routing device does not perform normalization, but instead LSP merging is done. However, when both LSP splitting and LSP merging are configured on the ingress router, LSP splitting is triggered on the ingress router when one of the two conditions is satisfied.

Node and Link Protection

Junos OS supports the following mechanisms for node and link protection:

- Fast-reroute
- Link protection
- Node-link protection

Only one of the above-mentioned modes of protection can be configured on an ingress routing device at any given time. All member LSPs (nominal and supplementary) use the same mode of protection that is configured.

Naming Convention

While configuring a container LSP, a name is assigned to the LSP. The name of a nominal and a supplementary LSP is formed by adding the configured-name suffix and an auto-generated suffix to the name of the container LSP. The name of the container LSP is unique and is checked for accuracy during the configuration parsing. The container LSP name should uniquely identify parameters, such as the ingress and egress router names.

NOTE: A container LSP member LSP and a point-to-point LSP on an ingress routing device cannot have the same LSP name.

The container LSPs follow a number-based LSP naming convention. For example, if the nominal LSP's configured name is `bob` and the number of member LSPs is N, the member LSPs are named `bob-<configured-suffix>-1`, `bob-<configured-suffix>-2`, ..., and `bob-<configured-suffix>-N`.

After a normalization event, the number of member LSPs can change. For example, if the number of member LSPs increases from six to eight, then the ingress routing device keeps the first six LSPs named `bob-<configured-suffix>-1`, `bob-<configured-suffix>-2`, ..., and `bob-<configured-suffix>-6`. The two additional LSPs are named `bob-7` and `bob-8`. The original LSPs might need to be re-optimized if their signaled bandwidth changes.

Similarly, if the number of member LSPs reduces from eight to six, the ingress routing device re-signals the member LSPs in such as a way that the remaining active LSPs in the system are named `bob-<configured-suffix>-1`, `bob-<configured-suffix>-2`, ..., and `bob-<configured-suffix>-6`.

In the process of creating new LSPs, an RSVP LSP named `bob-<configured-suffix>-7` can be configured.

Normalization

Operational Overview

Normalization is an event that happens periodically. When it happens, a decision is made on the number of member LSPs that should remain active and their respective bandwidths in a container LSP. More specifically, the decision is made on whether new supplementary LSPs are to be created, or any existing LSPs are required to be re-signaled or deleted during the normalization event.

Between two normalization events, a member LSP can undergo several autobandwidth adjustments. A normalization timer, similar to re-optimization timer, is configured. The normalization timer interval should be no less than the adjustment interval or optimization timer.

NOTE: Normalization is not triggered based on network events, such as topology changes.

Operational Constraints

Normalization has the following operational constraints:

- Normalization happens only when none of the member LSPs are undergoing re-optimization or make-before-break. Normalization starts when all the member LSPs complete their ongoing make-

before-break. If normalization is pending, new optimization should not be attempted until the normalization is complete.

- After normalization, an ingress routing device first computes a set of bandwidth-feasible paths using constraint-based routing computations. If enough constraint-based routing computed paths are not brought up with an aggregate bandwidth value that exceeds the desired bandwidth, several failover actions are taken.

- After a set of bandwidth-feasible paths are available, the ingress routing device signals those paths while keeping the original set of paths up with the old bandwidth values. The make-before-break is done with shared explicit (SE) sharing style, and when some of the LSPs do not get successfully re-signaled, a bounded number of retries is attempted for a specified duration. Only when all the LSPs are successfully signaled does the ingress router switch from the old instance of the container LSP to the newer instance. If all LSPs could not be successfully signaled, the ingress router keeps those instances of members that are up with higher bandwidth values.

  For example, if the bandwidth of an old instance of a member LSP (LSP-1) is 1G, the LSP is split into LSP-1 with bandwidth 2G and LSP-2 with bandwidth 2G. If the signaling of LSP-1 with bandwidth 2G fails, the ingress router keeps LSP-1 with bandwidth 1G and LSP-2 with bandwidth 2G.

  When there is a signaling failure, the ingress routing device stays in the error state, where some LSPs have updated bandwidth values only if the aggregate bandwidth has increased. The ingress router makes an attempt to bring up those LSPs that could not be successfully signaled, resulting in minimum traffic loss.

- If an LSP goes down between two normalization events, it can increase the load on other LSPs that are up. In order to prevent overuse of other LSPs, premature normalization can be configured in case of LSP failure. LSPs can go down because of pre-emption or lack of node or link protection. It might not be necessary to bring up the LSPs that are down because the normalization process re-runs the constraint-based routing path computations.

Inter-Operation with Autobandwidth

Taking as an example, there is one nominal LSP named LSP-1 configured with the following parameters:

- Splitting-bandwidth and maximum-signaling-bandwidth of 1G
- Merging-bandwidth and minimum-signaling-bandwidth of 0.8G
- Autobandwidth

Normalization is performed differently in the following scenarios:

Changes in Per-LSP Autobandwidth Adjustments

Table 17 on page 700 illustrates how normalization splits and merges member LSPs as autobandwidth adjustments change per-LSP bandwidth with unconditional normalization.

Table 17: Normalization with Per-LSP Autobandwidth Adjustment Changes

Normalization Time	Current State	Events	Adjusted State
T0	No state.	Initialization	LSP-1 is signaled with bandwidth of 0.8G
T1	LSP-1 usage increases to 1.5G	• Multiple autobandwidth adjustments since T0 is possible. • The ingress router decides to split LSP-1 into two LSPs, and creates LSP-2.	LSP-1 = 0.8G LSP-2 = 0.8G
T2	LSP-1 usage increase to 2G LSP-2 usage increases to 0.9G (within limits)	• Aggregate bandwidth is 2.9G, which exceeds aggregate splitting maximum of 2G. • The ingress router decides to split LSP-1 into three LSPs, and creates LSP-3.	LSP-1 = 1G LSP-2 = 1G LSP-3 = 1G
T3	LSP-3 usage increases to 1.5G	• Aggregate bandwidth is 3.5G with a maximum aggregate splitting of 3G. • The ingress router decides to split LSP-1 into four LSPs, and creates LSP-4.	LSP-1 = 1G LSP-2 = 1G LSP-3 = 1G LSP-4 = 1G
T4	LSP-2 usage drops to 0.5G	• Aggregate bandwidth is 3G. • The ingress router decides to merge LSP-1 and removes LSP-4.	LSP-1 = 1G LSP-2 = 1G LSP-3 = 1G

Because autobandwidth is configured on a per-LSP basis, every time there is an autobandwidth adjustment, the ingress router re-signals each LSP with `Max Avg Bw`.

Another approach to handling the changes in per-LSP autobandwidth adjustments is to not allow individual LSPs to run autobandwidth on the ingress router, but to run autobandwidth in passive (monitor) mode. This way, sampling is done at every statistics interval for member LSPs only, and normalization is performed for the container LSP alone instead of acting on individual LSPs adjustment timer expiry.

As a result, the number of re-signaling attempts and bandwidth fluctuations for a given member LSP is reduced. Only the computed bandwidth-values per-member LSP is used by the ingress router to find an aggregate bandwidth to be used during normalization. Configuring autobandwidth adjustment followed by normalization (adjustments and normalization intervals are comparable) can lead to considerable overhead because of re-signaling.

Taking the same example, and applying the second approach, LSP-1 goes from 0.8G to 1.5G and then back to 0.8G. If the normalization timer is of the same order as the adjustment interval, the ingress router leaves LSP-1 alone with its original 0.8G and only signals LSP-2 with 0.8G. This helps achieve the final result of normalization, thus avoiding the extra signaling attempt on LSP-1 with 1.5G at adjustment timer expiry.

Because member LSPs always use equal bandwidth, any adjustment done on member LSPs is undone. The member LSPs are re-signaled with reduced bandwidth when compared to the reserved capacity in adjustment trigger with normalization trigger. Therefore, avoiding adjustment trigger for member LSPs might be useful assuming that normalization and adjustment intervals are of the same order.

NOTE: We recommend that the normalization timer be higher than the autobandwidth adjustment interval and regular optimization duration, as the traffic trends are observed at a longer time scale and normalization is performed one-to-three times per day. An LSP can undergo optimization for the following reasons:

- Normal optimization
- Autobandwidth adjustment
- Normalization

Changes in Traffic Growth

Table 18 on page 702 illustrates how normalization is performed when traffic grows in large factor.

Table 18: Normalization with Traffic Growth

Normalization Time	Current State	Events	Adjusted State
T0	No state		LSP-1 is signaled with bandwidth of 0.8G
T1	LSP-1 usage increase to 3G	• Aggregate usage exceeds maximum splitting bandwidth • The ingress router decides to split LSP-1, and creates two more supplementary LSPs	LSP-1 = 1G LSP-2 = 1G LSP-3 = 1G

Having fewer LSPs is preferred over signaling four LSPs each with 0.8G bandwidth, unless there is a constraint on the minimum number of LSPs.

Computed Range and Configured Feasible Ranges

When an ingress router is configured with the minimum and maximum number of LSPs, and per LSP splitting-bandwidth and merging-bandwidth values, the bandwidth thresholds are used for splitting and merging. For this, the number of LSPs (N) should satisfy the following constraints:

```
minimum-member-lsps ≤ N ≤ maximum-member-lsps
```

At the time of normalization, based on the aggregate demand X:

```
[X/splitting-bandwidth]  ≤ N ≤ [X/merging-bandwidth]
```

The above-mentioned constraints provide two ranges for N to work from. If the two ranges for N are overlapping, N will be selected from the overlapping interval (lowest possible N) to keep the number of LSPs small in the network.

Otherwise, if maximum-member-lsps is less than [X/splitting-bandwidth], the ingress router keeps (at maximum) the maximum-member-lsps in the system, and the bandwidth of each LSP is [X/maximum-member-lsps] or the maximum-signaling-bandwidth, whichever is less. It is possible that some LSPs might not get signaled successfully.

Similarly, if minimum-member-lsps is greater than [X/merging-bandwidth], the ingress router keeps (at minimum) the minimum-member-lsps in the system, and the bandwidth of each LSP is [X/minimum-member-lsps] or the minimum-signaling-bandwidth, whichever is less.

Taking as an example, normalization is performed as following in these cases:

- Case 1
  - minimum-member-lsps = 2
  - maximum-member-lsps = 10
  - aggregate demand = 10G
  - merging-bandwidth = 1G
  - splitting-bandwidth = 2.5G

  In this case, the ingress routing device signals four member LSPs each with a bandwidth of 2G.
- Case 2
  - minimum-member-lsps = 5
  - maximum-member-lsps = 10
  - aggregate demand = 10G
  - merging-bandwidth = 2.5G
  - splitting-bandwidth = 10G

  In this case, the ingress routing device signals five member LSPs each with a bandwidth of 2G. Here, the static configuration on the number of member LSPs takes precedence.
- Case 3
  - minimum-signaling-bandwidth = 5G
  - maximum-signaling-bandwidth = 40G
  - merging-bandwidth = 10G
  - splitting-bandwidth = 50G

When a container LSP comes up, the nominal LSP is signaled with minimum-signaling-bandwidth. At the time of normalization, the new-aggregate-bandwidth is 100G. To find N and the bandwidth of each LSP, N should satisfy the following constraint:

```
100/50 ≤ N ≤ 100/10, which gives 2 ≤ N ≤ 10
```

Therefore, N is equal to:

- N = 2, bandwidth = min {100/2G, 40G} = 40G

  This option does not satisfy the new aggregate of 100G.

- N = 3, bandwidth = min {100/3G, 40G} = 33.3G

  This option makes the aggregate bandwidth equal to 100G.

In this case, the ingress routing device signals three LSPs each with a bandwidth of 33.3G.

NOTE: The ingress router does not signal an LSP smaller than the minimum-signaling-bandwidth.

Constraint-Based Routing Path Computation

Although there are no changes in the general constraint-based routing path computation, with a container LSP, there is a separate module that oversees the normalization process, schedules constraint-based routing events, and schedules switchover from an old instance to a new instance, when appropriate. An ingress routing device has to handle the constraint-based routing path computation periodically. When normalization occurs, an ingress router has to compute constraint-based routing paths, if the number of LSPs or the bandwidth of the LSPs needs to be changed.

For example, there are K LSPs at the ingress router with bandwidth values X-1, X-2, ..., and X-K. The current aggregate bandwidth value is Y, which is the sum of X-1 plus X-2 plus X-K. If there is a new demand of W, the ingress router first computes how many LSPs are required. If the ingress router only needs N LSPs (LSP-1, LSP-2, .., and LSP-N) each with bandwidth value B, the task of the constraint-based routing module is to provide a set of bandwidth-feasible LSPs that can accommodate the new aggregate demand which is not less than Y.

The ingress router then tries to see if the constraint-based routing paths can be computed successfully for all N LSPs. If the paths for all the LSPs are found successfully, the constraint-based routing module returns the set to the normalization module.

It is possible that the constraint-based routing computation is not successful for some LSPs. In this case, the ingress routing device takes the following action:

- If the configuration allows for incremental-normalization, implying if the ingress router has enough LSPs whose aggregate exceeds Y, the constraint-based routing module returns that set of paths.
- Whether increment-normalization is configured or not, if constraint-based routing paths could not be computed for a sufficient number of LSPs, the ingress router has to repeat the process of finding a new set of LSPs. Initially, the ingress router starts with the lowest value of N from the feasible region. Every time, the ingress router has to revise the number, it linearly increases it by 1. As a result, per LSP bandwidth becomes less and therefore, there is a greater chance of successful signaling. The process is repeated for all feasible values of N (or some bounded number of times or duration as configured).

  The ingress router signals the LSPs after successful computations of the constraint-based routing path computation. It might happen that when the LSPs are signaled, signaling of many LSPs fail. In addition to the constraint-based routing path computations to be successful, the RSVP signaling should also succeed, such that the new aggregate is not less than the old aggregate bandwidth.

Sampling

Sampling is important for normalization to function. With sampling configured, an ingress routing device is able to make a statistical estimate of the aggregate traffic demands. Every time the sampling timer fires, the ingress routing device can consider traffic rates on different LSPs and compute an aggregate bandwidth sample. This sampling timer is different from the statistics sampling done periodically by RSVP on all LSPs. The aggregate bandwidth is a sample to be used at the time of normalization. An ingress routing device can save past samples to compute an average (or some other statistical measure) and use it the next time normalization happens.

To remove any outlier samples, a sampling token is configured. In other words, from all the aggregate samples collected during the configured time, the bottom and top outliers are ignored before computing a statistical measure from the remaining samples.

The following two methods of computing an aggregate bandwidth value are supported:

- Average—All the aggregate bandwidth samples are considered by the ingress routing device, and then all the outlier samples are removed. The average bandwidth value is computed from the remaining samples to be used during normalization.
- Max—All the aggregate bandwidth samples are considered by the ingress routing device, and then all the outlier samples are removed. The maximum bandwidth value is picked from the remaining samples to be used during normalization.

The time duration, the number of past aggregate samples to store, the percentile value to determine, and the ignore outliers are user-configurable parameters.

Support for NSR, IPG-FA, and Static Routes

Starting with Junos OS Release 15.1, container label-switched paths (LSPs) provide support for nonstop active routing (NSR), IGP forwarding adjacency (FA), and static routes to address the requirements of wider business cases.

NSR Support

A container LSP has the characteristics of ECMP and RSVP traffic engineering. Because a container LSP consists of several member LSPs between an ingress and an egress router, with each member LSP taking a different path to the same destination, the ingress router is configured with all the parameters necessary to compute an RSVP ECMP LSP. These parameters along with the forwarding state information have to be synchronized between the primary and backup Routing Engines to enable the support for nonstop active routing (NSR) for container LSPs. While some of the forwarding state information on the backup Routing Engine is locally built based on the configuration, most of it is built based on periodic updates from the primary Routing Engine. The container LSPs are created dynamically using the replicated states on the backup Routing Engine.

By default, normalization occurs once in every 6 hours and during this time, a number of autobandwidth adjustments happen over each member LSP. A member LSP is resized according to the traffic it carries and the configured autobandwidth configuration parameters. The aggregate demand on a container LSP is tracked by summing up the bandwidth across all the member LSPs.

For RSVP point-to-point LSPs, a Routing Engine switchover can be under any one of the following:

- **Steady state**

  In the steady state, the LSP state is up and forwards traffic; however, no other event, such as the make-before-break (MBB), occurs on the LSP. At this stage, the RPD runs on both the Routing Engines, and the switchover event toggles between the primary and backup Routing Engine. The backup Routing Engine has the LSP information replicated already. After the switchover, the new primary uses the information of the replicated structure to construct the container LSP and en-queues the path (ERO) of LSP in the retrace mode. RSVP signals and checks if the path mentioned in the ERO is reachable. If the RSVP checks fail, then the LSP is restarted. If the RSVP checks succeed, the LSP state remains up.

- **Action leading to make-before-break (MBB)**

  A container LSP can be optimized with updated bandwidth, and this change is done in a MBB fashion. During an MBB process, there are two path instances for a given LSP, and the LSP switches from one instance to another. For every Routing Engine switchover, the path is checked to find out where in the MBB process the path is. If the path is in the middle of the MBB process, with the main

instance being down and the re-optimized path being up, then MBB can switch over to the new instance. The `show mpls lsp extensive` command output, in this case, is as follows:

```
13 Dec  3 01:33:38.941 Make-before-break: Switched to new instance
   12 Dec  3 01:33:37.943 Record Route:  10.1.1.1
   11 Dec  3 01:33:37.942 Up
   10 Dec  3 01:33:37.942 Automatic Autobw adjustment succeeded: BW changes from 100 bps to
281669 bps
    9 Dec  3 01:33:37.932 Originate make-before-break call
    8 Dec  3 01:33:37.931 CSPF: computation result accepted  10.1.1.1
    7 Dec  3 01:28:44.228 CSPF: ERO retrace was successful  10.1.1.1
    6 Dec  3 01:19:39.931 10.1.1.2 Down: mbb/reopt
    5 Dec  3 01:18:29.286 Up: mbb/reopt
    4 Dec  3 01:14:47.119 10.1.1.2 Down: mbb/reopt
    3 Dec  3 01:13:29.285 Up: mbb/reopt
    2 Dec  3 01:10:59.755 Selected as active path: selected by master RE
```

A similar behavior is retained for member LSPs during bandwidth optimization.

A Routing Engine switchover under the steady state (when normalization is not in progress), keeps the container LSPs up and running without any traffic loss. Events, such as an MBB due to autobandwidth adjustments, link status being down, or double failure, in the steady state are similar to a normal RSVP point-to-point LSP.

If the container LSP is in the process of normalization, and the normalization event is triggered either manually or periodically, it goes through the computation and execution phase. In either of the cases, zero percent traffic loss is not guaranteed.

- Normalization in the computation phase

  During the computation phase, the primary Routing Engine calculates the targeted member LSP count and bandwidth with which each member LSP should be re-signaled. The backup Routing Engine has limited information about the container LSP, such as the LSP name, LSP ID, current bandwidth of its member LSP, member LSP count, and the normalization retry count. If the switchover happens during the computation phase, then the backup Routing Engine is not aware of the targeted member LSP count and the bandwidth to be signaled. Since traffic statistics are not copied to the backup Routing Engine, it cannot compute the targeted member count and bandwidth. In this case, the new primary Routing Engine uses the old data stored in the targeted member LSP count and the targeted bandwidth to signal the LSPs.

- Normalization in the execution phase

  During the execution phase, RSVP of the primary Routing Engine tries to signal the LSPs with the newly calculated bandwidth. If the switchover occurs during the signaling of LSPs with greater

bandwidth or during LSP splitting or merging, then the new primary Routing Engine uses the information of the targeted member count and bandwidth value to be signaled with, to bring up the LSPs.

IPG-FA Support

A forwarding adjacency (FA) is a traffic engineering label-switched path (LSP) that is configured between two nodes and used by an interior gateway protocol (IGP) to forward traffic. By default, an IGP does not consider MPLS traffic-engineering tunnels between sites, for traffic forwarding. Forwarding adjacency treats a traffic engineering LSP tunnel as a link in an IGP topology, thus allowing the nodes in the network also to forward the IP traffic to reach the destination over this FA LSP. A forwarding adjacency can be created between routing devices regardless of their location in the network.

To advertise a container LSP as an IGP-FA, the LSP name needs to be configured either under IS-IS or OSPF. For example:

IS-IS

```
[edit]
protocols {
    isis {
        label-switched-path container-lsp-name;
    }
}
```

OSPF

```
[edit]
protocols {
    ospf {
        area 0.0.0.0 {
            label-switched-path container-lsp-name;
        }
    }
}
```

NOTE: The IGP-FA is applied to both container LSPs and regular point-to-point LSPs. If a container LSP and a point-to-point LSP share the same name, the point-to-point LSP is given preference for FA.

Static Route Support

Static routes often include only one or very few paths to a destination and generally do not change. These routes are used for stitching services when policies and other protocols are not configured.

To advertise a container LSP as a static route, the LSP name needs to be configured under the static route configuration. For example:

Static Route

```
[edit]
routing-options {
    static {
        route destination {
            lsp-next-hop container-lsp-name;
        }
    }
}
```

NOTE: The static route support is applied to both container LSPs and regular point-to-point LSPs. If a container LSP and a point-to-point LSP share the same name, the point-to-point LSP is given preference for static routing.

Configuration Statements Supported for Container LSPs

Table 19 on page 710 lists the MPLS LSP configuration statements that apply to RSVP LSP and a container LSP (nominal and supplementary).

The configuration support is defined using the following terms:

- Yes—The configuration statement is supported for this type of LSP.
- No—The configuration statement is not supported for this type of LSP.
- N/A—The configuration statement is not applicable for this type of LSP.

Table 19: Applicability of RSVP LSPs Configuration to a Container LSP

Configuration Statement	RSVP LSP (Ingress)	Member LSP (Ingress)
adaptive (Default: non-adaptive)	Yes	Yes
admin-down	Yes	Yes
admin-group	Yes	Yes
admin-groups-except	Yes	Yes
apply-groups	Yes	Yes
apply-groups-except	Yes	Yes
associate-backup-pe-groups	Yes	No
associate-lsp (No bidirectional support)	Yes	No
auto-bandwidth	Yes	Yes
backup	Yes	No

ultimate-hop-popping	Yes	Yes

Impact of Configuring Container LSPs on Network Performance

A container LSP is a container LSP that allows multiple member LSPs to co-exist and be managed as a bundle. The member LSPs are similar to independent point-to-point RSVP LSPs. As a result, resource consumption is similar to the sum of resources consumed by each point-to-point RSVP LSP. However, provisioning a container LSP is more efficient, as under-utilized member LSPs are dynamically removed, thus saving memory and CPU resources.

The container LSP features are dependent on the presence of a functional base MPLS RSVP implementation. As a result, a container LSP does not introduce any security considerations beyond the existing considerations for the base MPLS RSVP functionality. The categories of possible attacks and countermeasures are as follows:

- Interaction with processes and router configuration

  No new communication mechanisms with external hosts are required for a container LSP. Data arrives at the RSVP module through local software processes and router configuration, other than RSVP neighbor adjacency. Junos OS provides security controls on access to the router and router configuration.

- Communication with external RSVP neighbors

  RSVP signaled MPLS LSPs depend on the services of RSVP and IGP to communicate RSVP messages among neighboring routers across the network . Because the RSVP sessions involve communication outside of the local router, they are subject to many forms of attack, such as spoofing of peers, injection of falsified RSVP messages and route updates, and attacks on the underlying TCP/UDP transport for sessions. Junos OS provides countermeasures for such attack vectors.

- Resource limits and denial of service

  Junos OS provides several mechanisms through policers and filters to protect against denial-of-service attacks based on injecting higher than the expected traffic demands. At the MPLS LSP level, Junos OS allows operators to configure limits on the LSP bandwidth and the number of LSPs. However, like point-to-point RSVP LSPs, container LSPs do not enforce limits on the volume of traffic forwarded over these LSPs.

Supported and Unsupported Features

Junos OS supports the following container LSP features:

- Equal-bandwidth-based LSP splitting mechanism
- Aggregate-bandwidth-based LSP splitting and merging in a make-before-break way
- LSP-number-based naming mechanism for dynamically created member LSPs
- Periodic sampling mechanisms to estimate aggregate bandwidth
- Interoperability with auto-bandwidth feature
- ECMP using the dynamically created LSPs
- LDP-tunneling on the dynamically created LSP
- Configuring container LSP using IGP shortcuts
- Aggregated Ethernet links
- Logical systems

Junos OS does **not** support the following container LSP functionality:

- Node and link disjoint paths for different LSPs between an ingress and an egress routing device
- Bandwidth allocation policy different from equal bandwidth policy at the normalization event
- Constraint-based routing path computation to find equal IGP cost paths for different LSPs
- RSVP objects, such as `MLSP_TUNNEL Sender Template`, and `MLSP_TUNNEL Filter Specification` defined in [KOMPELLA-MLSP]
- Change in topology as a trigger for LSP splitting and merging
- Change in topology and link failure as a trigger for normalization, unless member LSPs go down
- Egress protection on container LSP
- Container LSP as a backup LSP for IGP interface
- Container LSP as provider tunnel for multicast VPNs
- Dynamic LSPs for normalization
- CCC using container LSP
- Secondary paths for container LSP
- Bidirectional container LSP
- Policing
- Static routes using container LSPs as next hops on a best-effort basis
- External path computing entity, such as PCE
- Multichassis
- IPv6

Example: Configuring Dynamic Bandwidth Management Using Container LSP

IN THIS SECTION

- Requirements | **717**
- Overview | **717**
- Configuration | **718**
- Verification | **730**

This example shows how to enable dynamic bandwidth management by configuring container label-switched paths (LSPs) that enable load balancing across multiple point-to-point member LSPs.

Requirements

This example uses the following hardware and software components:

- Five routers that can be a combination of M Series, MX Series, or T Series routers, out of which two routers are provider edge (PE) routers and three routers are provider (P) routers
- Junos OS Release 14.2 or later running on all the routers

Before you begin:

1. Configure the device interfaces.
2. Configure the autonomous system numbers and router IDs for the devices.
3. Configure the following protocols:
   - RSVP
   - MPLS
   - BGP
   - OSPF

Overview

IN THIS SECTION

Topology | **718**

Starting with Junos OS Release 14.2, a new type of LSP, called a container LSP, is introduced to enable load balancing across multiple point-to-point LSPs. A container LSP includes one or more member LSPs between the same ingress and egress routing devices. The member LSPs are similar to independent point-to-point LSPs, and each member LSP takes a different path to the same destination and can be routed along a different IGP cost path.

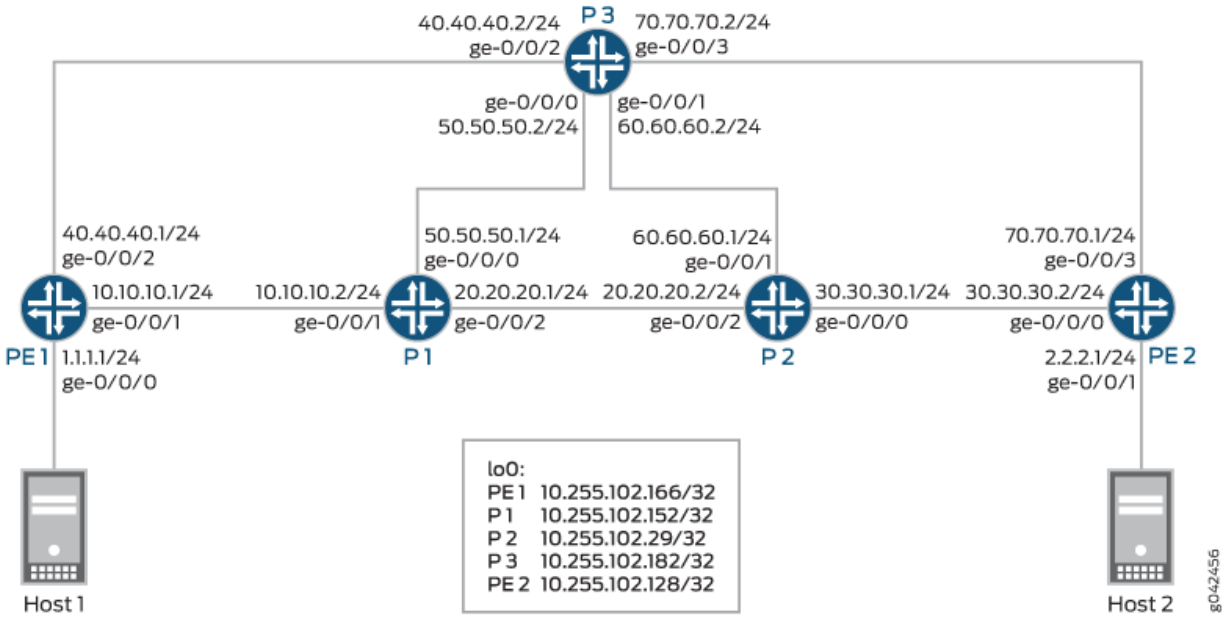
A container LSP provides support for dynamic bandwidth management by enabling the ingress router to dynamically add and remove member LSPs through a process called LSP splitting and LSP merging,

respectively, based on configuration and aggregate traffic. Besides addition and deletion, member LSPs can also be re-optimized with different bandwidth values in a make-before-break way.

Topology

Figure 47 on page 718 is a sample topology configured with container LSPs.

Figure 47: Dynamic Bandwidth Management Using Container LSP



In this example, Routers PE1 and PE2 are the PE routers connected to hosts Host1 and Host2, respectively. The core routers, Routers P1, and P2, and P3 connect to the PE routers.

Configuration

IN THIS SECTION

- CLI Quick Configuration | **719**
- Procedure | **723**

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the `[edit]` hierarchy level, and then enter `commit` from configuration mode.

Procedure

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the CLI User Guide.

To configure Router PE1:

1. Configure the Router PE1 interfaces.

```
[edit interfaces]
user@PE1# set ge-0/0/0 unit 0 family inet address 1.1.1.1/24
user@PE1# set ge-0/0/1 unit 0 family inet address 10.10.10.1/24
user@PE1# set ge-0/0/1 unit 0 family mpls
user@PE1# set ge-0/0/2 unit 0 family inet address 40.40.40.1/24
user@PE1# set ge-0/0/2 unit 0 family mpls
user@PE1# set lo0 unit 0 family inet address 10.255.102.166/32
user@PE1# set lo0 unit 0 family mpls
```

2. Configure the router ID and autonomous system number for Router PE1.

```
[edit routing-options]
user@PE1# set router-id 10.255.102.166
user@PE1# set autonomous-system 1234
```

3. Enable the policy to load-balance traffic.

```
[edit routing-options]
user@PE1# set forwarding-table export pplb
```

4. Enable RSVP on all Router PE1 interfaces (excluding the management interface).

```
[edit protocols]
user@PE1# set rsvp preemption aggressive
user@PE1# set rsvp interface all aggregate
user@PE1# set rsvp interface fxp0.0 disable
user@PE1# set rsvp interface ge-0/0/1.0
user@PE1# set rsvp interface ge-0/0/2.0
```

5. Enable MPLS on all the interfaces of Router PE1 (excluding the management interface).

```
[edit protocols]
user@PE1# set mpls interface all
user@PE1# set mpls interface fxp0.0 disable
```

6. Configure the MPLS statistics parameters.

```
[edit protocols]
user@PE1# set mpls statistics file auto-bw
user@PE1# set mpls statistics file size 10m
user@PE1# set mpls statistics interval 10
user@PE1# set mpls statistics auto-bandwidth
```

7. Configure the label-switched path (LSP) template parameters.

```
[edit protocols]
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 template
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 optimize-timer 30
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 link-protection
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 adaptive
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 auto-bandwidth adjust-interval
300
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 auto-bandwidth adjust-threshold
```

```
5
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 auto-bandwidth minimum-
bandwidth 10m
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 auto-bandwidth maximum-
bandwidth 10m
```

8. Configure a container LSP between Router PE1 and Router PE2, and assign the PE1-to-PE2-template1 LSP template.

```
[edit protocols]
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100 to 10.255.102.128
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100 label-switched-path-
template PE1-to-PE2-template1
```

9. Configure the container LSP parameters.

```
[edit protocols]
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100 splitting-merging
maximum-member-lsps 20
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100 splitting-merging
minimum-member-lsps 2
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100 splitting-merging
splitting-bandwidth 40m
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100 splitting-merging
merging-bandwidth 6m
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100 splitting-merging
maximum-signaling-bandwidth 10m
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100 splitting-merging
minimum-signaling-bandwidth 10m
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100 splitting-merging
normalization normalize-interval 400
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100 splitting-merging
normalization failover-normalization
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100 splitting-merging
normalization normalization-retry-duration 20
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100 splitting-merging
normalization normalization-retry-limits 3
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100 splitting-merging
sampling cut-off-threshold 1
```

```
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100 splitting-merging
sampling use-percentile 90
```

10. Configure the BGP group, and assign the local and neighbor IP addresses.

```
[edit protocols]
user@PE1# set bgp group to-PE2 type internal
user@PE1# set bgp group to-PE2 local-address 10.255.102.166
user@PE1# set bgp group to-PE2 neighbor 10.255.102.128
user@PE1# set bgp group to-PE2 family inet-vpn unicast
user@PE1# set bgp group to-PE2 export direct
```

11. Enable OSPF on all the interfaces of Router PE1 (excluding the management interface) along with traffic engineering capabilities.

```
[edit protocols]
user@PE1# set ospf traffic-engineering
user@PE1# set ospf area 0.0.0.0 interface all
user@PE1# set ospf area 0.0.0.0 interface fxp0.0 disable
user@PE1# set ospf area 0.0.0.0 interface ge-0/0/2.0 metric 100
```

12. Configure the policy statement to load-balance traffic.

```
[edit policy-options]
user@PE1# set policy-statement direct term 1 from protocol direct
user@PE1# set policy-statement direct term 1 then accept
user@PE1# set policy-statement pplb then load-balance per-packet
```

13. Configure a routing instance on Router PE1, and assign the routing instance interface.

```
[edit routing-instances]
user@PE1# set vpn1 instance-type vrf
user@PE1# set vpn1 interface ge-0/0/0.0
```

14. Configure the route distinguisher, vrf target, and vrf-table label values for the VRF routing instance.

```
[edit routing-instances]
user@PE1# set vpn1 route-distinguisher 10.255.102.166:1
```

```
user@PE1# set vpn1 vrf-target target:1:1
user@PE1# set vpn1 vrf-table-label
```

Results

From configuration mode, confirm your configuration by entering the `show interfaces`, `show routing-options`, `show protocols`, `show policy-options`, and `show routing-options` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1# show interfaces
ge-0/0/0 {
    unit 0 {
        family inet {
            address 1.1.1.1/24;
        }
    }
}
ge-0/0/1 {
    unit 0 {
        family inet {
            address 10.10.10.1/24;
        }
        family mpls;
    }
}
ge-0/0/2 {
    unit 0 {
        family inet {

Confirm that the configuration is working properly.

Verifying the Container LSP Status Without Bandwidth

Purpose

Verify the status of the container LSP.

Action

From operational mode, run the **show mpls container-lsp extensive** command.

```
user@PE1> show mpls container-lsp extensive
Ingress LSP: 1 sessions
Container LSP name: PE1-PE2-container-100, State: Up, Member count: 2
 Normalization
  Min LSPs: 2, Max LSPs: 20
  Aggregate bandwidth: 20Mbps, Sampled Aggregate bandwidth: 0bps

Meaning

The container LSP is established between Routers PE1 and PE2.

Verifying the Container LSP Status with Increased Bandwidth (Before Normalization)

Purpose

Verify the status of the container LSP with increased bandwidth before normalization happens.

Action

From operational mode, run the **show mpls container-lsp extensive** command.

```
user@PE1> show mpls container-lsp extensive
Ingress LSP: 1 sessions
Container LSP name: PE1-PE2-container-100, State: Up, Member count: 2
 Normalization
  Min LSPs: 2, Max LSPs: 20
  Aggregate bandwidth: 20Mbps, Sampled Aggregate bandwidth: 42.6984Mbps
  NormalizeTimer: 400 secs, NormalizeThreshold: 10%
  Max Signaling BW: 10Mbps, Min Signaling BW: 10Mbps, Splitting BW: 40Mbps, Merging BW: 6Mbps
  Mode: incremental-normalization, failover-normalization
  Sampling: Outlier cut-off 1, Percentile 90 of Aggregate
  Normalization in 321 second(s)
    3 Jun  5 21:22:34.731 Normalization complete: container (PE1-PE2-container-100) with 2
members
    2 Jun  5 21:22:15.503 Normalize: container (PE1-PE2-container-100) create 2 LSPs, min bw
10000000bps, member count 0
    1 Jun  5 21:22:15.503 Normalize: normalization with aggregate bandwidth 0 bps

Total 0 displayed, Up 0, Down 0
```

```
Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Meaning

At the expiry of the normalization timer, the container LSP is split into five member LSPs, each with 10 Mbps (minimum and maximum signaling bandwidth). As a result, the aggregate bandwidth is 50 Mbps.

Verifying the Container LSP Splitting Process

Purpose

Verify the container LSP splitting process after normalization happens.

Action

From operational mode, run the **show route 2.2.2** command.

```
user@PE1> show route 2.2.2
vpn1.inet.0: 3 destinations, 3 routes (3 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

2.2.2.0/24         *[BGP/170] 00:12:14, localpref 100, from 10.255.102.128
                      AS path: I, validation-state: unverified
>to 10.10.10.2 via ge-0/0/1.0,label-switched-path PE1-PE2-container100-1
to 10.10.10.2 via ge-0/0/1.0, label-switched-path PE1-PE2-container100-2
to 10.10.10.2 via ge-0/0/1.0, label-switched-path PE1-PE2-container100-3
to 10.10.10.2 via ge-0/0/1.0, label-switched-path PE1-PE2-container100-4
to 10.10.10.2 via ge-0/0/1.0, label-switched-path PE1-PE2-container100-5
```

Meaning

After LSP splitting, Router PE1 has injected the forwarding adjacency.

Verifying the Container LSP Statistics

Purpose

Verify the container LSP statistics after normalization happens.

Action

From operational mode, run the **show mpls container-lsp statistics** command.

```
user@PE1> show mpls container-lsp statistics
Ingress LSP: 1 sessions
Container LSP name                              State     Member LSP count
PE1-PE2-container-100                           Up                5
To              From            State     Packets            Bytes LSPname
10.255.102.128   10.255.102.166  Up   15166271       2062612856 PE1-PE2-container-100-1
10.255.102.128   10.255.102.166  Up   12289912       1671428032 PE1-PE2-container-100-2
10.255.102.128   10.255.102.166  Up   13866911       1885899896 PE1-PE2-container-100-3
10.255.102.128   10.255.102.166  Up   12558707       1707984152 PE1-PE2-container-100-4
10.255.102.128   10.255.102.166  Up   11512151       1565652536 PE1-PE2-container-100-5
```

Meaning

Traffic is load-balanced across the newly created member LSPs.

Verifying the Container LSP Status with Decreased Bandwidth (Before Normalization)

Purpose

Verify the status of the container LSP with decreased bandwidth before normalization happens.

Action

From operational mode, run the **show mpls container-lsp detail** command.

```
user@PE1> show mpls container-lsp detail
Ingress LSP: 1 sessions
Container LSP name: PE1-PE2-container-100, State: Up, Member count: 5
 Normalization
  Min LSPs: 2, Max LSPs: 20
  Aggregate bandwidth: 50Mbps, Sampled Aggregate bandwidth: 2.0215Mbps
  NormalizeTimer: 400 secs, NormalizeThreshold: 10%
  Max Signaling BW: 10Mbps, Min Signaling BW: 10Mbps, Splitting BW: 40Mbps, Merging BW: 6Mbps
  Mode: incremental-normalization, failover-normalization
  Sampling: Outlier cut-off 1, Percentile 90 of Aggregate
```

```
  Normalization in 384 second(s)
---Output truncated---
```

Meaning

Because normalization has not happened, the member LSP count remains at 5.

Verifying the Container LSP Status with Decreased Bandwidth (After Normalization)

Purpose

Verify the status of the container LSP with decreased bandwidth after normalization happens.

Action

From operational mode, run the **show mpls container-lsp detail** command.

```
user@PE1> show mpls container-lsp detail
Ingress LSP: 1 sessions
Container LSP name: PE1-PE2-container-100, State: Up, Member count: 2
 Normalization
  Min LSPs: 2, Max LSPs: 20
  Aggregate bandwidth: 20Mbps, Sampled Aggregate bandwidth: 0bps
  NormalizeTimer: 400 secs, NormalizeThreshold: 10%
  Max Signaling BW: 10Mbps, Min Signaling BW: 10Mbps, Splitting BW: 40Mbps, Merging BW: 6Mbps
  Mode: incremental-normalization, failover-normalization
  Sampling: Outlier cut-off 1, Percentile 90 of Aggregate
  Normalization in 397 second(s)
   22 Jun  5 22:30:37.094 Clear history and statistics: on container (PE1-PE2-container-100)
   21 Jun  5 22:30:37.094 Delete member LSPs: PE1-PE2-container-100-3 through PE1-PE2-
container-100-5
   20 Jun  5 22:30:37.090 Normalize: container (PE1-PE2-container-100) into 2 members - each
with bandwidth 10000000 bps
   19 Jun  5 22:30:37.090 Normalize: normalization with aggregate bandwidth 2037595 bps
   18 Jun  5 22:30:37.090 Normalize: normalizaton with 2037595 bps
---Output truncated---
```

Meaning

At the expiry of the normalization timer, the container LSP merging takes place because there is an overall reduction in bandwidth. The member LSPs are merged, and the member LSP count is 2 after normalization.

Verifying the Container LSP Merging Process

Purpose

Verify the container LSP splitting process after normalization happens.

Action

From operational mode, run the **show route 2.2.2** command.

```
user@PE1> show route 2.2.2
vpn1.inet.0: 3 destinations, 3 routes (3 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

2.2.2.0/24         *[BGP/170] 01:09:45, localpref 100, from 10.255.102.128
                      AS path: I, validation-state: unverified
                    > to 10.10.10.2 via ge-0/0/1.0, label-switched-path PE1-PE2-container-100-1
                      to 10.10.10.2 via ge-0/0/1.0, label-switched-path PE1-PE2-container-100-2
```

Meaning

After LSP merging, Router PE1 has deleted the merged member LSPs.

Verifying Failover Normalization

Purpose

Verify load redistribution when traffic is sent at 35 Mbps and the link between Routers P1 and P2 is disabled. Arrival of PathErr on link failure triggers immediate normalization.

To enable failover normalization, include the `failover-normalization` configuration statement at the `[edit protocols mpls container-label-switched-path container-lsp-name splitting-merging normalization]` hierarchy level.

Action

From operational mode, run the **show mpls container-lsp** command.

```
user@PE1> show mpls container-lsp
Ingress LSP: 1 sessions
Container LSP name                              State     Member LSP count

```

After the ge-0/0/2 link between Routers P1 and P2 goes down, normalization is immediately triggered.

From operational mode, run the **show mpls container-lsp detail** command.

```
user@PE1> show mpls container-lsp detail

```

Meaning

Arrival of PathErr message on link failure triggers immediate normalization.

Verifying Incremental Normalization

Purpose

Verify incremental normalization when enough bandwidth is not available.

On Router PE1, the RSVP interfaces static bandwidth is restricted to 22 Mbps each.

Action

From operational mode, run the **show rsvp interface** command.

```
user@PE1> show rsvp interface
RSVP interface: 4 active
                  Active Subscr- Static      Available   Reserved    Highwater
Interface   State resv   iption  BW          BW          BW          mark
ge-0/0/2.0  Up         0   100%  22Mbps      22Mbps      0bps        21.4031Mbps
ge-0/0/1.0  Up         2   100%  22Mbps      12Mbps      10Mbps      21.7011Mbps
```

Before normalization happens:

From operational mode, run the **show mpls container-lsp** command.

```
user@PE1> show mpls container-lsp
Ingress LSP: 1 sessions
Container LSP name                              State     Member LSP count
PE1-PE2-container-100                           Up                  2
To              From            State Rt P     ActivePath       LSPname
10.255.102.128   10.255.102.166  Up     0 *                      PE1-PE2-container-100-1
10.255.102.128   10.255.102.166  Up     0 *                      PE1-PE2-container-100-2
```

After normalization happens:

From operational mode, run the **show mpls container-lsp** command.

```
user@PE1> show mpls container-lsp
Ingress LSP: 1 sessions
Container LSP name                              State     Member LSP count

```

```
    2 Jun 5 18:38:59.822 Normalize: container (PE1-PE2-container-100) create 2 LSPs, min bw
5000000bps, member count 0
    1 Jun 5 18:38:59.822 Normalize: normalization with aggregate bandwidth 0 bps
```

Meaning

After normalization, the aggregate bandwidth after three retries is 40.8326 Mbps.

Configuring Dynamic Bandwidth Management Using Container LSP

You can configure a container LSP to enable load balancing across multiple point-to-point LSPs dynamically. A container LSP includes one or more member LSPs between the same ingress and egress routing devices. The member LSPs are similar to independent point-to-point LSPs, and each member LSP takes a different path to the same destination and can be routed along a different IGP cost path.

A container LSP provides support for dynamic bandwidth management by enabling the ingress router to dynamically add and remove member LSPs through a process called LSP splitting and LSP merging, respectively, based on configuration and aggregate traffic. Besides addition and deletion, member LSPs can also be re-optimized with different bandwidth values in a make-before-break way.

Before you begin:

1. Configure the device interfaces.
2. Configure the device router ID and autonomous system number.
3. Configure the following protocols:
   - RSVP
   - BGP

     Configure a BGP group to peer device with remote provider edge (PE) device.
   - OSPF

     Enable traffic engineering capabilities.
4. Configure a VRF routing instance.

To configure the PE device:

1. Enable MPLS on all the interfaces (excluding the management interface).

```
[edit protocols]
user@PE1# set mpls interface all
user@PE1# set mpls interface fxp0.0 disable
```

2. Configure the MPLS statistics parameters.

```
[edit protocols]
user@PE1# set mpls statistics file file-name
user@PE1# set mpls statistics file size size
user@PE1# set mpls statistics interval seconds
user@PE1# set mpls statistics auto-bandwidth
```

3. Configure the label-switched path (LSP) template parameters.

```
[edit protocols]
user@PE1# set mpls label-switched-path template-name template
user@PE1# set mpls label-switched-path template-name optimize-timer seconds
user@PE1# set mpls label-switched-path template-name link-protection
user@PE1# set mpls label-switched-path template-name adaptive
user@PE1# set mpls label-switched-path template-name auto-bandwidth adjust-interval seconds
user@PE1# set mpls label-switched-path template-name auto-bandwidth adjust-threshold seconds
user@PE1# set mpls label-switched-path template-name auto-bandwidth minimum-bandwidth mbps
user@PE1# set mpls label-switched-path template-name auto-bandwidth maximum-bandwidth mbps
```

4. Configure a container LSP between the two PE routers, and assign the LSP template.

```
[edit protocols]
user@PE1# set mpls container-label-switched-path container-lsp-name to remote-PE-ip-address
user@PE1# set mpls container-label-switched-path container-lsp-name label-switched-path-
template template-name
```

5. Configure the container LSP parameters.

```
[edit protocols]
user@PE1# set mpls container-label-switched-path container-lsp-name splitting-merging maximum-
member-lsps number
user@PE1# set mpls container-label-switched-path container-lsp-name splitting-merging minimum-
member-lsps number
```

```
user@PE1# set mpls container-label-switched-path container-lsp-name splitting-merging
splitting-bandwidth mbps
user@PE1# set mpls container-label-switched-path container-lsp-name splitting-merging merging-
bandwidth mbps
user@PE1# set mpls container-label-switched-path container-lsp-name splitting-merging maximum-
signaling-bandwidth mbps
user@PE1# set mpls container-label-switched-path container-lsp-name splitting-merging minimum-
signaling-bandwidth mbps
user@PE1# set mpls container-label-switched-path container-lsp-name splitting-merging
normalization normalize-interval seconds
user@PE1# set mpls container-label-switched-path container-lsp-name splitting-merging
normalization failover-normalization
user@PE1# set mpls container-label-switched-path container-lsp-name splitting-merging
normalization normalization-retry-duration seconds
user@PE1# set mpls container-label-switched-path container-lsp-name splitting-merging
normalization normalization-retry-limits number
user@PE1# set mpls container-label-switched-path container-lsp-name splitting-merging
sampling cut-off-threshold number
user@PE1# set mpls container-label-switched-path container-lsp-name splitting-merging
sampling use-percentile number
```

6. Configure the policy statement to load-balance traffic.

```
[edit policy-options]
user@PE1# set policy-statement first-policy-name term 1 from protocol direct
user@PE1# set policy-statement first-policy-name term 1 then accept
user@PE1# set policy-statement second-policy-name then load-balance per-packet
```

NOTE: The policy to load-balance traffic should be assigned to the forwarding table configuration under the [edit routing-options] hierarchy level.

```
user@PE1# set forwarding-table export pplb
```

7. Verify and commit the configuration.

   For example:

```
[edit protocols]
user@PE1# set rsvp preemption aggressive
user@PE1# set rsvp interface all aggregate
```

```
user@PE1# set rsvp interface fxp0.0 disable
user@PE1# set rsvp interface ge-0/0/1.0
user@PE1# set rsvp interface ge-0/0/2.0
user@PE1# set mpls statistics file auto-bw
user@PE1# set mpls statistics file size 10m
user@PE1# set mpls statistics interval 10
user@PE1# set mpls statistics auto-bandwidth
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 template
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 optimize-timer 30
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 link-protection
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 adaptive
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 auto-bandwidth adjust-interval 300
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 auto-bandwidth adjust-threshold 5
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 auto-bandwidth minimum-bandwidth
10m
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 auto-bandwidth maximum-bandwidth
10m
user@PE1# set mpls label-switched-path PE1-PE2-template-1 template
user@PE1# set mpls label-switched-path PE1-PE2-template-1 auto-bandwidth adjust-interval 8000
user@PE1# set mpls label-switched-path PE1-PE2-template-1 auto-bandwidth minimum-bandwidth 5m
user@PE1# set mpls label-switched-path PE1-PE2-template-1 auto-bandwidth maximum-bandwidth 10m

Multiclass LSP Overview

A multiclass LSP is an LSP that can carry several class types. One multiclass LSP can be used to support up to four class types. On the packets, the class type is specified by the EXP bits (also known as the class-of-service bits) and the per-hop behavior (PHB) associated with the EXP bits. The mapping between the EXP bits and the PHB is static, rather than being signaled in RSVP.

Once a multiclass LSP is configured, traffic from all of the class types can:

- Follow the same path
- Be rerouted along the same path
- Be taken down at the same time

Class types must be configured consistently across the Differentiated Services domain, meaning the class type configuration must be consistent from router to router in the network.

You can unambiguously map a class type to a queue. On each node router, the CoS queue configuration for an interface translates to the available bandwidth for a particular class type on that link.

The combination of a class type and a priority level forms a traffic engineering class. The IGPs can advertise up to eight traffic engineering classes for each link.

For more information about the EXP bits, see "MPLS Label Allocation" on page 509.

For more information about forwarding classes, see the Junos OS Class of Service User Guide for Routing Devices.

Multiclass LSPs

Multiclass LSPs function like standard LSPs, but they also allow you to configure multiple class types with guaranteed bandwidth. The EXP bits of the MPLS header are used to distinguish between class types. Multiclass LSPs can be configured for a variety of purposes. For example, you can configure a

multiclass LSP to emulate the behavior of an ATM circuit. An ATM circuit can provide service-level guarantees to a class type. A multiclass LSP can provide a similar guaranteed level of service.

The following sections discuss multiclass LSPs:

- "Multiclass LSP Overview" on page 753
- "Establishing a Multiclass LSP on the Differentiated Services Domain" on page 754

Establishing a Multiclass LSP on the Differentiated Services Domain

The following occurs when a multiclass LSP is established on the differentiated services domain:

1. The IGPs advertise how much unreserved bandwidth is available for the traffic engineering classes.
2. When calculating the path for a multiclass LSP, CSPF is used to ensure that the constraints are met for all the class types carried by the multiclass LSP (a set of constraints instead of a single constraint).
3. Once a path is found, RSVP signals the LSP using an RSVP object in the path message. At each node in the path, the available bandwidth for the class types is adjusted as the path is set up. The RSVP object is a hop-by-hop object. Multiclass LSPs cannot be established through routers that do not understand this object. Preventing routers that do not understand the RSVP object from carrying traffic helps to ensure consistency throughout the differentiated services domain by preventing the multiclass LSP from using a router that is incapable of supporting differentiated services.

By default, multiclass LSPs are signaled with setup priority 7 and holding priority 0. A multiclass LSP configured with these values cannot preempt another LSP at setup time and cannot be preempted.

It is possible to have both multiclass LSPs and regular LSPs configured at the same time on the same physical interfaces. For this type of heterogeneous environment, regular LSPs carry best-effort traffic by default. Traffic carried in the regular LSPs must have the correct EXP settings.

Point-to-Multipoint LSPs Overview

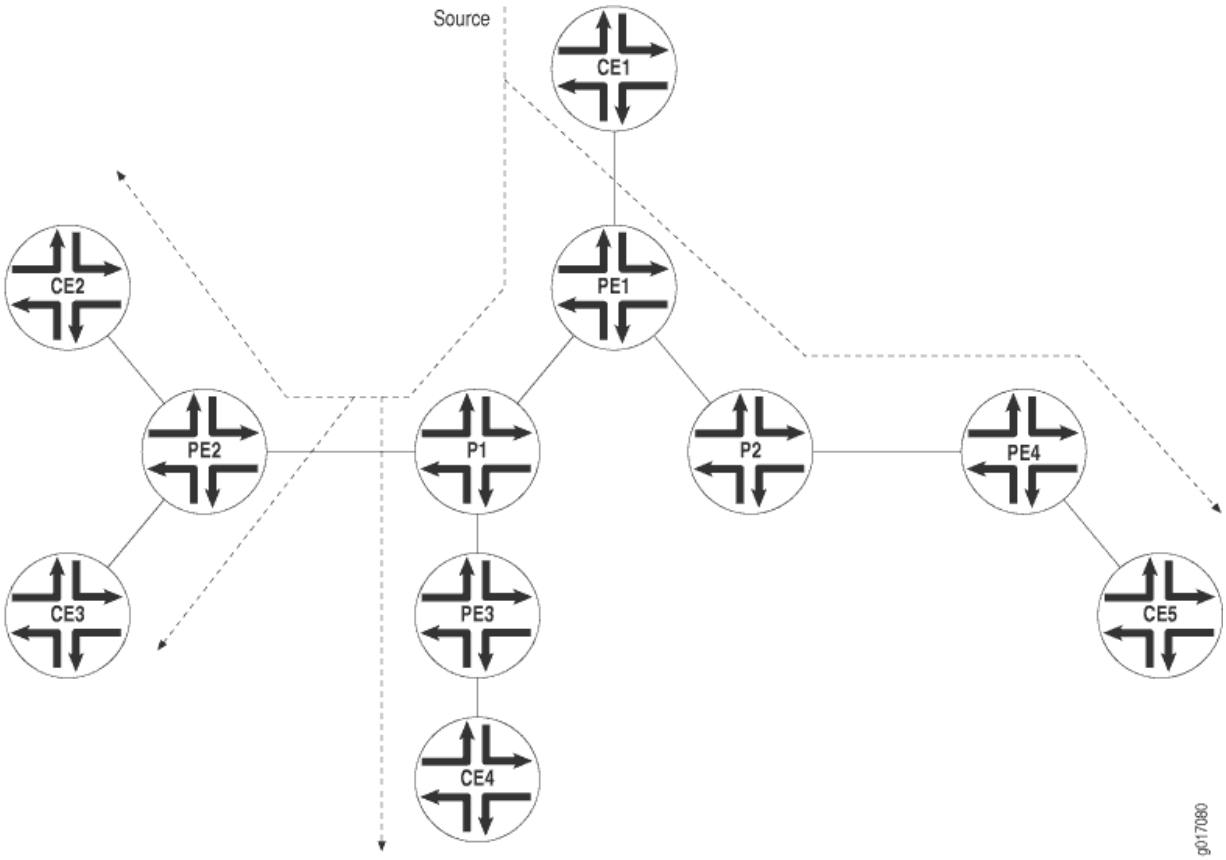
A point-to-multipoint MPLS LSP is an LSP with a single source and multiple destinations. By taking advantage of the MPLS packet replication capability of the network, point-to-multipoint LSPs avoid unnecessary packet replication at the ingress router. Packet replication takes place only when packets are forwarded to two or more different destinations requiring different network paths.

This process is illustrated in Figure 48 on page 756. Router PE1 is configured with a point-to-multipoint LSP to Routers PE2, PE3, and PE4. When Router PE1 sends a packet on the point-to-multipoint LSP to Routers P1 and P2, Router P1 replicates the packet and forwards it to Routers PE2 and PE3. Router P2 sends the packet to Router PE4.

This feature is described in detail in the Internet drafts draft-raggarwa-mpls-p2mp-te-02.txt (expired February 2004), *Establishing Point to Multipoint MPLS TE LSPs*, draft-ietf-mpls-rsvp-te-p2mp-02.txt, *Extensions to Resource Reservation Protocol-Traffic Engineering (RSVP-TE) for Point-to-Multipoint TE Label-Switched Paths (LSPs)*, and RFC 6388, *Label Distribution Protocol Extensions for Point-to-*

Multipoint and Multipoint-to-Multipoint Label Switched Paths (only point-to-multipoint LSPs are supported).

Figure 48: Point-to-Multipoint LSPs



The following are some of the properties of point-to-multipoint LSPs:

- A point-to-multipoint LSP enables you to use MPLS for point-to-multipoint data distribution. This functionality is similar to that provided by IP multicast.
- You can add and remove branch LSPs from a main point-to-multipoint LSP without disrupting traffic. The unaffected parts of the point-to-multipoint LSP continue to function normally.
- You can configure a node to be both a transit and an egress router for different branch LSPs of the same point-to-multipoint LSP.
- You can enable link protection on a point-to-multipoint LSP. Link protection can provide a bypass LSP for each of the branch LSPs that make up the point-to-multipoint LSP. If any of the primary paths fail, traffic can be quickly switched to the bypass.

- You can configure branch LSPs either statically, dynamically, or as a combination of static and dynamic LSPs.
- You can enable *graceful Routing Engine switchover* (GRES) and graceful restart for point-to-multipoint LSPs at ingress and egress routers. The point-to-multipoint LSPs must be configured using either static routes or circuit cross-connect (CCC). GRES and graceful restart allow the traffic to be forwarded at the Packet Forwarding Engine based on the old state while the control plane recovers. Feature parity for GRES and graceful restart for MPLS point-to-multipoint LSPs on the Junos Trio chipset is supported in Junos OS Releases 11.1R2, 11.2R2, and 11.4.

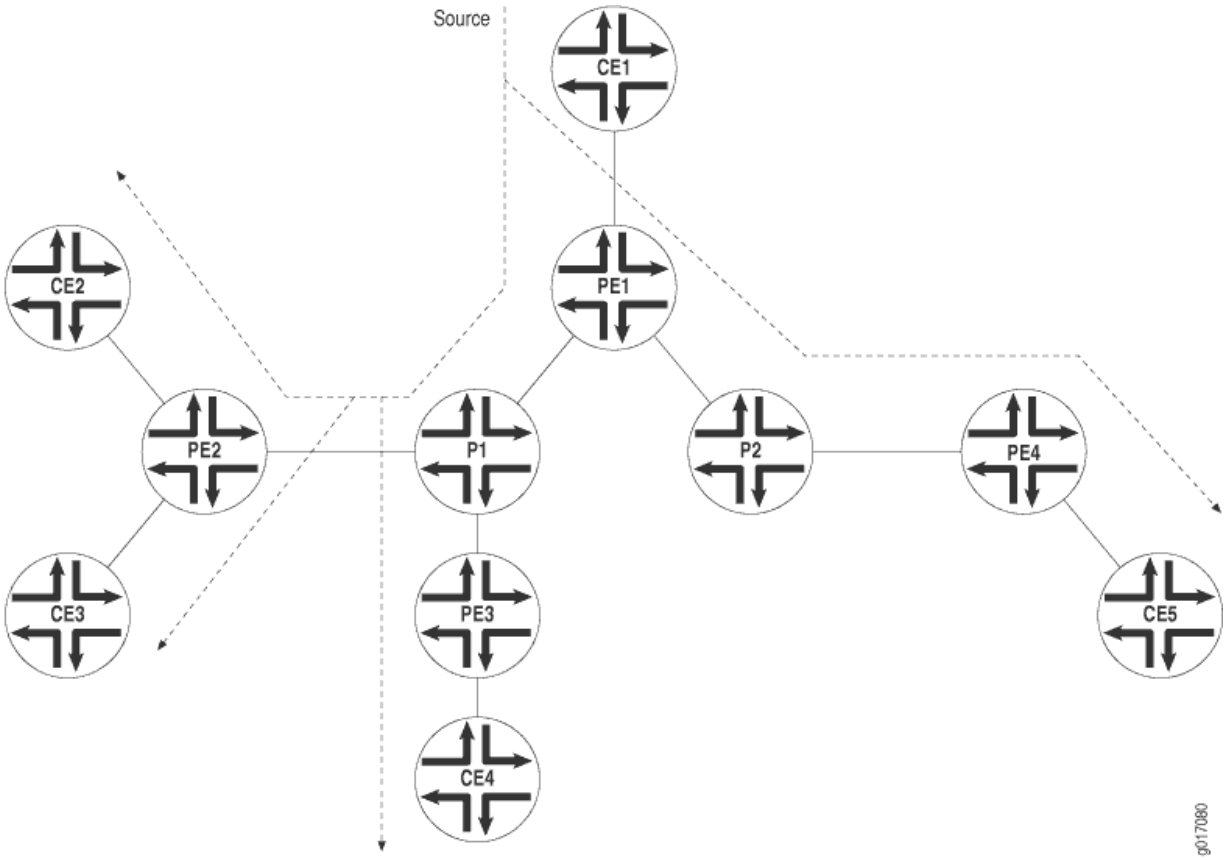
Understanding Point-to-Multipoint LSPs

A point-to-multipoint MPLS label-switched path (LSP) is an LDP-signaled or RSVP-signaled LSP with a single source and multiple destinations. By taking advantage of the MPLS packet replication capability of the network, point-to-multipoint LSPs avoid unnecessary packet replication at the inbound (ingress) router. Packet replication takes place only when packets are forwarded to two or more different destinations requiring different network paths.

This process is illustrated in Figure 49 on page 758. Device PE1 is configured with a point-to-multipoint LSP to Routers PE2, PE3, and PE4. When Device PE1 sends a packet on the point-to-

multipoint LSP to Routers P1 and P2, Device P1 replicates the packet and forwards it to Routers PE2 and PE3. Device P2 sends the packet to Device PE4.

Figure 49: Point-to-Multipoint LSPs



Following are some of the properties of point-to-multipoint LSPs:

- A point-to-multipoint LSP allows you to use MPLS for point-to-multipoint data distribution. This functionality is similar to that provided by IP multicast.
- You can add and remove branch LSPs from a main point-to-multipoint LSP without disrupting traffic. The unaffected parts of the point-to-multipoint LSP continue to function normally.
- You can configure a node to be both a transit and an outbound (egress) router for different branch LSPs of the same point-to-multipoint LSP.
- You can enable link protection on a point-to-multipoint LSP. Link protection can provide a bypass LSP for each of the branch LSPs that make up the point-to-multipoint LSP. If any primary paths fail, traffic can be quickly switched to the bypass.
- You can configure subpaths either statically or dynamically.

- You can enable graceful restart on point-to-multipoint LSPs.

Point-to-Multipoint LSP Configuration Overview

To set up a point-to-multipoint LSP:

1. Configure the primary LSP from the ingress router and the branch LSPs that carry traffic to the egress routers.
2. Specify a pathname on the primary LSP and this same path name on each branch LSP.

> **NOTE**: By default, the branch LSPs are dynamically signaled by means of Constrained Shortest Path First (CSPF) and require no configuration. You can alternatively configure the branch LSPs as static paths.

Example: Configuring a Collection of Paths to Create an RSVP-Signaled Point-to-Multipoint LSP

IN THIS SECTION

- Requirements | **759**
- Overview | **760**
- Configuration | **761**
- Verification | **785**

This example shows how to configure a collection of paths to create an RSVP-signaled point-to-multipoint label-switched path (LSP).

Requirements

In this example, no special configuration beyond device initialization is required.

Overview

IN THIS SECTION

- Topology Diagram | 761

In this example, multiple routing devices serve as the transit, branch, and leaf nodes of a single point-to-multipoint LSP. On the provider edge (PE), Device PE1 is the ingress node. The branches go from PE1 to PE2, PE1 to PE3, and PE1 to PE4. Static unicast routes on the ingress node (PE1) point to the egress nodes.

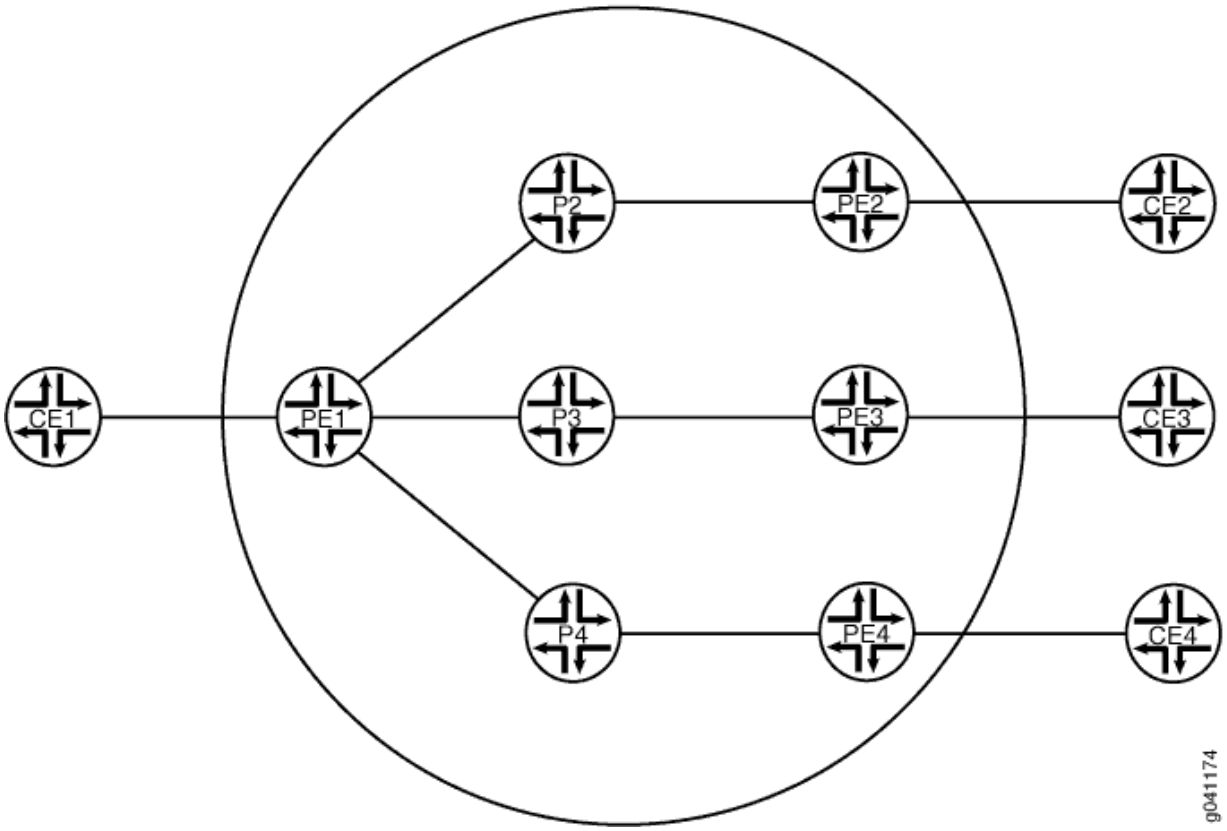
This example also demonstrates static routes with a next hop that is a point-to-multipoint LSP, using the `p2mp-lsp-next-hop` statement. This is useful when implementing filter-based forwarding.

NOTE: Another option is to use the *`lsp-next-hop`* statement to configure a regular point-to-point LSP to be the next hop. Though not shown in this example, you can optionally assign an independent preference and metric to the next hop.

Topology Diagram

Figure 50 on page 761 shows the topology used in this example.

Figure 50: RSVP-Signaled Point-to-Multipoint LSP



Configuration

IN THIS SECTION

- CLI Quick Configuration | **762**
- Configuring the Ingress Label-Switched Router (LSR) (Device PE1) | **764**
- Configuring the Transit and Egress LSRs (Devices P2, P3, P4, PE2, PE3, and PE4) | **766**
- Configuring Device CE1 | **780**
- Configuring Device CE2 | **781**
- Configuring Device CE3 | **782**

- Configuring Device CE4 | 783

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the `[edit]` hierarchy level.

Device PE1

```
set interfaces ge-2/0/2 unit 0 description PE1-to-CE1
set interfaces ge-2/0/2 unit 0 family inet address 10.0.244.10/30
set interfaces fe-2/0/10 unit 1 description PE1-to-P2
set interfaces fe-2/0/10 unit 1 family inet address 2.2.2.1/24
set interfaces fe-2/0/10 unit 1 family mpls
set interfaces fe-2/0/9 unit 8 description PE1-to-P3
set interfaces fe-2/0/9 unit 8 family inet address 6.6.6.1/24
set interfaces fe-2/0/9 unit 8 family mpls
set interfaces fe-2/0/8 unit 9 description PE1-to-P4
set interfaces fe-2/0/8 unit 9 family inet address 3.3.3.1/24
set interfaces fe-2/0/8 unit 9 family mpls
set interfaces lo0 unit 1 family inet address 100.10.10.10/32

set protocols mpls label-switched-path PE1-PE2 to 100.50.50.50
set protocols mpls label-switched-path PE1-PE2 link-protection
set protocols mpls label-switched-path PE1-PE2 p2mp p2mp1
set protocols mpls label-switched-path PE1-PE3 to 100.70.70.70
set protocols mpls label-switched-path PE1-PE3 link-protection
set protocols mpls label-switched-path PE1-PE3 p2mp p2mp1
set protocols mpls label-switched-path PE1-PE4 to 100.40.40.40
set protocols mpls label-switched-path PE1-PE4 link-protection
set protocols mpls label-switched-path PE1-PE4 p2mp p2mp1
set protocols mpls interface fe-2/0/10.1
set protocols mpls interface fe-2/0/9.8
set protocols mpls interface fe-2/0/8.9
```

```
set protocols mpls interface lo0.1
set protocols ospf traffic-engineering
set protocols ospf area 0.0.0.0 interface ge-2/0/2.0
set protocols ospf area 0.0.0.0 interface fe-2/0/10.1
set protocols ospf area 0.0.0.0 interface fe-2/0/9.8
set protocols ospf area 0.0.0.0 interface fe-2/0/8.9
set protocols ospf area 0.0.0.0 interface lo0.1
set routing-options static route 5.5.5.0/24 p2mp-lsp-next-hop p2mp1
set routing-options static route 7.7.7.0/24 p2mp-lsp-next-hop p2mp1
set routing-options static route 4.4.4.0/24 p2mp-lsp-next-hop p2mp1
set routing-options router-id 100.10.10.10
```

Device CE1

```
set interfaces ge-1/3/2 unit 0 family inet address 10.0.244.9/30
set interfaces ge-1/3/2 unit 0 description CE1-to-PE1
set routing-options static route 10.0.104.8/30 next-hop 10.0.244.10
set routing-options static route 10.0.134.8/30 next-hop 10.0.244.10
set routing-options static route 10.0.224.8/30 next-hop 10.0.244.10
```

Device CE2

```
set interfaces ge-1/3/3 unit 0 family inet address 10.0.224.9/30
set interfaces ge-1/3/3 unit 0 description CE2-to-PE2
set routing-options static route 10.0.244.8/30 next-hop 10.0.224.10
```

Device CE3

```
set interfaces ge-2/0/1 unit 0 family inet address 10.0.134.9/30
set interfaces ge-2/0/1 unit 0 description CE3-to-PE3
set routing-options static route 10.0.244.8/30 next-hop 10.0.134.10
```

Device CE4

```
set interfaces ge-3/1/3 unit 0 family inet address 10.0.104.10/30
set interfaces ge-3/1/3 unit 0 description CE4-to-PE4
set routing-options static route 10.0.244.8/30 next-hop 10.0.104.9
```

Configuring the Ingress Label-Switched Router (LSR) (Device PE1)

Step-by-Step Procedure

To configure Device PE1:

1. Configure the interfaces, interface encapsulation, and protocol families.

```
[edit interfaces]
user@PE1# set ge-2/0/2 unit 0 description PE1-to-CE1
user@PE1# set ge-2/0/2 unit 0 family inet address 10.0.244.10/30
user@PE1# set fe-2/0/10 unit 1 description PE1-to-P2
user@PE1# set fe-2/0/10 unit 1 family inet address 2.2.2.1/24
user@PE1# set fe-2/0/10 unit 1 family mpls
user@PE1# set fe-2/0/9 unit 8 description PE1-to-P3
user@PE1# set fe-2/0/9 unit 8 family inet address 6.6.6.1/24
user@PE1# set fe-2/0/9 unit 8 family mpls
user@PE1# set fe-2/0/8 unit 9 description PE1-to-P4
user@PE1# set fe-2/0/8 unit 9 family inet address 3.3.3.1/24
user@PE1# set fe-2/0/8 unit 9 family mpls
user@PE1# set lo0 unit 1 family inet address 100.10.10.10/32
```

2. Enable RSVP, MPLS, and OSPF on the interfaces.

```
[edit protocols]
user@PE1# set rsvp interface fe-2/0/10.1
user@PE1# set rsvp interface fe-2/0/9.8
user@PE1# set rsvp interface fe-2/0/8.9
user@PE1# set rsvp interface lo0.1
user@PE1# set mpls interface fe-2/0/10.1
user@PE1# set mpls interface fe-2/0/9.8
user@PE1# set mpls interface fe-2/0/8.9
user@PE1# set mpls interface lo0.1
user@PE1# set ospf area 0.0.0.0 interface ge-2/0/2.0
user@PE1# set ospf area 0.0.0.0 interface fe-2/0/10.1
user@PE1# set ospf area 0.0.0.0 interface fe-2/0/9.8
user@PE1# set ospf area 0.0.0.0 interface fe-2/0/8.9
user@PE1# set ospf area 0.0.0.0 interface lo0.1
```

3. Configure the MPLS point-to-multipoint LSPs.

```
[edit protocols]
user@PE1# set mpls label-switched-path PE1-PE2 to 100.50.50.50
user@PE1# set mpls label-switched-path PE1-PE2 p2mp p2mp1
user@PE1# set mpls label-switched-path PE1-PE3 to 100.70.70.70
user@PE1# set mpls label-switched-path PE1-PE3 p2mp p2mp1
user@PE1# set mpls label-switched-path PE1-PE4 to 100.40.40.40
user@PE1# set mpls label-switched-path PE1-PE4 p2mp p2mp1
```

4. (Optional) Enable link protection on the LSPs.

   Link protection helps to ensure that traffic sent over a specific interface to a neighboring router can continue to reach the router if that interface fails.

```
[edit protocols]
user@PE1# set mpls label-switched-path PE1-PE2 link-protection
user@PE1# set mpls label-switched-path PE1-PE3 link-protection
user@PE1# set mpls label-switched-path PE1-PE4 link-protection
```

5. Enable MPLS to perform traffic engineering for OSPF.

```
[edit protocols]
user@PE1# set mpls traffic-engineering bgp-igp
```

   This causes the ingress routes to be installed in the inet.0 routing table. By default, MPLS performs traffic engineering for BGP only. You need to enable MPLS traffic engineering on the ingress LSR only.

6. Enable traffic engineering for OSPF.

```
[edit protocols]
user@PE1# set ospf traffic-engineering
```

   This causes the shortest-path first (SPF) algorithm to take into account the LSPs configured under MPLS.

7. Configure the router ID.

```
[edit routing-options]
user@PE1# set router-id 100.10.10.10
```

8. Configure static IP unicast routes with the point-to-multipoint LSP name as the next hop for each route.

```
[edit routing-options]
user@PE1# set static route 5.5.5.0/24p2mp-lsp-next-hop p2mp1
user@PE1# set static route 7.7.7.0/24 p2mp-lsp-next-hop p2mp1
user@PE1# set static route 4.4.4.0/24 p2mp-lsp-next-hop p2mp1
```

9. If you are done configuring the device, commit the configuration.

```
[edit]
user@PE1# commit
```

Configuring the Transit and Egress LSRs (Devices P2, P3, P4, PE2, PE3, and PE4)

Step-by-Step Procedure

To configure the transit and egress LSRs:

1. Configure the interfaces, interface encapsulation, and protocol families.

```
[edit]
user@P2# set interfaces fe-2/0/10 unit 2 description P2-to-PE1
user@P2# set interfaces fe-2/0/10 unit 2 family inet address 2.2.2.2/24
user@P2# set interfaces fe-2/0/10 unit 2 family mpls
user@P2# set interfaces fe-2/0/9 unit 10 description P2-to-PE2
user@P2# set interfaces fe-2/0/9 unit 10 family inet address 5.5.5.1/24
user@P2# set interfaces fe-2/0/9 unit 10 family mpls
user@P2# set interfaces lo0 unit 2 family inet address 100.20.20.20/32
user@PE2# set interfaces ge-2/0/3 unit 0 description PE2-to-CE2
user@PE2# set interfaces ge-2/0/3 unit 0 family inet address 10.0.224.10/30
user@PE2# set interfaces fe-2/0/10 unit 5 description PE2-to-P2
user@PE2# set interfaces fe-2/0/10 unit 5 family inet address 5.5.5.2/24
user@PE2# set interfaces fe-2/0/10 unit 5 family mpls
```

```
user@PE2# set interfaces lo0 unit 5 family inet address 100.50.50.50/32
user@P3# set interfaces fe-2/0/10 unit 6 description P3-to-PE1
user@P3# set interfaces fe-2/0/10 unit 6 family inet address 6.6.6.2/24
user@P3# set interfaces fe-2/0/10 unit 6 family mpls
user@P3# set interfaces fe-2/0/9 unit 11 description P3-to-PE3
user@P3# set interfaces fe-2/0/9 unit 11 family inet address 7.7.7.1/24
user@P3# set interfaces fe-2/0/9 unit 11 family mpls
user@P3# set interfaces lo0 unit 6 family inet address 100.60.60.60/32

user@PE2# set protocols ospf area 0.0.0.0 interface ge-2/0/3.0
user@PE2# set protocols ospf area 0.0.0.0 interface fe-2/0/10.5
user@PE2# set protocols ospf area 0.0.0.0 interface lo0.5
user@P3# set protocols rsvp interface fe-2/0/10.6
user@P3# set protocols rsvp interface fe-2/0/9.11
user@P3# set protocols rsvp interface lo0.6
user@P3# set protocols mpls interface fe-2/0/10.6
user@P3# set protocols mpls interface fe-2/0/9.11
user@P3# set protocols mpls interface lo0.6
user@P3# set protocols ospf area 0.0.0.0 interface fe-2/0/10.6
user@P3# set protocols ospf area 0.0.0.0 interface fe-2/0/9.11
user@P3# set protocols ospf area 0.0.0.0 interface lo0.6
user@PE3# set protocols rsvp interface fe-2/0/10.7
user@PE3# set protocols rsvp interface lo0.7
user@PE3# set protocols mpls interface fe-2/0/10.7
user@PE3# set protocols mpls interface lo0.7
user@PE3# set protocols ospf area 0.0.0.0 interface ge-2/0/1.0
user@PE3# set protocols ospf area 0.0.0.0 interface fe-2/0/10.7
user@PE3# set protocols ospf area 0.0.0.0 interface lo0.7
user@P4# set protocols rsvp interface fe-2/0/10.3
user@P4# set protocols rsvp interface fe-2/0/9.12
user@P4# set protocols rsvp interface lo0.3
user@P4# set protocols mpls interface fe-2/0/10.3
user@P4# set protocols mpls interface fe-2/0/9.12
user@P4# set protocols mpls interface lo0.3
user@P4# set protocols ospf area 0.0.0.0 interface fe-2/0/10.3
user@P4# set protocols ospf area 0.0.0.0 interface fe-2/0/9.12
user@P4# set protocols ospf area 0.0.0.0 interface lo0.3
user@PE4# set protocols rsvp interface fe-2/0/10.4
user@PE4# set protocols rsvp interface lo0.4
user@PE4# set protocols mpls interface fe-2/0/10.4
user@PE4# set protocols mpls interface lo0.4
user@PE4# set protocols ospf area 0.0.0.0 interface ge-2/0/0.0
user@PE4# set protocols ospf area 0.0.0.0 interface fe-2/0/10.4
user@PE4# set protocols ospf area 0.0.0.0 interface lo0.4
```

3. Enable traffic engineering for OSPF.

```
[edit]
user@P2# set protocols ospf traffic-engineering
```

```
user@P3# set protocols ospf traffic-engineering
user@P4# set protocols ospf traffic-engineering
user@PE2# set protocols ospf traffic-engineering
user@PE3# set protocols ospf traffic-engineering
user@PE4# set protocols ospf traffic-engineering
```

This causes the shortest-path first (SPF) algorithm to take into account the LSPs configured under MPLS.

4. Configure the router IDs.

```
[edit]
user@P2# set routing-options router-id 100.20.20.20
user@P3# set routing-options router-id 100.60.60.60
user@P4# set routing-options router-id 100.30.30.30
user@PE2# set routing-options router-id 100.50.50.50
user@PE3# set routing-options router-id 100.70.70.70
user@PE4# set routing-options router-id 100.40.40.40
```

5. If you are done configuring the devices, commit the configuration.

```
[edit]
user@host# commit
```

Results

From configuration mode, confirm your configuration by entering the `show interfaces`, `show protocols`, and `show routing-options` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

Device PE1

```
user@PE1# show interfaces
ge-2/0/2 {
    unit 0 {
        description R1-to-CE1;

Configuring Device CE1

Step-by-Step Procedure

To configure Device CE1:

1. Configure an interface to Device PE1.

```
[edit interfaces]
user@CE1# set ge-1/3/2 unit 0 family inet address 10.0.244.9/30
user@CE1# set ge-1/3/2 unit 0 description CE1-to-PE1
```

2. Configure static routes from Device CE1 to the three other customer networks, with Device PE1 as the next hop.

```
[edit routing-options]
user@CE1# set static route 10.0.104.8/30 next-hop 10.0.244.10
user@CE1# set static route 10.0.134.8/30 next-hop 10.0.244.10
user@CE1# set static route 10.0.224.8/30 next-hop 10.0.244.10
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@CE1# commit
```

Results

From configuration mode, confirm your configuration by entering the `show interfaces` and `show routing-options` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@CE1# show interfaces
ge-1/3/2 {
    unit 0 {
        family inet {
            address 10.0.244.9/30;
            description CE1-to-PE1;
        }
```

```
    }
}
```

```
user@CE1# show routing-options
static {
    route 10.0.104.8/30 next-hop 10.0.244.10;
    route 10.0.134.8/30 next-hop 10.0.244.10;
    route 10.0.224.8/30 next-hop 10.0.244.10;
}
```

Configuring Device CE2

Step-by-Step Procedure

To configure Device CE2:

1. Configure an interface to Device PE2.

```
[edit interfaces]
user@CE2# set ge-1/3/3 unit 0 family inet address 10.0.224.9/30
user@CE2# set ge-1/3/3 unit 0 description CE2-to-PE2
```

2. Configure a static route from Device CE2 to CE1, with Device PE2 as the next hop.

```
[edit routing-options]
user@CE2# set static route 10.0.244.8/30 next-hop 10.0.224.10
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@CE2# commit
```

Results

From configuration mode, confirm your configuration by entering the `show interfaces` and `show routing-options` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@CE2# show interfaces
ge-1/3/3 {
    unit 0 {
        family inet {
            address 10.0.224.9/30;
            description CE2-to-PE2;
        }
    }
}
```

```
user@CE2# show routing-options
static {
    route 10.0.244.8/30 next-hop 10.0.224.10;
}
```

Configuring Device CE3

Step-by-Step Procedure

To configure Device CE3:

1. Configure an interface to Device PE3.

```
[edit interfaces]
user@CE3# set ge-2/0/1 unit 0 family inet address 10.0.134.9/30
user@CE3# set ge-2/0/1 unit 0 description CE3-to-PE3
```

2. Configure a static route from Device CE3 to CE1, with Device PE3 as the next hop.

```
[edit routing-options]
user@CE3# set static route 10.0.244.8/30 next-hop 10.0.134.10
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@CE3# commit
```

Results

From configuration mode, confirm your configuration by entering the `show interfaces` and `show routing-options` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@CE3# show interfaces
ge-2/0/1 {
    unit 0 {
        family inet {
            address 10.0.134.9/30;
            description CE3-to-PE3;
        }
    }
}
```

```
user@CE3# show routing-options
static {
    route 10.0.244.8/30 next-hop 10.0.134.10;
}
```

Configuring Device CE4

Step-by-Step Procedure

To configure Device CE4:

1. Configure an interface to Device PE4.

```
[edit interfaces]
user@CE4# set ge-3/1/3 unit 0 family inet address 10.0.104.10/30
user@CE4# set ge-3/1/3 unit 0 description CE4-to-PE4
```

2. Configure a static route from Device CE4 to CE1, with Device PE4 as the next hop.

```
[edit routing-options]
user@CE4# set static route 10.0.244.8/30 next-hop 10.0.104.9
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@CE4# commit
```

Results

From configuration mode, confirm your configuration by entering the `show interfaces` and `show routing-options` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@CE4# show interfaces
ge-3/1/3 {
    unit 0 {
        family inet {
            address 10.0.104.10/30;
            description CE4-to-PE4;
        }
    }
}
```

```
user@CE4# show routing-options
static {
    route 10.0.244.8/30 next-hop 10.0.104.9;
}
```

Verification

IN THIS SECTION

- Verifying Connectivity | 785
- Verifying the State of the Point-to-Multipoint LSP | 786
- Checking the Forwarding Table | 787

Confirm that the configuration is working properly.

Verifying Connectivity

Purpose

Make sure that the devices can ping each other.

Action

Run the `ping` command from CE1 to the interface on CE2 connecting to PE2.

```
user@CE1> ping 10.0.224.9
PING 10.0.224.9 (10.0.224.9): 56 data bytes
64 bytes from 10.0.224.9: icmp_seq=0 ttl=61 time=1.387 ms
64 bytes from 10.0.224.9: icmp_seq=1 ttl=61 time=1.394 ms
64 bytes from 10.0.224.9: icmp_seq=2 ttl=61 time=1.506 ms
^C
--- 10.0.224.9 ping statistics ---
3 packets transmitted, 3 packets received, 0% packet loss
round-trip min/avg/max/stddev = 1.387/1.429/1.506/0.055 ms
```

Run the `ping` command from CE1 to the interface on CE3 connecting to PE3.

```
user@CE1> ping 10.0.134.9
PING 10.0.134.9 (10.0.134.9): 56 data bytes
64 bytes from 10.0.134.9: icmp_seq=0 ttl=61 time=1.068 ms
64 bytes from 10.0.134.9: icmp_seq=1 ttl=61 time=1.062 ms
64 bytes from 10.0.134.9: icmp_seq=2 ttl=61 time=1.053 ms
```

```
^C
--- 10.0.134.9 ping statistics ---
3 packets transmitted, 3 packets received, 0% packet loss
round-trip min/avg/max/stddev = 1.053/1.061/1.068/0.006 ms
```

Run the `ping` command from CE1 to the interface on CE4 connecting to PE4.

```
user@CE1> ping 10.0.104.10
PING 10.0.104.10 (10.0.104.10): 56 data bytes
64 bytes from 10.0.104.10: icmp_seq=0 ttl=61 time=1.079 ms
64 bytes from 10.0.104.10: icmp_seq=1 ttl=61 time=1.048 ms
64 bytes from 10.0.104.10: icmp_seq=2 ttl=61 time=1.070 ms
^C
--- 10.0.104.10 ping statistics ---
3 packets transmitted, 3 packets received, 0% packet loss
round-trip min/avg/max/stddev = 1.048/1.066/1.079/0.013 ms
```

Verifying the State of the Point-to-Multipoint LSP

Purpose

Make sure that the ingress, transit, and egress LSRs are in the Up state.

Action

Run the `show mpls lsp p2mp` command on all of the LSRs. Only the ingress LSR is shown here.

```
user@PE1> show mpls lsp p2mp
Ingress LSP: 1 sessions
P2MP name: p2mp1, P2MP branch count: 3
To              From            State Rt P     ActivePath       LSPname
100.40.40.40    100.10.10.10    Up     0 *                      PE1-PE4
100.70.70.70    100.10.10.10    Up     0 *                      PE1-PE3
100.50.50.50    100.10.10.10    Up     0 *                      PE1-PE2
Total 3 displayed, Up 3, Down 0
...
```

Checking the Forwarding Table

Purpose

Make sure that the routes are set up as expected by running the *show route forwarding-table* command. Only the routes to the remote customer networks are shown here.

Action

```
user@PE1> show route forwarding-table
Routing table: default.inet
Internet:
Destination        Type RtRef Next hop           Type Index NhRef Netif
...
10.0.104.8/30      user     0 3.3.3.2            ucst  1006     6 fe-2/0/8.9
10.0.134.8/30      user     0 6.6.6.2            ucst  1010     6 fe-2/0/9.8

...
```

Configuring Primary and Branch LSPs for Point-to-Multipoint LSPs

IN THIS SECTION

- Configuring the Primary Point-to-Multipoint LSP | **787**
- Configuring a Branch LSP for Point-to-Multipoint LSPs | **788**

A point-to-multipoint MPLS label-switched path (LSP) is an RSVP LSP with multiple destinations. By taking advantage of the MPLS packet replication capability of the network, point-to-multipoint LSPs avoid unnecessary packet replication at the ingress router. For more information about point-to-multipoint LSPs, see "Point-to-Multipoint LSPs Overview" on page 755.

To configure a point-to-multipoint LSP, you need to configure the primary LSP from the ingress router and the branch LSPs that carry traffic to the egress routers, as described in the following sections:

Configuring the Primary Point-to-Multipoint LSP

A point-to-multipoint LSP must have a configured primary point-to-multipoint LSP to carry traffic from the ingress router. The configuration of the primary point-to-multipoint LSP is similar to a signaled LSP.

See "Configuring the Ingress Router for MPLS-Signaled LSPs" on page 579 for more information. In addition to the conventional LSP configuration, you need to specify a path name for the primary point-to-multipoint LSP by including the p2mp statement:

```
p2mp p2mp-lsp-name;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls label-switched-path *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name*]

You can enable the optimization timer for point-to-multipoint LSPs. See "Optimizing Signaled LSPs" on page 605 for more information.

Configuring a Branch LSP for Point-to-Multipoint LSPs

The primary point-to-multipoint LSP sends traffic to two or more branch LSPs carrying traffic to each of the egress provider edge (PE) routers. In the configuration for each of these branch LSPs, the point-to-multipoint LSP path name you specify must be identical to the path name configured for the primary point-to-multipoint LSP. See "Configuring the Primary Point-to-Multipoint LSP" on page 787 for more information.

To associate a branch LSP with the primary point-to-multipoint LSP, specify the point-to-multipoint LSP name by including the p2mp statement:

```
p2mp p2mp-lsp-name;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls label-switched-path *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name*]

> **NOTE**: Any change in any of the branch LSPs of a point-to-multipoint LSP, either due to a user action or an automatic adjustment made by the router, causes the primary and branch LSPs to be resignaled. The new point-to-multipoint LSP is signaled first before the old path is taken down.

The following sections describe how you can configure the branch LSP as a dynamically signaled path using Constrained Shortest Path First (CSPF), as a static path, or as a combination of dynamic and static paths:

Configuring the Branch LSP as a Dynamic Path

By default, the branch LSP for a point-to-multipoint LSP is signaled dynamically using CSPF and requires no configuration.

When a point-to-multipoint LSP is changed, either by the addition or deletion of new destinations or by the recalculation of the path to existing destinations, certain nodes in the tree might receive data from more than one incoming interface. This can happen under the following conditions:

- Some of the branch LSPs to destinations are statically configured and might intersect with statically or dynamically calculated paths to other destinations.
- When a dynamically calculated path for a branch LSP results in a change of incoming interface for one of the nodes in the network, the older path is not immediately torn down after the new one has been signaled. This ensures that any data in transit relying on the older path can reach its destination. However, network traffic can potentially use either path to reach the destination.
- A faulty router at the ingress calculates the paths to two different branch destinations such that a different incoming interface is chosen for these branch LSPs on a router node common to these branch LSPs.

Configuring the Branch LSP as a Static Path

You can configure the branch LSP for a point-to-multipoint LSP as a static path. See "Configuring Static LSPs" on page 667 for more information.

Configuring Inter-Domain Point-to-Multipoint LSPs

An inter-domain P2MP LSP is a P2MP LSP that has one or more sub-LSPs (branches) that span multiple domains in a network. Examples of such domains include IGP areas and autonomous systems (ASs). A sub-LSP of an inter-domain P2MP LSP may be intra-area, inter-area, or inter-AS, depending on the location of the egress node (leaf) with respect to the ingress node (source).

On the ingress node, a name is assigned to the inter-domain P2MP LSP and shared by all constituent sub-LSPs. Each sub-LSP is configured separately, with its own egress node and optionally an explicit path. The location of the egress node of the sub-LSP with respect to the ingress node determines whether the sub-LSP is intra-area, inter-area, or inter-AS.

Inter-domain P2MP LSPs can be used to transport traffic in the following applications in a multi-area or multi-AS network:

- Layer 2 broadcast and multicast over MPLS
- Layer 3 BGP/MPLS VPN
- VPLS

On each domain boundary node (ABR or ASBR) along the path of the P2MP LSP, the `expand-loose-hop` statement must be configured at the `[edit protocols mpls]` hierarchy level so that CSPF can extend a loose-hop ERO (usually the first entry of the ERO list carried by RSVP Path message) towards the egress node or the next domain boundary node.

CSPF path computation for inter-domain P2MP LSPs:

- CSPF path computation is supported on each sub-LSP for inter-domain P2MP LSPs. A sub-LSP may be intra-area, inter-area, or inter-AS. CSPF treats an inter-area or inter-AS sub-LSP in the same manner as an inter-domain P2P LSP.
- On an ingress node or a domain boundary node (ABR or ASBR), CSPF can perform an Explicit Route Object (ERO) expansion per-RSVP query. The destination queried could be an egress node or a received loose-hop ERO. If the destination resides in a neighboring domain that the node is connected to, CSPF generates either a sequence of strict-hop EROs towards it or a sequence of strict-hop EROs towards another domain boundary node that can reach the destination.
- If RSVP fails to signal a path through a previously selected domain bounday node, RSVP attempts to signal a path through other available domain boundary nodes in a round-robin fashion.
- When a sub-LSP is added or removed to or from an inter-domain P2MP LSP, causing its path (branch) to be merged or pruned with or from the current P2MP tree, the paths being taken by the other sub-LSPs should not be affected, helping to prevent traffic disruption on those sub-LSPs.

Be aware of the following when deploying inter-domain P2MP LSPs in your network:

- Periodic path re-optimization is supported for inter-domain P2MP LSPs on ingress nodes. It can be turned on for an inter-domain P2MP LSP by configuring the `optimize-timer` statement at the `[edit protocols mpls label-switched-path` *`lsp-name`*`]` hierarchy level with the same interval for every sub-LSP.
- Only link protection bypass LSPs are supported for inter-domain P2MP LSPs. To enable it for an inter-domain P2MP LSP, link-protection must be configured for all sub-LSPs and on all of the RSVP interfaces that the P2MP LSP might travel through.
- Only OSPF areas are supported for inter-domain P2MP LSPs. IS-IS levels are not supported.

Configuring Link Protection for Point-to-Multipoint LSPs

Link protection helps to ensure that traffic going over a specific interface to a neighboring router can continue to reach this router if that interface fails. When link protection is configured for an interface and a point-to-multipoint LSP that traverses this interface, a bypass LSP is created that handles this traffic if the interface fails. The bypass LSP uses a different interface and path to reach the same destination.

To extend link protection to all of the paths used by a point-to-multipoint LSP, link protection must be configured on each router that each branch LSP traverses. If you enable link protection on a point-to-multipoint LSP, you must enable link protection on all of the branch LSPs.

The Internet draft draft-ietf-mpls-rsvp-te-p2mp-01.txt, *Extensions to RSVP-TE for Point to Multipoint TE LSPs*, describes link protection for point-to-multipoint LSPs.

To enable link protection on point-to-multipoint LSPs, complete the following steps:

1. Configure link protection on each branch LSP. To configure link protection, include the `link-protection` statement:

   ```
   link-protection;
   ```

   You can include this statement at the following hierarchy levels:

   - `[edit protocols mpls label-switched-path branch-lsp-name]`
   - `[edit logical-systems logical-system-name protocols mpls label-switched-path branch-lsp-name]`

2. Configure link protection for each RSVP interface on each router that the branch LSP traverses. For information about how to configure link protection on RSVP interfaces, see "Configuring Link Protection on Interfaces Used by LSPs" on page 458.

For more information on how to configure link protection, see "Configuring Node Protection or Link Protection for LSPs" on page 467.

Configuring Graceful Restart for Point-to-Multipoint LSPs

You can configure graceful restart on point-to-multipoint LSPs. Graceful restart allows a router undergoing a restart to inform its adjacent neighbors of its condition. The restarting router requests a grace period from the neighbor or peer, which can then cooperate with the restarting router. The restarting router can still forward MPLS traffic during the restart period; convergence in the network is not disrupted. The restart is not apparent to the rest of the network, and the restarting router is not removed from the network topology. RSVP graceful restart can be enabled on both transit routers and ingress routers.

To enable graceful restart on a router handling point-to-multipoint LSP traffic, include the `graceful-restart` statement:

```
graceful-restart;
```

You can include this statement at the following hierarchy levels:

- `[edit routing-options]`
- `[edit logical-systems logical-system-name routing-options]`

The graceful restart configuration for point-to-multipoint LSPs is identical to that of point-to-point LSPs. For more information on how to configure graceful restart, see "Configuring RSVP Graceful Restart" on page 1239.

Configuring a Multicast RPF Check Policy for Point-to-Multipoint LSPs

IN THIS SECTION

- Example: Configuring Multicast RPF Check Policy for a Point-to-Multipoint LSP | **793**

You can control whether a reverse path forwarding (RPF) check is performed for a source and group entry before installing a route in the multicast forwarding cache. This makes it possible to use point-to-multipoint LSPs to distribute multicast traffic to PIM islands situated downstream from the egress routers of the point-to-multipoint LSPs.

By configuring the `rpf-check-policy` statement, you can disable RPF checks for a source and group pair. You would typically configure this statement on the egress routers of a point-to-multipoint LSP, because the interface receiving the multicast traffic on a point-to-multipoint LSP egress router might not always be the RPF interface.

You can also configure a routing policy to act upon a source and group pair. This policy behaves like an import policy, so if no policy term matches the input data, the default policy action is “acceptance.” An accept policy action enables RPF checks. A reject policy action (applied to all source and group pairs that are not accepted) disables RPF checks for the pair.

To configure a multicast RPF check policy for a point-to-multipoint LSP, specify the RPF check policy using the `rpf-check-policy` statement:

```
rpf-check-policy policy;
```

You can include this statement at the following hierarchy levels:

- `[edit routing-options multicast]`
- `[edit logical-systems logical-system-name routing-options multicast]`

You also must configure a policy for the multicast RPF check. You configure policies at the `[edit policy-options]` hierarchy level. For more information, see the Routing Policies, Firewall Filters, and Traffic Policers User Guide.

NOTE: When you configure the `rpf-check-policy` statement, the Junos OS cannot perform RPF checks on incoming traffic and therefore cannot detect traffic arriving on the wrong interface. This might cause routing loops to form.

Example: Configuring Multicast RPF Check Policy for a Point-to-Multipoint LSP

Configure a policy to ensure that an RPF check is not performed for sources with prefix `128.83/16` or longer that belong to groups having a prefix of `228/8` or longer:

```
[edit]
policy-options {
    policy-statement rpf-sg-policy {
        from {
            route-filter 228.0.0.0/8 orlonger;
            source-address-filter 128.83.0.0/16 orlonger;
        }
        then {
            reject;
        }
    }
}
```

Configuring Ingress PE Router Redundancy for Point-to-Multipoint LSPs

You can configure one or more PE routers as part of a backup PE router group to enable ingress PE router redundancy. You accomplish this by configuring the IP addresses of the backup PE routers (at least one backup PE router is required) and the local IP address used by the local PE router.

You must also configure a full mesh of point-to-point LSPs between the primary and backup PE routers. You also need to configure BFD on these LSPs. See "Configuring BFD for RSVP-Signaled LSPs" on page 206 and "Configuring BFD for LDP LSPs" on page 1366 for more information.

To configure ingress PE router redundancy for point-to-multipoint LSPs, include the `backup-pe-group` statement:

```
backup-pe-group pe-group-name {
    backups [addresses];
```

```
    local-address address;
}
```

For a list of hierarchy levels at which you can include these statements, see the statement summary sections for these statements.

After you configure the ingress PE router redundancy backup group, you must also apply the group to a static route on the PE router. This ensures that the static route is active (installed in the forwarding table) when the local PE router is the designated forwarder for the backup PE group. You can only associate a backup PE router group with a static route that also has the `p2mp-lsp-next-hop` statement configured. For more information, see "Configuring Static Unicast Routes for Point-to-Multipoint LSPs" on page 667.

Configuring a Service to Correlate Point-to-Multipoint sub-LSPs with FPCs

In addition to acting as the ingress or egress for a given sub-LSP, the Packet Forwarding Engine on an FPC also serves as a transit point for other sub-LSPs of the same point-to-multipoint LSP. If an FPC fails, then all the sub-LSPs that it serves are affected.

You can configure a service that enables you to monitor the correlation between FPCs and the point-to-multipoint sub-LSPs—branch paths—that are on an LSR. This information helps you evaluate the effect a failed FPC has on the correlated sub-LSPs. When tracing is enabled, the service also provides syslog messages in the event of an FPC outage that provide detailed information about the sub-LSPs affected.

You can configure a service that enables you to monitor the correlation between FPCs and the point-to-multipoint sub-LSPs—branch paths—on an LSR. An FPC can act as an ingress, egress, or transit point for more than one sub-LSP of the same point-to-multipoint LSP. If an FPC fails, then all the sub-LSPs that it serves are affected.

The information provided by this service helps you evaluate the effect a failure in any FPC has on the correlated sub-LSPs and the point-to-multipoint network. You can use this knowledge to help plan controlled FPC outages.

You can also enable tracing of some or all service operations. The service then provides syslog messages with detailed information about the affected sub-LSPs that facilitates analysis of an FPC outage.

To enable the monitoring and correlation of sub-LSPs and FPCs in the point-to-multipoint network:

1. Configure the point-to-multipoint polling (`p2mp_polling_duration`) and FPC polling (`fpc_polling_duration`) by setting the frequency duration (in seconds) in the config.xml file located at the **/etc/p2mp_lsp_correlation** directory. You can also enable log levels in the config.xml file to configure

traceoptions and the logs are created at the **/var/log/p2mp_lsp_correlation** directory. The log level and message types are as follows:

```
5 = DEBUG
4 = INFO
3 = WARNING
2 = ERROR
1 = CRITICAL
```

The following is a sample config.xml file:

```
user@host:~# cat /etc/p2mp_lsp_correlation/config.xml
 <p2mp_sub_lsp_config>
      <p2mp_polling_duration>240</p2mp_polling_duration>
      <fpc_polling_duration>60</fpc_polling_duration>
      <log_level>5</log_level>
</p2mp_sub_lsp_config>
```

- `p2mp_polling_duration`–Refreshes the database by executing various RE/PFE RPC requests. The default value for point-to-multipoint polling duration is 240.
- `fpc_polling_duration`–Polls for status of the FPC/PFE to log the impact of point-to-multipoint sub-LSPs. The default for FPC polling duration is 60.

NOTE: The config.xml file is applicable only for Junos OS Evolved. You need to restart the application after making changes to the config.xml file.

2. Enable the service.

```
[edit services]
user@host# set p2mp-sublsp-correlation
```

3. Configure tracing of the service operations.

```
[edit services]
user@host# set p2mp-sublsp-correlation traceoptions flag all
```

NOTE: The `set p2mp-sublsp-correlation traceoptions flag all` command is not applicable for Junos OS Evolved.

When an FPC on an LSR fails or goes offline, all point-to-multipoint sub-LSPs on that FPC are affected. If you have previously enabled FPC correlation for the point-to-multipoint LSPs, and configured tracing for the correlation service, then upon FPC failure messages are logged that provide details about the affected sub-LSPs.

In this case, you need to examine the system log messages and the FPC correlation table to analyze the impact of an FPC failure.

The following is a sample system log output showing information about the point-to-multipoint sub-LSP when the impacted FPC goes offline:

```
Aug  5 12:47:33  host mdiag[24321]: MDIAGD_P2MP_SUBLSP_IMPACTED: FPC 0
    PFEInst 0 Role (I,E,T) DOWN P2MP-Tunnel-Name p2mp-2-456 Sub-LSP-Dest 4.4.4.4 Sub-LSP-
    Name lsp-2-4 Tunnel-ID 53322 LSP-ID 1 Src-Addr 2.2.2.2 Sub-Group-ID 10 Ingress-
    Interface ae8.0 Egress-Interface et-0/0/7.0
```

To view the point-to-multipoint sub-LSP correlation information for ingress interface, use the `show services p2mp-sublsp-correlation ingress-interface` command as follows:

```
user@host> show services p2mp-sublsp-correlation ingress-interface ae8.0
Last Refreshed : Aug 05 2021 12:06:50

Enabling Point-to-Point LSPs to Monitor Egress PE Routers

Configuring an LSP with the associate-backup-pe-groups statement enables it to monitor the status of the PE router to which it is configured. You can configure multiple backup PE router groups using the same router's address. A failure of this LSP indicates to all of the backup PE router groups that the destination PE router is down. The associate-backup-pe-groups statement is not tied to a specific backup PE router group. It applies to all groups that are interested in the status of the LSP to that address.

To allow an LSP to monitor the status of the egress PE router, include the associate-backup-pe-groups statement:

```
associate-backup-pe-groups;
```

This statement can be configured at the following hierarchy levels:

- [edit protocols mpls label-switched-path *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name*]

If you configure the associate-backup-pe-groups statement, you must configure BFD for the point-to-point LSP. For information about how to configure BFD for an LSP, see "Configuring BFD for MPLS IPv4 LSPs" on page 206 and "Configuring BFD for LDP LSPs" on page 1366.

You also must configure a full mesh of point-to-point LSPs between the PE routers in the backup PE router group. A full mesh is required so that each PE router within the group can independently determine the status of the other PE routers, allowing each router to independently determine which PE router is currently the designated forwarder for the backup PE router group.

If you configure multiple LSPs with the associate-backup-pe-groups statement to the same destination PE router, the first LSP configured is used to monitor the forwarding state to that PE router. If you configure multiple LSPs to the same destination, make sure to configure similar parameters for the LSPs. With this

configuration scenario, a failure notification might be triggered even though the remote PE router is still up.

Preserving Point-to-Multipoint LSP Functioning with Different Junos OS Releases

In Junos OS Release 9.1 and earlier, Resv messages that include the S2L_SUB_LSP object are rejected by default. In Junos OS Release 9.2 and later, such messages are accepted by default. To ensure proper functioning of point-to-multipoint LSPs in a network that includes both devices running Junos OS Release 9.1 and earlier and devices running Junos 9.2 and later, you must include the `no-p2mp-sublsp` statement in the configuration of the devices running Junos 9.2 and later:

```
no-p2mp-sublsp;
```

You can include this statement at the following hierarchy levels:

- `[edit protocols rsvp]`
- `[edit logical-systems` *`logical-system-name`* `protocols rsvp]`

Re-merge Behavior on Point-to-Multipoint LSP Overview

IN THIS SECTION

- Benefits of Controlling the P2MP LSP Re-merge | **799**
- What is P2MP LSP Re-merge? | **800**
- Modify the Default P2MP LSP Re-merge Behavior | **801**

This section talks about the benefits and overview of controlling the re-merge behavior on RSVP Point-to-Multipoint (P2MP) LSPs.

Benefits of Controlling the P2MP LSP Re-merge

- Reduces the RSVP signalling load on the ingress (headend routers) by avoiding path computation of sub LSPs which creates a re-merge condition.
- Saves the network bandwidth by rejecting the P2MP sub LSP re-merge at the transit node.

What is P2MP LSP Re-merge?

In a P2MP MPLS LSP network, the term re-merge refers to the case of an ingress (headend) or transit node (re-merge node) that creates a re-merge branch intersecting the P2MP LSP at another node down the tree. This may occur due to events such as an error in path calculation, an error in manual configuration, or network topology changes during the establishment of the P2MP LSP.

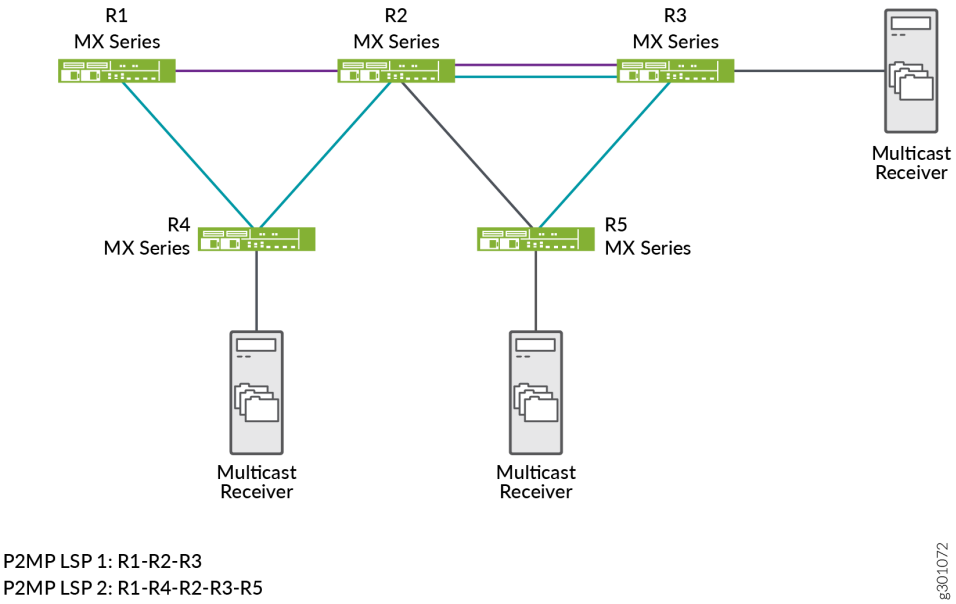
RFC 4875 defines the following two approaches for handling the P2MP LSP re-merge:

- First, the node detecting the re-merge allows the re-merge case to persist, but data from all but one incoming interface is dropped at the re-merge node. This works by default without any configuration.
- Second, the re-merge node initiates the pruning of the re-merge sub LSPs through signaling.

On Juniper Networks MX Series routers, the first approach (as defined by RFC 4875) works by default. The second approach can be implemented by one of the following CLI configuration statements depending upon where the Juniper Networks MX Series routers are placed (ingress node or transit node) in the P2MP RSVP MPLS network:

- `no-re-merge`—This CLI configuration statement when enabled at the ingress (headend) router avoids the path computation of P2MP sub LSPs which creates a re-merge condition. When this CLI configuration statement is configured at the ingress, then configuring the `no-p2mp-re-merge` CLI configuration statement at the transit router is not required.
- `no-p2mp-re-merge`—This CLI configuration statement when enabled at the transit router changes the default behavior of allowing the P2MP sub LSP sessions re-merge to rejecting the re-merge. This CLI configuration statement is primarily required when the ingress (headend router) is not a Juniper Networks MX Series router.
- `single-abr`—This command when enabled reduces re-merge condition beyond the inter-area, or inter-domain, or inter-AS RSVP P2MP LSPs.

The following topology explains the re-merge behavior in a P2MP LSP network:



In this topology, R1 acts as an ingress (headend) router and R2 as the transit (re-merge node) router. There are two sub LSP sessions created in this network, LSP 1 and LSP 2. LSP 1 is a session established among R1, R2, and R3 devices. LSP 2 is a session established between R1, R4, R2, R3, and R5 devices. By default, the transit router allows the re-merge to happen from both the sub LSPs and drops one of the sub LSP branch traffic at the re-merge node. You can control this re-merge behavior by enabling the `no-re-merge` CLI configuration statement at the ingress router, or the `no-p2mp-re-merge` CLI configuration statement at the transit router.

If you enable the `no-re-merge` CLI configuration statement at the ingress router (R1), only one of the two sub LSP sessions is established. For example, if LSP 1 (R1-R2-R3) session is established first, then the other sub LSP session (LSP 2) will not be established.

If you enable the `no-p2mp-re-merge` CLI configuration statement at the transit router (R2), the transit router rejects the re-merge of one of the sub LSPs and sends a path error message to the ingress router (R1) preventing the ingress router from creating the second P2MP LSP re-merge branch. You can use the `show rsvp statistics` CLI command to view the path error message.

Modify the Default P2MP LSP Re-merge Behavior

You can modify the default re-merge behavior either at the ingress (headend) node, or at the transit node in a P2MP RSVP MPLS network.

On the ingress (headend router), disable the default re-merge behavior so that the ingress router does not do the path computation of sub LSPs which creates the re-merge condition. The default behavior allows the path computation of sub LSPs.

```
[edit protocols]
user@host#set mpls p2mp-lsp no-re-merge
```

On the transit router, disable the default re-merge behavior so that the transit router rejects the re-merge of sub LSPs.

```
[edit protocols]
user@host#set rsvp no-p2mp-re-merge
```

For inter-area, or inter-domain, or inter-AS RSVP P2MP LSPs, use the `single-abr` CLI configuration statement at the ingress (headend router) so that all the P2MP sub LSPs prefer to select the same exit router (ABR or ASBR), thereby reducing the re-merge condition.

```
[edit protocols]
user@host#set mpls p2mp-lsp single-abr
```

Pop-and-Forward LSP Configuration

IN THIS SECTION

- Benefits of RSVP-TE Pop-and-Forward LSP Tunnels | 803
- Pop-and-Forward LSP Tunnel Terminology | 803
- Pop-and-Forward LSP Tunnel Label and Signaling | 804
- Pop-and-Forward LSP Tunnel Label Stacking | 805
- Pop-and-Forward LSP Tunnel Link Protection | 807

RSVP-TE Pop-and-Forward LSP Tunnel Supported and Unsupported Features | 808

Pop-and-forward LSPs introduces the notion of pre-installed per traffic engineering link pop labels that are shared by RSVP-TE LSPs that traverse these links and significantly reducing the required forwarding plane state . A transit label-switching router (LSR) allocates a unique pop label per traffic engineering link with a forwarding action to pop the label and forward the packet over that traffic engineering link should the label appear at the top of the packet. These pop labels are sent back in the RESV message of the LSP at each LSR and further recorded in the record route object (RRO). The label stack is constructed from the recorded labels in the RRO and pushed by the ingress label edge router (LER), as each transit hop performs a pop-and-forward action on its label. The pop-and-forward tunnels enhances the RSVP-TE control plane feature benefits with the simplicity of the shared MPLS forwarding plane.

Benefits of RSVP-TE Pop-and-Forward LSP Tunnels

- **Scaling advantage of RSVP-TE**—Any platform-specific label space limit on an LSR is prevented from being a constraint to the control plane scaling on that interface.
- **Reduced forwarding plane state**—The transit labels on a traffic engineering link are shared across RSVP-TE tunnels traversing the link, and are used independent of the ingress and egress devices of the LSPs, thereby significantly reducing the required forwarding plane state.
- **Reduced transit data plane state**—Because the pop labels are allocated per traffic engineering link and shared across LSPs, the total label state in the forwarding plane is reduced to a function of the number of RSVP neighbors on that interface.
- **Faster LSP setup time**—The forwarding plane state is not programmed during the LSP setup and teardown. As a result, the control plane need not wait sequentially at each hop for the forwarding plane to be programmed prior to sending the label upstream in the RESV message, resulting in reduced LSP setup time.
- **Backward compatibility**—This allows backward compatibility with transit LSRs that provide regular labels in RESV messages. Labels can be mixed across transit hops in a single MPLS RSVP-TE LSP. Certain LSRs can use traffic engineering link labels and others can use regular labels. The ingress can construct a label stack appropriately based on what type of label is recorded from every transit LSR.

Pop-and-Forward LSP Tunnel Terminology

The following terminology is used in the implementation of RSVP-TE pop-and-forward LSP tunnels:

- **Pop label**—An incoming label at an LSR that is popped and forwarded over a specific traffic-engineering link to a neighbor.

- **Swap label**—An incoming label at an LSR that is swapped to an outgoing label and forwarded over a specific downstream traffic engineering link.
- **Delegation label**—An incoming label at an LSR that is popped. A new set of labels is pushed before the packet is forwarded.
- **Delegation hop**— A transit hop that allocates a delegation label.
- **Application label depth (AppLD)**—Maximum number of application or service labels (for example, VPN, LDP, or IPv6 explicit-null labels) that can be beneath the RSVP transport labels. It is configured on a per-node basis, and is equally applicable for all LSPs, and is neither signaled nor advertised.
- **Outbound label depth (OutLD)**—Maximum number of labels that can be pushed before a packet is forwarded. This is local to the node, and is neither signaled nor advertised.
- **Additional transport label depth (AddTLD)**—Maximum number of other transport labels that can be added (for example, bypass label). This is a per-LSP parameter that is neither signaled or advertised. The value is discerned by checking if the LSP has been signaled with link protection (AddTLD=1) or without link protection (AddTLD=0).
- **Effective transport label depth (ETLD)**— Number of transport labels that the LSP hop can potentially send to its downstream hop. This value is signaled per LSP in the hop attributes subobject. The hop attributes subobject is added to the record route object (RRO) in the path message.

Pop-and-Forward LSP Tunnel Label and Signaling

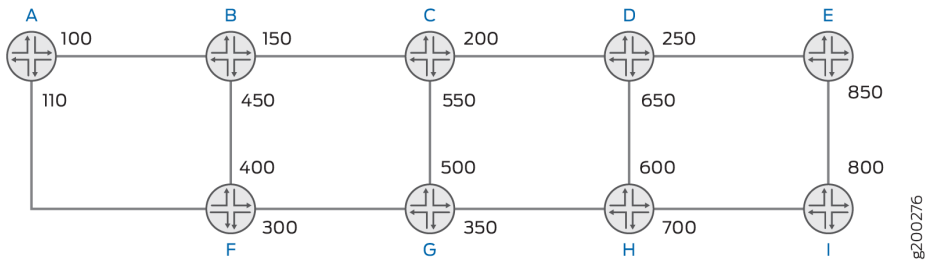
Every traffic engineering link is allocated a pop label that is installed in the mpls.0 routing table with a forwarding action to pop the label and forward the packet over the traffic engineering link to the downstream neighbor of the RSVP-TE tunnel.

For pop-and-forward LSP tunnels, the pop label for the traffic engineering link is allocated when the first RESV message for a pop-and-forward transit LSP arrives over that traffic engineering link. This is done to avoid preallocating pop labels and installing them in networks where pop-and-forward LSPs are not configured.

> **NOTE**: For the pop-and-forward LSP tunnels to function effectively, we recommend that you configure the `maximum-labels` statement on all the interfaces in the RSVP-TE network.

Figure 51 on page 805 displays pop labels at all interfaces for neighboring devices.

Figure 51: Pop-and-Forward LSP Tunnel Labels



There are two pop-and-forward LSP tunnels—T1 and T2. Tunnel T1 is from Device A to Device E on path A-B-C-D-E. Tunnel T2 is from Device F to Device E on path F-B-C-D-E. Both the tunnels, T1 and T2, share the same traffic engineering links B-C, C-D, and D-E.

As RSVP-TE signals the setup of the pop-and-forward tunnel T1, the LSR D receives the RESV message from the egress E. Device D checks the next-hop traffic engineering link (D-E) and provides the pop label (250) in the RESV message for the tunnel. The label is sent in the label object and is also recorded in the label subobject (with the pop label bit set) carried in the RRO. Similarly, Device C provides the pop label (200) for the next- hop traffic engineering link C-D and Device B provides the pop label (150) for the next-hop traffic engineering link B-C. For the tunnel T2, the transit LSRs provide the same pop labels as described for tunnel T1.

Both the label edge routers (LERs), Device A and Device F, push the same stack of labels [150(top), 200, 250] for tunnels T1 and T2, respectively. The recorded labels in the RRO are used by the ingress LER to construct a stack of labels.

The pop-and-forward LSP tunnel labels are compatible with transit interfaces that use swap labels. Labels can be mixed across transit hops in a single MPLS RSVP-TE LSP, where certain LSRs can use pop labels and others can use swap labels. The ingress device constructs the appropriate label stack based on the label type recorded from every transit LSR.

Pop-and-Forward LSP Tunnel Label Stacking

Construction of Label Stack at the Ingress

The ingress LER checks the type of label received from each transit hop as recorded in the RRO in the RESV message and generates the appropriate label stack to use for the pop-and-forward tunnel.

The following logic is used by the ingress LER while constructing the label stack:

- Each RRO label subobject is processed starting with the label subobject from the first downstream hop.
- Any label provided by the first downstream hop is always pushed on the label stack. If the label type is a pop label, then any label from the succeeding downstream hop is also pushed on the constructed label stack.
- If the label type is a swap label, then any label from the succeeding downstream hop is not pushed on the constructed label stack.

Auto-Delegation of Label Stack

The ingress device runs the Constrained Shortest Path First (CSPF) to compute the path, and if the hop length is greater than the OutLD-AppLD-AddTLD, the ingress device cannot impose the entire label stack to reach the egress device.

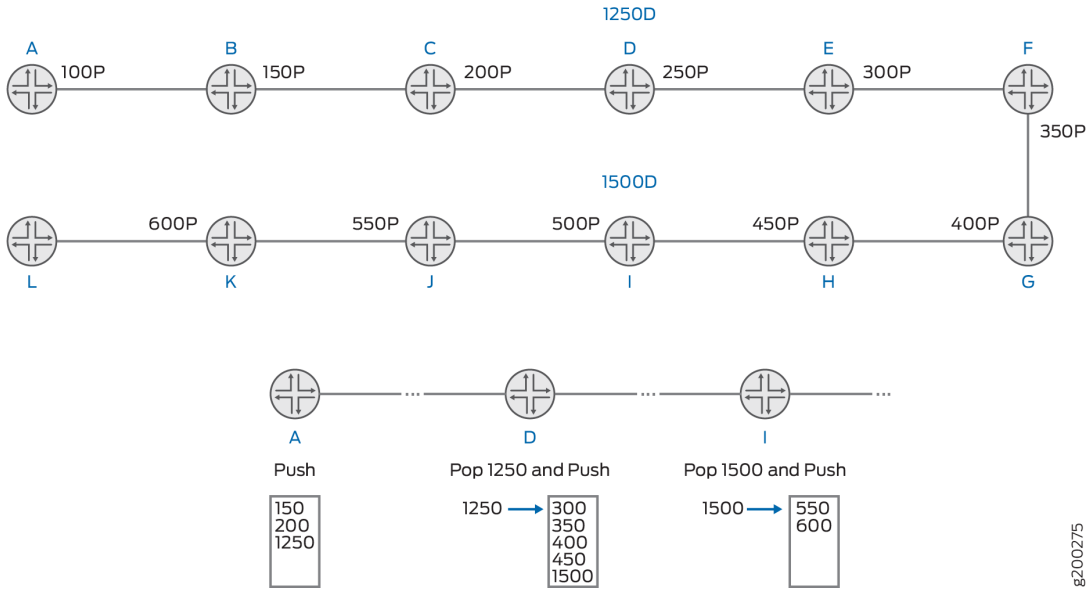
When requesting RSVP-TE to signal the path, the ingress device always requests autodelegation for the LSP, where one or more transit hops automatically select themselves as delegation hops to push the label stack to reach the next delegation hop. Junos OS uses an algorithm based on the received Effective Transport Label-Stack Depth (ETLD), that each transit executes to decide whether it should autoselect itself as a delegation hop. This algorithm is based on the section on ETLD in the Internet draft draft-ietf-mpls-rsvp-shared-labels-00.txt (expires September 11 2017), *Signaling RSVP-TE Tunnels on a Shared MPLS Forwarding Plane*.

The label stack imposed by the ingress device delivers the packet up to the first delegation hop. Each delegation hop's label stack also includes the delegation label of the next delegation hop at the bottom of the stack.

Figure 52 on page 807 displays labels at every device interface, where Device D and Device I are delegation hops, *[Label]* P is the pop label, and *[Label]* D is the delegation label. The RSVP-TE pop-and-

forward LSP tunnel is A-B-C-D-E-F-G-H-I-J-K-L. Delegation label 1250 represents (300, 350, 400, 450, 1500); Delegation label 1500 represents (550, 600).

Figure 52: Pop-and-Forward LSP Tunnel Pop and Delegation Labels



In this approach, for the tunnel, the ingress LER Device A pushes (150, 200, 1250). At LSR Device D, the delegation label 1250 gets popped and labels 300, 350, 400, 450, and 1500 get pushed. At LSR Device I, the delegation label 1500 gets popped and the remaining set of labels (550, 600) get pushed. In Junos OS, the pop and push action occurs as a swap to the bottom label of the outgoing stack and push the remaining labels.

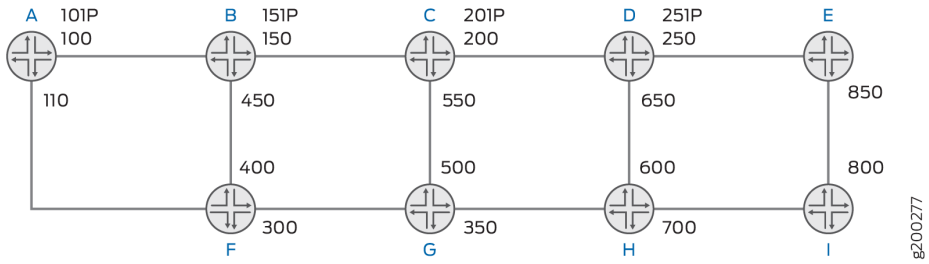
A delegation label and the LSP segment that it covers can be shared by multiple pop-and-forward LSPs. A LSP delegation segment consist of an ordered set of hops (IP addresses and labels) as seen in the RESV RRO. The delegation label (and the segment that it covers) is not owned by a particular LSP, but can be shared. When all LSPs using a delegation label are deleted, the delegation label (and route) is deleted.

Pop-and-Forward LSP Tunnel Link Protection

To provide link protection at a point of local repair (PLR) with a pop-and-forward data plane, the LSR allocates a separate pop label for the traffic engineering link that is used for the RSVP-TE tunnels that request link protection from the ingress device. No signaling extensions are required to support link protection for the RSVP-TE tunnels over the pop-and-forward data plane.

Figure 53 on page 808 displays pop labels at every device interface; labels marked with P are pop labels that offer link protection for the traffic-engineering link.

Figure 53: Pop-and Forward LSP Tunnel Link Protection



At each LSR, link-protected pop labels can be allocated for each traffic engineering link, and a link-protecting facility bypass LSP (which is not a pop-and-forward LSP, but rather a normal bypass LSP) can be created to protect the traffic engineering link. These labels can be sent in the RESV message by the LSR for LSPs requesting link protection over the specific traffic engineering link. Because the facility bypass terminates at the next hop (merge point), the incoming pop label on the packet at the PLR is what the merge point expects.

For example, LSR Device B can install a facility bypass LSP for the link-protected pop label 151. When the traffic engineering link B-C is up, LSR Device B pops 151 and sends the packet to C. If the traffic engineering link B-C is down, the LSR can pop 151 and send the packet through the facility backup to Device C.

RSVP-TE Pop-and-Forward LSP Tunnel Supported and Unsupported Features

Junos OS supports the following features with RSVP-TE pop-and-forward LSP tunnels:

- Pop labels per RSVP neighbor for unprotected LSP.
- Pop labels per RSVP neighbor for LSPs requesting link protection using facility bypass
- Autodelegation of LSP segment.
- Mixed label mode, where certain transit LSRs do not support pop-and-forward LSP tunnels
- LSP ping and traceroute
- All existing CSPF constraint.
- Load balancing of traffic between pop-and-forward LSPs and regular point-to-point RSVP-TE LSP.
- Autobandwidth, LDP tunneling, and TE++ container LSP.

- Aggregated Ethernet interface.
- Virtual platforms support, such as Juniper Networks vMX Virtual Router.
- 64-bit support
- Logical systems

Junos OS does not support the following functionality for RSVP-TE pop-and-forward LSP tunnels:

- Node link protection
- Detour protection for MPLS fast reroute
- Point-to-multipoint LSPs.
- Switch-away LSP.
- Generalized MPLS (GMPLS) LSPs (including bidirectional LSPs, associated LSPs, VLAN user-to-network interface [UNI] and so on)
- IP Flow Information Export (protocol) (IPFIX) inline flow sampling for MPLS template
- RFC 3813, *Multiprotocol Label Switching (MPLS) Label Switching Router (LSR) Management Information Base (MIB)*
- IPv4 Explicit-null (Inserting label 0 at the bottom of the label stack is not supported. If there are service labels beneath the RSVP-TE pop-and-forward label stack, because the penultimate hop for the LSP copies the EXP value to the service label, this can allow continuity of class of service (CoS) across the MPLS forwarding plane).
- Ultimate-hop popping (UHP)
- Graceful Routing Engine switchover (GRES)
- Nonstop active routing (NSR)

Prior to Junos OS Release 19.2R1S1, for traffic engineering of segment routing paths, you could either explicitly configure static paths, or use computed paths from an external controller. With the distributed Constrained Shortest Path First (CSPF) for segment routing LSP feature, you can compute a segment routing LSP locally on the ingress device according to the constraints you have configured. With this feature, the LSPs are optimized based on the configured constraints and metric type (traffic-engineering or IGP). The LSPs are computed to utilize the available ECMP paths to the destination with segment routing label stack compression enabled or disabled.

Distributed CSPF Computation Constraints

Segment routing LSP paths are computed when all the configured constraints are met.

The distributed CSPF computation feature supports the following subset of constraints specified in the Internet draft, draft-ietf-spring-segment-routing-policy-03.txt, *Segment Routing Policy for Traffic Engineering*:

- Inclusion and exclusion of administrative groups.

- Inclusion of loose or strict hop IP addresses.

  NOTE: You can specify only router IDs in the loose or strict hop constraints. Labels and other IP addresses cannot be specified as loose or strict hop constraints in Junos OS Release 19.2R1-S1.

- Maximum number of segment IDs (SIDs) in the segment list.
- Maximum number of segment lists per candidate segment routing path.

The distributed CSPF computation feature for segment routing LSPs does not support the following types of constraints and deployment scenarios:

- IPV6 addresses.
- Inter domain segment routing traffic engineering (SRTE) LSPs.
- Unnumbered interfaces.
- Multiple protocols routing protocols such as, OSPF, ISIS, and BGP-LS, enabled at the same time.
- Computation with prefixes or anycast addresses as destinations.
- Including and excluding interface IP addresses as constraints.

Distributed CSPF Computation Algorithm

The distributed CSPF computation feature for segment routing LSPs uses the label stack compression algorithm with CSPF.

Label Stack Compression Enabled

A compressed label stack represents a set of paths from a source to a destination. It generally consists of node SIDs and adjacency SIDs. When label stack compression is enabled, the result of the computation is a set of paths that maximize ECMP to the destination, with minimum number of SIDs in the stack, while conforming to constraints.

Label Stack Compression Disabled

The multipath CSPF computation with label stack compression disabled finds up to *N* segment lists to destination, where:

- The cost of all segment lists is equal to and the same as the shortest traffic-engineering metric to reach the destination.

- Each segment list is comprised of adjacency SIDs.
- The value of *N* is the maximum number of segment lists allowed for the candidate path by configuration.
- No two segment lists are identical.
- Each segment list satisfies all the configured constraints.

Distributed CSPF Computation Database

The database used for SRTE computation has all links, nodes, prefixes and their characteristics irrespective of whether traffic-engineering is enabled in those advertising nodes. In other words, it is the union of the traffic-engineering database (TED) and the IGP link state database of all domains that the computing node has learnt from.

Configuring Distributed CSPF Computation Constraints

You can use a compute profile to logically group the computation constraints. These compute profiles are referenced by the segment routing paths for computing the primary and secondary segment routing LSPs.

To configure a compute profile, include the "compute-profile" on page 2433 statement at the `[edit protocols source-packet-routing]` hierarchy level.

The configuration for the supported computation constraints include:

- **Administrative groups**

  You can configure "admin-groups" on page 2398 under the `[edit protocols mpls]` hierarchy level. Junos OS applies the administrative group configuration to the segment routing traffic-engineering (SRTE) interfaces.

  To configure the computation constraints you can specify three categories for a set of administrative groups. The computation constraint configuration can be common to all candidate segment routing paths, or it can be under individual candidate paths.

  - `include-any`—Specifies that any link with at least one of the configured administrative groups in the list is acceptable for the path to traverse.
  - `include-all`—Specifies that any link with all of the configured administrative groups in the list is acceptable for the path to traverse.
  - `exclude`—Specifies that any link which does not have any of the configured administrative groups in the list is acceptable for the path to traverse.

- **Explicit path**

You can specify a series of router IDs in the compute profile as a constraint for computing the SRTE candidate paths. Each hop has to be an IPv4 address and can be of type strict or loose. If the type of a hop is not configured, strict is used. You must include the `compute` option under the *segment-list* statement when specifying the explicit path constraint.

- **Maximum number of segment lists (ECMP paths)**

  You can associate a candidate path with a number of dynamic segment-lists. The paths are ECMP paths, where each segment-list translates into a next hop gateway with active weight. These paths are a result of path computation with or without compression.

  You can configure this attribute using the `maximum-computed-segment-lists` *maximum-computed-segment-lists* option under the "compute-profile" on page 2433 configuration statement. This configuration determines the maximum number of such segment lists computed for a given primary and secondary LSP.

- **Maximum segment list depth**

  The maximum segment list depth computation parameter ensures that amongst the ECMP paths that satisfy all other constraints such as administrative group, only the paths that have segment lists less than or equal to the maximum segment list depth are used. When you configure this parameter as a constraint under the compute-profile, it overrides the `maximum-segment-list-depth` configuration under the `[edit protocols source-packet-routing]` hierarchy level, if present.

  You can configure this attribute using the `maximum-segment-list-depth` *maximum-segment-list-depth* option under the "compute-profile" on page 2433 configuration statement.

- **Protected or unprotected adjacency SIDs**

  You can configure protected or unprotected adjacency SID as a constraint under the "compute-profile" on page 2433 to avoid links with the specified SID type.

- **Metric type**

  You can specify the type of metric on the link to be used for computation. By default, SR-TE LSPs use traffic-engineering metrics of the links for computation. The traffic-engineering metric for links is advertised by traffic-engineering extensions of IGP protocols. However, you may also choose to use the IGP-metric for computation by using the metric-type configuration in the compute profile.

  You can configure this attribute using the `metric-type (`*igp* `/` *te*`)` option under the "compute-profile" on page 2433 configuration statement.

Distributed CSPF Computation

The SRTE candidate paths are computed locally such that they satisfy the configured constraints. When label stack compression is disabled, the multi-path CSPF computation result is a set of adjacency SID

stacks. When label stack compression is enabled, the result is a set of compressed label stacks (composed of adjacent SIDs and node SIDs).

When secondary paths are computed, the links, nodes and SRLGs taken by the primary paths are not avoided for computation. For more information on primary and secondary paths, see "Configuring Primary and Secondary LSPs" on page 663.

For any LSPs with unsuccessful computation result, the computation is retried as traffic-engineering database (TED) changes.

Interaction Between Distributed CSPF Computation and SRTE Features

Weights Associated With Paths of an SRTE Policy

You can configure weights against computed and static SRTE paths, which contribute to the next hops of the route. However, a single path that has computation enabled can result in multiple segment lists. These computed segment lists are treated as ECMP amongst themselves. You can assign hierarchical ECMP weights to these segments, considering the weights assigned to each of the configured primaries.

BFD Liveliness Detection

You can configure BFD liveliness detection for the computed primary or secondary paths. Every computed primary or secondary path can result in multiple segment lists, as a result, the BFD parameters configured against the segment lists are applied to all the computed segment lists. If all the active primary paths go down, the pre-programmed secondary path (if provided) becomes active.

inherit-label-nexthops

You are not required to explicitly enable the `inherit-label-nexthops` configuration under the `[edit protocols source-packet-routing segment-list segment-list-name]` hierarchy for the computed primary or secondary paths, as it is a default behavior.

Auto-Translate Feature

You can configure the auto-translate feature on the segment lists, and the primary or secondary paths with the auto-translate feature reference these segment lists. On the other hand, the primary or secondary on which compute feature is enabled cannot reference any segment list. As a result, you cannot enable both the compute feature and the auto-translate feature for a given primary or secondary path. However, you could have an LSP configured with a primary path with compute type and another with auto-translate type.

Distributed CSPF Computation Sample Configurations

Example 1

In Example 1,

- The non-computed primary path references a configured segment-list. In this example, the configured segment list *static_sl1* is referenced, and it also serves as the name for this primary path.
- A computed primary should have a name configured, and this name should not reference any configured segment list. In this example, *compute_segment1* is not a configured segment list.
- The *compute_profile_red* compute-profile is applied to the primary path with the name *compute_segment1*.
- The *compute_profile_red* compute-profile includes a segment list of type `compute`, which is used to specify the explicit path constraint for the computation.

```
[edit protocols source-packet-routing]
segment-list static_sl1{
    hop1 label 80000
}
segment-list exp_path1 {
    hop1 ip-address 10.1.1.1 loose
    hop2 ip-address 2.2.2.2
    compute
}
compute-profile compute_profile_red {
    include-any red
    segment-list exp_path1
    maximum-segment-list-depth 5
}
```

The weights for computed path next-hops and static next-hops are 2 and 3, respectively. Assuming the next-hops for computed paths are *comp_nh1*, *comp_nh2*, and *comp_nh3*, and the next-hop for static path is *static_nh*, the weights are applied as follows:

Next-Hop	Weight
comp_nh1	2

(Continued)

Next-Hop	Weight
comp_nh2	2
comp_nh3	2
static_nh	9

Example 2

In Example 2, both the primary and secondary paths can be of compute type and can have their own compute-profiles.

```
[edit protocols source-packet-routing]
compute-profile compute_profile_green{
    include-any green
    maximum-segment-list-depth 5
}
compute-profile compute_profile_red{
    include-any red
    maximum-segment-list-depth 8
}
```

Example 3

In Example 3, when compute is mentioned under a primary or secondary path, it results in local computation of a path to the destination without any constraints or other parameters for the computation.

```
[edit protocols source-packet-routing]
source-routing-path srte_colored_policy1 {
    to 5.5.5.5
    color 5
    binding-sid 10001
    primary {
        compute_segment1 {
```

```
            compute
        }
    }
}
```

Static Segment Routing Label Switched Path

- Understanding Static Segment Routing LSP in MPLS Networks | **817**
- Example: Configuring Static Segment Routing Label Switched Path | **843**

The segment routing architecture enables the ingress devices in a core network to steer traffic through explicit paths. You can configure these paths using segment lists to define the paths that the incoming traffic should take. The incoming traffic may be labeled or IP traffic, causing the forwarding operation at the ingress device to be either a label swap, or a destination-based lookup.

Source packet routing or segment routing is a control-plane architecture that enables an ingress router to steer a packet through a specific set of nodes and links in the network without relying on the intermediate nodes in the network to determine the actual path it should take.

Introduction to Segment Routing LSPs

Segment routing leverages the source routing paradigm. A device steers a packet through an ordered list of instructions, called segments. A segment can represent any instruction, topological or service-based. A segment can have a local semantic to a segment routing node or to a global node within a segment routing domain. Segment routing enforces a flow through any topological path and service chain while maintaining per-flow state only at the ingress device to the segment routing domain. Segment routing can be directly applied to the MPLS architecture with no change on the forwarding plane. A segment is encoded as an MPLS label. An ordered list of segments is encoded as a stack of labels. The segment to process is on the top of the stack. Upon completion of a segment, the related label is popped from the stack.

Segment routing LSPs can either be dynamic or static in nature.

Dynamic segment routing LSPs—When a segment routing LSP is created either by an external controller and downloaded to an ingress device through Path Computation Element Protocol (PCEP) extensions, or from a BGP segment routing policy through BGP segment routing extensions, the LSP is dynamically provisioned. The segment list of the dynamic segment routing LSP is contained in the PCEP Explicit Route Object (ERO), or the BGP segment routing policy of the LSP.

Static segment routing LSPs—When a segment routing LSP is created on the ingress device through local configuration, the LSP is statically provisioned.

A static segment routing LSP can further be classified as colored and non-colored LSPs based on the configuration of the `color` statement at the `[edit protocols source-packet-routing source-routing-path lsp-name]` hierarchy level.

For example:

```
[edit protocols]
    source-packet-routing {
    source-routing-path lsp_name {
        to destination_address;
        color color_value;
        binding-sid binding-label;
        primary segment_list_1_name weight weight;
        ...
        primary segment_list_n_name weight weight;
        secondary segment_list_n_name;
        sr-preference sr_preference_value;
    }
}
```

Here, each primary and secondary statement refers to a segment list.

```
[edit protocols]
source-packet-routing {
    segment-list segment_list_name {
        hop_1_name label sid_label;
        ...
        hop_n_name label sid_label;
    }
}
```

Benefits of using Segment Routing LSPs

- Static segment routing does not rely on per LSP forwarding state on transit routers. Hence, removing the need of provisioning and maintaining per LSP forwarding state in the core.
- Provide higher scalability to MPLS networks.

Colored Static Segment Routing LSP

A static segment routing LSP configured with the `color` statement is called a colored LSP.

Understanding Colored Static Segment Routing LSPs

Similar to a BGP segment routing policy, the ingress route of the colored LSP is installed in the `inetcolor.0` or `inet6color.0` routing tables, with `destincation-ip-address, color` as key for mapping IP traffic.

A static colored segment routing LSP may have a binding SID, for which a route is installed in the `mpls.0` routing table. This binding SID label is used to map labeled traffic to the segment routing LSP. The gateways of the route are derived from the segment list configurations under the primary and secondary paths.

Segment List of Colored Segment Routing LSPs

The colored static segment routing LSPs already provde support for first hop label mode of resolving an LSP. However, first hop IP mode is not supported for colored segment routing LSPs. Starting in Junos OS Release 19.1R1, a commit check feature is introduced to ensure that all the segment lists contributing to the colored routes have the minimum label present for all hops. If this requirement is not met, the commit is blocked.

Non-Colored Static Segment Routing LSP

A static segment routing LSP that is configured without the `color` statement is a non-colored LSP. Similar to PCEP segment routing tunnels, the ingress route is installed in the `inet.3` or `inet6.3` routing tables.

Junos OS supports non-colored static segment routing LSPs on ingress routers. You can provision non-colored static segment routing LSP by configuring one source routed path and one or more segment lists. These segment lists can be used by multiple non-colored segment routing LSPs.

Understanding Non-Colored Segment Routing LSPs

The non-colored segment routing LSP has a unique name and a destination IP address. An ingress route to the destination is installed in the inet.3 routing table with a default preference of 8 and a metric of 1. This route allows non-colored services to be mapped to the segment routing LSP pertaining to the destination. In case the non-colored segment routing LSP does not require an ingress route then the ingress route can be disabled. A non-colored segment routing LSP uses binding SID label to achieve segment routing LSP stitching. This label that can be used to model the segment routing LSP as a segment that may be further used to construct other segment routing LSPs in a hierarchical manner. The transit of the binding SID label, by default, has a preference of 8 and a metric of 1.

Starting in Junos OS Release 18.2R1, statically configured non-colored segment routing LSPs on the ingress device are reported to the Path Computation Element (PCE) through a Path Computation Element Protocol (PCEP) session. These non-colored segment routing LSPs may have binding service identifier (SID) labels associated with them. With this feature, the PCE can use this binding SID label in the label stack to provision PCE-initiated segment routing LSP paths.

A non-colored segment routing LSP can have a maximum of 8 primary paths. If there are multiple operational primary paths then the packet forwarding engine (PFE) distributes traffic over the paths based on the load balancing factors like the weight configured on the path. This is equal cost multi path (ECMP) if none of the paths have a weight configured on them or weighted ECMP if at least one of the paths has a non-zero weight configured on the paths. In both the cases, when one or some of the paths fail, the PFE rebalances the traffic over the remaining paths that automatically leads to achieving path protection. A non-colored segment routing LSP can have a secondary path for dedicated path protection. Upon failure of a primary path, the PFE rebalances the traffic to the remaining functional primary paths. Otherwise, the PFE switches the traffic to the backup path, hence achieving path protection. A non-colored segment routing LSP may specify a metric at `[edit protocols source-packet-routing source-routing-path` *`lsp-name`*`]` for its ingress and binding-SID routes. Multiple non-colored segment routing LSPs have the same destination address that contribute to the next hop of the ingress route.

Multiple non-colored segment routing LSPs have the same destination address that contribute to the next hop of the ingress route. Each path ,either primary or secondary, of each segment routing LSP is considered as a gateway candidate, if the path is functional and the segment routing LSP has the best preference of all these segment routing LSPs. However, the maximum number of gateways that the next-hop can hold cannot exceed the RPD multi-path limit, which is 128 by default. Extra paths are pruned, firstly secondary paths and then primary paths. A given segment list may be referred multiple times as primary or secondary paths by these segment routing LSPs. In this case, there are multiple gateways, each having a unique segment routing LSP tunnel ID. These gateways are distinct, although they have identical outgoing label stack and interface. A non-colored segment routing LSP and a colored segment routing LSP may also have the same destination address. However, they correspond to different destination addresses for ingress routes, as the colored segment routing LSP's destination address is constructed with both its destination address and color.

NOTE: In the case where a static non-colored segment routing LSP and a PCEP-created segment routing LSP co-exist and have the same to address that contributes to the same ingress route, if they also have the same preference. Otherwise, the segment routing LSP with the best preference is installed for the route.

Segment List of Non-Colored Segment Routing LSPs

A segment list consists of a list of hops. These hops are based on the SID label or an IP address. The number of SID labels in the segment list should not exceed the maximum segment list limit. Maximum segment-list binding to a LSP tunnel is increased from 8 to 128, with maximum 1000 tunnels per system. A maximum of 128 primary paths are supported per static segment routing LSP. You can configure the maximum segment list limit at the `[edit protocols source-packet-routing]` hierarchy level.

Prior to Junos OS Release 19.1R1, for a non-colored static segment routing LSP to be usable, the first hop of the segment list had to be an IP address of an outgoing interface and the second to *n*th hops could be SID labels. Starting in Junos OS Release 19.1R1, this requirement does not apply, as the first

hop of the non-colored static LSPs now provides support for SID labels, in addition to IP addresses. With the first hop label support, MPLS fast reroute (FRR) and weighted equal-cost multipath is enabled for resolving the static non-colored segment routing LSPs, similar to colored static LSPs.

For the first-hop label mode to take effect, you must include the `inherit-label-nexthops` statement globally or individually for a segment list, and the first hop of the segment list must include both IP address and label. If the first hop includes only IP address, the `inherit-label-nexthops` statement does not have any effect.

You can configure `inherit-label-nexthops` at any one of the following hierarchies. The `inherit-label-nexthops` statement takes effect only if the segment list first hop includes both IP address and label.

- **Segment list level**—At the `[edit protocols source-packet-routing segment-list` *`segment-list-name`*`]` hierarchy level.
- **Globally**—At the `[edit protocols source-packet-routing]` hierarchy level.

When the `inherit-label-nexthops` statement is configured globally, it takes precedence over the segment-list level configuration, and the `inherit-label-nexthops` configuration is applied to all the segment lists. When the `inherit-label-nexthops` statement is not configured globally, only segment lists with both labels and IP address present in the first hop, and configured with `inherit-label-nexthops` statement are resolved using SID labels.

For dynamic non-colored static LSPs, that is the PCEP-driven segment routing LSPs, the `inherit-label-nexthops` statement must be enabled globally, as the segment-level configuration is not applied.

Table 1 describes the mode of segment routing LSP resolution based on the first hop specification.

Table 20: Non-Colored Static LSP Resolution Based on First Hop Specification

First Hop Specification	Mode of LSP Resolution

IP address only
 	
For example:
 	
`segment-list path-1 {`
`  hop-1 ip-address 172.0.12.2;`
`  hop-2 label 1000012;`
`  hop-3 label 1000013;`
`  hop-4 label 1000014;`
`}`
	The segment list is resolved using the IP address.

Table 20: Non-Colored Static LSP Resolution Based on First Hop Specification *(Continued)*

First Hop Specification	Mode of LSP Resolution

SID only
 	
For example:
 	
`segment-list path-2 {`
`  hop-1 label 1000011;`
`  hop-2 label 1000012;`
`  hop-3 label 1000013;`
`  hop-4 label 1000014;`
`}`
	The segment list is resolved using SID labels.

IP address and SID (without the `inherit-label-nexthops` configuration)
 	
For example:
 	
`segment-list path-3 {`
`  hop1 {`
`  **label 801006**;`
`  **ip-address 172.24.1.2**;`
`  }`
`  hop-2 label 1000012;`
`  hop-3 label 1000013;`
`  hop-4 label 1000014;`
`}`
	By default, the segment list is resolved using IP address.

Table 20: Non-Colored Static LSP Resolution Based on First Hop Specification *(Continued)*

First Hop Specification	Mode of LSP Resolution

IP address and SID (with the `inherit-label-nexthops` configuration)
 	
For example:
 	
`segment-list path-3 {`
`  **inherit-label-nexthops**;`
`  hop1 {`
`  **label 801006**;`
`  **ip-address 172.24.1.2**;`
`  }`
`  hop-2 label 1000012;`
`  hop-3 label 1000013;`
`  hop-4 label 1000014;`
`}`
	The segment list is resolved using SID labels.

You can use the `show route` *ip-address* `protocol spring-te active-path table inet.3` command to view the non-colored segment routing traffic-engineered LSPs having multiple segment lists installed in the inet.3 routing table.

For example:

```
user@host> show route 7.7.7.7 protocol spring-te active-path table inet.3
inet.3: 42 destinations, 59 routes (41 active, 0 holddown, 1 hidden)
+ = Active Route, - = Last Active, * = Both

7.7.7.7/32         *[SPRING-TE/8] 00:01:25, metric 1, metric2 0
                    > to 11.1.1.2 via et-0/0/0.1, Push 801007
                      to 21.1.1.2 via et-0/0/2.1, Push 801007
                      to 11.102.1.2 via et-0/0/0.2, Push 801007, Push 801002(top)
                      to 21.202.1.2 via et-0/0/2.2, Push 801007, Push 801005(top)
                      to 11.103.1.2 via et-0/0/0.3, Push 801007, Push 801003(top)
                      to 21.203.1.2 via et-0/0/2.3, Push 801007, Push 801006(top)
                      to 11.104.1.2 via et-0/0/0.4, Push 801007, Push 801003, Push 801002(top)
                      to 21.204.1.2 via et-0/0/2.4, Push 801007, Push 801006, Push 801005(top)
```

NOTE: The first hop type of segment lists of a static segment routing LSP can cause a commit to fail, if:

- Different segment lists of a tunnel have different first hop resolution types. This is applicable to both colored and non-colored static segment routing LSPs. However, this does not apply for PCEP-driven LSPs; a system log message is generated for the mismatch in the first hop resolution type at the time of computing the path.

  For example:

  ```
  segment-list path-1 {
      hop-1 ip-address 172.0.12.2;
      hop-2 label 1000012;
      hop-3 label 1000013;
      hop-4 label 1000014;
  }
  segment-list path-2 {
      hop-1 label 1000011;
      hop-2 label 1000012;
      hop-3 label 1000013;
      hop-4 label 1000014;
  }
  source-routing-path lsp1 {
      to 172.10.10.1;
      primary {
          path-1;
          path-2;
      }
  }
  ```

  The commit of tunnel *lsp1* fails, as path-1 is of IP addressmode and path-2 is of label mode.

- The binding SID is enabled for the static non-colored LSP whose segment list type is SID label.

  For example:

  ```
  segment-list path-3 {
      hop-1 label 1000011;
      hop-2 label 1000012;
  ```

```
        hop-3 label 1000013;
        hop-4 label 1000014;
    }
    source-routing-path lsp1 {
        to 172.10.10.1;
        binding-sid 333;
        primary {
            path-3;
        }
    }
```

Configuring binding SID over label segment list is supported only for colored static LSPs and not for no-colored static LSPs.

Static Segment Routing LSP Provisioning

Segment provisioning is performed on per-router basis. For a given segment on a router, a unique service identifier (SID) label is allocated from a desired label pool which may be from the dynamic label pool for an adjacency SID label or from the segment routing global block (SRGB) for a prefix SID or node SID. The adjacency SID label can be dynamically allocated, which is the default behavior, or be allocated from a local static label pool (SRLB). A route for the SID label is then installed in the mpls.0 table.

Junos OS allows static segment routing LSPs by configuring the `segment` statement at the `[edit protocols mpls static-label-switched-path` *`static-label-switched-path`*`]` hierarchy level. A static segment LSP is identified by a unique SID label that falls under Junos OS static label pool. You can configure the Junos OS static label pool by configuring the `static-label-range` *`static-label-range`* statement at the `[edit protocols mpls label-range]` hierarchy level.

Static Segment Routing LSP Limitations

- Junos OS currently has a limitation that the next hop cannot be built to push more than the maximum segment list depth labels. So, a segment list with more than the maximum SID labels (excluding the SID label of the first hop which is used to resolve forwarding next-hop) is not usable for colored or non-colored segment routing LSPs. Also, the actual number allowed for a given segment routing LSP may be even lower than the maximum limit, if an MPLS service is on the segment routing LSP or the segment routing LSP is on a link or a node protection path. In all cases, the total number of service labels, SID labels, and link or node protection labels must not exceed the maximum segment list depth. You can configure the maximum segment list limit at `[edit protocols source-packet-routing]` hierarchy level. Multiple non-colored segment routing LSPs with less than or equal to the maximum SID labels can be stitched together to construct a longer segment routing LSP. This is called segment routing LSP stitching. It can be achieved using binding-SID label.

- The segment routing LSP stitching is actually performed at path level. If a non-colored segment routing LSP has multiple paths that is multiple segment lists, each path can be independently stitched to another non-colored segment routing LSP at a stitching point. A non-colored segment routing LSP which is dedicated to stitching may disable ingress route installation by configuring `no-ingress` statement at `[edit protocols source-packet-routing source-routing-path lsp-name]` hierarchy level.
- A maximum of 128 primary paths and 1 secondary path are supported per non-colored static segment routing LSP. If there is a violation in configuration, commit check fails with an error.
- Maximum segment-list binding to a LSP tunnel is increased from 8 to 128, with maximum 1000 tunnels per system. A maximum of 128 primary paths are supported per static segment routing LSP. As a limitation, the maximum sensor support for LSP path is 32000 only.
- If any segment-list is configured with more labels than the maximum segment list depth, the configuration commit check fails with an error.

Dynamic Creation of Segment Routing LSPs

In segment routing networks that have each provider edge (PE) device connected to every other PE device, a large amount of configuration is required for setting up the segment routing label-switched paths (LSPs), although only a few segment routing traffic-engineered (SR-TE) paths may be used. You can enable BGP-trigerred dynamic creation of these LSPs to reduce the amount of configuration in such deployments.

Configuring Dynamic Segment Routing LSP Template

To configure the template for enabling dynamic creation of segment routing LSPs, you must include the "spring-te" on page 2717 statement at the `[edit routing-options dynamic-tunnels]` hierarchy.

- The following is a sample configuration for color dynamic segment routing LSP template:

```
[edit routing-options]
dynamic-tunnels {
    <dynamic-tunnel-name> {
        spring-te {
            source-routing-path-template {
                <template-name1> color [c1 c2];
                <template-name2> color [c3];
                <template-name3> color-any;
            }
            destination-networks {
                <dest1>;
                <dest2>;
```

```
            }
        }
    }
}
```

- The following is a sample configuration for non-color dynamic segment routing LSP template:

```
dynamic-tunnels {
    <dynamic-tunnel-name> {
        spring-te {
            source-routing-path-template {
                <template-name1>;
            }
            destination-networks {
                <dest1>;
                <dest2>;
            }
        }
    }
}
```

Resolving Dynamic Segment Routing LSPs

Resolving Colored Dynamic Segment Routing LSP

When the BGP prefixes are assigned with color community, they initially get resolved over the catch-all-route-for-that–particular-color policy, and in turn, the SR-TE template on which the BGP prefix should be resolved onto is identified. The destinations SID is then derived from the BGP payload prefix next-hop attribute. For example, if the next hop of the BGP payload prefix is an IP address that belongs to Device A, then the node-SID of Device A is taken and a corresponding label is prepared and pushed to the bottom of the stack. The BGP payload prefix is resolved in a color-only mode, where the node-SID of Device A is at the bottom of the final label stack, and the SR-TE path labels are on top.

The final LSP template name is a combination of prefix, color, and tunnel name; for example, `<prefix>:<color>:dt-srte-<tunnel-name>`. The color in the LSP name is displayed in hexadecimal format, and the format of the tunnel name is similar to that o RSVP-triggered tunnel LSP names.

To successfully resolve a colored destination network, the color should have a valid template mapping, either to a specific color, or through the `color-any` template. Without a valid mapping, the tunnel is not created and the BGP route requesting for resolution remains unresolved.

Resolving Uncolored Dynamic Segment Routing LSPs

The catch-all routes for non-colored LSPs are added to the inet.3 routing table. The non-colored tunnel destination must be configured in a different `spring-te` configuration with only one template name in the mapping list. This template name is used for all the tunnel routes matching any of the destination networks configured under the same `spring-te` configuration. These tunnels are similar to RSVP tunnels in functionality.

The final LSP template name is a combination of prefix and tunnel name; for example, `<prefix>:dt-srte-<tunnel-name>`.

Dynamic Segment Routing LSP Sample Configuration

The dynamic segment routing LSP template always carries a partial path. The last hop node SID is derived automatically at the tunnel creation time depending on the protocol next-hop address (PNH) node SID. The same template can be used by multiple tunnels to different destinations. In such cases, the partial path remains the same, and only the last hop changes depending on the PNH. Dynamic segment routing LSP templates are not common to a single tunnel, as a result a full path cannot be carried on it. You can use a segment list if a full path is to be used.

Colored Dynamic Segment Routing LSPs

Sample configuration for colored dynamic segment routing LSPs:

```
protocols source-packet-routing {
    source-routing-path-template sr_lsp1 {
        primary sr_sl1
        primary sr_sl2 weight 2
        sr-preference 180;
    }
}
dynamic-tunnels tunnel1 {
    spring-te {
        source-routing-path-template {
            sr_lsp1 color [ 123 124 125 ];
            sr_lsp2 color-any
        }
        destination-networks {
            22.33.44.0/24;
        }
```

```
    }
}
```

For the above-mentioned sample configuration, the route entries are as follows:

1. **inetcolor.0 tunnel route**: 22.33.44.0-0/24 --> RT_NH_TUNNEL
2. **inetcolor6.0 tunnel route**: ffff::22.33.44.0-0/120 --> RT_NH_TUNNEL
3. **BGP prefix to tunnel mapping**:

   R1(prefix) -> 22.33.44.55-101(PNH) LSP tunnel name = 22.33.44.55:65:dt-srte-tunnel1

   R1(prefix) -> ffff::22.33.44.55-101(PNH) LSP tunnel name = 22.33.44.55:65:dt-srte-tunnel1

   R1(prefix) -> ffff::22.33.44.55-124(PNH) LSP tunnel name = 22.33.44.55:7c:dt-srte-tunnel1

4. **inetcolor.0 tunnel route**:

   22.33.44.55-101/64 --> <next-hop>

   22.33.44.55-124/64 --> <next-hop>

5. **inetcolor6.0 tunnel route:**

   ffff::22.33.44.55-101/160 --> <next-hop>

   ffff::22.33.44.55-124/160 --> <next-hop>

Non-Colored Dynamic Segment Routing LSPs

Sample configuration for non-colored dynamic segment routing LSPs:

```
protocols source-packet-routing {
    source-routing-path-template sr_lsp1 {
        primary sr_sl1
        primary sr_sl2 weight 2
        sr-preference 180;
    }
}
dynamic-tunnels {
    tunnel1 {
        spring-te {
            source-routing-path-template {
                sr_lsp1 color [ 101 ];
            }
```

```
            destination-networks {
                22.33.44.0/24;
            }
        }
    }
    tunnel2 {
        spring-te {
            source-routing-path-template {
                sr_lsp1;
            }
            destination-networks {
                22.33.44.0/24;
            }
        }
    }
}
```

For the above-mentioned sample configuration, the route entries are as follows:

1. **inet.3 tunnel route**: 22.33.44.0/24 --> RT_NH_TUNNEL
2. **inet6.3 tunnel route**: ffff::22.33.44.0/120 --> RT_NH_TUNNEL
3. **BGP prefix to tunnel mapping**:

   R1(prefix) -> 22.33.44.55(PNH) LSP template name = LSP1 --- 22.33.44.55:dt-srte-tunnel2

   R1(prefix) -> ffff::22.33.44.55(PNH) LSP template name = LSP1 --- 22.33.44.55:dt-srte-tunnel2
4. **inet.3 tunnel route**: 22.33.44.55/32 --> <next-hop>
5. **inet6.3 tunnel route**: ffff::22.33.44.55/128 --> <next-hop>

Unresolved Dynamic Segment Routing LSP

Sample configuration for unresolved dynamic segment routing LSPs:

```
protocols source-packet-routing {
    source-routing-path-template sr_lsp1 {
        primary sr_sl1
        primary sr_sl2 weight 2
        sr-preference 180;
    }
}
```

```
dynamic-tunnels tunnel1 {
    spring-te {
        source-routing-path-template {
            sr_lsp1 color [120 121 122 123];
        }
        destination-networks {
            22.33.44.0/24;
            1.1.1.0/24;
        }
    }
}
```

For the above-mentioned sample configuration, the route entries are as follows:

1. **inetcolor.0 tunnel route**: 22.33.44.0 - 0/24 --> RT_NH_TUNNEL 1.1.1.0 - 0 /24 --> RT_NH_TUNNEL
2. **inetcolor6.0 tunnel route**: ffff::22.33.44.0 - 0/120 --> RT_NH_TUNNEL ffff::1.1.1.0 - 0 /24 --> RT_NH_TUNNEL
3. **BGP prefix to tunnel mapping**: R1(prefix) -> 22.33.44.55-124(PNH) Tunnel will not be created. (Template not found for the color).

Considerations for Configuring Dynamic Creation of Segment Routing LSPs

When configuring the dynamic creation of segment routing LSPs, take the following into consideration:

- A template can be assigned with a color object. When the dynamic tunnel `spring-te` configuration includes a template with a color object, you must configure all other templates with color objects as well. All destinations are assumed to be colored within that configuration.
- A template can have a list of colors defined on it, or can be configured with the `color-any` option. Both these options can coexist in the same `spring-te` configuration. In such cases, templates assigned with specific colors have a higher preference.
- In a `spring-te` configuration, only one template can be defined with the `color-any` option.
- The color-to-template mapping is done on a one-to-one basis. One color cannot map to multiple templates.
- The template name should be configured in the `spring-te` statement under the `[edit protocols]` hierarchy, and should have the `primary` option enabled.
- Colored and non-colored destinations cannot co-exist in the same `spring-te` configuration.
- You cannot configure same destination networks, with or without color, under different `spring-te` configuration statements.

- In non-colored `spring-te` configuration, only one template can be configured without color object.

Services Supported over Dynamic Segment Routing LSPs

The following services are supported over colored dynamic segment routing LSPs:

- Layer 3 VPN
- BGP EVPN
- Export policy services

The following services are supported over non-colored dynamic segment routing LSPs:

- Layer 3 VPN
- Layer 2 VPN
- Multipath configurations

Behavior With Multiple Tunnel Sources in Segment Routing

When two sources download routes to the same destination from segment routing (for example static and dynamic sourced tunnels), then the segment routing preference is used for choosing the active route entry. A higher value has greater preference. In case the preference remains the same, then the tunnel source is used to determine the route entry.

Dynamic Segment Routing LSPs Limitations

The dynamic SR-TE LSPs do not support the following features and functionalities:

- IPv6 segment routing tunnels.
- Static tunnels.
- 6PE is not supported.
- Distributed CSPF.
- sBFD and LDP tunnelling is not supported for dynamic SR-TE LSPs and in a template.
- Install and B-SID routes in a template.

Color-Based Mapping of VPN Services

You can specify color as a protocol next hop constraint (in addition to the IPv4 or IPv6 address) for resolving transport tunnels over static colored and BGP segment routing traffic-engineered (SRTE) LSPs. This is called the color-IP protocol next hop resolution, where you are required to configure a resolution-map and apply to the VPN services. With this feature, you can enable color-based traffic steering of Layer 2 and Layer 3 VPN services.

Junos OS supports colored SRTE LSPs associated with a single color. The color-based mapping of VPN services feature is supported on static colored LSPs and BGP SRTE LSPs.

VPN Service Coloring

In general, a VPN service may be assigned a color on the egress router where the VPN NLRI is advertised, or on an ingress router where the VPN NLRI is received and processed.

You can assign a color to the VPN services at different levels:

- Per routing instance.
- Per BGP group.
- Per BGP neighbor.
- Per prefix.

Once you assign a color, the color is attached to a VPN service in the form of BGP color extended community.

You can assign multiple colors to a VPN service, referred to as multi-color VPN services. In such cases, the last color attached is considered as the color of the VPN service, and all other colors are ignored.

Multiple colors are assigned by egress and/or ingress devices through multiple policies in the following order:

- BGP export policy on the egress device.
- BGP import policy on the ingress device.
- VRF import policy on the ingress device.

The two modes of VPN service coloring are:

Egress Color Assignment

In this mode, the egress device (that is, the advertiser of the VPN NLRI) is responsible for coloring the VPN service. To enable this mode, you can define a routing policy, and apply it in the VPN service's

routing-instance `vrf-export`, group export, or group neighbor export at the `[edit protocols bgp]` hierarchy level. The VPN NLRI is advertised by BGP with the specified color extended community.

For example:

```
[edit routing-options]
community red-comm {
    members color:0:50;
}
```

```
[edit policy-options]
policy-statement pol-color {
    term t1 {
        from {
            [any match conditions];
        }
        then {
            community add red-comm;
            accept;
        }
    }
}
```

```
[edit routing-instances]
vpn-X {
    ...
    vrf-export pol-color ...;
}
```

Or

NOTE: When you apply the routing policy as an export policy of a BGP group or BGP neighbor, you must include the `vpn-apply-export` statement at the BGP, BGP group, or BGP neighbor level in order for the policy to take an effect on the VPN NLRI.

```
[edit protocols bgp]
group PEs {
```

```
    ...
    neighbor PE-A {
        export pol-color ...;
        vpn-apply-export;
    }
}
```

The routing policies are applied to Layer 3 VPN prefix NLRIs, Layer 2 VPN NRLIs, and EVPN NLRIs. The color extended community is inherited by all the VPN routes, imported, and installed in the target VRFs on one or multiple ingress devices.

Ingress Color Assignment

In this mode, the ingress device (that is, the receiver of the VPN NLRI) is responsible for coloring the VPN service. To enable this mode, you can define a routing policy, and apply it to the VPN service's routing-instance `vrf-import`, group import, or group neighbor import at the `[edit protocols bgp]` hierarchy level. All the VPN routes matching the routing policy is attached with the specified color extended community.

For example:

```
[edit routing-options]
community red-comm {
    members color:0:50;
}
```

```
[edit policy-options]
policy-statement pol-color {
    term t1 {
        from {
            [any match conditions];
        }
        then {
            community add red-comm;
            accept;
        }
```

```
    }
}
```

```
[edit routing-instances]
vpn-Y {
    ...
    vrf-import pol-color ...;
}
```

Or

```
[edit protocols bgp]
group PEs {
    ...
    neighbor PE-B {
        import pol-color ...;
    }
}
```

Specifying VPN Service Mapping Mode

To specify flexible VPN service mapping modes, you must define a policy using the `resolution-map` statement, and refer the policy in a VPN service's routing-instance `vrf-import`, group import, or group neighbor import at the `[edit protocols bgp]` hierarchy level. All the VPN routes matching the routing policy are attached with the specified resolution-map.

For example:

```
[edit policy-options]
resolution-map map-A {
    <mode-1>;
    <mode-2>;
    ...
}
policy-statement pol-resolution {
    term t1 {
        from {
            [any match conditions];
        }
```

```
        then {
            resolution-map map-A;
            accept;
        }
    }
}
```

You can apply import policy to the VPN service's routing-instance.

```
[edit routing-instances]
vpn-Y {
    ...
    vrf-import pol-resolution ...;
}
```

You can also apply the import policy to a BGP group or BGP neighbor.

```
[edit protocols bgp]
group PEs {
    ...
    neighbor PE-B {
        import pol-resolution ...;
    }
}
```

NOTE: Each VPN service mapping mode should have a unique name defined in the resolution-map. Only a single entry of IP-color is supported in the resolution-map, where the VPN route(s) are resolved using a colored-IP protocol next hop in the form of `ip-address:color`.

Color-IP Protocol Next Hop Resolution

The protocol next hop resolution process is enhanced to support colored-IP protocol next hop resolution. For a colored VPN service, the protocol next hop resolution process takes a color and a resolution-map, builds a colored-IP protocol next hop in the form of *IP-address:color*, and resolves the protocol next hop in the inet6color.0 routing table.

You must configure a policy to support multipath resolution of colored Layer 2 VPN, Layer 3 VPN, or EVPN services over colored LSPs. The policy must then be applied with the relevant RIB table as the resolver import policy.

For example:

```
[edit policy-options]
policy-statement mpath {
    then multipath-resolve;
}
```

```
[edit routing-options]
resolution {
    rib bgp.l3vpn.0 {
        inetcolor-import mpath;
    }
}

resolution {
    rib bgp.l3vpn-inet6.0 {
        inet6color-import mpath;
    }
}

resolution {
    rib bgp.l2vpn.0 {
        inetcolor-import mpath;
    }
}

resolution {
    rib mpls.0 {
        inetcolor-import mpath;
    }
}

resolution {
    rib bgp.evpn.0 {
        inetcolor-import mpath;
    }
}
```

Fallback to IP Protocol Next Hop Resolution

If a colored VPN service does not have a resolution-map applied to it, the VPN service ignores its color and falls back to the IP protocol next hop resolution. Conversely, if a non-colored VPN service has a resolution-map applied to it, the resolution-map is ignored, and the VPN service uses the IP protocol next hop resolution.

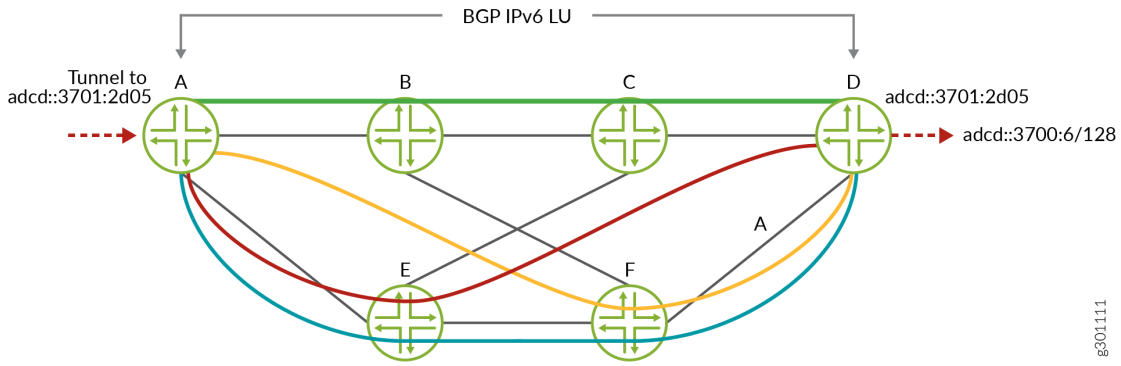
The fallback is a simple process from colored SRTE LSPs to LDP LSPs, by using a RIB group for LDP to install routes in inet{6}color.0 routing tables. A longest prefix match for a colored-IP protocol next hop ensures that if a colored SRTE LSP route does not exist, an LDP route with a matching IP address should be returned.

BGP Labeled Unicast Color-based Mapping over SR-TE

Starting in Junos OS Release 20.2R1, BGP Labeled Unicast (BGP-LU) can resolve IPv4 or IPv6 routes over segment routing–traffic engineering (SR-TE) for both IPv4 and IPv6 address families. BGP-LU supports mapping a BGP community color and defining a `resolution map` for SR-TE. A colored protocol next hop is constructed and it is resolved on a colored SR-TE tunnel in the `inetcolor.0` or `inet6color.0` table. BGP uses `inet.3` and `inet6.3` tables for non-color based mapping. This enables you to advertise BGP-LU IPv6 and IPv4 prefixes with an IPv6 next-hop address in IPv6-only networks where routers do not have any IPv4 addresses configured. With this feature, Currently we support BGP IPv6 LU over SR-TE with IS-IS underlay.

In *Figure 1*, the controller configures 4 colored tunnels in an IPv6 core network configured with SR-TE. Each colored tunnel takes a different path to the destination router D depending on the defined resolution map. The controller configures a colored SR-TE tunnel to abcd:3701:2d05 interface in router D . BGP imports policies to assign a color and resolution map to the received prefix abcd::3700:6/128. Based on the assigned community color, BGP-LU resolves the colored next hop for BGP IPv6 LU prefix according to the assigned resolution map policy.

Figure 54: BGP IPv6 LU over colored IPv6 SR-TE



BGP-LU supports the following scenarios:

- BGP IPv4 LU over colored BGP IPv4 SR-TE, with ISIS/OSPF IPv4 SR extensions.
- BGP IPv4 LU over static colored and non-colored IPv4 SR-TE, with ISIS/OSPF IPv4 SR extensions.
- BGP IPv6 LU over colored BGP IPv6 SR-TE, with ISIS IPv6 SR extensions.
- BGP IPv6 LU over static colored and non-colored IPv6 SR-TE, with ISIS IPv6 SR extensions.
- IPv6 Layer 3 VPN services with IPv6 local address and IPv6 neighbor address.
- IPv6 Layer 3 VPN services over BGP IPv6 SR-TE, with ISIS IPv6 SR extensions.
- IPv6 Layer 3 VPN services over static-colored and non-colored IPv6 SR-TE, with ISIS IPv6 SR extensions.

Supported and Unsupported Features for Color-Based Mapping of VPN Services

The following features and functionality are supported with color-based mapping of VPN services:

- BGP Layer 2 VPN (Kompella Layer 2 VPN)
- BGP EVPN
- Resolution-map with a single IP-color option.
- Colored IPv4 and IPv6 protocol next hop resolution.
- Routing information base (also known as routing table) group based fallback to LDP LSP in inetcolor.0 routing table.
- Colored SRTE LSP.
- Virtual platforms.
- 64-bit Junos OS.
- Logical systems.
- BGP labeled unicast.

The following features and functionality are not supported with color-based mapping of VPN services:

- Colored MPLS LSPs, such as RSVP, LDP, BGP-LU, static.
- Layer 2 circuit
- FEC-129 BGP auto-discovered and LDP-signaled Layer 2 VPN.

- VPLS
- MVPN
- IPv4 and IPv6 using resolution-map.

Tunnel Templates for PCE-Initiated Segment Routing LSPs

You can configure a tunnel template for PCE-initiated segment routing LSPs to pass down two additional parameters for these LSPs - Bidirectional forwarding detection (BFD) and LDP tunneling.

When a PCE-Initiated segment routing LSP is being created, the LSP is checked against policy statements (if any) and if there is a match, the policy applies the configured template for that LSP. The template configuration is inherited only if it is not provided by the LSP source (PCEP); for example, metric.

To configure a template:

1. Include the "source-routing-path-template" on page 2712 statement at the `[edit protocols source-packet-routing]` hierarchy level. You can configure the additional BFD and LDP tunneling parameters here.
2. Include the source-routing-path-template-map statement at the `[edit protocols source-packet-routing]` hierarchy level to list the policy statements against which the PCE-initiated LSP should be checked.
3. Define a policy to list the LSPs on which the template should be applied.

   The `from` statement can include either the LSP name or LSP regular expression using the `lsp` and `lsp-regex` match conditions. These options are mutually exclusive, so you can specify only one option at a given point in time.

   The `then` statement must include the `sr-te-template` option with an accept action. This applies the template to the PCE-initiated LSP.

Take the following into consideration when configuring a template for PCE-initiated LSPs:

- Template configuration is not applicable to staticalyy configured segment routing LSPs, or any other client's segment routing LSP.
- PCEP-provided configuration has precedence over template configuration.
- PCEP LSP does not inherit template segment-list configuration.

Example: Configuring Static Segment Routing Label Switched Path

IN THIS SECTION

- Requirements | 843
- Overview | 843
- Configuration | 844
- Verification | 858

This example shows how to configure static segment routing label switched paths (LSPs) in MPLS networks. This configuration helps to bring higher scalability to MPLS networks.

Requirements

This example uses the following hardware and software components:

- Seven MX Series 5G Universal Routing Platforms
- Junos OS Release 18.1 or later running on all the routers

Before you begin, be sure you configure the device interfaces.

Overview

IN THIS SECTION

- Topology | 844

Junos OS a set of explicit segment routing paths are configured on the ingress router of a non-colored static segment routing tunnel by configuring the `segment-list` statement at the `[edit protocols source-packet-routing]` hierarchy level. You can configure segment routing tunnel by configuring the `source-routing-path` statement at `[edit protocols source-packet-routing]` hierarchy level. The segment routing tunnel has a destination address and one or more primary paths and optionally secondary paths that refer to the segment list. Each segment list consists of a sequence of hops. For non-colored static segment routing tunnel, the first hop of the segment list specifies an immediate next hop IP address and the second to Nth hop specifies the segment identifies (SID) labels corresponding to the link or node which the path traverses. The route to the destination of the segment routing tunnel is installed in inet.3 table.

Topology

In this example, configure layer 3 VPN on the provider edge routers PE1 and PE5. Configure the MPLS protocol on all the routers. The segment routing tunnel is configured from router PE1 to router PE5 with a primary path configured on router PE1 and router PE5 . Router PE1 is also configured with secondary path for path protection. The transit routers PE2 to PE4 are configured with adjacency SID labels with label pop and an outgoing interface.

Configuration

IN THIS SECTION

- CLI Quick Configuration | **844**
- Configuring Device PE1 | **848**
- Configuring Device PE2 | **855**
- Results | **856**

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the `[edit]` hierarchy level, and then enter `commit` from configuration mode.

Configuring Device PE1

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the CLI User Guide.

To configure Device PE1:

1. Configure the interfaces.

```
[edit interfaces]
set ge-0/0/0 unit 0 family inet address 10.10.12.1/24
set ge-0/0/0 unit 0 family mpls maximum-labels 5
set ge-0/0/1 unit 0 family inet address 10.10.13.1/24
set ge-0/0/1 unit 0 family mpls maximum-labels 5
set ge-0/0/5 unit 0 family inet address 10.10.17.1/24
```

2. Configure autonomous system number and options to control packet forwarding routing options.

```
[edit routing-options]
set autonomous-system 65000
set forwarding-table export load-balance-policy
set forwarding-table chained-composite-next-hop ingress l3vpn
```

3. Configure the interfaces with the MPLS protocol and configure the MPLS label range.

```
[edit protocols mpls]
set interface ge-0/0/0.0
set interface ge-0/0/1.0
set label-range static-label-range 1000000 1000999
```

4. Configure the type of peer group, local address, protocol family for NLRIs in updates, and IP address of a neighbor for the peer group.

```
[edit protocols bgp]
set group pe type internal
set group pe local-address 192.168.147.211
set group pe family inet-vpn unicast
set group pe neighbor 192.168.146.181
```

5. Configure the protocol area interfaces.

```
[edit protocols ospf]
set area 0.0.0.0 interface ge-0/0/0.0
```

```
set area 0.0.0.0 interface lo0.0
set area 0.0.0.0 interface ge-0/0/1.0
```

6. Configure the IPv4 address and labels of primary and secondary paths for source routing-traffic engineering (TE) policies of protocol source packet routing (SPRING).

```
[edit protocols source-packet-routing segment-list]
set sl-15-primary hop-1 ip-address 10.10.13.3
set sl-15-primary hop-2 label 1000134
set sl-15-primary hop-3 label 1000145
set sl-15-backup hop-1 ip-address 10.10.12.2
set sl-15-backup hop-2 label 1000123
set sl-15-backup hop-3 label 1000134
set sl-15-backup hop-4 label 1000145
```

7. Configure destination IPv4 address, binding SID label, primary, and secondary source routing path for protocol SPRING.

```
[edit protocols source-packet-routing source-routing-path]
set lsp-15 to 192.168.146.181
set lsp-15 binding-sid 1000999
set lsp-15 primary sl-15-primary
set lsp-15 secondary sl-15-backup
```

8. Configure policy options.

```
[edit policy-options policy-statement]
set VPN-A-export term a from protocol ospf
set VPN-A-export term a from protocol direct
set VPN-A-export term a then community add VPN-A
set VPN-A-export term a then accept
set VPN-A-export term b then reject
set VPN-A-import term a from protocol bgp
set VPN-A-import term a from community VPN-A
set VPN-A-import term a then accept
set VPN-A-import term b then reject
set bgp-to-ospf from protocol bgp
set bgp-to-ospf from route-filter 10.10.0.0/16 orlonger
```

```
set bgp-to-ospf then accept
set load-balance-policy then load-balance per-packet
```

9. Configure BGP community information.

```
[edit policy-options]
set community VPN-A members target:65000:1
```

10. Configure routing instance VRF1 with instance type, interface, router distinguisher, VRF import, export and table label. Configure export policy and interface of area for protocol OSPF.

```
[edit routing-instances VRF1]
set instance-type vrf
set interface ge-0/0/5.0
set route-distinguisher 192.168.147.211:1
set vrf-import VPN-A-import
set vrf-export VPN-A-export
set vrf-table-label
set protocols ospf export bgp-to-ospf
set protocols ospf area 0.0.0.0 interface ge-0/0/5.0
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show policy-options**, **show protocols**, **show routing-options**, and **show routing-instances** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1# show interfaces
    ge-0/0/0 {
        unit 0 {
            family inet {
                address 55.1.12.1/24;
            }
            family mpls {
                maximum-labels 5;
            }
        }
    }
```

```

Configuring Device PE2

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the CLI User Guide.

1. Configure the interfaces.

```
[edit interfaces]
set ge-0/0/0 unit 0 family inet address 10.10.12.2/24
set ge-0/0/0 unit 0 family mpls
set ge-0/0/1 unit 0 family inet address 10.10.23.2/24
set ge-0/0/1 unit 0 family mpls
```

2. Configure the static LSP for protocol MPLS.

```
[edit protocols mpls static-label-switched-path]
set adj-23 segment 1000123
set adj-23 segment next-hop 10.10.23.3
set adj-23 segment pop
set adj-21 segment 1000221
set adj-21 segment next-hop 10.10.12.1
set adj-21 segment pop
```

3. Configure interfaces and static label range for protocol MPLS.

```
[edit protocols mpls]
set interface ge-0/0/0.0
set interface ge-0/0/1.0
set label-range static-label-range 1000000 1000999
```

4. Configure interfaces for protocol OSPF.

```
[edit protocols ospf area 0.0.0.0]
set interface ge-0/0/0.0
set interface ge-0/0/1.0
```

Results

From configuration mode on router PE2, confirm your configuration by entering the **show interfaces** and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE2# show interfaces
ge-0/0/0 {
    unit 0 {
        family inet {
            address 55.1.12.2/24;
        }
        family mpls;
    }
}
ge-0/0/1 {
```

```
    unit 0 {
        family inet {
            address 55.1.23.2/24;
        }
        family mpls;
    }
}
```

```
user@PE2# show protocols
mpls {
    static-label-switched-path adj-23 {
        segment {
            1000123;
            next-hop 55.1.23.3;
            pop;
        }
    }
    static-label-switched-path adj-21 {
        segment {
            1000221;
            next-hop 55.1.12.1;
            pop;
        }
    }
    interface ge-0/0/0.0;
    interface ge-0/0/1.0;
    label-range {
        static-label-range 1000000 1000999;
    }
}
ospf {
    area 0.0.0.0 {
        interface ge-0/0/0.0;
        interface ge-0/0/1.0;
    }
}
```

Verification

IN THIS SECTION

- Verifying Route Entry of Routing Table inet.3 of Router PE1 | 858
- Verifying Route Table Entries of Routing Table mpls.0 of Router PE1 | 859
- Verifying SPRING Traffic Engineered LSP of Router PE1 | 859
- Verifying SPRING Traffic Engineered LSPs on the Ingress Router of Router PE1 | 860
- Verifying the Routing Table Entries of Routing Table mpls.0 of Router PE2 | 861
- Verifying the Status of Static MPLS LSP Segments of Router PE2 | 862

Confirm that the configuration is working properly.

Verifying Route Entry of Routing Table inet.3 of Router PE1

Purpose

Verify the route entry of routing table inet.3 of router PE1.

Action

From operational mode, enter the `show route table inet.3` command.

```
user@PE1> show route table inet.3
inet.3: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192.168.146.181/32   *[SPRING-TE/8] 03:09:26, metric 1
                    > to 10.10.13.3 via ge-0/0/1.0, Push 1000145, Push 1000134(top)
                      to 10.10.12.2 via ge-0/0/0.0, Push 1000145, Push 1000134, Push 1000123(top)
```

Meaning

The output displays the ingress routes of segment routing tunnels.

Verifying Route Table Entries of Routing Table mpls.0 of Router PE1

Purpose

Verify the route entries of routing table mpls.0

Action

From operational mode, enter the `show route table mpls.0` command.

```
user@PE1> show route table mpls.0
mpls.0: 6 destinations, 6 routes (6 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

0                  *[MPLS/0] 03:25:52, metric 1
                      Receive
1                  *[MPLS/0] 03:25:52, metric 1
                      Receive
2                  *[MPLS/0] 03:25:52, metric 1
                      Receive
13                 *[MPLS/0] 03:25:52, metric 1
                      Receive
16                 *[VPN/0] 03:25:52
                    > via lsi.0 (VRF1), Pop
1000999            *[SPRING-TE/8] 03:04:03, metric 1
                    > to 10.10.13.3 via ge-0/0/1.0, Swap 1000145, Push 1000134(top)
                      to 10.10.12.2 via ge-0/0/0.0, Swap 1000145, Push 1000134, Push 1000123(top)
```

Meaning

The output displays the SID labels of segment routing tunnels.

Verifying SPRING Traffic Engineered LSP of Router PE1

Purpose

Verify SPRING traffic engineered LSPs on the ingress routers.

Action

From operational mode, enter the `show spring-traffic-engineering overview` command.

```
user@PE1> show spring-traffic-engineering overview
Overview of SPRING-TE:
  Route preference: 8
  Number of LSPs: 1 (Up: 1, Down: 0)
  External controllers:
            < Not configured >
```

Meaning

The output displays the overview of SPRING traffic engineered LSPs on the ingress router.

Verifying SPRING Traffic Engineered LSPs on the Ingress Router of Router PE1

Purpose

Verify SPRING traffic engineered LSPs on the ingress router.

Action

From operational mode, enter the `show spring-traffic-engineering lsp detail` command.

```
user@PE1# show spring-traffic-engineering lsp detail
Name: lsp-15
To: 192.168.146.181
State: Up
  Path: sl-15-primary
  Outgoing interface: ge-0/0/1.0
  BFD status: N/A (Up: 0, Down: 0)
  SR-ERO hop count: 3
    Hop 1 (Strict):
      NAI: IPv4 Adjacency ID, 0.0.0.0 -> 10.10.13.3
      SID type: None
    Hop 2 (Strict):
      NAI: None
      SID type: 20-bit label, Value: 1000134
```

```
    Hop 3 (Strict):
      NAI: None
      SID type: 20-bit label, Value: 1000145
  Path: sl-15-backup
  Outgoing interface: ge-0/0/0.0
  BFD status: N/A (Up: 0, Down: 0)
  SR-ERO hop count: 4
    Hop 1 (Strict):
      NAI: IPv4 Adjacency ID, 0.0.0.0 -> 10.10.12.2
      SID type: None
    Hop 2 (Strict):
      NAI: None
      SID type: 20-bit label, Value: 1000123
    Hop 3 (Strict):
      NAI: None
      SID type: 20-bit label, Value: 1000134
    Hop 4 (Strict):
      NAI: None
      SID type: 20-bit label, Value: 1000145

Total displayed LSPs: 1 (Up: 1, Down: 0)
```

Meaning

The output displays details of SPRING traffic engineered LSPs on the ingress router

Verifying the Routing Table Entries of Routing Table mpls.0 of Router PE2

Purpose

Verify the routing table entries of routing table mpls.0 of router PE2.

Action

From operational mode, enter the `show route table mpls.0` command.

```
user@PE2> show route table mpls.0
mpls.0: 8 destinations, 8 routes (8 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
```

```
0                  *[MPLS/0] 03:22:29, metric 1
                      Receive
1                  *[MPLS/0] 03:22:29, metric 1
                      Receive
2                  *[MPLS/0] 03:22:29, metric 1
                      Receive
13                 *[MPLS/0] 03:22:29, metric 1
                      Receive
1000123            *[MPLS/6] 03:22:29, metric 1
                       > to 10.10.23.3 via ge-0/0/1.0, Pop
1000123(S=0)       *[MPLS/6] 03:22:29, metric 1
                       > to 10.10.23.3 via ge-0/0/1.0, Pop
1000221            *[MPLS/6] 03:22:29, metric 1
                       > to 10.10.12.1 via ge-0/0/0.0, Pop
1000221(S=0)       *[MPLS/6] 03:22:29, metric 1
                       > to 10.10.12.1 via ge-0/0/0.0, Pop
```

Verifying the Status of Static MPLS LSP Segments of Router PE2

Purpose

Verify the status of MPLS LSP segments of router PE2.

Action

From operational mode, enter the `show mpls static-lsp` command.

```
user@PE2> show mpls static-lsp
Ingress LSPs:
Total 0, displayed 0, Up 0, Down 0

Transit LSPs:
Total 0, displayed 0, Up 0, Down 0

Bypass LSPs:
Total 0, displayed 0, Up 0, Down 0

Segment LSPs:
LSPname                             SID-label       State
adj-21                              1000221         Up
```

```
adj-23                              1000123         Up
Total 2, displayed 2, Up 2, Down 0
```

Meaning

The output displays the status of static MPLS LSP segments of router PE2.

Routing Engine-based S-BFD for Segment-Routing Traffic Engineering with First-Hop Label Resolution

- Verify the S-BFD Session of the Primary Path | **872**

You can run seamless Bidirectional Forwarding Detection (S-BFD) over non-colored and colored label-switched paths (LSPs) with first-hop label resolution, using S-BFD as a fast mechanism to detect path failures.

Understanding RE-based S-BFD for Segment-Routing Traffic Engineering with First-Hop Label Resolution

IN THIS SECTION

- S-BFD Static Segment-Routing Tunnels for First-Hop Labels | **864**
- Limitations | **865**

S-BFD Static Segment-Routing Tunnels for First-Hop Labels

Segment-routing architecture enables ingress nodes in a core network to steer traffic through explicit paths through the network. The segment-routing traffic engineering (TE) next hop is a list or lists of segment identifiers (SIDs). These segment lists represent paths in the network that you want incoming traffic to take. The incoming traffic may be labeled or IP traffic and the forwarding operation at the ingress node may be a label swap or a destination-based lookup to steer the traffic onto these segment-routing TE paths in the forwarding path.

You can run seamless BFD (S-BFD) over non-colored and colored static segment-routing LSPs with first-hop label resolution and use S-BFD as a fast mechanism to detect path failures and to trigger global convergence. S-BFD requires fewer state changes than BFD requires, thus speeding up the reporting of path failures.

Given a segment-routing tunnel with one or multiple primary LSPs and optionally a secondary LSP, you can enable S-BFD on any of those LSPs. If an S-BFD session goes down, the software updates the segment-routing tunnel's route by deleting the next hops of the failed LSPs. If the first-hop label of the LSP points to more than one immediate next hop, the kernel continues to send S-BFD packets if *at least* one next hop is available (underlying next-hop reachability failure detection must be faster than the duration of the S-BFD detection timer).

NOTE: This model is supported for auto-translate-derived LSPs.

LSP-level S-BFD

An S-BFD session is created for each unique label-stack+address-family combination. You can configure identical segment lists and enable S-BFD for all of them. The segment lists that have identical label-stack +address-family combinations share the same S-BFD session. The source address for the S-BFD session is set to the least configured loopback address (except the special addresses) under the main instance.

NOTE: Ensure that the chosen source address is routable.

The address family of an LSP is derived based on the address family of the "to" address in the segment-routing TE tunnel. The state of the LSP with S-BFD configured also depends on whether BFD is up—if S-BFD is configured for an LSP, the LSP route isn't calculated until S-BFD reports the path is alive.

S-BFD Parameters

The following S-BFD parameters are supported for segment-routing TE paths:

- Remote discriminator

- Minimum interval
- Multiplier
- No router alert option

In S-BFD, each responder may have multiple discriminators. The discriminators may be advertised by IGP to other routers, or they may be statically configured on these routers. On an initiator, a particular discriminator is chosen as the remote discriminator for an S-BFD session by static configuration, based on the decision or resolution made by you or by a central controller. When multiple LSPs are created with the same key label stack and S-BFD is enabled on each of them with different parameters, the aggressive value of each parameter is used in the shared S-BFD session. For the discriminator parameter, the lowest value is considered as most aggressive. Similarly for the router alert option, if one of the configurations no router alert is configured, the derived S-BFD parameter will have no router alert option.

Limitations

- Only global repair is supported.
- Even though S-BFD detects failures depending on the configured timer values, convergence time depends on the global repair time (*seconds*).

Configuring RE-based S-BFD for Segment-Routing Traffic Engineering with First-Hop Label Resolution

To enable LSP-level S-BFD for a segment list, you configure the `bfd-liveness-detection` configuration statement at the `[edit protocols source-packet-routing source-routing-path` *`lsp-path-name`* `primary` *`segment-list-name`*`]` hierarchy and the `[edit protocols source-packet-routing source-routing-path` *`lsp-path-name`* `secondary` *`segment-list-name`*`]` hierarchy.

The following steps give the basic configuration and then operation of S-BFD with first-hop label resolution:

- The steps immediately below describe the outlines of the basic *configuration*:

  1. On an ingress router, you configure one or more segment lists with first-hop labels for a static segment-routing tunnel to use as primary and secondary paths.
  2. On the ingress router, you configure the static segment-routing tunnel, with either multiple primary paths (for load balancing), or one primary path and one secondary path (for path protection). Each primary or secondary path (LSP) refers to one of the segment lists you configured already, creating routes using the next hops derived from the first-hop labels from contributing LSPs.

3. On the ingress router, you enable per-packet load-balancing so that routes resolving over ingress routes and the binding-SID route (which all have first-hop labels) install all active paths in the Packet Forwarding Engine. An S-BFD session under an LSP protects all routes that use that LSP.

4. On the egress router of the segment-routing tunnel, you configure S-BFD responder mode with a local discriminator D, creating a distributed S-BFD listener session for D on each FPC.

5. On the ingress router, you configure S-BFD for any LSP for which you want to see path-failure detection. You specify a remote-discriminator D to match the local S-BFD discriminator of the egress router. An S-BFD initiator session is created with the LSP label-stack+address-family combination as the key, if an initiator session doesn't already exist for the current LSP key. The S-BFD parameters in the case of a matching BFD session are reevaluated with the new shared LSPs taken into consideration. When the S-BFD parameters are derived, the aggressive value of each parameter is chosen.

The steps immediately below describe basic *operation* :

1. The S-BFD initiator session runs in a centralized mode on the Routing Engine. The software tracks S-BFD session up and down states.

2. When the S-BFD state moves to UP, the LSP is considered for the relevant routes.

3. On the ingress router, if the software detects an S-BFD session DOWN, a session-down notification is sent to the routing daemon (RPD), and RPD deletes the next hop of the failed LSPs from the segment-routing tunnel's route.

4. The total traffic loss in the procedure is bound to the S-BFD failure detection time and the global repair time. The S-BFD failure detection time is determined by the S-BFD minimum-interval and multiplier parameters. The global repair time depends on the segment-routing TE process time and the redownload of the routes to forwarding.

LSP label stacks are changed as follows:

1. The particular LSP is detached from the existing S-BFD session. If the existing S-BFD session has at least one LSP referring to it, the old BFD session is preserved, but the S-BFD parameters are re-evaluated so that the aggressive parameter values among the existing LSP sessions is chosen. Also, the name of the S-BFD session is updated to the least one if there is a change. If the old S-BFD session has no more LSPs attached to it, that S-BFD session is removed.

2. The software attempts to find an existing BFD session that matches the new-label-stack+address-family combination value; if such a match exists, the LSP refers to that existing S-BFD session. The S-BFD session is re-evaluated for any change in parameters or session name similarly to the re-evaluations in step 1.

3. If there is no matching BFD session in the system, a new BFD session is created, and the S-BFD parameters are derived from this LSP.

NOTE: An S-BFD session's minimum interval and multiplier determine the failure detection time for the session. The repair time additionally depends on the global repair time.

The following output shows configuration statements you would use for a colored LSP with primary LSPs:

```
[edit protocols]
source-packet-routing {
    source-routing-path lsp_name {
        to destination_address;
        color color_value;
        binding-sid binding-label;
        primary segment_list_1_name weight weight;
            ... {
            bfd-liveness-detection {
                sbfd {
                    remote-discriminator value;
                }
            }
        }
    }
}
```

At the responder side, you must configure the correct discriminator:

```
[edit protocols bfd]
sbfd {
    local-discriminator value;
}
```

By default, router alerts are configured for S-BFD packets. When the MPLS header is removed at the responder end, the packet is sent to the host for processing without a destination address lookup for the packet. If you enable the no-router-alert option on the ingress router, the router-alert option is removed from the IP options and hence from the egress side. You must configure the destination address explicitly in lo0; otherwise the packet is discarded, and S-BFD remains down.

```
[edit interfaces lo0 unit 0 family inet]
address 127.0.0.1/32;
```

You can use a new trace flag, `bfd`, to trace BFD activities:

```
user@host# set protocols source-packet-routing traceoptions flag bfd
```

Example

The following configuration is an example of a non-colored static segment-routing tunnel with LSP protection.

```
protocols {
    source-packet-routing {
        source-routing-path ncsrlsp5 {
            to 10.10.10.10;
            primary {
                ncsrpath12 {
                    weight 1;
                    bfd-liveness-detection {
                        sbfd {
                            remote-discriminator 100;
                        }
                        minimum-interval 100;
                    }
                }
                ncsrpath13 {
                    weight 2;
                    bfd-liveness-detection {
                        sbfd {
                            remote-discriminator 100;
                        }
                        minimum-interval 100;
                    }
                }
                ncsrpath14 {
                    weight 3;
                    bfd-liveness-detection {
                        sbfd {
                            remote-discriminator 100;
                        }
                        minimum-interval 100;
                    }
                }
```

```
                ncsrpath15 {
                    weight 4;
                    bfd-liveness-detection {
                        sbfd {
                            remote-discriminator 100;
                        }
                        minimum-interval 100;
                    }
                }
                segment-list ncsrpath12 {
                    hop1 label 50191;
                    hop2 label 801000;
                }
                segment-list ncsrpath13 {
                    hop1 label 50191;
                    hop2 label 801001;
                    hop3 label 801000;
                }
                segment-list ncsrpath14 {
                    hop1 label 801000;
                }
                segment-list ncsrpath15 {
                    hop1 label 801002;
                    hop2 label 801000;
                }
            }
        }
    }
}
```

Verify That LSPs Are Configured for Static Segment-Routing Tunnels and That S-BFD Session Status Is Visible

IN THIS SECTION

- Purpose | 870
- Action | 870

Purpose

Use the `show spring-traffic-engineering lsp detail` command to show LSPs for static segment-routing tunnels, with S-BFD session status.

Action

```
user@host> show spring-traffic-engineering lsp detail

Name: abc
To: 77.77.77.77
State: Up
  Path: sl1
  Outgoing interface: NA
  BFD status: Up BFD name: V4-sl1
  SR-ERO hop count: 3
    Hop 1 (Strict):
      NAI: None
      SID type: 20-bit label, Value: 801007
    Hop 2 (Strict):
      NAI: None
      SID type: 20-bit label, Value: 22222
    Hop 3 (Strict):
      NAI: None
      SID type: 20-bit label, Value: 3333
  Path: sl2
  Outgoing interface: NA
  BFD status: Up BFD name: V4-sl2
  SR-ERO hop count: 2
    Hop 1 (Strict):
      NAI: None
      SID type: 20-bit label, Value: 801006
    Hop 2 (Strict):
      NAI: None
      SID type: 20-bit label, Value: 121212
  Path: sl2
  Outgoing interface: NA
  BFD status: Up BFD name: V4-sl2
  SR-ERO hop count: 2
    Hop 1 (Strict):
      NAI: None
      SID type: 20-bit label, Value: 801006
```

```
    Hop 2 (Strict):
      NAI: None
      SID type: 20-bit label, Value: 121212

Total displayed LSPs: 1 (Up: 1, Down: 0)
```

Because many LSPs can share the same BFD session, when the first LSP with a unique label-stack +address-family combination comes up, the name of the S-BFD session uses address-family+lsp-name. If more LSPs later share the same session, the name of the session can change to address-family+least-lsp-name, without affecting the state of the S-BFD session. The name of the S-BFD session appears in output from the `show bfd session extensive` command as well. Output for each LSP shows the S-BFD status as well as the S-BFD name it is referring to as shown in the preceding example as `BFD status: Up BFD name: V4-sl2`. Because there might not be one S-BFD session per LSP, the LSP-level S-BFD counters are not displayed.

Verify the Segment-Routing Tunnel Route with a Primary Next Hop and a Secondary Next Hop

IN THIS SECTION

- Purpose | 871
- Action | 871

Purpose

On the Routing Engine of the ingress router, verify the segment-routing tunnel route with a primary next hop and a secondary next hop.

Action

```
user@host> show route table inet.3

inet.3: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

128.9.146.157/32   *[SPRING-TE/8] 00:43:16, metric 1
```

```
                    > to 55.1.12.2 via ge-0/0/0.0, Push 1000145, Push 1000134, Push 1000123(top)
                      to 55.1.12.2 via ge-0/0/1.0, Push 1000934, Push 1000923(top)
```

Verify the S-BFD Session of the Primary Path

IN THIS SECTION

- Purpose | 872
- Action | 872

Purpose

On the Routing Engine of the ingress router, verify the S-BFD session of the primary path.

Action

```
user@host> show bfd session extensive
                                                Detect   Transmit
Address                 State     Interface     Time     Interval  Multiplier
127.0.0.1               Up                      4.000     1.000        4
 Client SPRING-TE, TX interval 1.000, RX interval 1.000
 Session up time 00:40:53, previous down time 00:02:08
 Local diagnostic None, remote diagnostic None
 Remote state Up, version 1
 Session type: Multi hop BFD (Seamless)
 Min async interval 1.000, min slow interval 1.000
 Adaptive async TX interval 1.000, RX interval 1.000
 Local min TX interval 1.000, minimum RX interval 1.000, multiplier 4
 Remote min TX interval 1.000, min RX interval 0.001, multiplier 4
 Local discriminator 28, remote discriminator 32
 Echo mode disabled/inactive
 Remote is control-plane independent
 Path-Name V4-sl-1

1 sessions, 1 clients
Cumulative transmit rate 1.0 pps, cumulative receive rate 1.0 pps
```

NOTE: On the Routing Engine of the ingress router, verify the S-BFD session of the secondary path also similarly.

Configuring Static Adjacency Segment Identifier for Aggregate Ethernet Member Links Using Single-Hop Static LSP

In a network where aggregate Ethernet (AE) bundles are in use, an aggregate link could be bundle of any number of physical links. The traffic sent over these AE bundle interfaces are forwarded on any of the member links of an AE interface. The traffic can take any physical link based on the hash defined for load-balancing the traffic, which makes it difficult to isolate which links have gone bad or are dropping the traffic. One way to test the forwarding path available in the network is to add a single-hop static label switched path (LSP) with the next hop pointing to a specific member link of the AE interface.

The default label operation for the static LSPs must be pop and forward. When a packet hits these labeled routes, the packet is forwarded on to a specific member link. A unique label is used to identify the member link. These labels are referred to as adjacency segment identifiers (SID) and are statically provisioned.

You can control the flow of the packets in the network by constructing a label stack in controller, which includes the labels allocated by all transit static LSP. Operation, Administration, and Maintenance (OAM) packets are crafted and injected into the network with entire label-stack.

When a packet hits this label route the label is popped and traffic is forwarded on the member link specified in the configuration. A destination MAC is chosen while forwarding the packet, the destination Mac is the aggregate interface MAC address (selected based on nexthop address configured).

When the member link goes down and aggregate interface is up, then the route corresponding to that member link is deleted. When an aggregate interface goes down, then all the routes corresponding to member links of the aggregate interface are deleted. When the child physical interface is LACP detached but the child physical interface is up, the labeled route for the child link is deleted. In the case of LACP detach, if the member link is up and invalid forwarding state, then the OAM packets is dropped in the PFE when the child physical interface is detached.

Use the following example to configure single-hop static LSP for an AE member link.

1. Define a static label range.

```
user@host# set protocols mpls label-range static-label-range 1000000 1048575;
```

NOTE: We recommend configuring the default static label range of 1000000-1048575 for the static LSP. If you wish to configure a label range other than the default static label range, configure multiple ranges.

2. Create a static LSP for the AE member link from the segment routing local block (SRLB) pool of the static label range.

```
user@host# set protocols mpls static-label-switched-path statc-lsp transit 100001 pop next-hop 10.1.1.1
member-interface ge-0/0/0
```

In this configuration, a transit labelled router is installed in mpls.0, pops the label, and forwards the packet down the next hop. The next hop address is mandatory for broadcast interfaces (such as ge-, xe-, ae-) and the if-name is used for P2P interfaces (such as so-). The address is required for broadcast interfaces because the next hop IP address is used to pick the destination MAC address. The source MAC address for the packet is the AE's MAC address.

The sample outputs display the member link name in the next hop output:

show mpls static-lsp extensive

```
user@host> show mpls static-lsp extensive
Ingress LSPs:
Total 0, displayed 0, Up 0, Down 0

Transit LSPs:
LSPname: static-lsp1, Incoming-label: 1000001
  Description: verify-static-lsp-behavior
  State: Up, Sub State: Traffic via primary but unprotected
  Nexthop: 10.2.1.1 Via ae0.0 -> ge-0/0/0
  LabelOperation: Pop
  Created: Thu May 25 15:31:26 2017
  Bandwidth: 0 bps
  Statistics: Packets 0, Bytes 0
```

show route label label-name extensive

```
user@host> show route label 1000001 extensive

mpls.0: 14 destinations, 14 routes (14 active, 0 holddown, 0 hidden)
```

```
1000001 (1 entry, 1 announced)
TSI:

Delay-based Metrics for Traffic Engineered Paths Overview

Leveraging dynamic delay-based metrics is becoming a desirable attribute in modern networks. Delay-based metrics is essential for a Path Computation Element (PCE) to compute traffic engineered paths. You can use delay-based metrics to steer packets on the least latency paths, or the least delay path. To do this, you need to measure the delay on every link and advertise it using a suitable routing protocol (IGP or BGP-LS), so that the ingress has the per link delay properties in its TED.

To understand how to advertise the delay on each link, or turn on link measurements, see How to Enable Link Delay Measurement and Advertising in ISIS.

The following sequence of events happen when you measure, advertise, and compute the detection of changes in the network and calculate traffic engineered path with shortest latency:

- Detect changes in the network by measuring the latency, with synthetic probes, router-to-router.
- Flood the results to ingress nodes through IGP extended TE-metric extensions.
- Advertise the results to centralized controllers with corresponding BGP-LS extensions.
- Compute shortest cumulative latency metric paths (Flex-algo).
- Compute traffic-engineered explicit paths (source to destination) with shortest cumulative latency or delay metrics (SR-TE).

Benefits of Delay-based Metrics for Path Computation

- Deploy value-added services based on the lowest latency throughout the network.
- Measure per path latency (minimum, maximum, average) using delay-based metrics.
- Steer delay sensitive services (such as VPN or 5G services) on ultra-low latency SR optimized paths.

DCSPF-based Computation with Delay Metrics for SR Path Overview

Using the distributed Constrained Shortest Path First (CSPF) for segment routing LSP feature, you can compute a segment routing LSP locally on the ingress device according to the constraints you have configured. With this feature, the LSPs are optimized based on the configured constraints and metric type (traffic-engineering or IGP). The LSPs are computed to utilize the available ECMP paths to the destination with segment routing label stack compression enabled or disabled.

You can configure distributed CSFP to run on multiple headends and do path computation independently on each headend. You can apply compute profile on the source path (source packet routing path). If you have configured compute profile optimized for delay average, you can also additionally apply a constraint called the `delay-variation-threshold`. When you configure a value for `delay-variation-threshold`, any link exceeding the threshold value would be excluded from path computation.

To configure delay metrics for DCSPF-based computation for SR path, you need to enable the `delay` configuration statement at the [`edit protocols source-packet-routing compute-profile` *`profile-name`* `metric-type delay`] hierarchy level. You can configure the delay metrics such as minimum, maximum, average, and delay variation threshold for path calculation.

- `minimum`—Minimum delay metric value from TED for cumulative lowest latency path calculation.
- `average`—Average delay metric value from TED for cumulative lowest latency path calculation.
- `maximum`—Maximum delay metric value from TED for cumulative lowest latency path calculation.
- `delay-variation-threshold`—Link delay variation threshold (1..16777215). Any link exceeding the delay variation threshold would be excluded from path calculation. The delay variation threshold is independent of whether you are doing optimization for minimum, maximum, or average. The `delay-variation-threshold` configuration statement appears at these hierarchy levels:
  - [`edit protocols source-packet-routing compute-profile` *`profile-name`* `metric-type delay`]
  - [`edit protocols source-packet-routing compute-profile` *`profile-name`* `metric-type delay minimum`]
  - [`edit protocols source-packet-routing compute-profile` *`profile-name`* `metric-type delay maximum`]
  - [`edit protocols source-packet-routing compute-profile` *`profile-name`* `metric-type delay average`]

You can configure delay metrics at the following CLI hierarchy:

```
[edit]
protocols {
    source-packet-routing {
        compute-profile <name> {
            metric-type delay {
                  minimum;
                  maximum;
                  average;
                  delay-variation-threshold <value>;
                 }
            }
      }
}
```

Delay Metrics for Interdomain and Intradomain Use Case Overview

With interdomain (within single-domain) case, the link delay is taken into consideration when doing path computation. Delay metrics for segment routing path computation is supported on both compressed SIDs and uncompressed SIDs. If you have uncompressed SIDs, then adjacency segments for segment lists is used to produce multiple segment lists if there are equal costs. You can configure uncompressed SIDs using the `no-label-stack-compression` configuration statement at the [`edit protocols source-packet-routing compute-profile` *`profile-name`*] hierarchy level. This provides a fully expanded path using adjacency SIDs. See compute-profile for more information.

The following is a sample configuration for delay metrics:

```
[edit protocols source-packet-routing]
user@host# show
compute-profile profile1 {
    no-label-stack-compression;
    metric-type {
        delay {
            maximum;
            delay-variation-threshold 300;
        }
    }
}
```

With intradomain (multi-domain) case, where there are multiple autonomous systems, you can use express segments to configure link delays for path computation. Express segments are links that connect border nodes or ASBRs. See Express Segment LSP Configuration to learn about express segments. You can configure the delay or inherit the delay of the underlying LSP in the express segment. You can configure `delay` at the [`edit protocols express-segments segment-template` *`template-name`* `metric`] hierarchy level and set the values for minimum, maximum, and average delays.

You can configure delay metrics in an express segment at the following CLI hierarchy:

```
[edit]
protocols {
    express-segments {
        segment-template <name> {
           metric delay [ min <value> | avg <value> | max <value>
            }
```

```
        }
  }
```

For intradomain path computation, you can assign delay metrics on BGP EPE links. You can configure a value for `delay-metric` at the [`edit protocols bgp group` *`group-name`* `neighbor` *`ip address`* `egress-te-adj-segment` *`segment-name`* `egress-te-link attribute`] hierarchy level as shown below:

```
[edit]
protocols {
    bgp {
        group <name> {
            type external;
        }
        neighbor <ip_addr> {
            egress-te-adj-segment <name> {
                egress-te-link-attribute {
                  delay-metric <value>
                  }
                }
              }
          }
      }
```

Delay Metrics in Optical Networks Use Case

The following topology depicts an example of an optical use case. Optical protection and restoration solutions result in the underlying physical attributes, mainly path length, changing due to link failures and subsequent DWDM network optimization. In figure A, the connection between A and C is through the optical nodes O1 and O3 with a latency of 10 microseconds. In figure B, you can see a link failure between optical nodes O1 and O3 and that the actual optical connection is rerouted through the optical node O2. This increases the latency of 15 microseconds. The metric for the link that connects A and B changes dynamically between time=0 and time=1.

When a change of delay is detected, the headend router reroutes the path over the next available least latency path. The change is not only in link delay but the path between A and C may go over a different set of links. For example, the path goes over A, B, and C in this topology.

Release History Table

Release	Description
20.2R1	Starting in Junos OS Release 20.2R1, BGP Labeled Unicast (BGP-LU) can resolve IPv4 or IPv6 routes over segment routing–traffic engineering (SR-TE) for both IPv4 and IPv6 address families.
19.4R1	You can configure a tunnel template for PCE-initiated segment routing LSPs to pass down two additional parameters for these LSPs - Bidirectional forwarding detection (BFD) and LDP tunneling.
19.1R1	Starting in Junos OS Release 19.1R1, a commit check feature is introduced to ensure that all the segment lists contributing to the colored routes have the minimum label present for all hops.
19.1R1	Starting in Junos OS Release 19.1R1, this requirement does not apply, as the first hop of the non-colored static LSPs now provides support for SID labels, in addition to IP addresses. With the first hop label support, MPLS fast reroute (FRR) and weighted equal-cost multipath is enabled for resolving the static non-colored segment routing LSPs, similar to colored static LSPs.
18.2R1	Starting in Junos OS Release 18.2R1, statically configured non-colored segment routing LSPs on the ingress device are reported to the Path Computation Element (PCE) through a Path Computation Element Protocol (PCEP) session.

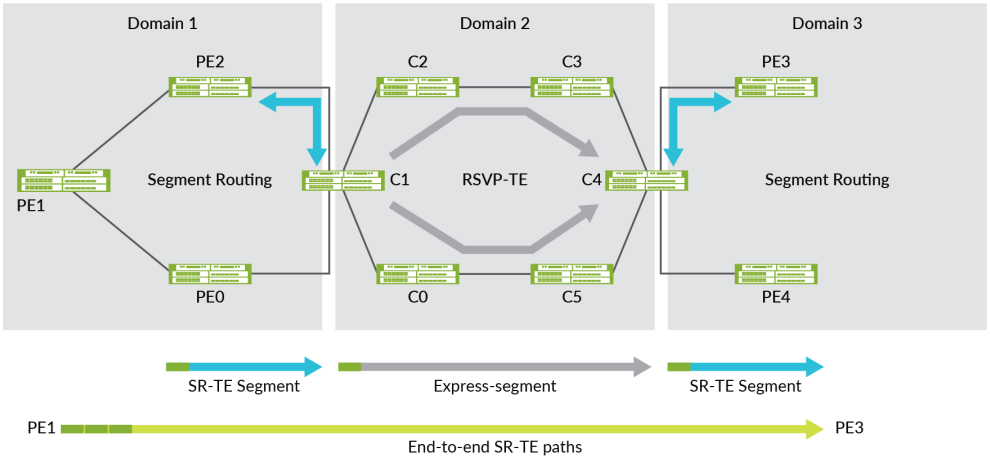
Learn about the benefits, use cases, and overview of how express segments work to establish an end-to-end segment routing path in a multi-domain network.

Benefits of Express Segments

- Express segments are a segment routing (SR) abstraction of an underlay path. Express segments facilitate the establishment of end-to-end SR paths using any underlay technology. The underlay technology currently supported are RSVP-TE and SR-TE. Express segment through RSVP-TE underlay is explained below.

In Figure 56 on page 882, Domain 2 leverages its RSVP-TE underlay LSPs for traffic engineering management and presents those underlay RSVP-TE LSPs as express segments to the adjacent domains (Domain 1 and Domain 3), therefore enabling end-to-end SR-TE path establishment.

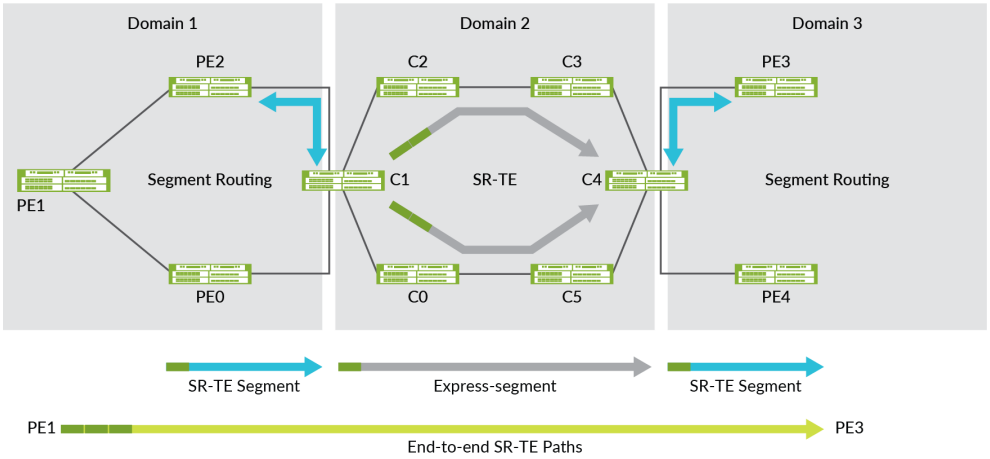
Figure 56: Multi-Domain End-to-End SR-TE with RSVP Underlay



- Express segments implicitly reduce the size of the SR segment list by compressing them (segment lists) to, at a minimum, one segment ID (SID)/label per domain. This becomes useful when end-to-end traffic engineered constraints would otherwise result in a segment list that exceeds the ingress router's label imposition capabilities. This also becomes beneficial when one or more domains are already implementing SR-TE for traffic engineered path management.

In Figure 57 on page 883, you can see Domain 2 is using SR-TE and how the use of express segments enables PE1 device to use three labels to traverse the multi-domain network instead of five.

Figure 57: Multi-Domain End-to-End SR-TE with Reduced Label Stack

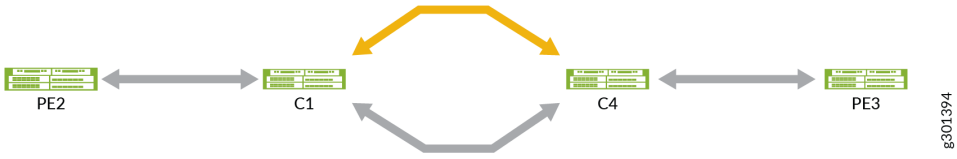


- Express segments allow operators to present an abstraction of the network to adjacent domains and/or higher layer systems.

  To establish a traffic engineered path through a series of interconnected domains or multi-domain network, it is necessary to have a certain amount of traffic engineering information about each network domain. Topology abstraction allows the use of policies to connect across domains. Topology abstraction does not necessarily offer all possible connectivity options but presents a view of potential connectivity according to the policies that determine how the domain resources need to be used. The domain could be constructed as a mesh of border node to border node express segments.

  Using Figure 57 on page 883, PE2's view of an end-to-end traffic engineered system is represented in its local traffic engineering database as shown in Figure 58 on page 883.

Figure 58: Abstracted Traffic Engineered Domain



Use Cases

This section describes a few use cases for establishing end-to-end SR-TE connectivity. *RFC7926* introduces a comprehensive set of terminology and use cases along with an architecture to facilitate traffic engineering link and node information exchange between domains. As Service providers' networks are expanding because of continued growth, multi-domain networks are becoming more prevalent. In these multi-domain networks, it is required to establish an end-to-end traffic engineered path between one or more domains from a source to a destination

Intra and Inter-domain SR-TE Connectivity Using Express Segments

Express segments have the capability to abstract traffic engineering information when the routing information exchange happens between domains. The traffic engineering information used as a criterion for path selection is the data relating to traffic engineered nodes and links. Traffic engineering information may be link metrics such as IGP, traffic engineering, latency, or administrative link attributes such as affinities. Express segments are best described as virtual traffic engineered Links that facilitate the abstraction of underlay LSPs.

Enhanced On-demand Next-hop

Enhanced On-demand Next-hop (EODN) (also known as BGP-triggered SR policies) facilitates the dynamic provisioning of end-to-end SR-TE policies, with constraints, upon the arrival of services routes. In large networks having hundreds of PE devices creating and maintaining traffic engineering policies on any ingress PE for every egress PE is challenging. Considering colors specific services (per VPN or per group of prefixes) makes things even more complicated and harder to maintain and troubleshoot. BGP triggered SR-TE addresses the task by automatically creating dynamic SR tunnels based on pre-configured templates. There is no need to provision ingress PEs with configuration for every egress PE.

How does Express Segment Work?

Express segments can be used to establish end-to-end traffic engineered paths between interconnected traffic engineered networks. Express segments (also known as virtual traffic engineering links) are generated dynamically through policies matching the underlay LSPs. Express segments and the corresponding abstracted topology (required by *RFC7926*) is generated with policies.

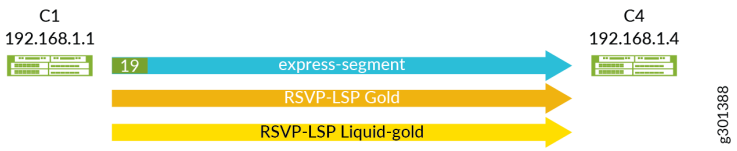
To apply a policy, include the `policy` *`policy-name`* configuration statement at the [`edit protocols express-segment traffic-engineering`] hierarchy level.

NOTE: The *policy-name* is optional. If a policy name is not defined, then the policy implicitly imports all the express segments into the local traffic engineering database. An express segment template automatically creates a one-on-one mapping of express links.

To configure express segment, include the `express-segment` configuration statement under the [`edit protocols`] hierarchy level.

Let us refer to Figure 56 on page 882 and use the pair of RSVP-TE LSPs shown between C1 and C4 border nodes and how express segments are generated representing the underlay LSPs. In Figure 59 on page 885, a policy is created to represent two RSVP-TE (gold and liquid-gold) LSPs as a single express segment.

Figure 59: A Pair of RSVP-TE LSPs Represented as an Express Segment



The following is a sample policy where the policy name is matched through a regular expression and the end-point of the RSVP-TE LSPs:

```
protocols {
    express-segment-set gold-exp-seg {
        policy gold;
        }
    }
policy-options {
    policy-statement gold {
        from {
            route-filter 10/8 {
                install-next-hop lsp-regex *gold;
            }
        }
        then accept;
    }
}
```

In the following sample output, you can see the newly created express segment (**Gold-Exp-Set-192.168.1.4**) along with the traffic engineering attributes are inherited from the underlay RSVP-TE tunnels:

```
user@C1#show express-segments name gold-exp-seg-192.168.1.4 detail
Gold-Exp-Set-192.168.1.4
  To: 192.168.1.4, Set: gold-exp-set
  Status: Up (since 4d 11:09:05)
  Label: 19 (Route installed in mpls.0, TED entry added)
  LinkAttributes:
    ID: 2147483655
    TE-Metric: 10*, IGP-Metric: 30
    AdminGroups: gold, liquid-gold
    SRLGs: fiber-span-101
    BW: 1000Mbps
  UnderlayPaths:
    RSVP-LSP C1_to_C4_gold
      TE-Metric: 30, IGP-Metric: 30
      AdminGroups: gold
      SRLGs: fiber-span-101
      BW: 500Mbps
    RSVP-LSP C1_to_C4_liquid_gold
      TE-Metric: 30, IGP-Metric: 30
      AdminGroups: liquid-gold
      SRLGs: None
      BW: 500Mbps
```

You can observe the following in the output:

- Automatic naming of the express segment (`Gold-Exp-Set-192.168.1.4`).
- Traffic engineering attributes (bandwidth, metrics, admin groups, SRLGs) of the underlay RSVP-LSPs are inherited by the express segment.
- The express segment is an unnumbered traffic engineered link and has been added to the traffic engineering database.
- Label 19 has been assigned and installed in the `mpls.0` forwarding table as the adjacency SID for the SR virtual traffic engineering link.

The following is an example where SR-TE LSP destination is matched:

```
protocols {
      express-segments {
        segment-set set1sr {
            membership-policy expresspolsr1;
        }
        traffic-engineering;
    }
policy-options {
    policy-statement expresspolsr1 {
        from {
            protocol spring-te;
            route-filter 3.3.3.3/32 exact;
        }
        then accept;
```

In the following sample output, you can see the newly created express segment (**set1sr-3.3.3.3**) from the uncolored SR-TE underlay tunnels:

```
user@C1show express-segments detail

Name: set1sr-3.3.3.3
  To: 3.3.3.3, Type: Dynamic (Set: set1sr)
  Label: 16 (Route installed in mpls.0, TED entry added)
  Status: Up (ElapsedTime: 5d 20:37:08)
  LinkAttributes:
    LocalID: 2147483649
    TE-Metric: 20, IGP-Metric: 20
    BW: 0bps
  UnderlayPaths: 1
    SRTE LSP: lsp1to3_sr
      TE-Metric: 0, IGP-Metric: 0
      BW: 0bps
```

How are Express Segments Advertised?

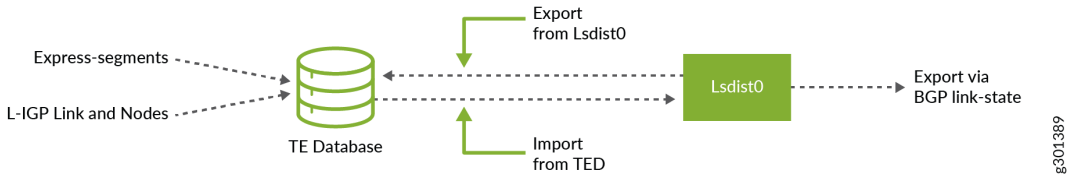
Express segments are advertised across domain boundaries or to higher-level controllers and Path Computing Elements (PCEs) using the BGP link state. When exchanging information through the BGP link state, the extensions for the BGP link state are used to advertise express segments as traffic engineered links. The express segment traffic engineered links and other normal traffic engineering links

appear in the traffic engineering link-state database of any LSR in the network and are used for computing end-to-end traffic engineered paths. Express segment traffic engineering database entries are imported and exported from the **lsdist.0** table (see, *Link-State Distribution Using BGP Overview*) for advertisement through the BGP link state with the following traffic-engineering database import and export configuration:

```
protocols {
    mpls {
        traffic-engineering {
            database {
                import {
                    l3-unicast-topology {
                        bgp-link-state;
                        }
                    policy es_2_bgpls;
                }
                export {
                    policy bgpls_2_ted;
                }
            }
        }
    }
    bgp {
        group te-peers {
            family traffic-engineering {
                unicast;
                }
            export abstract-topo;
        }
    }
}
```

Figure 60 on page 889 provides a visual representation of how traffic engineering links and nodes are mirrored between the local traffic engineering database and the **lsdist.0** RIB that BGP-LS uses for advertisement. As illustrated, there are several policy attachment points.

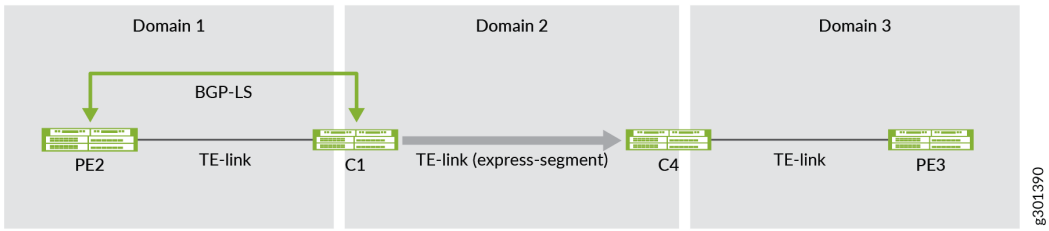
Figure 60: Advertising Express Segments



How are Express Segments Used by a Path Computing Element?

The BGP link state export policy is an effective place to create an abstract or customized topology that is advertised to a traffic engineered peer. For example, you may want to advertise only the express segment and Domain 3's TE links and nodes to PE2 such that the traffic engineered topology is abstracted as shown in Figure 61 on page 889. The abstracted view is then used by PE2 for end-to-end path computation.

Figure 61: Abstracting Traffic Engineered Domain 2 with Express Segment



The following is a sample configuration of a BGP link state export policy on C1:

```
policy-options {
    policy-statement abstract-topo {
        from {
            traffic-engineering {
                protocol express-segment;
                ipv4-prefix {
                    as 3;
```

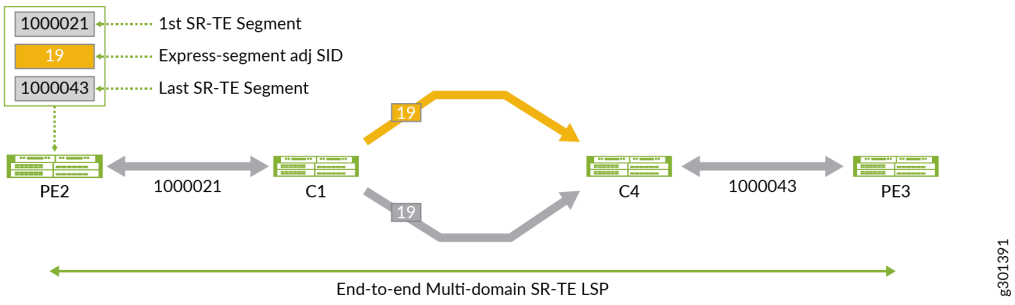
```
                }
            }
        }
        then accept;
    }
}
```

The following is a sample SR policy configuration on PE2 router to establish an end-to-end multi-domain path from PE2 to PE3:

```
protocols {
    source-packet-routing {
        source-routing-path pe2-to-pe3 {
            to 192.168.70.1;
            color 10;
            primary {
                sl1 {
                    compute {
                        profile_any-path;
                    }
                }
            }
        }
    }
}
```

The resulting end-to-end path is represented in Figure 62 on page 890. You can see the express segment's adjacency SID (label 19) is used in the SR segment-list resulting in traffic being load-balanced over both the gold and liquid-gold RSVP-TE LSPs within Domain 2.

Figure 62: Multi-domain End-to-End SR-TE LSP



Example: Inter-domain SR-TE Connectivity Using Express Segments Through RSVP-TE Underlay

IN THIS SECTION

- Requirements | 891
- Overview | 891
- Configuration | 896
- Verification | 987

Use this example to learn how to establish an end-to-end inter-domain SR-TE connectivity using express segments.

Requirements

This example uses the following hardware and software components:

- MX Series routers as provider edge, border nodes, and intermediate routers.
- Junos OS Release 20.4R1 or later running on all devices.

Overview

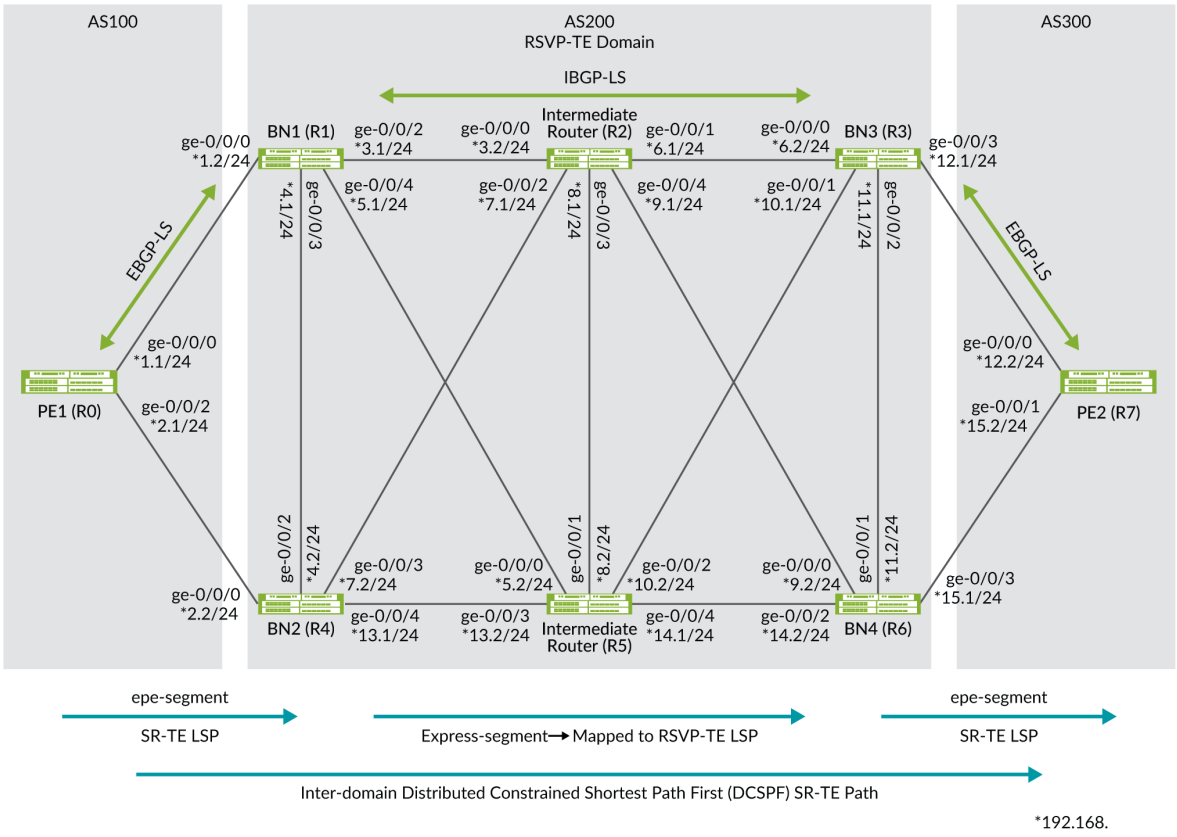
IN THIS SECTION

- Topology | 892

The following topology (Figure 63 on page 892) shows two SR-TE domains (AS100 and AS300) running EBGP-LS inter-connected through an RSVP-TE (AS200) domain:

Topology

Figure 63: Inter-domain SR-TE Connectivity Using Express Segments



In this topology, an end-to-end SR-TE path between PE1 router to PE2 router is established. Egress peer engineering (EPE) segments are defined on PE1 and PE2 routers to steer traffic towards their directly connected border nodes BN1/BN2 and BN3/BN4, respectively. EPE segments defined on the border nodes are advertised internally through the BGP link state. These two SR-TE domains are interconnected through the domain (AS200) that is leveraging RSVP-TE LSPs for internal path establishment.

The border nodes of the AS200 domain facilitate the abstraction of SR-TE information between domains. Express segments are created on border nodes (BN1, BN2, BN3, and BN4). Express segments are created in a one-on-one relationship with the underlying RSVP-TE LSPs and all express segments are inserted into the border node's local TE database for subsequent BGP link-state advertisement. The AS200 domain leverages RSVP-TE LSP underlays for TE management and presents those underlay RSVP-TE LSPs as express segments to the AS100 and the AS300 domains, enabling the domains to have end-to-end SR-TE LSP connectivity.

The following table describes the domains, routers, and connections in the topology:

Table 21: Describes the domains, routers, and connections in the Topology

Domain	Devices	Router ID/Lo) Address	Connection Details
AS100 (EBGP-LS/ SR-TE LSP)	R0 (PE1 router)	100.100.100.100 100.100.100.101	Connected to R1 (BN1 router) through interface ge-0/0/0, assigned IP address 192.168.1.1/24. Connected to R4 (BN2 router) through interface ge-0/0/2, assigned IP address 192.168.2.1/24.
AS200 (RSVP-TE LSP)	R1 (BN1 router)	1.1.1.1	Connected to R0 (PE1 router) through interface ge-0/0/0, assigned IP address 192.168.1.2/24. Connected to R4 (BN2 router) through interface ge-0/0/3, assigned IP address 192.168.4.1/24. Connected to R2 (Intermediate router) through interface ge-0/0/2, assigned IP address 192.168.3.1/24. Connected to R5 (Intermediate router) through interface ge-0/0/4, assigned IP address 192.168.5.1/24.
	R4(BN2 router)	4.4.4.4	Connected to R0 (PE1 router) through interface ge-0/0/0, assigned IP address 192.168.2.2/24. Connected to R1 (BN1 router) through interface ge-0/0/2, assigned IP address 192.168.4.2/24. Connected to R2 (Intermediate router) through interface ge-0/0/3, assigned IP address 192.168.7.1/24. Connected to R5 (Intermediate router) through interface ge-0/0/4, assigned IP address 192.168.13.1/24.

Table 21: Describes the domains, routers, and connections in the Topology *(Continued)*

Domain	Devices	Router ID/Lo) Address	Connection Details
	R2(Intermediate router)	2.2.2.2	Connected to R1 (BN1 router) through interface ge-0/0/0, assigned IP address 192.168.3.2/24. Connected to R4 (BN2 router) through interface ge-0/0/2, assigned IP address 192.168.7.1/24. Connected to R5 (Intermediate router) through interface ge-0/0/3, assigned IP address 192.168.8.1/24. Connected to R3 (BN3 router) through interface ge-0/0/1, assigned IP address 192.168.6.1/24. Connected to R6 (BN4 router) through interface ge-0/0/4, assigned IP address 192.168.9.1/24.
	R5 (Intermediate router)	5.5.5.5	Connected to R1 (BN1 router) through interface ge-0/0/0, assigned IP address 192.168.5.2/24. Connected to R4 (BN2 router) through interface ge-0/0/3, assigned IP address 192.168.13.2/24. Connected to R2 (Intermediate router) through interface ge-0/0/1, assigned IP address 192.168.8.2/24. Connected to R3 (BN3 router) through interface ge-0/0/2, assigned IP address 192.168.10.2/24. Connected to R6 (BN4 router) through interface ge-0/0/4, assigned IP address 192.168.14.1/24.

Table 21: Describes the domains, routers, and connections in the Topology *(Continued)*

Domain	Devices	Router ID/Lo) Address	Connection Details
	R3 (BN3 router)	3.3.3.3	Connected to R7 (PE2 router) through interface ge-0/0/3, assigned IP address 192.168.12.1/24. Connected to R6 (BN4 router) through interface ge-0/0/2, assigned IP address 192.168.11.1/24. Connected to R2 (Intermediate router) through interface ge-0/0/0, assigned IP address 192.168.6.2/24. Connected to R5 (Intermediate router) through interface ge-0/0/1, assigned IP address 192.168.10.1/24.
	R6 (BN4 router)	6.6.6.6	Connected to R7 (PE2 router) through interface ge-0/0/3, assigned IP address 192.168.15.1/24. Connected to R3 (BN3 router) through interface ge-0/0/1, assigned IP address 192.168.11.2/24. Connected to R2 (Intermediate router) through interface ge-0/0/0, assigned IP address 192.168.9.2/24. Connected to R5 (Intermediate router) through interface ge-0/0/2, assigned IP address 192.168.14.2/24.
AS300 (EBGP-LS/SR-TE LSP)	R7 (PE2 router)	7.7.7.7	Connected to R3 (BN3 router) through interface ge-0/0/0, assigned IP address 192.168.12.2/24. Connected to R6 (BN4 router) through interface ge-0/0/1, assigned IP address 192.168.15.2/24.

Configuration

IN THIS SECTION

- CLI Quick Configuration | 896
- Configure R0 (PE1 router) | 913
- Configure R1 (BN1 router) | 922
- Configure R4 (BN2 router) | 932
- Configure R2 (Intermediate router) | 942
- Configure R5 (Intermediate router) | 951
- Configure R3 (BN3 router) | 958
- Configure R6 (BN4 router) | 969
- Configure R7 (PE2 router) | 979

To inter-connect a multi-domain network and establish an end-to-end SR path using express segments, perform these tasks:

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the `[edit]` hierarchy level, and then enter `commit` from configuration mode.

```

Configure R0 (PE1 router)

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the CLI User Guide.

To configure device R0:

1. Configure the network services mode as Enhanced IP. Enhanced IP sets the router's network services to enhanced Internet Protocol and uses enhanced mode capabilities.

   ```
   [edit]
   user@R0#set chassis network-services enhanced-ip
   ```

   After you configure the `enhanced-ip` statement and commit the configuration, the following warning message appears prompting you to reboot the router:

   ```
   'chassis'
   WARNING: Chassis configuration for network services has been changed. A system reboot is
   mandatory. Please reboot the system NOW. Continuing without a reboot might result in
   unexpected system behavior.
   commit complete
   ```

   The reboot brings up the FPCs on the router.

2. Configure the interfaces to enable IP, MPLS, and ISO transport.

   ```
   [edit]
   user@R0#set interfaces ge-0/0/0 description To_R1_1
   user@R0#set interfaces ge-0/0/0 unit 0 family inet address 192.168.1.1/24
   user@R0#set interfaces ge-0/0/0 unit 0 family iso
   user@R0#set interfaces ge-0/0/0 unit 0 family mpls maximum-labels 8
   user@R0#set interfaces ge-0/0/2 description To_R4_1
   user@R0#set interfaces ge-0/0/2 unit 0 family inet address 192.168.2.1/24
   ```

```
user@R0#set interfaces ge-0/0/2 unit 0 family iso
user@R0#set interfaces ge-0/0/2 unit 0 family mpls maximum-labels 8
```

3. Configure the loopback interface to enable tunnel endpoints and service endpoints.

```
[edit]
user@R0#set interfaces lo0 unit 0 family inet address 100.100.100.100/32
user@R0#set interfaces lo0 unit 0 family inet address 100.100.100.101/32
user@R0#set interfaces lo0 unit 0 family iso address 49.0001.000a.0a0a.0a00
```

4. Configure routing options to identify the router in the domain.

```
[edit]
user@R0#set routing-options router-id 100.100.100.100
user@R0#set routing-options autonomous-system 100
user@R0#set routing-options static route 7.7.7.71/32 next-hop 7.7.7.7
user@R0#set routing-options static route 7.7.7.71/32 resolve
```

5. Define import and export policies. For example, configure policies that export EPE TE links from the local TE database to **lsdist.0** and policies to import from **lsdist.0** into the local TE database. You can configure policies to advertise the BGP routes to a peer.

```
[edit]
user@R0#set policy-options policy-statement nlri2bgp_epe term 1 from family traffic-
engineering
user@R0#set policy-options policy-statement nlri2bgp_epe term 1 from protocol bgp-ls-epe
user@R0#set policy-options policy-statement nlri2bgp_epe term 1 then next-hop self
user@R0#set policy-options policy-statement nlri2bgp_epe term 1 then accept
user@R0#set policy-options policy-statement nlri2ted_bgp term 1 from protocol bgp
user@R0#set policy-options policy-statement nlri2ted_bgp term 1 then accept
user@R0#set policy-options policy-statement pplb then load-balance per-packet
user@R0#set policy-options policy-statement ted2nlri term 1 from protocol bgp-ls-epe
user@R0#set policy-options policy-statement ted2nlri term 1 then accept
```

6. Configure BGP to enable BGP-LS route advertisement to the connected peers and define the EPE links. Since express segment is an internal TE link, this configuration creates an external TE link.

```
[edit]
user@R0#set protocols bgp group ebgp1 type external
```

```
user@R0#set protocols bgp group ebgp1 family inet unicast
user@R0#set protocols bgp group ebgp1 family traffic-engineering unicast
user@R0#set protocols bgp group ebgp1 export nlri2bgp_epe
user@R0#set protocols bgp group ebgp1 neighbor 192.168.1.2 peer-as 200
user@R0#set protocols bgp group ebgp1 neighbor 192.168.1.2 egress-te-adj-segment
epe_adj1_toR1 label 7101
user@R0#set protocols bgp group ebgp1 neighbor 192.168.1.2 egress-te-adj-segment
epe_adj1_toR1 next-hop 192.168.1.2
user@R0#set protocols bgp group ebgp1 neighbor 192.168.1.2 egress-te-adj-segment

epe_adj1_toR4 te-link-attribute admin-group red
user@R0#set protocols bgp group ebgp1 neighbor 192.168.2.2 egress-te-adj-segment
epe_adj1_toR4 te-link-attribute admin-group brown
```

7. Enable import and export of traffic engineering database parameters using policies.

```
[edit]
user@R0#set protocols mpls traffic-engineering database import l3-unicast-topology bgp-link-
state
user@R0#set protocols mpls traffic-engineering database import policy ted2nlri
user@R0#set protocols mpls traffic-engineering database export policy nlri2ted_bgp
user@R0#set protocols mpls traffic-engineering database export l3-unicast-topology
```

8. Configure MPLS administrative group policies for LSP path computation.

```
[edit]
user@R0#set protocols mpls admin-groups red 0
user@R0#set protocols mpls admin-groups blue 1
user@R0#set protocols mpls admin-groups brown 5
```

9. Configure the MPLS label range to assign static labels for the EPE links.

```
[edit]
user@R0#set protocols mpls label-range static-label-range 7000 70000
```

10. Configure MPLS on the interfaces.

```
[edit]
user@R0#set protocols mpls interface all
```

11. Configure SR-TE policies on the ingress router to enable end-to-end SR-TE policy.

```
[edit]
user@R0#set protocols source-packet-routing compute-profile compute1 no-label-stack-
compression
user@R0#set protocols source-packet-routing compute-profile ecompute1 admin-group include-

user@R0#set protocols source-packet-routing source-routing-path computelsp1 primary p1
compute compute1
user@R0#set protocols source-packet-routing source-routing-path ecomputelsp1 to 7.7.7.7
```

```
user@R0#set protocols source-packet-routing source-routing-path ecomputelsp1 color 7000
user@R0#set protocols source-packet-routing source-routing-path ecomputelsp1 primary p1
compute ecompute1
user@R0#set protocols source-packet-routing source-routing-path ecomputelsp2 to 7.7.7.7
user@R0#set protocols source-packet-routing source-routing-path ecomputelsp2 color 7001
user@R0#set protocols source-packet-routing source-routing-path ecomputelsp2 primary p1
compute ecompute2
```

Results

From configuration mode, confirm your configuration by entering the `show chassis`, `show interfaces`, `show policy-optionsshow routing-options`, and `show protocols` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
chassis {
    network-services enhanced-ip;
}

Configure R1 (BN1 router)

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the CLI User Guide.

To configure device R1:

1. Configure the network services mode as Enhanced IP. Enhanced IP sets the router's network services to enhanced Internet Protocol and uses enhanced mode capabilities.

```
[edit]
user@R1#set chassis network-services enhanced-ip
```

After you configure the `enhanced-ip` statement and commit the configuration, the following warning message appears prompting you to reboot the router:

```
'chassis'
WARNING: Chassis configuration for network services has been changed. A system reboot is
mandatory. Please reboot the system NOW. Continuing without a reboot might result in
unexpected system behavior.
commit complete
```

The reboot brings up the FPCs on the router.

2. Configure the interfaces to enable IP, MPLS, and ISO transport.

```
[edit]
user@R1#set interfaces ge-0/0/0 description To_R0_1
user@R1#set interfaces ge-0/0/0 unit 0 family inet address 192.168.1.2/24
user@R1#set interfaces ge-0/0/0 unit 0 family iso
user@R1#set interfaces ge-0/0/0 unit 0 family mpls maximum-labels 8
user@R1#set interfaces ge-0/0/2 description To_R2
user@R1#set interfaces ge-0/0/2 unit 0 family inet address 192.168.3.1/24
user@R1#set interfaces ge-0/0/2 unit 0 family iso
user@R1#set interfaces ge-0/0/2 unit 0 family mpls maximum-labels 8
user@R1#set interfaces ge-0/0/3 description to-R4
user@R1#set interfaces ge-0/0/3 unit 0 family inet address 192.168.4.1/24
user@R1#set interfaces ge-0/0/3 unit 0 family iso
user@R1#set interfaces ge-0/0/3 unit 0 family mpls maximum-labels 8
```

```
user@R1#set interfaces ge-0/0/4 description to-R5
user@R1#set interfaces ge-0/0/4 unit 0 family inet address 192.168.5.1/24
user@R1#set interfaces ge-0/0/4 unit 0 family iso
user@R1#set interfaces ge-0/0/4 unit 0 family mpls maximum-labels 8
```

3. Configure the loopback interface to enable tunnel endpoints and service endpoints.

```
[edit]
user@R1#set interfaces lo0 unit 0 family inet address 1.1.1.1/32
user@R1#set interfaces lo0 unit 0 family iso address 49.0001.0001.0101.0100
```

4. Configure routing options to identify the router in the domain.

```
[edit]
user@R1#set routing-options router-id 1.1.1.1
user@R1#set routing-options autonomous-system 200
```

5. Define import and export policies. For example, configure policies that export EPE TE links from the local TE database to lsdist.0 and policies to import from lsdist.0 into the local TE database. You can configure policies to advertise the BGP routes to a peer.

```
[edit]
user@R1#set policy-options policy-statement expresspol1 from route-filter 6.6.6.6/32 exact
install-nexthop lsp lsp1to6_a
user@R1#set policy-options policy-statement expresspol1 then accept
user@R1#set policy-options policy-statement expresspol2 from route-filter 3.3.3.3/32 exact
install-nexthop lsp lsp1to3_a
user@R1#set policy-options policy-statement expresspol2 then accept
user@R1#set policy-options policy-statement nlri2bgp_epe term 1 from family traffic-
engineering
user@R1#set policy-options policy-statement nlri2bgp_epe term 1 from protocol bgp-ls-epe
user@R1#set policy-options policy-statement nlri2bgp_epe term 1 then next-hop self
user@R1#set policy-options policy-statement nlri2bgp_epe term 1 then accept
user@R1#set policy-options policy-statement nlri2bgp_stat term 1 from family traffic-
engineering
user@R1#set policy-options policy-statement nlri2bgp_stat term 1 from protocol express-
segments
user@R1#set policy-options policy-statement nlri2bgp_stat term 1 then accept
user@R1#set policy-options policy-statement pplb then load-balance per-packet
user@R1#set policy-options policy-statement ted2nlri_epe_stat term 1 from family traffic-
```

```
engineering
user@R1#set policy-options policy-statement ted2nlri_epe_stat term 1 from protocol express-
segments
user@R1#set policy-options policy-statement ted2nlri_epe_stat term 1 then accept
user@R1#set policy-options policy-statement ted2nlri_epe_stat term 2 from family traffic-
engineering
user@R1#set policy-options policy-statement ted2nlri_epe_stat term 2 from protocol bgp-ls-
epe
user@R1#set policy-options policy-statement ted2nlri_epe_stat term 2 then accept
user@R1#set policy-options policy-statement ted2nlri_epe_stat term 3 from protocol isis
user@R1#set policy-options policy-statement ted2nlri_epe_stat term 3 then reject
```

6. Configure BGP to enable BGP-LS route advertisement to the connected peers and define the EPE links. Since express segment is an internal TE link, this configuration creates an external TE link.

```
[edit]
user@R1#set protocols bgp group ebgp1 type external
user@R1#set protocols bgp group ebgp1 family inet-vpn unicast
user@R1#set protocols bgp group ebgp1 family traffic-engineering unicast
user@R1#set protocols bgp group ebgp1 export nlri2bgp_stat
user@R1#set protocols bgp group ebgp1 neighbor 192.168.1.1 peer-as 100
user@R1#set protocols bgp group ebgp1 neighbor 192.168.1.1 egress-te-adj-segment
epe_adj1_toR0 label 8110
user@R1#set protocols bgp group ebgp1 neighbor 192.168.1.1 egress-te-adj-segment
epe_adj1_toR0 next-hop 192.168.1.1
user@R1#set protocols bgp group ebgp1 neighbor 192.168.1.1 egress-te-adj-segment
epe_adj1_toR0 te-link-attribute te-metric 20
user@R1#set protocols bgp group ebgp1 neighbor 192.168.1.1 egress-te-adj-segment
epe_adj1_toR0 te-link-attribute igp-metric 10
user@R1#set protocols bgp group ebgp1 neighbor 192.168.1.1 egress-te-adj-segment
epe_adj1_toR0 te-link-attribute admin-group red
user@R1#set protocols bgp group ebgp1 neighbor 192.168.1.1 egress-te-adj-segment
epe_adj1_toR0 te-link-attribute admin-group brown
user@R1#set protocols bgp group ibgp1 type internal
user@R1#set protocols bgp group ibgp1 local-address 1.1.1.1
user@R1#set protocols bgp group ibgp1 family traffic-engineering unicast
user@R1#set protocols bgp group ibgp1 export nlri2bgp_epe
user@R1#set protocols bgp group ibgp1 neighbor 2.2.2.2
user@R1#set protocols bgp group ibgp1 neighbor 5.5.5.5
```

7. Configure the express segment set and express segment templates. What the express segment template does is it manually assigns or overrides inherited attributes to the express segments regardless of what the underlay attributes are. The express segment name `r1-exp-set1` is prefixed to the underlay end point for automatic naming.

```
[edit]
user@R1#set protocols express-segments segment-template template1 admin-group red
user@R1#set protocols express-segments segment-template template1 metric te 200
user@R1#set protocols express-segments segment-template template1 metric igp 100
user@R1#set protocols express-segments segment-set r1-exp-set1 membership-policy expresspol1
user@R1#set protocols express-segments segment-set r1-exp-set1 template template1
user@R1#set protocols express-segments segment-set r1-exp-set2 membership-policy expresspol2
user@R1#set protocols express-segments traffic-engineering
```

8. Configure IS-IS protocol on the interfaces and apply MPLS administrative groups to those interfaces.

```
[edit]
user@R1#set protocols isis interface ge-0/0/2.0
user@R1#set protocols isis interface ge-0/0/3.0
user@R1#set protocols isis interface ge-0/0/4.0
user@R1#set protocols isis interface lo0.0 passive
user@R1#set protocols isis level 1 disable
user@R1#set protocols isis level 2 wide-metrics-only
user@R1#set protocols mpls interface ge-0/0/3.0 admin-group red
user@R1#set protocols mpls interface ge-0/0/2.0 admin-group brown
user@R1#user@R1#set protocols mpls interface ge-0/0/4.0 admin-group blue
user@R1#set protocols mpls interface all
```

9. Enable link protection on all the RSVP interfaces. Using link protection, you can configure a network to reroute traffic quickly around broken links.

```
[edit]
user@R1#set protocols rsvp interface all link-protection
```

10. Enable import and export of traffic engineering database parameters using the policies.

```
[edit]
user@R1#set protocols mpls traffic-engineering database import l3-unicast-topology bgp-link-
```

```
state
user@R1#set protocols mpls traffic-engineering database import policy ted2nlri_epe_stat
user@R1#set protocols mpls traffic-engineering database export l3-unicast-topology
```

11. Configure MPLS administrative group policies for LSP path computation.

```
[edit]
user@R1#set protocols mpls admin-groups red 0
user@R1#set protocols mpls admin-groups blue 1
user@R1#set protocols mpls admin-groups brown 5
```

12. Configure MPLS with a label-switched path (LSP) and include administrative groups.

```
[edit]
user@R1#set protocols mpls label-switched-path lsp1to6_a to 6.6.6.6
user@R1#set protocols mpls label-switched-path lsp1to6_a admin-group include-any brown
user@R1#set protocols mpls label-switched-path lsp1to6_a admin-group include-any red
user@R1#set protocols mpls label-switched-path lsp1to6_b to 6.6.6.6
user@R1#set protocols mpls label-switched-path lsp1to6_b admin-group include-any brown
user@R1#set protocols mpls label-switched-path lsp1to6_b admin-group include-any blue
user@R1#set protocols mpls label-switched-path lsp1to6_c to 6.6.6.6
user@R1#set protocols mpls label-switched-path lsp1to6_c admin-group include-any blue
user@R1#set protocols mpls label-switched-path lsp1to3_a to 3.3.3.3
user@R1#set protocols mpls label-switched-path lsp1to3_a admin-group include-any brown
user@R1#set protocols mpls label-switched-path lsp1to3_a admin-group include-any red
user@R1#set protocols mpls label-switched-path lsp1to3_b to 3.3.3.3
user@R1#set protocols mpls label-switched-path lsp1to3_b admin-group include-any blue
user@R1#set protocols mpls label-range static-label-range 7000 70000
```

Results

From configuration mode, confirm your configuration by entering the `show chassis`, `show interfaces`, `show policy-options`, `show routing-options`, and `show protocols` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

Configure R4 (BN2 router)

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the CLI User Guide.

To configure device R4:

1. Configure the network services mode as Enhanced IP. Enhanced IP sets the router's network services to enhanced Internet Protocol and uses enhanced mode capabilities.

```
[edit]
user@R4#set chassis network-services enhanced-ip
```

After you configure the `enhanced-ip` statement and commit the configuration, the following warning message appears prompting you to reboot the router:

```
'chassis'
WARNING: Chassis configuration for network services has been changed. A system reboot is
mandatory. Please reboot the system NOW. Continuing without a reboot might result in
unexpected system behavior.
commit complete
```

The reboot brings up the FPCs on the router.

2. Configure the interfaces to enable IP, MPLS, and ISO transport.

```
user@R4#set interfaces ge-0/0/0 description To_R0
user@R4#set interfaces ge-0/0/0 unit 0 family inet address 192.168.2.2/24
user@R4#set interfaces ge-0/0/0 unit 0 family iso
user@R4#set interfaces ge-0/0/0 unit 0 family mpls maximum-labels 8
user@R4#set interfaces ge-0/0/2 description To_R1
user@R4#set interfaces ge-0/0/2 unit 0 family inet address 192.168.4.2/24
user@R4#set interfaces ge-0/0/2 unit 0 family iso
user@R4#set interfaces ge-0/0/2 unit 0 family mpls maximum-labels 8
user@R4#set interfaces ge-0/0/3 description To_R2
user@R4#set interfaces ge-0/0/3 unit 0 family inet address 24.24.10.4/24
user@R4#set interfaces ge-0/0/3 unit 0 family iso
user@R4#set interfaces ge-0/0/3 unit 0 family mpls maximum-labels 8
user@R4#set interfaces ge-0/0/4 description To_R5
user@R4#set interfaces ge-0/0/4 unit 0 family inet address 192.168.13.1/24
user@R4#set interfaces ge-0/0/4 unit 0 family iso
user@R4#set interfaces ge-0/0/4 unit 0 family mpls maximum-labels 8
```

3. Configure the loopback interface to enable tunnel endpoints and service endpoints.

```
[edit]
user@R4#set interfaces lo0 unit 0 family inet address 4.4.4.4/32
user@R4#set interfaces lo0 unit 0 family iso address 49.0001.0004.0404.0400
```

4. Configure routing options to identify the router in the domain.

```
[edit]
user@R4#set routing-options router-id 4.4.4.4
user@R4#set routing-options autonomous-system 200
```

5. Define import and export policies. For example, configure policies that export EPE TE links from the local TE database to **lsdist.0** and policies to import from **lsdist.0** into the local TE database. You can configure policies to advertise the BGP routes to a peer.

```
[edit]
user@R4#set policy-options policy-statement expresspol1 from route-filter 6.6.6.6/32 exact
install-nexthop lsp lsp4to6_a
user@R4#set policy-options policy-statement expresspol1 then accept
user@R4#set policy-options policy-statement expresspol2 from route-filter 3.3.3.3/32 exact
install-nexthop lsp lsp4to3_a
user@R4#set policy-options policy-statement expresspol2 then accept
user@R4#set policy-options policy-statement nlri2bgp_epe term 1 from family traffic-
engineering
user@R4#set policy-options policy-statement nlri2bgp_epe term 1 from protocol bgp-ls-epe
user@R4#set policy-options policy-statement nlri2bgp_epe term 1 then next-hop self
user@R4#set policy-options policy-statement nlri2bgp_epe term 1 then accept
user@R4#set policy-options policy-statement nlri2bgp_stat term 1 from family traffic-
engineering
user@R4#set policy-options policy-statement nlri2bgp_stat term 1 from protocol express-
segments
user@R4#set policy-options policy-statement nlri2bgp_stat term 1 then accept
user@R4#set policy-options policy-statement pplb then load-balance per-packet
user@R4#set policy-options policy-statement ted2nlri_epe_stat term 1 from family traffic-
engineering
user@R4#set policy-options policy-statement ted2nlri_epe_stat term 1 from protocol express-
segments
user@R4#set policy-options policy-statement ted2nlri_epe_stat term 1 then accept
user@R4#set policy-options policy-statement ted2nlri_epe_stat term 2 from family traffic-
```

```
engineering
user@R4#set policy-options policy-statement ted2nlri_epe_stat term 2 from protocol bgp-ls-
epe
user@R4#set policy-options policy-statement ted2nlri_epe_stat term 2 then accept
user@R4#set policy-options policy-statement ted2nlri_epe_stat term 3 from protocol isis
user@R4#set policy-options policy-statement ted2nlri_epe_stat term 3 then reject
```

6. Configure the express segment set and express segment templates. What the express segment template does is it manually assigns or overrides inherited attributes to the express segments regardless of what the underlay attributes are. The express segment name `r4-exp-set1` is prefixed to the underlay end point for automatic naming.

```
[edit]
user@R4#set protocols express-segments segment-set r4-exp-set1 membership-policy expresspol1
user@R4#set protocols express-segments segment-set r4-exp-set2 membership-policy expresspol2
user@R4#set protocols express-segments traffic-engineering
```

7. Configure IS-IS and MPLS protocol on the interfaces.

```
[edit]
user@R4#set protocols isis interface ge-0/0/0.0
user@R4#set protocols isis interface ge-0/0/2.0
user@R4#set protocols isis interface ge-0/0/3.0
user@R4#set protocols isis interface ge-0/0/4.0
user@R4#set protocols isis interface lo0.0 passive
user@R4#set protocols isis level 1 disable
user@R4#set protocols isis level 2 wide-metrics-only
user@R4#set protocols mpls interface ge-0/0/2.0 admin-group red
user@R4#set protocols mpls interface ge-0/0/4.0 admin-group brown
user@R4#set protocols mpls interface all
```

8. Enable import and export of traffic engineering database parameters using policies.

```
[edit]
user@R4#set protocols mpls traffic-engineering database import l3-unicast-topology bgp-link-
state
user@R4#set protocols mpls traffic-engineering database import policy ted2nlri_epe_stat
user@R4#set protocols mpls traffic-engineering database export l3-unicast-topology
```

9. Configure MPLS administrative group policies for LSP path computation.

```
[edit]
user@R4#set protocols mpls admin-groups red 0
user@R4#set protocols mpls admin-groups blue 1
user@R4#set protocols mpls admin-groups brown 5
```

10. Configure MPLS with a label-switched path (LSP) and include administrative groups.

```
[edit]
user@R4#set protocols mpls label-switched-path lsp4to6_a to 6.6.6.6
user@R4#set protocols mpls label-switched-path lsp4to6_a admin-group include-any brown
user@R4#set protocols mpls label-switched-path lsp4to6_a admin-group include-any red
user@R4#set protocols mpls label-switched-path lsp4to6_b to 6.6.6.6
user@R4#set protocols mpls label-switched-path lsp4to6_b admin-group include-any blue
user@R4#set protocols mpls label-switched-path lsp4to3_a to 3.3.3.3
user@R4#set protocols mpls label-switched-path lsp4to3_a admin-group include-any brown
user@R4#set protocols mpls label-switched-path lsp4to3_a admin-group include-any red
user@R4#set protocols mpls label-switched-path lsp4to3_b to 3.3.3.3
user@R4#set protocols mpls label-switched-path lsp4to3_b admin-group include-any brown
user@R4#set protocols mpls label-switched-path lsp4to3_c to 3.3.3.3
user@R4#set protocols mpls label-switched-path lsp4to3_c admin-group include-any brown
```

11. Configure the MPLS label range to assign static labels for the EPE links.

```
[edit]
user@R4#set protocols mpls label-range static-label-range 7000 70000
```

12. Enable link protection on all the RSVP interfaces. Using link protection, you can configure a network to reroute traffic quickly around broken links.

```
[edit]
user@R4#set protocols rsvp interface all link-protection
```

Results

From configuration mode, confirm your configuration by entering the `show chassis`, `show interfaces`, `show policy-options`, `show routing-options`, and `show protocols` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

```

Configure R2 (Intermediate router)

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the CLI User Guide.

To configure device R2:

1. Configure the network services mode as Enhanced IP. Enhanced IP sets the router's network services to enhanced Internet Protocol and uses enhanced mode capabilities.

```
[edit]
user@R2#set chassis network-services enhanced-ip
```

After you configure the `enhanced-ip` statement and commit the configuration, the following warning message appears prompting you to reboot the router:

```
'chassis'
WARNING: Chassis configuration for network services has been changed. A system reboot is
mandatory. Please reboot the system NOW. Continuing without a reboot might result in
unexpected system behavior.
commit complete
```

The reboot brings up the FPCs on the router.

2. Configure the interfaces to enable IP, MPLS, and ISO transport.

```
user@R2#set interfaces ge-0/0/0 description To_R1
user@R2#set interfaces ge-0/0/0 unit 0 family inet address 192.168.3.2/24
user@R2#set interfaces ge-0/0/0 unit 0 family iso
user@R2#set interfaces ge-0/0/0 unit 0 family mpls maximum-labels 8
user@R2#set interfaces ge-0/0/1 description To_R3
user@R2#set interfaces ge-0/0/1 unit 0 family inet address 192.168.6.1/24
user@R2#set interfaces ge-0/0/1 unit 0 family iso
user@R2#set interfaces ge-0/0/1 unit 0 family mpls maximum-labels 8
user@R2#set interfaces ge-0/0/2 description To_R4
user@R2#set interfaces ge-0/0/2 unit 0 family inet address 192.168.7.1/24
user@R2#set interfaces ge-0/0/2 unit 0 family iso
user@R2#set interfaces ge-0/0/2 unit 0 family mpls maximum-labels 8
user@R2#set interfaces ge-0/0/3 description To_R5
user@R2#set interfaces ge-0/0/3 unit 0 family inet address 192.168.8.1/24
user@R2#set interfaces ge-0/0/3 unit 0 family iso
user@R2#set interfaces ge-0/0/3 unit 0 family mpls maximum-labels 8
user@R2#set interfaces ge-0/0/4 description To_R6
user@R2#set interfaces ge-0/0/4 unit 0 family inet address 192.168.9.1/24
user@R2#set interfaces ge-0/0/4 unit 0 family iso
user@R2#set interfaces ge-0/0/4 unit 0 family mpls maximum-labels 8
```

3. Configure the loopback interface to enable tunnel endpoints and service endpoints.

```
[edit]
user@R2#set interfaces lo0 unit 0 family inet address 2.2.2.2/32
user@R2#set interfaces lo0 unit 0 family iso address 49.0001.0002.0202.0200
```

4. Configure routing options to identify the router in the domain.

```
[edit]
user@R2#set routing-options router-id 2.2.2.2
user@R2#set routing-options autonomous-system 200
```

5. Define import and export policies. For example, configure policies that export EPE TE links from the local TE database to **lsdist.0** and policies to import from **lsdist.0** into the local TE database. You can configure policies to advertise the BGP routes to a peer.

```
[edit]
user@R2#set policy-options policy-statement bgplsepe_rt_2_ted term 1 from protocol bgp
user@R2#set policy-options policy-statement bgplsepe_rt_2_ted term 1 then accept
user@R2#set policy-options policy-statement nlri2bgp term 1 from family traffic-engineering
user@R2#set policy-options policy-statement nlri2bgp term 1 then next-hop self
user@R2#set policy-options policy-statement nlri2bgp term 1 then accept
user@R2#set policy-options policy-statement nlri2bgp_igp term 1 from family traffic-
engineering
user@R2#set policy-options policy-statement nlri2bgp_igp term 1 from protocol isis
user@R2#set policy-options policy-statement nlri2bgp_igp term 1 then accept
user@R2#set policy-options policy-statement nlri2ted_igp term 1 from traffic-engineering
protocol isis-level-2
user@R2#set policy-options policy-statement nlri2ted_igp term 1 then accept
user@R2#set policy-options policy-statement pplb then load-balance per-packet
user@R2#set policy-options policy-statement ted2nlri term 1 from protocol bgp-ls-epe
user@R2#set policy-options policy-statement ted2nlri term 1 then accept
user@R2#set policy-options policy-statement ted2nlri_1 term 1 from traffic-engineering
user@R2#set policy-options policy-statement ted2nlri_1 term 1 then accept
user@R2#set policy-options policy-statement ted2nlri_igp term 1 from family traffic-
engineering
user@R2#set policy-options policy-statement ted2nlri_igp term 1 from protocol isis
user@R2#set policy-options policy-statement ted2nlri_igp term 1 then accept
```

6. Configure BGP to enable BGP-LS route advertisement to the connected peers.

```
[edit]
user@R2#set protocols bgp group RR1 type internal
user@R2#set protocols bgp group RR1 local-address 2.2.2.2
user@R2#set protocols bgp group RR1 family traffic-engineering unicast
user@R2#set protocols bgp group RR1 neighbor 1.1.1.1
user@R2#set protocols bgp group RR1 neighbor 3.3.3.3
user@R2#set protocols bgp group RR1 neighbor 6.6.6.6
user@R2#set protocols bgp group RR1 neighbor 4.4.4.4
user@R2#set protocols bgp cluster 2.2.2.2
```

7. Configure IS-IS and MPLS protocol on the interfaces.

```
[edit]
user@R2#set protocols isis interface ge-0/0/0.0
user@R2#set protocols isis interface ge-0/0/1.0
user@R2#set protocols isis interface ge-0/0/2.0
user@R2#set protocols isis interface ge-0/0/3.0
user@R2#set protocols isis interface ge-0/0/4.0
user@R2#set protocols isis interface lo0.0 passive
user@R2#set protocols isis level 1 disable
user@R2#set protocols isis level 2 wide-metrics-only
user@R2#set protocols mpls interface ge-0/0/0.0 admin-group brown
user@R2#set protocols mpls interface ge-0/0/3.0 admin-group red
user@R2#set protocols mpls interface ge-0/0/4.0 admin-group blue
user@R2#set protocols mpls interface ge-0/0/1.0 admin-group brown
user@R2#set protocols mpls interface all
```

8. Configure MPLS administrative group policies for LSP path computation.

```
[edit]
user@R2#set protocols mpls admin-groups red 0
user@R2#set protocols mpls admin-groups blue 1
user@R2#set protocols mpls admin-groups brown 5
```

9. Configure the MPLS label range to assign static labels for the EPE links.

```
[edit]
user@R2#set protocols mpls label-range static-label-range 7000 70000
```

10. Enable link protection on all the RSVP interfaces. Using link protection, you can configure a network to reroute traffic quickly around broken links.

```
[edit]
user@R2#set protocols rsvp interface all link-protection
```

Results

From configuration mode, confirm your configuration by entering the `show chassis`, `show interfaces`, `show policy-options`, `show routing-options`, and `show protocols` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
chassis {
    network-services enhanced-ip;
}
interfaces {
    ge-0/0/0 {
        description To_R1;
        unit 0 {
            family inet {
                address 192.168.3.2/24;
            }
            family iso;
            family mpls {
                maximum-labels 8;
            }
        }
    }
    ge-0/0/1 {

    }
}
```

Configure R5 (Intermediate router)

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the CLI User Guide.

To configure device R5:

1. Configure the network services mode as Enhanced IP. Enhanced IP sets the router's network services to enhanced Internet Protocol and uses enhanced mode capabilities.

   ```
   [edit]
   user@R5#set chassis network-services enhanced-ip
   ```

   After you configure the `enhanced-ip` statement and commit the configuration, the following warning message appears prompting you to reboot the router:

   ```
   'chassis'
   WARNING: Chassis configuration for network services has been changed. A system reboot is
   mandatory. Please reboot the system NOW. Continuing without a reboot might result in
   unexpected system behavior.
   commit complete
   ```

   The reboot brings up the FPCs on the router.

2. Configure the interfaces to enable IP, MPLS, and ISO transport.

   ```
   user@R5#set interfaces ge-0/0/0 description To_R1
   user@R5#set interfaces ge-0/0/0 unit 0 family inet address 192.168.5.2/24
   user@R5#set interfaces ge-0/0/0 unit 0 family iso
   user@R5#set interfaces ge-0/0/0 unit 0 family mpls maximum-labels 8
   user@R5#set interfaces ge-0/0/1 description To_R2
   user@R5#set interfaces ge-0/0/1 unit 0 family inet address 192.168.8.2/24
   ```

```
user@R5#set interfaces ge-0/0/1 unit 0 family iso
user@R5#set interfaces ge-0/0/1 unit 0 family mpls maximum-labels 8
user@R5#set interfaces ge-0/0/2 description To_R3
user@R5#set interfaces ge-0/0/2 unit 0 family inet address 192.168.10.2/24
user@R5#set interfaces ge-0/0/2 unit 0 family iso
user@R5#set interfaces ge-0/0/2 unit 0 family mpls maximum-labels 8
user@R5#set interfaces ge-0/0/3 description To_R4
user@R5#set interfaces ge-0/0/3 unit 0 family inet address 192.168.13.2/24
user@R5#set interfaces ge-0/0/3 unit 0 family iso
user@R5#set interfaces ge-0/0/3 unit 0 family mpls maximum-labels 8
user@R5#set interfaces ge-0/0/4 description To_R6
user@R5#set interfaces ge-0/0/4 unit 0 family inet address 192.168.14.1/24
user@R5#set interfaces ge-0/0/4 unit 0 family iso
user@R5#set interfaces ge-0/0/4 unit 0 family mpls maximum-labels 8
```

3. Configure the loopback interface to enable tunnel endpoints and service endpoints.

```
[edit]
user@R5#set interfaces lo0 unit 0 family inet address 5.5.5.5/32
user@R5#set interfaces lo0 unit 0 family iso address 49.0001.0005.0505.0500
```

4. Configure routing options to identify the router in the domain.

```
[edit]
user@R5#set routing-options router-id 5.5.5.5
user@R5#set routing-options autonomous-system 200
```

5. Define import and export policies. For example, configure policies that export EPE TE links from the local TE database to **lsdist.0** and policies to import from **lsdist.0** into the local TE database. You can configure policies to advertise the BGP routes to a peer.

```
[edit]
user@R5#set policy-options policy-statement nlri2bgp term 1 from family traffic-engineering
user@R5#set policy-options policy-statement nlri2bgp term 1 then next-hop self
user@R5#set policy-options policy-statement nlri2bgp term 1 then accept
user@R5#set policy-options policy-statement nlri2ted_igp term 1 from traffic-engineering
protocol isis-level-2
user@R5#set policy-options policy-statement nlri2ted_igp term 1 then accept
user@R5#set policy-options policy-statement pplb then load-balance per-packet
user@R5#set policy-options policy-statement ted2nlri term 1 from protocol bgp-ls-epe
```

```
user@R5#set policy-options policy-statement ted2nlri term 1 then accept
user@R5#set policy-options policy-statement ted2nlri_igp term 1 from family traffic-
engineering
user@R5#set policy-options policy-statement ted2nlri_igp term 1 from protocol isis
user@R5#set policy-options policy-statement ted2nlri_igp term 1 then accept
```

6. Configure IS-IS and MPLS protocol on the interfaces.

```
[edit]
user@R5#set protocols isis interface ge-0/0/0.0
user@R5#set protocols isis interface ge-0/0/1.0
user@R5#set protocols isis interface ge-0/0/2.0
user@R5#set protocols isis interface ge-0/0/3.0
user@R5#set protocols isis interface ge-0/0/4.0
user@R5#set protocols isis interface lo0.0 passive
user@R5#set protocols isis level 1 disable
user@R5#set protocols isis level 2 wide-metrics-only
user@R5#set protocols mpls interface ge-0/0/0.0 admin-group blue
user@R5#set protocols mpls interface ge-0/0/1.0 admin-group red
user@R5#set protocols mpls interface ge-0/0/3.0 admin-group brown
user@R5#set protocols mpls interface ge-0/0/4.0 admin-group brown
user@R5#set protocols mpls interface all
```

7. Configure BGP to enable BGP-LS route advertisement to the connected peers.

```
[edit]
user@R5#set protocols bgp group RR2 type internal
user@R5#set protocols bgp group RR2 family inet unicast
user@R5#set protocols bgp group RR2 family traffic-engineering unicast
user@R5#set protocols bgp group RR2 neighbor 1.1.1.1
user@R5#set protocols bgp group RR2 neighbor 3.3.3.3
user@R5#set protocols bgp group RR2 neighbor 6.6.6.6
user@R5#set protocols bgp group RR2 neighbor 4.4.4.4
user@R5#set protocols bgp cluster 5.5.5.5
```

8. Configure MPLS administrative group policies for LSP path computation.

```
[edit]
user@R5#set protocols mpls admin-groups red 0
```

```
user@R5#set protocols mpls admin-groups blue 1
user@R5#set protocols mpls admin-groups brown 5
```

9. Configure the MPLS label range to assign static labels for the EPE links.

```
[edit]
user@R5#set protocols mpls label-range static-label-range 7000 70000
```

10. Enable link protection on all the RSVP interfaces. Using link protection, you can configure a network to reroute traffic quickly around broken links.

```
[edit]
user@R5#set protocols rsvp interface all link-protection
```

Results

From configuration mode, confirm your configuration by entering the `show chassis`, `show interfaces`, `show policy-options`, `show routing-options`, and `show protocols` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
chassis {
    network-services enhanced-ip;
}
interfaces {
    ge-0/0/0 {
        description To_R1;
        unit 0 {
            family inet {
                address 192.168.5.2/24;
            }
            family iso;
            family mpls {
                maximum-labels 8;
            }
        }
    }
    ge-0/0/1 {

}
```

Configure R3 (BN3 router)

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the CLI User Guide.

To configure device R3:

1. Configure the network services mode as Enhanced IP. Enhanced IP sets the router's network services to enhanced Internet Protocol and uses enhanced mode capabilities.

```
[edit]
user@R3#set chassis network-services enhanced-ip
```

After you configure the `enhanced-ip` statement and commit the configuration, the following warning message appears prompting you to reboot the router:

```
'chassis'
WARNING: Chassis configuration for network services has been changed. A system reboot is
mandatory. Please reboot the system NOW. Continuing without a reboot might result in
unexpected system behavior.
commit complete
```

The reboot brings up the FPCs on the router.

2. Configure the interfaces to enable IP, MPLS, and ISO transport.

```
user@R3#set interfaces ge-0/0/0 description To_R2
user@R3#set interfaces ge-0/0/0 unit 0 family inet address 192.168.6.2/24
user@R3#set interfaces ge-0/0/0 unit 0 family iso
user@R3#set interfaces ge-0/0/0 unit 0 family mpls maximum-labels 8
user@R3#set interfaces ge-0/0/1 description To_R5
user@R3#set interfaces ge-0/0/1 unit 0 family inet address 192.168.10.1/24
user@R3#set interfaces ge-0/0/1 unit 0 family iso
user@R3#set interfaces ge-0/0/1 unit 0 family mpls maximum-labels 8
user@R3#set interfaces ge-0/0/2 description To_R6
user@R3#set interfaces ge-0/0/2 unit 0 family inet address 192.168.11.1/24
user@R3#set interfaces ge-0/0/2 unit 0 family iso
user@R3#set interfaces ge-0/0/2 unit 0 family mpls maximum-labels 8
user@R3#set interfaces ge-0/0/3 description To_R7
user@R3#set interfaces ge-0/0/3 unit 0 family inet address 192.168.12.1/24
user@R3#set interfaces ge-0/0/3 unit 0 family iso
user@R3#set interfaces ge-0/0/3 unit 0 family mpls maximum-labels 8
```

3. Configure the loopback interface to enable tunnel endpoints and service endpoints.

```
[edit]
user@R3#set interfaces lo0 unit 0 family inet address 3.3.3.3/32
user@R3#set interfaces lo0 unit 0 family iso address 49.0001.0003.0303.0300
```

4. Configure routing options to identify the router in the domain.

```
[edit]
user@R3#set routing-options router-id 3.3.3.3
user@R3#set routing-options autonomous-system 200
```

5. Define import and export policies. For example, configure policies that export EPE TE links from the local TE database to **lsdist.0** and policies to import from **lsdist.0** into the local TE database. You can configure policies to advertise the BGP routes to a peer.

```
[edit]
user@R3#set policy-options policy-statement expresspol1 from route-filter 1.1.1.1/32 exact
install-nexthop lsp lsp3to1_a
user@R3#set policy-options policy-statement expresspol1 then accept
user@R3#set policy-options policy-statement expresspol2 from route-filter 4.4.4.4/32 exact
install-nexthop lsp lsp3to4_a
user@R3#set policy-options policy-statement expresspol2 then accept
user@R3#set policy-options policy-statement nlri2bgp_epe term 1 from family traffic-
engineering
user@R3#set policy-options policy-statement nlri2bgp_epe term 1 from protocol bgp-ls-epe
user@R3#set policy-options policy-statement nlri2bgp_epe term 1 then next-hop self
user@R3#set policy-options policy-statement nlri2bgp_epe term 1 then accept
user@R3#set policy-options policy-statement nlri2bgp_stat term 1 from family traffic-
engineering
user@R3#set policy-options policy-statement nlri2bgp_stat term 1 from protocol express-
segments
user@R3#set policy-options policy-statement nlri2bgp_stat term 1 then accept
user@R3#set policy-options policy-statement pplb then load-balance per-packet
user@R3#set policy-options policy-statement ted2nlri_epe_stat term 1 from family traffic-
engineering
user@R3#set policy-options policy-statement ted2nlri_epe_stat term 1 from protocol static
user@R3#set policy-options policy-statement ted2nlri_epe_stat term 1 then accept
user@R3#set policy-options policy-statement ted2nlri_epe_stat term 2 from family traffic-
engineering
```

```
user@R3#set policy-options policy-statement ted2nlri_epe_stat term 2 from protocol bgp-ls-
epe
user@R3#set policy-options policy-statement ted2nlri_epe_stat term 2 then accept
user@R3#set policy-options policy-statement ted2nlri_epe_stat term 3 from protocol isis
user@R3#set policy-options policy-statement ted2nlri_epe_stat term 3 then reject
```

6. Configure BGP to enable BGP-LS route advertisement for peer and define the EPE links. Since express segment is an internal TE link, this configuration creates an external TE link.

```
[edit]
user@R3#set protocols bgp group ibgp1 type internal
user@R3#set protocols bgp group ibgp1 local-address 3.3.3.3
user@R3#set protocols bgp group ibgp1 family traffic-engineering unicast
user@R3#set protocols bgp group ibgp1 export nlri2bgp_epe
user@R3#set protocols bgp group ibgp1 neighbor 2.2.2.2
user@R3#set protocols bgp group ibgp1 neighbor 5.5.5.5
user@R3#set protocols bgp group ebgp1 type external
user@R3#set protocols bgp group ebgp1 family traffic-engineering unicast
user@R3#set protocols bgp group ebgp1 export nlri2bgp_stat
user@R3#set protocols bgp group ebgp1 neighbor 192.168.12.2 peer-as 300
user@R3#set protocols bgp group ebgp1 neighbor 192.168.12.2 egress-te-adj-segment
epe_adj1_toR7 label 7137
user@R3#set protocols bgp group ebgp1 neighbor 192.168.12.2 egress-te-adj-segment
epe_adj1_toR7 next-hop 192.168.12.2
user@R3#set protocols bgp group ebgp1 neighbor 192.168.12.2 egress-te-adj-segment
epe_adj1_toR7 te-link-attribute te-metric 20
user@R3#set protocols bgp group ebgp1 neighbor 192.168.12.2 egress-te-adj-segment
epe_adj1_toR7 te-link-attribute igp-metric 10
user@R3#set protocols bgp group ebgp1 neighbor 192.168.12.2 egress-te-adj-segment
epe_adj1_toR7 te-link-attribute admin-group red
user@R3#set protocols bgp group ebgp1 neighbor 192.168.12.2 egress-te-adj-segment
epe_adj1_toR7 te-link-attribute admin-group brown
user@R3#set protocols bgp group ebgp1 vpn-apply-export
```

7. Define a mechanism to automatically (dynamic) create express segments and insert them in to the TE database so that they can be advertised through BGP-LS. In this example, express segments are created for all the underlay RSVP tunnels automatically. This is done by configuring a template with a policy and then express segments are automatically created based on the policies.

```
[edit]
user@R3#set protocols express-segments segment-set set1 membership-policy expresspol1
```

```
user@R3#set protocols express-segments segment-set set2 membership-policy expresspol2
user@R3#set protocols express-segments traffic-engineering
```

8. Configure IS-IS and MPLS protocol on the interfaces.

```
[edit]
user@R3#set protocols isis interface ge-0/0/0.0
user@R3#set protocols isis interface ge-0/0/1.0
user@R3#set protocols isis interface ge-0/0/2.0
user@R3#set protocols isis interface ge-0/0/3.0 passive
user@R3#set protocols isis interface lo0.0 passive
user@R3#set protocols isis level 1 disable
user@R3#set protocols isis level 2 wide-metrics-only
user@R3#set protocols mpls interface ge-0/0/0.0 admin-group brown
user@R3#set protocols mpls interface ge-0/0/2.0 admin-group red
user@R3#set protocols mpls interface ge-0/0/3.0 admin-group red
user@R3#set protocols mpls interface ge-0/0/3.0 admin-group brown
user@R3#set protocols mpls interface all
```

9. Enable import and export of traffic engineering database parameters using policies.

```
[edit]
user@R3#set protocols mpls traffic-engineering database import l3-unicast-topology bgp-link-
state
user@R3#set protocols mpls traffic-engineering database import policy ted2nlri_epe_stat
user@R3#set protocols mpls traffic-engineering database export l3-unicast-topology
```

10. Configure MPLS administrative group policies for LSP path computation.

```
[edit]
user@R3#set protocols mpls admin-groups red 0
user@R3#set protocols mpls admin-groups blue 1
user@R3#set protocols mpls admin-groups brown 5
```

11. Configure MPLS with a label-switched path (LSP) and include administrative groups.

```
[edit]
user@R3#set protocols mpls label-switched-path lsp3to1_a to 1.1.1.1
user@R3#set protocols mpls label-switched-path lsp3to1_a admin-group include-any red
```

```
user@R3#set protocols mpls label-switched-path lsp3to1_a admin-group include-any brown
user@R3#set protocols mpls label-switched-path lsp3to4_a to 4.4.4.4
user@R3#set protocols mpls label-switched-path lsp3to4_a admin-group include-any red
user@R3#set protocols mpls label-switched-path lsp3to4_a admin-group include-any brown
```

12. Configure the MPLS label range to assign static labels for the EPE links.

```
[edit]
user@R3#set protocols mpls label-range static-label-range 7000 70000
```

13. Enable link protection on all the RSVP interfaces. Using link protection, you can configure a network to reroute traffic quickly around broken links.

```
[edit]
user@R3#set protocols rsvp interface all link-protection
```

Results

From configuration mode, confirm your configuration by entering the `show chassis`, `show interfaces`, `show policy-options`, `show routing-options`, and `show protocols` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

```

```
    }
}
```

Configure R6 (BN4 router)

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the CLI User Guide.

To configure device R6:

1. Configure the network services mode as Enhanced IP. Enhanced IP sets the router's network services to enhanced Internet Protocol and uses enhanced mode capabilities.

   ```
   [edit]
   user@R6#set chassis network-services enhanced-ip
   ```

   After you configure the `enhanced-ip` statement and commit the configuration, the following warning message appears prompting you to reboot the router:

   ```
   'chassis'
   WARNING: Chassis configuration for network services has been changed. A system reboot is
   mandatory. Please reboot the system NOW. Continuing without a reboot might result in
   unexpected system behavior.
   commit complete
   ```

   The reboot brings up the FPCs on the router.

2. Configure the interfaces to enable IP, MPLS, and ISO transport.

   ```
   user@R6#set interfaces ge-0/0/0 description To_R2
   user@R6#set interfaces ge-0/0/0 unit 0 family inet address 192.168.9.2/24
   user@R6#set interfaces ge-0/0/0 unit 0 family iso
   user@R6#set interfaces ge-0/0/0 unit 0 family mpls maximum-labels 8
   user@R6#set interfaces ge-0/0/1 description To_R3
   user@R6#set interfaces ge-0/0/1 unit 0 family inet address 192.168.11.2/24
   user@R6#set interfaces ge-0/0/1 unit 0 family iso
   user@R6#set interfaces ge-0/0/1 unit 0 family mpls maximum-labels 8
   user@R6#set interfaces ge-0/0/2 description To_R5
   ```

```
user@R6#set interfaces ge-0/0/2 unit 0 family inet address 192.168.14.2/24
user@R6#set interfaces ge-0/0/2 unit 0 family iso
user@R6#set interfaces ge-0/0/2 unit 0 family mpls maximum-labels 8
user@R6#set interfaces ge-0/0/3 description To_R7
user@R6#set interfaces ge-0/0/3 unit 0 family inet address 192.168.15.1/24
user@R6#set interfaces ge-0/0/3 unit 0 family iso
user@R6#set interfaces ge-0/0/3 unit 0 family mpls maximum-labels 8
```

3. Configure the loopback interface to enable tunnel endpoints and service endpoints.

```
[edit]
user@R6#set interfaces lo0 unit 0 family inet address 6.6.6.6/32
user@R6#set interfaces lo0 unit 0 family iso address 49.0001.0006.0606.0600
```

4. Configure routing options to identify the router in the domain.

```
[edit]
user@R6#set routing-options router-id 6.6.6.6
user@R6#set routing-options autonomous-system 200
```

5. Define import and export policies. For example, configure policies that export EPE TE links from the local TE database to **lsdist.0** and policies to import from **lsdist.0** into the local TE database. You can configure policies to advertise the BGP routes to a peer.

```
[edit]
user@R6#set policy-options policy-statement expresspol1 from route-filter 1.1.1.1/32 exact
install-nexthop lsp lsp6to1_a
user@R6#set policy-options policy-statement expresspol1 then accept
user@R6#set policy-options policy-statement expresspol2 from route-filter 4.4.4.4/32 exact
install-nexthop lsp lsp6to4_a
user@R6#set policy-options policy-statement expresspol2 then accept
user@R6#set policy-options policy-statement nlri2bgp_epe term 1 from family traffic-
engineering
user@R6#set policy-options policy-statement nlri2bgp_epe term 1 from protocol bgp-ls-epe
user@R6#set policy-options policy-statement nlri2bgp_epe term 1 then next-hop self
user@R6#set policy-options policy-statement nlri2bgp_epe term 1 then accept
user@R6#set policy-options policy-statement nlri2bgp_stat term 1 from family traffic-
engineering
user@R6#set policy-options policy-statement nlri2bgp_stat term 1 from protocol express-
segments
```

```
user@R6#set policy-options policy-statement nlri2bgp_stat term 1 then accept
user@R6#set policy-options policy-statement pplb then load-balance per-packet
user@R6#set policy-options policy-statement ted2nlri_epe_stat term 1 from family traffic-
engineering
user@R6#set policy-options policy-statement ted2nlri_epe_stat term 1 from protocol static
user@R6#set policy-options policy-statement ted2nlri_epe_stat term 1 then accept
user@R6#set policy-options policy-statement ted2nlri_epe_stat term 2 from family traffic-
engineering
user@R6#set policy-options policy-statement ted2nlri_epe_stat term 2 from protocol bgp-ls-
epe
user@R6#set policy-options policy-statement ted2nlri_epe_stat term 2 then accept
user@R6#set policy-options policy-statement ted2nlri_epe_stat term 3 from protocol isis
user@R6#set policy-options policy-statement ted2nlri_epe_stat term 3 then reject
```

6. Configure BGP to enable BGP-LS route advertisement for peer and define the EPE links. Since express segment is an internal TE link, this configuration creates an external TE link.

```
[edit]
user@R6#set protocols bgp group ibgp1 type internal
user@R6#set protocols bgp group ibgp1 local-address 6.6.6.6
user@R6#set protocols bgp group ibgp1 family traffic-engineering unicast
user@R6#set protocols bgp group ibgp1 export nlri2bgp_epe
user@R6#set protocols bgp group ibgp1 neighbor 2.2.2.2
user@R6#set protocols bgp group ibgp1 neighbor 5.5.5.5
user@R6#set protocols bgp group ebgp1 type external
user@R6#set protocols bgp group ebgp1 family traffic-engineering unicast
user@R6#set protocols bgp group ebgp1 export nlri2bgp_stat
user@R6#set protocols bgp group ebgp1 neighbor 192.168.15.2 peer-as 300
user@R6#set protocols bgp group ebgp1 neighbor 192.168.15.2 egress-te-adj-segment
epe_adj1_toR7 label 7167
user@R6#set protocols bgp group ebgp1 neighbor 192.168.15.2 egress-te-adj-segment
epe_adj1_toR7 next-hop 192.168.15.2
user@R6#set protocols bgp group ebgp1 neighbor 192.168.15.2 egress-te-adj-segment
epe_adj1_toR7 te-link-attribute te-metric 20
user@R6#set protocols bgp group ebgp1 neighbor 192.168.15.2 egress-te-adj-segment
epe_adj1_toR7 te-link-attribute igp-metric 10
user@R6#set protocols bgp group ebgp1 neighbor 192.168.15.2 egress-te-adj-segment
epe_adj1_toR7 te-link-attribute admin-group red
user@R6#set protocols bgp group ebgp1 neighbor 192.168.15.2 egress-te-adj-segment
epe_adj1_toR7 te-link-attribute admin-group brown
```

7. Define a mechanism to automatically (dynamic) create express segments and insert them in to the TE database so that they can be advertised through BGP-LS. In this example, express segments are created for all the underlay RSVP tunnels automatically. This is done by configuring a template with a policy and then express segments are automatically created based on the policies.

```
[edit]
user@R6#set protocols express-segments segment-set set1 membership-policy expresspol1
user@R6#set protocols express-segments segment-set set2 membership-policy expresspol2
user@R6#set protocols express-segments traffic-engineering
```

8. Configure IS-IS and MPLS protocol on the interfaces.

```
[edit]
user@R6#set protocols isis interface ge-0/0/0.0
user@R6#set protocols isis interface ge-0/0/1.0
user@R6#set protocols isis interface ge-0/0/2.0
user@R6#set protocols isis interface lo0.0 passive
user@R6#set protocols isis level 1 disable
user@R6#set protocols isis level 2 wide-metrics-only
user@R6#set protocols mpls interface ge-0/0/0.0 admin-group blue
user@R6#set protocols mpls interface ge-0/0/1.0 admin-group red
user@R6#set protocols mpls interface ge-0/0/2.0 admin-group brown
user@R6#set protocols mpls interface ge-0/0/3.0 admin-group red
user@R6#set protocols mpls interface ge-0/0/3.0 admin-group brown
user@R6#set protocols mpls interface all
```

9. Enable import and export of traffic engineering database parameters using policies.

```
[edit]
user@R6#set protocols mpls traffic-engineering database import l3-unicast-topology bgp-link-
state
user@R6#set protocols mpls traffic-engineering database import policy ted2nlri_epe_stat
user@R6#set protocols mpls traffic-engineering database export l3-unicast-topology
```

10. Configure MPLS administrative group policies for LSP path computation.

```
[edit]
user@R6#set protocols mpls admin-groups red 0
```

```
user@R6#set protocols mpls admin-groups blue 1
user@R6#set protocols mpls admin-groups brown 5
```

11. Configure MPLS with a label-switched path (LSP) and include administrative groups.

```
[edit]
user@R6#set protocols mpls label-switched-path lsp6to1_a to 1.1.1.1
user@R6#set protocols mpls label-switched-path lsp6to1_a admin-group include-any red
user@R6#set protocols mpls label-switched-path lsp6to1_a admin-group include-any brown
user@R6#set protocols mpls label-switched-path lsp6to4_a to 4.4.4.4
user@R6#set protocols mpls label-switched-path lsp6to4_a admin-group include-any red
user@R6#set protocols mpls label-switched-path lsp6to4_a admin-group include-any brown
```

12. Configure the MPLS label range to assign static labels for the EPE links.

```
[edit]
user@R6#set protocols mpls label-range static-label-range 7000 70000
```

13. Enable link protection on all the RSVP interfaces. Using link protection, you can configure a network to reroute traffic quickly around broken links.

```
[edit]
user@R6#set protocols rsvp interface all link-protection
```

Results

From configuration mode, confirm your configuration by entering the `show chassis`, `show interfaces`, `show policy-options`, `show routing-options`, and `show protocols` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
chassis {
    network-services enhanced-ip;
}

        interface all;
    }
    rsvp {
        interface all {
            link-protection;
        }
    }
}
```

Configure R7 (PE2 router)

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the CLI User Guide.

To configure device R7:

1. Configure the network services mode as Enhanced IP. Enhanced IP sets the router's network services to enhanced Internet Protocol and uses enhanced mode capabilities.

   ```
   [edit]
   user@R7#set chassis network-services enhanced-ip
   ```

   After you configure the `enhanced-ip` statement and commit the configuration, the following warning message appears prompting you to reboot the router:

   ```
   'chassis'
   WARNING: Chassis configuration for network services has been changed. A system reboot is
   mandatory. Please reboot the system NOW. Continuing without a reboot might result in
   unexpected system behavior.
   commit complete
   ```

The reboot brings up the FPCs on the router.

2. Configure the interfaces to enable IP, MPLS, and ISO transport.

```
user@R7#set interfaces ge-0/0/0 description To_R3
user@R7#set interfaces ge-0/0/0 unit 0 family inet address 192.168.12.2/24
user@R7#set interfaces ge-0/0/0 unit 0 family iso
user@R7#set interfaces ge-0/0/0 unit 0 family mpls maximum-labels 8
user@R7#set interfaces ge-0/0/1 description To_R6
user@R7#set interfaces ge-0/0/1 unit 0 family inet address 192.168.15.2/24
user@R7#set interfaces ge-0/0/1 unit 0 family iso
user@R7#set interfaces ge-0/0/1 unit 0 family mpls maximum-labels 8
```

3. Configure the loopback interface to enable tunnel endpoints and service endpoints.

```
[edit]
user@R7#set interfaces lo0 unit 0 family inet address 7.7.7.7/32
user@R7#set interfaces lo0 unit 0 family inet address 7.7.7.71/32
```

4. Configure routing options to identify the router in the domain.

```
[edit]
user@R7#set routing-options router-id 7.7.7.7
user@R7#set routing-options autonomous-system 300
user@R7#set routing-options static route 100.100.100.101/32 next-hop 100.100.100.100
user@R7#set routing-options static route 100.100.100.101/32 resolve
```

5. Define import and export policies. For example, configure policies that export EPE TE links from the local TE database to **lsdist.0** and policies to import from **lsdist.0** into the local TE database. You can configure policies to advertise the BGP routes to a peer.

```
[edit]
user@R7#set policy-options policy-statement nlri2bgp_epe term 1 from family traffic-
engineering
user@R7#set policy-options policy-statement nlri2bgp_epe term 1 from protocol bgp-ls-epe
user@R7#set policy-options policy-statement nlri2bgp_epe term 1 then next-hop self
user@R7#set policy-options policy-statement nlri2bgp_epe term 1 then accept
user@R7#set policy-options policy-statement nlri2ted_bgp term 1 from protocol bgp
user@R7#set policy-options policy-statement nlri2ted_bgp term 1 then accept
```

```
user@R7#set policy-options policy-statement pplb then load-balance per-packet
user@R7#set policy-options policy-statement ted2nlri term 1 from protocol bgp-ls-epe
user@R7#set policy-options policy-statement ted2nlri term 1 then accept
user@R7#set policy-options resolution-map map1 mode ip-color
```

6. Configure BGP to enable BGP-LS route advertisement for peer and define the EPE links. Since express segment is an internal TE link, this configuration creates an external TE link.

```
[edit]
user@R7#set protocols bgp group ebgp1 type external
user@R7#set protocols bgp group ebgp1 family inet unicast
user@R7#set protocols bgp group ebgp1 family traffic-engineering unicast
user@R7#set protocols bgp group ebgp1 export nlri2bgp_epe
user@R7#set protocols bgp group ebgp1 neighbor 192.168.12.1 peer-as 200
user@R7#set protocols bgp group ebgp1 neighbor 192.168.12.1 egress-te-adj-segment
epe_adj1_toR3 label 8173
user@R7#set protocols bgp group ebgp1 neighbor 192.168.12.1 egress-te-adj-segment
epe_adj1_toR3 next-hop 192.168.12.1
user@R7#set protocols bgp group ebgp1 neighbor 192.168.12.1 egress-te-adj-segment
epe_adj1_toR3 te-link-attribute te-metric 20
user@R7#set protocols bgp group ebgp1 neighbor 192.168.12.1 egress-te-adj-segment
epe_adj1_toR3 te-link-attribute igp-metric 10
user@R7#set protocols bgp group ebgp1 neighbor 192.168.12.1 egress-te-adj-segment
epe_adj1_toR3 te-link-attribute admin-group red
user@R7#set protocols bgp group ebgp1 neighbor 192.168.12.1 egress-te-adj-segment
epe_adj1_toR3 te-link-attribute admin-group brown
user@R7#set protocols bgp group ebgp1 neighbor 192.168.15.1 peer-as 200
user@R7#set protocols bgp group ebgp1 neighbor 192.168.15.1 egress-te-adj-segment
epe_adj1_toR6 label 8176
user@R7#set protocols bgp group ebgp1 neighbor 192.168.15.1 egress-te-adj-segment
epe_adj1_toR6 next-hop 192.168.15.1
user@R7#set protocols bgp group ebgp1 neighbor 192.168.15.1 egress-te-adj-segment
epe_adj1_toR6 te-link-attribute te-metric 20
user@R7#set protocols bgp group ebgp1 neighbor 192.168.15.1 egress-te-adj-segment
epe_adj1_toR6 te-link-attribute igp-metric 10
user@R7#set protocols bgp group ebgp1 neighbor 192.168.15.1 egress-te-adj-segment
epe_adj1_toR6 te-link-attribute admin-group red
user@R7#set protocols bgp group ebgp1 neighbor 192.168.15.1 egress-te-adj-segment
epe_adj1_toR6 te-link-attribute admin-group brown
```

7. Configure MPLS protocol on the interfaces.

```
[edit]
user@R7#set protocols mpls interface all
```

8. Enable import and export of traffic engineering database parameters using policies.

```
[edit]
user@R7#set protocols mpls traffic-engineering database import l3-unicast-topology bgp-link-
state
user@R7#set protocols mpls traffic-engineering database import policy ted2nlri
user@R7#set protocols mpls traffic-engineering database export policy nlri2ted_bgp
user@R7#set protocols mpls traffic-engineering database export l3-unicast-topology
```

9. Configure MPLS administrative group policies for LSP path computation.

```
[edit]
user@R7#set protocols mpls admin-groups red 0
user@R7#set protocols mpls admin-groups blue 1
user@R7#set protocols mpls admin-groups brown 5
```

10. Configure the MPLS label range to assign static labels for the EPE links.

```
[edit]
user@R7#set protocols mpls label-range static-label-range 7000 70000
```

11. Configure SR-TE policies on the ingress router to enable end-to-end SR-TE policy.

```
[edit]
user@R7#set protocols source-packet-routing compute-profile compute1 no-label-stack-
compression
user@R7#set protocols source-packet-routing source-routing-path computelsp1 to
100.100.100.100
user@R7#set protocols source-packet-routing source-routing-path computelsp1 install
100.100.100.101
user@R7#set protocols source-packet-routing source-routing-path computelsp1 primary p1
compute compute1
```

Results

From configuration mode, confirm your configuration by entering the `show chassis`, `show interfaces`, `show policy-options`, `show routing-options`, and `show protocols` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
chassis {
    network-services enhanced-ip;
}
interfaces {
    ge-0/0/0 {
        description To_R3;
        unit 0 {
            family inet {
                address 192.168.12.2/24;
            }
            family iso;
            family mpls {
                maximum-labels 8;
            }
        }
    }
    ge-0/0/1 {
        description To_R6;
        unit 0 {
            family inet {
                address 192.168.15.2/24;
            }
            family iso;
            family mpls {
                maximum-labels 8;
            }
        }
    }

                    }
                }
            }
        }
    }
}
```

Verification

IN THIS SECTION

- Verify the Express Segment | 987
- Verify the Express Segment Advertisements | 989
- Verify the TE Topology Information | 995

To confirm that the configuration is working properly, perform the following tasks:

Verify the Express Segment

Purpose

Verify that the express segments are created correctly.

Action

From operational mode, run the following commands:

- `show express-segments detail`—Verify whether the express segments are created.
- `show ted database topology-type express-segments detail`—Verify that the newly created express segments are inserted into the TE database.
- `show route table mpls.0 protocol express-segments`—Verify whether the forwarding entries have been created.

```
user@R1>show express-segments detail

Name: r1-exp-set1-6.6.6.6
  To: 6.6.6.6, Type: Dynamic (Set: r1-exp-set1)
  Label: 25 (Route installed in mpls.0, TED entry added)
  Status: Up (ElapsedTime: 09:32:00)
  LinkAttributes:
    LocalID: 2147483686
    TE-Metric: 200*, IGP-Metric: 100*
    BW: 0bps
    AdminGroups: red*
```

```
  UnderlayPaths: 1
    RSVP LSP: lsp1to6_a
      TE-Metric: 29, IGP-Metric: 20
      BW: 0bps
      AdminGroups: brown red

Name: r1-exp-set2-3.3.3.3
  To: 3.3.3.3, Type: Dynamic (Set: r1-exp-set2)
  Label: 24 (Route installed in mpls.0, TED entry added)
  Status: Up (ElapsedTime: 09:32:00)
  LinkAttributes:
    LocalID: 2147483685
    TE-Metric: 19, IGP-Metric: 20
    BW: 0bps
    AdminGroups: brown red
  UnderlayPaths: 1
    RSVP LSP: lsp1to3_a
      TE-Metric: 19, IGP-Metric: 20
      BW: 0bps
      AdminGroups: brown red
```

On R1

```
user@R1>show ted database topology-type express-segments detail

TED database: 0 ISIS nodes 4 INET nodes 0 INET6 nodes
NodeID: 1.1.1.1
  Type: Rtr, Age: 119174 secs, LinkIn: 0, LinkOut: 3
  Protocol: EXPRESS-SEG(0)
    To: 3.3.3.3, Local: 1.1.1.1, Remote: 3.3.3.3
      Local interface index: 2147483685, Remote interface index: 0
      Link name: r1-exp-set2-3.3.3.3
    To: 6.6.6.6, Local: 1.1.1.1, Remote: 6.6.6.6
      Local interface index: 2147483686, Remote interface index: 0
      Link name: r1-exp-set1-6.6.6.6
NodeID: 3.3.3.3
  Type: Rtr, Age: 34364 secs, LinkIn: 1, LinkOut: 0
  Protocol: EXPRESS-SEG(0)
NodeID: 6.6.6.6
  Type: Rtr, Age: 34364 secs, LinkIn: 1, LinkOut: 0
  Protocol: EXPRESS-SEG(0)
```

On R1

```
user@R1>show route table mpls.0 protocol express-segments

mpls.0: 13 destinations, 13 routes (13 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

24                 *[EXPRESS-SEG/6] 09:33:24, metric 1
                    >  to 192.168.3.2 via ge-0/0/2.0, Swap 33
25                 *[EXPRESS-SEG/6] 09:33:24, metric 1
                    >  to 192.168.3.2 via ge-0/0/2.0, Swap 34
```

Meaning

- In the `show express-segments detail` output, you can see the name of the express segments (**r1-exp-set1-6.6.6.6, r1-exp-set2-3.3.3.3**), express segment labels (**25, 24**), and the underlay LSPs (**lsp1to6_a, lsp1to3_a**).
- In the `show ted database topology-type express-segments detail` output, you can see the express segment entries are inserted into the TE database. The express segments (virtual TE links) are dynamically created. The protocol used is **EXPRESS-SEG(0)**.
- In the `show route table mpls.0 protocol express-segments` output, you can see the express segment labels (**24,25**). Because the express segment is a construct that relies on the underlay LSPs, the express segment label gets swapped to the underlay LSP labels (**33,34**), which is RSVP-LSP.

Verify the Express Segment Advertisements

Purpose

Verify that the originating node advertises express segments to its eBGP/iBGP LS neighbors.

Action

From operational mode, run the following commands:

- `show route table lsdist.0`—Verify that the express segments in the RIB BGP-LS are being advertised.

- `show route advertising-protocol bgp` *neighbor*—Verify that the express segments are sent to the eBGP/iBGP LS neighbors.

```
user@R1>show route table lsdist.0

lsdist.0: 25 destinations, 37 routes (25 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

Meaning

- In the `show route table lsdist.0` output, BGP advertises the routes in the routing table. The routing table is created from the TE database. You can see the express segments (**EXPRESS-SEG/6**) links and the EPE links (**BGP-LS-EPE:0 }/1216**).
- In the `show route advertising-protocol bgp 2.2.2.2` output, you can see what R1 is advertising to. The express segments are inserted into the TE database, which is copied to RIB. BGP-LS advertises the RIB to the peer router. On the peer, the received RIB information is copied into the local database. The policy in this example only advertises express segments and EPE segments.

Verify the TE Topology Information

Purpose

Verify that the ingress nodes receive TE topology information through eBGP/iBGP LS.

Action

From operational mode, run the following commands:

- `show route receive-protocol bgp` *neighbor*—Verify that the express segments are received from eBGP/iBGP LS neighbors.
- `show route table lsdist.0`—Verify that the express segments are in the BGP-LS RIB.
- `show ted database topology-type l3-unicast detail`—Verify that the express segments are imported into the ingress router's TE database.

- `show spring-traffic-engineering lsp`—Verify that the end-to-end SR policy has been successfully computed and installed.

On R0

```
user@R0>show route receive-protocol bgp 192.168.1.2

```

Meaning

- In the `show route receive-protocol bgp 1.1.1.1` output, it shows the routes that have been received by the ingress router (R0) from the BGP neighbor, which describes the express segment (virtual TE links).
- In the `show route table lsdist.0` output, it shows the routes that have been received by the ingress router (R0) and whether they are inserted into the **lsdist.0** RIB. It also shows whether the **lsdist.0** RIB is copied into the local TE database.
- In the `show ted database topology-type l3-unicast detail` output, the routes are copied into the local TE database. The **r1-exp-set1-6.6.6.6** is an express segment with end point as 6.6.6.6 and is sucessfully created on R1. R1 has advertised the express segment and R0 has inserted it into the local TE database. You can also see the EPE segments (**epe_adj1_toR7**).
- In the `show spring-traffic-engineering lsp` output, you can see that the SR policies are up. It shows that you are now able to compute a multi-domain end-to-end (R0 to R7) SR policy.
- In the `show spring-traffic-engineering lsp detail` output, you can see the labels that are selected. In the **computelsp1** LSP, the label **7104** is an EPE segment, **21** is the express segment, and **7167** is also an EPE segment. It shows that you are now able to compute a multi-domain end-to-end (R0 to R7) SR policy.

Example: Inter-domain SR-TE Connectivity Using Express Segments Through SR-TE Underlay

IN THIS SECTION

- Requirements | 1004
- Overview | 1004
- Configuration | 1009
- Verification | 1155

Use this example to learn how to establish an end-to-end inter-domain SR-TE connectivity using express segments through SR-TE underlay.

Requirements

This example uses the following hardware and software components:

- MX Series routers as provider edge, border nodes, and intermediate routers.
- Junos OS Release 21.2R1 or later releases.

Overview

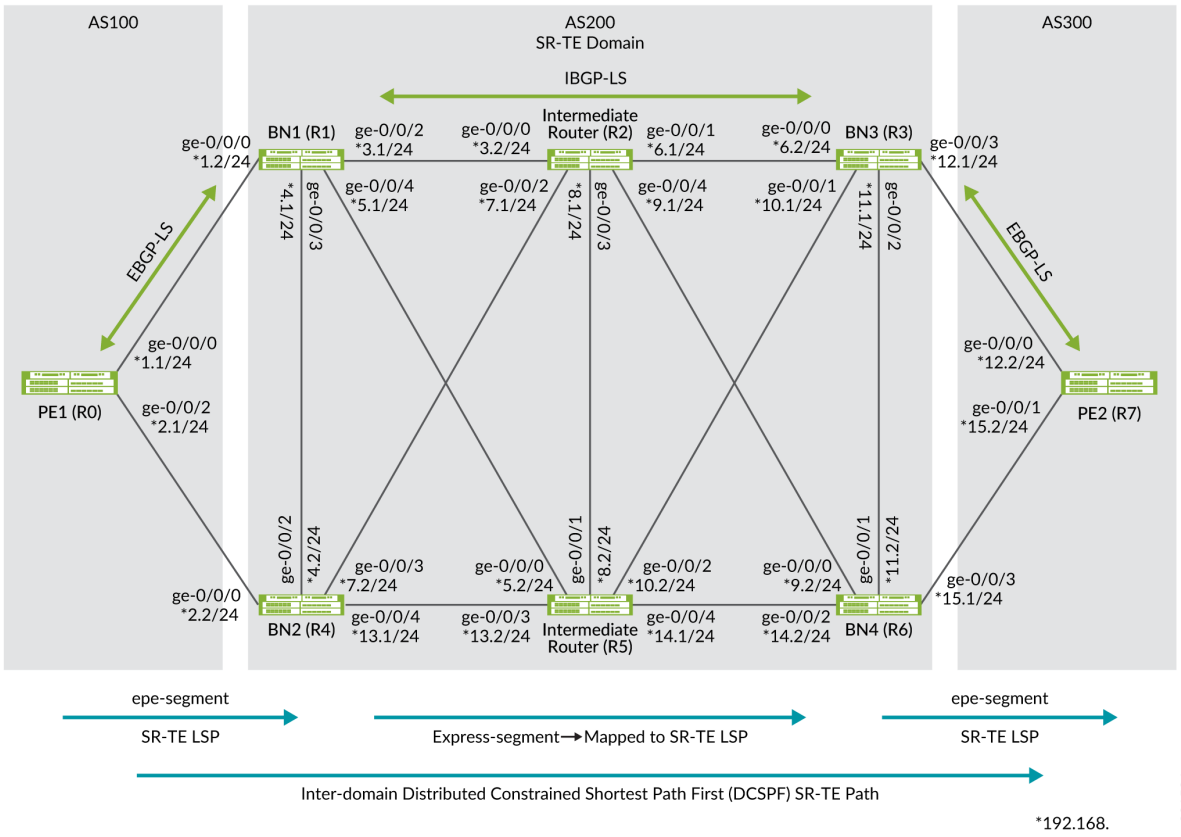
IN THIS SECTION

- Topology | 1005

The following topology (Figure 64 on page 1005) shows two SR-TE domains (AS100 and AS300) running EBGP-LS inter-connected through another SR-TE (AS200) domain:

Topology

Figure 64: Inter-domain SR-TE Connectivity Using Express Segments Through SR-TE Underlay



In this topology, an end-to-end SR-TE path between PE1 router to PE2 router is established. Egress peer engineering (EPE) segments are defined on PE1 and PE2 routers to steer traffic towards their directly connected border nodes BN1/BN2 and BN3/BN4, respectively. EPE segments defined on the border nodes are advertised internally through the BGP link state. These two SR-TE domains are interconnected through the domain (AS200) that is leveraging SR-TE LSPs for internal path establishment.

The border nodes of the AS200 domain facilitate the abstraction of SR-TE information between domains. Express segments are created on border nodes (BN1, BN2, BN3, and BN4). Express segments are created in a one-on-one relationship with the underlying SR-TE LSPs and all express segments are inserted into the border node's local TE database for subsequent BGP link-state advertisement. The AS200 domain leverages SR-TE LSP underlays for TE management and presents those underlay SR-TE LSPs as express segments to the AS100 and the AS300 domains, enabling the domains to have end-to-end SR-TE LSP connectivity.

The following table describes the domains, routers, and connections in the topology:

Table 22: Describes the domains, routers, and connections in the Topology

Domain	Devices	Router ID/Lo) Address	Connection Details
AS100 (EBGP-LS/ SR-TE LSP)	R0 (PE1 router)	100.100.100.100 100.100.100.101	Connected to R1 (BN1 router) through interface ge-0/0/0, assigned IP address 192.168.1.1/24. Connected to R4 (BN2 router) through interface ge-0/0/2, assigned IP address 192.168.2.1/24.
AS200 (SR-TE LSP)	R1 (BN1 router)	1.1.1.1	Connected to R0 (PE1 router) through interface ge-0/0/0, assigned IP address 192.168.1.2/24. Connected to R4 (BN2 router) through interface ge-0/0/3, assigned IP address 192.168.4.1/24. Connected to R2 (Intermediate router) through interface ge-0/0/2, assigned IP address 192.168.3.1/24. Connected to R5 (Intermediate router) through interface ge-0/0/4, assigned IP address 192.168.5.1/24.
	R4(BN2 router)	4.4.4.4	Connected to R0 (PE1 router) through interface ge-0/0/0, assigned IP address 192.168.2.2/24. Connected to R1 (BN1 router) through interface ge-0/0/2, assigned IP address 192.168.4.2/24. Connected to R2 (Intermediate router) through interface ge-0/0/3, assigned IP address 192.168.7.1/24. Connected to R5 (Intermediate router) through interface ge-0/0/4, assigned IP address 192.168.13.1/24.

Table 22: Describes the domains, routers, and connections in the Topology *(Continued)*

Domain	Devices	Router ID/Lo) Address	Connection Details
	R2(Intermediate router)	2.2.2.2	Connected to R1 (BN1 router) through interface ge-0/0/0, assigned IP address 192.168.3.2/24. Connected to R4 (BN2 router) through interface ge-0/0/2, assigned IP address 192.168.7.1/24. Connected to R5 (Intermediate router) through interface ge-0/0/3, assigned IP address 192.168.8.1/24. Connected to R3 (BN3 router) through interface ge-0/0/1, assigned IP address 192.168.6.1/24. Connected to R6 (BN4 router) through interface ge-0/0/4, assigned IP address 192.168.9.1/24.
	R5 (Intermediate router)	5.5.5.5	Connected to R1 (BN1 router) through interface ge-0/0/0, assigned IP address 192.168.5.2/24. Connected to R4 (BN2 router) through interface ge-0/0/3, assigned IP address 192.168.13.2/24. Connected to R2 (Intermediate router) through interface ge-0/0/1, assigned IP address 192.168.8.2/24. Connected to R3 (BN3 router) through interface ge-0/0/2, assigned IP address 192.168.10.2/24. Connected to R6 (BN4 router) through interface ge-0/0/4, assigned IP address 192.168.14.1/24.

Table 22: Describes the domains, routers, and connections in the Topology *(Continued)*

Domain	Devices	Router ID/Lo) Address	Connection Details
	R3 (BN3 router)	3.3.3.3	Connected to R7 (PE2 router) through interface ge-0/0/3, assigned IP address 192.168.12.1/24. Connected to R6 (BN4 router) through interface ge-0/0/2, assigned IP address 192.168.11.1/24. Connected to R2 (Intermediate router) through interface ge-0/0/0, assigned IP address 192.168.6.2/24. Connected to R5 (Intermediate router) through interface ge-0/0/1, assigned IP address 192.168.10.1/24.
	R6 (BN4 router)	6.6.6.6	Connected to R7 (PE2 router) through interface ge-0/0/3, assigned IP address 192.168.15.1/24. Connected to R3 (BN3 router) through interface ge-0/0/1, assigned IP address 192.168.11.2/24. Connected to R2 (Intermediate router) through interface ge-0/0/0, assigned IP address 192.168.9.2/24. Connected to R5 (Intermediate router) through interface ge-0/0/2, assigned IP address 192.168.14.2/24.
AS300 (EBGP-LS/SR-TE LSP)	R7 (PE2 router)	7.7.7.7	Connected to R3 (BN3 router) through interface ge-0/0/0, assigned IP address 192.168.12.2/24. Connected to R6 (BN4 router) through interface ge-0/0/1, assigned IP address 192.168.15.2/24.

Configuration

IN THIS SECTION

- CLI Quick Configuration | **1009**
- Configure R0 (PE1 router) | **1037**
- Configure R1 (BN1 router) | **1049**
- Configure R4 (BN2 router) | **1066**
- Configure R2 (Intermediate router) | **1081**
- Configure R5 (Intermediate router) | **1095**
- Configure R3 (BN3 router) | **1109**
- Configure R6 (BN4 router) | **1127**
- Configure R7 (PE2 router) | **1142**

To inter-connect a multi-domain network and establish an end-to-end SR path using express segments, perform these tasks:

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the `[edit]` hierarchy level, and then enter `commit` from configuration mode.

The quick configuration commands provided below can be used to configure express segments through uncolored SR-TE underlay path.

To configure colored SR-TE underlay path, you must do additional configurations on BN1 (R1), BN2 (R4), BN3 (R3), and BN4 (R6) routers. Below are the uncolored configurations for N1 (R1), BN2 (R4), BN3 (R3), and BN4 (R6) routers, you can find the additional colored configuration.

Configure R0 (PE1 router)

Configure R0 (PE1 router)

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see Using the CLI Editor in Configuration Mode in the CLI User Guide.

To configure device R0:

1. Configure the network services mode as Enhanced IP. Enhanced IP sets the router's network services to enhanced Internet Protocol and uses enhanced mode capabilities.

```
[edit]
user@R0#set chassis network-services enhanced-ip
```

After you configure the `enhanced-ip` statement and commit the configuration, the following warning message appears prompting you to reboot the router:

```
'chassis'
WARNING: Chassis configuration for network services has been changed. A system reboot is
mandatory. Please reboot the system NOW. Continuing without a reboot might result in
unexpected system behavior.
commit complete
```

The reboot brings up the FPCs on the router.

2. Configure the interfaces to enable IP, MPLS, and ISO transport.

```
[edit]
user@R0#set interfaces ge-0/0/0 description To_R1_1
user@R0#set interfaces ge-0/0/0 vlan-tagging
user@R0#set interfaces ge-0/0/0 unit 0 vlan-id 1
user@R0#set interfaces ge-0/0/0 unit 0 family inet address 192.168.1.1/24
user@R0#set interfaces ge-0/0/0 unit 0 family iso
user@R0#set interfaces ge-0/0/0 unit 0 family inet6 address 1000:10::100/64
user@R0#set interfaces ge-0/0/0 unit 0 family mpls maximum-labels 8
user@R0#set interfaces ge-0/0/2 description To_R4_1
user@R0#set interfaces ge-0/0/2 vlan-tagging
user@R0#set interfaces ge-0/0/2 unit 0 vlan-id 1
user@R0#set interfaces ge-0/0/2 unit 0 family inet address 192.168.2.1/24
user@R0#set interfaces ge-0/0/2 unit 0 family iso
user@R0#set interfaces ge-0/0/2 unit 0 family inet6 address 4000:10::100/64
user@R0#set interfaces ge-0/0/2 unit 0 family mpls maximum-labels 8
```

3. Configure the loopback interface to enable tunnel endpoints and service endpoints.

```
[edit]
user@R0#set interfaces lo0 unit 0 family inet address 100.100.100.100/32
user@R0#set interfaces lo0 unit 0 family inet address 100.100.100.101/32
```

```
user@R0#set interfaces lo0 unit 0 family iso address 49.0001.000a.0a0a.0a00
user@R0#set interfaces lo0 unit 0 family inet6 address abcd::100:100:100:100/128
```

4. Define import and export policies. For example, configure policies that export EPE TE links from the local TE database to **lsdist.0** and policies to import from **lsdist.0** into the local TE database. You can configure policies to advertise the BGP routes to a peer.

   Route filter routs are advertised from external AS.

```
[edit]
user@R0#set policy-options policy-statement bgplsepe_rt_2_ted term 1 from protocol bgp
user@R0#set policy-options policy-statement bgplsepe_rt_2_ted term 1 then accept

user@R0#set policy-options policy-statement vpn1_res_map1 then resolution-map map1
user@R0#set policy-options policy-statement vpn2_res_map1 from route-filter 110.0.0.1/16
orlonger
user@R0#set policy-options policy-statement vpn2_res_map1 then accept
user@R0#set policy-options policy-statement vpn2_res_map1 then resolution-map map1
```

5. Configure policy-options of community to add color attributes and set resolution map.

```
[edit]
user@R0#set policy-options community color7000 members color:0:7000
user@R0#set policy-options community color7001 members color:0:7001
user@R0#set policy-options resolution-map map1 mode ip-color
```

6. Configure routing options to identify the router in the domain.

```
[edit]
user@R0#set routing-options router-id 100.100.100.100
user@R0#set routing-options autonomous-system 100
user@R0#set routing-options static route 7.7.7.71/32 next-hop 7.7.7.7
user@R0#set routing-options static route 7.7.7.71/32 resolve
```

7. Configure BGP to enable BGP-LS route advertisement to the connected peers and define the EPE links. Since express segment is an internal TE link, this configuration creates an external TE link.

```

Results

From configuration mode, confirm your configuration by entering the `show chassis`, `show interfaces`, `show policy-optionsshow routing-options`, and `show protocols` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

Configure R1 (BN1 router)

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see Using the CLI Editor in Configuration Mode in the CLI User Guide.

To configure device R1:

1. Configure the network services mode as Enhanced IP. Enhanced IP sets the router's network services to enhanced Internet Protocol and uses enhanced mode capabilities.

```
[edit]
user@R1#set chassis network-services enhanced-ip
```

After you configure the `enhanced-ip` statement and commit the configuration, the following warning message appears prompting you to reboot the router:

```
'chassis'
WARNING: Chassis configuration for network services has been changed. A system reboot is
mandatory. Please reboot the system NOW. Continuing without a reboot might result in
unexpected system behavior.
commit complete
```

The reboot brings up the FPCs on the router.

2. Configure the interfaces to enable IP, MPLS, and ISO transport.

```
[edit]
user@R1#set interfaces ge-0/0/0 description To_R0_1

user@R1#set interfaces ge-0/0/4 unit 1 family mpls maximum-labels 8
```

3. Configure the loopback interface to enable tunnel endpoints and service endpoints.

```
[edit]
user@R1#set interfaces lo0 unit 0 family inet address 1.1.1.1/32
user@R1#set interfaces lo0 unit 0 family iso address 49.0001.0001.0101.0100
user@R1#set interfaces lo0 unit 0 family inet6 address abcd::01:01:01:01/128
```

4. Define import and export policies. For example, configure policies that export EPE TE links from the local TE database to lsdist.0 and policies to import from lsdist.0 into the local TE database. You can configure policies to advertise the BGP routes to a peer.

```

```

5. Configure routing options to identify the router in the domain.

```
[edit]
user@R1#set routing-options router-id 1.1.1.1
user@R1#set routing-options autonomous-system 200
```

6. Define the RIB group to copy inetcolor.0 to inet.3 routing table.

```
[edit]
user@R1#set routing-options rib-groups color-to-inet3 import-rib [ inetcolor.0 inet.3 ]
```

7. Configure BGP to enable BGP-LS route advertisement to the connected peers and define the EPE links. Since express segment is an internal TE link, this configuration creates an external TE link.

```
[edit]
user@R1#set protocols bgp group ebgp1 type external
user@R1#set protocols bgp group ebgp1 family inet-vpn unicast
user@R1#set protocols bgp group ebgp1 family traffic-engineering unicast

```

Results

From configuration mode, confirm your configuration by entering the `show chassis`, `show interfaces`, `show policy-options`, `show routing-options`, and `show protocols` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

The following result includes colored SR-TE underlay path configuration also.

```
chassis {
    network-services enhanced-ip;
}
interfaces {
    ge-0/0/0 {

```

Configure R4 (BN2 router)

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see Using the CLI Editor in Configuration Mode in the CLI User Guide.

To configure device R4:

1. Configure the network services mode as Enhanced IP. Enhanced IP sets the router's network services to enhanced Internet Protocol and uses enhanced mode capabilities.

```
[edit]
user@R4#set chassis network-services enhanced-ip
```

After you configure the `enhanced-ip` statement and commit the configuration, the following warning message appears prompting you to reboot the router:

```
'chassis'
WARNING: Chassis configuration for network services has been changed. A system reboot is
mandatory. Please reboot the system NOW. Continuing without a reboot might result in
unexpected system behavior.
commit complete
```

The reboot brings up the FPCs on the router.

2. Configure the interfaces to enable IP, MPLS, and ISO transport.

```
[edit]
user@R4#set interfaces ge-0/0/0 description To_R0
```

```
user@R4#set interfaces ge-0/0/0 vlan-tagging
user@R4#set interfaces ge-0/0/0 unit 0 vlan-id 1
user@R4#set interfaces ge-0/0/0 unit 0 family inet address 192.168.12.1192.168.2.2/24
user@R4#set interfaces ge-0/0/0 unit 0 family iso
user@R4#set interfaces ge-0/0/0 unit 0 family inet6 address 4000:10::4/64

user@R4#set interfaces ge-0/0/4 unit 1 family inet6 address 4500:20::4/64
user@R4#set interfaces ge-0/0/4 unit 1 family mpls maximum-labels 8
```

3. Configure the loopback interface to enable tunnel endpoints and service endpoints.

```
[edit]
user@R4#set interfaces lo0 unit 0 family inet address 4.4.4.4/32
user@R4#set interfaces lo0 unit 0 family iso address 49.0001.0004.0404.0400
user@R4#set interfaces lo0 unit 0 family inet6 address abcd::04:04:04:04/128
```

4. Define import and export policies. For example, configure policies that export EPE TE links from the local TE database to **lsdist.0** and policies to import from **lsdist.0** into the local TE database. You can configure policies to advertise the BGP routes to a peer.

```
[edit]
user@R4#set policy-options policy-statement expresspolsr1 from protocol spring-te
user@R4#set policy-options policy-statement expresspolsr1 from route-filter 6.6.6.6/32 exact
user@R4#set policy-options policy-statement expresspolsr1 then accept
user@R4#set policy-options policy-statement nlri2bgp_epe term 1 from family traffic-
engineering
user@R4#set policy-options policy-statement nlri2bgp_epe term 1 from protocol bgp-ls-epe
user@R4#set policy-options policy-statement nlri2bgp_epe term 1 then next-hop self
user@R4#set policy-options policy-statement nlri2bgp_epe term 1 then accept
user@R4#set policy-options policy-statement nlri2bgp_stat term 1 from family traffic-
engineering
user@R4#set policy-options policy-statement nlri2bgp_stat term 1 from protocol express-
segments
user@R4#set policy-options policy-statement nlri2bgp_stat term 1 then accept
user@R4#set policy-options policy-statement pplb then load-balance per-packet
user@R4#set policy-options policy-statement prefix-sid term 1 from route-filter 4.4.4.4/32
exact
user@R4#set policy-options policy-statement prefix-sid term 1 then prefix-segment index 1004
user@R4#set policy-options policy-statement prefix-sid term 1 then prefix-segment node-
segment
user@R4#set policy-options policy-statement ted2nlri_epe_stat term 1 from family traffic-
engineering
user@R4#set policy-options policy-statement ted2nlri_epe_stat term 1 from protocol express-
segments
user@R4#set policy-options policy-statement ted2nlri_epe_stat term 1 then accept
user@R4#set policy-options policy-statement ted2nlri_epe_stat term 2 from family traffic-
engineering
user@R4#set policy-options policy-statement ted2nlri_epe_stat term 2 from protocol bgp-ls-
epe
user@R4#set policy-options policy-statement ted2nlri_epe_stat term 2 then accept
```

```
user@R4#set policy-options policy-statement ted2nlri_epe_stat term 3 from protocol isis
user@R4#set policy-options policy-statement ted2nlri_epe_stat term 3 then reject
```

5. Configure routing options to identify the router in the domain.

```
[edit]
user@R4#set routing-options router-id 4.4.4.4
user@R4#set routing-options autonomous-system 200
```

6. Define the RIB group to copy inetcolor.0 to inet.3 routing table.

```
[edit]
user@R4#set routing-options rib-groups color-to-inet3 import-rib [ inetcolor.0 inet.3 ]
```

7. Configure BGP to enable BGP-LS route advertisement to the connected peers and define the EPE links. Since express segment is an internal TE link, this configuration creates an external TE link.

```
[edit]
user@R4#set protocols bgp group ibgp1 type internal
user@R4set protocols bgp group ibgp1 local-address 4.4.4.4
user@R4set protocols bgp group ibgp1 family traffic-engineering unicast
user@R4set protocols bgp group ibgp1 export nlri2bgp_epe

user@R4#set protocols isis backup-spf-options use-source-packet-routing
user@R4#set protocols isis traffic-engineering l3-unicast-topology
user@R4#set protocols isis traffic-engineering advertisement always
user@R4#set protocols isis export prefix-sid
```

10. Enable import and export of traffic engineering database parameters using policies.

```
[edit]
user@R4#set protocols mpls traffic-engineering database import l3-unicast-topology bgp-link-state
user@R4#set protocols mpls traffic-engineering database import policy ted2nlri_epe_stat
user@R4#set protocols mpls traffic-engineering database export l3-unicast-topology
```

11. Configure MPLS administrative group policies for LSP path computation.

```
[edit]
user@R4#set protocols mpls admin-groups red 0
user@R4#set protocols mpls admin-groups blue 1
user@R4#set protocols mpls admin-groups green 2
user@R4#set protocols mpls admin-groups yellow 3
user@R4#set protocols mpls admin-groups orange 4
user@R4#set protocols mpls admin-groups brown 5
user@R4#set protocols mpls admin-groups black 6
user@R4#set protocols mpls admin-groups pink 7
```

12. Configure the MPLS label range to assign static labels for the EPE links.

```
[edit]
user@R4#set protocols mpls label-range static-label-range 1000 70000
```

13. Configure MPLS with interface and include administrative groups.

```
[edit]
user@R4#set protocols mpls interface ge-0/0/2.0 admin-group red
user@R4#set protocols mpls interface ge-0/0/3.0 admin-group green
user@R4#set protocols mpls interface ge-0/0/4.0 admin-group brown
user@R4#set protocols mpls interface all
user@R4#set protocols mpls interface fxp0.0 disable
```

14. Configure ST-TE LSP from R4 device to R6 device..

```
[edit]
user@R4#set protocols source-packet-routing no-chained-composite-next-hop
```

```
user@R4#set protocols source-packet-routing segment-list R4-R5-R6 hop1 label 4511
user@R4#set protocols source-packet-routing segment-list R4-R5-R6 hop2 label 5601

user@R4#set protocols source-packet-routing source-routing-path lsp4to6_sr color 1000
user@R4#set protocols source-packet-routing source-routing-path lsp4to6_sr primary R4-R5-R6
user@R4#set protocols source-packet-routing rib-group ipv4-color color-to-inet3
```

Results

From configuration mode, confirm your configuration by entering the `show chassis`, `show interfaces`, `show policy-options`, `show routing-options`, and `show protocols` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

The following result includes colored SR-TE underlay path configuration also.

```
chassis {
    network-services enhanced-ip;
}
interfaces {
    ge-0/0/0 {
        description To_R0;
        vlan-tagging;
        unit 0 {

```

Configure R2 (Intermediate router)

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see Using the CLI Editor in Configuration Mode in the CLI User Guide.

To configure device R2:

1. Configure the network services mode as Enhanced IP. Enhanced IP sets the router's network services to enhanced Internet Protocol and uses enhanced mode capabilities.

   ```
   [edit]
   user@R2#set chassis network-services enhanced-ip
   ```

   After you configure the `enhanced-ip` statement and commit the configuration, the following warning message appears prompting you to reboot the router:

   ```
   'chassis'
   WARNING: Chassis configuration for network services has been changed. A system reboot is
   mandatory. Please reboot the system NOW. Continuing without a reboot might result in
   unexpected system behavior.
   commit complete
   ```

   The reboot brings up the FPCs on the router.

2. Configure the interfaces to enable IP, MPLS, and ISO transport.

   ```
   user@R2#set interfaces ge-0/0/0 description To_R1
   user@R2#set interfaces ge-0/0/0 vlan-tagging
   user@R2#set interfaces ge-0/0/0 unit 0 vlan-id 1
   user@R2#set interfaces ge-0/0/0 unit 0 family inet address 192.168.3.2/24
   user@R2#set interfaces ge-0/0/0 unit 0 family iso
   user@R2#set interfaces ge-0/0/0 unit 0 family inet6 address 1200:10::2/64
   ```

```
user@R2#set interfaces ge-0/0/0 unit 0 family mpls maximum-labels 8
user@R2#set interfaces ge-0/0/0 vlan-tagging
user@R2#set interfaces ge-0/0/0 unit 1 vlan-id 2
user@R2#set interfaces ge-0/0/0 unit 1 family inet address 192.168.21.2/24
user@R2#set interfaces ge-0/0/0 unit 1 family iso
user@R2#set interfaces ge-0/0/0 unit 1 family inet6 address 1200:20::2/64
user@R2#set interfaces ge-0/0/0 unit 1 family mpls maximum-labels 8

user@R2#set interfaces ge-0/0/2 unit 1 family mpls maximum-labels 8
user@R2#set interfaces ge-0/0/3 description To_R5
user@R2#set interfaces ge-0/0/3 vlan-tagging
user@R2#set interfaces ge-0/0/3 unit 0 vlan-id 1
user@R2#set interfaces ge-0/0/3 unit 0 family inet address 192.168.8.1/24
user@R2#set interfaces ge-0/0/3 unit 0 family iso
user@R2#set interfaces ge-0/0/3 unit 0 family inet6 address 2500:10::2/64
user@R2#set interfaces ge-0/0/3 unit 0 family mpls maximum-labels 8
user@R2#set interfaces ge-0/0/4 description To_R6
user@R2#set interfaces ge-0/0/4 vlan-tagging
user@R2#set interfaces ge-0/0/4 unit 0 vlan-id 1
user@R2#set interfaces ge-0/0/4 unit 0 family inet address 192.168.9.1/24
user@R2#set interfaces ge-0/0/4 unit 0 family iso
```

```
user@R2#set interfaces ge-0/0/4 unit 0 family inet6 address 2600:10::2/64
user@R2#set interfaces ge-0/0/4 unit 0 family mpls maximum-labels 8
user@R2#set interfaces ge-0/0/4 unit 1 vlan-id 2
user@R2#set interfaces ge-0/0/4 unit 1 family inet address 192.168.26.1/24
user@R2#set interfaces ge-0/0/4 unit 1 family iso
user@R2#set interfaces ge-0/0/4 unit 1 family inet6 address 2600:20::2/64
user@R2#set interfaces ge-0/0/4 unit 1 family mpls maximum-labels 8
```

3. Configure the loopback interface to enable tunnel endpoints and service endpoints.

```
[edit]
user@R2#set interfaces lo0 unit 0 family inet address 2.2.2.2/32
user@R2#set interfaces lo0 unit 0 family iso address 49.0001.0002.0202.0200
user@R2#set interfaces lo0 unit 0 family inet6 address abcd::02:02:02:02/128
```

4. Define import and export policies. For example, configure policies that export EPE TE links from the local TE database to **lsdist.0** and policies to import from **lsdist.0** into the local TE database. You can configure policies to advertise the BGP routes to a peer.

```
[edit]
user@R2#set policy-options policy-statement bgplsepe_rt_2_ted term 1 from protocol bgp
user@R2#set policy-options policy-statement bgplsepe_rt_2_ted term 1 then accept
user@R2#set policy-options policy-statement nlri2bgp term 1 from family traffic-engineering
user@R2#set policy-options policy-statement nlri2bgp term 1 then next-hop self
user@R2#set policy-options policy-statement nlri2bgp term 1 then accept
user@R2#set policy-options policy-statement nlri2bgp_igp term 1 from family traffic-
engineering
user@R2#set policy-options policy-statement nlri2bgp_igp term 1 from protocol isis
user@R2#set policy-options policy-statement nlri2bgp_igp term 1 then accept
user@R2#set policy-options policy-statement nlri2ted_igp term 1 from traffic-engineering
protocol isis-level-2
user@R2#set policy-options policy-statement nlri2ted_igp term 1 then accept
user@R2#set policy-options policy-statement pplb then load-balance per-packet
user@R2#set policy-options policy-statement prefix-sid term 1 from route-filter 2.2.2.2/32
exact
user@R2#set policy-options policy-statement prefix-sid term 1 then prefix-segment index 1002
user@R2#set policy-options policy-statement prefix-sid term 1 then prefix-segment node-
segment
user@R2#set policy-options policy-statement ted2nlri term 1 from protocol bgp-ls-epe
user@R2#set policy-options policy-statement ted2nlri term 1 then accept
user@R2#set policy-options policy-statement ted2nlri_1 term 1 from traffic-engineering
```

```
user@R2#set policy-options policy-statement ted2nlri_1 term 1 then accept
user@R2#set policy-options policy-statement ted2nlri_igp term 1 from family traffic-
engineering
user@R2#set policy-options policy-statement ted2nlri_igp term 1 from protocol isis
user@R2#set policy-options policy-statement ted2nlri_igp term 1 then accept
```

5. Configure routing options to identify the router in the domain.

```
[edit]
user@R2#set routing-options router-id 2.2.2.2
user@R2#set routing-options autonomous-system 200user@R2#set routing-options forwarding-
table export pplb
```

6. Configure BGP to enable BGP-LS route advertisement to the connected peers.

```
[edit]

user@R2#set protocols mpls interface ge-0/0/1.0 admin-group brown
user@R2#set protocols mpls interface all
user@R2#set protocols mpls interface fxp0.0 disable
```

Results

From configuration mode, confirm your configuration by entering the `show chassis`, `show interfaces`, `show policy-options`, `show routing-options`, and `show protocols` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

    }
}
```

Configure R5 (Intermediate router)

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see Using the CLI Editor in Configuration Mode in the CLI User Guide.

To configure device R5:

1. Configure the network services mode as Enhanced IP. Enhanced IP sets the router's network services to enhanced Internet Protocol and uses enhanced mode capabilities.

```
[edit]
user@R5#set chassis network-services enhanced-ip
```

After you configure the `enhanced-ip` statement and commit the configuration, the following warning message appears prompting you to reboot the router:

```
'chassis'
WARNING: Chassis configuration for network services has been changed. A system reboot is
mandatory. Please reboot the system NOW. Continuing without a reboot might result in
unexpected system behavior.
commit complete
```

The reboot brings up the FPCs on the router.

2. Configure the interfaces to enable IP, MPLS, and ISO transport.

```
user@R5#set interfaces ge-0/0/0 description To_R1
user@R5#set interfaces ge-0/0/0 vlan-tagging
user@R5#set interfaces ge-0/0/0 unit 0 vlan-id 1

user@R5#set interfaces ge-0/0/3 unit 1 family mpls maximum-labels 8
user@R5#set interfaces ge-0/0/4 description To_R6
user@R5#set interfaces ge-0/0/4 vlan-tagging
user@R5#set interfaces ge-0/0/4 unit 0 vlan-id 1
user@R5#set interfaces ge-0/0/4 unit 0 family inet address 192.168.14.1/24
user@R5#set interfaces ge-0/0/4 unit 0 family iso
user@R5#set interfaces ge-0/0/4 unit 0 family inet6 address 5600:10::5/64
user@R5#set interfaces ge-0/0/4 unit 0 family mpls maximum-labels 8
user@R5#set interfaces ge-0/0/4 unit 1 vlan-id 2
user@R5#set interfaces ge-0/0/4 unit 1 family inet address 192.168.56.1/24
user@R5#set interfaces ge-0/0/4 unit 1 family iso
user@R5#set interfaces ge-0/0/4 unit 1 family inet6 address 5600:20::5/64
user@R5#set interfaces ge-0/0/4 unit 1 family mpls maximum-labels 8
```

3. Configure the loopback interface to enable tunnel endpoints and service endpoints.

```
[edit]
user@R5#set interfaces lo0 unit 0 family inet address 5.5.5.5/32
user@R5#set interfaces lo0 unit 0 family iso address 49.0001.0005.0505.0500
user@R5#set interfaces lo0 unit 0 family inet6 address abcd::05:05:05:05/128
```

4. Define import and export policies. For example, configure policies that export EPE TE links from the local TE database to **lsdist.0** and policies to import from **lsdist.0** into the local TE database. You can configure policies to advertise the BGP routes to a peer.

```
[edit]
user@R5#set policy-options policy-statement nlri2bgp term 1 from family traffic-engineering
user@R5#set policy-options policy-statement nlri2bgp term 1 then next-hop self
user@R5#set policy-options policy-statement nlri2bgp term 1 then accept
user@R5#set policy-options policy-statement nlri2ted_igp term 1 from traffic-engineering
protocol isis-level-2
user@R5#set policy-options policy-statement nlri2ted_igp term 1 then accept
user@R5#set policy-options policy-statement pplb then load-balance per-packet
user@R5#set policy-options policy-statement prefix-sid term 1 from route-filter 5.5.5.5/32
exact
user@R5#set policy-options policy-statement prefix-sid term 1 then prefix-segment index 1005
user@R5#set policy-options policy-statement prefix-sid term 1 then prefix-segment node-
segment
user@R5#set policy-options policy-statement ted2nlri term 1 from protocol bgp-ls-epe
user@R5#set policy-options policy-statement ted2nlri term 1 then accept
user@R5#set policy-options policy-statement ted2nlri_igp term 1 from family traffic-
engineering
user@R5#set policy-options policy-statement ted2nlri_igp term 1 from protocol isis
user@R5#set policy-options policy-statement ted2nlri_igp term 1 then accept
```

5. Configure routing options to identify the router in the domain.

```
[edit]
user@R5#set routing-options router-id 5.5.5.5
user@R5#set routing-options autonomous-system 200
```

6. Define export policies for forwarding table.

```
[edit]
user@R5#set routing-options forwarding-table export pplb
```

7. Configure BGP to enable BGP-LS route advertisement to the connected peers.

```
[edit]
user@R5#set protocols bgp group RR2 type internal
```

```
user@R5#set protocols bgp group RR2 family inet unicast
user@R5#set protocols bgp group RR2 family traffic-engineering unicast
user@R5#set protocols bgp group RR2 neighbor 1.1.1.1
user@R5#set protocols bgp group RR2 neighbor 3.3.3.3
user@R5#set protocols bgp group RR2 neighbor 6.6.6.6
user@R5#set protocols bgp group RR2 neighbor 4.4.4.4
user@R5#set protocols bgp cluster 5.5.5.5
```

8. Configure IS-IS protocol on the interfaces.

```
[edit]
user@R5#set protocols isis interface ge-0/0/0.0 level 2 lan-neighbor 0100.0101.0101 ipv4-
adjacency-segment protected label 5111
user@R5#set protocols isis interface ge-0/0/0.0 level 2 lan-neighbor 0100.0101.0101 ipv4-
adjacency-segment unprotected label 5101

user@R5#set protocols isis interface ge-0/0/2.0 level 2 post-convergence-lfa node-protection
user@R5#set protocols isis interface ge-0/0/3.0 level 2 lan-neighbor 0100.0404.0404 ipv4-
adjacency-segment protected label 5411
user@R5#set protocols isis interface ge-0/0/3.0 level 2 lan-neighbor 0100.0404.0404 ipv4-
adjacency-segment unprotected label 5401
user@R5#set protocols isis interface ge-0/0/3.0 level 2 post-convergence-lfa node-protection
user@R5#set protocols isis interface ge-0/0/4.0 level 2 lan-neighbor 0100.0606.0606 ipv4-
adjacency-segment protected label 5611
user@R5#set protocols isis interface ge-0/0/4.0 level 2 lan-neighbor 0100.0606.0606 ipv4-
adjacency-segment unprotected label 5601
user@R5#set protocols isis interface ge-0/0/4.0 level 2 post-convergence-lfa node-protection
user@R5#set protocols isis interface fxp0.0 disable
user@R5#set protocols isis interface lo0.0 passive
user@R5#set protocols isis source-packet-routing srgb start-label 800000 index-range 50000
user@R5#set protocols isis level 1 disable
```

```
user@R5#set protocols isis backup-spf-options use-post-convergence-lfa
user@R5#set protocols isis backup-spf-options use-source-packet-routing
user@R5#set protocols isis traffic-engineering l3-unicast-topology
user@R5#set protocols isis traffic-engineering advertisement always
user@R5#set protocols isis export prefix-sid
```

9. Configure MPLS administrative group policies for LSP path computation.

```
[edit]
user@R5#set protocols mpls admin-groups red 0
user@R5#set protocols mpls admin-groups blue 1
user@R5#set protocols mpls admin-groups green 2
user@R5#set protocols mpls admin-groups yellow 3
user@R5#set protocols mpls admin-groups orange 4
user@R5#set protocols mpls admin-groups brown 5
user@R5#set protocols mpls admin-groups black 6
user@R5#set protocols mpls admin-groups pink 7
```

10. Configure the MPLS label range to assign static labels for the EPE links.

```
[edit]
user@R5#set protocols mpls label-range static-label-range 1000 70000
```

11. Configure MPLS with interface and include administrative groups

```
[edit]
user@R5#set protocols mpls interface ge-0/0/0.0 admin-group blue
user@R5#set protocols mpls interface ge-0/0/1.0 admin-group red
user@R5#set protocols mpls interface ge-0/0/2.0 admin-group green
user@R5#set protocols mpls interface ge-0/0/3.0 admin-group brown
```

Results

From configuration mode, confirm your configuration by entering the `show chassis`, `show interfaces`, `show policy-options`, `show routing-options`, and `show protocols` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

```

Configure R3 (BN3 router)

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see Using the CLI Editor in Configuration Mode in the CLI User Guide.

To configure device R3:

1. Configure the network services mode as Enhanced IP. Enhanced IP sets the router's network services to enhanced Internet Protocol and uses enhanced mode capabilities.

```
[edit]
user@R3#set chassis network-services enhanced-ip
```

After you configure the `enhanced-ip` statement and commit the configuration, the following warning message appears prompting you to reboot the router:

```
'chassis'
WARNING: Chassis configuration for network services has been changed. A system reboot is
mandatory. Please reboot the system NOW. Continuing without a reboot might result in
```

```
unexpected system behavior.
commit complete
```

The reboot brings up the FPCs on the router.

2. Configure the interfaces to enable IP, MPLS, and ISO transport.

```
user@R3#set interfaces ge-0/0/0 description To_R2
user@R3#set interfaces ge-0/0/0 vlan-tagging
user@R3#set interfaces ge-0/0/0 unit 0 vlan-id 1
user@R3#set interfaces ge-0/0/0 unit 0 family inet address 192.168.6.2/24
user@R3#set interfaces ge-0/0/0 unit 0 family iso
user@R3#set interfaces ge-0/0/0 unit 0 family inet6 address 2300:10::3/64
user@R3#set interfaces ge-0/0/0 unit 0 family mpls maximum-labels 8
user@R3#set interfaces ge-0/0/0 unit 1 vlan-id 2

user@R3#set interfaces ge-0/0/2 unit 0 family iso
user@R3#set interfaces ge-0/0/2 unit 0 family inet6 address 3600:10::3/64
```

```
user@R3#set interfaces ge-0/0/2 unit 0 family mpls maximum-labels 8
user@R3#set interfaces ge-0/0/3 description To_R7
user@R3#set interfaces ge-0/0/3 vlan-tagging
user@R3#set interfaces ge-0/0/3 unit 0 vlan-id 1
user@R3#set interfaces ge-0/0/3 unit 0 family inet address 192.168.12.1/24
user@R3#set interfaces ge-0/0/3 unit 0 family iso
user@R3#set interfaces ge-0/0/3 unit 0 family inet6 address 3700:10::3/6
user@R3#set interfaces ge-0/0/3 unit 0 family mpls maximum-labels 8
user@R3#set interfaces ge-0/0/3 unit 1 vlan-id 2
user@R3#set interfaces ge-0/0/3 unit 1 family inet address 192.168.37.1/24
user@R3#set interfaces ge-0/0/3 unit 1 family iso
user@R3#set interfaces ge-0/0/3 unit 1 family inet6 address 3700:20::3/6
user@R3#set interfaces ge-0/0/3 unit 1 family mpls maximum-labels 8
```

3. Configure the loopback interface to enable tunnel endpoints and service endpoints.

```
[edit]
user@R3#set interfaces lo0 unit 0 family inet address 3.3.3.3/32
user@R3#set interfaces lo0 unit 0 family iso address 49.0001.0003.0303.0300
user@R3#set interfaces lo0 unit 0 family inet6 address abcd::03:03:03:03/128
```

4. Define import and export policies. For example, configure policies that export EPE TE links from the local TE database to **lsdist.0** and policies to import from **lsdist.0** into the local TE database. You can configure policies to advertise the BGP routes to a peer.

```
[edit]
user@R3#set policy-options policy-statement bgplsepe_rt_2_ted term 1 from protocol bgp
user@R3#set policy-options policy-statement bgplsepe_rt_2_ted term 1 then accept
user@R3#set policy-options policy-statement expresspol1 from route-filter 1.1.1.1/32 exact

user@R3#set policy-options policy-statement ted2nlri_epe_stat term 3 from protocol isis
user@R3#set policy-options policy-statement ted2nlri_epe_stat term 3 then reject
user@R3#set policy-options policy-statement ted2nlri_igp from family traffic-engineering
user@R3#set policy-options policy-statement ted2nlri_igp from protocol isis
user@R3#set policy-options policy-statement ted2nlri_igp then accept
```

5. Configure routing options to identify the router in the domain.

```
[edit]
user@R3#set routing-options router-id 3.3.3.3
user@R3#set routing-options autonomous-system 200
```

6. Define the RIB group to copy inetcolor.0 to inet.3 routing table.

```
[edit]
user@R3#set routing-options rib-groups color-to-inet3 import-rib [ inetcolor.0 inet.3 ]
```

7. Configure BGP to enable BGP-LS route advertisement for peer and define the EPE links. Since express segment is an internal TE link, this configuration creates an external TE link.

```
[edit]
user@R3#set protocols bgp group ibgp1 type internal
user@R3#set protocols bgp group ibgp1 local-address 3.3.3.3
user@R3#set protocols bgp group ibgp1 family traffic-engineering unicast
user@R3#set protocols bgp group ibgp1 export nlri2bgp_epe
user@R3#set protocols bgp group ibgp1 neighbor 2.2.2.2
user@R3#set protocols bgp group ibgp1 neighbor 5.5.5.5
user@R3#set protocols bgp group ebgp1 type external
user@R3#set protocols bgp group ebgp1 family traffic-engineering unicast
user@R3#set protocols bgp group ebgp1 export nlri2bgp_stat
user@R3#set protocols bgp group ebgp1 neighbor 192.168.12.2 peer-as 300
user@R3#set protocols bgp group ebgp1 neighbor 192.168.12.2 egress-te-adj-segment
epe_adj1_toR7 label 7137
user@R3#set protocols bgp group ebgp1 neighbor 192.168.12.2 egress-te-adj-segment
epe_adj1_toR7 next-hop 192.168.12.2
user@R3#set protocols bgp group ebgp1 neighbor 192.168.12.2 egress-te-adj-segment
epe_adj1_toR7 te-link-attribute te-metric 20
user@R3#set protocols bgp group ebgp1 neighbor 192.168.12.2 egress-te-adj-segment
epe_adj1_toR7 te-link-attribute igp-metric 10
user@R3#set protocols bgp group ebgp1 neighbor 192.168.12.2 egress-te-adj-segment
epe_adj1_toR7 te-link-attribute admin-group red
user@R3#set protocols bgp group ebgp1 neighbor 192.168.12.2 egress-te-adj-segment
epe_adj1_toR7 te-link-attribute admin-group brown
user@R3#set protocols bgp group ebgp1 vpn-apply-export
```

8. Define a mechanism to automatically (dynamic) create express segments and insert them in to the TE database so that they can be advertised through BGP-LS. In this example, express segments are

created for all the underlay SR tunnels automatically. This is done by configuring a template with a policy and then express segments are automatically created based on the policies.

```
[edit]
user@R3#set protocols express-segments segment-set set3sr membership-policy expresspolsr1
user@R3#set protocols express-segments traffic-engineering
```

9. Configure IS-IS protocol on the interfaces.

```
[edit]
user@R3#set protocols isis interface ge-0/0/0.0 level 2 lan-neighbor 0100.0202.0202 ipv4-
adjacency-segment protected label 3211
user@R3#set protocols isis interface ge-0/0/0.0 level 2 lan-neighbor 0100.0202.0202 ipv4-

192.168.3.1
user@R3#set protocols source-packet-routing source-routing-path lsp3to1_sr to 1.1.1.1
user@R3#set protocols source-packet-routing source-routing-path lsp3to1_sr color 1000
user@R3#set protocols source-packet-routing source-routing-path lsp3to1_sr primary R3-R2-R1
user@R3#set protocols source-packet-routing rib-group ipv4-color color-to-inet3
```

Results

From configuration mode, confirm your configuration by entering the `show chassis`, `show interfaces`, `show policy-options`, `show routing-options`, and `show protocols` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

The following result includes colored SR-TE underlay path configuration also.

```
chassis {
    network-services enhanced-ip;
}
interfaces {
    ge-0/0/0 {
        description To_R2;
        vlan-tagging;
        unit 0 {
            vlan-id 1;
            family inet {
                address 192.168.6.2/24;
            }
            family iso;
            family inet6 {
                address 2300:10::3/64;
            }
            family mpls {
                maximum-labels 8;
```

```
            }
        }
        unit 1 {
            vlan-id 2;
            family inet {
                address 192.168.23.2/24;
            }
            family iso;
            family inet6 {

Configure R6 (BN4 router)

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see Using the CLI Editor in Configuration Mode in the CLI User Guide.

To configure device R6:

1. Configure the network services mode as Enhanced IP. Enhanced IP sets the router's network services to enhanced Internet Protocol and uses enhanced mode capabilities.

```
[edit]
user@R6#set chassis network-services enhanced-ip
```

After you configure the `enhanced-ip` statement and commit the configuration, the following warning message appears prompting you to reboot the router:

```
'chassis'
WARNING: Chassis configuration for network services has been changed. A system reboot is
mandatory. Please reboot the system NOW. Continuing without a reboot might result in
unexpected system behavior.
commit complete
```

The reboot brings up the FPCs on the router.

2. Configure the interfaces to enable IP, MPLS, and ISO transport.

```
user@R6#set interfaces ge-0/0/0 description To_R2
user@R6#set interfaces ge-0/0/0 vlan-tagging
user@R6#set interfaces ge-0/0/0 unit 0 vlan-id 1

```

3. Configure the loopback interface to enable tunnel endpoints and service endpoints.

```
[edit]
user@R6#set interfaces lo0 unit 0 family inet address 6.6.6.6/32
user@R6#set interfaces lo0 unit 0 family iso address 49.0001.0006.0606.0600
user@R6#set interfaces lo0 unit 0 family inet6 address abcd::06:06:06:06/128
```

4. Define import and export policies. For example, configure policies that export EPE TE links from the local TE database to **lsdist.0** and policies to import from **lsdist.0** into the local TE database. You can configure policies to advertise the BGP routes to a peer.

```
[edit]
user@R6#set policy-options policy-statement expresspolsr1 from protocol spring-te
user@R6#set policy-options policy-statement expresspolsr1 from route-filter 4.4.4.4/32 exact
user@R6#set policy-options policy-statement expresspolsr1 then accept
user@R6#set policy-options policy-statement nlri2bgp_epe term 1 from family traffic-
engineering
user@R6#set policy-options policy-statement nlri2bgp_epe term 1 from protocol bgp-ls-epe
user@R6#set policy-options policy-statement nlri2bgp_epe term 1 then next-hop self
user@R6#set policy-options policy-statement nlri2bgp_epe term 1 then accept
user@R6#set policy-options policy-statement nlri2bgp_stat term 1 from family traffic-
engineering
user@R6#set policy-options policy-statement nlri2bgp_stat term 1 from protocol express-
segments
user@R6#set policy-options policy-statement nlri2bgp_stat term 1 then accept
user@R6#set policy-options policy-statement pplb then load-balance per-packet
user@R6#set policy-options policy-statement prefix-sid term 1 from route-filter 6.6.6.6/32
exact
user@R6#set policy-options policy-statement prefix-sid term 1 then prefix-segment index 1006
user@R6#set policy-options policy-statement prefix-sid term 1 then prefix-segment node-
segment
user@R6#set policy-options policy-statement ted2nlri_epe_stat term 1 from family traffic-
engineering
user@R6#set policy-options policy-statement ted2nlri_epe_stat term 1 from protocol static
user@R6#set policy-options policy-statement ted2nlri_epe_stat term 1 then accept
user@R6#set policy-options policy-statement ted2nlri_epe_stat term 2 from family traffic-
engineering
user@R6#set policy-options policy-statement ted2nlri_epe_stat term 2 from protocol bgp-ls-
epe
user@R6#set policy-options policy-statement ted2nlri_epe_stat term 2 then accept
user@R6#set policy-options policy-statement ted2nlri_epe_stat term 3 from protocol isis
user@R6#set policy-options policy-statement ted2nlri_epe_stat term 3 then reject
```

5. Configure routing options to identify the router in the domain.

```
[edit]
user@R6#set routing-options router-id 6.6.6.6
user@R6#set routing-options autonomous-system 200
```

6. Define the RIB group to copy inetcolor.0 to inet.3 routing table.

```
[edit]
user@R6#set routing-options rib-groups color-to-inet3 import-rib [ inetcolor.0 inet.3 ]
```

7. Configure BGP to enable BGP-LS route advertisement for peer and define the EPE links. Since express segment is an internal TE link, this configuration creates an external TE link.

```
[edit]
user@R6#set protocols bgp group ibgp1 type internal
user@R6#set protocols bgp group ibgp1 local-address 6.6.6.6
user@R6#set protocols bgp group ibgp1 family traffic-engineering unicast
user@R6#set protocols bgp group ibgp1 export nlri2bgp_epe
user@R6#set protocols bgp group ibgp1 neighbor 2.2.2.2
user@R6#set protocols bgp group ibgp1 neighbor 5.5.5.5
user@R6#set protocols bgp group ebgp1 type external
user@R6#set protocols bgp group ebgp1 family traffic-engineering unicast
user@R6#set protocols bgp group ebgp1 export nlri2bgp_stat
user@R6#set protocols bgp group ebgp1 neighbor 192.168.15.2 peer-as 300
user@R6#set protocols bgp group ebgp1 neighbor 192.168.15.2 egress-te-adj-segment
epe_adj1_toR7 label 7167
user@R6#set protocols bgp group ebgp1 neighbor 192.168.15.2 egress-te-adj-segment
epe_adj1_toR7 next-hop 192.168.15.2
user@R6#set protocols bgp group ebgp1 neighbor 192.168.15.2 egress-te-adj-segment
epe_adj1_toR7 te-link-attribute te-metric 20
user@R6#set protocols bgp group ebgp1 neighbor 192.168.15.2 egress-te-adj-segment
epe_adj1_toR7 te-link-attribute igp-metric 10
user@R6#set protocols bgp group ebgp1 neighbor 192.168.15.2 egress-te-adj-segment
epe_adj1_toR7 te-link-attribute admin-group red
user@R6#set protocols bgp group ebgp1 neighbor 192.168.15.2 egress-te-adj-segment
epe_adj1_toR7 te-link-attribute admin-group brown
```

8. Define a mechanism to automatically (dynamic) create express segments and insert them in to the TE database so that they can be advertised through BGP-LS. In this example, express segments are

created for all the underlay SR tunnels automatically. This is done by configuring a template with a policy and then express segments are automatically created based on the policies.

```
[edit]
user@R6#set protocols express-segments segment-set set6sr membership-policy expresspolsr1
user@R6#set protocols express-segments traffic-engineering
```

9. Configure IS-IS protocol on the interfaces.

```
[edit]
user@R6#set protocols isis interface ge-0/0/0.0 level 2 lan-neighbor 0100.0202.0202 ipv4-
adjacency-segment protected label 6211
user@R6#set protocols isis interface ge-0/0/0.0 level 2 lan-neighbor 0100.0202.0202 ipv4-
adjacency-segment unprotected label 6201
user@R6#set protocols isis interface ge-0/0/0.0 level 2 post-convergence-lfa node-protection
user@R6#set protocols isis interface ge-0/0/1.0 level 2 lan-neighbor 0100.0303.0303 ipv4-
adjacency-segment protected label 6311
user@R6#set protocols isis interface ge-0/0/1.0 level 2 lan-neighbor 0100.0303.0303 ipv4-
adjacency-segment unprotected label 6301
user@R6#set protocols isis interface ge-0/0/1.0 level 2 post-convergence-lfa node-protection
user@R6#set protocols isis interface ge-0/0/2.0 level 2 lan-neighbor 0100.0505.0505 ipv4-
adjacency-segment protected label 6511
user@R6#set protocols isis interface ge-0/0/2.0 level 2 lan-neighbor 0100.0505.0505 ipv4-

user@R6#set protocols isis interface ge-0/0/3.0 level 2 post-convergence-lfa node-protection
user@R6#set protocols isis interface ge-0/0/3.0 passive
user@R6#set protocols isis interface fxp0.0 disable
user@R6#set protocols isis interface lo0.0 passive
user@R6#set protocols isis source-packet-routing srgb start-label 800000 index-range 50000
user@R6#set protocols isis level 1 disable
user@R6#set protocols isis level 2 wide-metrics-only
user@R6#set protocols isis backup-spf-options use-post-convergence-lfa
user@R6#set protocols isis backup-spf-options use-source-packet-routing
user@R6#set protocols isis traffic-engineering l3-unicast-topology
user@R6#set protocols isis traffic-engineering advertisement always
user@R6#set protocols isis export prefix-sid
```

10. Enable import and export of traffic engineering database parameters using policies.

```
[edit]
user@R6#set protocols mpls traffic-engineering database import l3-unicast-topology bgp-link-state
user@R6#set protocols mpls traffic-engineering database import policy ted2nlri_epe_stat
user@R6#set protocols mpls traffic-engineering database export l3-unicast-topology
```

11. Configure MPLS administrative group policies for LSP path computation.

```
[edit]
user@R6#set protocols mpls admin-groups red 0
user@R6#set protocols mpls admin-groups blue 1
user@R6#set protocols mpls admin-groups green 2
user@R6#set protocols mpls admin-groups yellow 3
user@R6#set protocols mpls admin-groups orange 4
user@R6#set protocols mpls admin-groups brown 5
user@R6#set protocols mpls admin-groups black 6
user@R6#set protocols mpls admin-groups pink 7
```

12. Configure the MPLS label range to assign static labels for the EPE links.

```
[edit]
user@R6#set protocols mpls label-range static-label-range 1000 70000
```

13. Configure MPLS with interface and include administrative groups.

```
[edit]
user@R6#set protocols mpls interface ge-0/0/0.0 admin-group blue
user@R6#set protocols mpls interface ge-0/0/1.0 admin-group red
user@R6#set protocols mpls interface ge-0/0/2.0 admin-group brown
user@R6#set protocols mpls interface ge-0/0/3.0 admin-group [ red brown ]
user@R6#set protocols mpls interface all
user@R6#set protocols mpls interface fxp0.0 disable
```

14. Configure ST-TE LSP from R6 device to R4 device.

```
[edit]
user@R6#set protocols source-packet-routing no-chained-composite-next-hop
user@R6#set protocols source-packet-routing segment-list R6-R5-R4 hop1 label 801005
user@R6#set protocols source-packet-routing segment-list R6-R5-R4 hop2 label 801004
user@R6#set protocols source-packet-routing source-routing-path lsp6to4_sr to 4.4.4.4
user@R6#set protocols source-packet-routing source-routing-path lsp6to4_sr color 1000
user@R6#set protocols source-packet-routing source-routing-path lsp6to4_sr primary R6-R5-R4
user@R6#set protocols source-packet-routing rib-group ipv4-color color-to-inet3
```

Results

From configuration mode, confirm your configuration by entering the `show chassis`, `show interfaces`, `show policy-options`, `show routing-options`, and `show protocols` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

The following result includes colored SR-TE underlay path configuration also.

```
chassis {
    network-services enhanced-ip;
}
interfaces {
    ge-0/0/0 {
        description To_R2;

        }
    }
}
```

Configure R7 (PE2 router)

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see Using the CLI Editor in Configuration Mode in the CLI User Guide.

To configure device R7:

1. Configure the network services mode as Enhanced IP. Enhanced IP sets the router's network services to enhanced Internet Protocol and uses enhanced mode capabilities.

   ```
   [edit]
   user@R7#set chassis network-services enhanced-ip
   ```

   After you configure the `enhanced-ip` statement and commit the configuration, the following warning message appears prompting you to reboot the router:

   ```
   'chassis'
   WARNING: Chassis configuration for network services has been changed. A system reboot is
   mandatory. Please reboot the system NOW. Continuing without a reboot might result in
   unexpected system behavior.
   commit complete
   ```

   The reboot brings up the FPCs on the router.

2. Configure the interfaces to enable IP, MPLS, and ISO transport.

```
user@R7#set interfaces ge-0/0/0 description To_R3
user@R7#set interfaces ge-0/0/0 vlan-tagging
user@R7#set interfaces ge-0/0/0 unit 0 vlan-id 1
user@R7#set interfaces ge-0/0/0 unit 0 family inet address 192.168.12.2/24
user@R7#set interfaces ge-0/0/0 unit 0 family iso
user@R7#set interfaces ge-0/0/0 unit 0 family inet6 address 3700:10::7/64
user@R7#set interfaces ge-0/0/0 unit 0 family mpls maximum-labels 8
user@R7#set interfaces ge-0/0/0 unit 1 vlan-id 2
user@R7#set interfaces ge-0/0/0 unit 1 family inet address 192.168.37.2/24
user@R7#set interfaces ge-0/0/0 unit 1 family iso
user@R7#set interfaces ge-0/0/0 unit 1 family inet6 address 3700:20::7/64
user@R7#set interfaces ge-0/0/0 unit 1 family mpls maximum-labels 8
user@R7#set interfaces ge-0/0/1 description To_R6
user@R7#set interfaces ge-0/0/1 vlan-tagging
user@R7#set interfaces ge-0/0/1 unit 0 vlan-id 1
user@R7#set interfaces ge-0/0/1 unit 0 family inet address 192.168.15.2/24
user@R7#set interfaces ge-0/0/1 unit 0 family iso
user@R7#set interfaces ge-0/0/1 unit 0 family inet6 address 6700:10::7/64
user@R7#set interfaces ge-0/0/1 unit 0 family mpls maximum-labels 8
user@R7#set interfaces ge-0/0/1 unit 1 vlan-id 2
user@R7#set interfaces ge-0/0/1 unit 1 family inet address 192.168.67.2/24
user@R7#set interfaces ge-0/0/1 unit 1 family iso
user@R7#set interfaces ge-0/0/1 unit 1 family inet6 address 6700:20::7/64
user@R7#set interfaces ge-0/0/1 unit 1 family mpls maximum-labels 8
```

3. Configure the loopback interface to enable tunnel endpoints and service endpoints.

```
[edit]
user@R7#set interfaces lo0 unit 0 family inet address 7.7.7.7/32
user@R7#set interfaces lo0 unit 0 family inet address 7.7.7.71/32
user@R7#set interfaces lo0 unit 0 family iso address 49.0001.0007.0707.0700
user@R7#set interfaces lo0 unit 0 family inet6 address abcd::07:07:07:07/128
user@R7#set interfaces lo0 unit 0 family inet6 address abcd::7:7:7:71/128
```

4. Define import and export policies. For example, configure policies that export EPE TE links from the local TE database to **lsdist.0** and policies to import from **lsdist.0** into the local TE database. You can configure policies to advertise the BGP routes to a peer.

Route filter routs are advertised from external AS.

```
[edit]
user@R7#set policy-options policy-statement bgplsepe_rt_2_ted term 1 from protocol bgp
user@R7#set policy-options policy-statement bgplsepe_rt_2_ted term 1 then accept
user@R7#set policy-options policy-statement direct from protocol direct
user@R7#set policy-options policy-statement direct then accept
user@R7#set policy-options policy-statement mpath then multipath-resolve
user@R7#set policy-options policy-statement nlri2bgp term 1 from family traffic-engineering
user@R7#set policy-options policy-statement nlri2bgp term 1 then accept
user@R7#set policy-options policy-statement nlri2bgp_epe term 1 from family traffic-
engineering
user@R7#set policy-options policy-statement nlri2bgp_epe term 1 from protocol bgp-ls-epe
user@R7#set policy-options policy-statement nlri2bgp_epe term 1 then next-hop self
user@R7#set policy-options policy-statement nlri2bgp_epe term 1 then accept
user@R7#set policy-options policy-statement nlri2ted_bgp term 1 from protocol bgp
user@R7#set policy-options policy-statement nlri2ted_bgp term 1 then accept
user@R7#set policy-options policy-statement nlri2ted_igp term 1 from traffic-engineering
protocol isis-level-2
user@R7#set policy-options policy-statement nlri2ted_igp term 1 then accept
user@R7#set policy-options policy-statement payload_vpn_109 term 1 from route-filter
109.0.0.1/16 orlonger
user@R7#set policy-options policy-statement payload_vpn_109 term 1 then community add
color7000
user@R7#set policy-options policy-statement payload_vpn_109 term 1 then next-hop 7.7.7.7
user@R7#set policy-options policy-statement payload_vpn_109 term 1 then accept
user@R7#set policy-options policy-statement payload_vpn_110 term 1 from route-filter
110.0.0.1/16 orlonger

user@R7#set policy-options community color7000 members color:0:7000
user@R7#set policy-options community color7001 members color:0:7001
user@R7#set policy-options resolution-map map1 mode ip-color
```

5. Configure routing options to identify the router in the domain.

```
[edit]
user@R7#set routing-options router-id 7.7.7.7
user@R7#set routing-options autonomous-system 300
user@R7#set routing-options static route 100.100.100.101/32 next-hop 100.100.100.100
user@R7#set routing-options static route 100.100.100.101/32 resolve
user@R7#set routing-options forwarding-table export pplb
```

6. Configure BGP to enable BGP-LS route advertisement for peer and define the EPE links. Since express segment is an internal TE link, this configuration creates an external TE link.

```
[edit]

user@R7#set protocols bgp group to-CE1 neighbor 192.168.50.2 local-as 300
```

7. Configure IS-IS protocol.

```
[edit]user@R7#set protocols isis interface fxp0.0 disable
user@R7#set protocols isis interface lo0.0 passive
user@R7#set protocols isis level 1 disable
user@R7#set protocols isis level 2 wide-metrics-only
user@R7#set protocols isis traffic-engineering l3-unicast-topology
user@R7#set protocols isis traffic-engineering advertisement always
```

8. Enable import and export of traffic engineering database parameters using policies.

```
[edit]
user@R7#set protocols mpls traffic-engineering database import l3-unicast-topology bgp-link-
state
user@R7#set protocols mpls traffic-engineering database import policy ted2nlri
user@R7#set protocols mpls traffic-engineering database export policy nlri2ted_bgp
user@R7#set protocols mpls traffic-engineering database export l3-unicast-topology
```

9. Configure MPLS administrative group policies for LSP path computation.

```
[edit]
user@R7#set protocols mpls admin-groups red 0
user@R7#set protocols mpls admin-groups blue 1
user@R7#set protocols mpls admin-groups green 2
user@R7#set protocols mpls admin-groups yellow 3
```

```
user@R7#set protocols mpls admin-groups orange 4
user@R7#set protocols mpls admin-groups brown 5
user@R7#set protocols mpls admin-groups black 6
user@R7#set protocols mpls admin-groups pink 7
```

10. Configure the MPLS label range to assign static labels for the EPE links.

```
[edit]
user@R7#set protocols mpls label-range static-label-range 1000 70000
```

11. Configure MPLS with interface and include administrative groups.

```
[edit]
user@R7#set protocols mpls interface ge-0/0/1.0 admin-group [ red brown ]
user@R7#set protocols mpls interface ge-0/0/0.0 admin-group [ red brown ]
user@R7#set protocols mpls interface all
user@R7#set protocols mpls interface fxp0.0 disable
```

12. Configure SR-TE policies on the ingress router to enable end-to-end SR-TE policy.

```
[edit]
user@R7#set protocols source-packet-routing compute-profile compute1 no-label-stack-
compression
user@R7#set protocols source-packet-routing source-routing-path computelsp1 to
100.100.100.100
user@R7#set protocols source-packet-routing source-routing-path computelsp1 install
100.100.100.101
user@R7#set protocols source-packet-routing source-routing-path computelsp1 primary p1
compute compute1
```

Results

From configuration mode, confirm your configuration by entering the `show chassis`, `show interfaces`, `show policy-options`, `show routing-options`, and `show protocols` commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
chassis {
    network-services enhanced-ip;
```

```
}
interfaces {
    ge-0/0/0 {
        description To_R3;

    }
```

Verification

IN THIS SECTION

- Verify the Express Segment | **1155**
- Verify the Express Segment Advertisements | **1157**
- Verify the TE Topology Information | **1164**

To confirm that the configuration is working properly, perform the following tasks:

Verify the Express Segment

Purpose

Verify that the express segments are created correctly.

Action

From operational mode, run the following commands:

- `show express-segments detail`—Verify whether the express segments are created.
- `show ted database topology-type express-segments detail`—Verify that the newly created express segments are inserted into the TE database.

- `show route table mpls.0 protocol express-segments`—Verify whether the forwarding entries have been created.

```
user@R1>show express-segments detail

Name: set1sr-3.3.3.3
  To: 3.3.3.3, Type: Dynamic (Set: set1sr)
  Label: 16 (Route installed in mpls.0, TED entry added)
  Status: Up (ElapsedTime: 5d 20:37:08)
  LinkAttributes:
    LocalID: 2147483649
    TE-Metric: 20, IGP-Metric: 20
    BW: 0bps
  UnderlayPaths: 1
    SRTE LSP: lsp1to3_sr
      TE-Metric: 0, IGP-Metric: 0
      BW: 0bps
```

On R1

```
user@R1>show ted database topology-type express-segments detail

TED database: 18 ISIS nodes 7 INET nodes 0 INET6 nodes
NodeID: R1.00(1.1.1.1)
  Type: Rtr, Age: 774 secs, LinkIn: 4, LinkOut: 6
  Protocol: EXPRESS-SEG(0)
    To: R3.00(3.3.3.3), Local: 1.1.1.1, Remote: 3.3.3.3
      Local interface index: 2147483649, Remote interface index: 0
      Link name: set1sr-3.3.3.3
NodeID: R3.00(3.3.3.3)
  Type: Rtr, Age: 580 secs, LinkIn: 4, LinkOut: 3
  Protocol: EXPRESS-SEG(0)
```

On R1

```
user@R1>show route table mpls.0 protocol express-segments

mpls.0: 33 destinations, 33 routes (33 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

16                 *[EXPRESS-SEG/6] 5d 14:13:37, metric 1
```

```
                    >  to 192.168.3.2 via ge-0/0/2.0, Swap 801003
                       to 192.168.21.2 via ge-0/0/2.1, Swap 801003
```

Meaning

- In the `show express-segments detail` output, you can see the name of the express segment (**set1sr-3.3.3.3**), express segment label (**16**), and the underlay LSP (**lsp1to3_sr**).
- In the `show ted database topology-type express-segments detail` output, you can see the express segment entries are inserted into the TE database. The express segments (virtual TE links) are dynamically created. The protocol used is **EXPRESS-SEG(0)**.
- In the `show route table mpls.0 protocol express-segments` output, you can see the express segment label (**16**). Because the express segment is a construct that relies on the underlay LSPs, the express segment label gets swapped to the underlay SR-TE labels (**801003**).

Verify the Express Segment Advertisements

Purpose

Verify that the originating node advertises express segments to its eBGP/iBGP LS neighbors.

Action

From operational mode, run the following commands:

- `show route table lsdist.0`—Verify that the express segments in the RIB BGP-LS are being advertised.
- `show route advertising-protocol bgp` *neighbor*—Verify that the express segments are sent to the eBGP/iBGP LS neighbors.

```
user@R1>show route table lsdist.0

lsdist.0: 23 destinations, 40 routes (23 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

```

Meaning

- In the `show route table lsdist.0` output, BGP advertises the routes in the routing table. The routing table is created from the TE database. You can see the express segments (**EXPRESS-SEG/6**) links and the EPE links (**BGP-LS-EPE:0 }/1216**).
- In the `show route advertising-protocol bgp 2.2.2.2` output, you can see what R1 is advertising to. The express segments are inserted into the TE database, which is copied to RIB. BGP-LS advertises the RIB to the peer router. On the peer, the received RIB information is copied into the local database. The policy in this example only advertises express segments and EPE segments.

Verify the TE Topology Information

Purpose

Verify that the ingress nodes receive TE topology information through eBGP/iBGP LS.

Action

From operational mode, run the following commands:

- `show route receive-protocol bgp` *neighbor*—Verify that the express segments are received from eBGP/iBGP LS neighbors.
- `show route table lsdist.0`—Verify that the express segments are in the BGP-LS RIB.
- `show ted database topology-type l3-unicast detail`—Verify that the express segments are imported into the ingress router's TE database.
- `show spring-traffic-engineering lsp`—Verify that the end-to-end SR policy has been successfully computed and installed.

Meaning

- In the `show route receive-protocol bgp 192.168.1.2` output, it shows the routes that have been received by the ingress router (R0) from the BGP neighbor, which describes the express segment (virtual TE links).
- In the `show route table lsdist.0` output, it shows the routes that have been received by the ingress router (R0) and whether they are inserted into the **lsdist.0** RIB. It also shows whether the **lsdist.0** RIB is copied into the local TE database.
- In the `show ted database topology-type l3-unicast detail` output, the routes are copied into the local TE database. The **set1sr-3.3.3.3** is an express segment with end point as 3.3.3.3 and is sucessfully created on R1. R1 has advertised the express segment and R0 has inserted it into the local TE database. You can also see the EPE segments (**epe_adj1_toR7**).
- In the `show spring-traffic-engineering lsp` output, you can see that the SR policies are up. It shows that you are now able to compute a multi-domain end-to-end (R0 to R7) SR policy.
- In the `show spring-traffic-engineering lsp detail` output, you can see the labels that are selected. In the **computelsp1** LSP, the label **7101** is an EPE segment, **16** is the express segment, and **7137** is also an

EPE segment. It shows that you are now able to compute a multi-domain end-to-end (R0 to R7) SR policy.

RSVP Overview

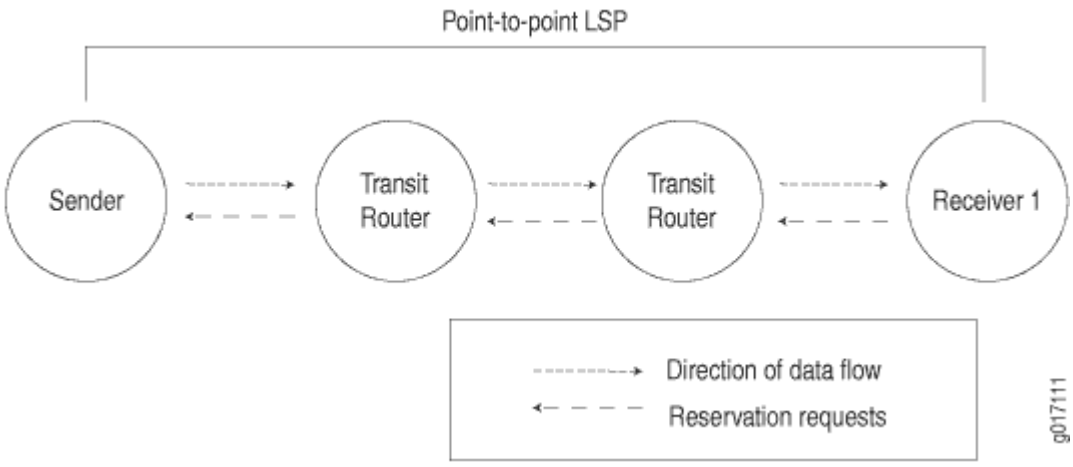
The RSVP protocol is used by routers to deliver quality-of-service (QoS) requests to all nodes along data flow path(s) and to establish and maintain state for the requested service. RSVP requests generally result in resource reservations in each node along the data path. RSVP has the following attributes:

- Makes resource reservations for unidirectional data flows.
- Allows the receiver of a data flow to initiate and maintain the resource reservation used for that flow, as shown in Figure 65 on page 1182.
- Maintains a soft state in routers and hosts, providing graceful support for dynamic membership changes and automatic adaptation to routing changes.
- Depends upon present and future routing protocols, but is not a routing protocol itself.
- Provides several reservation models or styles to fit a variety of applications.
- Supports both IPv4 and IPv6 packets that can be sent over RSVP-signaled LSPs.

Figure 65: RSVP Reservation Request and Data Flow



RSVP Operation Overview

RSVP creates independent sessions to handle each data flow. A session is identified by a combination of the destination address, an optional destination port, and a protocol. Within a session, there can be one or more senders. Each sender is identified by a combination of its source address and source port. An out-of-band mechanism, such as a session announcement protocol or human communication, is used to communicate the session identifier to all senders and receivers.

A typical RSVP session involves the following sequence of events:

1. A potential sender starts sending RSVP path messages to the session address.
2. A receiver, wanting to join the session, registers itself if necessary. For example, a receiver in a multicast application would register itself with IGMP.
3. The receiver receives the path messages.
4. The receiver sends appropriate Resv messages toward the sender. These messages carry a flow descriptor, which is used by routers along the path to make reservations in their link-layer media.
5. The sender receives the Resv message and then starts sending application data.

This sequence of events is not necessarily strictly synchronized. For example, receivers can register themselves before receiving path messages from the sender, and application data can flow before the sender receives Resv messages. Application data that is delivered before the actual reservation contained in the Resv message typically is treated as best-effort, non-real-time traffic with no CoS guarantee.

Understanding the RSVP Signaling Protocol

IN THIS SECTION

- RSVP Fundamentals | **1184**
- Bandwidth Reservation Requirement | **1184**
- Explicit Route Objects | **1184**
- Constrained Shortest Path First | **1185**
- Link Coloring | **1186**

RSVP is a signaling protocol that handles bandwidth allocation and true traffic engineering across an MPLS network. Like LDP, RSVP uses discovery messages and advertisements to exchange LSP path information between all hosts. However, RSVP also includes a set of features that control the flow of traffic through an MPLS network. Whereas LDP is restricted to using the configured IGP's shortest path as the transit path through the network, RSVP uses a combination of the Constrained Shortest Path First (CSPF) algorithm and Explicit Route Objects (EROs) to determine how traffic is routed through the network.

Basic RSVP sessions are established in exactly the same way that LDP sessions are established. By configuring both MPLS and RSVP on the appropriate transit interfaces, you enable the exchange of RSVP packets and the establishment of LSPs. However, RSVP also lets you configure link authentication, explicit LSP paths, and link coloring.

This topic contains the following sections:

RSVP Fundamentals

RSVP uses unidirectional and simplex flows through the network to perform its function. The inbound router initiates an RSVP path message and sends it downstream to the outbound router. The path message contains information about the resources needed for the connection. Each router along the path begins to maintain information about a reservation.

When the path message reaches the outbound router, resource reservation begins. The outbound router sends a reservation message upstream to the inbound router. Each router along the path receives the reservation message and sends it upstream, following the path of the original path message. When the inbound router receives the reservation message, the unidirectional network path is established.

The established path remains open as long as the RSVP session is active. The session is maintained by the transmission of additional path and reservation messages that report the session state every 30 seconds. If a router does not receive the maintenance messages for 3 minutes, it terminates the RSVP session and reroutes the LSP through another active router.

Bandwidth Reservation Requirement

When a bandwidth reservation is configured, reservation messages propagate the bandwidth value throughout the LSP. Routers must reserve the bandwidth specified across the link for the particular LSP. If the total bandwidth reservation exceeds the available bandwidth for a particular LSP segment, the LSP is rerouted through another LSR. If no segments can support the bandwidth reservation, LSP setup fails and the RSVP session is not established.

Explicit Route Objects

Explicit Route Objects (EROs) limit LSP routing to a specified list of LSRs. By default, RSVP messages follow a path that is determined by the network IGP's shortest path. However, in the presence of a configured ERO, the RSVP messages follow the path specified.

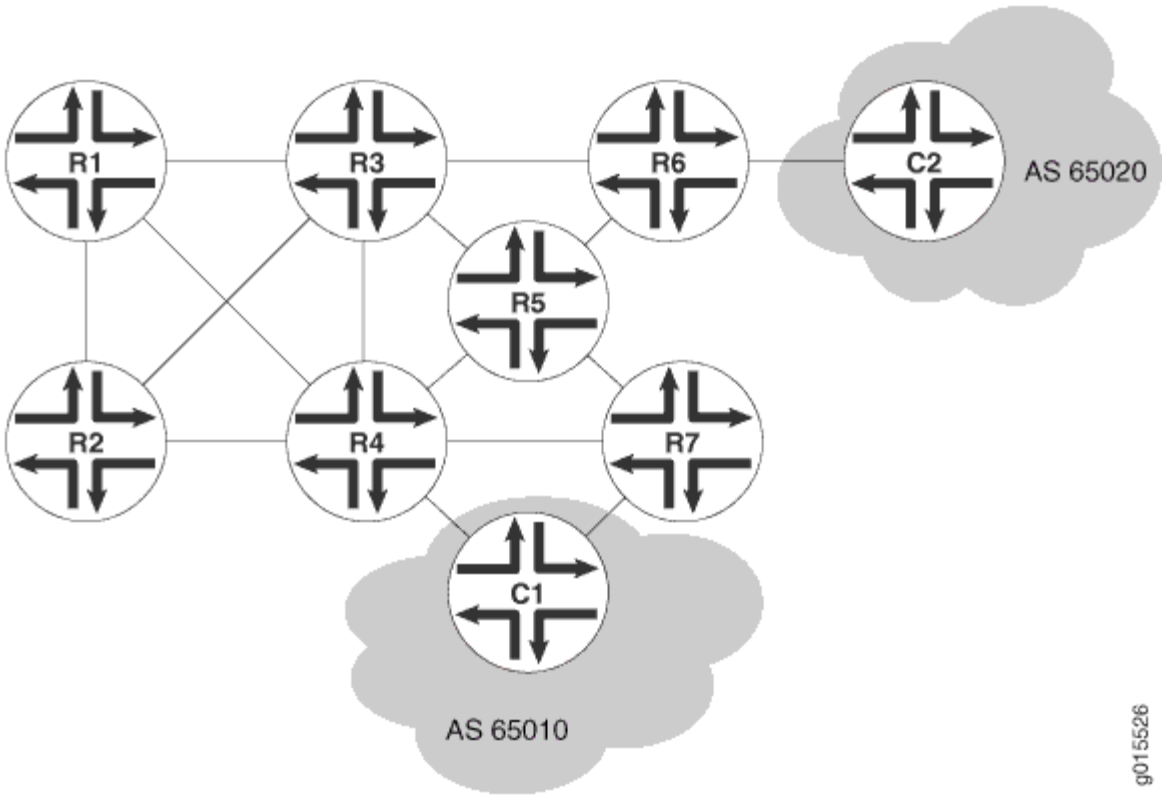
EROs consist of two types of instructions: loose hops and strict hops. When a loose hop is configured, it identifies one or more transit LSRs through which the LSP must be routed. The network IGP determines the exact route from the inbound router to the first loose hop, or from one loose hop to the next. The loose hop specifies only that a particular LSR be included in the LSP.

When a strict hop is configured, it identifies an exact path through which the LSP must be routed. Strict-hop EROs specify the exact order of the routers through which the RSVP messages are sent.

You can configure loose-hop and strict-hop EROs simultaneously. In this case, the IGP determines the route between loose hops, and the strict-hop configuration specifies the exact path for particular LSP path segments.

Figure 66 on page 1185 shows a typical RSVP-signaled LSP that uses EROs.

Figure 66: Typical RSVP-Signaled LSP with EROs



In the topology shown in Figure 66 on page 1185, traffic is routed from Host C1 to Host C2. The LSP can pass through Routers R4 or Router R7. To force the LSP to use R4, you can set up either a loose-hop or strict-hop ERO that specifies R4 as a hop in the LSP. To force a specific path through Router R4, R3, and R6, configure a strict-hop ERO through the three LSRs.

Constrained Shortest Path First

Whereas IGPs use the Shortest Path First (SPF) algorithm to determine how traffic is routed within a network, RSVP uses the Constrained Shortest Path First (CSPF) algorithm to calculate traffic paths that are subject to the following constraints:

- LSP attributes—Administrative groups such as link coloring, bandwidth requirements, and EROs
- Link attributes—Colors on a particular link and available bandwidth

These constraints are maintained in the traffic engineering database (TED). The database provides CSPF with up-to-date topology information, the current reservable bandwidth of links, and the link colors.

In determining which path to select, CSPF follows these rules:

- Computes LSPs one at a time, beginning with the highest priority LSP—the one with the lowest setup priority value. Among LSPs of equal priority, CSPF starts with those that have the highest bandwidth requirement.
- Prunes the traffic engineering database of links that are not full duplex and do not have sufficient reservable bandwidth.
- If the LSP configuration includes the `include` statement, prunes all links that do not share any included colors.
- If the LSP configuration includes the `exclude` statement, prunes all links that contain excluded colors. If a link does not have a color, it is accepted.
- Finds the shortest path toward the LSP's outbound router, taking into account any EROs. For example, if the path must pass through Router A, two separate SPF algorithms are computed: one from the inbound router to Router A and one from Router A to the outbound router.
- If several paths have equal cost, chooses the one with a last-hop address the same as the LSP's destination.
- If several equal-cost paths remain, selects the path with the least number of hops.
- If several equal-cost paths remain, applies CSPF load-balancing rules configured on the LSP.

Link Coloring

RSVP allows you to configure administrative groups for CSPF path selection. An administrative group is typically named with a color, assigned a numeric value, and applied to the RSVP interface for the appropriate link. Lower numbers indicate higher priority.

After configuring the administrative group, you can either exclude, include, or ignore links of that color in the TED:

- If you exclude a particular color, all segments with an administrative group of that color are excluded from CSPF path selection.
- If you include a particular color, only those segments with the appropriate color are selected.
- If you neither exclude nor include the color, the metrics associated with the administrative groups and applied on the particular segments determine the path cost for that segment.

The LSP with the lowest total path cost is selected into the TED.

RSVP-TE protocol extensions for FRR

Starting with Junos OS Release 16.1, RSVP Traffic Engineering (TE) protocol extensions to support Refresh-interval Independent RSVP (RI-RSVP) defined RFC 8370 for fast reroute (FRR) facility

protection were introduced to allow greater scalability of label-switched paths (LSPs) faster convergence times and decrease RSVP signaling message overhead from periodic refreshes. Junos RSVP-TE runs in enhanced FRR aka RI-RSVP mode by default that includes protocol extensions to support RI-RSVP for FRR facility bypass originally specified in RFC 4090.

The RI-RSVP protocol extensions implemented in Junos are fully backward compatible. In mixed environments, where a subset of LSPs traverse nodes that do not include this feature, Junos RSVP-TE running in enhanced FRR mode will automatically turn off the new protocol extensions in its signaling exchanges with nodes that do not support the new extensions.

As part of enhanced FRR profile, a number of changes were made and new defaults adopted. These are listed here.

- RSVP-TE runs “enhanced” FRR, or RI-RSVP mode, by default, which includes enhancements to facilitate scaled up scenarios. These new protocol extensions can be disabled on a router with the "no-enhanced-frr-bypass" on page 2822 command.
- RSVP refresh reduction extensions defined in RFC 2961 are enabled by default. The user can disable them with the no-reliable command (see below).

  > **NOTE**: Node-id based Hellos are enabled by default as enhanced FRR or RI-RSVP extensions require the exchange of Node-id based Hello messages. Node-id based Hellos can be disabled with `node-hello` command. As refresh-reduction extensions and node-id based Hello messages are essential for enhanced FRR or RI-RSVP extensions, disabling either of them will automatically turn off enhanced FRR extensions on the node.

- The default refresh time for RSVP messages has increased from 30 seconds to 20 minutes.
- The default value for "keep-multiplier" on page 2800, which is 3, is applied to the new default refresh time.
- Local reversion is disabled by default. The existing CLI configuration for node Hellos, `[edit protocols rsvp node-hello]`, is still available but the action is redundant. If enabled, a message is displayed to indicate that the configuration is not necessary in conjunction with enhanced FRR.
- The existing commands to disable message reliability are now used to disable RSVP refresh reduction. To revert back to the previous default enabling refresh reduction, use the `delete` version of the following commands:
  - Set `no-reliable` on a given interface to disable FRR scalability enhancements automatically for all LSPs traversing the interface. Likewise, to run RSVP-TE without FRR facility protection enhancements, and without refresh-reduction, disable refresh reduction on each interface. Use one of the commands shown here:
    - `[edit protocols rsvp interface` *`name`* `no-reliable]`

    - [edit logical-systems *name* protocols rsvp interface *name* no-reliable]

- Graceful restart and nonstop active routing (NSR) are not supported while the LSP undergoes local repair or while the LSP is refreshed during backup LSP signaling. This limitation exists already in the implementation because GR or NSR switchover during FRR local-repair makes for multiple failure scenario.

- The following operational commands have been updated to include new information about the new procedures introduced for the RSVP TE protocol extensions for FRR facility protection.

    - show rsvp version displays whether enhanced FRR procedures are enabled.

    - show rsvp neighbor detail displays whether enhanced FRR procedures are enabled on the neighbor.

    - show rsvp interface detail displays conditional PathTear statistics.

    - show rsvp statistics displays sent and received statistics for conditional PathTear, along with other statistics.

    - show rsvp session extensive displays whether the node is a merge point, and if it is, shows the Point of Local Repair (PLR) address.

- The previous CLI configuration options for enabling or disabling message bundling have been deprecated (the existing configurations are accepted, but a warning is displayed in the show configuration output). These commands are the following:

    - [edit protocols rsvp interface *name* aggregate]

    - [edit logical-systems *name* protocols rsvp interface *name* aggregate]

    - [edit protocols rsvp interface *name* no-aggregate]

    - [edit logical-systems *name* protocols rsvp interface *name* no-aggregate]

- The following CLI configuration options have been made redundant by the current changes (the existing configurations are accepted, but a warning is displayed in the show configuration output):

    - [edit protocols rsvp interface *name* reliable]

    - [edit logical-systems *name* protocols rsvp interface *name* reliable]

Junos OS RSVP Protocol Implementation

The Junos implementation of RSVP supports RSVP version 1. The software includes support for all mandatory objects and RSVP message types, and supports message integrity and node authentications through the Integrity object.

The primary purpose of the Junos RSVP software is to support dynamic signaling within MPLS label-switched paths (LSPs). Supporting resource reservations over the Internet is only a secondary purpose of

the Junos OS implementation. Since supporting resource reservations is secondary, the Junos RSVP software does not support the following features:

- IP multicasting sessions.
- Traffic control. The software cannot make resource reservations for real-time video or audio sessions.

With regard to the protocol mechanism, packet processing, and RSVP objects supported, the Junos OS implementation of the software is interoperable with other RSVP implementations.

RSVP Authentication

The Junos OS supports both the RSVP authentication style described in RFC 2747 (allowing for multivendor compatibility) and the RSVP authentication style described in Internet draft draft-ietf-rsvp-md5-03.txt. The Junos OS uses the authentication style described in Internet draft draft-ietf-rsvp-md5-08.txt by default. If the router receives an RFC 2747-style RSVP authentication from a neighbor, it switches to this style of authentication for that neighbor. The RSVP authentication style for each neighboring router is determined separately.

RSVP and IGP Hello Packets and Timers

RSVP monitors the status of the interior gateway protocol (IGP) (IS-IS or OSPF) neighbors and relies on the IGP protocols to detect when a node fails. If an IGP protocol declares a neighbor down (because hello packets are no longer being received), RSVP also brings down that neighbor. However, the IGP protocols and RSVP still act independently when bringing a neighbor up.

In the Junos OS, RSVP typically relies on IGP hello packet detection to check for node failures. Configuring a short time for the IS-IS or OSPF hello timers allows these protocols to detect node failures quickly. When the node fails or a node failure is detected, a path error message is generated, and although the RSVP session goes down, the IGP neighbors remain up.

RSVP hellos can be relied on when the IGP does not recognize a particular neighbor (for example, if IGP is not enabled on the interface) or if the IGP is RIP (not IS-IS or OSPF). Also, the equipment of other vendors might be configured to monitor RSVP sessions based on RSVP hello packets. This equipment might also take an RSVP session down due to a loss of RSVP hello packets.

We do not recommend configuring a short RSVP hello timer. If quick discovery of a failed neighbor is needed, configure short IGP (OSPF or IS-IS) hello timers.

OSPF and IS-IS have infrastructure to manage rapid hello message sending and receiving reliably, even if the routing protocols or some other process are straining the processing capability of the router. Under the same circumstances, RSVP hellos might time out prematurely even though the neighbor is functioning normally.

RSVP Message Types

- ResvErr Messages | 1191
- ResvConfirm Messages | 1191

RSVP uses the following types of messages to establish and remove paths for data flows, establish and remove reservation information, confirm the establishment of reservations, and report errors:

Path Messages

Each sender host transmits path messages downstream along the routes provided by the unicast and multicast routing protocols. Path messages follow the exact paths of application data, creating path states in the routers along the way, thus enabling routers to learn the previous-hop and next-hop node for the session. Path messages are sent periodically to refresh path states.

The refresh interval is controlled by a variable called the *refresh-time*, which is the periodical refresh timer expressed in seconds. A path state times out if a router does not receive a specified number of consecutive path messages. This number is specified by a variable called *keep-multiplier*. Path states are kept for ((*keep-multiplier* + 0.5) x 1.5 x *refresh-time*) seconds.

Resv Messages

Each receiver host sends reservation request (Resv) messages upstream toward senders and sender applications. Resv messages must follow exactly the reverse path of path messages. Resv messages create and maintain a reservation state in each router along the way.

Resv messages are sent periodically to refresh reservation states. The refresh interval is controlled by the same refresh time variable, and reservation states are kept for ((*keep-multiplier* + 0.5) x 1.5 x *refresh-time*) seconds.

PathTear Messages

PathTear messages remove (tear down) path states as well as dependent reservation states in any routers along a path. PathTear messages follow the same path as path messages. A PathTear typically is initiated by a sender application or by a router when its path state times out.

PathTear messages are not required, but they enhance network performance because they release network resources quickly. If PathTear messages are lost or not generated, path states eventually time out when they are not refreshed, and the resources associated with the path are released.

ResvTear Messages

ResvTear messages remove reservation states along a path. These messages travel upstream toward senders of the session. In a sense, ResvTear messages are the reverse of Resv messages. ResvTear messages typically are initiated by a receiver application or by a router when its reservation state times out.

ResvTear messages are not required, but they enhance network performance because they release network resources quickly. If ResvTear messages are lost or not generated, reservation states eventually time out when they are not refreshed, and the resources associated with the reservation are released.

PathErr Messages

When path errors occur (usually because of parameter problems in a path message), the router sends a unicast PathErr message to the sender that issued the path message. PathErr messages are advisory; these messages do not alter any path state along the way.

ResvErr Messages

When a reservation request fails, a ResvErr error message is delivered to all the receivers involved. ResvErr messages are advisory; these messages do not alter any reservation state along the way.

ResvConfirm Messages

Receivers can request confirmation of a reservation request, and this confirmation is sent with a ResvConfirm message. Because of the complex RSVP flow-merging rules, a confirmation message does not necessarily provide end-to-end confirmation of the entire path. Therefore, ResvConfirm messages are an indication, not a guarantee, of potential success.

Juniper Networks routers never request confirmation using the ResvConfirm message; however, a Juniper Networks router can send a ResvConfirm message if it receives a request from another vendor's equipment.

Understanding RSVP Automatic Mesh

When adding sites to BGP and MPLS VPNs that use RSVP signaling, more configuration is needed to add provider edge (PE) routers than is needed to add customer edge (CE) devices. RSVP automatic mesh helps to reduce this configuration burden.

Service providers often use BGP and MPLS VPNs to efficiently scale the network while delivering revenue-generating services. In these environments, BGP is used to distribute the VPN routing information across the service provider's network, while MPLS is used to forward that VPN traffic from one VPN site to another. BGP and MPLS VPNs are based on a peer model. To add a new CE device (site) to an existing VPN, you need to configure the CE router at the new site and the PE router connected to the CE router. You do not have to modify the configuration of all of the other PE routers participating in the VPN. The other PE routers automatically learn about the routes associated with the new site, a process called automatic discovery (AD).

The requirements are a bit different if you need to add a new PE router to the network. A BGP and MPLS VPN requires that the BGP session be fully meshed and that there also be a full mesh of PE router-to-PE router MPLS label-switched paths (LSPs) between all of the PE routers in the network. When you add a new PE router to the network, all of the existing PE routers must be reconfigured to peer with the new PE router. Much of the configuration effort can be reduced if you configure BGP route reflectors (mitigating the full mesh requirement for BGP) and if you configure (LDP) as the signaling protocol for MPLS.

However, if you need to add a new PE router to a network configured with a full mesh of RSVP-signaled LSPs, you must reconfigure each of the PE routers to have a peer relationship with the new PE router. You can configure RSVP automatic mesh to address this particular operational scenario. When you enable RSVP automatic mesh, RSVP LSPs are dynamically created between a new PE router and the existing PE routers, eliminating the need to reconfigure all of the PE routers manually. For dynamic LSP creation to function properly, BGP must be configured to exchange routes between all of the participating PE routers. If two BGP peers do not exchange routes, it is not possible to configure a dynamic LSP between them. The local router’s inet.3 routing table must include a labeled route to each potential IBGP next-hop (future potential PE routers or LSP destinations).

RSVP includes numerous capabilities that are not available in LDP, including fast reroute, end-point control, and link management. RSVP automatic mesh helps to reduce the operation and maintenance requirements for RSVP, making it possible to deploy RSVP in larger and more complicated networks.

Every PE router can reach every other PE router in the network because this information is distributed by the IGP. A PE router can set up a point-to-point RSVP LSP to any other PE router in the network as long as it knows that such an LSP is required. To build a full mesh of LSPs between the PE routers requires that each PE router know which of the other PE routers make up the full mesh.

NOTE: In Junos OS, RSVP automatic mesh is configured using the `rsvp-te` configuration statement at the `[edit routing-options dynamic-tunnels dynamic-tunnel-name]` hierarchy level. The `rsvp-te` configuration statement is also available for use in routing instances as a provider-tunnel option. When implemented as a provider-tunnel option, `rsvp-te` is used to configure the RSVP point-to-multipoint LSPs for multiprotocol BGP multicast VPNs, not to configure RSVP automatic mesh.

RSVP Reservation Styles

A reservation request includes options for specifying the reservation style. The reservation styles define how reservations for different senders within the same session are treated and how senders are selected.

Two options specify how reservations for different senders within the same session are treated:

- Distinct reservation—Each receiver establishes its own reservation with each upstream sender.
- Shared reservation—All receivers make a single reservation that is shared among many senders.

Two options specify how senders are selected:

- Explicit sender—List all selected senders.
- Wildcard sender—Select all senders, which then participate in the session.

The following reservation styles, formed by a combination of these four options, currently are defined:

- Fixed filter (FF)—This reservation style consists of distinct reservations among explicit senders. Examples of applications that use fixed-filter-style reservations are video applications and unicast applications, which both require flows that have a separate reservation for each sender. The fixed filter reservation style is enabled on RSVP LSPs by default.
- Wildcard filter (WF)—This reservation style consists of shared reservations among wildcard senders. This type of reservation reserves bandwidth for any and all senders, and propagates upstream toward all senders, automatically extending to new senders as they appear. A sample application for wildcard filter reservations is an audio application in which each sender transmits a distinct data stream. Typically, only a few senders are transmitting at any one time. Such a flow does not require a separate reservation for each sender; a single reservation is sufficient.
- Shared explicit (SE)—This reservation style consists of shared reservations among explicit senders. This type of reservation reserves bandwidth for a limited group of senders. A sample application is an audio application similar to that described for wildcard filter reservations.

RSVP Refresh Reduction

RSVP relies on soft-state to maintain the path and reservation states on each router. If the corresponding refresh messages are not sent periodically, the states eventually time out and reservations are deleted. RSVP also sends its control messages as IP datagrams with no reliability guarantee. It relies on periodic refresh messages to handle the occasional loss of Path or Resv messages.

The RSVP refresh reduction extensions, based on RFC 2961, addresses the following problems that result from relying on periodic refresh messages to handle message loss:

- Scalability—The scaling problem arises from the periodic transmission and processing overhead of refresh messages, which increases as the number of RSVP sessions increases.
- Reliability and latency—The reliability and latency problem stems from the loss of nonrefresh RSVP messages or one-time RSVP messages such as PathTear or PathErr. The time to recover from such a loss is usually tied to refresh interval and the keepalive timer.

The RSVP refresh reduction capability is advertised by enabling the refresh reduction (RR) capable bit in the RSVP common header. This bit is only significant between RSVP neighbors.

RSVP refresh reduction includes the following features:

- RSVP message bundling using the bundle message
- RSVP Message ID to reduce message processing overhead
- Reliable delivery of RSVP messages using Message ID, Message Ack, and Message Nack
- Summary refresh to reduce the amount of information transmitted every refresh interval

The RSVP refresh reduction specification (RFC 2961) allows you to enable some or all of the above capabilities on a router. It also describes various procedures that a router can use to detect the refresh reduction capabilities of its neighbor.

The Junos OS supports all of the refresh reduction extensions, some of which can be selectively enabled or disabled. The Junos OS supports Message ID and therefore can perform reliable message delivery only for Path and Resv messages.

For information about how to configure RSVP refresh reduction, see "Configuring RSVP Refresh Reduction" on page 1201.

MTU Signaling in RSVP

The maximum transmission unit (MTU) is the largest size packet or frame, in bytes, that can be sent in a network. An MTU that is too large might cause retransmissions. Too small an MTU might cause the router to send and handle relatively more header overhead and acknowledgments. There are default values for MTUs associated with various protocols. You can also explicitly configure an MTU on an interface.

When an LSP is created across a set of links with different MTU sizes, the ingress router does not know what the smallest MTU is on the LSP path. By default, the MTU for an LSP is 1,500 bytes.

If this MTU is larger than the MTU of one of the intermediate links, traffic might be dropped, because MPLS packets cannot be fragmented. Also, the ingress router is not aware of this type of traffic loss, because the control plane for the LSP would still function normally.

To prevent this type of packet loss in MPLS LSPs, you can configure MTU signaling in RSVP. This feature is described in RFC 3209. Juniper Networks supports the Integrated Services object for MTU signaling in RSVP. The Integrated Services object is described in RFCs 2210 and 2215. MTU signaling in RSVP is disabled by default.

To avoid packet loss due to MTU mismatches, the ingress router needs to do the following:

- Signal the MTU on the RSVP LSP—To prevent packet loss from an MTU mismatch, the ingress router needs to know what the smallest MTU value is along the path taken by the LSP. Once this MTU value is obtained, the ingress router can assign it to the LSP.
- Fragment packets—Using the assigned MTU value, packets that exceed the size of the MTU can be fragmented into smaller packets on the ingress router before they are encapsulated in MPLS and sent over the RSVP-signaled LSP.

Once both MTU signaling and packet fragmentation have been enabled on an ingress router, any route resolving to an RSVP LSP on this router uses the signaled MTU value. For information about how to configure this feature, see "Configuring MTU Signaling in RSVP" on page 1226.

The following sections describe how MTU signaling in RSVP works:

- "How the Correct MTU Is Signaled in RSVP" on page 1195
- "Determining an Outgoing MTU Value" on page 1196
- "MTU Signaling in RSVP Limitations" on page 1196

How the Correct MTU Is Signaled in RSVP

How the correct MTU is signaled in RSVP varies depending on whether the network devices (for example, routers) explicitly support MTU signaling in RSVP or not.

If the network devices support MTU signaling in RSVP, the following occur when you enable MTU signaling:

- The MTU is signaled from the ingress router to the egress router by means of the Adspec object. Before forwarding this object, the ingress router enters the MTU value associated with the interface over which the path message is sent. At each hop in the path, the MTU value in the Adspec object is updated to the minimum of the received value and the value of the outgoing interface.

- The ingress router uses the traffic specification (Tspec) object to specify the parameters for the traffic it is going to send. The MTU value signaled for the Tspec object at the ingress router is the maximum MTU value (9192 bytes for M Series and T Series routers, 9500 bytes for PTX Series Packet Transport Routers). This value does not change en route to the egress router.
- When the Adspec object arrives at the egress router, the MTU value is correct for the path (meaning it is the smallest MTU value discovered). The egress router compares the MTU value in the Adspec object to the MTU value in the Tspec object. It signals the smaller MTU using the Flowspec object in the Resv message.
- When the Resv object arrives at the ingress router, the MTU value in this object is used as the MTU for the next hops that use the LSP.

In a network where there are devices that do not support MTU signaling in RSVP, you might have the following behaviors:

- If the egress router does not support MTU signaling in RSVP, the MTU is set to 1,500 bytes by default.
- A Juniper Networks transit router that does not support MTU signaling in RSVP sets an MTU value of 1,500 bytes in the Adspec object by default.

Determining an Outgoing MTU Value

The outgoing MTU value is the smaller of the values received in the Adspec object compared to the MTU value of the outgoing interface. The MTU value of the outgoing interface is determined as follows:

- If you configure an MTU value under the `[family mpls]` hierarchy level, this value is signaled.
- If you do not configure an MTU, the `inet` MTU is signaled.

MTU Signaling in RSVP Limitations

The following are limitations to MTU signaling in RSVP:

- Changes in the MTU value might cause a temporary loss of traffic in the following situations:
  - For link protection and node protection, the MTU of the bypass is only signaled at the time the bypass becomes active. During the time it takes for the new path MTU to be propagated, packet loss might occur because of an MTU mismatch.
  - For fast reroute, the MTU of the path is updated only after the detour becomes active, causing a delay in an update to the MTU at the ingress router. Until the MTU is updated, packet loss might occur if there is an MTU mismatch.

    In both cases, only packets that are larger than the detour or bypass MTU are lost.

- When an MTU is updated, it triggers a change in the next hop. Any change in the next hop causes the route statistics to be lost.
- The minimum MTU supported for MTU signaling in RSVP is 1,488 bytes. This value prevents a false or incorrectly configured value from being used.
- For single-hop LSPs, the MTU value displayed by the `show` commands is the RSVP-signaled value. However, this MPLS value is ignored and the correct IP value is used.

Release History Table

Release	Description
16.1	Starting with Junos OS Release 16.1, RSVP Traffic Engineering (TE) protocol extensions to support Refresh-interval Independent RSVP (RI-RSVP) defined RFC 8370 for fast reroute (FRR) facility protection were introduced to allow greater scalability of label-switched paths (LSPs) faster convergence times and decrease RSVP signaling message overhead from periodic refreshes.

Minimum RSVP Configuration

To enable RSVP on a single interface, include the `rsvp` statement and specify the interface using the `interface` statement. This is the minimum RSVP configuration. All other RSVP configuration statements are optional.

```
rsvp {
    interface interface-name;
}
```

You can include these statements at the following hierarchy levels:

- [edit protocols]
- [edit logical-systems *logical-system-name* protocols]

To enable RSVP on all interfaces, substitute `all` for the *interface-name* variable.

If you have configured interface properties on a group of interfaces and want to disable RSVP on one of the interfaces, include the `disable` statement:

```
interface interface-name {
    disable;
}
```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp interface *interface-name*]
- [edit logical-systems *logical-system-name* protocols rsvp interface *interface-name*]

Configuring RSVP and MPLS

IN THIS SECTION

- Example: Configuring RSVP and MPLS | **1200**

The primary purpose of the Junos RSVP software is to support dynamic signaling within label-switched paths (LSPs). When you enable both MPLS and RSVP on a router, MPLS becomes a client of RSVP. No additional configuration is required to bind MPLS and RSVP.

You can configure MPLS to set up signaled paths by using the `label-switched-path` statement at the `[edit protocols mpls]` hierarchy level. Each LSP translates into a request for RSVP to initiate an RSVP session. This request is passed through the internal interface between label switching and RSVP. After examining the request information, checking RSVP states, and checking the local routing tables, RSVP initiates one session for each LSP. The session is sourced from the local router and is destined for the target of the LSP.

When an RSVP session is successfully created, the LSP is set up along the paths created by the RSVP session. If the RSVP session is unsuccessful, RSVP notifies MPLS of its status. It is up to MPLS to initiate backup paths or continue retrying the initial path.

To pass label-switching signaling information, RSVP supports four additional objects: Label Request object, Label object, Explicit Route object, and Record Route object. For an LSP to be set up successfully, all routers along the path must support MPLS, RSVP, and the four objects. Of the four objects, the Record Route object is not mandatory.

To configure MPLS and make it a client of RSVP, do the following:

- Enable MPLS on all routers that will participate in the label switching (this is, on all routers that might be part of a label-switching path).
- Enable RSVP on all routers and on all router interfaces that form the LSP.
- Configure the routers at the beginning of the LSP.

Example: Configuring RSVP and MPLS

The following shows a sample configuration for a router at the beginning of an LSP:

```
[edit]
protocols {
    mpls {
        label-switched-path sf-to-london {
            to 192.168.1.4;
        }
    }
    rsvp {
        interface so-0/0/0;
    }
}
```

The following shows a sample configuration for all the other routers that form the LSP:

```
[edit]
protocols {
    mpls {
        interface so-0/0/0;
    }
    rsvp {
        interface so-0/0/0;
    }
}
```

Configuring RSVP Interfaces

The following sections describe how to configure RSVP interfaces:

Configuring RSVP Refresh Reduction

You can configure RSVP refresh reduction on each interface by including the following statements in the interface configuration:

- `aggregate` and `reliable`—Enable all RSVP refresh reduction features: RSVP message bundling, RSVP message ID, reliable message delivery, and summary refresh.

  In order to have refresh reduction and reliable delivery, you must include the `aggregate` and `reliable` statements.

- `no-aggregate`—Disable RSVP message bundling and summary refresh.

- `no-reliable`—Disable RSVP message ID, reliable message delivery, and summary refresh.

For more information on RSVP refresh reduction, see "RSVP Refresh Reduction" on page 1194.

If the `no-reliable` statement is configured on the router (reliable message delivery is disabled), the router accepts RSVP messages that include the Message ID object but ignores the Message ID object and continues performing standard message processing. No error is generated in this case, and RSVP operates normally.

However, not all combinations between two neighbors with different refresh reduction capabilities function correctly. For example, a router is configured with either the `aggregate` statement and `no-reliable` statement or with the `reliable` and `no-aggregate` statements. If an RSVP neighbor sends a Summary Refresh object to this router, no error is generated, but the Summary Refresh object cannot be processed. Consequently, RSVP states can time out on this router if the neighbor is relying only on Summary Refresh to refresh those RSVP states.

We recommend, unless there are specific requirements, that you configure RSVP refresh reduction in a similar manner on each RSVP neighbor.

To enable all RSVP refresh reduction features on an interface, include the `aggregate` statement:

```
aggregate;
```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp interface *interface-name*]
- [edit logical-systems *logical-system-name* protocols rsvp interface *interface-name*]

To disable RSVP message bundling and summary refresh, include the `no-aggregate` statement:

```
no-aggregate;
```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp interface *interface-name*]
- [edit logical-systems *logical-system-name* protocols rsvp interface *interface-name*]

To enable RSVP message ID and reliable message delivery on an interface, include the `reliable` statement:

```
reliable;
```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp interface *interface-name*]
- [edit logical-systems *logical-system-name* protocols rsvp interface *interface-name*]

To disable RSVP message ID, reliable message delivery, and summary refresh, include the `no-reliable` statement:

```
no-reliable;
```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp interface *interface-name*]
- [edit logical-systems *logical-system-name* protocols rsvp interface *interface-name*]

Determining the Refresh Reduction Capability of RSVP Neighbors

To determine the RSVP refresh reduction capability of an RSVP neighbor, you need the following information:

- The RR bit advertised by the neighbor
- The local configuration of RSVP refresh reduction
- The actual RSVP messages received from the neighbor

To obtain this information, you can issue a `show rsvp neighbor detail` command. Sample output follows:

```
user@host> show rsvp neighbor detail
RSVP neighbor: 6 learned
    Address: 192.168.224.178 via: fxp1.0 status: Up
      Last changed time: 10:06, Idle: 5 sec, Up cnt: 1, Down cnt: 0
      Message received: 36
      Hello: sent 69, received: 69, interval: 9 sec
      Remote instance: 0x60b8feba, Local instance: 0x74bc7a8d
      Refresh reduction:  not operational

    Address: 192.168.224.186 via: fxp2.0 status: Down
      Last changed time: 10:17, Idle: 40 sec, Up cnt: 0, Down cnt: 0
      Message received: 6
      Hello: sent 20, received: 0, interval: 9 sec
      Remote instance: 0x0, Local instance: 0x2ae1b339
      Refresh reduction:  incomplete
        Remote end: disabled, Ack-extension: enabled

    Address: 192.168.224.188 via: fxp2.0 status: Up
      Last changed time: 4:15, Idle: 0 sec, Up cnt: 1, Down cnt: 0
      Message received: 55
      Hello: sent 47, received: 31, interval: 9 sec
      Remote instance: 0x6436a35b, Local instance: 0x663849f0
      Refresh reduction:  operational
        Remote end: enabled, Ack-extension: enabled
```

For more information on the `show rsvp neighbor detail` command.

Configuring the RSVP Hello Interval

RSVP monitors the status of the interior gateway protocol (IGP) (IS-IS or OSPF) neighbors and relies on the IGP protocols to detect when a node fails. If an IGP protocol declares a neighbor down (because hello packets are no longer being received), RSVP also brings down that neighbor. However, the IGP protocols and RSVP still act independently when bringing a neighbor up.

For Juniper Networks routers, configuring a shorter or longer RSVP hello interval has no impact on whether or not an RSVP session is brought down. RSVP sessions are kept up even if RSVP hello packets are no longer being received. RSVP sessions are maintained until either the router stops receiving IGP hello packets or the RSVP Path and Resv messages time out. However, starting from Junos OS Release 16.1, when RSVP hello messages time-out, the RSVP sessions are brought down.

The RSVP hello interval might also be impacted when another vendor's equipment brings down an RSVP session. For example, a neighboring non-Juniper Networks router might be configured to monitor RSVP hello packets.

To modify how often RSVP sends hello packets, include the `hello-interval` statement:

```
hello-interval seconds;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section.

Configuring RSVP Authentication

All RSVP protocol exchanges can be authenticated to guarantee that only trusted neighbors participate in setting up reservations. By default, RSVP authentication is disabled.

RSVP authentication uses a Hashed Message Authentication Code (HMAC)-MD5 message-based digest. This scheme produces a message digest based on a secret authentication key and the message contents. (The message contents also include a sequence number.) The computed digest is transmitted with RSVP messages. Once you have configured authentication, all received and transmitted RSVP messages with all neighbors are authenticated on this interface.

MD5 authentication provides protection against forgery and message modification. It also can prevent replay attacks. However, it does not provide confidentiality, because all messages are sent in clear text.

By default, authentication is disabled. To enable authentication, configure a key on each interface by including the `authentication-key` statement:

```
authentication-key key;
```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp interface *interface-name*]
- [edit logical-systems *logical-system-name* protocols rsvp interface *interface-name*]

Configuring the Bandwidth Subscription for Class Types

By default, RSVP allows 100 percent of the bandwidth for a class type to be used for RSVP reservations. When you oversubscribe a class type for a multiclass LSP, the aggregate demand of all RSVP sessions is allowed to exceed the actual capacity of the class type.

For detailed instructions on how to configure the bandwidth subscription for class types, see "Configuring the Bandwidth Subscription Percentage for LSPs" on page 660.

Configuring the RSVP Update Threshold on an Interface

The interior gateway protocols (IGPs) maintain the traffic engineering database, but the current available bandwidth on the traffic engineering database links originates from RSVP. When a link's bandwidth changes, RSVP informs the IGPs, which can then update the traffic engineering database and forward the new bandwidth information to all network nodes. The network nodes then know how much bandwidth is available on the traffic engineering database link (local or remote), and CSPF can correctly compute the paths.

However, IGP updates can consume excessive system resources. Depending on the number of nodes in a network, it might not be desirable to perform an IGP update for small changes in bandwidth. By configuring the `update-threshold` statement at the `[edit protocols rsvp]` hierarchy level, you can adjust the threshold at which a change in the reserved bandwidth triggers an IGP update.

You can configure a value of from 0.001 percent through 20 percent (the default is 10 percent) for when to trigger an IGP update. If the change in the reserved bandwidth is greater than or equal to the configured threshold percentage of the static bandwidth on that interface, then an IGP update occurs. For example, if you have configured the `update-threshold` statement to be 15 percent and the router discovers that the reserved bandwidth on a link has changed by 10 percent of the link bandwidth, RSVP does not trigger an IGP update. However, if the reserved bandwidth on a link changes by 20 percent of the link bandwidth, RSVP triggers an IGP update.

You can also configure the threshold as an absolute value using the `threshold-value` option under the `update-threshold` statement.

If the threshold-value is configured to greater than 20% of bandwidth on that link, the threshold-value is capped at 20% of bandwidth.

For instance, if bandwidth on an interface is 1Gbps, and the `threshold-value` is configured greater than 200Mbps, the `threshold-value` is capped at 200Mbps. The *threshold-percent* is displayed as 20.000% and the `threshold-value` as 200Mbps.

NOTE: The two options, *threshold-percent* and `threshold-value`, are mutually exclusive. You can configure only one option at a given point in time to generate an IGP update for lower bandwidth reservations. As a result, when one option is configured, the other option is calculated and displayed on the CLI.

For instance, on a link of 1Gbps, if the *threshold-percent* is configured to 5%, the `threshold-value` is calculated and displayed as 50Mbps. Similarly, if the `threshold-value` is configured to 50m, then the *threshold-percent* is calculated and displayed as 5%.

To adjust the threshold at which a change in the reserved bandwidth triggers an IGP update, include the "update-threshold" on page 2856 statement. Because of the update threshold, it is possible for Constrained Shortest Path First (CSPF) to compute a path using outdated traffic engineering database bandwidth information on a link. If RSVP attempts to establish an LSP over that path, it might find that there is insufficient bandwidth on that link. When this happens, RSVP triggers an IGP traffic engineering database update, flooding the updated bandwidth information on the network. CSPF can then recompute the path by using the updated bandwidth information, and attempt to find a different path, avoiding the congested link. Note that this functionality is the default and does not need any additional configuration.

You can configure the `rsvp-error-hold-time` statement at the `[edit protocols mpls]` hierarchy level or the `[edit logical-systems` *`logical-system-name`* `protocols mpls]` hierarchy level to improve the accuracy of the traffic engineering database (including the accuracy of bandwidth estimates for LSPs) using information provided by PathErr messages. See "Improving Traffic Engineering Database Accuracy with RSVP PathErr Messages" on page 1655.

Configuring RSVP for Unnumbered Interfaces

The Junos OS supports RSVP traffic engineering over unnumbered interfaces. Traffic engineering information about unnumbered links is carried in the IGP traffic engineering extensions for OSPF and IS-IS as described in RFC 4203, *OSPF Extensions in Support of Generalized Multi-Protocol Label Switching (GMPLS)*, and RFC 4205, *Intermediate System to Intermediate System (IS-IS) Extensions in Support of Generalized Multi-Protocol Label Switching (GMPLS)*. Unnumbered links can also be specified in the MPLS traffic engineering signaling as described in RFC 3477, *Signalling Unnumbered Links in Resource ReSerVation Protocol - Traffic Engineering (RSVP-TE)*. This feature allows you avoid having to configure IP addresses for each interface participating in the RSVP-signaled network.

To configure RSVP for unnumbered interfaces, you must configure the router with a router ID using the `router-id` statement specified at the `[edit routing-options]` hierarchy level. The router ID must be available for routing (you can typically use the loopback address). The RSVP control messages for the unnumbered links are sent using the router ID address (rather than a randomly selected address).

To configure link protection and fast reroute on a router with unnumbered interfaces enabled, you must configure at least two addresses. We recommend that you configure a secondary interface on the loopback in addition to configuring the router ID.

Configuring RSVP Node-ID Hellos

You can configure node-ID based RSVP hellos to ensure that Juniper Networks routers can interoperate with the equipment of other vendors. By default, Junos OS uses interface-based RSVP hellos. Node-ID based RSVP hellos are specified in RFC 4558, *Node-ID Based Resource Reservation Protocol (RSVP) Hello: A Clarification Statement*. RSVP node-ID hellos are useful if you have configured BFD to detect problems over RSVP interfaces, allowing you to disable interface hellos for these interfaces. You can also use node-ID hellos for graceful restart procedures.

Node-ID hellos can be enabled globally for all RSVP neighbors. By default, node-ID hello support is disabled. If you have not enabled RSVP node IDs on the router, the Junos OS does not accept any node-ID hello packets.

To enable RSVP node-ID hellos globally on the router, include the "node-hello" on page 2811 statement at the following hierarchy levels:

- `[edit protocols rsvp]`
- `[edit logical-systems` *`logical-systems-name`* `protocols rsvp]`

You can also explicitly disable RSVP interface hellos globally. This type of configuration might be necessary in networks where the Juniper Networks router has numerous RSVP connections with equipment from other vendors. However, if you disable RSVP interface hellos globally, you can also configure a hello interval on an RSVP interface using the "hello-interval" on page 2794 statement. This configuration disables RSVP interface hellos globally, but enables RSVP interface hellos on the specified interface (the RSVP interface you configure the `hello-interval` statement on). This configuration might be necessary in a heterogeneous network in which some devices support RSVP node-ID hellos and other devices support RSVP interface hellos.

To disable RSVP interface hellos globally on the router, include the "no-interface-hello" on page 2817 statement at the following hierarchy levels:

- `[edit protocols rsvp]`
- `[edit logical-systems` *`logical-systems-name`* `protocols rsvp]`

Example: Configuring RSVP-Signaled LSPs

IN THIS SECTION

- Requirements | 1208
- Overview and Topology | 1208
- Configuration | 1209
- Verification | 1212

This example shows how to create an LSP between routers in an IP network using RSVP as the signaling protocol.

Requirements

Before you begin, delete security services from the device. See Example: Deleting Security Services.

Overview and Topology

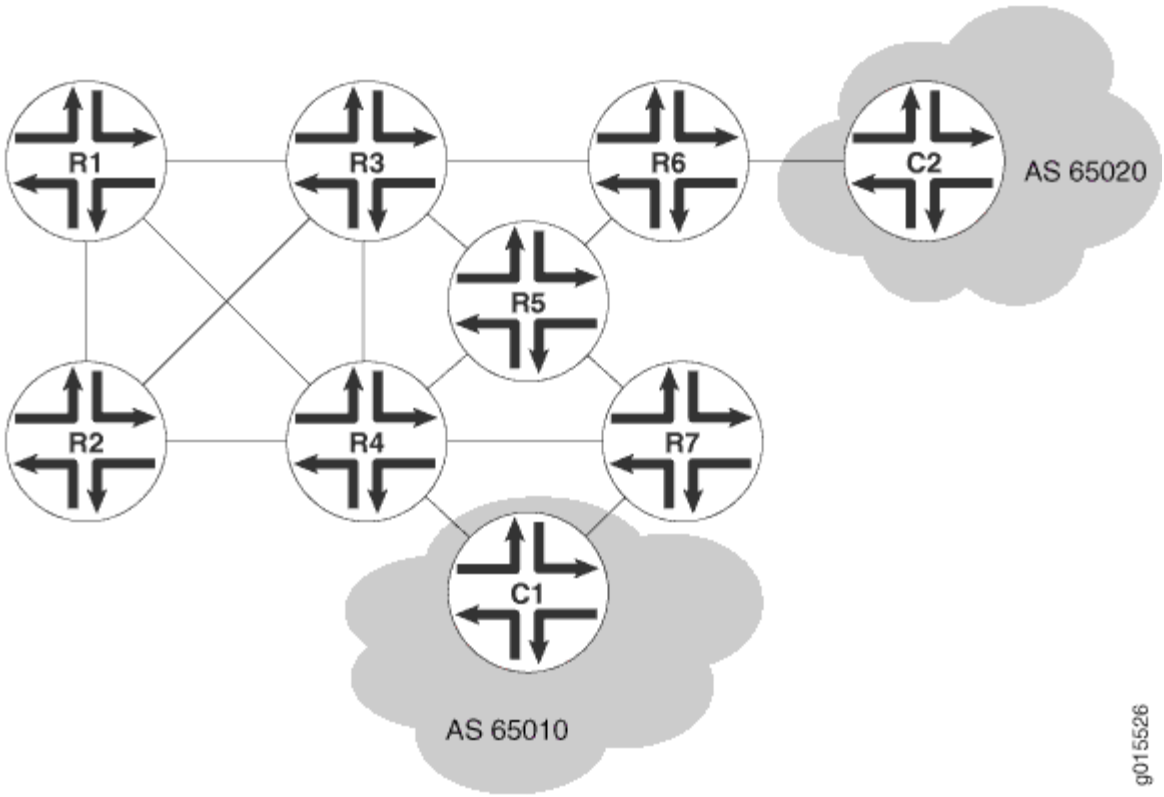
IN THIS SECTION

- Topology | 1209

Using RSVP as a signaling protocol, you can create LSPs between routers in an IP network. In this example, you configure a sample network as shown in Figure 67 on page 1209.

Topology

Figure 67: Typical RSVP-Signaled LSP



To establish an LSP between routers, you must individually enable the MPLS family and configure RSVP on each of the transit interfaces in the MPLS network. This example shows how to enable MPLS and configure RSVP on the ge-0/0/0 transit interface. Additionally, you must enable the MPLS process on all of the MPLS interfaces in the network.

This example shows how to define an LSP from R1 to R7 on the ingress router (R1) using R7's loopback address (10.0.9.7). The configuration reserves 10 Mbps of bandwidth. Additionally, the configuration disables the CSPF algorithm, ensuring that Hosts C1 and C2 use the RSVP-signaled LSP that correspond to the network IGP's shortest path.

Configuration

IN THIS SECTION

- Procedure | **1210**

Procedure

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the `[edit]` hierarchy level.

```
set interfaces ge-0/0/0 unit 0 family mpls
set protocols rsvp interface ge-0/0/0.0
set protocols mpls label-switched-path r1-r7 to 10.0.9.7
set protocols mpls label-switched-path r1-r7 bandwidth 10m
set protocols mpls interface all
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the CLI User Guide.

To configure RSVP:

1. Enable the MPLS family on all transit interfaces in the MPLS network.

```
[edit]
user@host# set interfaces ge-0/0/0 unit 0 family mpls
```

2. Enable RSVP on each transit interface in the MPLS network.

```
[edit]
user @host# set protocols rsvp interface ge-0/0/0
```

3. Enable the MPLS process on the transit interface in the MPLS network.

```
[edit]
user@host# set protocols mpls interface ge-0/0/0
```

4. Define the LSP on the ingress router.

```
[edit protocols mpls]
user@host# set label-switched-path r1-r7 to 10.0.9.7
```

5. Reserve 10 Mbps of bandwidth on the LSP.

```
[edit protocols mpls]
user @host# set label-switched-path r1-r7 bandwidth 10m
```

Results

Confirm your configuration by entering the `show` command from configuration mode. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

For brevity, this `show` command output includes only the configuration that is relevant to this example. Any other configuration on the system has been replaced with ellipses (...).

```
user@host# show
...
    interfaces {
    ge-0/0/0 {
        family mpls;
        }
    }
    }
    ...
    protocols {
        rsvp {
            interface ge-0/0/0.0;
        }
        mpls {
            label-switched-path r1-r7 {
                to 10.0.9.7;
                bandwidth 10m;
            }
            interface all;
        }
```

```
    }
...
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

IN THIS SECTION

- Verifying RSVP Neighbors | **1212**
- Verifying RSVP Sessions | **1213**
- Verifying the Presence of RSVP-Signaled LSPs | **1214**

To confirm that the configuration is working properly, perform these tasks:

Verifying RSVP Neighbors

Purpose

Verify that each device shows the appropriate RSVP neighbors—for example, that Router R1 in Figure 67 on page 1209 lists both Router R3 and Router R2 as RSVP neighbors.

Action

From the CLI, enter the `show rsvp neighbor` command.

```
user@r1> show rsvp neighbor
RSVP neighbor: 2 learned
Address            Idle Up/Dn LastChange HelloInt HelloTx/Rx
10.0.6.2              0  3/2       13:01        3   366/349
10.0.3.3              0  1/0       22:49        3   448/448
```

The output shows the IP addresses of the neighboring routers. Verify that each neighboring RSVP router loopback address is listed.

Verifying RSVP Sessions

Purpose

Verify that an RSVP session has been established between all RSVP neighbors. Also, verify that the bandwidth reservation value is active.

Action

From the CLI, enter the `show rsvp session detail` command.

```
user@r1> show rsvp session detail
Ingress RSVP: 1 sessions

10.0.9.7
  From: 10.0.6.1, LSPstate: Up, ActiveRoute: 0
  LSPname: r1-r7, LSPpath: Primary
  Bidirectional, Upstream label in: -, Upstream label out: -
  Suggested label received: -, Suggested label sent: -
  Recovery label received: -, Recovery label sent: 100000
  Resv style: 1 FF, Label in: -, Label out: 100000
  Time left:    -,  Since: Thu Jan 26 17:57:45 2002
  Tspec: rate 10Mbps size 10Mbps peak Infbps m 20 M 1500
  Port number: sender 3 receiver 17 protocol 0
  PATH rcvfrom: localclient
  PATH sentto: 10.0.4.13 (ge-0/0/1.0) 1467 pkts
  RESV rcvfrom: 10.0.4.13  (ge-0/0/1.0) 1467 pkts
  Record route: <self> 10.0.4.13  10.0.2.1  10.0.8.10
```

The output shows the detailed information, including session IDs, bandwidth reservation, and next-hop addresses, for each established RSVP session. Verify the following information:

- Each RSVP neighbor address has an entry for each neighbor, listed by loopback address.
- The state for each LSP session is **Up**.
- For **Tspec**, the appropriate bandwidth value, **10Mbps**, appears.

Verifying the Presence of RSVP-Signaled LSPs

Purpose

Verify that the routing table of the entry (ingress) router has a configured LSP to the loopback address of the other router. For example, verify that the **inet.3** routing table of the R1 entry router in Figure 67 on page 1209 has a configured LSP to the loopback address of Router R7.

Action

From the CLI, enter the `show route table inet.3` command.

```
user@r1> show route table inet.3
inet.3: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.0.9.7/32         *[RSVP/7] 00:05:29, metric 10
                    > to 10.0.4.17 via ge-0/0/0.0, label-switched-path r1-r7
```

The output shows the RSVP routes that exist in the **inet.3** routing table. Verify that an RSVP-signaled LSP is associated with the loopback address of the exit (egress) router, R7, in the MPLS network.

Example: Configuring RSVP Automatic Mesh

IN THIS SECTION

- Requirements | **1215**
- Overview | **1215**
- Configuration | **1216**
- Verification | **1218**

Service providers often use BGP and MPLS VPNs to efficiently scale the network while delivering revenue-generating services. In these environments, BGP is used to distribute the VPN routing information across the service provider's network, while MPLS is used to forward that VPN traffic from one VPN site to another.

When adding a new PE router that will participate in BGP and MPLS VPNs, all of the previously existing PE routers must be configured to peer with the new PE router for both BGP and MPLS. As each new PE

router is added to the service provider's network, the configuration burden soon becomes too much to handle.

The configuration requirements for BGP peering can be reduced with the use of route reflectors. In RSVP signaled MPLS networks, RSVP automatic mesh can minimize the configuration burden for the MPLS portion of the network. Configuring `rsvp-te` on all PE routers allows RSVP to automatically create the needed LSPs when a new PE router is added.

Requirements

This example uses the following hardware and software components:

- A router running Junos OS Release 10.1 or later.
- A BGP and MPLS VPN using RSVP as the MPLS label-switched path (LSP) signaling protocol.

Overview

IN THIS SECTION

- Topology | **1215**

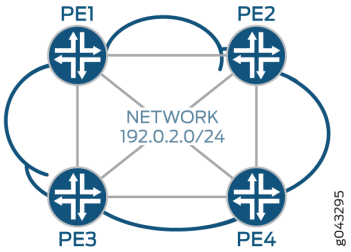
This example shows how to configure RSVP automatic mesh on a PE router using the `rsvp-te` configuration statement. In order for RSVP automatic mesh to function properly, all of the PE routers in the full mesh configuration must have the `rsvp-te` statement configured. This ensures that any new PE routers that are added later will also benefit from the automatic mesh feature, provided that they too are configured with the `rsvp-te` statement.

Given this requirement, this example only shows the configuration on the newly added PE router. It is assumed that RSVP automatic mesh has already been configured on the existing PE routers.

Topology

In Figure 68 on page 1216, there are three existing PE routers, PE1, PE2, and PE3, in the topology. PE4 has been added, and RSVP automatic mesh will be configured. The cloud represents the service provider network, and the network address, 192.0.2.0/24, is shown in the center of the figure.

Figure 68: Service Provider Network with PE Routers



Configuration

IN THIS SECTION

- CLI Quick Configuration | **1217**
- Configuring RSVP Automatic Mesh | **1217**
- Results | **1217**

Configuring RSVP automatic mesh involves performing these tasks:

- Enabling the `rsvp-te` configuration statement at the `[edit routing-options dynamic-tunnels` *`dynamic-tunnel-name`*`]` hierarchy level.
- Configuring the required `destination-networks` element.

  This configuration element specifies the IPv4 prefix range for the destination network. Only tunnels within the specified prefix range can be created.

- Configuring the required `label-switched-path-template` element.

  This configuration element takes either `default-template` or the name of a preconfigured LSP template as an argument. The `default-template` is a system-defined template that requires no user configuration.

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the `[edit]` hierarchy level.

PE4 Router

```
set routing-options dynamic-tunnels dt-1 rsvp-te rsvp-te-1 label-switched-path-template default-template
set routing-options dynamic-tunnels dt-1 rsvp-te rsvp-te-1 destination-networks 192.0.2.0/24
```

Configuring RSVP Automatic Mesh

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the CLI User Guide.

To enable RSVP automatic mesh:

1. Configure `rsvp-te` at the `[edit routing-options dynamic-tunnels]` hierarchy level.

```
[edit routing-options dynamic-tunnels]
user@PE4# set dt-1 rsvp-te rsvp-te-1 label-switched-path-template default-template
```

2. Configure `destination-networks` at the `[edit routing-options dynamic-tunnels]` hierarchy level.

```
[edit routing-options dynamic-tunnels]
user@PE4# set dt-1 rsvp-te rsvp-te-1 destination-networks 192.0.2.0/24
```

Results

Issue the `show` command from the `[edit routing-options dynamic-tunnels]` hierarchy level to see the results of your configuration:

```
[edit routing-options dynamic-tunnels]
user@PE4#show
dt-1 {
```

```
    rsvp-te rsvp-te-1 {
        label-switched-path-template {
            default-template;
        }
        destination-networks {
            192.0.2.0/24;
        }
    }
}
```

Verification

IN THIS SECTION

- Verifying the Existence of RSVP Automatic Mesh Tunnels on Router PE4 | **1218**
- Verifying the Existence of MPLS LSPs on Router PE4 | **1219**

Verifying the Existence of RSVP Automatic Mesh Tunnels on Router PE4

Purpose

To verify the operation of the newly configured PE4 router, issue the `show dynamic-tunnels database` command from operational mode. This command will show the destination network to which dynamic tunnels can be created.

Action

```
user@PE4> show dynamic-tunnels database
Table: inet.3
Destination-network: 192.0.2.0/24
```

Verifying the Existence of MPLS LSPs on Router PE4

Purpose

To verify the existence of MPLS LSPs on the PE4 router, issue the `show mpls lsp` command from operational mode. This command will show the state of the MPLS LSPs.

Action

```
user@PE4> show mpls lsp
```

```
Ingress LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

Egress LSP: 3 sessions
To              From            State   Rt Style Labelin Labelout LSPname
192.0.2.104     192.0.2.103     Up       0  1 FF       3        - PE2-PE4
192.0.2.104     192.0.2.102     Up       0  1 FF       3        - PE2-PE4
192.0.2.104     192.0.2.101     Up       0  1 FF       3        - PE1-PE4
Total 3 displayed, Up 3, Down 0

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Configuring Hello Acknowledgments for Nonsession RSVP Neighbors

The `hello-acknowledgements` statement controls the hello acknowledgment behavior between RSVP neighbors regardless of whether or not they are in the same session.

Hello messages received from RSVP neighbors that are not part of a common RSVP session are discarded. If you configure the `hello-acknowledgements` statement at the `[edit protocols rsvp]` hierarchy level, hello messages from nonsession neighbors are acknowledged with a hello acknowledgment message. When hellos are received from nonsession neighbors, an RSVP neighbor relationship is created and periodic hello messages can now be received from the nonsession neighbor. The `hello-acknowledgements` statement is disabled by default. Configuring this statement allows RSVP-capable routers to be discovered using hello packets and verifies that the interface is able to receive RSVP packets before sending any MPLS LSP setup messages.

Once you enable hello acknowledgments for nonsession RSVP neighbors, the router continues to acknowledge hello messages from any nonsession RSVP neighbors unless the interface itself goes down or you change the configuration. Interface-based neighbors are not automatically aged out.

```
hello-acknowledgements;
```

You can include this statement at the following hierarchy levels:

- `[edit protocols rsvp]`
- `[edit logical-systems` *`logical-system-name`* `protocols rsvp]`

Switching LSPs Away from a Network Node

You can configure the router to switch active LSPs away from a network node using a bypass LSP enabled for an interface. This feature might be used to maintain active networks when a device needs to be replaced without interrupting traffic transiting the network. The LSPs can be either static or dynamic.

1. You first need to configure either link or node protection for the traffic that needs to pass around the network device you intend to disable. To function properly, the bypass LSP must use a different logical interface than the protected LSP.
2. To prepare the router to begin switching traffic away from a network node, configure the `always-mark-connection-protection-tlv` statement:

   ```
   always-mark-connection-protection-tlv;
   ```

   The router then marks all OAM traffic transiting this interface in preparation for switching the traffic to an alternate path based on the OAM functionality.

   You can configure this statement at the following hierarchy levels:

   - `[edit protocols mpls interface` *`interface-name`*`]`
   - `[edit logical-systems` *`logical-system-name`* `protocols mpls interface` *`interface-name`*`]`
3. You then need to configure the `switch-away-lsps` statement to switch the traffic from the protected LSP to the bypass LSP, effectively bypassing the default downstream network device. The actual link itself is not brought down by this configuration.

   To configure the router to switch traffic away from a network node, configure the `switch-away-lsps` statement:

   ```
   switch-away-lsps;
   ```

You can configure this statement at the following hierarchy levels:

- [edit protocols mpls interface *interface-name*]
- [edit logical-systems *logical-system-name* protocols mpls interface *interface-name*]

Note the following limitations related to switching active LSPs away from a network node:

- The switch-away feature is supported on MX Series routers only.
- The switch-away feature is not supported for switching traffic from primary point-to-multipoint LSPs to bypass point-to-multipoint LSPs. If you configure the switch-away-lsps statement for a point-to-multipoint LSP, traffic is not switched to the bypass point-to-multipoint LSP.
- If you configure the switch-away feature on an interface along the path of a dynamic LSP, new dynamic LSPs cannot be established over that path. The switch-away feature prevents the make-before-break behavior of RSVP-signaled LSPs. The make-before-break behavior normally causes the router to first attempt to re-signal a dynamic LSP before tearing down the original.

Configuring RSVP Setup Protection

You can configure the facility-backup fast reroute mechanism to provide setup protection for LSPs which are in the process of being signaled. Both point-to-point LSPs and point-to-multipoint LSPs are supported. This feature is applicable in the following scenario:

1. A failed link or node is present on the strict explicit path of an LSP before the LSP is signaled.
2. There is also a bypass LSP protecting the link or node.
3. RSVP signals the LSP through the bypass LSP. The LSP appears as if it was originally set up along its primary path and then failed over to the bypass LSP because of the link or node failure.
4. When the link or node has recovered, the LSP can be automatically reverted to the primary path.

You should configure the setup-protection statement at the [edit protocols rsvp] on each of the routers along the LSP path on which you want to enable LSP setup protection. You should also configure IGP traffic engineering on all of the routers on the LSP path. You can issue a show rsvp session command to determine whether or not the LSP has setup protection enabled on a router acting as a point of local repair (PLR) or a merge point.

To enable RSVP setup protection, include the setup-protection statement

```
setup-protection;
```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp]

- [edit logical-systems *logical-system-name* protocols rsvp]

Configuring Load Balancing Across RSVP LSPs

By default, when you have configured several RSVP LSPs to the same egress router, the LSP with the lowest metric is selected and carries all traffic. If all of the LSPs have the same metric, one of the LSPs is selected at random and all traffic is forwarded over it.

Alternatively, you can load-balance traffic across all of the LSPs by enabling per-packet load balancing.

To enable per-packet load balancing on an ingress LSP, configure the policy-statement statement as follows:

```
[edit policy-options]
policy-statement policy-name {
    then {
        load-balance per-packet;
    }
    accept;
}
```

You then need to apply this statement as an export policy to the forwarding table.

Once per-packet load balancing is applied, traffic is distributed equally between the LSPs (by default).

You need to configure per-packet load balancing if you want to enable PFE fast reroute. To enable PFE fast reroute, include the policy-statement statement for per-packet load balancing shown in this section in the configuration of each of the routers where a reroute might take place. See also "Configuring Fast Reroute" on page 565.

You can also load-balance the traffic between the LSPs in proportion to the amount of bandwidth configured for each LSP. This capability can better distribute traffic in networks with asymmetric bandwidth capabilities across external links, since the configured bandwidth of an LSP typically reflects the traffic capacity of that LSP.

To configure RSVP LSP load balancing, include the load-balance statement with the bandwidth option:

```
load-balance {
    bandwidth;
}
```

You can configure this statement at the following hierarchy levels:

- [edit protocols rsvp]

- [edit logical-systems *logical-system-name* protocols rsvp]

Keep the following information in mind when you use the load-balance statement:

- If you configure the load-balance statement, the behavior of currently running LSPs is not altered. To force currently running LSPs to use the new behavior, you can issue a clear mpls lsp command.
- The load-balance statement only applies to ingress LSPs that have per-packet load balancing enabled.
- For Differentiated Services–aware traffic engineered LSPs, the bandwidth of an LSP is calculated by summing the bandwidth of all of the class types.

Configuring RSVP Automatic Mesh

You can configure RSVP to establish point-to-point label-switched paths (LSPs) automatically for any new PE router added to a full mesh of LSPs. To enable this feature, you must configure the rsvp-te statement on all of the PE routers in the full mesh.

NOTE: You cannot configure RSVP automatic mesh in conjunction with CCC. CCC cannot use the dynamically generated LSPs.

To configure RSVP automatic mesh, include the rsvp-te statement:

```
rsvp-te {
    destination-networks network-prefix;
    label-switched-path-template (Multicast) {
        default-template;
        template-name;
    }
}
```

You can configure these statements at the following hierarchy levels:

- [edit routing-options dynamic-tunnels *tunnel-name*]
- [edit logical-systems *logical-system-name* routing-options dynamic-tunnels *tunnel-name*]

You must also configure the following statements to enable RSVP automatic mesh:

- destination-networks—Specify the IP version 4 (IPv4) prefix range for the destination network. Dynamic tunnels within the specified IPv4 prefix range can be initiated.

- label-switched-path-template (Multicast)—You can configure either the default template explicitly using the default-template option, or you can configure an LSP template of your own using the *template-name* option. The LSP template acts as a model configuration for the dynamically generated LSPs.

Configuring Timers for RSVP Refresh Messages

RSVP uses two related timing parameters:

- refresh-time—The refresh time controls the interval between the generation of successive refresh messages. The default value for the refresh time is 45 seconds. This number is derived from the refresh-time statement's default value of 30, multiplied by a fixed value of 1.5. This computation differs from RFC 2205, which states that the refresh time should be multiplied by a random value in the range from 0.5 through 1.5.

  Refresh messages include path and Resv messages. Refresh messages are sent periodically so that reservation states in neighboring nodes do not time out. Each path and Resv message carries the refresh timer value, and the receiving node extracts this value from the messages.

- keep-multiplier—The keep multiplier is a small, locally configured integer from 1 through 255. The default value is 3. It indicates the number of messages that can be lost before a particular state is declared stale and must be deleted. The keep multiplier directly affects the lifetime of an RSVP state.

To determine the lifetime of a reservation state, use the following formula:

```
lifetime = (keep-multiplier + 0.5) x (1.5 x refresh-time)
```

In the worst case, (*keep-multiplier* – 1) successive refresh messages must be lost before a reservation state is deleted.

We do not recommend configuring a short RSVP hello timer. If quick discovery of a failed neighbor is needed, configure short IGP (OSPF or IS-IS) hello timers.

By default, the refresh timer value is 30 seconds. To modify this value, include the refresh-time statement:

```
refresh-time seconds;
```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp]
- [edit logical-systems *logical-system-name* protocols rsvp]

The default value of the keep multiplier is 3. To modify this value, include the `keep-multiplier` statement:

```
keep-multiplier number;
```

You can include this statement at the following hierarchy levels:

- `[edit protocols rsvp]`
- `[edit logical-systems logical-system-name protocols rsvp]`

Preempting RSVP Sessions

Whenever bandwidth is insufficient to handle all RSVP sessions, you can control the preemption of RSVP sessions. By default, an RSVP session is preempted only by a new higher-priority session.

To always preempt a session when the bandwidth is insufficient, include the `preemption` statement with the `aggressive` option:

```
preemption aggressive;
```

You can include this statement at the following hierarchy levels:

- `[edit protocols rsvp]`
- `[edit logical-systems logical-system-name protocols rsvp]`

To disable RSVP session preemption, include the `preemption` statement with the `disabled` option:

```
preemption disabled;
```

To return to the default (that is, preempt a session only for a new higher-priority session), include the `preemption` statement with the `normal` option:

```
preemption normal;
```

You can include this statement at the following hierarchy levels:

- `[edit protocols rsvp]`
- `[edit logical-systems logical-system-name protocols rsvp]`

Configuring MTU Signaling in RSVP

IN THIS SECTION

- Enabling MTU Signaling in RSVP | **1226**
- Enabling Packet Fragmentation | **1227**

To configure maximum transmission unit (MTU) signaling in RSVP, you need to configure MPLS to allow IP packets to be fragmented before they are encapsulated in MPLS. You also need to configure MTU signaling in RSVP. For troubleshooting purposes, you can configure MTU signaling alone without enabling packet fragmentation.

To configure MTU signaling in RSVP, include the `path-mtu` statement:

```
path-mtu {
    allow-fragmentation;
    rsvp {
        mtu-signaling;
    }
}
```

You can include this statement at the following hierarchy levels:

- `[edit protocols mpls]`
- `[edit logical-systems` *`logical-system-name`* `protocols mpls]`

The following sections describe how to enable packet fragmentation and MTU signaling in RSVP:

Enabling MTU Signaling in RSVP

To enable MTU signaling in RSVP, include the `rsvp mtu-signaling` statement:

```
rsvp mtu-signaling;
```

You can include this statement at the following hierarchy levels:

- `[edit protocols mpls path-mtu]`
- `[edit logical-systems` *`logical-system-name`* `protocols mpls path-mtu]`

Once you have committed the configuration, changes in the MTU signaling behavior for RSVP take effect the next time the path is refreshed.

You can configure the `mtu-signaling` statement by itself at the `[edit protocols mpls path-mtu rsvp]` hierarchy level. This can be useful for troubleshooting. If you configure just the `mtu-signaling` statement, you can use the `show rsvp session detail` command to determine what the smallest MTU is on an LSP. The `show rsvp session detail` command displays the MTU value received and sent in the Adspec object.

Enabling Packet Fragmentation

To allow IP packets to be fragmented before they are encapsulated in MPLS, include the `allow-fragmentation` statement:

```
allow-fragmentation;
```

You can include this statement at the following hierarchy levels:

- `[edit protocols mpls path-mtu]`
- `[edit logical-systems` *`logical-system-name`* `protocols mpls path-mtu]`

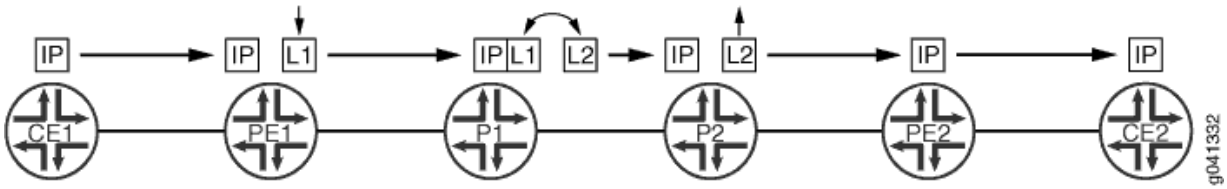
> **NOTE**: Do not configure the `allow-fragmentation` statement alone. Always configure it in conjunction with the `mtu-signaling` statement.

Configuring Ultimate-Hop Popping for LSPs

By default, RSVP-signaled LSPs use penultimate-hop popping (*PHP*). Figure 69 on page 1228 illustrates a penultimate-hop popping LSP between Router PE1 and Router PE2. Router CE1 forwards a packet to its next hop (Router PE1), which is also the LSP ingress. Router PE1 pushes label 1 on the packet and forwards the labeled packet to Router P1. Router P1 completes the standard MPLS label swapping operation, swapping label 1 for label 2, and forwards the packet to Router P2. Since Router P2 is the penultimate-hop router for the LSP to Router PE2, it first pops the label and then forwards the packet to

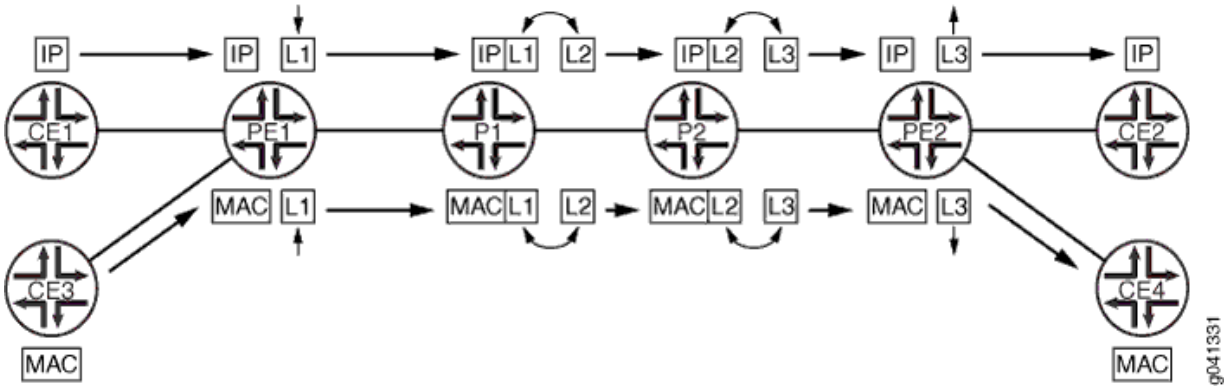
Router PE2. When Router PE2 receives it, the packet can have a service label, an explicit-null label, or just be a plain IP or VPLS packet. Router PE2 forwards the unlabeled packet to Router CE2.

Figure 69: Penultimate-Hop Popping for an LSP



You can also configure ultimate-hop popping (*UHP*) (as shown in Figure 70 on page 1228) for RSVP-signaled LSPs. Some network applications can require that packets arrive at the egress router (Router PE2) with a non-null outer label. For an ultimate- hop popping LSP, the penultimate router (Router P2 in Figure 70 on page 1228) performs the standard MPLS label swapping operation (in this example, label 2 for label 3) before forwarding the packet to egress Router PE2. Router PE2 pops the outer label and performs a second lookup of the packet address to determine the end destination. It then forwards the packet to the appropriate destination (either Router CE2 or Router CE4).

Figure 70: Ultimate-Hop Popping for an LSP



The following network applications require that you configure UHP LSPs:

- MPLS-TP for performance monitoring and in-band *OAM*
- Edge protection virtual circuits

The following features do not support the UHP behavior:

- LDP-signaled LSPs
- Static LSPs

- Point-to-multipoint LSPs
- CCC
- `traceroute` command

For more information about UHP behavior, see Internet draft draft-ietf-mpls-rsvp-te-no-php-oob-mapping-01.txt, *Non PHP behavior and Out-of-Band Mapping for RSVP-TE LSPs*.

For point-to-point RSVP-signaled LSPs, UHP behavior is signaled from the LSP ingress. Based on the ingress router configuration, RSVP can signal the UHP LSP with the non-PHP flag set. RSVP PATH messages carry the two flags in the LSP-ATTRIBUTES object. When the egress router receives the PATH message, it assigns a non-null label to the LSP. RSVP also creates and installs two routes in the mpls.0 routing table. S refers to the S bit of the MPLS label, which indicates whether or not the bottom of the label stack has been reached.

- Route S=0—Indicates that there are more labels in the stack. The next hop for this route points to the mpls.0 routing table, triggering a chained MPLS label lookup to discover the remaining MPLS labels in the stack.
- Route S=1—Indicates that there are no more labels. The next hop points to the inet.0 routing table if the platform supports chained and multi-family lookup. Alternatively, the label route can point to a *VT* interface to initiate IP forwarding.

If you enable UHP LSPs, MPLS applications such as Layer 3 VPNs, VPLS, Layer 2 VPNs, and Layer 2 circuits can use the UHP LSPs. The following explains how UHP LSPs affect the different types of MPLS applications:

- Layer 2 VPNs and Layer 2 circuits—A packet arrives at the PE router (egress of the UHP LSP) with two labels. The outer label (S=0) is the UHP label, and the inner label (S=1) is the *VC* label. A lookup based on the transport label results in a table handle for the mpls.0 routing table. There is an additional route in the mpls.0 routing table corresponding to the inner label. A lookup based on the inner label results in the CE router next hop.
- Layer 3 VPN—A packet arrives at the PE router (egress of the UHP LSP) with two labels. The outer label (S=0) is the UHP label, and the inner label is the VPN label (S=1). A lookup based on the transport label results in the table handle for the mpls.0 routing table. There are two cases in this scenario. By default, Layer 3 VPNs advertise the per-next hop label. A lookup based on the inner label results in the next hop toward the CE router. However, if you have configured the `vrf-table-label` statement for the Layer 3 VPN routing instance, the inner *LSI* label points to the VRF routing table. An IP lookup is also completed for the VRF routing table.

  NOTE: UHP for Layer 3 VPNs configured with the `vrf-table-label` statement is supported on MX Series 5G Universal Routing Platforms only.

- VPLS—A packet arrives at the PE router (egress of the UHP LSP) with two labels. The outer label is the transport label (S=0) and the inner label is the VPLS label (S=1). A lookup based on the transport label results in the table handle for the mpls.0 routing table. A lookup based on the inner label in mpls.0 routing table results in the LSI tunnel interface of the VPLS routing instance if tunnel-services is not configured (or a VT interface not available). MX 3D Series routers support chained lookup and multi-family lookup.

  NOTE: UHP for VPLS configured with the `no-tunnel-service` statement is supported on MX 3D Series routers only.

- IPv4 over MPLS—A packet arrives at the PE router (egress of the UHP LSP) with one label (S=1). A lookup based on this label returns a VT tunnel interface. Another IP lookup is completed on the VT interface to determine where to forward the packet. If the routing platform supports multi-family and chained lookups (for example, MX 3D routers and PTX Series Packet Transport Routers), lookup based on label route (S=1) points to the inet.0 routing table.

- IPv6 over MPLS—For IPv6 tunneling over MPLS, PE routers advertise IPv6 routes to each other with a label value of 2. This is the explicit null label for IPv6. As a result, the forwarding next hops for IPv6 routes that are learned from remote PE routers normally push two labels. The inner label is 2 (it could be different if the advertising PE router is from another vendor), and the router label is the LSP label. Packets arrive at the PE router (egress of the UHP LSP) with two labels. The outer label is the transport label (S=0), and the inner label is the IPv6 explicit-null label (label 2). Lookup based on the inner label in the mpls.0 routing table redirects back to the mpls.0 routing table. On MX 3D Series routers, the inner label (label 2) is stripped off and an IPv6 lookup is done using the inet6.0 routing table.

- Enabling both PHP and UHP LSPs—You can configure both PHP and UHP LSPs over the same network paths. You can separate PHP and UHP traffic by selecting forwarding LSP next hops using a regular expression with the `install-nexthop` statement. You can also separate traffic by simply naming the LSPs appropriately.

The following statements enable ultimate-hop popping for an LSP. You can enable this feature on a specific LSP or for all of the ingress LSPs configured on the router. Configure these statements on the router at the LSP ingress.

1. To enable ultimate-hop popping, include the `ultimate-hop-popping` statement:

   ```
   ultimate-hop-popping;
   ```

   Include this statement at the `[edit protocols mpls label-switched-path` *`label-switched-path-name`*`]` hierarchy level to enable ultimate-hop popping on a specific LSP. Include this statement at the `[edit protocols mpls]` hierarchy level to enable ultimate-hop popping on all of the ingress LSPs configured on the

router. You can also configure the `ultimate-hop-popping` statement under the equivalent `[edit logical-routers]` hierarchy levels.

> **NOTE**: When you enable ultimate-hop popping, RSVP attempts to resignal existing LSPs as ultimate-hop popping LSPs in a make-before-break fashion. If an egress router does not support ultimate-hop popping, the existing LSP is torn down (RSVP sends a *PathTear message* along an LSP's path, removing the path state and dependent reservation state and releasing the associated networking resources).
>
> If you disable ultimate-hop popping, RSVP resignals existing LSPs as penultimate-hop popping LSPs in a make-before-break fashion.

2. If you want to enable both ultimate-hop-popping and chained next hops on MX 3D Series routers only, you also need to configure the `enhanced-ip` option for the `network-services` statement:

```
network-services enhanced-ip;
```

   You configure this statement at the `[edit chassis]` hierarchy level. Once you have configured the `network-services` statement, you need to reboot the router to enable UHP behavior.

Configuring RSVP to Pop the Label on the Ultimate-Hop Router

You can control the label value advertised on the egress router of an LSP. The default advertised label is label 3 (Implicit Null label). If label 3 is advertised, the penultimate-hop router removes the label and sends the packet to the egress router. When ultimate-hop popping is enabled, label 0 (IP version 4 [IPv4] Explicit Null label) is advertised. Ultimate-hop popping ensures that any packets traversing an MPLS network include a label.

> **NOTE**: Juniper Networks routers queue packets based on the incoming label. Routers from other vendors might queue packets differently. Keep this in mind when working with networks containing routers from multiple vendors.

To configure ultimate-hop popping for RSVP, include the `explicit-null` statement:

```
explicit-null;
```

You can include this statement at the following hierarchy levels:

- `[edit protocols mpls]`
- `[edit logical-systems logical-system-name protocols mpls]`

Enabling Ultimate-Hop Popping on Point-to-Multipoint LSPs

By default, for both point-to-point and point-to-multipoint LSPs, penultimate-hop popping is used for MPLS traffic. MPLS labels are removed from packets on the router just before the egress router of the LSP. The plain IP packets are then forwarded to the egress router. For ultimate-hop popping, the egress router is responsible for both removing the MPLS label and processing the plain IP packet.

It can be beneficial to enable ultimate-hop popping on point-to-multipoint LSPs, particularly when transit traffic is traversing the same egress device. If you enable ultimate-hop popping, a single copy of traffic can be sent over the incoming link, saving significant bandwidth. By default, ultimate-hop popping is disabled.

You enable ultimate-hop popping for point-to-multipoint LSPs by configuring the `tunnel-services` statement. When you enable ultimate-hop popping, the Junos OS selects one of the available virtual loopback tunnel (VT) interfaces to loop back the packets to the PFE for IP forwarding. By default, the VT interface selection process is performed automatically. Bandwidth admission control is used to limit the number of LSPs that can be used on one VT interface. Once all the bandwidth is consumed on one interface, the Junos OS selects another VT interface with sufficient bandwidth for admission control.

If an LSP requires more bandwidth than is available from any of the VT interfaces, ultimate-hop popping cannot be enabled and penultimate-hop popping is enabled instead.

For ultimate-hop popping on point-to-multipoint LSPs to function properly, the egress router must have a PIC that provides tunnel services, such as the tunnel services PIC or the adaptive services PIC. Tunnel services are needed for popping the final MPLS label and for returning packets for IP address lookups.

You can explicitly configure which VT interfaces handle the RSVP traffic by including the `devices` option for the `tunnel-services` statement. The `devices` option allows you to specify which VT interfaces are to be used by RSVP. If you do not configure this option, all of the VT interfaces available to the router can be used.

To enable ultimate-hop popping for the egress point-to-multipoint LSPs on a router, configure the `tunnel-services` statement:

```
tunnel-services {
    devices device-names;
}
```

You can configure this statement at the following hierarchy levels:

- `[edit protocols rsvp]`
- `[edit logical-systems logical-system-name protocols rsvp]`

To enable ultimate-hop popping for egress point-to-multipoint LSPs, you must also configure the `interface` statement with the `all` option:

```
interface all;
```
