## YEAR 2000 NOTICE

Juniper Networks hardware and software products are Year 2000 compliant. Junos OS has no known time-related limitations through the year 2038. However, the NTP application is known to have some difficulty in the year 2036.

## END USER LICENSE AGREEMENT

The Juniper Networks product that is the subject of this technical documentation consists of (or is intended for use with) Juniper Networks software. Use of such software is subject to the terms and conditions of the End User License Agreement ("EULA") posted at <https://support.juniper.net/support/eula/>. By downloading, installing or using such software, you agree to the terms and conditions of that EULA.

# Table of Contents

About This Guide | xxxii

1

## Login Classes and Login Settings

Login Classes Overview | 2

Login Classes Overview | 2

Example: Create Login Classes with Specific Privileges | 8

Login Settings | 9

Display a System Login Announcement or Message | 9

Display System Alarms Upon Login | 12

Configure Login Tips | 13

Configure Time-Based User Access | 13

Configure the Timeout Value for Idle Login Sessions | 15

Login Retry Options | 16

Limit the Number of User Login Attempts for SSH and Telnet Sessions | 18

Example: Configure Login Retry Options | 20

Requirements | 21

Overview | 21

Configuration | 22

Verification | 24

2

## User Accounts

User Accounts | 26

User Accounts Overview | 26

Junos-FIPS Crypto Officer and User Accounts Overview | 28

Example: Configure New User Accounts | 29

Requirements | 29

Overview | 29

Configuration | 30

Verification | 33

Configure User Accounts in a Configuration Group | 34

## **Administrative Roles | 37**

How to Design Administrative Roles | 38

Example: How to Configure Administrative Roles | 40

Requirements | 40

Overview | 40

Configuration | 41

Verification | 48

How to Configure a Local Administrator Account | 49

## **User Access Privileges | 50**

Access Privilege Levels Overview | 51

Example: Configure User Permissions with Access Privilege Levels | 56

Requirements | 57

Overview | 57

Configuration | 58

Verification | 59

Regular Expressions to Allow and Deny Operational Mode Commands, Configuration Statements, and Hierarchies | 61

How to Define Access Privileges with allow-configuration and deny-configuration Statements | 82

Example: Use Additive Logic with Regular Expressions to Specify Access Privileges | 85

Requirements | 85

Overview | 85

Configuration | 86

Examples | 87

Example: Configure User Permissions with Access Privileges for Operational Mode Commands | 89

Requirements | 90

Overview and Topology | 90

Configuration | 91

Verification | 97

Example: Configure User Permissions with Access Privileges for Configuration Statements and Hierarchies | **101**

Requirements | **101**

Overview and Topology | **102**

Configuration | **102**

Verification | **108**

## Passwords for User Access

### Root Password | **112**

Configure the Root Password | **112**

Example: Configure a Plain-Text Password for Root Logins | **114**

Requirements | **114**

Overview | **115**

Configuration | **115**

Verification | **116**

### Recover a Root Password | **117**

How to Recover the Root Password for Junos OS | **118**

How to Recover the Root Password on Junos OS with Upgraded FreeBSD | **120**

How to Recover the Root Password on Switches | **123**

### Plain-Text Passwords | **126**

Change the Requirements for Plain-Text Passwords | **127**

How to Change the Requirements for Plain-Text Passwords | **127**

Overview | **128**

Configuration | **128**

### Master Password for Configuration Encryption | **130**

Hardening Shared Secrets in Junos OS | **130**

Using Trusted Platform Module to Bind Secrets on SRX Series Devices | **133**

Using Trusted Platform Module on MX Series Devices | **136**

## Trusted Platform Module

### Encryption with Trusted Platform Module | **140**

### Remote Integrity Verification | **141**

## User Authentication

### User Authentication Overview | 144

User Authentication Methods | 144

Configure Local User Template Accounts for User Authentication | 145

Configure Remote User Template Accounts for User Authentication | 149

Example: Create Template Accounts | 150

Requirements | 150

Overview | 150

Configuration | 151

Verification | 153

What Are Remote Authentication Servers? | 153

### Authentication Order for LDAPS, RADIUS, TACACS+, and Local Password | 155

Authentication Order Overview | 155

Configure the Authentication Order for LDAPS, RADIUS, TACACS+ and Local Password Authentication | 164

Example: Configure Authentication Order | 166

Requirements | 167

Overview | 167

Configuration | 167

Verification | 170

Example: Configure System Authentication for LDAPS, RADIUS, TACACS+, and Password Authentication | 171

### LDAP over TLS Authentication | 173

LDAP Authentication over TLS | 173

Configure LDAP Authentication over TLS | 177

Configure the Order of Authentication | 177

Configure LDAPS Client | 178

Configure LDAPS Server | 181

Configure TLS Parameters | 183

Configure System Administrative Parameters for LDAPS Authentication | 185

Juniper Networks Vendor-Specific RADIUS and LDAP Attributes | 187

## **RADIUS Authentication | 192**

Configure RADIUS Server Authentication | 192

Why Use RADIUS | 193

Configure RADIUS Server Details | 193

Configure RADIUS to Use the Management Instance | 197

Example: Configure a RADIUS Server for System Authentication | 198

Requirements | 198

Overview | 198

Configuration | 199

Verification | 201

Configure RADIUS Authentication (QFX Series or OCX Series) | 202

Configure RADIUS Server Details | 202

Configure MS-CHAPv2 for Password-Change Support | 203

Specify a Source Address for the Junos OS to Access External RADIUS Servers | 204

Juniper Networks Vendor-Specific RADIUS and LDAP Attributes | 205

Use Regular Expressions on a RADIUS or TACACS+ Server to Allow or Deny Commands | 210

Juniper-Switching-Filter VSA Guidelines, Match Conditions and Actions | 214

Understanding RADIUS Accounting | 218

Configure RADIUS System Accounting | 219

Configure Auditing of User Events on a RADIUS Server | 219

## **TACACS+ Authentication | 223**

Configure TACACS+ Authentication | 224

Configure TACACS+ Server Details | 224

Configure TACACS+ to Use the Management Instance | 229

Configure the Same Authentication Service for Multiple TACACS+ Servers | 229

Configure Juniper Networks Vendor-Specific TACACS+ Attributes | 230

Configure Periodic Refresh of the TACACS+ Authorization Profile | 231

Example: Configure a TACACS+ Server for System Authentication | 232

Requirements | 232

- Overview | 233
- Configuration | 233
- Verification | 235

Juniper Networks Vendor-Specific TACACS+ Attributes | 236

Use Regular Expressions on a RADIUS or TACACS+ Server to Allow or Deny Commands | 238

Configuring TACACS+ System Accounting | 243

- Configure TACACS+ Server Accounting | 244

## Authentication for Routing Protocols | 248

Authentication Methods for Routing Protocols | 248

Example: Configure the Authentication Key for BGP and IS-IS Routing Protocols | 249

Configure the Authentication Key Update Mechanism for Routing Protocols | 252

- Configure Authentication Key Updates | 252

- Configure BGP and LDP for Authentication Key Updates | 253

# 6

## Remote Access Management

### Remote Access Overview | 256

System Services Overview | 256

Configure Telnet Service for Remote Access to a Router or Switch | 257

Configure FTP Service for Remote Access to the Router or Switch | 258

Configure Finger Service for Remote Access to the Router | 259

Configure SSH Service for Remote Access to the Router or Switch | 259

- Configure the Root Login Through SSH | 261

- Configure Incoming SFTP Connections | 262

- Configure the SSH Protocol Version | 262

- Configure the Client Alive Mechanism | 263

- Configure the SSH Fingerprint Hash Algorithm | 263

The telnet Command | 264

The ssh Command | 265

Configure SSH Host Keys for Secure Copying of Data | 267

- Configure SSH Known Hosts | 267

Configure Support for SCP File Transfer | 268

Update SSH Host Key Information | 269

Configure the SSH Service to Support Legacy Cryptography | 270

Configure Outbound SSH Service | 272

Send the Public SSH Host Key to the Outbound SSH Client | 273

Configure Keepalive Messages for Outbound SSH Connections | 275

Configure a New Outbound SSH Connection | 275

Configure the Outbound SSH Client to Accept NETCONF as an Available Service | 275

Configure Outbound SSH Clients | 276

Configure Routing Instances for Outbound SSH Clients | 276

Configure NETCONF-Over-SSH Connections on a Specified TCP Port | 276

Configure Password Retry Limits for Telnet and SSH Access | 277

Example: Configure a Filter to Block Telnet and SSH Access | 278

Requirements | 279

Overview and Topology | 279

Configuration | 280

Verify the Stateless Firewall Filter | 288

## **USB Modems for Remote Management of Security Devices | 292**

USB Modem Interface Overview | 293

USB Modem Configuration Overview | 296

Example: Configuring a USB Modem Interface | 299

Requirements | 300

Overview | 300

Configuration | 300

Verification | 302

Example: Configuring a Dialer Interface | 303

Requirements | 303

Overview | 304

Configuration | 304

Verification | 306

Example: Configuring a Dialer Interface for USB Modem Dial-In | 308

- Requirements | 309

- Overview | 309

- Configuration | 310

- Verification | 311

Configuring a Dial-Up Modem Connection Remotely | 311

Connecting to the Device Remotely | 312

Modifying USB Modem Initialization Commands | 312

Resetting USB Modems | 313

## **Secure Web Access for Remote Management | 314**

- Secure Web Access Overview | 314

- Generating SSL Certificates for Secure Web Access (SRX Series Devices) | 315

- Generating SSL Certificates to Be Used for Secure Web Access (EX Series Switch) | 316

- Generating a Self-Signed SSL Certificate Automatically | 317

- Manually Generating Self-Signed SSL Certificates | 317

- Deleting Self-Signed Certificates (CLI Procedure) | 318

- Understanding Self-Signed Certificates on EX Series Switches | 319

- Manually Generating Self-Signed Certificates on Switches (CLI Procedure) | 320

- Generating a Public-Private Key Pair on Switches | 320

- Generating Self-Signed Certificates on Switches | 321

- Example: Configuring Secure Web Access | 322

- Requirements | 322

- Overview | 322

- Configuration | 323

- Verification | 324

## **Example: Control Management Access on Juniper Networking Devices | 326**

- Requirements | 326

- Overview | 327

- Configure an IP Address List to Restrict Management Access to a Device | 328

- Verify the Stateless Firewall Filter | 333

## Configuration Guidelines for Securing Console Port Access | 336

Secure the Console Port | 337

Secure Mini-USB Ports | 338

## Configuring the Console Port Type (CLI Procedure) | 339

## Access Control on Switches

### Preventing Unauthorized Access to EX Series Switches Using Unattended Mode for U-Boot | 343

Understanding Unattended Mode for U-Boot on EX Series Switches | 343

Using Unattended Mode for U-Boot to Prevent Unauthorized Access | 345

Configuring the Boot Loader Password | 346

Configuring Unattended Mode for U-Boot | 347

Accessing the U-Boot CLI | 347

### RADIUS Server Configuration for Authentication | 348

Specifying RADIUS Server Connections on Switches (CLI Procedure) | 349

Configuring a RADIUS Server Using an FQDN | 351

Configuring MS-CHAPv2 to Provide Password-Change Support (CLI Procedure) | 354

Configuring MS-CHAPv2 for Password-Change Support | 354

Understanding Server Fail Fallback and Authentication on Switches | 355

Configuring RADIUS Server Fail Fallback (CLI Procedure) | 357

### RADIUS over TLS (RADSEC) | 359

Configure the RADSEC Destination | 360

Configure TLS Connection Parameters | 361

Example: Simple RADSEC Configuration | 362

Monitoring Certificates | 363

Monitoring RADSEC Destinations | 363

### 802.1X Authentication | 363

802.1X for Switches Overview | 364

Configuring 802.1X Interface Settings (CLI Procedure) | 369

Understanding RADIUS-Initiated Changes to an Authorized User Session | 371

Filtering 802.1X Supplicants by Using RADIUS Server Attributes | 375

Configuring Firewall Filters on the RADIUS Server | 376

Applying a Locally Configured Firewall Filter from the RADIUS Server | 378

Example: Connecting a RADIUS Server for 802.1X to an EX Series Switch | 380

Requirements | 380

Overview and Topology | 381

Configuration | 384

Verification | 386

Understanding Dynamic Filters Based on RADIUS Attributes | 387

Understanding Dynamic VLAN Assignment Using RADIUS Attributes | 388

Understanding Guest VLANs for 802.1X on Switches | 389

Example: Configuring 802.1X Authentication Options When the RADIUS Server Is Unavailable to an EX Series Switch | 389

Requirements | 390

Overview and Topology | 391

Configuration | 393

Verification | 395

Example: Configuring Fallback Options on EX Series Switches for EAP-TTLS Authentication and Odyssey Access Clients | 397

Requirements | 398

Overview and Topology | 398

Configuration | 401

Verification | 403

Monitoring 802.1X Authentication | 404

Verifying 802.1X Authentication | 405

Troubleshooting Authentication of End Devices on EX Series Switches | 407

## MAC RADIUS Authentication | 410

Configuring MAC RADIUS Authentication (CLI Procedure) | 410

Example: Configuring MAC RADIUS Authentication on an EX Series Switch | 411

Requirements | 412

Overview and Topology | 413

Configuration | 415

Verification | 417

## **802.1X and RADIUS Accounting | 419**

Understanding 802.1X and RADIUS Accounting on Switches | 420

Configuring 802.1X RADIUS Accounting (CLI Procedure) | 423

## **Example: Setting Up 802.1X for Single-Supplicant or Multiple-Supplicant Configurations on an EX Series Switch | 426**

Requirements | 427

Overview and Topology | 428

Configuration of 802.1X to Support Multiple Supplicant Modes | 430

Verification | 432

## **Example: Setting Up 802.1X in Conference Rooms to Provide Internet Access to Corporate Visitors on an EX Series Switch | 435**

Requirements | 435

Overview and Topology | 436

Configuration of a Guest VLAN That Includes 802.1X Authentication | 439

Verification | 441

## **Interfaces Enabled for 802.1X or MAC RADIUS Authentication | 443**

Example: Applying a Firewall Filter to 802.1X-Authenticated Supplicants by Using RADIUS Server Attributes on an EX Series Switch | 443

Requirements | 444

Overview and Topology | 445

Configuring the Port Firewall Filter and Counters | 450

Applying the Port Firewall Filter to the Supplicant User Profiles on the RADIUS Server | 452

Verification | 453

Example: Applying Firewall Filters to Multiple Supplicants on Interfaces Enabled for 802.1X or MAC RADIUS Authentication | 455

Requirements | 455

Overview and Topology | 456

Configuration | 458

Verification | **461**

Example: Applying Firewall Filters to Multiple Supplicants on Interfaces Enabled for 802.1X or MAC RADIUS Authentication on EX Series Switches with ELS Support | **462**

Requirements | **463**

Overview and Topology | **464**

Configuration | **466**

Verification | **469**

## **Static MAC Bypass of 802.1X and MAC RADIUS Authentication | 470**

Configuring Static MAC Bypass of 802.1X and MAC RADIUS Authentication (CLI Procedure) | **471**

Example: Configuring Static MAC Bypass of 802.1X and MAC RADIUS Authentication on an EX Series Switch | **472**

Requirements | **472**

Overview and Topology | **473**

Configuration | **476**

Verification | **478**

## **Configuring PEAP for MAC RADIUS Authentication | 479**

## **Captive Portal Authentication | 482**

Example: Setting Up Captive Portal Authentication on an EX Series Switch | **482**

Requirements | **483**

Overview and Topology | **483**

Configuration | **484**

Verification | **488**

Troubleshooting | **489**

Configuring Captive Portal Authentication (CLI Procedure) | **490**

Configuring Secure Access for Captive Portal | **491**

Enabling an Interface for Captive Portal | **491**

Configuring Bypass of Captive Portal Authentication | **492**

Designing a Captive Portal Authentication Login Page on Switches | **492**

Configuring Captive Portal Authentication (CLI Procedure) on an EX Series Switch with ELS Support | **496**

Configuring Secure Access for Captive Portal | **496**

Enabling an Interface for Captive Portal | **497**

Configuring Bypass of Captive Portal Authentication | 497

Example: Setting Up Captive Portal Authentication on an EX Series Switch with ELS Support | 498

Requirements | 498

Overview and Topology | 499

Configuration | 499

Verification | 503

Troubleshooting | 504

## Flexible Authentication Order on EX Series Switches | 505

Configuring Flexible Authentication Order | 505

Configuring EAPoL Block to Maintain an Existing Authentication Session | 508

## Server Fail Fallback and Authentication | 510

| 510

| 510

Configuring RADIUS Reachability to Reauthenticate Server Fail Sessions | 510

## Authentication Session Timeout | 511

Understanding Authentication Session Timeout | 511

Controlling Authentication Session Timeouts (CLI Procedure) | 513

Retaining the Authentication Session Based on IP-MAC Address Bindings | 515

Benefits | 515

CLI Configuration | 515

RADIUS Server Attributes | 516

Verification | 517

## Central Web Authentication | 518

Understanding Central Web Authentication | 518

Configuring Central Web Authentication | 522

Configuring Dynamic Firewall Filters for Central Web Authentication | 522

Configuring the Redirect URL for Central Web Authentication | 523

Guidelines for Configuring Central Web Authentication | 524

## Dynamic VLAN Assignment for Colorless Ports | 525

## VoIP on EX Series Switches | 528

Understanding 802.1X and VoIP on EX Series Switches | **528**

Example: Setting Up VoIP with 802.1X and LLDP-MED on an EX Series Switch | **531**

Requirements | **532**

Overview and Topology | **533**

Configuration | **536**

Verification | **540**

Example: Configuring VoIP on an EX Series Switch Without Including LLDP-MED Support | **543**

Requirements | **544**

Overview | **544**

Configuring VoIP Without LLDP-MED by Using a Voice VLAN on an Access Port | **545**

Configuring VoIP Without LLDP-MED by Using a Trunk Port with Native VLAN Option | **548**

Verification | **550**

Example: Configuring VoIP on an EX Series Switch Without Including LLDP-MED Support | **551**

Requirements | **552**

Overview | **552**

Configuring VoIP Without LLDP-MED by Using a Voice VLAN on an Access Port | **553**

Configuring VoIP Without LLDP-MED by Using a Trunk Port with Native VLAN Option | **556**

Verification | **558**

Example: Configuring VoIP on an EX Series Switch Without Including 802.1X Authentication | **559**

Requirements | **559**

Overview | **560**

Configuration | **560**

Verification | **564**

Example: Setting Up VoIP with 802.1X and LLDP-MED on an EX Series Switch with ELS Support | **568**

Requirements | **568**

Overview and Topology | **569**

Configuration | **574**

Verification | **577**

Example: Configuring VoIP on an EX Series Switch with ELS Support Without Including 802.1X Authentication | **581**

Requirements | **582**

Overview | **582**

Configuration | 583

Verification | 586

## 8

### Configuring IEEE 802.1x Port-Based Network Access Control

IEEE 802.1x Port-Based Network Access Control Overview | 592

Understanding the Administrative State of the Authenticator Port | 593

Understanding the Administrative Mode of the Authenticator Port | 593

Configuring the Authenticator | 594

Viewing the dot1x Configuration | 595

## 9

### Configuring IEEE 802.1x Port-Based Network Access Control in Enhanced LAN Mode

802.1X for MX Series Routers in Enhanced LAN Mode Overview | 599

Understanding 802.1X and LLDP and LLDP-MED on MX Series Routers in Enhanced LAN Mode | 602

Understanding 802.1X and RADIUS Accounting on MX Series Routers in Enhanced LAN Mode | 605

Understanding 802.1X and VoIP on MX Series Routers in Enhanced LAN Mode | 606

Understanding Guest VLANs for 802.1X on MX Series Routers in Enhanced LAN Mode | 609

Understanding Dynamic VLANs for 802.1X on MX Series Routers in Enhanced LAN Mode | 609

Understanding Server Fail Fallback and Authentication on MX Series Routers in Enhanced LAN Mode | 610

Configuring 802.1X RADIUS Accounting on MX Series Routers in Enhanced LAN Mode | 611

Configuring 802.1X Interface Settings on MX Series Routers in Enhanced LAN Mode | 614

Configuring LLDP-MED on MX Series Routers in Enhanced LAN Mode | 616

Enabling LLDP-MED on Interfaces | 616

Configuring Location Information Advertised by the Router | 616

Configuring for Fast Start | 617

Configuring LLDP on MX Series Routers in Enhanced LAN Mode | 618

Enabling LLDP on Interfaces | 618

Adjusting LLDP Advertisement Settings | 619

Adjusting SNMP Notification Settings of LLDP Changes | 620

Specifying a Management Address for the LLDP Management TLV | 622

**Configuring Server Fail Fallback on MX Series Routers in Enhanced LAN Mode | 622**

**Understanding Captive Portal Authentication on the MX Series Routers | 624**

**Understanding Authentication Session Timeout on MX Series Routers | 626**

**Authentication Process Flow for MX Series Routers in Enhanced LAN Mode | 627**

**Specifying RADIUS Server Connections on an MX Series Router in Enhanced LAN Mode | 630**

**Configuring Captive Portal Authentication on MX Series Routers in Enhanced LAN Mode | 632**

Configuring Secure Access for Captive Portal | 633

Enabling an Interface for Captive Portal | 633

Configuring Bypass of Captive Portal Authentication | 634

**Designing a Captive Portal Authentication Login Page on an MX Series Router | 634**

**Configuring Static MAC Bypass of Authentication on MX Series Routers in Enhanced LAN Mode | 638**

**Controlling Authentication Session Timeouts on an MX Series Router in Enhanced LAN Mode | 639**

**Configuring MAC RADIUS Authentication on MX Series Routers in Enhanced LAN Mode | 640**

**Example: Configuring MAC RADIUS Authentication on an MX Series Router | 642**

Requirements | 642

Overview and Topology | 643

Configuration | 644

Verification | 646

**Example: Setting Up Captive Portal Authentication on an MX Series Router | 649**

Requirements	649
Overview and Topology	650
Configuration	650
Verification	654
Troubleshooting	655

#### **Example: Connecting a RADIUS Server for 802.1X to an MX Series Router | 656**

Requirements	657
Overview and Topology	657
Configuration	658
Verification	660

#### **Example: Setting Up 802.1X in Conference Rooms to Provide Internet Access to Corporate Visitors on an MX Series Router | 661**

Requirements	662
Overview and Topology	662
Configuration of a Guest VLAN That Includes 802.1X Authentication	663
Verification	665

#### **Example: Configuring Static MAC Bypass of Authentication on an MX Series Router | 667**

Requirements	667
Overview and Topology	668
Configuration	669
Verification	671

#### **Example: Applying Firewall Filters to Multiple Supplicants on Interfaces Enabled for 802.1X or MAC RADIUS Authentication on MX Series Routers | 672**

Requirements	672
Overview and Topology	673
Configuration	675
Verification	678

## Device Discovery

### Device Discovery Using LLDP | 681

Understanding LLDP | 681

Configuring LLDP (CLI Procedure) | 682

Enable LLDP on Interfaces | 683

Adjust LLDP Advertisement Settings | 683

Adjust SNMP Notification Settings of LLDP Changes | 684

Specify a Management Address for the LLDP Management TLV | 685

Specify a Management Interface for the LLDP Management TLV | 686

Configure LLDP Power Negotiation | 686

Disable LLDP TLVs | 687

Configuring LLDP (J-Web Procedure) | 689

Understanding LLDP and LLDP-MED on EX Series Switches | 690

Configuring LLDP-MED (CLI Procedure) | 694

Enabling LLDP-MED on Interfaces | 694

Configuring Location Information Advertised by the Switch | 695

Configuring a Fast Start for LLDP-MED | 695

Disabling LLDP-MED TLVs | 696

### NetBIOS Snooping on EX Series Switches | 698

Understanding NetBIOS Snooping | 699

Configuring NetBIOS Snooping (CLI Procedure) | 700

Enabling NetBIOS Snooping | 700

Disabling NetBIOS Snooping | 700

## Domain Name Security

### DNSSEC Overview | 703

### Configuring the TTL Value for DNS Server Caching | 703

Requirements | 704

Overview | 704

Configuration | 704

Verification | 705

**Example: Configuring DNSSEC | 706**

**Example: Configuring Secure Domains and Trusted Keys for DNSSEC | 706**

Requirements | 707

Overview | 707

Configuration | 708

**Example: Configuring Keys for DNSSEC | 710**

**DNS Proxy Overview | 710**

**Configuring the Device as a DNS Proxy | 717**

## About This Guide

Junos OS enables you to configure user access and authentication features at the `[edit system]` hierarchy level of the CLI. Essential user access features include login classes, user accounts, access privilege levels, and user authentication methods. Use the topics on this page to configure essential user access features for your system.

# Login Classes Overview

## IN THIS SECTION

- [Login Classes Overview | 2](#)
- [Example: Create Login Classes with Specific Privileges | 8](#)

Junos OS login classes define the access privileges, permissions for using CLI commands and statements, and session idle time for the users assigned to that class. You (the system administrator) can apply a login class to an individual user account, thereby assigning certain privileges and permissions to the user.

## Login Classes Overview

### IN THIS SECTION

- [Permission Bits | 3](#)
- [Deny or Allow Individual Commands and Statement Hierarchies | 7](#)

All users who can log in to a device running Junos OS must be in a login class. Each login class defines the following:

- Access privileges that users have when they log in to the network device
- Commands that users can and cannot execute
- Configuration statements that users can and cannot view or modify
- Amount of time a login session can be idle before the system disconnects the user

You can define any number of login classes. However, you only assign one login class to an individual user account.

Junos OS includes predefined login classes, which are listed in [Table 1 on page 3](#). You cannot modify the predefined login classes.

**Table 1: Predefined System Login Classes**

Login Class	Permission Flag Set
operator	clear, network, reset, trace, and view
read-only	view
superuser or super-user	all
unauthorized	None

**NOTE:**

- You cannot modify a predefined login class name. If you issue the set command on a predefined class name, the device appends -local to the login class name and issues the following warning:

warning: '*<class-name>*' is a predefined class name; changing to '*<class-name>-local*'

- You cannot issue the rename or the copy command on a predefined login class. Doing so results in the following error message:

error: target '*<class-name>*' is a predefined class

**Permission Bits**

Each top-level CLI command and each *configuration statement* has an access privilege level associated with it. Users can execute only those commands and configure and view only those statements for which they have access privileges. Each login class defines one or more permission bits that determine the access privileges.

Two forms for the permissions control whether a user can view or modify the individual parts of the configuration:

- "Plain" form—Provides read-only capability for that permission type. An example is interface.

- `-control` form—Provides read and write capability for that permission type. An example is `interface-control`.

Table 2 on page 4 outlines the permission flags and associated access privileges.

**Table 2: Login Class Permission Flags**

Permission Flag	Description
<code>access</code>	Can view the access configuration in operational mode or configuration mode.
<code>access-control</code>	Can view and configure access information at the <code>[edit access]</code> hierarchy level.
<code>admin</code>	Can view user account information in operational mode or configuration mode.
<code>admin-control</code>	Can view user account information and configure it at the <code>[edit system]</code> hierarchy level.
<code>all</code>	Can access all operational mode commands and configuration mode commands. Can modify the configuration in all the configuration hierarchy levels.
<code>clear</code>	Can clear (delete) information that the device learns from the network and stores in various network databases (using the <code>clear</code> commands).
<code>configure</code>	Can enter configuration mode (using the <code>configure</code> command) and commit configurations (using the <code>commit</code> command).
<code>control</code>	Can perform all control-level operations—all operations configured with the <code>-control</code> permission flags.
<code>field</code>	Can view field debug commands. Reserved for debugging support.
<code>firewall</code>	Can view the <i>firewall filter</i> configuration in operational mode or configuration mode.
<code>firewall-control</code>	Can view and configure firewall filter information at the <code>[edit firewall]</code> hierarchy level.

Table 2: Login Class Permission Flags *(Continued)*

Permission Flag	Description
<code>floppy</code>	Can read from and write to the removable media.
<code>flow-tap</code>	Can view the flow-tap configuration in operational mode or configuration mode.
<code>flow-tap-control</code>	Can view and configure flow-tap information at the [edit services flow-tap] hierarchy level.
<code>flow-tap-operation</code>	<p>Can make flow-tap requests to the router or switch. For example, a Dynamic Tasking Control Protocol (DTCP) client must have flow-tap-operation permission to authenticate itself to Junos OS as an administrative user.</p> <p><b>NOTE:</b> The flow-tap-operation option is not included in the all-control permissions flag.</p>
<code>idp-profiler-operation</code>	Can view profiler data.
<code>interface</code>	Can view the interface configuration in operational mode and configuration mode.
<code>interface-control</code>	<p>Can view chassis, <i>class of service</i> (CoS), groups, forwarding options, and interfaces configuration information. Can modify the configuration at the following hierarchy levels:</p> <ul style="list-style-type: none"> <li>• [edit chassis]</li> <li>• [edit class-of-service]</li> <li>• [edit groups]</li> <li>• [edit forwarding-options]</li> <li>• [edit interfaces]</li> </ul>
<code>maintenance</code>	Can perform system maintenance, including starting a local shell on the device and becoming the superuser in the shell (using the <code>su root</code> command) and halting and rebooting the device (using the <code>request system</code> commands).

**Table 2: Login Class Permission Flags** *(Continued)*

Permission Flag	Description
<code>network</code>	Can access the network by using the ping, ssh, telnet, and traceroute commands.
<code>pgcp-session-mirroring</code>	Can view the pgcp session mirroring configuration.
<code>pgcp-session-mirroring-control</code>	Can modify the pgcp session mirroring configuration.
<code>reset</code>	Can restart software processes by using the restart command.
<code>rollback</code>	Can use the rollback command to return to a previously committed configuration.
<code>routing</code>	Can view general routing, routing protocol, and routing policy configuration information in configuration mode and operational mode.
<code>routing-control</code>	Can view and configure general routing at the [edit routing-options] hierarchy level, routing protocols at the [edit protocols] hierarchy level, and routing policy information at the [edit policy-options] hierarchy level.
<code>secret</code>	Can view passwords and other authentication keys in the configuration.
<code>secret-control</code>	Can view and modify passwords and other authentication keys in the configuration.
<code>security</code>	Can view security configuration information in operational mode and configuration mode.
<code>security-control</code>	Can view and configure security information at the [edit security] hierarchy level.
<code>shell</code>	Can start a local shell on the router or switch by using the start shell command.
<code>snmp</code>	Can view Simple Network Management Protocol (SNMP) configuration information in operational mode or configuration mode.

**Table 2: Login Class Permission Flags (Continued)**

Permission Flag	Description
<code>snmp-control</code>	Can view and modify SNMP configuration information at the <code>[edit snmp]</code> hierarchy level.
<code>system</code>	Can view system-level information in operational mode or configuration mode.
<code>system-control</code>	Can view and modify system-level configuration information at the <code>[edit system]</code> hierarchy level.
<code>trace</code>	Can view trace file settings and configure trace file properties.
<code>trace-control</code>	Can modify trace file settings and configure trace file properties.
<code>view</code>	Can use various commands to display current system-wide, routing table, and protocol-specific values and statistics. Cannot view the secret configuration.
<code>view-configuration</code>	<p>Can view all of the configuration excluding secrets, system scripts, and event options.</p> <p><b>NOTE:</b> Only users with the <code>maintenance</code> permission can view commit script, op script, or event script configuration.</p>

## Deny or Allow Individual Commands and Statement Hierarchies

By default, all top-level CLI commands and statements have associated access privilege levels. Users can execute only those commands and view and configure only those statements for which they have access privileges. For each login class, you can explicitly deny or allow users the use of operational mode commands and configuration mode commands and configuration statement hierarchies that are otherwise allowed or denied by a permission bit.

## Example: Create Login Classes with Specific Privileges

You define login classes to assign certain permissions or restrictions to groups of users, ensuring that sensitive commands are only accessible to the appropriate users. By default, Juniper Networks devices have four types of login classes with preset permissions: operator, read-only, superuser or super-user, and unauthorized.

You can create custom login classes to define different combinations of permissions that are not found in the default login classes. The following example shows three custom login classes, each with specific privileges and inactivity timers. Inactivity timers help protect network security by disconnecting a user from the network if the user is inactive for too long. Disconnecting the user prevents potential security risks that result when a user leaves an unattended account logged in to a switch or router. The permissions and inactivity timers shown here are only examples; you should customize the values to your organization.

The three login classes and their privileges are as follows. All three login classes use the same inactivity timer of 5 minutes.

- observation—Can only view statistics and the configuration
- operation—Can view and modify the configuration
- engineering—Unlimited access and control

```
[edit]
system {
  login {
    class observation {
      idle-timeout 5;
      permissions [ view ];
    }
    class operation {
      idle-timeout 5;
      permissions [ admin clear configure interface interface-control network
reset routing routing-control snmp snmp-control trace-control
firewall-control rollback ];
    }
    class engineering {
      idle-timeout 5;
      permissions all;
    }
  }
}
```

# Login Settings

## IN THIS SECTION

- [Display a System Login Announcement or Message | 9](#)
- [Display System Alarms Upon Login | 12](#)
- [Configure Login Tips | 13](#)
- [Configure Time-Based User Access | 13](#)
- [Configure the Timeout Value for Idle Login Sessions | 15](#)
- [Login Retry Options | 16](#)
- [Limit the Number of User Login Attempts for SSH and Telnet Sessions | 18](#)
- [Example: Configure Login Retry Options | 20](#)

Junos OS enables you to define various settings for users when they log in to a device. You (the system administrator) can configure:

- Messages or announcements to display before or after login
- Whether to display system alarms upon login
- Login tips
- Time-based user access
- Timeout values for idle sessions
- Limits on the number of login attempts
- Whether to lock a user account after a number of failed authentication attempts

## Display a System Login Announcement or Message

Sometimes you want to make announcements only to authorized users after they log in to a device. For example, you might want to announce an upcoming maintenance event. At other times, it might be appropriate to display a message, such as a security warning, to any user that connects to the device.

By default, Junos OS does not display any login message or announcement. You can configure the device to display a login message or announcement by including the `message` statement or the `announcement` statement at the `[edit system login]` hierarchy level. Whereas the device displays a login *message* after a user connects to the device but before the user logs in, it displays an *announcement* only after the user successfully logs in to the device.

You can format the message or announcement text using the following special characters. If the text contains spaces, enclose it in quotation marks:

- `\n`—New line
- `\t`—Horizontal tab
- `\'`—Single quotation mark
- `\"`—Double quotation mark
- `\\`—Backslash

To configure an announcement that only authorized users can see and a message that any user can see:

1. Include the `announcement` statement and the `message` statement at the `[edit system login]` hierarchy level.

```
[edit system login]
user@host# set announcement text
user@host# set message text
```

For example:

```
system {
  login {
    announcement "\tJuly 27th 1:00 AM to 8:00\n\nPlanned Network Maintenance\n\nAFFECTED LOCATIONS: Sunnyvale\n\nPLANNED ACTIVITY: Upgrade all 6200 switch firmware to the Enterprise TAC recommended firmware version\n\nPURPOSE: This activity will help to minimize the impact of unplanned power outages as well as address known issues within our currently installed firmware version(s)\n\nWHAT TO EXPECT: During the maintenance window for your site, the office network will not be available.\n\n";
    message "\n\tAcme Router Lab\n\n\tUNAUTHORIZED USE OF THIS ROUTER\n\tIS STRICTLY PROHIBITED!\n\n\tPlease contact \'jsmith@example.com\' to gain\n\taccess to this equipment if you need authorization.\n\n"
  }
}
```

## 2. Commit the configuration.

```
[edit system login]
user@host# commit
```

## 3. Connect to the device to verify the presence of the new message.

The preceding configuration example displays the following login message after the user connects to the device. The example displays the announcement after the user logs in:

```
server% ssh host

Acme Router Lab

UNAUTHORIZED USE OF THIS ROUTER
IS STRICTLY PROHIBITED!

Please contact 'jsmith@example.com' to gain
access to this equipment if you need authorization.

Password:

July 27th 1:00 AM to 8:00

Planned Network Maintenance

AFFECTED LOCATIONS: Sunnyvale

PLANNED ACTIVITY: Upgrade all 6200 switch firmware to the Enterprise TAC recommended firmware
version

PURPOSE: This activity will help to minimize the impact of unplanned power outages as well as
address known issues within our currently installed firmware version(s)

WHAT TO EXPECT: During the maintenance window for your site, the office network will not be
available.
```

## Display System Alarms Upon Login

You can configure Juniper Networks devices to execute the `show system alarms` command whenever a user in a given login class logs in to the device.

To display alarms whenever a user in a specific login class logs in to the device:

1. Configure the `login-alarms` statement for the appropriate login class.

```
[edit system login class class-name]  
user@host# set login-alarms
```

For example, to display alarms whenever a user in the `admin` login class logs in to the device:

```
[edit system login class admin]  
user@host# set login-alarms
```

2. Commit the configuration.

```
[edit system login class class-name]  
user@host# commit
```

When a user in the given login class logs in to the device, the device displays the current alarms.

```
$ ssh user@host.example.com  
Password:  
--- JUNOS 21.1R2.6-EVO Linux (none) 4.8.28-WR2.2.1_standard-g3999f55 #1 SMP PREEMPT Fri Jun 4  
00:19:58 PDT 2021 x86_64 x86_64 x86_64 GNU/Linux  
  
2 alarms currently active  
Alarm time           Class Description  
2021-07-22 15:00:14 PDT Minor port-1/0/0: Optics does not support configured speed  
2021-07-22 15:00:14 PDT Minor port-1/0/1: Optics does not support configured speed
```

## Configure Login Tips

You can configure the Junos OS CLI to display a tip whenever a user in the given login class logs in to the device. The device does not display tips by default.

To enable tips:

1. Configure the login-tip statement at the [edit system login class *class-name*] hierarchy level.

```
[edit system login class class-name]  
user@host# set login-tip
```

2. Commit the configuration.

```
[edit system login class class-name]  
user@host# commit
```

When you configure the login-tip statement, the device displays a tip to any user in the specified class who logs in to the device.

```
$ ssh user@host.example.com  
Password:  
  
JUNOS tip:  
In configuration mode, the [edit] banner displays the current location  
in the configuration hierarchy.  
  
user@host>
```

## Configure Time-Based User Access

You can configure supported Juniper Networks devices to enforce time-based user access for users in a given class. Time-based user access restricts the time and duration of user logins for all users belonging to the class. You can restrict user access based on the time of day or day of the week.

To restrict user access to certain days or times, include the following statements at the [edit system login class *class-name*] hierarchy level:

- allowed-days—Configure user access on specific days of the week.

- `access-start` and `access-end`—Configure user access between the specified start time and end time (*hh:mm*).

To configure time-based user access:

1. Enable access on specific days of the week.

```
[edit system login class class-name]
user@host# set allowed-days [ day1 day2 ]
```

For example, to configure user access for the `operator-round-the-clock-access` login class from Monday through Friday without any restriction on access time:

```
[edit system login class operator-round-the-clock-access]
user@host# set allowed-days [ monday tuesday wednesday thursday friday ]
```

2. Enable access at specific times of the day.

```
[edit system login class class-name]
user@host# set access-start hh:mm
user@host# set access-end hh:mm
```

For example, to configure user access for the `operator-day-shift-all-days-of-the-week` login class from 8:30 AM through 4:30 PM on all days of the week:

```
[edit system login class operator-day-shift-all-days-of-the-week]
user@host# set access-start 08:30
user@host# set access-end 16:30
```

You can also configure access to include both days and times. The following example configures user access for the `operator-day-shift` login class on Monday, Wednesday, and Friday from 8:30 AM through 4:30 PM:

```
[edit system login class operator-day-shift]
user@host# set allowed-days [ monday wednesday friday ]
user@host# set access-start 08:30
user@host# set access-end 16:30
```

Alternatively, you can specify the login start time and end time for the operator-day-shift login class by using the following format:

```
[edit system login class operator-day-shift]
user@host# set allowed-days [ monday wednesday friday ]
user@host# set access-start 08:30am
user@host# set access-end 04:30pm
```

**NOTE:** The access start and end times might span across 12:00 AM on a given day. In that case, the user still has access until the next day, even if you do not explicitly configure that day in the `allowed-days` statement.

## Configure the Timeout Value for Idle Login Sessions

An idle login session is one in which the CLI displays the operational mode or configuration mode prompt but there is no input from the keyboard. By default, a login session remains established until a user logs out of the device, even if that session is idle. To close idle sessions automatically, you must configure a time limit for each login class. If a session established by a user in that class remains idle for the configured time limit, the session automatically closes. Automatically closing idle login sessions helps to prevent malicious users from gaining access to the device and performing operations with an authorized user account.

You can configure an idle timeout only for user-defined classes. You cannot configure this option for the system predefined classes: `operator`, `read-only`, `super-user` or `superuser`, and `unauthorized`.

To define the timeout value for idle login sessions:

1. Specify the number of minutes that a session can be idle before the system automatically closes the session.

```
[edit system login class class-name]
user@host# set idle-timeout minutes
```

For example, to automatically disconnect idle sessions of users in the `admin` class after fifteen minutes:

```
[edit system login class admin]
user@host# set idle-timeout 15
```

## 2. Commit the configuration.

```
[edit system login class class-name]  
user@host# commit
```

If you configure a timeout value, the CLI displays messages similar to the following when timing out an idle user. The CLI starts displaying these messages 5 minutes before disconnecting the user.

```
user@host> Session will be closed in 5 minutes if there is no activity.  
Warning: session will be closed in 1 minute if there is no activity  
Warning: session will be closed in 10 seconds if there is no activity  
Idle timeout exceeded: closing session
```

If you configure a timeout value, the session closes after the specified time elapses, except in the following cases:

- The user is running the `ssh` or `telnet` command.
- The user is logged into the local UNIX shell.
- The user is monitoring interfaces using the `monitor interface` or the `monitor traffic` command.

## Login Retry Options

You can configure login retry options on Juniper Network devices to protect the devices from malicious users. You can configure the following options:

- The number of times a user can enter invalid login credentials before the system closes the connection.
- Whether and for how long to lock a user account after the user reaches the threshold of failed authentication attempts.

Limiting the login attempts and locking the user account help to protect the device from malicious users attempting to access the system by guessing the password of an authorized user account. You can unlock the user account or define a time period for the user account to remain locked.

You configure login retry options at the `[edit system login retry-options]` hierarchy level. The `tries-before-disconnect` statement defines the threshold of failed login attempts before the device disconnects the user. The device allows three unsuccessful login attempts by default.

The `lockout-period` statement instructs the device to lock the user account for the specified amount of time if the user reaches the threshold of unsuccessful login attempts. The lock prevents the user from performing activities that require authentication, until the lockout time period has elapsed or a system administrator manually clears the lock. Any existing locks are ignored when the user attempts to log in from the local console.

To configure login retry options:

1. Configure the number of times a user can attempt to enter a password.

```
[edit system login retry-options]
user@host# set tries-before-disconnect number
```

For example, to enable a user to enter a password four times before the device closes the connection:

```
[edit system login retry-options]
user@host# set tries-before-disconnect 4
```

2. Configure the number of minutes that the user account remains locked after a user reaches the threshold of failed login attempts.

```
[edit system login retry-options]
user@host# set lockout-period minutes
```

For example, to lock a user account for 120 minutes after a user reaches the threshold of failed login attempts:

```
[edit system login retry-options]
user@host# set lockout-period 120
```

3. Commit the configuration.

```
[edit system login retry-options]
user@host# commit
```

You can limit the number of times a user can attempt to enter a password while logging in to a device through SSH or Telnet. The device terminates the connection if a user fails to log in after the number of specified attempts. You can also specify a delay, in seconds, before a user can try to enter a password after a failed attempt. In addition, you can specify the threshold for the number of failed attempts before the user experiences a delay in being able to enter a password again.

```
[edit system login]

retry-options {
    tries-before-disconnect number;
    backoff-threshold number;
    backoff-factor seconds;
    lockout-period minutes;
    maximum-time seconds
    minimum-time seconds;
}
```

- `tries-before-disconnect`—Maximum number of times a user can enter a password when logging in to the device through SSH or Telnet. The connection closes if a user fails to log in after the number specified. The range is from 1 through 10, and the default is 3.
- `backoff-threshold`—Threshold for the number of failed login attempts before the user experiences a delay in being able to enter a password again. The range is from 1 through 3, and the default is 2. Use the `backoff-factor` option to specify the length of the delay.

- **backoff-factor**—Length of time, in seconds, that the user must wait after a failed login attempt above the **backoff-threshold**. The delay increases by the specified value for each subsequent attempt after the **backoff-threshold** value. The range is from 5 through 10, and the default is 5 seconds.
- **lockout-period**—Length of time, in minutes, that a user account is locked after reaching the **tries-before-disconnect** threshold. The range is 1 through 43,200 minutes.
- **maximum-time *seconds***—Maximum length of time, in seconds, that the connection remains open for the user to enter a username and password to log in. If the user remains idle and does not enter a username and password within the configured **maximum-time**, the connection closes. The range is from 20 through 300 seconds, and the default is 120 seconds.
- **minimum-time**—Minimum length of time, in seconds, that a connection remains open while a user is attempting to enter a correct password. The range is from 20 through 60, and the default is 20 seconds.

Limiting the number of SSH and Telnet login attempts per user is one of the most effective methods of stopping brute force attacks from compromising your network security. Brute force attackers execute a large number of login attempts in a short period of time to illegitimately gain access to a private network. By configuring the **retry-options** statements, you can create an increasing delay after each failed login attempt, eventually disconnecting any user who passes your set threshold of login attempts.

To limit the login attempts when a user logs in through SSH or Telnet:

1. Configure the limit on the number of login attempts.

```
[edit system login retry-options]
user@host# set tries-before-disconnect number
```

2. Configure the number of login attempts before the user experiences a delay.

```
[edit system login retry-options]
user@host# set backoff-threshold number
```

3. Configure the number of seconds the user must wait for the login prompt after reaching the **backoff-threshold** value.

```
[edit system login retry-options]
user@host# set backoff-factor seconds
```

4. Configure the number of seconds that the connection remains open while a user attempts to log in.

```
[edit system login retry-options]
user@host# set minimum-time seconds
```

For the following configuration, the user experiences a delay of 5 seconds after the second attempt to enter a correct password fails. After each subsequent failed attempt, the delay increases by 5 seconds. After the fourth and final failed attempt to enter a correct password, the user experiences an additional 10-second delay. The connection closes after a total of 40 seconds.

```
[edit]
system {
  login {
    retry-options {
      backoff-threshold 2;
      backoff-factor 5;
      minimum-time 40;
      tries-before-disconnect 4;
    }
  }
}
```

## Example: Configure Login Retry Options

### IN THIS SECTION

- [Requirements | 21](#)
- [Overview | 21](#)
- [Configuration | 22](#)
- [Verification | 24](#)

This example shows how to configure login retry options to protect a device from malicious users.

## Requirements

Before you begin, you should understand "[Limit the Number of User Login Attempts for SSH and Telnet Sessions](#)" on page 18.

No special configuration beyond device initialization is required before configuring this feature.

## Overview

Malicious users sometimes try to log in to a secure device by guessing the password of an authorized user account. You can lock a user account after a certain number of failed authentication attempts. This precaution helps protect devices from malicious users.

You can configure the number of failed login attempts before the device locks the user account, and you can configure the amount of time that the account remains locked. You can also configure the amount of time the user must wait between failed login attempts.

**NOTE:** This example includes the following settings:

- **backoff-factor**—Length of delay in seconds that the user must wait after each failed login attempt above the **backoff-threshold**. The delay increases by this value for each subsequent login attempt after the value specified in the **backoff-threshold** statement.
- **backoff-threshold**—Threshold for the number of failed login attempts on the device before the user experiences a delay when attempting to reenter a password. When a user reaches the threshold of failed login attempts, the user experiences the delay set in the **backoff-factor** statement. After the delay, the user can make another login attempt.
- **lockout-period**—Number of minutes that the user account is locked after the user reaches the **tries-before-disconnect** threshold. The user must wait the configured number of minutes before they can log in to the device again.
- **tries-before-disconnect**—Maximum number of times the user can enter a password to attempt to log in to the device through SSH or Telnet.

**NOTE:** If you are locked out of the device, you can log in to the device's console port, which ignores any user locks. This provides a way for administrators to remove the user lock on their own user account.

This example sets the **tries-before-disconnect** option to 3. As a result, the user has three attempts to log in to the device. If the number of failed login attempts is equal to the value specified in the **backoff-threshold** statement, the user must wait for the **backoff-threshold** multiplied by the **backoff-factor** interval, in seconds,

to get the login prompt. In this example, the user must wait 5 seconds after the first failed login attempt and 10 seconds after the second failed login attempt to get the login prompt. The device disconnects the user after the third failed attempt.

If the user does not successfully log in after three attempts, the user account is locked. The user cannot log in until 120 minutes have elapsed, unless a system administrator manually clears the lock during that time.

A system administrator can manually unlock an account by issuing the `clear system login lockout user <username>` command. The `show system login lockout` command displays which user accounts are locked and when the lockout period begins and ends for each user.

## Configuration

### IN THIS SECTION

- [Procedure | 22](#)

## Procedure

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the `[edit]` hierarchy level, and then enter `commit` from configuration mode.

```
set system login retry-options backoff-factor 5
set system login retry-options backoff-threshold 1
set system login retry-options lockout-period 120
set system login retry-options tries-before-disconnect 3
```

## Step-by-Step Procedure

To configure system retry-options:

1. Configure the backoff factor.

```
[edit]
user@host# set system login retry-options backoff-factor 5
```

2. Configure the backoff threshold.

```
[edit]
user@host# set system login retry-options backoff-threshold 1
```

3. Configure the number of minutes that the user account remains locked after a user reaches the threshold of failed login attempts.

```
[edit]
user@host# set system login retry-options lockout-period 120
```

4. Configure the number of times a user can attempt to enter a password.

```
[edit]
user@host# set system login retry-options tries-before-disconnect 3
```

## Results

From configuration mode, confirm your configuration by entering the `show system login retry-options` command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show system login retry-options
tries-before-disconnect 3;
backoff-threshold 1;
backoff-factor 5;
lockout-period 120;
```

If you are done configuring the device, enter `commit` from configuration mode.

## Verification

### IN THIS SECTION

- [Display the Locked User Logins | 24](#)

### Display the Locked User Logins

#### Purpose

Verify that the login lockout configuration is enabled.

#### Action

Attempt three unsuccessful logins for a particular username. The device will be locked for that username. Then log in to the device with a different username. From operational mode, issue the `show system login lockout` command to view the locked accounts.

```
user@host> show system login lockout
User                Lockout start      Lockout end
jsmith             2021-08-17 16:27:28 PDT 2021-08-17 18:27:28 PDT
```

#### Meaning

After you perform three unsuccessful login attempts with a particular username, the device is locked for that user for 120 minutes, as configured in the example. You can verify that the device is locked for that user by logging in to the device with a different username and entering the `show system login lockout` command.

# User Accounts

## IN THIS SECTION

- [User Accounts Overview | 26](#)
- [Junos-FIPS Crypto Officer and User Accounts Overview | 28](#)
- [Example: Configure New User Accounts | 29](#)
- [Configure User Accounts in a Configuration Group | 34](#)

Junos OS enables you (the system administrator) to create accounts for router, switch, and security users. All users belong to one of the system login classes.

You create user accounts so that users can access a router, switch, or security device. All users must have a predefined user account before they can log in to the device. You create user accounts and then define the login name and identifying information for each user account.

## User Accounts Overview

User accounts provide one way for users to access a device. For each account, you define the user's login name, password, and any additional user information. After you have created an account, the software creates a home directory for the user.

An account for the user `root` is always present in the configuration. You can configure the password for root using the `root-authentication` statement.

While it is common to use remote authentication servers to centrally store information about users, it is also good practice to configure at least one non-root user on each device. This way, you can still access the device if its connection to the remote authentication server is disrupted. This non-root user usually has a generic name such as `admin`.

For each user account, you can define the following:

- **Username (Required):** Name that identifies the user. It must be unique. Avoid using spaces, colons, or commas in the username. The username can include up to 64 characters.
- **User's full name: (Optional)** If the full name contains spaces, enclose it in quotation marks. Avoid the use of colons or commas.

- **User identifier (UID):** (Optional) Numeric identifier that is associated with the user account name. The UID is assigned automatically when you commit the configuration, so you do not need to set it manually. However, if you choose to configure the UID manually, use a unique value in the range from 100 through 64,000.
- **User's access privilege:** (Required) One of the login classes you defined in the `class` statement at the `[edit system login]` hierarchy or one of the default login classes.
- **Authentication method or methods and passwords for device access** (Required): You can use a SSH key, a Message Digest 5 (MD5) password, or a plain-text password that Junos OS encrypts using MD5-style encryption before entering it in the password database. For each method, you can specify the user's password. If you configure the `plain-text-password` option, you receive a prompt to enter and confirm the password:

```
[edit system login user username]
user@host# set authentication plain-text-password
New password: type password here
Retype new password: retry password here
```

To create valid plain-text passwords, make sure that they:

- Contain between 6 and 128 characters.
- Include most character classes (uppercase letters, lowercase letters, numbers, punctuation marks, and other special characters) but do not include control characters.
- Contain at least one change of case or character class.

Junos-FIPS and Common Criteria have the following special password requirements. They must:

- Be between 10 and 20 characters long.
- Use at least three of the five defined character sets (uppercase letters, lowercase letters, digits, punctuation marks, and other special characters).

If Junos-FIPS is installed on the device, you must adhere to the special password requirements, or the passwords are not configured.

For SSH authentication, you can copy the contents of an SSH key file into the configuration. You can also configure SSH key information directly. Use the `load-key-file` statement to load an SSH key file that was generated previously, (for example, by using `ssh-keygen`). The `load-key-file` argument is the path to the file location and name. The `load-key-file` statement loads RSA (SSH version 1 and SSH version 2) public keys. The contents of the SSH key file are copied into the configuration immediately after you configure the `load-key-file` statement.

Avoid using the following Transport Layer Security (TLS) version and cipher suite (RSA host key) combinations, which will fail:

With RSA host keys:

- TLS\_1.0@DHE-RSA-AES128-SHA
- TLS\_1.0@DHE-RSA-AES256-SHA

For each user account and for root logins, you can configure more than one public RSA key for user authentication. When a user logs in using a user account or as root, the configured public keys are referenced to determine whether the private key matches any of the user accounts.

To view the SSH key entries, use the configuration mode `show` command. For example:

```
[edit system login user boojum]
user@host# set authentication load-key-file my-host:.ssh/id_rsa.pub
.file.19692          |          0 KB |   0.3 kB/s | ETA: 00:00:00 | 100%
[edit system login user boojum]
user@host# show
authentication {
    ssh-rsa "$ABC123"; # SECRET-DATA
}
```

## Junos-FIPS Crypto Officer and User Accounts Overview

### IN THIS SECTION

- [Crypto Officer User Configuration | 29](#)
- [FIPS User Configuration | 29](#)

Junos-FIPS defines a restricted set of user roles. Unlike the Junos OS, which enables a wide range of capabilities to users, FIPS 140-2 defines specific types of users (Crypto Officer, User, and Maintenance). Crypto Officers and FIPS Users perform all FIPS-related configuration tasks and issue all FIPS-related commands. Crypto Officer and FIPS User configurations must follow FIPS 140-2 guidelines. Typically, only a Crypto Officer can perform FIPS-related tasks.

## Crypto Officer User Configuration

Junos-FIPS offers you finer control of user permissions than those mandated by FIPS 140-2. For FIPS 140-2 conformance, any Junos-FIPS user with the secret, security, and maintenance permission bits set is a Crypto Officer. In most cases, you should reserve the super-user class for a Crypto Officer. A FIPS User can be defined as any Junos-FIPS user that does not have the secret, security, and maintenance bits set.

## FIPS User Configuration

A Crypto Officer sets up FIPS Users. FIPS Users certain permissions normally reserved for a Crypto Officer; for example, you can grant a FIPS User permission to zeroize the system and individual AS-II FIPS PICs.

## Example: Configure New User Accounts

### IN THIS SECTION

- [Requirements | 29](#)
- [Overview | 29](#)
- [Configuration | 30](#)
- [Verification | 33](#)

This example shows how to configure new user accounts.

### Requirements

You do not need any special configurations before using this feature.

### Overview

You can add new user accounts to the device's local database. For each account, you (the system administrator) define a login name and password for the user and specify a login class for access privileges. The login password must meet the following criteria:

- The password must be at least six characters long.
- You can include most character classes in the password (alphabetic, numeric, and special characters), but not control characters.

- The password must contain at least one change of case or character class.

In this example, you create a login class named `operator-and-boot` and allow it to reboot the device. You can define any number of login classes. Then, allow the `operator-and-boot` login class to use commands defined in the following bits:

- `clear`
- `network`
- `reset`
- `trace`
- `view permission`

Next, create user accounts to enable access to the device. Set the username as `randomuser` and the login class as `superuser`. Finally, define the encrypted password for the user.

## Configuration

### IN THIS SECTION

- [Procedure](#) | 30

## Procedure

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the `[edit]` hierarchy level, and then enter `commit` in configuration mode.

```
set system login class operator-and-boot allow-commands "request system reboot"
set system login class operator-and-boot permissions [clear network reset trace view]
set system login user randomuser class superuser authentication encrypted-password $1$ABC123
```

## Step-by-Step Procedure

To configure new users:

1. Set the name of the login class and allow the use of the reboot command.

```
[edit system login]
user@host# set class operator-and-boot allow-commands "request system reboot"
```

2. Set the permission bits for the login class.

```
[edit system login]
user@host# set class operator-and-boot permissions [clear network reset trace view]
```

3. Set the username, login class, and encrypted password for the user.

```
[edit system login]
user@host# set userrandomuser class superuser authentication encrypted-password $1$ABC123
```

## GUI Quick Configuration

### Step-by-Step Procedure

To configure new users:

1. In the J-Web user interface, select **Configure>System Properties>User Management**.
2. Click **Edit**. The **Edit User Management** dialog box appears.
3. Select the **Users** tab.
4. Click **Add** to add a new user. The **Add User** dialog box appears.
5. In the **User name** box, type a unique name for the user.  
Avoid spaces, colons, and commas in the username.
6. In the **User ID** box, type a unique ID for the user.
7. In the **Full Name** box, type the user's full name.  
If the full name contains spaces, enclose it in quotation marks. Avoid colons and commas.
8. In the **Password** and **Confirm Password** boxes, enter a login password for the user and verify your entry.
9. From the **Login Class** list, select the user's access privilege:

- operator
- read-only
- unauthorized

This list also includes any user-defined login classes.

10. Click OK in the Add User dialog box and Edit User Management dialog box.
11. Click OK to check your configuration and save it as a candidate configuration.
12. After you configure the device, click Commit Options>Commit.

## Results

In configuration mode, confirm your configuration by entering the `show system login` command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show system login
    class operator-and-boot {
    permissions [ clear network reset trace view ];
    allow-commands "request system reboot";
    }
user randomuser {
    class superuser;
    authentication {
    encrypted-password "$1$ABC123";
    }
}
```

The following example shows how to create accounts for four users. It also shows how to create an account for the template user `remote`. All users use one of the default system login classes.

```
[edit]
system {
    login {
    user philip {
    full-name "Philip of Macedonia";
    uid 1001;
    class super-user;
    }
```

```

        authentication {
            encrypted-password "$ABC123";
        }
    }
    user alexander {
        full-name "Alexander the Great";
        uid 1002;
        class operator;
        authentication {
            encrypted-password "$ABC123";
        }
    }
    user darius {
        full-name "Darius King of Persia";
        uid 1003;
        class operator;
        authentication {
            ssh-rsa "1024 37 12341234@ecbatana.per";
        }
    }
    user anonymous {
        class unauthorized;
    }
    user remote {
        full-name "All remote users";
        uid 9999;
        class read-only;
    }
}
}

```

After you configure the device, enter `commit` in configuration mode.

## Verification

### IN THIS SECTION

- [Verify the New Users Configuration | 34](#)

Confirm that the configuration is working properly.

## Verify the New Users Configuration

### Purpose

Verify that the new users are configured.

### Action

Log in to the device with the new user account or accounts and password to confirm that you have access.

## Configure User Accounts in a Configuration Group

To make it easier to configure the same user accounts on multiple devices, configure the accounts inside of a configuration group. The examples shown here are in a configuration group called `global`. Using a configuration group for your user accounts is optional.

To create a user account:

1. Add a new user, using the user's assigned account login name.

```
[edit groups global]
user@host# edit system login user username
```

2. (Optional) Configure a descriptive name for the account.

If the name includes spaces, enclose the entire name in quotation marks.

```
[edit groups global system login user user-name]
user@host# set full-name complete-name
```

For example:

```
user@host# show groups
global {
  system {
    login {
      user admin {
        full-name "general administrator";
      }
    }
  }
}
```

```
    }
  }
}
```

### 3. (Optional) Set the user identifier (UID) for the account.

As with UNIX systems, the UID enforces user permissions and file access. If you do not set the UID, the software assigns one for you. The format of the UID is a number between 100 and 64,000.

```
[edit groups global system login user user-name]
user@host# set uid uid-value
```

For example:

```
user@host# show groups
global {
    system {
        login {
            user admin {
                uid 9999;
            }
        }
    }
}
```

### 4. Assign the user to a login class.

You can define your own login classes or assign one of the predefined login classes.

The predefined login classes are as follows:

- super-user—all permissions
- operator—clear, network, reset, trace, and view permissions
- read-only—view permissions
- unauthorized—no permissions

```
[edit groups global system login user user-name]
user@host# set class class-name
```

For example:

```
user@host# show groups
global {
    system {
        login {
            user admin {
                class super-user;
            }
        }
    }
}
```

5. Use one of the following methods to configure the user password:

- To enter a clear-text password that the system encrypts for you, use the following command to set the user password:

```
[edit groups global system login user user-name]
user@host# set authentication plain-text-password
New Password: type password here
Retype new password: retry password here
```

As you enter the password in plain text, the software encrypts it. You do not need to configure the software to encrypt the password. Plain-text passwords are hidden and marked as ## SECRET-DATA in the configuration.

- To enter a password that is encrypted, use the following command to set the user password:

**CAUTION:** Do not use the encrypted-password option unless the password is *already* encrypted and you are entering the encrypted version of the password.

If you accidentally configure the encrypted-password option with a plain-text password or with blank quotation marks (" "), you will not be able to log in to the device as this user.

```
[edit groups global system login user user-name]
user@host# set authentication encrypted-password "password"
```

- To load previously generated public keys from a named file at a specified URL location, use the following command:

```
[edit groups global system login user user-name]
user@host# set authentication load-key-file URL filename
```

- To enter an SSH public string, use the following command:

```
[edit groups global system login user user-name]
user@host# set authentication (ssh-ecdsa | ssh-ed25519 | ssh-rsa) authorized-key
```

6. At the top level of the configuration, apply the configuration group.

If you use a configuration group, you must apply it for it to take effect.

```
[edit]
user@host# set apply-groups global
```

7. Commit the configuration.

```
user@host# commit
```

8. To verify the configuration, log out and log back in as the new user.

## Administrative Roles

### IN THIS SECTION

- [How to Design Administrative Roles | 38](#)
- [Example: How to Configure Administrative Roles | 40](#)
- [How to Configure a Local Administrator Account | 49](#)

Junos OS enables you to define a system user to act as a specific kind of administrator for the system. You can assign an administrative role to a user by configuring a login class to have the administrative

role attributes. You can assign one of the role attributes such as audit-officer crypto-officer, security-officer, ids-officer to an administrative user.

## How to Design Administrative Roles

A system user can be a member of a class that allows the user to act as a specific kind of administrator for the system. Requiring a specific role to view or modify an item restricts the extent of information a user can obtain from the system. It also limits how much of the system is open to modification or observation by a user. You (the system administrator) should use the following guidelines when you are designing administrative roles:

- Do not allow any user to log in to the system as root.
- Restrict each user to the smallest set of privileges needed to perform the user's duties.
- Do not allow any user to belong to a login class containing the shell permission flag. The shell permission flag allows users to run the `start shell` command from the CLI.
- Allow users to have rollback permissions. Rollback permissions allow users to undo an action performed by an administrator but does not allow them to commit the changes.

You can assign an administrative role to a user by configuring a login class to have the privileges required for the role. You can configure each class to allow or deny access to configuration statements and commands by name. These restrictions override and take precedence over any permission flags also configured in the class. You can assign one of the following role attributes to an administrative user:

- **Crypto-administrator**—Allows the user to configure and monitor cryptographic data.
- **Security-administrator**—Allows the user to configure and monitor security data.
- **Audit-administrator**—Allows the user to configure and monitor audit data.
- **IDS-administrator**—Allows the user to monitor and clear the intrusion detection service (IDS) security logs.

Each role can perform the following specific management functions:

- **Cryptographic Administrator**
  - Configures the cryptographic self-test.
  - Modifies the cryptographic security data parameters.
- **Audit Administrator**
  - Configures and deletes the audit review search-and-sort feature.

- Searches and sorts audit records.
- Configures search and sort parameters.
- Manually deletes audit logs.
- **Security Administrator**
  - Invokes, determines, and modifies the cryptographic self-test behavior.
  - Enables, disables, determines, and modifies the audit analysis and audit selection functions, and configures the device to automatically delete audit logs.
  - Enables or disables security alarms.
  - Specifies limits for quotas on Transport Layer connections.
  - Specifies the limits, network identifiers, and time periods for quotas on controlled connection-oriented resources.
  - Specifies the network addresses permitted to use Internet Control Message Protocol (ICMP) or Address Resolution Protocol (ARP).
  - Configures the time and date used in time stamps.
  - Queries, modifies, deletes, and creates the information flow or access control rules and attributes for the unauthenticated information flow security function policy (SFP), the authenticated information flow security function policy, the unauthenticated device services, and the discretionary access control policy.
  - Specifies initial values that override default values when object information is created under unauthenticated information flow SFP, the authenticated information flow SFP, the unauthenticated target of evaluation (TOE) services, and the discretionary access control policy.
  - Creates, deletes, or modifies the rules that control the address from which management sessions can be established.
  - Specifies and revokes security attributes associated with the users, subjects, and objects.
  - Specifies the percentage of audit storage capacity at which the device alerts administrators.
  - Handles authentication failures and modifies the number of failed authentication attempts through SSH or from the CLI that can occur before progressive throttling is enforced for further authentication attempts and before the connection is dropped.
  - Manages basic network configuration of the device.
- **IDS Administrator**—Specifies IDS security alarms, intrusion alarms, audit selections, and audit data.

You must set the security-role attribute in the classes created for these administrative roles. This attribute restricts which users can show and clear the security logs, actions that cannot be performed through configuration alone.

For example, you must set the security-role attribute in the `ids-admin` class created for the IDS administrator role if you want to restrict clearing and showing IDS logs to the IDS administrator role. Likewise, you must set the security-role to one of the other admin values to restrict that class from being able to clear and show non-IDS logs only.

**NOTE:** When a user deletes an existing configuration, the configuration statements under the hierarchy level of the deleted configuration (the child objects that the user does not have permission to modify) remain in the device.

## Example: How to Configure Administrative Roles

### IN THIS SECTION

- [Requirements | 40](#)
- [Overview | 40](#)
- [Configuration | 41](#)
- [Verification | 48](#)

This example shows how to configure individual administrative roles for a distinct, unique set of privileges apart from all other administrative roles.

### Requirements

No action beyond device initialization is required before configuring this feature.

### Overview

This example illustrates how to configure four admin user roles:

- `audit-officer` of the class `audit-admin`
- `crypto-officer` of the class `crypto-admin`

- security-officer of the class security-admin
- ids-officer of the class ids-admin

When a security-admin class is configured, the privileges for creating administrators are revoked from the user who created the security-admin class. Creation of new users and logins is at the discretion of the security-officer.

In this example, you create the four administrative user roles shown in the preceding list (audit admin, crypto admin, security admin, and ids admin). For each role, you assign relevant permission flags for the role. You then allow or deny access to configuration statements and commands by name for each administrative role. These specific restrictions take precedence over the permission flags configured in the class. For example, only the crypto-admin can run the `request system set-encryption-key` command, which requires having the security permission flag to access it. Only the security-admin can include the `system time-zone` statement in the configuration, which requires having the system-control permission flag.

## Configuration

## Procedure

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the `[edit]` hierarchy level, and then enter `commit` in configuration mode.

```
set system login class audit-admin permissions security
set system login class audit-admin permissions trace
set system login class audit-admin permissions maintenance
set system login class audit-admin allow-commands "^clear (log|security log)"
set system login class audit-admin deny-commands "^clear (security alarms|system login logout)|
^file (copy|delete|rename)|^request (security|system set-encryption-key)|^rollback|^set date|
^show security (alarms|dynamic-policies|match-policies|policies)|^start shell";
set system login class audit-admin security-role audit-administrator
set system login class crypto-admin permissions admin-control
```

```

set system login class crypto-admin permissions configure
set system login class crypto-admin permissions maintenance
set system login class crypto-admin permissions security-control
set system login class crypto-admin permissions system-control
set system login class crypto-admin permissions trace
set system login class crypto-admin allow-commands "^request system set-encryption-key"
set system login class crypto-admin deny-commands "^clear (log|security alarms|security log|
system login lockout)|^file (copy|delete|rename)|^rollback|^set date|^show security (alarms|
dynamic-policies|match-policies|policies)|^start shell"
set system login class crypto-admin allow-configuration-regexps ["security (ike|ipsec) (policy|
proposal)" "security ipsec ^vpn$ .* manual (authentication|encryption|protocol|spi)" "system
fips self-test after-key-generation"]
set system login class crypto-admin security-role crypto-administrator
set system login class security-admin permissions all
set system login class security-admin deny-commands "^clear (log|security log)|^(clear|show)
security alarms alarm-type idp|^request (security|system set-encryption-key)|^rollback|^start
shell"
set system login class security-admin deny-configuration-regexps ["security alarms potential-
violation idp" "security (ike|ipsec) (policy|proposal)" "security ipsec ^vpn$ .* manual
(authentication|encryption|protocol|spi)" "security log cache" "security log exclude .* event-id
IDP_.*" "system fips self-test after-key-generation"]
set system login class security-admin security-role security-administrator
set system login class ids-admin permissions configure
set system login class ids-admin permissions security-control
set system login class ids-admin permissions trace
set system login class ids-admin permissions maintenance
set system login class ids-admin allow-configuration-regexps ["security alarms potential-
violation idp" "security log exclude .* event-id IDP_.*"]
set system login class ids-admin deny-commands "^clear log|^(clear|show) security alarms (alarm-
id|all|newer-than|older-than|process|severity)|^(clear|show) security alarms alarm-type
(authentication|cryptographic-self-test|decryption-failures|encryption-failures|ike-phase1-
failures|ike-phase2-failures|key-generation-self-test|non-cryptographic-self-test|policy|replay-
attacks)|^file (copy|delete|rename)|^request (security|system set-encryption-key)|^rollback|^set
date|^show security (dynamic-policies|match-policies|policies)|^start shell"
set system login class ids-admin deny-configuration-regexps ["security alarms potential-
violation (authentication|cryptographic-self-test|decryption-failures|encryption-failures|ike-
phase1-failures|ike-phase2-failures|key-generation-self-test|non-cryptographic-self-test|policy|
replay-attacks)"]
set system login class ids-admin security-role ids-admin
set system login user audit-officer class audit-admin
set system login user crypto-officer class crypto-admin
set system login user security-officer class security-admin
set system login user ids-officer class ids-admin

```

```
set system login user audit-officer authentication plain-text-password
set system login user crypto-officer authentication plain-text-password
set system login user security-officer authentication plain-text-password
set system login user ids-officer authentication plain-text-password
```

## Step-by-Step Procedure

To configure administrative roles:

1. Create the audit-admin login class.

```
[edit]
user@host# edit system login class audit-admin
[edit system login class audit-admin]
user@host# set permissions security
user@host# set permissions trace
user@host# set permissions maintenance
```

2. Configure the audit-admin login class restrictions.

```
[edit system login class audit-admin]
user@host# set allow-commands "^clear (log|security log)"
user@host# set deny-commands "^clear (security alarms|system login logout)|^file (copy|
delete|rename)|^request (security|system set-encryption-key)|^rollback|^set date|^show
security (alarms|dynamic-policies|match-policies|policies)|^start shell"
user@host# set security-role audit-administrator
```

3. Create the crypto-admin login class.

```
[edit]
user@host# edit system login class crypto-admin
[edit system login class crypto-admin]
user@host# set permissions admin-control
user@host# set permissions configure
user@host# set permissions maintenance
user@host# set permissions security-control
user@host# set permissions system-control
user@host# set permissions trace
```

4. Configure the crypto-admin login class restrictions.

```
[edit system login class crypto-admin]
user@host# set allow-commands "^request system set-encryption-key"
user@host# set deny-commands "^clear (log|security alarms|security log|system login
lockout)|^file (copy|delete|rename)|^rollback|^set date|^show security (alarms|dynamic-
policies|match-policies|policies)|^start shell"
user@host# set allow-configuration-regexps ["security (ike|ipsec) (policy|proposal)"
"security ipsec ^vpn$ .* manual (authentication|encryption|protocol|spi)" "system fips self-
test after-key-generation"]
user@host# set security-role crypto-administrator
```

5. Create the security-admin login class.

```
[edit]
user@host# edit system login class security-admin
[edit system login class security-admin]
user@host# set permissions all
```

6. Configure the security-admin login class restrictions.

```
[edit system login class security-admin]
user@host# set deny-commands "^clear (log|security log)|^(clear|show) security alarms alarm-
type idp|^request (security|system set-encryption-key)|^rollback|^start shell"
user@host# set deny-configuration-regexps ["security alarms potential-violation idp"
"security (ike|ipsec) (policy|proposal)" "security ipsec ^vpn$ .* manual (authentication|
encryption|protocol|spi)" "security log cache" "security log exclude .* event-id IDP_.*"
"system fips self-test after-key- generation"]
user@host# set security-role security-administrator
```

7. Create the ids-admin login class.

```
[edit]
user@host# edit system login class ids-admin
[edit system login class ids-admin]
user@host# set permissions configure
user@host# set permissions maintenance
```

```
user@host# set permissions security-control
user@host# set permissions trace
```

8. Configure the ids-admin login class restrictions.

```
[edit system login class ids-admin]
user@host# set allow-configuration-regexps ["security alarms potential-violation idp"
"security log exclude .* event-id IDP_.*"]
user@host# set deny-commands "^clear log|^((clear|show) security alarms (alarm-id|all|newer-
than|older-than|process|severity))|^((clear|show) security alarms alarm-type (authentication|
cryptographic-self-test|decryption-failures|encryption-failures|ike-phase1-failures|ike-
phase2-failures|key-generation-self-test|non-cryptographic-self-test|policy|replay-attacks))|
^file (copy|delete|rename)|^request (security|system set-encryption-key)|^rollback|^set
date|^show security (dynamic-policies|match-policies|policies)|^start shell"
user@host# set deny-configuration-regexps ["security alarms potential-violation
(authentication|cryptographic-self-test|decryption-failures|encryption-failures|ike-phase1-
failures|ike-phase2-failures|key-generation-self-test|non-cryptographic-self-test|policy|
replay-attacks)"]
user@host# set security-role ids-administrator
```

9. Assign users to the roles.

```
[edit]
user@host# edit system login
[edit system login]
user@host# set user audit-officer class audit-admin
user@host# set user crypto-officer class crypto-admin
user@host# set user security-officer class security-admin
user@host# set user ids-officer class ids-admin
```

10. Configure passwords for the users.

```
[edit system login]
user@host# set user audit-officer authentication plain-text-password
user@host# set user crypto-officer authentication plain-text-password
user@host# set user security-officer authentication plain-text-password
user@host# set user ids-officer authentication plain-text-password
```

## Results

In configuration mode, confirm your configuration by entering the **show system** command. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show system
system {
    login {
        class audit-admin {
            permissions [ maintenance security trace ];
            allow-commands "^clear (log|security log)";
            deny-commands "^clear (security alarms|system login logout)|^file (copy|delete|
rename)|^request (security|system set-encryption-key)|^rollback|^set date|^show security (alarms|
dynamic-policies|match-policies|policies)|^start shell";
            security-role audit-administrator;
        }
        class crypto-admin {
            permissions [ admin-control configure maintenance security-control system-control
trace ];
            allow-commands "^request (system set-encryption-key)";
            deny-commands "^clear (log|security alarms|security log|system login logout)|^file
(copy|delete|rename)|^rollback|^set date|^show security (alarms|dynamic-policies|match-policies|
policies)|^start shell";
            allow-configuration-regexps [ "security (ike|ipsec) (policy|proposal)" "security
ipsec ^vpn$ .* manual (authentication|encryption|protocol|spi)" "system fips self-test after-key-
generation" ];
            security-role crypto-administrator;
        }
        class security-admin {
            permissions [all];
            deny-commands "^clear (log|security log)|^(clear|show) security alarms alarm-type
idp|^request (security|system set-encryption-key)|^rollback|^start shell";
            deny-configuration-regexps [ "security alarms potential-violation idp" "security
(ike|ipsec) (policy|proposal)" "security ipsec ^vpn$ .* manual (authentication|encryption|
protocol|spi)" "security log exclude .* event-id IDP_.*" "system fips self-test after-key-
generation" ];
            security-role security-administrator;
        }
        class ids-admin {
            permissions [ configure maintenance security-control trace ];
```

```

deny-commands "^clear log|^clear|^show security alarms (alarm-id|all|newer-than|
older-than|process|severity)|^clear|^show security alarms alarm-type
(authentication | cryptographic-self-test | decryption-failures | encryption-failures
| ike-phase1-failures | ike-phase2-failures|key-generation-self-test |
non-cryptographic-self-test |policy | replay-attacks) | ^file (copy|delete|rename)
|^request (security|system set-encryption-key) | ^rollback |
^set date | ^show security (dynamic-policies|match-policies|policies) |^start shell";
allow-configuration-regexps [ "security alarms potential-violation idp" "security
log exclude .* event-id IDP_.*" ];
deny-configuration-regexps "security alarms potential-violation (authentication|
cryptographic-self-test|decryption-
failures|encryption-failures|ike-phase1-failures|ike-phase2-failures|
key-generation-self-test|non-cryptographic-self-test|policy|replay-attacks)"
security-role ids-administrator;
}
user audit-officer {
class audit-admin;
authentication {
encrypted-password "$1$ABC123"; ## SECRET-DATA
}
}
user crypto-officer {
class crypto-admin;
authentication {
encrypted-password "$1$ABC123."; ## SECRET-DATA
}
}
user security-officer {
class security-admin;
authentication {
encrypted-password "$1$ABC123."; ##SECRET-DATA
}
}
user ids-officer {
class ids-admin;
authentication {
encrypted-password "$1$ABC123/"; ## SECRET-DATA
}
}
}
}

```

After you configure the device, enter **commit** in configuration mode.

## Verification

### IN THIS SECTION

- [Verify the Login Permissions](#) | 48

Confirm that the configuration is working properly.

### Verify the Login Permissions

#### Purpose

Verify the login permissions for the current user.

#### Action

In operational mode, enter the `show cli authorization` command to verify the user's login permissions.

```
user@host> show cli authorization
Current user: 'example' class 'super-user'
Permissions:
  admin      -- Can view user accounts
  admin-control-- Can modify user accounts
  clear      -- Can clear learned network info
  configure  -- Can enter configuration mode
  control    -- Can modify any config
  edit       -- Can edit full files
  field      -- Can use field debug commands
  floppy     -- Can read and write the floppy
  interface  -- Can view interface configuration
  interface-control-- Can modify interface configuration
  network    -- Can access the network
  reset      -- Can reset/restart interfaces and daemons
  routing    -- Can view routing configuration
  routing-control-- Can modify routing configuration
  shell      -- Can start a local shell
  snmp       -- Can view SNMP configuration
  snmp-control-- Can modify SNMP configuration
```

```

system      -- Can view system configuration
system-control-- Can modify system configuration
trace       -- Can view trace file settings
trace-control-- Can modify trace file settings
view        -- Can view current values and statistics
maintenance -- Can become the super-user
firewall    -- Can view firewall configuration
firewall-control-- Can modify firewall configuration
secret      -- Can view secret statements
secret-control-- Can modify secret statements
rollback    -- Can rollback to previous configurations
security    -- Can view security configuration
security-control-- Can modify security configuration
access      -- Can view access configuration
access-control-- Can modify access configuration
view-configuration-- Can view all configuration (not including secrets)
flow-tap    -- Can view flow-tap configuration
flow-tap-control-- Can modify flow-tap configuration
idp-profiler-operation-- Can Profiler data
pgcp-session-mirroring-- Can view pgcp session mirroring configuration
pgcp-session-mirroring-control-- Can modify pgcp session mirroring configuration
tion
storage     -- Can view fibre channel storage protocol configuration
storage-control-- Can modify fibre channel storage protocol configuration
all-control -- Can modify any configuration
Individual command authorization:
Allow regular expression: none
Deny regular expression: none
Allow configuration regular expression: none
Deny configuration regular expression: none

```

This output summarizes the login permissions.

## How to Configure a Local Administrator Account

Superuser privileges give a user permission to use any command on the router and are generally reserved for a select few users such as system administrators. You (the system administrator) need to protect the local administrator account with a password to prevent unauthorized users from gaining access to superuser commands. These superuser commands can be used to alter the system configuration. Users with RADIUS authentication should also configure a local password. If the RADIUS

server does not respond, the login process reverts to local password authentication on the local administrator account.

The following example shows how to configure a password-protected local administration account called `admin` with superuser privileges:

```
[edit]
system {
  login {
    user admin {
      uid 1000;
      class superuser;
      authentication {
        encrypted-password "<PASSWORD>"; ## SECRET-DATA
      }
    }
  }
}
```

## User Access Privileges

### IN THIS SECTION

- [Access Privilege Levels Overview | 51](#)
- [Example: Configure User Permissions with Access Privilege Levels | 56](#)
- [Regular Expressions to Allow and Deny Operational Mode Commands, Configuration Statements, and Hierarchies | 61](#)
- [How to Define Access Privileges with allow-configuration and deny-configuration Statements | 82](#)
- [Example: Use Additive Logic with Regular Expressions to Specify Access Privileges | 85](#)
- [Example: Configure User Permissions with Access Privileges for Operational Mode Commands | 89](#)
- [Example: Configure User Permissions with Access Privileges for Configuration Statements and Hierarchies | 101](#)

You (the system administrator) grant users access or permissions to commands and configuration hierarchy levels and statements. Users can execute only those commands and view and configure only those statements for which they have access privileges. You can also use extended regular expressions to specify which operational mode commands, configuration statements, and hierarchies are allowed or denied for users. This practice prevents unauthorized users from executing sensitive commands or configuring statements that could cause damage to the network.

## Access Privilege Levels Overview

### IN THIS SECTION

- [Login Class Permission Flags | 51](#)
- [Allow and Deny Individual Commands and Statement Hierarchies for Login Classes | 56](#)

Each top-level CLI command and *configuration statement* has an associated access privilege level. Users can execute only those commands and configure and view only those statements for which they have access privileges. One or more permission flags define the access privileges for each login class.

For each login class, you can also explicitly allow or deny the use of operational mode and configuration mode commands and statement hierarchies that would otherwise be allowed or denied by a privilege level specified in the `permissions` statement.

### Login Class Permission Flags

You use permission flags to grant a user access to operational mode commands and configuration hierarchy levels and statements. You configure permission flags for the user's login class at the `[edit system login class]` hierarchy level. When you specify a certain permission flag, the user gains access to the commands and to the configuration hierarchy levels and statements that correspond to that flag. To grant access to all commands and configuration statements, use the `all` permissions flag.

**NOTE:** Each command listed represents that command and all subcommands with that command as a prefix. Each *configuration statement* listed represents the top of the configuration hierarchy to which that flag grants access.

The `permissions` statement specifies one or more of the permission flags listed in [Table 3 on page 52](#). Permission flags are not cumulative. For each class you must list all the permission flags needed,

including `view` to display information and `configure` to enter configuration mode. Two forms of permissions control a user's access to the individual parts of the configuration:

- "Plain" form—Provides read-only capability for that permission type. An example is `interface`.
- `-control` form—Provides read and write capability for that permission type. An example is `interface-control`.

For permission flags that grant access to configuration hierarchy levels and statements, the plain form flags grant read-only privilege to that configuration. For example, the `interface` permission flag grants read-only access to the `[edit interfaces]` hierarchy level. The `-control` form of the flag grants read-write access to that configuration. For example, the `interface-control` flag grants read-write access to the `[edit interfaces]` hierarchy level.

[Table 3 on page 52](#) lists the login class permission flags that you can configure by including the permissions statement at the `[edit system login class class-name]` hierarchy level.

The permission flags grant a specific set of access privileges. Each permission flag is listed with the operational mode or configuration mode commands and configuration hierarchy levels and statements for which that flag grants access.

**Table 3: Login Class Permission Flags**

Permission Flag	Description
<code>access</code>	Can view the access configuration in operational mode or configuration mode.
<code>access-control</code>	Can view and configure access information at the <code>[edit access]</code> hierarchy level.
<code>admin</code>	Can view user account information in operational mode or configuration mode.
<code>admin-control</code>	Can view user account information and configure it at the <code>[edit system]</code> hierarchy level.
<code>all</code>	Can access all operational mode commands and configuration mode commands. Can modify the configuration in all the configuration hierarchy levels.
<code>clear</code>	Can clear (delete) information that the device learns from the network and stores in various network databases (using the <code>clear</code> commands).

Table 3: Login Class Permission Flags *(Continued)*

Permission Flag	Description
<code>configure</code>	Can enter configuration mode (using the <code>configure</code> command) and commit configurations (using the <code>commit</code> command).
<code>control</code>	Can perform all control-level operations—all operations configured with the <code>-control</code> permission flags.
<code>field</code>	Can view field debug commands. Reserved for debugging support.
<code>firewall</code>	Can view the <i>firewall filter</i> configuration in operational mode or configuration mode.
<code>firewall-control</code>	Can view and configure firewall filter information at the <code>[edit firewall]</code> hierarchy level.
<code>floppy</code>	Can read from and write to the removable media.
<code>flow-tap</code>	Can view the flow-tap configuration in operational mode or configuration mode.
<code>flow-tap-control</code>	Can view and configure flow-tap information at the <code>[edit services flow-tap]</code> hierarchy level.
<code>flow-tap-operation</code>	<p>Can make flow-tap requests to the router or switch. For example, a Dynamic Tasking Control Protocol (DTCP) client must have <code>flow-tap-operation</code> permission to authenticate itself to Junos OS as an administrative user.</p> <p><b>NOTE:</b> The <code>flow-tap-operation</code> option is not included in the <code>all-control</code> permissions flag.</p>
<code>idp-profiler-operation</code>	Can view profiler data.
<code>interface</code>	Can view the interface configuration in operational mode and configuration mode.

**Table 3: Login Class Permission Flags (Continued)**

Permission Flag	Description
<code>interface-control</code>	<p>Can view chassis, <i>class of service</i> (CoS), groups, forwarding options, and interfaces configuration information. Can modify the configuration at the following hierarchy levels:</p> <ul style="list-style-type: none"> <li>• [edit chassis]</li> <li>• [edit class-of-service]</li> <li>• [edit groups]</li> <li>• [edit forwarding-options]</li> <li>• [edit interfaces]</li> </ul>
<code>maintenance</code>	Can perform system maintenance, including starting a local shell on the device and becoming the superuser in the shell (using the <code>su root</code> command) and halting and rebooting the device (using the <code>request system</code> commands).
<code>network</code>	Can access the network by using the <code>ping</code> , <code>ssh</code> , <code>telnet</code> , and <code>traceroute</code> commands.
<code>pgcp-session-mirroring</code>	Can view the pgcp session mirroring configuration.
<code>pgcp-session-mirroring-control</code>	Can modify the pgcp session mirroring configuration.
<code>reset</code>	Can restart software processes by using the <code>restart</code> command.
<code>rollback</code>	Can use the <code>rollback</code> command to return to a previously committed configuration.
<code>routing</code>	Can view general routing, routing protocol, and routing policy configuration information in configuration mode and operational mode.
<code>routing-control</code>	Can view and configure general routing at the [edit routing-options] hierarchy level, routing protocols at the [edit protocols] hierarchy level, and routing policy information at the [edit policy-options] hierarchy level.

**Table 3: Login Class Permission Flags (Continued)**

Permission Flag	Description
<code>secret</code>	Can view passwords and other authentication keys in the configuration.
<code>secret-control</code>	Can view and modify passwords and other authentication keys in the configuration.
<code>security</code>	Can view security configuration information in operational mode and configuration mode.
<code>security-control</code>	Can view and configure security information at the [edit security] hierarchy level.
<code>shell</code>	Can start a local shell on the router or switch by using the start shell command.
<code>snmp</code>	Can view Simple Network Management Protocol (SNMP) configuration information in operational mode or configuration mode.
<code>snmp-control</code>	Can view and modify SNMP configuration information at the [edit snmp] hierarchy level.
<code>system</code>	Can view system-level information in operational mode or configuration mode.
<code>system-control</code>	Can view and modify system-level configuration information at the [edit system] hierarchy level.
<code>trace</code>	Can view trace file settings and configure trace file properties.
<code>trace-control</code>	Can modify trace file settings and configure trace file properties.
<code>view</code>	Can use various commands to display current system-wide, routing table, and protocol-specific values and statistics. Cannot view the secret configuration.

Table 3: Login Class Permission Flags *(Continued)*

Permission Flag	Description
<a href="#">view-configuration</a>	<p>Can view all of the configuration excluding secrets, system scripts, and event options.</p> <p><b>NOTE:</b> Only users with the maintenance permission can view commit script, op script, or event script configuration.</p>

### Allow and Deny Individual Commands and Statement Hierarchies for Login Classes

By default, all top-level CLI commands and configuration hierarchy levels have associated access privilege levels. Users can execute only those commands and view and configure only those statements for which they have access privileges. For each login class, you can explicitly allow and deny the use of operational mode and configuration mode commands and statement hierarchies that would otherwise be allowed or denied by a privilege level specified in the `permissions` statement.

Permission flags grant a user access to operational mode and configuration mode commands and to configuration hierarchy levels and statements. By specifying a specific permission flag on the user's login class at the `[edit system login class]` hierarchy level, you grant the user access to the corresponding commands and configuration hierarchy levels and statements. To grant access to all commands and configuration statements, use the `all` permissions flag.

You can explicitly allow or deny the use of commands and statements by configuring the `allow-commands`, `deny-commands`, `allow-configuration`, and `deny-configuration` statements for a login class. In the statements, you use extended regular expressions to define which commands and statements to allow or deny for users assigned to the class.

### Example: Configure User Permissions with Access Privilege Levels

IN THIS SECTION

- [Requirements | 57](#)
- [Overview | 57](#)
- [Configuration | 58](#)
- [Verification | 59](#)

This example configures the user permissions for a login class. You configure user permissions for a login class to prevent users from performing unauthorized network actions. Users can execute only those commands and view and modify only those statements for which they have access privileges. This constraint prevents unauthorized users from executing sensitive commands or configuring statements that could cause damage to the network.

## Requirements

No special configuration beyond device initialization is required before configuring this example.

## Overview

Each top-level CLI command and each configuration statement has an access privilege level associated with it. When you configure a login class, you can explicitly allow or deny the use of operational mode and configuration mode commands and configuration statements. Users can execute only those commands and view and configure only those statements for which they have access privileges.

You define the access privileges for each login class by specifying one or more permission flags in the `permissions` statement. Permission flags grant a user access to commands, statements, and hierarchies. Permission flags are not cumulative. For each login class you must list all the permission flags needed, including `view` to display information and `configure` to enter configuration mode. By specifying a specific permission flag on the user's login class, you grant the user access to the corresponding commands, statements, and hierarchies. To grant access to all commands and configuration statements, use the `all` permissions flag. The permission flags provide read-only ("plain" form) and read and write (form that ends in `-control`) capability for a permission type.

**NOTE:** The `all` login class permission bits take precedence over extended regular expressions when a user issues a `rollback` command with the `rollback` permission flag enabled.

To configure user access privilege levels for a login class, include the `permissions` statement at the `[edit system login class class-name]` hierarchy level, followed by the permission flags. Configure multiple permissions as a space-separated list enclosed in square brackets:

```
[edit system login]
user@host# set class class-name permissions permission-flag
user@host# set class class-name permissions [flag1 flag2 flag3]
```

**TIP:** To view the available permissions, use the CLI's context-sensitive help and type a question mark (?) after the `permissions` statement:

```
[edit system login]
user@host# set class class-name permissions ?
```

## Configuration

### IN THIS SECTION

- [Configure User Permissions with Access Privilege Levels | 58](#)
- [Results | 59](#)

This example configures the `snmp-admin` login class. Users in this login class can configure and view SNMP parameters only.

### Configure User Permissions with Access Privilege Levels

#### Step-by-Step Procedure

To configure access privileges for the login class:

1. Configure the `snmp-admin` login class with the `configure`, `snmp`, and `snmp-control` permission flags.

```
[edit system login]
user@host# set class snmp-admin permissions [configure snmp snmp-control]
```

The configured permission flags provide both read (`snmp`) and read-and-write (`snmp-control`) capability for SNMP, and this is the only allowed access privilege for this login class. All other access privileges are denied.

2. Create the user accounts that are assigned to the `snmp-admin` login class.

```
[edit system login]
user@host# set user snmpuser class snmp-admin authentication plain-text-password
New password:
Retype new password:
```

## Results

In configuration mode, confirm your configuration by entering the `show system login` command. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@host# show system login
class snmp-admin {
  permissions [ configure snmp snmp-control ];
}
user snmpuser {
  class snmp-admin;
  authentication {
    encrypted-password "$ABC123"; ## SECRET-DATA
  }
}
```

After configuring the device, enter `commit` in configuration mode.

## Verification

### IN THIS SECTION

- [Verify SNMP Configuration | 59](#)
- [Verify non-SNMP Configuration | 60](#)

Log in using a username assigned to the new login class, and confirm that the configuration is working properly.

### Verify SNMP Configuration

#### Purpose

Verify that a user in the `snmp-admin` login class can configure SNMP.

## Action

In configuration mode, configure SNMP statements at the `[edit snmp]` hierarchy level.

```
[edit snmp]
user@host# set name device1
user@host# set description switch1
user@host# set location Lab1
user@host# set contact example.com
user@host# commit
```

## Meaning

The user in the `snmp-admin` login class is able to configure SNMP parameters. The user can configure these parameters because the permission flags specified for this class include both `snmp` (read capabilities) and `snmp-control` (read and write capabilities) permission bits.

## Verify non-SNMP Configuration

### Purpose

Verify that a user in the `snmp-admin` login class cannot modify non-SNMP configuration statements.

## Action

In configuration mode, attempt to configure any non-SNMP statement, such as a statement in the `interfaces` hierarchy.

```
[edit]
user@host# edit interfaces
Syntax error, expecting <statement> or <identifier>.
```

## Meaning

The user in the `snmp-admin` login class is not able to configure the `[edit interfaces]` hierarchy because the permission flags specified for this class do not allow it. In this case, the CLI issues an error message.

## Regular Expressions to Allow and Deny Operational Mode Commands, Configuration Statements, and Hierarchies

This topic contains the following sections:

### Understanding the Allow and Deny Statements

Each top-level CLI command and configuration statement hierarchy has an access privilege level associated with it. Each login class can explicitly allow or deny the use of operational mode and configuration mode commands and configuration hierarchies and statements that would otherwise be allowed or denied by a privilege level. Users can execute only those commands and view and configure only those statements for which they have access privileges.

The access privileges for each login class are defined by one or more permission flags specified in the permissions statement at the `[edit system login class class-name]` hierarchy level. In addition, you can allow or deny the use of specific commands and configuration hierarchies by defining extended regular expressions. You can specify the regular expressions by configuring the following statements for a login class:

- `allow-commands` and `deny-commands`—Allow or deny access to operational mode and configuration mode commands.
- `allow-configuration` and `deny-configuration`—Allow or deny access to specific configuration hierarchies.

**NOTE:** These statements perform slower matching, with more flexibility, especially in wildcard matching. However, it can take a very long time to evaluate all of the possible statements if a great number of full-path regular expressions or wildcard expressions are configured, possibly negatively affecting performance.

- `allow-commands-regexps` and `deny-commands-regexps`—Allow or deny access to particular commands using strings of regular expressions.
- `allow-configuration-regexps` and `deny-configuration-regexps`—Allow or deny access to specific configuration hierarchies using strings of regular expressions.

**NOTE:** If your existing configurations use the `allow/deny-commands` or `allow/deny-configuration` statements, using the same configuration options with the `allow/deny-commands-regexps` or `allow/deny-configuration-regexps` statements might not produce the same results. The search and match methods differ in the two forms of these statements.

Explicitly allowing commands and configuration statement hierarchies using the `allow/deny-*` statements adds to the permissions that the `permissions` statement already defines. Likewise, explicitly denying commands and configuration statement hierarchies using the `allow/deny-*` statements removes permissions that the `permissions` statement already defines.

For example, in the following configuration, the `configure` permission enables users in the `login` class to enter configuration mode. Additionally, the `allow-configuration` expression allows users to modify the configuration at the `[edit system services]` hierarchy level and commit it.

```
[edit system login class test]
user@host# set permissions configure allow-configuration "system services"
```

Similarly, in the following configuration, the `login` class user can perform all operations that the `all` permissions flag allows, except that the user cannot view or modify the configuration at the `[edit system services]` hierarchy level:

```
[edit system login class test]
user@host# set permissions all deny-configuration "system services"
```

## Understanding the Allow and Deny Statement Syntax

You can configure an `allow/deny-*` statement only once in each login class. When you configure a statement:

- You can configure as many regular expressions as needed.
- Regular expressions are not case-sensitive

The `allow/deny-commands` statements are mutually exclusive with the `allow/deny-commands-regexps` statements, and the `allow/deny-configuration` statements are mutually exclusive with the `allow/deny-configuration-regexps` statements. For example, you cannot configure both `allow-configuration` and `allow-configuration-regexps` in the same login class.

To define access privileges to commands, specify extended regular expressions using the `allow-commands` and `deny-commands` statements. Enclose each complete standalone expression in parentheses ( ), and use the pipe ( | ) symbol to separate the expressions. Do not use spaces between regular expressions that are connected with the pipe symbol. The complete expression is enclosed in double quotation marks.

```
allow-commands "(cmd1)|(cmd2)|(cmdn)"
allow-configuration "(config1)|(config2)|(confign)"
```

For example:

```
[edit system login class test]
user@host# set allow-commands "(ping .*)|(traceroute .*)|(show .*)|(configure .*)|(edit)|(exit)|
(commit)|(rollback .*)"
```

You must use anchors when specifying complex regular expressions with the `allow-commands` statement. For example:

```
[edit system login]
user@host# set class test allow-commands "(^monitor)|(^ping)|(^show)|(^exit)"
```

To define access privileges to parts of the configuration hierarchy, specify extended regular expressions in the `allow-configuration` and `deny-configuration` statements. Enclose the full paths in parentheses ( ), and use the pipe ( | ) symbol to separate the expressions. Do not use spaces between regular expressions

that are connected with the pipe symbol. The complete expression is enclosed in double quotation marks.

```
allow-configuration "(config1)|(config2)|(confign)"
```

For example:

```
[edit system login class test]
user@host# set deny-configuration "(system login class)|(system services)"
```

When specifying extended regular expressions using the `allow/deny-commands-regexps` or `allow/deny-configuration-regexps` statements, enclose each expression within quotation marks (" "), and separate the expressions using a space. Enclose multiple expressions in square brackets [ ]. For example:

```
[edit system login class test]
user@host# set allow-configuration-regexps ["interfaces .* description .*" "interfaces .*
unit .* description .*" "interfaces .* unit .* family inet address .*" "interfaces.* disable"]
```

Modifiers such as `set`, `log`, and `count` are not supported within the regular expression string to be matched. If you use a modifier, then nothing is matched.

Correct configuration:

```
[edit system login class test]
user@host# set deny-commands protocols
```

Incorrect configuration:

```
[edit system login class test]
user@host# set deny-commands "set protocols"
```

## Understanding the Allow and Deny Statement Precedence and Matching

By default, the `allow-commands` and `allow-configuration` regular expressions take precedence over `deny-commands` and `deny-configuration` expressions. Thus, if you configure the same command for both the `allow-commands` and `deny-commands` statements, then the `allow` operation takes precedence over the `deny` operation. Similarly, if you configure the same statement for both the `allow-configuration` and `deny-configuration` statements, then the `allow` operation takes precedence over the `deny` operation.

For instance, the following configuration allows a user in the test login class to install software using the `request system software add` command, even though the `deny-commands` statement includes the same command:

```
[edit system login class test]
user@host# set allow-commands "request system software add"
user@host# set deny-commands "request system software add"
```

Similarly, the following configuration allows a user in the test login class test to view and modify the `[edit system services]` configuration hierarchy, even though the `deny-configuration` statement includes the same hierarchy:

```
[edit system login class test]
user@host# set allow-configuration "system services"
user@host# set deny-configuration "system services"
```

If the `allow-commands` and `deny-commands` statements have two different variants of a command, the longest match is always executed. The following configuration allows a user in the test login class to execute the `commit synchronize` command but not the `commit` command. This is because `commit synchronize` is the longest match between `commit` and `commit synchronize`, and it is specified for `allow-commands`.

```
[edit system login class test]
user@host# set allow-commands "commit synchronize"
user@host# set deny-commands commit
```

The following configuration allows a user in the test login class to execute the `commit` command but not the `commit synchronize` command. This is because `commit synchronize` is the longest match between `commit` and `commit synchronize`, and it is specified for `deny-commands`.

```
[edit system login class test]
user@host# set allow-commands commit
user@host# set deny-commands "commit synchronize"
```

In contrast to the other statements, the default behavior for the `*-regexps` statements is that the `deny-commands-regexps` and `deny-configuration-regexps` regular expressions take precedence over `allow-commands-regexps` and `allow-configuration-regexps` expressions. You can configure the `regex-additive-logic` statement at the `[edit system]` hierarchy level to force the `allow-configuration-regexps` regular expressions to take precedence over the `deny-configuration-regexps` statements. Configuring the statement enables you to

deny configuration hierarchies at a higher level and then only allow the user access to specific sub-hierarchies.

## Understanding the Allow and Deny Statement Rules

The `allow/deny-commands`, `allow/deny-configuration`, `allow/deny-commands-regexps`, and `allow/deny-configuration-regexps` statements take precedence over the login class permissions. When you configure these statements, the following rules apply:

- Regular expressions for `allow-commands` and `deny-commands` statements can also include the `commit`, `load`, `rollback`, `save`, `status`, and `update` commands.
- The all login class permission bits take precedence over extended regular expressions when a user issues the `rollback` command with the `rollback` permission flag enabled.
- Users cannot issue the `load` override command when specifying an extended regular expression. Users can only issue the `merge`, `replace`, and `patch` configuration commands.
- You can use the `*` wildcard character when denoting regular expressions. However, you must use it as part of a regular expression. You cannot use `[ * ]` or `[ .* ]` as the only expression. Additionally, you cannot configure the `allow-configuration` statement with an expression such as `(interfaces (description (|.*)`), because this evaluates to `allow-configuration .*`.

## Understanding Differences for the \*-regexps Statements

This section outlines the differences between the `allow/deny-configuration` statements and the `allow/deny-configuration-regexps` statements.

The `allow/deny-configuration-regexps` statements split up the regular expression into tokens and match each piece against each part of the specified configuration's full path, whereas the `allow/deny-configuration` statements match against the full string. For `allow/deny-configuration-regexps` statements, you configure a set of strings in which each string is a regular expression, with spaces between the terms of the string. This syntax provides very fast matching but offers less flexibility. For specifying wildcard expressions, you must set up wildcards for each token of the space-delimited string you want to match, which makes it more difficult to use wildcard expressions for these statements.

For example:

- **Regular expression matching one token using `allow-configuration-regexps`**

This example shows that `options` is the only matched expression against the first token of the statement.

```
[edit system]
login {
  class test {
    permissions configure;
    allow-configuration-regexps .*options;
  }
}
```

The preceding configuration matches the following statements:

- set policy-**options** condition *condition* dynamic-db
- set routing-**options** static route *static-route* next-hop *next-hop*
- set event-**options** generate-event *event* time-interval *seconds*

The preceding configuration does not match the following statements:

- system host-name host-**options**
- interfaces *interface-name* description **options**
- **Regular expression matching three tokens using allow-configuration-regexps**

This example shows that `ssh` is the only matched expression against the third token of the statement.

```
[edit system]
login {
  class test {
    permissions configure;
    allow-configuration-regexps ".* .* .*ssh";
  }
}
```

In the preceding example, the three tokens include `.*`, `.*`, and `.*ssh`, respectively.

The preceding configuration matches the following statements:

- system host-name hostname-**ssh**
- system services **ssh**
- system services outbound-**ssh**

The preceding configuration does not match the following statement:

- interfaces *interface-name* description **ssh**

It is easier to use the deny-configuration statement to restrict configuration access than to use the deny-configuration-regexps statement. [Table 4 on page 68](#) illustrates the use of both the deny-configuration and deny-configuration-regexps statements in different configurations to achieve the same result of restricting access to a particular configuration.

**Table 4: Restricting Configuration Access Using deny-configuration and deny-configuration-regexps Statements**

Configuration Denied	Using: deny-configuration	Using: deny-configuration-regexps	Result
xnm-ssl	<pre>[edit system] login {   class test {     permissions configure;     allow-configuration .*;     deny-configuration .*xnm-ssl;   } }</pre>	<pre>[edit system] login {   class test {     permissions configure;     allow-configuration .*;     deny-configuration-regexps     ".* .* .*-ssl";   } }</pre>	<p>The following configuration statement is denied:</p> <ul style="list-style-type: none"><li>• system services xnm-ssl</li></ul>

ssh	<pre>[edit system] login {     class test {         permissions configure;         allow-configuration .*;         deny-configuration         ".*ssh";     } }</pre>	<pre>[edit system] login {     class test {         permissions configure;         allow-configuration .*;         deny-configuration-regexps         ".*ssh";         deny-configuration-regexps         ".* .*ssh";         deny-configuration-regexps         ".* .* .*ssh";     } }</pre>	<p>The following configuration statements are denied:</p> <ul style="list-style-type: none"> <li>• system host-name hostname-ssh</li> <li>• system services ssh</li> <li>• system services outbound-ssh</li> <li>• security ssh-known-host</li> </ul>
-----	--	---	---

Although the allow/deny-configuration statements are also useful when you want a simple configuration, the allow/deny-configuration-regexps statements provide better performance and overcome the ambiguity that existed when combining expressions in the allow/deny-configuration statements.

## Using Regular Expressions on Remote Authorization Servers

You can use extended regular expressions to specify which operational mode and configuration mode commands and configuration statements and hierarchies are allowed or denied for certain users. You specify these regular expressions locally in the allow/deny-commands, allow/deny-configuration, allow/deny-commands-regexps and allow/deny-configuration-regexps statements at the [edit system login class *class-name*] hierarchy level. You specify these regular expressions remotely by specifying Juniper Networks vendor-specific TACACS+ or RADIUS attributes in your authorization server's configuration. When you configure authorization parameters both locally and remotely, the device merges the regular expressions received during TACACS+ or RADIUS authorization with any regular expressions defined on the local device.

**NOTE:** Starting in Junos OS Release 18.1, the allow-commands-regexps and deny-commands-regexps statements are supported for TACACS+ authorization.

When specifying multiple regular expressions in a local configuration using the allow-commands, deny-commands, allow-configuration, or deny-configuration statements, you configure regular expressions within

parentheses and separate them using the pipe symbol. You enclose the complete expression in double quotation marks. For example, you can specify multiple `allow-commands` parameters with the following syntax:

```
allow-commands "(cmd1)|(cmd2)|(cmdn)"
```

The RADIUS authorization server uses the following attributes and syntax:

```
Juniper-Allow-Commands += "(cmd1)|(cmd2)|(cmd3)",
Juniper-Deny-Commands += "(cmd1)|(cmd2)",
Juniper-Allow-Configuration += "(config1)|(config2)",
Juniper-Deny-Configuration += "(config1)|(config2)",
```

The TACACS+ authorization server uses the following attributes and syntax:

```
allow-commands = "(cmd1)|(cmd2)|(cmdn)"
deny-commands = "(cmd1)|(cmd2)|(cmdn)"
allow-configuration = "(config1)|(config2)|(confign)"
deny-configuration = "(config1)|(config2)|(confign)"
```

When specifying multiple regular expressions in a local configuration using the `allow-commands-regexps`, `deny-commands-regexps`, `allow-configuration-regexps`, or `deny-configuration-regexps` statements, you configure regular expressions within double quotation marks and separate them using the space operator. You enclose the complete expression in square brackets. For example, you can specify multiple `allow-commands` parameters with the following syntax:

```
allow-commands-regexps [ "cmd1" "cmd2" "cmdn" ]
```

The RADIUS authorization server uses the following attributes and syntax:

```
Juniper-Allow-Configuration-Regexps += "(config1)|(config2)|(confign)",
Juniper-Deny-Configuration-Regexps += "(config1)|(config2)|(confign)",
```

The TACACS+ authorization server uses the following attributes and syntax:

```
allow-commands-regexps = "(cmd1)|(cmd2)|(cmdn)"
deny-commands-regexps = "(cmd1)|(cmd2)|(cmdn)"
```

```
allow-configuration-regexps = "(config1)|(config2)|(config)"  
deny-configuration-regexps = "(config1)|(config2)|(config)"
```

RADIUS and TACACS+ servers also support a simplified syntax where you specify each individual expression on a separate line. For example, the RADIUS server simplified syntax is:

```
Juniper-Allow-Commands += "cmd1",  
Juniper-Allow-Commands += "cmd2",  
Juniper-Allow-Commands += "cmdn",
```

Similarly, the TACACS+ server simplified syntax is:

```
allow-commands-regexps1 = "cmd1"  
allow-commands-regexps2 = "cmd2"  
allow-commands-regexpsn = "cmdn"
```

[Table 5 on page 72](#) differentiates the local authorization configuration and the TACACS+ server authorization configuration using regular expressions.

Table 5: Sample Local and Remote Authorization Configuration Using Regular Expressions

Local Configuration	Remote TACACS+ Configuration
<pre>login {   class local {     permissions configure;     allow-commands "(ping .*)  (traceroute .*) (show .*)  (configure .*) (edit) (exit) (commit)  (rollback .*)";     deny-commands .*;     allow-configuration "(interfaces .* unit 0 family ethernet-switching vlan mem.* .*)  (interfaces .* native.* .*)  (interfaces .* unit 0 family ethernet- switching interface-mo.* .*)  (interfaces .* unit .*)  (interfaces .* disable)  (interfaces .* description .*)  (vlans .* vlan-.* .*)"     deny-configuration .*;   } }</pre>	<pre>user = remote {   login = username   service = junos-exec {     allow-commands1 = "ping .*"     allow-commands2 = "traceroute .*"     allow-commands3 = "show .*"     allow-commands4 = "configure"     allow-commands5 = "edit"     allow-commands6 = "exit"     allow-commands7 = "commit"     <b>allow-commands8 = ".*xml-mode"</b>     <b>allow-commands9 = ".*netconf.*"</b>     <b>allow-commands10 = ".*need-trailer"</b>     allow-commands11 = "rollback.*"     allow-commands12 = "junoscript"     deny-commands1 = ".*"     allow-configuration1 = "interfaces .* unit 0 family ethernet- switching vlan mem.* .*"     allow-configuration2 = "interfaces .* native.* .*"     allow-configuration3 = "interfaces .* unit 0 family ethernet- switching interface-mo.* .*"     allow-configuration4 = "interfaces .* unit .*"     allow-configuration5 = "interfaces .* disable"     allow-configuration6 = "interfaces .* description .*"     allow-configuration7 = "interfaces .*"     allow-configuration8 = "vlans .* vlan-.* .*"     deny-configuration1 = ".*"     local-user-name = <i>local-username</i>     user-permissions = "configure"   } }</pre>

**NOTE:**

- You need to explicitly allow access to the NETCONF mode, either locally or remotely, by issuing the following three commands: `xml-mode`, `netconf`, and `need-trailer`.

- When you use the `deny-configuration = ".*"` statement, you must allow all the desired configurations using the `allow-configuration` statement. However, this configuration can affect the allowed regular expressions buffer limit for the `allow-configuration` statement. If this limit is exceeded, the allowed configuration might not work.

## Specify Regular Expressions

**WARNING:** When you specify regular expressions for commands and configuration statements, pay close attention to the following examples. A regular expression with invalid syntax might not produce the desired results, even if the configuration is committed without any error.

You should specify regular expressions for commands and configuration statements in the same manner as executing the complete command or statement. [Table 6 on page 74](#) lists the regular expressions for configuring access privileges for the `[edit interfaces]` and `[edit vlans]` statement hierarchies.

Table 6: Specify Regular Expressions

Statement	Regular Expression	Configuration Notes
<p><b>[edit interfaces]</b></p> <p>The set command for interfaces is executed as follows:</p> <p>[edit]  user@host# <b>set interfaces</b>  <i>interface-name</i> unit  <i>interface-unit-number</i></p>	<p>The set interfaces statement is incomplete by itself and requires the unit option to execute the statement.</p> <p>As a result, the regular expression required for denying the set interfaces configuration must specify the entire executable string with the .* operator in place of statement variables:</p> <p>[edit system login class <i>class-name</i>]  user@host# <b>set permissions</b>  <b>configure</b>  user@host# <b>set deny-configuration</b>  <b>"interfaces .* unit ."</b></p>	<ul style="list-style-type: none"> <li>The .* operator denotes everything from the specified point onward for that particular command or statement. In this example, it denotes any interface name with any unit value.</li> <li>Specifying only the deny-configuration "interfaces .*" statement is incorrect and does not deny access to the interfaces configuration for the specified login class.</li> <li>Other valid options can be included in the regular expression. For example:</li> </ul> <p>[edit system login class <i>class-name</i>]  user@host# <b>set permissions configure</b>  user@host# <b>set deny-configuration</b>  <b>"interfaces .* description ."</b></p> <p>[edit system login class <i>class-name</i>]  user@host# <b>set permissions configure</b>  user@host# <b>set allow-configuration-regexps [ "interfaces .*</b>  <b>description ."</b> "interfaces .*  <b>unit .* description ."</b>  <b>"interfaces .* unit .* family inet</b>  <b>address ."</b> "interfaces.* disable" ]</p> <p>[edit system login class <i>class-name</i>]  user@host# <b>set permissions configure</b>  user@host# <b>set allow-configuration</b>  <b>"interfaces .* unit 0 family</b>  <b>ethernet-switching vlan mem.* ."</b></p> <p>Note: The mem.* regular expression in this example is used when multiple</p>

Table 6: Specify Regular Expressions (*Continued*)

Statement	Regular Expression	Configuration Notes
		<p>strings starting with the <i>mem</i> keyword are expected to be included in the specified regular expression.</p> <p>When only one member string is expected to be included, the member <i>.*</i> regular expression is used.</p>
<p><b>[edit vlans]</b></p> <p>The set command for VLANs is executed as follows:</p> <p>[edit]  user@host# <b>set vlans <i>vlan-name</i> <i>vlan-id</i> <i>vlan-id</i></b></p>	<p>Here, the set vlans statement is incomplete by itself, and requires the <i>vlan-id</i> option to execute the statement.</p> <p>As a result, the regular expression required for allowing the set vlans configuration must specify the entire executable string with the <i>.*</i> operator in place of statement variables:</p> <pre>[edit system login class <i>class-name</i>] user@host# set permissions configure user@host# set allow-configuration "vlans .* <i>vlan-id</i> .*"</pre>	<ul style="list-style-type: none"> <li>The <i>.*</i> operator denotes everything from the specified point onward for that particular command or statement. In this example, it denotes any VLAN name with any VLAN ID.</li> <li>Other valid options under the [edit vlans] statement hierarchy can be included in the regular expression. For example: <pre>[edit system login class <i>class-name</i>] user@host# set permissions configure user@host# set allow-configuration- regexps [ "vlans .* <i>vlan-id</i> .*" "vlans .* <i>vlan-id</i> .* description .*" "vlans .* <i>vlan-id</i> .* filter .*" ]</pre> </li> </ul>

## Regular Expressions Operators

Table 7 on page 76 lists common regular expression operators that you can use for allowing or denying operational and configuration modes.

Command regular expressions implement the extended (modern) regular expressions, as defined in POSIX 1003.2.

Table 7: Common Regular Expression Operators

Operator	Match	Example
	One of two or more terms separated by the pipe. Each term must be a complete standalone expression enclosed in parentheses ( ), with no spaces between the pipe and the adjacent parentheses.	<pre>[edit system login class test] user@host# set permissions configure user@host# set allow-commands "(ping) (traceroute) (show system alarms) (show system software)" user@host# set deny-configuration "(access) (access-profile) (accounting-options) (applications) (apply-groups) (bridge-domains) (chassis) (class-of-service)"</pre> <p>With the preceding configuration, the users assigned to the test login class have operational mode access restricted to only the commands specified in the allow-commands statement. They also have access to configuration mode, excluding the hierarchy levels specified in the deny-configuration statement.</p>
^	At the beginning of an expression, used to denote where the command begins, where there might be some ambiguity.	<pre>[edit system login class test] user@host# set permissions interface user@host# set permissions interface-control user@host# set allow-commands " (^show) (log interfaces policer)) (^monitor)"</pre> <p>With the preceding configuration, the users assigned to the test login class have access to viewing and configuring the interface configuration. The allow-commands statement grants access to commands that begin with the show and monitor keywords.</p> <p>For the first filter, the commands specified include the show log, show interfaces, and show policer commands. The second filter specifies all commands starting with the monitor keyword, such as the monitor interfaces or the monitor traffic commands.</p>

Table 7: Common Regular Expression Operators *(Continued)*

Operator	Match	Example
\$	Character at the end of a command. Used to denote a command that must be matched exactly up to that point.	<pre>[edit system login class test] user@host# set permissions interface user@host# set allow-commands "(show interfaces\$)"</pre> <p>With the preceding configuration, the users assigned to the test login class can view the interfaces configuration in configuration mode. The users can also view the interface configuration with the show configuration operational mode command. However, the regular expression specified in the allow-commands statement restricts the users to execute only the show interfaces command and denies access to the command extensions such as show interfaces detail or show interfaces extensive.</p>
[]	Range of letters or digits. To separate the start and end of a range, use a hyphen ( - ).	<pre>[edit system login class test] user@host# set permissions clear user@host# set permissions configure user@host# set permissions network user@host# set permissions trace user@host# set permissions view user@host# set allow-configuration-regexps [ "interfaces [gx]e-.* unit [0-9]* description .*" ]</pre> <p>With the preceding configuration, the users assigned to the test login class have operator-level user permissions. These users also have access to configure interfaces within the specified range of interface name and unit number (0 through 9).</p>

Table 7: Common Regular Expression Operators *(Continued)*

Operator	Match	Example
()	A group of commands indicating a complete, standalone expression to be evaluated. The result is then evaluated as part of the overall expression. Parentheses must be used in conjunction with pipe operators, as explained.	<pre>[edit system login class test] user@host# set permissions all user@host# set allow-commands "(clear) (configure)" user@host# deny-commands "(mtrace) (start) (delete)"</pre> <p>With the above configuration, users assigned to the test login class have superuser-level permissions and have access to the commands specified in the allow-commands statement.</p>
*	Zero or more terms.	<pre>[edit system login class test] user@host# set permissions configure user@host# set deny-configuration "(system login class m*)"</pre> <p>With the above configuration, users assigned to the test login class whose login username begins with <code>m</code> are denied configuration access.</p>
+	One or more terms.	<pre>[edit system login class test] user@host# set permissions configure user@host# set deny-configuration "(system login class m+)"</pre> <p>With the above configuration, users assigned to the test login class whose login username begins with <code>m</code> are denied configuration access.</p>

Table 7: Common Regular Expression Operators (*Continued*)

Operator	Match	Example
.	Any character except for a space " ".	<pre>[edit system login class test] user@host# set permissions configure user@host# set deny-configuration "(system login class m.)"</pre> <p>With the above configuration, users assigned to the test login class whose login username begins with <code>m</code> are denied configuration access.</p>
.*	Everything from the specified point onward.	<pre>[edit system login class test] user@host# set permissions configure user@host# set deny-configuration "(system login class m .*)"</pre> <p>With the above configuration, users assigned to the test login class whose login username begins with <code>m</code> are denied configuration access.</p> <p>Similarly, the deny-configuration "protocols .*" statement denies all configuration access under the [edit protocols] hierarchy level.</p> <p><b>NOTE:</b></p> <ul style="list-style-type: none"> <li>• The *, +, and . operations can be achieved by using .*.</li> <li>• The deny-commands .* and deny-configuration .* statements deny access to all operational mode commands and configuration hierarchies, respectively.</li> </ul>

**NOTE:** The ! regular expression operator is not supported.

## Regular Expression Examples

Table 8 on page 80 lists the regular expressions used to allow configuration options under two configuration hierarchies—[edit system ntp server] and [edit protocols rip]—as an example for specifying regular expressions.

**NOTE:** Table 8 on page 80 does not provide a comprehensive list of all regular expressions and keywords for all configuration statements and hierarchies. The regular expressions listed in the

table are validated only for the [edit system ntp server] and [edit protocols rip] statement hierarchies.

**Table 8: Regular Expressions Examples**

Statement Hierarchy	Regular Expressions	Allowed Configuration	Denied Configuration
[edit system ntp server]			
key <i>key-number</i>	<pre>[edit system login class test] set permissions configure set allow-configuration-regexps [ "system ntp server .*" "system ntp server .* key .*" ] set deny-configuration-regexps [ "system ntp server .* version .*" "system ntp server .* prefer" ]</pre>	<ul style="list-style-type: none"> <li>server IP</li> <li>server IP and key</li> </ul>	<ul style="list-style-type: none"> <li>version</li> <li>prefer</li> </ul>
version <i>version-number</i>	<pre>[edit system login class test] set permissions configure set allow-configuration-regexps [ "system ntp server .*" "system ntp server .* version .*" ] set deny-configuration-regexps [ "system ntp server .* key .*" "system ntp server .* prefer" ]</pre>	<ul style="list-style-type: none"> <li>server IP</li> <li>server IP and version</li> </ul>	<ul style="list-style-type: none"> <li>key</li> <li>prefer</li> </ul>
prefer	<pre>[edit system login class test] set permissions configure set allow-configuration-regexps [ "system ntp server .*" "system ntp server .* prefer" ]; set deny-configuration-regexps [ "system ntp server .* key .*" "system ntp server .* version .*" ]</pre>	<ul style="list-style-type: none"> <li>server IP</li> <li>server IP and prefer</li> </ul>	<ul style="list-style-type: none"> <li>key</li> <li>version</li> </ul>

Table 8: Regular Expressions Examples (*Continued*)

Statement Hierarchy	Regular Expressions	Allowed Configuration	Denied Configuration
[edit protocols rip]			
message-size <i>message-size</i>	<pre>[edit system login class test] set permissions configure set allow-configuration-regexps "protocols rip message-size .*" set deny-configuration-regexps [ "protocols rip metric-in .*" "protocols rip route-timeout .*" "protocols rip update-interval .*" ]</pre>	<ul style="list-style-type: none"> <li>• message-size</li> </ul>	<ul style="list-style-type: none"> <li>• metric-in</li> <li>• route-timeout</li> <li>• update-interval</li> </ul>
metric-in <i>metric-in</i>	<pre>[edit system login class test] set permissions configure set allow-configuration-regexps "protocols rip metric-in .*" set deny-configuration-regexps [ "protocols rip message-size .*" "protocols rip route-timeout .*" "protocols rip update-interval .*" ]</pre>	<ul style="list-style-type: none"> <li>• metric-in</li> </ul>	<ul style="list-style-type: none"> <li>• message-size</li> <li>• route-timeout</li> <li>• update-interval</li> </ul>
route-timeout <i>route-timeout</i>	<pre>[edit system login class test] set permissions configure set allow-configuration-regexps "protocols rip route-timeout .*" set deny-configuration-regexps [ "protocols rip metric-in .*" "protocols rip message-size .*" "protocols rip update-interval .*" ]</pre>	<ul style="list-style-type: none"> <li>• route-timeout</li> </ul>	<ul style="list-style-type: none"> <li>• message-size</li> <li>• metric-in</li> <li>• update-interval</li> </ul>

Table 8: Regular Expressions Examples (*Continued*)

Statement Hierarchy	Regular Expressions	Allowed Configuration	Denied Configuration
update-interval <i>update-interval</i>	<pre>[edit system login class test] set permissions configure set allow-configuration-regexps "protocols rip update-interval .*" set deny-configuration-regexps [ "protocols rip metric-in .*" "protocols rip route-timeout .*" "protocols rip message-size .*" ]</pre>	<ul style="list-style-type: none"> <li>• update-interval</li> </ul>	<ul style="list-style-type: none"> <li>• message-size</li> <li>• metric-in</li> <li>• route-timeout</li> </ul>

## How to Define Access Privileges with allow-configuration and deny-configuration Statements

You can define access privileges for configuration statement hierarchies by using a combination of the following types of statements:

- permission flags
- allow-configuration and deny-configuration statements

The permission flags define the larger boundaries of what a person or login class can access and control. The allow-configuration and deny-configuration statements contain one or more regular expressions that allow or deny specific configuration hierarchies and statements. The allow-configuration and deny-configuration statements take precedence over permission flags and give the administrator finer control over exactly what hierarchies and statements the user can view and configure.

This topic explains how to define access privileges using allow-configuration and deny-configuration statements by showing examples of login class configurations that use these statements. Examples 1 through 3 create login classes that allow users access to all commands and statements except those defined in the deny-configuration statement.

Notice that *permission bit* and *permission flag* are used interchangeably.

### Example 1

To create a login class that allows the user to execute all commands and configure everything except telnet parameters:

1. Set the user's login class permissions to all.

```
[edit system login]
user@host# set class all-except-telnet permissions all
```

2. Include the following deny-configuration statement.

```
[edit system login class all-except-telnet]
user@host# set deny-configuration "system services telnet"
```

### Example 2

To create a login class that allows the user to execute all commands and configure everything except statements within any login class whose name begins with "m":

1. Set the user's login class permissions to all.

```
[edit system login]
user@host# set class all-except-login-class-m permissions all
```

2. Include the following deny-configuration statement.

```
[edit system login class all-except-login-class-m]
user@host# set deny-configuration "system login class m.*"
```

### Example 3

To create a login class that allows the user to execute all commands and configure everything except the [edit system login class] or [edit system services] hierarchy levels:

1. Set the user's login class permissions to all.

```
[edit system login]
user@host# set class all-except-login-class-or-system-services permissions all
```

2. Include the following deny-configuration statement:

```
[edit system login class all-except-login-class-or-system-services]
user@host# set deny-configuration "(system login class) | (system services)"
```

The following examples show how to use the allow-configuration and deny-configuration statements to determine permissions inverse to each other for the [edit system services] hierarchy level.

#### Example 4

To create a login class that allows the user to have full configuration privileges only at the [edit system services] hierarchy level:

1. Set the user's login class permissions to configure.

```
[edit system login]
user@host# set class configure-only-system-services permissions configure
```

2. Include the following allow-configuration statement:

```
[edit system login class configure-only-system-services]
user@host# set allow-configuration "system services"
```

#### Example 5

To create a login class that allows the user full permissions for all commands and all configuration hierarchies except the [edit system services] hierarchy level:

1. Set the user's login class permissions to all.

```
[edit system login]
user@host# set class all-except-system-services permissions all
```

2. Include the following deny-configuration statement.

```
[edit system login class all-except-system-services]
user@host# set deny-configuration "system services"
```

## Example: Use Additive Logic with Regular Expressions to Specify Access Privileges

### IN THIS SECTION

- [Requirements | 85](#)
- [Overview | 85](#)
- [Configuration | 86](#)
- [Examples | 87](#)

This example shows how to use additive logic when using regular expressions to set up configuration access privileges.

### Requirements

This example uses a device running Junos OS Release 16.1 or later.

### Overview

You can define regular expressions to control who can make changes to the configuration and what they can change. These regular expressions indicate specific configuration hierarchies that users in a login class are permitted to access. For example, you can define regular expressions that allow users to modify a group of routing instances and define regular expressions that prevent the users from making changes to any other routing instances or to other configuration levels. You define the regular expressions by configuring the `allow-configuration-regexps` and `deny-configuration-regexps` statements for a login class.

By default, the `deny-configuration-regexps` statement takes precedence over the `allow-configuration-regexps` statement. If a configuration hierarchy appears in a `deny-configuration-regexps` statement for a login class, it is not visible to the users in that class, regardless of the contents of the `allow-configuration-regexps` statement. If a configuration hierarchy does not appear in a `deny-configuration-regexps` statement, it is visible to the users in that class if it appears in an `allow-configuration-regexps` statement.

You can change this default behavior by enabling additive logic for the `*-configuration-regexps` statements. When you enable additive logic, the `allow-configuration-regexps` statement takes precedence over the `deny-configuration-regexps` statement.

Thus, if the `deny-configuration-regexps` statement denies access to all configuration hierarchies at a given level (protocols .\*) but the `allow-configuration-regexps` statement allows access to one sub-hierarchy (protocols bgp .\*), then by default the device denies access to the hierarchies for users in that login class

because the `deny-configuration-regexps` statement takes precedence. However, if you enable additive logic, the device allows access to the specified sub-hierarchy for users in that login class because the `allow-configuration-regexps` takes precedence in this case.

## Configuration

### IN THIS SECTION

- [Step-by-Step Procedure | 86](#)

### Step-by-Step Procedure

To enable additive logic to explicitly allow users in a given login class access to one or more individual configuration hierarchies:

1. Include the `deny-configuration-regexps` statement, and explicitly deny access to configuration hierarchies.

```
[edit system login class class-name]
user@host# set deny-configuration-regexps ["regular expression 1" "regular expression 2"
"regular expression 3"]
```

For example:

```
[edit system login class class-name]
user@host# set deny-configuration-regexps "protocols .*"

```

2. Include the `allow-configuration-regexps` statement, and define regular expressions for the specific hierarchies to allow.

```
[edit system login class class-name]
user@host# set allow-configuration-regexps ["regular expression 1" "regular expression 2"
"regular expression 3"]
```

For example:

```
[edit system login class class-name]
user@host# set allow-configuration-regexps ["protocols bgp .*" "protocols ospf .*"]
```

3. Enable additive logic for the allow-configuration-regexps and deny-configuration-regexps regular expressions.

```
[edit system]
user@host# set regex-additive-logic
```

4. Assign the login class to one or more users.

```
[edit system login]
user@host# set user username class class-name
```

5. Commit your changes.

Users assigned to this login class have access to the configuration hierarchies included in the allow-configuration-regexps statement but do not have access to the other hierarchies specified in the deny-configuration-regexps statement.

**NOTE:** When you configure the regex-additive-logic statement, the behavior change applies to all allow-configuration-regexps and deny-configuration-regexps statements present in all login classes. If you enable additive logic, you should evaluate existing statements for any impact, and update the regular expressions in those statements as appropriate.

## Examples

### IN THIS SECTION

- [Use Regular Expressions with Additive Logic | 88](#)

## Use Regular Expressions with Additive Logic

### Purpose

This section provides examples of regular expressions that use additive logic to give you ideas for creating configurations appropriate for your system.

### Allow Specific Routing Instances

The following example login class includes a regular expression that allows configuration of routing instances whose names start with CUST-VRF-; for example, CUST-VRF-1, CUST-VRF-25, CUST-VRF-100, and so on. The example also includes a regular expression that prevents the configuration of any routing instances.

```
[edit system login class class-name]
user@host# set permissions [configure routing-control view view-configuration]
user@host# set deny-configuration-regexps "routing-instances .*"
user@host# set allow-configuration-regexps "routing-instances CUST-VRF-.* ."
```

By default, the deny-configuration-regexps statement takes precedence, and the previous configuration prevents the users in the login class from configuring any routing instances, regardless of the name.

However if you configure the following statement, the allow-configuration-regexps statement takes precedence. Thus, the users can configure routing instances whose names start with CUST-VRF-, but the users cannot configure any other routing instances.

```
[edit system]
user@host# set regex-additive-logic
```

### Allow BGP Peer Configuration Only

The following example login class includes regular expressions that prevent configuration at the [edit protocols] hierarchy level but allow configuration of BGP peers:

```
[edit system login class class-name]
user@host# set permissions [configure routing-control view view-configuration]
user@host# set deny-configuration-regexps "protocols .*"
user@host# set allow-configuration-regexps "protocols bgp group *"
```

By default, the previous configuration prevents the users in the login class from making changes to any hierarchies under [edit protocols].

However, if you configure the following statement, the users in the login class can make changes to BGP peers, but the users cannot configure other protocols or other BGP statements outside of the allowed hierarchy level.

```
[edit system]
user@host# set regex-additive-logic
```

## Verification

To verify that you have set the access privileges correctly:

1. Configure a login class and commit the changes.
2. Assign the login class to a *username*.
3. Log in as the *username* assigned with the new login class.
4. Attempt to configure the hierarchy levels that are allowed.
  - You should be able to configure statements in hierarchy levels that have been allowed.
  - Hierarchy levels that are denied should not be visible.
  - Any allowed or denied expressions should take precedence over any permissions granted with the permissions statement.

## Example: Configure User Permissions with Access Privileges for Operational Mode Commands

### IN THIS SECTION

- [Requirements | 90](#)
- [Overview and Topology | 90](#)
- [Configuration | 91](#)
- [Verification | 97](#)

This example shows how to configure custom login classes and assign access privileges for operational mode commands. Users in the login class can execute only the commands for which they have access.

This prevents unauthorized users from executing sensitive commands that could cause damage to the network.

## Requirements

This example uses the following hardware and software components:

- One Juniper Networks device
- One TACACS+ (or RADIUS) server

Before you begin, establish a TCP connection between the device and the TACACS+ server. In the case of the RADIUS server, establish a UDP connection between the device and the RADIUS server.

## Overview and Topology

Figure 1 on page 90 illustrates a simple topology, where Router R1 is a Juniper Networks device and has a TCP connection established with a TACACS+ server.

**Figure 1: Topology**

This example configures R1 with three customized login classes: Class1, Class2, and Class3. Each class defines access privileges for the user by configuring the `permissions` statement and by defining extended regular expressions using the `allow-commands` and `deny-commands` statements.

The purpose of each login class is as follows:

- **Class1**—Defines access privileges for the user with the `allow-commands` statement only. This login class provides operator-level user permissions and authorization for rebooting the device.
- **Class2**—Defines access privileges for the user with the `deny-commands` statement only. This login class provides operator-level user permissions and denies access to set commands.
- **Class3**—Defines access privileges for the user with both the `allow-commands` and `deny-commands` statements. This login class provides superuser-level user permissions and authorization for accessing interfaces and viewing device information. It also denies access to the `edit` and `configure` commands.

Router R1 has three different users, User1, User2, and User3 assigned to the Class1, Class2, and Class3 login classes, respectively .

## Configuration

### IN THIS SECTION

- [CLI Quick Configuration | 91](#)
- [Configure Authentication Parameters for Router R1 | 92](#)
- [Configure Access Privileges with the allow-commands Statement \(Class1\) | 93](#)
- [Configure Access Privileges with the deny-commands Statement \(Class2\) | 94](#)
- [Configure Access Privileges with Both the allow-commands and deny-commands Statements \(Class3\) | 94](#)
- [Results | 95](#)

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the [edit] hierarchy level, and then enter `commit` in configuration mode.

#### R1

```
set system authentication-order tacplus
set system authentication-order radius
set system authentication-order password
set system radius-server 10.209.1.66 secret "$ABC123"
set system tacplus-server 10.209.1.66 secret "$ABC123"
set system radius-options enhanced-accounting
set system tacplus-options enhanced-accounting
set system accounting events login
set system accounting events change-log
set system accounting events interactive-commands
set system accounting traceoptions file auditlog
set system accounting traceoptions flag all
set system accounting destination tacplus server 10.209.1.66 secret "$ABC123"
set system login class Class1 permissions clear
set system login class Class1 permissions network
set system login class Class1 permissions reset
set system login class Class1 permissions trace
set system login class Class1 permissions view
```

```

set system login class Class1 allow-commands "request system reboot"
set system login class Class2 permissions clear
set system login class Class2 permissions network
set system login class Class2 permissions reset
set system login class Class2 permissions trace
set system login class Class2 permissions view
set system login class Class2 deny-commands set
set system login class Class3 permissions all
set system login class Class3 allow-commands configure
set system login class Class3 deny-commands .*
set system login user User1 uid 2001
set system login user User1 class Class1
set system login user User1 authentication encrypted-password "$ABC123"
set system login user User2 uid 2002
set system login user User2 class Class2
set system login user User2 authentication encrypted-password "$ABC123"
set system login user User3 uid 2003
set system login user User3 class Class3
set system login user User3 authentication encrypted-password "$ABC123"
set system syslog file messages any any

```

## Configure Authentication Parameters for Router R1

### Step-by-Step Procedure

To configure Router R1 authentication:

1. Configure the order in which R1 attempts to authenticate the user. In this example, TACACS+ server authentication is first, followed by RADIUS server authentication, and then the local password.

```

[edit system]
user@R1# set authentication-order tacplus
user@R1# set authentication-order radius
user@R1# set authentication-order password

```

2. Configure the TACACS+ server.

```

[edit system]
user@R1# set tacplus-server 10.209.1.66 secret "$ABC123"

```

```

user@R1# set tacplus-options enhanced-accounting
user@R1# set accounting destination tacplus server 10.209.1.66 secret "$ABC123"

```

### 3. Configure the RADIUS server.

```

[edit system]
user@R1# set radius-server 10.209.1.66 secret "$ABC123"
user@R1# set radius-options enhanced-accounting

```

### 4. Configure R1 accounting parameters.

```

[edit system]
user@R1# set accounting events login
user@R1# set accounting events change-log
user@R1# set accounting events interactive-commands
user@R1# set accounting traceoptions file auditlog
user@R1# set accounting traceoptions flag all

```

## Configure Access Privileges with the allow-commands Statement (Class1)

### Step-by-Step Procedure

To specify regular expressions using the `allow-commands` statement:

#### 1. Configure the Class1 login class and assign operator-level user permissions.

```

[edit system login]
user@R1# set class Class1 permissions [clear network reset trace view]

```

#### 2. Configure the allow-commands regular expression to enable users in the class to reboot the device.

```

[edit system login]
user@R1# set class Class1 allow-commands "request system reboot"

```

3. Configure the user account for the Class1 login class.

```
[edit system login]
user@R1# set user User1 uid 2001
user@R1# set user User1 class Class1
user@R1# set user User1 authentication encrypted-password "$ABC123"
```

## Configure Access Privileges with the deny-commands Statement (Class2)

### Step-by-Step Procedure

To specify regular expressions using the `deny-commands` statement:

1. Configure the Class2 login class and assign operator-level user permissions.

```
[edit system login]
user@R1# set class Class1 permissions [clear network reset trace view]
```

2. Configure the `deny-commands` regular expression to prevent users in the class from executing `set` commands.

```
[edit system login]
user@R1# set class Class1 deny-commands "set"
```

3. Configure the user account for the Class2 login class.

```
[edit system login]
user@R1# set user User2 uid 2002
user@R1# set user User2 class Class2
user@R1# set user User2 authentication encrypted-password "$ABC123"
```

## Configure Access Privileges with Both the allow-commands and deny-commands Statements (Class3)

### Step-by-Step Procedure

To specify regular expressions using both the `allow-commands` and `deny-commands` statements:

1. Configure the Class3 login class and assign superuser-level permissions.

```
[edit system login]
user@R1# set class Class3 permissions all
```

2. Configure the deny-commands regular expression to prevent users in the class from executing any commands.

```
[edit system login]
user@R1# set class Class3 deny-commands ".*"
```

3. Configure the allow-commands regular expression to allow users to enter configuration mode.

```
[edit system login]
user@R1# set class Class3 allow-commands configure
```

4. Configure the user account for the Class3 login class.

```
[edit system login]
user@R1# set user User3 uid 2003
user@R1# set user User3 class Class3
user@R1# set user User3 authentication encrypted-password "$ABC123"
```

## Results

In configuration mode, confirm your configuration by entering the `show system` command. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R1# show system
authentication-order [ tacplus radius password ];
radius-server {
    10.209.1.66 secret "$ABC123";
}
tacplus-server {
    10.209.1.66 secret "$ABC123";
}
radius-options {
```

```

    enhanced-accounting;
}
tacplus-options {
    enhanced-accounting;
}
accounting {
    events [ login change-log interactive-commands ];
    traceoptions {
        file auditlog;
        flag all;
    }
    destination {
        tacplus {
            server {
                10.209.1.66 secret "$ABC123";
            }
        }
    }
}
login {
    class Class1 {
        permissions [ clear network reset trace view ];
        allow-commands "request system reboot";
    }
    class Class2 {
        permissions [ clear network reset trace view ];
        deny-commands set;
    }
    class Class3 {
        permissions all;
        allow-commands configure;
        deny-commands .*;
    }
    user User1 {
        uid 2001;
        class Class1;
        authentication {
            encrypted-password "$ABC123";
        }
    }
    user User2 {
        uid 2002;
        class Class2;
    }
}

```

```

        authentication {
            encrypted-password "$ABC123";
        }
    }
    user User3 {
        uid 2003;
        class Class3;
        authentication {
            encrypted-password "$ABC123";
        }
    }
}
syslog {
    file messages {
        any any;
    }
}

```

## Verification

### IN THIS SECTION

- [Verifying the Class1 Configuration | 97](#)
- [Verifying the Class2 Configuration | 99](#)
- [Verifying Class3 Configuration | 100](#)

Log in as the username assigned with the new login class, and confirm that the configuration is working properly.

### Verifying the Class1 Configuration

#### Purpose

Verify that the permissions and commands allowed in the Class1 login class are working.

## Action

In operational mode, run the `show system users` command.

```
User1@R1> show system users
12:39PM up 6 days, 23 mins, 6 users, load averages: 0.00, 0.01, 0.00
USER      TTY      FROM          LOGIN@  IDLE WHAT
User1    p0        abc.example.net 12:34AM 12:04 cli
User2    p1        abc.example.net 12:36AM 12:02 -cli (cli)
User3    p2        abc.example.net 10:41AM 11 -cli (cli)
```

In operational mode, run the `request system reboot` command.

```
User1@R1> request system ?
Possible completions:
  reboot          Reboot the system
```

## Meaning

The Class1 login class to which User1 is assigned has operator-level user permissions and allows users in the class to execute the `request system reboot` command.

The predefined operator login class has the following permission flags specified:

- **clear**—Can use `clear` commands to clear (delete) information that the device learns from the network and stores in various network databases.
- **network**—Can access the network by using the `ping`, `ssh`, `telnet`, and `traceroute` commands.
- **reset**—Can restart software processes by using the `restart` command.
- **trace**—Can view trace file settings and configure trace file properties.
- **view**—Can use various commands to display current system-wide, routing table, and protocol-specific values and statistics. Cannot view the secret configuration.

For the Class1 login class, in addition to the above-mentioned user permissions, User1 can execute the `request system reboot` command. The first output displays the view permissions as an operator, and the second output shows that the only `request system` command that User1 can execute as an operator is the `request system reboot` command.

## Verifying the Class2 Configuration

### Purpose

Verify that the permissions and commands allowed for the Class2 login class are working.

### Action

In operational mode, run the ping command.

```
User2@R1> ping 10.209.1.66
ping 10.209.1.66
PING 10.209.1.66 (10.209.1.66): 56 data bytes
64 bytes from 10.209.1.66: icmp_seq=0 ttl=52 time=212.521 ms
64 bytes from 10.209.1.66: icmp_seq=1 ttl=52 time=212.844 ms
64 bytes from 10.209.1.66: icmp_seq=2 ttl=52 time=211.304 ms
64 bytes from 10.209.1.66: icmp_seq=3 ttl=52 time=210.963 ms
^C
--- 10.209.1.66 ping statistics ---
4 packets transmitted, 4 packets received, 0% packet loss
round-trip min/avg/max/stddev = 210.963/211.908/212.844/0.792 ms
```

From the CLI prompt, check the available commands.

```
User2@R1> ?
Possible completions:
clear          Clear information in the system
file           Perform file operations
help           Provide help information
load           Load information from file
monitor        Show real-time debugging information
mtrace         Trace multicast path from source to receiver
op             Invoke an operation script
ping           Ping remote target
quit           Exit the management session
request        Make system-level requests
restart        Restart software process
save           Save information to file
show           Show system information
ssh            Start secure shell on another host
start          Start shell
```

telnet	Telnet to another host
test	Perform diagnostic debugging
tracert	Trace route to remote host

From the CLI prompt, execute any set command.

```
User2@R1> set
      ^
unknown command.
```

## Meaning

The Class2 login class to which User2 is assigned has operator-level user permissions and denies access to all set commands.

The permission flags specified for the predefined operator login class are the same as those specified for Class1.

## Verifying Class3 Configuration

### Purpose

Verify that the permissions and commands allowed for the Class3 login class are working.

### Action

In operational mode, check the available commands.

```
User3@R1> ?
Possible completions:
  configure      Manipulate software configuration information
```

Enter configuration mode.

```
User3@R1> configure
Entering configuration mode

[edit]
User3@R1#
```

## Meaning

The Class3 login class to which User3 is assigned has superuser (all) permissions, but this class only allows users to execute the `configure` command. The class denies access to all other operational mode commands. Because the regular expressions specified in the `allow/deny-commands` statements take precedence over the user permissions, User3 on R1 has access only to configuration mode and is denied access to all other operational mode commands.

## Example: Configure User Permissions with Access Privileges for Configuration Statements and Hierarchies

### IN THIS SECTION

- [Requirements | 101](#)
- [Overview and Topology | 102](#)
- [Configuration | 102](#)
- [Verification | 108](#)

This example shows how to configure custom login classes and assign access privileges to specific configuration hierarchies. Users in the login class can view and modify only those configuration statements and hierarchies to which they have access. This prevents unauthorized users from modifying device configurations that could cause damage to the network.

## Requirements

This example uses the following hardware and software components:

- One Juniper Networks device
- One TACACS+ (or RADIUS) server

Before you begin, establish a TCP connection between the device and the TACACS+ server. In the case of the RADIUS server, establish a UDP connection between the device and the RADIUS server.

## Overview and Topology

Figure 2 on page 102 illustrates a simple topology, where Router R1 is a Juniper Networks device and has a TCP connection established with a TACACS+ server.

Figure 2: Topology

This example configures R1 with two customized login classes: Class1 and Class2. Each class defines access privileges for the user by configuring the `permissions` statement and by defining extended regular expressions using the `allow-configuration`, `deny-configuration`, `allow-configuration-regexps`, and `deny-configuration-regexps` statements.

The purpose of each login class is as follows:

- **Class1**—Defines access privileges for the user with the `allow-configuration` and `deny-configuration` statements. This login class provides access to configure the `[edit interfaces]` hierarchy only and denies all other access on the device. To do this, the user permissions include `configure` to provide configuration access. In addition, the `allow-configuration` statement allows access to the interfaces configuration, and the `deny-configuration` statement denies access to all other configuration hierarchies. Because the `allow` statement takes precedence over the `deny` statement, the users assigned to the Class1 login class can access only the `[edit interfaces]` hierarchy level.
- **Class2**—Defines access privileges for the user with the `allow-configuration-regexps` and `deny-configuration-regexps` statements. This login class provides superuser-level user permissions and explicitly allows configuration under multiple hierarchy levels for interfaces. It also denies access to the `[edit system]` and `[edit protocols]` hierarchy levels.

Router R1 has two users, User1 and User2, assigned to the Class1 and Class2 login classes, respectively.

## Configuration

### IN THIS SECTION

- [CLI Quick Configuration | 103](#)
- [Configure Authentication Parameters for Router R1 | 104](#)

- [Configure Access Privileges with the allow-configuration and deny-configuration Statements \(Class1\) | 105](#)
- [Configure Access Privileges with the allow-configuration-regexps and deny-configuration-regexps Statements \(Class2\) | 106](#)
- [Results | 107](#)

## CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the [edit] hierarchy level, and then enter `commit` in configuration mode.

### R1

```
set system authentication-order tacplus
set system authentication-order radius
set system authentication-order password
set system radius-server 10.209.1.66 secret "$ABC123"
set system tacplus-server 10.209.1.66 secret "$ABC123"
set system radius-options enhanced-accounting
set system tacplus-options enhanced-accounting
set system accounting events login
set system accounting events change-log
set system accounting events interactive-commands
set system accounting traceoptions file auditlog
set system accounting traceoptions flag all
set system accounting destination tacplus server 10.209.1.66 secret "$ABC123"
set system login class Class1 permissions configure
set system login class Class1 allow-configuration "interfaces .* unit .*"
set system login class Class1 deny-configuration .*
set system login class Class2 permissions all
set system login class Class2 allow-configuration-regexps [ "interfaces .* description .*"
"interfaces .* unit .* description .*" "interfaces .* unit .* family inet address .*"
"interfaces.* disable" ]
set system login class Class2 deny-configuration-regexps [ "system" "protocols" ]
set system login user User1 uid 2004
set system login user User1 class Class1
set system login user User1 authentication encrypted-password "$ABC123"
set system login user User2 uid 2006
```

```
set system login user User2 class Class2
set system login user User2 authentication encrypted-password "$ABC123"
set system syslog file messages any any
```

## Configure Authentication Parameters for Router R1

### Step-by-Step Procedure

To configure Router R1 authentication:

1. Configure the order in which R1 attempts to authenticate the user. In this example, TACACS+ server authentication is first, followed by RADIUS server authentication, and then the local password.

```
[edit system]
user@R1# set authentication-order tacplus
user@R1# set authentication-order radius
user@R1# set authentication-order password
```

2. Configure the TACACS+ server.

```
[edit system]
user@R1# set tacplus-server 10.209.1.66 secret "$ABC123"
user@R1# set tacplus-options enhanced-accounting
user@R1# set accounting destination tacplus server 10.209.1.66 secret "$ABC123"
```

3. Configure the RADIUS server.

```
[edit system]
user@R1# set radius-server 10.209.1.66 secret "$ABC123"
user@R1# set radius-options enhanced-accounting
```

4. Configure the R1 accounting parameters.

```
[edit system]
user@R1# set accounting events login
user@R1# set accounting events change-log
user@R1# set accounting events interactive-commands
```

```
user@R1# set accounting traceoptions file auditlog
user@R1# set accounting traceoptions flag all
```

## Configure Access Privileges with the allow-configuration and deny-configuration Statements (Class1)

### Step-by-Step Procedure

To specify regular expressions using the allow-configuration and deny-configuration statements:

1. Configure the Class1 login class with configure permissions.

```
[edit system login]
user@R1# set class Class1 permissions configure
```

2. Configure the allow-configuration regular expression to allow users in the class to view and modify part of the [edit interfaces] hierarchy level.

```
[edit system login]
user@R1# set class Class1 allow-configuration "interfaces .* unit ."
```

3. Configure the deny-configuration regular expression to deny access to all configuration hierarchies.

```
[edit system login]
user@R1# set class Class1 deny-configuration .*
```

4. Configure the user account for the Class1 login class.

```
[edit system login]
user@R1# set user User1 uid 2004
user@R1# set user User1 class Class1
user@R1# set user User1 authentication encrypted-password "$ABC123"
```

## Configure Access Privileges with the allow-configuration-regexps and deny-configuration-regexps Statements (Class2)

### Step-by-Step Procedure

To specify regular expressions using the allow-configuration-regexps and deny-configuration-regexps statements:

1. Configure the Class2 login class and assign superuser (all) permissions.

```
[edit system login]
user@R1# set class Class2 permissions all
```

2. Configure the allow-configuration-regexps regular expression to allow users in the class to access multiple hierarchies under the [edit interfaces] hierarchy level.

```
[edit system login]
user@R1# set class Class2 allow-configuration-regexps [ "interfaces .* description .*"
"interfaces .* unit .* description .*" "interfaces .* unit .* family inet address .*"
"interfaces.* disable" ]
```

3. Configure the deny-configuration-regexps regular expression to prevent users in the class from viewing or modifying the configuration at the [edit system] and [edit protocols] hierarchy levels.

```
[edit system login]
user@R1# set class Class2 deny-configuration-regexps [ "system" "protocols" ]
```

4. Configure the user account for the Class2 login class.

```
[edit system login]
user@R1# set user User2 uid 2006
user@R1# set user User2 class Class2
user@R1# set user User2 authentication encrypted-password "$ABC123"
```

## Results

In configuration mode, confirm your configuration by entering the `show system` command. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

user@R1# show system
authentication-order [ tacplus radius password ];
radius-server {
    10.209.1.66 secret "$ABC123";
}
tacplus-server {
    10.209.1.66 secret "$ABC123";
}
radius-options {
    enhanced-accounting;
}
tacplus-options {
    enhanced-accounting;
}
accounting {
    events [ login change-log interactive-commands ];
    traceoptions {
        file auditlog;
        flag all;
    }
    destination {
        tacplus {
            server {
                10.209.1.66 secret "$ABC123";
            }
        }
    }
}
login {
    class Class1 {
        permissions configure;
        allow-configuration "interfaces .* unit .*";
        deny-configuration .*;
    }
    class Class2 {
        permissions all;
    }
}

```

```
allow-configuration-regexps [ "interfaces .* description .*" "interfaces .* unit .*
description .*" "interfaces .* unit .* family inet address .*" "interfaces.* disable" ];
deny-configuration-regexps [ "system" "protocols" ];
}
user User1 {
    uid 2001;
    class Class1;
    authentication {
        encrypted-password "$ABC123";
    }
}
user User2 {
    uid 2002;
    class Class2;
    authentication {
        encrypted-password "$ABC123";
    }
}
}
syslog {
    file messages {
        any any;
    }
}
}
```

## Verification

### IN THIS SECTION

- [Verify the Class1 Configuration | 109](#)
- [Verify the Class2 Configuration | 110](#)

Log in as the username assigned with the new login class, and confirm that the configuration is working properly.

## Verify the Class1 Configuration

### Purpose

Verify that the permissions allowed in the Class1 login class are working.

### Action

In operational mode, check the available commands.

```
User1@R1> ?  
Possible completions:  
clear          Clear information in the system  
configure      Manipulate software configuration information  
file           Perform file operations  
help           Provide help information  
load           Load information from file  
op             Invoke an operation script  
quit           Exit the management session  
request        Make system-level requests  
save           Save information to file  
set            Set CLI properties, date/time, craft interface message  
start          Start shell  
test           Perform diagnostic debugging
```

In configuration mode, check the available configuration permissions.

```
User1@R1# edit ?  
Possible completions:  
> interfaces   Interface configuration
```

### Meaning

User1 has configure user permissions, as seen in the first output. Additionally, in configuration mode, User1 has access to the interfaces hierarchy level, but only that hierarchy level, as seen in the second output.

Verify the Class2 Configuration

Purpose

Verify that the Class2 configuration is working as expected.

Action

In configuration mode, access the interfaces configuration.

```
[edit interfaces]
User2@R1# set ?
Possible completions:
  <interface-name> Interface name
+ apply-groups      Groups from which to inherit configuration data
+ apply-groups-except Don't inherit configuration data from these groups
  ge-0/0/3          Interface name
> interface-range   Interface ranges configuration
> interface-set      Logical interface set configuration
> traceoptions       Interface trace options
```

In configuration mode, access the system and protocols configuration hierarchies.

```
User2@R1# edit system
      ^
Syntax error, expecting <statement> or <identifier>.
User2@R1# edit protocols
      ^
Syntax error, expecting <statement> or <identifier>.
```

Meaning

User2 has permissions to configure interfaces on R1, but the user does not have permission to view or modify the [edit system] or [edit protocols] hierarchy levels.

Release History Table

Release	Description
18.1	Starting in Junos OS Release 18.1, the allow-commands-regexps and deny-commands-regexps statements are supported for TACACS+ authorization.

# 3

CHAPTER

## Passwords for User Access

[Root Password | 112](#)

[Recover a Root Password | 117](#)

[Plain-Text Passwords | 126](#)

[Master Password for Configuration Encryption | 130](#)

---

# Root Password

## IN THIS SECTION

- [Configure the Root Password | 112](#)
- [Example: Configure a Plain-Text Password for Root Logins | 114](#)

When the device is powered on for the first time, it is ready to be configured. Initially, you log in as the user `root` with no password. You must configure a plain-text password for the root-level user (whose username is `root`) the first time you modify and commit the configuration. Configuring a plain-text password is one way to protect access to the root level by unauthorized users. If you forget the root password for the device, you can use the password recovery procedure to reset the root password.

## Configure the Root Password

When you power on the router or switch, it is ready to be configured. Initially, you log in as the user `root` with no password. The root directory is the entry point to all other folders and files on that device. As a result, access to the root directory is restricted by default to a predefined user account known as the *root user*. The root user (also referred to as *superuser*) has unrestricted access and full permissions within the system. The expression “log in as root” is commonly used when an action requires the user to log in to the device as the root user.

**NOTE:** If you configure a blank password using the encrypted-password statement at the `[edit system root-authentication]` hierarchy level for root authentication, you can commit a configuration. You *cannot*, however, log in as the root user and gain root level access to the router or switch.

After you log in, you should configure the root (superuser) password by including the `root-authentication` statement at the `[edit system]` hierarchy level and configuring one of the password options:

```
[edit system]
root-authentication {
  (encrypted-password "password" | plain-text-password);
  load-key-file URL filename;
```

```
ssh-ecdsa "public-key" <from hostname>;
ssh-rsa "public-key" <from hostname>;
}
```

If you configure the `plain-text-password` option, you are prompted to enter and confirm the password:

```
[edit system]
user@host# set root-authentication plain-text-password
New password: type password here
Retype new password: retype password here
```

The default requirements for plain-text passwords are:

- The password must be between 6 and 128 characters long.
- You can include most character classes in a password (uppercase letters, lowercase letters, numbers, punctuation marks, and other special characters). Control characters are not recommended.
- Valid passwords must contain at least one uppercase letter or one lowercase letter, or one character class.

**NOTE:** Junos-FIPS software has special password requirements. FIPS passwords must be between 10 and 20 characters in length. Passwords must use at least three of the five defined character sets (uppercase letters, lowercase letters, digits, punctuation marks, and other special characters). If Junos-FIPS is installed on the router or switch, you cannot configure passwords unless they meet this standard.

If you use the `encrypted-password` option, then a null-password (empty) is not permitted. You must configure a password whose number of characters range from 1 through 128 characters and enclose the password in quotation marks.

You can use the `load-key-file URL filename` statement to load an SSH key file that was previously generated using `ssh-keygen`. The `URL filename` option is the path to the file's location and name. When using this option, the contents of the key file are copied into the configuration immediately after entering the `load-key-file URL` statement. This command loads RSA (SSH version 1 and SSH version 2) and DSA (SSH version 2) public keys.

Optionally, you can use the `ssh-ecdsa` or `ssh-rsa` statements to directly configure SSH RSA and ECDSA keys to authenticate root logins. You can configure more than one public key for SSH authentication of

root logins as well as for user accounts. When a user logs in as root, the device determines whether the private key matches any of the configured public keys.

```
[edit system]
user@host# set root-authentication load-key-file my-host:.ssh/id_rsa.pub
.file.19692          |          0 KB |   0.3 kB/s | ETA: 00:00:00 | 100%
```

In configuration mode, you can confirm your SSH key entries by entering the `show` command. It should look similar to the following output:

```
[edit system]
user@host# show
root-authentication {
    ssh-rsa "$ABC123"; ## SECRET-DATA
}
```

## Example: Configure a Plain-Text Password for Root Logins

### IN THIS SECTION

- [Requirements | 114](#)
- [Overview | 115](#)
- [Configuration | 115](#)
- [Verification | 116](#)

This example shows how to configure a plain-text password for the root-level user (the username is `root`). Configuring a plain-text password is one way to prevent unauthorized users from accessing the root level. You must prevent unauthorized users from gaining access to superuser commands that can be used to alter your system configuration.

### Requirements

No special configuration beyond device initialization is required before configuring this example.

The default requirements for a plain-text password are as follows:

- Must be from 6 up to 128 characters long.
- Can include most character classes (uppercase letters, lowercase letters, numbers, punctuation marks, and other special characters). Control characters are not recommended.
- Must contain at least one change of case or character class.

## Overview

When you power on the router, it is ready to be configured. Initially, you log in as the root-level user with no password. To set the root password, you have several options. This example shows how to enter a plain-text password that the device then encrypts for you.

## Configuration

### IN THIS SECTION

- [CLI Quick Configuration | 115](#)
- [Configure a Plain-Text Password for User Root | 115](#)
- [Results | 116](#)

## CLI Quick Configuration

To quickly configure this example, copy the following command and paste it into the window. When prompted, type the new password, and then when prompted, retype it.

```
set system root-authentication plain-text-password
```

## Configure a Plain-Text Password for User Root

## Step-by-Step Procedure

To configure a plain-text password for the root-level user:

1. Type the set command for the plain-text password and press Enter.

```
[edit]
user@host# set system root-authentication plain-text-password
New password:
```

2. Type the new password next to the New password prompt and press Enter.

```
New password: new-password
Retype new password:
```

3. Retype the same password next to the Retype new password prompt and press Enter.

```
New password: new-password
Retype new password: new-password
```

## Results

In configuration mode, confirm your configuration by using the `show system` command. It should look something like this:

```
[edit]
user@host# show system
root-authentication {
    encrypted-password "$ABC123"; ## SECRET-DATA
}
```

If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

After you have confirmed that the configuration is correct, enter `commit` in configuration mode.

## Verification

### IN THIS SECTION

- [Verify the Configuration of a Plain-Text Password for User Root | 117](#)

## Verify the Configuration of a Plain-Text Password for User Root

### Purpose

Verify the configuration of a plain-text password for the root-level user.

### Action

In operational mode, confirm your configuration by entering the `show configuration system` command.

```
user@host> show configuration system
root-authentication {
    encrypted-password "$ABC123"; ## SECRET-DATA
}
```

### Meaning

If you use a plain-text password, the device automatically encrypts the password as soon as you configure it. You do not have to configure the device to encrypt the password, as in some other systems. Plain-text passwords are hidden and marked as `## SECRET-DATA` in the configuration. When a user views the configuration, the user sees only the encrypted string, not the unencrypted password.

### Release History Table

Release	Description
18.3R1	Starting in Junos OS Release 18.3R1, the <code>ssh-dss</code> and <code>ssh-dsa</code> hostkey algorithms are deprecated— rather than immediately removed—to provide backward compatibility and a chance to bring your configuration into compliance with the new configuration.

# Recover a Root Password

### IN THIS SECTION

- [How to Recover the Root Password for Junos OS | 118](#)
- [How to Recover the Root Password on Junos OS with Upgraded FreeBSD | 120](#)

If you forget the root password, you can use the password recovery procedure to reset the root password.

## How to Recover the Root Password for Junos OS

If you forget the root password for the router, you can use the password recovery procedure to reset the root password.

Before you begin, note the following:

- You need console access to recover the root password.

**Video:** [How to Recover the Root Password in Junos OS](#)

To recover the root password:

1. Power off the router by pressing the power button on the front panel.
2. Turn off the power to the management device (usually a computer) that you use to access the CLI.
3. Plug one end of the Ethernet rollover cable (supplied with the router) into the RJ-45 to DB-9 serial port adapter supplied with the router.
4. Plug the RJ-45 to DB-9 serial port adapter into the serial port on the management device.
5. Connect the other end of the Ethernet rollover cable to the console port on the router.
6. Turn on the power to the management device.
7. From the management device, start your asynchronous terminal emulation application (such as Microsoft Windows Hyperterminal), and select the appropriate COM port to use (for example, COM1).
8. Configure the port settings as follows:
  - Bits per second: 9600
  - Data bits: 8
  - Parity: None
  - Stop bits: 1
  - Flow control: None

9. Power on the router by pressing the power button on the front panel.

Verify that the POWER LED on the front panel turns green.

The terminal emulation screen on your management device displays the router's boot sequence.

10. When the following prompt appears, press the Spacebar to access the router's bootstrap loader command prompt.

Depending on your device hardware, the bootstrap loader might proceed quickly at this step without pausing for input. Therefore, you might need to press the spacebar multiple times at the beginning of the boot sequence.

```
Hit [Enter] to boot immediately, or space bar for command prompt.
Booting [kernel] in 9 seconds...
```

11. At the following prompt, type `boot -s` to start the system in single-user mode.

```
ok boot -s
```

12. At the following prompt, type `recovery` to start the root password recovery procedure.

```
Enter full pathname of shell or 'recovery' for root password recovery or RETURN for /bin/
sh: recovery
```

13. Enter configuration mode in the CLI.

14. Set the root password.

```
[edit]
user@host# set system root-authentication plain-text-password
```

When you configure a plain-text password, the system encrypts the password for you.

**CAUTION:** Avoid using the `encrypted-password` option unless the password is *already* encrypted and you are entering the encrypted version of the password. If you commit the `encrypted-password` option with a plain-text password or with blank quotation marks (" "), you will not be able to log in to the device as root, and you will need to repeat this password recovery process.

15. At the following prompt, enter the new root password. For example:

```
New password: password
```

16. At the second prompt, reenter the new root password.

```
Retype new password:
```

17. After you have finished configuring the password, commit the configuration.

```
root@host# commit
commit complete
```

18. Exit configuration mode in the CLI.
19. Exit operational mode in the CLI.
20. At the prompt, type y to reboot the router.

```
Reboot the system? [y/n] y
```

## How to Recover the Root Password on Junos OS with Upgraded FreeBSD

If you forget the root password for a device running Junos OS with Upgraded FreeBSD, you can use the password recovery procedure to reset the root password.

For the list of Junos OS devices with upgraded FreeBSD, see [Junos kernel upgrade to FreeBSD 10+](#)

**Video:** [How to Recover the Root Password in Junos OS with Upgraded FreeBSD](#)

**NOTE:** You need console access to recover the root password.

To recover the root password:

1. Power off the router by pressing the power button on the front panel.
2. Turn off the power to the management device (usually a computer) that you will use to access the CLI.

3. Plug one end of the Ethernet rollover cable (supplied with the router) into the RJ-45 to DB-9 serial port adapter (supplied with the router).
4. Plug the RJ-45 to DB-9 serial port adapter into the serial port on the management device.
5. Connect the other end of the Ethernet rollover cable to the console port on the router.
6. Turn on the power to the management device.
7. On the management device, start your asynchronous terminal emulation application (such as Microsoft Windows Hyperterminal), and select the appropriate COM port to use (for example, COM1).
8. Configure the port settings as follows:
  - Bits per second: 9600
  - Data bits: 8
  - Parity: None
  - Stop bits: 1
  - Flow control: None
9. Power on the router by pressing the power button on the front panel.  
Verify that the POWER LED on the front panel turns green.

The terminal emulation screen on your management device displays the router's boot sequence.

10. Access the Junos Main Menu.
  - Prior to Junos OS Release 17.3, the Junos Main Menu appears for 3 seconds on startup before automatically booting the Junos volume. Press any key within the 3 second window to stop the automatic boot sequence and display the Junos Main Menu.

**NOTE:** The Junos Main Menu will appear every time you reboot the router while connected to the console.

- Press Ctrl+c at the following part in the reboot to bring up the Junos Main Menu:

```
FreeBSD/x86 bootstrap loader, Revision 1.1
(builder@feyrith.juniper.net, Sun Feb  4 13:06:24 PST 2018)
/
Autoboot in 1 seconds... (press Ctrl-C to interrupt)
```

1. Boot [J]unos volume
2. Boot Junos volume in [S]afe mode

- 3. [R]eboot
- 4. [B]oot menu
- 5. [M]ore options

**11.** At the Junos Main Menu, press the **M** or **5** key to activate the 5. [M]ore options menu:

- 1. Recover [J]unos volume
- 2. Recovery mode - [C]LI
- 3. Check [F]ile system
- 4. Enable [V]erbose boot
- 5. [B]oot prompt
- 6. [M]ain menu

- 12.** Press the **C** or **2** key to access the 2. Recovery mode - [C]LI option. The router will reboot into CLI recovery mode.
- 13.** When prompted, press the **Enter** key to immediately boot the router, or press any other key to bring up the command prompt.
- 14.** Enter configuration mode in the CLI.

```
root># configure
Entering configuration mode
```

**15.** Set the root password.

When you configure a plain-text password, Junos OS encrypts the password for you.

```
[edit]
root# set system root-authentication plain-text-password
```

**CAUTION:** Do not use the encrypted-password option unless the password is *already* encrypted, and you are entering the encrypted version of the password. If you commit the encrypted-password option with a plain-text password or with blank

quotation marks (" "), you will not be able to log in to the router as root, and you will need to repeat this password recovery process.

16. At the following prompt, enter the new root password. For example:

```
New password: password
```

17. At the second prompt, reenter the new root password.

```
Retype new password: password
```

18. After you have finished configuring the password, commit the configuration.

```
root@host# commit  
commit complete
```

## How to Recover the Root Password on Switches

### IN THIS SECTION

- [Problem | 123](#)
- [Solution | 124](#)

### Problem

#### Description

If you forget the root password for a switch, use the password recovery procedure to reset the root password.

Before you begin, note the following:

- You need physical access to the switch to recover the root password.

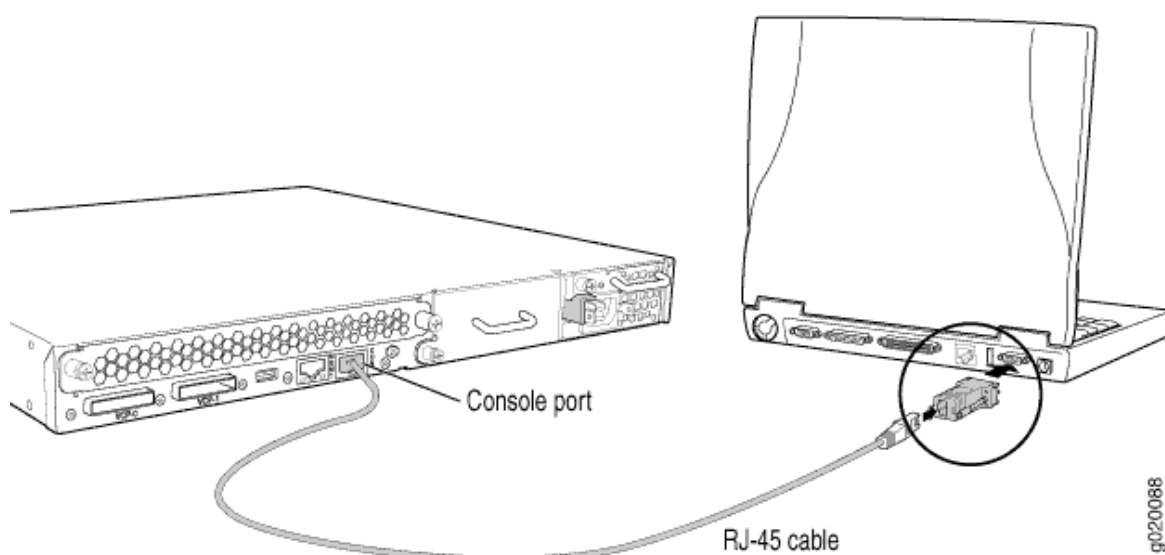

**TIP:** For a video on recovering the root password for routers, see ["Recovering the Root Password on Routers" on page 118](#). The procedure is similar for switches.

## Solution

To recover the root password:

1. Power off your switch by unplugging the power cord or turning off the power at the wall switch.
2. Insert one end of the Ethernet cable into the serial port on the management device and connect the other end to the console port on the back of the switch. See [Figure 3 on page 124](#).

**Figure 3: Connecting to the Console Port on the EX Series Switch**

3. On the management device, start your asynchronous terminal emulation application (such as Microsoft Windows Hyperterminal). Then, select the appropriate COM port to use (for example, COM1).
4. Configure the port settings as follows:
  - Bits per second: 9600
  - Data bits: 8
  - Parity: None

- Stop bits: 1
  - Flow control: None
5. Power on your switch by plugging in the power cord or turning on the power at the wall switch.
  6. When the following prompt appears, press the Spacebar to access the switch's bootstrap loader command prompt.

```
Hit [Enter] to boot immediately, or space bar for command prompt.
Booting [kernel] in 1 second...
```

**NOTE:** If the switch is in unattended mode for U-Boot, access to the bootstrap loader command prompt is blocked. If the root password is lost, you must reset the switch to the factory default configuration using the LCD panel.

7. At the following prompt, type `boot -s` to start up the system in single-user mode:

```
loader> boot -s
```

8. At the following prompt, type `recovery` to start the root password recovery procedure:

```
Enter full path name of shell or 'recovery' for root password recovery or RETURN for /bin/
sh: recovery
```

A series of messages describe consistency checks, mounting of filesystems, and initialization and checkout of management services. Then the CLI prompt appears.

9. Enter configuration mode in the CLI:

```
user@switch> configure
```

10. Set the root password.

```
user@switch# set system root-authentication plain-text-password
```

11. At the following prompt, enter the new root password:

```
New password: password
```

12. At the second prompt, reenter the new root password.

```
Retype new password: password
```

13. After you finish configuring the device, commit the configuration.

```
root@switch# commit  
commit complete
```

14. Exit configuration mode in the CLI.

```
root@switch# exit
```

15. Exit operational mode in the CLI.

```
root@switch> exit
```

16. At the prompt, enter y to reboot the switch.

```
Reboot the system? [y/n] y
```

## Plain-Text Passwords

### IN THIS SECTION

- [Change the Requirements for Plain-Text Passwords | 127](#)
- [How to Change the Requirements for Plain-Text Passwords | 127](#)

## Change the Requirements for Plain-Text Passwords

To change the requirements for plain-text passwords, include the password statement at the [edit system login] hierarchy level:

```
[edit system login]
password {
  change-type (set-transitions | character-set);
  format (sha1 | sha256 | sha512);
  maximum-length length;
  maximum-lifetime days
  minimum-changes number;
  minimum-character-changes number
  minimum-length length;
  minimum-lifetime days
  minimum-lower-cases number;
  minimum-numeric number;
  minimum-reuse number
  minimum-punctuations number;
  minimum-upper-cases number;
}
```

**NOTE:** These statements apply to plain-text passwords only, not encrypted passwords.

## How to Change the Requirements for Plain-Text Passwords

### IN THIS SECTION

- [Overview | 128](#)
- [Configuration | 128](#)

This example shows how to set various maximum and minimum requirements for plain-text passwords to increase password strength.

## Overview

You can use a variety of requirements to strengthen plain-text passwords for greater security. Many possible configurations exist at the [edit system login password] hierarchy level that allow you to require users to create plain-text passwords conforming to a particular set of requirements. These requirements may include such things as password length, number of changes, type of characters, numbers, or letter case.

## Configuration

### IN THIS SECTION

- [CLI Quick Configuration | 128](#)
- [Configure the Requirements for Plain-Text Passwords | 128](#)
- [Results | 129](#)

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level.

```
set system login password minimum-length 12
set system login password maximum-length 22
set system login password minimum-numeric 1
set system login password minimum-upper-cases 1
set system login password minimum-lower-cases 1
set system login password minimum-punctuations 1
```

### Configure the Requirements for Plain-Text Passwords

#### Step-by-Step Procedure

This example configures password requirements that require the user to create a password with at least 12 characters but no more than 22 characters. The password requirements also specify at least one lowercase letter and one uppercase letter, at least one punctuation character, and at least one numeric character.

1. Enter configuration mode and navigate to the [edit system login password] hierarchy level.

```
user@host> configure
[edit]
user@host# edit system login password
```

2. Set a minimum length requirement of 12 characters and a maximum length requirement of 22 characters for user passwords.

```
[edit system login password]
user@host# set minimum-length 12
[edit system login password]
user@host# set maximum-length 22
```

3. Require users to set a password that has at least one lowercase letter and at least one uppercase letter.

```
[edit system login password]
user@host# set minimum-lower-cases 1
[edit system login password]
user@host# set minimum-upper-cases 1
```

4. Require users to set a password that has at least one punctuation character and at least one numeric character.

```
[edit system login password]
user@host# set minimum-punctuations 1
[edit system login password]
user@host# set minimum-numeric 1
```

## Results

In configuration mode, confirm your configuration by entering the show command at the [edit system login password] hierarchy level..

```
[edit system login password]
user@host# show
minimum-length 12;
```

```
maximum-length 22;  
minimum-numeric 1;  
minimum-upper-cases 1;  
minimum-lower-cases 1;  
minimum-punctuations 1;
```

If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

After you have confirmed that the configuration is correct, enter `commit` in configuration mode.

## Master Password for Configuration Encryption

### IN THIS SECTION

- [Hardening Shared Secrets in Junos OS | 130](#)
- [Using Trusted Platform Module to Bind Secrets on SRX Series Devices | 133](#)
- [Using Trusted Platform Module on MX Series Devices | 136](#)

Junos OS supports encryption method for configuration secrets using a master password. The master password derives an encryption key that uses AES256-GCM to protect certain secrets such as private keys, system master passwords, and other sensitive data by storing it in an AES256 encrypted format. For more information, read this topic.

## Hardening Shared Secrets in Junos OS

### IN THIS SECTION

- [Understanding Hardening Shared Secrets | 131](#)

## Understanding Hardening Shared Secrets

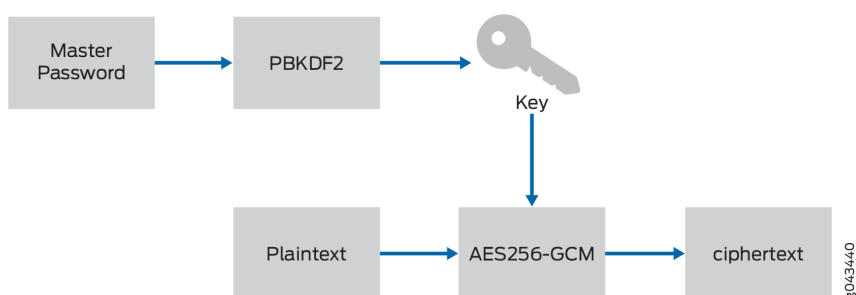

Existing shared secrets (\$9\$ format) in Junos OS currently use an obfuscation algorithm, which is not a very strong encryption for configuration secrets. If you want a strong encryption for your configuration secrets, you can configure a master password. The master password is used to derive an encryption key that is used with AES256-GCM to encrypt configuration secrets. This new encryption method uses the \$8\$ formatted strings.

Starting with Junos OS Release 15.1X49-D50, new CLI commands are introduced to configure a system master password to provide stronger encryption for configuration secrets. The master password encrypts secrets like the RADIUS password, IKE preshared keys, and other shared secrets in the Junos OS management process (mgd) configuration. The master password itself is not saved as part of the configuration. The password quality is evaluated for strength, and the device gives feedback if weak passwords are used.

The master password is used as input to the password based key derivation function (PBKDF2) to generate an encryption key. The key is used as input to the Advanced Encryption Standard in Galois/Counter Mode (AES256-GCM). The plain text that the user enters is processed by the encryption algorithm (with key) to produce the encrypted text (cipher text). See [Figure 4 on page 131](#)

**NOTE:** Enabling Master Password Encryption through the Trusted Platform Module (TPM) can result in increased commit times. This is because of the encryption processing that occurs each time the configuration is committed. The increase in delay varies according to CPU capability and current loading.

**Figure 4: Master Password Encryption**

The \$8\$ configuration secrets can only be shared between devices using the same master password.

The \$8\$-encrypted passwords have the following format:

\$8\$crypt-algo\$hash-algo\$iterations\$salt\$iv\$tag\$encrypted. See [Table 9 on page 132](#) for the master password format details.

**Table 9: \$8\$-encrypted Password Format**

Format	Description
crypt-algo	Encryption/decryption algorithm to be used. Currently only AES256-GCM is supported.
hash-algo	Hash (prf) algorithm to be used for the PBKDF2 key derivation.
iterations	The number of iterations to use for the PBKDF2 hash function. Current iteration-count default is 100. The iteration count slows the hashing count, thus slowing attacker guesses.
salt	Sequence of ASCII64-encoded pseudorandom bytes generated during encryption that are to be used to <i>salt</i> (a random, but known string) the password and input to the PBKDF2 key derivation.
iv	A sequence of ASCII64-encoded pseudorandom bytes generated during encryption that are to be used as initialization vector for the AES256-GCM encryption function.
tag	ASCII64-encoded representation of the tag.
encrypted	ASCII64-encoded representation of the encrypted password.

The ASCII64 encoding is Base64 (RFC 4648) compatible, except no padding (character “=”) is used to keep the strings short. For example: \$8\$aes256-gcm\$hmacc-sha2-256\$100\$y/4YMC4YDLU\$fzYDI4jjN6YCYQsYLSaf8A  
\$Ilu4jLcZarD9YnyD /Hejww\$okhB1c0cGakSqYxKww

## Chassis Cluster Considerations

When defining a chassis cluster on SRX Series devices, be aware of the following restrictions:

- For SRX Series devices, first configure the master password on each node, and then build the cluster. The same master password should be configured on each node.
- In chassis cluster mode, if Master Encryption Key (MEK) is set, the master password cannot be deleted but you can reset master password. You can only delete master password by zeroize the Routing Engine.

**NOTE:** A change in the master password would mean disruption in chassis clustering; therefore you must change the password on both nodes independently.

## Using Trusted Platform Module to Bind Secrets on SRX Series Devices

### IN THIS SECTION

- [Limitations | 134](#)
- [Configuring Master Encryption Password | 134](#)
- [Verifying the Status of the TPM | 135](#)
- [Changing the Master Encryption Password | 135](#)

By enabling the Trusted Platform Module (TPM) on the SRX Series devices, the software layer leverages the use of the underlying TPM chip. TPM is a specialized chip that protects certain secrets at rest such as private keys, system primary passwords, and other sensitive data by storing it in an AES256 encrypted format (instead of storing sensitive data in a clear text format). The device also generates a new SHA256 hash of the configuration each time the administrator commits the configuration. This hash is verified each time the system boots up. If the configuration has been tampered with, the verification fails and the device will not continue to boot. Both the encrypted data and the hash of the configuration is protected by the TPM module using the master encryption password.

**NOTE:** Hash validation is performed during any commit operation by performing a validation check of the configuration file against the saved hash from previous commits. In a chassis cluster system, hash is independently generated on the backup system as part of the commit process. A commit from any mode, that is, batch-config, dynamic-config, exclusive-config, or private config generates the integrity hash.

**NOTE:** Hash is saved only for the current configuration and not for any rollback configurations. Hash is not generated during reboot or shutdown of the device.

The TPM encrypts the following secrets:

- SHA256 hash of the configuration
- device primary-password
- all key-pairs on the device

The TPM chip is available on the SRX300, SRX320, SRX340, SRX345, SRX380 SRX5400, SRX5600, and SRX5800 devices. On SRX5400, SRX5600, and SRX5800 devices, TPM is supported only with SRX5K-RE3-128G Routing Engine (RE3). The TPM chip is enabled by default to make use of TPM functionality. You must configure master encryption password to encrypt PKI key-pairs and configuration hash. To configure master encryption password, see ["Configuring Master Encryption Password" on page 134](#).

## Limitations

The following limitations and exceptions apply to the configuration file integrity feature using TPM:

- This feature is supported only on the SRX300, SRX320, SRX340, SRX345, SRX380 SRX5400, SRX5600, and SRX5800 devices. On SRX5400, SRX5600, and SRX5800 devices, TPM is supported only with RE3.
- If the master encryption password is not set, data is stored unencrypted.
- The file integrity feature is not supported along with the configuration file encryption feature that uses keys saved in EEPROM. You can enable only one function at a time.
- In a chassis cluster, both nodes must have the same TPM settings. This means that both nodes in the chassis cluster must have TPM enabled, or both nodes in the chassis cluster must have TPM disabled. The chassis cluster must not have one node set to TPM enabled and the another node set to TPM disabled.

**NOTE:** After the Master Encryption Key (MEK) is configured and operational, downgrading to a Junos version that does not support TPM functionality is not recommended. This is because the non-TPM capable image is not able to decrypt the secrets that were encrypted by TPM after the device reboots to the non-TPM cable version.

If you must downgrade to a non-TPM capable image you must first zeroize the device. The zeroization process ensures the device does not contain any secrets and removes all the keys. After zeroization the device be downgraded to the desired non-TPM capable image .

## Configuring Master Encryption Password

**NOTE:** Before configuring master encryption password, ensure that you have configured set system master-password plain-text-password otherwise, certain sensitive data will not be protected by the TPM.

Set the master encryption password using the following CLI command:

```
request security tpm master-encryption-password set plain-text-password
```

You will be prompted to enter the master encryption password twice, to make sure that these passwords match. The master encryption password is validated for required password strength.

After master encryption password is set, the system proceeds to encrypt the sensitive data with the master encryption password which is encrypted by the Master Binding Key that is owned and protected by the TPM chip.

**NOTE:** If there is any issue with setting the master encryption password, a critical ERROR message is logged on the console and the process is terminated.

## Verifying the Status of the TPM

You can use the `show security tpm status` command to verify the status of the TPM. The following information is displayed:

- TPM enabled/disabled
- TPM ownership
- TPM's Master Binding Key status (created or not created)
- master encryption password status (set or not set)

Starting with Junos OS Release 15.1X49-D120 and Junos OS Release 17.4R1, Trusted Platform Module (TPM) firmware has been updated. The upgraded firmware version provides additional secure cryptography and improves security. Updated TPM firmware is available along with the Junos OS package. For updating TPM Firmware, see [Upgrading TPM Firmware on SRX-Devices](#). To confirm the TPM firmware version, use the `show security tpm status` command. TPM Family and TPM Firmware *version* output fields are introduced.

## Changing the Master Encryption Password

Changing the master encryption password is done using the CLI.

To change the master encryption password, enter the following command from operational mode:

```
request security tpm master-encryption-password set plain-text-password
```

**NOTE:** It is recommended that no configuration changes are made while you are changing the master encryption password.

The system checks if the master encryption password is already configured. If master encryption password is configured, then you are prompted to enter the current master encryption password.

The entered master encryption password is validated against the current master encryption password to make sure these master encryption passwords match. If the validation succeeds, you will be prompted to enter the new master encryption password as plain text. You will be asked to enter the key twice to validate the password.

The system then proceeds to re-encrypt the sensitive data with the new master encryption password. You must wait for this process of re-encryption to complete before attempting to change the master encryption password again.

If for some reason, the encrypted master encryption password file is lost or corrupted, the system will not be able to decrypt the sensitive data. The system can only be recovered by re-importing the sensitive data in clear text, and re-encrypting them.

If the system is compromised, the administrator can recover the system using of the following method:

- Clear the TPM ownership in u-boot and then install the image in boot loader using TFTP or USB (if USB port is not restricted).

**NOTE:** If the installed software version is older than Junos OS Release 15.1X49-D110 and the master encryption password is enabled, then installation of Junos OS Release 15.1X49-D110 will fail. You must backup the configuration, certificates, key-pairs, and other secrets and use the TFTP/USB installation procedure.

## Using Trusted Platform Module on MX Series Devices

### IN THIS SECTION

- [Limitations | 137](#)

Trusted Platform Module (TPM) is supported on MX240, MX480, MX960, MX2010, MX2020, and MX10003 devices. A master password is used to encrypt the configuration files stored in the device. TPM is used to protect the sensitive data such as master password of system by encryption. TPM is used to encrypt and decrypt the data using keys.

To change the master encryption password, enter the following command from operational mode:

```
request security tpm master-encryption-password set plain-text-password
```

## Limitations

- If Master Encryption Key (MEK) is deleted, the data cannot be decrypted. To delete MEK, you have to zeroize the device.
- If MEK is set, the master password cannot be deleted but you can reset master password. You can only delete master password by zeroize the Routing Engine.
- To downgrade the Routing Engine, you must zeroize the Routing Engine. Once the device is zeroized it can then be safely downgraded to the image which does not support this feature.
- In dual Routing Engine configuration, if backup Routing Engine needs to be recovered, due to MEK mismatch, GRES needs to be disabled and backup Routing Engine must be zeroized. Once backup Routing Engine comes up, configure MEK using `request security tpm master-encryption-password set plain-text-password` command on Master RE.
- In dual Routing Engine configuration, if backup Routing Engine needs to be replaced, new backup Routing Engine must be zeroized first before adding in dual Routing Engine configuration, GRES must be disabled and re-configure MEK on master RE using `request security tpm master-encryption-password set plain-text-password` command.

## Release History Table

Release	Description
17.4R1	Starting with Junos OS Release 15.1X49-D120 and Junos OS Release 17.4R1, Trusted Platform Module (TPM) firmware has been updated. The upgraded firmware version provides additional secure cryptography and improves security. Updated TPM firmware is available along with the Junos OS package. For updating TPM Firmware, see <a href="#">Upgrading TPM Firmware on SRX-Devices</a> . To confirm the TPM firmware version, use the <code>show security tpm status</code> command. TPM Family and TPM Firmware <i>version</i> output fields are introduced.
15.1X49-D50	Starting with Junos OS Release 15.1X49-D50, new CLI commands are introduced to configure a system master password to provide stronger encryption for configuration secrets.

# Encryption with Trusted Platform Module

## IN THIS SECTION

- [Benefits of File-System Encryption | 140](#)
- [File-System Encryption with Trusted Platform Module \(TPM\) | 140](#)

Encryption provides the support to protect sensitive information in the configuration files, logs, and private keys on the file-system of the disk drives. Encryption also prevents unauthorized access to data stored in files on a disk or disk volume.

File-system encryption is supported on MX240, MX480, and MX960 devices for bulk encryption of file names, folder names, file contents, and other meta-data that operates on an entire volume. In this method, the data is automatically encrypted when written to disk and decrypted when read from it. The files are accessible immediately after the encryption key is provided.

## Benefits of File-System Encryption

- Prevents revealing of confidential information from offline attacks.
- Provides data destruction for secure data erasure by destroying the cryptographic keys.
- All files are automatically encrypted, by default without any user action.

## File-System Encryption with Trusted Platform Module (TPM)

TPM is a chip used for the identification and authentication of a device on the network and to ensure the software loaded on the system is in the correct state when it started up. Each TPM chip is unique to a particular device. Using TPM on the device, the hard disk drive cannot be connected and accessed outside to another device. The encryption key is enclosed to the TPM 2.0 device. The data stored on the encrypted file-system is read using the encryption keys.

# Remote Integrity Verification

## IN THIS SECTION

- [Benefits | 141](#)

Trusted Platform Module (TPM) 1.2 is supported on MX240, MX480, MX960, MX2008, MX2010, and MX2020 with RE-S-X6-128G-S. TPM is a chip used to identify a device on the network and the evidence of the integrity of software loaded on that device when it boots up. One of the features of the TPM is to measure various software components during device boot. The data is stored as a cryptographic hash in the TPM's Platform Configuration Registers (PCR). You can use PCR as proof of the integrity of the MX Series devices software version. The chip includes multiple physical security mechanisms to make it tamper resistant and the malicious software cannot tamper the security functions of the TPM.

Remote Integrity Verification (RIV) defines set of protocols and procedures to determine if a particular device is launched with untampered software version. The roles involved in RIV process are Attester and Verifier.

The Attester provides evidence of identity and software state to the Verifier on demand. The Verifier verifies the evidence and makes a judgment about the integrity of the software image running on the Attester.

## Benefits

- Provides the integrity of the host platform and ensures that the host platform is not hacked.
- Provides restricted access to the stored secrets (keys).

- Stores data that is not secret such as public keys used for platform identity. You cannot change the public keys without authorization.
- Creates and manages a TPM key used to sign the evidence

- [Configure Remote User Template Accounts for User Authentication | 149](#)
- [Example: Create Template Accounts | 150](#)
- [What Are Remote Authentication Servers? | 153](#)

Junos OS supports different authentication methods that you (the network administrator) use to control user access to the network. These methods include local password authentication, Lightweight Directory Access Protocol (LDAP), RADIUS, and TACACS+. Some login users use Transport Layer Security (TLS). Starting with Junos OS Release 20.2R1, we introduced LDAP support for login users with TLS (LDAPS) between the LDAPS client and the LDAPS server. (The LDAPS client is the device running Junos OS.) You use one of these authentication methods to validate users and devices that attempt to access the router or switch using SSH and Telnet. Authentication prevents unauthorized devices and users from gaining access to your LAN.

## User Authentication Methods

Junos OS supports four methods of user authentication: local password authentication, LDAP over TLS (LDAPS), RADIUS, and TACACS+.

With local password authentication, you configure a password for each user allowed to log in to the router or switch.

LDAPS, RADIUS, and TACACS+ are authentication methods for validating users who attempt to access the router or switch using any of the login methods. They are distributed client/server systems—the LDAPS, RADIUS, and TACACS+ clients run on the router or switch, and the server runs on a remote network system.

You can configure the router or switch to be an LDAPS, RADIUS, or TACACS+ client, or a combination. You can also configure authentication passwords in the Junos OS configuration file. You can prioritize the methods to configure the order in which the software tries the different authentication methods when verifying user access.

## Configure Local User Template Accounts for User Authentication

You use local user template accounts to assign different login classes, and thus grant different permissions, to users who are authenticated through a remote authentication server. Each template can define a different set of permissions appropriate for the users assigned to that template. You define the templates locally on the router or switch, and the TACACS+, RADIUS, and LDAPS authentication servers reference the templates. When an authenticated user is assigned to a template account, the CLI username is the login name, but the user inherits privileges, file ownership, and effective user ID from the template account.

When you configure local user templates and a user logs in, Junos OS issues a request to the authentication server to authenticate the user's login name. If the user is authenticated, the server returns the local username to Junos OS (`juniperLocalUserName` for LDAPS, `local-user-name` for TACACS+, and `Juniper-Local-User-Name` for RADIUS). Junos OS then determines whether a local username is specified for that login name, and if so, Junos OS assigns the user to that local user template. If a local user template does not exist for the authenticated user, the router or switch defaults to the `remote` template, if configured.

To configure a local user template, define the template username at the `[edit system login]` hierarchy level. Assign a class to specify the privileges you want to grant to the local users to whom the template applies:

```
[edit system login]
user local-username {
    full-name "Local user account";
    uid uid-value;
    class class-name;
}
```

To assign a user to the local user template, configure the remote authentication server with the appropriate parameter (`juniperLocalUserName` for LDAPS, `local-user-name` for TACACS+, and `Juniper-Local-User-Name` for RADIUS), and specify the username defined for the local user template. To configure different access privileges for users who share the local user template account, you can use vendor-specific attributes in the authentication server configuration file to allow or deny specific commands and configuration hierarchies for a user.

The following example configures the `u_ldap` user template on the local device, and the LDAP Data Interchange Format (LDIF) configuration file assigns a user to the template:

```
[edit]
system {
    login {
```

```

        user u-ldap {
            class class-name;
        }
    }
}

```

```

user.ldif snippet:
dn: uid=simon,dc=example,dc=com
uid: simon
sn: User
cn: Auth User
objectClass: person
objectClass: organizationalPerson
objectClass: posixAccount
objectClass: top
objectClass: shadowAccount
objectClass: juniperAuthAccount
loginShell: /bin/bash
homeDirectory: /home/simon
userPassword: secret
uidNumber: 1002
gidNumber: 1002
shadowMax: 10
juniperLocalUserName: u_ldap
juniperUserPerms: clear view shell admin-control
juniperAllowConf: (show cli authorization)|(ping)
juniperDenyConf: (show ospf)|(show log)
juniperAllowCmds: configure
juniperDenyCmds: shutdown

```

The following example configures the `u_ldap` and `auth` user templates on the local device, and the authentication server configuration assigns each user to the appropriate template. When the users John and Harry are authenticated, the router or switch applies the `u_ldap` local user template. When the users Tom and Dave are authenticated, the router or switch applies the `auth` local user template.

```

[edit]
system {
    login {
        user u-ldap {
            uid 6001;
            class ldap-class;
        }
    }
}

```

```

        user auth {
            uid 6002;
            class operator;
        }
    }
}

```

```

user = john {
    ...
    service = junos-exec {
        juniperLocalUserName = u-ldap
        juniperAllowCmds= "(start shell)|(show cli authorization)|(clear ipsec)|(show firewall)|
(show interfaces)|(show version)"
        juniperDenyCmds= "(show ospf)|(show log)|(show system certificate)|(show ppp)|(show
policy)|restart|request"
    }
}
user = harry {
    ...
    service = junos-exec {
        juniperLocalUserName = u-ldap
        juniperAllowCmds = "(start shell)|(show cli authorization)|(clear ipsec)|(show firewall)|
(show interfaces)|(show version)"
        juniperDenyCmds = "(show ospf)|(show log)|(show system certificate)|(show ppp)|(show
policy)|restart|request"
    }
}
user = tom {
    ...
    service = junos-exec {
        juniperLocalUserName = auth
        juniperAllowCmds = "(start shell)|(show cli authorization)"
        juniperDenyCmds = "show ppp statistics"
    }
}
user = dave {
    ...
    service = junos-exec {
        juniperLocalUserName = auth
        juniperAllowCmds = "show bgp neighbor"
        juniperDenyCmds = "telnet | ssh"
    }
}

```

```

    }
}

```

This example configures the sales and engineering user templates on the local device. The TACACS+ server configuration file then assigns users to specific templates.

```

[edit]
system {
  login {
    user sales {
      uid 6003;
      class sales-class;
    }
    user engineering {
      uid 6004;
      class super-user;
    }
  }
}

```

When the users Simon and Rob are authenticated, the router or switch applies the sales local user template. When login users Harold and Jim are authenticated, the router or switch applies the engineering local user template.

```

user = simon {
  ...
  service = junos-exec {
    local-user-name = sales
    allow-commands = "configure"
    deny-commands = "shutdown"
  }
}
user = rob {
  ...
  service = junos-exec {
    local-user-name = sales
    allow-commands = "(request system) | (show rip neighbor)"
    deny-commands = "clear"
  }
}
user = harold {

```

```

...
service = junos-exec {
    local-user-name = engineering
    allow-commands = "monitor | help | show | ping | traceroute"
    deny-commands = "configure"
}
}
user = jim {
    ...
    service = junos-exec {
        local-user-name = engineering
        allow-commands = "show bgp neighbor"
        deny-commands = "telnet | ssh"
    }
}

```

## Configure Remote User Template Accounts for User Authentication

The network device can map remotely-authenticated users to a locally defined user account or user template account, which determines authorization. The `remote` template account is a special user template. By default, Junos OS assigns remotely-authenticated users to the `remote` template account, if configured, when:

- The authenticated user does not have a user account configured on the local device.
- The remote authentication server either does not assign the user to a local user template, or the template that the server assigns is not configured on the local device.

To configure the `remote` template account, include the `user remote` statement at the `[edit system login]` hierarchy level, and specify the login class for users assigned to the `remote` template:

```

[edit system login]
user remote {
    full-name "remote users";
    uid uid-value;
    class class-name;
}

```

To configure different access privileges for users who share the `remote` template account, you can use vendor-specific attributes in the authentication server configuration file to allow or deny specific commands and configuration hierarchies for a user.

## Example: Create Template Accounts

### IN THIS SECTION

- [Requirements | 150](#)
- [Overview | 150](#)
- [Configuration | 151](#)
- [Verification | 153](#)

This example shows how to create template accounts.

### Requirements

No special configuration beyond device initialization is required before configuring this feature.

### Overview

You can create template accounts that are shared by a set of users when you are using LDAPS, RADIUS, or TACACS+ authentication. When an authenticated user is assigned to a template account, the CLI username is the login name, but the user inherits privileges, file ownership, and effective user ID from the template account.

By default, Junos OS assigns remotely-authenticated users to the `remote` template account when:

- The authenticated user does not have a user account configured on the local device.
- The remote authentication server either does not assign the user to a local user template, or the template that the server assigns is not configured on the local device.

In this example, you create the `remote` template account and set the username to `remote` and the login class for the user as `operator`. The device assigns the `remote` template to users who are authenticated by LDAPS, RADIUS, or TACACS+ but who do not have a local user account or belong to a different local template account.

You then create a local template account and set the username as admin and the login class as superuser. You use local template accounts when you need to assign remotely authenticated users to different login classes. Thus, each template can grant a different set of permissions appropriate for the users assigned to that user template.

## Configuration

### IN THIS SECTION

- [Create a Remote Template Account | 151](#)
- [Create a Local Template Account | 152](#)

## Create a Remote Template Account

### Step-by-Step Procedure

To create the remote template account:

- Set the username and the login class for the remote user.

```
[edit system login]
user@host# set user remote class operator
```

## Results

In configuration mode, confirm your configuration by entering the `show system login` command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show system login
    user remote {
        class operator;
    }
```

After you configure the device, enter `commit` in configuration mode.

## Create a Local Template Account

### Step-by-Step Procedure

To create a local template account:

1. Set the username and the login class for the user template.

```
[edit system login]
user@host# set user admin class superuser
```

### Results

In configuration mode, confirm your configuration by entering the `show system login` command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show system login
    user admin {
        class super-user;
    }
```

After you configure the device, enter `commit` in configuration mode.

**NOTE:** To completely set up LDAPS, RADIUS, or TACACS+ authentication, you must configure at least one LDAPS, RADIUS, or TACACS+ server and specify a system authentication order. For more information, see the following tasks:

- Configure a RADIUS server. See ["Example: Configure a RADIUS Server for System Authentication" on page 198](#).
- Configure a TACACS+ server. See ["Example: Configure a TACACS+ Server for System Authentication" on page 232](#).
- Configure an LDAP server. See ["Configure LDAP Authentication over TLS" on page 177](#).
- Configure system authentication order. See ["Example: Configure Authentication Order" on page 166](#).

## Verification

### IN THIS SECTION

- [Verify the Template Accounts Creation | 153](#)

Confirm that the configuration is working properly.

### Verify the Template Accounts Creation

#### Purpose

Verify that the template accounts have been created.

#### Action

In operational mode, enter the `show system login` command.

## What Are Remote Authentication Servers?

You probably already use a remote authentication server (or servers) in your network. Using these servers is a best practice, because they allow you to create a consistent set of user accounts centrally for all devices in your network. Managing user accounts is much easier when you use remote authentication servers to implement an authentication, authorization, and accountability (AAA) solution in your network.

Most enterprises use one or more of three basic remote authentication methods: LDAPS, RADIUS, and TACACS+. Junos OS supports all three methods, and you can configure Junos OS to query any type of remote authentication server. The idea behind an LDAPS, RADIUS, or TACACS+ server is simple: Each acts as a central authentication server that routers, switches, security devices, and servers can use to authenticate users as they attempt to access these systems. Think of the advantages that a central user directory offers for authentication auditing and access control in a client/server model. The LDAPS, RADIUS, and TACACS+ authentication methods offer comparable advantages for your network infrastructure.

Using a central server has multiple advantages over the alternative of creating local users on each device, a time-consuming and error-prone task. A central authentication system also simplifies the use of one-time password systems such as SecureID, which offer protection against password sniffing and

password replay attacks. In such attacks, someone can use a captured password to pose as a system administrator.

- **RADIUS**—You should use RADIUS when your priorities are interoperability and performance.
  - **Interoperability**—RADIUS is more interoperable than TACACS+, primarily because of the proprietary nature of TACACS+. While TACACS+ supports more protocols, RADIUS is universally supported.
  - **Performance**—RADIUS is much lighter on your routers and switches than TACACS+. For this reason, network engineers generally prefer RADIUS over TACACS+.
- **TACACS+**—You should use TACACS+ when your priorities are security and flexibility.
  - **Security**—TACACS+ is more secure than RADIUS. Not only is the full session encrypted, but authorization and authentication are done separately to prevent anyone from trying to force their way into your network.
  - **Flexibility**—Transmission Control Protocol (TCP) is a more flexible transport protocol than UDP. You can do more with TCP in more advanced networks. In addition, TACACS+ supports more of the enterprise protocols, such as NetBIOS.
- **LDAPS**—You should use LDAPS when your priorities are security and scalability.
  - **Security**—For enhanced security, LDAPS uses a private key to encrypt data. The private key prevents unauthorized access to information and secures data effectively, unlike the shared key that RADIUS and TACACS+ use.
  - **Scalability**—LDAPS provides higher scalability without loss of reliability. There is no limit to the number of users LDAPS supports. Users maintain their own certificates, and certificate authentication involves data exchange between client and server only.

#### Release History Table

Release	Description
Junos OS Release 20.2R1	Starting in Junos OS Release 20.2R1, we introduce LDAP support for login users with TLS security between the LDAPS client (device running Junos OS) and the LDAPS server.

# Authentication Order for LDAPS, RADIUS, TACACS+, and Local Password

## IN THIS SECTION

- [Authentication Order Overview | 155](#)
- [Configure the Authentication Order for LDAPS, RADIUS, TACACS+ and Local Password Authentication | 164](#)
- [Example: Configure Authentication Order | 166](#)
- [Example: Configure System Authentication for LDAPS, RADIUS, TACACS+, and Password Authentication | 171](#)

Junos OS supports different authentication methods, including local password authentication, LDAPS, RADIUS, and TACACS+, to control access to the network.

When you configure a device to support multiple authentication methods, you can prioritize the order in which the device tries the different methods. This topic discusses how the authentication order works and how to configure it on a device.

## Authentication Order Overview

### IN THIS SECTION

- [Using Remote Authentication | 156](#)
- [How to Use Local Password Authentication | 157](#)
- [Order of Authentication Attempts | 157](#)

You (the network administrator) can configure the `authentication-order` statement to prioritize the order in which Junos OS tries different authentication methods to verify user access to a router or switch. If you

do not set an authentication order, by default, Junos OS verifies users based on their configured local passwords.

If the authentication order includes LDAPS, RADIUS, or TACACS+ servers, but the servers do not respond to a request, Junos OS always defaults to trying local password authentication as a last resort.

If the authentication order includes LDAPS, RADIUS, or TACACS+ servers, but the servers reject the request, the handling of the request is more complicated.

- If `password` (local password authentication) *is* included at the end of the authentication order and the remote authentication servers reject the authentication request, the device attempts local password authentication.
- If `password` (local password authentication) is *not* included in the authentication order and the remote authentication servers reject the authentication request, the request ends with the rejection.

Thus, the device must include `password` as a final authentication order option for the device to attempt local password authentication in the event that the remote authentication servers reject the request.

If the authentication order is set to `authentication-order password`, then the device uses only local password authentication.

## Using Remote Authentication

You can configure Junos OS to be an LDAPS, RADIUS, or TACACS+ authentication client (or a combination).

If an authentication method included in the `authentication-order` statement is not available, or if the authentication method is available but the corresponding authentication server returns a reject response, Junos OS tries the next authentication method included in the `authentication-order` statement.

The LDAP, RADIUS, or TACACS+ server authentication might fail for one or more of the following reasons:

- The authentication method is configured, but the corresponding authentication servers are not configured. For instance, the RADIUS and TACACS+ authentication methods are included in the `authentication-order` statement, but the corresponding RADIUS or TACACS+ servers are not configured at the respective `[edit system radius-server]` and `[edit system tacplus-server]` hierarchy levels.
- The authentication server does not respond before the configured timeout value for that server, or before the default timeout, if no timeout is configured.
- The authentication server is not reachable because of a network problem.

The authentication server might return a reject response for one or both of the following reasons:

- The user profile of a user accessing a router or switch is not configured on the authentication server.

- The user enters incorrect logon credentials.

## How to Use Local Password Authentication

You can explicitly configure the password authentication method in the `authentication-order` statement or use this method as a fallback mechanism when remote authentication servers fail. The password authentication method consults the local user profiles configured at the `[edit system login]` hierarchy level. Users can log in to a router or switch using their local username and password in the following scenarios:

- The password authentication method (`password`) is explicitly configured as one of the authentication methods in the `authentication-order` statement.

In this case, the device tries local password authentication if no previous authentication method accepts the logon credentials. This is true whether the previous authentication methods fail to respond or they return a reject response because of an incorrect username or password.

- The password authentication method is not explicitly configured as one of the authentication methods in the `authentication-order` statement.

In this case, the operating system only tries local password authentication if all configured authentication methods fail to respond. The operating system does not use local password authentication if any configured authentication method returns a reject response because of an incorrect username or password.

## Order of Authentication Attempts

[Table 10 on page 158](#) describes how the `authentication-order` statement at the `[edit system]` hierarchy level determines the procedure that Junos OS uses to authenticate users for access to a device.

**Table 10: Order of Authentication Attempts**

Syntax	Order of Authentication Attempts
<code>authentication-order radius;</code>	<ol style="list-style-type: none"> <li>1. Try configured RADIUS authentication servers.</li> <li>2. If an LDAP server is available and authentication is accepted, grant access.</li> <li>3. If the LDAP servers fail to respond or the servers return a reject response, try local password authentication, because it is explicitly configured in the authentication order.</li> </ol>
<p>authentication-order [ ldaps tacplus ];</p>	<ol style="list-style-type: none"> <li>1. Try configured LDAP authentication servers.</li> <li>2. If an LDAP server is available and authentication is accepted, grant access.</li> <li>3. If the LDAP servers fail to respond or the servers return a reject response, try configured TACACS+ servers.</li> <li>4. If a TACACS+ server is available and authentication is accepted, grant access.</li> <li>5. If a TACACS+ server is available but authentication is rejected, deny access.</li> <li>6. If no LDAP or TACACS+ servers are available, try local password authentication.</li> </ol>

```
authentication-order [ ldaps tacplus password ];
```

1. Try configured LDAP authentication servers.
2. If an LDAP server is available and authentication is accepted, grant access.
3. If the LDAP servers fail to respond or the servers return a reject response, try configured TACACS+ servers.
4. If a TACACS+ server is available and authentication is accepted, grant access.
5. If the TACACS+ servers fail to respond or the servers return a reject response, try local password authentication, because it is explicitly configured in the authentication order.

**NOTE:** If SSH public keys are configured, SSH user authentication first tries to perform public key authentication before using the authentication methods configured in the `authentication-order` statement. If you want SSH logins to use the authentication methods configured in the `authentication-order` statement without first trying to perform public key authentication, do not configure SSH public keys.

## Configure the Authentication Order for LDAPS, RADIUS, TACACS+ and Local Password Authentication

Using the `authentication-order` statement, you can prioritize the order in which Junos OS tries the different authentication methods when verifying user access to a router or switch. If you do not set an authentication order, by default, users are verified based on their locally configured passwords.

When configuring a password using plain text and relying on Junos OS to encrypt it, you are still sending the password over the Internet in plain text. Using pre-encrypted passwords is more secure because it means that the plain text of the password never has to be sent over the internet. Also, with passwords, only one user can be assigned to a password at a time.

On the other hand, LDAPS, RADIUS, and TACACS+ encrypt passwords. These authentication methods let you assign a set of users at a time instead of assigning users one by one. But here are how these authentication systems differ:

- RADIUS uses UDP; TACACS+ and LDAPS use TCP.

- RADIUS encrypts only the password during transmission, whereas TACACS+ and LDAPS encrypt the entire session.
- RADIUS and LDAPS combine authentication (device) and authorization (user), whereas TACACS+ separates authentication, authorization, and accountability.

In short, TACACS+ is more secure than RADIUS. However, RADIUS has better performance and is more interoperable. RADIUS is widely supported, whereas TACACS+ is a Cisco proprietary product and not widely supported outside of Cisco.

LDAPS is more secure than RADIUS and TACACS+, as it relies on a private key mechanism instead of the shared key used in the case of RADIUS and TACACS+. The TLS protocol secures the transmission of data effectively between the LDAP client and the LDAP server.

You can configure the authentication order based on your system, its restrictions, and your IT policy and operational preferences.

To configure the authentication order, include the `authentication-order` statement at the `[edit system]` hierarchy level.

```
[edit system]
user@host# set authentication-order [authentication-methods ]
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

The following are the possible authentication order entry options:

- `radius`—Verify the user using RADIUS authentication servers.
- `tacplus`—Verify the user using TACACS+ authentication servers.
- `ldaps`—Verify the user using LDAPS authentication servers.
- `password`—Verify the user using the username and password configured locally in the authentication statement at the `[edit system login user]` hierarchy level.

The Challenge Handshake Authentication Protocol (CHAP) authentication sequence cannot take more than 30 seconds. If it takes longer than 30 seconds to authenticate a client, the authentication is abandoned and a new sequence is initiated.

For example, assume that you configure three RADIUS servers so that the router or switch attempts to contact each server three times. Assume further that, with each retry, the server times out after 3 seconds. In this scenario, the maximum time given to the RADIUS authentication method before CHAP considers it a failure is 27 seconds. If you add more RADIUS servers to this configuration, they

might not be contacted because the authentication process might be abandoned before these servers are tried.

Junos OS enforces a limit on the number of standing authentication server requests that the CHAP authentication can have at one time. Thus, an authentication server method—RADIUS, for example—might fail to authenticate a client when this limit is exceeded. If authentication fails, the authentication sequence is reinitiated by the router or switch until authentication succeeds and the link is established. However, if the RADIUS servers are unavailable and additional authentication methods such as `tacplus` or `password` are also configured, the next authentication method is tried.

The following example shows how to configure `radius` and `password` authentication:

```
[edit system]
user@switch# set authentication-order [ radius password ]
```

The following example shows how to insert the `tacplus` statement after the `radius` statement:

```
[edit system]
user@switch# insert authentication-order tacplus after radius
```

The following example shows how to delete the `radius` statement from the authentication order:

```
[edit system]
user@switch# delete authentication-order radius
```

## Example: Configure Authentication Order

### IN THIS SECTION

- [Requirements | 167](#)
- [Overview | 167](#)
- [Configuration | 167](#)
- [Verification | 170](#)

This example shows how to configure authentication order for user login.

## Requirements

Before you begin, perform the initial device configuration. See the Getting Started Guide for your device.

## Overview

You can configure the authentication method order that a device uses to verify user access to the device. For each login attempt, the device tries the authentication methods in the order configured, until the password matches or all authentication methods have been tried. If you do not configure remote authentication, users are verified based on their configured local passwords.

This example configures the device to attempt user authentication with RADIUS authentication services first, then with TACACS+ authentication services, and finally with local password authentication.

When you use local password authentication, you must create a local user account for every user who wants to access the system. However, when you use remote authentication servers, you can create template accounts (for authorization purposes) that a set of users shares. When a user is assigned to a template account, the command-line interface (CLI) username is the login name; however, the user inherits the privileges, file ownership, and effective user ID from the template account.

## Configuration

### IN THIS SECTION

- [Procedure](#) | 167

## Procedure

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the [edit] hierarchy level, and then enter `commit` in configuration mode.

```
delete system authentication-order
set system authentication-order radius
```

```
insert system authentication-order tacplus after radius
insert system authentication-order password after tacplus
```

## GUI Quick Configuration

### Step-by-Step Procedure

To configure authentication order:

1. In the J-Web user interface, select **Configure>System Properties>User Management**.
2. Click **Edit**. The **Edit User Management** dialog box appears.
3. Select the **Authentication Method and Order** tab.
4. Under **Available Methods**, select the authentication method the device should use to authenticate users. Use the arrow button to move the item to the **Selected Methods** list. Available methods include:
  - RADIUS
  - TACACS+
  - Local Password

If you want to use multiple methods to authenticate users, repeat this step to add the other methods to the **Selected Methods** list.

5. Under **Selected Methods**, use the **Up Arrow** and **Down Arrow** to specify the order in which the device should execute the authentication methods.
6. Click **OK** to check your configuration and save it as a candidate configuration.
7. After you configure the device, click **Commit Options>Commit**.

### Step-by-Step Procedure

To configure authentication order:

1. Delete any existing authentication-order statement.

```
[edit]
user@host# delete system authentication-order
```

2. Add RADIUS authentication to the authentication order.

```
[edit]  
user@host# set system authentication-order radius
```

3. Add TACACS+ authentication to the authentication order.

```
[edit]  
user@host# insert system authentication-order tacplus after radius
```

4. Add local password authentication to the authentication order.

```
[edit]  
user@host# insert system authentication-order password after tacplus
```

## Results

In configuration mode, confirm your configuration by entering the `show system authentication-order` command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]  
user@host# show system authentication-order  
authentication-order [ radius tacplus password ];
```

After you configure the device, enter `commit` in configuration mode.

**NOTE:** To completely set up LDAPS, RADIUS, or TACACS+ authentication, you must configure at least one LDAPS, RADIUS, or TACACS+ server and create user accounts or user template accounts.

- Configure an LDAP server over TLS. See ["Configure LDAP Authentication over TLS" on page 177](#)
- Configure a RADIUS server. See ["Example: Configure a RADIUS Server for System Authentication" on page 198](#).

- Configure a TACACS+ server. See ["Example: Configure a TACACS+ Server for System Authentication" on page 232](#).
- Configure a user. See ["Example: Configure New User Accounts" on page 29](#).
- Configure template accounts. See ["Example: Create Template Accounts" on page 150](#).

## Verification

### IN THIS SECTION

- [Verify the Authentication Order Configuration | 170](#)

Confirm that the configuration is working properly.

### Verify the Authentication Order Configuration

#### Purpose

Verify that the device uses the authentication methods in the order configured.

#### Action

Create a test user that has a different password for each authentication method. Log in to the device using the different passwords. Verify that the device queries subsequent authentication methods when the previous methods reject the password or fail to respond.

Alternatively, in a test environment, you can deactivate the authentication server configuration or the local user account configuration (or both) to test each authentication method. For example, to test the TACACS+ server, you can deactivate the RADIUS server configuration and the user's local account. However, if you deactivate the user's local account, you must ensure that the user still maps to a local user template account such as the `remote` user template.

## Example: Configure System Authentication for LDAPS, RADIUS, TACACS+, and Password Authentication

The following example shows how to configure system authentication for LDAPS, RADIUS, TACACS+, and password authentication on a device running Junos OS.

In this example, only the user Philip and users authenticated by a remote LDAP server can log in. If a user logs in and is not authenticated by the LDAP server, the user is denied access to the router or switch. If the LDAP server is not available, the user is authenticated using the password authentication method and allowed access to the router or switch. For more information about the password authentication method, see ["Authentication Order Overview" on page 155](#).

When Philip tries to log in to the system, if the LDAP server authenticates him, he is given access and privileges for the super-user class. Local accounts are not configured for other users. When they log in to the system and the LDAP server authenticates them, they are given access using the same user ID (UID) 9999 and the privileges associated with the operator class.

```
[edit]
system {
  authentication-order ldaps;
  login {
    user philip {
      full-name "Philip";
      uid 1001;
      class super-user;
    }
    user remote {
      full-name "All remote users";
      uid 9999;
      class operator;
    }
  }
}
```

**NOTE:** For authorization purposes, you can use a template account to create a single account that a set of users can share at the same time. For example, when you create a remote template account, a set of remote users can concurrently share a single UID. For more information about template accounts, see ["Example: Configure Authentication Order" on page 166](#).

When a user logs in to a device, the LDAP, RADIUS, or TACACS+ server uses the user's login name for authentication. If the authentication server authenticates the user successfully and the user is not configured at the [edit system login user] hierarchy level, this is the result: The device uses the default remote template user account for the user, provided a remote template account is configured at the edit system login user remote hierarchy level. The remote template account serves as a default template user account for all users that are authenticated by the authentication server but lack a locally configured user account on the device. Such users share the same login class and UID.

To configure an alternate template user, specify the user-name parameter returned in the LDAPS authentication response packet. Not all LDAP servers allow you to change this parameter. The following shows a sample Junos OS configuration:

```
[edit]
system {
  authentication-order ldaps;
  login {
    user philip {
      full-name "Philip";
      uid 1001;
      class super-user;
    }
    user operator {
      full-name "All operators";
      uid 9990;
      class operator;
    }
    user remote {
      full-name "All remote users";
      uid 9999;
      class read-only;
    }
  }
}
```

Assume that your LDAP server is configured with the following information:

- User Philip with password "olympia"
- User Alexander with password "bucephalus" and username "operator"
- User Darius with password "redhead" and username "operator"
- User Roxane with password "athena"

Philip would be given access as a superuser (super-user) because of having a unique, local user account. Alexander and Darius share UID 9990 and have access as operators. Roxane has no template-user override and therefore shares access with all the other remote users, getting read-only access.

#### Release History Table

Release	Description
20.2R1	Starting in Junos OS Release 20.2R1, we introduce Lightweight Directory Access Protocol (LDAP) support for user login with Transport Layer Security (TLS) between the LDAP TLS (LDAPS) client and the LDAPS server.

## LDAP over TLS Authentication

### IN THIS SECTION

- [LDAP Authentication over TLS | 173](#)
- [Configure LDAP Authentication over TLS | 177](#)
- [Juniper Networks Vendor-Specific RADIUS and LDAP Attributes | 187](#)

The Junos OS supports LDAP over TLS (LDAPS) authentication and authorization for Junos OS user login with TLS security between the device running Junos OS (which is the LDAPS client) and the LDAPS server. For more information, read this topic.

## LDAP Authentication over TLS

## Junos OS User Authentication Overview

Junos OS authenticates users trying to log in either locally or by using a centralized database. Local authentication or authorization is possible for users whose username and password are configured using the Junos OS CLI or RPCs. In Junos OS Release 20.2R1, Junos OS supports LDAP with TLS security (LDAPS) support for user login and ensures secure transmission of data between the LDAPS client and the LDAPS server.

In releases before Junos OS Release 20.2R1, Junos OS supports centralized user authentication and authorization through standard RADIUS and TACACS protocols.

**Figure 5: Centralized Authentication, Authorization, and Accounting (AAA) Setup**

Junos OS supports these methods of user authentication:

- Local password authentication
- LDAP over TLS (LDAPS)
- RADIUS
- TACACS+

## Benefits of LDAP Authentication over TLS

- **Encryption and data integrity**—LDAPS ensures that user credentials are encrypted, thereby maintaining privacy of communications. The user encrypts the data using the private key and only the intended recipient that possesses the private key can decrypt the signed data using the signer's public key. This ensures data integrity.
- **Enhanced security**—The TLS protocol ensures the data is securely sent and received over the network. TLS uses certificates to authenticate and encrypt the communication that provides advanced security.
- **Scalability**—LDAPS provides greater performance and scalability without loss of reliability. There is no limit to the number of users who can be supported using this feature as users maintain their own certificates, and certificate authentication involves exchange of data between client and server only.

## Supported and Unsupported Features

- Junos OS supports LDAPS for user authentication and authorization only. Junos OS does not support accounting. over LDAPS.
- The LDAPS client is implemented and integrated as part of Junos OS. However, implementation of the LDAPS server on Junos OS is not supported. Instead, this feature is implemented using the OpenLdap 2.4.46 server.

## LDAP Overview

Lightweight Directory Access Protocol (LDAP) is a standard application protocol for accessing and maintaining distributed directory information services over an Internet Protocol (IP) network. You can accomplish authentication and authorization using the following rich set of LDAP security functions such as:

- Search
- Retrieve
- Directory content manipulation

## Transport Layer Security (TLS) Overview

TLS is an application-level protocol that provides encryption technology for the Internet. It is the most widely used security protocol for applications that require data to be securely exchanged over a network, such as file transfers, VPN connections, instant messaging, and voice over IP (VoIP). TLS relies on certificates and private-public key exchange pairs to secure the transmission of data between the

LDAPS client and the LDAPS server. LDAPS uses local certificates that are dynamically acquired from the Junos public key infrastructure (PKI) .

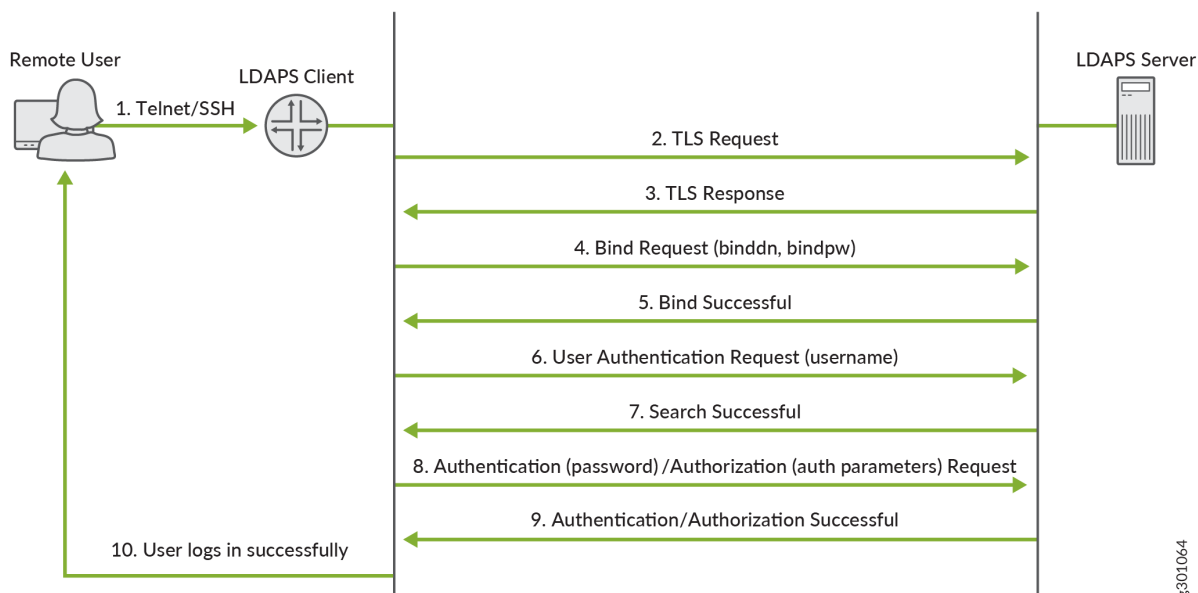

TLS ensures secure transmission of data between a client and a server effectively and ensures privacy of communications, authentication, confidentiality, and data integrity. You can use the TLS protocol for certificate exchange, mutual authentication, and cipher negotiation to secure the stream from potential tampering and ethical hacking.

## How LDAPS Authentication Works

To provide secure LDAPS support for Junos OS operator login, user credentials and configurations are stored in either the LDAPS server or the LDAP-supported databases. An LDAPS client on the device running Junos OS communicates with a configured LDAPS server. To achieve this, the LDAPS client is implemented and integrated as part of the device running Junos OS.

Figure 6 on page 176 shows the LDAPS authentication process.

**Figure 6: LDAPS Authentication Process**

1. A remote user logs in to a device running Junos OS through SSH, TELNET or any other login utility.
2. The LDAPS client (which is the device running Junos OS) establishes a TCP connection with the LDAPS authorization server using a TLS protocol request.
3. After the client receives the TLS response, the client and server authenticate their identities.

4. The LDAPS client authenticates itself using the proxy account that is preconfigured on the LDAPS server using the bind request (binddn and bindpw).
5. If the bind operation is successful, the LDAPS server sends an acknowledgment to the LDAPS client.
6. The LDAPS client then sends an authentication request to the LDAPS server with the login credentials of the user trying to log in.
7. After successful authorization, the LDAPS client notifies the user of the successful login. The authorization data of the user is saved into a file that is used later to enforce authorization.
8. The client closes the connection with the LDAPS server.

## Configure LDAP Authentication over TLS

### IN THIS SECTION

- [Configure the Order of Authentication | 177](#)
- [Configure LDAPS Client | 178](#)
- [Configure LDAPS Server | 181](#)
- [Configure TLS Parameters | 183](#)
- [Configure System Administrative Parameters for LDAPS Authentication | 185](#)

LDAP over TLS (LDAPS) is a method of authenticating users who attempt to access the device running Junos OS with TLS security between the LDAPS client and the LDAPS server. This topic includes the following tasks:

### Configure the Order of Authentication

Junos OS supports the following methods of user authentication: local password authentication, LDAP over TLS (LDAPS), RADIUS, TACACS+.

You can use the `authentication-order` statement to prioritize the order in which Junos OS uses the different authentication methods when verifying user access to a device running Junos OS. If you do not set an authentication order, by default Junos OS verifies users based on their configured passwords.

If a user tries to log in and if `authentication-order` has the `ldaps` option configured, the user's credentials are passed to the external LDAP server for user validation.

To configure the authentication order, include the authentication-order statement at the [edit system] hierarchy level:

```
[edit system]
authentication-order [ method1 method2...];
```

For example:

```
[edit system]
user@host# set authentication-order [ldaps radius password];
```

The following are the possible authentication order entry options:

- **ldaps**—Verify the user using secure LDAP authentication servers.
- **password**—Verify the user using the username and password configured locally by including the authentication-order statement at the [edit system login user] hierarchy level.
- **radius**—Verify the user using RADIUS authentication servers.
- **tacplus**—Verify the user using TACACS+ authentication servers.

## Configure LDAPS Client

To configure LDAP authentication on the client:

1. Configure an IPv4 or IPv6 server address.

```
[edit]
user@host# set system ldap-server server-ip-address
```

For example, configure the following IPv4 or IPv6 address:

```
[edit]
user@host# set system ldap-server 192.168.17.28
[edit]
user@host# set system ldap-server 2001:db8:4139:e382:8000:36bf:3fff:fdd2
```

The server address is a unique IPv4 or IPv6 address that is assigned to a particular LDAP server and used to route information to the server.

2. Configure the distinguished name of the search base (LDAP base) that specifies the base of user directory. Every entry in the directory has a distinguished name (DN). The DN is the name that uniquely identifies an entry in the directory.

```
[edit system]
user@host# set ldap-server base base domain
```

For example, if the domain is example.com, then the syntax is dc=example, dc=com.

```
[edit system]
user@host# set ldap-server base dc=example,dc=com
```

3. Configure the distinguished name (binddn) to bind the LDAPS client with the LDAPS server.

```
[edit system]
user@host# set ldap-server binddn node proxyacc username
```

For example, if the domain is example.com, then the syntax is dc=example, dc=com. cn is the common name.

```
[edit system]
user@host# set ldap-server binddn cn=manager,dc=example,dc=com
```

4. Configure the public key (LDAP bindpw) password.

```
[edit system]
user@host# set ldap-server bindpw node proxyaccount password
```

For example, to set the password as secret:

```
[edit system]
user@host# set ldap-server bindpw secret
```

5. To enable LDAPS, you must specify the name of the local certificate. For information about configuring the local certificate and certificate authority (CA), see *Configuring Digital Certificates*. Specify the name of the local certificate to be used for TLS communications.

You generate the local digital certificate request using `request security pki generate-certificate-request`. Sign the certificates offline and install on the device using `request security pki ca-certificate load`.

```
[edit system]
user@host# set ldap-server ldaps-cert certificate-name
```

For example, to specify the name of the local certificate as `ldap-tls-cert`:

```
[edit system]
user@host# set ldap-server ldaps-cert ldap-tls-cert
```

**NOTE:** The *certificate name* is the name of the public-private key pair mapped to the local digital certificate that is added using `request security pki ca-certificate load`

6. Specify a port on the LDAPS server to which the LDAPS client can connect to.

```
[edit system]
user@host# set ldap-server port port-number
```

For example, to set the port number as 432 for the LDAPS server:

```
[edit system]
user@host# set port ldap-server 432
```

7. By default, Junos OS routes authentication and authorization packets for LDAPS through the default routing instance. LDAPS also supports a management interface in a nondefault VRF instance.

When you configure the `mgmt_junos` option for the `routing-instance` and the `management-interfaces` statement, the management instances `mgmt_junos` routes the , LDAPS packets.

```
[edit system]
user@host# set ldap-server server-address routing-instance routing-instance
```

For example:

```
[edit system]
user@host# set ldap-server 10.209.11.93 routing-instance mgmt_junos
```

## Configure LDAPS Server

OpenLDAP server is one of the open-source implementations of LDAP and LDAPS. We've implemented the LDAP over TLS authentication and authorization feature using the OpenLDAP 2.4.46 server.

**NOTE:** You can configure a maximum of two LDAPS servers.

To configure a typical OpenLDAP server:

1. Define attribute types for LDAP user authorization parameters in the schema file of the LDAP server.

For a typical OpenLDAP server, the attribute can be part of **nis.schema**:

```
attributetype ( <serial number> NAME 'juniperLocalUserName'
EQUALITY caseExactIA5Match
SUBSTR caseExactIA5SubstringsMatch
SYNTAX <OID as per schema>)
```

```
attributetype (<serial number> NAME 'juniperUserPerms'
EQUALITY caseExactIA5Match
SUBSTR caseExactIA5SubstringsMatch
SYNTAX <OID as per schema>)
```

```
attributetype ( <serial number> NAME 'juniperAllowCmds'
EQUALITY caseExactIA5Match
SUBSTR caseExactIA5SubstringsMatch
SYNTAX <OID as per schema>)
```

```
attributetype ( <serial number> NAME 'juniperDenyCmds'
EQUALITY caseExactIA5Match
SUBSTR caseExactIA5SubstringsMatch
SYNTAX <OID as per schema>)
```

```
attributetype ( <serial number> NAME 'juniperAllowConf'
EQUALITY caseExactIA5Match
```

```
SUBSTR caseExactIA5SubstringsMatch
SYNTAX <OID as per schema>)
```

```
attributetype ( <serial number> NAME 'juniperDenyConf'
EQUALITY caseExactIA5Match
SUBSTR caseExactIA5SubstringsMatch
SYNTAX <OID as per schema>)
```

```
attributetype ( <serial number> NAME 'juniperAllowCmdsRegexps'
EQUALITY caseExactIA5Match
SUBSTR caseExactIA5SubstringsMatch
SYNTAX <OID as per schema>)
```

```
attributetype ( <serial number> NAME 'juniperDenyCmdsRegexps'
EQUALITY caseExactIA5Match
SUBSTR caseExactIA5SubstringsMatch
SYNTAX <OID as per schema>)
```

```
attributetype ( <serial number> NAME NAME 'juniperDenyConfRegexps'
EQUALITY caseExactIA5Match
SUBSTR caseExactIA5SubstringsMatch
SYNTAX <OID as per schema>)
```

2. Include the schema file defined as part of Step 1 in the configuration file of the LDAP server. For a typical OpenLDAP server, you can load the definitions to the LDAP server by defining attributes in **nis.schema** and including the **nis.schema** schema file in the **slapd.conf** file.
3. Configure the user authorization parameters in an LDAP Data Interchange Format (LDIF) file.

For example:

```
user.ldif snippet:
dn: uid=u_ldap,dc=example,dc=com
uid: u_ldap
sn: User
cn: Auth User
objectClass: person
objectClass: organizationalPerson
```

```

objectClass: posixAccount
objectClass: top
objectClass: shadowAccount
objectClass: juniperAuthAccount
loginShell: /bin/bash
homeDirectory: /home/u_ldap
userPassword: secret
uidNumber: 1002
gidNumber: 1002
shadowMax: 10
juniperLocalUserName: remote
juniperUserPerms: clear view shell admin-control
juniperAllowConf: (show cli authorization)|(ping)
juniperDenyConf: (show ospf)|(show log)

```

4. Load the user configuration in a running LDAP server. In a typical OpenLDAP setup, you can load the LDIF file with the following command:

```

ldapadd -D 'cn=manager,dc=example,dc=com' -f /.ldif -w -> ldapadd -D <binddn> -f /.ldif -w
<bindpw>

```

After you complete the preceding steps, any client can log in with the username and password mentioned in the LDIF file.

## Configure TLS Parameters

The TLS protocol ensures that data is securely sent and received over the network. TLS uses certificates to authenticate and encrypt the communication. The client authenticates the server by requesting its certificate and public key. Optionally, the server can also request a certificate from the client, thus ensuring mutual authentication.

For TLS handshake to be successful, the client must have the server certificate authority (CA) profile to validate the server certificate. The server may or may not have the client CA based on the settings. However, if the server mandates client certificate, the server must have the client CA to validate the certificate. Later, the public key is used to encrypt and private key to decrypt the data respectively.

The CA profile defines every parameter associated with a specific certificate to establish secure connection between two endpoints. For more information about configuring CA profiles, see *Certificate Authority*.

To configure TLS parameters, you need to perform the following tasks:

- Configure security public key infrastructure (PKI) traceoptions.

- Create a CA profile.
  - Create a revocation check to specify a method for checking certificate revocation.
1. Configure PKI traceoptions if you want to retrieve syslog messages from the PKI.
    - To trace syslog messages from the TLS certificate validation during the initial handshake:

```
[edit]
user@host# set security pki traceoptions flag all
```

- To trace the syslog messages output to a file:

```
[edit]
user@host# set security pki traceoptions flag file name
```

For example, to trace the output to the ldap\_pki file:

```
[edit]
user@host# set security pki traceoptions flag ldap_pki
```

2. Create a CA profile to validate the server certificate.

A root certificate is issued by a trusted CA. A subordinate CA is the CA between the root CA and end entity certificates. The root CA is self-signed and signs all subordinate CAs immediately below it. These CAs, in turn, sign the entities below them, either additional subordinate CAs or the ultimate end entity certificates.

```
[edit]
user@host# set security pki ca-profile ca-profile-name ca-identity identity
```

To create a root CA:

```
[edit]
user@host# set security pki ca-profile root ca-identity root
```

To create a subordinate CA:

```
[edit]
user@host# set security pki ca-profile subca ca-identity root
```

3. Create a revocation check to specify a method for checking certificate revocation.

```
[edit]
user@host# set security pki ca-profile root revocation-check disable
```

```
[edit]
user@host# set security pki ca-profile subca revocation-check disable
```

## Configure System Administrative Parameters for LDAPS Authentication

As part of this configuration, you're creating administrative parameters for LDAP-authenticated users.

You can assign different user templates and login classes to LDAPS-authenticated users. This allows LDAPS-authenticated users to be granted different administrative permissions on the device running Junos OS. By default, LDAPS-authenticated users use the `remote` user template, if it is configured, and the LDAPS-authenticated users are assigned to the associated class that is specified in the `remote` user template.

The username `remote` is a special case in Junos OS. It acts as a template for users that are authenticated by a remote server, but do not have a locally configured user account on the device. In this method, Junos OS applies the permissions of the `remote` template to those authenticated users without a locally defined account. All users mapped to the `remote` template are of the same login class.

In the Junos OS configuration, a user template is configured in the same way as a regular local user account, except that no local authentication password is configured because the authentication is remotely performed on the LDAPS server.

To assign login classes, permissions, and encrypted password for LDAPS-authenticated users, perform the following steps:

1. Assign the login class.

```
[edit system login]
user@host# set user remote class class
```

For example:

```
[edit system login]
user@host# set user remote class juniper
```

2. Assign permissions to the login class. You can assign all permissions for LDAPS-authenticated users or specific permissions to different users.

To assign all permissions to LDAPS-authenticated users:

```
[edit system login]
user@host# set user remote class class permissions-all
```

For example:

```
[edit system login]
user@host# set user remote class juniper permissions-all
```

To specify permissions to different users, do one of the following tasks:

- Create multiple user templates in the Junos OS configuration.
- Have the LDAPS server specify the template to be applied to the authenticated user.

#### Create multiple user templates in the Junos OS configuration.

Every user template can be assigned a different login class.

For example:

```
[edit system login]
set user RO class read-only
set user OP class operator
set user SU class super-user
set user remote full-name "default remote access user template"
set user remote class read-only
```

#### Have the LDAPS server specify the template to be applied to the authenticated user.

For an LDAPS server to indicate which user template is to be applied, it needs to include the `juniperLocalUserName` attribute (Vendor 2636, type 1, string) Juniper VSA (vendor-specific attribute) in the LDAPS Access-Accept message which indicates the user template to be used in the Junos OS device. The string value in the `juniperLocalUserName` must correspond to the name of a configured user template on the device.

From the example in the previous step, the string would be RO, OP, or SU. Configuration of the LDAPS server depends on the server being used.

If the `juniperLocalUserName` attribute is not included in the Access-Accept message or the string contains a user template name that does not exist on the device, the user is assigned to the remote user template, if configured. If it is not configured, authentication fails for the user.

After logging in, the remotely authenticated user retains the same username that was used to log in. However, the user inherits the user class from the assigned user template.

### 3. Assign an encrypted password for the user.

You must specify a password in the *encrypted-password* statement. If the password contains spaces, enclose it in quotation marks. The “secret” password used by the local router must match that used by the server.

```
[edit system login]
user@host# set user username class class name authentication encrypted-password
```

For example:

```
[edit system login]
user@host# set user u_ldap authentication encrypted-password "$ABC123"
```

## Juniper Networks Vendor-Specific RADIUS and LDAP Attributes

Junos OS supports configuring Juniper Networks RADIUS and LDAP vendor-specific attributes (VSAs) on the authentication server. These VSAs are encapsulated in a RADIUS or LDAP vendor-specific attribute with the vendor ID set to the Juniper Networks ID number, 2636.

[Table 11 on page 188](#) lists the Juniper Networks VSAs that you can configure.

Some of the attributes accept extended regular expressions, as defined in POSIX 1003.2. If the regular expression contains any spaces, operators, or wildcard characters, enclose it in quotation marks. For more information, see:

- ["Regular Expressions to Allow and Deny Operational Mode Commands, Configuration Statements, and Hierarchies" on page 61](#)

- ["Use Regular Expressions on a RADIUS or TACACS+ Server to Allow or Deny Commands"](#) on page 238

**Table 11: Juniper Networks Vendor-Specific RADIUS and LDAP Attributes**

Name	Description	Type	Length	String
Juniper-Local-User-Name	Indicates the name of the user template assigned to this user when the user logs in to a device. This attribute is used only in Access-Accept packets.	1	≥3	One or more octets containing printable ASCII characters.
Juniper-Allow-Commands	Contains an extended regular expression that enables the user to run commands in addition to those commands authorized by the user's login class permission bits. This attribute is used only in Access-Accept packets.	2	≥3	One or more octets containing printable ASCII characters, in the form of an extended regular expression.
Juniper-Deny-Commands	Contains an extended regular expression that denies the user permission to run commands authorized by the user's login class permission bits. This attribute is used only in Access-Accept packets.	3	≥3	One or more octets containing printable ASCII characters, in the form of an extended regular expression.
Juniper-Allow-Configuration	Contains an extended regular expression that enables the user to view and modify configuration statements in addition to those statements authorized by the user's login class permission bits. This attribute is used only in Access-Accept packets.	4	≥3	One or more octets containing printable ASCII characters, in the form of an extended regular expression.

**Table 11: Juniper Networks Vendor-Specific RADIUS and LDAP Attributes** *(Continued)*

Name	Description	Type	Length	String
Juniper-Deny-Configuration	Contains an extended regular expression that denies the user permission to view or modify configuration statements authorized by the user's login class permission bits. This attribute is used only in Access-Accept packets.	5	≥3	One or more octets containing printable ASCII characters, in the form of an extended regular expression.
Juniper-Interactive-Command	Indicates the interactive command entered by the user. This attribute is used only in Accounting-Request packets.	8	≥3	One or more octets containing printable ASCII characters.
Juniper-Configuration-Change	Indicates the interactive command that results in a configuration (database) change. This attribute is used only in Accounting-Request packets.	9	≥3	One or more octets containing printable ASCII characters.

Table 11: Juniper Networks Vendor-Specific RADIUS and LDAP Attributes (*Continued*)

Name	Description	Type	Length	String
Juniper-User-Permissions	<p>Contains information the server uses to specify user permissions. This attribute is used only in Access-Accept packets.</p> <p><b>NOTE:</b> When the RADIUS or LDAP server defines the Juniper-User-Permissions attribute to grant the maintenance permission or all permission to a user, the user's list of group memberships does not automatically include the UNIX wheel group. Some operations such as running the <code>su root</code> command from a local shell require wheel group membership permissions. However, when the network device defines a local user account with the permissions maintenance or all, the user is automatically granted membership to the UNIX wheel group. Therefore, we recommend that you create a user template account with the required permissions and associate individual user accounts with the user template account.</p>	10	≥3	<p>One or more octets containing printable ASCII characters.</p> <p>The string is a list of permission flags separated by a space. The exact name of each flag must be specified in its entirety.</p> <p>See <a href="#">"Access Privilege Levels Overview"</a> on page 51.</p>

**Table 11: Juniper Networks Vendor-Specific RADIUS and LDAP Attributes (Continued)**

Name	Description	Type	Length	String
Juniper-Authentication-Type	Indicates the authentication method (local database, LDAP or RADIUS server) used to authenticate a user. If the user is authenticated using a local database, the attribute value shows 'local'. If the user is authenticated using a RADIUS or LDAP server, the attribute value shows 'remote'.	11	≥5	One or more octets containing printable ASCII characters.
Juniper-Session-Port	Indicates the source port number of the established session.	12	size of integer	Integer
Juniper-Allow-Configuration-Regexps (RADIUS only)	Contains an extended regular expression that enables the user to view and modify configuration statements in addition to those statements authorized by the user's login class permission bits. This attribute is used only in Access-Accept packets.	13	≥3	One or more octets containing printable ASCII characters, in the form of an extended regular expression.
Juniper-Deny-Configuration-Regexps (RADIUS only)	Contains an extended regular expression that denies the user permission to view or modify configuration statements authorized by the user's login class permission bits. This attribute is used only in Access-Accept packets.	14	≥3	One or more octets containing printable ASCII characters, in the form of an extended regular expression.

For more information about the VSAs, see RFC 2138, *Remote Authentication Dial In User Service (RADIUS)*.

# RADIUS Authentication

## IN THIS SECTION

- [Configure RADIUS Server Authentication | 192](#)
- [Example: Configure a RADIUS Server for System Authentication | 198](#)
- [Configure RADIUS Authentication \(QFX Series or OCX Series\) | 202](#)
- [Juniper Networks Vendor-Specific RADIUS and LDAP Attributes | 205](#)
- [Use Regular Expressions on a RADIUS or TACACS+ Server to Allow or Deny Commands | 210](#)
- [Juniper-Switching-Filter VSA Guidelines, Match Conditions and Actions | 214](#)
- [Understanding RADIUS Accounting | 218](#)
- [Configure RADIUS System Accounting | 219](#)

Junos OS supports RADIUS for central authentication of users on network devices. To use RADIUS authentication on the device, you (the network administrator) must configure information about one or more RADIUS servers on the network. You can also configure RADIUS accounting on the device to collect statistical data about the users logging in to or out of a LAN and send the data to a RADIUS accounting server.

## Configure RADIUS Server Authentication

### IN THIS SECTION

- [Why Use RADIUS | 193](#)

- [Configure RADIUS Server Details | 193](#)
- [Configure RADIUS to Use the Management Instance | 197](#)

RADIUS authentication is a method of authenticating users who attempt to access a network device. The following sections describe why you would use RADIUS and how to configure it.

## Why Use RADIUS

You (the network administrator) can use different protocols for the central authentication of users on network devices including RADIUS and TACACS+. We recommend RADIUS because it is a multivendor IETF standard and its features are more widely accepted than those of TACACS+ or other proprietary systems. In addition, we recommend using a one-time-password system for increased security, and all vendors of these systems support RADIUS.

You should use RADIUS when your priorities are interoperability and performance:

- Interoperability—RADIUS is more interoperable than TACACS+, primarily because of the proprietary nature of TACACS+. While TACACS+ supports more protocols, RADIUS is universally supported.
- Performance—RADIUS is much lighter on your routers and switches. For this reason, network engineers generally prefer RADIUS over TACACS+.

## Configure RADIUS Server Details

To use RADIUS authentication on the device, configure information about one or more RADIUS servers on the network by including one `radius-server` statement at the `[edit system]` hierarchy level for each RADIUS server. The device queries the RADIUS servers in the order in which they are configured. If the primary server (the first one configured) is unavailable, the device attempts to contact each server in the list until it receives a response.

The network device can map RADIUS-authenticated users to a locally defined user account or user template account, which determines authorization. By default, Junos OS assigns RADIUS-authenticated users to the user template account `remote`, if configured, when:

- The authenticated user does not have a user account configured on the local device.
- The RADIUS server either does not assign the user to a local user template, or the template that the server assigns is not configured on the local device.

The RADIUS server can assign an authenticated user to a different user template to grant different administrative permissions to that user. The user retains the same login name in the CLI but inherits the login class, access privileges, and effective user ID from the assigned template. If the RADIUS-

authenticated user does not map to any locally defined user account or user template, and the `remote` template is not configured, then authentication fails.

**NOTE:** The `remote` username is a special case in Junos OS and must always be lowercase. It acts as a template for users who are authenticated by a remote server but do not have a locally configured user account on the device. Junos OS applies the permissions of the `remote` template to those authenticated users without a locally defined account. All users mapped to the `remote` template are in the same login class.

Because you configure remote authentication on multiple devices, it is common to configure it inside of a configuration group. The steps shown here are in a configuration group called `global`. Using a configuration group is optional.

To configure authentication by a RADIUS server:

1. Configure the IPv4 address or the IPv6 address of the RADIUS authentication server.

```
[edit groups global system radius-server]
user@host# set server-address
```

For example:

```
[edit groups global system radius-server]
user@host# set 192.168.17.28
```

```
[edit groups global system radius-server]
user@host# set 2001:db8:0:f101::8
```

2. (Optional) Configure the packet source address for requests sent to the RADIUS server.

```
[edit groups global system radius-server server-address]
user@host# set source-address source-address
```

For example:

```
[edit groups global system radius-server 192.168.17.28]
user@host# set source-address 192.168.17.1
```

```
[edit groups global system radius-server 2001:db8:0:f101::8]
user@host# set source-address 2001:db8:0:f101::1
```

The source address is a valid IPv4 address or IPv6 address configured on one of the router interfaces or switch interfaces. If the network device has several interfaces that can reach the RADIUS server, assign an IP address that the device can use for all its communication with the RADIUS server. Doing this sets a fixed address as the source address for locally generated IP packets.

3. Configure the shared secret password that the network device uses to authenticate with the RADIUS server.

The configured password must match the password that is configured on the RADIUS server. If the password contains spaces, enclose it in quotation marks. The device stores the password as an encrypted value in the configuration database.

```
[edit groups global system radius-server server-address]
user@host# set secret password
```

For example:

```
[edit groups global system radius-server 192.168.17.28]
user@host# set secret Radiussecret1
```

4. (Optional) Specify the port on which to contact the RADIUS server, if different from the default. The default port is 1812 (as specified in RFC 2865).

```
[edit groups global system radius-server server-address]
user@host# set port port-number
```

For example:

```
[edit groups global system radius-server 192.168.17.28]
user@host# set port 51812
```

**NOTE:** You can also configure the `accounting-port` statement to specify to which RADIUS server port to send accounting packets. The default is 1813 (as specified in RFC 2866).

5. (Optional) Configure the number of times that the device attempts to contact the RADIUS server and the amount of time that the device waits to receive a response from the server.

By default, the device attempts to contact the server three times and waits three seconds. You can configure the `retry` value from 1 through 100 times and the `timeout` value from 1 through 1000 seconds.

```
[edit groups global system radius-server server-address]
user@host# set retry number
user@host# set timeout seconds
```

For example, to contact a RADIUS server 2 times and wait 10 seconds for a response:

```
[edit groups global system radius-server 192.168.17.28]
user@host# set retry 2
user@host# set timeout 10
```

6. Specify the authentication order, and include the `radius` option.

```
[edit groups global system]
user@host# set authentication-order [ authentication-methods ]
```

In the following example, whenever a user attempts to log in, Junos OS first queries the RADIUS server for authentication. If that fails, it queries the TACACS+ server. If that fails, it attempts authentication with locally configured user accounts.

```
[edit groups global system]
user@host# set authentication-order [ radius tacplus password ]
```

7. Assign a login class to RADIUS-authenticated users who do not have a locally defined user account. You configure a user template account in the same way as a local user account, except that you do not configure a local authentication password because the RADIUS server authenticates the user.

- To use the same permissions for all RADIUS-authenticated users, configure the `remote user` template.

```
[edit groups global system login]
user@host# set user remote class class
```

For example:

```
[edit groups global system login]
user@host# set user remote class super-user
```

- To use different login classes for different RADIUS-authenticated users, granting them different permissions:
  - a. Create multiple user templates in the Junos OS configuration. For example:

```
[edit groups global system login]
user@host# set user RO class read-only
user@host# set user OP class operator
user@host# set user SU class super-user
user@host# set user remote full-name "default remote access user template"
user@host# set user remote class read-only
```

- b. Configure the RADIUS server to map the authenticated user to the appropriate user template.

Set the Juniper-Local-User-Name Juniper VSA (vendor-specific attribute) (Vendor 2636, type 1, string) to the name of a user template configured on the device, which in the previous example is RO, OP, or SU. The RADIUS server includes the attribute in the RADIUS Access-Accept message. Authentication fails if the device cannot assign a user to a local user account or user template, and the `remote user` template is not configured.

## Configure RADIUS to Use the Management Instance

By default, Junos OS routes authentication, authorization, and accounting packets for RADIUS through the default routing instance. You can also route RADIUS packets through a management interface in a non-default VRF instance.

To route RADIUS packets through the `mgmt_junos` management instance:

1. Enable the `mgmt_junos` management instance.

```
[edit system]
user@host# set management-instance
```

2. Configure the routing-instance `mgmt_junos` statement for the RADIUS authentication server and the RADIUS accounting server, if configured.

```
[edit system]
user@host# set radius-server server-address routing-instance mgmt_junos
user@host# set accounting destination radius server server-address routing-instance mgmt_junos
```

## Example: Configure a RADIUS Server for System Authentication

### IN THIS SECTION

- [Requirements | 198](#)
- [Overview | 198](#)
- [Configuration | 199](#)
- [Verification | 201](#)

This example configures system authentication through a RADIUS server.

### Requirements

Before you begin:

- Perform the initial device configuration. See the Getting Started Guide for your device.
- Set up at least one RADIUS server on your network.

### Overview

In this example, you add a new RADIUS server with an IP address of 172.16.98.1. You specify the shared secret password of the RADIUS server as `Radiussecret1`. The device stores the secret in the configuration database as an encrypted value. Finally, you specify the source address that the device

uses in RADIUS server requests. In most cases, you can use the loopback address of the device, which in this example is 10.0.0.1.

You can configure support for multiple user authentication methods, such as local password authentication, RADIUS, and TACACS+, on the network device. When you configure multiple authentication methods, you can prioritize the order in which the device tries the different methods. In this example, you configure the device to use RADIUS authentication services first and then, if that fails, to attempt local password authentication.

A RADIUS-authenticated user must map to a local user account or a local user template account on the network device, which determines authorization. By default, if a RADIUS-authenticated user does not map to a local user account or a specific user template, the user is assigned to the `remote` user template, if configured. This example configures the `remote` user template.

## Configuration

### IN THIS SECTION

- [Procedure | 199](#)

## Procedure

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the `[edit]` hierarchy level, and then enter `commit` from configuration mode.

```
set system radius-server 172.16.98.1
set system radius-server 172.16.98.1 secret Radiussecret1
set system radius-server 172.16.98.1 source-address 10.0.0.1
set system authentication-order [radius password]
set system login user remote class operator
```

## Step-by-Step Procedure

To configure a RADIUS server for system authentication:

1. Add a new RADIUS server and set its IP address.

```
[edit system]
user@host# set radius-server 172.16.98.1
```

2. Specify the shared secret (password) of the RADIUS server.

```
[edit system]
user@host# set radius-server 172.16.98.1 secret Radiussecret1
```

3. Specify the device's loopback address as the source address.

```
[edit system]
user@host# set radius-server 172.16.98.1 source-address 10.0.0.1
```

4. Specify the device's order of authentication, and include the radius option.

```
[edit system]
user@host# set authentication-order [radius password]
```

5. Configure the remote user template and its login class.

```
[edit system]
user@host# set login user remote class operator
```

## Results

In configuration mode, confirm your configuration by entering the `show system` command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

The following output includes only those portions of the configuration hierarchy that are relevant to this example.

```
[edit]
user@host# show system
login {
```

```
user remote {  
    class operator;  
}  
}  
authentication-order [ radius password ];  
radius-server {  
    172.16.98.1 {  
        secret "$9$ABC123"; ## SECRET-DATA  
        source-address 10.0.0.1;  
    }  
}
```

After configuring the device, enter `commit` in configuration mode.

## Verification

### IN THIS SECTION

- [Verify the RADIUS Server Configuration | 201](#)

Confirm that the configuration is working properly.

### Verify the RADIUS Server Configuration

#### Purpose

Verify that the RADIUS server authenticates users.

#### Action

Log in to the network device, and verify that the login is successful. To verify that the device uses the RADIUS server for authentication, you can attempt to log in with an account that does not define a local authentication password in the configuration.

## Configure RADIUS Authentication (QFX Series or OCX Series)

### IN THIS SECTION

- [Configure RADIUS Server Details | 202](#)
- [Configure MS-CHAPv2 for Password-Change Support | 203](#)
- [Specify a Source Address for the Junos OS to Access External RADIUS Servers | 204](#)

RADIUS authentication is a method of authenticating users who attempt to access the router or switch. Tasks to configure RADIUS authentication are:

**NOTE:** The `source-address` statement is not supported at `[edit system-radius-server name]` hierarchy level on the QFabric system.

### Configure RADIUS Server Details

To use RADIUS authentication on the router or switch, configure information about one or more RADIUS servers on the network by including one `radius-server` statement at the `[edit system]` hierarchy level for each RADIUS server:

```
[edit system]
radius-server server-address {
    accounting-port port-number;
    accounting-retry number;
    accounting-timeout seconds;
    dynamic-request-port number;
    max-outstanding-requests value;
    port number;
    preauthentication-port number;
    preauthentication-secret secret;
    retry number;
    routing-instance routing-instance-name;
    secret password;
    source-address source-address;
    timeout seconds;
}
```

*server-address* is the address of the RADIUS server.

You can specify a port on which to contact the RADIUS server. By default, port number 1812 is used (as specified in RFC 2865). You can also specify an accounting port to send accounting packets. The default is 1813 (as specified in RFC 2866).

You must specify a password in the secret *password* statement. If the password contains spaces, enclose it in quotation marks. The secret used by the local router or switch must match that used by the server.

Optionally, you can specify the amount of time that the local router or switch waits to receive a response from a RADIUS server (in the *timeout* statement) and the number of times that the router or switch attempts to contact a RADIUS authentication server (in the *retry* statement). By default, the router or switch waits 3 seconds. You can configure this to be a value from 1 through 90 seconds. By default, the router or switch retries connecting to the server three times. You can configure this to be a value from 1 through 10 times.

You can use the *source-address* statement to specify a logical address for individual servers or multiple RADIUS servers.

To configure multiple RADIUS servers, include multiple *radius-server* statements.

To configure a set of users that share a single account for authorization purposes, you create a template user. To do this, include the *user* statement at the [edit system login] hierarchy level, as described in ["Example: Configure Authentication Order" on page 166](#).

You can also configure RADIUS authentication at the [edit access] and [edit access profile] hierarchy levels. Junos OS uses the following search order to determine which set of servers is used for authentication:

1. [edit access profile *profile-name* radius-server *server-address*]
2. [edit access radius-server *server-address*]
3. [edit system radius-server *server-address*]

## Configure MS-CHAPv2 for Password-Change Support

Before you configure MS-CHAPv2 for password-change support, ensure that you:

- Configure the RADIUS server authentication parameters.
- Set the **authentication-order** to use the RADIUS server for the initial password attempt.

You can configure the Microsoft implementation of the Challenge Handshake Authentication Protocol version 2 (MS-CHAPv2) on the router or switch to support changing of passwords. This feature provides users accessing a router or switch the option of changing the password when the password expires, is reset, or is configured to be changed at the next login.

To configure MS-CHAP-v2, include the following statements at the [edit system radius-options] hierarchy level:

```
[edit system radius-options]
password-protocol mschap-v2;
```

The following example shows statements for configuring the MS-CHAPv2 password protocol, password authentication order, and user accounts:

```
[edit]
system {
  authentication-order [ radius password ];
  radius-server {
    192.168.69.149 secret "$ABC123"; ## SECRET-DATA
  }
  radius-options {
    password-protocol mschap-v2;
  }
  login {
    user bob {
      class operator;
    }
  }
}
```

## Specify a Source Address for the Junos OS to Access External RADIUS Servers

You can specify which source address Junos OS uses when accessing your network to contact an external RADIUS server for authentication. You can also specify which source address Junos OS uses when contacting a RADIUS server for sending accounting information.

To specify a source address for a RADIUS server, include the `source-address` statement at the [edit system radius-server *server-address*] hierarchy level:

```
[edit system radius-server server-address]
source-address source-address;
```

*source-address* is a valid IP address configured on one of the router interfaces or switch interfaces.

RELATED DOCUMENTATION

<a href="#">Juniper Networks Vendor-Specific RADIUS and LDAP Attributes   205</a>
<a href="#">Example: Configure Authentication Order   166</a>
<a href="#">Use Regular Expressions on a RADIUS or TACACS+ Server to Allow or Deny Commands   238</a>
<a href="#">User Authentication Methods   144</a>

## Juniper Networks Vendor-Specific RADIUS and LDAP Attributes

Junos OS supports configuring Juniper Networks RADIUS and LDAP vendor-specific attributes (VSAs) on the authentication server. These VSAs are encapsulated in a RADIUS or LDAP vendor-specific attribute with the vendor ID set to the Juniper Networks ID number, 2636.

Table 12 on page 205 lists the Juniper Networks VSAs that you can configure.

Some of the attributes accept extended regular expressions, as defined in POSIX 1003.2. If the regular expression contains any spaces, operators, or wildcard characters, enclose it in quotation marks. For more information, see:

- ["Regular Expressions to Allow and Deny Operational Mode Commands, Configuration Statements, and Hierarchies" on page 61](#)
- ["Use Regular Expressions on a RADIUS or TACACS+ Server to Allow or Deny Commands" on page 238](#)

Table 12: Juniper Networks Vendor-Specific RADIUS and LDAP Attributes

Name	Description	Type	Length	String
Juniper-Local-User-Name	Indicates the name of the user template assigned to this user when the user logs in to a device. This attribute is used only in Access-Accept packets.	1	≥3	One or more octets containing printable ASCII characters.

Table 12: Juniper Networks Vendor-Specific RADIUS and LDAP Attributes (*Continued*)

Name	Description	Type	Length	String
Juniper-Allow-Commands	Contains an extended regular expression that enables the user to run commands in addition to those commands authorized by the user's login class permission bits. This attribute is used only in Access-Accept packets.	2	≥3	One or more octets containing printable ASCII characters, in the form of an extended regular expression.
Juniper-Deny-Commands	Contains an extended regular expression that denies the user permission to run commands authorized by the user's login class permission bits. This attribute is used only in Access-Accept packets.	3	≥3	One or more octets containing printable ASCII characters, in the form of an extended regular expression.
Juniper-Allow-Configuration	Contains an extended regular expression that enables the user to view and modify configuration statements in addition to those statements authorized by the user's login class permission bits. This attribute is used only in Access-Accept packets.	4	≥3	One or more octets containing printable ASCII characters, in the form of an extended regular expression.
Juniper-Deny-Configuration	Contains an extended regular expression that denies the user permission to view or modify configuration statements authorized by the user's login class permission bits. This attribute is used only in Access-Accept packets.	5	≥3	One or more octets containing printable ASCII characters, in the form of an extended regular expression.

Name	Description	Type	Length	String
Juniper-User-Permissions	<p>Contains information the server uses to specify user permissions. This attribute is used only in Access-Accept packets.</p> <p><b>NOTE:</b> When the RADIUS or LDAP server defines the Juniper-User-Permissions attribute to grant the maintenance permission or all permission to a user, the user's list of group memberships does not automatically include the UNIX wheel group. Some operations such as running the <code>su root</code> command from a local shell require wheel group membership permissions. However, when the network device defines a local user account with the permissions maintenance or all, the user is automatically granted membership to the UNIX wheel group. Therefore, we recommend that you create a user template account with the required permissions and associate individual user accounts with the user template account.</p>	10	≥3	<p>One or more octets containing printable ASCII characters.</p> <p>The string is a list of permission flags separated by a space. The exact name of each flag must be specified in its entirety.</p> <p>See <a href="#">"Access Privilege Levels Overview"</a> on page 51.</p>

**Table 12: Juniper Networks Vendor-Specific RADIUS and LDAP Attributes (Continued)**

Name	Description	Type	Length	String
Juniper-Authentication-Type	Indicates the authentication method (local database, LDAP or RADIUS server) used to authenticate a user. If the user is authenticated using a local database, the attribute value shows 'local'. If the user is authenticated using a RADIUS or LDAP server, the attribute value shows 'remote'.	11	≥5	One or more octets containing printable ASCII characters.
Juniper-Session-Port	Indicates the source port number of the established session.	12	size of integer	Integer
Juniper-Allow-Configuration-Regexps (RADIUS only)	Contains an extended regular expression that enables the user to view and modify configuration statements in addition to those statements authorized by the user's login class permission bits. This attribute is used only in Access-Accept packets.	13	≥3	One or more octets containing printable ASCII characters, in the form of an extended regular expression.
Juniper-Deny-Configuration-Regexps (RADIUS only)	Contains an extended regular expression that denies the user permission to view or modify configuration statements authorized by the user's login class permission bits. This attribute is used only in Access-Accept packets.	14	≥3	One or more octets containing printable ASCII characters, in the form of an extended regular expression.

For more information about the VSAs, see RFC 2138, *Remote Authentication Dial In User Service (RADIUS)*.

## Use Regular Expressions on a RADIUS or TACACS+ Server to Allow or Deny Commands

Junos OS can map RADIUS- and TACACS+-authenticated users to a locally defined user account or user template account, which defines the user's access privileges. You can also optionally configure a user's access privileges by defining Juniper Networks RADIUS and TACACS+ vendor-specific attributes (VSAs) on the respective authentication server.

A user's login class defines the set of permissions that determines which operational mode and configuration mode commands a user is authorized to execute and which areas of the configuration a user can view and modify. A login class can also define regular expressions that allow or deny a user the ability to execute certain commands or view and modify certain areas of the configuration, in addition to what the permission flags authorize. A login class can include the following statements to define user authorization:

- `permissions`
- `allow-commands`
- `allow-commands-regexps`
- `allow-configuration`
- `allow-configuration-regexps`
- `deny-commands`
- `deny-commands-regexps`
- `deny-configuration`
- `deny-configuration-regexps`

Similarly, a RADIUS or TACACS+ server configuration can use Juniper Networks VSAs to define specific permissions or regular expressions that determine a user's access privileges. For the list of supported RADIUS and TACACS+ VSAs, see the following:

- ["Juniper Networks Vendor-Specific RADIUS and LDAP Attributes" on page 205](#)
- ["Juniper Networks Vendor-Specific TACACS+ Attributes" on page 236](#)

You can define user permissions on the RADIUS or TACACS+ server as a list of space-separated values.

- A RADIUS server uses the following attribute and syntax:

```
Juniper-User-Permissions += "flag1 flag2 flag3",
```

For example:

```
Juniper-User-Permissions += "interface interface-control configure",
```

- A TACACS+ server uses the following attribute and syntax:

```
user-permissions = "flag1 flag2 flag3"
```

For example:

```
user-permissions = "interface interface-control configure"
```

A RADIUS or TACACS+ server can also define Juniper Networks VSAs that use a single extended regular expression (as defined in POSIX 1003.2) to allow or deny a user the ability to execute certain commands or view and modify areas of the configuration. You enclose multiple commands or configuration hierarchies in parentheses and separate them using a pipe symbol. If the regular expression contains any spaces, operators, or wildcard characters, enclose it in quotation marks. When you configure authorization parameters both locally and remotely, the device merges the regular expressions received during TACACS+ or RADIUS authorization with any regular expressions defined on the local device.

- A RADIUS server uses the following attributes and syntax:

```
Juniper-Allow-Commands += "(cmd1)|(cmd2)|(cmdn)",
Juniper-Deny-Commands += "(cmd1)|(cmd2)|(cmdn)",
Juniper-Allow-Configuration += "(config1)|(config2)|(confign)",
Juniper-Deny-Configuration += "(config1)|(config2)|(confign)",
```

For example:

```
Juniper-Allow-Commands += "(test)|(ping)|(quit)",
Juniper-Deny-Commands += "(request)|(restart)",
Juniper-Allow-Configuration += "(groups re0)|(system radius-server)",
Juniper-Deny-Configuration += "(system radius-options)|(system accounting)",
```

- A TACACS+ server uses the following attributes and syntax:

```
allow-commands = "(cmd1)|(cmd2)|(cmdn)"
deny-commands = "(cmd1)|(cmd2)|(cmdn)"
allow-configuration = "(config1)|(config2)|(confign)"
deny-configuration = "(config1)|(config2)|(confign)"
```

For example:

```
allow-commands = "(test)|(ping)|(quit)"
deny-commands = "(request)|(restart)"
allow-configuration = "(groups re0)|(system tacplus-server)"
deny-configuration = "(system tacplus-options)|(system accounting)"
```

RADIUS and TACACS+ servers also support configuring attributes that correspond to the same \*-regexps statements that you can configure on the local device. The \*-regexps TACACS+ attributes and the \*-Regexps RADIUS attributes use the same regular expression syntax as the previous attributes, but they enable you to configure regular expressions with variables.

- A RADIUS server uses the following attributes and syntax:

```
Juniper-Allow-Configuration-Regexps += "(config1)|(config2)|(confign)",
Juniper-Deny-Configuration-Regexps += "(config1)|(config2)|(confign)",
```

- A TACACS+ server uses the following attributes and syntax:

```
allow-commands-regexps = "(cmd1)|(cmd2)|(cmdn)"
deny-commands-regexps = "(cmd1)|(cmd2)|(cmdn)"
allow-configuration-regexps = "(config1)|(config2)|(confign)"
deny-configuration-regexps = "(config1)|(config2)|(confign)"
```

For example, the TACACS+ server configuration might define the following attributes:

```
allow-commands-regexps = "(show cli .*)|(ping 10.1.1.*)"
deny-commands-regexps = "(configure .*)|(edit)|(commit)|(rollback .*)"
```

On a RADIUS or TACACS+ server, you can also define the attributes using a simplified syntax where you specify each individual expression on a separate line.

For a RADIUS server, specify the individual regular expressions using the following syntax:

```
Juniper-User-Permissions += "permission-flag1",
Juniper-User-Permissions += "permission-flag2",
Juniper-User-Permissions += "permission-flagn",
Juniper-Allow-Commands += "cmd1",
Juniper-Allow-Commands += "cmd2",
Juniper-Allow-Commands += "cmdn",
Juniper-Deny-Commands += "cmd1",
Juniper-Deny-Commands += "cmd2",
Juniper-Deny-Commands += "cmdn",
Juniper-Allow-Configuration += "config1",
Juniper-Allow-Configuration += "config2",
Juniper-Allow-Configuration += "confign",
Juniper-Deny-Configuration += "config1",
Juniper-Deny-Configuration += "config2",
Juniper-Deny-Configuration += "confign",
```

For a TACACS+ server, specify the individual regular expressions using the following syntax:

```
user-permissions1 = "permission-flag1"
user-permissions2 = "permission-flag2"
user-permissionsn = "permission-flagn"
allow-commands1 = "cmd1"
allow-commands2 = "cmd2"
allow-commandsn = "cmdn"
deny-commands1 = "cmd1"
deny-commands2 = "cmd2"
deny-commandsn = "cmdn"
allow-configuration1 = "config1"
allow-configuration2 = "config2"
allow-configurationn = "confign"
deny-configuration1 = "config1"
deny-configuration2 = "config2"
deny-configurationn = "confign"
```

**NOTE:**

- In the TACACS+ server syntax, numeric values 1 through  $n$  must be unique but need not be sequential. For example, the following syntax is valid:

```
allow-commands1="cmd1"
allow-commands3="cmd3"
allow-commands2="cmd2"
deny-commands3="cmd3"
deny-commands2="cmd2"
deny-commands1="cmd1"
```

- The RADIUS or TACACS+ server imposes a limit on the number of individual regular expression lines.
- When you issue the `show cli authorization` command, the command output displays the regular expression in a single line, even if you specify each individual expression on a separate line.

Users can verify their class, permissions, and command and configuration authorization by issuing the `show cli authorization` operational mode command.

```
user@host> show cli authorization
```

**NOTE:** When you configure the authorization parameters both locally on the network device and remotely on the RADIUS or TACACS+ server, the device merges the regular expressions received during TACACS+ or RADIUS authorization with any locally configured regular expressions. If the final expression contains a syntax error, the overall result is an invalid regular expression.

## Juniper-Switching-Filter VSA Guidelines, Match Conditions and Actions

### IN THIS SECTION

- [VSA Guidelines | 215](#)
- [Match Conditions | 216](#)
- [Actions | 217](#)

Devices support the configuration of RADIUS server attributes specific to Juniper Networks. These attributes are known as vendor-specific attributes (VSAs) and are described in RFC 2138, *Remote Authentication Dial In User Service* (RADIUS). Vendor-specific attributes extend the functionality of the RADIUS server beyond that provided by the public standard attributes, enabling the implementation of many useful features necessary for subscriber management and service support.

Juniper Networks VSAs have the vendor ID set to 2636.

Attributes are cleartext fields sent from the RADIUS server to the device as a result of authentication success or failure. Authentication prevents unauthorized user access by blocking a supplicant at the port until the device is authenticated by the RADIUS server. Implementing filtering attributes with authentication on the RADIUS server provides a central location for controlling LAN access for supplicants.

The Juniper-Switching-Filter attribute works in conjunction with 802.1X authentication to centrally control access of supplicants to the network. You can use this attribute to configure filters on the RADIUS server. These filters are sent to the switch and applied to users that have been authenticated using 802.1X authentication.

The Juniper-Switching-Filter can contain one or more filter terms. Filter terms are configured using one or more *match conditions* with a resulting *action*. Match conditions are the criteria that a packet must meet for a configured action to be applied on it. The configured action is the action that the switch takes if a packet meets the criteria specified in the match conditions. The action that the switch can take is to either accept or deny a packet.

Adding a port firewall filter to a RADIUS server eliminates the need to add the filter to multiple ports and devices. One way to do this is to apply a previously configured port firewall filter directly to the RADIUS server using the [Juniper-Firewall-filter-name VSA](#). Like port-filtering attributes, this filter is applied during the authentication process, and its actions are applied at the device port.

## VSA Guidelines

Vendor-specific RADIUS attributes have a maximum of 247 characters per attribute. If more length is required, Juniper supports multiple instances of the same attribute, up to 4000 characters. To support filters that exceed 247 characters, use multiple Juniper-Switching-Filter attributes. The example below shows two attributes, each containing a new filter term that is within the 247 character limit:

```
Juniper-Switching-Filter = "Match ip-protocol 17 destination-port 67 Destination-ip
192.168.1.0/24 Action deny, match destination-ip 10.1.7.253 destination-port 53 action allow"
Juniper-Switching-Filter += "Match ip-protocol 1 destination-port 4000 Destination-ip
192.168.21.0/24 Action deny"
```

**NOTE:** The 4000 character limit is subject to supported MTU on both the RADIUS server and the Juniper device, and the number of other RADIUS attributes used.

The following guidelines apply to VSA match conditions and actions:

- Both the `match` statement and the `action` statement are mandatory.
- If no match condition is specified, any packet is considered a match by default.
- If no action is specified, the default action is to deny the packet.
- Any or all options can be included in each `match` and `action` statement.
- The AND operation is performed on fields that are of a different type, separated by commas. Fields of the same type cannot be repeated.
- For the `forwarding-class` option to be applied, the forwarding class must be configured on the switch. If the forwarding class is not configured on the switch, this option is ignored.

## Match Conditions

Table 13 on page 216 describes the match conditions that you can specify when you configure a VSA attribute as a firewall filter by using the `match` command on the RADIUS server. The string that defines a match condition is called a *match statement*.

**Table 13: Match Conditions**

Option	Description
<code>destination-mac mac-address</code>	Destination media access control (MAC) address of the packet.
<code>source-dot1q-tag tag</code>	Tag value in the 802.1Q header, in the range 0 through 4095.
<code>destination-ip ip-address</code>	Address of the final destination node.
<code>ip-protocol protocol-id</code>	IPv4 protocol value. In place of the numeric value, you can specify one of the following text synonyms:  ah, egp (8), esp (50), gre (47), icmp (1), igmp (2), ipip (4), ipv6 (41), ospf (89), pim (103), rsvp (46), tcp (6), or udp (17)

**Table 13: Match Conditions (Continued)**

Option	Description
source-port <i>port</i>	TCP or User Datagram Protocol (UDP) source port field. Normally, you specify this match statement in conjunction with the ip-protocol match statement to determine which protocol is being used on the port. In place of the numeric field, you can specify one of the text options listed under destination-port.
destination-port <i>port</i>	<p>TCP or UDP destination port field. Normally, you specify this match statement in conjunction with the ip-protocol match statement to determine which protocol is being used on the port. In place of the numeric value, you can specify one of the following text synonyms (the port numbers are also listed):</p> <p>afs (1483), bgp (179), biff (512), bootpc (68), bootps (67), cvspserver (2401), cmd (514), dhcp (67), domain (53), eklogin (2105), ekshell (2106), exec (512), finger (79), ftp (21), ftp-data (20), http (80), https (443), ident (113), imap (143), kerberos-sec (88), klogin (543), kpasswd (761), krb-prop (754), krbupdate (760), kshell (544), ldap (389), login (513), mobileip-agent (434), mobilip-mn (435), msdp (639), netbios-dgm (138), netbios-ns (137), netbios-ssn (139), nfsd (2049), nntp (119), ntalk (518), ntp (123), pop3 (110), pptp (1723), printer (515), radacct (1813), radius (1812), rip (520), rkinit (2108), smtp (25), snmp (161), snmptrap (162), snpp (444), socks (1080), ssh (22), sunrpc (111), syslog (514), telnet (23), tacacs-ds (65), talk (517), tftp (69), timed (525), who (513), xdmcp (177), zephyr-clt (2103), zephyr-hm (2104)</p>

## Actions

When you define one or more terms that specify the filtering criteria, you also define the action to take if the packet matches all criteria. [Table 14 on page 217](#) shows the actions that you can specify in a term.

**Table 14: Actions for VSAs**

Option	Description
(allow   deny)	Accept a packet or discard a packet silently without sending an Internet Control Message Protocol (ICMP) message.

Table 14: Actions for VSAs (Continued)

Option	Description
forwarding-class <i>class-of-service</i>	(Optional) Classify the packet in one of the following forwarding classes: <ul style="list-style-type: none"> <li>• assured-forwarding</li> <li>• best-effort</li> <li>• expedited-forwarding</li> <li>• network-control</li> </ul>
loss-priority (low   medium   high)	(Optional) Set the packet loss priority (PLP) to low, medium, or high. Specify both the forwarding class and the loss priority.

## SEE ALSO

[Filtering 802.1X Supplicants by Using RADIUS Server Attributes | 375](#)
[Understanding Dynamic Filters Based on RADIUS Attributes | 387](#)

## Understanding RADIUS Accounting

Network devices support IETF RFC 2866, *RADIUS Accounting*. You can configure RADIUS accounting on a device to collect statistical data about users logging in to or out of a LAN and send the data to a RADIUS accounting server. The statistical data can be used for general network monitoring, analyzing and tracking usage patterns, or billing a user based on the duration of the session or type of services accessed.

To configure RADIUS accounting, specify:

- One or more RADIUS accounting servers to receive the statistical data from the device
- The type of accounting data to collect

You can use the same server for both RADIUS accounting and authentication, or you can use separate servers. You can specify a list of RADIUS accounting servers. The device queries the servers in the order

in which they are configured. If the primary server (the first one configured) is unavailable, the device attempts to contact each server in the list until it receives a response.

The RADIUS accounting process between the device and a RADIUS server works like this:

1. A RADIUS accounting server listens for User Datagram Protocol (UDP) packets on a specific port. The default port for RADIUS accounting is 1813.
2. The device forwards an *Accounting-Request* packet containing an event record to the accounting server. The event record associated with this supplicant contains an *Acct-Status-Type* attribute whose value indicates the beginning of user service for this supplicant. When the supplicant's session ends, the accounting request contains an *Acct-Status-Type* attribute value indicating the end of user service. The RADIUS accounting server records this as a stop-accounting record containing session information and the length of the session.
3. The RADIUS accounting server logs these events in a file as start-accounting or stop-accounting records. On FreeRADIUS, the filename is the server's address, such as 192.0.2.0.
4. The accounting server sends an *Accounting-Response* packet to the device confirming that it has received the accounting request.
5. If the device does not receive an *Accounting-Response* packet from the server, it continues to send accounting requests until the server returns a response.

You can view the statistics collected through this process on the RADIUS server. To see those statistics, access the log file configured to receive them.

## Configure RADIUS System Accounting

### IN THIS SECTION

- [Configure Auditing of User Events on a RADIUS Server | 219](#)

When you enable RADIUS accounting, Juniper Networks devices, acting as RADIUS clients, can notify the RADIUS server about user activities such as software logins, configuration changes, and interactive commands. The framework for RADIUS accounting is described in RFC 2866, *RADIUS Accounting*.

### Configure Auditing of User Events on a RADIUS Server

To configure RADIUS accounting:

### 1. Configure the events to audit.

```
[edit system accounting]  
user@host# set events [ events ]
```

For example:

```
[edit system accounting]  
user@host# set events [ login change-log interactive-commands ]
```

*events* can include one or more of the following:

- login—Audit logins
- change-log—Audit configuration changes
- interactive-commands—Audit interactive commands (any command-line input)

### 2. Enable RADIUS accounting.

```
[edit]  
user@host# set system accounting destination radius
```

### 3. Configure the address for one or more RADIUS accounting servers.

```
[edit system accounting destination radius]  
user@host# set server server-address
```

For example:

```
[edit system accounting destination radius]  
user@host# set server 192.168.17.28
```

**NOTE:** If you do not configure any RADIUS servers at the [edit system accounting destination radius] hierarchy level, the device uses the RADIUS servers configured at the [edit system radius-server] hierarchy level.

4. (Optional) Configure the source address for RADIUS accounting requests.

```
[edit system accounting destination radius server server-address]  
user@host# set source-address source-address
```

For example:

```
[edit system accounting destination radius server 192.168.17.28]  
user@host# set source-address 192.168.17.1
```

The source address is a valid IPv4 address or IPv6 address configured on one of the router interfaces or switch interfaces. If the network device has several interfaces that can reach the RADIUS server, assign an IP address that the device can use for all its communication with the RADIUS server. Doing this sets a fixed address as the source address for locally generated IP packets.

5. Configure the shared secret password that the network device uses to authenticate with the RADIUS accounting server.

The configured password must match the password that is configured on the RADIUS server. If the password contains spaces, enclose it in quotation marks. The device stores the password as an encrypted value in the configuration database.

```
[edit system accounting destination radius server server-address]  
user@host# set secret password
```

For example:

```
[edit system accounting destination radius server 192.168.17.28]  
user@host# set secret Radiussecret1
```

6. (Optional) If necessary, specify to which RADIUS accounting server port to send accounting packets, if different from the default (1813).

```
[edit system accounting destination radius server server-address]  
user@host# set accounting-port port-number
```

**NOTE:** If you enable RADIUS accounting at the [edit access profile *profile-name* accounting-order] hierarchy level, accounting is triggered on the default port of 1813 even if you do not specify a value for the accounting-port statement.

7. (Optional) Configure the number of times that the device attempts to contact a RADIUS accounting server and the amount of time that the device waits to receive a response from a server.

By default, the device attempts to contact the server three times and waits three seconds. You can configure the retry value from 1 through 100 times and the timeout value from 1 through 1000 seconds.

```
[edit system accounting destination radius server server-address]
user@host# set retry number
user@host# set timeout seconds
```

For example, to contact a server 2 times and wait 10 seconds for a response:

```
[edit system accounting destination radius server 192.168.17.28]
user@host# set retry 2
user@host# set timeout 10
```

8. (Optional) To route RADIUS accounting packets through the non-default management instance instead of the default routing instance, configure the routing-instance `mgmt_junos` statement.

```
[edit system accounting destination radius server server-address]
user@host# set routing-instance mgmt_junos
```

9. (Optional) Configure the enhanced-accounting statement at the [edit system radius-options] hierarchy level to include additional accounting attributes, including access method, remote port, and access privileges, for user login events.

```
[edit system radius-options]
user@host# set enhanced-accounting
```

**NOTE:** To limit the number of attribute values to audit, configure the enhanced-avs-max *<number>* statement at the [edit system accounting] hierarchy level.

The following example configures three servers (10.5.5.5, 10.6.6.6, and 10.7.7.7) for RADIUS accounting:

```
system {
  accounting {
    events [ login change-log interactive-commands ];
    destination {
      radius {
        server {
          10.5.5.5 {
            accounting-port 3333;
            secret $ABC123;
            source-address 10.1.1.1;
            retry 3;
            timeout 3;
          }
          10.6.6.6 secret $ABC123;
          10.7.7.7 secret $ABC123;
        }
      }
    }
  }
}
```

Release History Table

Release	Description
18.1R1	Starting in Junos OS Release 18.1R1, existing RADIUS behavior is enhanced to support a management interface in a non-default VRF instance.

# TACACS+ Authentication

IN THIS SECTION

- [Configure TACACS+ Authentication | 224](#)

- [Configure Periodic Refresh of the TACACS+ Authorization Profile | 231](#)
- [Example: Configure a TACACS+ Server for System Authentication | 232](#)
- [Juniper Networks Vendor-Specific TACACS+ Attributes | 236](#)
- [Use Regular Expressions on a RADIUS or TACACS+ Server to Allow or Deny Commands | 238](#)
- [Configuring TACACS+ System Accounting | 243](#)

Junos OS supports TACACS+ for central authentication of users on network devices. To use TACACS+ authentication on the device, you (the network administrator) must configure information about one or more TACACS+ servers on the network. You can also configure TACACS+ accounting on the device to collect statistical data about the users logging in to or out of a LAN and send the data to a TACACS+ accounting server.

## Configure TACACS+ Authentication

### IN THIS SECTION

- [Configure TACACS+ Server Details | 224](#)
- [Configure TACACS+ to Use the Management Instance | 229](#)
- [Configure the Same Authentication Service for Multiple TACACS+ Servers | 229](#)
- [Configure Juniper Networks Vendor-Specific TACACS+ Attributes | 230](#)

TACACS+ authentication is a method of authenticating users who attempt to access a network device.

To configure TACACS+, perform the following tasks:

### Configure TACACS+ Server Details

To use TACACS+ authentication on the device, configure information about one or more TACACS+ servers on the network by including one `tacplus-server` statement at the `[edit system]` hierarchy level for each TACACS+ server. The device queries the TACACS+ servers in the order in which they are configured. If the primary server (the first one configured) is unavailable, the device attempts to contact each server in the list until it receives a response.

The network device can map TACACS+-authenticated users to a locally defined user account or user template account, which determines authorization. By default, Junos OS assigns TACACS+-authenticated users to the user template account `remote`, if configured, when:

- The authenticated user does not have a user account configured on the local device.
- The TACACS+ server either does not assign the user to a local user template, or the template that the server assigns is not configured on the local device.

The TACACS+ server can assign an authenticated user to a different user template to grant different administrative permissions to that user. The user retains the same login name in the CLI but inherits the login class, access privileges, and effective user ID from the assigned template. If the TACACS+-authenticated user does not map to any locally defined user account or user template, and the `remote` template is not configured, then authentication fails.

**NOTE:** The `remote` username is a special case in Junos OS and must always be lowercase. It acts as a template for users who are authenticated by a remote server but do not have a locally configured user account on the device. Junos OS applies the permissions of the `remote` template to those authenticated users without a locally defined account. All users mapped to the `remote` template are in the same login class.

Because remote authentication is configured on multiple devices, it is commonly configured inside of a configuration group. The steps shown here are in a configuration group called `global`. Using a configuration group is optional.

To configure authentication by a TACACS+ server:

1. Configure the IPv4 address or IPv6 address of the TACACS+ authentication server.

```
[edit groups global system tacplus-server]
user@host# set server-address
```

For example:

```
[edit groups global system tacplus-server]
user@host# set 192.168.17.28
```

```
[edit groups global system tacplus-server]
user@host# set 2001:db8:0:f101::8
```

2. (Optional) Configure the packet source address for requests sent to the TACACS+ server.

```
[edit groups global system tacplus-server server-address]
user@host# set source-address source-address
```

For example:

```
[edit groups global system tacplus-server 192.168.17.28]
user@host# set source-address 192.168.17.1
```

```
[edit groups global system tacplus-server 2001:db8:0:f101::8]
user@host# set source-address 2001:db8:0:f101::1
```

The source address is a valid IPv4 address or IPv6 address configured on one of the router interfaces or switch interfaces. If the network device has several interfaces that can reach the TACACS+ server, assign an IP address that the device can use for all its communication with the TACACS+ server. Doing this sets a fixed address as the source address for locally generated IP packets.

3. Configure the shared secret password that the network device uses to authenticate with the TACACS+ server.

The configured password must match the password that is configured on the TACACS+ server. If the password contains spaces, enclose it in quotation marks. The device stores the password as an encrypted value in the configuration database.

```
[edit groups global system tacplus-server server-address]
user@host# set secret password
```

For example:

```
[edit groups global system tacplus-server 192.168.17.28]
user@host# set secret Tacplussecret1
```

4. (Optional) Specify the port on which to contact the TACACS+ server, if different from the default port (49).

```
[edit groups global system tacplus-server server-address]
user@host# set port port-number
```

For example:

```
[edit groups global system tacplus-server 192.168.17.28]
user@host# set port 50049
```

5. (Optional) Configure the amount of time that the device waits to receive a response from the TACACS+ server.

By default, the device waits 10 seconds. You can configure the `timeout` value from 1 through 90 seconds.

```
[edit groups global system tacplus-server server-address]
user@host# set timeout seconds
```

For example, to wait 15 seconds for a response from the server:

```
[edit groups global system tacplus-server 192.168.17.28]
user@host# set timeout 15
```

6. (Optional) Configure the device to maintain one open TCP connection to the server for multiple requests rather than opening a separate connection for each connection attempt.

```
[edit groups global system tacplus-server 192.168.17.28]
user@host# set single-connection
```

**NOTE:** Early versions of the TACACS+ server do not support the `single-connection` option. If you specify this option and the server does not support it, the device will be unable to communicate with that TACACS+ server.

7. (Optional) To route TACACS+ packets through a specific routing instance, configure the `routing-instance` statement and specify a valid routing instance.

By default, Junos OS routes authentication, authorization, and accounting packets for TACACS+ through the default routing instance.

```
[edit groups global system tacplus-server server-address]
user@host# set routing-instance routing-instance
```

8. Specify the authentication order, and include the `tacplus` option.

```
[edit groups global system]
user@host# set authentication-order [ authentication-methods ]
```

In the following example, whenever a user attempts to log in, Junos OS first queries the TACACS+ server for authentication. If that fails, it queries the RADIUS server. If that fails, it attempts authentication with locally configured user accounts.

```
[edit groups global system]
user@host# set authentication-order [ tacplus radius password ]
```

9. Assign a login class to TACACS+-authenticated users who do not have a locally defined user account. You configure a user template account in the same way as a local user account, except that you do not configure a local authentication password because the TACACS+ server authenticates the user.
  - To use the same permissions for all TACACS+-authenticated users, configure the `remote user` template.

```
[edit groups global system login]
user@host# set user remote class class
```

For example:

```
[edit groups global system login]
user@host# set user remote class super-user
```

- To use different login classes for different TACACS+-authenticated users, granting them different permissions:
  - a. Create multiple user templates in the Junos OS configuration. For example:

```
[edit groups global system login]
user@host# set user R0 class read-only
user@host# set user OP class operator
user@host# set user SU class super-user
user@host# set user remote full-name "default remote access user template"
user@host# set user remote class read-only
```

- b. Configure the TACACS+ server to map the authenticated user to the appropriate user template.

For example, set the `local-user-name` Juniper vendor-specific attribute (VSA) to the name of a user template configured on the device, which in the previous example is RO, OP, or SU. Authentication fails if the device cannot assign a user to a local user account or user template and the `remote` user template is not configured.

## Configure TACACS+ to Use the Management Instance

By default, Junos OS routes authentication, authorization, and accounting packets for TACACS+ through the default routing instance. You can also route TACACS+ packets through a management interface in a non-default VRF instance.

To route TACACS+ packets through the `mgmt_junos` management instance:

1. Enable the `mgmt_junos` management instance.

```
[edit system]
user@host# set management-instance
```

2. Configure the `routing-instance mgmt_junos` statement for the TACACS+ authentication server and the TACACS+ accounting server, if configured.

```
[edit system]
user@host# set tacplus-server server-address routing-instance mgmt_junos
user@host# set accounting destination tacplus server server-address routing-instance
mgmt_junos
```

## Configure the Same Authentication Service for Multiple TACACS+ Servers

You can configure the same authentication service for multiple TACACS+ servers by including statements at the `[edit system tacplus-server]` and `[edit system tacplus-options]` hierarchy levels.

To assign the same authentication service to multiple TACACS+ servers:

1. Configure the TACACS+ servers as described in ["Configure TACACS+ Authentication" on page 224](#).
2. Configure the `service-name` statement at the `[edit system tacplus-options]` hierarchy level.

*service-name* is the name of the authentication service, which by default is `junos-exec`.

```
[edit system tacplus-options]
user@host set service-name service-name
```

For example:

```
[edit system tacplus-options]
service-name bob;
```

The following example shows how to configure the same authentication service for multiple TACACS+ servers:

```
[edit system]
tacplus-server {
  10.2.2.2 secret "$ABC123"; ## SECRET-DATA
  10.3.3.3 secret "$ABC123"; ## SECRET-DATA
}
tacplus-options {
  service-name bob;
}
```

## Configure Juniper Networks Vendor-Specific TACACS+ Attributes

Junos OS can map TACACS+-authenticated users to a locally defined user account or user template account, which determines authorization. You can also optionally configure a user's access privileges by defining Juniper Networks vendor-specific TACACS+ attributes on the TACACS+ server. You define the attributes in the TACACS+ server configuration file on a per-user basis. The network device retrieves these attributes through an authorization request of the TACACS+ server after authenticating a user.

To specify these attributes, include a service statement of the following form in the TACACS+ server configuration file:

```
service = junos-exec {
  local-user-name = <username-local-to-router>
  allow-commands = "<allow-commands-regex>"
  allow-configuration-regexps = "<allow-configuration-regex>"
  deny-commands = "<deny-commands-regex>"
}
```

```
deny-configuration-regexps = "<deny-configuration-regex>"
}
```

You can define the service statement in a user statement or a group statement.

## Configure Periodic Refresh of the TACACS+ Authorization Profile

When you configure a device running Junos OS to use a TACACS+ server for authentication, the device prompts users for login information, which is verified by the TACACS+ server. After a user is successfully authenticated, the network device sends an authorization request to the TACACS+ server to obtain the authorization profile for the user. Authorization profiles specify the access permissions for authenticated users or devices.

The TACACS+ server sends the authorization profile as part of an authorization REPLY message. The remote user configured on the TACACS+ server is mapped to a local user or user template configured on the device running Junos OS. Junos OS combines the user's remote authorization profile and locally configured authorization profile, the latter of which is configured at the [edit system login class] hierarchy level.

By default, the exchange of authorization request and reply messages occurs only once, after successful authentication. You can configure the devices so that Junos OS periodically fetches the remote authorization profile from the TACACS+ server and refreshes the locally stored authorization profile. This periodic refresh ensures that the local device reflects any change in the authorization parameters without requiring that the user restart the authentication process.

To enable periodic refresh of the authorization profile, you must set the time interval at which the local device checks the authorization profile configured remotely on the TACACS+ server. If the remote authorization profile changes, the device fetches the authorization profile from the TACACS+ server and the authorization profile configured under the login class hierarchy. The device refreshes the authorization profile stored locally by combining the remote and locally configured authorization profiles.

You can configure the refresh time interval locally on the device running Junos OS or directly on the TACACS+ server. The time interval can range from 15 through 1440 minutes.

- To configure periodic refresh of the authorization profile on the local device, include the `authorization-time-interval` statement at the [edit system tacplus-options] hierarchy level, as follows:

```
[edit system tacplus-options]
user@host# set authorization-time-interval minutes
```

- To configure periodic refresh on the TACACS+ server, add the `refresh-time-interval` parameter in the authorization profile using the following syntax:

```
refresh-time-interval=minutes
```

Use the following guidelines to determine which time interval configuration takes precedence:

- If the refresh time interval is configured only on the TACACS+ server or only on the device running Junos OS, then the configured value takes effect.
- If the refresh time interval is configured on both the TACACS+ server and the device running Junos OS, the value configured on the TACACS+ server takes precedence.
- If no refresh time interval is configured on either the TACACS+ server or the device running Junos OS, then no periodic refresh occurs.
- If the refresh time interval configured on the TACACS+ server is out of range or invalid, the locally configured refresh time interval takes effect. If no refresh time interval is configured locally, then no periodic refresh occurs.

After the periodic refresh time interval is set, if the user changes the refresh interval before the authorization request is sent from the local device, the updated refresh interval takes effect after the next immediate periodic refresh.

## Example: Configure a TACACS+ Server for System Authentication

### IN THIS SECTION

- [Requirements | 232](#)
- [Overview | 233](#)
- [Configuration | 233](#)
- [Verification | 235](#)

This example configures system authentication through a TACACS+ server.

### Requirements

Before you begin:

- Perform the initial device configuration. See the Getting Started Guide for your device.
- Set up at least one TACACS+ server on your network.

## Overview

In this example, you add a new TACACS+ server with an IP address of 172.16.98.1. You specify the shared secret password of the TACACS+ server as Tacacssecret1. The device stores the secret in the configuration database as an encrypted value. Finally, you specify the source address that the device uses in TACACS+ server requests. In most cases, you can use the loopback address of the device, which in this example is 10.0.0.1.

You can configure support for multiple user authentication methods, such as local password authentication, TACACS+, and RADIUS, on the network device. When you configure multiple authentication methods, you can prioritize the order in which the device tries the different methods. In this example, you configure the device to use TACACS+ authentication services first and, if that fails, to then attempt local password authentication.

A TACACS+-authenticated user must map to a local user account or a local user template account on the network device, which determines authorization. By default, if a TACACS+-authenticated user does not map to a local user account or a specific user template, the user is assigned to the remote user template, if configured. This example configures the remote user template.

## Configuration

### IN THIS SECTION

- [Procedure](#) | 233

## Procedure

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the [edit] hierarchy level, and then enter `commit` in configuration mode.

```
set system tacplus-server 172.16.98.1
set system tacplus-server 172.16.98.1 secret Tacacssecret1
set system tacplus-server 172.16.98.1 source-address 10.0.0.1
```

```
set system authentication-order [tacplus password]
set system login user remote class operator
```

## Step-by-Step Procedure

To configure a TACACS+ server for system authentication:

1. Add a new TACACS+ server and set its IP address.

```
[edit system]
user@host# set tacplus-server 172.16.98.1
```

2. Specify the shared secret (password) of the TACACS+ server.

```
[edit system]
user@host# set tacplus-server 172.16.98.1 secret Tacacssecret1
```

3. Specify the device's loopback address as the source address.

```
[edit system]
user@host# set tacplus-server 172.16.98.1 source-address 10.0.0.1
```

4. Specify the device's order of authentication, and include the tacplus option.

```
[edit system]
user@host# set authentication-order [tacplus password]
```

5. Configure the remote user template and its login class.

```
[edit system]
user@host# set login user remote class operator
```

## Results

In configuration mode, confirm your configuration by entering the `show system` command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

The following output includes only those portions of the configuration hierarchy that are relevant to this example:

```
[edit]
user@host# show system
login {
    user remote {
        class operator;
    }
}
authentication-order [ tacplus password ];
tacplus-server {
    172.16.98.1 {
        secret "$9$ABC123"; ## SECRET-DATA
        source-address 10.0.0.1;
    }
}
```

After you configure the device, enter `commit` in configuration mode.

## Verification

### IN THIS SECTION

- [Verify the TACACS+ Server Configuration | 235](#)

Confirm that the configuration is working properly.

### Verify the TACACS+ Server Configuration

#### Purpose

Verify that the TACACS+ server authenticates users.

#### Action

Log in to the network device, and verify that the login is successful. To verify that the device uses the TACACS+ server for authentication, you can attempt to log in with an account that does not define a local authentication password in the configuration.

## Juniper Networks Vendor-Specific TACACS+ Attributes

Junos OS supports configuring Juniper Networks TACACS+ vendor-specific attributes (VSAs) on the TACACS+ server. [Table 15 on page 236](#) lists the supported Juniper Networks VSAs.

Some of the attributes accept extended regular expressions, as defined in POSIX 1003.2. If the regular expression contains any spaces, operators, or wildcard characters, enclose it in quotation marks. For more information, see:

- ["Regular Expressions to Allow and Deny Operational Mode Commands, Configuration Statements, and Hierarchies" on page 61](#)
- ["Use Regular Expressions on a RADIUS or TACACS+ Server to Allow or Deny Commands" on page 238](#)

**Table 15: Juniper Networks Vendor-Specific TACACS+ Attributes**

Name	Description	Length	String
local-user-name	Indicates the name of the user template assigned to this user when the user logs in to a device.	≥3	One or more octets containing printable ASCII characters.
allow-commands	Contains an extended regular expression that enables the user to run commands in addition to those commands authorized by the user's login class permission bits.	≥3	One or more octets containing printable ASCII characters, in the form of an extended regular expression.
allow-commands-regexps	Contains an extended regular expression that enables the user to run commands in addition to those commands authorized by the user's login class permission bits.	≥3	One or more octets containing printable ASCII characters, in the form of an extended regular expression.
allow-configuration	Contains an extended regular expression that enables the user to view and modify configuration statements in addition to those statements authorized by the user's login class permission bits.	≥3	One or more octets containing printable ASCII characters, in the form of an extended regular expression.

**Table 15: Juniper Networks Vendor-Specific TACACS+ Attributes (Continued)**

Name	Description	Length	String
allow-configuration-regexps	Contains an extended regular expression that enables the user to view and modify configuration statements in addition to those statements authorized by the user's login class permission bits.	≥3	One or more octets containing printable ASCII characters, in the form of an extended regular expression.
deny-commands	Contains an extended regular expression that denies the user permission to run commands authorized by the user's login class permission bits.	≥3	One or more octets containing printable ASCII characters, in the form of an extended regular expression.
deny-commands-regexps	Contains an extended regular expression that denies the user permission to run commands authorized by the user's login class permission bits.	≥3	One or more octets containing printable ASCII characters, in the form of an extended regular expression.
deny-configuration	Contains an extended regular expression that denies the user permission to view or modify configuration statements authorized by the user's login class permission bits.	≥3	One or more octets containing printable ASCII characters, in the form of an extended regular expression.
deny-configuration-regexps	Contains an extended regular expression that denies the user permission to view or modify configuration statements authorized by the user's login class permission bits.	≥3	One or more octets containing printable ASCII characters, in the form of an extended regular expression.

Table 15: Juniper Networks Vendor-Specific TACACS+ Attributes (Continued)

Name	Description	Length	String
user-permissions	<p>Contains information the server uses to specify user permissions.</p> <p><b>NOTE:</b> When the TACACS+ server defines the user-permissions attribute to grant the maintenance permission or all permission to a user, the user's list of group memberships does not automatically include the UNIX wheel group. Some operations such as running the su root command from a local shell require wheel group membership permissions. However, when the network device defines a local user account with the permissions maintenance or all, the user is automatically granted membership to the UNIX wheel group. Therefore, we recommend that you create a user template account with the required permissions and associate individual user accounts with the user template account.</p>	≥3	<p>One or more octets containing printable ASCII characters.</p> <p>See <a href="#">"Access Privilege Levels Overview"</a> on page 51.</p>
authentication-type	Indicates the authentication method (local database or TACACS+ server) used to authenticate a user. If the user is authenticated using a local database, the attribute value shows 'local'. If the user is authenticated using a TACACS+ server, the attribute value shows 'remote'.	≥5	One or more octets containing printable ASCII characters.
session-port	Indicates the source port number of the established session.	size of integer	Integer

## Use Regular Expressions on a RADIUS or TACACS+ Server to Allow or Deny Commands

Junos OS can map RADIUS- and TACACS+-authenticated users to a locally defined user account or user template account, which defines the user's access privileges. You can also optionally configure a user's

access privileges by defining Juniper Networks RADIUS and TACACS+ vendor-specific attributes (VSAs) on the respective authentication server.

A user's login class defines the set of permissions that determines which operational mode and configuration mode commands a user is authorized to execute and which areas of the configuration a user can view and modify. A login class can also define regular expressions that allow or deny a user the ability to execute certain commands or view and modify certain areas of the configuration, in addition to what the permission flags authorize. A login class can include the following statements to define user authorization:

- `permissions`
- `allow-commands`
- `allow-commands-regexps`
- `allow-configuration`
- `allow-configuration-regexps`
- `deny-commands`
- `deny-commands-regexps`
- `deny-configuration`
- `deny-configuration-regexps`

Similarly, a RADIUS or TACACS+ server configuration can use Juniper Networks VSAs to define specific permissions or regular expressions that determine a user's access privileges. For the list of supported RADIUS and TACACS+ VSAs, see the following:

- ["Juniper Networks Vendor-Specific RADIUS and LDAP Attributes" on page 205](#)
- ["Juniper Networks Vendor-Specific TACACS+ Attributes" on page 236](#)

You can define user permissions on the RADIUS or TACACS+ server as a list of space-separated values.

- A RADIUS server uses the following attribute and syntax:

```
Juniper-User-Permissions += "flag1 flag2 flag3",
```

For example:

```
Juniper-User-Permissions += "interface interface-control configure",
```

- A TACACS+ server uses the following attribute and syntax:

```
user-permissions = "flag1 flag2 flag3"
```

For example:

```
user-permissions = "interface interface-control configure"
```

A RADIUS or TACACS+ server can also define Juniper Networks VSAs that use a single extended regular expression (as defined in POSIX 1003.2) to allow or deny a user the ability to execute certain commands or view and modify areas of the configuration. You enclose multiple commands or configuration hierarchies in parentheses and separate them using a pipe symbol. If the regular expression contains any spaces, operators, or wildcard characters, enclose it in quotation marks. When you configure authorization parameters both locally and remotely, the device merges the regular expressions received during TACACS+ or RADIUS authorization with any regular expressions defined on the local device.

- A RADIUS server uses the following attributes and syntax:

```
Juniper-Allow-Commands += "(cmd1)|(cmd2)|(cmdn)",
Juniper-Deny-Commands += "(cmd1)|(cmd2)|(cmdn)",
Juniper-Allow-Configuration += "(config1)|(config2)|(confign)",
Juniper-Deny-Configuration += "(config1)|(config2)|(confign)",
```

For example:

```
Juniper-Allow-Commands += "(test)|(ping)|(quit)",
Juniper-Deny-Commands += "(request)|(restart)",
Juniper-Allow-Configuration += "(groups re0)|(system radius-server)",
Juniper-Deny-Configuration += "(system radius-options)|(system accounting)",
```

- A TACACS+ server uses the following attributes and syntax:

```
allow-commands = "(cmd1)|(cmd2)|(cmdn)"
deny-commands = "(cmd1)|(cmd2)|(cmdn)"
allow-configuration = "(config1)|(config2)|(confign)"
deny-configuration = "(config1)|(config2)|(confign)"
```

For example:

```
allow-commands = "(test)|(ping)|(quit)"
deny-commands = "(request)|(restart)"
allow-configuration = "(groups re0)|(system tacplus-server)"
deny-configuration = "(system tacplus-options)|(system accounting)"
```

RADIUS and TACACS+ servers also support configuring attributes that correspond to the same \*-regexps statements that you can configure on the local device. The \*-regexps TACACS+ attributes and the \*-Regexps RADIUS attributes use the same regular expression syntax as the previous attributes, but they enable you to configure regular expressions with variables.

- A RADIUS server uses the following attributes and syntax:

```
Juniper-Allow-Configuration-Regexps += "(config1)|(config2)|(config)",
Juniper-Deny-Configuration-Regexps += "(config1)|(config2)|(config)",
```

- A TACACS+ server uses the following attributes and syntax:

```
allow-commands-regexps = "(cmd1)|(cmd2)|(cmdn)"
deny-commands-regexps = "(cmd1)|(cmd2)|(cmdn)"
allow-configuration-regexps = "(config1)|(config2)|(config)"
deny-configuration-regexps = "(config1)|(config2)|(config)"
```

For example, the TACACS+ server configuration might define the following attributes:

```
allow-commands-regexps = "(show cli .*)|(ping 10.1.1..*)"
deny-commands-regexps = "(configure .*)|(edit)|(commit)|(rollback .*)"
```

On a RADIUS or TACACS+ server, you can also define the attributes using a simplified syntax where you specify each individual expression on a separate line.

For a RADIUS server, specify the individual regular expressions using the following syntax:

```
Juniper-User-Permissions += "permission-flag1",
Juniper-User-Permissions += "permission-flag2",
Juniper-User-Permissions += "permission-flagn",
Juniper-Allow-Commands += "cmd1",
```

```

Juniper-Allow-Commands += "cmd2",
Juniper-Allow-Commands += "cmdn",
Juniper-Deny-Commands += "cmd1",
Juniper-Deny-Commands += "cmd2",
Juniper-Deny-Commands += "cmdn",
Juniper-Allow-Configuration += "config1",
Juniper-Allow-Configuration += "config2",
Juniper-Allow-Configuration += "confign",
Juniper-Deny-Configuration += "config1",
Juniper-Deny-Configuration += "config2",
Juniper-Deny-Configuration += "confign",

```

For a TACACS+ server, specify the individual regular expressions using the following syntax:

```

user-permissions1 = "permission-flag1"
user-permissions2 = "permission-flag2"
user-permissionsn = "permission-flagn"
allow-commands1 = "cmd1"
allow-commands2 = "cmd2"
allow-commandsn = "cmdn"
deny-commands1 = "cmd1"
deny-commands2 = "cmd2"
deny-commandsn = "cmdn"
allow-configuration1 = "config1"
allow-configuration2 = "config2"
allow-configurationn = "confign"
deny-configuration1 = "config1"
deny-configuration2 = "config2"
deny-configurationn = "confign"

```

#### NOTE:

- In the TACACS+ server syntax, numeric values 1 through *n* must be unique but need not be sequential. For example, the following syntax is valid:

```

allow-commands1="cmd1"
allow-commands3="cmd3"
allow-commands2="cmd2"

```

```
deny-commands3="cmd3"
deny-commands2="cmd2"
deny-commands1="cmd1"
```

- The RADIUS or TACACS+ server imposes a limit on the number of individual regular expression lines.
- When you issue the `show cli authorization` command, the command output displays the regular expression in a single line, even if you specify each individual expression on a separate line.

Users can verify their class, permissions, and command and configuration authorization by issuing the `show cli authorization` operational mode command.

```
user@host> show cli authorization
```

**NOTE:** When you configure the authorization parameters both locally on the network device and remotely on the RADIUS or TACACS+ server, the device merges the regular expressions received during TACACS+ or RADIUS authorization with any locally configured regular expressions. If the final expression contains a syntax error, the overall result is an invalid regular expression.

## Configuring TACACS+ System Accounting

### IN THIS SECTION

- [Configure TACACS+ Server Accounting | 244](#)

You can configure TACACS+ accounting on a device to collect statistical data about users logging in to or out of a LAN and send the data to a TACACS+ accounting server. The statistical data can be used for general network monitoring, analyzing and tracking usage patterns, or billing a user based on the duration of the session or type of services accessed.

To configure TACACS+ accounting, specify:

- One or more TACACS+ accounting servers to receive the statistical data from the device
- The type of accounting data to collect

You can use the same server for both TACACS+ accounting and authentication, or you can use separate servers. You can specify a list of TACACS+ accounting servers. The device queries the servers in the order in which they are configured. If the primary server (the first one configured) is unavailable, the device attempts to contact each server in the list until it receives a response.

When you enable TACACS+ accounting, Juniper Networks devices, acting as TACACS+ clients, can notify the TACACS+ server about user activities such as software logins, configuration changes, and interactive commands.

## Configure TACACS+ Server Accounting

To configure TACACS+ server accounting:

1. Configure the events to audit.

```
[edit system accounting]
user@host# set events [ events ]
```

For example:

```
[edit system accounting]
user@host# set events [ login change-log interactive-commands ]
```

*events* can include one or more of the following:

- login—Audit logins
- change-log—Audit configuration changes
- interactive-commands—Audit interactive commands (any command-line input)

2. Enable TACACS+ accounting.

```
[edit]
user@host# set system accounting destination tacplus
```

3. Configure the address for one or more TACACS+ accounting servers.

```
[edit system accounting destination tacplus]
user@host# set server server-address
```

For example:

```
[edit system accounting destination tacplus]
user@host# set server 192.168.17.28
```

**NOTE:** If you do not configure any TACACS+ servers at the [edit system accounting destination tacplus] hierarchy level, the device uses the TACACS+ servers configured at the [edit system tacplus-server] hierarchy level.

4. (Optional) Configure the source address for TACACS+ accounting requests.

```
[edit system accounting destination tacplus server server-address]
user@host# set source-address source-address
```

For example:

```
[edit system accounting destination tacplus server 192.168.17.28]
user@host# set source-address 192.168.17.1
```

The source address is a valid IPv4 address or IPv6 address configured on one of the router interfaces or switch interfaces. If the network device has several interfaces that can reach the TACACS+ server, assign an IP address that the device can use for all its communication with the TACACS+ server. Doing this sets a fixed address as the source address for locally generated IP packets.

5. Configure the shared secret password that the network device uses to authenticate with the TACACS+ accounting server.

The configured password must match the password that is configured on the TACACS+ server. If the password contains spaces, enclose it in quotation marks. The device stores the password as an encrypted value in the configuration database.

```
[edit system accounting destination tacplus server server-address]
user@host# set secret password
```

For example:

```
[edit system accounting destination tacplus server 192.168.17.28]
user@host# set secret Tacplussecret1
```

6. (Optional) If necessary, specify to which TACACS+ accounting server port to send accounting packets, if different from the default (49).

```
[edit system accounting destination tacplus server server-address]
user@host# set accounting-port port-number
```

7. (Optional) Configure the amount of time that the device waits to receive a response from the TACACS+ accounting server.

By default, the device waits three seconds. You can configure the `timeout` value from 1 through 90 seconds.

```
[edit system accounting destination tacplus server server-address]
user@host# set timeout seconds
```

For example, to wait 15 seconds for a response from the server:

```
[edit system accounting destination tacplus server 192.168.17.28]
user@host# set timeout 15
```

8. (Optional) Configure the device to maintain one open TCP connection to the server for multiple requests rather than opening a separate connection for each connection attempt.

```
[edit system accounting destination tacplus server server-address]
user@host# set single-connection
```

**NOTE:** Early versions of the TACACS+ server do not support the `single-connection` option. If you specify this option and the server does not support it, the device will be unable to communicate with that TACACS+ server.

9. (Optional) To route TACACS+ accounting packets through the non-default management instance or another routing instance instead of the default routing instance, configure the `routing-instance` statement and specify the routing instance.

```
[edit system accounting destination tacplus server server-address]
user@host# set routing-instance routing-instance
```

For example:

```
[edit system accounting destination tacplus server 192.168.17.28]
user@host# set routing-instance mgmt_junos
```

10. To ensure that start and stop requests for login events are correctly logged in the TACACS+ server Accounting log file instead of the Administration log file, include either the `no-cmd-attribute-value` statement or the `exclude-cmd-attribute` statement at the `[edit system tacplus-options]` hierarchy level.

```
[edit system tacplus-options]
user@host# set (no-cmd-attribute-value | exclude-cmd-attribute)
```

**NOTE:** Both statements support the correct logging of accounting requests in the Accounting file instead of the Administration file. If you configure the `no-cmd-attribute-value` statement, the value of the `cmd` attribute is set to a null string in the start and stop requests. If you configure the `exclude-cmd-attribute` statement, the `cmd` attribute is totally excluded from the start and stop requests.

#### Release History Table

Release	Description
18.2R1	Starting in Junos OS Release 18.2R1, you can route TACACS+ traffic through any routing instance you configure in authentication.
17.4R1	Starting in Junos OS Release 17.4R1, existing TACACS+ behavior is enhanced to support routing TACACS+ packets through a management interface in a non-default VRF instance named <code>mgmt_junos</code> .

# Authentication for Routing Protocols

## IN THIS SECTION

- [Authentication Methods for Routing Protocols | 248](#)
- [Example: Configure the Authentication Key for BGP and IS-IS Routing Protocols | 249](#)
- [Configure the Authentication Key Update Mechanism for Routing Protocols | 252](#)

You can configure an authentication method and password for routing protocol messages for many routing protocols including BGP, IS-IS, OSPF, RIP, and RSVP. To prevent the exchange of unauthenticated or forged packets, routers must ensure that they form routing protocol relationships (peering or neighboring relationships) to trusted peers. One way of doing this is by authenticating routing protocol messages. Neighboring routers use the password to verify the authenticity of packets sent by the protocol from the router or from a router interface.

This topic provides a high-level overview and some basic examples for authenticating routing protocols. For detailed information about configuring authentication for a specific routing protocol, see the user guide for that protocol.

## Authentication Methods for Routing Protocols

Some routing protocols—BGP, IS-IS, OSPF, RIP, and RSVP—enable you to configure an authentication method and password. Neighboring routers use the password to verify the authenticity of packets that the protocol sends from the router or from a router interface. The following authentication methods are supported:

- Simple authentication (IS-IS, OSPF, and RIP)—Uses a simple text password. The receiving router uses an authentication key (password) to verify the packet. Because the password is included in the transmitted packet, this method of authentication is relatively insecure. We recommend that you *avoid* using this authentication method.
- MD5 and HMAC-MD5 (BGP, IS-IS, OSPF, RIP, and RSVP)—MD5 creates an encoded checksum that is included in the transmitted packet. HMAC-MD5, which combines HMAC authentication with MD5, adds the use of an iterated cryptographic hash function. With both types of authentication, the receiving router uses an authentication key (password) to verify the packet. HMAC-MD5 authentication is defined in RFC 2104, *HMAC: Keyed-Hashing for Message Authentication*.

In general, authentication passwords are text strings consisting of some maximum number of letters and digits. Passwords can include any ASCII characters. If you include spaces in a password, enclose all characters in quotation marks (" ").

Junos-FIPS has special password requirements. FIPS passwords must be between 10 and 20 characters in length. Passwords must use at least three of the five defined character sets (uppercase letters, lowercase letters, digits, punctuation marks, and other special characters). If Junos-FIPS is installed on the router, you cannot configure passwords unless they meet this standard.

## Example: Configure the Authentication Key for BGP and IS-IS Routing Protocols

### IN THIS SECTION

- [Configure BGP | 250](#)
- [Configure IS-IS | 251](#)

The main task of a router is to use its routing and forwarding tables to forward user traffic to its intended destination. Attackers can send forged routing protocol packets to a router with the intent of changing or corrupting the contents of its routing table or other databases, which in turn can degrade the functionality of the router and the network. To prevent such attacks, routers must ensure that they form routing protocol relationships (peering or neighboring relationships) to trusted peers. One way of doing this is by authenticating routing protocol messages. We strongly recommend using authentication when configuring routing protocols.

Junos OS supports HMAC-MD5 authentication for BGP, IS-IS, OSPF, RIP, and RSVP. HMAC-MD5 uses a secret key combined with the data being transmitted to compute a hash. The computed hash is transmitted along with the data. The receiver uses the matching key to recompute and validate the message hash. If an attacker has forged or modified the message, the hash will not match, and the data is discarded.

In the following examples, we configure BGP as the exterior gateway protocol (EGP) and IS-IS as the interior gateway protocol (IGP). If you use OSPF, configure it similarly to the IS-IS configuration shown.

## Configure BGP

The following example shows the configuration of a single authentication key for the different BGP peer groups. You can also configure BGP authentication at the neighbor or routing instance levels, or for all BGP sessions. As with any security configuration, there is a trade-off between the degree of granularity (and to some extent, the degree of security) and the amount of management necessary to maintain the system.

This example also configures a number of tracing options for routing protocol events and errors, which can be good indicators of attacks against routing protocols. These events include protocol authentication failures, which might point to an attacker. The attacker may be sending spoofed or otherwise malformed routing packets to the router in an attempt to elicit a particular behavior.

```
[edit]
protocols {
  bgp {
    group ibgp {
      type internal;
      traceoptions {
        file bgp-trace size 1m files 10;
        flag state;
        flag general;
      }
      local-address 10.10.5.1;
      log-updown;
      neighbor 10.2.1.1;
      authentication-key "$9$aH1j8gqQ1gjyjjghgjgiiiiii";
    }
    group ebgp {
      type external;
      traceoptions {
        file ebgp-trace size 10m files 10;
        flag state;
        flag general;
      }
      local-address 10.10.5.1;
      log-updown;
      peer-as 2;
      neighbor 10.2.1.2;
      authentication-key "$9$aH1j8gqQ1gjyjjghgjgiiiiii";
    }
  }
}
```

```

    }
}

```

## Configure IS-IS

Although Junos OS supports authentication for all IGPs, some IGPs are inherently more secure than others. Most service providers use OSPF or IS-IS to allow fast internal convergence and scalability and to use traffic engineering capabilities with MPLS. Because IS-IS does not operate at the network layer, it is more difficult to spoof than OSPF. OSPF is encapsulated in IP and is therefore subject to remote spoofing and denial of service (DoS) attacks.

The following example configures authentication for IS-IS. It also configures a number of tracing options for routing protocol events and errors, which can be good indicators of attacks against routing protocols. These events include protocol authentication failures, which might point to an attacker. The attacker may be sending spoofed or otherwise malformed routing packets to the router in an attempt to elicit a particular behavior.

```

[edit]
protocols {
  isis {
    level 1 {
      authentication-key "$9$aH1j8gqQ1gjyjjhgjgiiii"; # SECRET-DATA
      authentication-type md5;
    }
    interface at-0/0/0.131 {
      lsp-interval 50;
      level 2 disable;
      level 1 {
        metric 3;
        hello-interval 5;
        hold-time 60;
      }
    }
    interface lo0.0 {
      passive;
    }
    traceoptions {
      file isis-trace size 10m files 10;
      flag normal;
      flag error;
    }
  }
}

```

```
}
}
```

## Configure the Authentication Key Update Mechanism for Routing Protocols

### IN THIS SECTION

- [Configure Authentication Key Updates | 252](#)
- [Configure BGP and LDP for Authentication Key Updates | 253](#)

You can configure an authentication key update mechanism for the BGP, LDP, and IS-IS routing protocols. This mechanism enables you to update authentication keys without interrupting associated routing and signaling protocols such as OSPF and RSVP.

To configure this feature, include the `authentication-key-chains` statement at the `[edit security]` hierarchy level. To apply the key chain, you must configure the key chain identifier and the key chain algorithm at the appropriate hierarchy level for the protocol.

The following sections provide more information about configuring authentication key updates for routing protocols. For detailed information about configuring authentication key updates for a specific routing protocol, see the user guide for that protocol.

### Configure Authentication Key Updates

To configure the authentication key update mechanism, include the `key-chain` statement at the `[edit security authentication-key-chains]` hierarchy level, and specify the `key` option to create a keychain consisting of several authentication keys.

```
[edit security authentication-key-chains]
key-chain key-chain-name {
  key key {
    algorithm (hmac-sha-1 | md5)
    options (basic | isis-enhanced)
    secret secret-data;
    start-time yyyy-mm-dd.hh:mm:ss;
```

```
    }
}
```

**key-chain**—Assign a name to the keychain mechanism. You reference this name at the appropriate hierarchy levels for the protocol to associate unique authentication key-chain attributes, as specified using the following options:

- **algorithm**—Authentication algorithm for IS-IS.
- **key**—Integer value that uniquely identifies each key within a keychain. The range is from 0 through 63.
- **options**—(IS-IS only) Protocol transmission encoding format for encoding the message authentication code in routing protocol packets.
- **secret**—Password in encrypted text or plain text format. Even if you enter the secret data in plain-text format, the secret always appears in encrypted format.
- **start-time**—Start time for authentication key transmission, specified in *UTC*. The start time must be unique within the keychain.

## Configure BGP and LDP for Authentication Key Updates

To configure the authentication key update mechanism for the BGP and LDP routing protocols, include the `authentication-key-chain` statement within the `[edit protocols (bgp | ldp)]` hierarchy level. Including the `authentication-key-chain` statement associates each routing protocol with the `[edit security authentication-key-chains]` authentication keys. You must also configure the `authentication-algorithm` statement and specify the algorithm. For example:

```
[edit protocols]
bgp {
  group group-name {
    neighbor address {
      authentication-algorithm algorithm;
      authentication-key-chain key-chain-name;
    }
  }
}
ldp {
  session session-addr {
    authentication-algorithm algorithm;
    authentication-key-chain key-chain-name;
  }
}
```

**NOTE:** When configuring the authentication key update mechanism for BGP, you cannot commit the `0.0.0.0/allow` statement with authentication keys or keychains. If you try this action, the CLI issues a warning, and the commit fails.

- [Configure NETCONF-Over-SSH Connections on a Specified TCP Port | 276](#)
- [Configure Password Retry Limits for Telnet and SSH Access | 277](#)
- [Example: Configure a Filter to Block Telnet and SSH Access | 278](#)

You (the network administrator) can access a router, switch, or security device remotely using services such as DHCP, Finger, FTP, rlogin, SSH, and Telnet services. This topic shows you how to configure remote access using Telnet, SSH, FTP, and Finger services.

## System Services Overview

For security reasons, remote access to the router is disabled by default. You must configure the router explicitly so that users on remote systems can access it. Users can access the router from a remote system by means of the DHCP, finger, FTP, rlogin, SSH, and Telnet services. In addition, Junos XML protocol client applications can use Secure Sockets Layer (SSL) or the Junos XML protocol-specific clear-text service, among other services.

**NOTE:** To protect system resources, you can limit the number of simultaneous connections that a service accepts and the number of processes owned by a single user. If either limit is exceeded, connection attempts fail.

## Configure Telnet Service for Remote Access to a Router or Switch

To configure the router or switch to accept Telnet as an access service, include the `telnet` statement at the `[edit system services]` hierarchy level:

```
[edit system services]
telnet {
  connection-limit limit;
  rate-limit limit;
}
```

By default, the router or switch supports a limited number of simultaneous Telnet sessions and connection attempts per minute.

Optionally, you can include either or both of the following statements to change the defaults:

- `connection-limit limit`—Maximum number of simultaneous connections per protocol (IPv4 and IPv6). The range is from 1 through 250. The default is 75. When you configure a connection limit, the limit is applicable to the number of telnet sessions per protocol (IPv4 and IPv6). For example, a connection limit of 10 allows 10 IPv6 telnet sessions and 10 IPv4 telnet sessions.
- `rate-limit limit`—Maximum number of connection attempts accepted per minute (from 1 through 250). The default is 150. When you configure a rate limit, the limit is applicable to the number of connection attempts per protocol (IPv4 and IPv6). For example, a rate limit of 10 allows 10 IPv6 telnet session connection attempts per minute and 10 IPv4 telnet session connection attempts per minute.

You cannot include the `telnet` statement on devices that run the Junos-FIPS software. We recommend that you do not use Telnet in a Common Criteria environment.

## Configure FTP Service for Remote Access to the Router or Switch

To configure the device to accept FTP as an access service, include the `ftp` statement at the `[edit system services]` hierarchy level:

```
[edit system services]
ftp {
  connection-limit limit;
  rate-limit limit;
}
```

By default, the router or switch supports a limited number of simultaneous FTP sessions and connection attempts per minute. You can include either or both of the following statements to change the defaults:

- `connection-limit limit`—Maximum number of simultaneous connections per protocol (IPv4 and IPv6). The range is a value from 1 through 250. The default is 75. When you configure a connection limit, the limit is applicable to the number of sessions per protocol (IPv4 and IPv6). For example, a connection limit of 10 allows 10 IPv6 FTP sessions and 10 IPv4 FTP sessions.
- `rate-limit limit`—Maximum number of connection attempts accepted per minute (a value from 1 through 250). The default is 150. When you configure a rate limit, the limit is applicable to the number of connection attempts per protocol (IPv4 and IPv6). For example, a rate limit of 10 allows 10 IPv6 FTP session connection attempts and 10 IPv4 FTP session connection attempts.

You can use passive FTP to access devices that accept only passive FTP services. All commands and statements that use FTP also accept passive FTP. Include the `ftp` statement at the `[edit system services]` hierarchy level to use either active FTP or passive FTP.

To start a passive FTP session, use `pasvftp` (instead of `ftp`) in the standard FTP format (**ftp:// destination**). For example:

```
request system software add pasvftp://name.com/jinstall.tgz
```

You cannot include the `ftp` statement on routers or switches that run the Junos-FIPS software. We recommend that you not use the FTP service in a Common Criteria environment.

## Configure Finger Service for Remote Access to the Router

To configure the router to accept finger as an access service, include the `finger` statement at the `[edit system services]` hierarchy level:

```
[edit system services]
finger {
    connection-limit limit;
    rate-limit limit;
}
```

By default, the router supports a limited number of simultaneous finger sessions and connection attempts per minute. Optionally, you can include either or both of the following statements to change the defaults:

- `connection-limit limit`—Maximum number of simultaneous connections per protocol (IPv4 and IPv6). The range is a value from 1 through 250. The default is 75. When you configure a connection limit, the limit is applicable to the number of sessions per protocol (IPv4 and IPv6). For example, a connection limit of 10 allows 10 IPv6 clear-text service sessions and 10 IPv4 clear-text service sessions
- `rate-limit limit`—Maximum number of connection attempts accepted per minute (a value from 1 through 250). The default is 150. When you configure a rate limit, the limit is applicable to the number of connection attempts per protocol (IPv4 and IPv6). For example, a rate limit of 10 allows 10 IPv6 session connection attempts per minute and 10 IPv4 session connection attempts per minute.

You cannot include the `finger` statement on routers that run the Junos-FIPS software. We recommend that you not use the finger service in a Common Criteria environment.

## Configure SSH Service for Remote Access to the Router or Switch

### IN THIS SECTION

- [Configure the Root Login Through SSH | 261](#)
- [Configure Incoming SFTP Connections | 262](#)
- [Configure the SSH Protocol Version | 262](#)

- [Configure the Client Alive Mechanism | 263](#)
- [Configure the SSH Fingerprint Hash Algorithm | 263](#)

To configure the router or switch to accept SSH as an access service, include the `ssh` statement at the [edit system services] hierarchy level:

```
[edit system services]
ssh {
  authentication-order [method 1 method2...];
  authorized-keys-command authorized-keys-command;
  authorized-keys-command-user authorized-keys-command-user;
  ciphers [ cipher-1 cipher-2 cipher-3 ...];
  client-alive-count-max number;
  client-alive-interval seconds;
  connection-limit limit;
  fingerprint-hash (md5 | sha2-256);
  hostkey-algorithm (algorithm | no-algorithm);
  key-exchange [algorithm1 algorithm2...];
  log-key-changes log-key-changes;
  macs [algorithm1 algorithm2...];
  max-pre-authentication-packets number;
  max-sessions-per-connection number;
  no-challenge-response;
  no-password-authentication;
  no-passwords;
  no-public-keys;
  no-tcp-forwarding;
  port port-number;
  protocol-version [v2];
  rate-limit number;
  rekey {
    data-limit bytes;
    time-limit minutes;
  }
  root-login (allow | deny | deny-password);
  sftp-server;
  tcp-forwarding;
}
```

By default, the router or switch supports a limited number of simultaneous SSH sessions and connection attempts per minute. Use the following statements to change the defaults:

- `connection-limit limit`—Maximum number of simultaneous connections per protocol (IPv4 and IPv6). The range is a value from 1 through 250. The default is 75. When you configure a connection limit, the limit is applicable to the number of SSH sessions per protocol (IPv4 and IPv6). For example, a connection limit of 10 allows 10 IPv6 SSH sessions and 10 IPv4 SSH sessions.
- `max-sessions-per-connection number`—Include this statement to specify the maximum number of SSH sessions allowed per single SSH connection. This allows you to limit the number of cloned sessions tunneled within a single SSH connection. The default value is 10.
- `rate-limit limit`—Maximum number of connection attempts accepted per minute (a value from 1 through 250). The default is 150. When you configure a rate limit, the limit is applicable to the number of connection attempts per protocol (IPv4 and IPv6). For example, a rate limit of 10 allows 10 IPv6 SSH session connection attempts per minute and 10 IPv4 SSH session connection attempts per minute.
- `data-limit`—Data limit before renegotiating session keys (bytes)
- `time-limit`—Time limit before renegotiating session keys (minutes)

Starting in Junos OS Release 19.4R1 and Junos OS Release 17.4R3, you can disable either the SSH login password or the challenge-response authentication using the `no-password-authentication` and `no-challenge-response` options at the `[edit system services ssh]` hierarchy level.

By default, a user can create an SSH tunnel over a CLI session to a router running Junos OS via SSH. This type of tunnel can be used to forward TCP traffic, bypassing any firewall filters or access control lists. By bypassing firewall filters or access control lists, this type of tunnel allows access to resources beyond the router. Use the `no-tcp-forwarding` option to prevent a user from creating an SSH tunnel to a router via SSH.

For information about other configuration settings, see the following topics:

## Configure the Root Login Through SSH

By default, users are allowed to log in to the router or switch as root through SSH when the authentication method does not require a password. To control user access through SSH, include the `root-login` statement at the `[edit systems services ssh]` hierarchy level:

```
[edit system services ssh]
root-login (allow | deny | deny-password);
```

`allow`—Allows users to log in to the router or switch as root through SSH.

`deny`—Disables users from logging in to the router or switch as root through SSH.

`deny-password`—Allows users to log in to the router or switch as root through SSH when the authentication method (for example, RSA) does not require a password.

The default is `deny-password`.

## Configure Incoming SFTP Connections

SSH File Transfer Protocol (SFTP) is a network protocol that provides file access, file transfer, and file management over any reliable data stream. Starting in Junos OS Release 19.1R1, we have globally disabled the incoming SFTP connections by default. If desired, you can globally enable incoming SFTP connections by configuring the statement `sftp-server` at the `[edit system services ssh]` hierarchy level. Prior to Junos OS Release 19.1R1, incoming SFTP connections were globally enabled by default.

**NOTE:** Only the incoming SFTP connections are disabled by default. For example, given devices A and B (where device A is running 19.1R1), you cannot connect through SFTP from B to A by default. However, you can connect through SFTP from device B to device A if you configure `sftp-server` on device A.

The incoming SFTP connections are disabled by default. To enable incoming SFTP connections:

1. Configure the `sftp-server` statement at the `[edit system services ssh]` hierarchy level:

```
[edit system services ssh]
user@host# set sftp-server
```

2. Commit the configuration.

```
[edit system services ssh]
user@host# commit
```

The `sftp-server` statement is now active. Therefore, the incoming SFTP connections are enabled.

## Configure the SSH Protocol Version

By default, only version 2 of the SSH protocol is enabled.

To configure the router or switch to use version 2 of the SSH protocol, include the `protocol-version` statement and specify `v2` at the `[edit system services ssh]` hierarchy level:

```
[edit system services ssh]
protocol-version [ v2 ];
```

Systems in FIPS mode always use SSH protocol version v2.

## Configure the Client Alive Mechanism

The client alive mechanism is valuable when the client or server depends on knowing when a connection has become inactive. It differs from the standard keepalive mechanism because the client alive messages are sent through the encrypted channel. The client alive mechanism is not enabled by default. To enable it, configure the `client-alive-count-max` and `client-alive-interval` statements. This option applies to SSH protocol version 2 only.

In the following example, unresponsive SSH clients will be disconnected after approximately 100 seconds (20 x 5):

```
[edit system services ssh]
client-alive-count-max 5;
client-alive-interval 20;
```

## Configure the SSH Fingerprint Hash Algorithm

To configure the hash algorithm used by the SSH server when it displays key fingerprints, include the `fingerprint-hash` statement and specify `md5` or `sha2-256` at the `[edit system services ssh]` hierarchy level:

```
[edit system services ssh]
fingerprint-hash (md5 | sha2-256);
```

The `md5` hash algorithm is unavailable on systems in FIPS mode.

# The telnet Command

You can use the CLI `telnet` command to open a Telnet session to a remote device:

```
user@host> telnet host <8bit> <bypass-routing> <inet> <interface interface-name> <no-resolve>
<port port> <routing-instance routing-instance-name> <source address>
```

**NOTE:** On SRX100, SRX210, SRX220, SRX240, SRX300, SRX320, SRX340, SRX345, and SRX1500 devices, the maximum number of concurrent Telnet sessions is indicated in the following table. Platform support depends on the Junos OS release in your installation.

SRX100	SRX210 SRX220	SRX240	SRX300 SRX320 SRX340	SRX345	SRX1500
3	3	5	3	5	5

To exit the Telnet session and return to the Telnet command prompt, press Ctrl-].

To exit the Telnet session and return to the CLI command prompt, enter `quit`.

**Table 16: CLI telnet Command Options**

Option	Description
8bit	Use an 8-bit data path.
bypass-routing	Bypass the routing tables and open a Telnet session only to hosts on directly attached interfaces. If the host is not on a directly attached interface, an error message is returned.
host	Open a Telnet session to the specified hostname or IP address.
inet	Force the Telnet session to an IPv4 destination.

**Table 16: CLI telnet Command Options (*Continued*)**

Option	Description
<code>interface <i>source-interface</i></code>	Open a Telnet session to a host on the specified interface. If you do not include this option, all interfaces are used.
<code>no-resolve</code>	Suppress the display of symbolic names.
<code>port <i>port</i></code>	Specify the port number or service name on the host.
<code>routing-instance <i>routing-instance-name</i></code>	Use the specified routing instance for the Telnet session.
<code>source <i>address</i></code>	Use the specified source address for the Telnet session.

## The ssh Command

You can use the CLI `ssh` command to use the secure shell (SSH) program to open a connection to a remote device:

```
user@host> ssh host <bypass-routing> <inet> <interface interface-name> <routing-instance routing-instance-name> <source address> <v1> <v2>
```

**NOTE:** On SRX100, SRX210, SRX220, SRX240, SRX300, SRX320, SRX340, SRX345, and SRX1500 devices, the maximum number of concurrent SSH sessions is indicated in the following table. Platform support depends on the Junos OS release in your installation.

SRX100	SRX210 SRX220	SRX240	SRX300 SRX320 SRX340	SRX345	SRX1500
3	3	5	3	5	5

Table 17 on page 266 describes the ssh command options.

**Table 17: CLI ssh Command Options**

Option	Description
bypass-routing	Bypass the routing tables and open an SSH connection only to hosts on directly attached interfaces. If the host is not on a directly attached interface, an error message is returned.
host	Open an SSH connection to the specified hostname or IP address.
inet	Force the SSH connection to an IPv4 destination.
interface <i>source-interface</i>	Open an SSH connection to a host on the specified interface. If you do not include this option, all interfaces are used.
routing-instance <i>routing-instance-name</i>	Use the specified routing instance for the SSH connection.
source <i>address</i>	Use the specified source address for the SSH connection.
v1	Force SSH to use version 1 for the connection.
v2	Force SSH to use version 2 for the connection.

## Configure SSH Host Keys for Secure Copying of Data

### IN THIS SECTION

- [Configure SSH Known Hosts | 267](#)
- [Configure Support for SCP File Transfer | 268](#)
- [Update SSH Host Key Information | 269](#)

Secure Shell (*SSH*) uses *encryption* algorithms to generate a host, server, and session key system that ensures secure data transfer. You can configure SSH host keys to support secure copy (*SCP*) as an alternative to *FTP* for the background transfer of data such as configuration archives and event logs. To configure SSH support for SCP, you must complete the following tasks:

- Specify SSH known hosts by including hostnames and host key information in the Routing Engine configuration hierarchy.
- Set an SCP URL to specify the host from which to receive data. Setting this attribute automatically retrieves SSH host key information from the SCP server.
- Verify that the host key is authentic.
- Accept the secure connection. Accepting this connection automatically stores host key information in the local host key database. Storing host key information in the configuration hierarchy automates the secure handshake and allows background data transfer using SCP.

Tasks to configure SSH host keys for secure copying of data are:

### Configure SSH Known Hosts

To configure SSH known hosts, include the `host` statement, and specify hostname and host key options for trusted servers at the `[edit security ssh-known-hosts]` hierarchy level:

```
[edit security ssh-known-hosts]
host corporate-archive-server {
    dsa-key key;
}
host archive-server-url {
    rsa-key key;
}
host server-with-ssh-version-1 {
```

```

    rsa1-key key;
}

```

Host keys are one of the following:

- dsa-key *key*—Base64 encoded Digital Signature Algorithm (DSA) key for SSH version 2.
- ecdsa-sha2-nistp256-key *key*—Base64 encoded ECDSA-SHA2-NIST256 key.
- ecdsa-sha2-nistp384-key *key*—Base64 encoded ECDSA-SHA2-NIST384 key.
- ecdsa-sha2-nistp521-key *key*—Base64 encoded ECDSA-SHA2-NIST521 key.
- ed25519-key *key*—Base64 encoded ED25519 key.
- rsa-key *key*—Base64 encoded public key algorithm that supports encryption and digital signatures for SSH version 1 and SSH version 2.
- rsa1-key *key*—Base64 encoded RSA public key algorithm, which supports encryption and digital signatures for SSH version 1.

## Configure Support for SCP File Transfer

To configure a known host to support background SCP file transfers, include the `archive-sites` statement at the `[edit system archival configuration]` hierarchy level.

```

[edit system archival configuration]
archive-sites {
    scp://username<:password>@host<:port>/url-path;
}

```

**NOTE:** When specifying a URL in a Junos OS statement using an IPv6 host address, you must enclose the entire URL in quotation marks (" ") and enclose the IPv6 host address in brackets ([ ]). For example, "`scp://username<:password>@[host]<:port>/url-path`";

Setting the `archive-sites` statement to point to an SCP URL triggers automatic host key retrieval. At this point, Junos OS connects to the SCP host to fetch the SSH public key, displays the host key message digest or fingerprint as output to the console, and terminates the connection to the server.

```
user@host# set system archival configuration archive-sites "<scp-url-path>"
The authenticity of host <my-archive-server (<server-ip-address>)> can't be established. RSA key
fingerprint is <ascii-text key>. Are you sure you want to continue connecting (yes/no)?
```

To verify that the host key is authentic, compare this fingerprint with a fingerprint that you obtain from the same host using a trusted source. If the fingerprints are identical, accept the host key by entering **yes** at the prompt. The host key information is then stored in the Routing Engine configuration and supports background data transfers using SCP.

## Update SSH Host Key Information

### IN THIS SECTION

- [Retrieve Host Key Information Manually | 269](#)
- [Import Host Key Information from a File | 270](#)

Typically, SSH host key information is automatically retrieved when you set a URL attribute for SCP using the `archival configuration archive-sites` statement at the `[edit system]` hierarchy level. However, if you need to manually update the host key database, use one of the following methods.

### Retrieve Host Key Information Manually

To manually retrieve SSH public host key information, configure the `fetch-from-server` option at the `[edit security ssh-known-hosts]` hierarchy level. You must specify the host from which to retrieve the SSH public key.

```
user@host# set security ssh-known-hosts fetch-from-server <hostname>
```

## Import Host Key Information from a File

To manually import SSH host key information from a **known\_hosts** file, include the `load-key-file` option at the `[edit security ssh-known-hosts]` hierarchy level. You must specify the path to the file from which to import host key information.

```
user@host# set security ssh-known-hosts load-key-file /var/tmp/known-hosts
```

## Configure the SSH Service to Support Legacy Cryptography

The SSH server in Junos OS is based on OpenSSH 7 and defaults to a more secure set of ciphers and key-exchange algorithms. OpenSSH 7 omits some legacy cryptography.

**NOTE:** Lack of support for legacy cryptography in devices causes Junos Space device discovery to fail. To work around this issue, configure the device to support the `3des-cbc` or `blowfish-cbc` cipher, or both, and the `dh-group1-sha1` key-exchange method. This issue does not affect devices running Junos OS with upgraded FreeBSD.

**NOTE:** See the OpenSSH 7 documentation at <https://www.openssh.com/> for more information about these extensions.

Junos OS supports the following set of ciphers by default:

- `chacha20-poly1305@openssh.com`
- `aes128-ctr`
- `aes192-ctr`
- `aes256-ctr`
- `aes128-gcm@openssh.com`
- `aes256-gcm@openssh.com`

In Junos OS, the following ciphers are not supported by default, but you can configure your device to support them. They are listed from the most secure to the least secure:

- `aes256-cbc`

- aes192-cbc
- aes128-cbc
- 3des-cbc
- blowfish-cbc
- cast128-cbc
- arcfour256
- arcfour128
- arcfour

Junos OS supports the following set of key-exchange methods by default:

- curve25519-sha256
- ecdh-sha2-nistp256
- ecdh-sha2-nistp384
- ecdh-sha2-nistp521
- group-exchange-sha2
- dh-group14-sha1

In Junos OS, the following key-exchange methods are not supported by default, but you can configure your device to support them:

- group-exchange-sha1
- dh-group1-sha1

To configure the SSH service to support legacy cryptography:

**NOTE:** By configuring an ordered set of ciphers, key-exchange methods, or message authentication codes (MACs), the newly defined set is applied to both server and client commands. Changes to the defaults affect the `file copy` command when you use Secure Copy Protocol (SCP).

1. Add support for ciphers by using the `set system services ssh ciphers [ cipher 1 cipher 2 ... ]` command. We recommend that you add the ciphers to the end of the configuration list so that they are among

the last options used. In the following example, the arcfour and blowfish-cbc ciphers are added to the default set:

```
[edit system services ssh]
user@device# set ciphers [ chacha20-poly1305@openssh.com aes128-ctr aes192-ctr aes256-ctr
aes128-gcm@openssh.com aes256-gcm@openssh.com arcfour blowfish-cbc ]
```

2. Add support for key-exchange methods by using the `set system services ssh key-exchange [ method 1 method 2 ... ]` command. We recommend that you add the key-exchange methods to the end of the configuration list so that they are among the last options used. In the following example, the `dh-group1-sha1` key-exchange method is added to the default set:

```
[edit system services ssh]
user@device# set key-exchange [ curve25519-sha256 ecdh-sha2-nistp256 ecdh-sha2-nistp384 ecdh-
sha2-nistp521 group-exchange-sha2 dh-group14-sha1 dh-group1-sha1 ]
```

3. Commit the configuration:

```
[edit]
user@device# commit
```

## Configure Outbound SSH Service

### IN THIS SECTION

- [Send the Public SSH Host Key to the Outbound SSH Client](#) | [273](#)
- [Configure Keepalive Messages for Outbound SSH Connections](#) | [275](#)
- [Configure a New Outbound SSH Connection](#) | [275](#)
- [Configure the Outbound SSH Client to Accept NETCONF as an Available Service](#) | [275](#)
- [Configure Outbound SSH Clients](#) | [276](#)

You can configure a device running Junos OS to initiate a TCP/IP connection with a client management application. If the management application does not reach a Juniper Networks device, for example, the device being a firewall. In such cases, `outbound-ssh` can be configured on the Juniper Networks device. An `outbound-ssh` configuration initiates a reverse SSH connection from server to client to the management application. This outbound SSH connection is closed only after the configuration are removed from the device.

**NOTE:** There is no initiation command with outbound SSH. After you configure and commit outbound SSH, the device begins to initiate an outbound SSH connection based on the committed configuration. The device repeatedly attempts to create this connection until successful. If the connection between the device and the client management application is dropped, the device again attempts to create a new outbound SSH connection until successful. This connection is maintained until the outbound SSH stanza is removed from the configuration.

To configure the device for outbound SSH connections, include the `outbound-ssh` statement at the `[edit system services]` hierarchy level:

```
[edit system services outbound-ssh]
```

The following topics describe the tasks for configuring the outbound SSH service.

## Send the Public SSH Host Key to the Outbound SSH Client

Each time the router or switch establishes an outbound SSH connection, it first sends an initiation sequence to the management client. This sequence identifies the router or switch to the management client. Within this transmission is the value of *device-id*.

To configure the device identifier of the router or switch, include the `device-id` statement at the `[edit system services outbound-ssh client client-id]` hierarchy level:

```
[edit system services outbound-ssh client client-id]  
device-id device-id;
```

The initiation sequence when `secret` is not configured:

```
MSG-ID: DEVICE-CONN-INFO\r\n
MSG-VER: V1\r\n
DEVICE-ID: <device-id>\r\n
```

During the initialization of an SSH connection, the client authenticates the identity of the device using the public SSH host key of the device. Therefore, before the client can initiate the SSH sequence, the client needs the public SSH key of the device. When you configure the `secret` statement, the device passes its public SSH key as part of the outbound SSH connection initiation sequence.

When the `secret` statement is set and the device establishes an outbound SSH connection, the device communicates its device ID, its public SSH key, and an SHA1 hash derived in part from the `secret` statement. The value of the `secret` statement is shared between the device and the management client. The client uses the shared secret to authenticate the public SSH host key it is receiving to determine whether the public key is from the device identified by the `device-id` statement.

Using the `secret` statement to transport the public SSH host key is optional. You can manually transport and install the public key onto the client system.

**NOTE:** Including the `secret` statement means that the device sends its public SSH host key every time it establishes a connection to the client. It is then up to the client to decide what to do with the SSH host key if the client already has an SSH key for that device. We recommend that you replace the client's copy of the SSH host key with the new key. Host keys can change for various reasons. By replacing the key each time a connection is established, you ensure that the client has the latest key.

To send the router's or switch's public SSH host key when the device connects to the client, include the `secret` statement at the `[edit system services outbound-ssh client client-id]` hierarchy level:

```
[edit system services outbound-ssh client client-id]
secret password;
```

The following message is sent by the device when the `secret` attribute is configured:

```
MSG-ID: DEVICE-CONN-INFO\r\n
MSG-VER: V1\r\n
DEVICE-ID: <device-id>\r\n
```

```
HOST-KEY: <public-host-key>\r\n
HMAC:<HMAC(pub-SSH-host-key, <secret>>)>\r\n
```

## Configure Keepalive Messages for Outbound SSH Connections

After the client application has the router's or switch's public SSH host key, it can initiate the SSH sequence as if it had created the TCP/IP connection. The client can then authenticate the device using its copy of the router's or switch's public host SSH key as part of that sequence. The device authenticates the client user through the mechanisms supported in Junos OS (RSA/DSA public string or password authentication).

To enable the device to send SSH protocol keepalive messages to the client application, configure the keep-alive statement at the [edit system services outbound-ssh client *client-id*] hierarchy level:

```
[edit system services outbound-ssh client client-id]
keep-alive {
    retry number;
    timeout seconds;
}
```

## Configure a New Outbound SSH Connection

When disconnected, the device begins to initiate a new outbound SSH connection. To specify how the device reconnects to the server after a connection is dropped, include the reconnect-strategy statement at the [edit system services outbound-ssh client *client-id*] hierarchy level:

```
[edit system services outbound-ssh client-id]
reconnect-strategy (sticky | in-order);
```

You can also specify the number of retry attempts and set the amount of time before the reconnection attempts stop. See ["Configure Keepalive Messages for Outbound SSH Connections" on page 275](#).

## Configure the Outbound SSH Client to Accept NETCONF as an Available Service

To configure the application to accept NETCONF as an available service, include the services netconf statement at the [edit system services outbound-ssh client *client-id*] hierarchy level:

```
[edit system services outbound-ssh client client-id]
services {
```

```
netconf;
}
```

## Configure Outbound SSH Clients

To configure the clients available for this outbound SSH connection, list each client with a separate address statement at the `[edit system services outbound-ssh client client-id]` hierarchy level:

```
[edit system services outbound-ssh client client-id]
  address address {
    retry number;
    timeout seconds;
    port port-number;
  }
```

**NOTE:** Outbound SSH connections support IPv4 and IPv6 address formats.

## Configure Routing Instances for Outbound SSH Clients

To use the management routing instance, first enable the `mgmt_junos` routing instance using the `set system management-instance` command.

To use any other routing instance, first configure the routing instance at the `[edit routing-instances]` hierarchy.

If you do not specify a routing instance, your device will establish the outbound SSH connection using the default routing table.

## Configure NETCONF-Over-SSH Connections on a Specified TCP Port

Junos OS enables you to restrict incoming NETCONF connections to a specified TCP port without configuring a firewall. To configure the TCP port used for NETCONF-over-SSH connections, include the `port` statement at the `[edit system services netconf ssh]` hierarchy level. The configured port accepts only NETCONF-over-SSH sessions. Regular SSH session requests for this port are rejected.

You can either configure the default port 830 for NETCONF connections over SSH, as specified in RFC 4742, *Using the NETCONF Configuration Protocol over Secure Shell (SSH)*, or configure any port from 1 through 65535.

**NOTE:**

- The default SSH port (22) continues to accept NETCONF sessions even with a configured NETCONF server port. To disable the SSH port from accepting NETCONF sessions, specify this in the login event script.
- We do not recommend configuring the default ports for FTP (21) and Telnet (23) services for configuring NETCONF-over-SSH connections.

## Configure Password Retry Limits for Telnet and SSH Access

To prevent brute force and dictionary attacks, a device performs the following actions for Telnet or SSH sessions by default:

- Disconnects a session after a maximum of 10 consecutive password retries.
- After the second password retry, introduces a delay in multiples of 5 seconds between subsequent password retries.

For example, the device introduces a delay of 5 seconds between the third and fourth password retry, a delay of 10 seconds between the fourth and fifth password retry, and so on.

- Enforces a minimum session time of 20 seconds, during which a session cannot be disconnected. Configuring the minimum session time prevents malicious users from disconnecting sessions before the password retry delay goes into effect. Configuring the minimum session time also prevents them from attempting brute force and dictionary attacks with multiple logins.

You can configure the password retry limits for Telnet and SSH access. In this example, you configure the device to take the following actions for Telnet and SSH sessions:

- Allow a maximum of four consecutive password retries before disconnecting a session.
- Introduce a delay in multiples of 5 seconds between password retries that occur after the second password retry.
- Enforce a minimum session time of 40 seconds, during which a session cannot be disconnected.

To configure password retry limits for Telnet and SSH access:

1. Set the maximum number of consecutive password retries before a Telnet or SSH or telnet session is disconnected. The default number is 10, but you can set a number from 1 through 10.

```
[edit system login retry-options]
user@host# set tries-before-disconnect 4
```

2. Set the threshold number of password retries after which a delay is introduced between two consecutive password retries. The default number is 2, but you can specify a value from 1 through 3.

```
[edit system login retry-options]
user@host# set backoff-threshold 2
```

3. Set the delay (in seconds) between consecutive password retries after the threshold number of password retries. The default delay is in multiples of 5 seconds, but you can specify a value from 5 through 10 seconds.

```
[edit system login retry-options]
user@host# set backoff-factor 5
```

4. Set the minimum length of time (in seconds) during which a Telnet or SSH session cannot be disconnected. The default is 20 seconds, but you can specify an interval from 20 through 60 seconds.

```
[edit system login retry-options]
user@host# set minimum-time 40
```

5. After you configure the device, enter `commit` in configuration mode.

## Example: Configure a Filter to Block Telnet and SSH Access

### IN THIS SECTION

- [Requirements | 279](#)
- [Overview and Topology | 279](#)
- [Configuration | 280](#)
- [Verify the Stateless Firewall Filter | 288](#)

## Requirements

You need two devices running Junos OS with a shared network link. No special configuration beyond basic device initialization (management interface, remote access, user login accounts, etc.) is required before configuring this example. While not a strict requirement, console access to the R2 device is recommended.

**NOTE:** Our content testing team has validated and updated this example.

## Overview and Topology

### IN THIS SECTION

- [Example Topology | 279](#)

In this example, you create an IPv4 stateless firewall filter that logs and rejects Telnet or SSH packets sent to the local Routing Engine, unless the packet originates from the 192.168.1.0/30 subnet. The filter is applied to the loopback interface to ensure that only traffic destined to the local device is affected. You apply the filter in the input direction. An output filter is not used. As a result all locally generated traffic is allowed.

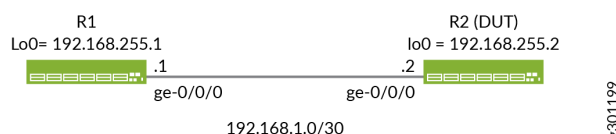

- To match packets originating from a specific subnet or IP prefix, you use the `source-address IPv4 match` condition applied in the input direction.
- To match packets destined for the Telnet port and SSH ports, you use the `protocol tcp match` condition combined with a `port telnet` and `port ssh` IPv4 match conditions applied in the input direction.

### Example Topology

[Figure 7 on page 280](#) shows the test topology for this example. The firewall filter is applied to the R2 device, making it the device under test (DUT). The R1 and the R2 devices share a link that is assigned a subnet of 192.168.1.0/30. Both devices have loopback addresses assigned from the 192.168.255.0/30

prefix using a /32 subnet mask. Static routes provide reachability between loopback addresses because an interior gateway protocol is not configured in this basic example.

**Figure 7: Example Topology**

## Configuration

### IN THIS SECTION

- [CLI Quick Configuration | 280](#)
- [Configure the R1 Device | 282](#)
- [Verify and Commit the Configuration at the R1 Device | 282](#)
- [Configure the R2 Device | 284](#)
- [Verify and Commit the Configuration at Device R2 | 286](#)

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

**CAUTION:** By design the sample filter restricts Telnet and SSH access to R2 unless it originates from the shared subnet at R1. If you use SSH or Telnet to access the R2 device directly, you will lose connectivity when the filter is applied. We recommend that you have console access when configuring this example. If needed you can use the R1 device as a jump host to launch an SSH session to R2 after the filter is applied. Alternatively, consider modifying the sample filter to also permit the IP subnet assigned to the machine you use to access the R2 device.

Perform the following tasks to configure this example:

### CLI Quick Configuration

#### Quick Configuration for the R1 Device

To quickly configure the R1 device, edit the following commands as needed and paste them into the CLI at the [edit] hierarchy level. Be sure to issue a `commit` in configuration mode to activate the changes.

```
set system host-name R1
set system services ssh root-login allow
set interfaces ge-0/0/0 description "Link from R1 to R2"
set interfaces ge-0/0/0 unit 0 family inet address 192.168.1.1/30
set interfaces lo0 unit 0 family inet address 192.168.255.1/32
set routing-options static route 192.168.255.2/32 next-hop 192.168.1.2
```

### Quick Configuration for the R2 Device

To quickly configure the R2 device, edit the following commands as needed and paste them into the CLI at the [edit] hierarchy level. Be sure to issue a `commit` in configuration mode to activate the changes.

**TIP:** Consider using `commit-confirmed` when making changes that might affect remote access to your device. *Activating a Junos OS Configuration but Requiring Confirmation*

```
set system host-name R2
set system services ssh root-login allow
set system services telnet
set interfaces ge-0/0/0 description "Link from R2 to R1"
set interfaces ge-0/0/0 unit 0 family inet address 192.168.1.2/30
set interfaces lo0 unit 0 family inet filter input local_acl
set interfaces lo0 unit 0 family inet address 192.168.255.2/32
set firewall family inet filter local_acl term terminal_access from source-address 192.168.1.0/30
set firewall family inet filter local_acl term terminal_access from protocol tcp
set firewall family inet filter local_acl term terminal_access from port ssh
set firewall family inet filter local_acl term terminal_access from port telnet
set firewall family inet filter local_acl term terminal_access then accept
set firewall family inet filter local_acl term terminal_access_denied from protocol tcp

set firewall family inet filter local_acl term tcp_estab from protocol tcp
set firewall family inet filter local_acl term tcp_estab from tcp-established
set firewall family inet filter local_acl term tcp_estab then accept
set firewall family inet filter local_acl term terminal_access_denied from port ssh
set firewall family inet filter local_acl term terminal_access_denied from port telnet
set firewall family inet filter local_acl term terminal_access_denied then log
set firewall family inet filter local_acl term terminal_access_denied then reject
```

```
set firewall family inet filter local_acl term default-term then accept
set routing-options static route 192.168.255.1/32 next-hop 192.168.1.1
```

## Configure the R1 Device

### Step-by-Step Procedure

Follow these steps to configure the R1 device:

1. Configure the interfaces:

```
[edit]
user@R1# set interfaces ge-0/0/0 description "Link from R1 to R2"
user@R1# set interfaces ge-0/0/0 unit 0 family inet address 192.168.1.1/30
user@R1# set interfaces lo0 unit 0 family inet address 192.168.255.1/32
```

2. Configure the host name and static route to the R2 device's loopback address. You also configure Telnet and SSH access:

```
[edit]
user@R1# set system host-name R1
user@R1# set system services ssh root-login allow
user@R1# set system services telnet
user@R1# set routing-options static route 192.168.255.2/32 next-hop 192.168.1.2
```

## Verify and Commit the Configuration at the R1 Device

### Step-by-Step Procedure

Complete the following steps to verify and commit your candidate configuration at the R1 device:

1. Confirm interface configuration with the `show interfaces configuration mode` command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@R1# show interfaces
ge-0/0/0 {
    description "Link from R1 to R2";
```

```

    unit 0 {
        family inet {
            address 192.168.1.1/30;
        }
    }
}
lo0 {
    unit 0 {
        family inet {
            address 192.168.255.1/32;
        }
    }
}

```

2. Verify the static route used to reach the R2 device's loopback address and that SSH and Telnet access are enabled. Use the `show routing-options` and `show system services configuration mode` commands. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

[edit]
user@R1# show routing-options
static {
    route 192.168.255.2/32 next-hop 192.168.1.2;
}
user@R1# show system services
ssh {
    root-login allow;
}
telnet;

```

3. When satisfied with the configuration on the R1 device, commit your candidate configuration.

```

[edit]
user@R1# commit

```

## Configure the R2 Device

### Step-by-Step Procedure

Complete the following steps to configure the R2 device. You begin by defining the stateless firewall filter that selectively blocks Telnet and SSH access:

1. Position yourself at the edit firewall family inet filter *local\_acl* hierarchy:

```
[edit]
user@R2# edit firewall family inet filter local_acl
```

2. Define the filter term *terminal\_access*. This term permits Telnet and SSH from the specified source prefix(s):

```
[edit firewall family inet filter local_acl]
user@R2# set term terminal_access from source-address 192.168.1.0/30
user@R2# set term terminal_access from protocol tcp
user@R2# set term terminal_access from port ssh
user@R2# set term terminal_access from port telnet
user@R2# set term terminal_access then accept
```

3. Define the filter term *terminal\_access\_denied*. This term rejects SSH and Telnet from *all other* source addresses. This term is configured to log matches to the term and to generate an explicit Internet Control Message Protocol (ICMP) destination unreachable response back to the packet's source. See *Firewall Filter Logging Actions* for details on filter logging options.

**TIP:** You can use the discard action to suppress generation of ICMP error messages back to the source. See *Firewall Filter Terminating Actions* for details.

```
[edit firewall family inet filter local_acl]
user@R2# set term terminal_access_denied from protocol tcp
user@R2# set term terminal_access_denied from port ssh
user@R2# set term terminal_access_denied from port telnet
user@R2# set term terminal_access_denied then log
user@R2# set term terminal_access_denied then reject
user@R2# set term default-term then accept
```

#### 4. Optional.

Define the filter term *tcp-estab*. This term permits outbound access to the Internet to support connections to the Juniper Mist cloud (*tcp-established* is a bit-field match condition, **tcp-flags "(ack | rst)"**, which indicates an established TCP session, but not the first packet of a TCP connection):

```
[edit firewall family inet filter local_acl]
user@R2# set term tcp-estab from protocol tcp
user@R2# set term tcp-estab from tcp-established
user@R2# set term tcp-estab then accept
```

5. Define the filter term *default-term*. This term accepts all other traffic. Recall that Junos OS stateless filters have an implicit *deny* term at their end. The *default-term* overrides this behavior by terminating the filter with an explicit *accept* action. The termination of the filter results in all other traffic being accepted by the filter.

**NOTE:** For this example we are allowing all other traffic, but for your network you might want to secure the routing engine. See [protecting the routing engine](#) for more information.

```
[edit firewall family inet filter local_acl]
user@R2# set term default-term then accept
```

6. Configure the loopback interface, and apply the filter in the input direction:

```
[edit]
user@R2# set interfaces lo0 unit 0 family inet filter input local_acl
user@R2# set interfaces lo0 unit 0 family inet address 192.168.255.2/32
```

7. Configure the host name, the ge-0/0/0 interface, the static route to the R1 device's loopback address, and enable remote access through SSH and Telnet:

```
[edit]
user@R2# set system host-name R2
user@R2# set system services ssh root-login allow
user@R2# set system services telnet
user@R2# set interfaces ge-0/0/0 description "Link from R2 to R1"
user@R2# set interfaces ge-0/0/0 unit 0 family inet address 192.168.1.2/30
user@R2# set routing-options static route 192.168.255.1/32 next-hop 192.168.1.1
```

## Verify and Commit the Configuration at Device R2

### Step-by-Step Procedure

Complete the following steps to verify and commit your candidate configuration at the R2 device:

1. Confirm the configuration of the stateless firewall filter with the `show firewall` configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@R2# show firewall
family inet {
  filter local_acl {
    term terminal_access {
      from {
        source-address {
          192.168.1.0/30;
        }
        protocol tcp;
        port [ssh telnet];
      }
      then accept;
    }
    term terminal_access_denied {
      from {
        protocol tcp;
        port [ssh telnet];
      }
      then {
        log;
        reject;
      }
    }
    term default-term {
      then accept;
    }
  }
}
```

2. Confirm interface configuration and filter application with the `show interfaces configuration mode` command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@R2# show interfaces
ge-0/0/0 {
    description "Link from R2 to R1";
    unit 0 {
        family inet {
            address 192.168.1.2/30;
        }
    }
}
lo0 {
    unit 0 {
        family inet {
            filter {
                input local_acl;
            }
            address 192.168.255.2/32;
        }
    }
}
```

3. Verify the static route used to reach the loopback address of the R1 device, and verify that Telnet and SSH access are enabled. Use the `show routing-options` and `show system services configuration mode` commands. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@R2# show routing-options
static {
    route 192.168.255.1/32 next-hop 192.168.1.1;
}
user@R2# show system services
ssh {
    root-login allow;
}
telnet;
```

4. When satisfied with the configuration on the R2 device, commit your candidate configuration.

**TIP:** Consider using `commit-confirmed` when making changes that might affect remote access to your device.

```
[edit]
user@R2# commit
```

## Verify the Stateless Firewall Filter

### IN THIS SECTION

- [Verify Accepted Packets | 288](#)
- [Verify Logged and Rejected Packets | 290](#)

Confirm that the firewall filter to limit Telnet and SSH access is working properly.

### Verify Accepted Packets

#### Purpose

Verify that the firewall filter correctly allows SSH and Telnet when the traffic is sourced from the 192.168.1.0/30 subnet.

#### Action

1. Clear the firewall log on your router or switch.

```
user@R2> clear firewall log
```

2. From a host at an IP address *within* the 192.168.1.0/30 subnet, use a `ssh 192.168.255.2` command to verify that you can log in to the device using SSH from an allowed source address. This packet should be accepted, but the packet header information for this packet should not be logged in the firewall filter log buffer in the Packet Forwarding Engine. You will be prompted to save the SSH host key if this is the first SSH login as *user* between these devices.

**NOTE:** By default the R1 device will source the SSH traffic from the egress interface used to reach the destination. As a result this traffic is sourced from the 192.168.1.1 address assigned to the R1 device's ge-0/0/0 interface.

```
user@R1>ssh 192.168.255.2
Password:
Last login: Wed Aug 19 09:23:58 2020 from 192.168.1.1
--- JUNOS 20.2R1.10 Kernel 64-bit  JNPR-11.0-20200608.0016468_buil
user@R2>
```

3. Log out of the CLI at the R2 device to close the SSH session.

```
user@R2> exit
logout
Connection to 192.168.255.2 closed.
user@R1>
```

4. From a host at an IP address *within* the 192.168.1.0/30 subnet, use the `telnet 192.168.255.2` command to verify that you can log in to your router or switch using Telnet from an allowed source address. This packet should be accepted, but the packet header information for this packet should not be logged in the firewall filter log buffer in the Packet Forwarding Engine.

```
user@host-A> telnet 192.168.255.2
Trying 192.168.255.2...
Connected to 192.168.255.2.
Escape character is '^]'.
login: user
Password:

--- JUNOS 20.2R1.10 Kernel 64-bit  JNPR-11.0-20200608.0016468_buil
user@R2>
```

5. Log out of the CLI to close the Telnet session to the R2 device.

```
user@R2:~ # exit
Connection closed by foreign host.
```

```
root@R1>
```

6. Use the `show firewall log` command to verify that the firewall log buffer on the R2 device's Packet Forwarding Engine (PFE) *does not* contain any entries with a source address in the 192.168.1.0/30 subnet.

```
user@R2> show firewall log
```

## Verify Logged and Rejected Packets

### Purpose

Verify that the firewall filter correctly rejects SSH and Telnet traffic that does *not* originate from the 192.168.1.0/30 subnet.

### Action

1. Clear the firewall log on your router or switch.

```
user@R2> clear firewall log
```

2. Generate SSH traffic sourced from the loopback address of the R1 device. The source address of this traffic is *outside of* the allowed 192.168.1.0/30 subnet. Use the `ssh 192.168.255.2 source 192.168.255.1` command to verify that you *cannot* log in to the device using SSH from this source address. This packet should be rejected, and the packet header information should be logged in the firewall filter log buffer.

```
user@R1 ssh 192.168.255.2 source 192.168.255.1
ssh: connect to host 192.168.255.2 port 22: Connection refused

root@R1>
```

The output shows that the SSH connection is rejected. This output confirms that the filter is generating an ICMP error message and that it correctly blocks SSH traffic when sent from a disallowed source address.

3. Generate Telnet traffic sourced from the loopback address of the R1 device. The source address of this traffic is *outside of* the allowed 192.168.1.0/30 subnet. Use the `telnet 192.168.255.2 source`

192.168.255.1 command to verify that you *cannot* log in to the device using Telnet from this source address. This packet should be rejected, and the packet header information for this packet should be logged in the firewall filter log buffer in the PFE.

```
user@R1> telnet 192.168.255.2 source 192.168.255.1
Trying 192.168.255.2...
telnet: connect to address 192.168.255.2: Connection refused
telnet: Unable to connect to remote host
```

The output shows that the Telnet connection is rejected. This output confirms that the filter is generating an ICMP error message and that it correctly blocks Telnet traffic when sent from a disallowed source address.

4. Use the `show firewall log` command to verify that the firewall log buffer on the R2 device contains entries showing that packets with a source address of 192.168.255.1 were rejected.

```
user@R2> show firewall log
Log :
Time      Filter Action Interface Protocol  Src Addr  Dest Addr
15:17:11 pfe      R      ge-0/0/0.0 TCP      192.168.255.1 192.168.255.2
15:12:04 pfe      R      ge-0/0/0.0 TCP      192.168.255.1 192.168.255.2
```

The output confirms that traffic from the 192.168.255.1 source address matched the filter's *terminal\_access\_denied* term. The Action column displays an R to indicate that these packets were rejected. The interface, transport protocol, and source and destination addresses are also listed. These results confirm that the firewall filter is working properly for this example.

## Release History Table

Release	Description
19.4R1	Starting in Junos OS Release 19.4R1 and Junos OS Release 17.4R3, you can disable either the SSH login password or the challenge-response authentication using the <code>no-password-authentication</code> and <code>no-challenge-response</code> options at the <code>[edit system services ssh]</code> hierarchy level.
19.1R1	Starting in Junos OS Release 19.1R1, we have globally disabled the incoming SFTP connections by default. If desired, you can globally enable incoming SFTP connections by configuring the statement <code>sftp-server</code> at the <code>[edit system services ssh]</code> hierarchy level.
18.3R1	Starting in Junos OS Release 18.3R1, the <code>ssh-dss</code> and <code>ssh-dsa</code> hostkey algorithms are deprecated— rather than immediately removed—to provide backward compatibility and a chance to bring your configuration into compliance with the new configuration.

- 18.3R1 (SRX Series and MX Series only) Starting in Junos OS Release 19.3R1, you can specify the name of the routing instance on which the outbound SSH connectivity needs to be established by including the routing-instance statement at the [edit system services outbound-ssh] hierarchy level:

Junos OS allows the use of USB modems for remote management on SRX Series device. You can use Telnet or SSH to connect to the device from a remote location through two modems over a telephone network. For more information, read this topic.

## USB Modem Interface Overview

### IN THIS SECTION

- [USB Modem Interfaces | 293](#)
- [Dialer Interface Rules | 294](#)
- [How the Device Initializes USB Modems | 295](#)

Juniper Networks SRX Series devices support the use of USB modems for remote management. You can use Telnet or SSH to connect to the device from a remote location through two modems over a telephone network. The USB modem is connected to the USB port on the device, and a second modem is connected to a remote management device such as a PC or laptop computer.

**NOTE:** USB modems are no longer supported for dial backup on SRX300, SRX320, SRX340, SRX345, SRX380, and SRX550HM devices.

You can configure your device to fail over to a USB modem connection when the primary Internet connection experiences interruption.

A USB modem connects to a device through modem interfaces that you configure. The device applies its own modem AT commands to initialize the attached modem. Modem setup requires that you connect and configure the USB modem at the device and the modem at the user end of the network.

You use either the J-Web configuration editor or CLI configuration editor to configure the USB modem and its supporting dialer interfaces.

**NOTE:** Low-latency traffic such as VoIP traffic is not supported over USB modem connections.

**NOTE:** We recommend using a US Robotics USB 56k V.92 Modem, model number USR Model 5637.

### USB Modem Interfaces

You configure two types of interfaces for USB modem connectivity:

- A physical interface which uses the naming convention `umdn`. The device creates this interface when a USB modem is connected to the USB port.
- A *logical interface* called the dialer interface. You use the dialer interface, `dln`, to configure dialing properties for USB modem connections. The dialer interface can be configured using Point-to-Point Protocol (PPP) encapsulation. You can also configure the dialer interface to support authentication protocols—PPP Challenge Handshake (CHAP) or Password Authentication Protocol (PAP). You can configure multiple dialer interfaces for different functions on the device. After configuring the dialer interface, you must configure a backup method such as a dialer backup, a dialer filter, or a dialer watch.

The USB modem provides a dial-in remote management interface, and supports dialer interface features by sharing the same dial pool as a dialer interface. The dial pool allows the logical dialer interface and the physical interface to be bound together dynamically on a per-call basis. You can configure the USB modem to operate either as a dial-in console for management or as a dial-in WAN backup interface. Dialer pool priority has a range from 1 to 255, with 1 designating the lowest priority interfaces and 255 designating the highest priority interfaces.

## Dialer Interface Rules

The following rules apply when you configure dialer interfaces for USB modem connections:

- The dialer interface must be configured to use PPP encapsulation. You cannot configure Cisco High-Level Data Link Control (HDLC) or Multilink PPP (MLPPP) encapsulation on dialer interfaces.
- The dialer interface cannot be configured as a constituent link in a multilink bundle.
- The dialer interface can perform backup, dialer filter, and dialer watch functions, but these operations are mutually exclusive. You can configure a single dialer interface to operate in only one of the following ways:
  - As a backup interface—for one primary interface
  - As a dialer filter
  - As a dialer watch interface

The backup dialer interfaces are activated only when the primary interface fails. USB modem backup connectivity is supported on all interfaces except `lsq-0/0/0`.

The dial-on-demand routing backup method allows a USB modem connection to be activated only when network traffic configured as an “interesting packet” arrives on the network. Once the network traffic is sent, an inactivity timer is triggered and the connection is closed. You define an interesting packet using the dialer filter feature of the device. To configure dial-on-demand routing backup using a dialer filter, you first configure the dialer filter and then apply the filter to the dialer interface.

Dialer watch is a backup method that integrates backup dialing with routing capabilities and provides reliable connectivity without relying on a dialer filter to trigger outgoing USB modem connections. With dialer watch, the device monitors the existence of a specified route. If the route disappears, the dialer interface initiates the USB modem connection as a backup connection.

## How the Device Initializes USB Modems

When you connect the USB modem to the USB port on the device, the device applies the modem AT commands configured in the `init-command-string` command to the initialization commands on the modem.

If you do not configure modem AT commands for the `init-command-string` command, the device applies the following default sequence of initialization commands to the modem: `AT S7=45 S0=0 V1 X4 &C1 E0 Q0 &Q8 %C0`. [Table 18 on page 295](#) describes the commands. For more information about these commands, see the documentation for your modem.

**Table 18: Default Modem Initialization Commands**

Modem Command	Description
AT	Attention. Informs the modem that a command follows.
S7=45	Instructs the modem to wait 45 seconds for a telecommunications service provider (carrier) signal before terminating the call.
S0=0	Disables the auto answer feature, whereby the modem automatically answers calls.
V1	Displays result codes as words.
&C1	Disables reset of the modem when it loses the carrier signal.
E0	Disables the display on the local terminal of commands issued to the modem from the local terminal.
Q0	Enables the display of result codes.
&Q8	Enables Microcom Networking Protocol (MNP) error control mode.

**Table 18: Default Modem Initialization Commands (Continued)**

Modem Command	Description
<code>%C0</code>	Disables data compression.

When the device applies the modem AT commands in the `init-command-string` command or the default sequence of initialization commands to the modem, it compares them to the initialization commands already configured on the modem and makes the following changes:

- If the commands are the same, the device overrides existing modem values that do not match. For example, if the initialization commands on the modem include `S0=0` and the device's `init-command-string` command includes `S0=2`, the device applies `S0=2`.
- If the initialization commands on the modem do not include a command in the device's `init-command-string` command, the device adds it. For example, if the `init-command-string` command includes the command `L2`, but the modem commands do not include it, the device adds `L2` to the initialization commands configured on the modem.

**NOTE:** On SRX210 devices, the USB modem interface can handle bidirectional traffic of up to 19 Kbps. On oversubscription of this amount (that is, bidirectional traffic of 20 Kbps or above), keepalives do not get exchanged, and the interface goes down. (Platform support depends on the Junos OS release in your installation.)

## USB Modem Configuration Overview

**NOTE:** USB modems are no longer supported for dial backup on SRX300, SRX320, SRX340, and SRX345 devices.

Before you begin:

1. Install device hardware. For more information, see the Getting Started Guide for your device.
2. Establish basic connectivity. For more information, see the Getting Started Guide for your device.
3. Order a US Robotics USB 56k V.92 Modem, model number USR Model 5637 (<http://www.usr.com/>).
4. Order a public switched telephone network (PSTN) line from your telecommunications service provider. Contact your service provider for more information.

5. Connect the USB modem to the device's USB port.

**NOTE:** When you connect the USB modem to the USB port on the device, the USB modem is initialized with the modem initialization string configured for the USB modem interface on the device.

- a. Plug the modem into the USB port.
- b. Connect the modem to your telephone network.
  - i.

Suppose you have a branch office router and a head office router each with a USB modem interface and a dialer interface. This example shows you how to establish a backup connection between the branch office and head office routers. See [Table 19 on page 297](#) for a summarized description of the procedure.

**Table 19: Configuring Branch Office and Head Office Routers for USB Modem Backup Connectivity**

Router Location	Configuration Requirement	Procedure
Branch Office	Configure the logical dialer interface on the branch office router for USB modem dial backup.	To configure the logical dialer interface, see <a href="#">"Example: Configuring a USB Modem Interface"</a> on page 299.

**Table 19: Configuring Branch Office and Head Office Routers for USB Modem Backup Connectivity**  
(Continued)

Router Location	Configuration Requirement	Procedure
	<p>Configure the dialer interface d10 on the branch office router using one of the following backup methods:</p> <ul style="list-style-type: none"> <li>• Configure the dialer interface d10 as the backup interface on the branch office router's primary T1 interface t1-1/0/0.</li> <li>• Configure a dialer filter on the branch office router's dialer interface.</li> <li>• Configure a dialer watch on the branch office router's dialer interface.</li> </ul>	<p>Configure the dialer interface using one of the following backup methods:</p> <ul style="list-style-type: none"> <li>• To configure d10 as a backup for t1-1/0/0 see <i>Example: Configuring Dialer Interfaces and Backup Methods for USB Modem Dial Backup</i>.</li> <li>• To configure a dialer filter on d10, see <i>Example: Configuring Dialer Interfaces and Backup Methods for USB Modem Dial Backup</i>.</li> <li>• To configure a dialer watch on d10, see <i>Example: Configuring Dialer Interfaces and Backup Methods for USB Modem Dial Backup</i>.</li> </ul>
Head Office	Configure dial-in on the dialer interface d10 on the head office router.	To configure dial-in on the head office router, see <a href="#">"Example: Configuring a Dialer Interface for USB Modem Dial-In"</a> on page 308.

If the dialer interface is configured to accept only calls from a specific caller ID, the device matches the incoming call's caller ID against the caller IDs configured on its dialer interfaces. If an exact match is not found and the incoming call's caller ID has more digits than the configured caller IDs, the device performs a right-to-left match of the incoming call's caller ID with the configured caller IDs and accepts the incoming call if a match is found. For example, if the incoming call's caller ID is 4085321091 and the caller ID configured on a dialer interface is 5321091, the incoming call is accepted. Each dialer interface accepts calls from only callers whose caller IDs are configured on it.

See [Table 20 on page 299](#) for a list of available incoming map options.

Table 20: Incoming Map Options

Option	Description
<b>accept-all</b>	<p>Dialer interface accepts all incoming calls.</p> <p>You can configure the accept-all option for only one of the dialer interfaces associated with a USB modem physical interface. The dialer interface with the accept-all option configured is used only if the incoming call's caller ID does not match the caller IDs configured on other dialer interfaces.</p>
<b>caller</b>	<p>Dialer interface accepts calls from a specific caller ID. You can configure a maximum of 15 caller IDs per dialer interface.</p> <p>The same caller ID must not be configured on different dialer interfaces. However, you can configure caller IDs with more or fewer digits on different dialer interfaces. For example, you can configure the caller IDs 14085551515, 4085551515, and 5551515 on different dialer interfaces.</p>

You configure dialer interfaces to support PAP. PAP allows a simple method for a peer to establish its identity using a two-way handshake during initial link establishment. After the link is established, an ID and password pair are repeatedly sent by the peer to the authenticator until authentication is acknowledged or the connection is terminated.

## Example: Configuring a USB Modem Interface

### IN THIS SECTION

- Requirements | 300
- Overview | 300
- Configuration | 300
- Verification | 302

This example shows how to configure a USB modem interface for dial backup.

**NOTE:** USB modems are no longer supported for dial backup on SRX300, SRX320, SRX340, and SRX345 devices.

## Requirements

No special configuration beyond device initialization is required before configuring this feature.

## Overview

In this example, you create an interface called as `umd0` for USB modem connectivity and set the dialer pool priority to 25. You also configure a modem initialization string to autoanswer after a specified number of rings. The default modem initialization string is `AT S7=45 S0=0 V1 X4 &C1 E0 Q0 &Q8 %C0`. The modem command `S0=0` disables the modem from autoanswering the calls. Finally, you set the modem to act as a dial-in WAN backup interface.

## Configuration

### IN THIS SECTION

- [Procedure](#) | 300

## Procedure

### CLI Quick Configuration

To quickly configure this example, copy the following command, paste it into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the command into the CLI at the `[edit]` hierarchy level, and then enter `commit` from configuration mode.

```
set interfaces umd0 dialer-options pool usb-modem-dialer-pool priority 25
set modem-options init-command-string "ATS0=2 \n" dialin routable
```

## Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the [CLI User Guide](#).

To configure a USB modem interface for dial backup:

1. Create an interface.

```
[edit]
user@host# edit interfaces umd0
```

2. Set the dialer options and priority.

```
[edit interfaces umd0]
user@host# set dialer-options pool usb-modem-dialer-pool priority 25
```

3. Specify the modem options.

```
[edit interfaces umd0]
user@host# set modem-options init-command-string "ATS0=2 \n"
```

4. Set the modem to act as a dial-in WAN backup interface.

```
[edit interfaces umd0]
user@host# set modem-options dialin routable
```

## Results

From configuration mode, confirm your configuration by entering the `show interface umd0` command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show interface umd0
modem-options {
  init-command-string "ATS0=2 \n";
  dialin routable;
}
dialer-options {
  pool usb-modem-dialer-pool priority 25;
}
```

If you are done configuring the device, enter `commit` from configuration mode.

## Verification

### IN THIS SECTION

- [Verifying the Configuration | 302](#)

Confirm that the configuration is working properly.

### Verifying the Configuration

#### Purpose

Verify a USB modem interface for dial backup.

#### Action

From configuration mode, enter the `show interfaces umd0 extensive` command. The output shows a summary of interface information and displays the modem status.

```
Physical interface:  umd0, Enabled, Physical link is Up
Interface index:      64, SNMP ifIndex: 33, Generation: 1
  Type: Async-Serial, Link-level type: PPP-Subordinate, MTU: 1504,
Clocking: Unspecified, Speed: MODEM
  Device flags      : Present Running
  Interface flags: Point-To-Point SNMP-Traps Internal: 0x4000
  Link flags        : None
  Hold-times        : Up 0 ms, Down 0 ms
  Last flapped      : Never
  Statistics last cleared: Never

Logical interface umd0.0 (Index 2) (SNMP ifIndex 34) (Generation 1)
Flags: Point-To-Point SNMP-Traps Encapsulation: PPP-Subordinate

```

## Example: Configuring a Dialer Interface

### IN THIS SECTION

- [Requirements | 303](#)
- [Overview | 304](#)
- [Configuration | 304](#)
- [Verification | 306](#)

This example shows how to configure a logical dialer interface for an SRX300, SRX320, SRX340, or SRX345 device.

### Requirements

Before you begin:

- Install device hardware and establish basic connectivity. See the Getting Started Guide for your device.

- Order a US Robotics USB 56k V.92 Modem, model number USR Model 5637, from US Robotics (<http://www.usr.com/>).
- Order a dial-up modem for the PC or laptop computer at the remote location from where you want to connect to the device.
- Order a PSTN line from your telecommunications service provider. Contact your service provider.

## Overview

In this example, you configure a logical dialer interface called `dl0` to establish USB connectivity. You can configure multiple dialer interfaces for different functions on the device. You add a description to differentiate among different dialer interfaces. For example, this modem is called `USB-modem-remote-management`. Configure PPP encapsulation and set the logical unit as 0. You then specify the name of the dialer pool as `usb-modem-dialer-pool` and set the source and destination IP addresses as 172.20.10.2, and 172.20.10.1, respectively.

**NOTE:** You cannot configure Cisco High-Level Data Link Control (HDLC) or Multilink PPP (MLPPP) encapsulation on dialer interfaces used in USB modem connections.

**NOTE:** If you configure multiple dialer interfaces, ensure that the same IP subnet address is not configured on different dialer interfaces. Configuring the same IP subnet address on multiple dialer interfaces can result in inconsistency in the route and packet loss. The device might route packets through another dialer interface with the IP subnet address instead of through the dialer interface to which the USB modem call is mapped.

## Configuration

### IN THIS SECTION

- Procedure | 305

## Procedure

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the [edit] hierarchy level, and then enter `commit` from configuration mode.

```
set interfaces dl0 description USB-modem-remote-management encapsulation ppp
set interfaces dl0 unit 0 dialer-options pool usb-modem-dialer-pool
set interfaces dl0 unit 0 family inet address 172.20.10.2 destination 172.20.10.1
```

### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the [CLI User Guide](#).

To configure a logical dialer interface for the device:

1. Create an interface.

```
[edit]
user@host# set interfaces dl0
```

2. Add a description and configure PPP encapsulation.

```
[edit interfaces dl0]
user@host# set description USB-modem-remote-management
user@host# set encapsulation ppp
```

3. Create the logical unit.

**NOTE:** The logical unit number must be 0.

```
[edit interfaces dl0]
user@host# set unit 0
```

4. Configure the name of the dialer pool to use for USB modem connectivity.

```
[edit interfaces dl0 unit 0]
user@host# set dialer-options pool usb-modem-dialer-pool
```

5. Configure source and destination IP addresses for the dialer interface.

```
[edit interfaces dl0 unit 0]
user@host# set family inet address 172.20.10.2 destination 172.20.10.1
```

## Results

From configuration mode, confirm your configuration by entering the `show interfaces dl0` command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show interfaces dl0
description USB-modem-remote-management;
  encapsulation ppp;
  unit 0 {
    family inet {
      address 172.20.10.2/32 {
        destination 172.20.10.1;
      }
    }
    dialer-options {
      pool usb-modem-dialer-pool;
    }
  }
}
```

If you are done configuring the device, enter `commit` from configuration mode.

## Verification

### IN THIS SECTION

- [Verifying a Dialer Interface | 307](#)

Confirm that the configuration is working properly.

## Verifying a Dialer Interface

### Purpose

Verify that the dialer interface has been configured.

### Action

From configuration mode, enter the `show interfaces dl0` extensive command. The output shows a summary of dialer interface information.

```
Physical interface: dl0, Enabled, Physical link is Up

## Example: Configuring a Dialer Interface for USB Modem Dial-In

### IN THIS SECTION

● [Requirements](#) | 309

- Overview | 309
- Configuration | 310
- Verification | 311

This example shows how to configure a dialer interface for USB modem dial-in.

**NOTE:** USB modems are no longer supported for dial-in to a dialer interface on SRX300, SRX320, SRX340, and SRX345 devices.

## Requirements

No special configuration beyond device initialization is required before configuring this feature.

## Overview

To enable connections to the USB modem from a remote location, you must configure the dialer interfaces set up for USB modem use to accept incoming calls. You can configure a dialer interface to accept all incoming calls or accept only calls from one or more caller IDs.

If the dialer interface is configured to accept only calls from a specific caller ID, the system matches the incoming call's caller ID against the caller IDs configured on its dialer interfaces. If an exact match is not found and the incoming call's caller ID has more digits than the configured caller IDs, the system performs a right-to-left match of the incoming call's caller ID with the configured caller IDs and accepts the incoming call if a match is found. For example, if the incoming call's caller ID is 4085550115 and the caller ID configured on a dialer interface is 5550115, the incoming call is accepted. Each dialer interface accepts calls from only callers whose caller IDs are configured on it.

You can configure the following incoming map options for the dialer interface:

- **accept-all**—Dialer interface accepts all incoming calls.

You can configure the **accept-all** option for only one of the dialer interfaces associated with a USB modem physical interface. The device uses the dialer interface with the **accept-all** option configured only if the incoming call's caller ID does not match the caller IDs configured on other dialer interfaces.

- **caller**—Dialer interface accepts calls from a specific caller ID— for example, 4085550115. You can configure a maximum of 15 caller IDs per dialer interface.

The same caller ID must not be configured on different dialer interfaces. However, you can configure caller IDs with more or fewer digits on different dialer interfaces. For example, you can configure the caller IDs 14085550115, 4085550115, and 5550115 on different dialer interfaces.

In this example, you configure the incoming map option as caller 4085550115 for dialer interface dl0.

## Configuration

### IN THIS SECTION

- [CLI Quick Configuration | 310](#)
- [Procedure | 310](#)

### CLI Quick Configuration

To quickly configure this example, copy the following command, paste it into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the command into the CLI at the [edit] hierarchy level, and then enter `commit` from configuration mode.

```
set interfaces dl0 unit 0 dialer-options incoming-map caller 4085550115
```

### Procedure

#### Step-by-Step Procedure

To configure a dialer interface for USB modem dial-in:

1. Select a dialer interface.

```
[edit]  
user@host# edit interfaces dl0
```

2. Configure the incoming map options.

```
[edit]  
user@host# edit unit 0 dialer-options incoming-map caller 4085551515
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

## Verification

To verify the configuration is working properly, enter the `show interface d10` command.

## Configuring a Dial-Up Modem Connection Remotely

To remotely connect to the USB modem connected to the USB port on the device, you must configure a dial-up modem connection on the PC or laptop computer at your remote location. Configure the dial-up modem connection properties to disable IP header compression.

To configure a dial-up modem connection remotely:

1. At your remote location, connect a modem to a management device such as a PC or laptop computer.
2. Connect the modem to your telephone network.
3. On the PC or laptop computer, select Start>Settings>Control Panel>Network Connections. The Network Connections page appears.
4. Click Create a new connection. The New Connection Wizard appears.
5. Click Next. The New Connection Wizard: Network Connection Type page appears.
6. Select Connect to the network at my workplace, and then click Next.  
The New Connection Wizard: Network Connection page appears.
7. Select Dial-up connection, and then click Next. The New Connection Wizard: Connection Name page appears.
8. In the Company Name box, type the dial-up connection name, for example USB-modem-connect. Then, click Next. The New Connection Wizard: Phone Number to Dial page appears.
9. In the Phone number box, type the telephone number of the PSTN line connected to the USB modem at the device end.
10. Click Next twice, and then click Finish. The Connect USB-modem-connect page appears.
11. If CHAP is configured on the dialer interface used for the USB modem interface at the device end, type the username and password configured in the CHAP configuration in the User name and Password boxes.
12. Click Properties. The USB-modem-connect Properties page appears.

13. In the Networking tab, select Internet Protocol (TCP/IP), and then click Properties. The Internet Protocol (TCP/IP) Properties page appears.
14. Click Advanced. The Advanced TCP/IP Settings page appears.
15. Clear the Use IP header compression check box.

## Connecting to the Device Remotely

To remotely connect to the device through a USB modem connected to the USB port on the device:

1. On the PC or laptop computer at your remote location, select Start>Settings>Control Panel>Network Connections. The Network Connections page appears.
2. Double-click the USB-modem-connect dial-up connection. The Connect USB-modem-connect page appears.
3. Click Dial to connect to the Juniper Networks device.

When the connection is complete, you can use Telnet or SSH to connect to the device.

## Modifying USB Modem Initialization Commands

**NOTE:** These instructions use Hayes-compatible modem commands to configure the modem. If your modem is not Hayes-compatible, see the documentation for your modem and enter equivalent modem commands. Applies to SRX300, SRX320, SRX340, SRX345 devices.

You can use the CLI configuration editor to override the value of an initialization command configured on the USB modem or configure additional commands for initializing USB modems.

**NOTE:** If you modify modem initialization commands when a call is in progress, the new initialization sequence is applied on the modem only when the call ends.

You can configure the following modem AT commands to initialize the USB modem:

- The command `S0=2` configures the modem to automatically answer calls on the second ring.
- The command `L2` configures medium speaker volume on the modem.

You can insert spaces between commands.

When you configure modem commands in the CLI configuration editor, you must follow these conventions:

- Use the newline character `\n` to indicate the end of a command sequence.
- Enclose the command string in double quotation marks.

You can override the value of the `S0=0` command in the initialization sequence configured on the modem and add the `L2` command.

To modify the initialization commands on a USB modem:

1. Configure the modem AT commands to initialize the USB modem.

```
[edit interfaces umd0]
user@host# set modem-options init-command-string "AT S0=2 L2 \n"
```

2. If you are done configuring the device, enter `commit` from configuration mode.

## Resetting USB Modems

For SRX300, SRX320, SRX340, and SRX345 devices, if the USB modem does not respond, you can reset the modem.

**CAUTION:** If you reset the modem when a call is in progress, the call is terminated.

To reset the USB modem, in operational mode, enter the following command:

```
user@host> request interface modem reset umd0
```

- [Example: Configuring Secure Web Access | 322](#)

You can manage a Juniper Networks device remotely through the J-Web interface. To enable secure Web access, the Juniper Networks devices support HTTP over Secure Sockets Layer (HTTPS). You can enable HTTP or HTTPS access on specific interfaces and ports on the device as needed. Read this topic for information.

## Secure Web Access Overview

You can manage a Juniper Networks device remotely through the J-Web interface. To communicate with the device, the J-Web interface uses the Hypertext Transfer Protocol (HTTP). HTTP allows easy Web access but no encryption. The data that is transmitted between the Web browser and the device by means of HTTP is vulnerable to interception and attack. To enable secure Web access, the Juniper Networks devices support HTTP over Secure Sockets Layer (HTTPS). You can enable HTTP or HTTPS access on specific interfaces and ports as needed.

The Juniper Networks device uses the Secure Sockets Layer (SSL) protocol to provide secure device management through the Web interface. SSL uses public-private key technology that requires a paired private key and an authentication certificate for providing the SSL service. SSL encrypts communication between your device and the Web browser with a session key negotiated by the SSL server certificate.

An SSL certificate includes identifying information such as a public key and a signature made by a certificate authority (CA). When you access the device through HTTPS, an SSL handshake authenticates the server and the client and begins a secure session. If the information does not match or the certificate has expired, you cannot access the device through HTTPS.

Without SSL encryption, communication between your device and the browser is sent in the open and can be intercepted. We recommend that you enable HTTPS access on your WAN interfaces.

HTTP access is enabled by default on the built-in management interfaces. By default, HTTPS access is supported on any interface with an SSL server certificate.

## SEE ALSO

[Configuring Device Addresses \(IPv4 and Loopback Addresses\)](#)

## Generating SSL Certificates for Secure Web Access (SRX Series Devices)

To generate an SSL certificate using the `openssl` command:

1. Enter `openssl` in the CLI. The `openssl` command generates a self-signed SSL certificate in privacy-enhanced mail (PEM) format. It writes the certificate and an unencrypted 1024-bit RSA private key to the specified file.

**NOTE:** Run this command on a LINUX or UNIX device because Juniper Networks Services Gateways do not support the `openssl` command.

```
% openssl req -x509 -nodes -newkey rsa:1024 -keyout filename.pem -out filename.pem
```

Replace *filename* with the name of a file in which you want the SSL certificate to be written—for example, `new.pem`.

2. When prompted, type the appropriate information in the identification form. For example, type US for the country name.
3. Display the contents of the file `new.pem`.

```
cat new.pem
```

Copy the contents of this file for installing the SSL certificate.

## Generating SSL Certificates to Be Used for Secure Web Access (EX Series Switch)

You can set up secure Web access for an EX Series switch. To enable secure Web access, you must generate a digital Secure Sockets Layer (SSL) certificate and then enable HTTPS access on the switch.

To generate an SSL certificate:

1. Enter the following `openssl` command in your SSH command-line interface on a BSD or Linux system on which **openssl** is installed. The `openssl` command generates a self-signed SSL certificate in the privacy-enhanced mail (PEM) format. It writes the certificate and an unencrypted 1024-bit RSA private key to the specified file.

```
% openssl req -x509 -nodes -newkey rsa:1024 -keyout filename.pem -out filename.pem
```

where *filename* is the name of a file in which you want the SSL certificate to be written—for example, `my-certificate`.

2. When prompted, type the appropriate information in the identification form. For example, type **US** for the country name.
3. Display the contents of the file that you created.

```
cat my-certificate.pem
```

You can use the J-Web Configuration page to install the SSL certificate on the switch. To do this, copy the file containing the certificate from the BSD or Linux system to the switch. Then open the file, copy its contents, and paste them into the Certificate box on the J-Web Secure Access Configuration page.

You can also use the following CLI statement to install the SSL certificate on the switch:

```
[edit]
user@switch# set security certificates local my-signed-cert load-key-file my-certificate.pem
```

For more information on installing certificates, see ["Example: Configuring Secure Web Access" on page 322](#).

### SEE ALSO

[Configuring Management Access for the EX Series Switch \(J-Web Procedure\)](#)

*Overview of Port Security*

## Generating a Self-Signed SSL Certificate Automatically

To generate a self-signed SSL certificate on Juniper Networks devices:

1. Establish basic connectivity.
2. Reboot the system. The self-signed certificate is automatically generated at bootup time.

```
user@host> request system reboot
Reboot the system ? [yes,no] yes
```

3. Specify system-generated-certificate under HTTPS Web management.

```
[edit]
user@host# show system services web-management https system-generated-certificate
```

## Manually Generating Self-Signed SSL Certificates

To manually generate a self-signed SSL certificate on Juniper Networks devices:

1. Establish basic connectivity.

2. If you have root login access, you can manually generate the self-signed certificate by using the following commands:

```
root@host> request security pki generate-key-pair size 512 certificate-id certname
```

Generated key pair sslcert, key size 512 bits

```
root@host> request security pki local-certificate generate-self-signed certificate-id cert-name email
email domain-name domain name ip-address IP address subject "DC= Domain name, CN= Common-Name, OU=
Organizational-Unit-name, O= Organization-Name, ST= state, C= Country"
```

Self-signed certificate generated and loaded successfully

**NOTE:** When generating the certificate, you must specify the subject, e-mail address, and either domain-name or ip-address.

3. To verify that the certificate was generated and loaded properly, enter the show security pki local-certificate operational command and specify local-certificate under HTTPS Web management.

```
[edit]
root@host# show system services web-management https local-certificate certname
```

## Deleting Self-Signed Certificates (CLI Procedure)

You can delete a self-signed certificate that is automatically or manually generated from the EX Series switch. When you delete the automatically generated self-signed certificate, the switch generates a new self-signed certificate and stores it in the file system.

- To delete the automatically generated certificate and its associated key pair from the switch:

```
user@switch> clear security pki local-certificate system-generated
```

- To delete a manually generated certificate and its associated key pair from the switch:

```
user@switch> clear security pki local-certificate certificate-id certificate-id-name
```

- To delete all manually generated certificates and their associated key pairs from the switch:

```
user@switch> clear security pki local-certificate all
```

## Understanding Self-Signed Certificates on EX Series Switches

When you initialize a Juniper Networks EX Series Ethernet Switch with the factory default configuration, the switch generates a self-signed certificate, allowing secure access to the switch through the Secure Sockets Layer (SSL) protocol. Hypertext Transfer Protocol over Secure Sockets Layer (HTTPS) and XML Network Management over Secure Sockets Layer (XNM-SSL) are the two services that can make use of the self-signed certificates.

**NOTE:** Self-signed certificates do not provide additional security as do those generated by Certificate Authorities (CAs). This is because a client cannot verify that the server he or she has connected to is the one advertised in the certificate.

The switches provide two methods for generating a self-signed certificate:

- Automatic generation

In this case, the creator of the certificate is the switch. An automatically generated (also called “system-generated”) self-signed certificate is configured on the switch by default.

After the switch is initialized, it checks for the presence of an automatically generated self-signed certificate. If it does not find one, the switch generates one and saves it in the file system.

A self-signed certificate that is automatically generated by the switch is similar to an SSH host key. It is stored in the file system, not as part of the configuration. It persists when the switch is rebooted, and it is preserved when a request `system snapshot` command is issued.

The switch uses the following distinguished name for the automatically generated certificate:

**" CN=<device serial number>, CN=system generated, CN=self-signed"**

If you delete the system-generated self-signed certificate on the switch, the switch generates a self-signed certificate automatically.

- Manual generation

In this case, you create the self-signed certificate for the switch. At any time, you can use the CLI to generate a self-signed certificate. Manually generated self-signed certificates are stored in the file system, not as part of the configuration.

Self-signed certificates are valid for five years from the time they are generated. When the validity of an automatically generated self-signed certificate expires, you can delete it from the switch so that the switch generates a new self-signed certificate.

System-generated self-signed certificates and manually generated self-signed certificates can coexist on the switch.

## Manually Generating Self-Signed Certificates on Switches (CLI Procedure)

### IN THIS SECTION

- [Generating a Public-Private Key Pair on Switches | 320](#)
- [Generating Self-Signed Certificates on Switches | 321](#)

EX Series switches allow you to generate custom self-signed certificates and store them in the file system. The certificate you generate manually can coexist with the automatically generated self-signed certificate on the switch. To enable secure access to the switch over SSL, you can use either the system-generated self-signed certificate or a certificate you have generated manually.

To generate self-signed certificates manually, you must complete the following tasks:

### Generating a Public-Private Key Pair on Switches

A digital certificate has an associated cryptographic key pair that is used to sign the certificate digitally. The cryptographic key pair comprises a public key and a private key. When you generate a self-signed certificate, you must provide a public-private key pair that can be used to sign the self-signed certificate. Therefore, you must generate a public-private key pair before you can generate a self-signed certificate.

To generate a public-private key pair:

```
user@switch> request security pki generate-key-pair certificate-id certificate-id-name
```

**NOTE:** Optionally, you can specify the encryption algorithm and the size of the encryption key. If you do not specify the encryption algorithm and encryption key size, default values are used. The default encryption algorithm is RSA, and the default encryption key size is 1024 bits.

After the public-private key pair is generated, the switch displays the following:

```
generated key pair certificate-id-name, key size 1024 bits
```

## Generating Self-Signed Certificates on Switches

To generate the self-signed certificate manually, include the certificate ID name, the subject of the distinguished name (DN), the domain name, the IP address of the switch, and the e-mail address of the certificate holder:

```
user@switch> request security pki local-certificate generate-self-signed certificate-id  
certificate-id-name domain-name domain-name email email-address ip-address switch-ip-address  
subject subject-of-distinguished-name
```

The certificate you have generated is stored in the switch's file system. The certificate ID you have specified while generating the certificate is a unique identifier that you can use to enable the HTTPS or XNM-SSL services.

To verify that the certificate was generated and loaded properly, enter the `show security pki local-certificate operational` command.

## Example: Configuring Secure Web Access

### IN THIS SECTION

- [Requirements | 322](#)
- [Overview | 322](#)
- [Configuration | 323](#)
- [Verification | 324](#)

This example shows how to configure secure Web access on your device.

### Requirements

No special configuration beyond device initialization is required before configuring this feature.

**NOTE:** You can enable HTTPS access on specified interfaces. If you enable HTTPS without specifying an interface, HTTPS is enabled on all interfaces.

### Overview

#### IN THIS SECTION

- [Topology | 322](#)

In this example, you import the SSL certificate that you have generated as a new and private key in PEM format. You then enable HTTPS access and specify the SSL certificate to be used for authentication. Finally, you specify the port as 8443 on which HTTPS access is to be enabled.

### Topology

## Configuration

### IN THIS SECTION

- Procedure | 323

## Procedure

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the `[edit]` hierarchy level, and then enter `commit` from configuration mode.

```
set security certificates local new load-key-file /var/tmp/new.pem
set system services web-management https local-certificate new port 8443
```

### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the [CLI User Guide](#).

To configure secure Web access on your device:

1. Import the SSL certificate and private key.

```
[edit security]
user@host# set certificates local new load-key-file /var/tmp/new.pem
```

2. Enable HTTPS access and specify the SSL certificate and port.

```
[edit system]
user@host# set services web-management https local-certificate new port 8443
```

## Results

From configuration mode, confirm your configuration by entering the `show security` command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security
certificates {
  local {
    new {
      "-----BEGIN RSA PRIVATE KEY-----\nMIICXQIBAAKBgQC/C5UI4frNqbi
qPwbTiOkJvqoDw2YgYse0Z5zzVJyErgSg954T\nEuHM67Ck8hA0rCnb0Y0+SY Y5rCXLf4+2s8k9EypLtYRw/

\n9w0BCQEWFW5iaGFyZ2F2YUB fLUYAnBYmsYWOH\n -----END CERTIFICATE-----\n"; ## SECRET-DATA
    }
  }
}
```

If you are done configuring the device, enter `commit` from configuration mode.

## Verification

### IN THIS SECTION

- [Verifying an SSL Certificate Configuration | 324](#)
- [Verifying a Secure Access Configuration | 325](#)

Confirm that the configuration is working properly.

### Verifying an SSL Certificate Configuration

#### Purpose

Verify the SSL certificate configuration.

## Action

From operational mode, enter the `show security` command.

## Verifying a Secure Access Configuration

### Purpose

Verify the secure access configuration.

## Action

From operational mode, enter the `show system services` command. The following sample output displays the sample values for secure Web access:

```
[edit]
user@host# show system services
web-management {
    http;
    https {
        port 8443;
        local-certificate new;
    }
}
```

### IN THIS SECTION

- [Example Topology | 327](#)

You can configure a firewall filter to limit the IP addresses that can manage a device. This firewall filter must include a term to deny all traffic except the IP addresses that are allowed to manage the device. You must apply the firewall filter to the loopback interface (lo0) to ensure that only management traffic, that is, traffic sent to the device itself, is filtered.

### Example Topology

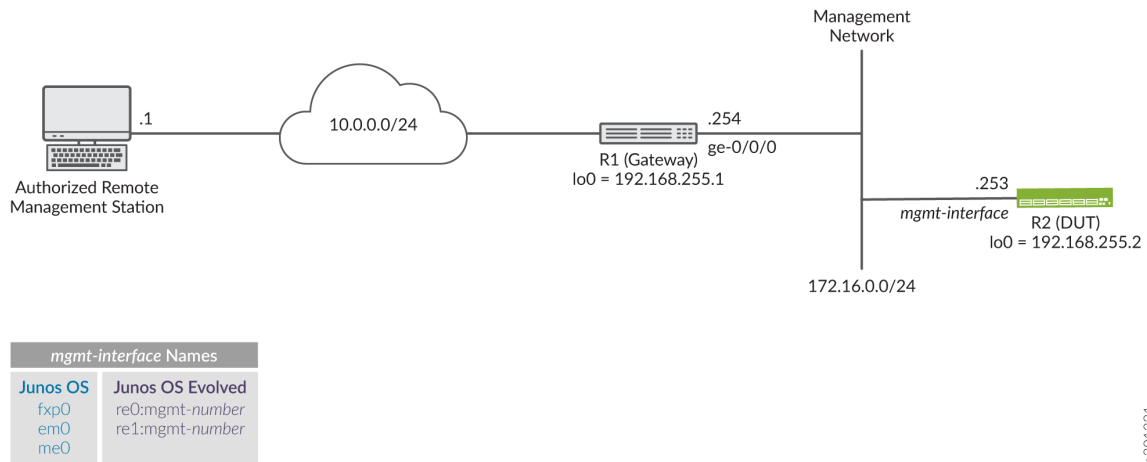

[Figure 8 on page 328](#) shows the topology for this example. The R1 device serves as the default gateway for the management network that is assigned the 172.16.0.0/24 subnet. You apply the filter that limits management access to the R2 device, making it the DUT in this example. The remote workstation is authorized to manage the DUT and has been assigned the 10.0.0.1/32 address.

In this example you:

- Configure a prefix-list called *manager-ip*. This list defines the set of IP addresses that are allowed to manage the device. In this example the list includes the management subnet itself (172.16.0.0/24), and the IP address of an authorized remote user (10.0.0.1/32).
- Configure a firewall filter *limit-mgmt-access* that rejects all source addresses *except* the specific set of addresses defined in the *manager-ip* prefix list. This ensures that only IP addresses listed in the prefix list can manage the device.

- Apply the *limit-mgmt-access* filter to the loopback interface. Any time a packet addressed to the local device arrives on any interface, the loopback interface applies the filter *limit-mgmt-access* to limit management access to only allowed addresses.

Figure 8: Example Network Topology

## Configure an IP Address List to Restrict Management Access to a Device

### IN THIS SECTION

- Procedure | 328

### Procedure

#### CLI Quick Configuration

To quickly configure this example, edit the following commands as needed and paste them into the CLI of the R2 device at the [edit] hierarchy level. For completeness the configuration includes commands to configure SSH (for non- users) and the Telnet system services. It also provides the configuration of the management interface and related static route. These commands are not needed if your device already has this functionality configured.

**NOTE:** Telnet does not support root login on Juniper Networks devices. SSH login for the root user is not configured in this example. Your device should have a non-root user configured to permit remote login. Alternatively, you can add the `root-login allow` argument to the `system services ssh` statement to permit root user login using SSH.

Be sure to issue a `commit` from configuration mode to activate the changes.

**TIP:** When applying a filter that restricts access to the device, consider using `commit confirmed`. This option automatically rolls back the configuration if you are unable to issue another `commit` in the specified time.

```
set system services ssh
set system services telnet
set interfaces fxp0 unit 0 family inet address 172.16.0.253/24
set interfaces lo0 unit 0 family inet address 192.168.255.2/32
set routing-options static route 0.0.0.0/0 next-hop 172.16.0.254 no-readvertise
set policy-options prefix-list manager-ip 172.16.0.0/24
set policy-options prefix-list manager-ip 10.0.0.1/32
set firewall filter limit-mgmt-access term block_non_manager from source-address 0.0.0.0/0
set firewall filter limit-mgmt-access term block_non_manager from source-prefix-list manager-ip
except
set firewall filter limit-mgmt-access term block_non_manager from protocol tcp
set firewall filter limit-mgmt-access term block_non_manager from destination-port ssh
set firewall filter limit-mgmt-access term block_non_manager from destination-port telnet
set firewall filter limit-mgmt-access term block_non_manager then log
set firewall filter limit-mgmt-access term block_non_manager then discard
set firewall filter limit-mgmt-access term accept_everything_else then accept
set interfaces lo0 unit 0 family inet filter input limit-mgmt-access
```

## Step-by-Step Procedure

The following steps require you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the [CLI User Guide](#).

1. Configure the management and loopback interfaces and ensure that the Telnet and SSH system services are enabled.

```
[edit]
user@R2# set interfaces fxp0 unit 0 family inet address 172.16.0.253/24
user@R2# set interfaces lo0 unit 0 family inet address 192.168.255.2/32
user@R2# set routing-options static route 0.0.0.0/0 next-hop 172.16.0.254 no-readvertise
user@R2# set system services ssh
user@R2# set system services telnet
```

2. Define the set of allowed host addresses in the prefix list. This list includes prefixes for the management subnet and for a single authorized remote management station.

```
[edit policy-options]
user@R2# set prefix-list manager-ip 172.16.0.0/24
user@R2# set prefix-list manager-ip 10.0.0.1/32
```

The prefix list is referenced in the firewall filter. Using a prefix list makes it easy to update the addresses that are permitted to access the device. This is because only the prefix list needs to be updated. No edits are required to the firewall filter itself when adding or removing allowed prefixes.

3. Configure a firewall filter to deny Telnet and SSH traffic from all IP addresses *except* those defined in the prefix list.

```
[edit firewall filter limit-mgmt-access]
user@R2# set term block_non_manager from source-address 0.0.0.0/0
user@R2# set term block_non_manager from source-prefix-list manager-ip except
user@R2# set term block_non_manager from protocol tcp
user@R2# set term block_non_manager from destination-port ssh
user@R2# set term block_non_manager from destination-port telnet
user@R2# set term block_non_manager then discard
```

Note the use of the `except` action modifier. The first term matches on all possible source addresses. The next term inverts the match for those source addresses in the specified prefix list. The result is that management traffic destined to the specified protocol and ports is only accepted when the traffic comes from an address in the list. Traffic from all other source prefixes to the same combination of protocol and ports is discarded. In this example a logging action is added to assist in filter debugging and verification.

4. Configure a default term to accept all other traffic. This ensures that other services and protocols, for example pings, BGP, or OSPF, are not affected by the filter.

**TIP:** The example filter is permissive by design. It can represent a security threat given it explicitly accepts all traffic that has not been rejected or discarded by previous filter terms. You can configure a stronger security filter by explicitly listing all protocols and services that should be accepted ending the filter with a deny all term, either implicitly or explicitly, to filter all other traffic. The drawback to a restrictive filter is it must be edited each time a supported service is added or removed.

```
[edit firewall filter limit-mgmt-access]
user@R2# set term accept_everything_else then accept
```

5. Apply the stateless firewall filter to the loopback interface as an input filter. Traffic sent from the local device is not filtered in this example.

```
[edit interfaces lo0 unit 0 ]
user@R2# set family inet filter input limit-mgmt-access
```

## Results

Confirm your work by entering the following `show` configuration commands from configuration mode. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
user@R2# show policy-options
prefix-list manager-ip {
    172.16.0.0/24;
    10.0.0.1/32;
}
```

```
user@R2# show firewall
filter limit-mgmt-access {
    term block_non_manager {
        from {
            source-address {
                0.0.0.0/0;
            }
            source-prefix-list {
```

```

        manager-ip except;
    }
    protocol tcp;
    destination-port [ ssh telnet ];
}
then {
    log;
    discard;
}
}
term accept_everything_else {
    then accept;
}
}

```

```

user@R2# show interfaces
fxp0 {
    unit 0 {
        family inet {
            address 172.16.0.253/24;
        }
    }
}
lo0 {
    unit 0 {
        family inet {
            filter {
                input limit-mgmt-access;
            }
            address 192.168.255.2/32;
        }
    }
}

```

```

user@R2# show routing-options
static {
    route 0.0.0.0/0 {
        next-hop 172.16.0.254;
        no-readvertise;
    }
}

```

```
}  
}
```

```
user@R2# show system services  
ssh;  
telnet;
```

When satisfied with your work enter `commit` from configuration mode.

**TIP:** When applying a filter that restricts access to the device, consider using `commit confirmed`. This option automatically rolls back the configuration if you are unable to issue another commit in the specified time.

## Verify the Stateless Firewall Filter

### IN THIS SECTION

- [Verify Accepted Packets | 333](#)
- [Verify Logged and Rejected Packets | 335](#)

Confirm that the firewall filter to limit management access is working properly.

### Verify Accepted Packets

#### Purpose

Verify that the firewall filter correctly allows SSH and Telnet when the traffic is sourced from the 172.16.0.0/24 subnet or from the 10.0.0.1 host prefix associated with the remote management station.

## Action

1. Clear the firewall log on your router or switch.

```
user@R2> clear firewall log
```

2. From a host attached *to* the 172.16.0.0/24 subnet, such as the R1 device, use the `ssh 172.16.0.253` command to initiate a connection to the DUT. By default the R1 device sources its traffic from the egress interface used to reach the destination. As a result the test traffic is sourced from R1's 172.16.0.254 address. This traffic does not match the *block\_non\_manager* filter term because of the *except* action modifier for addresses that match the referenced prefix list. This traffic matches the *accept\_everything\_else* filter term causing it to be accepted

**NOTE:** You will be prompted to save the SSH host key if this is the first SSH login as *user* between these devices.

```
user@R1>ssh user@172.16.0.253
Password:
Last login: Tue Sep  8 09:46:58 2020 from 10.107.199.39
--- JUNOS 20.2R1.10 Kernel 64-bit XEN JNPR-11.0-20200608.0016468_buil
user@R2>
```

3. Logout out of the CLI at the R2 device to close the SSH session.

```
user@R2> exit
logout
Connection to 172.16.0.253 closed.
user@R1>
```

**NOTE:** Repeat this step using the `telnet` command. The Telnet connection should succeed.

4. Use the `show firewall log` command at the R2 device to verify that the firewall log buffer on the R2 device *does not* contain entries with a source address in the 172.16.0.0/24 subnet. This means the

packet header information for this traffic is *not* logged in the firewall filter log. Only traffic that matches the *block\_non\_manager* term is logged in this example.

```
user@R2> show firewall log
user@R2>
```

## Meaning

The output confirms that SSH (and Telnet) connections are accepted when sourced from the management network. It also shows that packets which don't match the *block\_non\_manager* term are not logged. The same results are expected if the SSH or Telnet traffic is generated by the remote management station that is assigned the 10.0.0.1 address.

## Verify Logged and Rejected Packets

### Purpose

Verify that the firewall filter correctly discards SSH and Telnet traffic that does *not* originate from one of the prefixes in the *manager-ip* prefix list.

### Action

1. Generate SSH traffic sourced from an address that is not specified in the *manager-ip* prefix list. You can source the session from the R1 device's loopback address to simulate a non-authorized IP. Alternatively, initiate the connection from any remote device that is not connected to the management subnet, and which has not been assigned an IP address of 10.0.0.1. The packets for this SSH session should be discarded, and the packet header information should be logged in the firewall filter log buffer.

**NOTE:** You should not expect any error message or reply. The connection attempt will time-out. This is because the sample filter uses a discard rather than a reject action.

```
user@unauthorized-remote-host ssh user@172.16.0.253
ssh: connect to host 172.16.0.253 port 22: Connection timed out
```

The output shows the SSH connection does not succeed. This confirms the filter correctly blocks SSH traffic when sent from a disallowed source address. The same result is expected for Telnet sessions initiated by any non-authorized IP source address.

2. Use the `show firewall log` command to verify that the firewall log buffer on the R2 device now contains entries for packets with a non-authorized source address.

```
user@R2> show firewall log
```

```
Log :
```

Time	Filter	Action	Interface	Protocol	Src Addr	Dest Addr
11:35:46	limit-mgmt-access	D	fxp0.0	TCP	10.0.0.119	172.16.0.253
11:35:14	limit-mgmt-access	D	fxp0.0	TCP	10.0.0.119	172.16.0.253
11:34:58	limit-mgmt-access	D	fxp0.0	TCP	10.0.0.119	172.16.0.253

## Meaning

The output confirms that traffic from the 10.0.0.119 source address has matched a logging term in the *limit-mgmt-access* filter. Recall that only the *block\_non\_manager* term has a log action in this example. The Action column displays a D to indicate the packets were discarded. The ingress interface for the filtered traffic is confirmed to be the management port `fxp0.0` on the device. The transport protocol TCP and IP addresses of the filtered packets are also shown. Note that the source address 10.0.0.119 for this traffic is not listed in the *manager-ip* prefix list.

These results confirm the firewall filter is working properly for this example.

# Configuration Guidelines for Securing Console Port Access

## IN THIS SECTION

- [Secure the Console Port | 337](#)
- [Secure Mini-USB Ports | 338](#)

We recommend that you (the network administrator) disable the console port to prevent unauthorized access to the device.

## Secure the Console Port

You can use the console port on a device to connect to the device through an RJ-45 serial cable. From the console port, you can use the CLI to configure the device. By default, the console port is enabled. To secure the console port, you can configure the device to take the following actions:

- Log out of the console session when you unplug the serial cable connected to the console port.
- Disable root login connections to the console. This action prevents a non-root user from performing password recovery operation using the console.
- Disable the console port. We recommend that you disable the console port to prevent unauthorized access to the device. Preventing unauthorized access is especially important when the device is used as customer premises equipment (CPE) and is forwarding sensitive traffic.

**NOTE:** It is not always possible to disable the console port, because console access is important during operations such as software upgrades.

**WARNING:** On SRX300, SRX320, SRX340, and SRX345 devices, if you configure both the `set system ports console insecure` and `set chassis routing-engine bios uninterrupt options`, there is no alternative recovery method available if Junos OS fails to boot.

To secure the console port:

**1.** Do one of the following:

- Disable the console port.

```
[edit system ports console]
user@host# set disable
```

- Disable root login connections to the console.

```
[edit system ports console]
user@host# set insecure
```

**NOTE:** After you configure the console port as insecure, if a user tries to perform the password recovery operation by booting in single-user mode, the device will prompt for the root password. This way, only a user who knows the root password will be able to log in to single-user mode for password recovery.

- Log out of the console session when the serial cable connected to the console port is unplugged. Enter

```
[edit system ports console]
user@host# set log-out-on-disconnect
```

**NOTE:** The log-out-on-disconnect statement is not operational on SRX1500, SRX4100, SRX4200, or SRX4600 devices; on these devices, you must manually log out of the console with the request system logout command.

2. After you configure the device, enter `commit` in configuration mode.

## Secure Mini-USB Ports

SRX320, SRX320, SRX340, and SRX345 devices have a mini-USB Type-B port. You can connect your management device to the Mini-USB Type-B console port for CLI management.

You can disable mini-USB ports on the SRX Series devices to block users from connecting a USB mass storage device to the services gateway. When you disable the mini-USB port on the device, any transactions in progress on the USB device are terminated.

Use the following command to disable mini-USB ports:

```
[edit]
user@host# set chassis usb storage disable
```

Use the following command to enable mini-USB ports:

```
[edit]
user@host# delete chassis usb storage disable
```

This action re-enables the disabled mini-USB ports.

Use the `show` command to verify the status of the mini-USB:

```
user@host> show chassis usb storage
```

The output displays the current status of the USB mass storage device and indicates whether the USB ports are enabled or disabled.

## Configuring the Console Port Type (CLI Procedure)

Some devices have two console ports: an RJ-45 console port and a Mini-USB Type-B console port. You can configure and manage the device using either port. To connect to the device using a passive port, you must first configure the port as active and then reboot the device.

When a console port is active, it can display all the early boot and low-level message output. You can access the device through this port in the debugger prompt. On some devices, only one console port is active at a time and the console input is active only on that port. Check the hardware guide for your particular device for whether both ports can be active at the same time.

The RJ-45 console port is the active port by default. To activate the Mini-USB Type-B console port:

1. Connect the host machine to the device directly using the active console port or remotely using the management interface. To connect using the active console port, which is the RJ-45 console port by default, see *Connect a Device to a Management Console Using an RJ-45 Connector*.
2. Connect to your device using the Mini-USB Type-B console port. See the hardware guide for your particular device for how to connect to the port.
3. Configure the port type as `mini-usb`:

```
[edit]  
user@switch# set system ports auxiliary port-type mini-usb
```

4. Commit the configuration and `Exit`. The initial logs will show the Mini-USB Type-B console port as active.
5. Reboot the switch. The boot log appears on the activated console. If your device supports both ports being active at the same time, both ports are now active and can be used as console ports.

**NOTE:** Do not use the `delete system ports auxiliary port-type` command to delete the port-type configuration. Always use the `set system ports auxiliary port-type type` command to change the active management console port type.

To configure the RJ-45 console port as the active port, use the same procedure with the `set system ports auxiliary port-type rj45` command.

# Preventing Unauthorized Access to EX Series Switches Using Unattended Mode for U-Boot

## IN THIS SECTION

- [Understanding Unattended Mode for U-Boot on EX Series Switches | 343](#)
- [Using Unattended Mode for U-Boot to Prevent Unauthorized Access | 345](#)

Junos OS allows you to configure unattended mode for U-Boot to prevent unauthorized access to the switch during the boot process. When you configure unattended mode, an user can access the CLI during the boot process by supplying the boot-loader password. This prevents unauthorized access during boot process. Read this topic for more information.

## Understanding Unattended Mode for U-Boot on EX Series Switches

Unattended mode for U-Boot can be configured to prevent unauthorized access to the switch that can occur during the boot process. After the CPU has been reset, there are several known methods of accessing the system before the JUNOS OS login prompt appears that do not require the user to enter authorization credentials. By gaining unauthorized access, the user can view, modify, or corrupt the switch configuration, or make the switch unavailable on the network.

When unattended mode is configured, the user can access the CLI during the boot process only by pressing <Ctrl+c> and entering the correct password, which is known as the boot-loader password. The boot-loader password must have been previously configured on the switch. Entering the correct boot-loader password will place the user in the U-Boot CLI. If the password is incorrect, or if no password is entered within one minute, access to the U-Boot CLI is blocked and the boot process continues automatically.

Access to the bootstrap loader command prompt (`loader>`) is blocked in unattended mode, which prevents the use of the following recovery mechanisms: root password recovery by using single-user mode, and booting the switch by using a software package stored on a USB flash drive.

**NOTE:** If the root password is lost while the switch is in unattended mode, the switch must be reset to the factory default configuration using the LCD panel. For more information see *Reverting to the Default Factory Configuration for the EX Series Switch*.

If unattended mode is not configured, but a boot-loader password has been configured, the user must enter the correct password to access the U-Boot CLI. If a boot-loader password has not been configured, the user can access the U-Boot CLI without entering a password. In either case, the user can access the bootstrap loader command prompt, which enables root password recovery by using single-user mode as well as booting from a USB flash drive.

Unattended mode is not enabled by default. When configured, unattended mode is turned on and will block unauthorized access to the switch. [Table 21 on page 344](#) summarizes the behaviors for U-Boot mode.

**Table 21: Unattended Mode Behavior**

Unattended Mode	Boot-loader password	Behavior
On	Set	<ul style="list-style-type: none"> <li>• Access to U-Boot CLI is allowed only after entering correct password.</li> <li>• Access to loader command prompt is blocked.</li> <li>• Booting from USB is blocked.</li> <li>• Root password recovery by using single-user mode is blocked.</li> </ul>
On	Not Set	<ul style="list-style-type: none"> <li>• Access to U-Boot CLI is blocked.</li> <li>• Access to loader command prompt is blocked.</li> <li>• Booting from USB is blocked.</li> <li>• Root password recovery by using single-user mode is blocked.</li> </ul>

Table 21: Unattended Mode Behavior *(Continued)*

Unattended Mode	Boot-loader password	Behavior
Off	Set	<ul style="list-style-type: none"><li>• Access to U-Boot CLI is allowed only after entering correct password.</li><li>• Access to loader command prompt is allowed.</li><li>• Booting from USB is allowed.</li><li>• Root password recovery by using single-user mode is allowed.</li></ul>
Off	Not Set	<ul style="list-style-type: none"><li>• Access to U-Boot CLI is allowed.</li><li>• Access to loader command prompt is allowed.</li><li>• Booting from USB is allowed.</li><li>• Root password recovery by using single-user mode is allowed.</li></ul>

| [Root Password](#) | 112

Using Unattended Mode for U-Boot to Prevent Unauthorized Access

IN THIS SECTION

- [Configuring the Boot Loader Password](#) | 346
- [Configuring Unattended Mode for U-Boot](#) | 347
- [Accessing the U-Boot CLI](#) | 347

Unattended mode for U-Boot can be used to prevent unauthorized access to the switch that can occur during the boot process. When unattended mode is configured, the user can access the CLI during the boot process only by entering the correct password, which is known as the boot-loader password. The boot-loader password must have been previously configured on the switch.

When unattended mode is configured, access to the bootstrap loader command prompt (loader>) is blocked, which prevents the use of the following recovery mechanisms: root password recovery by using single-user mode, and booting the switch by using a software package stored on a USB flash drive.

**WARNING:** On EX2200 switches, if both the root and unattended mode password are lost while the switch is in unattended mode, there is no alternative recovery method available. The switch must be returned to Juniper Networks. For more information, see [Returning an EX2200 Switch or Component for Repair or Replacement](#).

To use unattended mode, follow the following procedures:

## Configuring the Boot Loader Password

To configure the boot loader password, you can use either a plain-text password that the system encrypts for you, or a password that has already been encrypted. If you use a plain-text password, Junos OS displays the password as an encrypted string so that users viewing the configuration cannot see it. As you enter the password in plain text, Junos OS encrypts it immediately. You do not have to configure Junos OS to encrypt the password. Plain-text passwords are hidden and marked as ## SECRET-DATA in the configuration.

To configure the boot-loader password:

1. Enter either a plain-text password or an encrypted password by using the `set system boot-loader authentication` command.
  - To enter a plain-text password, use the `plain-text-password` option, and re-enter the password when prompted:

```
[edit]
root@# set system boot-loader-authentication plain-text-password
New Password: type password here
Retype new password: retype password here
```

- To enter a password that is already encrypted, use the `encrypted-password` option:

```
[edit]
root@# set system boot-loader-authentication encrypted-password password
```

2. Commit the changes.

```
[edit]  
root@# commit
```

3. To view the encrypted password entries, use the configuration mode `show` command. For example:

```
[edit]  
root@# show system boot-loader-authentication  
encrypted-password "$ABC123"; ## SECRET-DATA
```

## Configuring Unattended Mode for U-Boot

Before enabling unattended mode for U-Boot, you must download and install the jloader firmware package `/volume/build/junos/13.2/service/13.2X51-D20.2/ship/jloader-ex-2200-13.2X51-D20.2-signed.tgz`, as described in [TSB16425](#).

Unattended mode for U-Boot is not enabled by default. Use the following procedure to configure unattended mode:

1. Configure unattended mode.

```
[edit]  
root@# set system unattended-boot
```

2. Commit the changes.

```
[edit]  
root@# commit
```

## Accessing the U-Boot CLI

When unattended mode for U-Boot is configured and the boot-loader password has been set, you can access the U-Boot CLI during the boot process by pressing `<Ctrl+c>` and entering the password at the prompt:

```
Press Ctrl-C in next 1 seconds to enter u-boot prompt...  
Enter password:
```

```
password correct...
=>
```

The correct password must be entered within one minute after the prompt appears. If the password is not entered within one minute, or if the password is incorrect or has not been configured, access to the U-Boot CLI will be blocked, and the boot process will continue. For more information about unattended mode behavior, see ["Understanding Unattended Mode for U-Boot on EX Series Switches" on page 343](#).

Juniper Networks Ethernet Switches use 802.1X, MAC RADIUS, or captive portal authentication to provide access control to the devices or users. When 802.1X, MAC RADIUS, or captive portal authentications are configured on the switch, end devices are evaluated at the initial connection by an authentication (RADIUS) server. To use 802.1X or MAC RADIUS authentication, you must specify the connections on the switch for each RADIUS server to which you want to connect. Read this topic for more information.

## Specifying RADIUS Server Connections on Switches (CLI Procedure)

### IN THIS SECTION

- [Configuring a RADIUS Server Using an FQDN | 351](#)

IEEE 802.1X and MAC RADIUS authentication both provide network edge security, protecting Ethernet LANs from unauthorized user access by blocking all traffic to and from devices at the interface until the supplicant's credentials or MAC address are presented and matched on the *authentication server* (a RADIUS server). When the supplicant is authenticated, the switch stops blocking access and opens the interface to the supplicant.

To use 802.1X or MAC RADIUS authentication, you must specify the connections on the switch for each RADIUS server to which you will connect.

To configure multiple RADIUS servers, include multiple `radius-server` statements. When multiple servers are configured, servers are accessed in order of configuration, by default. The first server configured is the primary server. If the primary server is unreachable, the router attempts to reach the second configured server, and so on. You can load balance the requests by configuring the round-robin method. The servers are tried in order and in a round-robin fashion until a valid response is received from one of the servers, or until all the configured retry limits are reached.

**NOTE:** The round-robin access method is not recommended for use with EX Series switches.

You can also configure a fully qualified domain name (FQDN) that resolves to one or more IP addresses. See ["Specifying RADIUS Server Connections on Switches \(CLI Procedure\)" on page 349](#).

To configure a RADIUS server on the switch:

1. Configure the IP address of the RADIUS server, the RADIUS server authentication port number, and the secret password. The secret password on the switch must match the secret password on the server.

```
[edit access]
```

```
user@switch# set radius-server server-address port 1812 secret password
```

**NOTE:** Specifying the authentication port is optional, and port 1812 is the default. However, we recommend that you configure it in order to avoid confusion as some RADIUS servers might refer to an older default.

2. (Optional) Specify the IP address by which the switch is identified by the RADIUS server. If you do not specify the IP address, the RADIUS server uses the address of the interface that sends the RADIUS request. We recommend that you specify this IP address because if the request gets diverted on an alternate route to the RADIUS server, the interface relaying the request might not be an interface on the switch.

```
[edit access]
user@switch# set radius-server source-address source-address
```

3. Configure the authentication order, making *radius* the first method of authentication:

```
[edit access]
user@switch# set profile profile-name authentication-order radius
```

4. (Optional) Configure the method the router uses to access RADIUS authentication and accounting servers when multiple servers are configured:
  - *direct*—The default method, in which there is no load balancing. The first server configured is the primary server; servers are accessed in order of configuration. If the primary server is unreachable, the router attempts to reach the second configured server, and so on.
  - *round-robin*—The method that provides load balancing by rotating router requests among the list of configured RADIUS servers. The server chosen for access is rotated based on which server was used last. The first server in the list is treated as a primary for the first authentication request, but for the second request, the second server configured is treated as primary, and so on. With this method, all of the configured servers receive roughly the same number of requests on average so that no single server has to handle all of the requests.

**NOTE:** When a RADIUS server in the round-robin list becomes unreachable, the next reachable server in the round-robin list is used for the current request. That same server is also used for the next request because it is at the top of the list of available servers. As a result, after a server failure, the server that is used takes up the load of two servers.

- To configure the method the router uses to access RADIUS accounting servers:

```
[edit access profile profile-name radius options]
user@host# set client-accounting-algorithm (direct | round-robin)
```

- To configure the method the router uses to access RADIUS authentication servers:

```
[edit access profile profile-name radius options]
user@host# set client-authentication-algorithm (direct | round-robin)
```

5. Create a profile and specify the list of RADIUS servers to be associated with the profile. For example, you might choose to group your RADIUS servers geographically by city. This feature enables easy modification whenever you want to change to a different set of authentication servers.

```
[edit access profile profile-name]
user@switch# set radius authentication-server server-address server-address
```

6. Specify the group of servers to be used for 802.1X or MAC RADIUS authentication by identifying the profile name:

```
[edit]
user@switch# set protocols dot1x authenticator authentication-profile-name access-profile-name
```

7. Configure the IP address of the switch in the list of clients on the RADIUS server. For information about configuring the RADIUS server, consult the documentation for your server.

## Configuring a RADIUS Server Using an FQDN

You can configure a fully qualified domain name (FQDN) that resolves to one or more IP addresses. Configure a RADIUS server using an FQDN at the `[edit access radius-server-name hostname]` hierarchy level. When an FQDN resolves to multiple addresses, the servers are accessed in order of configuration, by default. The first resolved address is the primary server. If the primary server is unreachable, the router attempts to reach the second server, and so on. You can load balance the requests by configuring the round-robin method. The servers are tried in order and in a round-robin fashion until a valid response is received from one of the servers, or until all the configured retry limits are reached.

1. Configure the FQDN of the RADIUS server, the RADIUS server authentication port number, and the secret password. The secret password on the switch must match the secret password on the server.

```
[edit access]
user@switch# set radius-server-name hostname port 1812 secret password
```

**NOTE:** Specifying the authentication port is optional, and port 1812 is the default. However, we recommend that you configure it in order to avoid confusion as some RADIUS servers might refer to an older default.

2. (Optional) Configure the interval for resolving an FQDN as the server address. The FQDN is resolved dynamically at fixed intervals based on the configured value.

```
[edit access]
user@switch# set radius-server-name hostname dns-query-interval minutes
```

3. (Optional) Specify the IP address by which the switch is identified by the RADIUS server. If you do not specify the IP address, the RADIUS server uses the address of the interface that sends the RADIUS request. We recommend that you specify this IP address because if the request gets diverted on an alternate route to the RADIUS server, the interface relaying the request might not be an interface on the switch.

```
[edit access]
user@switch# set radius-server-name hostname source-address source-address
```

4. Configure the authentication order, making radius the first method of authentication:

```
[edit access]
user@switch# set profile profile-name authentication-order radius
```

5. (Optional) Configure the method the switch uses to access RADIUS authentication and accounting servers when multiple servers are configured:
  - **direct**—The default method, in which there is no load balancing. The first server configured is the primary server; servers are accessed in order of configuration. If the primary server is unreachable, the router attempts to reach the second configured server, and so on.
  - **round-robin**—The method that provides load balancing by rotating requests among the list of configured RADIUS servers. The server chosen for access is rotated based on which server was used last. The first server in the list is treated as a primary for the first authentication request, but

for the second request, the second server configured is treated as primary, and so on. With this method, all of the configured servers receive roughly the same number of requests on average so that no single server has to handle all of the requests.

**NOTE:** When a RADIUS server in the round-robin list becomes unreachable, the next reachable server in the round-robin list is used for the current request. That same server is also used for the next request because it is at the top of the list of available servers. As a result, after a server failure, the server that is used takes up the load of two servers.

- To configure the method the switch uses to access RADIUS accounting servers:

```
[edit access profile profile-name radius options]
user@host# set client-accounting-algorithm (direct | round-robin)
```

- To configure the method the switch uses to access RADIUS authentication servers:

```
[edit access profile profile-name radius options]
user@host# set client-authentication-algorithm (direct | round-robin)
```

6. Create a profile and specify the list of RADIUS servers to be associated with the profile. For example, you might choose to group your RADIUS servers geographically by city. This feature enables easy modification whenever you want to change to a different set of authentication servers.

```
[edit access profile profile-name]
user@switch# set radius authentication-server-name hostname
```

7. Specify the group of servers to be used for 802.1X or MAC RADIUS authentication by identifying the profile name:

```
[edit]
user@switch# set protocols dot1x authenticator authentication-profile-name access-profile-name
```

8. Configure the IP address of the switch in the list of clients on the RADIUS server. For information about configuring the RADIUS server, consult the documentation for your server.

## Configuring MS-CHAPv2 to Provide Password-Change Support (CLI Procedure)

Junos OS for EX Series switches enables you to configure the Microsoft Corporation implementation of the Challenge Handshake Authentication Protocol version 2 (MS-CHAPv2) on the switch to provide password-change support. Configuring MS-CHAPv2 on the switch provides users accessing a switch the option of changing the password when the password expires, is reset, or is configured to be changed at next login.

See RFC 2433, *Microsoft PPP CHAP Extensions*, for information about MS-CHAP.

Before you configure MS-CHAPv2 to provide password-change support, ensure that you have:

- Configured RADIUS server authentication. Configure users on the authentication server and set the first-tried option in the authentication order to radius. See "[Example: Connecting a RADIUS Server for 802.1X to an EX Series Switch](#)" on page 380.

To configure MS-CHAPv2, specify the following:

```
[edit system radius-options]
user@switch# set password-protocol mschap-v2
```

You must have the required access permission on the switch in order to change your password.

### SEE ALSO

[Managing Users \(J-Web Procedure\)](#)

---

[Junos OS Access Privilege Configuration Guide](#)

## Configuring MS-CHAPv2 for Password-Change Support

Before you configure MS-CHAPv2 for password-change support, ensure that you have done the following:

- Configured RADIUS server authentication parameters.
- Set the first tried option in the authentication order to RADIUS server.

You can configure the Microsoft implementation of the Challenge Handshake Authentication Protocol version 2 (MS-CHAPv2) on the router or switch to support changing of passwords. This feature provides users accessing a router or switch the option of changing the password when the password expires, is reset, or is configured to be changed at next login.

To configure MS-CHAP-v2, include the following statements at the [edit system radius-options] hierarchy level:

```
[edit system radius-options]
password-protocol mschap-v2;
```

The following example shows statements for configuring the MS-CHAPv2 password protocol, password authentication order, and user accounts:

```
[edit]
system {
  authentication-order [ radius password ];
  radius-server {
    192.168.69.149 secret "$9$G-j.5Qz6tpBk.1hr1XxUjiq5Qn/C"; ## SECRET-DATA
  }
  radius-options {
    password-protocol mschap-v2;
  }
  login {
    user bob {
      class operator;
    }
  }
}
```

## Understanding Server Fail Fallback and Authentication on Switches

Juniper Networks Ethernet Switches use authentication to implement access control in an enterprise network. If 802.1X, MAC RADIUS, or captive portal authentication is configured on the switch, end devices are evaluated at the initial connection by an authentication (RADIUS) server. If the end device is

configured on the authentication server, the device is granted access to the LAN and the EX Series switch opens the interface to permit access.

Server fail fallback enables you to specify how end devices connected to the switch are supported if the RADIUS authentication server becomes unavailable. Server fail fallback is triggered most often during reauthentication when the already configured and in-use RADIUS server becomes inaccessible. However, server fail fallback can also be triggered by an end device's first attempt at authentication through the RADIUS server.

Server fail fallback enables you to specify one of four actions to be taken for end devices awaiting authentication when the server is timed out. The switch can accept or deny access to supplicants or maintain the access already granted to supplicants before the RADIUS timeout occurred. You can also configure the switch to move the supplicants to a specific VLAN. The VLAN must already be configured on the switch. The configured VLAN name overrides any attributes sent by the server.

- *Permit* authentication, allowing traffic to flow from the end device through the interface as if the end device were successfully authenticated by the RADIUS server.
- *Deny* authentication, preventing traffic from flowing from the end device through the interface. This is the default.
- *Move* the end device to a specified VLAN if the switch receives a RADIUS access-reject message. The configured VLAN name overrides any attributes sent by the server. (The VLAN must already exist on the switch.)
- *Sustain* authenticated end devices that already have LAN access and *deny* unauthenticated end devices. If the RADIUS servers time out during reauthentication, previously authenticated end devices are reauthenticated and new users are denied LAN access.

[Configuring 802.1X Interface Settings \(CLI Procedure\) | 369](#)

## Configuring RADIUS Server Fail Fallback (CLI Procedure)

You can configure authentication fallback options to specify how end devices connected to a switch are supported if the RADIUS authentication server becomes unavailable.

When you set up 802.1X or MAC RADIUS authentication on the switch, you specify a primary authentication server and one or more backup authentication servers. If the primary authentication server cannot be reached by the switch and the secondary authentication servers are also unreachable, a RADIUS server timeout occurs. If this happens, because it is the authentication server that grants or denies access to the end devices awaiting authentication, the switch does not receive access instructions for end devices attempting access to the LAN, and normal authentication cannot be completed.

You can configure the server fail fallback feature to specify an action that the switch applies to end devices when the authentication servers are unavailable. The switch can accept or deny access to supplicants or maintain the access already granted to supplicants before the RADIUS timeout occurred. You can also configure the switch to move the supplicants to a specific VLAN.

You can also configure the server reject fallback feature for end devices that receive a RADIUS access-reject message from the authentication server. The server reject fallback feature provides limited access to a LAN, typically only to the Internet, for responsive end devices that are 802.1X-enabled but that have sent the wrong credentials.

Server fail fallback is supported for voice traffic starting in Release 14.1X53-D40 and Release 15.1R4. To configure server fail fallback actions for VoIP clients sending voice traffic, use the `server-fail-voip` statement. For all data traffic, use the `server-fail` statement. The switch determines the fallback method to use based on the type of traffic sent by the client. Untagged data frames are subject to the action configured with `server-fail`, even if they are sent by a VoIP client. Tagged VoIP VLAN frames are subject to the action configured with `server-fail-voip`. If `server-fail-voip` is not configured, the voice traffic is dropped.

**NOTE:** Server reject fallback is not supported for VoIP VLAN tagged traffic. If a VoIP client starts authentication by sending untagged data traffic to a VLAN while server reject fallback is in effect, the VoIP client is allowed to access the fallback VLAN. If the same client subsequently sends tagged voice traffic, the voice traffic is dropped.

If a VoIP client starts authentication by sending tagged voice traffic while server reject fallback is in effect, the VoIP client is denied access to the fallback VLAN.

You can use the following procedure to configure server fail actions for data clients. To configure server fail fallback for VoIP clients sending voice traffic, use the `server-fail-voip` statement in place of the `server-fail` statement.

To configure server fail fallback actions:

- Configure an interface to allow traffic to flow from a supplicant to the LAN if a RADIUS server timeout occurs (as if the end device had been successfully authenticated by a RADIUS server):

```
[edit protocols dot1x authenticator]
user@switch# set interface interface-name server-fail permit
```

- Configure an interface to prevent traffic flow from an end device to the LAN (as if the end device had failed authentication and had been denied access by the RADIUS server):

```
[edit protocols dot1x authenticator]
user@switch# set interface interface-name server-fail deny
```

- Configure an interface to move an end device to a specified VLAN if a RADIUS server timeout occurs:

```
[edit protocols dot1x authenticator]
user@switch# set interface interface-name server-fail vlan-name
```

- Configure an interface to recognize already connected end devices as reauthenticated if there is a RADIUS timeout during reauthentication (new end devices are denied access):

```
[edit protocols dot1x authenticator]
user@switch# set interface interface-name server-fail use-cache
```

You can configure an interface that receives a RADIUS access-reject message from the authentication server to move end devices attempting LAN access on the interface to a server-reject VLAN, a specified VLAN already configured on the switch.

To configure a server reject fallback VLAN:

- ```
[edit protocols dot1x authenticator]
user@switch# set interface interface-name server-reject-vlan vlan-sf
```

## RADIUS over TLS (RADSEC)

**IN THIS SECTION**

- [Configure the RADSEC Destination](#) | 360
- [Configure TLS Connection Parameters](#) | 361
- [Example: Simple RADSEC Configuration](#) | 362
- [Monitoring Certificates](#) | 363
- [Monitoring RADSEC Destinations](#) | 363

To use 802.1X or MAC RADIUS authentication, you must specify the connections on the switch for each RADIUS server to which you will connect. RADIUS over TLS is designed to provide secure communication of RADIUS requests using the Transport Secure Layer (TLS) protocol. RADIUS over TLS,

also known as RADSEC, redirects regular RADIUS traffic to remote RADIUS servers connected over TLS. RADSec allows RADIUS authentication, authorization and accounting data to be passed safely across untrusted networks.

RADSEC uses TLS in combination with the Transmission Control Protocol (TCP). This transport profile provides stronger security than the User Datagram Protocol (UDP) which was originally used for RADIUS transmission. RADIUS over UDP encrypts the shared secret password using the MD5 algorithm, which is vulnerable to attacks. RADSEC mitigates the risk of attacks on MD5 by exchanging RADIUS packet payloads over an encrypted TLS tunnel.

**NOTE:** Due to limitations of the TCP protocol, RADSEC can have no more than 255 RADIUS messages in flight.

## Configure the RADSEC Destination

RADSEC servers are represented by RADSEC destination objects. To configure RADSEC, you must define the RADSEC server as a destination, and direct RADIUS traffic to that destination.

You define the RADSEC server as a destination using the `radsec` statement at the `[edit access]` hierarchy level. RADSEC destinations are identified by a unique numeric ID. You can configure multiple RADSEC destinations with different parameters pointing to the same RADSEC server.

To redirect traffic from a standard RADIUS server to a RADSEC server, associate the RADIUS server with a RADSEC destination. For example, the RADIUS server 10.1.1.1 is associated with RADSEC destination 10:

```
access {
  radius-server 10.1.1.1 {
    secret zzz;
    radsec-destination 10;
  }
}
```

You can also associate the RADIUS server with a RADSEC destination inside an access profile. For example, RADIUS server 10.2.2.2 in profile `acc_profile` is associated with RADSEC destination 10:

```
access {
  profile acc_profile {
    secret zzz;
```

```

    radsec-destination 10;
  }
}

```

**NOTE:** You can redirect more than one RADIUS server to the same RADSEC destination.

To configure RADSEC:

1. Configure the RADSEC destination with a unique ID and an IP address.

```

[edit access]
user@host# radsec destination id-number address server-address

```

2. Configure the port of the RADSEC server. If no port is configured, the default RADSEC port 2083 is used.

```

[edit access radsec destination id-number]
user@host# port port-number

```

3. Redirect traffic from a RADIUS server to the RADSEC destination:

```

[edit access]
user@host# radius-server server-address radsec-destination id-number

```

## Configure TLS Connection Parameters

The TLS connection provides encryption, authentication, and data integrity for the exchange of RADIUS messages. TLS relies on certificates and private-public key exchange pairs to secure the transmission of data between the RADSEC client and server. The RADSEC destination uses local certificates that are dynamically acquired from the Junos PKI infrastructure.

To enable RADSEC, you must specify the name of the local certificate. For information on configuring the local certificate and certificate authority (CA), see *Configuring Digital Certificates*.

1. Specify the name of the local certificate to be used for TLS communications.

```
[edit access]
user@host# radsec destination id-number tls-certificate certificate-name
```

2. Configure the certified name of the RADSEC server.

```
[edit access]
user@host# radsec destination id-number tls-peer-name cert-server-name
```

3. (Optional) Configure the TLS connection timeout (default is 5 seconds).

```
[edit access]
user@host# radsec destination id-number tls-timeout seconds
```

## Example: Simple RADSEC Configuration

The following example is a simple RADSEC configuration with one RADIUS server and one RADSEC destination. RADIUS traffic is redirected from RADIUS server 10.1.1.1 to RADSEC destination 10.

```
access {
  radius-server 10.1.1.1 {
    secret zzz;
    radsec-destination 10;
  }
  radsec {
    destination 10 {
      address 10.10.1.1;
      max-tx-buffers 1000;
      id-reuse-timeout 30;
      port 1777;
      source-address 10.1.1.2;
      tls-certificate my_cert;
      tls-min-version { v1.1 | v1.2 };
      tls-peer-name x0.radsec.com
      tls-timeout 10;
    }
  }
}
```

```
}
}
```

## Monitoring Certificates

To view information about the state and statistics of local certificate acquisition: **show network-access radsec local-certificate**.

## Monitoring RADSEC Destinations

To view statistics for the RADSEC destinations: **show network-access radsec statistics**.

To view the state of the RADSEC destinations: **show network-access radsec state**.

IEEE 802.1X standard for port-based network access control and protects Ethernet LANs from unauthorized user access. It blocks all traffic to and from a supplicant (client) at the interface until the supplicant's credentials are presented and matched on the authentication server (a RADIUS server). When the supplicant is authenticated, the switch stops blocking access and opens the interface to the supplicant. Read this topic for more information.

## 802.1X for Switches Overview

### IN THIS SECTION

- [How 802.1X Authentication Works | 364](#)
- [802.1X Features Overview | 365](#)
- [802.1X Authentication on Trunk Ports | 366](#)
- [802.1X Authentication on Layer 3 Interfaces | 367](#)
- [802.1X Authentication on Layer 2 Interfaces | 368](#)

## How 802.1X Authentication Works

802.1X authentication works by using an authenticator port access entity (the switch) to block ingress traffic from a supplicant (end device) at the port until the supplicant's credentials are presented and

match on the authentication server (a RADIUS server). When authenticated, the switch stops blocking traffic and opens the port to the supplicant.

The end device is authenticated in *single supplicant* mode, *single-secure supplicant* mode, or *multiple supplicant* mode:

- **single supplicant**—Authenticates only the first end device. All other end devices that connect later to the port are allowed full access without any further authentication. They effectively *piggyback* on the first end device's authentication.
- **single-secure supplicant**—Allows only one end device to connect to the port. No other end device is allowed to connect until the first device logs out.
- **multiple supplicant**—Allows multiple end devices to connect to the port. Each end device is authenticated individually.

Network access can be further defined by using VLANs and firewall filters, both of which act as filters to separate and match groups of end devices to the areas of the LAN they require. For example, you can configure VLANs to handle different categories of authentication failures depending upon:

- Whether or not the end device is 802.1X-enabled.
- Whether or not MAC RADIUS authentication is configured on the switch interfaces to which the hosts are connected.
- Whether the RADIUS authentication server becomes unavailable or sends a RADIUS access-reject message. See ["Configuring RADIUS Server Fail Fallback \(CLI Procedure\)" on page 357](#).

## 802.1X Features Overview

The following 802.1X features are supported on Juniper Networks Ethernet Switches:

- **Guest VLAN**—Provides limited access to a LAN, typically only to the Internet, for nonresponsive end devices that are not 802.1X-enabled when MAC RADIUS authentication is not configured on the switch interfaces to which the hosts are connected. Also, a guest VLAN can be used to provide limited access to a LAN for guest users. Typically, the guest VLAN provides access only to the Internet and to other guests' end devices.
- **Server-reject VLAN**—Provides limited access to a LAN, typically only to the Internet, for responsive end devices that are 802.1X-enabled but that have sent the wrong credentials. If the end device that is authenticated using the server-reject VLAN is an IP phone, voice traffic is not allowed.
- **Server-fail VLAN**—Provides limited access to a LAN, typically only to the Internet, for 802.1X end devices during a RADIUS server timeout.
- **Dynamic VLAN**—Enables an end device, after authentication, to be a member of a VLAN dynamically.

- **Private VLAN**—Enables configuration of 802.1X authentication on interfaces that are members of private VLANs (PVLANS).
- **Dynamic changes to a user session**—Enables the switch administrator to terminate an already authenticated session. This feature is based on support of the RADIUS Disconnect Message defined in RFC 3576.
- **VoIP VLAN**—Supports IP telephones. The implementation of a voice VLAN on an IP telephone is vendor-specific. If the phone is 802.1X-enabled, it is authenticated as any other supplicant is. If the phone is not 802.1X-enabled, but has another 802.1X-compatible device connected to its data port, that device is authenticated, and then VoIP traffic can flow to and from the phone (provided that the interface is configured in single supplicant mode and not in single-secure supplicant mode).

**NOTE:** Configuring a VoIP VLAN on private VLAN (PVLAN) interfaces is not supported.

- **RADIUS accounting**—Sends accounting information to the RADIUS accounting server. Accounting information is sent to the server whenever a subscriber logs in or logs out and whenever a subscriber activates or deactivates a subscription.
- **RADIUS server attributes for 802.1X**—The `Juniper-Switching-Filter` is a vendor-specific attribute (VSA) that can be configured on the RADIUS server to further define a supplicant's access during the 802.1X authentication process. Centrally configuring attributes on the authentication server obviates the need to configure these same attributes in the form of firewall filters on every switch in the LAN to which the supplicant might connect to the LAN. This feature is based on RLI 4583, AAA RADIUS BRAS VSA Support.

The following features are supported to authenticate devices that are not 802.1X-enabled:

- **Static MAC bypass**—Provides a bypass mechanism to authenticate devices that are not 802.1X-enabled (such as printers). Static MAC bypass connects these devices to 802.1X-enabled ports, bypassing 802.1X authentication.
- **MAC RADIUS authentication**—Provides a means to permit hosts that are not 802.1X-enabled to access the LAN. MAC-RADIUS simulates the supplicant functionality of the client device, using the MAC address of the client as username and password.

## 802.1X Authentication on Trunk Ports

Starting in Junos OS Release 18.3R1, you can configure 802.1X authentication on trunk interfaces, which allows the network access device (NAS) to authenticate an access point (AP) or another connected Layer 2 device. An AP or switch connected to the NAS will support multiple VLANs, so must connect to a trunk port. Enabling 802.1X authentication on the trunk interface protects the NAS from a

security breach in which an attacker might disconnect the AP and connect a laptop to get free access to network for all the configured VLANs.

Please note the following caveats when configuring 802.1X authentication on trunk interfaces.

- Only single and single-secure supplicant modes are supported on trunk interfaces.
- You must configure 802.1X authentication locally on the trunk interface. If you configure 802.1X authentication globally using the `set protocol dot1x interface all` command, the configuration is not applied to the trunk interface.
- Dynamic VLANs are not supported on trunk interfaces.
- Guest VLAN and server-reject VLAN are not supported on trunk interfaces.
- Server fail fallback for VoIP clients is not supported on trunk interfaces (`server-fail-voip`).
- Authentication on trunk port is not supported using captive portal.
- Authentication on trunk port is not supported on aggregated interfaces.
- Configuration of 802.1X authentication on interfaces that are members of private VLANs (PVLANS) is not supported on trunk ports.

## 802.1X Authentication on Layer 3 Interfaces

Starting in Junos OS Release 20.2R1, you can configure 802.1X authentication on layer 3 interfaces.

Please note the following caveats when configuring 802.1X authentication on layer 3 interfaces:

- Only EAP-capable clients are supported.
- Only single supplicant mode is supported.
- You must configure 802.1X authentication locally on layer 3 interfaces. If you configure 802.1X authentication globally using the `set protocol dot1x interface all` command, the configuration is not applied to layer 3 interfaces.
- Support for layer 3 interfaces does not include IRB or sub-interfaces.
- Guest VLAN, server-reject VLAN, and server-fail VLAN are not supported.
- Server fail fallback for VoIP clients is not supported (`server-fail-voip`).
- Only the following attributes are accepted from the authentication server as part of RADIUS access-accept or COA messages for clients authenticated on layer 3 interfaces:
  - User-Name
  - Session-Timeout

- Calling-Station-ID
- Acct-Session-ID
- NAS-Port-Id
- Port-Bounce

## 802.1X Authentication on Layer 2 Interfaces

Starting in Junos OS Evolved Release 22.3R1, you can configure 802.1X authentication on layer 2 interfaces. Follow caveats apply for 802.1X authentication on layer 2 interfaces.

- Unsupported features include:
  - Guest VLAN, server-reject VLAN, and server-fail VLAN
  - Server fail fallback for VoIP clients (server-fail-voip)
  - Dynamic VLAN
  - Authentication on layer 2 interfaces using captive portal and central Web authentication (CWA).
- Unsupported attributes from the authentication server of RADIUS access-accept or COA messages for clients authenticated on layer 2 interfaces include:
  - Ip-Mac-Session-Binding
  - Juniper-CWA-Redirect
  - Juniper-Switching-Filter
  - Filter-Id
  - Tunnel-Medium-Type
  - Juniper-VoIP-VLAN
  - Egress-VLAN-Name
  - Egress-VLAN-ID
  - Tunnel-Type
  - Tunnel-Private-Group-Id
- If IRB is in the bridge domain, 802.1x enabled ports do not drop routed traffic for single-secure and multiple supplicant modes, even if the user is not authenticated. 802.1x enabled ports on layer 2 interface drop routed traffic only for single supplicant mode configuration.

## Configuring 802.1X Interface Settings (CLI Procedure)

IEEE 802.1X authentication provides network edge security, protecting Ethernet LANs from unauthorized user access by blocking all traffic to and from a supplicant (client) at the interface until the supplicant's credentials are presented and matched on the *authentication server* (a RADIUS server). When the supplicant is authenticated, the switch stops blocking access and opens the interface to the supplicant.

### NOTE:

- You can also specify an 802.1X exclusion list to specify supplicants that can bypass authentication and be automatically connected to the LAN. See "[Configuring Static MAC Bypass of 802.1X and MAC RADIUS Authentication \(CLI Procedure\)](#)" on page 471.
- You cannot configure 802.1X user authentication on interfaces that have been enabled for Q-in-Q tunneling.

Before you begin, specify the RADIUS server or servers to be used as the authentication server. See "[Specifying RADIUS Server Connections on Switches \(CLI Procedure\)](#)" on page 349.

To configure 802.1X on an interface:

1. Configure the supplicant mode as **single** (authenticates the first supplicant), **single-secure** (authenticates only one supplicant), or **multiple** (authenticates multiple supplicants):

```
[edit protocols dot1x]
user@switch# set authenticator interface interface-name supplicant multiple
```

**NOTE:** Multiple supplicant mode is not supported on trunk interfaces.

2. Enable reauthentication and specify the reauthentication interval:

```
[edit protocols dot1x]
user@switch# set authenticator interface interface-name reauthentication interval seconds
```

3. Configure the interface timeout value for the response from the supplicant:

```
[edit protocols dot1x]
user@switch# set authenticator interface interface-name supplicant-timeout seconds
```

4. Configure the timeout for the interface before it resends an authentication request to the RADIUS server:

```
[edit protocols dot1x]
user@switch# set authenticator interface interface-name server-timeout seconds
```

5. Configure how long, in seconds, the interface waits before retransmitting the initial EAPOL PDUs to the supplicant:

```
[edit protocols dot1x]
user@switch# set authenticator interface interface-name transmit-period seconds
```

6. Configure the maximum number of times an EAPOL request packet is retransmitted to the supplicant before the authentication session times out:

```
[edit protocols dot1x]
user@switch# set authenticator interface interface-name maximum-requests number
```

7. Configure the number of times the switch attempts to authenticate the port after an initial failure. The port remains in a wait state during the quiet period after the authentication attempt.

```
[edit protocols dot1x]
user@switch# set authenticator interface interface-name retries number
```

8. Set the server-fail to deny so that the server does not fail.

```
[edit protocols dot1x authenticator interface interface-name]
user@switch# set server-fail deny
```

**NOTE:** This setting specifies the number of attempts before the switch puts the interface in a *HELD* state.

## Understanding RADIUS-Initiated Changes to an Authorized User Session

### IN THIS SECTION

- [Disconnect Messages](#) | [372](#)
- [Change of Authorization Messages](#) | [372](#)
- [CoA Request Port Bounce](#) | [373](#)
- [Error-Cause Codes](#) | [373](#)

When using an authentication service that is based on a client/server RADIUS model, requests are typically initiated by the client and sent to the RADIUS server. There are instances in which a request might be initiated by the server and sent to the client in order to dynamically modify an authenticated user session already in progress. The client that receives and processes the messages is the switch, which acts as the network access server, or NAS. The server can send the switch a Disconnect message requesting to terminate a session, or a Change of Authorization (CoA) message requesting to modify the session authorization attributes.

The switch listens for unsolicited RADIUS requests on UDP port 3799, and accepts requests only from a trusted source. Authorization to send a Disconnect or CoA request is determined based on the source address and the corresponding shared secret, which must be configured on the switch as well as on the RADIUS server. For more information about configuring the source address and shared secret on the switch, see "[Example: Connecting a RADIUS Server for 802.1X to an EX Series Switch](#)" on [page 380](#).

## Disconnect Messages

The RADIUS server sends a Disconnect-Request message to the switch in order to terminate a user session and discard all associated session context. The switch responds to a Disconnect-Request packet with a Disconnect-ACK message if the request is successful, that is, all associated session context is discarded and the user session is no longer connected, or with a Disconnect-NAK packet if the request fails, that is, the authenticator is unable to disconnect the session and discard all associated session context.

In Disconnect-Request messages, RADIUS attributes are used to uniquely identify the switch (NAS) and the user session. The combination of NAS identification attributes and session identification attributes included in the message must match at least one session for the request to be successful; otherwise, the switch responds with a Disconnect-NAK message. A Disconnect-Request message can contain only NAS and session identification attributes; if any other attributes are included, the switch responds with a Disconnect-NAK message.

## Change of Authorization Messages

Change of Authorization (CoA) messages contain information for dynamically modifying the authorization attributes for a user session to change the authorization level. This occurs as part of a two-step authentication process, in which the endpoint is first authenticated using MAC RADIUS authentication, and is then profiled based on the type of device. The CoA message is used to apply an enforcement policy that is appropriate for the device, typically by changing the data filters or the VLAN.

The switch responds to a CoA message with a CoA-ACK message if the authorization change is successful, or with a CoA-NAK message if the change is unsuccessful. If one or more authorization changes specified in a CoA-Request message cannot be carried out, the switch responds with a CoA-NAK message.

In CoA-Request messages, RADIUS attributes are used to uniquely identify the switch (acting as the NAS) and the user session. The combination of NAS identification attributes and session identification attributes included in the message must match the identification attributes of at least one session for the request to be successful; otherwise, the switch responds with a CoA-NAK message.

CoA-Request packets also include the session authorization attributes that will be modified if the request is accepted. The supported session authorization attributes are listed below. The CoA message can contain any or all of these attributes. If any attribute is not included as part of the CoA-Request message, the NAS assumes that the value for that attribute is to remain unchanged.

- Filter-ID
- Tunnel-Private-Group-ID
- Juniper-Switching-Filter

- Juniper-VoIP-VLAN
- Session-Timeout

## CoA Request Port Bounce

When a CoA message is used to change the VLAN for an authenticated host, end devices such as printers do not have a mechanism to detect the VLAN change, so they do not renew the lease for their DHCP address in the new VLAN. Starting in Junos OS Release 17.3, the port bounce feature can be used to force the end device to initiate DHCP re-negotiation by causing a link flap on the authenticated port.

The command to bounce the port is sent from the RADIUS server using a Juniper Networks vendor-specific attribute (VSA). The port is bounced if the following VSA attribute-value pair is received in the CoA message from the RADIUS server:

- Juniper-AV-Pair = "Port-Bounce"

To enable the port bounce feature, you must update the Junos dictionary file (**juniper.dct**) on the RADIUS server with the Juniper-AV-Pair VSA. Locate the dictionary file and add the following text to the file:

```
ATTRIBUTE Juniper-AV-Pair      Juniper-VSA(52, string) r
```

For more information about adding the VSA, consult the FreeRADIUS documentation.

You can disable the feature by configuring the `ignore-port-bounce` statement at the `[edit protocols dot1x authenticator interface interface-name]` hierarchy level.

## Error-Cause Codes

When a disconnect or CoA operation is unsuccessful, an Error-Cause attribute (RADIUS attribute 101) can be included in the response message sent by the NAS to the server to provide detail about the cause of the problem. If the detected error does not map to one of the supported Error-Cause attribute values, the router sends the message without an error-cause attribute. See [Table 22 on page 374](#) for descriptions of error-cause codes that can be included in response messages sent from the NAS.

**Table 22: Error-Cause Codes (RADIUS Attribute 101)**

| Code | Value                            | Description                                                                                                                                                                                                                  |
|------|----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 201  | Residual session context removed | Sent in response to a Disconnect-Request message if one or more user sessions are no longer active, but residual session context was found and successfully removed. This code is sent only within a Disconnect-ACK message. |
| 401  | Unsupported attribute            | The request contains an attribute that is not supported (for example, a third-party attribute).                                                                                                                              |
| 402  | Missing attribute                | A critical attribute (for example, the session identification attribute) is missing from a request.                                                                                                                          |
| 403  | NAS identification mismatch      | Request contains one or more NAS identification attributes that do not match the identity of the NAS receiving the request.                                                                                                  |
| 404  | Invalid request                  | Some other aspect of the request is invalid—for example, if one or more attributes are not formatted properly.                                                                                                               |
| 405  | Unsupported service              | The Service-Type attribute included with the request contains an invalid or unsupported value.                                                                                                                               |
| 406  | Unsupported extension            | The entity receiving the request (either an NAS or a RADIUS proxy) does not support RADIUS-initiated requests.                                                                                                               |
| 407  | Invalid attribute value          | The request contains an attribute with an unsupported value.                                                                                                                                                                 |
| 501  | Administratively prohibited      | The NAS is configured to prohibit honoring of Disconnect-Request or CoA-Request messages for the specified session.                                                                                                          |
| 503  | Session context not found        | The session context identified in the request does not exist on the NAS.                                                                                                                                                     |
| 504  | Session context not removable    | The subscriber identified by attributes in the request is owned by a component that is not supported. This code is sent only within a Disconnect-NAK message.                                                                |

Table 22: Error-Cause Codes (RADIUS Attribute 101) (*Continued*)

| Code | Value                                  | Description                                                                                                                                                   |
|------|----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 506  | Resources unavailable                  | A request could not be honored because of lack of available NAS resources (such as memory).                                                                   |
| 507  | Request initiated                      | The CoA-Request message includes a Service-Type attribute with a value of Authorize Only.                                                                     |
| 508  | Multiple session selection unsupported | The session identification attributes included in the request match multiple sessions, but the NAS does not support requests that apply to multiple sessions. |

## Filtering 802.1X Supplicants by Using RADIUS Server Attributes

### IN THIS SECTION

- [Configuring Firewall Filters on the RADIUS Server | 376](#)
- [Applying a Locally Configured Firewall Filter from the RADIUS Server | 378](#)

There are two ways to configure the a RADIUS server with port firewall filters (Layer 2 firewall filters):

- Include one or more filter terms in the Juniper-Switching-Filter attribute. The Juniper-Switching-Filter attribute is a vendor-specific attribute (VSA) listed under attribute ID number 48 in the Juniper dictionary on the RADIUS server. Use this VSA to configure simple filter conditions for 802.1X authenticated users. Nothing needs to be configured on the switch; all of the configuration is on the RADIUS server.
- Configure a local firewall filter on each switch and apply that firewall filter to users authenticated through the RADIUS server. Use this method for more complex filters. The firewall filter must be configured on each switch.

**NOTE:** If the firewall filter configuration is modified after users are authenticated using the 802.1X authentication, then the established 802.1X authentication session must be terminated and re-established for the firewall filter configuration changes to take effect.

This topic includes the following tasks:

## Configuring Firewall Filters on the RADIUS Server

You can configure simple filter conditions by using the `Juniper-Switching-Filter` attribute in the Juniper dictionary on the RADIUS server. These filters are sent to a switch whenever a new user is authenticated successfully. The filters are created and applied on all EX Series switches that authenticate users through that RADIUS server without the need for you to configure anything on each individual switch.

**NOTE:** This procedure describes using FreeRADIUS software to configure the Juniper-Switching-Filter VSA. For specific information about configuring your server, consult the AAA documentation included with your server.

To configure the Juniper-Switching-Filter attribute, enter one or more filter terms by using the CLI for the RADIUS server. Each filter term consists of match conditions with a corresponding action. Enter the filter terms enclosed within quotation marks ( " ") by using the following syntax:

```
Juniper-Switching-Filter = "match <destination-mac mac-address> <source-vlan vlan-name> <source-dot1q-tag tag> <destination-ip ip-address> <ip-protocol protocol-id> <source-port port> <destination-port port> action (allow | deny) <forwarding-class class-of-service> <loss-priority (low | medium | high)>"
```

More than one match condition can be included in a filter term. When multiple conditions are specified in a filter term, they must all be fulfilled for the packet to match the filter term. For example, the following filter term requires a packet to match *both* the destination IP address and the destination MAC address to meet the term criteria:

```
Juniper-Switching-Filter = "match destination-ip 10.10.10.8 destination-mac 00:00:00:01:02:03 action allow"
```

Multiple filter terms should be separated with commas—for example:

```
Juniper-Switching-Filter = "match destination-mac 00:00:00:01:02:03 action allow, match destination-port 80 destination-mac 00:aa:bb:cc:dd:ee action allow"
```

See ["Juniper-Switching-Filter VSA Match Conditions and Actions" on page 214](#) for definitions of match conditions and actions.

**NOTE:** On EX9200 switches, and in a Junos Fusion Enterprise with EX9200 as the aggregate device, the dynamic firewall filter is strictly applied for all IP packets. If the filter is configured to allow only a specific destination IP address, packets with other IP addresses as the destination IP will be dropped per the filter rules. This includes any IP protocol packets, such as DHCP, IGMP and ARP packets.

To configure match conditions on the RADIUS server:

1. Verify that the Juniper dictionary is loaded on your RADIUS server and includes the filtering attribute **Juniper-Switching-Filter** (attribute ID 48):

```
[root@freeradius]# cat /usr/local/share/freeradius/dictionary.juniper

# dictionary.juniper
#
# Version:      $Id: dictionary.juniper,v 1.2.6.1 2005/11/30 22:17:25 aland Exp
$
#  VENDOR      Juniper      2636
BEGIN-VENDOR   Juniper
ATTRIBUTE      Juniper-Local-User-Name      1      string
ATTRIBUTE      Juniper-Allow-Commands       2      string
ATTRIBUTE      Juniper-Deny-Commands        3      string
ATTRIBUTE      Juniper-Allow-Configuration  4      string
ATTRIBUTE      Juniper-Deny-Configuration   5      string
ATTRIBUTE      Juniper-Switching-Filter      48     string
<-
```

2. Enter the match conditions and actions. For example:

- To deny authentication based on the 802.1Q tag (here, the 802.1Q tag is **10**):

```
[root@freeradius]#
cd /usr/local/etc/raddb
vi users
```

For each relevant user, add the **Juniper-Switching-Filter** attribute:

```
Juniper-Switching-Filter = "Match Source-dot1q-tag 10 Action deny"
```

- To deny access based on a destination IP address:

```
[root@freeradius]# cd /usr/local/etc/raddb
vi users
```

For each relevant user, add the **Juniper-Switching-Filter** attribute:

```
Juniper-Switching-Filter = "Match Destination-ip 192.168.1.0/31 Action deny"
```

- To set the packet loss priority (PLP) to **high** based on a destination MAC address and the IP protocol:

```
[root@freeradius]# cd /usr/local/etc/raddb
vi users
```

For each relevant user, add the **Juniper-Switching-Filter** attribute:

```
Juniper-Switching-Filter = "Match Destination-mac 00:04:0f:fd:ac:fe, Ip-protocol 2,
forwarding-class high, Action loss-priority high"
```

**NOTE:** For the **forwarding-class** option to be applied, the forwarding class must be configured on the switch and the packet loss priority specified. If it is not configured on the switch, this option is ignored. You must specify both the forwarding class and the packet loss priority.

3. Stop and restart the RADIUS process to activate the configuration.

## Applying a Locally Configured Firewall Filter from the RADIUS Server

You can apply a port firewall filter (Layer 2 firewall filter) to user policies centrally from the RADIUS server. The RADIUS server can then specify the firewall filters that are to be applied to each user that requests authentication, reducing the need to configure the same firewall filter on multiple switches. Use this method when the firewall filter contains a large number of conditions or you want to use

different conditions for the same filter on different switches. The firewall filters must be configured on each switch.

For more information about firewall filters, see *Firewall Filters for EX Series Switches Overview*.

To apply a port firewall filter centrally from the RADIUS server:

**NOTE:** If port firewall filters are also configured locally for the interface, then the firewall filters configured by using VSAs take precedence if they conflict with the locally configured port firewall filters. If there is no conflict, they are merged.

1. Create the firewall filter on the local switch. See *Configuring Firewall Filters (CLI Procedure)* for more information on configuring a port firewall filter.
2. On the RADIUS server, open the **users** file to display the local user profiles of the end devices to which you want to apply the filter:

```
[root@freeradius]#  
cat /usr/local/etc/raddb/usersvi users
```

3. Apply the filter to each user profile by adding the Filter-ID attribute with the filter name as the attribute value:

**Filter-Id =*filter-name***

For example, the user profile below for `supplicant1` includes the Filter-ID attribute with the filter name `filter1`:

```
[root@freeradius]# cat /usr/local/etc/raddb/users  
  
supplicant1 Auth-Type := EAP, User-Password == "supplicant1"  
    Tunnel-Type = VLAN,  
    Tunnel-Medium-Type = IEEE-802,  
    Tunnel-Private-Group-Id = "1005",  
    Filter-Id = "filter1"
```

**NOTE:** Multiple filters are not supported on a single interface. However, you can support multiple filters for multiple users that are connected to the switch on the same interface by configuring a single filter with policies for each of those users.

4. Stop and restart the RADIUS process to activate the configuration.

## Example: Connecting a RADIUS Server for 802.1X to an EX Series Switch

### IN THIS SECTION

- [Requirements | 380](#)
- [Overview and Topology | 381](#)
- [Configuration | 384](#)
- [Verification | 386](#)

802.1X is the IEEE standard for port-based network access control (PNAC). You use 802.1X to control network access. Only users and devices providing credentials that have been verified against a user database are allowed access to the network. You can use a RADIUS server as the user database for 802.1X authentication, as well as for MAC RADIUS authentication.

This example describes how to connect a RADIUS server to an EX Series switch, and configure it for 802.1X:

### Requirements

This example uses the following software and hardware components:

- Junos OS Release 9.0 or later for EX Series switches

- One EX Series switch acting as an authenticator port access entity (PAE). The ports on the authenticator PAE form a control gate that blocks all traffic to and from supplicants until they are authenticated.
- One RADIUS authentication server that supports 802.1X. The authentication server acts as the backend database and contains credential information for hosts (supplicants) that have permission to connect to the network.

Before you connect the server to the switch, be sure you have:

- Performed basic bridging and VLAN configuration on the switch. See the documentation that describes setting up basic bridging and a VLAN for your switch. If you are using a switch that supports the Enhanced Layer 2 Software (ELS) configuration style, see *Example: Setting Up Basic Bridging and a VLAN for an EX Series Switch with ELS Support*. For all other switches, see *Example: Setting Up Basic Bridging and a VLAN for an EX Series Switch*.

**NOTE:** For more about ELS, see *Using the Enhanced Layer 2 Software CLI*.

- Configured users on the RADIUS authentication server.

## Overview and Topology

The EX Series switch acts as an authenticator PAE. It blocks all traffic and acts as a control gate until the supplicant (client) is authenticated by the server. All other users and devices are denied access.

Figure 9 on page 383 shows one EX4200 switch that is connected to the devices listed in Table 23 on page 384.

Figure 9: Topology for Configuration

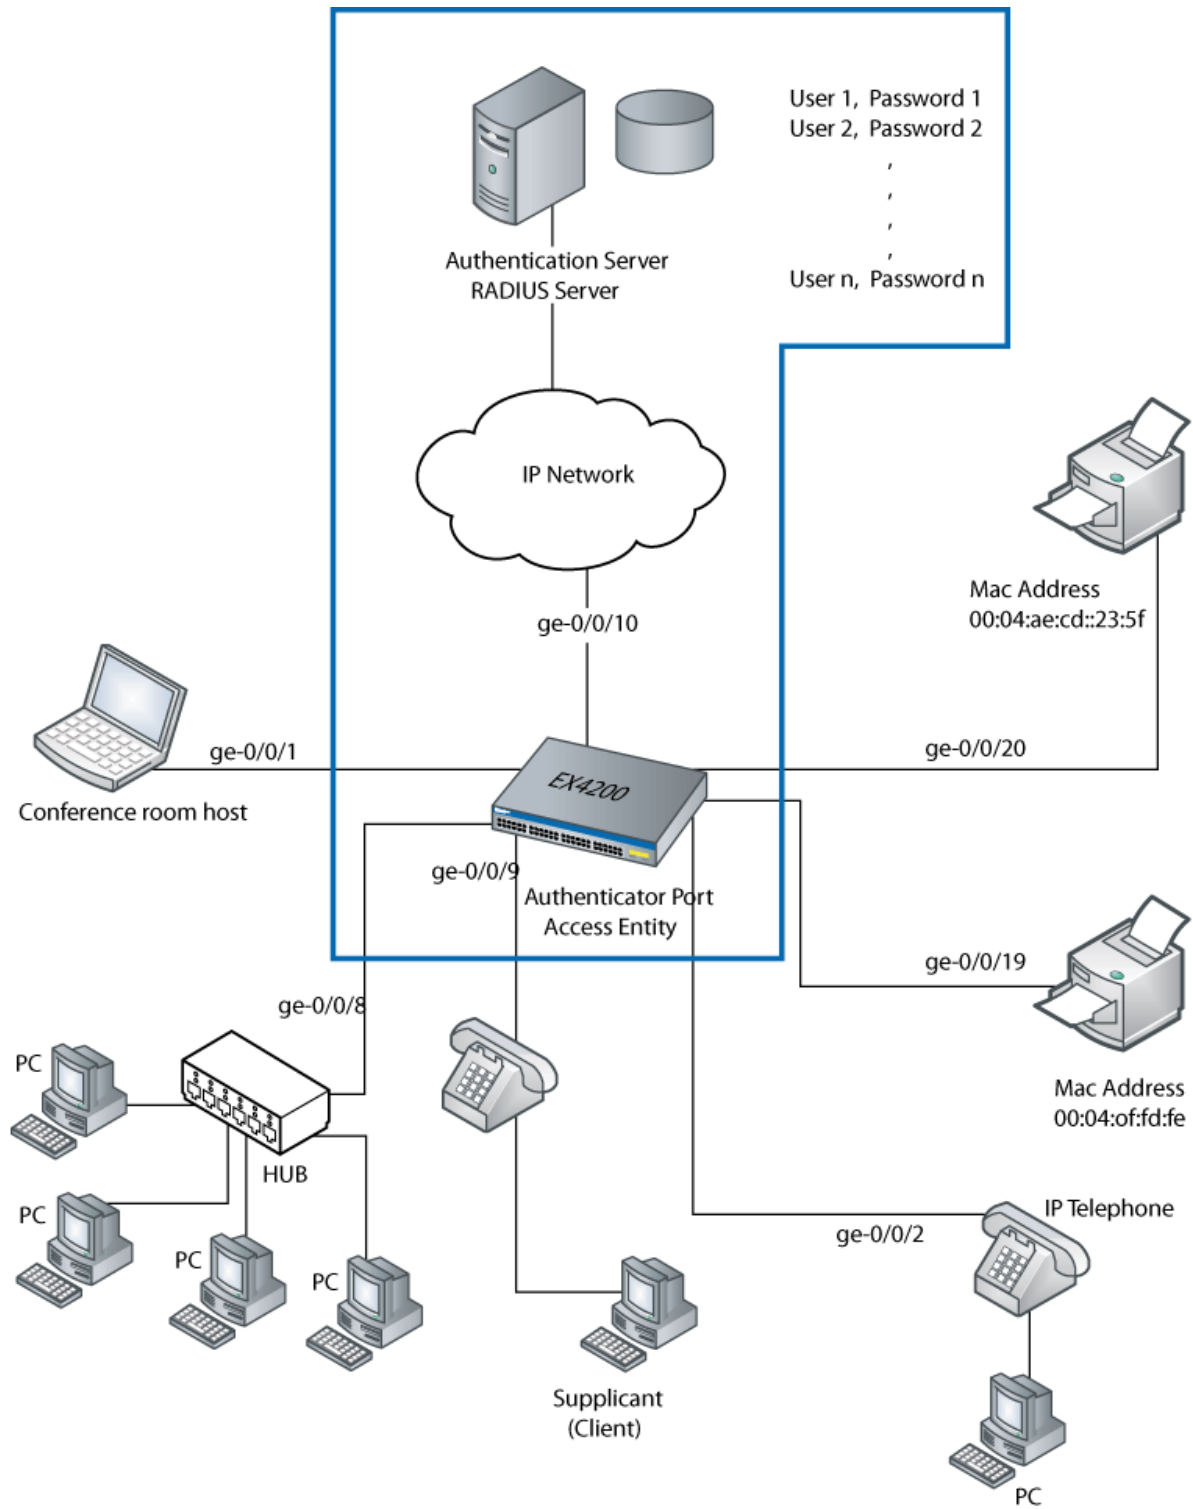

Table 23: Components of the Topology

| Property          | Settings                                                                                                                                   |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| Switch hardware   | EX4200 access switch, 24 Gigabit Ethernet ports: 8 PoE ports (ge-0/0/0 through ge-0/0/7) and 16 non-PoE ports (ge-0/0/8 through ge-0/0/23) |
| VLAN name         | default                                                                                                                                    |
| One RADIUS server | Backend database with an address <b>10.0.0.100</b> connected to the switch at port <b>ge-0/0/10</b>                                        |

In this example, connect the RADIUS server to access port ge-0/0/10 on the EX4200 switch. The switch acts as the authenticator and forwards credentials from the supplicant to the user database on the RADIUS server. You must configure connectivity between the EX4200 and the RADIUS server by specifying the address of the server and configuring the secret password. This information is configured in an access profile on the switch.

**NOTE:** For more information about authentication, authorization, and accounting (AAA) services, see the [Junos OS System Basics Configuration Guide](#).

Configuration

IN THIS SECTION

- Procedure | 384

Procedure

CLI Quick Configuration

To quickly connect the RADIUS server to the switch, copy the following commands and paste them into the switch terminal window:

```
[edit]
set access radius-server 10.0.0.100 secret juniper
set access radius-server 10.0.0.200 secret juniper
```

```
set access profile profile1 authentication-order radius
set access profile profile1 radius authentication-server [10.0.0.100 10.0.0.200]
```

## Step-by-Step Procedure

To connect the RADIUS server to the switch:

1. Define the address of the servers, and configure the secret password. The secret password on the switch must match the secret password on the server:

```
[edit]
user@switch# set access radius-server 10.0.0.100 secret juniper
user@switch# set access radius-server 10.0.0.200 secret juniper
```

2. Configure the authentication order, making **radius** the first method of authentication:

```
[edit]
user@switch# set access profile profile1 authentication-order radius
```

3. Configure a list of server IP addresses to be tried in sequential order to authenticate the supplicant:

```
[edit]
user@switch# set access profile profile1 radius authentication-server [10.0.0.100 10.0.0.200]
```

## Results

Display the results of the configuration:

```
user@switch> show configuration access
radius-server {
  10.0.0.100
    port 1812;
    secret "$ABC123"; ## SECRET-DATA
  }
}
profile profile1{
  authentication-order radius;
  radius {
```

```
        authentication-server 10.0.0.100 10.0.0.200;  
    }  
}  
}
```

## Verification

### IN THIS SECTION

- [Verify That the Switch and RADIUS Server Are Properly Connected | 386](#)

To confirm that the configuration is working properly, perform these tasks:

### Verify That the Switch and RADIUS Server Are Properly Connected

#### Purpose

Verify that the RADIUS server is connected to the switch on the specified port.

#### Action

Ping the RADIUS server to verify the connection between the switch and the server:

```
user@switch> ping 10.0.0.100  
PING 10.0.0.100 (10.0.0.100): 56 data bytes  
64 bytes from 10.93.15.218: icmp_seq=0 ttl=64 time=9.734 ms  
64 bytes from 10.93.15.218: icmp_seq=1 ttl=64 time=0.228 ms
```

#### Meaning

ICMP echo request packets are sent from the switch to the target server at 10.0.0.100 to test whether the server is reachable across the IP network. ICMP echo responses are being returned from the server, verifying that the switch and the server are connected.

## Understanding Dynamic Filters Based on RADIUS Attributes

You can use RADIUS server attributes to implement port firewall filters on a RADIUS authentication server. These filters can be dynamically applied to supplicants that request authentication through that server. RADIUS server attributes are clear-text fields encapsulated in Access-Accept messages sent from the authentication server to the switch when a supplicant connected to the switch is successfully authenticated. The switch, acting as the authenticator, uses the information in the RADIUS attributes to apply the related filters to the supplicant. Dynamic filters can be applied to multiple ports on the same switch, or to multiple switches that use the same authentication server, providing centralized access control for the network.

You can define firewall filters directly on the RADIUS server by using the Juniper-Switching-Filter attribute, which is a RADIUS attribute specific to Juniper Networks, also known as a vendor-specific attribute (VSA). VSAs are described in RFC 2138, *Remote Authentication Dial In User Service (RADIUS)*. The Juniper-Switching-Filter VSA is listed under attribute ID number 48 in the Juniper dictionary on the RADIUS server, with the vendor ID set to the Juniper Networks ID number 2636. Using this attribute, you define filters on the authentication server, which are applied on all switches that authenticate supplicants through that server. This method eliminates the need to configure the same filters on multiple switches.

Alternatively, you can apply a port firewall filter to multiple ports on the same switch by using the Filter-ID attribute, which is RADIUS attribute ID number 11. To use the Filter-ID attribute, you must first configure a filter on the switch, and then add the filter name to user policies on the RADIUS server as the value of the Filter-ID attribute. When a supplicant defined in one of those policies is authenticated by the RADIUS server, the filter is applied to the switch port that has been authenticated for the supplicant. Use this method when the firewall filter has complex conditions, or if you want to use different conditions for the same filter on different switches. The filter named in the Filter-ID attribute must be configured locally on the switch at the [edit firewall family ethernet-switching filter] hierarchy level.

VSAs are supported only for 802.1X single supplicant configurations and multiple supplicant configurations.

## Understanding Dynamic VLAN Assignment Using RADIUS Attributes

VLANs can be dynamically assigned by a RADIUS server to supplicants requesting 802.1X authentication through that server. You configure the VLAN on the RADIUS server using RADIUS server attributes, which are clear-text fields encapsulated in messages sent from the authentication server to the switch when a supplicant connected to the switch requests authentication. The switch, acting as the authenticator, uses the information in the RADIUS attributes to assign the VLAN to the supplicant. Based on the results of the authentication, a supplicant that began authentication in one VLAN might be assigned to another VLAN.

Successful authentication requires that the VLAN ID or VLAN name is configured on the switch acting as 802.1X authenticator, and that it matches the VLAN ID or VLAN name sent by the RADIUS server during authentication. If neither exists, the end device is not authenticated. If a guest VLAN is established, the unauthenticated end device is automatically moved to the guest VLAN.

The RADIUS server attributes used for dynamic VLAN assignment described in RFC 2868, *RADIUS Attributes for Tunnel Protocol Support*.

- Tunnel-Type—Defined as RADIUS attribute type 64. The value should be set to VLAN.
- Tunnel-Medium-Type—Defined as RADIUS attribute type 65. The value should be set to IEEE-802.
- Tunnel-Private-Group-ID—Defined as RADIUS attribute type 81. The value should be set to the VLAN ID or the VLAN name.

For more information about configuring dynamic VLANs on your RADIUS server, see the documentation for your RADIUS server.

[Example: Setting Up 802.1X in Conference Rooms to Provide Internet Access to Corporate Visitors on an EX Series Switch | 435](#)

## Understanding Guest VLANs for 802.1X on Switches

Guest VLANs can be configured on switches that are using 802.1X authentication to provide limited access—typically only to the Internet—for corporate guests. Guest VLAN is used as a fallback when:

- The supplicant is not 802.1X-enabled and does not respond to EAP messages.
- MAC RADIUS authentication has not been configured on the switch interfaces to which the supplicant is connected.
- Captive portal has not been configured on the switch interfaces to which the supplicant is connected.

A guest VLAN is not used for supplicants that send incorrect credentials. Those supplicants are directed to the server-reject VLAN instead.

For end devices that are not 802.1X-enabled, a guest VLAN can allow limited access to a server from which the non-802.1X-enabled end device can download the supplicant software and attempt authentication again.

## Example: Configuring 802.1X Authentication Options When the RADIUS Server Is Unavailable to an EX Series Switch

### IN THIS SECTION

- [Requirements | 390](#)
- [Overview and Topology | 391](#)
- [Configuration | 393](#)
- [Verification | 395](#)

Server fail fallback enables you to specify how 802.1X supplicants connected to the switch are supported if the RADIUS authentication server becomes unavailable.

You use 802.1X to control network access. Only users and devices (supplicants) providing credentials that have been verified against a user database are allowed access to the network. You use a RADIUS server as the user database.

This example describes how to configure an interface to move a supplicant to a VLAN in the event of a RADIUS server timeout:

## Requirements

This example uses the following software and hardware components:

**NOTE:** This example also applies to QFX5100 switches.

- Junos OS Release 9.3 or later for EX Series switches
- One EX Series switch acting as an authenticator port access entity (PAE). The ports on the authenticator PAE form a control gate that blocks all traffic to and from supplicants until they are authenticated.
- One RADIUS authentication server that supports 802.1X. The authentication server acts as the backend database and contains credential information for hosts (supplicants) that have permission to connect to the network.

Before you connect the server to the switch, be sure you have:

- Performed basic bridging and VLAN configuration on the switch. See the documentation that describes setting up basic bridging and a VLAN for your switch. If you are using a switch that supports the Enhanced Layer 2 Software (ELS) configuration style, see *Example: Setting Up Basic Bridging and a VLAN for an EX Series Switch with ELS Support* or *Example: Setting Up Basic Bridging and a VLAN on Switches*. For all other switches, see *Example: Setting Up Basic Bridging and a VLAN for an EX Series Switch*.

**NOTE:** For more about ELS, see *Using the Enhanced Layer 2 Software CLI*.

- Set up a connection between the switch and the RADIUS server. See ["Example: Connecting a RADIUS Server for 802.1X to an EX Series Switch"](#) on page 380.
- Configured users on the authentication server.

## Overview and Topology

### IN THIS SECTION

- [Topology | 393](#)

A RADIUS server timeout occurs if no authentication RADIUS servers are reachable when a supplicant logs in and attempts to access the LAN. Using server fail fallback, you configure alternative options for supplicants attempting LAN access. You can configure the switch to accept or deny access to supplicants or to maintain the access already granted to supplicants before the RADIUS server timeout. Additionally, you can configure the switch to move supplicants to a specific VLAN if a RADIUS timeout occurs.

[Figure 10 on page 392](#) shows the topology used for this example. The RADIUS server is connected to the EX4200 switch on access port **ge-0/0/10**. The switch acts as the authenticator port access entity (PAE) and forwards credentials from the supplicant to the user database on the RADIUS server. The switch blocks all traffic and acts as a control gate until the supplicant is authenticated by the authentication server. A supplicant is connected to the switch through interface ge-0/0/1.

**NOTE:** This figure also applies to QFX5100 switches.

**Figure 10: Topology for Configuring 802.1X Options**

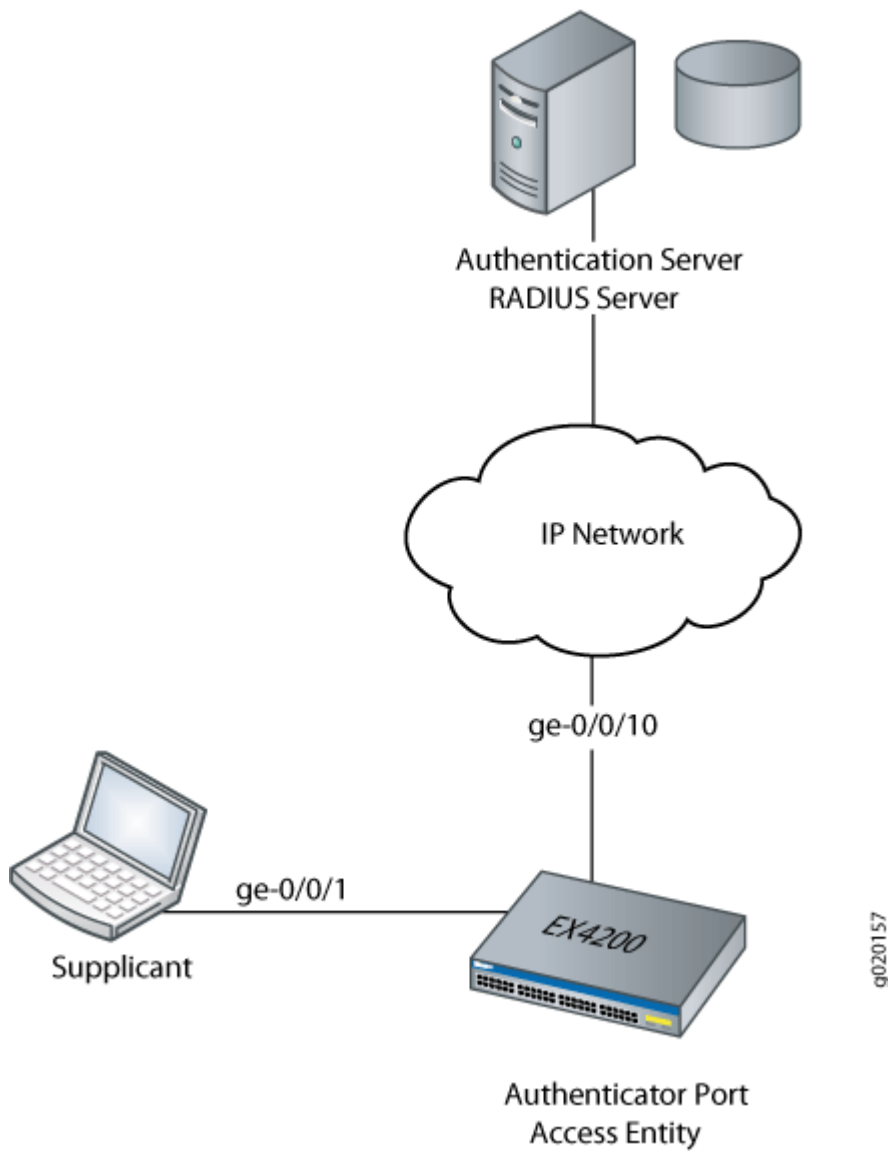

Table 24 on page 393 describes the components in this topology.

Table 24: Components of the Topology

| Property          | Settings                                                                                               |
|-------------------|--------------------------------------------------------------------------------------------------------|
| Switch hardware   | EX4200 access switch, 24 Gigabit Ethernet ports: 16 non-PoE ports and 8 PoE ports.                     |
| VLAN names        | <b>default</b> VLAN<br><b>vlan-sf</b> VLAN                                                             |
| Supplicant        | Supplicant attempting access on interface <b>ge-0/0/1</b>                                              |
| One RADIUS server | Backend database with an address of <b>10.0.0.100</b> connected to the switch at port <b>ge-0/0/10</b> |

In this example, configure interface ge-0/0/1 to move a supplicant attempting access to the LAN during a RADIUS timeout to another VLAN. A RADIUS timeout prevents the normal exchange of EAP messages that carry information from the RADIUS server to the switch and permit the authentication of a supplicant. The default VLAN is configured on interface ge-0/0/1. When a RADIUS timeout occurs, supplicants on the interface will be moved from the default VLAN to the VLAN named vlan-sf.

## Topology

## Configuration

### IN THIS SECTION

- Procedure | [394](#)

## Procedure

### CLI Quick Configuration

To quickly configure server fail fallback on the switch, copy the following commands and paste them into the switch terminal window:

```
[edit protocols dot1x authenticator]
set interface ge-0/0/1 server-fail vlan-name vlan-sf
```

### Step-by-Step Procedure

To configure an interface to divert supplicants to a specific VLAN when a RADIUS timeout occurs (here, the VLAN is **vlan-sf**):

1. Define the VLAN to which supplicants are diverted:

```
[edit protocols dot1x authenticator]
user@switch# set interface ge-0/0/1 server-fail vlan-name vlan-sf
```

## Results

Display the results of the configuration:

```
user@switch> show configuration
  interfaces {
    ge-0/0/1 {
      unit 0 {
        family ethernet-switching {
          vlan {
            members default;
          }
        }
      }
    }
  }
  protocols {
    dot1x {
      authenticator {
        interface {
```

```
ge-0/0/1.0 {
  server-fail vlan-name vlan-sf;
}
}
}
}
}
```

Verification

IN THIS SECTION

Verifying That the Supplicants Are Moved to an Alternative VLAN During a RADIUS Timeout | 395

To confirm that the configuration is working properly, perform these tasks:

Verifying That the Supplicants Are Moved to an Alternative VLAN During a RADIUS Timeout

Purpose

Verify that the interface moves supplicants to an alternative VLAN during a RADIUS timeout.

**NOTE:** On switches running Junos OS for EX Series with support for ELS, the output for the `show vlans` command will contain additional information. If your switch runs software that supports ELS, see `show vlans`. For ELS details, see *Using the Enhanced Layer 2 Software CLI*

Action

Display the VLANs configured on the switch; the interface **ge-0/0/1.0** is a member of the **default** VLAN:

```
user@switch> show vlans
Name      Tag      Interfaces
default
          ge-0/0/0.0, ge-0/0/1.0*, ge-0/0/5.0*, ge-0/0/10.0,
          ge-0/0/12.0*, ge-0/0/14.0*, ge-0/0/15.0, ge-0/0/20.0
```

```

v2          77
            None
vlan-sf     50
            None
mgmt
            me0.0*

```

Display 802.1X protocol information on the switch to view supplicants that are authenticated on interface `ge-0/0/1.0`:

```

user@switch> show dot1x interface brief
802.1X Information:
Interface   Role           State           MAC address     User
ge-0/0/1.0  Authenticator  Authenticated   00:00:00:00:00:01  abc
ge-0/0/10.0 Authenticator  Initialize
ge-0/0/14.0 Authenticator  Connecting
ge-0/0/15.0 Authenticator  Initialize
ge-0/0/20.0 Authenticator  Initialize

```

A RADIUS server timeout occurs. Display the Ethernet switching table to show that the supplicant with the MAC address `00:00:00:00:00:01` previously accessing the LAN through the **default** VLAN is now being learned on the VLAN named **vlan-sf**:

```

user@switch> show ethernet-switching
table
Ethernet-switching table: 3 entries, 1 learned
VLAN        MAC address    Type    Age Interfaces
v1          *              Flood   - All-members
vlan-sf     00:00:00:00:00:01 Learn    1:07 ge-0/0/1.0
default     *              Flood   - All-members

```

Display 802.1X protocol information to show that interface **ge-0/0/1.0** is connecting and will open LAN access to supplicants:

```

user@switch> show dot1x interface brief

802.1X Information:
Interface   Role           State           MAC address     User
ge-0/0/1.0  Authenticator  Connecting

```

```

ge-0/0/10.0  Authenticator  Initialize
ge-0/0/14.0  Authenticator  Connecting
ge-0/0/15.0  Authenticator  Initialize
ge-0/0/20.0  Authenticator  Initialize

```

## Meaning

The `show vlans` command displays interface **ge-0/0/1.0** as a member of the **default** VLAN. The `show dot1x interface brief` command shows that a supplicant (**abc**) is authenticated on interface **ge-0/0/1.0** and has the MAC address **00:00:00:00:00:01**. A RADIUS server timeout occurs, and the authentication server cannot be reached by the switch. The **show-ethernet-switching table** command shows that MAC address **00:00:00:00:00:01** is learned on VLAN **vlan-sf**. The supplicant has been moved from the **default** VLAN to the **vlan-sf** VLAN. The supplicant is then connected to the LAN through the VLAN named **vlan-sf**.

[Understanding Server Fail Fallback and Authentication on Switches | 355](#)

## Example: Configuring Fallback Options on EX Series Switches for EAP-TTLS Authentication and Odyssey Access Clients

### IN THIS SECTION

- [Requirements | 398](#)
- [Overview and Topology | 398](#)
- [Configuration | 401](#)
- [Verification | 403](#)

For 802.1X user authentication, EX Series switches support RADIUS authentication servers that are using Extensible Authentication Protocol–Tunneled TLS (EAP-TTLS) to authenticate Odyssey Access Client (OAC) supplicants. OAC networking software runs on endpoint computers (desktop, laptop, or notepad computers and supported wireless devices) and provides secure access to both wired and wireless networks.

This example describes how to configure an 802.1X-enabled interface on the switch to provide fallback support for OAC users who have entered incorrect login credentials:

## Requirements

This example uses the following software and hardware components:

**NOTE:** This example also applies to QFX5100 switches.

- Junos OS Release 11.2 or later for EX Series switches
- One EX Series switch acting as an authenticator port access entity (PAE). The ports on the authenticator PAE form a control gate that blocks all traffic to and from supplicants until they are authenticated.
- One RADIUS authentication server that supports 802.1X. The authentication server acts as the backend database and contains credential information for hosts (supplicants) that have permission to connect to the network.
- One OAC end device acting as a supplicant.

Before you begin configuring the fallback option, ensure that you have:

- Set up a connection between the switch and the RADIUS server. See ["Example: Connecting a RADIUS Server for 802.1X to an EX Series Switch" on page 380](#).
- Configured EAP-TTLS on the server. See your RADIUS server documentation.
- Configured users on the RADIUS server. See your RADIUS server documentation.

## Overview and Topology

### IN THIS SECTION

- [Topology | 400](#)

OAC is networking software that runs on endpoint computers (desktop, laptop, or notepad) and supported wireless devices. OAC provides full support for EAP, which is required for secure wireless LAN access.

In this topology, OAC is deployed with an 802.1X-enabled switch and a RADIUS server. The switch functions as an enforcement point in the network security architecture. This topology:

- Ensures that only authorized users can connect.
- Maintains privacy of login credentials.
- Maintains data privacy over the wireless link.

This example includes the configuration of a server-reject VLAN on the switch, which can be used to prevent accidental lockout for users who have entered incorrect login credentials. These users can be given limited LAN access.

However, this fallback configuration is complicated by the fact that the OAC supplicant and RADIUS server are using EAP-TTLS. EAP-TTLS creates a secure encrypted tunnel between the server and the end device to complete the authentication process. When the user enters incorrect login credentials, the RADIUS server sends EAP failure messages directly to the client through this tunnel. The EAP failure message causes the client to restart the authentication procedure, so that the switch's 802.1X authentication process tears down the session that was established with the switch using the server-reject VLAN. You can enable the remedial connection to continue by configuring:

- **eapol-block**—Enable the EAPoL block timer on the 802.1X interface that is configured to belong to the server-reject VLAN. The block timer causes the authentication port access entity to ignore EAP start messages from the client, attempting to restart the authentication procedure.

**NOTE:** The EAPoL block timer is triggered only after the configured number of allowed reattempts (using the **retries** option) on the 802.1X interface have been exhausted. You can configure **retries** to specify the number of times the switch attempts to authenticate the port after an initial failure. The default is three retries.

- **block-interval**—Configure the amount of time that you want the EAPoL block timer to continue to ignore EAP start messages. If you do not configure the block interval, the EAPoL block timer defaults to 120 seconds.

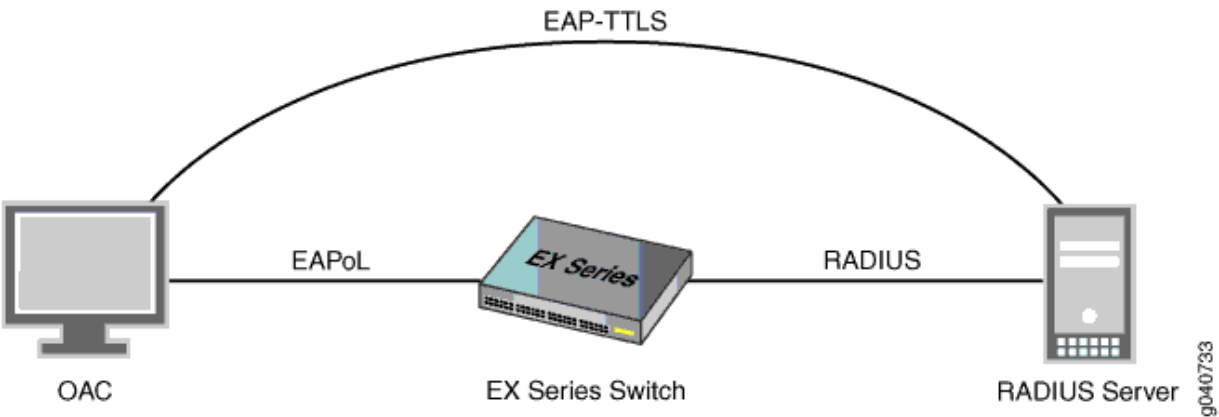

When the 802.1X interface ignores the EAP start messages from the client, the switch allows the existing remedial session that was established through the server-reject VLAN to remain open.

These configuration options apply to single, single-secure, and multiple supplicant authentication modes. In this example, the 802.1X interface is configured in single supplicant mode.

Figure 11 on page 400 shows an EX Series switch connecting an OAC end device to a RADIUS server, and indicates the protocols being used to connect the network entities.

**NOTE:** This figure also applies to QFX5100 switches.

Figure 11: EX Series Switch Connecting OAC to RADIUS Server Using EAP-TTLS Authentication

Topology

Table 25 on page 400 describes the components in this OAC deployment:.

Table 25: Components of the OAC Deployment

| Property                         | Settings                                                                                            |

## Configuration

### IN THIS SECTION

- Procedure | [401](#)
- Results | [402](#)

### Procedure

#### CLI Quick Configuration

To quickly configure the fallback options for EAP-TTLS and OAC supplicants, copy the following commands and paste them into the switch terminal window:

```
[edit]
set vlans remedial vlan-id 700
set protocols dot1x authenticator interface ge-0/0/8 retries 4
set protocols dot1x authenticator interface ge-0/0/8 server-reject-vlan remedial
set protocols dot1x authenticator interface ge-0/0/8 server-reject-vlan eapol-block
set protocols dot1x authenticator interface ge-0/0/8 server-reject-vlan block-interval 130
```

#### Step-by-Step Procedure

To configure the fallback options for EAP-TTLS and OAC supplicants:

**TIP:** In this example, the switch has only one server-reject VLAN. Therefore, the configuration specifies **eapol-block** and **block-interval** directly after **server-reject-vlan**. However, if you have configured multiple VLANs on the switch, you must include the VLAN name or VLAN ID directly after **server-reject-vlan** to indicate which VLAN is being modified.

1. Configure a VLAN that will function as the server-reject VLAN to provide limited LAN access for users who have entered incorrect login credentials:

```
[edit]
user@switch# set vlans remedial vlan-id 700
```

2. Configure the number of times for the client to be prompted for username and password before an incorrect login is directed to the server-reject VLAN:

```
[edit protocols dot1x authenticator interface ge-0/0/8]
user@switch# set retries 4
```

3. Configure the 802.1X authenticator interface to use the server-reject VLAN as a fallback for incorrect logins:

```
[edit protocols dot1x authenticator interface ge-0/0/8]
user@switch# set server-reject-vlan remedial
```

4. Enable the EAPoL block timer on the 802.1X interface that is configured to belong to the server-reject VLAN.

```
[edit protocols dot1x authenticator interface ge-0/0/8]
user@switch# set server-reject-vlan eapol-block
```

5. Configure the amount of time for the EAPoL block to remain in effect:

```
[edit protocols dot1x authenticator interface ge-0/0/8]
user@switch# set server-reject-vlan block-interval 130
```

## Results

Check the results of the configuration:

```
user@switch> show configuration
  protocols {
    dot1x {
      authenticator {
        interface {
          ge-0/0/8.0 {
            supplicant single;
            retries 4;
            server-reject-vlan remedial block-interval 130 eapol-block;
          }
        }
      }
    }
  }
```

## Verification

### IN THIS SECTION

- [Verifying the Configuration of the 802.1X Interface | 403](#)

To confirm that the configuration and the fallback options are working correctly, perform this task:

### Verifying the Configuration of the 802.1X Interface

#### Purpose

Verify that the 802.1X interface is configured with the desired options.

#### Action

```
user@switch> show dot1x interface ge-0/0/8.0 detail
ge-0/0/8.0
  Role: Authenticator
  Administrative state: Auto
  Supplicant mode: Single
  Number of retries: 4
  Quiet period: 60 seconds
  Transmit period: 30 seconds
  Mac Radius: Disabled
  Mac Radius Restrict: Disabled
  Reauthentication: Enabled
  Configured Reauthentication interval: 120 seconds
  Supplicant timeout: 30 seconds
  Server timeout: 30 seconds
  Maximum EAPoL requests: 2
  Guest VLAN member: guest
  Number of connected supplicants: 1
    Supplicant: tem, 2A:92:E6:F2:00:00
      Operational state: Authenticated
      Backend Authentication state: Idle
      Authentication method: Radius
      Authenticated VLAN: remedial
```

```
Session Reauth interval: 120 seconds
Reauthentication due in 68 seconds
```

## Meaning

The `show dot1x ge-0/0/8 detail` command output shows that the **ge-0/0/8** interface is in the **Authenticated** state and that it is using the **remedial** VLAN.

# Monitoring 802.1X Authentication

### IN THIS SECTION

- [Purpose | 404](#)
- [Action | 404](#)
- [Meaning | 405](#)

## Purpose

**NOTE:** This topic applies only to the J-Web Application package.

Use the monitoring feature to display details of authenticated users and users that failed authentication.

## Action

To display authentication details in the J-Web interface, select **Monitoring > Security > 802.1X**.

To display authentication details in the CLI, enter the following commands:

- `show dot1x interface detail | display xml`

- `show dot1x interface detail <interface> | display xml`
- `show dot1x auth-failed-users`

## Meaning

The details displayed include:

- A list of authenticated users.
- The number of connected users.
- A list of users that failed authentication.

You can also specify an interface for which the details must be displayed.

## SEE ALSO

[Configuring 802.1X Authentication \(J-Web Procedure\)](#)

[Example: Setting Up 802.1X for Single-Suppliant or Multiple-Suppliant Configurations on an EX Series Switch | 426](#)

## Verifying 802.1X Authentication

### IN THIS SECTION

- [Purpose | 405](#)
- [Action | 406](#)
- [Meaning | 406](#)

## Purpose

Verify that supplicants are being authenticated on an interface on a switch with the interface configured for 802.1X authentication, and display the method of authentication being used.

## Action

Display detailed information about an interface configured for 802.1X (here, the interface is ge-0/0/16):

```
user@switch> show dot1x interface ge-0/0/16.0 detail
ge-0/0/16.0
  Role: Authenticator
  Administrative state: Auto
  Supplicant mode: Single
  Number of retries: 3
  Quiet period: 60 seconds
  Transmit period: 30 seconds
  Mac Radius: Enabled
  Mac Radius Strict: Disabled
  Reauthentication: Enabled Reauthentication interval: 40 seconds
  Supplicant timeout: 30 seconds
  Server timeout: 30 seconds
  Maximum EAPOL requests: 1
  Guest VLAN member: <not configured>
  Number of connected supplicants: 1
    Supplicant: user5, 00:30:48:8C:66:BD
      Operational state: Authenticated
      Authentication method: Radius
      Authenticated VLAN: v200
      Reauthentication due in 17 seconds
```

## Meaning

The sample output from the `show dot1x interface detail` command shows that the Number of connected supplicants is 1. The supplicant that was authenticated and is now connected to the LAN is known as **user5** on the RADIUS server and has the MAC address **00:30:48:8C:66:BD**. The supplicant was authenticated by means of the 802.1X authentication method called RADIUS authentication, as indicated by `Radius` in the output. When RADIUS authentication is used, the supplicant is configured on the RADIUS server, the RADIUS server communicates this to the switch, and the switch opens LAN access on the interface to which the supplicant is connected. The sample output also shows that the supplicant is connected to VLAN **v200**.

Other 802.1X authentication methods supported on EX Series switches in addition to RADIUS authentication are:

- Guest VLAN—A nonresponsive host is granted Guest-VLAN access.

- **MAC Radius**—A nonresponsive host is authenticated based on its MAC address. The MAC address is configured as permitted on the RADIUS server, the RADIUS server notifies the switch that the MAC address is a permitted address, and the switch grants LAN access to the nonresponsive host on the interface to which it is connected.
- **Server-fail deny**—If the RADIUS servers time out, all supplicants are denied access to the LAN, preventing traffic from the supplicant from traversing through the interface. This is the default.
- **Server-fail permit**—When the RADIUS server is unavailable, a supplicant is still permitted access to the LAN as if the supplicant were successfully authenticated by the RADIUS server.
- **Server-fail use-cache**—If the RADIUS servers time out during reauthentication, previously authenticated supplicants are granted LAN access, but new supplicants are denied LAN access.
- **Server-fail VLAN**—A supplicant is configured to be moved to a specified VLAN if the RADIUS server is unavailable to reauthenticate the supplicant. (The VLAN must already exist on the switch.)

## Troubleshooting Authentication of End Devices on EX Series Switches

### IN THIS SECTION

● [Problem | 408](#)

● [Cause | 409](#)

● [Solution | 409](#)

## Problem

### Description

End devices configured using static MAC addresses lose connection to the switch after the clear dot1x interface command is run to clear all learned MAC addresses.

Before clearing MAC addresses:

```
user@switch# run show ethernet-switching table
Ethernet-switching table: 3 entries, 1 learned, 0 persistent entries
  VLAN          MAC address      Type      Age Interfaces
  ----          -
vlan100         *                Flood     - All-members
default         *                Flood     - All-members
default         00:a0:d4:00:03:00 Learn     0 ge-3/0/16.0

user@switch> show dot1x authentication-bypassed-users
MAC address      Interface      VLAN
00:a0:d4:00:03:00 ge-3/0/16.0    configured/default
```

To clear MAC addresses:

```
user@switch> clear dot1x interface
```

After clearing MAC addresses:

```
user@switch> show ethernet-switching table
Ethernet-switching table: 2 entries, 0 learned, 0 persistent entries
  VLAN          MAC address      Type      Age Interfaces
  ----          -
vlan100         *                Flood     - All-members
default         *                Flood     - All-members

user@switch> show dot1x authentication-bypassed-users
```

Note that there are no end devices on the authentication bypass list.

### Cause

Static MAC addresses are treated the same as other learned MAC addresses on an interface. When the clear dot1x interface command is run, it clears all learned MAC addresses from the interface, including the static MAC bypass list (also known as the exclusion list).

### Solution

If you run the clear dot1x interfaces command for an interface that has static MAC addresses configured for authentication bypass, re-add the static MAC addresses to the static MAC bypass list.

# MAC RADIUS Authentication

## IN THIS SECTION

- [Configuring MAC RADIUS Authentication \(CLI Procedure\) | 410](#)
- [Example: Configuring MAC RADIUS Authentication on an EX Series Switch | 411](#)

You can control access to your network through a switch by using several different authentication methods. Junos OS switches support 802.1X, MAC RADIUS, and captive portal as an authentication methods to devices requiring to connect to a network.

You can configure MAC RADIUS authentication on the switch interfaces to which the hosts are connected to provide LAN access. For more information, read this topic.

## Configuring MAC RADIUS Authentication (CLI Procedure)

You can permit devices that are not 802.1X-enabled LAN access by configuring MAC RADIUS authentication on the switch interfaces to which the hosts are connected.

**NOTE:** You can also allow non-802.1X-enabled devices to access the LAN by configuring their MAC address for static MAC bypass of authentication.

You can configure MAC RADIUS authentication on an interface that also allows 802.1X authentication, or you can configure either authentication method alone.

If both MAC RADIUS and 802.1X authentication are enabled on the interface, the switch first sends the host three EAPoL requests to the host. If there is no response from the host, the switch sends the host's MAC address to the RADIUS server to check whether it is a permitted MAC address. If the MAC address is configured as permitted on the RADIUS server, the RADIUS server sends a message to the switch that the MAC address is a permitted address, and the switch opens LAN access to the nonresponsive host on the interface to which it is connected.

If MAC RADIUS authentication is configured on the interface but 802.1X authentication is not (by using the **mac-radius restrict** option), the switch attempts to authenticate the MAC address with the RADIUS server without delaying by attempting 802.1X authentication first.

Before you configure MAC RADIUS authentication, be sure you have:

- Configured basic access between the switch and the RADIUS server. See "[Example: Connecting a RADIUS Server for 802.1X to an EX Series Switch](#)" on page 380.

To configure MAC RADIUS authentication by using the CLI:

- On the switch, configure the interfaces to which the nonresponsive hosts are attached for MAC RADIUS authentication, and add the **restrict** qualifier for interface **ge-0/0/20** to have it use only MAC RADIUS authentication:

```
[edit]
user@switch# set protocols dot1x authenticator interface ge-0/0/19 mac-radius
user@switch# set protocols dot1x authenticator interface ge-0/0/20 mac-radius restrict
```

- On a RADIUS authentication server, create user profiles for each nonresponsive host using the MAC address (without colons) of the nonresponsive host as the username and password (here, the MAC addresses are **00:04:0f:fd:ac:fe** and **00:04:ae:cd:23:5f**):

```
[root@freeradius]#
edit /etc/raddb
vi users
00040ffdacfe Auth-type:=Local, User-Password = "00040ffdacfe"
0004aecd235f Auth-type:=Local, User-Password = "0004aecd235f"
```

## Example: Configuring MAC RADIUS Authentication on an EX Series Switch

### IN THIS SECTION

● [Requirements](#) | 412

- Overview and Topology | 413
- Configuration | 415
- Verification | 417

To permit hosts that are not 802.1X-enabled to access a LAN, you can configure MAC RADIUS authentication on the switch interfaces to which the non-802.1X-enabled hosts are connected. When MAC RADIUS authentication is configured, the switch will attempt to authenticate the host with the RADIUS server by using the host's MAC address.

This example describes how to configure MAC RADIUS authentication for two non-802.1X-enabled hosts:

## Requirements

This example uses the following software and hardware components:

**NOTE:** This example also applies to QFX5100 switches.

- Junos OS Release 9.3 or later for EX Series switches.
- An EX Series switch acting as an authenticator port access entity (PAE). The ports on the authenticator PAE form a control gate that blocks all traffic to and from supplicants until they are authenticated.
- A RADIUS authentication server. The authentication server acts as the backend database and contains credential information for hosts (supplicants) that have permission to connect to the network.

Before you configure MAC RADIUS authentication, be sure you have:

- Configured basic access between the EX Series switch and the RADIUS server. See ["Example: Connecting a RADIUS Server for 802.1X to an EX Series Switch" on page 380](#).
- Performed basic bridging and VLAN configuration on the switch. See the documentation that describes setting up basic bridging and a VLAN for your switch. If you are using a switch that supports the Enhanced Layer 2 Software (ELS) configuration style, see *Example: Setting Up Basic Bridging and a VLAN for an EX Series Switch with ELS Support* or *Example: Setting Up Basic Bridging and a VLAN on Switches*. For all other switches, see *Example: Setting Up Basic Bridging and a VLAN for an EX Series Switch*.

**NOTE:** For more about ELS, see: *Using the Enhanced Layer 2 Software CLI*

- Performed basic 802.1X configuration. See "[Configuring 802.1X Interface Settings \(CLI Procedure\)](#)" on page 369.

## Overview and Topology

### IN THIS SECTION

- [Topology](#) | 415

IEEE 802.1X port-based network access control (PNAC) authenticates and permits devices access to a LAN if the devices can communicate with the switch by using the 802.1X protocol (that is, the devices are 802.1X-enabled). To permit non-802.1X-enabled end devices to access the LAN, you can configure MAC RADIUS authentication on the interfaces to which the end devices are connected. When the MAC address of the end device appears on the interface, the switch consults the RADIUS server to check whether it is a permitted MAC address. If the MAC address of the end device is configured as permitted on the RADIUS server, the switch opens LAN access to the end device.

You can configure both MAC RADIUS authentication and 802.1X authentication methods on an interface configured for multiple supplicants. Additionally, if an interface is connected only to a non-802.1X-enabled host, you can enable MAC RADIUS and not enable 802.1X authentication by using the **mac-radius restrict** option, and thus avoid the delay that occurs while the switch determines that the device does not respond to EAP messages.

[Figure 12 on page 414](#) shows the two printers connected to the switch.

**NOTE:** This figure also applies to QFX5100 switches.

**Figure 12: Topology for MAC RADIUS Authentication Configuration**

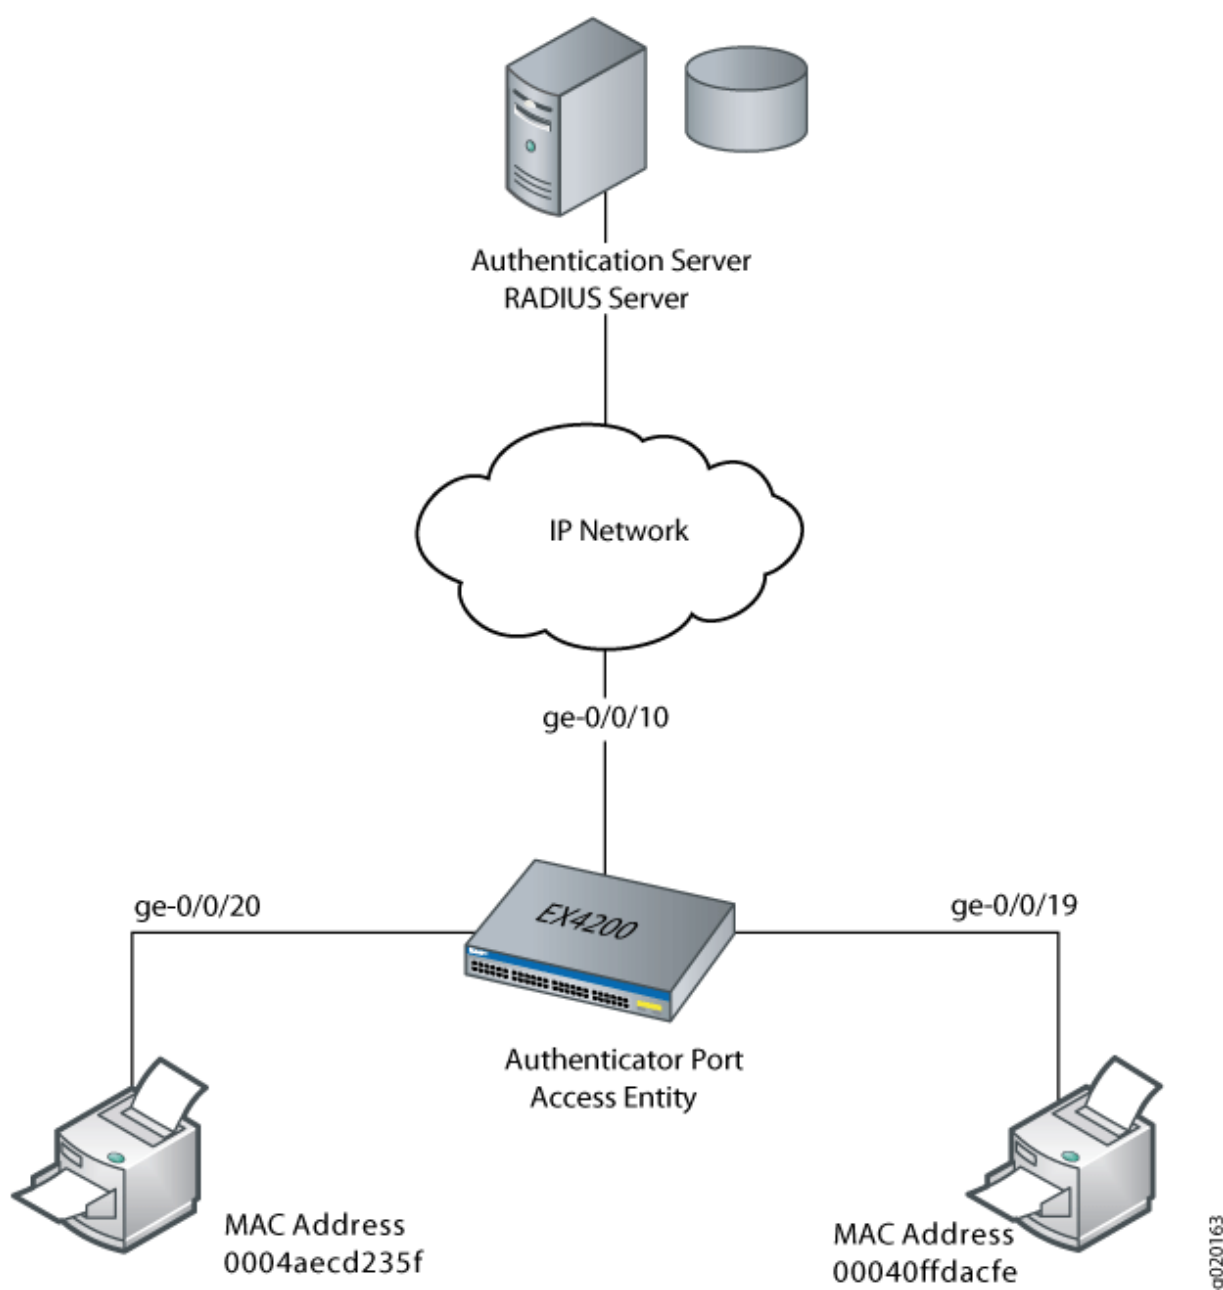

Table 26 on page 415 shows the components in the example for MAC RADIUS authentication.

Table 26: Components of the MAC RADIUS Authentication Configuration Topology

| Property                                  | Settings                                                                  |
|-------------------------------------------|---------------------------------------------------------------------------|
| Switch hardware                           | EX4200 ports (ge-0/0/0 through ge-0/0/23)                                 |
| VLAN name                                 | sales                                                                     |
| Connections to printers (no PoE required) | ge-0/0/19, MAC address 00040ffdacfe<br>ge-0/0/20, MAC address 0004aec235f |
| RADIUS server                             | Connected to the switch on interface <b>ge-0/0/10</b>                     |

The printer with the MAC address 00040ffdacfe is connected to access interface ge-0/0/19. A second printer with the MAC address 0004aec235f is connected to access interface ge-0/0/20. In this example, both interfaces are configured for MAC RADIUS authentication on the switch, and the MAC addresses (without colons) of both printers are configured on the RADIUS server. Interface ge-0/0/20 is configured to eliminate the normal delay while the switch attempts 802.1X authentication; MAC RADIUS authentication is enabled and 802.1X authentication is disabled using the `mac radius restrict` option.

## Topology

## Configuration

### IN THIS SECTION

- [Procedure | 416](#)

## Procedure

### CLI Quick Configuration

To quickly configure MAC RADIUS authentication, copy the following commands and paste them into the switch terminal window:

```
[edit]
set protocols dot1x authenticator interface ge-0/0/19 mac-radius

set protocols dot1x authenticator interface ge-0/0/20 mac-radius restrict
```

**NOTE:** You must also configure the two MAC addresses as usernames and passwords on the RADIUS server, as is done in step 2 of the Step-by-Step Procedure.

### Step-by-Step Procedure

Configure MAC RADIUS authentication on the switch and on the RADIUS server:

1. On the switch, configure the interfaces to which the printers are attached for MAC RADIUS authentication, and configure the restrict option on interface ge-0/0/20, so that only MAC RADIUS authentication is used:

```
[edit]
user@switch# set protocols dot1x authenticator interface ge-0/0/19 mac-
radius
user@switch# set protocols dot1x authenticator interface ge-0/0/20 mac-radius restrict
```

2. On the RADIUS server, configure the MAC addresses 00040ffdacfe and 0004aec235f as usernames and passwords:

```
[root@freeradius]#
edit /etc/raddb
vi users
00040ffdacfe Auth-type:=EAP, User-Password = "00040ffdacfe"
0004aec235f Auth-type:=EAP, User-Password = "0004aec235f"
```

## Results

Display the results of the configuration on the switch:

```
user@switch> show configuration
protocols {
  dot1x {
    authenticator {
      authentication-profile-name profile52;
      interface {
        ge-0/0/19.0 {
          mac-radius;
        }
        ge-0/0/20.0 {
          mac-radius {
            restrict;
          }
        }
      }
    }
  }
}
```

## Verification

### IN THIS SECTION

- [Verifying That the Supplicants Are Authenticated | 417](#)

Verify that the supplicants are authenticated:

### Verifying That the Supplicants Are Authenticated

#### Purpose

After supplicants are configured for MAC RADIUS authentication on the switch and on the RADIUS server, verify that they are authenticated and display the method of authentication.

## Action

Display information about the 802.1X-configured interfaces ge-0/0/19 and ge-0/0/20:

```

user@switch> show dot1x interface ge-0/0/19.0 detail
ge-0/0/19.0
  Role: Authenticator
  Administrative state: Auto
  Supplicant mode: Single
  Number of retries: 3
  Quiet period: 60 seconds
  Transmit period: 30 seconds
  Mac Radius: Enabled
  Mac Radius Restrict: Disabled
  Reauthentication: Enabled
  Configured Reauthentication interval: 3600 seconds
  Supplicant timeout: 30 seconds
  Server timeout: 30 seconds
  Maximum EAPOL requests: 2
  Guest VLAN member: <not configured>
  Number of connected supplicants: 1
    Supplicant: user101, 00:04:0f:fd:ac:fe
      Operational state: Authenticated
      Authentication method: Radius
      Authenticated VLAN: vo11
      Dynamic Filter: match source-dot1q-tag 10 action deny
      Session Reauth interval: 60 seconds
      Reauthentication due in 50 seconds

user@switch> show dot1x interface ge-0/0/20.0 detail
ge-0/0/20.0
  Role: Authenticator
  Administrative state: Auto
  Supplicant mode: Single
  Number of retries: 3
  Quiet period: 60 seconds
  Transmit period: 30 seconds
  Mac Radius: Enabled
  Mac Radius Restrict: Enabled
  Reauthentication: Enabled
  Configured Reauthentication interval: 3600 seconds
  Supplicant timeout: 30 seconds

```

```

Server timeout: 30 seconds
Maximum EAPOL requests: 2
Guest VLAN member: <not configured>
Number of connected supplicants: 1
  Supplicant: user102, 00:04:ae:cd:23:5f
    Operational state: Authenticated
    Authentication method: Radius
    Authenticated VLAN: vo11
    Dynamic Filter: match source-dot1q-tag 10 action deny
    Session Reauth interval: 60 seconds
    Reauthentication due in 50 seconds

```

## Meaning

The sample output from the `show dot1x interface detail` command displays the MAC address of the connected end device in the **Supplicant** field. On interface `ge-0/0/19`, the MAC address is **00:04:0f:fd:ac:fe**, which is the MAC address of the first printer configured for MAC RADIUS authentication. The **Authentication method** field displays the authentication method as **Radius**. On interface `ge-0/0/20`, the MAC address is **00:04:ae:cd:23:5f**, which is the MAC address of the second printer configured for MAC RADIUS authentication. The **Authentication method** field displays the authentication method as **Radius**.

# 802.1X and RADIUS Accounting

## IN THIS SECTION

- [Understanding 802.1X and RADIUS Accounting on Switches | 420](#)
- [Configuring 802.1X RADIUS Accounting \(CLI Procedure\) | 423](#)

EX Series Switches support RADIUS accounting. You can configure RADIUS accounting on an EX Series switch to collect statistical data about users logging in to or out of a LAN and send that data to a RADIUS accounting server. The data gathered is used for network monitoring purpose.

## Understanding 802.1X and RADIUS Accounting on Switches

### IN THIS SECTION

- [RADIUS Accounting Process | 420](#)
- [Supported RADIUS Attributes | 421](#)

Juniper Networks EX Series Ethernet Switches support IETF RFC 2866, *RADIUS Accounting*. By configuring RADIUS accounting on an EX Series switch, you can collect statistical data about users logging in to or out of a LAN and send that data to a RADIUS accounting server. The statistical data gathered can be used to perform general network monitoring, to analyze and track usage patterns, or to bill a user based on the amount of time or type of services accessed.

### RADIUS Accounting Process

RADIUS accounting is based on a client/server model in which the switch, operating as the network access server (NAS), is the client. The client forwards user accounting statistics to a designated RADIUS accounting server. The RADIUS accounting server must send a response to the client when it has successfully received and recorded the accounting statistics.

The RADIUS accounting process between a switch and a RADIUS server is based on the exchange of two types of RADIUS messages—Accounting-Request and Accounting-Response. Accounting-Request messages are sent from the switch to the server and convey information used to account for a service provided to a user. Accounting-Response messages are sent from the server to acknowledge receipt of the Accounting-Request packets. The exchange of messages between the switch and the server proceeds as follows:

1. A RADIUS accounting server listens for User Datagram Protocol (UDP) packets on a specific port. For example, on FreeRADIUS, the default port is 1813.
2. When a supplicant is authenticated through 802.1X authentication and then connected to the LAN, the switch forwards an Accounting-Request message with a record of the event to the accounting server. The Accounting-Request message sent by the switch includes the RADIUS attribute Acct-

Status-Type with a value of Start, which indicates the beginning of user service for this supplicant. The accounting server records this event in the accounting log file as a start record.

3. The accounting server sends an Accounting-Response message back to the switch confirming that it received the accounting request. If the switch does not receive a response from the server, it continues to send accounting requests until an accounting response is returned from the accounting server.
4. The switch might send an interim message to the accounting server to periodically update the server with information pertaining to a specific session. Interim messages are sent as Accounting-Request messages with the Acct-Status-Type attribute value of Interim-Update. The accounting server sends an Accounting-Response message back to the switch to confirm receipt of an interim update.
5. When the supplicant's session ends, the switch forwards an Accounting-Request message with the Acct-Status-Type attribute value set to Stop, indicating the end of user service. The accounting server records this event in the accounting log file as a stop record that contains session information and the length of the session.

The statistics collected through this process can be displayed from the RADIUS server. To view those statistics, the user needs to access the accounting log file configured to receive them. On FreeRADIUS, the filename is the server's address—for example, 122.69.1.250.

## Supported RADIUS Attributes

RADIUS accounting statistics are conveyed through the attributes included in each Accounting-Request message sent from the NAS to the server. [Table 27 on page 421](#) list the RADIUS attributes supported for Accounting-Request messages.

**Table 27: RADIUS Accounting Request Attributes**

| Type | Attribute         | Description                                                                                                                                                                        |
|------|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1    | User-Name         | The name of the authenticated user.                                                                                                                                                |
| 5    | NAS-Port          | The physical port number of the NAS that authenticates the user. Either NAS-Port or NAS-Port-ID must be contained in the packet.                                                   |
| 8    | Framed-IP-Address | The IP address of the authenticated user.<br><br><b>NOTE:</b> The Framed-IP-Address attribute is sent only if a valid DHCP binding exists for the host in the DHCP snooping table. |

**Table 27: RADIUS Accounting Request Attributes (Continued)**

| Type | Attribute          | Description                                                                                                                                                                   |
|------|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 11   | Filter-ID          | The name of the filter list for the user.                                                                                                                                     |
| 12   | Framed-MTU         | The maximum transmission unit that can be configured for the user.                                                                                                            |
| 26   | Client-System-Name | Vendor-specific attribute (VSA) used to indicate the client's hostname. Supported for LLDP-capable devices only.                                                              |
| 27   | Session-Timeout    | Sets the maximum time (in seconds) that a session stays active before it terminates or a prompt is issued notifying its termination.                                          |
| 28   | Idle-Timeout       | The maximum number of consecutive seconds of idle connection allowed to the user before termination of the session or prompt.                                                 |
| 30   | Called-Station-ID  | Enables the NAS to identify the phone number that the user called, using Dialed Number Identification (DNIS) or a similar technology.                                         |
| 31   | Calling-Station-ID | Enables the NAS to identify the phone number that the call came from, using Automatic Number Identification (ANI) or a similar technology.                                    |
| 32   | NAS-Identifier     | Contains a string identifying the NAS originating the Accounting-Request message.                                                                                             |
| 40   | Acct-Status-Type   | Indicates whether this Accounting-Request message marks the beginning (Start) or the end (Stop) of the user session. Can also be used for an interim update (Interim-Update). |
| 44   | Acct-Session-ID    | A unique ID for a specific accounting session that can be used to match start and stop records for a session in the log file.                                                 |
| 45   | Acct-Authentic     | Indicates whether the user was authenticated locally, by the RADIUS server, or by another remote authentication protocol.                                                     |
| 55   | Event-Timestamp    | Records the time an event occurred.                                                                                                                                           |

**Table 27: RADIUS Accounting Request Attributes** *(Continued)*

| Type | Attribute   | Description                                                                                                                     |
|------|-------------|---------------------------------------------------------------------------------------------------------------------------------|
| 87   | NAS-Port-ID | Text string that identifies the port that authenticates the user. Either NAS-Port or NAS-Port-ID must be present in the packet. |

**SEE ALSO**[802.1X for Switches Overview | 364](#)[Example: Connecting a RADIUS Server for 802.1X to an EX Series Switch | 380](#)[Configuring 802.1X RADIUS Accounting \(CLI Procedure\) | 423](#)

## Configuring 802.1X RADIUS Accounting (CLI Procedure)

RADIUS accounting enables statistical data about users logging in to or out of a LAN to be collected and sent to a RADIUS accounting server. The statistical data gathered can be used to perform general network monitoring, to analyze and track usage patterns, or to bill a user based upon the amount of time or type of services accessed.

RADIUS accounting is based on a client/server model in which the switch, operating as the network access server (NAS), is the client. The client is responsible for forwarding user accounting statistics to a designated RADIUS accounting server. To configure RADIUS accounting, specify one or more RADIUS accounting servers to receive the statistical data from the switch, and select the type of accounting data to be collected.

The RADIUS accounting server you specify can be the same server used for RADIUS authentication, or it can be a separate RADIUS server. You can specify a list of RADIUS accounting servers. If the primary server (the first one configured) is unavailable, then each RADIUS server in the list is tried in the order in which the servers are configured in Junos OS.

To configure RADIUS accounting by using the CLI:

1. Configure an access profile and specify the accounting servers to which the switch forwards accounting statistics:

```
[edit access]
user@switch# set profile profile-name radius accounting-server [server-
addresses]
```

2. Define the address of RADIUS accounting servers and configure the secret password (the secret password on the switch must match the secret password on the server):

```
[edit access]
user@switch# set radius-server server-address secret password
```

3. Enable accounting for the access profile:

```
[edit access]
user@switch# set profile profile-name accounting
```

4. Configure the accounting order, making RADIUS the first method for sending accounting messages and updates:

```
[edit access]
user@switch# set profile profile-name accounting order radius
```

5. Configure the statistics to be collected on the switch and forwarded to the accounting server:

```
[edit access]
user@switch# set profile profile-name accounting accounting-stop-on-access-deny
user@switch# set profile profile-name accounting accounting-stop-on-
failure
```

6. (Optional) Configure the switch to send periodic updates for a user session at a specified interval to the accounting server:

```
[edit access]
user@switch# set profile profile-name accounting update-interval minutes
```

7. Display accounting statistics collected on the switch using the `show network-access aaa statistics accounting` command, for example:

```
user@switch> show network-access aaa statistics accounting
Accounting module statistics
  Requests received: 1
  Accounting Response failures: 0
  Accounting Response Success: 1
  Requests timedout: 0
```

8. Open an accounting log on the RADIUS accounting server by using the server's address, and view accounting statistics, for example:

```
[root@freeradius]# cd /usr/local/var/log/radius/radacct/192.168.0.1
[root@freeradius 192.168.0.1]# ls

detail-20071214
```

```
[root@freeradius 192.168.0.1]# vi details-20071214
```

```

## RELATED DOCUMENTATION

[RADIUS Server Configuration for Authentication | 348](#)

# Example: Setting Up 802.1X for Single-Supplicant or Multiple-Supplicant Configurations on an EX Series Switch

## IN THIS SECTION

- [Requirements | 427](#)
- [Overview and Topology | 428](#)
- [Configuration of 802.1X to Support Multiple Supplicant Modes | 430](#)
- [Verification | 432](#)

802.1x port-based network access control (PNAC) authentication on EX Series switches provides three types of authentication to meet the access needs of your enterprise LAN:

- Authenticate the first end device (supplicant) on an authenticator port, and allow all other end devices also connecting to have access to the LAN.
- Authenticate only one end device on an authenticator port at one time.
- Authenticate multiple end devices on an authenticator port. Multiple supplicant mode is used in VoIP configurations.

This example configures an EX Series switch to use IEEE 802.1X to authenticate end devices that use three different administrative modes.

## Requirements

This example uses the following software and hardware components:

**NOTE:** This example also applies to QFX5100 switches.

- Junos OS Release 9.0 or later for EX Series switches
- One EX Series switch acting as an authenticator port access entity (PAE). The ports on the authenticator PAE form a control gate that blocks all traffic to and from end devices until they are authenticated.
- One RADIUS authentication server that supports 802.1X. The authentication server acts as the backend database and contains credential information for end devices (supplicants) that have permission to connect to the network.

Before you configure the ports for 802.1X authentication, be sure you have:

- Performed the initial switch configuration. See *Connecting and Configuring an EX Series Switch (CLI Procedure)*.
- Performed basic bridging and VLAN configuration on the switch. See the documentation that describes setting up basic bridging and a VLAN for your switch. If you are using a switch that supports the Enhanced Layer 2 Software (ELS) configuration style, see *Example: Setting Up Basic Bridging and a VLAN for an EX Series Switch with ELS Support* or *Example: Setting Up Basic Bridging and a VLAN on Switches*. For all other switches, see *Example: Setting Up Basic Bridging and a VLAN for an EX Series Switch*.

**NOTE:** For more about ELS, see *Using the Enhanced Layer 2 Software CLI*.

- Configured users on the authentication server.

## Overview and Topology

### IN THIS SECTION

- [Topology | 429](#)

As shown in [Figure 13 on page 429](#), the topology contains an EX4200 access switch connected to the authentication server on port ge-0/0/10. Interfaces ge-0/0/8, ge-0/0/9, and ge-0/0/11 will be configured for three different administrative modes.

**NOTE:** This figure also applies to QFX5100 switches.

## Topology

Figure 13: Topology for Configuring Supplicant Modes

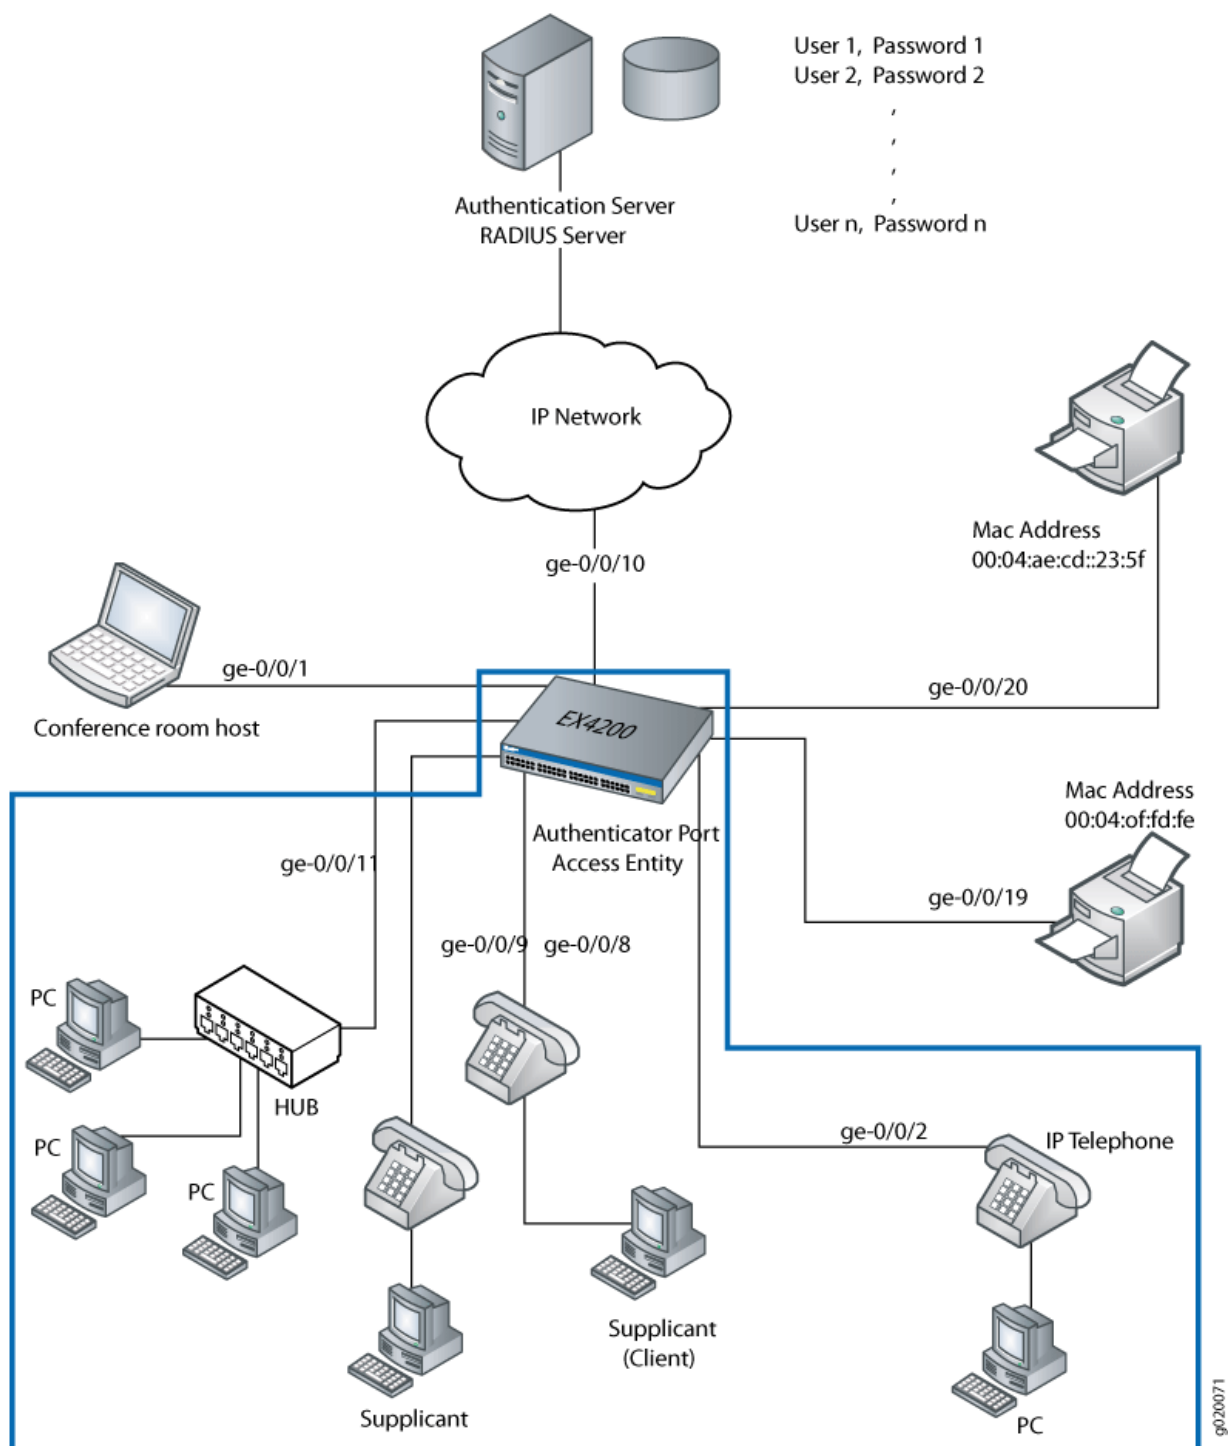

Table 28: Components of the Supplicant Mode Configuration Topology

| Property                                                                                                          | Settings                                                                                                                            |
|-------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| Switch hardware                                                                                                   | EX4200 switch, 24 Gigabit Ethernet ports: 8 PoE ports (ge-0/0/0 through ge-0/0/7) and 16 non-PoE ports (ge-0/0/8 through ge-0/0/23) |
| Connections to Avaya phones—with integrated hub, to connect phone and desktop PC to a single port; (requires PoE) | ge-0/0/8, ge-0/0/9, and ge-0/0/11                                                                                                   |

To configure the administrative modes to support supplicants in different areas of the Enterprise network:

- Configure access port ge-0/0/8 for single supplicant mode authentication.
- Configure access port ge-0/0/9 for single secure supplicant mode authentication.
- Configure access port ge-0/0/11 for multiple supplicant mode authentication.

*Single supplicant mode* authenticates only the first end device that connects to an authenticator port. All other end devices connecting to the authenticator port after the first has connected successfully, whether they are 802.1X-enabled or not, are permitted access to the port without further authentication. If the first authenticated end device logs out, all other end devices are locked out until an end device authenticates.

*Single-secure supplicant mode* authenticates only one end device to connect to an authenticator port. No other end device can connect to the authenticator port until the first logs out.

*Multiple supplicant mode* authenticates multiple end devices individually on one authenticator port. If you configure a maximum number of devices that can be connected to a port through port security, the lesser of the configured values is used to determine the maximum number of end devices allowed per port.

## Configuration of 802.1X to Support Multiple Supplicant Modes

### IN THIS SECTION

 Procedure | 431

## Procedure

### CLI Quick Configuration

To quickly configure the ports with different 802.1X authentication modes, copy the following commands and paste them into the switch terminal window:

```
[edit]
set protocols dot1x authenticator interface ge-0/0/8 supplicant single
set protocols dot1x authenticator interface ge-0/0/9 supplicant single-secure

set protocols dot1x authenticator interface ge-0/0/11 supplicant multiple
```

### Step-by-Step Procedure

Configure the administrative mode on the interfaces:

1. Configure the supplicant mode as single on interface ge-0/0/8:

```
[edit protocols]
user@switch# set dot1x authenticator interface ge-0/0/8 supplicant single
```

2. Configure the supplicant mode as single secure on interface ge-0/0/9:

```
[edit protocols]
user@switch# set dot1x authenticator interface ge-0/0/9 supplicant single-secure
```

### 3. Configure multiple supplicant mode on interface ge-0/0/11:

```
[edit protocols]
user@switch# set dot1x authenticator interface ge-0/0/11 supplicant multiple
```

## Results

Check the results of the configuration:

```
[edit]
user@access-switch> show configuration
protocols {
  dot1x {
    authenticator {
      interface {
        ge-0/0/8.0 {
          supplicant single;
        }
        ge-0/0/9.0 {
          supplicant single-secure;
        }
        ge-0/0/11.0 {
          supplicant multiple;
        }
      }
    }
  }
}
```

## Verification

### IN THIS SECTION

- [Verifying the 802.1X Configuration | 433](#)

To confirm that the configuration is working properly, perform these tasks:

## Verifying the 802.1X Configuration

### Purpose

Verify the 802.1X configuration on interfaces ge-0/0/8, ge-0/0/9, and ge-0/0/11.

### Action

Verify the 802.1X configuration by issuing the operational mode command `show dot1x interface`:

```
user@switch> show dot1x interface ge-0/0/8.0 detail
ge-0/0/8.0
  Role: Authenticator
  Administrative state: Auto
  Supplicant mode: Single
  Number of retries: 3
  Quiet period: 60 seconds
  Transmit period: 30 seconds
  Mac Radius: Disabled
  Mac Radius Restrict: Disabled
  Reauthentication: Enabled
  Configured Reauthentication interval: 3600 seconds
  Supplicant timeout: 30 seconds
  Server timeout: 30 seconds
  Maximum EAPOL requests: 2
  Guest VLAN member: <not configured>
user@switch> show dot1x interface ge-0/0/9.0 detail
ge-0/0/9.0
  Role: Authenticator
  Administrative state: Auto
  Supplicant mode: Single-Secure
  Number of retries: 3
  Quiet period: 60 seconds
  Transmit period: 30 seconds
  Mac Radius: Disabled
  Mac Radius Restrict: Disabled
  Reauthentication: Enabled
  Configured Reauthentication interval: 3600 seconds
  Supplicant timeout: 30 seconds
```

```

Server timeout: 30 seconds
Maximum EAPOL requests: 2
Guest VLAN member: <not configured>
Number of connected supplicants: 0

user@switch> show dot1x interface ge-0/0/11.0 detail
ge-0/0/11.0
  Role: Authenticator
  Administrative state: Auto
  Supplicant mode: Multiple
  Number of retries: 3
  Quiet period: 60 seconds
  Transmit period: 30 seconds
  Mac Radius: Disabled
  Mac Radius Restrict: Disabled
  Reauthentication: Enabled
  Configured Reauthentication interval: 3600 seconds
  Supplicant timeout: 30 seconds
  Server timeout: 30 seconds
  Maximum EAPOL requests: 2
  Guest VLAN member: <not configured>
  Number of connected supplicants: 0

```

## Meaning

The **Supplicant mode** output field displays the configured administrative mode for each interface. Interface **ge-0/0/8.0** displays **Single** supplicant mode. Interface **ge-0/0/9.0** displays **Single-Secure** supplicant mode. Interface **ge-0/0/11.0** displays **Multiple** supplicant mode.

## IN THIS SECTION

- [Requirements | 435](#)
- [Overview and Topology | 436](#)
- [Configuration of a Guest VLAN That Includes 802.1X Authentication | 439](#)
- [Verification | 441](#)

802.1X on EX Series switches provides LAN access to users who do not have credentials in the RADIUS database. These users, referred to as *guests*, are authenticated and typically provided with access to the Internet.

This example describes how to create a guest VLAN and configure 802.1X authentication for it.

## Requirements

This example uses the following software and hardware components:

**NOTE:** This example also applies to QFX5100 switches.

- Junos OS Release 9.0 or later for EX Series switches
- One EX Series switch acting as a port access entity (PAE). The interfaces on the authenticator PAE form a control gate that blocks all traffic to and from supplicants until they are authenticated.
- One RADIUS authentication server that supports 802.1X. The authentication server acts as the backend database and contains credential information for hosts (supplicants) that have permission to connect to the network.

Before you configure guest VLAN authentication, be sure you have:

- Performed the initial switch configuration. See *Connecting and Configuring an EX Series Switch (CLI Procedure)*.
- Performed basic bridging and VLAN configuration on the switch. See the documentation that describes setting up basic bridging and a VLAN for your switch. If you are using a switch that supports the Enhanced Layer 2 Software (ELS) configuration style, see *Example: Setting Up Basic Bridging and a VLAN for an EX Series Switch with ELS Support* or *Example: Setting Up Basic Bridging and a VLAN on Switches*. For all other switches, see *Example: Setting Up Basic Bridging and a VLAN for an EX Series Switch*.

**NOTE:** For more about ELS, see: *Using the Enhanced Layer 2 Software CLI*

## Overview and Topology

### IN THIS SECTION

- [Topology | 437](#)

As part of IEEE 802.1X port-based network access control (PNAC), you can provide limited network access to supplicants who do not belong to a VLAN authentication group by configuring authentication for a guest VLAN. Typically, guest VLAN access is used to provide Internet access to visitors to a corporate site. However, you can also use the guest VLAN feature to provide access to a VLAN with limited resources to supplicants that fail 802.1X authentication on a corporate LAN.

**NOTE:** This figure also applies to QFX5100 switches.

## Topology

[Figure 14 on page 438](#) shows the conference room connected to the switch at interface ge-0/0/1.

Figure 14: Topology for Guest VLAN Example

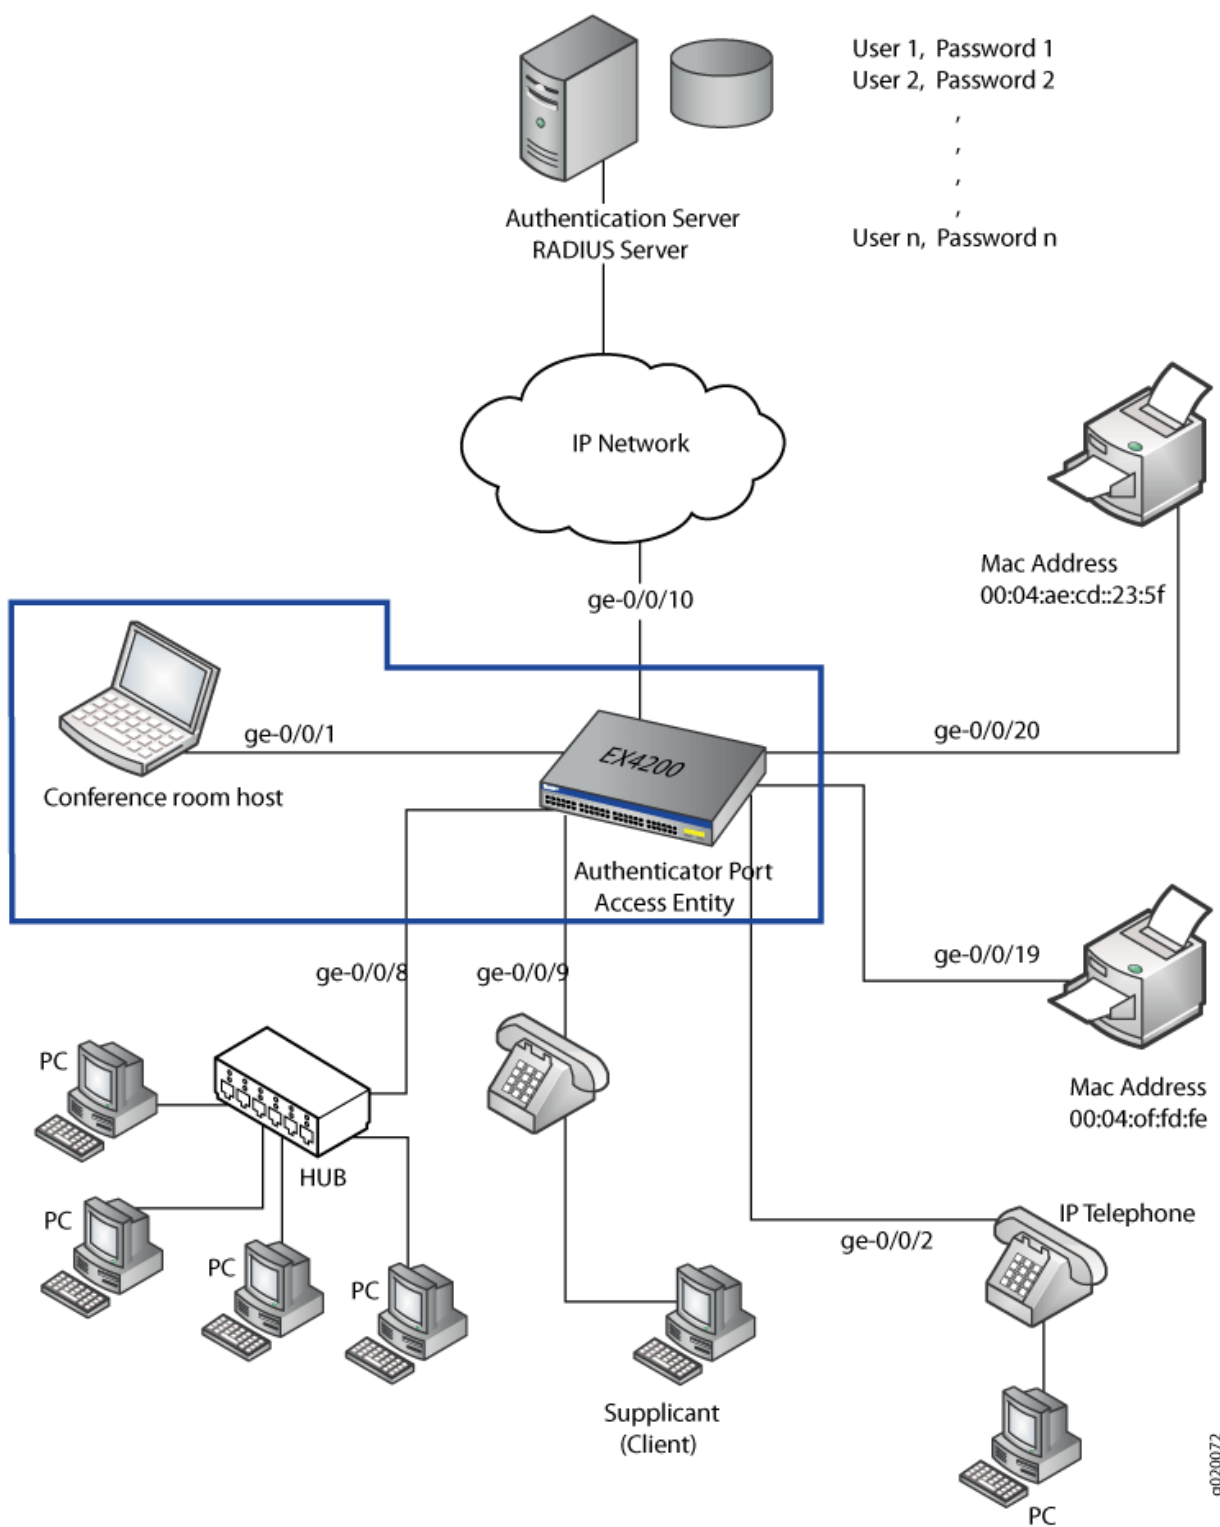

Table 29: Components of the Guest VLAN Topology

| Property               | Settings                                                                                                                                                                           |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Switch hardware        | EX4200 switch, 24 Gigabit Ethernet interfaces: 8 PoE interfaces ( <b>ge-0/0/0</b> through <b>ge-0/0/7</b> ) and 16 non-PoE interfaces ( <b>ge-0/0/8</b> through <b>ge-0/0/23</b> ) |
| VLAN names and tag IDs | <b>sales</b> , tag <b>100</b><br><b>support</b> , tag <b>200</b><br><b>guest-vlan</b> , tag <b>300</b>                                                                             |
| One RADIUS server      | Backend database connected to the switch through interface <b>ge-0/0/10</b>                                                                                                        |

In this example, access interface **ge-0/0/1** provides LAN connectivity in the conference room. Configure this access interface to provide LAN connectivity to visitors in the conference room who are not authenticated by the corporate VLAN.

## Configuration of a Guest VLAN That Includes 802.1X Authentication

### IN THIS SECTION

- [Procedure | 439](#)

## Procedure

### CLI Quick Configuration

To quickly configure a guest VLAN, with 802.1X authentication, copy the following commands and paste them into the switch terminal window:

```
[edit]
set vlans guest-vlan vlan-id 300
set protocols dot1x authenticator interface all guest-vlan guest-vlan
```

## Step-by-Step Procedure

To configure a guest VLAN that includes 802.1X authentication on an EX Series switch:

1. Configure the VLAN ID for the guest VLAN:

```
[edit]
user@switch# set vlans guest-vlan vlan-id 300
```

2. Configure the guest VLAN under **dot1x** protocol:

```
[edit]
user@switch# set protocols dot1x authenticator interface all guest-vlan guest-
vlan
```

## Results

Check the results of the configuration:

```
user@switch> show configuration
protocols {
  dot1x {
    authenticator {
      interface {
        all {
          guest-vlan {
            guest-vlan;
          }
        }
      }
    }
  }
}
vlans {
  guest-vlan {
    vlan-id 300;
  }
}
```

# Verification

IN THIS SECTION

- [Verifying That the Guest VLAN Is Configured | 441](#)

To confirm that the configuration is working properly, perform these tasks:

## Verifying That the Guest VLAN Is Configured

### Purpose

Verify that the guest VLAN is created and that an interface has failed authentication and been moved to the guest VLAN.

**NOTE:** On switches running Junos OS for EX Series with support for ELS, the output for the `show vlans` command will contain additional information. If your switch runs software that supports ELS, see *show vlans*. For ELS details, see *Using the Enhanced Layer 2 Software CLI*.

### Action

Issue the operational mode commands:

```
user@switch> show vlans
```

| Name       | Tag | Interfaces  |
|------------|-----|-------------|
| default    |     | ge-0/0/3.0* |
| dynamic    | 40  | None        |
| guest      | 30  | None        |
| guest-vlan | 300 | ge-0/0/1.0* |
| vlan_dyn   |     | None        |

```

user@switch> show dot1x interface ge-0/0/1.0 detail
ge-0/0/1.0
  Role: Authenticator
  Administrative state: Auto
  Supplicant mode: Single
  Number of retries: 3
  Quiet period: 60 seconds
  Transmit period: 30 seconds
  Mac Radius: Enabled
  Mac Radius Restrict: Disabled
  Reauthentication: Enabled
  Configured Reauthentication interval: 3600 seconds
  Supplicant timeout: 30 seconds
  Server timeout: 30 seconds
  Maximum EAPOL requests: 2
  Guest VLAN member: guest-vlan
  Number of connected supplicants: 1
    Supplicant: user1, 00:00:00:00:13:23
      Operational state: Authenticated
      Authentication method: Guest VLAN
      Authenticated VLAN: guest-vlan
      Dynamic Filter: match source-dot1q-tag 10 action deny
      Session Reauth interval: 60 seconds
      Reauthentication due in 50 seconds

```

## Meaning

The output of the `show vlans` command shows **guest-vlan** as the name of the VLAN and the VLAN ID as **300**.

The output of the `show dot1x interface ge-0/0/1.0 detail` command displays the **Guest VLAN membership** field, indicating that a supplicant at this interface failed 802.1X authentication and was passed through to the **guest-vlan**.

- [Example: Applying Firewall Filters to Multiple Supplicants on Interfaces Enabled for 802.1X or MAC RADIUS Authentication on EX Series Switches with ELS Support | 462](#)

EX Series switches support port firewall filters. Port firewall filters are configured on a single EX Series switch, but in order for them to operate throughout an enterprise, they must be configured on multiple switches. To reduce the need to configure the same port firewall filter on multiple switches, you can instead apply the filter centrally on the RADIUS server by using RADIUS server attributes. Terms are applied after a device is successfully authenticated through 802.1X. For more information, read this topic.

### Example: Applying a Firewall Filter to 802.1X-Authenticated Supplicants by Using RADIUS Server Attributes on an EX Series Switch

#### IN THIS SECTION

- [Requirements | 444](#)
- [Overview and Topology | 445](#)
- [Configuring the Port Firewall Filter and Counters | 450](#)

- [Applying the Port Firewall Filter to the Supplicant User Profiles on the RADIUS Server | 452](#)
- [Verification | 453](#)

You can use RADIUS server attributes and a port firewall filter to centrally apply terms to multiple supplicants (end devices) connected to an EX Series switch in your enterprise. Terms are applied after a device is successfully authenticated through 802.1X. If the firewall filter configuration is modified after end devices are authenticated using the 802.1X authentication, then the established 802.1X authentication session must be terminated and re-established for the firewall filter changes to take effect.

EX Series switches support port firewall filters. Port firewall filters are configured on a single EX Series switch, but in order for them to operate throughout an enterprise, they must be configured on multiple switches. To reduce the need to configure the same port firewall filter on multiple switches, you can instead apply the filter centrally on the RADIUS server by using RADIUS server attributes.

The following example uses FreeRADIUS to apply a port firewall filter on a RADIUS server. For information about configuring your server, consult the documentation that was included with your RADIUS server.

This example describes how to configure a port firewall filter with terms, create counters to count packets for the supplicants, apply the filter to user profiles on the RADIUS server, and display the counters to verify the configuration:

## Requirements

This example uses the following software and hardware components:

**NOTE:** This example also applies to QFX5100 switches.

- Junos OS Release 9.3 or later for EX Series switches
- One EX Series switch acting as an authenticator port access entity (PAE). The ports on the authenticator PAE form a control gate that blocks all traffic to and from supplicants until they are authenticated.
- One RADIUS authentication server. The authentication server acts as the backend database and contains credential information for hosts (supplicants) that have permission to connect to the network.

Before you connect the server to the switch, be sure you have:

- Set up a connection between the switch and the RADIUS server. See ["Example: Connecting a RADIUS Server for 802.1X to an EX Series Switch" on page 380](#).
- Configured 802.1X authentication on the switch, with the supplicant mode for interface ge-0/0/2 set to **multiple**. See ["Configuring 802.1X Interface Settings \(CLI Procedure\)" on page 369](#) and ["Example: Setting Up 802.1X for Single-Supplicant or Multiple-Supplicant Configurations on an EX Series Switch" on page 426](#).
- Configured users on the RADIUS authentication server (in this example, the user profiles for Supplicant 1 and Supplicant 2 in the topology are modified on the RADIUS server).

## Overview and Topology

### IN THIS SECTION

- [Topology | 446](#)

When the 802.1X configuration on an interface is set to **multiple** supplicant mode, you can apply a single port firewall filter configured through the Junos OS CLI on the EX Series switch to any number of end devices (supplicants) by adding the filter centrally to the RADIUS server. Only a single filter can be applied to an interface; however, the filter can contain multiple terms for separate end devices.

For more information about firewall filters, see *Firewall Filters for EX Series Switches Overview* or *Overview of Firewall Filters (QFX Series)*.

RADIUS server attributes are applied to the port where the end device is connected after the device is successfully authenticated using 802.1X. To authenticate an end device, the switch forwards the end device's credentials to the RADIUS server. The RADIUS server matches the credentials against preconfigured information about the supplicant located in the supplicant's user profile on the RADIUS server. If a match is found, the RADIUS server instructs the switch to open an interface to the end device. Traffic then flows from and to the end device on the LAN. Further instructions configured in the port firewall filter and added to the end device's user profile using a RADIUS server attribute further define the access that the end device is granted. Filtering terms configured in the port firewall filter are applied to the port where the end device is connected after 802.1X authentication is complete.

**NOTE:** If you modify the port firewall filter after an end device is successfully authenticated using 802.1X, you must terminate and re-establish the 802.1X authentication session for the firewall filter configuration changes to be effective.

## Topology

[Figure 15 on page 448](#) shows the topology used for this example. The RADIUS server is connected to an EX4200 switch on access port ge-0/0/10. Two end devices (supplicants) are accessing the LAN on interface ge-0/0/2. Supplicant 1 has the MAC address 00:50:8b:6f:60:3a. Supplicant 2 has the MAC address 00:50:8b:6f:60:3b.

**NOTE:** This figure also applies to QFX5100 switches.

Figure 15: Topology for Firewall Filter and RADIUS Server Attributes Configuration

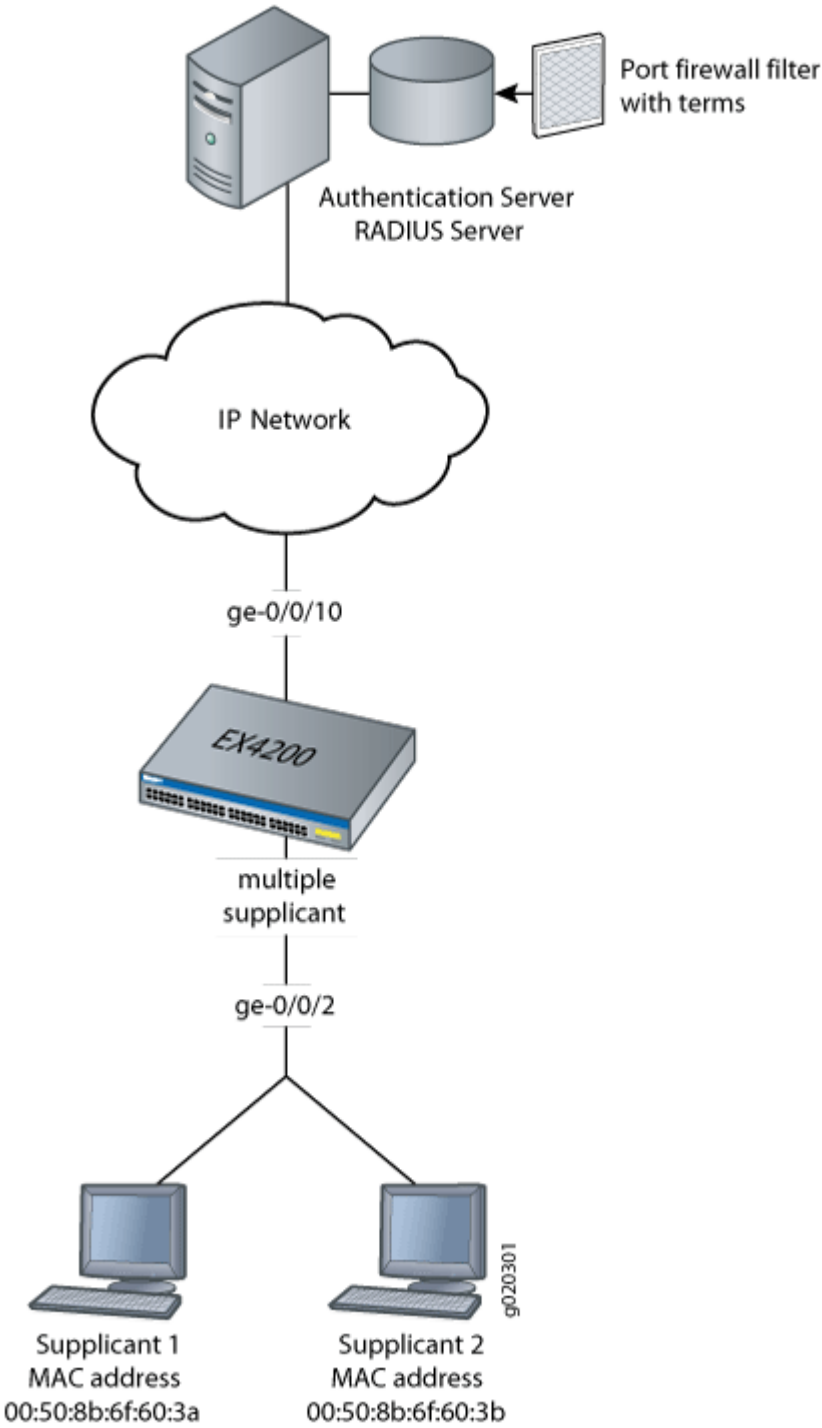

Table 30 on page 449 describes the components in this topology.

Table 30: Components of the Firewall Filter and RADIUS Server Attributes Topology

| One RADIUS server                                                       | Backend database with the address <b>10.0.0.100</b> connected to the switch at port <b>ge-0/0/10</b> .                                                                                     |
| 802.1X supplicants connected to the switch on interface <b>ge-0/0/2</b> | <ul style="list-style-type: none"> <li>• <b>Supplicant 1</b> has MAC address <b>00:50:8b:6f:60:3a</b>.</li> <li>• <b>Supplicant 2</b> has MAC address <b>00:50:8b:6f:60:3b</b>.</li> </ul> |
| Port firewall filter to be applied on the RADIUS server                 | <b>filter1</b>                                                                                                                                                                             |
| Counters                                                                | <b>counter1</b> counts packets from Supplicant 1, and <b>counter2</b> counts packets from Supplicant 2.                                                                                    |
| Policer                                                                 | <b>policer p1</b>                                                                                                                                                                          |
| User profiles on the RADIUS server                                      | <ul style="list-style-type: none"> <li>• Supplicant 1 has the user profile <b>supplicant1</b>.</li> <li>• Supplicant 2 has the user profile <b>supplicant2</b>.</li> </ul>                 |

In this example, you configure a port firewall filter named **filter1**. The filter contains terms that will be applied to the end devices based on the MAC addresses of the end devices. When you configure the filter, you also configure the counters **counter1** and **counter2**. Packets from each end device are counted, which helps you verify that the configuration is working. Policer **p1** limits the traffic rate based on the values for **exceeding** and **discard** parameters. Then, you check to see that the RADIUS server attribute is available on the RADIUS server and apply the filter to the user profiles of each end device on the RADIUS server. Finally, you verify the configuration by displaying output for the two counters.

## Configuring the Port Firewall Filter and Counters

### IN THIS SECTION

- [Procedure | 450](#)

### Procedure

#### CLI Quick Configuration

To quickly configure a port firewall filter with terms for Supplicant 1 and Supplicant 2 and create parallel counters for each supplicant, copy the following commands and paste them into the switch terminal window:

```
[edit]
set firewall family ethernet-switching filter filter1 term supplicant1 from source-mac-address 00:50:8b:6f:60:3a
set firewall family ethernet-switching filter filter1 term supplicant2 from source-mac-address 00:50:8b:6f:60:3b
set firewall policer p1 if-exceeding bandwidth-limit 1m
set firewall policer p1 if-exceeding burst-size-limit 1k
set firewall policer p1 then discard
set firewall family ethernet-switching filter filter1 term supplicant1 then count counter1
set firewall family ethernet-switching filter filter1 term supplicant1 then policer p1
set firewall family ethernet-switching filter filter1 term supplicant2 then count counter2
```

#### Step-by-Step Procedure

To configure a port firewall filter and counters on the switch:

1. Configure a port firewall filter (here, **filter1**) with terms for each end device based on the MAC address of each end device:

```
[edit firewall family ethernet-switching]
user@switch# set filter filter1 term supplicant1 from source-mac-address 00:50:8b:6f:60:3a
user@switch# set filter filter1 term supplicant2 from source-mac-address 00:50:8b:6f:60:3b
```

## 2. Set policer definition:

```
[edit]
user@switch# set firewall policer p1 if-exceeding bandwidth-limit 1m
user@switch# set firewall policer p1 if-exceeding burst-size-limit 1k
user@switch# set firewall policer p1 then discard
```

## 3. Create two counters that will count packets for each end device and a policer that limits the traffic rate:

```
[edit firewall family ethernet-switching]
user@switch# set filter filter1 term supplicant1 then count counter1
user@switch# set filter filter1 term supplicant1 then policer p1
user@switch# set filter filter1 term supplicant2 then count counter2
```

## Results

Display the results of the configuration:

```
user@switch> show configuration
  firewall {
    family ethernet-switching {
      filter filter1 {
        term supplicant1 {
          from {
            source-mac-address {
              00:50:8b:6f:60:3a;
            }
          }
          then count counter1;
          then policer p1;
        }
        term supplicant2 {
          from {
            source-mac-address {
              00:50:8b:6f:60:3b;
            }
          }
          then count counter2;
        }
      }
    }
  }
```

```

    }
  }
}
policer p1 {
  if-exceeding {
    bandwidth-limit 1m;
    burst-size-limit 1k;
  }
  then discard;
}

```

## Applying the Port Firewall Filter to the Supplicant User Profiles on the RADIUS Server

### IN THIS SECTION

- [Procedure | 452](#)

### Procedure

#### Step-by-Step Procedure

To verify that the RADIUS server attribute **Filter-ID** is on the RADIUS server and to apply the filter to the user profiles:

1. Display the dictionary **dictionary.rfc2865** on the RADIUS server, and verify that the attribute **Filter-ID** is in the dictionary:

```
[root@freeradius]# cd usr/share/freeradius/dictionary.rfc2865
```

2. Close the dictionary file.
3. Display the local user profiles of the end devices to which you want to apply the filter (here, the user profiles are called **supplicant1** and **supplicant2**):

```
[root@freeradius]# cat /usr/local/etc/raddb/users
```

The output shows:

```

supplicant1 Auth-Type := EAP, User-Password == "supplicant1"
    Tunnel-Type = VLAN,
    Tunnel-Medium-Type = IEEE-802,
    Tunnel-Private-Group-Id = "1005"

supplicant2 Auth-Type := EAP, User-Password == "supplicant2"
    Tunnel-Type = VLAN,
    Tunnel-Medium-Type = IEEE-802,
    Tunnel-Private-Group-Id = "1005"

```

4. Apply the filter to both user profiles by adding the line **Filter-Id = "filter1"** to each profile, and then close the file:

```
[root@freeradius]# cat /usr/local/etc/raddb/users
```

After you paste the line into the files, the files look like this:

```

supplicant1 Auth-Type := EAP, User-Password == "supplicant1"
    Tunnel-Type = VLAN,
    Tunnel-Medium-Type = IEEE-802,
    Tunnel-Private-Group-Id = "1005",
    Filter-Id = "filter1"

supplicant2 Auth-Type := EAP, User-Password == "supplicant2"
    Tunnel-Type = VLAN,
    Tunnel-Medium-Type = IEEE-802,
    Tunnel-Private-Group-Id = "1005",
    Filter-Id = "filter1"

```

## Verification

### IN THIS SECTION

- [Verifying That the Filter Has Been Applied to the Supplicants](#) | 454

## Verifying That the Filter Has Been Applied to the Supplicants

### Purpose

After the end devices are authenticated on interface ge-0/0/2, verify that the filter has been configured on the switch and includes the results for both supplicants:

### Action

```
user@switch> show dot1x firewall

Filter: dot1x-filter-ge-0/0/2
Counters
counter1_dot1x_ge-0/0/2_user1 100
counter2_dot1x_ge-0/0/2_user2 400
```

### Meaning

The output of the `show dot1x firewall` command displays **counter1** and **counter2**. Packets from User\_1 are counted using **counter1**, and packets from User 2 are counted using **counter2**. The output displays packets incrementing for both counters. The filter has been applied to both end devices.

## Example: Applying Firewall Filters to Multiple Supplicants on Interfaces Enabled for 802.1X or MAC RADIUS Authentication

### IN THIS SECTION

- Requirements | 455
- Overview and Topology | 456
- Configuration | 458
- Verification | 461

On EX Series switches, firewall filters that you apply to interfaces enabled for 802.1X or MAC RADIUS authentication are dynamically combined with the per-user policies sent to the switch from the RADIUS server. The switch uses internal logic to dynamically combine the interface firewall filter with the user policies from the RADIUS server and create an individualized policy for each of the multiple users or nonresponsive hosts that are authenticated on the interface.

This example describes how dynamic firewall filters are created for multiple supplicants on an 802.1X-enabled interface (the same principles shown in this example apply to interfaces enabled for MAC RADIUS authentication):

### Requirements

This example uses the following hardware and software components:

- Junos OS Release 9.5 or later for EX Series switches
- One EX Series switch
- One RADIUS authentication server. The authentication server acts as the backend database and contains credential information for hosts (supplicants) that have permission to connect to the network.

Before you apply firewall filters to an interface for use with multiple supplicants, be sure you have:

- Set up a connection between the switch and the RADIUS server. See [Example: Connecting a RADIUS Server for 802.1X to an EX Series Switch](#).
- Configured 802.1X authentication on the switch, with the authentication mode for interface **ge-0/0/2** set to **multiple**. See [Configuring 802.1X Interface Settings \(CLI Procedure\)](#) and [Example: Setting Up 802.1X for Single-Supplicant or Multiple-Supplicant Configurations on an EX Series Switch](#).

- Configured users on the RADIUS authentication server.

## Overview and Topology

### IN THIS SECTION

- [Topology | 456](#)

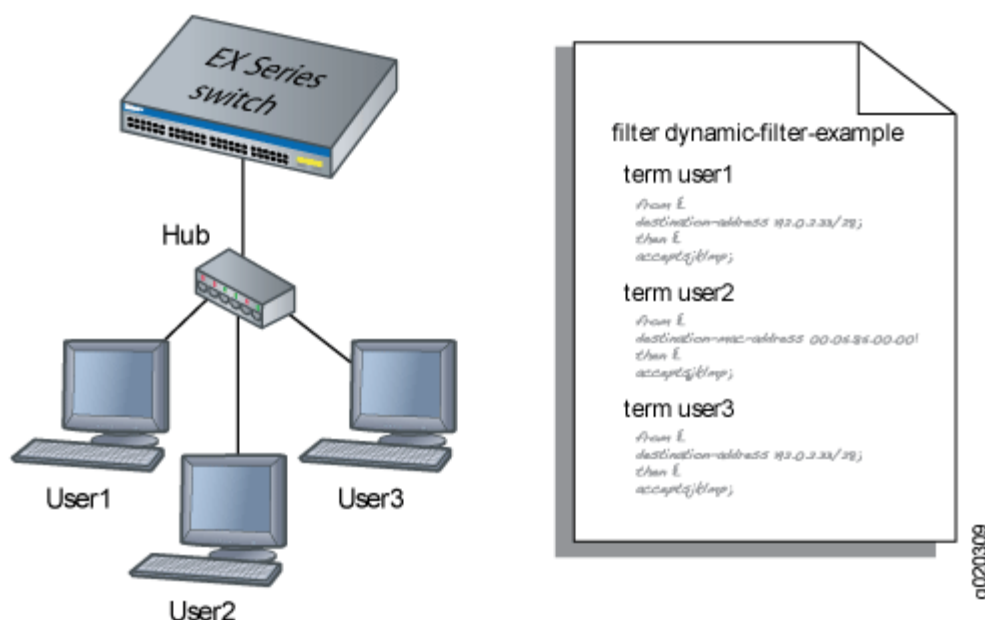

### Topology

When the 802.1X configuration on an interface is set to multiple supplicant mode, the system dynamically combines interface firewall filter with the user policies sent to the switch from the RADIUS server during authentication and creates separate terms for each user. Because there are separate terms for each user authenticated on the interface, you can, as shown in this example, use counters to view the activities of individual users that are authenticated on the same interface.

When a new user (or a nonresponsive host) is authenticated on an interface, the system adds a term to the firewall filter associated with the interface, and the term (policy) for each user is associated with the MAC address of the user. The term for each user is based on the user-specific filters set on the RADIUS server and the filters configured on the interface. For example, as shown in [Figure 16 on page 457](#),

when User1 is authenticated by the EX Series switch, the system creates the firewall filter **dynamic-filter-example**. When User2 is authenticated, another term is added to the firewall filter, and so on.

Figure 16: Conceptual Model: Dynamic Filter Updated for Each New User

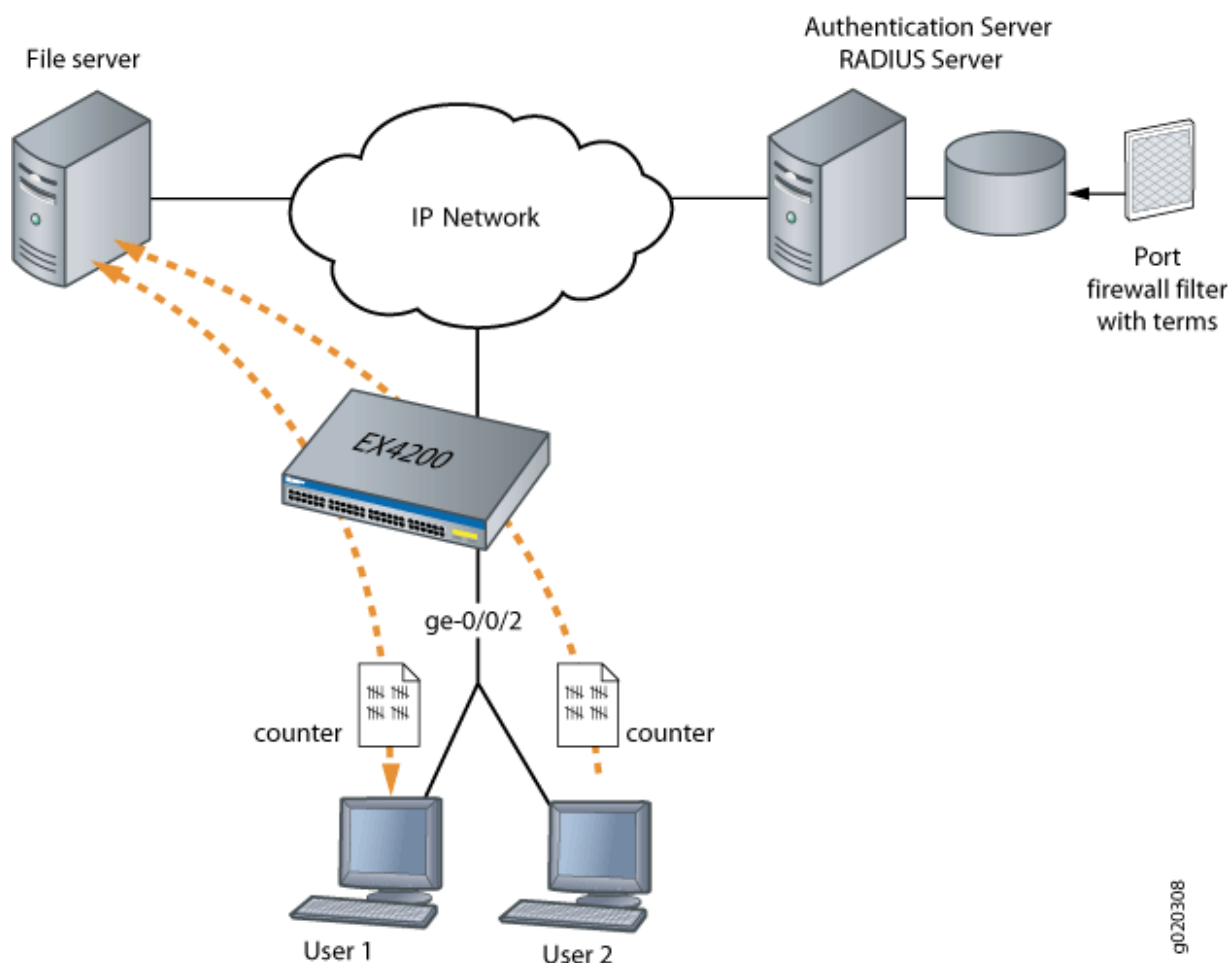

This is a conceptual model of the internal process—you cannot access or view the dynamic filter.

**NOTE:** If the firewall filter on the interface is modified after the user (or nonresponsive host) is authenticated, the modifications are not reflected in the dynamic filter unless the user is reauthenticated.

In this example, you configure a firewall filter to count the requests made by each endpoint authenticated on interface **ge-0/0/2** to the file server, which is located on subnet **192.0.2.16/28**, and

set policer definitions to rate limit the traffic. [Figure 17 on page 458](#) shows the network topology for this example.

**Figure 17: Multiple Supplicants on an 802.1X-Enabled Interface Connecting to a File Server**

## Configuration

### IN THIS SECTION

- [Configuring Firewall Filters on Interfaces with Multiple Supplicants | 459](#)

To configure firewall filters for multiple supplicants on 802.1X-enabled interfaces:

## Configuring Firewall Filters on Interfaces with Multiple Supplicants

### CLI Quick Configuration

To quickly configure firewall filters for multiple supplicants on an 802.1X-enabled interface copy the following commands and paste them into the switch terminal window:

```
[edit]
set protocols dot1x authenticator interface ge-0/0/2 supplicant
multiple
set firewall family ethernet-switching filter filter1 term term1 from
destination-address 192.0.2.16/28
set firewall policer p1 if-exceeding bandwidth-limit 1m
set firewall policer p1 if-exceeding burst-size-limit 1k
set firewall family ethernet-switching filter filter1 term term1 then
count counter1
set firewall family ethernet-switching filter filter1 term term2 then policer p1
```

### Step-by-Step Procedure

To configure firewall filters on an interface enabled for multiple supplicants:

1. Configure interface **ge-0/0/2** for multiple supplicant mode authentication:

```
[edit protocols dot1x]
user@switch# set authenticator interface ge-0/0/2 supplicant multiple
```

2. Set policer definition:

```
user@switch# show policer p1 |display set
set firewall policer p1 if-exceeding bandwidth-limit 1m
set firewall policer p1 if-exceeding burst-size-limit 1k
set firewall policer p1 then discard
```

3. Configure a firewall filter to count packets from each user and a policer that limits the traffic rate. As each new user is authenticated on the multiple supplicant interface, this filter term will be included in the dynamically created term for the user:

```
[edit firewall family ethernet-switching]
user@switch# set filter filter1 term term1 from destination-address 192.0.2.16/28
user@switch# set filter filter1 term term1 then count counter1
user@switch# set filter filter1 term term2 then policer p1
```

## Results

Check the results of the configuration:

```
user@switch> show configuration

firewall {
  family ethernet-switching {
    filter filter1 {
      term term1 {
        from {
          destination-address {
            192.0.2.16/28;
          }
        }
        then count counter1;
      }
      term term2 {
        from {
          destination-address {
            192.0.2.16/28;
          }
        }
        then policer p1;
      }
    }
  }
}

policer p1 {
  if-exceeding {
    bandwidth-limit 1m;
    burst-size-limit 1k;
  }
  then discard;
}
```

```

    }
}
protocols {
    dot1x {
        authenticator
            interface ge-0/0/2 {
                suppliant multiple;
            }
    }
}
}

```

## Verification

### IN THIS SECTION

- [Verifying Firewall Filters on Interfaces with Multiple Supplicants | 461](#)

To confirm that the configuration is working properly, perform these tasks:

### Verifying Firewall Filters on Interfaces with Multiple Supplicants

#### Purpose

Verify that firewall filters are functioning on the interface with multiple supplicants.

#### Action

1. Check the results with one user authenticated on the interface. In this case, the user is authenticated on **ge-0/0/2**:

```
user@switch> show dot1x firewall
```

```
Filter: dot1x_ge-0/0/2
```

```
Counters
```

```
counter1_dot1x_ge-0/0/2_user1 100
```

2. When a second user, User2, is authenticated on the same interface, **ge-0/0/2**, you can verify that the filter includes the results for both of the users authenticated on the interface:

```
user@switch> show dot1x firewall

Filter: dot1x-filter-ge-0/0/0
Counters
counter1_dot1x_ge-0/0/2_user1 100
counter1_dot1x_ge-0/0/2_user2 400
```

## Meaning

The results displayed by the `show dot1x firewall` command output reflect the dynamic filter created with the authentication of each new user. User1 accessed the file server located at the specified destination address 100 times, while User2 accessed the same file server 400 times.

[Filtering 802.1X Supplicants by Using RADIUS Server Attributes](#)

## Example: Applying Firewall Filters to Multiple Supplicants on Interfaces Enabled for 802.1X or MAC RADIUS Authentication on EX Series Switches with ELS Support

### IN THIS SECTION

- [Requirements | 463](#)
- [Overview and Topology | 464](#)
- [Configuration | 466](#)
- [Verification | 469](#)

**NOTE:** This example uses Junos OS for EX Series switches with support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that does not support ELS, see *Example: Applying Firewall Filters to Multiple Supplicants on Interfaces Enabled for 802.1X or MAC RADIUS Authentication*. For ELS details, see *Using the Enhanced Layer 2 Software CLI*.

On EX Series switches, firewall filters that you apply to interfaces enabled for 802.1X or MAC RADIUS authentication are dynamically combined with the per-user policies sent to the switch from the RADIUS server. The switch uses internal logic to dynamically combine the interface firewall filter with the user policies from the RADIUS server and create an individualized policy for each of the multiple users or nonresponsive hosts that are authenticated on the interface.

This example describes how dynamic firewall filters are created for multiple supplicants on an 802.1X-enabled interface (the same principles shown in this example apply to interfaces enabled for MAC RADIUS authentication):

## Requirements

This example uses the following software and hardware components:

**NOTE:** This example also applies to QFX5100 switches.

- Junos OS Release 13.2 or later for EX Series switches
- One EX Series switch with support for ELS
- One RADIUS authentication server. The authentication server acts as the backend database and contains credential information for hosts (supplicants) that have permission to connect to the network.

Before you apply firewall filters to an interface for use with multiple supplicants, be sure you have:

- Set up a connection between the switch and the RADIUS server. See ["Example: Connecting a RADIUS Server for 802.1X to an EX Series Switch" on page 380](#).
- Configured 802.1X authentication on the switch, with the authentication mode for the interface ge-0/0/2 set to multiple. See ["Configuring 802.1X Interface Settings \(CLI Procedure\)" on page 369](#) and ["Example: Setting Up 802.1X for Single-Supplicant or Multiple-Supplicant Configurations on an EX Series Switch" on page 426](#).
- Configured users on the RADIUS authentication server.

## Overview and Topology

### IN THIS SECTION

- [Topology | 464](#)

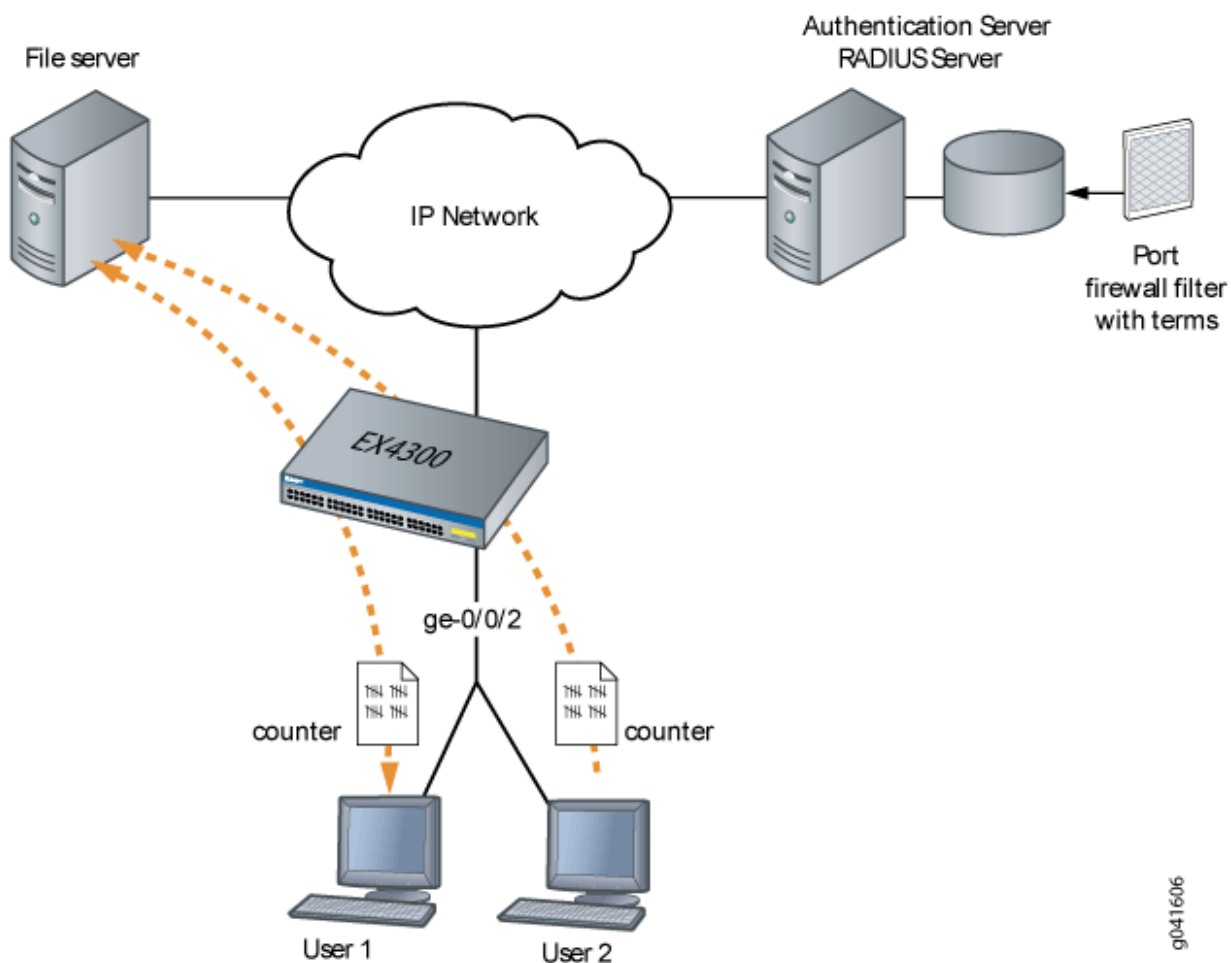

### Topology

When the 802.1X configuration on an interface is set to multiple supplicant mode, the system dynamically combines the interface firewall filter with the user policies sent to the switch from the RADIUS server during authentication and creates separate terms for each user. Because there are separate terms for each user authenticated on the interface, you can, as shown in this example, use counters to view the activities of individual users that are authenticated on the same interface.

When a new user (or a nonresponsive host) is authenticated on an interface, the system adds a term to the firewall filter associated with the interface, and the term (policy) for each user is associated with the MAC address of the user. The term for each user is based on the user-specific filters set on the RADIUS server and the filters configured on the interface. For example, as shown in [Figure 18 on page 465](#), when User 1 is authenticated by the EX Series switch, the system adds a term to the firewall filter **dynamic-filter-example**. When User 2 is authenticated, another term is added to the firewall filter, and so on.

**NOTE:** This figure also applies to QFX5100 switches.

**Figure 18: Conceptual Model: Dynamic Filter Updated for Each New User**

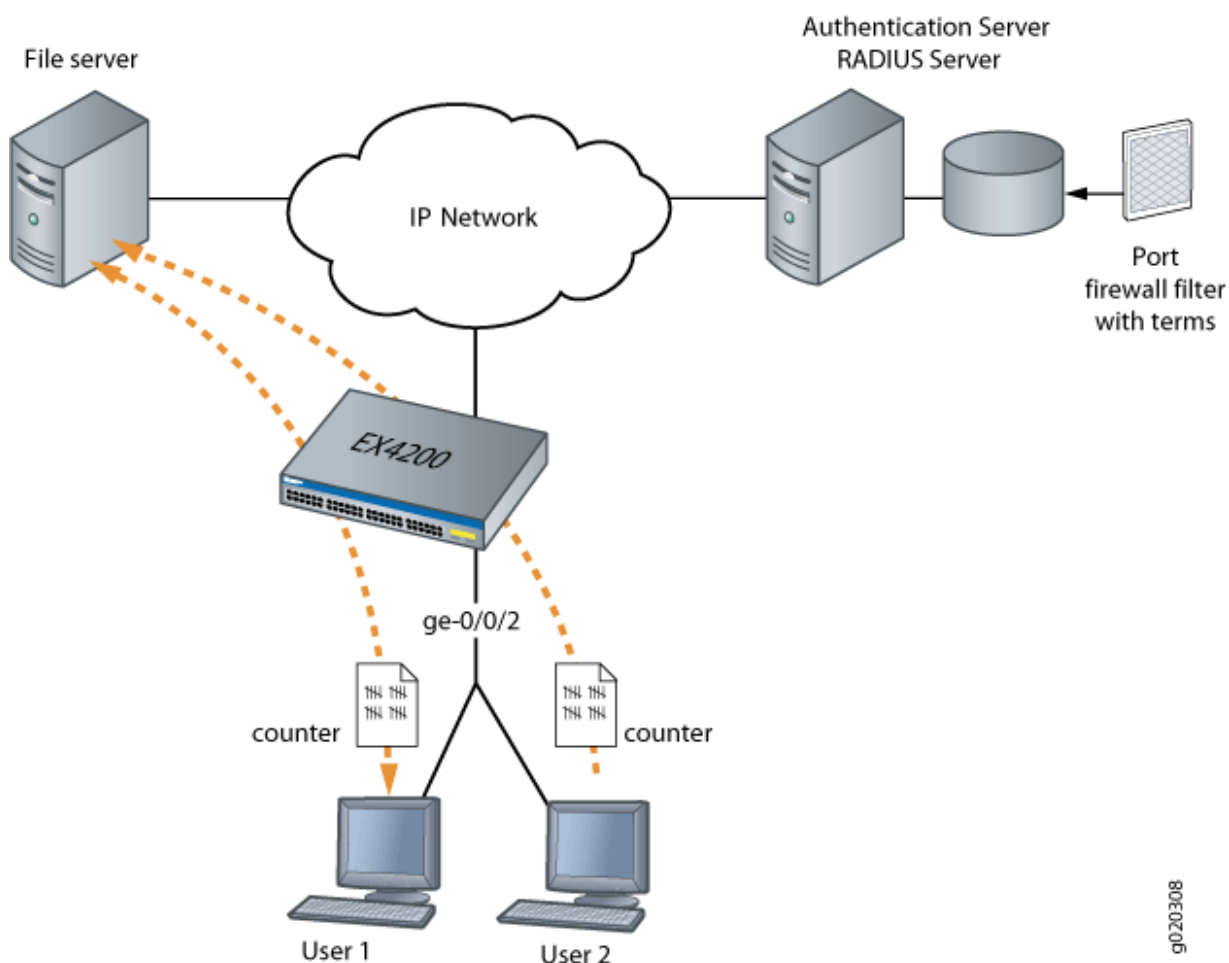

This is a conceptual model of the internal process—you cannot access or view the dynamic filter.

**NOTE:** If the firewall filter on the interface is modified after the user (or nonresponsive host) is authenticated, the modifications are not reflected in the dynamic filter unless the user is reauthenticated.

In this example, you configure a firewall filter to count the requests made by each endpoint authenticated on interface ge-0/0/2 to the file server, which is located on subnet 192.0.2.16/28, and

set policer definitions to rate-limit the traffic. [Figure 19 on page 466](#) shows the network topology for this example.

**Figure 19: Multiple Supplicants on an 802.1X-Enabled Interface Connecting to a File Server**

## Configuration

### IN THIS SECTION

- [Configuring Firewall Filters on Interfaces with Multiple Supplicants](#) | 467

## Configuring Firewall Filters on Interfaces with Multiple Supplicants

### CLI Quick Configuration

To quickly configure firewall filters for multiple supplicants on an 802.1X-enabled interface copy the following commands and paste them into the switch terminal window:

```
[edit]
        set firewall family ethernet-switching filter filter1 term term1 from
ip-destination-address 192.0.2.16/28
        set firewall family ethernet-switching filter filter1 term term2 from
ip-destination-address 192.0.2.16/28
set firewall policer p1 if-exceeding bandwidth-limit 1m
set firewall policer p1 if-exceeding burst-size-limit 1500
set firewall policer p1 then discard
        set firewall family ethernet-switching filter filter1 term term1 then
count counter1
set firewall family ethernet-switching filter filter1 term term2 then policer p1
```

### Step-by-Step Procedure

To configure firewall filters on an interface enabled for multiple supplicants:

1. Set the policer definition:

```
user@switch# show policer p1 |display set
set firewall policer p1 if-exceeding bandwidth-limit 1m
set firewall policer p1 if-exceeding burst-size-limit 1500
set firewall policer p1 then discard
```

2. Configure a firewall filter to count packets from each user and a policer that limits the traffic rate. As each new user is authenticated on the multiple supplicant interface, this filter term will be included in the dynamically created term for the user:

```
[edit firewall family ethernet-switching]
user@switch# set filter filter1 term term1 from ip-destination-address 192.0.2.16/28
user@switch# set filter filter1 term term2 from ip-destination-address 192.0.2.16/28
user@switch# set filter filter1 term term1 then count counter1
user@switch# set filter filter1 term term2 then policer p1
```

## Results

Check the results of the configuration:

```
user@switch> show configuration

firewall {
  family ethernet-switching {
    filter filter1 {
      term term1 {
        from {
          ip-destination-address {
            192.0.2.16/28;
          }
        }
        then count counter1;
      }
      term term2 {
        from {
          ip-destination-address {
            192.0.2.16/28;
          }
        }
        then policer p1;
      }
    }
  }
  policer p1 {
    if-exceeding {
      bandwidth-limit 1m;
      burst-size-limit 1500;
    }
    then discard;
  }
}

protocols {
  dot1x {
    authenticator
    interface ge-0/0/2 {
      supplicant multiple;
    }
  }
}
```

```
}
}
```

## Verification

### IN THIS SECTION

## Verifying Firewall Filters on Interfaces with Multiple Supplicants

### Purpose

Verify that firewall filters are functioning on the interface with multiple supplicants.

### Action

1. Check the results with one user authenticated on the interface. In this case, User 1 is authenticated on ge-0/0/2:

```
user@switch> show dot1x firewall

Filter: dot1x_ge-0/0/2
Counters
counter1_dot1x_ge-0/0/2_user1 100
```

2. When a second user, User 2, is authenticated on the same interface, ge-0/0/2, you can verify that the filter includes the results for both of the users authenticated on the interface:

```
user@switch> show dot1x firewall

Filter: dot1x-filter-ge-0/0/0
Counters
counter1_dot1x_ge-0/0/2_user1 100
counter1_dot1x_ge-0/0/2_user2 400
```

## Meaning

The results displayed by the `show dot1x firewall` command output reflect the dynamic filter created with the authentication of each new user. User 1 accessed the file server located at the specified destination address 100 times, while User 2 accessed the same file server 400 times.

# Static MAC Bypass of 802.1X and MAC RADIUS Authentication

## IN THIS SECTION

- [Configuring Static MAC Bypass of 802.1X and MAC RADIUS Authentication \(CLI Procedure\) | 471](#)
- [Example: Configuring Static MAC Bypass of 802.1X and MAC RADIUS Authentication on an EX Series Switch | 472](#)

Junos OS allows you to configure access to your LAN through 802.1X-configured interfaces without authentication, by configuring a static MAC bypass list on the EX Series switch. The static MAC bypass list, also known as the *exclusion list*, specifies MAC addresses that are allowed on the switch without sending a request to an authentication server. For more information, read this topic.

**NOTE:** If you add a static MAC address entry to the Ethernet switching table, this has the same effect as adding a MAC address to the static MAC bypass list. For information on configuring static MAC address entries see *MAC Addresses*.

## Configuring Static MAC Bypass of 802.1X and MAC RADIUS Authentication (CLI Procedure)

You can configure a static MAC bypass list (sometimes called the exclusion list) on the switch to specify MAC addresses of devices allowed access to the LAN without 802.1X or MAC RADIUS authentication requests to the RADIUS server.

To configure the static MAC bypass list:

- Specify a MAC address to bypass authentication:

```
[edit protocols dot1x]  
user@switch# set authenticator static 00:04:0f:fd:ac:fe
```

- Configure a supplicant to bypass authentication if it is connected through a particular interface:

```
[edit protocols dot1x]  
user@switch# set authenticator static 00:04:0f:fd:ac:fe interface ge-0/0/5
```

- Configure a supplicant to be moved to a specific VLAN after it is authenticated:

```
[edit protocols dot1x]  
user@switch# set authenticator static 00:04:0f:fd:ac:fe interface ge-0/0/5 vlan-assignment  
default-vlan
```

[Configuring 802.1X Interface Settings \(CLI Procedure\) | 369](#)

[Configuring 802.1X Authentication \(J-Web Procedure\)](#)

## Example: Configuring Static MAC Bypass of 802.1X and MAC RADIUS Authentication on an EX Series Switch

### IN THIS SECTION

- [Requirements | 472](#)
- [Overview and Topology | 473](#)
- [Configuration | 476](#)
- [Verification | 478](#)

To allow devices to access your LAN through 802.1X-configured interfaces without authentication, you can configure a static MAC bypass list on the EX Series switch. The static MAC bypass list, also known as the *exclusion list*, specifies MAC addresses that are allowed on the switch without sending a request to an authentication server.

You can use static MAC bypass of authentication to allow connection for devices that are not 802.1X-enabled, such as printers. If a host's MAC address is compared and matched against the static MAC address list, the nonresponsive host is authenticated and an interface opened for it.

This example describes how to configure static MAC bypass of authentication for two printers:

### Requirements

This example uses the following software and hardware components:

**NOTE:** This example also applies to QFX5100 switches.

- Junos OS Release 9.0 or later for EX Series switches
- One EX Series switch acting as an authenticator port access entity (PAE). The ports on the authenticator PAE form a control gate that blocks all traffic to and from supplicants until they are authenticated.

Before you configure static MAC bypass of authentication, be sure you have:

- Performed basic bridging and VLAN configuration on the switch. See the documentation that describes setting up basic bridging and a VLAN for your switch. If you are using a switch that supports the Enhanced Layer 2 Software (ELS) configuration style, see *Example: Setting Up Basic*

*Bridging and a VLAN for an EX Series Switch with ELS Support* or *Example: Setting Up Basic Bridging and a VLAN on Switches*. For all other switches, see *Example: Setting Up Basic Bridging and a VLAN for an EX Series Switch*.

For more about ELS, see: *Using the Enhanced Layer 2 Software CLI*.

- Specified the RADIUS server connections and configured an access profile on the switch. See ["Example: Connecting a RADIUS Server for 802.1X to an EX Series Switch" on page 380](#).

## Overview and Topology

### IN THIS SECTION

- [Topology | 476](#)

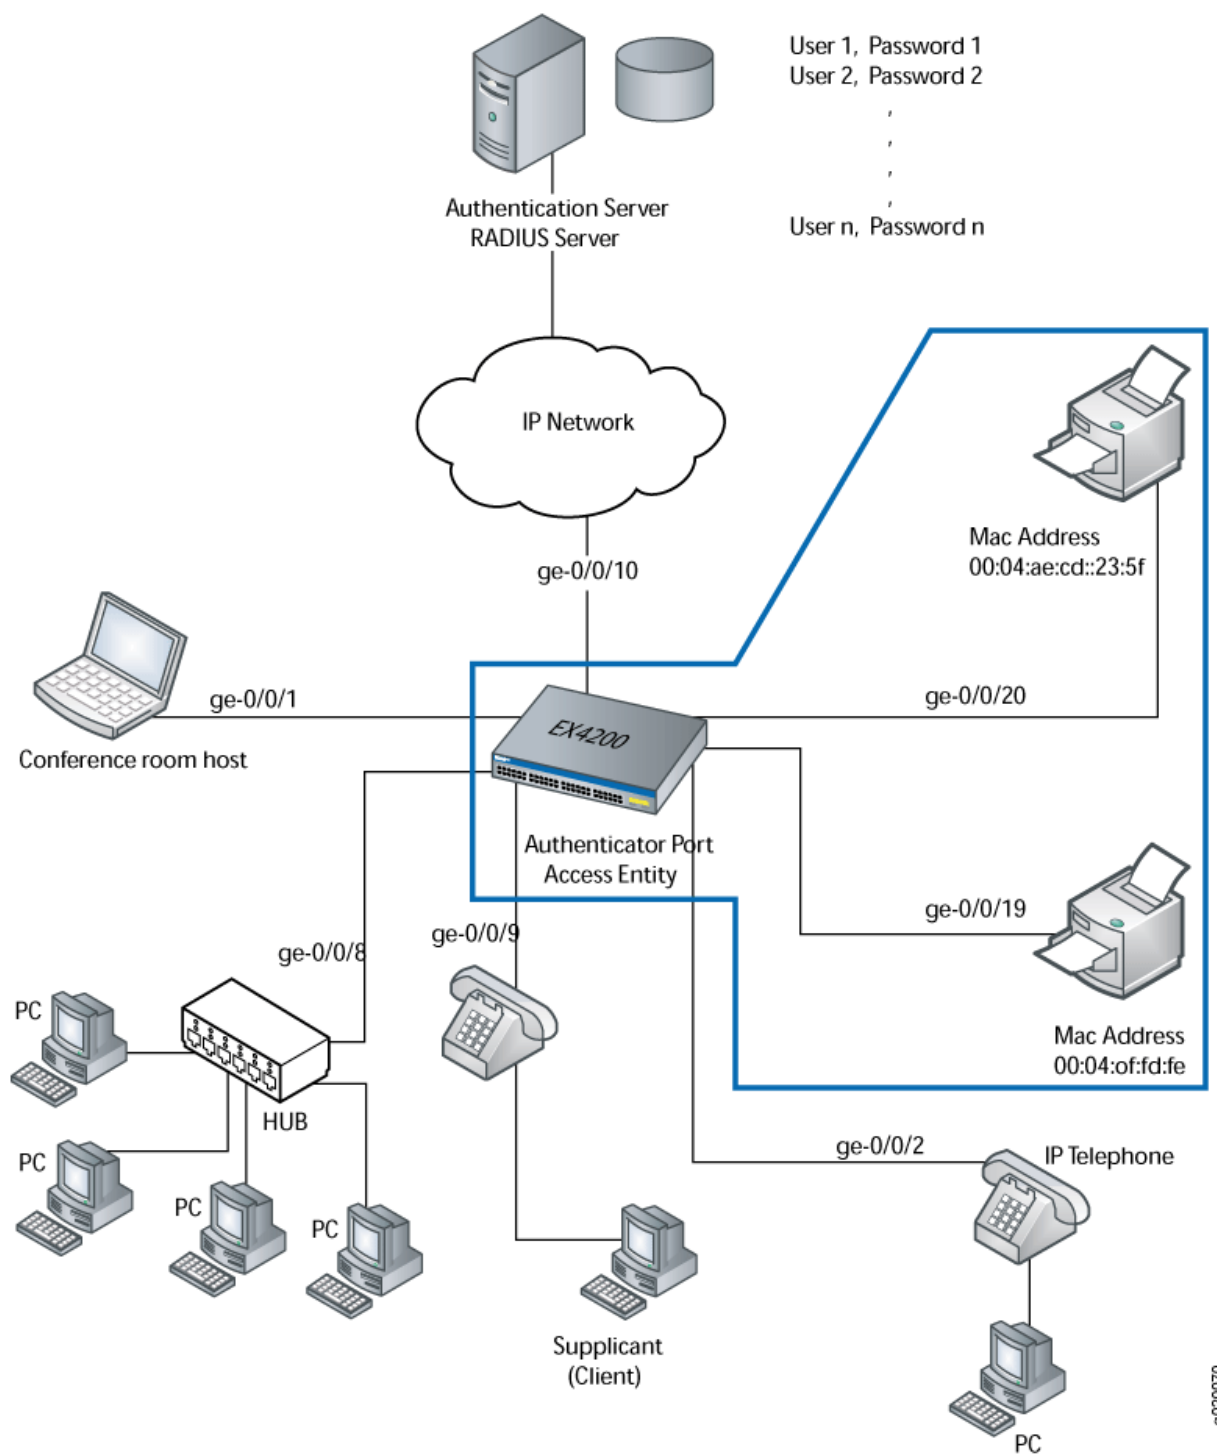

To permit printers access to the LAN, add them to the static MAC bypass list. The MAC addresses on this list are permitted access without authentication from the RADIUS server.

[Figure 20 on page 475](#) shows the two printers connected to the EX4200.

**NOTE:** This figure also applies to QFX5100 switches.

Figure 20: Topology for Static MAC Bypass of Authentication Configuration

The interfaces shown in [Table 31 on page 476](#) will be configured for static MAC bypass of authentication.

**Table 31: Components of the Static MAC Bypass of Authentication Configuration Topology**

| Property                                                                | Settings                                                                                         |
|-------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------|
| Switch hardware                                                         | EX4200, 24 Gigabit Ethernet ports: 16 non-PoE ports and 8 PoE ports (ge-0/0/0 through ge-0/0/23) |
| VLAN name                                                               | default                                                                                          |
| Connections to integrated printer/fax/copier machines (no PoE required) | ge-0/0/19, MAC address 00:04:0f:fd:ac:fe<br>ge-0/0/20, MAC address 00:04:ae:cd:23:5f             |

The printer with the MAC address 00:04:0f:fd:ac:fe is connected to access interface ge-0/0/19. A second printer with the MAC address 00:04:ae:cd:23:5f is connected to access interface ge-0/0/20. Both printers will be added to the static list and bypass 802.1X authentication.

Topology

Configuration

IN THIS SECTION

Procedure | 476

Procedure

CLI Quick Configuration

To quickly configure the static MAC bypass list, copy the following commands and paste them into the switch terminal window:

```
[edit]  
  
set protocols dot1x authenticator static [00:04:0f:fd:ac:fe 00:04:ae:cd:23:5f]
```

```
set protocols dot1x authenticator interface all supplicant multiple
set protocols dot1x authenticator authentication-profile-name profile1
```

## Step-by-Step Procedure

Configure the static MAC bypass list:

1. Configure MAC addresses 00:04:0f:fd:ac:fe and 00:04:ae:cd:23:5f as static MAC addresses:

```
[edit protocols]
user@switch# set dot1x authenticator static [00:04:0f:fd:ac:fe 00:04:ae:cd:23:5f]
```

2. Configure the 802.1X authentication method:

```
[edit protocols]
user@switch# set dot1x authenticator interface all supplicant multiple
```

3. Configure the authentication profile name (access profile name) to use for authentication:

```
[edit protocols]
user@switch# set dot1x authenticator authentication-profile-name profile1
```

**NOTE:** Access profile configuration is required only for 802.1X clients, not for static MAC clients.

## Results

Display the results of the configuration:

```
user@switch> show
interfaces {
  ge-0/0/19 {
    unit 0 {
      family ethernet-switching {
        vlan members default;
      }
    }
  }
}
```

```

    }
  }
  ge-0/0/20 {
    unit 0 {
      family ethernet-switching {
        vlan members default;
      }
    }
  }
}
protocols {
  dot1x {
    authenticator {
      authentication-profile-name profile1
      static [00:04:0f:fd:ac:fe 00:04:ae:cd:23:5f];
      interface {
        all {
          supplicant multiple;
        }
      }
    }
  }
}
}

```

## Verification

### IN THIS SECTION

- [Verifying Static MAC Bypass of Authentication | 478](#)

To confirm that the configuration is working properly, perform these tasks:

### Verifying Static MAC Bypass of Authentication

#### Purpose

Verify that the MAC addresses of both printers are configured and associated with the correct interfaces.

## Action

Issue the operational mode command:

```
user@switch> show dot1x static-mac-address
```

| MAC address       | VLAN-Assignment | Interface   |
|-------------------|-----------------|-------------|
| 00:04:0f:fd:ac:fe | default         | ge-0/0/19.0 |
| 00:04:ae:cd:23:5f | default         | ge-0/0/20.0 |

## Meaning

The output field `MAC address` shows the MAC addresses of the two printers.

The output field `Interface` shows that the MAC address `00:04:0f:fd:ac:fe` can connect to the LAN through interface `ge-0/0/19.0` and that the MAC address `00:04:ae:cd:23:5f` can connect to the LAN through interface `ge-0/0/20.0`.

# Configuring PEAP for MAC RADIUS Authentication

Extensible Authentication Protocol (EAP) is an extensible protocol that provides support for multiple authentication methods, including password-based authentication methods and more secure certificate-

based authentication methods. EAP facilitates the negotiation between the authenticator, or switching device, and the authentication server, to determine which authentication method to use for a supplicant. The default authentication method used for MAC RADIUS authentication is EAP-MD5, in which the server sends the client a random challenge value, and the client proves its identity by hashing the challenge and its password with MD5. Because EAP-MD5 only provides for client authentication and not for server authentication, it can be vulnerable to spoofing attacks.

You can configure the Protected Extensible Authentication Protocol, also known as Protected EAP or simply PEAP, to address the security vulnerabilities of EAP-MD5. PEAP is a protocol that encapsulates EAP packets within an encrypted and authenticated Transport Layer Security (TLS) tunnel. PEAP is referred to as the outer authentication protocol because it sets up the tunnel and is not directly involved with authenticating the endpoints. The inner authentication protocol, used to authenticate the client's MAC address inside the tunnel, is Microsoft Challenge Handshake Authentication Protocol version 2 (MS-CHAPv2). The encrypted exchange of information inside the tunnel ensures that user credentials are safe from eavesdropping.

One of the advantages of PEAP, when used with MS-CHAPv2, is that it requires only a server-side certificate to establish the secure tunnel, and uses server-side public key certificates to authenticate the server. This eliminates the overhead involved in deploying digital certificates for every client that requires authentication.

Once a client has been authenticated on the switch using MAC RADIUS authentication, subsequent clients can use the same outer tunnel that was established by the first client to communicate with the server. This is achieved using the session resumption functionality provided by SSL. Session resumption reduces latency that can occur as subsequent clients wait for a new TLS tunnel to be established.

Before you configure the PEAP authentication protocol for MAC RADIUS authentication, make sure that the authentication server is also configured to use PEAP with MS-CHAPv2 as the inner authentication protocol. For information about configuring the authentication server, consult the documentation for your server.

**NOTE:** The authentication protocol can be configured globally using the `interface all` option as well as locally using the individual interface name. If the authentication protocol is configured both for an individual interface and for all interfaces, the local configuration for that interface overrides the global configuration.

To configure the PEAP authentication protocol for MAC RADIUS authentication:

1. Configure the eap-peap option for the authentication-protocol statement:

```
[edit]
user@switch# set protocols dot1x authenticator interface interface-name mac-radius
authentication-protocol eap-peap
```

2. (Optional) Enable session resumption to allow for faster authentication of subsequent clients:

```
[edit]
user@switch# set protocols dot1x authenticator interface interface-name mac-radius
authentication-protocol eap-peap resume
```

3. Load the server-side SSL certificate using either the filename or path.

- a. To load the certificate using the file name:

```
[edit]
user@root# run load ssl-certificate file certificate-name
```

- b. To load the certificate using the file path:

```
[edit]
user@root# run load ssl-certificate path certificate-path
```

**NOTE:** If you are using an SSL certificate with a path other than the default path of /var/tmp/, you must first configure the SSL certificate path using the following command:

```
[edit]
set protocols dot1x ssl-certificate-path certificate-path
```

- c. To verify the certificates:

```
[edit]
user@root# run show ssl-certificates

# Captive Portal Authentication

## IN THIS SECTION

- [Example: Setting Up Captive Portal Authentication on an EX Series Switch | 482](#)
- [Configuring Captive Portal Authentication \(CLI Procedure\) | 490](#)
- [Designing a Captive Portal Authentication Login Page on Switches | 492](#)
- [Configuring Captive Portal Authentication \(CLI Procedure\) on an EX Series Switch with ELS Support | 496](#)
- [Example: Setting Up Captive Portal Authentication on an EX Series Switch with ELS Support | 498](#)

You can control access to your network through a switch by using several different authentication. Junos OS switches support 802.1X, MAC RADIUS, and captive portal as an authentication methods to devices requiring to connect to a network. You can set up captive portal authentication on a switch to redirect Web browser requests to a login page that requires the user to input a username and password. For more information, read this topic.

## Example: Setting Up Captive Portal Authentication on an EX Series Switch

### IN THIS SECTION

- [Requirements | 483](#)
- [Overview and Topology | 483](#)
- [Configuration | 484](#)
- [Verification | 488](#)
- [Troubleshooting | 489](#)

You can set up captive portal authentication (hereafter referred to as captive portal) on a switch to redirect Web browser requests to a login page that requires the user to input a username and password.

Upon successful authentication, the user is allowed to continue with the original page request and subsequent access to the network.

This example describes how to set up captive portal on an EX Series switch:

## Requirements

This example uses the following hardware and software components:

- An EX Series switch that supports captive portal
- Junos OS Release 10.1 or later for EX Series switches

Before you begin, be sure you have:

- Performed basic bridging and VLAN configuration on the switch. See *Example: Setting Up Basic Bridging and a VLAN for an EX Series Switch*.
- Generated an SSL certificate and installed it on the switch. See ["Generating SSL Certificates to Be Used for Secure Web Access \(EX Series Switch\)" on page 316](#).
- Designed your captive portal login page. See ["Designing a Captive Portal Authentication Login Page on Switches" on page 492](#).

## Overview and Topology

### IN THIS SECTION

- [Topology | 483](#)

This example shows the configuration required on the switch to enable captive portal on an interface. To permit a printer connected to the captive portal interface to access the LAN without going through captive portal, add its MAC address to the authentication allowlist. The MAC addresses in this list are permitted access on the interface without captive portal.

### Topology

The topology for this example consists of one EX Series switch connected to a RADIUS authentication server. One interface on the switch is configured for captive portal. In this example, the interface is configured in multiple supplicant mode.

## Configuration

### IN THIS SECTION

- [CLI Quick Configuration | 484](#)
- [Procedure | 484](#)

To configure captive portal on your switch:

### CLI Quick Configuration

To quickly configure captive portal on the switch after completing the tasks in the Requirements section, copy the following commands and paste them into the switch terminal window:

```
[edit]
set access radius-server 10.204.96.165 port 1812
set access radius-server 10.204.96.165 secret "ABC123"
set access profile profile1 authentication-order radius
set access profile profile1 radius authentication-server 10.204.96.165
set system services web-management http
set system services web-management https local-certificate my-signed-cert
set services captive-portal secure-authentication https
set services captive-portal interface ge-0/0/10.0 supplicant multiple
set services captive-portal authentication-profile-name profile1
set ethernet-switching-options authentication-whitelist 00:10:12:e0:28:22
set services captive-portal custom-options post-authentication-url http://www.my-home-page.com
```

### Procedure

#### Step-by-Step Procedure

To configure captive portal on the switch:

1. Define the server IP address, the server authentication port number, and configure the secret password. The secret password on the switch must match the secret password on the server:

```
[edit]
user@switch# set access radius-server 10.204.96.165 port 1812
[edit]
user@switch# set access radius-server 10.204.96.165 secret "ABC123"
```

2. Configure the authentication order, making radius the first method of authentication:

```
[edit]
user@switch# set access profile profile1 authentication-order radius
```

3. Configure the server IP address to be tried in order to authenticate the supplicant:

```
[edit]
user@switch# set access profile profile1 radius authentication-server 10.204.96.165
```

4. Enable HTTP access on the switch:

```
[edit]
user@switch# set system services web-management http
```

5. To create a secure channel for Web access to the switch, configure captive portal for HTTPS:

**NOTE:** You can enable HTTP without enabling HTTPS, but we recommend HTTPS for security purposes.

## Step-by-Step Procedure

- a. Associate the security certificate with the Web server and enable HTTPS access on the switch:

```
[edit]
user@switch# set system services web-management https local-certificate my-signed-cert
```

- b. Configure captive portal to use HTTPS:

```
[edit]
user@switch# set services captive-portal secure-authentication https
```

6. Enable an interface for captive portal:

```
[edit]
user@switch# set services captive-portal interface ge-0/0/10 supplicant multiple
```

7. Specify the name of the access profile to be used for captive portal authentication:

```
[edit]
user@switch# set services captive-portal authentication-profile-name profile1
```

8. (Optional) Allow specific clients to bypass captive portal:

**NOTE:** If the client is already attached to the switch, you must clear its MAC address from the captive portal authentication by using the `clear captive-portal mac-address mac-address` command after adding its MAC address to the allowlist. Otherwise the new entry for the MAC address will not be added to the Ethernet switching table and authentication bypass will not be allowed.

```
[edit]
user@switch# set ethernet-switching-options authentication-whitelist 00:10:12:e0:28:22
```

**NOTE:** Optionally, you can use `set ethernet-switching-options authentication-whitelist 00:10:12:e0:28:22 interface ge-0/0/10.0` to limit the scope to the interface.

9. (Optional) To redirect clients to a specified page rather than the page they originally requested, configure the post-authentication URL:

```
[edit]
user@switch# set services captive-portal custom-options post-authentication-url http://www.my-
home-page.com
```

## Results

Display the results of the configuration:

```
[edit]
user@switch> show
system {
  services {
    web-management {
      http;
      https {
        local-certificate my-signed-cert;
      }
    }
  }
}
security {
  certificates {
    local {
      my-signed-cert {
        "-----BEGIN RSA PRIVATE KEY-----ABC123
...
ABC123-----END CERTIFICATE-----\n"; ## SECRET-DATA
      }
    }
  }
}
services {
  captive-portal {
    interface {
      ge-0/0/10.0 {
        supplicant multiple;
      }
    }
  }
}
```

```

        secure-authentication https;
    }
}
ethernet-switching-options {
    authentication-whitelist {
        00:10:12:e0:28:22/48;
    }
}
}

```

## Verification

### IN THIS SECTION

- [Verifying That Captive Portal Is Enabled on the Interface | 488](#)
- [Verify That Captive Portal Is Working Correctly | 489](#)

To confirm that captive portal is configured and working properly, perform these tasks:

### Verifying That Captive Portal Is Enabled on the Interface

#### Purpose

Verify that captive portal is configured on interface ge-0/0/10.

#### Action

Use the operational mode command `show captive-portal interface interface-name detail`:

```

user@switch> show captive-portal interface ge-0/0/10.0 detail
ge-0/0/10.0
  Supplicant mode: Multiple
  Number of retries: 3
  Quiet period: 60 seconds
  Configured CP session timeout: 3600 seconds
  Server timeout: 15 seconds

```

## Meaning

The output confirms that captive portal is configured on interface ge-0/0/10 with the default settings for number of retries, quiet period, CP session timeout, and server timeout.

## Verify That Captive Portal Is Working Correctly

### Purpose

Verify that captive portal is working on the switch.

### Action

Connect a client to interface ge-0/0/10. From the client, open a Web browser and request a webpage. The captive portal login page that you designed should be displayed. After you enter your login information and are authenticated against the RADIUS server, the Web browser should display either the page you requested or the post-authentication URL that you configured.

## Troubleshooting

### IN THIS SECTION

- [Troubleshooting Captive Portal | 489](#)

To troubleshoot captive portal, perform these tasks:

### Troubleshooting Captive Portal

#### Problem

The switch does not return the captive portal login page when a user connected to a captive portal interface on the switch requests a Web page.

#### Solution

You can examine the ARP, DHCP, HTTPS, and DNS counters—if one or more of these counters are not incrementing, this provides an indication of where the problem lies. For example, if the client cannot get

an IP address, check the switch interface to determine whether the DHCP counter is incrementing—if the counter increments, the DHCP packet was received by the switch.

```
user@switch> show captive-portal firewall ge-0/0/10.0
ge-0/0/10.0
  Filter name: dot1x_ge-0/0/10
Counters:
Name                               Bytes      Packets
dot1x_ge-0/0/10_CP_arp             7616       119
dot1x_ge-0/0/10_CP_dhcp             0           0
dot1x_ge-0/0/10_CP_http             0           0
dot1x_ge-0/0/10_CP_https            0           0
dot1x_ge-0/0/10_CP_t_dns            0           0
dot1x_ge-0/0/10_CP_u_dns            0           0
```

## Configuring Captive Portal Authentication (CLI Procedure)

### IN THIS SECTION

- [Configuring Secure Access for Captive Portal | 491](#)
- [Enabling an Interface for Captive Portal | 491](#)
- [Configuring Bypass of Captive Portal Authentication | 492](#)

Configure captive portal authentication (hereafter referred to as captive portal) on an EX Series switch so that users connected to the switch are authenticated before being allowed to access the network. When the user requests a web page, a login page is displayed that requires the user to input a username and password. Upon successful authentication, the user is allowed to continue with the original page request and subsequent access to the network.

Before you begin, be sure you have:

- Performed basic bridging and VLAN configuration on the switch. See *Example: Setting Up Basic Bridging and a VLAN for an EX Series Switch*.
- Generated an SSL certificate and installed it on the switch. See ["Generating SSL Certificates to Be Used for Secure Web Access \(EX Series Switch\)"](#) on page 316.

- Configured basic access between the EX Series switch and the RADIUS server. See ["Example: Connecting a RADIUS Server for 802.1X to an EX Series Switch" on page 380.](#)
- Designed your captive portal login page. See ["Designing a Captive Portal Authentication Login Page on Switches" on page 492.](#)

This topic includes the following tasks:

## Configuring Secure Access for Captive Portal

To configure secure access for captive portal:

1. Enable HTTP access on the switch:

```
[edit]
user@switch# set system services web-management http
```

2. Associate the security certificate with the Web server and enable HTTPS access on the switch:

```
[edit]
user@switch# set system services web-management https local-certificate my-signed-cert
```

**NOTE:** You can enable HTTP without HTTPS, but we recommend HTTPS for security purposes.

3. Configure captive portal to use HTTPS:

```
[edit]
user@switch# set services captive-portal secure-authentication https
```

## Enabling an Interface for Captive Portal

To enable an interface for captive portal:

```
[edit]
user@switch# set services captive-portal interface interface-name
```

For example, to enable captive portal on the interface ge-0/0/10:

```
[edit]
user@switch# set services captive-portal interface ge-0/0/10
```

## Configuring Bypass of Captive Portal Authentication

To allow specific clients to bypass captive portal:

```
[edit]
user@switch# set ethernet-switching-options authentication-whitelist mac-address
```

For example, to allow specific clients to bypass captive portal:

```
[edit]
user@switch# set ethernet-switching-options authentication-whitelist 00:10:12:e0:28:22
```

**NOTE:** Optionally, you can use `set ethernet-switching-options authentication-whitelist 00:10:12:e0:28:22 interface ge-0/0/10.0` to limit the scope to the interface.

**NOTE:** If the client is already attached to the switch, you must clear its MAC address from the captive portal authentication by using the `clear captive-portal mac-address mac-address` command after adding its MAC address to the allowlist. Otherwise the new entry for the MAC address will not be added to the Ethernet switching table and authentication bypass will not be allowed.

## Designing a Captive Portal Authentication Login Page on Switches

You can set up captive portal authentication on your switch to redirect all Web browser requests to a login page that requires users to input a username and password before they are allowed access. Upon successful authentication, users are allowed access to the network and redirected to the original page requested.

Junos OS provides a customizable template for the captive portal window that allows you to easily design and modify the look of the captive portal login page. You can modify the design elements of the

template to change the look of your captive portal login page and to add instructions or information to the page. You can also modify any of the design elements of a captive portal login page.

The first screen displayed before the captive login page requires the user to read the terms and conditions of use. By clicking the Agree button, the user can access the captive portal login page.

Figure 21 on page 493 shows an example of a captive portal login page:

Figure 21: Example of a Captive Portal Login Page

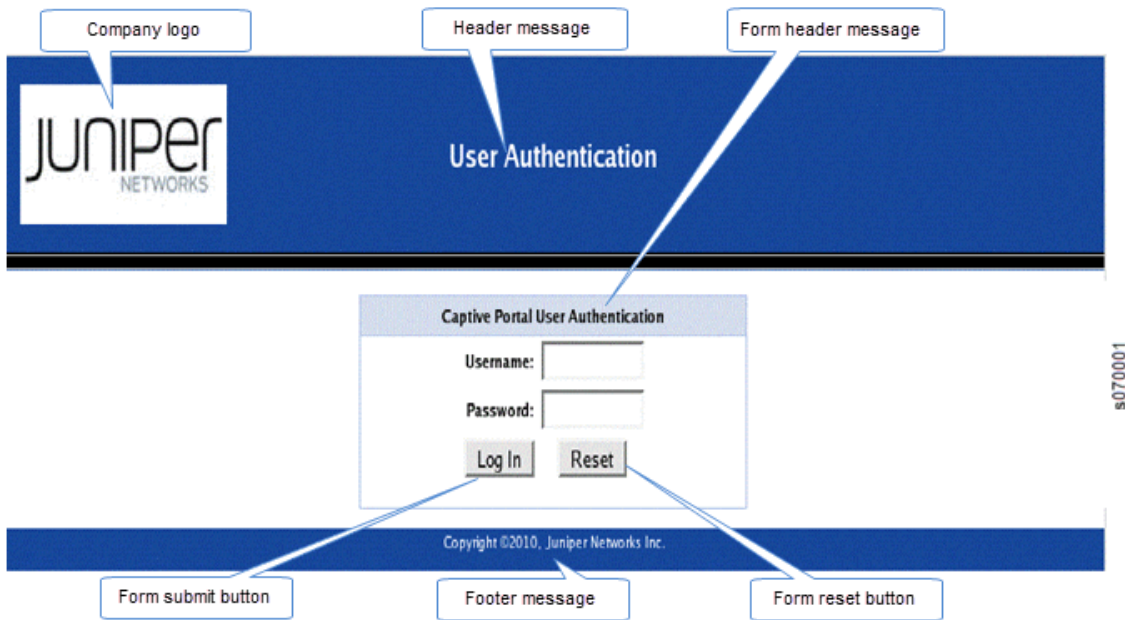

Table 32 on page 493 summarizes the configurable elements of a captive portal login page.

Table 32: Configurable Elements of a Captive Portal Login Page

| Element                 | CLI Statement                            | Description                                                                                                                                                                                                                                                                                        |

The default color is white.                                                                                                                                                                                                                                                                                                                                                                                          |
| Form header background color | <b>form-header-bgcolor</b><br><i>hex-color</i>   | The HTML hexadecimal code for the background color of the header bar across the top of the form area of the captive portal login page.                                                                                                                                                                                                                                                                                                                |
| Form header message          | <b>form-header-message</b><br><i>text-string</i> | Text displayed in the header of the captive portal login page. The default text is <b>Captive Portal User Authentication</b> .                                                                                                                                                                                                                                                                                                                        |
| Form header text color       | <b>form-header- text-color</b><br><i>color</i>   | Color of the text in the form header. The default color is black.                                                                                                                                                                                                                                                                                                                                                                                     |
| Form reset button label      | <b>form-reset-label</b><br><i>label-name</i>     | Using the <b>Reset</b> button, the user can clear the username and password fields on the form.                                                                                                                                                                                                                                                                                                                                                       |
| Form submit button label     | <b>form-submit-label</b><br><i>label-name</i>    | Using the <b>Login</b> button, the user can submit the login information.                                                                                                                                                                                                                                                                                                                                                                             |
| Header background color      | <b>header-bgcolor</b> <i>hex-color</i>           | The HTML hexadecimal code for the background color of the captive portal login page header.                                                                                                                                                                                                                                                                                                                                                           |
| Header logo                  | <b>header-logo</b> <i>filename</i>               | <p>Filename of the file containing the image of the logo that you want to appear in the header of the captive portal login page. The image file can be in GIF, JPEG, or PNG format.</p> <p>You can upload a logo image file to the switch. Copy the logo to the /var/tmp directory on the switch (during commit, the files are saved to persistent locations).</p> <p>If you do not specify a logo image, the Juniper Networks logo is displayed.</p> |
| Header message               | <b>header-message</b> <i>text-string</i>         | Text displayed in the page header. The default text is <b>User Authentication</b> .                                                                                                                                                                                                                                                                                                                                                                   |

Table 32: Configurable Elements of a Captive Portal Login Page (*Continued*)

| Element                 | CLI Statement                             | Description                                                                                                                                 |
|-------------------------|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| Header text color       | <b>header-text-color</b> <i>color</i>     | Color of the text in the header. The default color is white.                                                                                |
| Post-authentication URL | <b>post-authentication-url</b> <i>url</i> | URL to which the users are directed on successful authentication. By default, users are directed to the page they had originally requested. |

To design the captive portal login page:

1. (Optional) Upload your logo image file to the switch:

```
user@switch> file copy ftp://username:prompt@ftp.hostname.net/var/tmp/my-logo.jpeg
```

2. Configure the custom options to specify the background colors and text displayed in the captive portal page:

```
[edit system services captive-portal]
user@switch# set custom-options header-bgcolor #006600
set custom-options header-message "Welcome to Our Network"
set custom-options banner-message "Please enter your username and password".The banner
displays the message "XXXXXXX" by default. The user can modify this message.
set custom-options footer-message "Copyright ©2010, Our Network"
```

Now you can commit the configuration.

**NOTE:** For the custom options that you do not specify, the default value is used.

## Configuring Captive Portal Authentication (CLI Procedure) on an EX Series Switch with ELS Support

### IN THIS SECTION

- [Configuring Secure Access for Captive Portal | 496](#)
- [Enabling an Interface for Captive Portal | 497](#)
- [Configuring Bypass of Captive Portal Authentication | 497](#)

**NOTE:** This task uses Junos OS for switches with support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that does not support ELS, see ["Configuring Captive Portal Authentication \(CLI Procedure\)" on page 490](#). For ELS details, see *Using the Enhanced Layer 2 Software CLI*.

Configure captive portal authentication (hereafter referred to as captive portal) on a switch so that users connected to the switch are authenticated before being allowed to access the network. When the user requests a webpage, a login page is displayed that requires the user to input a username and password. Upon successful authentication, the user is allowed to continue with the original page request and subsequent access to the network.

Before you begin, be sure you have:

- Performed basic bridging and VLAN configuration on the switch. See *Example: Setting Up Basic Bridging and a VLAN for an EX Series Switch with ELS Support*.
- Generated an SSL certificate and installed it on the switch. See ["Generating SSL Certificates to Be Used for Secure Web Access \(EX Series Switch\)" on page 316](#).
- Configured basic access between the switch and the RADIUS server. See ["Example: Connecting a RADIUS Server for 802.1X to an EX Series Switch" on page 380](#).
- Designed your captive portal login page. See ["Designing a Captive Portal Authentication Login Page on Switches" on page 492](#).

This topic includes the following tasks:

### Configuring Secure Access for Captive Portal

To configure secure access for captive portal:

1. Associate the security certificate with the Web server and enable HTTPS on the switch:

```
[edit]
user@switch# set system services web-management https local-certificate certificate-name
```

**NOTE:** You can enable HTTP instead of HTTPS, but we recommend HTTPS for security purposes.

2. Configure captive portal to use HTTPS:

```
[edit]
user@switch# set services captive-portal secure-authentication https
```

## Enabling an Interface for Captive Portal

To enable an interface for use with captive portal authentication:

```
[edit]
user@switch# set services captive-portal interface interface-name
```

## Configuring Bypass of Captive Portal Authentication

You can allow specific clients to bypass captive portal authentication:

```
[edit]
user@switch# set switch-options authentication-whitelist mac-address
```

**NOTE:** Optionally, you can use `set switch-options authentication-whitelist mac-address interface interface-name` to limit the scope to the interface.

**NOTE:** If the client is already attached to the switch, you must clear its MAC address from the captive portal authentication by using the `clear captive-portal mac-address session-mac-addr` command after adding its MAC address to the allowlist. Otherwise, the new entry for the MAC

address is not added to the Ethernet switching table and the authentication bypass is not allowed.

## Example: Setting Up Captive Portal Authentication on an EX Series Switch with ELS Support

### IN THIS SECTION

- Requirements | 498
- Overview and Topology | 499
- Configuration | 499
- Verification | 503
- Troubleshooting | 504

**NOTE:** This example uses Junos OS for EX Series switches with support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that does not support ELS, see ["Example: Setting Up Captive Portal Authentication on an EX Series Switch" on page 482](#). For ELS details, see *Using the Enhanced Layer 2 Software CLI*.

You can set up captive portal authentication (hereafter referred to as captive portal) on a switch to redirect Web browser requests to a login page that requires the user to input a username and password. Upon successful authentication, the user is allowed to continue with the original page request and subsequent access to the network.

This example describes how to set up captive portal on an EX Series switch:

### Requirements

This example uses the following software and hardware components:

- Junos OS Release 13.2X50 or later for EX Series switches
- An EX Series switch with support for ELS

Before you begin, be sure you have:

- Performed basic bridging and VLAN configuration on the switch. See *Example: Setting Up Basic Bridging and a VLAN for an EX Series Switch with ELS Support*.
- Generated an SSL certificate and installed it on the switch. See ["Generating SSL Certificates to Be Used for Secure Web Access \(EX Series Switch\)" on page 316](#).
- Configured basic access between the EX Series switch and the RADIUS server. See ["Example: Connecting a RADIUS Server for 802.1X to an EX Series Switch" on page 380](#).
- Designed your captive portal login page. See ["Designing a Captive Portal Authentication Login Page on Switches" on page 492](#).

## Overview and Topology

### IN THIS SECTION

- [Topology | 499](#)

This example shows the configuration required on the switch to enable captive portal on an interface. To permit a printer connected to the captive portal interface to access the LAN, add its MAC address to the authentication allowlist and assign it to a VLAN, vlan1. The MAC addresses on this list are permitted access on the interface without captive portal authentication.

### Topology

The topology for this example consists of one EX Series switch connected to a RADIUS authentication server. One interface on the switch is configured for captive portal. In this example, the interface is configured in multiple supplicant mode.

## Configuration

### IN THIS SECTION

- [CLI Quick Configuration | 500](#)
- [Procedure | 500](#)

To configure captive portal on your switch:

### CLI Quick Configuration

To quickly configure captive portal on the switch after completing the tasks in the Requirements section, copy the following commands and paste them into the switch terminal window:

```
[edit]
set system services web-management https local-certificate my-signed-cert
set services captive-portal secure-authentication https
set services captive-portal interface ge-0/0/10.0 supplicant multiple
set switch-options authentication-whitelist 00:10:12:e0:28:22 vlan-assignment vlan1
set custom-options post-authentication-url http://www.my-home-page.com
```

### Procedure

#### Step-by-Step Procedure

1. To create a secure channel for Web access to the switch, configure captive portal for HTTPS:

#### Step-by-Step Procedure

- a. Associate the security certificate with the Web server and enable HTTPS on the switch:

```
[edit]
user@switch# set system services web-management https local-certificate my-signed-cert
```

**NOTE:** You can enable HTTP instead of HTTPS, but we recommend that you enable HTTPS for security purposes.

- b. Configure captive portal to use HTTPS:

```
[edit]
user@switch# set services captive-portal secure-authentication https
```

2. Enable an interface for captive portal:

```
[edit]
user@switch# set services captive-portal interface ge-0/0/10 supplicant multiple
```

3. (Optional) Allow specific clients to bypass captive portal authentication:

**NOTE:** If the client is already attached to the switch, you must clear its MAC address from the captive portal authentication by using the `clear captive-portal mac-address mac-address` command after adding its MAC address to the allowlist. Otherwise, the new entry for the MAC address will not be added to the Ethernet switching table and the authentication bypass will not be allowed.

```
[edit]
user@switch# set switch-options authentication-whitelist 00:10:12:e0:28:22 vlan-assignment
vlan1
```

**NOTE:** Optionally, you can use `set switch-options authentication-whitelist 00:10:12:e0:28:22 vlan-assignment vlan1 interface ge-0/0/10.0` to limit the scope to the interface.

4. (Optional) To redirect clients to a specified page rather than the page they originally requested, configure the post-authentication URL:

```
[edit services captive-portal]
user@switch# set custom-options post-authentication-url http://www.my-home-page.com
```

## Results

Display the results of the configuration:

```
[edit]
user@switch# show
system {
  services {
```

```

        web-management {
            https {
                local-certificate my-signed-cert;
            }
        }
    }
}

security {
    certificates {
        local {
            my-signed-cert {
                "-----BEGIN RSA PRIVATE KEY-----\ABC123
ABC123ABC123ABC123 ... ABC123
-----END CERTIFICATE-----\n"; ## SECRET-DATA
            }
        }
    }
}

services {
    captive-portal {
        interface {
            ge-0/0/10.0 {
                supplicant multiple;
            }
        }
        secure-authentication https;
        custom-options {
            post-authentication-url http://www.my-home-page.com;
        }
    }
}

switch-options {
    authentication-whitelist {
        00:10:12:e0:28:22/48 {
            vlan-assignment vlan1;
        }
    }
}
}

```

## Verification

### IN THIS SECTION

- [Verifying That Captive Portal Is Enabled on the Interface | 503](#)
- [Verify That Captive Portal Is Working Correctly | 503](#)

To confirm that captive portal authentication is configured and working properly, perform these tasks:

### Verifying That Captive Portal Is Enabled on the Interface

#### Purpose

Verify that captive portal is configured on the interface `ge-0/0/10`.

#### Action

Use the operational mode command `show captive-portal interface interface-name detail`:

```
user@switch> show captive-portal interface ge-0/0/10.0 detail
ge-0/0/10.0
  SupPLICant mode: Multiple
  Number of retries: 3
  Quiet period: 60 seconds
  Configured CP session timeout: 3600 seconds
  Server timeout: 15 seconds
```

#### Meaning

The output confirms that captive portal is configured on the interface `ge-0/0/10`, with the default settings for number of retries, quiet period, CP session timeout, and server timeout.

### Verify That Captive Portal Is Working Correctly

#### Purpose

Verify that captive portal is working on the switch.

# Action

Connect a client to the interface ge-0/0/10. From the client, open a Web browser and request a webpage. The captive portal login page that you designed should be displayed. After you enter your login information and are authenticated against the RADIUS server, the Web browser should display either the page you requested or the post-authentication URL that you configured.

# Troubleshooting

## IN THIS SECTION

- [Troubleshooting Captive Portal | 504](#)

To troubleshoot captive portal, perform this task:

## Troubleshooting Captive Portal

### Problem

The switch does not return the captive portal login page when a user connected to a captive portal interface on the switch requests a webpage.

### Solution

You can examine the ARP, DHCP, HTTPS, and DNS counters—if one or more of these counters are not incrementing, this provides an indication of where the problem lies. For example, if the client cannot get an IP address, you might check the switch interface to determine whether the DHCP counter is incrementing—if the counter increments, the DHCP packet was received by the switch.

```
user@switch> show captive-portal firewall ge-0/0/10.0
ge-0/0/10.0
  Filter name: dot1x_ge-0/0/10
Counters:
Name                               Bytes      Packets
dot1x_ge-0/0/10_CP_arp             7616       119
dot1x_ge-0/0/10_CP_dhcp             0           0
dot1x_ge-0/0/10_CP_http             0           0
dot1x_ge-0/0/10_CP_https            0           0
```

|                          |   |   |
|--------------------------|---|---|
| dot1x_ge-0/0/10_CP_t_dns | 0 | 0 |
| dot1x_ge-0/0/10_CP_u_dns | 0 | 0 |

# Flexible Authentication Order on EX Series Switches

## IN THIS SECTION

- [Configuring Flexible Authentication Order | 505](#)
- [Configuring EAPoL Block to Maintain an Existing Authentication Session | 508](#)

Junos OS switches support 802.1X, MAC RADIUS, and captive portal as an authentication methods to devices requiring to connect to a network. You can use the flexible authentication order feature to specify the order of authentication methods that the switch uses when attempting to authenticate a client. If multiple authentication methods are configured on a single interface, when one authentication method fails, the switch falls back to another method. For more information, read this topic.

## Configuring Flexible Authentication Order

You can use the flexible authentication order feature to specify the order of authentication methods that the switch uses when attempting to authenticate a client. If multiple authentication methods are configured on a single interface, when one authentication method fails, the switch falls back to another method.

By default, the switch attempts to authenticate a client by using 802.1X authentication first. If 802.1X authentication fails because there is no response from the client, and MAC RADIUS authentication is configured on the interface, the switch will attempt authentication using MAC RADIUS. If MAC RADIUS

fails, and captive portal is configured on the interface, the switch attempts authentication using captive portal.

With a flexible authentication order, the sequence of authentication method used can be changed based on the type of clients connected to the interface. You can configure the `authentication-order` statement to specify whether 802.1X authentication or MAC RADIUS authentication must be the first authentication method tried. Captive portal is always the last authentication method tried.

If MAC RADIUS authentication is configured as the first authentication method in the order, then on receiving data from any client, the switch attempts to authenticate the client by using MAC RADIUS authentication. If MAC RADIUS authentication fails, then the switch uses 802.1X authentication to authenticate the client. If 802.1X authentication fails, and captive portal is configured on the interface, the switch attempts authentication using captive portal.

**NOTE:** If 802.1X authentication and MAC RADIUS authentication fail, and captive portal is not configured on the interface, the client is denied access to the LAN unless a server fail fallback method is configured. See ["Configuring RADIUS Server Fail Fallback \(CLI Procedure\)" on page 357](#) for more information.

Different authentication methods can be used in parallel on an interface that is configured in multiple-suplicant mode. Therefore, if an end device is authenticated on the interface by using captive portal, another end device connected to that interface can still be authenticated using 802.1X or MAC RADIUS authentication.

Before you configure the flexible authentication order on an interface, make sure that the authentication methods are configured on that interface. The switch does not attempt authentication using a method that is not configured on the interface, even if that method is included in the authentication order; the switch ignores that method and attempts the next method in the authentication order that is enabled on that interface.

Use the following guidelines when configuring the `authentication-order` statement:

- The authentication order must include at least two methods of authentication.
- 802.1X authentication must be one of the methods included in the authentication order.
- If captive portal is included in the authentication order, it must be the last method in the order.
- If `mac-radius-restrict` is configured on an interface then the authentication order cannot be configured on that interface.

To configure a flexible authentication order, use one of the following valid combinations:

**NOTE:** The authentication order can be configured globally using the `interface all` option as well as locally using the individual interface name. If the authentication order is configured both for an individual interface and for all interfaces, the local configuration for that interface overrides the global configuration.

- To configure 802.1X authentication as the first authentication method, followed by MAC RADIUS authentication, and then captive portal:

```
[edit]
user@switch# set protocols dot1x authenticator interface interface-name authentication-order
[dot1x mac-radius captive-portal]
```

- To configure 802.1X authentication as the first authentication method, followed by captive portal:

```
[edit]
user@switch# set protocols dot1x authenticator interface interface-name authentication-order
[dot1x captive-portal]
```

- To configure 802.1X authentication as the first authentication method, followed by MAC RADIUS authentication:

```
[edit]
user@switch# set protocols dot1x authenticator interface interface-name authentication-order
[dot1x mac-radius]
```

- To configure MAC RADIUS authentication as the first authentication method, followed by 802.1X, followed by captive portal:

```
[edit]
user@switch# set protocols dot1x authenticator interface interface-name authentication-order
[mac-radius dot1x captive-portal]
```

After you configure the authentication order, you must use the `insert` command to make any modifications to the authentication order. Using the `set` command does not change the configured order.

To change the authentication order after initial configuration:

```
[edit]
user@switch# insert protocols dot1x authenticator interface interface-name authentication-order
authentication-method before authentication-method
```

For example, to change the order from [mac-radius dot1x captive portal] to [dot1x mac-radius captive portal]:

```
[edit]
user@switch# insert protocols dot1x authenticator interface interface-name authentication-order
dot1x before mac-radius
```

## SEE ALSO

[Understanding Authentication on Switches](#)

[Example: Configuring MAC RADIUS Authentication on an EX Series Switch | 411](#)

## Configuring EAPoL Block to Maintain an Existing Authentication Session

When a switch acting as an 802.1X authenticator receives an EAP-Start message from an authenticated client, the switch tries to re-authenticate the client using the 802.1X method and typically returns an EAP-Request message, and waits for a response. If the client fails to respond, the switch attempts to re-authenticate the client using MAC RADIUS or captive portal method if these methods were configured. Clients that have been authenticated using MAC RADIUS or captive portal authentication are non-responsive, and traffic is dropped on the interface as the switch attempts re-authentication.

If you have configured flexible authentication order on the interface so that MAC RADIUS is the first method used to authenticate a client, the switch still reverts to using 802.1X for re-authentication if the client sends an EAP-Start message, even if the client was successfully authenticated using MAC RADIUS authentication. You can configure an EAPoL block with either a fixed or flexible authentication order. If you do not configure the authentication-order statement, the order is fixed by default. The eapol-block statement can be configured with or without configuring the authentication-order statement.

You can configure a switch to ignore EAP-Start messages sent from a client that has been authenticated using MAC RADIUS authentication or captive portal authentication using the eapol-block statement. With a block of EAPoL messages in effect, if the switch receives an EAP-Start message from the client, it does not return an EAP-Request message, and the existing authentication session is maintained.

**NOTE:** If the endpoint has not been authenticated with MAC RADIUS authentication or captive portal authentication, the EAPoL block does not take effect. The endpoint can authenticate using 802.1X authentication.

If `eapol-block` is configured with the `mac-radius` option, then once the client is authenticated with MAC RADIUS authentication or CWA (Central Web Authentication), the client remains in authenticated state even if it sends an EAP-Start message. If `eapol-block` is configured with the `captive-portal` option, then once the client is authenticated with captive portal, the client remains in authenticated state even if it sends an EAP-Start message.

**NOTE:** This feature is supported on EX4300 and EX9200 switches.

To configure a block of EAPoL messages to maintain an existing authentication session:

- To configure EAPoL block for a client authenticated using MAC RADIUS authentication:

```
[edit]
user@switch# set protocols dot1x authenticator interface interface-name eapol-block mac-radius
```

- To configure EAPoL block for a client authenticated using captive portal authentication:

```
[edit]
user@switch# set protocols dot1x authenticator interface interface-name eapol-block captive-portal
```

# Server Fail Fallback and Authentication

## SUMMARY

## IN THIS SECTION

- | 510
- | 510
- [Configuring RADIUS Reachability to Reauthenticate Server Fail Sessions | 510](#)

## Configuring RADIUS Reachability to Reauthenticate Server Fail Sessions

When an authentication attempt triggers server fail fallback, the end device can reattempt authentication after a period of time. The default time interval that the end device must wait for reauthentication is 60 minutes. The reauthentication time interval can be configured using the `reauthentication` CLI statement.

The server might become available before the reauthentication timer expires. When the RADIUS reachability feature is enabled, it triggers reauthentication once it detects that the server is reachable, without waiting for the reauthentication timer to expire. Once a session moves to server fail fallback, the authenticator will periodically query the server by initiating authentication for that session. When the authenticator receives a response, indicating that the server is reachable, it will initiate authentication for all server fail sessions.

To enable RADIUS reachability, you must configure the query period, which determines how often the authenticator queries the server for reachability. Configure the query period using the following command:

```
set protocols dot1x authenticator radius-reachability query-period
```

**NOTE:** The query period can not be longer than the quiet period. The quiet period is the period during which the interface remains in the wait state following a failed authentication attempt before reattempting authentication.

## Authentication Session Timeout

### IN THIS SECTION

- [Understanding Authentication Session Timeout | 511](#)
- [Controlling Authentication Session Timeouts \(CLI Procedure\) | 513](#)
- [Retaining the Authentication Session Based on IP-MAC Address Bindings | 515](#)

You can control access to your network through a switch by using several different authentication. Junos OS switches support 802.1X, MAC RADIUS, and captive portal as an authentication methods to devices requiring to connect to a network. Read this topic for more information.

### Understanding Authentication Session Timeout

Information about authentication sessions—including the associated interfaces and VLANs for each MAC address that is authenticated—is stored in the authentication session table. The authentication session table is tied to the Ethernet switching table (also called the MAC table). Each time the switch detects traffic from a MAC address, it updates the timestamp for that network node in the Ethernet switching table. A timer on the switch periodically checks the timestamp and if its value exceeds the user-configured `mac-table-aging-time` value, the MAC address is removed from the Ethernet switching table. When a MAC address ages out of the Ethernet switching table, the entry for that MAC address is also removed from the authentication session table, with the result that the session ends.

When the authentication session ends due to MAC address aging, the host must re-attempt authentication. To limit the downtime resulting from re-authentication, you can control the timeout of authentication sessions in the following ways:

- For 802.1X and MAC RADIUS authentication sessions, disassociate the authentication session table from the Ethernet switching table by using the `no-mac-table-binding` statement. This setting prevents the termination of the authentication session when the associated MAC address ages out of the Ethernet switching table.
- For captive portal authentication sessions, configure a keep-alive timer using the `user-keepalive` statement. With this option configured, when the associated MAC address ages out of the Ethernet switching table, the keep-alive timer is started. If traffic is received within the keep-alive timeout period, the timer is deleted. If there is no traffic within the keep-alive timeout period, the session is deleted.

You can also specify timeout values for authentication sessions to end the session before the MAC aging timer expires. After the session times out, the host must re-attempt authentication.

- For 802.1X and MAC RADIUS authentication sessions, the duration of the session before timeout depends on the value of the `reauthentication` statement. If the MAC aging timer expires before the session times out, and the `no-mac-table-binding` statement is not configured, the session is ended, and the host must re-authenticate.
- For captive portal authentication sessions, the duration of the session depends on the value configured for the `session-expiry` statement. If the MAC aging timer expires before the session times out, and the `user-keepalive` statement is not configured, the session is ended, and the host must re-authenticate.

**NOTE:** If the authentication server sends an authentication session timeout to the client, this takes priority over the value configured locally using either the `reauthentication` statement or the `session-expiry` statement. The session timeout value is sent from the server to the client as an attribute of the RADIUS Access-Accept message. For information about configuring the authentication server to send an authentication session timeout, see the documentation for your server.

*Configuring MAC Table Aging on Switches*

## Controlling Authentication Session Timeouts (CLI Procedure)

The expiration of an authentication session can result in downtime because the host must re-attempt authentication. You can limit this downtime by controlling the timeout period for authentication sessions.

An authentication session can end when the MAC address associated with the authenticated host ages out of the Ethernet switching table. When the MAC address is cleared from the Ethernet switching table, the authenticated session for that host ends, and the host must re-attempt authentication.

To prevent the authentication session from ending when the MAC address ages out of the Ethernet switching table:

- For sessions authenticated using 802.1X or MAC RADIUS authentication, you can prevent authentication session timeouts due to MAC address aging by disassociating the authentication session table from the Ethernet switching table using the `no-mac-table-binding` statement:

```
[edit]
user@switch# set protocols dot1x authenticator no-mac-table-binding;
```

- For sessions authenticated using captive portal authentication, you can prevent authentication session timeouts due to MAC address aging by extending the timeout period using the `user-keepalive` statement:

```
[edit]
user@switch# set services captive-portal interface interface-name user-keepalive minutes;
```

You can also configure timeout values for authentication sessions to end an authenticated session before the MAC aging timer expires.

**NOTE:** Configuring the session timeout for an authentication session does not extend the session after the MAC aging timer expires. You must configure either the `no-mac-table-binding` statement for 802.1X and MAC RADIUS authentication, or the `user-keepalive` statement for captive portal authentication, to prevent session timeout due to MAC aging.

For 802.1X and MAC RADIUS authentication sessions, configure the timeout value using the `reauthentication` statement.

- To configure the timeout value on a single interface:

```
[edit]
user@switch# set protocols dot1x authenticator interface interface-name reauthentication
seconds;
```

- To configure the timeout value on all interfaces:

```
[edit]
user@switch# set protocols dot1x authenticator interface all reauthentication seconds;
```

For captive portal authentication sessions, configure the timeout value using the `session-expiry` statement.

- To configure the timeout value on a single interface:

```
[edit]
user@switch# set services captive-portal interface interface-name session-expiry minutes;
```

- To configure the timeout value on all interfaces:

```
[edit]
user@switch# set services captive-portal interface all session-expiry minutes;
```

**NOTE:** If the authentication server sends an authentication session timeout to the client, this takes priority over the value configured using the `reauthentication` statement or the `session-expiry` statement. The session timeout value is sent from the server to the client as an attribute of the RADIUS Access-Accept message.

## SEE ALSO

*Configuring MAC Table Aging on Switches*

[Example: Setting Up 802.1X for Single-Supplicant or Multiple-Supplicant Configurations on an EX Series Switch | 426](#)

## Retaining the Authentication Session Based on IP-MAC Address Bindings

### IN THIS SECTION

- [Benefits | 515](#)
- [CLI Configuration | 515](#)
- [RADIUS Server Attributes | 516](#)
- [Verification | 517](#)

MAC RADIUS authentication is often used to permit hosts that are not enabled for 802.1X authentication to access the LAN. End devices such as printers are not very active on the network. If the MAC address associated with an end device ages out due to inactivity, the MAC address is cleared from the Ethernet switching table, and the authentication session ends. This means that other devices will not be able to reach the end device when necessary.

If the MAC address that ages out is associated with an IP address in the DHCP, DHCPv6, or SLAAC snooping table, that MAC-IP address binding will be cleared from the table. This can result in dropped traffic when the DHCP client tries to renew its lease.

You can configure the switching device to check for an IP-MAC address binding in the DHCP, DHCPv6, or SLAAC snooping table before terminating the authentication session when the MAC address ages out. If the MAC address for the end device is bound to an IP address, then it will be retained in the Ethernet switching table, and the authentication session will remain active.

This feature can be configured globally for all authenticated sessions using the CLI, or on a per-session basis using RADIUS attributes.

### Benefits

This feature provides the following benefits:

- Ensures that an end device is reachable by other devices on the network even if the MAC address ages out.
- Prevents traffic from dropping when the end device tries to renew its DHCP lease.

### CLI Configuration

Before you can configure this feature:

- DHCP snooping, DHCPv6 snooping, or SLAAC snooping must be enabled on the device.

- The `no-mac-table-binding` CLI statement must be configured. This disassociates the authentication session table from the Ethernet switching table, so that when a MAC address ages out, the authentication session will be extended until the next reauthentication.

```
[edit]
user@switch# set protocols dot1x authenticator no-mac-table-binding;
```

To configure this feature globally for all authenticated sessions:

- Configure the switching device to check for an IP-MAC address binding in the DHCP, DHCPv6, or SLAAC snooping table before terminating the authentication session when the MAC address ages out using the `ip-mac-session-binding` CLI statement:

```
[edit]
user@switch# set protocols dot1x authenticator ip-mac-session-binding;
```

**NOTE:** You cannot commit the `ip-mac-session-binding` configuration unless the `no-mac-table-binding` is also configured.

## RADIUS Server Attributes

You can configure this feature for a specific authentication session using RADIUS server attributes. RADIUS server attributes are clear-text fields encapsulated in Access-Accept messages sent from the authentication server to the switching device when a supplicant connected to the switch is successfully authenticated.

To retain the authentication session based on IP-MAC address bindings, configure both of the following attribute-value pairs on the RADIUS server:

- Juniper-AV-Pair = "Ip-Mac-Session-Binding"
- Juniper-AV-Pair = "No-Mac-Binding-Reauth"

The Juniper-AV-Pair attribute is a Juniper Networks vendor-specific attribute (VSA). Verify that the Juniper dictionary is loaded on the RADIUS server and includes the Juniper-AV-Pair VSA (ID# 52).

If you need to add the attribute to the dictionary, locate the dictionary file (**juniper.dct**) on the RADIUS server and add the following text to the file:

```
ATTRIBUTE Juniper-AV-Pair      Juniper-VSA(52, string) r
```

**NOTE:** For specific information about configuring your RADIUS server, consult the AAA documentation included with your server.

## Verification

Verify the configuration by issuing the operational mode command `show dot1x interface interface-name detail` and confirm that the `Ip Mac Session Binding` and `No Mac Session Binding` output fields indicate that the feature is enabled.

```
user@switch> show dot1x interface ge-0/0/16.0 detail
```

```
ge-0/0/16.0
Role: Authenticator
Administrative state: Auto
Supplicant mode: Multiple
Number of retries: 3
Quiet period: 60 seconds
Transmit period: 5 seconds
Mac Radius: Enabled
Mac Radius Restrict: Disabled
Mac Radius Authentication Protocol: EAP-MD5
Reauthentication: Disabled
Configured Reauthentication interval: 3600 seconds
Supplicant timeout: 30 seconds
Server timeout: 30 seconds
Maximum EAPOL requests: 2
Guest VLAN member: <not configured>
No Mac Session Binding: Enabled
Ip Mac Session Binding: Enabled
Number of connected supplicants: 1
  Supplicant: abc, 00:00:5E:00:53:00
    Operational state: Authenticated
    Backend Authentication state: Idle
    Authentication method: Mac Radius
    Authenticated VLAN: v100
    Session Reauth interval: 3600 seconds
    Reauthentication due in 0 seconds
    Ip Mac Session Binding: Enabled
    No Mac Binding Reauth: Enabled
```

Eapol-Block: Not In Effect

Clients authenticated with MAC RADIUS should remain authenticated, and MAC address entries in the Ethernet switching table should also be retained after expiration of the MAC timer.

# Central Web Authentication

## IN THIS SECTION

- [Understanding Central Web Authentication | 518](#)
- [Configuring Central Web Authentication | 522](#)

Web authentication provides access to network for users by redirecting the client's Web browser to a central Web authentication server (CWA server), which handles the complete login process. Web authentication can also be used as a fallback authentication method for regular network users who have 802.1X-enabled devices, but fail authentication because of other issues, such as expired network credentials.

## Understanding Central Web Authentication

## IN THIS SECTION

- [Central Web Authentication Process | 519](#)

- [Dynamic Firewall Filters for Central Web Authentication | 521](#)
- [Redirect URL for Central Web Authentication | 521](#)

Web authentication redirects Web browser requests to a login page that requires the user to input a username and password. Upon successful authentication, the user is allowed access to the network. Web authentication is useful for providing network access to temporary users, such as visitors to a corporate site, who try to access the network using devices that are not 802.1X-enabled. Web authentication can also be used as a fallback authentication method for regular network users who have 802.1X-enabled devices, but fail authentication because of other issues, such as expired network credentials.

Web authentication can be done locally on the switch using captive portal, but this requires that the Web portal pages be configured on each switch used as a network access device. Central Web authentication (CWA) provides efficiency and scaling benefits by redirecting the client's Web browser to a central Web authentication server (CWA server), which handles the complete login process.

**NOTE:** CWA is supported with MAC RADIUS authentication only. CWA is not supported with 802.1X authentication.

## Central Web Authentication Process

Central Web authentication is invoked after a host has failed MAC RADIUS authentication. The host can attempt authentication using 802.1X authentication first, but must then attempt MAC RADIUS authentication before attempting central Web authentication. The switch, operating as the authenticator, exchanges RADIUS messages with the authentication, authorization, and accounting (AAA) server. After MAC RADIUS authentication fails, the switch receives an Access-Accept message from the AAA server. This message includes a dynamic firewall filter and a redirect URL for central Web authentication. The switch applies the filter, which allows the host to receive an IP address, and uses the URL to redirect the host to the Web authentication page.

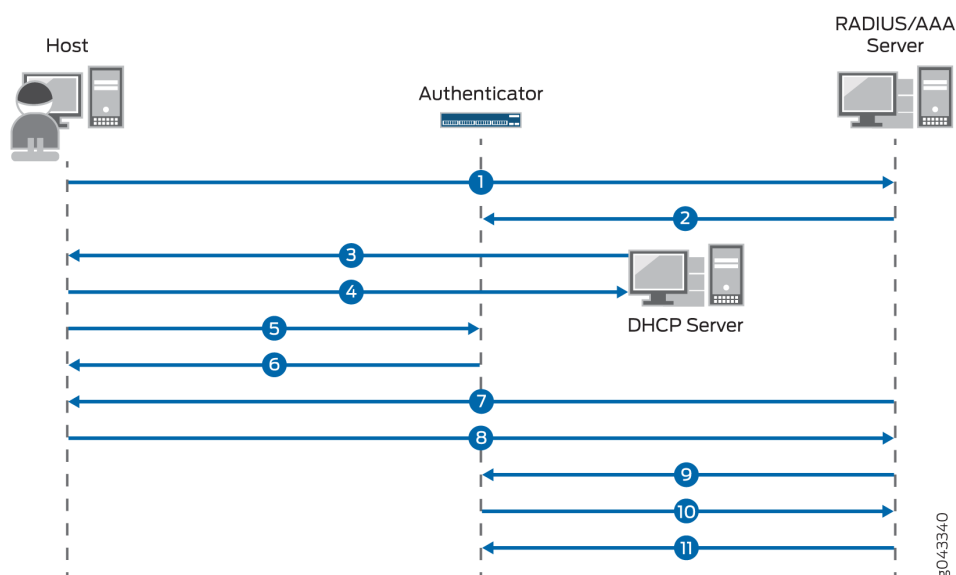

The host is prompted for login credentials and might also be asked to agree to an acceptable use policy. If Web authentication is successful, the AAA server sends a Change of Authorization (CoA) message, which updates the terms of the authorized session in progress. This enables the authenticator to update the filter or VLAN assignment applied to the controlled port, to allow the host to access the LAN.

The sequence of events in central Web authentication is as follows (see [Figure 22 on page 520](#)):

1. A host connected to the switch (authenticator) initiates MAC RADIUS authentication.

2. MAC RADIUS authentication fails. Instead of sending an Access-Reject message to the switch, the AAA server sends an Access-Accept message that includes a dynamic firewall filter and a CWA redirect URL.
3. The host is allowed by the terms of the filter to send DHCP requests.
4. The host receives an IP address and DNS information from the DHCP server. The AAA server initiates a new session that has a unique session ID.
5. The host opens a Web browser.
6. The authenticator sends the CWA redirect URL to the host.
7. The host is redirected to the CWA server and is prompted for login credentials.
8. The host provides the username and password.
9. After successful Web authentication, the AAA server sends a CoA message to update the filter or VLAN assignment applied on the controlled port, allowing the host to access the LAN.
10. The authenticator responds with a CoA-ACK message and sends a MAC RADIUS authentication request to the AAA server.
11. The AAA server matches the session ID to the appropriate access policy and sends an Access-Accept message to authenticate the host.

**Figure 22: Central Web Authentication Process**

## Dynamic Firewall Filters for Central Web Authentication

Central Web authentication uses dynamic firewall filters, which are centrally defined on the AAA server and dynamically applied to supplicants that request authentication through that server. The filter allows the host to get an IP address dynamically using DHCP. You define the filters by using RADIUS attributes, which are included in the Access-Accept messages sent from the server. Filters can be defined using either the Juniper-Switching-Filter attribute, which is a vendor-specific attribute (VSA), or the Filter-ID attribute, which is an IETF RADIUS attribute.

To use the Juniper-Switching-Filter VSA for central Web authentication, you must configure the filter with the correct terms that allow the destination IP address of the CWA server. This configuration is done directly on the AAA server. To use the Filter-ID attribute for central web authentication, enter the value as JNPR\_RSVD\_FILTER\_CWA on the AAA server. The filter terms for this attribute are internally defined for central Web authentication, because of which no additional configuration is required. For more information about configuring dynamic firewall filters for central web authentication, see ["Configuring Central Web Authentication" on page 522](#).

## Redirect URL for Central Web Authentication

In central Web authentication, the authenticator redirects the host's Web browser request to the CWA server by using a redirect URL. After redirection, the CWA server completes the login process. The redirect URL for central web authentication can be configured on the AAA server or on the authenticator. The redirect URL, along with the dynamic firewall filter, must be present to trigger the central web authentication process after the failure of MAC RADIUS authentication.

The redirect URL can be centrally defined on the AAA server by using the Juniper-CWA-Redirect VSA, which is attribute number 50 in the Juniper RADIUS dictionary. The URL is forwarded from the AAA server to the switch in the same RADIUS Access-Accept message that contains the dynamic firewall filter. You can also configure the redirect URL locally on the host interface by using the CLI statement `redirect-url` at the `[edit protocols dot1x authenticator interface interface-name]` hierarchy level. For more information about configuring the redirect URL, see ["Configuring Central Web Authentication" on page 522](#).

## Configuring Central Web Authentication

### IN THIS SECTION

- [Configuring Dynamic Firewall Filters for Central Web Authentication | 522](#)
- [Configuring the Redirect URL for Central Web Authentication | 523](#)
- [Guidelines for Configuring Central Web Authentication | 524](#)

Central Web authentication is a fallback method of authentication in which the host's Web browser is redirected to a central Web authentication (CWA) server. The CWA server provides a web portal where the user can enter a username and password. If these credentials are validated by the CWA server, the user is authenticated and is allowed access to the network.

Central Web authentication is invoked after a host has failed MAC RADIUS authentication. The switch, operating as the authenticator, receives a RADIUS Access-Accept message from the AAA server that includes a dynamic firewall filter and a redirect URL for central Web authentication. The dynamic firewall filter and the redirect URL must both be present for the central Web authentication process to be triggered.

### Configuring Dynamic Firewall Filters for Central Web Authentication

Dynamic firewall filters are used in central Web authentication to enable the host to get an IP address from a DHCP server, which allows the host to access the network. The filters are defined on the AAA server using RADIUS attributes, which are sent to the authenticator in an Access-Accept message. You can define the filter using either the Juniper-Switching-Filter attribute, which is a vendor-specific attribute (VSA), or the Filter-ID attribute, which is an IETF RADIUS attribute.

- To use the Juniper-Switching-Filter VSA for central Web authentication, you must configure the filter terms directly on the AAA server. The filter must include a term to match the destination IP address of the CWA server with the action allow.

For example:

```
001122334455 Auth-Type := EAP, Cleartext-Password := "001122334455"  
    Session-Timeout = "300",  
    Juniper-CWA-Redirect-URL = "https://10.10.10.10",  
    Juniper-Switching-Filter = "Match Destination-ip 10.10.10.10 Action allow, Match ip-  
protocol 17 Action allow, Match Destination-mac 00:01:02:33:44:55 Action deny"
```

**NOTE:** The switch does not resolve the DNS queries for the redirect URL. You must configure the Juniper-Switching-Filter attribute to allow the destination IP address of the CWA server.

- To use the Filter-ID attribute for central Web authentication, enter JNPR\_RSVD\_FILTER\_CWA as the value for the attribute on the AAA server. The filter terms for this attribute are internally defined for central Web authentication, because of which no additional configuration is required.

For example:

```
001122334455 Auth-Type := EAP, Cleartext-Password := "001122334455"
    Session-Timeout = "300",
    Juniper-CWA-Redirect-URL = "https://10.10.10.10",
    Filter-Id = "JNPR_RSVD_FILTER_CWA",
```

For more information about configuring dynamic firewall filters on the AAA server, see the documentation for your AAA server.

## Configuring the Redirect URL for Central Web Authentication

In central Web authentication, the authenticator redirects the host's Web browser request to the CWA server by using a redirect URL. The redirect URL for central Web authentication can be configured on the AAA server or locally on the host interface.

- To configure the redirect URL on the AAA server, use the Juniper-CWA-Redirect VSA, which is attribute number 50 in the Juniper RADIUS dictionary. The URL is forwarded from the AAA server to the switch in the same RADIUS Access-Accept message that contains the dynamic firewall filter.

For example:

```
001122334455 Auth-Type := EAP, Cleartext-Password := "001122334455"
    Session-Timeout = "300",
    Juniper-CWA-Redirect-URL = "https://10.10.10.10",
    Filter-Id = "JNPR_RSVD_FILTER_CWA",
```

**NOTE:** When the special Filter-ID attribute JNPR\_RSVD\_FILTER\_CWA is used for the dynamic firewall filter, the redirect URL must include the IP address of the AAA server, for example, **https://10.10.10.10**.

- To configure the redirect URL locally on the host interface, use the following CLI statement:

```
[edit]
user@switch# set protocols dot1x authenticator interface interface-name redirect-url
```

For example:

```
user@switch# show protocols dot1x
authenticator {
  authentication-name-profile auth1;
  interface {
    ge-0/0/1.0 {
      supplicant single;
      mac-radius;
      redirect-url https://10.10.10.10;
    }
  }
}
```

## Guidelines for Configuring Central Web Authentication

Central Web authentication is triggered after the failure of MAC RADIUS authentication when the redirect URL and dynamic firewall filter are both present. The redirect URL and dynamic firewall filter can be configured in any of the following combinations:

1. The AAA server sends both the CWA redirect URL and dynamic firewall filter to the authenticator. The redirect URL is configured on the AAA server by using the Juniper-CWA-Redirect VSA and the dynamic firewall filter is configured on the AAA server by using the Juniper-Switching-Filter VSA. The filter must be configured to allow the destination IP address of the CWA server in this case.
2. The AAA server sends the dynamic firewall filter to the authenticator and the redirect URL is configured locally on the host port. The redirect URL is configured on the authenticator by using the `redirect-url` CLI statement and the dynamic firewall filter is configured on the AAA server by using the Juniper-Switching-Filter VSA. The filter must be configured to allow the destination IP address of the CWA server in this case.
3. The AAA server sends both the CWA redirect URL and dynamic firewall filter to the authenticator. The redirect URL is configured on the AAA server by using the Juniper-CWA-Redirect VSA and the dynamic firewall filter is configured on the AAA server by using the Filter-ID attribute with the value `JNPR_RSVD_FILTER_CWA`. The redirect URL must contain the IP address of the CWA server in this case.

4. The AAA server sends the dynamic firewall filter to the authenticator and the redirect URL is configured locally on the host port. The redirect URL is configured on the authenticator by using the `redirect-url` CLI statement and the dynamic firewall filter is configured on the AAA server by using the `Filter-ID` attribute with the value `JNPR_RSVD_FILTER_CWA`. The redirect URL must contain the IP address of the CWA server in this case.

**NOTE:** The `redirect-url` command statement is required in the CLI only if the RADIUS server is not sending the redirect URL in the "Juniper-CWA-Redirect" VSA.

# Dynamic VLAN Assignment for Colorless Ports

## IN THIS SECTION

- [Benefits of Dynamic VLAN Assignment for Colorless Ports | 526](#)
- [Overview | 526](#)
- [Egress-VLAN attributes | 526](#)
- [Supplicant mode attributes | 527](#)

Enterprises typically have a variety of users and endpoints, which results in multiple use cases that need to be addressed by their policy infrastructure. The policy infrastructure should enable any supported user device to connect to any port on the access switch and to be authenticated based on the capabilities of the device, the authorization level of the user, or both.

Colorless ports support attaching any device to any switch port because they all have the same initial configuration. The initial configuration places devices on a default VLAN that is used to authenticate and then profile the device or user. The colorless port concept relies on device profiling for VLAN assignment. Based on the type of the device that is connected to the port (AP, IP camera, or printer), the NAC server returns the appropriate VLAN using RADIUS attributes.

## Benefits of Dynamic VLAN Assignment for Colorless Ports

- Allow any device to be connected to any port on an access switch.
- Deploy consistent security policies across the enterprise.

## Overview

When 802.1X authentication is enabled on a port, the switch (known as the authenticator) blocks all traffic to and from the end device (known as a supplicant) until the supplicant's credentials are presented and matched on a NAC server. The NAC server is typically a RADIUS server or a policy manager that acts as a RADIUS server. After the supplicant is authenticated, the switch opens the port to the supplicant.

As part of the authentication process, a RADIUS server can return IETF-defined attributes that provide VLAN assignments to the switch. You can configure a policy manager to pass different RADIUS attributes back to the switch based on the endpoint access policy. The switch dynamically changes the VLAN assigned to the port according to the RADIUS attributes it receives.

## Egress-VLAN attributes

To support both access and trunk ports as colorless ports, the RADIUS attribute must indicate if the frames on the VLAN for this port are to be represented in tagged or untagged format. The following attributes are supported for dynamically assigning a VLAN and also specifying the frame format:

- Egress-VLAN-ID
- Egress-VLAN-Name

The Egress-VLAN-ID or Egress-VLAN-Name attribute contains two parts; the first part indicates if frames on the VLAN for this port are to be represented in tagged or untagged format, the second part is the VLAN name.

For Egress-VLAN-ID:

- 0x31 = tagged
- 0x32 = untagged

For example, the following RADIUS profile includes one tagged and one untagged VLAN:

```
001094001177 Cleartext-Password := "001094001177"
    Tunnel-Type = VLAN,
    Tunnel-Medium-Type = IEEE-802,
    Egress-VLANID += 0x3100033,
    Egress-VLANID += 0x3200034,
```

For Egress-VLAN-Name:

- 1 = tagged
- 2 = untagged

In the example below, VLAN 1vlan-2 is tagged, and VLAN 2vlan-3 is untagged:

```
001094001144 Cleartext-Password := "001094001144"
    Tunnel-Type = VLAN,
    Tunnel-Medium-Type = IEEE-802,
    Egress-VLAN-Name += 1vlan-2,
    Egress-VLAN-Name += 2vlan-3,
```

**NOTE:** It is mandatory to include the Tunnel-Type and Tunnel-Medium-Type attributes in the profile with Egress-VLAN-ID or Egress-VLAN-Name.

When the switch receives a VLAN assignment with "Egress-VLAN-ID," it checks if the VLAN is already present in the system. If not, it creates the dynamic VLAN. If the Egress-VLAN-Name is used, the VLAN should be already in the system.

## Supplicant mode attributes

RADIUS attributes can also be used to change the supplicant mode for 802.1X authentication. Using a Juniper Networks vendor-specific attribute (VSA), you can set the supplicant mode to either single or single-secure:

- Juniper-AV-Pair = Supplicant-Mode-Single
- Juniper-AV-Pair = Supplicant-Mode-Single-Secure

When these attributes are received from the NAC server, the configured supplicant mode will be changed to match the VSA value after the session is authenticated. When the session ends, the supplicant mode reverts to the mode that was configured on the system before receiving the VSA from the NAC server.

## VoIP on EX Series Switches

- [Example: Configuring VoIP on an EX Series Switch with ELS Support Without Including 802.1X Authentication | 581](#)

You can configure voice over IP (VoIP) on an EX Series switch to support IP telephones. When you use VoIP, you can connect IP telephones to the switch and configure IEEE 802.1X authentication for 802.1X-compatible IP telephones. For more information, read this topic.

## Understanding 802.1X and VoIP on EX Series Switches

### IN THIS SECTION

- [Multi Domain 802.1X Authentication | 530](#)

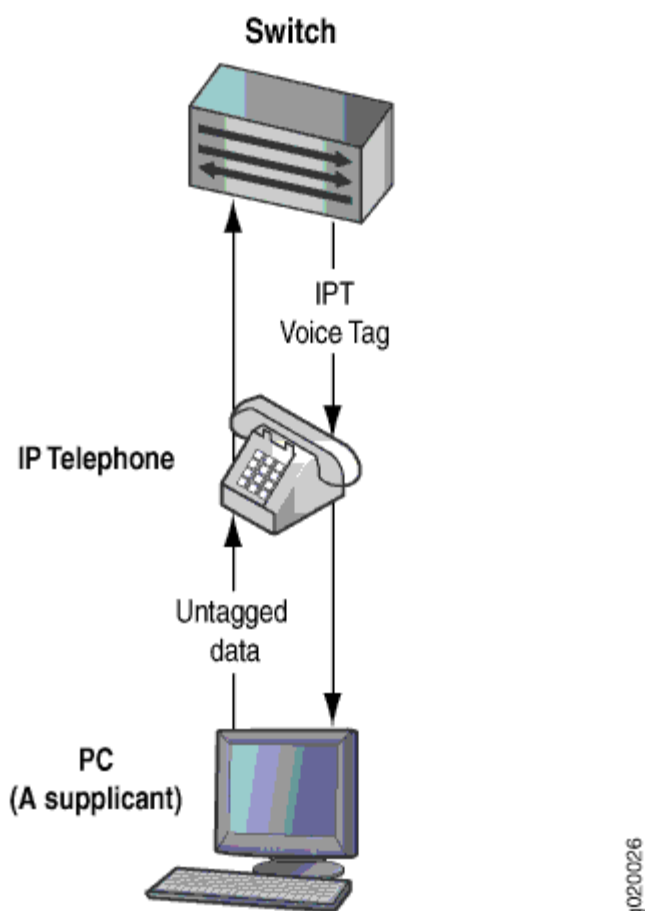

When you use VoIP, you can connect IP telephones to the switch and configure IEEE 802.1X authentication for 802.1X-compatible IP telephones. The 802.1X authentication provides network edge security, protecting Ethernet LANs from unauthorized user access.

VoIP is a protocol used for the transmission of voice through packet-switched networks. VoIP transmits voice calls by using a network connection instead of an analog phone line.

When VoIP is used with 802.1X, the RADIUS server authenticates the phone, and Link Layer Discovery Protocol–Media Endpoint Discovery (LLDP-MED) provides the class-of-service (CoS) parameters to the phone.

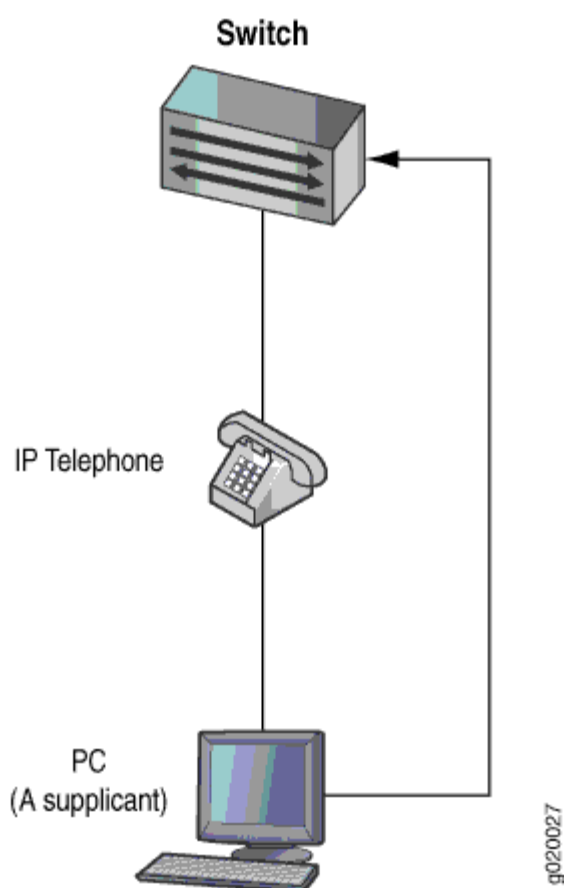

You can configure 802.1X authentication to work with VoIP in multiple supplicant or single supplicant mode. In *multiple supplicant* mode, the 802.1X process allows multiple supplicants to connect to the interface. Each supplicant is authenticated individually. For an example of a VoIP multiple supplicant topology, see [Figure 23 on page 529](#).

**Figure 23: VoIP Multiple Supplicant Topology**

If an 802.1X-compatible IP telephone does not have an 802.1X host but has another 802.1X-compatible device connected to its data port, you can connect the phone to an interface in single supplicant mode. In *single supplicant* mode, the 802.1X process authenticates only the first supplicant. All other supplicants who connect later to the interface are allowed full access without any further authentication. They effectively “piggyback” on the first supplicant’s authentication. For an example of a VoIP single supplicant topology, see [Figure 24 on page 530](#).

**Figure 24: VoIP Single Supplicant Topology**

If an IP telephone does not support 802.1X, you can configure VoIP to bypass 802.1X and LLDP-MED and have the packets forwarded to a VoIP VLAN.

## Multi Domain 802.1X Authentication

Multi-domain 802.1X authentication is an extension of multiple supplicant mode that allows one default VoIP device and multiple data devices to authenticate on a single port. Multi-domain 802.1X authentication provides enhanced security over multiple supplicant mode by restricting the number of

authenticated data and VoIP sessions on the port. In multiple supplicant mode, any number of VoIP or data sessions can be authenticated; the number of sessions can be restricted using MAC limiting, but there is no way to apply the limit specifically to either data or VoIP sessions.

With multi-domain 802.1X authentication, the single port is divided into two domains; one is the data domain and the other is the voice domain. Multi-domain 802.1X authentication maintains separate session counts based on the domain. You can configure the maximum number of authenticated data sessions allowed on the port. The number of VoIP sessions is not configurable; only one authenticated VoIP session is allowed on the port.

If a new client attempts to authenticate on the interface after the maximum session count has been reached, the default action is to drop the packet and generate an error log message. You can also configure the action to shut down the interface. The port can be manually recovered from the down state by issuing the `clear dot1x recovery-timeout` command, or by can recover automatically after a configured recovery timeout period.

Multi-domain authentication does not enforce the order of device authentication. However, for the best results, the VoIP device should be authenticated before a data device on a multi domain 802.1X-enabled port. Multi-domain authentication is supported only in multiple supplicant mode.

## SEE ALSO

[Understanding LLDP and LLDP-MED on EX Series Switches](#) | 690

## Example: Setting Up VoIP with 802.1X and LLDP-MED on an EX Series Switch

### IN THIS SECTION

- [Requirements](#) | 532
- [Overview and Topology](#) | 533
- [Configuration](#) | 536
- [Verification](#) | 540

You can configure voice over IP (VoIP) on an EX Series switch to support IP telephones. The Link Layer Discovery Protocol–Media Endpoint Discovery (LLDP-MED) protocol forwards VoIP parameters from

the switch to the phone. You also configure 802.1X authentication to allow the telephone access to the LAN. Authentication is done through a backend RADIUS server.

This example describes how to configure VoIP on an EX Series switch to support an Avaya IP phone, as well as the LLDP-MED protocol and 802.1X authentication:

**NOTE:** If your switch runs Junos OS for EX Series switches with support for the Enhanced Layer 2 Software (ELS) configuration style, see ["Example: Setting Up VoIP with 802.1X and LLDP-MED on an EX Series Switch with ELS Support"](#) on page 568. For ELS details, see *Using the Enhanced Layer 2 Software CLI*.

## Requirements

This example uses the following hardware and software components:

- Junos OS Release 9.1 or later for EX Series switches
- One EX Series switch acting as an authenticator port access entity (PAE). The interfaces on the authenticator PAE form a control gate that blocks all traffic to and from supplicants until they are authenticated.
- An Avaya 9620 IP telephone that supports LLDP-MED and 802.1X

Before you configure VoIP, be sure you have:

- Installed your EX Series switch. See [Installing and Connecting an EX3200 Switch](#).
- Performed the initial switch configuration. See *Connecting and Configuring an EX Series Switch (J-Web Procedure)*.
- Performed basic bridging and VLAN configuration on the switch. See *Example: Setting Up Basic Bridging and a VLAN for an EX Series Switch*.
- Configured the RADIUS server for 802.1X authentication and set up the access profile. See ["Example: Connecting a RADIUS Server for 802.1X to an EX Series Switch"](#) on page 380.
- (Optional) Configured interface **ge-0/0/2** for Power over Ethernet (PoE). The PoE configuration is not necessary if the VoIP supplicant is using a power adapter. For information about configuring PoE, see *Configuring PoE Interfaces on EX Series Switches*.

**NOTE:** If the IP address isn't configured on the Avaya IP phone, the phone exchanges LLDP-MED information to get the VLAN ID for the voice VLAN. You must configure the `voip` statement on the interface to designate the interface as a VoIP interface and allow the switch to forward the

VLAN name and VLAN ID for the voice VLAN to the IP telephone. The IP telephone then uses the voice VLAN (that is, it references the voice VLAN's ID) to send a DHCP discover request and exchange information with the DHCP server (voice gateway).

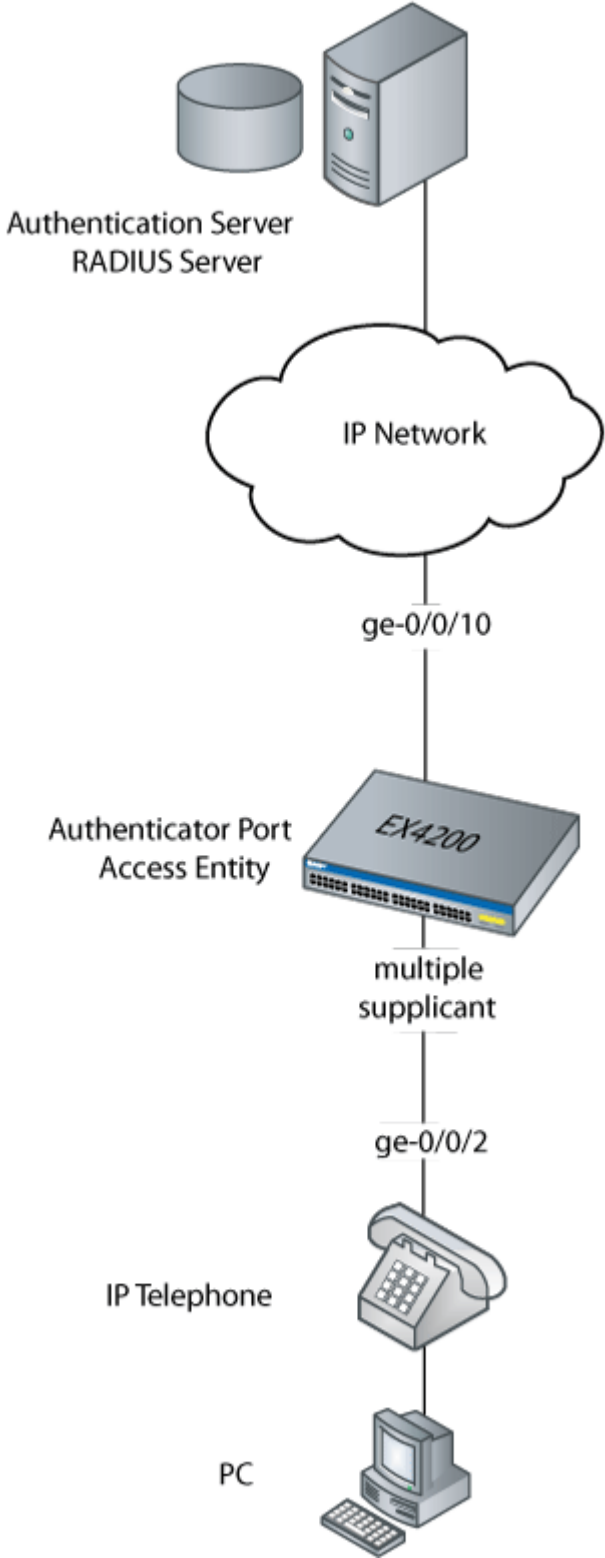

## Overview and Topology

Instead of using a regular telephone, you connect an IP telephone directly to the switch. An IP phone has all the hardware and software needed to handle VoIP. You also can power an IP telephone by connecting it to one of the Power over Ethernet (PoE) interfaces on the switch.

In this example, the access interface **ge-0/0/2** on the EX4200 switch is connected to an Avaya 9620 IP telephone. Avaya phones have a built-in bridge that allows you to connect a desktop PC to the phone,

so the desktop and phone in a single office require only one interface on the switch. The EX Series switch is connected to a RADIUS server on interface **ge-0/0/10** (see [Figure 25 on page 535](#)).

Figure 25: VoIP Topology

In this example, you configure VoIP parameters and specify the forwarding class **assured-forward** for voice traffic to provide the highest quality of service.

Table 33 on page 536 describes the components used in this VoIP configuration example.

Table 33: Components of the VoIP Configuration Topology

| Property                                                                                                            | Settings                                                                               |
|---------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| Switch hardware                                                                                                     | EX4200 switch                                                                          |
| VLAN names                                                                                                          | <b>data-vlan</b><br><b>voice-vlan</b>                                                  |
| Connection to Avaya phone—with integrated hub, to connect phone and desktop PC to a single interface (requires PoE) | <b>ge-0/0/2</b>                                                                        |
| One RADIUS server                                                                                                   | Provides backend database connected to the switch through interface <b>ge-0/0/10</b> . |

As well as configuring a VoIP for interface **ge-0/0/2**, you configure:

- 802.1X authentication. Authentication is set to **multiple** supplicant to support more than one supplicant's access to the LAN through interface **ge-0/0/2**.
- LLDP-MED protocol information. The switch uses LLDP-MED to forward VoIP parameters to the phone. Using LLDP-MED ensures that voice traffic gets tagged and prioritized with the correct values at the source itself. For example, 802.1p class of service and 802.1Q tag information can be sent to the IP telephone.

**NOTE:** A PoE configuration is not necessary if an IP telephone is using a power adapter.

Configuration

IN THIS SECTION

- Procedure | 537

To configure VoIP, LLDP-MED, and 802.1X authentication:

## Procedure

### CLI Quick Configuration

To quickly configure VoIP, LLDP-MED, and 802.1X, copy the following commands and paste them into the switch terminal window:

```
[edit]
set vlans data-vlan vlan-id 77
set vlans voice-vlan vlan-id 99
set vlans data-vlan interface ge-0/0/2.0
set interfaces ge-0/0/2 unit 0 family ethernet-switching vlan members data-vlan
set interfaces ge-0/0/2 unit 0 family ethernet-switching port-mode access
set ethernet-switching-options voip interface ge-0/0/2.0 vlan voice-vlan
set ethernet-switching-options voip interface ge-0/0/2.0 forwarding-class assured-forwarding
set protocols lldp-med interface ge-0/0/2.0
set protocols dot1x authenticator interface ge-0/0/2.0 supplicant multiple
```

### Step-by-Step Procedure

To configure VoIP with LLDP-MED and 802.1X:

1. Configure the VLANs for voice and data:

```
[edit vlans]
user@switch# set data-vlan vlan-id 77
user@switch# set voice-vlan vlan-id 99
```

2. Associate the VLAN **data-vlan** with the interface:

```
[edit vlans]
user@switch# set data-vlan interface ge-0/0/2.0
```

3. Configure the interface as an access interface, configure support for Ethernet switching, and add the **data-vlan** VLAN:

```
[edit interfaces]
user@switch# set ge-0/0/2 unit 0 family ethernet-switching vlan members data-vlan
user@switch# set ge-0/0/2 unit 0 family ethernet-switching port-mode access
```

4. Configure VoIP on the interface and specify the **assured-forwarding** forwarding class to provide the most dependable class of service:

```
[edit ethernet-switching-options]
user@switch# set voip interface ge-0/0/2.0 vlan voice-vlan
user@switch# set voip interface ge-0/0/2.0 forwarding-class assured-forwarding
```

5. Configure LLDP-MED protocol support:

```
[edit protocols]
user@switch# set lldp-med interface ge-0/0/2.0
```

6. To authenticate an IP phone and a PC connected to the IP phone on the interface, configure 802.1X authentication support and specify **multiple** supplicant mode:

**NOTE:** If you do not want to authenticate any device, skip the 802.1X configuration on this interface.

```
[edit protocols]
user@switch# set dot1x authenticator interface ge-0/0/2.0 supplicant
multiple
```

## Results

Display the results of the configuration:

```
[edit]
user@switch# show configuration
```

```

interfaces {
    ge-0/0/2 {
        unit 0 {
            family ethernet-switching {
                port-mode access;
                vlan {
                    members data-vlan;
                }
            }
        }
    }
}

protocols {
    lldp-med {
        interface ge-0/0/2.0;
    }
    dot1x {
        authenticator {
            interface {
                ge-0/0/2.0 {
                    supplicant multiple;
                }
            }
        }
    }
}

vlans {
    data-vlan {

        interface {
            ge-0/0/2.0;
        }
    }
    voice-vlan {
        vlan-id 99;
    }
}

ethernet-switching options {
    voip {
        interface ge-0/0/2.0 {
            vlan voice-vlan;
            forwarding-class assured-forwarding;
        }
    }
}

```

```
}  
}
```

Verification

IN THIS SECTION

- Verifying LLDP-MED Configuration | 540
- Verifying 802.1X Authentication for IP Phone and Desktop PC | 541
- Verifying the VLAN Association with the Interface | 542

To confirm that the configuration is working properly, perform these tasks:

Verifying LLDP-MED Configuration

Purpose

Verify that LLDP-MED is enabled on the interface.

Action

```
user@switch> show lldp detail  
LLDP : Enabled  
Advertisement interval : 30 Second(s)  
Transmit delay : 2 Second(s)  
Hold timer : 2 Second(s)  
Config Trap Interval : 300 Second(s)  
Connection Hold timer : 60 Second(s)  
  
LLDP MED : Enabled  
MED fast start count : 3 Packet(s)  
  
Interface LLDP LLDP-MED Neighbor count  
all Enabled - 0  
ge-0/0/2.0 - Enabled 0
```

| Interface   | VLAN-id | VLAN-name     |
|-------------|---------|---------------|
| ge-0/0/0.0  | 0       | default       |
| ge-0/0/1.0  | 0       | employee-vlan |
| ge-0/0/2.0  | 0       | data-vlan     |
| ge-0/0/2.0  | 99      | voice-vlan    |
| ge-0/0/3.0  | 0       | employee-vlan |
| ge-0/0/8.0  | 0       | employee-vlan |
| ge-0/0/10.0 | 0       | default       |
| ge-0/0/11.0 | 20      | employee-vlan |
| ge-0/0/23.0 | 0       | default       |

LLDP basic TLVs supported:

Chassis identifier, Port identifier, Port description, System name, System description, System capabilities, Management address.

LLDP 802 TLVs supported:

Power via MDI, Link aggregation, Maximum frame size, Port VLAN tag, Port VLAN name.

LLDP MED TLVs supported:

LLDP MED capabilities, Network policy, Endpoint location, Extended power Via MDI.

## Meaning

The `show lldp detail` output shows that both LLDP and LLDP-MED are configured on the **ge-0/0/2.0** interface. The end of the output shows the list of supported LLDP basic TLVs, 802.3 TLVs, and LLDP-MED TLVs that are supported.

## Verifying 802.1X Authentication for IP Phone and Desktop PC

### Purpose

Display the 802.1X configuration to confirm that the VoIP interface has access to the LAN.

### Action

```
user@switch> show dot1x interface ge/0/0/2.0 detail
ge-0/0/2.0
  Role: Authenticator
```

```

Administrative state: Auto
Supplicant mode: Multiple
Number of retries: 3
Quiet period: 60 seconds
Transmit period: 30 seconds
Mac Radius: Disabled
Mac Radius Restrict: Disabled
Reauthentication: Enabled
Configured Reauthentication interval: 3600 seconds
Supplicant timeout: 30 seconds
Server timeout: 30 seconds
Maximum EAPOL requests: 2
Guest VLAN member: <not configured>
Number of connected supplicants: 1
  Supplicant: user101, 00:04:0f:fd:ac:fe
    Operational state: Authenticated
    Authentication method: Radius
    Authenticated VLAN: vo11
    Dynamic Filter: match source-dot1q-tag 10 action deny
    Session Reauth interval: 60 seconds
    Reauthentication due in 50 seconds

```

## Meaning

The field **Role** shows that the **ge-0/0/2.0** interface is in the authenticator state. The **Supplicant** field shows that the interface is configured in multiple supplicant mode, permitting multiple supplicants to be authenticated on this interface. The MAC addresses of the supplicants currently connected are displayed at the bottom of the output.

## Verifying the VLAN Association with the Interface

### Purpose

Display the interface state and VLAN membership.

### Action

```

user@switch> show ethernet-switching interfaces
Ethernet-switching table: 0 entries, 0 learned

user@switch> show ethernet-switching interfaces

```

| Interface   | State | VLAN members  | Blocking  |
|-------------|-------|---------------|-----------|
| ge-0/0/0.0  | down  | default       | unblocked |
| ge-0/0/1.0  | down  | employee-vlan | unblocked |
| ge-0/0/5.0  | down  | employee-vlan | unblocked |
| ge-0/0/3.0  | down  | employee-vlan | unblocked |
| ge-0/0/8.0  | down  | employee-vlan | unblocked |
| ge-0/0/10.0 | down  | default       | unblocked |
| ge-0/0/11.0 | down  | employee-vlan | unblocked |
| ge-0/0/23.0 | down  | default       | unblocked |
| ge-0/0/2.0  | up    | voice-vlan    | unblocked |
|             |       | data-vlan     | unblocked |

## Meaning

The field **VLAN members** shows that the **ge-0/0/2.0** interface supports both the **data-vlan** VLAN and **voice-vlan** VLAN. The **State** field shows that the interface is up.

## Example: Configuring VoIP on an EX Series Switch Without Including LLDP-MED Support

### IN THIS SECTION

● [Requirements | 544](#)

● [Overview | 544](#)

● [Configuring VoIP Without LLDP-MED by Using a Voice VLAN on an Access Port | 545](#)

- [Configuring VoIP Without LLDP-MED by Using a Trunk Port with Native VLAN Option | 548](#)
- [Verification | 550](#)

You can configure voice over IP (VoIP) on an EX Series switch to support IP telephones. The Link Layer Discovery Protocol–Media Endpoint Discovery (LLDP-MED) protocol is sometimes used with IP phones to forward VoIP parameters from the switch to the phone. However, not all IP phones support LLDP-MED.

This example describes how to configure VoIP on an EX Series switch without using LLDP-MED:

## Requirements

This example uses the following hardware and software components:

- One EX Series switch with support for ELS acting as an authenticator port access entity (PAE). The interfaces on the authenticator PAE form a control gate that blocks all traffic to and from supplicants until they are authenticated.
- An IP phone that does not support LLDP-MED.
- Junos OS Release 13.2X50 or later for EX Series switches.

Before you configure VoIP, be sure you have:

- Performed basic bridging and VLAN configuration on the switch. See *Example: Setting Up Basic Bridging and a VLAN for an EX Series Switch with ELS Support*.
- Configured the IP phone as a member of the voice VLAN.
- (Optional) Configured interface ge-0/0/2 for Power over Ethernet (PoE). The PoE configuration is not necessary if the VoIP supplicant is using a power adapter. See *Configuring PoE Interfaces on EX Series Switches*.

## Overview

### IN THIS SECTION

- [Topology | 545](#)

Instead of using a regular telephone, you connect an IP telephone directly to the switch. An IP phone has all the hardware and software needed to handle VoIP. You can also power an IP telephone by connecting it to one of the Power over Ethernet (PoE) interfaces on the switch.

EX Series switches can accommodate an IP telephone and end host connected to a single switch port. In such a scenario, voice and data traffic must be separated into different broadcast domains, or VLANs. One method for accomplishing this is by configuring a voice VLAN, which enables access ports to accept untagged data traffic as well as tagged voice traffic from IP phones, and associate each type of traffic with separate and distinct VLANs. Voice traffic (tagged) can then be treated differently, generally with a higher priority than data traffic (untagged).

The voice VLAN delivers the greatest benefit when used with IP phones that support LLDP-MED, but it is flexible enough that IP phones that do not support LLDP-MED can also use it effectively. However, in the absence of LLDP-MED, the voice VLAN ID must be set manually on the IP phone because LLDP-MED is not available to accomplish this dynamically. For information about setting up a voice VLAN for IP phones that support LLDP-MED, see ["Example: Setting Up VoIP with 802.1X and LLDP-MED on an EX Series Switch with ELS Support" on page 568](#).

Another method to separate voice (tagged) and data (untagged) traffic into different VLANs is to use a trunk port with the native VLAN ID option. The trunk port is added as a member of the voice VLAN, and processes only tagged voice traffic from that VLAN. The trunk port must also be configured with the native VLAN ID for the data VLAN so that it can process untagged data traffic from the data VLAN. This configuration also requires that the voice VLAN ID be set manually on the IP phone.

This example illustrates both methods. In this example, the interface ge-0/0/2 on the switch is connected to a non-LLDP-MED IP phone.

**NOTE:** The implementation of a voice VLAN on an IP telephone is vendor-specific. Consult the documentation that came with your IP telephone for instructions on configuring a voice VLAN. For example, on an Avaya phone, you can ensure that the phone gets the correct VoIP VLAN ID even in the absence of LLDP-MED by enabling DHCP option 176.

## Topology

## Configuring VoIP Without LLDP-MED by Using a Voice VLAN on an Access Port

### IN THIS SECTION

- [Procedure | 546](#)

## Procedure

### CLI Quick Configuration

To quickly configure VoIP, copy the following commands and paste them into the switch terminal window:

```
[edit]
set vlans data-vlan vlan-id 77
set vlans voice-vlan vlan-id 99
set vlans data-vlan switch-options interface ge-0/0/2.0
set interfaces ge-0/0/2 unit 0 family ethernet-switching port-mode access
set interfaces ge-0/0/2 unit 0 family ethernet-switching vlan members data-vlan
set switch-options voip interface ge-0/0/2.0 vlan voice-vlan
set switch-options voip interface ge-0/0/2.0 forwarding-class assured-forwarding
```

### Step-by-Step Procedure

1. Configure two VLANs: one for data traffic and one for voice traffic:

```
[edit vlans]
user@switch# set data-vlan vlan-id 77
user@switch# set voice-vlan vlan-id 99
```

**NOTE:** The voice VLAN ID must be set manually on the IP phone.

2. Associate the VLAN data-vlan with the interface ge-0/0/2:

```
[edit vlans]
user@switch# set data-vlan switch-options interface ge-0/0/2.0
```

3. Configure the interface ge-0/0/2 as an access port belonging to the data VLAN:

```
[edit interfaces]
user@switch# set ge-0/0/2 unit 0 family ethernet-switching port-mode access
user@switch# set ge-0/0/2 unit 0 family ethernet-switching vlan member data-vlan
```

4. Configure VoIP on the interface ge-0/0/2 and add this interface to the voice VLAN:

```
[edit switch-options]
user@switch# set voip interface ge-0/0/2.0 vlan voice-vlan
```

5. Specify the assured-forwarding forwarding class to provide the most dependable class of service:

```
[edit switch-options]
user@switch# set voip interface ge-0/0/2.0 forwarding-class assured-forwarding
```

## Results

Display the results of the configuration:

```
[edit]
user@switch> show configuration
interfaces {
  ge-0/0/2 {
    unit 0 {
      family ethernet-switching {
        port-mode access;
        vlan {
          members data-vlan;
        }
      }
    }
  }
}
vlans {
  data-vlan {
    vlan-id 77;
    interface {
      ge-0/0/2.0;
    }
  }
  voice-vlan {
    vlan-id 99;
  }
}
ethernet-switching options {
```

```

    voip {
        interface ge-0/0/2.0 {
            vlan voice-vlan;
            forwarding-class assured-forwarding;
        }
    }
}

```

## Configuring VoIP Without LLDP-MED by Using a Trunk Port with Native VLAN Option

### IN THIS SECTION

- [Procedure | 548](#)

### Procedure

#### CLI Quick Configuration

To quickly configure VoIP, copy the following commands and paste them into the switch terminal window:

```

[edit]
set vlans data-vlan vlan-id 77
set vlans voice-vlan vlan-id 99
set interfaces ge-0/0/2 unit 0 family ethernet-switching port-mode trunk

set interfaces ge-0/0/2 unit 0 family ethernet-switching vlan members voice-vlan
set interfaces ge-0/0/2 unit 0 family ethernet-switching native-vlan-id data-vlan

```

## Step-by-Step Procedure

1. Configure two VLANs: one for data traffic and one for voice traffic:

```
[edit vlans]
user@switch# set data-vlan vlan-id 77
user@switch# set voice-vlan vlan-id 99
```

**NOTE:** The voice VLAN ID must be set manually on the IP phone.

2. Configure interface ge-0/0/2 as a trunk port that includes only the voice VLAN:

```
[edit interfaces]
user@switch# set ge-0/0/2 unit 0 family ethernet-switching port-mode trunk
user@switch# set ge-0/0/2 unit 0 family ethernet-switching vlan member voice-vlan
```

3. Configure the native VLAN ID for the data VLAN on the trunk port:

```
[edit interfaces]
user@switch# set ge-0/0/2 unit 0 family ethernet-switching native-vlan-id data-vlan
```

## Results

Display the results of the configuration:

```
[edit]
user@switch> show configuration
interfaces {
  ge-0/0/2 {
    unit 0 {
      family ethernet-switching {
        port-mode trunk;
        vlan {
          members voice-vlan;
        }
        native-vlan-id data-vlan;
      }
    }
  }
}
```

```

    }
  }
}
vlans {
  data-vlan {
    vlan-id 77;
  }
  voice-vlan {
    vlan-id 99;
  }
}
}

```

## Verification

### IN THIS SECTION

- [Verifying the VLAN Association With the Interface | 550](#)

To confirm that the configuration is working properly, perform the following task:

### Verifying the VLAN Association With the Interface

#### Purpose

Display the interface state and VLAN membership.

#### Action

```

user@switch> show ethernet-switching
interfaces
Ethernet-switching table: 0 entries, 0 learned

user@switch> show ethernet-switching interfaces
Interface   State   VLAN members   Blocking
ge-0/0/0.0  down   default        unblocked
ge-0/0/1.0  down   employee-vlan   unblocked
ge-0/0/5.0  down   employee-vlan   unblocked
ge-0/0/3.0  down   employee-vlan   unblocked

```

|             |      |               |           |
|-------------|------|---------------|-----------|
| ge-0/0/8.0  | down | employee-vlan | unblocked |
| ge-0/0/10.0 | down | default       | unblocked |
| ge-0/0/11.0 | down | employee-vlan | unblocked |
| ge-0/0/23.0 | down | default       | unblocked |
| ge-0/0/2.0  | up   | voice-vlan    | unblocked |
|             |      | data-vlan     | unblocked |

## Meaning

The field `VLAN members` shows that the `ge-0/0/2.0` interface supports both the data VLAN, `data-vlan`, and the voice VLAN, `voice-vlan`. The `State` field shows that the interface is up.

## Example: Configuring VoIP on an EX Series Switch Without Including LLDP-MED Support

### IN THIS SECTION

- [Requirements](#) | 552
- [Overview](#) | 552
- [Configuring VoIP Without LLDP-MED by Using a Voice VLAN on an Access Port](#) | 553
- [Configuring VoIP Without LLDP-MED by Using a Trunk Port with Native VLAN Option](#) | 556
- [Verification](#) | 558

You can configure voice over IP (VoIP) on an EX Series switch to support IP telephones. The Link Layer Discovery Protocol–Media Endpoint Discovery (LLDP-MED) protocol is sometimes used with IP phones to forward VoIP parameters from the switch to the phone. However, not all IP phones support LLDP-MED.

This example describes how to configure VoIP on an EX Series switch without using LLDP-MED:

## Requirements

This example uses the following hardware and software components:

- One EX4200 switch acting as an authenticator port access entity (PAE). The interfaces on the authenticator PAE form a control gate that blocks all traffic to and from supplicants until they are authenticated.
- An IP phone that does not support LLDP-MED.
- Junos OS Release 9.1 or later for EX Series switches.

Before you configure VoIP, be sure you have:

- Performed basic bridging and VLAN configuration on the switch. See *Example: Setting Up Basic Bridging and a VLAN for an EX Series Switch*.
- Configured the IP phone as a member of the voice VLAN.
- (Optional) Configured interface ge-0/0/2 for Power over Ethernet (PoE). The PoE configuration is not necessary if the VoIP supplicant is using a power adapter. See *Configuring PoE Interfaces on EX Series Switches*.

## Overview

### IN THIS SECTION

- [Topology | 553](#)

Instead of using a regular telephone, you connect an IP telephone directly to the switch. An IP phone has all the hardware and software needed to handle VoIP. You can also power an IP telephone by connecting it to one of the Power over Ethernet (PoE) interfaces on the switch.

EX Series switches can accommodate an IP telephone and end host connected to a single switch port. In such a scenario, voice and data traffic must be separated into different broadcast domains, or VLANs. One method for accomplishing this is by configuring a voice VLAN, which enables access ports to accept untagged data traffic as well as tagged voice traffic from IP phones, and associate each type of traffic with separate and distinct VLANs. Voice traffic (tagged) can then be treated differently, generally with a higher priority than data traffic (untagged).

The voice VLAN delivers the greatest benefit when used with IP phones that support LLDP-MED, but it is flexible enough that IP phones that do not support LLDP-MED can also use it effectively. However, in the absence of LLDP-MED, the voice VLAN ID must be set manually on the IP phone because LLDP-

MED is not available to accomplish this dynamically. For information about setting up a voice VLAN for IP phones that support LLDP-MED, see ["Example: Setting Up VoIP with 802.1X and LLDP-MED on an EX Series Switch" on page 531](#).

Another method to separate voice (tagged) and data (untagged) traffic into different VLANs is to use a trunk port with the native VLAN ID option. The trunk port is added as a member of the voice VLAN, and processes only tagged voice traffic from that VLAN. The trunk port must also be configured with the native VLAN ID for the data VLAN so that it can process untagged data traffic from the data VLAN. This configuration also requires that the voice VLAN ID be set manually on the IP phone.

This example illustrates both methods. In this example, the interface ge-0/0/2 on the EX4200 switch is connected to a non-LLDP-MED IP phone.

**NOTE:** The implementation of a voice VLAN on an IP telephone is vendor-specific. Consult the documentation that came with your IP telephone for instructions on configuring a voice VLAN. For example, on an Avaya phone, you can ensure that the phone gets the correct VoIP VLAN ID even in the absence of LLDP-MED by enabling DHCP option 176.

## Topology

## Configuring VoIP Without LLDP-MED by Using a Voice VLAN on an Access Port

### IN THIS SECTION

- [Procedure | 553](#)

## Procedure

### CLI Quick Configuration

To quickly configure VoIP, copy the following commands and paste them into the switch terminal window:

```
[edit]
set vlans data-vlan vlan-id 77
set vlans voice-vlan vlan-id 99
```

```

set vlans data-vlan interface ge-0/0/2.0
set interfaces ge-0/0/2 unit 0 family ethernet-switching port-mode access
set interfaces ge-0/0/2 unit 0 family ethernet-switching vlan members data-vlan
set ethernet-switching-options voip interface ge-0/0/2.0 vlan voice-vlan

```

## Step-by-Step Procedure

1. Configure two VLANs: one for data traffic and one for voice traffic:

```

[edit vlans]
user@switch# set data-vlan vlan-id 77
user@switch# set voice-vlan vlan-id 99

```

**NOTE:** The voice VLAN ID must be set manually on the IP phone.

2. Configure the VLAN **data-vlan** on the interface ge-0/0/2:

```

[edit vlans]
user@switch# set data-vlan interface ge-0/0/2.0

```

3. Configure the interface ge-0/0/2 as an access port belonging to the data VLAN:

```

[edit interfaces]
user@switch# set ge-0/0/2 unit 0 family ethernet-switching port-mode access
user@switch# set ge-0/0/2 unit 0 family ethernet-switching vlan member data-vlan

```

4. Configure VoIP on the interface ge-0/0/2 and add this interface to the voice VLAN:

```

[edit ethernet-switching-options]
user@switch# set voip interface ge-0/0/2.0 vlan voice-vlan

```

## Results

Display the results of the configuration:

```
[edit]
user@switch> show configuration
interfaces {
  ge-0/0/2 {
    unit 0 {
      family ethernet-switching {
        port-mode access;
        vlan {
          members data-vlan;
        }
      }
    }
  }
}
vlands {
  data-vlan {
    vlan-id 77;
    interface {
      ge-0/0/2.0;
    }
  }
  voice-vlan {
    vlan-id 99;
  }
}
ethernet-switching options {
  voip {
    interface ge-0/0/2.0 {
      vlan voice-vlan;
    }
  }
}
```

## Configuring VoIP Without LLDP-MED by Using a Trunk Port with Native VLAN Option

### IN THIS SECTION

- [Procedure | 556](#)

### Procedure

#### CLI Quick Configuration

To quickly configure VoIP, copy the following commands and paste them into the switch terminal window:

```
[edit]
set vlans data-vlan vlan-id 77
set vlans voice-vlan vlan-id 99
set interfaces ge-0/0/2 unit 0 family ethernet-switching port-mode trunk

set interfaces ge-0/0/2 unit 0 family ethernet-switching vlan members voice-vlan
set interfaces ge-0/0/2 unit 0 family ethernet-switching native-vlan-id data-vlan
```

#### Step-by-Step Procedure

1. Configure two VLANs: one for data traffic and one for voice traffic:

```
[edit vlans]
user@switch# set data-vlan vlan-id 77
user@switch# set voice-vlan vlan-id 99
```

**NOTE:** The voice VLAN ID must be set manually on the IP phone.

2. Configure interface ge-0/0/2 as a trunk port that includes only the voice VLAN:

```
[edit interfaces]
user@switch# set ge-0/0/2 unit 0 family ethernet-switching port-mode trunk
user@switch# set ge-0/0/2 unit 0 family ethernet-switching vlan member voice-vlan
```

3. Configure the native VLAN ID for the data VLAN on the trunk port:

```
[edit interfaces]
user@switch# set ge-0/0/2 unit 0 family ethernet-switching native-vlan-id data-vlan
```

## Results

Display the results of the configuration:

```
[edit]
user@switch> show configuration
interfaces {
  ge-0/0/2 {
    unit 0 {
      family ethernet-switching {
        port-mode trunk;
        vlan {
          members voice-vlan;
        }
        native-vlan-id data-vlan;
      }
    }
  }
}
vlans {
  data-vlan {
    vlan-id 77;
  }
  voice-vlan {
    vlan-id 99;
  }
}
```

Verification

IN THIS SECTION

Verifying the VLAN Association With the Interface | 558

To confirm that the configuration is working properly, perform the following task:

Verifying the VLAN Association With the Interface

Purpose

Display the interface state and VLAN membership.

Action

```
user@switch> show ethernet-switching
interfaces
Ethernet-switching table: 0 entries, 0 learned

user@switch> show ethernet-switching interfaces
Interface  State  VLAN members  Blocking
ge-0/0/0.0 down   default        unblocked
ge-0/0/1.0 down   employee-vlan  unblocked
ge-0/0/5.0 down   employee-vlan  unblocked
ge-0/0/3.0 down   employee-vlan  unblocked
ge-0/0/8.0 down   employee-vlan  unblocked
ge-0/0/10.0 down  default        unblocked
ge-0/0/11.0 down  employee-vlan  unblocked
ge-0/0/23.0 down  default        unblocked
ge-0/0/2.0 up    voice-vlan     unblocked
              data-vlan      unblocked
```

Meaning

The field `VLAN members` shows that the `ge-0/0/2.0` interface supports both the data VLAN, `data-vlan`, and the voice VLAN, `voice-vlan`. The `State` field shows that the interface is up.

**SEE ALSO**

[Understanding LLDP and LLDP-MED on EX Series Switches](#) | 690

## Example: Configuring VoIP on an EX Series Switch Without Including 802.1X Authentication

**IN THIS SECTION**

- [Requirements](#) | 559
- [Overview](#) | 560
- [Configuration](#) | 560
- [Verification](#) | 564

You can configure voice over IP (VoIP) on an EX Series switch to support IP telephones.

To configure VoIP on an EX Series switch to support an IP phone that does not support 802.1X authentication, you must either add the MAC address of the phone to the static MAC bypass list or enable MAC RADIUS authentication on the switch.

This example describes how to configure VoIP on an EX Series switch without 802.1X authentication using static MAC bypass of authentication:

### Requirements

This example uses the following hardware and software components:

- Junos OS Release 9.1 or later for EX Series switches
- An IP telephone

Before you configure VoIP, be sure you have:

- Installed your EX Series switch. See the installation information for your switch.
- Performed the initial switch configuration. See *Connecting and Configuring an EX Series Switch (CLI Procedure)*.
- Performed basic bridging and VLAN configuration on the switch. See *Example: Setting Up Basic Bridging and a VLAN for an EX Series Switch*.

- Configured the RADIUS server for 802.1X authentication and set up the access profile. See ["Example: Connecting a RADIUS Server for 802.1X to an EX Series Switch" on page 380.](#)
- (Optional) Configured interface `ge-0/0/2` for Power over Ethernet (PoE). The PoE configuration is not necessary if the VoIP supplicant is using a power adapter. For information about configuring PoE, see *Configuring PoE Interfaces on EX Series Switches*.

**NOTE:** If the IP address isn't configured on the Avaya IP phone, the phone exchanges LLDP-MED information to get the VLAN ID for the voice VLAN. You must configure the `voip` statement on the interface to designate the interface as a VoIP interface and allow the switch to forward the VLAN name and VLAN ID for the voice VLAN to the IP telephone. The IP telephone then uses the voice VLAN (that is, it references the voice VLAN's ID) to send a DHCP discover request and exchange information with the DHCP server (voice gateway).

## Overview

Instead of using a regular telephone, you connect an IP telephone directly to the switch. An IP phone has all the hardware and software needed to handle VoIP. You also can power an IP telephone by connecting it to one of the Power over Ethernet (PoE) interfaces on the switch.

In this example, the access interface `ge-0/0/2` on the EX4200 switch is connected to a non-802.1X IP phone.

To configure VoIP on an EX Series switch to support an IP phone that does not support 802.1X authentication, add the MAC address of the phone as a static entry in the authenticator database and set the supplicant mode to multiple.

## Configuration

### IN THIS SECTION

- [Procedure | 561](#)

To configure VoIP without 802.1X authentication:

## Procedure

### CLI Quick Configuration

To quickly configure VoIP, copy the following commands and paste them into the switch terminal window:

```
[edit]
set vlans data-vlan vlan-id 77
set vlans voice-vlan vlan-id 99
set vlans data-vlan interface ge-0/0/2.0
set interfaces ge-0/0/2 unit 0 family ethernet-switching vlan members data-vlan
set interfaces ge-0/0/2 unit 0 family ethernet-switching port-mode access
set ethernet-switching-options voip interface ge-0/0/2.0 vlan voice-vlan
set ethernet-switching-options voip interface ge-0/0/2.0 forwarding-class assured-forwarding
set protocols lldp-med interface ge-0/0/2.0
set protocols dot1x authenticator authentication-profile-name auth-profile
set protocols dot1x authenticator static 00:04:f2:11:aa:a7
set protocols dot1x authenticator interface ge-0/0/2.0 supplicant multiple
```

### Step-by-Step Procedure

To configure VoIP without 802.1X:

1. Configure the VLANs for voice and data:

```
[edit vlans]
user@switch# set data-vlan vlan-id 77
user@switch# set voice-vlan vlan-id 99
```

2. Associate the VLAN data-vlan with the interface:

```
[edit vlans]
user@switch# set data-vlan interface ge-0/0/2.0
```

3. Configure the interface as an access interface, configure support for Ethernet switching, and add the data-vlan VLAN:

```
[edit interfaces]
user@switch# set ge-0/0/2 unit 0 family ethernet-switching vlan members data-vlan
user@switch# set ge-0/0/2 unit 0 family ethernet-switching port-mode access
```

4. Configure VoIP on the interface and specify the assured-forwarding forwarding class to provide the most dependable class of service:

```
[edit ethernet-switching-options]
user@switch# set voip interface ge-0/0/2.0 vlan voice-vlan
user@switch# set voip interface ge-0/0/2.0 forwarding-class assured-forwarding
```

5. Configure LLDP-MED protocol support:

```
[edit protocols]
user@switch# set lldp-med interface ge-0/0/2.0
```

6. Set the authentication profile (see ["Configuring 802.1X Interface Settings \(CLI Procedure\)"](#) on page 369 and ["Configuring 802.1X RADIUS Accounting \(CLI Procedure\)"](#) on page 423):

```
[edit protocols]
set dot1x authenticator authentication-profile-name auth-profile
```

7. Add the MAC address of the phone to the static MAC bypass list:

```
[edit protocols]
set dot1x authenticator static 00:04:f2:11:aa:a7
```

8. Set the supplicant mode to multiple:

```
[edit protocols]
set dot1x authenticator interface ge-0/0/2.0 supplicant multiple
```

## Results

Display the results of the configuration:

```
[edit]
user@switch# show configuration
interfaces {
  ge-0/0/2 {
    unit 0 {
      family ethernet-switching {
        port-mode access;
        vlan {
          members data-vlan;
        }
      }
    }
  }
}
protocols {
  lldp-med {
    interface ge-0/0/2.0;
  }
  dot1x {
    authenticator {
      authentication-profile-name auth-profile;
      static {
        00:04:f2:11:aa:a7;
      }
    }
    interface {
      ge-0/0/2.0 {
        supplicant multiple;
      }
    }
  }
}
vlans {
  data-vlan {
    vlan-id 77;
    interface {
      ge-0/0/2.0;
    }
  }
}
```

```

    }
    voice-vlan {
        vlan-id 99;
    }
}
ethernet-switching options {
    voip {
        interface ge-0/0/2.0 {
            vlan voice-vlan;
            forwarding-class assured-forwarding;
        }
    }
}
}

```

## Verification

### IN THIS SECTION

- [Verifying LLDP-MED Configuration | 564](#)
- [Verifying Authentication for the Desktop PC | 566](#)
- [Verifying the VLAN Association with the Interface | 567](#)

To confirm that the configuration is working properly, perform these tasks:

### Verifying LLDP-MED Configuration

#### Purpose

Verify that LLDP-MED is enabled on the interface.

#### Action

```

user@switch> show lldp detail
LLDP                : Enabled
Advertisement interval : 30 Second(s)
Transmit delay       : 2 Second(s)
Hold timer           : 2 Second(s)

```

```
Config Trap Interval   : 300 Second(s)
Connection Hold timer  : 60 Second(s)
```

```
LLDP MED               : Enabled
MED fast start count   : 3 Packet(s)
```

| Interface  | LLDP    | LLDP-MED | Neighbor count |
|------------|---------|----------|----------------|
| all        | Enabled | -        | 0              |
| ge-0/0/2.0 | -       | Enabled  | 0              |

| Interface   | VLAN-id | VLAN-name     |
|-------------|---------|---------------|
| ge-0/0/0.0  | 0       | default       |
| ge-0/0/1.0  | 0       | employee-vlan |
| ge-0/0/2.0  | 0       | data-vlan     |
| ge-0/0/2.0  | 99      | voice-vlan    |
| ge-0/0/3.0  | 0       | employee-vlan |
| ge-0/0/8.0  | 0       | employee-vlan |
| ge-0/0/10.0 | 0       | default       |
| ge-0/0/11.0 | 20      | employee-vlan |
| ge-0/0/23.0 | 0       | default       |

LLDP basic TLVs supported:

Chassis identifier, Port identifier, Port description, System name, System description, System capabilities, Management address.

LLDP 802 TLVs supported:

Power via MDI, Link aggregation, Maximum frame size, Port VLAN tag, Port VLAN name.

LLDP MED TLVs supported:

LLDP MED capabilities, Network policy, Endpoint location, Extended power Via MDI.

## Meaning

The `show lldp detail` output shows that both LLDP and LLDP-MED are configured on the `ge-0/0/2.0` interface. The end of the output shows the list of supported LLDP basic TLVs, 802.3 TLVs, and LLDP-MED TLVs that are supported.

## Verifying Authentication for the Desktop PC

### Purpose

Display the 802.1X configuration for the desktop PC connected to the VoIP interface through the IP phone.

### Action

```
user@switch> show dot1x interface ge-0/0/2.0 detail
ge-0/0/2.0
  Role: Authenticator
  Administrative state: Auto
  Supplicant mode: Multiple
  Number of retries: 3
  Quiet period: 60 seconds
  Transmit period: 30 seconds
  Mac Radius: Disabled
  Mac Radius Restrict: Disabled
  Reauthentication: Enabled
  Configured Reauthentication interval: 3600 seconds
  Supplicant timeout: 30 seconds
  Server timeout: 30 seconds
  Maximum EAPOL requests: 2
  Guest VLAN member: <not configured>
  Number of connected supplicants: 1
    Supplicant: user101, 00:04:0f:fd:ac:fe
      Operational state: Authenticated
      Authentication method: Radius
      Authenticated VLAN: vo11
      Dynamic Filter: match source-dot1q-tag 10 action deny
      Session Reauth interval: 60 seconds
      Reauthentication due in 50 seconds
```

### Meaning

The field `Role` shows that the `ge-0/0/2.0` interface is in the authenticator state. The `Supplicant` field shows that the interface is configured in multiple supplicant mode, permitting multiple supplicants to be authenticated on this interface. The MAC addresses of the supplicants currently connected are displayed at the bottom of the output.

Verifying the VLAN Association with the Interface

Purpose

Display the interface state and VLAN membership.

Action

```
user@switch> show ethernet-switching interfaces
Ethernet-switching table: 0 entries, 0 learned

user@switch> show ethernet-switching interfaces
Interface  State  VLAN members  Blocking
ge-0/0/0.0 down   default        unblocked
ge-0/0/1.0 down   employee-vlan  unblocked
ge-0/0/5.0 down   employee-vlan  unblocked
ge-0/0/3.0 down   employee-vlan  unblocked
ge-0/0/8.0 down   employee-vlan  unblocked
ge-0/0/10.0 down  default        unblocked
ge-0/0/11.0 down  employee-vlan  unblocked
ge-0/0/23.0 down  default        unblocked
ge-0/0/2.0 up      voice-vlan     unblocked
              data-vlan      unblocked
```

Meaning

The field VLAN members shows that the ge-0/0/2.0 interface supports both the data-vlan VLAN and voice-vlan VLAN. The State field shows that the interface is up.

## Example: Setting Up VoIP with 802.1X and LLDP-MED on an EX Series Switch with ELS Support

### IN THIS SECTION

- [Requirements | 568](#)
- [Overview and Topology | 569](#)
- [Configuration | 574](#)
- [Verification | 577](#)

**NOTE:** This example uses Junos OS for EX Series switches with support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that does not support ELS, see ["Example: Setting Up VoIP with 802.1X and LLDP-MED on an EX Series Switch" on page 531](#). For ELS details, see *Using the Enhanced Layer 2 Software CLI*.

You can configure VoIP on an EX Series switch to support IP telephones. The Link Layer Discovery Protocol–Media Endpoint Discovery (LLDP-MED) protocol forwards VoIP parameters from the switch to the phone. You also configure 802.1X authentication to allow the telephone access to the LAN. Authentication is done through a backend RADIUS server.

This example describes how to configure VoIP on an EX Series switch to support an Avaya IP phone, as well as how to configure the LLDP-MED protocol and 802.1X authentication:

### Requirements

This example uses the following software and hardware components:

**NOTE:** This example also applies to QFX5100 switches.

- Junos OS Release 13.2X50 or later for EX Series switches
- One EX Series switch with support for ELS acting as an authenticator port access entity (PAE). The interfaces on the authenticator PAE form a control gate that blocks all traffic to and from supplicants until they are authenticated.
- An Avaya IP telephone that supports LLDP-MED and 802.1X

Before you configure VoIP, be sure you have:

- Installed your EX Series switch. See the installation information for your switch.
- Performed the initial switch configuration. See *Connecting and Configuring an EX Series Switch (CLI Procedure)*.
- Performed basic bridging and VLAN configuration on the switch. See *Example: Setting Up Basic Bridging and a VLAN for an EX Series Switch with ELS Support* or *Example: Setting Up Basic Bridging and a VLAN on Switches*.
- Configured the RADIUS server for 802.1X authentication and set up the access profile. See ["Example: Connecting a RADIUS Server for 802.1X to an EX Series Switch" on page 380](#).
- (Optional) Configured the interface ge-0/0/2 for Power over Ethernet (PoE). The PoE configuration is not necessary if the VoIP supplicant uses a power adapter. For information about configuring PoE, see *Configuring PoE Interfaces on EX Series Switches*.

**NOTE:** If the IP address is not configured on the Avaya IP phone, the phone exchanges LLDP-MED information to get the VLAN ID for the voice VLAN. You must configure the `voip` statement on the interface to designate the interface as a VoIP interface and allow the switch to forward the VLAN name and VLAN ID for the voice VLAN to the IP telephone. The IP telephone then uses the voice VLAN (that is, it references the voice VLAN's ID) to send a DHCP discover request and exchange information with the DHCP server (voice gateway).

## Overview and Topology

### IN THIS SECTION

- [Topology | 573](#)

Instead of using a regular telephone, you connect an IP telephone directly to the switch. An IP phone has all the hardware and software needed to handle VoIP. You also can power an IP telephone by connecting it to one of the Power over Ethernet (PoE) interfaces on the switch.

EX Series switches can accommodate an IP telephone and end host connected to a single switch port. In such a scenario, voice and data traffic must be separated into different broadcast domains, or VLANs. One method for accomplishing this is by configuring a voice VLAN, which enables access ports to accept untagged data traffic as well as tagged voice traffic from IP phones, and associate each type of traffic

with separate and distinct VLANs. Voice traffic (tagged) can then be treated differently, generally with a higher priority than data traffic (untagged).

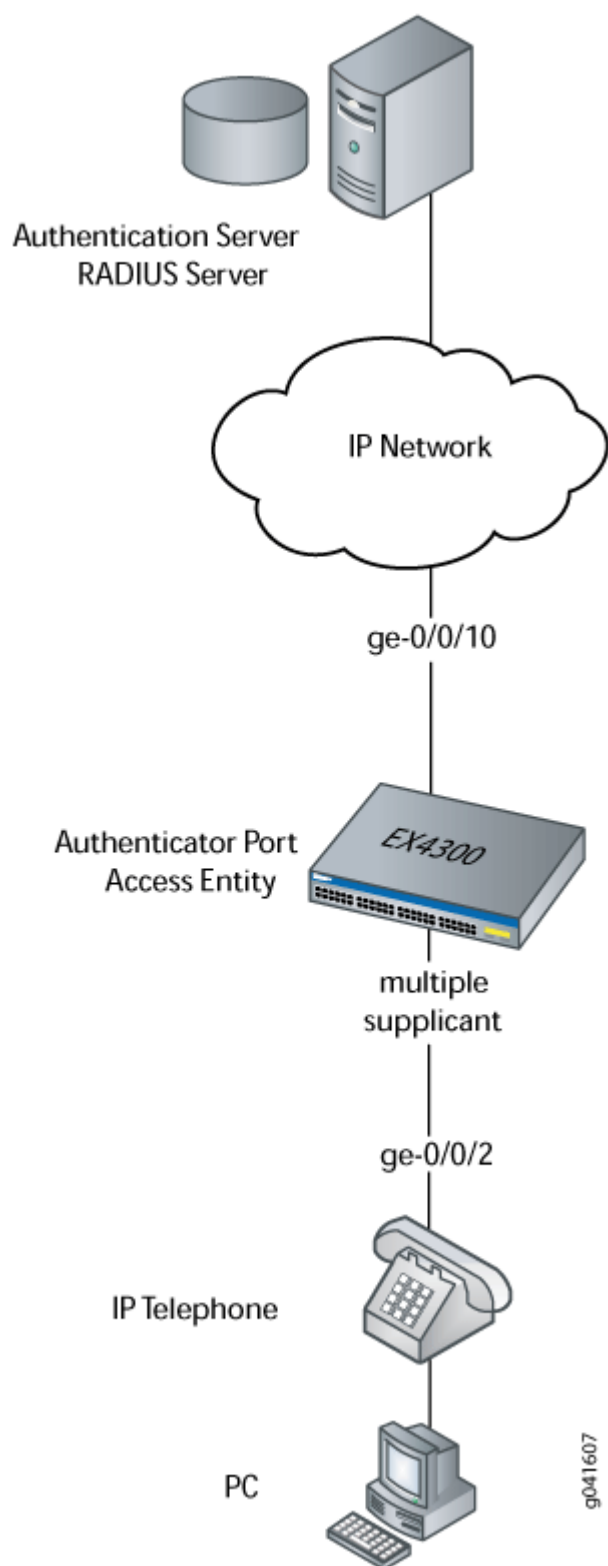

**NOTE:** If a MAC addresses has been learned on both the data and voice VLANs, it remains active unless it ages out of both VLANs, or both VLANs are deleted.

In this example, the access interface ge-0/0/2 on the EX Series switch is connected to an Avaya IP telephone. Avaya phones have a built-in bridge that enables you to connect a desktop PC to the phone, so the desktop and phone in a single office require only one interface on the switch. The EX Series switch is connected to a RADIUS server on the ge-0/0/10 interface (see [Figure 26 on page 572](#)).

**NOTE:** This figure also applies to QFX5100 switches.

Figure 26: VoIP Topology

In this example, you configure VoIP parameters and specify the forwarding class assured-forward for voice traffic to provide the highest quality of service.

Table 34 on page 573 describes the components used in this VoIP configuration example.

Table 34: Components of the VoIP Configuration Topology

| Property                                                                                                            | Settings                                                                       |
|---------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------|
| Switch hardware                                                                                                     | EX Series switch with support for ELS.                                         |
| VLAN names and IDs                                                                                                  | data-vlan, 77<br>voice-vlan, 99                                                |
| Connection to Avaya phone—with integrated hub, to connect phone and desktop PC to a single interface (requires PoE) | ge-0/0/2                                                                       |
| One RADIUS server                                                                                                   | Provides backend database connected to the switch through interface ge-0/0/10. |

Besides configuring a VoIP for interface ge-0/0/2, you configure:

- 802.1X authentication. Authentication is set to multiple supplicant mode to support more than one supplicant's access to the LAN through interface ge-0/0/2.
- LLDP-MED protocol information. The switch uses LLDP-MED to forward VoIP parameters to the phone. Using LLDP-MED ensures that voice traffic gets tagged and prioritized with the correct values at the source itself. For example, 802.1p class of service and 802.1Q tag information can be sent to the IP telephone.

**NOTE:** A PoE configuration is not necessary if an IP telephone uses a power adapter.

Topology

## Configuration

### IN THIS SECTION

- [Procedure | 574](#)

## Procedure

### CLI Quick Configuration

To quickly configure VoIP, LLDP-MED, and 802.1X, copy the following commands and paste them into the switch terminal window:

```
[edit]
set vlans data-vlan vlan-id 77
set vlans voice-vlan vlan-id 99
set vlans data-vlan switch-options interface ge-0/0/2.0
set interfaces ge-0/0/2 unit 0 family ethernet-switching interface-mode access
set interfaces ge-0/0/2 unit 0 family ethernet-switching vlan members data-vlan
set switch-options voip interface ge-0/0/2.0 vlan voice-vlan
set switch-options voip interface ge-0/0/2.0 forwarding-class assured-forwarding
set protocols lldp-med interface ge-0/0/2
set protocols dot1x authenticator interface ge-0/0/2.0 supplicant multiple
```

### Step-by-Step Procedure

To configure VoIP with LLDP-MED and 802.1X:

1. Configure the VLANs for voice and data:

```
[edit vlans]
user@switch# set data-vlan vlan-id 77
user@switch# set voice-vlan vlan-id 99
```

2. Associate the VLAN **data-vlan** with the interface:

```
[edit vlans]
user@switch# set data-vlan switch-options interface ge-0/0/2.0
```

3. Configure the interface as an access interface, configure support for Ethernet switching, and add the interface as a member of the **data-vlan** VLAN:

```
[edit interfaces]
user@switch# set ge-0/0/2 unit 0 family ethernet-switching interface-mode access
user@switch# set ge-0/0/2 unit 0 family ethernet-switching vlan members data-vlan
```

**NOTE:** You must not configure both data and voice on the same VLAN. If you configure data and voice on the same VLAN, the configuration will not be accepted.

If you have enabled 802.1X authentication on your switch and:

- The voice VLAN you have configured is the same as the data VLAN that the authentication server sends,
- The data VLAN you have configured is the same as the voice VLAN that the authentication server sends, or
- The data VLAN and the voice VLAN that the authentication server sends are the same

The client would move to HELD state.

4. Configure VoIP on the interface and specify the assured-forwarding forwarding class to provide the most dependable class of service:

```
[edit switch-options]
user@switch# set voip interface ge-0/0/2.0 vlan voice-vlan
user@switch# set voip interface ge-0/0/2.0 forwarding-class assured-forwarding
```

## 5. Configure LLDP-MED protocol support:

```
[edit protocols]
user@switch# set lldp-med interface ge-0/0/2
```

## 6. To authenticate an IP phone and a PC connected to the IP phone on the interface, configure 802.1X authentication support and specify multiple supplicant mode:

**NOTE:** If you do not want to authenticate any device, skip the 802.1X configuration on this interface.

```
[edit protocols]
user@switch# set dot1x authenticator interface ge-0/0/2.0 supplicant
multiple
```

## Results

Display the results of the configuration:

```
[edit]
user@switch# show configuration
interfaces {
  ge-0/0/2 {
    unit 0 {
      family ethernet-switching {
        interface-mode access;
        vlan {
          members data-vlan;
        }
      }
    }
  }
}
protocols {
  lldp-med {
    interface ge-0/0/2;
  }
}
```

```

dot1x {
    authenticator {
        interface {
            ge-0/0/2.0 {
                supplicant multiple;
            }
        }
    }
}
vlangs {
    data-vlan {
        vlan-id 77;
        switch-options {
            interface ge-0/0/2.0;
        }
    }
    voice-vlan {
        vlan-id 99;
    }
}
switch-options {
    voip {
        interface ge-0/0/2.0 {
            vlan voice-vlan;
            forwarding-class assured-forwarding;
        }
    }
}
}

```

## Verification

### IN THIS SECTION

- [Verifying LLDP-MED Configuration | 578](#)
- [Verifying 802.1X Authentication for IP Phone and Desktop PC | 579](#)
- [Verifying the VLAN Association with the Interface | 580](#)

To confirm that the configuration is working properly, perform these tasks:

Verifying LLDP-MED Configuration

Purpose

Verify that LLDP-MED is enabled on the interface.

Action

```
user@switch> show lldp detail
LLDP : Enabled
Advertisement interval : 30 seconds
Transmit delay : 2 seconds
Hold timer : 120 seconds
Notification interval : 0 Second(s)
Config Trap Interval : 0 seconds
Connection Hold timer : 300 seconds

LLDP MED : Enabled
MED fast start count : 3 Packets

Port ID TLV subtype : locally-assigned

Interface      Parent Interface  LLDP      LLDP-MED    Power Negotiation
Neighbor count
all            -                Enabled    Enabled      Enabled
0
ge-0/0/2       -                -          Enabled      -
0

Interface      Parent Interface  Vlan-id    Vlan-name
ge-0/0/0       -                1          vlan-1
ge-0/0/1       -                1          vlan-1
ge-0/0/2       -                77         vlan-77
ge-0/0/2       -                99         vlan-99
ge-0/0/3       -                1          vlan-1
ge-0/0/4       -                1          vlan-1
ge-0/0/5       -                1          vlan-1
ge-0/0/6       -                1          vlan-1
ge-0/0/7       -                1          vlan-1
ge-0/0/8       -                1          vlan-1
ge-0/0/9       -                1          vlan-1
ge-0/0/10      -                1          vlan-1
```

Basic Management TLVs supported:

End Of LLDPDU, Chassis ID, Port ID, Time To Live, Port Description, System Name,  
System Description, System Capabilities, Management Address

Organizationally Specific TLVs supported:

MAC/PHY configuration/status, Power via MDI, Link aggregation, Maximum Frame Size,  
Port VLAN tag, Port VLAN name.

## Meaning

The `show lldp detail` output shows that both LLDP and LLDP-MED are configured on the `ge-0/0/2` interface. The end of the output shows the list of supported LLDP basic management TLVs and organizationally specific TLVs that are supported.

## Verifying 802.1X Authentication for IP Phone and Desktop PC

### Purpose

Display the 802.1X configuration to confirm that the VoIP interface has access to the LAN.

### Action

```
user@switch> show dot1x interface ge/0/0/2.0 detail
ge-0/0/2.0
  Role: Authenticator
  Administrative state: Auto
  Supplicant mode: Multiple
  Number of retries: 3
  Quiet period: 60 seconds
  Transmit period: 30 seconds
  Mac Radius: Disabled
  Mac Radius Restrict: Disabled
  Reauthentication: Enabled
  Configured Reauthentication interval: 3600 seconds
  Supplicant timeout: 30 seconds
  Server timeout: 30 seconds
  Maximum EAPOL requests: 2
  Guest VLAN member: <not configured>
  Number of connected supplicants: 1
  Supplicant: user101, 00:04:0f:fd:ac:fe
```

```

Operational state: Authenticated
Authentication method: Radius
Authenticated VLAN: vo11
Dynamic Filter: match source-dot1q-tag 10 action deny
Session Reauth interval: 60 seconds
Reauthentication due in 50 seconds

```

### Meaning

The field **Role** shows that the `ge-0/0/2.0` interface is in the authenticator state. The **Supplicant mode** field shows that the interface is configured in multiple supplicant mode, permitting multiple supplicants to be authenticated on this interface. The MAC addresses of the supplicants currently connected are displayed at the bottom of the output.

### Verifying the VLAN Association with the Interface

#### Purpose

Display the interface's VLAN membership.

#### Action

```

user@switch> show ethernet-switching interface ge-0/0/2.0
Routing Instance Name : default-switch
Logical Interface flags (DL - disable learning, AD - packet action drop,
                        LH - MAC limit hit, DN - interface down )
Logical      Vlan      TAG  MAC      STP      Logical      Tagging
interface    members    limit state   interface flags
ge-0/0/2.0
    voice-vlan 99
                        65535
                        Discarding
    data-vlan 77
                        65535
                        Discarding

```

### Meaning

The field **VLAN members** shows that the `ge-0/0/2.0` interface supports both the **data-vlan** VLAN and **voice-vlan** VLAN.

## Example: Configuring VoIP on an EX Series Switch with ELS Support Without Including 802.1X Authentication

### IN THIS SECTION

- [Requirements | 582](#)
- [Overview | 582](#)
- [Configuration | 583](#)
- [Verification | 586](#)

**NOTE:** This example uses Junos OS for EX Series switches with support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that does not support ELS, see ["Example: Configuring VoIP on an EX Series Switch Without Including 802.1X Authentication" on page 559](#). For ELS details, see *Using the Enhanced Layer 2 Software CLI*.

You can configure voice over IP (VoIP) on an EX Series switch to support IP telephones.

To configure VoIP on an EX Series switch to support an IP phone that does not support 802.1X authentication, you must either add the MAC address of the phone to the static MAC bypass list or enable MAC RADIUS authentication on the switch.

This example describes how to configure VoIP on an EX Series switch without 802.1X authentication by using static MAC bypass of authentication:

## Requirements

This example uses the following hardware and software components:

**NOTE:** This figure also applies to QFX5100 switches.

- One EX Series switch with support for ELS
- Junos OS Release 13.2 or later for EX Series switches
- An Avaya IP telephone

Before you configure VoIP, be sure you have:

- Installed your EX Series switch. See the installation information for your switch.
- Performed the initial switch configuration. See *Connecting and Configuring an EX Series Switch (CLI Procedure)*.
- Performed basic bridging and VLAN configuration on the switch. See *Example: Setting Up Basic Bridging and a VLAN for an EX Series Switch with ELS Support* or *Example: Setting Up Basic Bridging and a VLAN on Switches*.
- Configured the RADIUS server for 802.1X authentication and set up the access profile. See ["Example: Connecting a RADIUS Server for 802.1X to an EX Series Switch" on page 380](#).
- (Optional) Configured the interface ge-0/0/2 for Power over Ethernet (PoE). The PoE configuration is not necessary if the VoIP supplicant uses a power adapter. For information about configuring PoE, see *Configuring PoE Interfaces on EX Series Switches*.

**NOTE:** If the IP address is not configured on the Avaya IP phone, the phone exchanges LLDP-MED information to get the VLAN ID for the voice VLAN. You must configure the `voip` statement on the interface to designate the interface as a VoIP interface and allow the switch to forward the VLAN name and VLAN ID for the voice VLAN to the IP telephone. The IP telephone then uses the voice VLAN (that is, it references the voice VLAN's ID) to send a DHCP discover request and exchange information with the DHCP server (voice gateway).

## Overview

Instead of using a regular telephone, you connect an IP telephone directly to the switch. An IP phone has all the hardware and software needed to handle VoIP. You also can power an IP telephone by connecting it to one of the Power over Ethernet (PoE) interfaces on the switch.

In this example, the access interface ge-0/0/2 on the EX Series switch is connected to a non-802.1X IP phone.

To configure VoIP on an EX Series switch to support an IP phone that does not support 802.1X authentication, add the MAC address of the phone as a static entry in the authenticator database and set the supplicant mode to multiple.

## Configuration

### IN THIS SECTION

- [Procedure | 583](#)

### Procedure

#### CLI Quick Configuration

To quickly configure VoIP without using 802.1X authentication, copy the following commands and paste them into the switch terminal window:

```
[edit]
set vlans data-vlan vlan-id 77
set vlans voice-vlan vlan-id 99
set interfaces ge-0/0/2 unit 0 family ethernet-switching interface-mode access
set interfaces ge-0/0/2 unit 0 family ethernet-switching vlan members data-vlan
set switch-options voip interface ge-0/0/2.0 vlan voice-vlan
set switch-options voip interface ge-0/0/2.0 forwarding-class assured-forwarding
set protocols lldp-med interface ge-0/0/2
set protocols dot1x authenticator authentication-profile-name auth-profile
set protocols dot1x authenticator static 00:04:f2:11:aa:a7
set protocols dot1x authenticator interface ge-0/0/2.0 supplicant multiple
```

### Step-by-Step Procedure

To configure VoIP without 802.1X authentication:

1. Configure the VLANs for voice and data:

```
[edit vlans]
user@switch# set data-vlan vlan-id 77
user@switch# set voice-vlan vlan-id 99
```

2. Configure the interface as an access interface, configure support for Ethernet switching, and add the interface as a member of the data-vlan VLAN:

```
[edit interfaces]
user@switch# set ge-0/0/2 unit 0 family ethernet-switching interface-mode access
user@switch# set ge-0/0/2 unit 0 family ethernet-switching vlan members data-vlan
```

**NOTE:** You must not configure both data and voice on the same VLAN. If you configure data and voice on the same VLAN, the configuration will not be accepted.

3. Configure VoIP on the interface and specify the assured-forwarding forwarding class to provide the most dependable class of service:

```
[edit switch-options]
user@switch# set voip interface ge-0/0/2.0 vlan voice-vlan
user@switch# set voip interface ge-0/0/2.0 forwarding-class assured-forwarding
```

4. Configure LLDP-MED protocol support:

```
[edit protocols]
user@switch# set lldp-med interface ge-0/0/2
```

5. Set the authentication profile with the name auth-profile (see ["Configuring 802.1X Interface Settings \(CLI Procedure\)" on page 369](#) and ["Configuring 802.1X RADIUS Accounting \(CLI Procedure\)" on page 423](#)):

```
[edit protocols]
user@switch# set dot1x authenticator authentication-profile-name auth-profile
```

6. Add the MAC address of the phone to the static MAC bypass list:

```
[edit protocols]
user@switch# set dot1x authenticator static 00:04:f2:11:aa:a7
```

7. Set the supplicant mode to multiple:

```
[edit protocols]
user@switch# set dot1x authenticator interface ge-0/0/2.0 supplicant multiple
```

## Results

Display the results of the configuration:

```
[edit]
user@switch# show configuration
interfaces {
  ge-0/0/2 {
    unit 0 {
      family ethernet-switching {
        interface-mode access;
        vlan {
          members data-vlan;
        }
      }
    }
  }
}
protocols {
  lldp-med {
    interface ge-0/0/2;
  }
  dot1x {
    authenticator {
      authentication-profile-name auth-profile;
      static {
        00:04:f2:11:aa:a7;
      }
    }
    interface {
```

```
        ge-0/0/2.0 {
            supplicant multiple;
        }
    }
}
vllans {
    data-vlan {
        vlan-id 77;
        switch-options {
            interface ge-0/0/2.0;
        }
    }
    voice-vlan {
        vlan-id 99;
    }
}
switch-options {
    voip {
        interface ge-0/0/2.0 {
            vlan voice-vlan;
            forwarding-class assured-forwarding;
        }
    }
}
```

## Verification

### IN THIS SECTION

- [Verifying LLDP-MED Configuration | 587](#)

  Administrative state: Auto
  Supplicant mode: Multiple
  Number of retries: 3
  Quiet period: 60 seconds
  Transmit period: 30 seconds
  Mac Radius: Disabled
  Mac Radius Restrict: Disabled
  Reauthentication: Enabled
  Configured Reauthentication interval: 3600 seconds
  Supplicant timeout: 30 seconds
  Server timeout: 30 seconds
  Maximum EAPOL requests: 2
  Guest VLAN member: <not configured>
```

```

Number of connected supplicants: 1
Supplicant: user101, 00:04:0f:fd:ac:fe
Operational state: Authenticated
Authentication method: Radius
Authenticated VLAN: vo11
Dynamic Filter: match source-dot1q-tag 10 action deny
Session Reauth interval: 60 seconds
Reauthentication due in 50 seconds

```

## Meaning

The field `Role` shows that the `ge-0/0/2.0` interface is in the authenticator role. The `Supplicant Mode` field shows that the interface is configured in multiple supplicant mode, permitting multiple supplicants to be authenticated on this interface. The MAC addresses of the supplicants currently connected are displayed at the bottom of the output.

## Verifying the VLAN Association with the Interface

## Purpose

Display the interface's VLAN membership.

## Action

```

user@switch> show ethernet-switching interface ge-0/0/2.0
Routing Instance Name : default-switch
Logical Interface flags (DL - disable learning, AD - packet action drop,
                        LH - MAC limit hit, DN - interface down )
Logical   Vlan   TAG   MAC   STP       Logical   Tagging
interface members limit state   interface flags
ge-0/0/2.0
      voice-vlan 99
                        65535
                        Discarding
      data-vlan 77
                        65535
                        Discarding

```

## Meaning

The `Vlan members` field shows that the `ge-0/0/2.0` interface supports both the `data-vlan VLAN` and `voice-vlan VLAN`.

# IEEE 802.1x Port-Based Network Access Control

## Overview

MX Series routers support the IEEE 802.1x Port-Based Network Access Control (dot1x) protocol on Ethernet interfaces for validation of client and user credentials to prevent unauthorized access to a specified router port. Before authentication is complete, only 802.1x control packets are allowed and forwarded to the router control plane for processing. All other packets are dropped.

Authentication methods used must be 802.1x compliant. Authentication using RADIUS and Microsoft Active Directory servers is supported. The following user/client authentication methods are allowed:

- EAP-MD5 (RFC 3748)
- EAP-TTLS requires a server certificate (RFC 2716)
- EAP-TLS requires a client and server certificate
- PEAP requires only a server certificate

You can use both client and server certificates in all types of authentication except EAP-MD5.

**NOTE:** On the MX Series router, 802.1x can be enabled on bridged ports only and not on routed ports.

Dynamic changes to a user session are supported to allow the router administrator to terminate an already authenticated session by using the “RADIUS disconnect” message defined in RFC 3576.

# Understanding the Administrative State of the Authenticator Port

The administrative state of an authenticator port can take any of the following three states:

- Force authorized—Allows network access to all users of the port without requiring them to be authenticated. This is equivalent to not having any authentication enabled on the port.
- Force unauthorized—Denies network access to all users of the port. This is equivalent to disabling the port.
- Automatic—This is the default mode where the authentication server response determines if the port is opened for traffic or not. Only the successfully authenticated clients are allowed access, all others are denied.

In Junos OS, the default mode is “automatic.” The “force authorized” and “force unauthorized” admin modes are not supported. You can achieve the functionality of “force authorized” mode by disabling dot1x on the required port. You can achieve the functionality of “force unauthorized” mode by disabling the port itself.

# Understanding the Administrative Mode of the Authenticator Port

Junos OS supports the supplicant mode “single” and not the “single secure” nor “multiple” modes. The “Single” mode option authenticates only the first client that connects to a port. All other clients that connect later (802.1x compliant or noncompliant) are allowed free access on that port without any

further authentication. If the first authenticated client logs out, all other users are locked out until a client authenticates again.

# Configuring the Authenticator

To configure the IEEE 802.1x Port-Based Network Access Control protocol on Ethernet interfaces you must configure the authenticator statement at the [edit protocols dot1x] hierarchy level. Use the authentication-profile-name *access-profile-name* statement to specify the authenticating RADIUS server, and use the interface statement to specify and configure the Gigabit Ethernet or Fast Ethernet interface on the router specifically for IEEE 802.1x protocol use; both at the [edit protocols dot1x authenticator] hierarchy level.

```
[edit protocols dot1x]
authenticator {
  authentication-profile-name access-profile-name;
  interface (xe-fpc/pic/port | ge-fpc/pic/port | fe-fpc/pic/port) {
    maximum-requests seconds;
    quiet-period seconds;
    reauthentication (disable | interval seconds);
    retries integer;
    server-timeout seconds;
    supplicant (single);
    supplicant-timeout seconds;
    transmit-period seconds;
  }
}
```

# 802.1X for MX Series Routers in Enhanced LAN Mode Overview

## IN THIS SECTION

- [How 802.1X Authentication Works | 600](#)
- [802.1X Features Overview | 601](#)
- [Supported Features Related to 802.1X Authentication | 601](#)

Starting with Junos OS Release 14.2, IEEE 802.1X provides network edge security, protecting Ethernet LANs from unauthorized user access. Support is implemented for controlling access to your network through an MX Series router by using several different authentication methods, such as 802.1X, MAC RADIUS, or a captive portal.

This functionality is supported on the following MPCs on MX240, MX480, and MX960 routers in enhanced LAN mode:

- MPC4E with two 100-Gigabit Ethernet ports and eight 10-Gigabit Ethernet ports
- MPC4E with thirty-two 10-Gigabit Ethernet ports
- MPC3E that contains a 2-port 40-Gigabit Ethernet MIC with QSFP+
- MPC1E with forty 1-Gigabit Ethernet ports or twenty 1-Gigabit Ethernet ports

You must reboot the router when you configure or delete the enhanced LAN mode on the router. Configuring the `network-services lan` option implies that the system is running in the enhanced IP mode. When you configure a device to function in MX-LAN mode, only the supported configuration statements and operational show commands that are available for enabling or viewing in this mode are displayed in the CLI interface. If your system contains parameters that are not supported in MX-LAN mode in a configuration file, you cannot commit those unsupported attributes. You must remove the settings that are not supported and then commit the configuration. After the successful CLI commit, a system reboot is required for the attributes to become effective. Similarly, if you remove the `network-services lan` statement, the system does not run in MX-LAN mode. Therefore, all of the settings that are supported outside of the MX-LAN mode are displayed and are available for definition in the CLI interface. If your configuration file contains settings that are supported only in MX-LAN mode, you must remove those attributes before you commit the configuration. After the successful CLI commit, a system reboot will be required for the CLI settings to take effect. The Layer 2 Next-Generation CLI

configuration settings are supported in MX-LAN mode. As a result, the typical MX Series-format of CLI configurations might differ in MX-LAN mode.

This functionality is supported on an MX Series Virtual Chassis combination that functions in enhanced LAN mode (by entering the `network-services lan` statement at the `[edit chassis]` hierarchy level). Port-based network access control is supported on MX240, MX480, and MX960 routers with MPCs in both the MX-LAN mode and the non-MX-LAN mode (with other supported network services modes on MPCs on these routers). To configure the IEEE 802.1x port-based network access control (PNAC) protocol on Ethernet interfaces, you must configure the authenticator statement at the `[edit protocols authentication-access- control]` hierarchy level. You can also configure captive portal authentication on a router so that users connected to the switch are authenticated before being allowed to access the network. You can also configure Junos Pulse Access Control Service as the access policy to authenticate and authorize users connected to the switch for admission to the network and for access to protected network resources by using the `uac-policy` statement.

## How 802.1X Authentication Works

802.1X authentication works by using an *Authenticator Port Access Entity* (the switch) to block all traffic to and from a supplicant (end device) at the port until the supplicant's credentials are presented and matched on the *Authentication server* (a RADIUS server). When authenticated, the switch stops blocking traffic and opens the port to the supplicant.

The end device is authenticated in either *single* mode, *single-secure* mode, or *multiple* mode:

- **single**—Authenticates only the first end device. All other end devices that connect later to the port are allowed full access without any further authentication. They effectively “piggyback” on the end devices’ authentication.
- **single-secure**—Allows only one end device to connect to the port. No other end device is allowed to connect until the first logs out.
- **multiple**—Allows multiple end devices to connect to the port. Each end device will be authenticated individually.

Network access can be further defined using VLANs and firewall filters, which both act as filters to separate and match groups of end devices to the areas of the LAN they require. For example, you can configure VLANs to handle different categories of authentication failures depending upon:

- Whether or not the end device is 802.1X-enabled.
- Whether or not MAC RADIUS authentication has been configured on the switch interfaces to which the hosts are connected.

- Whether the RADIUS authentication server becomes unavailable or sends a RADIUS access-reject message. See ["Configuring RADIUS Server Fail Fallback \(CLI Procedure\)" on page 357](#).

## 802.1X Features Overview

**NOTE:** The 802.1X features available on the MX Series routers depend upon which switch you are using.

802.1X features on Juniper Networks MX Series routers are:

- **Guest VLAN**—Provides limited access to a LAN, typically just to the Internet, for nonresponsive end devices that are not 802.1X-enabled when MAC RADIUS authentication has not been configured on the switch interfaces to which the hosts are connected. Also, a guest VLAN can be used to provide limited access to a LAN for guest users. Typically, the guest VLAN provides access just to the Internet and to other guests' end devices.
- **Server-reject VLAN**—Provides limited access to a LAN, typically just to the Internet, for responsive end devices that are 802.1X-enabled but that have sent the wrong credentials.
- **Server-fail VLAN**—Provides limited access to a LAN, typically just to the Internet, for 802.1X end devices during a RADIUS server timeout.
- **Dynamic VLAN**—Enables an end device, after authentication, to be a member of a VLAN dynamically.
- **Private VLAN**—Enables configuration of 802.1X authentication on interfaces that are members of private VLANs (PVLANS).
- **Dynamic changes to a user session**—Allows the switch administrator to terminate an already authenticated session. This feature is based on support of the RADIUS Disconnect Message defined in RFC 3576.
- **RADIUS accounting**—Sends accounting information to the RADIUS accounting server. Accounting information is sent to the server whenever a subscriber logs in or logs out and whenever a subscriber activates or deactivates a subscription.

## Supported Features Related to 802.1X Authentication

802.1X does not replace other security technologies. 802.1X works together with port security features, such as DHCP snooping, dynamic ARP inspection (DAI), and MAC limiting, to guard against spoofing.

Supported features related to authentication include:

- Static MAC bypass—Provides a bypass mechanism to authenticate devices that are not 802.1X-enabled (such as printers). Static MAC bypass connects these devices to 802.1X-enabled ports, bypassing 802.1X authentication.
- MAC RADIUS authentication—Provides a means to enable or disable MAC authentication independently of whether 802.1X authentication is enabled.

**Release History Table**

# Understanding 802.1X and LLDP and LLDP-MED on MX Series Routers in Enhanced LAN Mode

Starting with Junos OS Release 14.2, Juniper Networks MX Series routers use Link Layer Discovery Protocol (LLDP) and Link Layer Discovery Protocol-Media Endpoint Discovery (LLDP-MED) to learn and distribute device information on network links. The information allows the router to quickly identify a variety of devices, resulting in a LAN that interoperates smoothly and efficiently.

LLDP-capable devices transmit information in type, length, and value (TLV) messages to neighbor devices. Device information can include information such as chassis and port identification and system name and system capabilities. The TLVs leverage this information from parameters that have already been configured in the Juniper Networks Junos operating system (Junos OS).

LLDP-MED goes one step further than LLDP, exchanging IP-telephony messages between the router and the IP telephone.

LLDP and LLDP-MED also provide PoE power management capabilities. LLDP power negotiation allows the router to manage PoE power by negotiating with LLDP-enabled powered devices to dynamically allocate PoE power as needed. LLDP power priority allows an LLDP-enabled powered device to set the PoE power priority on the router interface to which it connects.

The router also uses these protocols to ensure that voice traffic gets tagged and prioritized with the correct values at the source itself. For example, 802.1p CoS and 802.1Q tag information can be sent to the IP telephone.

EX Series routers support the following basic TLVs:

- **Chassis Identifier**—The MAC address associated with the local system.

**NOTE:** The Chassis ID TLV has a subtype for Network Address Family. LLDP frames are validated only if this subtype has a value of 1 (IPv4) or 2 (IPv6). For any other value, the transmitting device is detected by LLDP as a neighbor and displayed in the output of the "show lldp neighbors" command, but is not assigned to the VLAN.

- **Port Identifier**—The port identification for the specified port in the local system.
- **Port Description**—Textual description of the interface or the logical unit. The description for the logical unit is used, if available; otherwise, the Port Description TLV will contain the description configured on the physical interface. For example, LAG member interfaces do not contain a logical unit, so only the description configured on the physical interface can be used.
- **System Name**—The user-configured name of the local system. The system name can be a maximum of 256 characters.
- **System Description**—The system description containing information about the software and current image running on the system. This information is not configurable, but taken from the software.
- **System Capabilities**—The primary function performed by the system. The capabilities that system supports; for example, bridge or router. This information is not configurable, but based on the model of the product.
- **Management Address**—The IPv4 or IPv6 management address of the local system.

EX Series routers support the following 802.3 TLVs:

- **Power via MDI**—A TLV that advertises MDI power support, PSE power pair, and power class information.
- **MAC/PHY Configuration Status**—A TLV that advertises information about the physical interface, such as autonegotiation status and support and MAU type. The information is not configurable, but based on the physical interface structure.

**NOTE:** The MAC/PHY Configuration Status TLV has a subtype for the PMD Auto-Negotiation Advertised Capability field. This field will contain a value of other or unknown if the LLDP packet was transmitted from a 10-gigabit SFP+ port.

- **Link Aggregation**—A TLV that advertises if the port is aggregated and its aggregated port ID.

- **Maximum Frame Size**—A TLV that advertises the Maximum Transmission Unit (MTU) of the interface sending LLDP frames.
- **Port Vlan**—A TLV that advertises the VLAN name configured on the interface.

EX Series routers support the following LLDP-MED TLVs:

- **LLDP MED Capabilities**—A TLV that advertises the primary function of the port. The capabilities values range 0 through 15:
  - **0**— Capabilities
  - **1**— Network Policy
  - **2**— Location Identification
  - **3**— Extended Power via MDI-PSE
  - **4**— Inventory
  - **5-15**— Reserved
- **LLDP-MED Device Class Values:**
  - **0**— Class not defined.
  - **1**— Class 1 Device.
  - **2**— Class 2 Device.
  - **3**— Class 3 Device.
  - **4**— Network Connectivity Device
  - **5-255**— Reserved.
- **Network Policy**—A TLV that advertises the port VLAN configuration and associated Layer 2 and Layer 3 attributes. Attributes include the policy identifier, application types, such as voice or streaming video, 802.1Q VLAN tagging, and 802.1p priority bits and Diffserv code points.
- **Endpoint Location**— A TLV that advertises the physical location of the endpoint.
- **Extended Power via MDI**— A TLV that advertises the power type, power source, power priority, and power value of the port. It is the responsibility of the PSE device (network connectivity device) to advertise the power priority on a port.

## Understanding 802.1X and RADIUS Accounting on MX Series Routers in Enhanced LAN Mode

Juniper Networks MX Series routers support IETF RFC 2866, *RADIUS Accounting*. Starting with Junos OS Release 14.2, you can configure RADIUS accounting on an MX Series router which enables statistical data about users logging onto or off a LAN to be collected and sent to a RADIUS accounting server. The statistical data gathered can be used for general network monitoring, to analyze and track usage patterns, or to bill a user based upon the amount of time or type of services accessed.

To configure RADIUS accounting, specify one or more RADIUS accounting servers to receive the statistical data from the switch, and select the type of accounting data to be collected.

The RADIUS accounting server you specify can be the same server used for RADIUS authentication, or it can be a separate RADIUS server. You can specify a list of RADIUS accounting servers. In the event that the primary server (the first one configured) is unavailable, each RADIUS server in the list is tried in the order in which they are configured in the Juniper Networks Junos operating system (Junos OS).

The RADIUS accounting process between a switch and a RADIUS server works like this:

1. A RADIUS accounting server listens for User Datagram Protocol (UDP) packets on a specific port. For example, on FreeRADIUS, the default port is 1813.
2. The switch forwards an *accounting-request* packet containing an event record to the accounting server. For example, a supplicant is authenticated through 802.1X authentication and connected to the LAN. The event record associated with this supplicant contains an *Acct-Status-Type* attribute whose value indicates the beginning of user service for this supplicant. When the supplicant's session ends, the accounting request will contain an *Acct-Status-Type* attribute value indicating the end of user service. The RADIUS accounting server records this as a stop-accounting record containing session information and the length of the session.
3. The RADIUS accounting server logs these events as start-accounting or stop-accounting records. The records are in a file. On FreeRADIUS, the file name is the server's address; for example, 122.69.1.250.

4. The accounting server sends an *accounting-response* packet back to the switch confirming it has received the accounting request.
5. If the switch does not receive a response from the server, it continues to send accounting requests until an accounting response is returned from the accounting server.

The statistics collected through this process can be displayed from the RADIUS server; to see those statistics, the user accesses the log file configured to receive them.

## Understanding 802.1X and VoIP on MX Series Routers in Enhanced LAN Mode

When you use Voice over IP (VoIP), you can connect IP telephones to the router and configure IEEE 802.1X authentication for 802.1X-compatible IP telephones. Starting with Junos OS Release 14.2, 802.1X authentication provides network edge security, protecting Ethernet LANs from unauthorized user access.

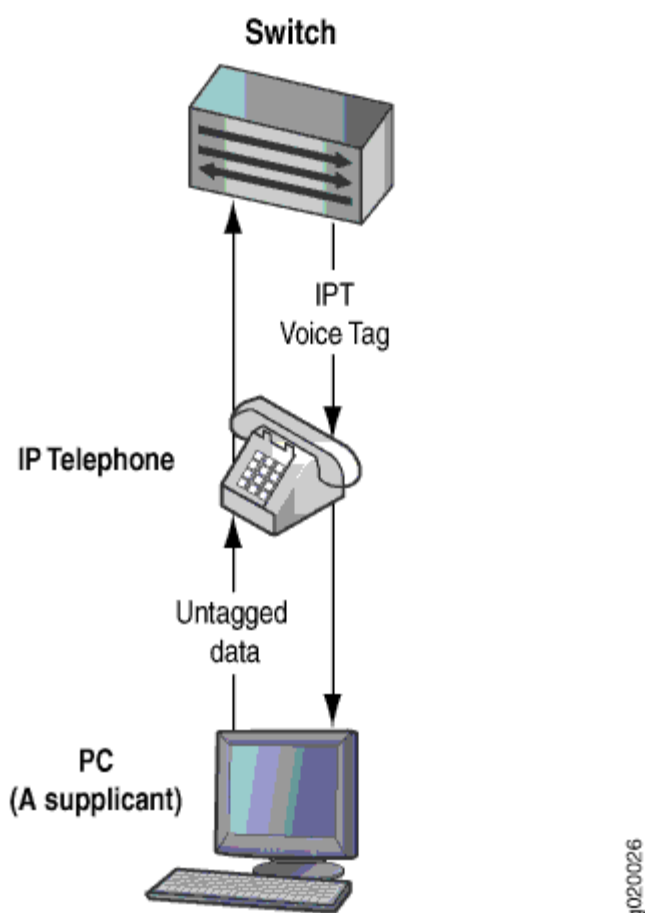

VoIP is a protocol used for the transmission of voice through packet-switched networks. VoIP transmits voice calls using a network connection instead of an analog phone line.

When VoIP is used with 802.1X, the RADIUS server authenticates the phone, and Link Layer Discovery Protocol–Media Endpoint Discovery (LLDP-MED) provides the class-of-service (CoS) parameters to the phone.

You can configure 802.1X authentication to work with VoIP in multiple supplicant or single supplicant mode. In *multiple-supplicant* mode, the 802.1X process allows multiple supplicants to connect to the

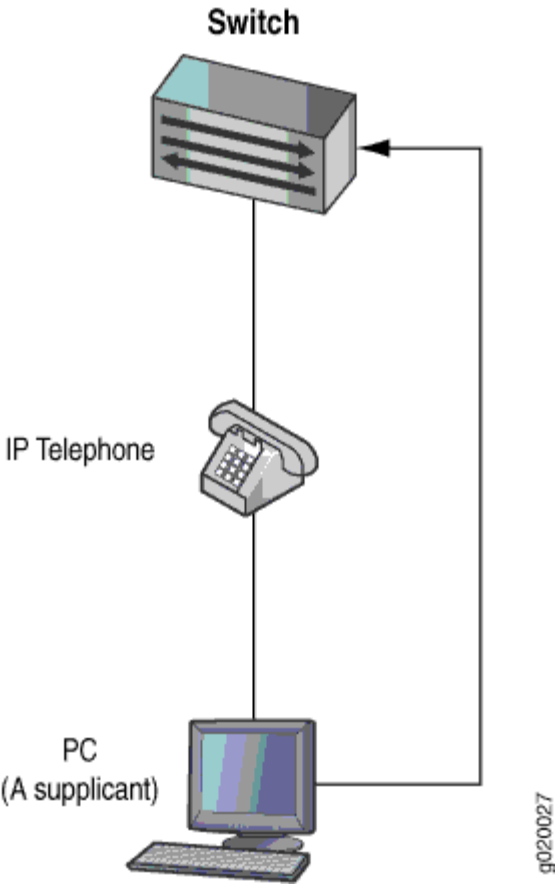

interface. Each supplicant will be authenticated individually. For an example of a VoIP multiple supplicant topology, see [Figure 27 on page 607](#).

**Figure 27: VoIP Multiple Supplicant Topology**

If an 802.1X-compatible IP telephone does not have an 802.1X host but has another 802.1X-compatible device connected to its data port, you can connect the phone to an interface in single-supplicant mode. In *single-supplicant* mode, the 802.1X process authenticates only the first supplicant. All other supplicants who connect later to the interface are allowed full access without any further authentication. They effectively “piggyback” on the first supplicant’s authentication. For an example of a VoIP single supplicant topology, see [Figure 28 on page 608](#).

Figure 28: VoIP Single Supplicant Topology

If an IP telephone does not support 802.1X, you can configure VoIP to bypass 802.1X and LLDP-MED and have the packets forwarded to a VoIP VLAN,

Release History Table

| Release | Description                                                                                                                                        |

## Understanding Guest VLANs for 802.1X on MX Series Routers in Enhanced LAN Mode

Starting with Junos OS Release 14.2, guest VLANs can be configured on switches that are using 802.1X authentication to provide limited access—typically only to the Internet—for:

- Corporate guests
- End devices that are not 802.1X-enabled
- Nonresponsive end devices when MAC RADIUS authentication has not been configured on the switch interfaces to which the hosts are connected

A guest VLAN is not used for supplicants sending incorrect credentials. Those supplicants are directed to the server-reject VLAN instead.

For end devices that are not 802.1X-enabled, a guest VLAN can allow limited access to a server from which the non-802.1X-enabled end device can download the supplicant software and attempt authentication again.

A guest VLAN is not used when MAC RADIUS authentication has been configured on the switch interfaces to which the hosts are connected. Some end devices, such as a printer, cannot be enabled for 802.1X. The hosts for such devices should be connected to switch interfaces that are configured for MAC RADIUS authentication.

## Understanding Dynamic VLANs for 802.1X on MX Series Routers in Enhanced LAN Mode

Starting with Junos OS Release 14.2, dynamic VLANs, in conjunction with the 802.1X authentication process, provide secure access to the LAN for end devices belonging to different VLANs on a single port.

When this feature is configured on the RADIUS server, an end device or user authenticating on the RADIUS server is assigned to the VLAN configured for it. The end device or user becomes a member of a VLAN dynamically after successful 802.1X authentication. For information on configuring dynamic VLANs on your RADIUS server, see the documentation for your RADIUS server.

Successful authentication requires that the VLAN ID or VLAN name exist on the router and match the VLAN ID or VLAN name sent by the RADIUS server during authentication. If neither exists, the end device is unauthenticated. If a guest VLAN is established, the unauthenticated end device is automatically moved to the guest VLAN.

#### Release History Table

## Understanding Server Fail Fallback and Authentication on MX Series Routers in Enhanced LAN Mode

Starting with Junos OS Release 14.2, server fail fallback allows you to specify how end devices connected to the router are supported if the RADIUS authentication server becomes unavailable or sends a RADIUS access-reject message.

Juniper Networks MX Series routers in enhanced LAN mode use authentication to implement access control in an enterprise network. If 802.1X, MAC RADIUS, or captive portal authentication are configured on the interface, end devices are evaluated at the initial connection by an authentication (RADIUS) server. If the end device is configured on the authentication server, the device is granted access to the LAN and the MX Series router opens the interface to permit access.

A RADIUS server timeout occurs if no RADIUS authentication servers are reachable when an end device logs in and attempts to access the LAN. Server fail fallback allows you to specify one of four actions to be taken toward end devices awaiting authentication when the server is timed out:

- *Permit* authentication, allowing traffic to flow from the end device through the interface as if the end device were successfully authenticated by the RADIUS server.
- *Deny* authentication, preventing traffic from flowing from the end device through the interface. This is the default.

- *Move* the end device to a specified VLAN. (The VLAN must already exist on the router.)
- *Sustain* authenticated end devices that already have LAN access and *deny* unauthenticated end devices. If the RADIUS servers time out during reauthentication, previously authenticated end devices are reauthenticated and new users are denied LAN access.

Server fail fallback is triggered most often during reauthentication when the already configured and in-use RADIUS server becomes inaccessible. However, server fail fallback can also be triggered by an end device's first attempt at authentication through the RADIUS server.

Server fail fallback allows you to specify that an end device be moved to a specified VLAN if the router receives a RADIUS access-reject message. The configured VLAN name overrides any attributes sent by the server.

| Release | Description                                                                                                                                                                                                                            |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 14.2    | Starting with Junos OS Release 14.2, server fail fallback allows you to specify how end devices connected to the router are supported if the RADIUS authentication server becomes unavailable or sends a RADIUS access-reject message. |

## Configuring 802.1X RADIUS Accounting on MX Series Routers in Enhanced LAN Mode

Starting with Junos OS Release 14.2, RADIUS accounting permits statistical data about users logging onto or off a LAN to be collected and sent to a RADIUS accounting server. The statistical data gathered can be used for general network monitoring, to analyze and track usage patterns, or to bill a user based upon the amount of time or type of services accessed.

To configure basic RADIUS accounting using the CLI:

1. Specify the accounting servers to which the switch will forward accounting statistics:

```
[edit access ]
user@router# set profile profile1 radius accounting-server [122.69.1.250
122.69.1.252]
```

2. Define the RADIUS accounting servers:

```
[edit access]
user@router# set radius-server 122.69.1.250 secret juniper
user@router# set radius-server 122.69.1.252 secret juniper1
```

3. Enable accounting for an access profile:

```
[edit access]
user@router# set profile profile1 accounting
```

4. Configure the RADIUS servers to use while sending accounting messages and updates:

```
[edit access]
user@router# set profile profile1 accounting order radius
```

5. Configure the statistics to be collected on the router and forwarded to the accounting server:

```
[edit access ]
user@router# set profile profile1 accounting accounting-stop-on-access-deny
user@router# set profile profile1 accounting accounting-stop-on-
failure
```

6. Display accounting statistics collected on the router:

```
user@router> show network-access aaa statistics accounting
Accounting module statistics
  Requests received: 1
  Accounting Response failures: 0
  Accounting Response Success: 1
  Requests timedout: 0
```

7. Open an accounting log on the RADIUS accounting server using the server's address, and view accounting statistics:

```
[root@freeradius]# cd /usr/local/var/log/radius/radacct/122.69.1.250
[root@freeradius 122.69.1.250]# ls

detail-20071214
```

```
[root@freeradius 122.69.1.250]# vi details-20071214
```

# Configuring 802.1X Interface Settings on MX Series Routers in Enhanced LAN Mode

Starting with Junos OS Release 14.2, IEEE 802.1X authentication provides network edge security, protecting Ethernet LANs from unauthorized user access by blocking all traffic to and from a supplicant (client) at the interface until the supplicant's credentials are presented and matched on the *authentication server* (a RADIUS server). When the supplicant is authenticated, the switch stops blocking access and opens the interface to the supplicant.

## NOTE:

- You can also specify an 802.1X exclusion list to specify supplicants that can bypass authentication and be automatically connected to the LAN.
- You cannot configure 802.1X user authentication on interfaces that have been enabled for Q-in-Q tunneling.
- You cannot configure 802.1X user authentication on redundant trunk groups (RTGs).

Before you begin, specify the RADIUS server or servers to be used as the authentication server.

To configure 802.1X on an interface:

1. Configure the supplicant mode as **single** (authenticates the first supplicant), **single-secure** (authenticates only one supplicant), or **multiple** (authenticates multiple supplicants):

```
[edit protocols authentication-access-control]
user@switch# set interface ge-0/0/5 supplicant multiple
```

2. Enable reauthentication and specify the reauthentication interval:

```
[edit protocols authentication-access-control]
user@switch# set interface ge-0/0/5/0 dot1x reauthentication interval 5
```

3. Configure the interface timeout value for the response from the supplicant:

```
[edit protocols authentication-access-control]
user@switch# set interface ge-0/0/5 dot1x supplicant-timeout 5
```

4. Configure the timeout for the interface before it resends an authentication request to the RADIUS server:

```
[edit protocols authentication-access-control]
user@switch# set interface ge-0/0/5 server-timeout 5
```

5. Configure how long, in seconds, the interface waits before retransmitting the initial EAPOL PDUs to the supplicant:

```
[edit protocols authentication-access-control]
user@switch# set interface ge-0/0/5 dot1x transmit-period 60
```

6. Configure the maximum number of times an EAPOL request packet is retransmitted to the supplicant before the authentication session times out:

```
[edit protocols authentication-access-control]
user@switch# set interface ge-0/0/5 dot1x maximum-requests 5
```

7. Configure the number of times the switch attempts to authenticate the port after an initial failure. The port remains in a wait state during the quiet period after the authentication attempt.

```
[edit protocols authentication-access-control]
user@switch# set interface ge-0/0/5 retries 1
```

**NOTE:** This setting specifies the number of tries before the switch puts the interface in a “HELD” state.

# Configuring LLDP-MED on MX Series Routers in Enhanced LAN Mode

## IN THIS SECTION

- [Enabling LLDP-MED on Interfaces | 616](#)
- [Configuring Location Information Advertised by the Router | 616](#)
- [Configuring for Fast Start | 617](#)

Link Layer Discovery Protocol–Media Endpoint Discovery (LLDP-MED) is an extension of LLDP. Starting with Junos OS Release 14.2, the router uses LLDP-MED to support device discovery of VoIP telephones and to create location databases for these telephone locations.

LLDP-MED is turned on by default on MX Series routers.

This topic describes:

## Enabling LLDP-MED on Interfaces

LLDP-MED is enabled on all interfaces by default. If it is disabled, you can enable LLDP-MED by configuring it on all interfaces or on specific interfaces.

To configure LLDP-MED on all interfaces or on a specific interface:

```
[edit protocols lldp-med]
user@router# set interface (LLDP-MED) ge-0/0/2.0
```

## Configuring Location Information Advertised by the Router

You can configure the location information that is advertised from the router to the LLDP-MED device. You can specify a civic-based location (geographic location) or a location based on an ELIN (Emergency Location Identification Number):

- To specify a location by geography:

```
[edit protocols lldp-med]

user@router# set interface ge-0/0/2.0 location civic-based country-code
US
user@router# set interface ge-0/0/2.0 location civic-based ca-type 1 ca-value "El Dorado
County"
user@router# set interface ge-0/0/2.0 location civic-based ca-type 2 ca-value CA
user@router# set interface ge-0/0/2.0 location civic-based ca-type 3 ca-value Somerset
user@router# set interface ge-0/0/2.0 location civic-based ca-type 6 ca-value "Mount Aukum
Road"
user@router# set interface ge-0/0/2.0 location civic-based ca-type 19 ca-value 6450
user@router# set interface ge-0/0/2.0 location civic-based ca-type 21 ca-value "Holiday
Market"
```

- To specify a location using an **elin** string:

```
[edit protocols lldp-med]

user@router# set interface ge-0/0/2.0 location elin 4085551212
```

## Configuring for Fast Start

You can specify the number of LLDP-MED advertisements sent from the router in the first second after it has detected an LLDP-MED device. The default is 3; to set it to another value:

```
[edit protocols lldp-med]
user@router# set fast-start 6
```

**NOTE:** If an interface is configured as a VoIP interface, then the router does not wait for an attached phone to identify itself as an LLDP-MED device before it performs an LLDP-MED fast start after a graceful Routing Engine switchover (GRES) or a reboot. Instead, it immediately performs an LLDP-MED fast start after a GRES or reboot. This behavior prevents certain models of IP phones from resetting after a GRES.

### Release History Table

| Release | Description                                                                                                                                                                  |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 14.2    | Starting with Junos OS Release 14.2, the router uses LLDP-MED to support device discovery of VoIP telephones and to create location databases for these telephone locations. |

## Configuring LLDP on MX Series Routers in Enhanced LAN Mode

### IN THIS SECTION

- [Enabling LLDP on Interfaces | 618](#)
- [Adjusting LLDP Advertisement Settings | 619](#)
- [Adjusting SNMP Notification Settings of LLDP Changes | 620](#)
- [Specifying a Management Address for the LLDP Management TLV | 622](#)

Starting with Junos OS Release 14.2, devices use Link Layer Discovery Protocol (LLDP) and Link Layer Discovery Protocol–Media Endpoint Discovery (LLDP-MED) to learn and distribute device information on network links. The information enables the device to quickly identify a variety of other devices, resulting in a LAN that interoperates smoothly and efficiently.

This topic describes:

### Enabling LLDP on Interfaces

LLDP is enabled on all interfaces by default. If it is disabled, you can enable LLDP by configuring it on all interfaces or on specific interfaces.

- To configure LLDP on all interfaces:

```
[edit protocols lldp]
user@router# set interface all
```

- To configure LLDP on a specific interface:

```
[edit protocols lldp]
user@router# set interface interface-name
```

**NOTE:** On MX Series routers, LLDP cannot be configured on the management Ethernet interface. Issuing the command `set protocols lldp interfaceem0` generates the following error message:

```
error: name: 'em0': Invalid interface
error: statement creation failed: interface
```

## Adjusting LLDP Advertisement Settings

You can adjust the following settings for LLDP advertisements for troubleshooting or verification purposes. The default values are applied when LLDP is enabled. For normal operations, we recommend that you do not change the default values.

- To specify the frequency at which LLDP advertisements are sent (in seconds):

```
[edit protocols lldp]
user@router# set advertisement-interval seconds
```

For example, using the default value:

```
[edit protocols lldp]
user@router# set advertisement-interval 45
```

- To specify the number of seconds that LLDP information is held before it is discarded (the multiplier value is used in combination with the **advertisement-interval** value):

```
[edit protocols lldp]
user@router# set hold-multiplier seconds
```

For example, using the default value:

```
[edit protocols lldp]
user@router# set hold-multiplier 5
```

- To specify the number of seconds the device delays before sending advertisements to neighbors after a change is made in a TLV (type, length, or value) element in LLDP or in the state of the local system, such as a change in hostname or management address, set the transmit delay. The transmit delay is enabled by default on switches to reduce the delay in notifying neighbors of a change in the local system. The default value is 2 seconds (if the **advertisement-interval** value is set to 8 seconds or more) or 1 second (if the **advertisement-interval** value is set to less than 8 seconds).

```
[edit protocols lldp]
user@router# set transmit-delay seconds
```

For example:

```
[edit protocols lldp]
user@router# set transmit-delay 2
```

**NOTE:** The **advertisement-interval** value must be greater than or equal to four times the **transmit-delay** value; otherwise, an error is returned when you attempt to commit the configuration.

## Adjusting SNMP Notification Settings of LLDP Changes

You can adjust the following settings for SNMP notifications of LLDP changes. If the values are not specified or if the interval values are set to **0**, the notifications are disabled.

- To specify the frequency at which LLDP database changes are sent (in seconds):

```
[edit protocols lldp]
user@router# set lldp-configuration-notification-interval seconds
```

For example:

```
[edit protocols lldp]
user@router# set lldp-configuration-notification-interval 600
```

- To configure the time interval for SNMP trap notifications to wait for topology changes (in seconds):

```
[edit protocols lldp]
user@router# set ptopo-configuration-trap-interval seconds
```

For example:

```
[edit protocols lldp]
user@router# set ptopo-configuration-trap-interval 600
```

- To specify the holding time (used in combination with the **ptopo-configuration-trap-interval** value) to maintain dynamic topology entries (in seconds):

```
[edit protocols lldp]
user@router# set ptopo-configuration-maximum-hold-time seconds
```

For example:

```
[edit protocols lldp]
user@router# set ptopo-configuration-maximum-hold-time 2147483647
```

# Specifying a Management Address for the LLDP Management TLV

You can configure an IPv4 or IPv6 management address to be used in the LLDP Management Address type, length, and value (TLV) messages. Only out-of-band management addresses must be used as the value for the `management-address` statement.

To configure the management address:

```
[edit protocols lldp]
user@router# set management-address ip-address
```

**NOTE:** Ensure that the interface with the configured management address has LLDP enabled using the `set protocols lldp interface` command. If you configure a customized management address for LLDP on an interface that has LLDP disabled, the `show lldp local-information` command output will not display the correct interface information.

Release History Table

| Release | Description                                                                                                                                                                                                              |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 14.2    | Starting with Junos OS Release 14.2, devices use Link Layer Discovery Protocol (LLDP) and Link Layer Discovery Protocol–Media Endpoint Discovery (LLDP-MED) to learn and distribute device information on network links. |

# Configuring Server Fail Fallback on MX Series Routers in Enhanced LAN Mode

Starting with Junos OS Release 14.2, server fail fallback allows you to specify how end devices connected to the router are supported if the RADIUS authentication server becomes unavailable or sends a RADIUS access-reject message.

802.1X and MAC RADIUS authentication work by using an *authenticator port access entity* (the router) to block all traffic to and from an end device at the interface until the end device's credentials are presented and matched on the *authentication server* (a RADIUS server). When the end device has been authenticated, the router stops blocking and opens the interface to the end device.

When you set up 802.1X or MAC RADIUS authentication on the router, you specify a primary authentication server and one or more backup authentication servers. If the primary authentication server cannot be reached by the router and the secondary authentication servers are also unreachable, a RADIUS server timeout occurs. Because the authentication server grants or denies access to the end devices awaiting authentication, the router does not receive access instructions for end devices attempting access to the LAN and normal authentication cannot be completed. Server fail fallback allows you to configure authentication alternatives that permit the router to take appropriate actions toward end devices awaiting authentication or reauthentication.

**NOTE:** The authentication fallback method called *server-reject VLAN* provides limited access to a LAN, typically just to the Internet, for responsive end devices that are 802.1X-enabled but that have sent the wrong credentials. If the end device that is authenticated using the server-reject VLAN is an IP phone, voice traffic is not allowed.

To configure basic server fail fallback options using the CLI:

- Configure an interface to allow traffic to flow from a supplicant to the LAN if a RADIUS server timeout occurs (as if the end device had been successfully authenticated by a RADIUS server):

```
[edit protocols authentication-access-control]
user@router# set interface ge-0/0/1 dot1x server-fail permit
```

- Configure an interface to prevent traffic flow from an end device to the LAN (as if the end device had failed authentication and had been rejected by the RADIUS server):

```
[edit protocols authentication-access-control]
user@router# set interface ge-0/0/1 dot1x server-fail deny
```

- Configure an interface to move an end device to a specified VLAN if a RADIUS server timeout occurs (in this case, the VLAN name is **vlan1**):

```
[edit protocols authentication-access-control]
user@router# set interface ge-0/0/1 dot1x server-fail vlan-name
vlan1
```

- Configure an interface to recognize already connected end devices as reauthenticated if there is a RADIUS timeout during reauthentication (new users will be denied access):

```
[edit protocols authentication-access-control]
user@router# set interface ge-0/0/1 dot1x server-fail use-cache
```

- Configure an interface that receives a RADIUS access-reject message from the authentication server to move end devices attempting LAN access on the interface to a specified VLAN already configured on the router (in this case, the VLAN name is **vlan-sf**):

```
[edit protocols authentication-access-control]
user@router# set interface ge-0/0/1 dot1x server-reject-vlan vlan-sf
```

**NOTE:** If an IP phone is authenticated in the server-reject VLAN, voice traffic is not allowed.

Release History Table

# Understanding Captive Portal Authentication on the MX Series Routers

IN THIS SECTION

- [Limitations of Captive Portal](#) | 625

Starting with Junos OS Release 14.2, captive portal authentication (hereafter referred to as captive portal) allows you to authenticate users on MX Series routers by redirecting Web browser requests to a

login page that requires users to input a username and password before they are allowed access to the network. Captive portal controls network access by requiring users to provide information that is authenticated against a RADIUS server database using EAP-MD5. You can also use captive portal to display an acceptable-use policy to users before they access your network.

Juniper Networks Junos Software for MX Series routers provides a template that allows you to easily design and modify the look of the captive portal login page. You enable specific interfaces for captive portal. The first time a client connected to a captive portal interface attempts to access a webpage, the switch presents the captive portal login page. Upon successful authentication, the user is allowed access to the network and to continue to the original page requested.

**NOTE:** If Hypertext Transfer Protocol Secure (HTTPS) is enabled, Hypertext Transfer Protocol (HTTP) requests are redirected to an HTTPS connection for the captive portal authentication process. After authentication, the client is returned to the HTTP connection.

If there are clients that are not HTTP-enabled connected to the captive portal interface, you can allow them to bypass captive portal authentication by adding their MAC address to an authentication allowlist. (If the MAC address has already been learned on the interface, you must clear it using the **clear captive-portal interface *interface-name*** before adding it to the allowlist.)

When the user is authenticated by the RADIUS server, any per-user policies (attributes) associated with that user are also sent to the switch.

## Limitations of Captive Portal

Captive portal on MX Series routers has the following limitations:

- The captive portal interface must be configured for **family ethernet-switching** and set to port mode access. The VLAN must be configured with a *routed VLAN interface (RV)*.
- The DHCP gateway IP address for the switch must be configured as the IP address of the routed VLAN interface.
- Captive portal does not support dynamic assignment of VLANs downloaded from the RADIUS server.
- If the user is idle for more than about 5 minutes and there is no traffic passed, the user is required to log back in to the captive portal.

|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 14.2    | Starting with Junos OS Release 14.2, captive portal authentication (hereafter referred to as captive portal) allows you to authenticate users on MX Series routers by redirecting Web browser requests to a login page that requires users to input a username and password before they are allowed access to the network. |

## Understanding Authentication Session Timeout on MX Series Routers

Starting with Junos OS Release 14.2, you can specify authentication session timeout values for captive portal authentication sessions and 802.1X and MAC RADIUS authentication sessions.

For captive portal authentication, the length of the session depends on the value configured for the `session-expiry` statement. The remainder of this topic pertains only to 802.1X and MAC RADIUS authentication sessions.

For 802.1X and MAC RADIUS authentication sessions, the timeout of the session depends on the value of **reauthentication interval** for **dot1x authentication**. The authentication session might also end when the MAC table aging time expires because, unless you configure it not to, the session is removed from the authentication session table when the MAC address is removed from the Ethernet switching table.

Information about each 802.1X and MAC RADIUS authentication session—including the associated interfaces and VLANs for each MAC address that is authenticated by 802.1X authentication or MAC RADIUS authentication—is stored in the authentication session table. The authentication session table is tied to the Ethernet switching table (also called the MAC table). Each time the switch detects traffic from a MAC address, it updates the timestamp for that network node in the Ethernet switching table. A timer on the switch periodically checks the timestamp and if its value exceeds the user-configured **mac-table-aging-time** value, the switch removes the MAC address from the Ethernet switching table. When a MAC address ages out of the Ethernet switching table, the entry for that MAC address is also removed from the authentication database, with the result that the session ends.

You can control variables affecting timeout of authentication sessions in the following ways:

- Set the authentication session timeout on all interfaces or on selected interfaces using the `reauthentication` statement.

- Disassociate the authentication session table from the Ethernet switching table using the `no-mac-table-binding` statement. This setting prevents the termination of the authentication session when the associated MAC address ages out of the Ethernet switching table.

# Authentication Process Flow for MX Series Routers in Enhanced LAN Mode

Starting with Junos OS Release 14.2, you can control access to your network through an MX Series router by using several different authentication methods—including 802.1X, MAC RADIUS, or captive portal.

Figure 29 on page 629 illustrates the authentication process:

Figure 29: Authentication Process Flow for an MX Series Router

## Release History Table

| Release | Description                                                                                                                                                                                                |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 14.2    | Starting with Junos OS Release 14.2, you can control access to your network through an MX Series router by using several different authentication methods—including 802.1X, MAC RADIUS, or captive portal. |

## Specifying RADIUS Server Connections on an MX Series Router in Enhanced LAN Mode

IEEE 802.1X and MAC RADIUS authentication both provide network edge security, protecting Ethernet LANs from unauthorized user access by blocking all traffic to and from devices at the interface until the supplicant's credentials or MAC address are presented and matched on the *authentication server* (a RADIUS server). When the supplicant is authenticated, the router stops blocking access and opens the interface to the supplicant.

Starting with Junos OS Release 14.2, to use 802.1X or MAC RADIUS authentication, you must specify the connections on the router for each RADIUS server to which you will connect.

To configure a RADIUS server on the router:

1. Define the IP address of the RADIUS server, the RADIUS server authentication port number, and the secret password. You can define more than one RADIUS server. The secret password on the router must match the secret password on the server:

```
[edit access]
user@router# set radius-server 10.0.0.100 port 1812 secret abc
```

**NOTE:** Specifying the authentication port is optional, and port 1812 is the default. However, we recommend that you configure it in order to avoid confusion as some RADIUS servers might refer to an older default.

2. (Optional) Specify the IP address by which the router is identified by the RADIUS server. If you do not specify this, the RADIUS server uses the address of the interface sending the RADIUS request. We recommend that you specify this IP address because if the request gets diverted on an alternate

route to the RADIUS server, the interface relaying the request might not be an interface on the router.

```
[edit access]
user@router# set radius-server source-address 10.93.14.100
```

- 3. Configure the authentication order, making **radius** the first method of authentication:

```
[edit access]
user@router# set profile profile1 authentication-order radius
```

- 4. Create a profile and specify the list of RADIUS servers to be associated with the profile. For example, you might choose to group your RADIUS servers geographically by city. This feature enables easy modification whenever you want to change to a different sent of authentication servers.

```
[edit access profile]
user@router# set atlanta radius authentication-server 10.0.0.100 10.2.14.200
```

- 5. Specify the group of servers to be used for 802.1X or MAC RADIUS authentication by identifying the profile name:

```
[edit access profile]
user@router# set protocols authentication-access-control authentication-profile-name denver
```

- 6. Configure the IP address of the MX Series router in the list of clients on the RADIUS server. For specifics on configuring the RADIUS server, consult the documentation for your server.

# Configuring Captive Portal Authentication on MX Series Routers in Enhanced LAN Mode

## IN THIS SECTION

- [Configuring Secure Access for Captive Portal | 633](#)
- [Enabling an Interface for Captive Portal | 633](#)
- [Configuring Bypass of Captive Portal Authentication | 634](#)

**NOTE:** This example uses Junos OS for MX240, MX480, and MX960 routers with support for the Enhanced LAN mode configuration style. If your router does not run MX-LAN mode, you cannot configure port-based authentication settings in the same manner as described in this section. If you remove the `network-services lan` statement at the `[edit chassis]` hierarchy level, the system does not run in MX-LAN mode. Therefore, all of the settings that are supported outside of the MX-LAN mode are displayed and are available for definition in the CLI interface. In such a scenario, you must use the statements at the `[edit protocols dot1x]` hierarchy level to configure 802.1x and MAC RADIUS authentication, and the options at the `[edit services captive-portal]` hierarchy level to configure captive portal authentication. In MX-LAN mode, you can configure all the port-based network access control methodologies using the statements at the `[edit protocols authentication-access-control]` hierarchy level.

Starting with Junos OS Release 14.2, configure captive portal authentication (hereafter referred to as captive portal) on an MX Series router so that users connected to the router are authenticated before being allowed to access the network. When the user requests a webpage, a login page is displayed that requires the user to input a username and password. Upon successful authentication, the user is allowed to continue with the original page request and subsequent access to the network.

Before you begin, be sure you have:

- Performed basic bridging and VLAN configuration on the router.
- Generated an SSL certificate and installed it on the router.
- Configured basic access between the MX Series router and the RADIUS server.
- Designed your captive portal login page.

This topic includes the following tasks:

## Configuring Secure Access for Captive Portal

To configure secure access for captive portal:

1. Associate the security certificate with the Web server and enable HTTPS on the router:

```
[edit]
user@router# set system services web-management https local-certificate my-signed-cert
```

**NOTE:** You can enable HTTP instead of HTTPS, but we recommend HTTPS for security purposes.

2. Configure captive portal to use HTTPS:

```
[edit]
user@router# set protocols custom-options-captive-portal secure-authentication https
```

## Enabling an Interface for Captive Portal

To enable an interface for use with captive portal authentication:

```
[edit]
user@router# set authentication-access-control interface ge-0/0/10
```

## Configuring Bypass of Captive Portal Authentication

You can allow specific clients to bypass captive portal authentication:

```
[edit]
user@router# set authentication-access-control static 00:10:12:e0:28:22
```

**NOTE:** Optionally, you can use `set authentication-access-control static 00:10:12:e0:28:22 interface ge-0/0/10.0` to limit the scope to the interface.

**NOTE:** If the client is already attached to the router, you must clear its MAC address from the captive portal authentication by using the `clear captive-portal mac-address session-mac-addr` command after adding its MAC address to the allowlist. Otherwise the new entry for the MAC address will not be added to the Ethernet switching table and the authentication bypass will not be allowed.

Release History Table

| Release | Description                                                                                                                                                                                                                                       |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 14.2    | Starting with Junos OS Release 14.2, configure captive portal authentication (hereafter referred to as captive portal) on an MX Series router so that users connected to the router are authenticated before being allowed to access the network. |

## Designing a Captive Portal Authentication Login Page on an MX Series Router

Starting with Junos OS Release 14.2, you can set up captive portal authentication on your switch to redirect all Web browser requests to a login page that requires the user to input a username and password before they are allowed access. Upon successful authentication, the user is allowed access to the network and redirected to the original page requested.

Junos OS provides a customizable template for the captive portal window that allows you to easily design and modify the look of the captive portal login page. You can modify the design elements of the

template to change the look of your captive portal login page and to add instructions or information to the page. You can also modify any of the design elements of a captive portal login page.

The first screen displayed before the captive login page requires the user to read the “Terms and Conditions of Use”. By clicking the Agree button, the user can access the captive portal login page.

Figure 30 on page 635 shows an example of a captive portal login page:

Figure 30: Example of a Captive Portal Login Page

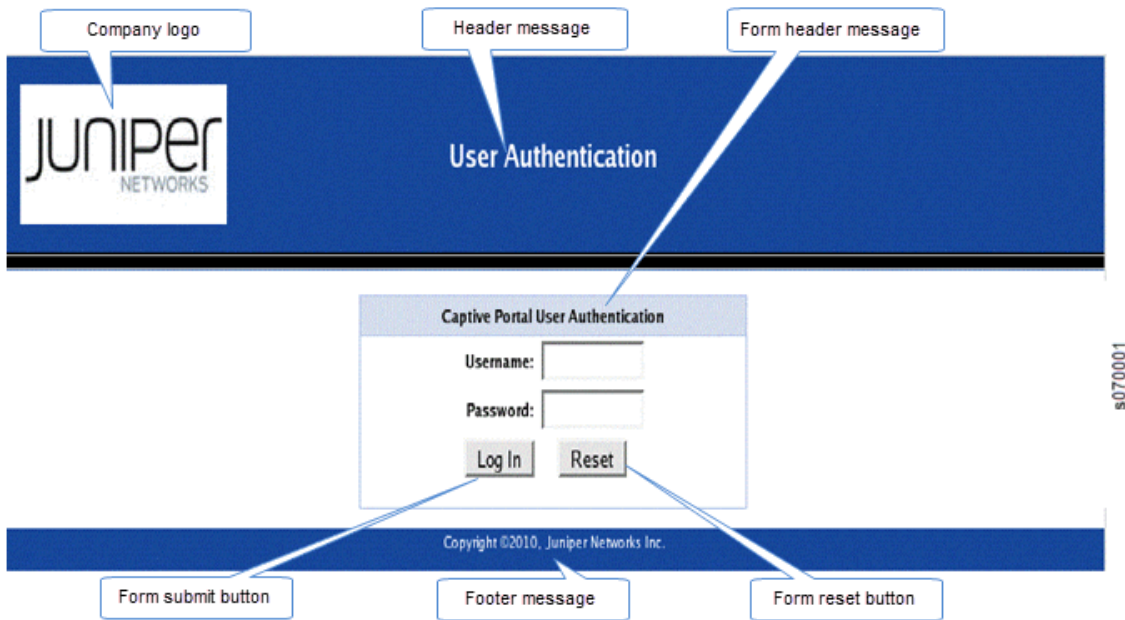

Table 35 on page 635 summarizes the configurable elements of a captive portal login page.

Table 35: Configurable Elements of a Captive Portal Login Page

The default color is white.                                                                                                                                                                                                                                                                                                                                                                                         |
| Form header background color | <b>form-header-bgcolor</b><br><i>hex-color</i>   | The HTML hexadecimal code for the background color of the header bar across the top of the form area of the captive portal login page.                                                                                                                                                                                                                                                                                                               |
| Form header message          | <b>form-header-message</b><br><i>text-string</i> | Text displayed in the header of the captive portal login page. The default text is <b>Captive Portal User Authentication</b>                                                                                                                                                                                                                                                                                                                         |
| Form header text color       | <b>form-header- text-color</b><br><i>color</i>   | Color of the text in the form header. The default color is black.                                                                                                                                                                                                                                                                                                                                                                                    |
| Form reset button label      | <b>form-reset-label</b><br><i>label-name</i>     | Using the <b>Reset</b> button, the user can clear the username and password fields on the form.                                                                                                                                                                                                                                                                                                                                                      |
| Form submit button label     | <b>form-submit-label</b><br><i>label-name</i>    | Using the <b>Login</b> button, the user can submit the login information.                                                                                                                                                                                                                                                                                                                                                                            |
| Header background color      | <b>header-bgcolor</b> <i>hex-color</i>           | The HTML hexadecimal code for the background color of the captive portal login page header.                                                                                                                                                                                                                                                                                                                                                          |
| Header logo                  | <b>header-logo</b> <i>filename</i>               | <p>Filename of the file containing the image of the logo that you want to appear in the header of the captive portal login page. The image file can be in GIF, JPEG, or PNG format</p> <p>You can upload a logo image file to the switch. Copy the logo to the /var/tmp directory on the switch (during commit, the files are saved to persistent locations).</p> <p>If you do not specify a logo image, the Juniper Networks logo is displayed.</p> |
| Header message               | <b>header-message</b> <i>text-string</i>         | Text displayed in the page header. The default text is <b>User Authentication</b> .                                                                                                                                                                                                                                                                                                                                                                  |

Table 35: Configurable Elements of a Captive Portal Login Page (*Continued*)

| Element                 | CLI Statement                             | Description                                                                                                                                 |
|-------------------------|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| Header text color       | <b>header-text-color</b> <i>color</i>     | Color of the text in the header. The default color is white.                                                                                |
| Post-authentication URL | <b>post-authentication-url</b> <i>url</i> | URL to which the users are directed on successful authentication. By default, users are directed to the page they had originally requested. |

To design the captive portal login page:

1. (Optional) Upload your logo image file to the switch:

```
user@router> file copy ftp://username:prompt@ftp.hostname.net/var/tmp/my-logo.jpeg
```

2. Configure the custom options to specify the background colors and text displayed in the captive portal page:

```
[edit protocols]
user@router# set captive-portal-custom-options header-bgcolor #006600
set captive-portal-custom-options header-message "Welcome to Our Network"
set captive-portal-custom-options banner-message "Please enter your username and
password".The banner displays the message "XXXXXXX" by default. The user can modify this
message.
set custom-options footer-message "Copyright ©2010, Our Network"
```

Now you can commit the configuration.

**NOTE:** For the custom options that you do not specify, the default value is used.

#### Release History Table

| Release | Description                                                                                                                                                                                                                                   |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 14.2    | Starting with Junos OS Release 14.2, you can set up captive portal authentication on your switch to redirect all Web browser requests to a login page that requires the user to input a username and password before they are allowed access. |

# Configuring Static MAC Bypass of Authentication on MX Series Routers in Enhanced LAN Mode

Starting with Junos OS Release 14.2, you can configure a static MAC bypass list (sometimes called the exclusion list) on the switch to specify MAC addresses of devices allowed access to the LAN without 802.1X or MAC RADIUS authentication requests to the RADIUS server.

To configure the static MAC bypass list:

- Specify a MAC address to bypass authentication:

```
[edit protocols authentication-access-control]
user@router# set static 00:04:0f:fd:ac:fe
```

- Configure a supplicant to bypass authentication if connected through a particular interface:

```
[edit protocols authentication-access-control]
user@router# set static 00:04:0f:fd:ac:fe interface ge-0/0/5
```

- You can configure a supplicant to be moved to a specific VLAN after it is authenticated:

```
[edit protocols authentication-access-control]
user@router# set static 00:04:0f:fd:ac:fe interface ge-0/0/5 vlan-assignment default-vlan
```

Release History Table

| Release | Description                                                                                                                                                                                                                                                                  |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 14.2    | Starting with Junos OS Release 14.2, you can configure a static MAC bypass list (sometimes called the exclusion list) on the switch to specify MAC addresses of devices allowed access to the LAN without 802.1X or MAC RADIUS authentication requests to the RADIUS server. |

# Controlling Authentication Session Timeouts on an MX Series Router in Enhanced LAN Mode

Starting with Junos OS Release 14.2, for 802.1X and MAC RADIUS authentication sessions, you can specify authentication session timeout values using the `reauthentication` statement.

The session might also end when the MAC table aging time expires, because the session is removed from the authentication session table when the MAC address is removed from the Ethernet switching table. In order to prevent the session from being removed from the authentication session table, you must disassociate the authentication table from the Ethernet switching table using the `no-mac-table-binding` statement.

Before you begin:

- Specify the RADIUS server or servers to be used as the authentication server.
- Configure 802.1X authentication on the router.

To configure the authentication session time on all interfaces:

```
[edit]
user@router# set protocols authentication-access-control interface all dot1x reauthentication
seconds;
```

To configure the authentication session time on a single interface:

```
[edit]
user@router# set protocols authentication-access-control interface interface-name dot1x
reauthentication seconds;
```

To disable removal of authentication sessions from the authentication session table when a MAC address ages out of the Ethernet switching table, remove the binding of the authentication table to the Ethernet switching table.

To remove the binding on all interfaces:

```
[edit]
user@router# set protocols authentication-access-control no-mac-table-binding interface all;
```

To remove the binding on a single interface:

```
[edit]
user@router# set protocols authentication-access-control no-mac-table-binding interface
interface-name;
```

|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 14.2    | Starting with Junos OS Release 14.2, for 802.1X and MAC RADIUS authentication sessions, you can specify authentication session timeout values using the reauthentication statement. |

## Configuring MAC RADIUS Authentication on MX Series Routers in Enhanced LAN Mode

Starting with Junos OS Release 14.2, you can permit devices that are not 802.1X-enabled LAN access by configuring MAC RADIUS authentication on the MX Series router interfaces to which the hosts are connected.

**NOTE:** You can also allow non-802.1X-enabled devices to access the LAN by configuring their MAC address for static MAC bypass of authentication.

You can configure MAC RADIUS authentication on an interface that also allows 802.1X authentication, or you can configure either authentication method alone.

If both MAC RADIUS and 802.1X authentication are enabled on the interface, the router first sends the host three EAPOL requests to the host. If there is no response from the host, the router sends the host's MAC address to the RADIUS server to check whether it is a permitted MAC address. If the MAC address is configured as permitted on the RADIUS server, the RADIUS server sends a message to the router that the MAC address is a permitted address, and the router opens LAN access to the nonresponsive host on the interface to which it is connected.

If MAC RADIUS authentication is configured on the interface but 802.1X authentication is not (by using the **mac-radius restrict** option), the router attempts to authenticate the MAC address with the RADIUS server without delaying by attempting 802.1X authentication first.

Before you configure MAC RADIUS authentication, be sure you have:

- Configured basic access between the MX Series router and the RADIUS server.
- Configured MX240, MX480, and MX960 routers to function in enhanced LAN mode by entering the `network-services lan` statement at the `[edit chassis]` hierarchy level.

To configure MAC RADIUS authentication using the CLI:

- On the router, configure the interfaces to which the nonresponsive hosts are attached for MAC RADIUS authentication, and add the **restrict** qualifier for interface **ge-0/0/20** to have it use only MAC RADIUS authentication:

```
[edit]
user@router# set protocols authentication-access-control interface ge-0/0/19 dot1x mac-radius
user@router# set protocols authentication-access-control interface ge-0/0/20 dot1x mac-radius
restrict
```

- On a RADIUS authentication server, create user profiles for each nonresponsive host using the MAC address (without colons) of the nonresponsive host as the username and password (here, the MAC addresses are **00:04:0f:fd:ac:fe** and **00:04:ae:cd:23:5f**):

```
[root@freeradius]#
edit /etc/raddb
vi users
00040ffdacfe Auth-type:=Local, User-Password = "00040ffdacfe"
0004aec235f Auth-type:=Local, User-Password = "0004aec235f"
```

# Example: Configuring MAC RADIUS Authentication on an MX Series Router

## IN THIS SECTION

- [Requirements | 642](#)
- [Overview and Topology | 643](#)
- [Configuration | 644](#)
- [Verification | 646](#)

Starting with Junos OS Release 14.2 to permit hosts that are not 802.1X-enabled to access the LAN, you can configure MAC RADIUS authentication on the router interfaces to which the non-802.1X-enabled hosts are connected. When MAC RADIUS authentication is configured, the router will attempt to authenticate the host with the RADIUS server using the host's MAC address.

This example describes how to configure MAC RADIUS authentication for two non-802.1X-enabled hosts:

## Requirements

This example uses the following hardware and software components:

- Junos OS Release 14.2 or later for MX240, MX480, or MX960 routers running in enhanced LAN mode.
- An MX Series router acting as an authenticator port access entity (PAE). The ports on the authenticator PAE form a control gate that blocks all traffic to and from supplicants until they are authenticated.
- A RADIUS authentication server. The authentication server acts as the backend database and contains credential information for hosts (supplicants) that have permission to connect to the network.

Before you connect the server to the router, be sure you have:

- Configured enhanced LAN mode on the router.

- Performed basic bridging and VLAN configuration on the router.
- Configured users on the RADIUS authentication server.

## Overview and Topology

IN THIS SECTION

- [Topology | 644](#)

IEEE 802.1X Port-Based Network Access Control (PNAC) authenticates and permits devices access to a LAN if the devices can communicate with the router using the 802.1X protocol (are 802.1X-enabled). To permit non-802.1X-enabled end devices to access the LAN, you can configure MAC RADIUS authentication on the interfaces to which the end devices are connected. When the MAC address of the end device appears on the interface, the router consults the RADIUS server to check whether it is a permitted MAC address. If the MAC address of the end device is configured as permitted on the RADIUS server, the router opens LAN access to the end device.

You can configure both MAC RADIUS authentication and 802.1X authentication methods on an interface configured for multiple supplicants. Additionally, if an interface is only connected to a non-802.1X-enabled host, you can enable MAC RADIUS and not enable 802.1X authentication using the **mac-radius restrict** option, and thus avoid the delay that occurs while the router determines that the device does not respond to EAP messages.

Two printers are connected to an MX Series router over interfaces, ge-0/0/19 and ge-0/0/20.

[Table 36 on page 643](#) shows the components in the example for MAC RADIUS authentication.

**Table 36: Components of the MAC RADIUS Authentication Configuration Topology**

| Property        | Settings                           |
|-----------------|------------------------------------|
| Router hardware | Ports (ge-0/0/0 through ge-0/0/23) |
| VLAN name       | sales                              |

**Table 36: Components of the MAC RADIUS Authentication Configuration Topology** *(Continued)*

| Property                | Settings                                                                   |
|-------------------------|----------------------------------------------------------------------------|
| Connections to printers | ge-0/0/19, MAC address 00040ffdacfe<br>ge-0/0/20, MAC address 0004aecd235f |
| RADIUS server           | Connected to the router on interface <b>ge-0/0/10</b>                      |

The printer with the MAC address 00040ffdacfe is connected to access interface ge-0/0/19. A second printer with the MAC address 0004aecd235f is connected to access interface ge-0/0/20. In this example, both interfaces are configured for MAC RADIUS authentication on the router, and the MAC addresses (without colons) of both printers are configured on the RADIUS server. Interface ge-0/0/20 is configured to eliminate the normal delay while the router attempts 802.1X authentication; MAC RADIUS authentication is enabled and 802.1X authentication is disabled using the `mac radius restrict` option.

## Topology

## Configuration

### IN THIS SECTION

- [Procedure | 645](#)

## Procedure

### CLI Quick Configuration

To quickly configure MAC RADIUS authentication, copy the following commands and paste them into the router terminal window:

```
[edit]
set protocols authentication-access-control interface ge-0/0/19 dot1x mac-radius

set protocols authentication-access-control authenticator interface ge-0/0/20 dot1x mac-radius
restrict
```

**NOTE:** You must also configure the two MAC addresses as usernames and passwords on the RADIUS server, as is done in step 2 of the Step-by-Step Procedure.

### Step-by-Step Procedure

Configure MAC RADIUS authentication on the router and on the RADIUS server:

1. On the router, configure the interfaces to which the printers are attached for MAC RADIUS authentication, and configure the **restrict** option on interface **ge-0/0/20**, so that only MAC RADIUS authentication is used:

```
[edit]
user@router# set protocols authentication-access-control interface ge-0/0/19 dot1x mac-radius

user@router# set protocols authentication-access-control authenticator interface ge-0/0/20
dot1x mac-radius restrict
```

2. On the RADIUS server, configure the MAC addresses **00040ffdacfe** and **0004aec235f** as usernames and passwords:

```
[root@freeradius]#
edit /etc/raddb
vi users
```

```
00040ffdacfe Auth-type:=EAP, User-Password = "00040ffdacfe"
0004aec235f Auth-type:=EAP, User-Password = "0004aec235f"
```

## Results

Display the results of the configuration on the router:

```
user@router> show configuration
protocols {
  authentication-access-control {
    authentication-profile-name profile52;
    interface {
      ge-0/0/19.0 {
        dot1x {
          mac-radius;
        }
      }
      ge-0/0/20.0 {
        dot1x {
          mac-radius {
            restrict;
          }
        }
      }
    }
  }
}
```

## Verification

### IN THIS SECTION

- [Verifying That the Supplicants Are Authenticated | 647](#)

Verify that the supplicants are authenticated:

## Verifying That the Supplicants Are Authenticated

### Purpose

After supplicants are configured for MAC RADIUS authentication on the router and on the RADIUS server, verify that they are authenticated and display the method of authentication:

### Action

Display information about 802.1X-configured interfaces **ge-0/0/19** and **ge-0/0/20**:

```
user@router> show dot1x interface ge-0/0/19.0 detail
ge-0/0/19.0
  Role: Authenticator
  Administrative state: Auto
  Supplicant mode: Single
  Number of retries: 3
  Quiet period: 60 seconds
  Transmit period: 30 seconds
  Mac Radius: Enabled
  Mac Radius Restrict: Disabled
  Reauthentication: Enabled
  Configured Reauthentication interval: 3600 seconds
  Supplicant timeout: 30 seconds
  Server timeout: 30 seconds
  Maximum EAPOL requests: 2
  Guest VLAN member: <not configured>
  Number of connected supplicants: 1
    Supplicant: user101, 00:04:0f:fd:ac:fe
      Operational state: Authenticated
      Authentication method: Radius
      Authenticated VLAN: vo11
      Dynamic Filter: match source-dot1q-tag 10 action deny
      Session Reauth interval: 60 seconds
      Reauthentication due in 50 seconds

user@router> show dot1x interface ge-0/0/20.0 detail
ge-0/0/20.0
  Role: Authenticator
  Administrative state: Auto
  Supplicant mode: Single
  Number of retries: 3
```

```

Quiet period: 60 seconds
Transmit period: 30 seconds
Mac Radius: Enabled
Mac Radius Restrict: Enabled
Reauthentication: Enabled
Configured Reauthentication interval: 3600 seconds
Supplicant timeout: 30 seconds
Server timeout: 30 seconds
Maximum EAPOL requests: 2
Guest VLAN member: <not configured>
Number of connected supplicants: 1
  Supplicant: user102, 00:04:ae:cd:23:5f
    Operational state: Authenticated
    Authentication method: Radius
    Authenticated VLAN: vo11
    Dynamic Filter: match source-dot1q-tag 10 action deny
    Session Reauth interval: 60 seconds
    Reauthentication due in 50 seconds

```

### Meaning

The sample output from the `show dot1x interface detail` command displays the MAC address of the connected end device in the **Supplicant** field. On interface `ge-0/0/19`, the MAC address is **00:04:0f:fd:ac:fe**, which is the MAC address of the first printer configured for MAC RADIUS authentication. The **Authentication method** field displays the authentication method as **MAC Radius**. On interface `ge-0/0/20`, the MAC address is **00:04:ae:cd:23:5f**, which is the MAC address of the second printer configured for MAC RADIUS authentication. The **Authentication method** field displays the authentication method as **MAC Radius**.

Release History Table

| Release | Description                                                                                                                                                                                                                  |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 14.2    | Starting with Junos OS Release 14.2 to permit hosts that are not 802.1X-enabled to access the LAN, you can configure MAC RADIUS authentication on the router interfaces to which the non-802.1X-enabled hosts are connected. |

# Example: Setting Up Captive Portal Authentication on an MX Series Router

## IN THIS SECTION

- [Requirements | 649](#)
- [Overview and Topology | 650](#)
- [Configuration | 650](#)
- [Verification | 654](#)
- [Troubleshooting | 655](#)

Starting with Junos OS Release 14.2, you can set up captive portal authentication (hereafter referred to as captive portal) on a router to redirect Web browser requests to a login page that requires the user to input a username and password. Upon successful authentication, the user is allowed to continue with the original page request and subsequent access to the network.

This example describes how to set up captive portal on an MX Series router:

## Requirements

This example uses the following hardware and software components:

- An MX Series router that supports captive portal
- Junos OS Release 14.2 or later for MX Series routers

Before you begin, be sure you have:

- Performed basic bridging and VLAN configuration on the router.
- Generated an SSL certificate and installed it on the router.
- Configured basic access between the MX Series router and the RADIUS server.
- Designed your captive portal login page. .

## Overview and Topology

### IN THIS SECTION

- [Topology | 650](#)

This example shows the configuration required on the router to enable captive portal on an interface. To permit a printer connected to the captive portal interface to access the LAN without going through captive portal, add its MAC address to the authentication allowlist. The MAC addresses in this list are permitted access on the interface without captive portal.

### Topology

The topology for this example consists of one MX Series router connected to a RADIUS authentication server. One interface on the router is configured for captive portal. In this example, the interface is configured in multiple supplicant mode.

## Configuration

### IN THIS SECTION

- [CLI Quick Configuration | 651](#)
- [Procedure | 651](#)

To configure captive portal on your router:

## CLI Quick Configuration

To quickly configure captive portal on the router after completing the tasks in the Requirements section, copy the following commands and paste them into the router terminal window:

```
[edit]
set system services web-management http
set system services web-management https local-certificate my-signed-cert
set protocols captive-portal-custom-options secure-authentication https
set protocols authentication-access-control interface ge-0/0/10.0 supplicant multiple
set protocols authentication-access-control static 00:10:12:e0:28:22
set protocols captive-portal-custom-options post-authentication-url http://www.my-home-page.com
```

## Procedure

### Step-by-Step Procedure

To configure captive portal on the router:

1. Enable HTTP access on the router:

```
[edit]
user@router# set system services web-management http
```

2. To create a secure channel for Web access to the router, configure captive portal for HTTPS:

**NOTE:** You can enable HTTP without enabling HTTPS, but we recommend HTTPS for security purposes.

### Step-by-Step Procedure

- a. Associate the security certificate with the Web server and enable HTTPS access on the router:

```
[edit]
user@router# set system services web-management https local-certificate my-signed-cert
```

- b. Configure captive portal to use HTTPS:

```
[edit]
user@router# set protocols captive-portal-custom-options secure-authentication https
```

3. Enable an interface for captive portal:

```
[edit]
user@router# set protocols authentication-access-control interface ge-0/0/10.0 supplicant
multiple
```

4. (Optional) Allow specific clients to bypass captive portal:

**NOTE:** If the client is already attached to the router, you must clear its MAC address from the captive portal authentication by using the `clear captive-portal mac-address mac-address` command after adding its MAC address to the allowlist. Otherwise the new entry for the MAC address will not be added to the Ethernet routing table and authentication bypass will not be allowed.

```
[edit]
user@router# set protocols authentication-access-control static 00:10:12:e0:28:22
```

**NOTE:** Optionally, you can use `set ethernet-switching-options authentication-whitelist 00:10:12:e0:28:22 interface ge-0/0/10.0` to limit the scope to the interface.

5. (Optional) To redirect clients to a specified page rather than the page they originally requested, configure the post-authentication URL:

```
[edit services captive-portal]
user@router# set protocols captive-portal-custom-options post-authentication-url http://
www.my-home-page.com
```

## Results

Display the results of the configuration:

```
[edit]
user@router> show
system {
  services {
    web-management {
      http;
      https {
        local-certificate my-signed-cert;
      }
    }
  }
}
security {
  certificates {
    local {
      my-signed-cert {
        "-----BEGIN RSA PRIVATE KEY-----\nMIICXwIBAAKBgQDk8sUggnXdDUMr7T vLv63yJq/

\n-----END CERTIFICATE-----\n"; ## SECRET-DATA
      }
    }
  }
}
protocols {
  authentication-access-control {
    static 00:10:12:e0:28:22/48;
    interface {
      ge-0/0/10.0 {
        supplicant multiple;
      }
    }
  }
  custom-captive-portal-options {
    secure-authentication https;
    post-authentication-url http://www.my-home-page.com;
```

```
}
}
```

## Verification

### IN THIS SECTION

- [Verifying That Captive Portal Is Enabled on the Interface | 654](#)
- [Verify That Captive Portal Is Working Correctly | 655](#)

To confirm that captive portal is configured and working properly, perform these tasks:

### Verifying That Captive Portal Is Enabled on the Interface

#### Purpose

Verify that captive portal is configured on interface ge-0/0/10.

#### Action

Use the operational mode command `show captive-portal interface interface-name detail`:

```
user@router> show captive-portal interface ge-0/0/10.0 detail
ge-0/0/10.0
  Supplicant mode: Multiple
  Number of retries: 3
  Quiet period: 60 seconds
  Configured CP session timeout: 3600 seconds
  Server timeout: 15 seconds
```

#### Meaning

The output confirms that captive portal is configured on interface ge-0/0/10 with the default settings for number of retries, quiet period, CP session timeout, and server timeout.

## Verify That Captive Portal Is Working Correctly

### Purpose

Verify that captive portal is working on the router.

### Action

Connect a client to interface ge-0/0/10. From the client, open a Web browser and request a webpage. The captive portal login page that you designed should be displayed. After you enter your login information and are authenticated against the RADIUS server, the Web browser should display either the page you requested or the post-authentication URL that you configured.

## Troubleshooting

### IN THIS SECTION

- [Troubleshooting Captive Portal | 655](#)

To troubleshoot captive portal, perform these tasks:

## Troubleshooting Captive Portal

### Problem

The router does not return the captive portal login page when a user connected to a captive portal interface on the router requests a Web page.

### Solution

You can examine the ARP, DHCP, HTTPS, and DNS counters—if one or more of these counters are not incrementing, this provides an indication of where the problem lies. For example, if the client cannot get

an IP address, check the router interface to determine whether the DHCP counter is incrementing—if the counter increments, the DHCP packet was received by the router.

```
user@router> show captive-portal firewall ge-0/0/10.0
ge-0/0/10.0
  Filter name: dot1x_ge-0/0/10
Counters:
Name                               Bytes      Packets
dot1x_ge-0/0/10_CP_arp             7616        119
dot1x_ge-0/0/10_CP_dhcp              0           0
dot1x_ge-0/0/10_CP_http              0           0
dot1x_ge-0/0/10_CP_https              0           0
dot1x_ge-0/0/10_CP_t_dns              0           0
dot1x_ge-0/0/10_CP_u_dns              0           0
```

Release History Table

# Example: Connecting a RADIUS Server for 802.1X to an MX Series Router

IN THIS SECTION

- [Requirements | 657](#)
- [Overview and Topology | 657](#)
- [Configuration | 658](#)
- [Verification | 660](#)

802.1X is the IEEE standard for Port-Based Network Access Control (PNAC). You use 802.1X to control network access. Only users and devices providing credentials that have been verified against a user database are allowed access to the network. Starting with Junos OS Release 14.2, you can use a RADIUS server as the user database for 802.1X authentication, as well as for MAC RADIUS authentication.

This example describes how to connect a RADIUS server to an MX Series router, and configure it for 802.1X:

## Requirements

This example uses the following hardware and software components:

- Junos OS Release 14.2 or later for MX240, MX480, or MX960 routers running in enhanced LAN mode and Junos OS Release 14.2R3 for all other routers.
- One router acting as an authenticator port access entity (PAE). The ports on the authenticator PAE form a control gate that blocks all traffic to and from supplicants until they are authenticated.
- One RADIUS authentication server that supports 802.1X. The authentication server acts as the backend database and contains credential information for hosts (supplicants) that have permission to connect to the network.

Before you connect the server to the router, be sure you have:

- Configured enhanced LAN mode on the router.
- Performed basic bridging and VLAN configuration on the router.
- Configured users on the RADIUS authentication server.

## Overview and Topology

The MX Series router acts as an authenticator Port Access Entity (PAE). It blocks all traffic and acts as a control gate until the supplicant (client) is authenticated by the server. All other users and devices are denied access.

Consider an MX Series router that functions as an authenticator port. It is connected using the interface, ge-0/0/10, over the IP network to a RADIUS server. The router is also linked to a conference room using the interface, ge-0/0/1, to a printer using the interface, ge-0/0/20, to a hub using the interface, ge-0/0/8, and to two supplicants or clients over interfaces, ge-0/0/2 and ge-0/0/9 respectively.

Table 37: Components of the Topology

| Property          | Settings                                                                                               |
|-------------------|--------------------------------------------------------------------------------------------------------|
| Router hardware   | MX Series router                                                                                       |
| VLAN name         | <b>default</b>                                                                                         |
| One RADIUS server | Backend database with an address of <b>10.0.0.100</b> connected to the switch at port <b>ge-0/0/10</b> |

In this example, connect the RADIUS server to access port **ge-0/0/10** on the MX Series router. The switch acts as the authenticator and forwards credentials from the supplicant to the user database on the RADIUS server. You must configure connectivity between the MX Series router and the RADIUS server by specifying the address of the server and configuring the secret password. This information is configured in an access profile on the switch.

## Configuration

IN THIS SECTION

- Procedure | 658

### Procedure

#### CLI Quick Configuration

To quickly connect the RADIUS server to the switch, copy the following commands and paste them into the switch terminal window:

```
[edit]
set access radius-server 10.0.0.100 secret juniper
set access radius-server 10.0.0.200 secret juniper
```

```
set access profile profile1 authentication-order radius
set access profile profile1 radius authentication-server [10.0.0.100 10.0.0.200]
```

## Step-by-Step Procedure

To connect the RADIUS server to the switch:

1. Define the address of the servers, and configure the secret password. The secret password on the switch must match the secret password on the server:

```
[edit]
user@switch# set access radius-server 10.0.0.100 secret juniper
user@switch# set access radius-server 10.0.0.200 secret juniper
```

2. Configure the authentication order, making **radius** the first method of authentication:

```
[edit]
user@switch# set access profile profile1 authentication-order radius
```

3. Configure a list of server IP addresses to be tried in order to authenticate the supplicant:

```
[edit]
user@switch# set access profile profile1 radius authentication-server [10.0.0.100 10.0.0.200]
```

## Results

Display the results of the configuration:

```
user@switch> show configuration access
radius-server {
    10.0.0.100
    port 1812;
    secret "$9$qPT3ApBSrv69rvWLVb.P5"; ## SECRET-DATA
}
}
profile profile1{
```

```
    authentication-order radius;
    radius {

        authentication-server 10.0.0.100 10.0.0.200;
    }
}
```

## Verification

### IN THIS SECTION

- [Verify That the Switch and RADIUS Server are Properly Connected | 660](#)

To confirm that the configuration is working properly, perform these tasks:

### Verify That the Switch and RADIUS Server are Properly Connected

#### Purpose

Verify that the RADIUS server is connected to the switch on the specified port.

#### Action

Ping the RADIUS server to verify the connection between the switch and the server:

```
user@switch> ping 10.0.0.100
PING 10.0.0.100 (10.0.0.100): 56 data bytes
64 bytes from 10.93.15.218: icmp_seq=0 ttl=64 time=9.734 ms
64 bytes from 10.93.15.218: icmp_seq=1 ttl=64 time=0.228 ms
```

## Meaning

ICMP echo request packets are sent from the switch to the target server at 10.0.0.100 to test whether it is reachable across the IP network. ICMP echo responses are being returned from the server, verifying that the switch and the server are connected.

### Release History Table

| Release | Description                                                                                                                                                |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 14.2    | Starting with Junos OS Release 14.2, you can use a RADIUS server as the user database for 802.1X authentication, as well as for MAC RADIUS authentication. |

## Example: Setting Up 802.1X in Conference Rooms to Provide Internet Access to Corporate Visitors on an MX Series Router

### IN THIS SECTION

- [Requirements | 662](#)
- [Overview and Topology | 662](#)
- [Configuration of a Guest VLAN That Includes 802.1X Authentication | 663](#)
- [Verification | 665](#)

Starting with Junos OS Release 14.2, 802.1X on MX Series routers provides LAN access to users who do not have credentials in the RADIUS database. These users, referred to as guests, are authenticated and typically provided with access to the Internet.

This example describes how to create a guest VLAN and configure 802.1X authentication for it.

## Requirements

This example uses the following hardware and software components:

- Junos OS Release 14.2 or later for MX240, MX480, or MX960 routers running in enhanced LAN mode.
- One router acting as an authenticator port access entity (PAE). The ports on the authenticator PAE form a control gate that blocks all traffic to and from supplicants until they are authenticated.
- One RADIUS authentication server that supports 802.1X. The authentication server acts as the backend database and contains credential information for hosts (supplicants) that have permission to connect to the network.

Before you connect the server to the router, be sure you have:

- Configured enhanced LAN mode on the router.
- Performed basic bridging and VLAN configuration on the router.
- Configured users on the RADIUS authentication server.

## Overview and Topology

The MX Series router acts as an authenticator Port Access Entity (PAE). It blocks all traffic and acts as a control gate until the supplicant (client) is authenticated by the server. All other users and devices are denied access.

Consider an MX Series router that functions as an authenticator port. It is connected using the interface, ge-0/0/10, over the IP network to a RADIUS server. The router is also linked to a conference room using the interface, ge-0/0/1, to a printer using the interface, ge-0/0/20, to a hub using the interface, ge-0/0/8, and to two supplicants or clients over interfaces, ge-0/0/2 and ge-0/0/9 respectively.

**Table 38: Components of the Topology**

| Property        | Settings         |
|-----------------|------------------|
| Router hardware | MX Series router |
| VLAN name       | <b>default</b>   |

Table 38: Components of the Topology *(Continued)*

| Property          | Settings                                                                                               |
|-------------------|--------------------------------------------------------------------------------------------------------|
| One RADIUS server | Backend database with an address of <b>10.0.0.100</b> connected to the switch at port <b>ge-0/0/10</b> |

In this example, access interface **ge-0/0/1** provides LAN connectivity in the conference room. Configure this access interface to provide LAN connectivity to visitors in the conference room who are not authenticated by the corporate VLAN.

## Configuration of a Guest VLAN That Includes 802.1X Authentication

### IN THIS SECTION

- [Procedure | 663](#)

### Procedure

#### CLI Quick Configuration

To quickly configure a guest VLAN, with 802.1X authentication, copy the following commands and paste them into the switch terminal window:

```
[edit]
set vlans bridge-domain-name vlan-id 300
set protocols dot1x authenticator interface all guest-bridge-domain bridge-domain-name
```

#### Step-by-Step Procedure

To configure a guest VLAN that includes 802.1X authentication on MX Series routers:

1. Configure the VLAN ID for the guest VLAN:

```
[edit]
user@switch# set bridge-domains bridge-domain-name vlan-id 300
```

2. Configure the guest VLAN under dot1x protocols:

```
[edit]
user@switch# set protocols dot1x authenticator interface all guest-bridge-domain bridge-
domain-name
```

## Results

Check the results of the configuration:

```
user@switch> show configuration
protocols {
  dot1x {
    authenticator {
      interface {
        all {
          guest-bridge-domain {
            bridge-domain-name;
          }
        }
      }
    }
  }
}
bridge-domains {
  bridge-domain-name {
    vlan-id 300;
  }
}
```

## Verification

IN THIS SECTION

- [Verifying That the Guest VLAN is Configured | 665](#)

To confirm that the configuration is working properly, perform these tasks:

### Verifying That the Guest VLAN is Configured

#### Purpose

Verify that the guest VLAN is created and that an interface has failed authentication and been moved to the guest VLAN.

#### Action

Use the operational mode commands:

```
user@switch> show bridge-domain
```

| Instance | Bridging Domain | Type   | Active |
|----------|-----------------|--------|--------|
|          | Primary Table   |        |        |
| vs1      | dynamic         | bridge | 2      |
|          | bridge.0        |        |        |
| vs1      | guest           | bridge | 0      |
|          | bridge.0        |        |        |
| vs1      | guest-vlan      | bridge | 0      |
|          | bridge.0        |        |        |
| vs1      | vlan_dyn        | bridge | 0      |
|          | bridge.0        |        |        |

```
user@switch> show dot1x interface ge-0/0/1.0 detail
ge-0/0/1.0
  Role: Authenticator
  Administrative state: Auto
```

```

Supplicant mode: Single
Number of retries: 3
Quiet period: 60 seconds
Transmit period: 30 seconds
Mac Radius: Enabled
Mac Radius Restrict: Disabled
Reauthentication: Enabled
Configured Reauthentication interval: 3600 seconds
Supplicant timeout: 30 seconds
Server timeout: 30 seconds
Maximum EAPOL requests: 2
Guest VLAN member: guest-vlan
Number of connected supplicants: 1
  Supplicant: user1, 00:00:00:00:13:23
    Operational state: Authenticated
    Authentication method: Radius
    Authenticated VLAN: vo11
    Dynamic Filter: match source-dot1q-tag 10 action deny
    Session Reauth interval: 60 seconds
    Reauthentication due in 50 seconds

```

## Meaning

The output from the `show bridge domain` command shows `bridge-domain-name` as the name of the VLAN and the VLAN ID as **300**.

The output from the `show dot1x interface ge-0/0/1.0 detail` command displays the bridge domain name , indicating that a supplicant at this interface failed 802.1X authentication and was passed through to the `bridge-domain-name`.

## Release History Table

| Release | Description                                                                                                                                       |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| 14.2    | Starting with Junos OS Release 14.2, 802.1X on MX Series routers provides LAN access to users who do not have credentials in the RADIUS database. |

# Example: Configuring Static MAC Bypass of Authentication on an MX Series Router

## IN THIS SECTION

- [Requirements | 667](#)
- [Overview and Topology | 668](#)
- [Configuration | 669](#)
- [Verification | 671](#)

Starting with Junos OS Release 14.2, to allow devices to access your LAN through 802.1X-configured interfaces without authentication, you can configure a static MAC bypass list on the MX Series router. The static MAC bypass list, also known as the *exclusion list*, specifies MAC addresses that are allowed on the router without a request to an authentication server.

You can use static MAC bypass of authentication to allow connection for devices that are not 802.1X-enabled, such as printers. If a host's MAC address is compared and matched against the static MAC address list, the nonresponsive host is authenticated and an interface opened for it.

This example describes how to configure static MAC bypass of authentication for two printers:

## Requirements

This example uses the following hardware and software components:

- Junos OS Release 14.2 or later for MX240, MX480, or MX960 routers running in enhanced LAN mode.
- One router acting as an authenticator port access entity (PAE). The ports on the authenticator PAE form a control gate that blocks all traffic to and from supplicants until they are authenticated.

Before you connect the server to the router, be sure you have:

- Configured enhanced LAN mode on the router.
- Performed basic bridging and VLAN configuration on the router.

- Configured users on the RADIUS authentication server.

## Overview and Topology

IN THIS SECTION

- [Topology | 668](#)

To permit printers access to the LAN, add them to the static MAC bypass list. The MAC addresses on this list are permitted access without authentication from the RADIUS server.

Consider an MX Series router that functions as an authenticator port. It is connected using the interface, ge-0/0/10, over the IP network to a RADIUS server. The router is also linked to a conference room using the interface, ge-0/0/1, to a printer using the interface, ge-0/0/20, to a hub using the interface, ge-0/0/8, and to two supplicants or clients over interfaces, ge-0/0/2 and ge-0/0/9 respectively.

The interfaces shown in [Table 39 on page 668](#) will be configured for static MAC authentication.

**Table 39: Components of the Static MAC Authentication Configuration Topology**

| Property                                                                | Settings                                                                                             |
|-------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------|
| Router hardware                                                         | MX Series router                                                                                     |
| VLAN name                                                               | <b>default</b>                                                                                       |
| Connections to integrated printer/fax/copier machines (no PoE required) | <b>ge-0/0/19</b> , MAC address 00:04:0f:fd:ac:fe<br><b>ge-0/0/20</b> , MAC address 00:04:ae:cd:23:5f |

The printer with the MAC address 00:04:0f:fd:ac:fe is connected to access interface **ge-0/0/19**. A second printer with the MAC address 00:04:ae:cd:23:5f is connected to access interface **ge-0/0/20**. Both printers will be added to the static list and bypass 802.1X authentication.

### Topology

## Configuration

### IN THIS SECTION

- Procedure | 669

## Procedure

### CLI Quick Configuration

To quickly configure static MAC authentication, copy the following commands and paste them into the router terminal window:

```
[edit]

set protocols authentication-access-control static [00:04:0f:fd:ac:fe 00:04:ae:cd:23:5f]
set protocols authentication-access-control interface all supplicant multiple
set protocols authentication-access-control authentication-profile-name profile1
```

### Step-by-Step Procedure

Configure static MAC authentication:

1. Configure MAC addresses **00:04:0f:fd:ac:fe** and **00:04:ae:cd:23:5f** as static MAC addresses:

```
[edit protocols]
user@router# set authentication-access-control static [00:04:0f:fd:ac:fe 00:04:ae:cd:23:5f]
```

2. Configure the 802.1X authentication method:

```
[edit protocols]
user@router# set authentication-access-control interface all supplicant multiple
```

### 3. Configure the authentication profile name (access profile name) to use for authentication:

```
[edit protocols]
user@router# set authentication-access-control authentication-profile-name profile1
```

**NOTE:** Access profile configuration is required only for 802.1X clients, not for static MAC clients.

## Results

Display the results of the configuration:

```
user@router> show
interfaces {
  ge-0/0/19 {
    unit 0 {
      family bridge {
        vlan-id 10;
      }
    }
  }
  ge-0/0/20 {
    unit 0 {
      family bridge {
        vlan-id 10;
      }
    }
  }
}
protocols {
  authentication-access-control {
    authentication-profile-name profile1;
    static [00:04:0f:fd:ac:fe 00:04:ae:cd:23:5f];
    interface {
      all {
        supplicant multiple;
      }
    }
  }
}
```

```
}  
}
```

## Verification

### IN THIS SECTION

- [Verifying Static MAC Bypass of Authentication | 671](#)

To confirm that the configuration is working properly, perform these tasks:

### Verifying Static MAC Bypass of Authentication

#### Purpose

Verify that the MAC address for both printers is configured and associated with the correct interfaces.

#### Action

Use the operational mode command:

```
user@switch> show dot1x static-mac-address
```

| MAC address       | VLAN-Assignment | Interface   |
|-------------------|-----------------|-------------|
| 00:04:0f:fd:ac:fe | default         | ge-0/0/19.0 |
| 00:04:ae:cd:23:5f | default         | ge-0/0/20.0 |

#### Meaning

The output field **MAC address** shows the MAC addresses of the two printers.

The output field **Interface** shows that the MAC address **00:04:0f:fd:ac:fe** can connect to the LAN through interface **ge-0/0/19.0** and that the MAC address **00:04:ae:cd:23:5f** can connect to the LAN through interface **ge-0/0/20.0**.

## Release History Table

| Release | Description                                                                                                                                                                                               |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 14.2    | Starting with Junos OS Release 14.2, to allow devices to access your LAN through 802.1X-configured interfaces without authentication, you can configure a static MAC bypass list on the MX Series router. |

# Example: Applying Firewall Filters to Multiple Supplicants on Interfaces Enabled for 802.1X or MAC RADIUS Authentication on MX Series Routers

## IN THIS SECTION

- [Requirements | 672](#)
- [Overview and Topology | 673](#)
- [Configuration | 675](#)
- [Verification | 678](#)

Starting with Junos OS Release 14.2, on MX Series routers, firewall filters that you apply to interfaces enabled for 802.1X or MAC RADIUS authentication are dynamically combined with the per-user policies sent to the switch from the RADIUS server. The switch uses internal logic to dynamically combine the interface firewall filter with the user policies from the RADIUS server and create an individualized policy for each of the multiple users or nonresponsive hosts that are authenticated on the interface.

This example describes how dynamic firewall filters are created for multiple supplicants on an 802.1X-enabled interface (the same principles shown in this example apply to interfaces enabled for MAC RADIUS authentication):

## Requirements

This example uses the following hardware and software components:

- Junos OS Release 14.2 or later for MX Series routers
- One MX Series router
- One RADIUS authentication server. The authentication server acts as the backend database and contains credential information for hosts (supplicants) that have permission to connect to the network.

Before you apply firewall filters to an interface for use with multiple supplicants, be sure you have:

- Set up a connection between the router and the RADIUS server.
- Configured 802.1X authentication on the router, with the authentication mode for interface **ge-0/0/2** set to **multiple**.
- Configured users on the RADIUS authentication server.

## Overview and Topology

### IN THIS SECTION

- [Topology | 673](#)

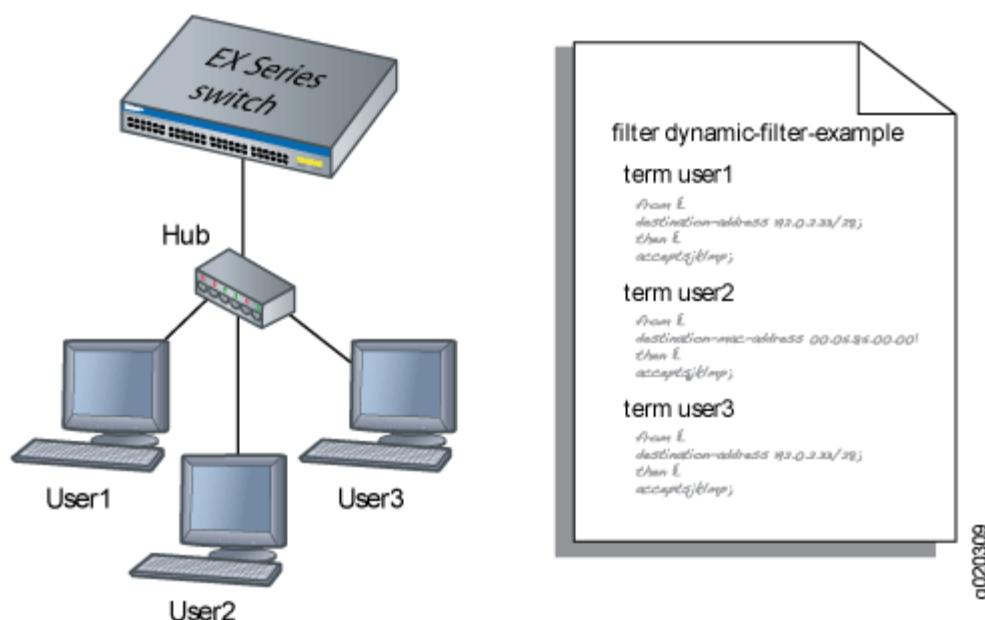

## Topology

When the 802.1X configuration on an interface is set to multiple supplicant mode, the system dynamically combines interface firewall filter with the user policies sent to the router from the RADIUS server during authentication and creates separate terms for each user. Because there are separate terms for each user authenticated on the interface, you can, as shown in this example, use counters to view the activities of individual users that are authenticated on the same interface.

When a new user (or a nonresponsive host) is authenticated on an interface, the system adds a term to the firewall filter associated with the interface, and the term (policy) for each user is associated with the MAC address of the user. The term for each user is based on the user-specific filters set on the RADIUS server and the filters configured on the interface. For example, as shown in [Figure 31 on page 674](#),

when User1 is authenticated by the MX Series router, the system creates the firewall filter **dynamic-filter-example**. When User2 is authenticated, another term is added to the firewall filter, and so on.

Figure 31: Conceptual Model: Dynamic Filter Updated for Each New User

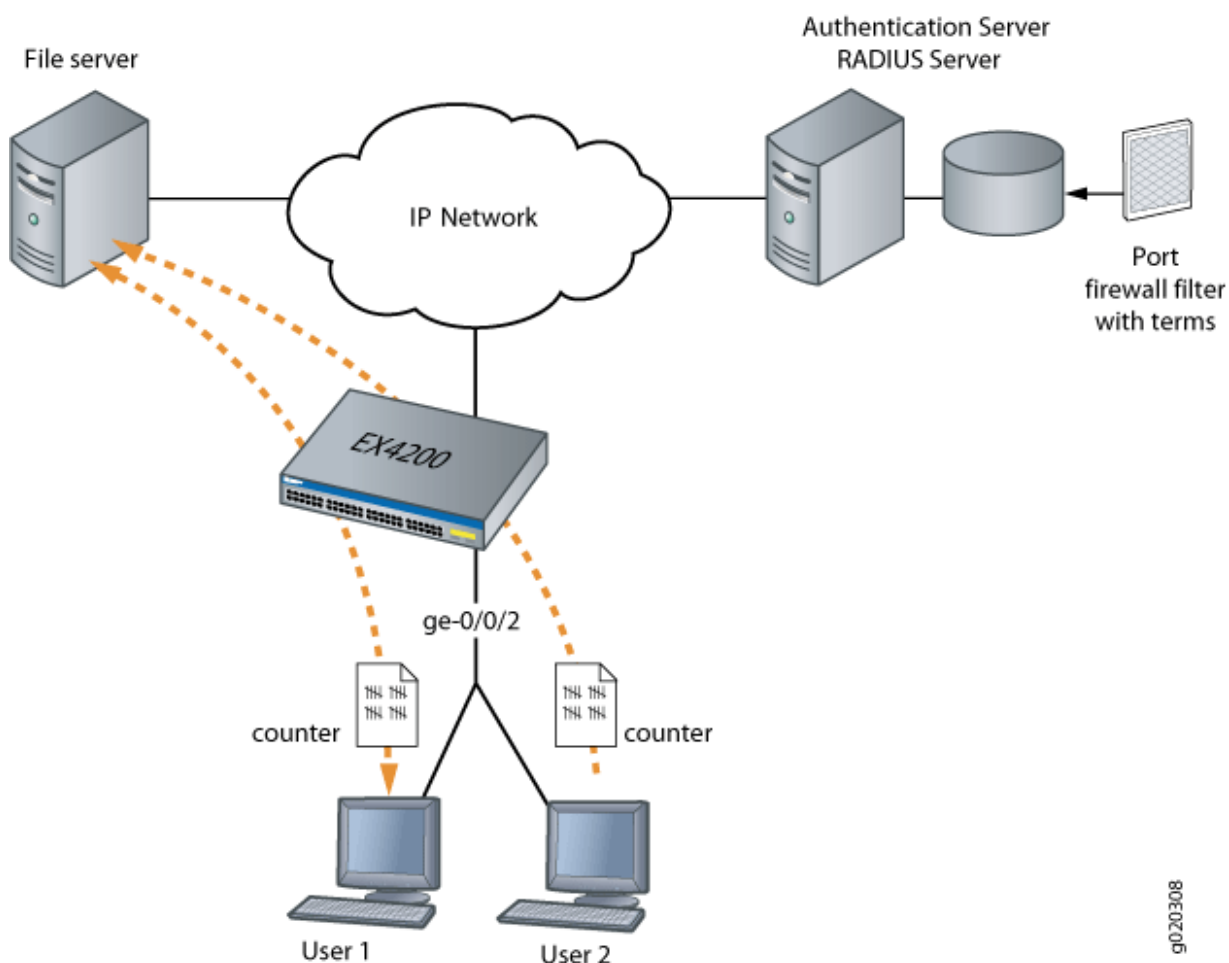

This is a conceptual model of the internal process—you cannot access or view the dynamic filter.

**NOTE:** If the firewall filter on the interface is modified after the user (or nonresponsive host) is authenticated, the modifications are not reflected in the dynamic filter unless the user is reauthenticated.

In this example, you configure a firewall filter to count the requests made by each endpoint authenticated on interface **ge-0/0/2** to the file server, which is located on subnet **192.0.2.16/28**, and

set policer definitions to rate limit the traffic. [Figure 32 on page 675](#) shows the network topology for this example.

**Figure 32: Multiple Supplicants on an 802.1X-Enabled Interface Connecting to a File Server**

## Configuration

### IN THIS SECTION

- Configuring Firewall Filters on Interfaces with Multiple Supplicants | 676

To configure firewall filters for multiple supplicants on 802.1X-enabled interfaces:

## Configuring Firewall Filters on Interfaces with Multiple Supplicants

### CLI Quick Configuration

To quickly configure firewall filters for multiple supplicants on an 802.1X-enabled interface copy the following commands and paste them into the router terminal window:

```
[edit]
set protocols authentication-access-control interface ge-0/0/2
supplicant multiple
set firewall family bridge filter filter1 term term1 from destination-
address 192.0.2.16/28
set firewall policer p1 if-exceeding bandwidth-limit 1m
set firewall policer p1 if-exceeding burst-size-limit 1k
set firewall family bridge filter filter1 term term1 then count
counter1
set firewall family bridge filter filter1 term term2 then policer p1
```

### Step-by-Step Procedure

To configure firewall filters on an interface enabled for multiple supplicants:

1. Configure interface **ge-0/0/2** for multiple supplicant mode authentication:

```
[edit protocols]
user@router# set authentication-access-control interface ge-0/0/2 supplicant
multiple
```

2. Set policer definition:

```
user@router# show policer p1 |display set
set firewall policer p1 if-exceeding bandwidth-limit 1m
set firewall policer p1 if-exceeding burst-size-limit 1k
set firewall policer p1 then discard
```

3. Configure a firewall filter to count packets from each user and a policer that limits the traffic rate. As each new user is authenticated on the multiple supplicant interface, this filter term will be included in the dynamically created term for the user:

```
[edit firewall family bridge]
user@router# set filter filter1 term term1 from destination-address 192.0.2.16/28
user@router# set filter filter1 term term1 then count counter1
user@router# set filter filter1 term term2 then policer p1
```

## Results

Check the results of the configuration:

```
user@router> show configuration

firewall {
  family bridge {
    filter filter1 {
      term term1 {
        from {
          destination-address {
            192.0.2.16/28;
          }
        }
        then count counter1;
      }
      term term2 {
        from {
          destination-address {
            192.0.2.16/28;
          }
        }
        then policer p1;
      }
    }
  }
}

policer p1 {
  if-exceeding {
    bandwidth-limit 1m;
    burst-size-limit 1k;
  }
  then discard;
}
```

```

    }
}
protocols {
    authentication-access-control {
        interface ge-0/0/2 {
            suppliant multiple;
        }
    }
}

```

## Verification

### IN THIS SECTION

- [Verifying Firewall Filters on Interfaces with Multiple Supplicants | 678](#)

To confirm that the configuration is working properly, perform these tasks:

### Verifying Firewall Filters on Interfaces with Multiple Supplicants

#### Purpose

Verify that firewall filters are functioning on the interface with multiple supplicants.

#### Action

1. Check the results with one user authenticated on the interface. In this case, the user is authenticated on **ge-0/0/2**:

```
user@router> show dot1x firewall
```

```
Filter: dot1x_ge-0/0/2
```

```
Counters
```

```
counter1_dot1x_ge-0/0/2_user1 100
```

2. When a second user, User2, is authenticated on the same interface, **ge-0/0/2**, you can verify that the filter includes the results for both of the users authenticated on the interface:

```
user@router> show dot1x firewall

Filter: dot1x-filter-ge-0/0/0
Counters
counter1_dot1x_ge-0/0/2_user1 100
counter1_dot1x_ge-0/0/2_user2 400
```

**Meaning**

The results displayed by the `show dot1x firewall` command output reflect the dynamic filter created with the authentication of each new user. User1 accessed the file server located at the specified destination address 100 times, while User2 accessed the same file server 400 times.

**Release History Table**

| Release | Description                                                                                                                                                                                                                                             |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 14.2    | Starting with Junos OS Release 14.2, on MX Series routers, firewall filters that you apply to interfaces enabled for 802.1X or MAC RADIUS authentication are dynamically combined with the per-user policies sent to the switch from the RADIUS server. |

# Device Discovery Using LLDP

## IN THIS SECTION

- [Understanding LLDP | 681](#)
- [Configuring LLDP \(CLI Procedure\) | 682](#)
- [Configuring LLDP \(J-Web Procedure\) | 689](#)
- [Understanding LLDP and LLDP-MED on EX Series Switches | 690](#)
- [Configuring LLDP-MED \(CLI Procedure\) | 694](#)

The Link Layer Discovery Protocol (LLDP) is an industry-standard, vendor-neutral method to allow networked devices to advertise capabilities, identity, and other information onto a LAN. It also provides additional types, lengths, and values (TLVs) for capabilities discovery, network policy, Power over Ethernet (PoE), and inventory management. For more information, read this topic.

## Understanding LLDP

The device uses LLDP to learn and to distribute device information on network links. The device uses this information to identify a variety of devices quickly. This quick identification results in a LAN that interoperates smoothly and efficiently.

LLDP-capable devices transmit information in type, length, and value (TLV) messages to neighbor devices. Device information can include specifics, such as the chassis identification, the port identification, the system name, and the system capabilities. The TLVs leverage this information from parameters that have already been configured in Junos OS.

The device supports the following basic TLVs:

- **Chassis Identifier**—The MAC address associated with the local system.
- **Port Identifier**—The port identification for the specified port in the local system.
- **Port Description**—The user-configured port description. The port description can be a maximum of 256 characters.
- **System Name**—The user-configured name of the local system. The system name can be a maximum of 256 characters.

- **System Description**—The system description containing information about the software and current image running on the system. This information is taken from the software. You cannot configure this information.
- **System Capabilities**—The primary function performed by the system, for example, bridge or router. This information cannot be configured, but is based on the model of the product.
- **Management Address**—The IP management address of the local system.

The device supports the following 802.3 TLVs:

- **Power via MDI**—A TLV that advertises media dependent interface (MDI) power support, power source equipment (PSE) power pair, and power class information.
- **MAC/PHY Configuration Status**—A TLV that advertises information about the physical interface, such as autonegotiation status and support and MAU type. The information is based on the physical interface structure. You cannot configure this information.
- **Link Aggregation**—A TLV that advertises whether the port is aggregated and its aggregated port ID.
- **Maximum Frame Size**—A TLV that advertises the Maximum Transmission Unit (MTU) of the interface sending LLDP frames.
- **Port VLAN**—A TLV that advertises the VLAN name configured on the interface.

## Configuring LLDP (CLI Procedure)

### IN THIS SECTION

- [Enable LLDP on Interfaces | 683](#)
- [Adjust LLDP Advertisement Settings | 683](#)
- [Adjust SNMP Notification Settings of LLDP Changes | 684](#)
- [Specify a Management Address for the LLDP Management TLV | 685](#)
- [Specify a Management Interface for the LLDP Management TLV | 686](#)
- [Configure LLDP Power Negotiation | 686](#)
- [Disable LLDP TLVs | 687](#)

Follow these steps to configure LLDP on your device.

## Enable LLDP on Interfaces

LLDP is enabled on all interfaces by default. If you disable it, you can re-enable LLDP by configuring it on all interfaces or on specific interfaces.

- To configure LLDP on all interfaces:

```
[edit protocols lldp]
user@device# set interface all
```

- To configure LLDP on a specific interface:

```
[edit protocols lldp]
user@device# set interface interface-name
```

## Adjust LLDP Advertisement Settings

You can adjust the following settings for LLDP advertisements for troubleshooting or verification purposes. LLDP uses the default values when it is enabled. For normal operations, we recommend that you do not change the default values.

- To specify the frequency at which LLDP advertisements are sent (in seconds):

```
[edit protocols lldp]
user@device# set advertisement-interval seconds
```

For example, using the default value of 30 seconds:

```
[edit protocols lldp]
user@device# set advertisement-interval 30
```

- To specify the number of seconds that LLDP information is held before it is discarded:

```
[edit protocols lldp]
user@device# set hold-multiplier number
```

For example, using the default value of 4:

```
[edit protocols lldp]
user@device# set hold-multiplier 4
```

The hold-multiplier value is used in combination with the advertisement-interval value. Using the default values means that the advertisement-interval value of 30 will be multiplied by the hold-multiplier value of 4, resulting in a LLDP hold time of 120 seconds.

- Set the transmit delay to specify the number of seconds the device waits before sending advertisements to neighbors after a change is made in a TLV (element in LLDP or in the state of the local system). A change in state of the local system includes a change in hostname or management address. The transmit delay is enabled by default to reduce the delay in notifying neighbors of a change in the local system. The default transmit delay is 1 second if the advertisement-interval value is set to less than 8 seconds. The default value is 2 seconds if the advertisement-interval value is set to 8 seconds or more.

```
[edit protocols lldp]
user@device# set transmit-delay seconds
```

For example:

```
[edit protocols lldp]
user@device# set transmit-delay 2
```

**NOTE:** The advertisement-interval value must be greater than or equal to four times the transmit-delay value; otherwise, an error is returned when you attempt to commit the configuration.

## Adjust SNMP Notification Settings of LLDP Changes

You can adjust the following settings for SNMP notifications of LLDP changes. If the values are not specified or if the interval values are set to 0, the notifications are disabled.

- To specify the frequency at which LLDP database changes are sent (in seconds):

```
[edit protocols lldp]
user@device# set lldp-configuration-notification-interval seconds
```

For example:

```
[edit protocols lldp]
user@device# set lldp-configuration-notification-interval 600
```

- To configure how long SNMP trap notifications wait for topology changes (in seconds):

```
[edit protocols lldp]
user@device# set ptopo-configuration-trap-interval seconds
```

For example:

```
[edit protocols lldp]
user@device# set ptopo-configuration-trap-interval 600
```

- To specify the holding time (used in combination with the ptopo-configuration-trap-interval value) to maintain dynamic topology entries (in seconds):

```
[edit protocols lldp]
user@device# set ptopo-configuration-maximum-hold-time seconds
```

For example:

```
[edit protocols lldp]
user@device# set ptopo-configuration-maximum-hold-time 2147483647
```

## Specify a Management Address for the LLDP Management TLV

You can configure an IPv4 or IPv6 management address to be used in the LLDP Management Address TLV messages. An out-of-band management address must be used as the value for the `management-address` statement.

To configure the management address:

```
[edit protocols lldp]
user@device# set management-address ip-address
```

**NOTE:** Ensure that the interface with the configured management address has LLDP enabled using the `set protocols lldp interface` command. If you configure a customized management address for LLDP on an interface that has LLDP disabled, the `show lldp local-information` command output does not display the correct interface information.

## Specify a Management Interface for the LLDP Management TLV

you can configure an interface to be used in the LLDP Management Address TLV messages.

**NOTE:** You cannot configure management address and management interface at the same time.

To configure the management interface:

```
[edit protocols lldp]
user@device# set management-interface interface-name
```

If the interface does not have an IP address, the IP address of the default management interfaces is used.

## Configure LLDP Power Negotiation

LLDP power negotiation enables the device's Power over Ethernet (PoE) controller to dynamically allocate PoE power to PoE interfaces, based on the needs of the powered device, by negotiating with LLDP-enabled powered devices.

**NOTE:** LLDP power negotiation is not supported on EX3200 or EX4200 switches (except for the EX4200-PX models).

LLDP power negotiation is supported on devices running PoE controller software version 4.04 or later.

LLDP power negotiation is automatically enabled when the PoE management mode is set to `class`:

- ```
[edit poe]
user@device# set management class
```

To disable LLDP power negotiation:

- On all device interfaces:

```
[edit protocols lldp interface all power-negotiation]
user@device# set disable
```

- On a specific interface:

```
[edit protocols lldp interface interface-name power-negotiation]
user@device# set disable
```

## Disable LLDP TLVs

LLDP sends TLV messages by default. You can configure LLDP to disable non-mandatory TLVs. The mandatory TLVs are: chassis-id, port-id, and time-to-live. In this procedure, any reference to disabling all TLVs means disabling all non-mandatory TLVs.

There are two options for disabling TLVs:

- **tlv-select**—Select which TLVs are allowed to be advertised by LLDP. This approach is useful if you want to allow only a few TLVs and nothing else.
- **tlv-filter**—Filter the TLVs that should not be advertised by LLDP. Use this option if you want to filter only a few TLVs and allow everything else.

**NOTE:** The **tlv-select** and **tlv-filter** options are mutually exclusive and cannot be used on the same configuration stanza at the same time.

You can disable TLVs on specific interfaces or on all interfaces. The configuration under the interface configuration stanza takes precedence over the global configuration.

To select which TLVs are allowed to be advertised by LLDP:

- On all interfaces:

```
[edit protocols lldp]
user@device# set tlv-select tlv-name
```

- On a specific interface:

```
[edit protocols lldp]
user@device# set interface interface-name tlv-select tlv-name
```

To filter TLVs that should not be advertised by LLDP:

- On all interfaces:

```
[edit protocols lldp]
user@device# set tlv-filter tlv-name
```

- On a specific interface:

```
[edit protocols lldp]
user@device# set interface interface-name tlv-filter tlv-name
```

The following example disables all TLVs except port-description:

```
[edit protocols lldp]
user@device# set tlv-select port-description
```

The following example disables the system-description TLV on the ge-2/1/1 interface:

```
[edit protocols lldp]
user@device# set interface ge-2/1/1 tlv-filter system-description
```

The following example disables all TLVs except port-description and system-description on all interfaces except on the ge-0/0/1 interface, where it disables only the system-name TLV:

```
[edit protocols lldp]
user@device# set tlv-select [port-description system-description]
user@device# set interface ge-0/0/1 tlv-filter system-name
```

# Configuring LLDP (J-Web Procedure)

**NOTE:** This topic applies only to the J-Web Application package.

Use the LLDP Configuration page to configure LLDP global and port settings for an EX Series switch on the J-Web interface.

To configure LLDP:

1. Select **Configure > Switching > LLDP**.

The LLDP Configuration page displays LLDP Global Settings and Port Settings.

The second half of the screen displays operational details for the selected port.

**NOTE:** After you make changes to the configuration on this page, you must commit the changes for them to take effect. To commit all changes to the active configuration, select **Commit Options > Commit**. See Using the Commit Options to Commit Configuration Changes for details about all commit options.

2. For an EX8200 Virtual Chassis configuration, select the member and the slot (FPC) from the list.

3. To modify LLDP Global Settings, click **Global Settings**.

Enter information as described in [Table 40 on page 689](#).

4. To modify Port Settings, click **Edit** in the Port Settings section.

Enter information as described in [Table 41 on page 690](#).

**Table 40: Global Settings**

Field	Function	Your Action
Advertising interval	Specifies the frequency of outbound LLDP advertisements. You can increase or decrease this interval.	Type the number of seconds.
Hold multiplier	Specifies the multiplier factor to be used by an LLDP-enabled switch to calculate the time-to-live (TTL) value for the LLDP advertisements it generates and transmits to LLDP neighbors.	Type the required number in the field.

Table 40: Global Settings *(Continued)*

Field	Function	Your Action
Fast start count	Specifies the number of LLDP advertisements sent in the first second after the device connects. The default is 3. Increasing this number results in the port initially advertising LLDP-MED at a faster rate for a limited time.	Type the Fast start count.

Table 41: Edit Port Settings

Field	Function	Your Action
LLDP Status	Specifies whether LLDP has been enabled on the port.	Select one: <b>Enabled</b> , <b>Disabled</b> , or <b>None</b> .
LLDP-MED Status	Specifies whether LLDP-MED has been enabled on the port.	Select <b>Enable</b> from the list.

## Understanding LLDP and LLDP-MED on EX Series Switches

### IN THIS SECTION

- Benefits of LLDP and LLDP-MED | 691
- LLDP and LLDP-MED Overview | 691
- Supported LLDP TLVs | 691
- Supported LLDP-MED TLVs | 693
- Disabling TLVs | 694

EX Series Ethernet Switches use Link Layer Discovery Protocol (LLDP) and Link Layer Discovery Protocol-Media Endpoint Discovery (LLDP-MED) to learn and distribute device information on network links. The information enables the switch to quickly identify a variety of devices, resulting in a LAN that interoperates smoothly and efficiently.

## Benefits of LLDP and LLDP-MED

- Enables the switch to quickly identify a variety of devices.
- Provides PoE power management capabilities.
- Ensures that voice traffic gets tagged and prioritized with the correct values at the source itself.

## LLDP and LLDP-MED Overview

LLDP-capable devices transmit information in type, length, and value (TLV) messages to neighbor devices. Device information can include information such as chassis and port identification and system name and system capabilities. The TLVs leverage this information from parameters that have already been configured in the Junos operating system (Junos OS).

LLDP-MED goes one step further than LLDP, exchanging IP-telephony messages between the switch and the IP telephone.

**NOTE:** If your IP telephone is configured for VoIP (VoIP), the switch automatically detects the configuration and assigns the telephone to the voice VLAN. The implementation of a voice VLAN on an IP telephone is vendor-specific. Consult the documentation that came with your IP telephone for instructions on configuring a voice VLAN. For example, on an Avaya phone, you can ensure that the phone gets the correct VoIP VLAN ID even in the absence of LLDP-MED by enabling DHCP option 176.

LLDP and LLDP-MED also provide PoE power management capabilities. LLDP power negotiation allows the switch to manage PoE power by negotiating with LLDP-enabled powered devices to dynamically allocate PoE power as needed. LLDP power priority allows an LLDP-enabled powered device to set the PoE power priority on the switch interface to which it connects.

The switch also uses these protocols to ensure that voice traffic gets tagged and prioritized with the correct values at the source itself. For example, 802.1p CoS and 802.1Q tag information can be sent to the IP telephone.

## Supported LLDP TLVs

EX Series switches and QFX5100 switches support the following basic management TLVs:

- Chassis ID—The MAC address associated with the local system.

**NOTE:** The Chassis ID TLV has a subtype for the network address family. LLDP frames are validated only if this subtype has a value of 1 (IPv4) or 2 (IPv6). For any other value, the transmitting device is detected by LLDP as a neighbor and displayed in the output of the `show lldp neighbors` command, but is not assigned to the VLAN.

- Port ID—The port identification for the specified port in the local system.
- Time to Live—The length of time that the received information should remain valid.
- Port Description—Textual description of the interface or the logical unit. The description for the logical unit is used, if available; otherwise, the Port Description TLV contains the description configured on the physical interface. For example, LAG member interfaces do not contain a logical unit; therefore, only the description configured on the physical interface can be used.
- System Name—The user-configured name of the local system. The system name can be a maximum of 256 characters. The system name field contains the host name and the domain name in the following format: *host-name.domain-name*.
- System Description—The system description that contains information about the software and current image running on the system. This information is not configurable, but taken from the software.
- System Capabilities—The primary function performed by the system. The capabilities that the system supports—for example, bridge or router. This information is not configurable, but based on the model of the product.
- Management Address—The IPv4 or IPv6 management address of the local system.

EX Series switches and QFX5100 switches support the following organizationally defined TLVs:

- Power via MDI—A TLV that advertises MDI (media dependent interface) power support, PSE (power sourcing equipment) power pair, and power class information.
- MAC/PHY Configuration Status—A TLV that advertises information about the physical interface, such as autonegotiation status and support and MAU (medium attachment unit) type. The information is not configurable, but based on the physical interface structure.

**NOTE:** The MAC/PHY Configuration Status TLV has a subtype for the PMD Auto-Negotiation Advertised Capability field. This field contains a value of *other* or *unknown* if the LLDP packet is transmitted from a 10-gigabit SFP+ port.

- Link Aggregation—A TLV that advertises whether the port is aggregated and its aggregated port ID.

- **Maximum Frame Size**—A TLV that advertises the maximum transmission unit (MTU) of the interface sending LLDP frames.
- **Port Vlan**—A TLV that advertises the VLAN name configured on the interface.

## Supported LLDP-MED TLVs

EX Series switches and QFX5100 switches support the following LLDP-MED TLVs:

- **LLDP-MED Capabilities**—A TLV that advertises the primary function of the port. The values of capabilities range from 0 through 15:
  - 0—Capabilities
  - 1—Network Policy
  - 2—Location Identification
  - 3—Extended Power via MDI-PSE
  - 4—Inventory
  - 5-15—Reserved
- **LLDP-MED Device Class Values**—Categorizes media endpoint devices into classes:
  - 0—Class not defined
  - 1—Class 1 (generic endpoints). This class definition is applicable to all endpoints that require the base LLDP discovery services.
  - 2—Class 2 (media endpoints). This class includes endpoints that have IP media capabilities.
  - 3—Class 3 (communication endpoints). Devices acting as end user communication appliances
  - 4—Network Connectivity Device
  - 5-255—Reserved
- **Network Policy**—A TLV that advertises the port VLAN configuration and associated Layer 2 and Layer 3 attributes. Attributes include the policy identifier, application types, such as voice or streaming video, 802.1Q VLAN tagging, and 802.1p priority bits and Diffserv code points.
- **Endpoint Location**— A TLV that advertises the physical location of the endpoint.
- **Extended Power via MDI**— A TLV that advertises the power type, power source, power priority, and power value of the port. It is the responsibility of the PSE device (network connectivity device) to advertise the power priority on a port.

## Disabling TLVs

In multi-vendor networks, it might not be desirable to send TLV messages because they can contain sensitive information about a network device. You can configure LLDP or LLDP-MED to disable any non-mandatory TLV message. Mandatory TLVs are: chassis-id, port-id, and time-to-live. All other TLVs can be disabled, either on specific interfaces or on a global basis. See ["Configuring LLDP \(CLI Procedure\)" on page 682](#) and ["Configuring LLDP-MED \(CLI Procedure\)" on page 694](#) for more information.

## Configuring LLDP-MED (CLI Procedure)

### IN THIS SECTION

- [Enabling LLDP-MED on Interfaces | 694](#)
- [Configuring Location Information Advertised by the Switch | 695](#)
- [Configuring a Fast Start for LLDP-MED | 695](#)
- [Disabling LLDP-MED TLVs | 696](#)

Link Layer Discovery Protocol–Media Endpoint Discovery (LLDP-MED) is an extension of LLDP. The EX Series switch uses LLDP-MED to support device discovery of VoIP telephones and to create location databases for these telephone locations.

LLDP-MED is enabled by default on EX Series switches.

This topic describes:

### Enabling LLDP-MED on Interfaces

LLDP-MED is enabled on all interfaces by default. If it is disabled, you can enable LLDP-MED by configuring it on all interfaces or on specific interfaces.

**NOTE:** On switches running Junos OS for EX Series switches with support for the Enhanced Layer 2 Software (ELS) configuration style, configure LLDP-MED on the physical interface—for example, on ge-0/0/2. For more about ELS, see *Using the Enhanced Layer 2 Software CLI*.

To configure LLDP-MED on all interfaces or on a specific interface:

```
[edit protocols lldp-med]
user@switch# set interface interface-name
```

## Configuring Location Information Advertised by the Switch

You can configure the location information that is advertised from the switch to the LLDP-MED device. You can specify a civic-based location (geographic location) or a location based on an ELIN (Emergency Location Identification Number):

- To specify a location by geography:

```
[edit protocols lldp-med]

user@switch# set interface ge-0/0/2.0 location civic-based country-code country-code
user@switch# set interface ge-0/0/2.0 location civic-based ca-type ca-type ca-value ca-value
```

- To specify a location by using an elin string:

```
[edit protocols lldp-med]

user@switch# set interface ge-0/0/2.0 location elin 4085551212
```

## Configuring a Fast Start for LLDP-MED

When the switch detects an LLDP-MED capable device, it begins to send LLDP advertisements from the port connected to the device. The fast start count indicates how many advertisements will be send in

the first second after the switch detects the LLDP-MED device. The default is 3; to set it to another value:

```
[edit protocols lldp-med]
user@switch# set fast-start seconds
```

For example:

```
[edit protocols lldp-med]
user@switch# set fast-start 6
```

**NOTE:** If an interface is configured as a VoIP interface, then the switch does not wait for an attached phone to identify itself as an LLDP-MED device before it performs an LLDP-MED fast start after a graceful Routing Engine switchover (GRES) or a reboot. Instead, it immediately performs an LLDP-MED fast start after a GRES or reboot. This behavior prevents certain models of IP phones from resetting after a GRES.

## Disabling LLDP-MED TLVs

LLDP-MED sends TLV messages by default. You can configure LLDP-MED to disable non-mandatory TLVs. Mandatory TLVs are: chassis-id, port-id, and time-to-live. In this procedure, any reference to disabling all TLVs means disabling all non-mandatory TLVs.

There are two options for disabling TLVs:

- **tlv-select**—Select which TLVs are allowed to be advertised by LLDP. This approach is useful if you want to allow only a few TLVs and nothing else.
- **tlv-filter**—Filter the TLVs that should not be advertised by LLDP. This approach is useful if you want to filter only few TLVs, and allow everything else.

**NOTE:** The **tlv-select** and **tlv-filter** are mutually exclusive and cannot be used on the same configuration stanza at the same time.

You can disable TLVs on a specific interfaces or on all interfaces. The configuration under the interface configuration stanza takes precedence over global the global configuration.

To select which TLVs are allowed to be advertised by LLDP-MED:

- On all interfaces:

```
[edit protocols lldp-med]
user@switch# set tlv-select tlv-name
```

- On a specific interface:

```
[edit protocols lldp-med]
user@switch# set interface interface-name tlv-select tlv-name
```

To filter TLVs that should not be advertised by LLDP-MED:

- On all interfaces:

```
[edit protocols lldp-med]
user@switch# set tlv-filter tlv-name
```

- On a specific interface:

```
[edit protocols lldp-med]
user@switch# set interface interface-name tlv-filter tlv-name
```

The following example disables all TLVs except location-id:

```
[edit protocols lldp-med]
user@switch# set tlv-select location-id
```

The following example disables the ext-power-via-mdi TLV on ge-2/1/1 interface:

```
[edit protocols lldp-med]
user@switch# set interface ge-2/1/1 tlv-filter ext-power-via-mdi
```

The following example disables all TLVs except location-id and ext-power-via-mdi on all interfaces except on the ge-0/0/1 interface, where it disables only the network-policy TLV:

```
[edit protocols lldp-med]
user@switch# set tlv-select [location-id ext-power-via-mdi]
user@switch# set interface ge-0/0/1 tlv-filter network-policy
```

You can also disable TLVs for the LLDP protocol. See ["Configuring LLDP \(CLI Procedure\)" on page 682](#) for more information.

# NetBIOS Snooping on EX Series Switches

## IN THIS SECTION

- [Understanding NetBIOS Snooping | 699](#)
- [Configuring NetBIOS Snooping \(CLI Procedure\) | 700](#)

NetBIOS snooping enables an EX Series switch to learn information about NetBIOS hosts that are connected to the switch. The NetBIOS snooping-enabled switch extracts the host details from the NetBIOS name registration packet and stores the details in the LLDP neighbor database. for more information, read this topic.

## Understanding NetBIOS Snooping

### IN THIS SECTION

- [What Is a NetBIOS Name? | 699](#)
- [How NetBIOS Snooping Works | 699](#)

NetBIOS snooping allows Juniper Networks EX Series Ethernet Switches to discover NetBIOS hosts that are connected to the switch.

### What Is a NetBIOS Name?

A NetBIOS name is a key element in communications between NetBIOS resources. A NetBIOS name identifies a NetBIOS resource on the network. A NetBIOS name is either a unique (exclusive) name or a group (nonexclusive) name. When a NetBIOS resource communicates with one other NetBIOS resource, a unique name is used in that communication. When a NetBIOS resource communicates with multiple resources, a group name is used.

The NetBIOS name of each NetBIOS resource is stored on the NetBIOS Name Server (NBNS). The NetBIOS name of a NetBIOS resource is mapped to its IP address.

A NetBIOS name is a 16-byte address. The first 15 bytes contain the name and the last byte contains the name type.

The NetBIOS name service is supported over UDP port 137.

### How NetBIOS Snooping Works

You can enable NetBIOS snooping on the switch so that the switch can identify NetBIOS resources that are connected to it.

When a host connected to the switch initializes itself, it attempts to register its NetBIOS name by sending a NetBIOS name registration request message. The host can opt for either a unique or a group NetBIOS name. For a unique NetBIOS name, the host either broadcasts a NetBIOS name query message on the local network or unicasts it to the NBNS to check whether the requested name is already being used by another host. If so, the host that previously registered the name or the NBNS responds with a negative name registration response. If the host receives no negative response, it broadcasts the NetBIOS name registration packet to confirm the name. For a NetBIOS group name, the host sends a

NetBIOS name registration packet, which generates no responses from other hosts because multiple hosts can use the same group name at the same time.

The NetBIOS snooping-enabled switch extracts the host details from the NetBIOS name registration packet and stores the details in the LLDP neighbor database.

# DNSSEC Overview

Junos OS devices support the domain name service security extensions (DNSSEC) standard. DNSSEC is an extension of DNS that provides authentication and integrity verification of data by using public-key based signatures.

In DNSSEC, all the resource records in a DNS are signed with the private key of the zone owner. The DNS resolver uses the public key of the owner to validate the signature. The zone owner generates a private key to encrypt the hash of a set of resource records. The private key is stored in RRSIG record. The corresponding public key is stored in the DNSKEY record. The resolver uses the public key to decrypt the RRSIG and compares the result with the hash of the resource record to verify that it has not been altered.

Similarly, the hash of the public DNSKEY is stored in a DS record in a parent zone. The zone owner generates a private key to encrypt the hash of the public key. The private key is stored in the RRSIG record. The resolver retrieves the DS record and its corresponding RRSIG record and public key. Using the public key, the resolver decrypts the RRSIG record and compares the result with the hash of the public DNSKEY to verify that it has not been altered. This establishes a chain of trust between the resolver and the name servers.

# Configuring the TTL Value for DNS Server Caching

## IN THIS SECTION

- [Requirements | 704](#)
- [Overview | 704](#)
- [Configuration | 704](#)
- [Verification | 705](#)

This section describes how to configure the TTL value for a DNS server cache to define the period for which DNS query results are cached.

## Requirements

No special configuration beyond device initialization is required before performing this task.

## Overview

### IN THIS SECTION

- [Topology | 704](#)

The DNS name server stores DNS query responses in its cache for the TTL period specified in the TTL field of the resource record. When the TTL value expires, the name server sends a fresh DNS query and updates the cache. You can configure the TTL value from 0 to 604,800 seconds. You can also configure the TTL value for cached negative responses. Negative caching is the storing of the record that a value does not exist. In this example, you set the maximum TTL value for cached (and negative cached) responses to 86,400 seconds.

## Topology

## Configuration

### IN THIS SECTION

- [Procedure | 705](#)

## Procedure

### Step-by-Step Procedure

To configure the TTL value for a DNS server cache:

1. Specify the maximum TTL value for cached responses, in seconds. (In this example, 86400 seconds equals 24 hours.)

```
[edit]
user@host# set system services dns max-cache-ttl 86400
```

2. Specify the maximum TTL value for negative cached responses, in seconds.

```
[edit]
user@host# set system services dns max-ncache-ttl 86400
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

## Verification

To verify the configuration is working properly, enter the `show system services` command.

### RELATED DOCUMENTATION

| *DNS Overview*

## Example: Configuring DNSSEC

DNS-enabled devices run a DNS resolver (proxy) that listens on loopback address 127.0.0.1 or ::1. The DNS resolver performs a hostname resolution for DNSSEC. Users need to set name server IP address to 127.0.0.1 or ::1 so the DNS resolver forwards all DNS queries to DNSSEC instead of to DNS. If the name server IP address is not set, DNS will handle all queries instead of to DNSSEC.

The following example shows how to set the server IP address to 127.0.0.1:

```
[edit]
user@host# set system name-server 127.0.0.1
```

The DNSSEC feature is enabled by default. You can disable DNSSEC in the server by using the following CLI command:

```
[edit]
set system services dns dnssec disable
```

### RELATED DOCUMENTATION

| [DNSSEC Overview](#) | [703](#)

## Example: Configuring Secure Domains and Trusted Keys for DNSSEC

### IN THIS SECTION

- [Requirements](#) | [707](#)
- [Overview](#) | [707](#)
- [Configuration](#) | [708](#)

This example shows how to configure secure domains and trusted keys for DNSSEC.

## Requirements

Set the name server IP address so the DNS resolver forwards all DNS queries to DNSSEC instead of DNS. See ["Example: Configuring DNSSEC" on page 706](#) for more information.

## Overview

### IN THIS SECTION

- [Topology | 707](#)

You can configure secure domains and assign trusted keys to the domains. Both signed and unsigned responses can be validated when DNSSEC is enabled.

When you configure a domain as a secure domain and if DNSSEC is enabled, all unsigned responses to that domain are ignored and the server returns a SERVFAIL error code to the client for the unsigned responses. If the domain is not configured as a secure domain, unsigned responses will be accepted.

When the server receives a signed response, it checks if the DNSKEY in the response matches any of the trusted keys that are configured. If it finds a match, the server accepts the signed response.

You can also attach a DNS root zone as a trusted anchor to a secure domain to validate the signed responses. When the server receives a signed response, it queries the DNS root zone for a DS record. When it receives the DS record, it checks if the DNSKEY in the DS record matches the DNSKEY in the signed response. If it finds a match, the server accepts the signed response.

## Topology

## Configuration

### IN THIS SECTION

- [Procedure](#) | 708

## Procedure

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the [edit] hierarchy level, and then enter `commit` from configuration mode.

```
set system services dns dnssec secure-domains domain1.net
set system services dns dnssec secure-domains domain2.net
set system services dns dnssec trusted-keys key domain1.net.ABC123ABCh
set system services dns dnssec dlz domain domain2.net trusted-anchor dlz.isc.org
```

### Step-by-Step Procedure

To configure secure domains and trusted keys for DNSSEC:

1. Configure domain1.net and domain2.net as secure domains.

```
[edit]
user@host# set system services dns dnssec secure-domains domain1.net
user@host# set system services dns dnssec secure-domains domain2.net
```

2. Configure trusted keys to domain1.net.

```
[edit]
user@host# set system services dns dnssec trusted-keys key "domain1.net.ABC123ABCh"
```

3. Attach a root zone div.isc.org as a trusted anchor to a secure domain.

[edit]

```
user@host# set system services dns dnssec dlv domain domain2.net trusted-anchor dlv.isc.org
```

## Results

From configuration mode, confirm your configuration by entering the `show system services` command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
dns {
  dnssec {
    trusted-keys {
      key domain1.net.ABC123ABCh; ## SECRET-DATA
    }
    dlv {
      domain domain2.net trusted-anchor dlv.isc.org;
    }
    secure-domains {
      domain1.net;
      domain2.net;
    }
  }
}
```

If you are done configuring the device, enter `commit` from configuration mode.

## RELATED DOCUMENTATION

[DNSSEC Overview](#) | 703

[Example: Configuring Keys for DNSSEC](#) | 710

## Example: Configuring Keys for DNSSEC

You can load a public key from a file or you can copy and paste the key file from a terminal. In both cases, you must save the keys to the configuration instead of to a file. The following example shows how to load a key from a file:

```
[edit system services dns dnssec trusted-keys]
#load-key filename
```

The following example explains how to load the key from a terminal:

```
[edit system services dns dnssec trusted-keys]
# set key "...pasted-text..."
```

If you are done loading the keys from the file or terminal, click `commit` in the CLI editor.

### RELATED DOCUMENTATION

[DNSSEC Overview | 703](#)

[Example: Configuring Secure Domains and Trusted Keys for DNSSEC | 706](#)

## DNS Proxy Overview

### IN THIS SECTION

- [DNS Proxy Cache | 711](#)
- [DNS Proxy with Split DNS | 711](#)
- [Dynamic Domain Name System Client | 714](#)

A domain name system (DNS) proxy allows clients to use an SRX300, SRX320, SRX340, SRX345, SRX550M, or SRX1500 device as a DNS proxy server. A DNS proxy improves domain lookup

performance by caching previous lookups. A typical DNS proxy processes DNS queries by issuing a new DNS resolution query to each name server that it has detected until the hostname is resolved.

## DNS Proxy Cache

When a DNS query is resolved by a DNS proxy, the result is stored in the device's DNS cache. This stored cache helps the device to resolve subsequent queries from the same domain and avoid network latency delay.

If the proxy cache is not available, the device sends the query to the configured DNS server, which results in network latency delays.

DNS proxy maintains a cache entry for each resolved DNS query. These entries have a time-to-live (TTL) timer so the device purges each entry from the cache as it reaches its TTL and expires. You can clear a cache by using the `clear system services dns-proxy cache` command, or the cache will automatically expire along with TTL when it goes to zero.

## DNS Proxy with Split DNS

The split DNS proxy feature allows you to configure your proxy server to split the DNS query based on both the interface and the domain name. You can also configure a set of name servers and associate them with a given domain name. When you query that domain name, the device sends the DNS queries to only those name servers that are configured for that domain name to ensure localization of DNS queries.

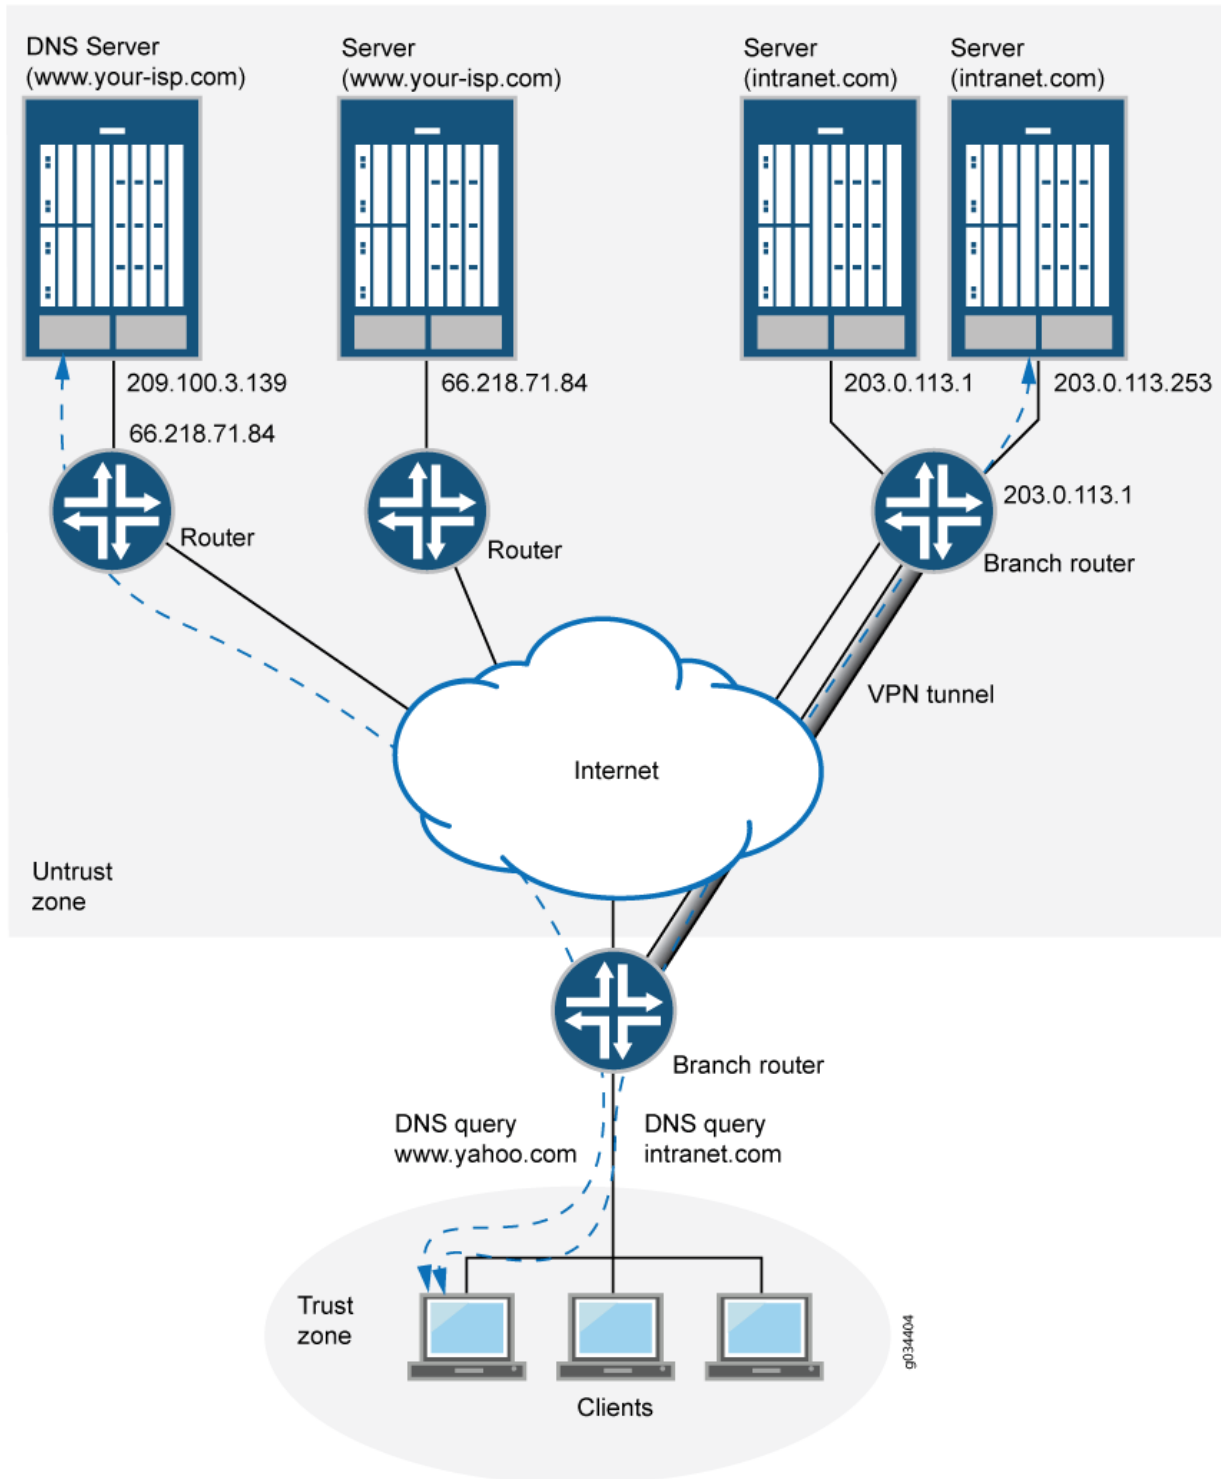

You can configure the transport method used to resolve a given domain name—for example, when the device connects to the corporate network through an IPsec VPN or any other secure tunnel. When you configure a secure VPN tunnel to transport the domain names belonging to the corporate network, the DNS resolution queries are not leaked to the ISP DNS server and are contained within the corporate network.

You can also configure a set of default domain (\*) and name servers under the default domain to resolve the DNS queries for a domain for which a name server is not configured.

Each DNS proxy must be associated with an interface. If an interface has no DNS proxy configuration, all the DNS queries received on that interface are dropped.

Figure 33 on page 713 shows how the split DNS proxy works in a corporate network.

Figure 33: DNS Proxy with Split DNS

In the corporate network shown in [Figure 33 on page 713](#), a PC client that points to the SRX Series device as its DNS server makes two queries—to `www.your-isp.com` and to `www.intranet.com`. The DNS proxy redirects the `www.intranet.com` query to the `www.intranet.com` DNS server (203.0.113.253), while the `www.your-isp.com` query is redirected to the ISP DNS server (209.100.3.130). Although the query for `www.your-isp.com` is sent to the ISP DNS server as a regular DNS query using clear text protocols (TCP/UDP), the query for the `www.intranet.com` domain goes to the intranet's DNS servers over a secure VPN tunnel.

A split DNS proxy has the following advantages:

- Domain lookups are usually more efficient. For example, DNS queries meant for a corporate domain (such as `acme.com`) can go to the corporate DNS server exclusively, while all others go to the ISP DNS server. Splitting DNS lookups reduces the load on the corporate server and can also prevent corporate domain information from leaking onto the Internet.
- A DNS proxy allows you to transmit selected DNS queries through a tunnel interface, which prevents malicious users from learning about the internal configuration of a network. For example, DNS queries bound for the corporate server can pass through a tunnel interface to use security features such as authentication and encryption.

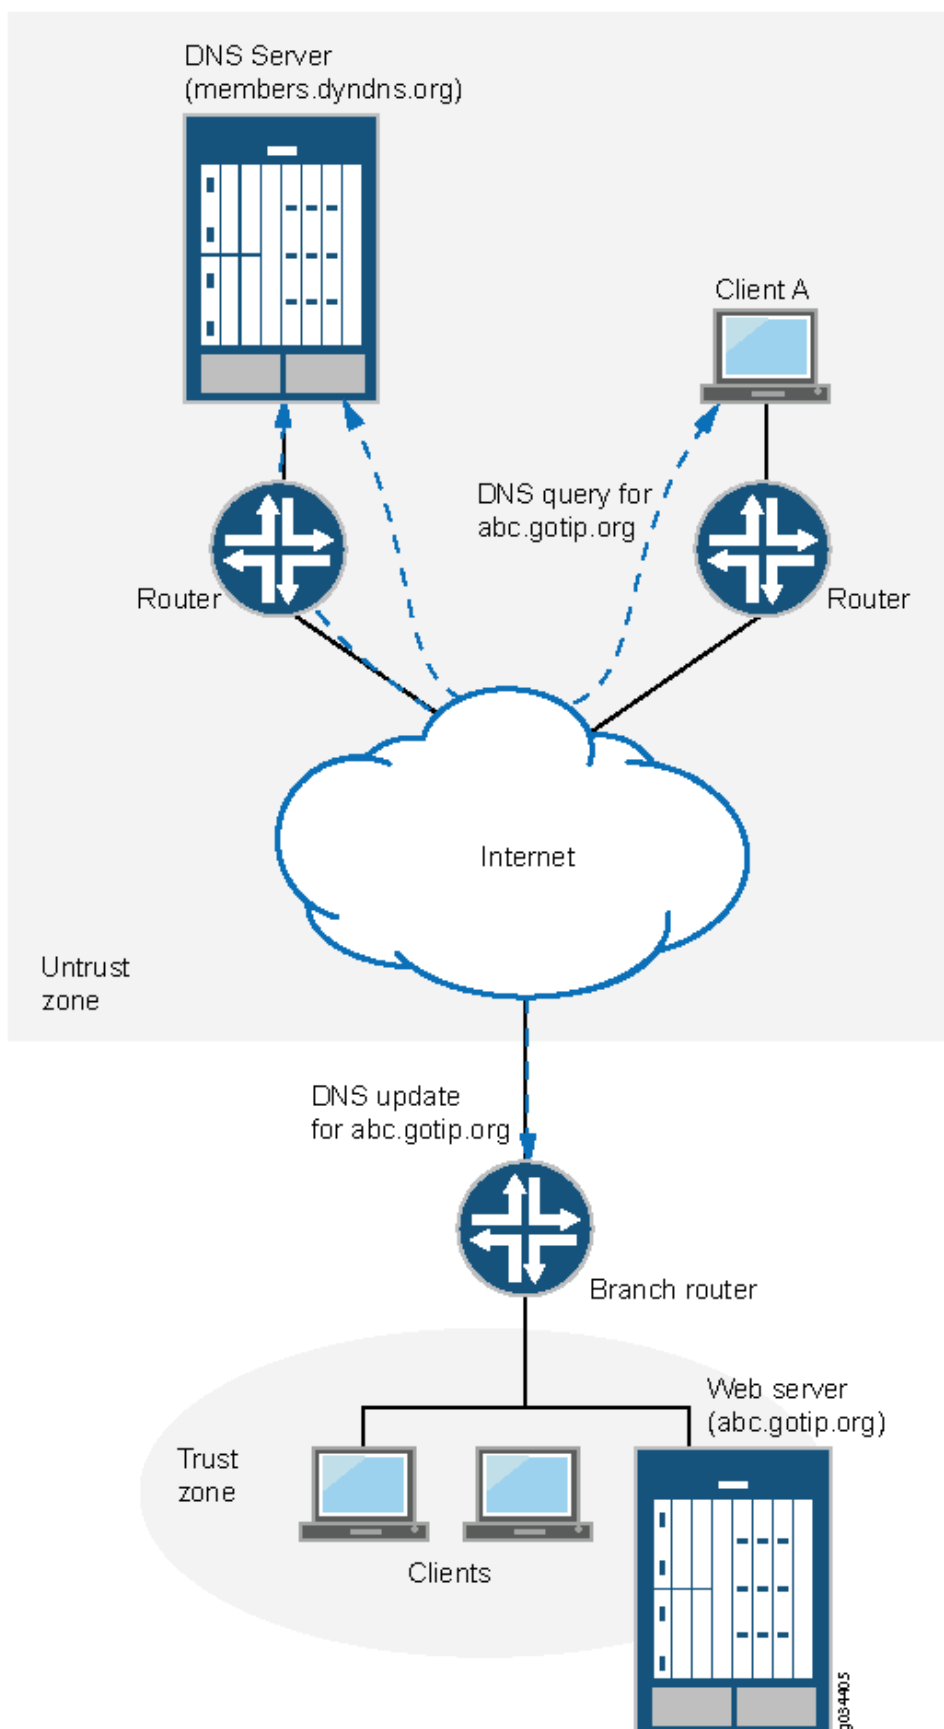

## Dynamic Domain Name System Client

Dynamic DNS (DDNS) allows clients to dynamically update IP addresses for registered domain names. This feature is useful when an ISP uses Point-to-Point Protocol (PPP), Dynamic Host Configuration Protocol (DHCP), or external authentication (XAuth) to dynamically change the IP address for a customer premises equipment (CPE) router (such as a security device) that protects a Web server. Internet clients can reach the Web server by using a domain name even if the IP address of the security device has previously changed dynamically.

A DDNS server maintains a list of the dynamically changed addresses and their associated domain names. The device updates these DDNS servers with this information periodically or in response to IP address changes. The Junos OS DDNS client supports popular DDNS servers such as `dyndns.org` and `ddo.jp`.

[Figure 34 on page 716](#) illustrates how the DDNS client works.

Figure 34: Dynamic DNS

The IP address of the internal Web server is translated by Network Address Translation (NAT) to the IP address of the untrust zone interface on the device. The hostname abc-host.com is registered with the DDNS server and is associated with the IP address of the device's untrust zone interface, which is monitored by the DDNS client on the device. When the IP address of abc-host.com is changed, the DDNS server is informed of the new address.

If a client in the network shown in [Figure 34 on page 716](#) needs to access abc-host.com, the client queries the DNS servers on the Internet. When the query reaches the DDNS server, it resolves the request and provides the client with the latest IP address of abc-host.com.

# Configuring the Device as a DNS Proxy

The Junos operating system (Junos OS) incorporates domain name system (DNS) support, which allows you to use domain names as well as IP addresses for identifying locations. A DNS server keeps a table of the IP addresses associated with domain names. Using DNS enables an SRX300, SRX320, SRX340, SRX345, SRX550M, or SRX1500 device to reference locations by domain name (such as www.example.net) in addition to using the routable IP address.

DNS features include:

- **DNS proxy cache**—The device proxies hostname resolution requests on behalf of the clients behind the SRX Series device. DNS proxy improves domain lookup performance by using caching.
- **Split DNS**—The device redirects DNS queries over a secure connection to a specified DNS server in the private network. Split DNS prevents malicious users from learning the network configuration, and thus also prevents domain information leaks. Once configured, split DNS operates transparently.
- **Dynamic DNS (DDNS) client**—Servers protected by the device remain accessible despite dynamic IP address changes. For example, a protected Web server continues to be accessible with the same hostname, even after the dynamic IP address is changed because of address reassignment by the Dynamic Host Configuration Protocol (DHCP) or Point-to-Point Protocol (PPP) by Internet service provider (ISP).

To configure the device as a DNS proxy, you enable DNS on a *logical interface* and configure DNS proxy servers. Configuring a static cache enables branch office and corporate devices to use hostnames to communicate. Configuring dynamic DNS (DDNS) clients allows IP address changes.

Perform the following procedure to configure the device as a DNS proxy server by enabling DNS proxy on a logical interface—for example, ge-2/0/0.0—and configuring a set of name servers that are to be used for resolving the specified domain names. You can specify a default domain name by using an asterisk (\*) and then configure a set of name servers for resolution. Use this approach when you need global name servers to resolve domain name entries that do not have a specific name server configured.

## 1. DNS proxy with non-split dns configuration

- Enable DNS proxy on a logical interface.

```
[edit]
user@host# set system services dns dns-proxy interface ge-0/0/3.0
```

- Set dns resolver to forward received dns query.

```
[edit]
user@host# set system services dns forwarders 192.0.2.0
```

- If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

To verify if the configuration is working properly, execute the show command.

```
user@host# show system services dns-proxy statistics
```

## 2. DNS proxy with split dns configuration

- Enable DNS proxy on a logical interface.

```
[edit]
user@host# set system services dns dns-proxy interface ge-2/0/0.0
```

- Configure view for split DNS, specify the internal IP interface to handle the DNS query and view the logical subnet address.

```
[edit]
user@host# set system services dns dns-proxy view internal match-clients 10.1.1.0/24
```

- Set a default internal domain name, and specify IP server for forwarding the DNS query according to their IP addresses.

```
[edit]
user@host# set system services dns dns-proxy view internal domain aa.internal.com
forwarders 10.1.1.1
user@host# set system services dns dns-proxy view internal domain bb.internal.com
forwarders 10.2.2.2
```

- Configure view for split DNS, specify the external IP interface to handle the DNS query and view the logical subnet address.

```
[edit]
user@host# set system services dns dns-proxy view external match-clients 10.11.1.0/24
```

- Set a default external domain name, and specify IP server for forwarding the DNS query according to their IP addresses.

```
[edit]
user@host# set system services dns dns-proxy view external domain aa.external.com
forwarders 10.3.3.3
user@host# set system services dns dns-proxy view external domain bb.external.com
forwarders 10.4.4.4
```

- If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

To verify if the configuration is working properly, execute the show command.

```
user@host# show system services dns-proxy statistics
```

### 3. DNS proxy cache configuration

- Configure the dns proxy static cache entries to specify the host's IPv4 address.

```
[edit]
user@host# set system services dns dns-proxy cache aa.example.net inet 10.10.10.10
user@host# set system services dns dns-proxy cache bb.example.net inet 10.20.20.20
```

- If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

To verify if the configuration is working properly, execute the show command.

```
user@host# show system services dns-proxy cache
```

### 4. Dynamic DNS proxy configuration

- Enable client.

```
[edit]
user@host# set system services dynamic-dns client abc.com agent juniper interface
ge-2/0/0.0 username test password test123
```

- Configure the server.

```
[edit]
user@host# set system services dynamic-dns client abc.com agent juniper interface
ge-2/0/0.0 username test password test123 server ddo
user@host# set system services dynamic-dns client abc.com agent juniper interface
ge-2/0/0.0 username test password test123 server dyndns
```

- If you are done configuring the device, commit the configuration.

```
[edit]  
user@host# commit
```

To verify if the configuration is working properly

```
user@host# show system services dynamic-dns client
```

[admin-control | 735](#)

# admin-control

Can view user account information and configure it at the [edit system] hierarchy level.

## Commands

```
show system audit
```

## Configuration Hierarchy Levels

```
[edit protocols uplink-failure-detection]
[edit system]
[edit system accounting]
[edit system diag-port-authentication]
[edit system extensions]

[admin | 730](#)

# all

Can access all operational mode commands and configuration mode commands. Can modify the configuration in all the configuration hierarchy levels.

## Commands

All CLI commands.

## Configuration Hierarchy Levels

All CLI configuration hierarchy levels and statements.

## clear

Can clear (delete) information learned from the network that is stored in various network databases.

### Commands

```
clear
clear access-security
clear access-security router-advertisement-entries
<clear-as-router-advertisement-entry>
clear amt
clear amt statistics
<clear-amt-statistics>
clear amt tunnel
clear-amt-tunnel

[flow-tap-control | 849](#)

# flow-tap-control

Can view the flow-tap configuration in configuration mode and can configure flow-tap configuration information at the [edit services flow-tap], [edit services radius-flow-tap], and [edit system services flow-tap-dtcp] hierarchy levels.

## Commands

No associated CLI commands.

## Configuration Hierarchy Levels

```
[edit services flow-tap]
[edit services radius-flow-tap]
[edit system services flow-tap-dtcp]
```

[flow-tap | 844](#)

## flow-tap-operation

Can make flow-tap requests to the router.

### Commands

No associated CLI commands.

### Configuration Hierarchy Levels

No associated CLI configuration hierarchy levels and statements.

# network

Can access the network by using the ping, ssh, telnet, and traceroute commands.

## Commands

```
mtrace
mtrace from-source
mtrace monitor
mtrace to-gateway
ping
    <ping>

ping atm
ping clns
ping ethernet
    <request-ping-ethernet>
ping fibre-channel
ping mpls
ping mpls bgp
    <request-ping-bgp-lsp>
ping mpls l2circuit
ping mpls l2circuit interface
    <request-ping-l2circuit-interface>

ping mpls l2circuit virtual-circuit
    <request-ping-l2circuit-virtual-circuit>

ping mpls l2vpn
ping mpls l2vpn fec129
ping mpls l2vpn fec129 interface
    <request-ping-l2vpn-fec129-interface>
ping mpls l2vpn instance
    <request-ping-l2vpn-instance>

ping mpls l2vpn interface
    <request-ping-l2vpn-interface>

ping mpls l3vpn
    <request-ping-l3vpn>
```

```
ping mpls ldp
    <request-ping-ldp-lsp>

ping mpls ldp p2mp
    <request-ping-ldp-p2mp-lsp>

ping mpls lsp-end-point

enhanced-avs-max <number>;
events (change-log | interactive-commands | login );
}

```

## Hierarchy Level

[edit system]

## Description

Configure an audit of TACACS+ or RADIUS authentication events, configuration changes, and interactive commands. Auditing these factors helps you track network usage for auditing and billing purposes.

## Options

- enhanced-avs-max** Configure the number of attribute-value pairs to be displayed, each of which can store a maximum of 250 bytes.
- **Default:** 7 pairs
  - **Range:** 7 through 15 pairs
- events** (Required) Configure the types of events to log.

- Values:
  - change-log—Configuration changes
  - interactive-commands—Interactive commands (any command-line input)
  - login—Login sessions

The remaining statements are explained separately. Search for a statement in [CLI Explorer](#) or click a linked statement in the Syntax section for details.

### IN THIS SECTION

- [Syntax | 1106](#)
- [Hierarchy Level | 1106](#)
- [Description | 1106](#)
- [Options | 1106](#)
- [Required Privilege Level | 1107](#)
- [Release Information | 1108](#)

## Syntax

```
archival {
  configuration {
    archive-sites {
      file://<path>/<filename>;
      ftp://username@host[:port]>url-path password password;
      http://username@host[:port]>url-path password password;
      pasvftp://username@host[:port]>url-path password password;
      scp://username@host[:port]>url-path password password;
    }
    transfer-interval interval;
    transfer-on-commit;
  }
  routing-instance routing-instance;
}
```

## Hierarchy Level

[edit system]

## Description

Configure copying of the currently active configuration to an archive site. An archive site can be a file, or an FTP, HTTP, passive FTP, or SCP location.

## Options

**configuration** Configure the router or switch to periodically transfer its currently active configuration (or after each commit). Parameters include archive-sites, transfer-interval, and transfer-on-commit.

**NOTE:** The [edit system archival] hierarchy is not available on QFabric systems.

**archive-sites** Specify where to transfer the current configuration files. When specifying a URL in a Junos OS statement using an IPv6 host address, you must enclose the entire URL in quotation marks (" ") and enclose the IPv6 host address in brackets ([ ]). For example: "scp://username<:password>@[ipv6-host-address]<:port>/url-path".

If you specify more than one archive site, the router or switch attempts to transfer the configuration files to the first archive site in the list, moving to the next only if the transfer fails. The destination filename is saved in the following format, where *n* corresponds to the number of the compressed configuration rollback file that has been archived:

```
router-name_YYYYMMDD_HHMMSS_juniper.conf.n.gz
```

**NOTE:** The time included in the destination filename is always in Coordinated Universal Time (UTC) regardless of whether the time on the router or switch is configured as UTC or the local time zone. The default time zone on the router or switch is UTC.

**transfer-interval** The frequency, in minutes, for transferring the current configuration to an archive site. Valid intervals are 15 to 2880 minutes.

**transfer-on-commit** Configure the router or switch to transfer its currently active configuration to an archive site each time you commit a candidate configuration.

**routing-instance** Defines the routing instance through which a server is reachable.

## Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

## Release Information

Statement introduced before Junos OS Release 7.4.

## Syntax

```
authentication-order [method1 method2...];
```

## Hierarchy Level

```
[edit system]
[edit system services ftp]
[edit system services ssh]
[edit system services telnet]
```

## Description

Configure the order in which the software tries different user authentication methods when attempting to authenticate a user. For each login attempt, the software tries the authentication methods in order, starting with the first one, until the password matches.

## Default

If you do not include the authentication-order statement, users are verified based on their configured passwords.

## Options

**authentication-order** [*method1 method2...*]

Specify the order in which the software tries different authentication methods when attempting to authenticate a user.

- **Values:** One or more of the following authentication methods listed in the order in which they must be tried:
  - **ldaps**—Use LDAP authentication services.
  - **password**—Use the password configured for the user with the authentication statement at the [edit system login user] hierarchy level.
  - **radius**—Use RADIUS authentication services.
  - **tacplus**—Use TACACS+ authentication services.

## Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

## Release Information

Statement introduced before Junos OS Release 7.4.

Option `ldaps` introduced in Junos OS Release 20.2R1.

## Syntax

```
authentication-order [dot1x | mac-radius | captive-portal];
```

## Hierarchy Level

```
[edit logical-systems name protocols dot1x authenticator
interface],
[edit protocols dot1x authenticator interface interface-name]
```

## Description

Configure the preferred order of authentication methods that the device will use when attempting to authenticate a client. If multiple authentication methods are configured on a single interface, when one authentication method fails, the device falls back to another method. You can configure the `authentication-order` statement to specify whether 802.1X authentication or MAC RADIUS authentication must be the first authentication method tried.

By default, the device attempts to authenticate a client by using 802.1X authentication first. If 802.1X authentication fails because there is no response from the client, and MAC RADIUS authentication is configured on the interface, the device falls back to MAC RADIUS authentication. If MAC RADIUS fails, and captive portal is configured on the device, the device falls back to captive portal.

Configuring MAC RADIUS authentication as the first method can help prevent the fallback timeout period which occurs after an 802.1X authentication attempt is made for a host that does not support 802.1X authentication. If MAC RADIUS authentication is configured as the first authentication method on an interface, then on receiving data from any client on that interface, the device attempts to authenticate the client by using MAC RADIUS authentication. If MAC RADIUS authentication fails, then the device falls back to 802.1X authentication. If 802.1X authentication fails, and captive portal is configured on the interface, the device falls back to captive portal.

802.1X authentication always has the highest priority, even if a client has been authenticated using another method. If the device receives an EAP packet from a client that has been authenticated using MAC RADIUS authentication, the device acknowledges the EAP packet and upgrades the authentication using 802.1X authentication credentials. Similarly, if a client has been authenticated through fallback to

captive portal, and the device receives an EAP packet from that client, the device attempts to authenticate the client by using 802.1X authentication.

The device attempts authentication using only methods that are configured on the interface. If an authentication method is included in the authentication order, but is not configured on the interface, the device ignores that method and attempts authentication using the next method in the order that is enabled. However, if a method is enabled on the interface, but is not included in the authentication order, the device does not attempt using that method. For example, if captive portal is enabled for an interface, but the authentication order is configured as `[mac-radius dot1x]`, the authentication method for that interface does not fall back to captive portal.

The authentication order can be configured for all interfaces by using the `interface all` option. If the authentication order is configured for an individual interface, and there is also an authentication order configured for all interfaces, then the order for the individual interface is followed. If there is no authentication order configured for an individual interface, and there is an authentication order configured for all interfaces, then the configuration for all interfaces is followed.

Use the following guidelines when configuring the `authentication-order` statement:

- The authentication order must include at least two methods of authentication.
- 802.1X authentication must be one of the methods included in the authentication order.
- If captive portal is included in the authentication order, it must be the last method in the order.
- If `mac-radius-restrict` is configured on an interface, then the authentication order cannot be configured.

The valid combinations for `authentication-order` are as follows:

- `[dot1x mac-radius captive-portal]`
- `[dot1x captive-portal]`
- `[dot1x mac-radius]`
- `[mac-radius dot1x captive-portal]`

## Default

If `authentication-order` is not configured, the device attempts to authenticate the client by using 802.1X authentication first, followed by MAC RADIUS authentication, and then captive portal, as follows:

1. 802.1X authentication—If 802.1X is configured on the interface, the device sends EAPoL requests to the end device and attempts to authenticate the end device through 802.1X authentication. If the

end device does not respond to the EAP requests, the device checks whether MAC RADIUS authentication is configured on the interface.

2. MAC RADIUS authentication—If MAC RADIUS authentication is configured on the interface, the device sends the MAC RADIUS address of the end device to the authentication server. If MAC RADIUS authentication is not configured, the device checks whether captive portal is configured on the interface.
3. Captive portal authentication—If captive portal is configured on the interface, the device attempts to authenticate the end device by using this method after attempting any other configured authentication methods.

## Options

`captive-portal`—Configure captive portal authentication in the order of authentication methods on the interface.

`dot1x`—Configure 802.1X authentication in the order of authentication methods on the interface.

`mac-radius`—Configure MAC RADIUS authentication in the order of authentication methods on the interface.

## Required Privilege Level

`routing`—To view this statement in the configuration.

`routing-control`—To add this statement to the configuration.

## Release Information

- [Default | 1117](#)
- [Options | 1117](#)
- [Required Privilege Level | 1118](#)
- [Release Information | 1118](#)

## Syntax

```
authentication-protocol {  
    eap-md5;  
    eap-peap {  
        resume;  
    }  
    pap;  
}
```

## Hierarchy Level

```
[edit logical-systems protocols dot1x authenticator interface interface-name mac-radius]  
[edit protocols dot1x authenticator interface interface-name mac-radius]
```

## Description

Specify the protocol to be used by a supplicant to provide authentication credentials for MAC RADIUS authentication. The protocols supported for MAC RADIUS authentication are EAP-MD5, which is the default, Protected Extensible Authentication Protocol (EAP-PEAP), and Password Authentication Protocol (PAP).

## Default

If `authentication-protocol` is not configured, the EAP-MD5 authentication protocol is used for MAC RADIUS authentication.

## Options

- |  |  |
|--|--|
| <b>eap-md5</b>                           | Use the EAP-MD5 protocol for MAC RADIUS authentication. EAP-MD5 is an authentication method belonging to the Extensible Authentication Protocol (EAP) authentication framework. EAP-MD5 uses MD5 to hash the username and password. EAP-MD5 provides for a one-way client authentication. The server sends the client a random request for which the client must provide a response containing an encryption of the request and its password for establishing its identity.  |
| <b>eap-peap</b><br><b>&lt;resume&gt;</b> | <p>Use the EAP-PEAP protocol, also known as Protected EAP or PEAP, for MAC RADIUS authentication. EAP-PEAP is a protocol that encapsulates EAP within a potentially encrypted and authenticated Transport Layer Security (TLS) tunnel. By encapsulating the authentication process in a TLS tunnel, PEAP addresses the vulnerabilities of an EAP like EAP-MD5.</p> <ul style="list-style-type: none"><li>• <b>Syntax:</b> <code>resume—</code>(Optional) Enable faster authentication when reconnecting by resuming the TLS session.</li></ul> |
| <b>pap</b>                               | Use the PAP authentication protocol for MAC RADIUS authentication. PAP provides a simple password-based authentication for users to establish their identity by using a two-way handshake. PAP transmits plaintext passwords over the network without encryption. PAP must be configured if the Lightweight Directory Access Protocol (LDAP), which supports only plaintext passwords for client authentication, is used for RADIUS authentication.  |

    use-vlan-id;
    use-vlan-name;
}
static mac-address {
    bridge-domain-assignment bridge-domain-assignment;
    interface interface;
    vlan-assignment vlan-identifier;
}
}

```

## Hierarchy Level

```

[edit logical-systems name protocols dot1x],
[edit protocols dot1x]

```

## Description

Specify the group of servers to be used for IEEE 802.1X or MAC RADIUS authentication for Port-Based Network Access Control, configure interfaces for 802.1x authentication, and configure static MAC bypass for 802.1x and MAC RADIUS authentication. 802.1X authentication is supported on interfaces that are members of private VLANs (PVLANS).

**NOTE:** You cannot configure 802.1X user authentication on interfaces that have been enabled for Q-in-Q tunneling.

## Default

802.1X authentication is disabled.

## Options

**authentication-  
profile-name**  
*access-profile-  
name*

Specify the name of the access profile to be used for 802.1X or MAC RADIUS user authentication. The access profile is configured at the [edit access profile] hierarchy level and contains the RADIUS server IP address and other information used for authentication.

**NOTE:** Access profile configuration is required only for 802.1X clients, not for static MAC clients.

- **Default:** No access profile is specified.

**ip-mac-session-  
binding**

Configure the switching device to check for an IP-MAC address binding in the DHCP, DHCPv6, or SLAAC snooping table before terminating the authentication session when the MAC address ages out. If the MAC address for the end device is bound to an IP address, then it will be retained in the Ethernet switching table, and the authentication session will remain active.

To configure this feature, you must also disassociate the authentication session table from the Ethernet switching table using the `no-mac-table-binding` statement. This extends the authentication session until the next re-authentication period.

**NOTE:** This feature requires DHCP, DHCPv6, or SLAAC snooping to be enabled on the device.

- **Default:** Not enabled

#### **no-mac-table-binding**

Specify that the device not remove the session from the authentication session table when the MAC address ages out of the Ethernet switching table.

- **Default:** Not enabled

The remaining statements are explained separately. Search for a statement in [CLI Explorer](#) or click a linked statement in the Syntax section for details.

### Syntax

```
boot-loader-authentication {  
    (encrypted-password password | plain-text-password);  
}
```

### Hierarchy Level

```
[edit system]
```

## Description

Set the boot-loader password for accessing the U-Boot CLI during the boot process. The password can be entered either as a plain-text password or as an encrypted password.

Encrypted passwords must be entered in Message Digest 5 (MD5) format. Plain-text passwords are encrypted by using MD5 by default. The encryption format for plain-text passwords can be changed by using the `set system login password format` command.

Encrypted passwords must be between 1 and 128 characters long. The password must be enclosed in quotation marks and cannot be blank within the quotation marks (" ").

The default requirements for plain-text passwords are as follows:

- The password must be between 6 and 128 characters long
- You can include most character classes in a password (uppercase letters, lowercase letters, numbers, punctuation marks, and other special characters). Control characters are not recommended.
- The password must contain at least one change of case or character class.

## Options

`encrypted-password password`— Enter a password that has already been encrypted. You can specify only one encrypted password.

`plain-text-password`—Enter a plain-text password. The CLI prompts you for the password and then encrypts it. The CLI displays the encrypted version, and the software places the encrypted version in its user database. You can specify only one plain-text password.

## Required Privilege Level

`admin`—To view this statement in the configuration.

`admin-control`—To add this statement to the configuration.

ca-type type {  
    ca-value value;  
}
```

## Hierarchy Level

```
[edit protocols lldp-med interface (all | interface-name location civic-based)]
```

## Description

For Link Layer Discovery Protocol–Media Endpoint Device (LLDP-MED), configure the location types and values that comprise the location information advertised from the device to the MED. This information is used during emergency calls to identify the location (civic or postal address) of the caller.

For further information about the types and values that can be used to comprise the location, refer to RFC 4776, *Dynamic Host Configuration Protocol (DHCPv4 and DHCPv6) Option for Civic Addresses Configuration Information*. A subset of those types, with sample values, is provided below.

## Default

Disabled.

## Options

**ca-type**  
*type* Specify category codes that together with values represent information about the civic or postal address of the caller's location. The address is divided into information types, with each information type represented by a code. Some of the codes, with corresponding sample values for the ca-value option, are:

- 0—A code that specifies the language used to describe the location.
- 16—The leading-street direction, such as "N".
- 17—A trailing street suffix, such as "SW".
- 18—A street suffix or type, such as "Ave" or "Road".
- 19—A house number, such as "6450".
- 20—A house-number suffix, such as "A" or "1/2".
- 21—A landmark, such as "Stanford University".
- 22—Additional location information, such as "South Wing".
- 23—The name and occupant of a location, such as "Carrillo's Holiday Market".
- 24—A house-number suffix, such as "95684".

- 25—A building structure, such as “East Library”.

**ca-value** Configure location information (civic or postal address) that is indexed by the ca-type code.  
**value** See the description of the ca-type option for examples.

## Description

Configure captive portal to authenticate clients connected to the switch for access to the network.

## Default

Captive portal is disabled.

## Options

**authentication-  
profile-name** *access-  
profile-name*

Specify the name of the access profile to be used for captive portal authentication. You configure the access profile at the [edit access profile] hierarchy level. The access profile contains the RADIUS server IP address and other information used for authentication.

- **Default:** No access profile is specified.

**secure-  
authentication (http |  
https)**

Enable HTTP or HTTPS access on the captive portal interface.

- **Default:** http
- **Values:** Specify one of the following:
  - http—Enables HTTP access on the captive portal interface.
  - https—Enables HTTPS access on the captive portal interface. HTTPS is recommended.

## Hierarchy Level

```
[edit protocols lldp-med interface (all | interface-name) location]
```

## Description

For Link Layer Discovery Protocol–Media Endpoint Discovery (LLDP-MED), configure the geographic location to be advertised from the device to the MED. This information is used during emergency calls to identify the location of the MED.

## Default

Disabled.

## Options

**country-code** *code* (Required) Configure the two-letter ISO 3166 country code in capital ASCII letters; for example, US or DE. The code is part of the location information. Location information is advertised from the device to the MED, and is used during emergency calls to identify the location of the MED. The country code is required when configuring LLDP-MED based on location.

- **Default:** Disabled.

**what** *number* Configure the location to which the DHCP entry refers. This information is advertised, along with other location information, from the switch to the MED. It is used during emergency calls to identify the location of the MED.

Options 0 and 1 should not be used unless you know that the DHCP client is in close physical proximity to the server or network element.

- **Values:** Location to which the DHCP entry refers:
  - 0—Location of the DHCP server.
  - 1—Location of a network element believed to be closest to the client.
  - 2—Location of the client.
- **Default:** 1

}

```

## Hierarchy Level

```
[edit system login]
```

## Description

Define a login class. All users who log in to the router or switch must be in a login class. Therefore, you must define a Junos OS login class for each user or type of user. You can define any number of login classes depending on the types of permissions the users need. You may not need to define any login classes; Junos OS has several predefined login classes, to suit a variety of needs. However, the predefined login classes cannot be modified. If you define a class with the same name as a predefined class, Junos OS appends `-local` to the login class name and creates a new login class. See [Predefined System Login Classes](#) for more information.

## Options

**class-name** A name you choose for the login class.

**access-end** Specify the end time in *HH:MM* (24-hour) format, where *HH* represents the hours and *MM* represents the minutes.

**NOTE:** Access start and end times that span across 12:00 AM starting on a specified day results in the user having access until the next day, even if the access day is not explicitly configured on the `allowed-days` statement.

**access-start** Specify the start time in *HH:MM* (24-hour) format, where *HH* represents the hours and *MM* represents the minutes.

**NOTE:** Access start and end times that span across 12:00 AM starting on a specified day results in the user having access until the next day, even if the access day is not explicitly configured on the `allowed-days` statement.

**( allow-commands | allow-commands-regexps )** Specify one or more regular expressions to allow users in this class to issue operational mode commands. You use the `allow-commands` or the `allow-commands-regexps` statement to explicitly allow authorization for commands that would otherwise be denied by the access privilege levels for a login class.

For the `allow-commands` statement, each expression separated by a pipe (|) symbol must be a complete standalone expression, and must be enclosed in parentheses ( ). Do not use spaces between regular expressions separated with parentheses and connected with the pipe (|) symbol.

For the `allow-commands-regexps` statement, you configure a set of strings in which each string is a regular expression, enclosed in double quotes and separated with a space operator. Each string is evaluated against the full path of the command, which provides faster matching than the `allow-command` statement. You can also include values for variables in the regular expressions, which is not supported using the `allow-commands` statement.

The `deny-commands` or the `deny-commands-regexps` statement takes precedence if it is used in the same login class definition.

**NOTE:** The `allow/deny-commands` and `allow/deny-commands-regexps` statements are mutually exclusive and cannot be configured together for a login class. At a given point in time, a login class can include either the `allow/deny-commands` statements, or the `allow/deny-commands-regexps` statements. If you have existing configurations using the `allow/deny-commands` statements, using the same configuration options with the `allow/deny-commands-regexps` statements might not produce the same results, as the search and match methods differ in the two forms of these statements.

Authorizations can also be configured remotely by specifying Juniper Networks vendor-specific TACACS+ attributes in your authentication server's configuration. For a remote user, when the authorization parameters are configured both remotely and locally, authorization parameters configured remotely and locally are both considered together for authorization. For a local user, only the authorization parameters configured locally for the class are considered.

- **Default:** If you do not configure authorizations for operational mode commands using the `allow/deny-commands` or `allow/deny-commands-regexps` statements, users can edit only those commands for which they have access privileges set with the `permissions` statement.
- **Syntax:** *regular-expression*—Extended (modern) regular expression as defined in POSIX 1003.2. If the regular expression contains any spaces, operators, or wildcard characters, enclose it in quotation marks. Enter as many expressions as needed.

( `allow-configuration` | `allow-configuration-regexps` )

Specify one or more regular expressions to explicitly allow users in this class to access the specified levels in the configuration hierarchy even if the permissions set with the `permissions` statement do not grant such access.

For the `allow-configuration` statement, each expression separated by a pipe (|) symbol must be a complete standalone expression, and must be enclosed in parentheses ( ). Do not use spaces between regular expressions separated with parentheses and connected with the pipe (|) symbol.

For the `allow-configuration-regexps` statement, you configure a set of strings in which each string is a regular expression, enclosed in double quotes and separated with a space operator. Each string is evaluated against the full path of the command, which provides faster matching than the `allow/deny-configuration` statements. You can also include values for variables in the regular expressions, which is not supported using the `allow/deny-configuration` statements.

The `deny-configuration` or `deny-configuration-regexps` statement takes precedence if it is used in the same login class definition.

**NOTE:** The `allow/deny-configuration` and `allow/deny-configuration-regexps` statements are mutually exclusive and cannot be configured together for a login class. At a given point in time, a login class can include either the `allow/deny-configuration` statements, or the `allow/deny-configuration-regexps` statements. If you have existing configurations using the `allow/deny-configuration` statements, using the same configuration options with the `allow/deny-configuration-regexps` statements might not produce the same results, as the search and match methods differ in the two forms of these statements.

- **Default:** If you omit the `allow-configuration/allow-configuration-regexps` statement and the `deny-configuration/deny-configuration-regexps` statement, users can edit only those commands for which they have access privileges through the `permissions` statement.
- **Syntax:** *regular-expression*—Extended (modern) regular expression as defined in POSIX 1003.2. If the regular expression contains any spaces, operators, or wildcard characters, enclose it in quotation marks. Enter as many expressions as needed.

#### **allow-hidden-commands**

Allow all hidden commands to be run. If the `no-hidden-commands` statement is specified at the [edit system] hierarchy level, overrides that restriction for this login class. Hidden commands are Junos OS commands that are not published but could be run on a router. Hidden commands serve a specific purpose, but for most part are not expected to be used, and as such are not actively supported. The `no-hidden-commands` statement at the [edit system] hierarchy level allows you to block all hidden commands to all users except the root users.

- **Default:** Hidden commands are enabled by default.

#### **allow-sources** [ *source-addresses ...*]

Restrict incoming remote access to only particular hosts. Specify one or more source addresses from which access is allowed. The source addresses can be IPv4 or IPv6 addresses, prefix lengths, or hostnames.

#### **allow-times** [ *times...*]

Restrict remote access to certain times.

#### **allowed-days** [ *days of the week*]

Specify one or more days of the week when users in this class are allowed to log in.

- Values:
  - monday—Monday
  - tuesday—Tuesday
  - wednesday—Wednesday
  - thursday—Thursday
  - friday—Friday
  - saturday—Saturday
  - sunday—Sunday

**cli** Set the CLI prompt specified for the login class. If a CLI prompt is also set at the [edit system login user cli] hierarchy level, the prompt set for the login user has precedence over the prompt set for the login class.

**prompt** *prompt* Specify the prompt string you want to see displayed in the CLI prompt.

**configuration-breadcrumbs** Enable the configuration breadcrumbs view in the CLI to display the location in the configuration hierarchy. For an example of how to enable this view, see *Enabling Configuration Breadcrumbs*.

**confirm-commands** Specify that confirmation for particular commands is explicitly required and, optionally, specify the wording of the message displayed at confirm time. You can specify the commands using a list of regular expressions or commands.

- **Syntax:** *message*
- **Default:** If you omit this option, then confirmation for commands is not required. If the optional message is not set, then the default "Do you want to continue?" message is displayed.

**( deny-commands | deny-commands-regexps )** Specify one or more regular expressions to explicitly deny users in this class permission to issue operational mode commands, even though the permissions set with the `permissions` statement would allow it.

For the `deny-commands` statement, each expression separated by a pipe (|) symbol must be a complete standalone expression, and must be enclosed in parentheses ( ). Do not use spaces between regular expressions separated with parentheses and connected with the pipe (|) symbol.

For the `deny-commands-regexps` statement, you configure a set of strings in which each string is a regular expression, enclosed in double quotes and separated with a space operator. Each string is evaluated against the full path of the command, which provides faster matching than the `allow/deny-command` statements. You can also include values for variables in the regular expressions, which is not supported using the `allow/deny-commands` statements.

Expressions configured with the `deny-commands` or the `deny-commands-regexps` statement take precedence over expressions configured with `allow-commands/allow-commands-regexps` if the two statements are used in the same login class definition.

**NOTE:** The `allow/deny-commands` and `allow/deny-commands-regexps` statements are mutually exclusive and cannot be configured together for a login class. At a given point in time, a login class can include either the `allow/deny-commands` statements, or the `allow/deny-commands-regexps` statements. If you have existing configurations using the `allow/deny-commands` statements, using the same configuration options with the `allow/deny-commands-regexps` statements might not produce the same results, as the search and match methods differ in the two forms of these statements.

Authorizations can also be configured remotely by specifying Juniper Networks vendor-specific TACACS+ attributes in your authentication server's configuration. For a remote user, when the authorization parameters are configured both remotely and locally, authorization parameters configured remotely and locally are both considered together for authorization. For a local user, only the authorization parameters configured locally for the class are considered.

- **Default:** If you do not configure authorizations for operational mode commands using `allow/deny-commands` or `allow/deny-commands-regexps`, users can edit only those commands for which they have access privileges set with the `permissions` statement.
- **Syntax:** *regular-expression*—Extended (modern) regular expression as defined in POSIX 1003.2. If the regular expression contains any spaces, operators, or wildcard characters, enclose it in quotation marks. Enter as many expressions as needed.

( `deny-configuration` | `deny-configuration-regexps` )

Specify one or more regular expressions to explicitly deny users in this class access to the specified levels in the configuration hierarchy even if the permissions set with the `permissions` statement grant such access. Note that the user cannot view a particular hierarchy if configuration access is denied for that hierarchy.

For the `deny-configuration` statement, each expression separated by a pipe (`|`) symbol must be a complete standalone expression, and must be enclosed in parentheses (`()`). Do not use spaces between regular expressions separated with parentheses and connected with the pipe (`|`) symbol.

For the `deny-configuration-regexps` statement, you configure a set of strings in which each string is a regular expression, enclosed in double quotes and separated with a space operator. Each string is evaluated against the full path of the command, which provides faster matching than the `allow/deny-configuration` statements. You can also include values for variables in the regular expressions, which is not supported using the `allow/deny-configuration` statements.

Expressions configured with `deny-configuration/deny-configuration-regexps` take precedence over expressions configured with `allow-configuration/allow-configuration-regexps` if the two statements are used in the same login class definition.

**NOTE:** The `allow/deny-configuration` and `allow/deny-configuration-regexps` statements are mutually exclusive and cannot be configured together for a login class. At a given point in time, a login class can include either the `allow/deny-configuration` statements, or the `allow/deny-configuration-regexps` statements. If you have existing configurations using the `allow/deny-configuration` statements, using the same configuration options with the `allow/deny-configuration-regexps` statements might not produce the same results, as the search and match methods differ in the two forms of these statements.

- **Default:** If you omit the `deny-configuration/deny-configuration-regexps` statement and the `allow-configuration/allow-configuration-regexps` statement, users can edit those levels in the configuration hierarchy for which they have access privileges through the `permissions` statement.
- **Syntax:** *regular-expression*—Extended (modern) regular expression as defined in POSIX 1003.2. If the regular expression contains any spaces, operators, or wildcard characters, enclose it in quotation marks. Enter as many expressions as needed.

**deny-sources**  
[*source-*  
*addresses*]

Never allow remote access from these hosts. The source addresses can be IPv4 or IPv6 addresses, prefix lengths, or hostnames.

**deny-times**  
[*times*]

Never allow remote access during these times.

**idle-timeout** For a login class, configure the maximum time in minutes that a session can be idle before the session times out and the user is logged out of the device. The session times out after remaining at the CLI operational mode prompt for the specified time.

**NOTE:** After the user logs in to a device from a shell prompt such as `csch`, if the user starts another program to run in the foreground of the CLI, the idle-timer control is stopped from being computed. The calculation of the idle time of the CLI session is restarted only after the foreground process exits and the control is returned to the shell prompt. When the restart of the idle-timer control occurs, if no interaction from the user occurs on the shell, the user is automatically logged out after the time set on this statement.

- **Default:** If you omit this statement, a user is never forced off the system after extended idle times.
- **Syntax:** *minutes*—Maximum time in minutes that a session can be idle before a user is logged out.
- **Range:** Range: 0 through 4294967295 minutes

**NOTE:** The idle-timeout feature is disabled if the value of *minutes* is set to 0.

**login-alarms** Display system alarms when a user with `admin` permissions logs in to the device. For more information about configuring this statement, see [Configuring System Alarms to Appear Automatically Upon Login](#).

**login-script** Run the specified `op` script when a user belonging to the class logs in to the CLI. The script must be enabled in the configuration.

**logical-system** Assign the users in this login class to a logical system. If you specify a logical system, you can't include the `satellite` configuration statement in the configuration for this login class.

**login-tip** Display CLI tips when logging in.

- **Default:** If this statement is not configured, CLI tips are not displayed.

**no-hidden-commands** Deny all hidden commands, except for those specified, for users in this login class. Each command listed as an exception must be enclosed in quotation marks.

- **Default:** Hidden commands are enabled by default.
- **Syntax:** except [*“command 1” “command 2”...*]

**no-scp-server** Disable incoming SCP connections for this login class.

**no-sftp-server** Disable incoming SFTP connections for this login class.

**permissions** Specify login access privileges for the login class.

- **Syntax:** *permissions*—One or more permission flags, which together specify the access privileges for the login class. Permission flags are not cumulative, so for each class, you must list all the permission flags needed, including *view* to display information and *configure* to enter configuration mode. For a list of permission flags, see [Login Class Permission Flags](#).

**satellite** Specify access to Junos Fusion satellite devices for the login class. All users assigned to the login class are satellite users. If you include this statement, you can't include the logical-system configuration statement in the configuration for this login class.

- Values:
  - all—Specify all Junos Fusion satellite devices.

**security-role** Specify one or more Common Criteria (ISO/IEC 15408) security roles for the login class.

- Values:

**audit-administrator** Specify which users are responsible for the regular review of specific target of evaluation (TOE) audit data and audit trail deletion. Audit administrators can also invoke the non-cryptographic self-test.

**crypto-administrator** Specify which users are responsible for the configuration and maintenance of cryptographic elements related to the establishment of secure connections to and from the TOE audit data.

**ids-administrator** Specify which users can act as intrusion detection service (IDS) administrators, who are responsible for all of the activities regarding identity and access management of the organization's employees.

<b>security-administrator</b>	Specify which users are responsible for ensuring that the organization's security policy is in place.
<b>tenant</b>	Assign the users in this class to a tenant system. Tenant systems are used when you need to separate departments, organizations, or customers and each of them can be limited to one virtual router. The main difference between a logical system and a tenant system is that a logical system supports advanced routing functionality using multiple routing instances. In comparison, a tenant system supports only one routing instance, but supports the deployment of significantly more tenants per system.
<b>web-ui-hidden-menus</b>	Enable hidden menus in the J-Web interface.
<b>web-ui-read-only-menus</b>	Enable read-only menus in the J-Web interface.

## Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

## Release Information

The class, allow-commands, deny-commands, allow-configuration, deny-configuration, idle-timeout, login-alarms, login-tip, and permissions statements were introduced before Junos OS Release 7.4.

All of the previously mentioned statements were introduced in Junos OS Release 9.0 for the EX Series.

The login-script statement was introduced in Junos OS Release 9.5.

The access-end, access-start, and allowed-days statements were introduced in Junos OS Release 10.1.

All of the previously mentioned statements were introduced in Junos OS Release 11.1 for the QFX Series.

All of the previously mentioned statements were introduced in Junos OS Release 11.2 for the SRX Series.

The allow-configuration-regexps, deny-configuration-regexps, and security-role statements were introduced in Junos OS Release 11.2.

The `configuration-breadcrumbs` statement was introduced in Junos OS Release 12.2.

All of the previously mentioned statements were introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

All of the previously mentioned statements were introduced in Junos OS Release 15.1X49-D70 for the vSRX, SRX4100, SRX4200 and SRX1500 devices.

All of the previously mentioned statements were introduced in Junos OS Release 16.1 for the MX Series and PTX Series.

The `allow-hidden-commands`, `confirm-commands`, `no-hidden-commands`, and `satellite` statements were introduced in Junos OS Release 16.1.

The `cli` statement was introduced in Junos OS Release 17.3.

The `allow-commands-regexps` and `deny-commands-regexps` statements were introduced in Junos OS Release 18.1.

The `tenant` statement was introduced in Junos OS 18.4.

The `no-scp-server` and `no-sftp-server` statements were introduced in Junos OS Release 19.2.

The `web-ui-hidden-menus` and `web-ui-read-only-menus` statements were introduced in Junos OS 21.3 for the SRX platforms.

## Syntax

```
connection-limit limit;
```

## Hierarchy Level

```
[edit system services netconf ssh],  
[edit system services ssh],
```

## Description

Configure the maximum number of connections sessions for each type of system service (finger, ftp, ssh, telnet, xnm-clear-text, or xnm-ssl) per protocol (either IPv6 or IPv4).

## Options

*limit*—(Optional) Maximum number of established connections per protocol (either IPv6 or IPv4).

- **Range:** 1 through 250
- **Default:** 75

**NOTE:** The actual number of maximum connections depends on the availability of system resources, and might be fewer than the configured `connection-limit` value if the system resources are limited.

## Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

## Release Information

Statement introduced before Junos OS Release 7.4.

    header-text-color color;  
    post-authentication-url url-string;  
}
```

## Hierarchy Level

```
[edit services captive-portal]
```

## Description

Specify the design elements of a captive portal login page.

## Options

banner-message—The first screen displayed before the captive portal login page is displayed—for example, a disclaimer message or a terms and conditions of use page.

- **Range:** 1–2047 characters

footer-bgcolor —The hexadecimal color code for the color of the footer bar across the bottom of the captive portal login page—for example, #2E8B57 (sea green).

- **Values:** # symbol followed by six characters.

footer-message—Text message displayed in the footer bar across the bottom of the captive portal login page.

- **Range:** 1–2047 characters
- **Default:** Copyright ©2010, Juniper Networks Inc.

footer-text-color — Color of the text in the footer.

- **Default:** The default color is white.

form-header-bgcolor —The hexadecimal color code for the background color of the header bar across the top of the form area of the captive portal login page.

- **Values:** # symbol followed by six characters.

form-header-message—Text message displayed in the header bar across the top of the form area of the captive portal login page.

- **Range:** 1–255 characters

- **Default:** Captive Portal User Authentication

form-header-text-color—Color of the text in the form header.

- **Default:** The default color is black.

form-reset-label—Label displayed in the button that the user can select to clear the username and password fields on the form.

- **Range:** 1–255 characters

- **Default:** Reset

form-submit-label —Label displayed in the button that the user selects to submit their login information—for example, Log In.

- **Range:** 1–255 characters

- **Default:** Log In

header-bgcolor—The hexadecimal color code for the color of the header bar across the top of the captive portal login page.

- **Values:** # symbol followed by six characters.

header-logo—Filename of the file containing the image of the logo displayed at the top of the captive portal login page. The image file can be in GIF, JPEG, or PNG format.

- **Default:** The Juniper Networks logo

header-message—Text displayed in the header bar across the bottom of the captive portal login page.

- **Range:** 1–2047 characters

- **Default:** User Authentication

header-text-color—Color of the text in the header.

- **Default:** The default color is white.

post-authentication-url—URL to which the users are directed upon successful authentication—for example [www.mycafe.com](http://www.mycafe.com).

- **Range:** 1–255 characters

- **Default:** The page originally requested by the user.

## Syntax

```
dynamic-requests {
    routing-instance routing-instance-name;
    source-address source-address;
    source-port source-port;
}
```

## Hierarchy Level

```
[edit access radsec destination ]
```

## Description

Configure RADSEC clients to receive and process dynamic requests. RADSEC servers can be a source of dynamic RADIUS requests such as Change of Authorization (CoA) and RADIUS-initiated disconnect (RID) messages.

You must configure the IP address of the RADSEC server as the source address for the requests. You can also specify the source port that the client monitors for dynamic requests. If the port is not explicitly configured, the default RADSEC port 2083 is used.

## Options

<b>routing-instance</b> <i>routing-instance-name</i>	Specify the routing instance name.
<b>source-address</b> <i>ip-address</i>	(Required) Configure the source IP address, which is the IP address of the RADSEC server. If the source address is not configured, dynamic requests will be rejected.
<b>source-port</b> <i>port-number</i>	(Optional) Specify the source port that the client monitors for dynamic requests. If the port is not explicitly configured, the default is used.

- **Default:** 2083
- **Range:** 1 through 65535

## Required Privilege Level

access—To view this statement in the configuration.

access-control—To add this statement to the configuration.

[edit protocols dot1x authenticator interface (all | [interface-names])]
[edit protocols dot1x authenticator interface (all | [interface-names]) server-reject-bridge-domain |
server-reject-vlan]
```

## Description

Enable the device to ignore Extensible Authentication Protocol over LAN (EAPoL)-Start messages received from a client that has been authenticated so that the device does not trigger re-authentication. The device typically attempts to restart the authentication procedure by contacting the authentication server when it receives an EAPoL-Start message from a client—even for authenticated clients. You can configure the `eapol-block` statement to help prevent unnecessary downtime that can occur when the device waits for a response from the authentication server.

If you configure the device to block EAPoL-Start messages, when the device receives an EAPoL-Start message from an authenticated client, the device ignores the message and does not attempt to contact the authentication server for reauthentication. The existing authentication session that was established for the client remains open.

The EAPoL-Start messages are blocked only if the client is in the authenticated state. EAPoL-Start messages from new clients are accepted.

## Default

If the `eapol-block` statement is not configured, the device attempts to contact the authentication server to authenticate the client when it receives an EAPoL-Start message.

## Options

<code>captive-portal</code>	Configure the device to ignore EAPoL-Start messages received from a client that has been authenticated using captive portal authentication.
<code>mac-radius</code>	Configure the device to ignore EAPoL-Start messages received from a client that has been authenticated using MAC RADIUS authentication. The <code>mac-radius</code> option is also valid for clients authenticated using central Web authentication (CWA).
<code>server-fail</code> < <i>seconds</i> >	Configure the device to ignore EAPoL-Start messages received from a client that has been authenticated using server fail fallback or server reject VLAN methods. Optionally, configure the time interval, in seconds, during which the device will not attempt to contact the authentication server to re-authenticate a client that has already been authenticated using server fail fallback.

- **Default:** 120 seconds.
- **Range:** 120 through 65,535 seconds.

## Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

## Release Information

Statement introduced in Junos OS Release 11.2.

Support at the [edit protocols dot1x authenticator interface *interface-name*] hierarchy level introduced in Junos OS Releases 14.1X53-D40 and 15.1X53-D51 for EX Series switches.

`captive-portal` and `mac-radius` introduced in Junos OS Release 17.2R1.

## Syntax

```
finger {  
    connection-limit limit;  
    rate-limit limit;  
}
```

## Hierarchy Level

```
[edit system services]
```

## Description

Allow finger requests from remote systems to the local device.

## Options

**connection-limit** *limit*

Configure the maximum number of connection sessions for the finger service per protocol (either IPv4 or IPv6).

**NOTE:** The actual number of maximum connections depends on the availability of system resources, and might be fewer than the configured `connection-limit` value if the system resources are limited.

- **Range:** 1 through 250 connections
- **Default:** 75 connections

**rate-limit** *limit*

Configure the maximum number of connection attempts per minute, per protocol (either IPv6 or IPv4). For example, a rate limit of 10 allows 10 IPv6 finger session connection attempts per minute and 10 IPv4 finger session connection attempts per minute.

- **Range:** 1 through 250 connections
- **Default:** 150 connections

    connection-limit limit;  
    rate-limit limit;  
}
```

## Hierarchy Level

```
[edit system services]
```

## Description

Allow FTP requests from remote systems to the local device.

## Options

### authentication-order [*authentication-methods*]

Configure the order in which the software tries different user authentication methods when attempting to authenticate a user. For each login attempt, the software tries the authentication methods in order, starting with the first one, until the password matches.

- **Values:** Specify one or more of the following authentication methods listed in the order in which they must be tried:
  - `ldaps`—Use LDAP authentication services.
  - `password`—Use the password configured for the user with the authentication statement at the [edit system login user] hierarchy level.
  - `radius`—Use RADIUS authentication services.
  - `tacplus`—Use TACACS+ authentication services.
- **Default:** If you do not include the authentication-order statement, users are verified based on their configured passwords.

### connection-limit *limit*

Configure the maximum number of connections sessions for the ftp service per protocol (either IPv6 or IPv4).

**NOTE:** The actual number of maximum connections depends on the availability of system resources, and might be fewer than the configured connection-limit value if the system resources are limited.

- **Range:** 1 through 250 connections
- **Default:** 75 connections

### rate-limit *limit*

Configure the maximum number of connections attempts per minute, per protocol (either IPv6 or IPv4) on an access service. For example, a rate limit of 10 allows 10 IPv6 ftp session connection attempts per minute and 10 IPv4 ftp session connection attempts per minute.

- **Range:** 1 through 250 connections
- **Default:** 150 connections

- [Syntax \(Starting in Junos OS Release 22.3R1\) | 1176](#)
- [Hierarchy Level | 1176](#)
- [Description | 1176](#)
- [Options | 1177](#)
- [Required Privilege Level | 1178](#)

## Syntax (Prior to Junos OS Release 22.3R1)

```
hostkey-algorithm {  
    (no-ssh-dss | ssh-dss);  
    (no-ssh-rsa | ssh-rsa);  
    (no-ssh-ecdsa | ssh-ecdsa);  
    (no-ssh-ed25519 | ssh-ed25519);  
}
```

## Syntax (Starting in Junos OS Release 22.3R1)

```
hostkey-algorithm-list (ecdsa-sha2-nistp256 | ecdsa-sha2-nistp384 | ecdsa-sha2-nistp521 |  
ed25519 | rsa)
```

## Hierarchy Level

```
[edit system services ssh]
```

## Description

Allow or disallow a host-key algorithm to authenticate another host through the SSH protocol. The host-key uses RSA, ECDSA, ED25519, and DSS algorithms.

The following are the behaviors when the `hostkey-algorithm` option is configured with SSH client and SSH server:

- On the SSH client, the host-key algorithms that are supported when talking to a server are:

1. RSA: Equal or greater-than to 1024 bit
  2. ECDSA: 256, 384, or 521 bit
  3. ED25519: 256 bit
  4. DSS: 1024 bit
- On the SSH server, the host-key algorithms that are generated and stored are:
    1. RSA: 2048 bit
    2. ECDSA: 256 bit (Prior to Junos OS Release 22.3R1).  
ECDSA: 256, 384, or 521 bit (Starting in Junos OS Release 22.3R1).
    3. ED25519: 256 bit
    4. DSS: 1024 bit

Starting in Junos OS Release 22.3R1, we've introduced the `hostkey-algorithm-list` statement at the `[edit system services ssh]` hierarchy level. This enhancement enables you to configure only the specified SSH hostkey algorithms. The system automatically disables the remaining unspecified hostkey algorithms. In earlier releases, you need to disable the hostkey algorithms explicitly. All the hostkey algorithms at this hierarchy enabled by default. The DSS algorithm is no longer available at this new hierarchy. In addition, we've deprecated the `hostkey-algorithm` statement at the `[edit system services ssh]` hierarchy level.

## Options

<b>ecdsa-sha2-nistp256</b>	Allow generation of ECDSA host-key with NIST P-256 curve.
<b>ecdsa-sha2-nistp384</b>	Allow generation of ECDSA host-key with NIST P-384 curve.
<b>ecdsa-sha2-nistp521</b>	Allow generation of ECDSA host-key with NIST P-521 curve
<b>ed25519</b>	Allow generation of EdDSA host-key with curve25519.
<b>rsa</b>	Allow generation of 2048-bit RSA host-key
<b>ssh-ecdsa</b>	Allow generation of an ECDSA host-key. Key pair sizes of 256, 384, or 521 bits are compatible with ECDSA.
<b>ssh-dss</b>	Allow generation of a 1024-bit DSA host-key.

**NOTE:** DSA keys are not supported in FIPS, so the `ssh-dss` option is not available on systems operating in FIPS mode.

<b>ssh-rsa</b>	Allow generation of RSA host-key. Key pair sizes greater than or equal to 1024 are compatible with RSA.
<b>no-ssh-dss</b>	Do not allow generation of a 1024-bit Digital Signature Algorithm (DSA) host-key.
<b>no-ssh-ecdsa</b>	Do not allow generation of an Elliptic Curve Digital Signature Algorithm (ECDSA) host-key.
<b>no-ssh-rsa</b>	Do not allow generation of an RSA host-key.

## Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

## Release Information

Statement introduced in Junos OS Release 11.2.

`hostkey-algorithm-list` option added in Junos OS Release 22.3R1.

## Description

Configure the secure version of the HTTP service, HTTPS, which is encrypted.

## Options

**interface**  
[ *interface-*  
*names* ]

Specify the name of one or more interfaces on which to accept access through the HTTPS service. By default, HTTPS access is allowed through any ingress interface, but HTTP access is allowed through built-in Fast Ethernet or Gigabit Ethernet interfaces only.

( *local-certificate*  
*name* | *pki-local-*  
*certificate name* |  
*system-*  
*generated-*  
*certificate* )

Specify the X.509 certificate type for a Secure Sockets Layer (SSL) connection.

- **Values:** Specify one of the following:
  - *local-certificate name*—Specify the name of the X.509 certificate. You configure the local certificate at the [edit security certificates local] hierarchy level.
  - *pki-local-certificate name*—(EX, QFX, and SRX Series only) Specify the name of the X.509 certificate that is generated by the public key infrastructure (PKI) and authenticated by a certificate authority (CA).
  - *system-generated-certificate*—(EX, QFX, and SRX Series only) Automatically generate a self-signed X.509 certificate for enabling the HTTPS service.

**port** *port-number*

Configure the TCP port number on which to connect the HTTPS service.

- **Range:** 1 through 65,535

## Required Privilege Level

```

## Hierarchy Level

```
[edit logical-systems name protocols dot1x authenticator],
[edit protocols dot1x authenticator]
```

## Description

Configure IEEE 802.1X authentication for Port-Based Network Access Control for all interfaces or for specific interfaces.

## Options

**(all | [ *interface-names* ])**

Configure either a list of interface names or all interfaces for 802.1x authentication.

**disable**

Disable 802.1X authentication on a specified interface or all interfaces.

- **Default:** 802.1X authentication is disabled on all interfaces.

**guest-bridge-domain *guest-bridge-domain***

(MX Series only) Specify the bridge domain tag identifier or the name of the guest bridge domain to which an interface is moved when no 802.1X supplicants are connected on the interface. The bridge domain specified must already exist on the device.

**guest-vlan (*vlan-id* | *vlan-name*)**

(EX, QFX, and SRX Series only) Specify the VLAN tag identifier or the name of the guest VLAN to which an interface is moved when no 802.1X supplicants are connected on the interface. The VLAN specified must already exist on the device. Guest VLANs can be configured on devices that are using 802.1X authentication to provide limited access—typically only to the Internet—for corporate guests. A guest VLAN is not used for supplicants that send incorrect credentials. Those supplicants are directed to the server-reject VLAN instead.

**ignore-port-bounce**

Ignore the port-bounce command contained in a Change of Authorization (CoA) request. CoA requests are RADIUS messages that are used to dynamically modify an authenticated user session already in progress. CoA requests are sent from the authentication, authorization, and accounting (AAA) server to the device, and are typically used to change the VLAN for the host based on device

profiling. End devices such as printers do not have a mechanism to detect the VLAN change, so they do not renew the lease for their DHCP address in the new VLAN. The port-bounce command is used to force the end device to initiate DHCP re-negotiation by causing a link flap on the authenticated port.

- **Default:** The port-bounce command is supported by default. If you do not configure the `ignore-port-bounce` statement, the device responds to a port-bounce command by flapping the link to re-initiate DHCP negotiation for the end device.

**maximum-requests  
number**

Specify the maximum number of times an EAPoL request packet is retransmitted to the supplicant before the authentication session times out.

- **Range:** 1 through 10
- **Default:** 2

**no-reauthentication |  
reauthentication  
seconds**

Either disable reauthentication or configure the number of seconds before the 802.1X authentication session times out and the client must reattempt authentication.

**NOTE:** If the authentication server sends an authentication session timeout to the client, this takes priority over the value configured locally using the `reauthentication` statement. The session timeout value is sent from the server to the client as an attribute of the RADIUS Access-Accept message.

- **Range:** 1 through 65,535 seconds
- **Default:** Reauthentication is enabled, with 3600 seconds until the client can attempt to authenticate again.

**no-tagged-mac-  
authentication**

Don't allow a tagged MAC address for RADIUS authentication.

**quiet-period seconds**

Specify the number of seconds the interface remains in the wait state following a failed authentication attempt by a supplicant before reattempting authentication.

- **Range:** 0 through 65,535 seconds
- **Default:** 60 seconds

**redirect-url *redirect-url***

Specify a URL that redirects unauthenticated hosts to a central Web authentication (CWA) server. The CWA server provides a web portal where the user can enter a username and password. If these credentials are validated by the CWA server, the user is authenticated and is allowed access to the network.

The redirect URL for central Web authentication can be configured centrally on the AAA server or locally on the switch. Use the `redirect-url` statement to configure the redirect URL locally on the interface connecting the host to the switch.

The redirect URL and a dynamic firewall filter must both be present for the central Web authentication process to be triggered. For more information about configuring the redirect URL and the dynamic firewall filter for central Web authentication, see ["Configuring Central Web Authentication" on page 522](#).

**NOTE:** When the dynamic firewall filter is configured using the special Filter-ID attribute `JNPR_RSVD_FILTER_CWA`, the CWA redirect URL must include the IP address of the AAA server, for example, **`https://10.10.10.10`**.

- **Syntax:** The redirect URL must use the HTTP or HTTPS protocol and include an IP address or website name. The following are examples of valid redirect URL formats:
  - `http://www.example.com`
  - `https://www.example.com`
  - `http://10.10.10.10`
  - `https://10.10.10.10`
  - `http://www.example.com/login.html`
  - `https://www.example.com/login.html`
  - `http://10.10.10.10/login.html`
  - `https://10.10.10.10/login.html`
- **Default:** Disabled. The redirect URL is not enabled for central Web authentication by default.

**request-retry-count**  
*number*

Configure the authentication server to retry sending an EAP request to the supplicant. This can help prevent a timeout of the authentication session due to an unresponsive supplicant. The number of retries is based on the configured value.

- **Range:** 1 through 10 retries
- **Default:** 2 retries

**retries** *number*

Specify the number of times the device attempts to authenticate the port after an initial failure. When the limit is exceeded, the port waits to reattempt authentication for the number of seconds specified with the `quiet-period` option configured at the same hierarchy level.

- **Range:** 1 through 10 retries
- **Default:** 3 retries

**server-fail** (*bridge-domain* *bridge-domain* | *deny* | *permit* | *use-cache* | *vlan-name* *vlan-name*)

Specify how end devices connected to a device are supported if the RADIUS authentication server becomes unavailable. Server fail fallback is triggered most often during reauthentication when the already configured and in-use RADIUS server becomes inaccessible. However, server fail fallback can also be triggered by a supplicant's initial attempt at authentication through the RADIUS server.

You must specify an action that the device applies to end devices when the authentication servers are unavailable. The device can accept or deny access to supplicants or maintain the access already granted to supplicants before the RADIUS timeout occurred. You can also configure the switch to move the supplicants to a specific VLAN or bridge domain. The VLAN or bridge domain must already be configured on the device.

**NOTE:** The `server-fail` statement is specifically for data traffic. For VoIP-tagged traffic, use the `server-fail-voip` statement. The same interface can have a `server-fail` VLAN and a `server-fail-voip` VLAN configured.

- **Values:** *bridge-domain*—(MX Series only) Move the supplicant on the interface to the bridge domain specified by this name or numeric identifier. This action is allowed only if it is the first supplicant connecting to an interface. If an authenticated supplicant is already connected, then the supplicant is not moved to the bridge domain and is not authenticated. The bridge domain must already be configured on the device.

**deny**—Force the supplicant authentication to fail. No traffic will flow through the interface.

**permit**—Force the supplicant authentication to succeed. Traffic will flow through the interface as if it were successfully authenticated by the RADIUS server.

**use-cache**—Force the supplicant authentication to succeed only if it was previously authenticated successfully. This action ensures that already authenticated supplicants are not affected.

**vlan-name**—(EX, QFX, or SRX Series only) Move the supplicant on the interface to the VLAN specified by this name or numeric identifier. This action is allowed only if it is the first supplicant connecting to the interface. If an authenticated supplicant is already connected, then the supplicant is not moved to the VLAN and is not authenticated. The VLAN must already be configured on the device.

- **Default:** If the RADIUS authentication server becomes unavailable, the end device is not authenticated and is denied access to the network.

**server-fail-voip**  
(deny | permit | use-cache | vlan-name  
vlan-name)

(EX, QFX Series only) Specify how VoIP clients sending voice traffic are supported if the RADIUS authentication server becomes unavailable. Server fail fallback is triggered most often during reauthentication when the already configured and in-use RADIUS server becomes inaccessible. However, server fail fallback can also be triggered by a VoIP client's initial attempt at authentication through the RADIUS server.

You must specify an action that the switch applies to VoIP clients when the authentication servers are unavailable. The switch can accept or deny access to VoIP clients or maintain the access already granted to clients before the RADIUS timeout occurred. You can also configure the switch to move the VoIP clients to a specific VLAN. The VLAN must already be configured on the switch.

The `server-fail-voip` statement is specific to the VoIP-tagged traffic sent by clients. VoIP clients still require that the `server-fail` statement be configured for the un-tagged traffic that they generate. Therefore, when you configure the `server-fail-voip` statement you must also configure the `server-fail` statement.

**NOTE:** An option other than `server-fail deny` must be configured for `server-fail-voip` to successfully commit.

- **Values:** *deny*—Force the VoIP client authentication to fail. No traffic will flow through the interface.

*permit*—Force the VoIP client authentication to succeed. Traffic will flow through the interface as if it were successfully authenticated by the RADIUS server.

*use-cache*—Force the VoIP client authentication to succeed only if it was previously authenticated successfully. This action ensures that already authenticated clients are not affected.

*vlan-name*—Move the VoIP client on the interface to the VLAN specified by this name or numeric identifier. This action is allowed only if it is the first VoIP client connecting to the interface. If an authenticated VoIP client is already connected, then the VoIP client is not moved to the VLAN and is not authenticated. The VLAN must already be configured on the switch.

- **Default:** If a RADIUS authentication server becomes unavailable, a VoIP client that begins authentication by sending voice traffic is not authenticated, and the voice traffic is dropped.

**server-timeout**  
*seconds*

Specify the amount of time a port will wait for a reply when relaying a response from the supplicant to the authentication server before timing out and invoking the server-fail action.

- **Range:** 1 through 60 seconds
- **Default:** 30 seconds

**supplicant (single |**  
**single-secure |**  
**multiple)**

Specify the MAC-based method used to authenticate clients.

- **Values:** Specify one of the following:
  - *single*—Authenticates only the first client that connects to an authenticator port. All other clients connecting to the authenticator port after the first are permitted free access to the port without further authentication. If the first authenticated client logs out, all other supplicants are locked out until a client authenticates again.
  - *single-secure*—Authenticates only one client to connect to an authenticator port. The host must be directly connected to the switch.

- **multiple**—Authenticates multiple clients individually on one authenticator port. You can configure the number of clients per port. If you also configure a maximum number of devices that can be connected to a port through port security settings, the lower of the configured values is used to determine the maximum number of clients allowed per port.

- **Default:** single

**supplicant-timeout**  
*seconds*

Specify the number of seconds the port waits for a response when relaying a request from the authentication server to the supplicant before re-sending the request.

- **Range:** 1 through 60 seconds
- **Default:** 30 seconds

**transmit-period**  
*seconds*

Specify the number of seconds the port waits before retransmitting the initial EAPoL PDUs to the supplicant.

- **Range:** 1 through 65,535 seconds
- **Default:** 30 seconds

The remaining statements are explained separately. Search for a statement in [CLI Explorer](#) or click a linked statement in the Syntax section for details.

routing-control—To add this statement to the configuration.

## Release Information

Statement introduced in Junos OS Release 9.0.

server-reject-vlan introduced in Junos OS Release 9.3 for EX Series switches.

eapol-block introduced in Junos OS Release 11.2.

authentication-order and redirect-url introduced in Junos OS Release 15.1R3.

server-fail-voip introduced in Junos OS Releases 14.1X53-D40 and 15.1R4 for EX and QFX Series switches.

ignore-port-bounce introduced in Junos OS Release 17.3R1.

multi-domain introduced in Junos OS Release 18.3R1.

- [Description | 1196](#)
- [Options | 1196](#)
- [Required Privilege Level | 1198](#)
- [Release Information | 1198](#)

## Syntax

```
interface (all | [interface-names]) {  
    quiet-period seconds;  
    retries number-of-retries;  
    server-timeout seconds;  
    session-expiry seconds;  
    supplicant ( multiple | single | single-secure);  
    user-keepalive minutes;  
}
```

## Hierarchy Level

```
[edit services captive-portal]
```

## Description

Configure captive portal authentication for all interfaces or for specific interfaces.

## Options

<b>all</b>	All interfaces to be configured for captive portal authentication.
<b>[<i>interface-names</i>]</b>	List of names of interfaces to be configured for captive portal authentication.
<b>quiet-period <i>seconds</i></b>	Configure time, in seconds, after a user exceeds the maximum number of retries before they can attempt to authenticate. <ul style="list-style-type: none"> <li>• <b>Range:</b> 1–65535 seconds</li> <li>• <b>Default:</b> 60 seconds</li> </ul>
<b>retries <i>number-of-tries</i></b>	Configure the number of times the user can attempt to submit authentication information. <ul style="list-style-type: none"> <li>• <b>Range:</b> 1–65535 tries</li> <li>• <b>Default:</b> 3 tries</li> </ul>
<b>server-timeout <i>seconds</i></b>	Configure the time in seconds an interface will wait for a reply when relaying a response from the client to the authentication server before timing out and invoking the server-fail action. <ul style="list-style-type: none"> <li>• <b>Range:</b> 1–65535 seconds</li> <li>• <b>Default:</b> 20 seconds</li> </ul>
<b>session-expiry <i>seconds</i></b>	Configure the number of seconds before the captive portal authentication session times out and the client must reattempt authentication.

**NOTE:** If the authentication server sends an authentication session timeout to the client, this takes priority over the value configured locally using the `session-expiry` statement. The session timeout value is sent from the server to the client as an attribute of the RADIUS Access-Accept message.

- **Range:** 1 through 65535 seconds
- **Default:** 3600 seconds

**supplicant**  
(multiple |  
single | single-  
secure)

Configure the MAC-based method used to authenticate clients for captive portal authentication.

- **Values:** Configure one of the following:
  - single—Authenticates only the first client that connects to an authenticator port. All other clients connecting to the authenticator port after the first are permitted free access to the port without further authentication. If the first authenticated client logs out, all other supplicants are locked out until a client authenticates again.
  - single-secure—Authenticates only one client to connect to an authenticator port. The host must be directly connected to the switch.
  - multiple—Authenticates multiple clients individually on one authenticator port. You can configure the number of clients per port. If you also configure a maximum number of devices that can be connected to a port through port security settings, the lower of the configured values is used to determine the maximum number of clients allowed per port.
- **Default:** single

**user-keepalive**  
*minutes*

Extend a captive portal authentication session after the MAC table aging timer expires, by the configured number of minutes. The keep-alive timer is started when the MAC address of the authenticated host ages out of the Ethernet switching table. If traffic is received within the keep-alive timeout period, the timer is deleted. If there is no traffic within the keep-alive timeout period, the session is deleted, and the host must re-authenticate.

- **Default:** Disabled. The captive portal authentication session ends when the associated MAC address ages out of the Ethernet switching table.
- **Range:** 7 through 65535 minutes

The remaining statements are explained separately. Search for a statement in [CLI Explorer](#) or click a linked statement in the Syntax section for details.

## Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

## Release Information

Statement introduced in Junos OS Release 10.1.

user-keepalive introduced in Junos OS Release 16.1 for EX Series switches.

## Description

Configure Link Layer Discovery Protocol (LLDP) on all interfaces or on a particular interface.

**NOTE:** On MX Series and T Series routers, you run LLDP on a physical interface, such as ge-1/0/0, and not at the logical interface (unit) level.

Starting with Junos OS Release 14.2, on MX Series devices, you can also configure LLDP on management interfaces, such as fxp or me.

LLDP is not supported on vme interfaces.

For information about interface names, see [Interface Naming Overview](#). For information about interface names for TX Matrix routers, see [TX Matrix Router Chassis and Interface Names](#). For information about FPC numbering on TX Matrix routers, see [Routing Matrix with a TX Matrix Router FPC Numbering](#).

For information about extended port names in the Junos Fusion technology, see *Understanding Junos Fusion Ports*.

## Options

<b>(all   [<i>interface-name-list</i>])</b>	Configure LLDP on all interfaces or on one or more interfaces.
<b>(disable   enable)</b>	<p>Disable or enable LLDP on all interfaces or on the specified interfaces.</p> <ul style="list-style-type: none"> <li>• <b>Default:</b> Disable</li> </ul>
<b>power-negotiation</b> <b>&lt;(disable   enable)&gt;</b>	<p>(EX, QFX Series only) Configure LLDP power negotiation, which negotiates with Power over Ethernet (PoE) powered devices to allocate power.</p> <p>You must also configure the <code>management class</code> statement at the <code>[edit poe]</code> hierarchy level to activate LLDP power negotiation.</p> <ul style="list-style-type: none"> <li>• <b>Values:</b> Configure one of the following: <ul style="list-style-type: none"> <li>• disable—Disable LLDP power negotiation.</li> <li>• enable—Enable LLDP power negotiation.</li> </ul> </li> </ul>
<b>trap-notification</b> <b>(disable   enable)</b>	<p>Disables or enables the LLDP and physical topology SNMP traps for the specific interface or all the interfaces.</p> <ul style="list-style-type: none"> <li>• <b>Values:</b> Configure one of the following: <ul style="list-style-type: none"> <li>• disable—Disable the LLDP and physical topology SNMP trap notifications.</li> <li>• enable—Enable the LLDP and physical topology SNMP trap notifications.</li> </ul> </li> <li>• <b>Default:</b> disable</li> </ul>

# interface (VoIP)

## IN THIS SECTION

- [Syntax | 1204](#)
- [Hierarchy Level | 1204](#)
- [Description | 1205](#)
- [Options | 1205](#)
- [Required Privilege Level | 1206](#)
- [Release Information | 1206](#)

## Syntax

```
interface (all | [interface-name] | access-ports) {  
    forwarding-class forwarding-class;  
    vlan (vlan-id | vlan-name | untagged));  
}
```

## Hierarchy Level

- For platforms with ELS:

```
[edit switch-options voip]
```

- For platforms without ELS:

```
[edit ethernet-switching-options voip],
```

## Description

(Required) Enable voice over IP (VoIP) on interfaces.

## Options

<b>all</b>	Enable VoIP on all interfaces.
<b><i>interface-name</i></b>	Enable VoIP on a specific interface.
<b>access-ports</b>	(Switches without ELS only) Enable VoIP on all access ports.
<b>forwarding-class</b> <b><i>forwarding-class</i></b>	(Optional) For EX Series switches, configure the forwarding class used to handle packets on the VoIP interface.

**NOTE:** The forwarding-class statement at the [edit ethernet-switching-options voip interface *interface-name*] hierarchy level is used only by LLDP-MED for advertising the capabilities of VoIP phones. It is not used to classify VoIP traffic.

- **Values:** Specify one of the following:
  - assured-forwarding— Assured forwarding (AF) provides a group of values you can define and includes four subclasses: AF1, AF2, AF3, and AF4, each with three drop probabilities: low, medium, and high.
  - best-effort—Provides no service profile. For the best effort forwarding class, loss priority is typically not carried in a class-of-service (CoS) value, and random early detection (RED) drop profiles are more aggressive.
  - expedited-forwarding—Provides a low loss, low latency, low jitter, assured bandwidth, end-to-end service.
  - network-control—Provides a typically high priority because it supports protocol control.
- **Default:** Disabled

<b>vlan (<i>vlan-id</i>   <i>vlan-name</i>   untagged)</b>	(Required) Specify the VLAN name or VLAN tag identifier associated with the VLAN to be sent from the authenticating server to the IP phone or allow untagged VLAN traffic.
--	--

- **Syntax:** Specify one of the following:
  - *vlan-name*—Name of a VLAN.
  - *vlan-id*—The VLAN tag identifier.
  - *untagged*—Allow untagged VLAN traffic.
- **Range:** *vlan-id* range is 1 through 4094. Tags 0 and 4095 are reserved by the Junos OS; do not configure them.

# interface-description-format

## IN THIS SECTION

- [Syntax | 1207](#)
- [Hierarchy Level | 1207](#)
- [Description | 1207](#)
- [Options | 1208](#)
- [Required Privilege Level | 1208](#)
- [Release Information | 1209](#)

## Syntax

```
interface-description-format {  
    exclude-adapter;  
    exclude-channel;  
    exclude-sub-interface;  
}
```

## Hierarchy Level

```
[edit access profile profile-name radius options]
```

## Description

Specify the information that is excluded from the interface description that the device passes to RADIUS for inclusion in the RADIUS attributes such as NAS-Port-ID (87) or Calling-Station-ID (31).

The default format for nonchannelized interfaces is as follows:

*interface-type-slot/adapter/port.subinterface[:svlan-vlan]*

For example, consider physical interface ge-1/2/0, with a subinterface of 100 and SVLAN identifier of 100. The interface description used in the NAS-Port-ID is ge-1/2/0.100:100. If you exclude the subinterface, the description becomes ge-1/2/0:100.

The default format for channelized interfaces is as follows:

*interface-type-slot/adapter/channel.subinterface[:svlan-vlan]*

The channel information (logical port number) is determined by this formula:

Logical port number =  $100 + (\text{actual-port-number} \times 20) + \text{channel-number}$ .

For example, consider a channelized interface 3 on port 2 where the:

- Physical interface is xe-0/1/2:3.
- Subinterface is 4.
- SVLAN is 5.
- VLAN is 6.

Using the formula, the logical port number =  $100 + (2 \times 20) + 3 = 143$ . Consequently, the default interface description is xe-0/1/143.4-5.6. If you exclude the channel information, the description becomes xe-0/1/2.4-5.6.

## Options

<b>exclude-adapter</b>	—(Optional) Exclude the adapter from the interface description.
<b>exclude-channel</b>	(Optional) Exclude the channel information from the interface description.
<b>exclude-sub-interface</b>	—(Optional) Exclude the subinterface from the interface description.

## Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

## Release Information

Statement introduced in Junos OS Release 9.1.

`exclude-adapter` and `exclude-sub-interface` options added in Junos OS Release 10.4.

`exclude-channel` option added in Junos OS Release 17.3R1.

# key (Authentication Keychain)

## IN THIS SECTION

- [Syntax | 1211](#)
- [Hierarchy Level | 1211](#)
- [Description | 1212](#)
- [Options | 1212](#)
- [Required Privilege Level | 1213](#)
- [Release Information | 1213](#)

## Syntax

```
key key-identifier {  
    algorithm (hmac-sha-1 | md5);  
    key-name authentication-key-name;  
    options (basic | isis-enhanced);  
    secret secret-data;  
    start-time yyyy-mm-dd.hh:mm:ss;  
}
```

## Hierarchy Level

```
[edit security authentication-key-chains key-chain key-chain-name]
```

## Description

Configure an authentication element (key). You include this statement several times in the configuration, thereby creating a keychain of authentication keys, each with its own identifier, secret (password), and start time. You can have up to 64 keys within a keychain.

## Options

<i>key-identifier</i>	<p>(Required) Each key within a keychain is identified by a unique integer value.</p> <ul style="list-style-type: none"> <li>• <b>Range:</b> 0 through 63</li> </ul>
<i>algorithm (hmac-sha-1   md5)</i>	<p>Configure the authentication algorithm for IS-IS.</p> <ul style="list-style-type: none"> <li>• <b>Values:</b> Configure one of these authentication algorithms: <ul style="list-style-type: none"> <li>• hmac-sha-1—96-bit hash-based message authentication code (SHA-1).</li> <li>• md5—Message digest 5.</li> </ul> </li> <li>• <b>Default:</b> md5</li> </ul>
<i>key-name</i> <i>authentication-key-name</i>	<p>Specify a key name in hexadecimal format, used for MACsec.</p>
<i>options (basic   isis-enhanced)</i>	<p>For IS-IS only, configure the protocol transmission encoding format for encoding the message authentication code in routing protocol packets.</p> <p>Because this setting is for IS-IS only, the TCP and the BFD protocol ignore the encoding option configured in the key.</p> <ul style="list-style-type: none"> <li>• <b>Values:</b> Configure one of the following: <ul style="list-style-type: none"> <li>• basic—RFC 5304 based encoding. Junos OS sends and receives RFC 5304-encoded routing protocol packets, and drops 5310-encoded routing protocol packets that are received from other devices.</li> <li>• isis-enhanced—RFC 5310 based encoding. Junos OS sends RFC 5310-encoded routing protocol packets and accepts both RFC 5304-encoded and RFC 5310-encoded routing protocol packets that are received from other devices.</li> </ul> </li> <li>• <b>Default:</b> basic</li> </ul>

<b>secret</b> <i>secret-data</i>	(Required) Specify a password in encrypted text or plain text format. The secret password always appears in encrypted format. The password can include spaces if the character string is enclosed in quotation marks.
<b>start-time</b> <i>yyyy-mm-dd.hh:mm:ss</i>	(Required) Specify a start time in UTC (Coordinated Universal Time) for key transmission. You do not need to specify an end time for the key. If a new key is present with a new start time, the keychain rolls over to the new one. The start time must be unique within the keychain.

## Required Privilege Level

## Syntax

```
key-exchange [algorithm1 algorithm2...];
```

## Hierarchy Level

```
[edit system services ssh]
```

## Description

Specify the set of Diffie-Hellman key exchange methods that the SSH server can use.

## Options

Specify one or more of the following Diffie-Hellman key exchange methods:

- `curve25519-sha256`—The EC Diffie-Hellman key exchange method on Curve25519 with SHA2-256.
- `dh-group1-sha1`—The Diffie-Hellman group1 algorithm using SHA-1.
- `dh-group14-sha1`—The Diffie-Hellman group14 algorithm using SHA-1.
- `ecdh-sha2-nistp256`—The ECDH key exchange method with ephemeral keys generated on the nistp256 curve.
- `ecdh-sha2-nistp384`—The ECDH key exchange method with ephemeral keys generated on the nistp384 curve.
- `ecdh-sha2-nistp521`—The ECDH key exchange method with ephemeral keys generated on the nistp521 curve.
- `group-exchange-sha1`—The group exchange algorithm using SHA-1.
- `group-exchange-sha2`—The group exchange algorithm using SHA-2.

**NOTE:** The key-exchange represents a set. To configure key-exchange:

```
user@host#set system services ssh key-exchange [ecdh-sha2-nistp256 group-exchange-sha1]
```

**NOTE:** [Table 42 on page 1218](#) shows the supportability of Diffie-Hellman key exchange methods on FIPS mode.

**Table 42: Supportability of Diffie-Hellman key exchange methods on FIPS mode**

Diffie-Hellman key exchange methods	Supported on FIPS mode
curve25519-sha256	No
dh-group1-sha1	No
dh-group14-sha1	Yes
ecdh-sha2-nistp256	Yes
ecdh-sha2-nistp384	Yes
ecdh-sha2-nistp521	Yes
group-exchange-sha1	No
group-exchange-sha2	No

[edit routing-instances routing-instance-name protocols]

```

## Description

Configure Link Layer Discovery Protocol (LLDP). The switch uses LLDP to advertise its identity and capabilities on a LAN, as well as to receive information about other network devices. LLDP is defined in the IEEE standard 802.1AB-2005.

**NOTE:** The transmit-delay and netbios-snooping options are not available on QFabric systems.

**NOTE:** On EX4300 switches, LLDP cannot be configured on the me0 or vme interface. Issuing the command `set protocols lldp interface me0` generates the following error message:

```
error: name: 'me0': Invalid interface
error: statement creation failed: interface
```

Issuing the command `set protocols lldp interface vme` generates the following error message:

```
error: name: 'vme': Invalid interface
error: statement creation failed: interface
```

## Default

LLDP is disabled. If you configure LLDP for all interfaces, you can later disable a particular interface.

**NOTE:** The interface-name must be the physical interface and not a logical interface (unit).

## Options

### advertisement-interval *seconds*

Specify the frequency at which LLDP advertisements are sent. This value is also used in combination with the hold-multiplier value to determine the length of time LLDP information is held before it is discarded.

The advertisement-interval value must be greater than or equal to four times the transmit-delay value, or an error will be returned when you attempt to commit the configuration.

**NOTE:** The default value of transmit-delay is 2 seconds. If you configure advertisement-interval as less than 8 seconds and you do not configure a value for transmit-delay, the value of transmit-delay is automatically changed to 1 second to satisfy the requirement that the advertisement-interval value be greater than or equal to four times the transmit-delay value.

- **Default:** 30 seconds

	<ul style="list-style-type: none"> <li>• <b>Range:</b> 5 through 32768 seconds</li> </ul>
<b>disable   enable</b>	<p>Disable or enable LLDP on the device.</p> <ul style="list-style-type: none"> <li>• <b>Default:</b> If you do not configure LLDP, it is disabled on the device.</li> </ul>
<b>hold-multiplier number</b>	<p>Specify the multiplier used in combination with the advertisement-interval value to determine the length of time LLDP information is held before it is discarded.</p> <ul style="list-style-type: none"> <li>• <b>Range:</b> 2 through 10</li> <li>• <b>Default:</b> 4 (or 120 seconds with the default of 30 seconds for advertisement-interval)</li> </ul>
<b>lldp-configuration- notification- interval seconds</b>	<p>Specify how often SNMP trap notifications are generated as a result of LLDP database changes.</p> <ul style="list-style-type: none"> <li>• <b>Range:</b> 5 through 3600 seconds</li> <li>• <b>Default:</b> Disabled</li> </ul>
<b>management- address ip- management- address;</b>	<p>Specify the management address to be used in LLDP Management Address type, length, and value (TLV) messages. The Management Address TLV typically contains the IPv4 or IPv6 management addresses of the local system. Only out-of-band management addresses can be used for the management-address. Other remote managers can use this address to obtain information related to the local device.</p> <ul style="list-style-type: none"> <li>• <b>Default:</b> The LLDP Management Address TLV uses the IP address of the switch's management Ethernet interface (me0), or the IP address of the virtual management Ethernet (VME) interface if the switch is a Virtual Chassis member.</li> </ul>
<b>mau-type</b>	<p>(EX4300, EX9200, and EX9250 switches only) Configure the switch to advertise information about the medium attachment unit (MAU) type. The MAU is a transceiver that interconnects the attachment unit interface (AUI) port on an attached host computer to an Ethernet cable. MAU types are defined in the IEEE 802.3 standard.</p> <p>The MAU type is included in the MAC/PHY Configuration Status type, length, and value (TLV) message. TLVs are used by LLDP-capable devices to transmit information to neighbor devices. The MAC/PHY Configuration Status TLV is an organizationally defined TLV that advertises information about the physical interface. In addition to the MAU type, the MAC/PHY Configuration Status TLV also includes information such as autonegotiation status, support, and advertised capabilities.</p>

The MAU type cannot be changed by configuration; however, you must configure the `mau-type` statement to include the MAU type value in the MAC/PHY Configuration Status TLV.

- **Default:** If the `mau-type` statement is not configured, the MAU type field of the MAC/PHY Configuration Status TLV contains the value `Unknown`.

**netbios-snooping** (EX2200, EX3200, EX3300, EX4200, EX4500, EX4550, EX6210, EX8208, and EX8216 switches only) Enable NetBIOS snooping to learn information about NetBIOS hosts that are connected to the switch.

**no-tagging** (EX2200, EX3200, EX3300, EX4200, EX4500, EX4550, EX6210, EX8208, and EX8216 switches only) Configure the switch to send LLDPDUs without including VLAN tags on the interfaces on which VLAN tagging is enabled (tagged interfaces).

- **Default:** Interfaces for which VLAN tagging is enabled include a VLAN tag (tag 0) in LLDPDUs if the `no-tagging` option is not configured.

**neighbour-port-info-display (port-description | port-id)**

Configure the type of LLDP neighbor port information that the device displays in the `Port info` field in the output of the [show lldp neighbors](#) CLI command.

Devices in a network use LLDP to learn about and identify neighbor devices. LLDP-capable devices transmit information in type, length, and value (TLV) messages to neighbor devices.

The `Port info` field of the `show lldp neighbors` command displays the port information received from LLDP neighbors. This information is sent from the LLDP neighbor to the device in a type, length, and value (TLV) message. You can use the `neighbour-port-info-display` statement to configure the device to display the information contained in either the Port Description TLV or the Port Identification TLV.

- **Values:** Configure one of the following:
  - `port-description`—Display the information from the Port Description TLV in the `Port info` field of the `show lldp neighbors` CLI command.

The Port Description TLV contains the textual description of the logical unit or the port. The description for the logical unit is used, if available; otherwise, the description for the physical interface (port) is used. For example, LAG member interfaces do not contain a logical unit; therefore, only the description configured on the physical interface is used.

- **port-id**—Display the information from the Port Identification TLV in the Port info field of the `show lldp neighbors` CLI command.

The Port Identification TLV contains the identifier for the neighbor port. The SNMP index of the interface is used as the port identifier.

- **Default:** **port-description**—The information contained in the Port Description TLV is displayed in the Port info field.

#### port-description-type (interface-alias | interface-description)

Configure the value to be used to generate the Port Description TLV that the device advertises to neighbors.

- **Values:** Configure one of the following:
  - **interface-alias**—Use the *ifAlias* MIB object value to generate the port description TLV. The LLDP MIB variable *lldpLocPortDesc* then contains the same value as *ifAlias*, which is the same as the description of the interface.
  - **interface-description**—Use the *ifDescr* MIB object value to generate the port description TLV. The LLDP MIB variable *lldpLocPortDesc* then contains the same value as *ifDescr*, which is the same as the interface name.
- **Default:** **interface-alias**—The interface-alias value is same as the description of an interface configured with `set interface name description description` command.

The remaining statements are explained separately. See [CLI Explorer](#).

## Required Privilege Level

**routing**—To view this statement in the configuration.

**routing-control**—To add this statement to the configuration.

## Release Information

Statement introduced in Junos OS Release 9.0.

**management-address** introduced in Junos OS Release 9.5.

**netbios-snooping** introduced in Junos OS Release 11.1 for EX2200, EX3200, EX3300, EX4200, EX4500, EX4550, EX6210, EX8208, and EX8216 switches.

port-description-type introduced in Junos OS Release 13.3R5, 14.2R2, 14.1R4, and 12.3R9.

no-tagging introduced in Junos OS Release 14.1X53-D10 for EX2200, EX3200, EX3300, EX4200, EX4500, EX4550, EX6210, EX8208, and EX8216 switches.

neighbour-port-info-display introduced in Junos OS Release 14.1X53-D40 and Release 15.1R5 and Release 16.1R3.

mau-type introduced in Junos OS Release 15.1 for EX4300, EX9200, and EX9250 switches.

## Hierarchy Level

[edit protocols]

## Description

Configure Link Layer Discovery Protocol–Media Endpoint Discovery. LLDP-MED is an extension of LLDP. The device uses LLDP-MED to support device discovery of VoIP telephones and to create

location databases for these telephone locations for emergency services. LLDP-MED is defined in the standard ANSI/TIA-1057 by the Telecommunications Industry Association (TIA).

## Default

Disabled.

## Options

**fast-start  
number** Configure the number of LLDP-MED advertisements sent from the device in the first second after it has detected an LLDP-MED device (such as an IP telephone).

- **Range:** 1 through 10 advertisements
- **Default:** 3 advertisements

```

## Description

Configure an LDAPS server for LDAPS authentication and authorization for Junos OS user login. LDAP support for users trying to log in is extended with TLS security between the device running Junos OS (LDAPS client) and the LDAPS server.

## Options

<b><i>address</i></b>	Address of the LDAP authentication server.
<b><i>base base domain</i></b>	Distinguished name of the search base.
<b><i>binddn node proxyaccount username</i></b>	Distinguished name of the proxy account of the LDAPS client to bind to the server with.
<b><i>bindpw node proxyaccount password</i></b>	Credentials of the LDAPS client to bind with.
<b><i>ldaps-cert client certificate name</i></b>	The client certificate for LDAPS client to establish an LDAP over TLS (LDAPS) connection. The <i>certificate-name</i> is the name that is added using <code>request security pki ca-certificate load</code> .
<b><i>routing-instance routing-instance-name</i></b>	The name of the routing instance. If you're configuring the nondefault management instance, use the value <code>mgmt_junos</code> .

**port** *number* Port number on which to contact the LDAP server.

- **Default:** None

```

## Description

Specify the SSL certificate to use to authenticate the local device.

Specify the name of a local certificate. There is no default for local-certificate. The value for local-certificate should be the same as the name provided during the import of the certificate. You can import the certificate using the CLI configuration statement local at the [edit security certificates] hierarchy level. Alternatively, on supported devices, you can import the certificate into the Junos public key infrastructure (PKI) by using the request security pki local-certificate load operational mode command.

**NOTE:** If you load the local certificate in the Junos PKI on supported devices, you must configure both the local-certificate statement and the use-pki statement at the same hierarchy level. The use-pki statement instructs the device to search the PKI database for local certificates.

## Hierarchy Level

[edit system]

## Description

Configure user access to the device.

## Options

### **announcement text**

Configure a system login announcement. This announcement appears after a user logs in. Sometimes you want to make announcements to authorized users only after they have logged in. For example, you might want to announce an upcoming maintenance event.

To display a message before the user logs in, configure a system login message using the `message` statement rather than configuring a system login announcement.

You can format the announcement using the following special characters:

- `\n`—New line
- `\t`—Horizontal tab
- `\'`—Single quotation mark
- `\"`—Double quotation mark
- `\\`—Backslash

If the text of the announcement contains any spaces, enclose the text in quotation marks.

- **Default:** No login announcement is displayed.

### **deny-sources**

(Mandatory) Never allow access from these hosts. The source addresses can be IPv4 or IPv6 addresses, prefix lengths, or hostnames.

- **Syntax:** address [*source-addresses*]

### **idle-timeout minutes**

For a login class, configure the maximum time in minutes that a session can be idle before the session times out and the user is logged out of the device. The session times out after remaining at the CLI operational mode prompt for the specified time.

**NOTE:** After the user logs in to a device from a shell prompt such as `csh`, if the user starts another program to run in the foreground of the CLI, the idle-timer

control is stopped from being computed. The calculation of the idle time of the CLI session is restarted only after the foreground process exits and the control is returned to the shell prompt. When the restart of the idle-timer control occurs, if no interaction from the user occurs on the shell, the user is automatically logged out after the time set on this statement.

- **Default:** If you omit this statement, a user is never forced off the system after extended idle times.
- **Range:** Range: 0 through 4294967295 minutes

**NOTE:** The idle-timeout feature is disabled if the value of *minutes* is set to 0.

#### **message text**

Configure a system login message. A login message displays a banner to users when they access the device, before they log in. To display a message only after the user logs in, configure a system login announcement using the `announcement statement` instead of configuring a system login message.

Before you create any user accounts, it's a good idea to configure an initial login message.

You can format the message using the following special characters:

- `\n`—New line
- `\t`—Horizontal tab
- `\'`—Single quotation mark
- `\"`—Double quotation mark
- `\\`—Backslash

If the text of the message contains any spaces, enclose the text in quotation marks.

- **Default:** No login message is displayed.

The remaining statements are explained separately. See [CLI Explorer](#) or click a linked statement in the Syntax section for details.

## Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

## Release Information

Statement introduced before Junos OS Release 7.4.

deny-sources option introduced in Junos OS Release 11.2.

All of the statements and options introduced previously were introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

    flap-on-disconnect;  
    restrict;  
}
```

## Hierarchy Level

```
[edit protocols dot1x authenticator interface interface-name]
```

## Description

Configure MAC RADIUS authentication for specific interfaces. MAC RADIUS authentication allows LAN access to permitted MAC addresses. When a new MAC address appears on an interface, the device consults the RADIUS server to check whether the MAC address is a permitted address. If the MAC address is configured on the RADIUS server, the device is allowed access to the LAN.

If MAC RADIUS is configured, the device first tries to get a response from the host for 802.1X authentication. If the host is unresponsive, the device attempts to authenticate using MAC RADIUS.

To restrict authentication to MAC RADIUS only, use the `restrict` option. In restrictive mode, all 802.1X packets are eliminated and the attached device on the interface is considered a nonresponsive host.

## Options

<b>flap-on-disconnect</b>	(Optional) When the RADIUS server sends a disconnect message to a supplicant, the device resets the interface on which the supplicant is authenticated. If the interface is configured for multiple supplicant mode, the device resets all the supplicants on the specified interface. This option takes effect only when the <code>restrict</code> option is also set.
<b>restrict</b>	(Optional) Restricts authentication to MAC RADIUS only. When <code>mac-radius restrict</code> is configured, the device drops all 802.1X packets. This option is useful when no other 802.1X authentication methods, such as guest VLAN, are needed on the interface, and eliminates the delay that occurs while the switch determines that a connected device is a non-802.1X-enabled host.

The remaining statements are explained separately. Search for a statement in [CLI Explorer](#) or click a linked statement in the Syntax section for details.

## Syntax

```
multi-domain {  
    max-data-session max-data-sessions;  
    packet-action (drop-and-log | shutdown);  
    recovery-timeout seconds;  
}
```

## Hierarchy Level

```
[edit logical-systems name protocols dot1x authenticator  
interface],  
[edit protocols dot1x authenticator interface]
```

## Description

Configure multi-domain authentication to restrict the number of authenticated data and VoIP sessions on the port. Multi-domain authentication is an extension of multiple supplicant mode for 802.1X authentication, and is designed to support VoIP and data clients on the same interface. The interface is divided into two domains; one is the data domain and the other is the voice domain.

In multiple supplicant mode, any number of VoIP or data sessions can be authenticated; the number of sessions can be restricted using MAC limiting, but there is no way to apply the limit specifically to either data or VoIP sessions. Multi-domain authentication maintains separate session counts based on the domain type.

The data device can be authenticated using 802.1X authentication or MAC RADIUS authentication. Multi-domain authentication does not enforce the order of authentication. For best results, the VoIP device should be authenticated before the data device.

You can configure the maximum number of authenticated data sessions allowed on the interface using the `max-data-session` statement. The number of VoIP sessions is not configurable; only one authenticated VoIP session is allowed.

If a new client attempts to authenticate on the interface after the maximum session count has been reached, the default action is to drop the packet and generate an error log message. You can also configure the action to shut down the interface. The port can be manually recovered from the down state by issuing the `clear dot1x recovery-timeout` command, or can recover automatically after a recovery timeout period. To configure automatic recovery, use the `recovery-timeout` option.

## Options

<b>max-data-session</b> <i>max-data-sessions</i>	<p>The maximum number of authenticated data sessions allowed in the data domain on the 802.1X-enabled interface.</p> <ul style="list-style-type: none"> <li>• <b>Range:</b> 1 through 1,000 sessions</li> <li>• <b>Default:</b> 1</li> </ul>
<b>packet-action</b> (drop-and-log   shutdown)	<p>Specify the action the device should take on packets that exceed the limit of authenticated sessions allowed on the interface. The limit for data sessions is configured using the <code>max-data-session</code> option. The number of VoIP sessions is not configurable; only one authenticated VoIP session is allowed.</p>

- **Values:** Specify one of the following:
  - drop-and-log—Drop the packet and generate an error syslog message.
  - shutdown—Shut down the interface.
- **Default:** drop-and-log

**recovery-  
timeout *seconds***

If you configure the packet action with the shutdown option and you configure the recovery timeout, the interface is temporarily disabled when the maximum number of authenticated sessions is reached. The interface will recover automatically after the number of seconds specified.

- **Range:** 60 through 3600 seconds
- **Default:** none

- [Description | 1252](#)
- [Options | 1252](#)
- [Required Privilege Level | 1253](#)
- [Release Information | 1253](#)

## Syntax

```
nas-port-extended-format {  
    adapter-width bits;  
    ae-width bits;  
    atm {  
        adapter-width bits;  
        port-width bits;  
        slot-width bits;  
        vci-width bits;  
        vpi-width bits;  
    }  
    port-width bits;  
    pw-width bits;  
    slot-width bits;  
    stacked-vlan-width bits;  
    vlan-width bits;  
}
```

## Hierarchy Level

```
[edit access profile profile-name radius options]
```

## Description

Configure the RADIUS client to use the extended format for RADIUS attribute 5 (NAS-Port) and specify the width in bits of the fields in the NAS-Port attribute.

The NAS-Port attribute specifies the physical port number of the NAS that is authenticating the user, and is formed by a combination of the physical port's slot number, port number, adapter number, VLAN ID, and S-VLAN ID. The NAS-Port extended format specifies the number of bits (bit width) for each field in the NAS-Port attribute: slot, adapter, port, aggregated, Ethernet, VLAN, and S-VLAN.

**NOTE:** The combined total of the widths of all fields for a subscriber must not exceed 32 bits, or the configuration fails. The router may truncate the values of individual fields depending on the bit width you specify.

## Options

adapter-width *width*—Number of bits in the adapter field.

ae-width *width*—(Ethernet subscribers only) Number of bits in the aggregated Ethernet identifier field.

atm—Specify width for fields for ATM subscribers.

port-width *width*—Number of bits in the port field.

pw-width *width*—(Ethernet subscribers only) Number of bits in the pseudowire field. Appears in the Cisco NAS-Port-Info AVP (100).

slot-width *width*—Number of bits in the slot field.

stacked-vlan-width *width*—Number of bits in the SVLAN ID field.

vci-width *width*—(ATM subscribers only) Number of bits in the ATM virtual circuit identifier (VCI) field.

vlan-width *width*—Number of bits in the VLAN ID field.

`vpi-width` *width*—(ATM subscribers only) Number of bits in the ATM virtual path identifier (VPI) field.

**NOTE:** The total of the widths must not exceed 32 bits, or the configuration will fail.

## Required Privilege Level

`admin`—To view this statement in the configuration.

`admin-control`—To add this statement to the configuration.

## Release Information

Statement introduced in Junos OS Release 9.1.

`ae-width` option added in Junos OS Release 12.1.

`atm` option added in Junos OS Release 12.3R3 and supported in later 12.3Rx releases.

`atm` option supported in Junos OS Release 13.2 and later releases. (Not supported in Junos OS Release 13.1.)

`pw-width` option added in Junos OS Release 15.1.

- [Default | 1255](#)
- [Options | 1255](#)
- [Required Privilege Level | 1256](#)
- [Release Information | 1256](#)

## Syntax

```
nas-port-id-format {
    agent-circuit-id;
    agent-remote-id;
    concatenated-vlan-tags (fixed-size-inner-tag | fixed-size-outer-tag)
    interface-description;
    interface-text-description;
    nas-identifier;
    order (agent-circuit-id | agent-remote-id | interface-description | interface-text-
description | nas-identifier | postpend-vlan-tags);
    postpend-vlan-tags;
}
```

## Hierarchy Level

```
[edit access profile profile-name radius options]
```

## Description

Specify the optional information that the router includes in the NAS-Port-ID (RADIUS attribute 87) that is passed to the RADIUS server during authentication and accounting. You can include any combination of the optional values.

When you specify the values for the NAS-Port-ID, you can configure the values to appear in either the default order or a custom order of your choice.

**NOTE:** The default and custom order methods are mutually exclusive. The configuration fails if you attempt to configure a NAS-Port-ID that includes values in both types of orders.

To specify that the optional values appear in the default order in the NAS-Port-ID, configure the values directly under the `nas-port-id-format` statement. The default order is as follows, in which the # character is the delimiter:

```
nas-identifier # interface-description # interface-text-description # agent-circuit-id # agent-remote-id #
postpend-vlan-tags
```

To specify a custom order for the NAS-Port-ID string, you use the `order` option. Include the `order` option before each optional value you want to include in the string, in the order in which you want the options to appear. For example, the configuration, `order interface-text-description order nas-identifier order agent-remote-id` produces the following NAS-Port-ID, in which the # character is the delimiter:

```
interface-text-description # nas-identifier # agent-remote-id
```

Starting in Junos OS Release 21.3R1, we have introduced a new NAS-Port-ID format for RADIUS server access request. The NAS-Port-ID format is `S-VLAN<concatenated 0's>C-VLAN:S-VLAN-C-VLAN`. For customer-VLAN (C-VLAN), if the number of digits is less than four, prepend it with zeroes. For example, NAS-Port-ID for an S-VLAN 72 and C-VLAN 82 is `720082:72-82`.

## Default

The router includes the interface description in the NAS-Port-ID when no optional values are specified.

## Options

`agent-circuit-id`—Include the agent circuit ID from either DHCP option 82 or the DSL forum VSAs.

`agent-remote-id`—Include the agent remote ID from either DHCP option 82 or the DSL forum VSAs.

`concatenated-vlan-tags`—Include the vlan tags as a concatenated string.

`fixed-size-inner-tag`—Fixed size inner VLAN tag value of 4 octets.

`fixed-size-outer-tag`—Fixed size outer VLAN tag value of 4 octets.

interface-description—Include the interface description (interface identifier).

interface-text-description—Include the textual interface description (the text description that is statically configured in the CLI).

nas-identifier—Include the NAS identifier value (RADIUS attribute 32).

order—Specify the optional values you want to include in the NAS-Port-ID and the customized order in which you want the values to appear. You must include the order option before each optional value (for example, order agent-circuit-id order interface-description).

postpend-vlan-tags—Include the VLAN tags. The router includes the tags in the format :<outer-tag>-<inner-tag> for a double-tagged VLAN, or :<outer-tag> for a single-tagged VLAN.

## Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

## Release Information

Statement introduced in Junos OS Release 11.4.

Options interface-text-description, order, and postpend-vlan-tags introduced in Junos OS Release 15.1.

## Hierarchy Level

```
[edit system]
```

## Description

Configure NTP on the device. In both standalone and chassis cluster modes, the primary Routing Engine runs the NTP process to get the time from the external NTP server. Although the secondary Routing Engine runs the NTP process in an attempt to get the time from the external NTP server, this attempt fails because of network issues. For this reason, the secondary Routing Engine uses NTP to get the time from the primary Routing Engine.

When configuring the NTP service in the management VRF (`mgmt_junos`), you must configure at least one IP address on a physical or logical interface within the default routing instance and ensure that this interface is up in order for the NTP service to work with the `mgmt_junos` VRF.

## Options

### **authentication-key** *key\_number*

Configure key (key ID, key type, and key value) to authenticate NTP packets with the devices (servers and clients). The authentication key has two fields:

- **type**—When authentication is specified, the key identifier (key ID) followed by the message digest is appended to the NTP packet header. The supported message digest formats are md5, sha1, sha256.

**NOTE:** EX4600 does not support SHA256 authentication for NTP and supports MD5 only.

- **value**—If the key value is available in ASCII format and without special characters, it can be entered directly. If the key value contains special characters or is available in hex format, consider the following:

For specifying the keys in hex format, prepend a "\x" for each two characters. For hex key example, af60112f...39af4ced,

```
set system ntp authentication-key <ID> value "\xaf\x60\x11\x2f\...\x39\xaf\x4c\xed".
```

If the key contains one of the characters from (null) 0x00, (space) 0x20, "0x22, & 0x26, ( 0x28 ) 0x29 prepend a "\\x". For example, \\x22.

- **Range:** 1 to 65534

**boot-server** (*address* | *hostname*)

Configure the server that NTP queries when the device boots to determine the local date and time.

When you boot the device, it issues an ntpdate request, which polls a network server to determine the local date and time. You must configure an NTP boot server that the device uses to determine the time when the device boots. Otherwise, NTP cannot synchronize to a time server if the server time significantly differs from the local device's time.

If you configure an NTP boot server, then when the device boots, it immediately synchronizes with the boot server even if the NTP process is explicitly disabled or if the time difference between the client and the boot server exceeds the threshold value of 1000 seconds.

- **Values:** Configure one of the following:
  - *address*—IP address of an NTP boot server.
  - *hostname*—Hostname of an NTP boot server. If you configure a hostname instead of an IP address, the ntpdate request resolves the hostname to an IP address when the device boots up.

**NOTE:** This option is deprecated starting in Junos OS Release 20.4R1. NTP boot-server is not supported in Junos OS Evolved.

Configure the server using set system ntp server under the edit system ntp server hierarchy.

**broadcast** <*address*>  
 <*key key-number*>  
 <*routing-instance-name*  
*routing-instance-name*>  
 <*ttl value*> <*version*  
*value*>

Configure the device to operate in broadcast mode with the remote system at the specified address. In this mode, the device sends periodic broadcast messages to a client population at the specified broadcast or multicast address. Normally, you include this statement only when the device is operating as a transmitter.

**address** Configure the broadcast address on one of the local networks or a multicast address assigned to NTP. You must specify an address, not a hostname. If the multicast address is used, it must be 224.0.1.1.

**key *key-number*** (Optional) All packets sent to the address include authentication fields that are encrypted using the specified key number (any unsigned 32-bit integer except 0). The key corresponds to the key number you specified in the authentication-key statement.

**routing-instance-name *routing-instance-name*** (Optional) Configure the routing instance name in which the interface has an address in the broadcast subnet.

- **Default:** The default routing instance is used to broadcast packets.

**ttl *value*** (Optional) Configure the time-to-live (TTL) value.

- **Range:** 1 through 255
- **Default:** 1

**version *value*** (Optional) Specify the version number to be used in outgoing NTP packets.

- **Range:** 1 through 4
- **Default:** 4

**broadcast-client** Configure the local device to listen for broadcast messages on the local network to discover other servers on the same subnet. To avoid accidental or malicious disruption in this mode, both the local and remote systems must use authentication and the same trusted key and key identifier.

<b>interval-range</b> <i>value</i>	Configure the poll interval range.
	<ul style="list-style-type: none"> <li>• <b>Range:</b> 0 through 3</li> </ul>
<b>multicast-client</b> <i>&lt;address&gt;</i>	Configure the local device to listen for multicast messages on the local network. To avoid accidental or malicious disruption in this mode, both the local and remote systems must use authentication and the same trusted key and key identifier.
	<ul style="list-style-type: none"> <li>• <b>Syntax:</b> <i>&lt;address&gt;</i>—(Optional) Specify one or more IP addresses. If you specify addresses, the device joins those multicast groups.</li> <li>• <b>Default:</b> 224.0.1.1</li> </ul>
<b>nts</b> <i>&lt;local-certificate local-certificate&gt;</i> <i>&lt;trusted-ca (trusted-ca-group trusted-ca-group   trusted-ca-profile trusted-ca-profile)&gt;</i>	Configure the Network Time Security (NTS) features for NTP on your device.
<b>local-certificate</b> <i>local-certificate</i>	Specify the certificate loaded in your device during certificate enrollment or loaded manually by specifying certificate file.
<b>trusted-ca</b>	Specify a trusted CA group or a CA profile. This configuration is optional. If you do not specify a trusted CA profile the NTP trust all CA profiles configured for NTS.
<b>trusted-ca-group</b> <i>trusted-ca-group</i>	Specify the trusted CA group defined under [set security pki trusted-ca-group].
<b>trusted-ca-profile</b> <i>trusted-ca-profile</i>	Specify the trusted CA profile.
<b>peer</b> <i>address</i> <i>&lt;key key-number&gt;</i> <i>&lt;prefer&gt;</i> <i>&lt;version value&gt;</i>	Configure the local device to operate in symmetric active mode with the remote system at the specified address. In this mode, the local device and the remote system can synchronize with each other. This configuration is useful in a network in which either the local device or the remote system might be a better source of time.
<b>address</b>	Address of the remote system. You must specify an address, not a hostname.
<b>key</b> <i>key-number</i>	(Optional) All packets sent to the address include authentication fields that are encrypted using the specified key number (any unsigned 32-bit integer except 0). The key corresponds to the key number you specified in the authentication-key statement.

**prefer** (Optional) Mark the remote system as the preferred host, which means that if all other factors are equal, this remote system is chosen for synchronization among a set of correctly operating systems.

**version value** (Optional) Specify the NTP version number to be used in outgoing NTP packets.

- **Range:** 1 through 4
- **Default:** 4

**restrict address mask  
network-mask noquery**

Restrict packets from hosts (including remote time servers) and subnets.

- **Syntax:**
  - *address*—Specify the IP address for a host or network.
  - *mask network-mask*—Specify the network mask for a host or network.
  - *noquery*—Deny ntpq and ntpdc queries from hosts and subnets. These queries can be used in amplification attacks.

**server**

Configure the local device to operate in client mode with the remote system at the specified address. In this mode, the device can be synchronized with the remote system, but the remote system can never be synchronized with the device.

If the NTP client time drifts so that the difference in time from the NTP server exceeds 128 milliseconds, the client is automatically stepped back into synchronization. If the offset between the NTP client and server exceeds the 1000-second threshold, the client still synchronizes with the server, but it also generates a system log message noting that the threshold was exceeded.

**address** Address of the remote system. You must specify an address, not a hostname.

**key key-number** (Optional) All packets sent to the address include authentication fields that are encrypted using the specified key number (any unsigned 32-bit integer except 0). The key corresponds to the key number you specified in the authentication-key statement.

**prefer** (Optional) Mark the remote system as the preferred host, which means that if all other factors are equal, this remote

system is chosen for synchronization among a set of correctly operating systems.

**routing-  
instance  
routing-  
instance**

(Optional) Routing instance through which the server is reachable.

**nts**

Enables NTS, which uses Transport Layer Security (TLS) protocol and Authenticated Encryption with Associated Data (AEAD) to obtain network time in an authenticated manner to the users. Specified server must also support the NTS feature when you enable NTS on a client device.

**version  
value**

(Optional) Specify the NTP version number to be used in outgoing NTP packets.

- **Range:** 1 through 4
- **Default:** 4

**source-address***source-  
address* <routing-  
instance [ *routing-  
instance-name* ]>

A valid IP address configured on one of the device's interfaces to be used as the source address for messages sent to the NTP server, and optionally, the routing instance in which the source address is configured.

- **Default:** The primary address of the interface

**threshold** *seconds*  
**action** (accept | reject)

Configure the maximum threshold in seconds allowed for NTP adjustment and specify the mode for NTP abnormal adjustment.

- **Range:** 1 through 600 seconds
- **Values:** Configure one of the following:
  - accept—Enable log mode for abnormal NTP adjustment.
  - reject—Enable reject mode for abnormal NTP adjustment.

**trusted-key** [ *key-  
numbers* ]

Configure one or more keys you are allowed to use to authenticate other time servers, when you configure the local device to synchronize its time with other systems on the network. Each key can be any 32-bit unsigned integer except 0. The key corresponds to the key number you specify in the authentication-key statement.

By default, network time synchronization is unauthenticated. The device synchronizes to whatever system appears to have the most accurate time.

We strongly encourage you to configure authentication of network time services.

## Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

## Release Information

Statement introduced before Junos OS Release 7.4.

routing-instance option for the server statement introduced in Junos OS Release 18.1.

restrict statement introduced in Junos OS Release 20.1.

    flag flag;  
    no-remote-trace;
```

```
}
}
```

## Hierarchy Level

```
[edit system services]
```

## Description

Configure a device running the Junos OS behind a firewall to initiate outbound SSH connections to communicate with client management applications on the other side of the firewall.

## Options

**client *client-id*** Defines a device-initiated connection. This value serves to uniquely identify the outbound-ssh configuration stanza. Each outbound-ssh stanza represents a single outbound SSH connection. Thus, the administrator is free to assign the client-id any meaningful unique value. This attribute is not sent to the client management application.

***address*** Hostname, IPv4 address, or IPv6 address of the management application server.

**NOTE:** Starting in Release 15.1, Junos OS supports outbound SSH connections with devices having IPv6 addresses.

- **Syntax:** You can list multiple servers by adding each server's IP address or hostname along with the following connection parameters:
  - *port port-number*—Specifies the port number at which a server listens for outbound SSH connection requests.

Default: port 22

- *retry number*—Specifies the maximum number of times the device attempts to establish an outbound SSH connection before giving up.

Default: 3 attempts

- *timeout seconds*—Specifies how long the device waits between attempts to reconnect to the specified IP address to establish an outbound SSH connection before giving up.

Default: 15 seconds

**device**  
***device-id***

(Required) Identifies the device to the management application. Each time the device establishes an outbound SSH connection, it first sends an initiation sequence (device-id) to the management application.

**keep-alive**

(Optional) When configured, specifies that the device should send SSH protocol keepalive messages to the management application.

- **Syntax:** To configure keepalive messages, you must set both the *retry* and *timeout* attributes:
  - *retry number*—specifies how many keepalive messages the device sends without receiving a response from the application. When that number is exceeded, the device disconnects from the application, ending the outbound SSH connection.

Default: 3 attempts

- *timeout seconds*—specifies how long the device waits to receive data before sending a request for acknowledgment from the application.

Default: 15 seconds

**reconnect-**  
**strategy (in-**  
**order|sticky)**

(Optional) Specify the method the device uses to reestablish a disconnected outbound SSH connection.

- **Values:** Two methods are available:
  - *in-order*—Configures the device to reconnect to the first configured server. If this server is unavailable, the device tries to connect to the next configured server. The device keeps trying each server in the configured list until the device can establish a connection.

- **sticky**—Specify that the device should first attempt to reconnect to the management server from which it disconnected. If that server is unavailable, the device then attempts to connect to the next configured server. The device keeps trying each server in the configured list until the device can establish a connection.

**routing-instance**  
**routing-instance-name** (SRX Series and MX Series only) Specify the name of the routing instance on which the outbound SSH connection needs to be established. If you do not specify a routing instance, your device will establish the outbound SSH connection using the default routing table.

**secret**  
**password** Configures the device to send the device's public SSH host key when the device connects to the management server. This is the recommended method of maintaining a current copy of the device's public key.

**services**  
**netconf** Configures the management application to accept NETCONF as an available service.

The remaining statements are explained separately. Search for a statement in [CLI Explorer](#) or click a linked statement in the Syntax section for details.

## Required Privilege Level

**interface**—To view this statement in the configuration.

**interface-control**—To add this statement to the configuration.

## Release Information

Statement introduced in Junos OS Release 8.4.

Support for IPv6 addresses added in Junos OS Release 12.1X47-D15.

**routing-instance** option introduced in Junos OS Release 19.3R1 for SRX Series and MX Series devices.

}
```

## Hierarchy Level

[edit system [login](#)]

## Description

Configure special requirements such as character length and encryption format for plain-text passwords. Newly created passwords must meet these requirements.

Using several password minimum requirement options will cause the `minimum-length` to be reset if the total sum of the required minimums exceeds the `minimum-length` setting.

## Options

**change-type** Set requirements for using character sets in plain-text passwords. When you combine this statement with the `minimum-changes` statement, you can check for the total number of character sets included in the password or for the total number of character-set changes in the password. Newly created passwords must meet these requirements.

- **Values:** Specify one of the following:
  - `character-sets`—The number of character sets in the password. Valid character sets include uppercase letters, lowercase letters, numbers, punctuation, and other special characters.
  - `set-transitions`—The number of transitions between character sets.

**format** Configure the authentication algorithm for plain-text passwords. The hash algorithm that authenticates the password can be one of these algorithms:

- **Values:**
  - `sha1`—Secure Hash Algorithm 1. Produces a 160-bit digest. The encrypted password starts with `$sha1$`. The option `sha1` is not supported in Junos OS Evolved.

- **sha2**—HMAC Secure Hash Algorithm. The encrypted password starts with \$sha2\$. The option sha1 is not supported in Junos OS Evolved.
- **sha256**—Secure Hash Algorithm 256. Produces a 256-bit digest. The encrypted password starts with \$5\$.
- **sha512**—Secure Hash Algorithm 512. Produces a 512-bit digest. The encrypted password starts with \$6\$.
- **Default:** For Junos OS, the default encryption format is sha512. For Junos-FIPS software, the default encryption format is sha1.

**maximum-length** *length*

Specify the maximum number of characters allowed in plain-text passwords. Newly created passwords must meet this requirement.

- **Range:** 20 through 128 characters
- **Default:** For Junos-FIPS software, the maximum number of characters for plain-text passwords is 20. For Junos OS, no maximum is set.

**maximum-lifetime** *days*

Specify the maximum duration of a password in days, where the password expires after the maximum duration is reached. If you have the required permissions, you are able to control the maximum duration of a password. If the age of the password reaches the maximum time configured, the password expires and must be changed. If your password has expired, you cannot commit a configuration until you change your password. Only passwords for local user accounts can expire based on time configured on the maximum lifetime statement.

**NOTE:** You cannot reuse the same password when the password expires, unless you also configure the number of times the password can be reused on the `minimum-reuse` statement. Older passwords cannot be re-configured on password expiry. Therefore, if you want to reuse an old password, you must configure the `minimum-reuse` statement as well as the `maximum-lifetime` statement in the new configuration, otherwise the commit fails.

If the `maximum-lifetime` statement is configured, a validation check for an expired password is performed at the time of login and at the time of commit based on the password timestamp. For passwords configured before the `minimum-reuse` configuration statement is committed, the timestamp of the passwords is the time at which any configuration under the [edit system login] hierarchy is committed following the commit for the `minimum-reuse` statement. For passwords configured after `minimum-reuse` configuration statement is committed, the

timestamp of the passwords is the time at which those passwords are committed.

- **Range:** 30 through 365 days

**minimum-  
changes  
number**

Specify the minimum number of character sets (or character set changes) required for plain-text passwords. Newly created passwords must meet this requirement.

This statement is used in combination with the `change-type` statement. If the `change-type` is `character-sets`, then the number of character sets included in the password is checked against the specified minimum. If `change-type` is `set-transitions`, then the number of character set changes in the password is checked against the specified minimum.

- **Default:** For Junos OS, the minimum number of changes is 1. For Junos-FIPS Software, the minimum number of changes is 3.

**minimum-  
character-  
changes  
number**

Specify the minimum number of character changes between old and new passwords. Newly created passwords must meet this requirement. If you have the required permissions, you are able to configure the number of character changes between passwords. If the number of character changes between the old password and new password is greater than or equal to the configured value for minimum number of character changes, the new password is accepted. If the number of character changes is less than the configured value, the new password is rejected.

- **Range:** 4 through 15 characters

**minimum-  
length *length***

Specify the minimum number of characters required in plain-text passwords. Newly created passwords must meet this requirement.

This statement can be used in combination with all of the other requirement options for plain-text passwords, such as `minimum-upper-cases`, `minimum-punctuations`, `minimum-lower-cases`, and so on.

Using several password minimum requirement options will cause the minimum password length to be reset if the total sum of the required minimums exceeds the setting configured on the `minimum-length` statement.

- **Default:** For Junos OS, the minimum number of characters for plain-text passwords is six. For Junos-FIPS software, the minimum number of characters for plain-text passwords is 10.
- **Range:** 6 through 20 characters

**minimum-lifetime**  
*days*

Specify in days the minimum duration of a password before the password can be changed. If you have the required permissions, you are able to control the minimum lifetime of a password. You cannot change the password if the age of the password does not exceed the duration configured on the `minimum-lifetime` statement. When you change a password, the age of the existing password is retrieved based on the time at which the password was configured and the current time is fetched. If the age of the password is less than or equal to the configured value for the `minimum-lifetime` statement, the new password is not accepted and an error message is displayed. If the age of the password is more than the configured value for the `minimum-lifetime` statement, the new password is accepted.

**NOTE:** The `minimum-lifetime` statement can be committed only after configuring the `minimum-reuse` statement. The `minimum lifetime` statement works in coordination with password history requirements, else the commit fails and an error message is displayed.

If `minimum-lifetime` is configured, password change for a user is accepted or rejected based on the timestamp of the current password for that user. For passwords configured before the `minimum-reuse` configuration statement is committed, the timestamp of the passwords is the time at which any configuration under the [edit system login] hierarchy is committed following the commit for the `minimum-reuse` statement. For passwords configured after `minimum-reuse` configuration statement is committed, the timestamp of the passwords is the time at which those passwords are committed.

- **Range:** 1 through 30 days

**minimum-lower-cases**  
*number*

Specify the minimum number of lower-case letters required in plain-text passwords. Newly created passwords must meet this requirement.

This statement can be used in combination with all of the other requirement options for plain-text passwords, such as `minimum-length`, `minimum-punctuations`, `minimum-upper-cases`, and so on.

Using several password minimum requirement options will cause the minimum password length to be reset if the total sum of the required minimums exceeds the setting configured on the `minimum-length` statement.

- **Range:** 1 through 128 lower-case letters

**minimum-numeric**  
*number*

Specify the minimum number of numeric-class characters required in plain-text passwords. Newly created passwords must meet this requirement.

This statement can be used in combination with all of the other requirement options for plain-text passwords, such as `minimum-length`, `minimum-punctuations`, `minimum-lower-cases`, and so on.

Using several password minimum requirement options will cause the minimum password length to be reset if the total sum of the required minimums exceeds the setting configured on the `minimum-length` statement.

- **Range:** 1 through 128 numeric-class characters

#### **minimum-punctuations number**

Specify the minimum number of punctuation-class characters required in plain-text passwords. Newly created passwords must meet this requirement.

This statement can be used in combination with all of the other requirement options for plain-text passwords, such as `minimum-length`, `minimum-upper-cases`, `minimum-lower-cases`, and so on.

Using several password minimum requirement options will cause the minimum password length to be reset if the total sum of the required minimums exceeds the setting configured on the `minimum-length` statement.

- **Range:** 1 through 128 punctuation-class characters

#### **minimum-reuse number**

Specify the number of old passwords which should not match the new password. Newly created passwords must meet this requirement. If you have the required permissions, you are able to control the number of old passwords that need to be compared. The number of old passwords to compare with the new password depends on the value configured. If a match is found between the new password and any of the old passwords, the device rejects the new password and terminates. If the new password is different from the configured number of old passwords, the new password is accepted.

- **Range:** 1 through 20 passwords

#### **minimum-upper-cases**

Specify the minimum number of upper-case letters required in plain-text passwords. Newly created passwords must meet this requirement.

This statement can be used in combination with all of the other requirement options for plain-text passwords, such as `minimum-length`, `minimum-punctuations`, `minimum-lower-cases`, and so on.

Using several password minimum requirement options will cause the minimum password length to be reset if the total sum of the required minimums exceeds the setting configured on the `minimum-length` statement.

- **Range:** 1 through 128 upper-case letters

## Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

## Release Information

Statement introduced in Junos OS Release 7.4.

Statements `minimum-lower-cases`, `minimum-numeric`s, `minimum-punctuations`, and `minimum-upper-cases` introduced in Junos OS Release 12.1.

All of the previously mentioned statements were introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

Statements `minimum-reuse` and `minimum-character-changes` introduced in Junos OS Release 18.3.

Statements `maximum-lifetime` and `minimum-lifetime` introduced in Junos OS Release 18.4.

Option `sha1` is not supported in Junos OS Evolved.

## Syntax

```
password-options {  
    apply-groups;  
    apply-groups-except;  
    tacplus-authorization;  
}
```

## Hierarchy Level

```
[edit system]
```

## Description

Configure options for local authentication.

**NOTE:** To enable password-options, you must configure password under [edit system authentication-order]. The feature does not work in a local fallback scenario because password is not configured under authentication-order for a local fallback scenario.

## Options

`apply-groups`—Choose the groups from which to inherit configuration data.

`apply-groups-except`—Choose the groups to be excluded from configuration data being inherited.

`tacplus-authorization`—Configure remote authorization on the TACACS+ server for locally authenticated users. Authorization parameters configured remotely for that user are combined with the authorization parameters configured locally.

- **Default:** If a user is authenticated locally, authorization for that user is done locally.

## Required Privilege Level

`system`—To view this statement in the configuration.

`system-control`—To add this statement to the configuration.

## Release Information

Statement introduced in Junos OS Release 19.3R1.

Option `tacplus-authorization` introduced in Junos OS Release 19.3R1 on MX Series routers.

# port (NETCONF)

## Syntax

```
port port-number;
```

## Hierarchy Level

```
[edit system services netconf ssh]
```

## Description

Configure the TCP port used for NETCONF-over-SSH connections.

### NOTE:

- The configured port accepts only NETCONF-over-SSH connections. Regular SSH session requests for this port are rejected.
- The default SSH port (22) continues to accept NETCONF sessions even with a configured NETCONF server port. To disable the SSH port from accepting NETCONF sessions, you can specify this in the login event script.
- We do not recommend configuring the default ports for FTP (21) and Telnet (23) services for configuring NETCONF-over-SSH connections.

## Options

`port port-number`—Port number on which to enable incoming NETCONF connections over SSH.

- **Default:** 830 (as specified in RFC 4742, *Using the NETCONF Configuration Protocol over Secure Shell (SSH)*)
- **Range:** 1 through 65535

## Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

- [Release Information | 1289](#)

## Syntax

```
provisioning-order (gx-plus | jsr | pcrf);
```

## Hierarchy Level

```
[edit access profile profile-name]
```

## Description

Configure AAA to use the specified application for subscriber service provisioning.

## Options

**gx-plus**—Specify Gx-Plus as the application used to communicate with a PCRF server for subscriber service provisioning. Sets the Subscription-Id-Type Diameter AVP sub-attribute (450) to 4 (END\_USER\_PRIVATE) and sets the Subscription-Id-Data Diameter AVP sub-attribute (444) to reserved. Both of these sub-attributes are conveyed in the Diameter AVP Subscription-ID (443) by a CCR-I message.

**jsrc**—Specify JSRC as the application used to communicate with the SAE for subscriber service provisioning. JSRC is used in an SRC environment to request services from the SAE for an authenticated subscriber. JSRC attempts to activate these services. If successful, JSRC returns an ACK message. If unsuccessful, the subscriber is denied access.

**pcrf**—Specify Policy Control and Charging Rules Function (PCRF) as the application used to request provisioning from the PCRF server over the Gx protocol. If you change this configuration, any existing subscriber sessions are unaffected.

## Required Privilege Level

**admin**—To view this statement in the configuration.

**admin-control**—To add this statement to the configuration.

## Release Information

Statement introduced in Junos OS Release 9.6.

Support for Gx-Plus introduced in Junos OS Release 11.2.

pcrf option added in Junos OS Release 16.2.

### Syntax

```
proxy {  
    password password;  
    port port-number;  
    server url;  
    username user-name;  
}
```

### Hierarchy Level

```
[edit system]
```

## Description

Specify the proxy information for the router.

## Options

- `password password`—Password configured in the proxy server.
- `port port number`—Proxy server port number.

**Range:** 0 through 65,535

- `server url`—URL or IP address of the proxy server host.
- `username username`—Username configured in the proxy server.

## Required Privilege Level

`system`—To view this statement in the configuration.

`system-control`—To add this statement to the configuration.

## Release Information

Statement introduced in Junos OS Release 8.5.

## Hierarchy Level

[edit system]

## Description

Configure the RADIUS authentication server for subscriber access management, Layer 2 Tunnelling Protocol (L2TP), or Point-to-Point Protocol (PPP).

To configure multiple RADIUS servers, include multiple `radius-server server-address` statements. The servers are tried in order and in a round-robin fashion until a valid response is received from one of the servers or until all the configured retry limits are reached.

**NOTE:** The accounting-port and source-address options are not available on QFabric systems.

## Options

<b><i>server-address</i></b>	Specify the IPv4 or IPv6 address of the RADIUS authentication server.
<b><i>accounting-port <i>port-number</i></i></b>	Configure the accounting port number on which to contact the RADIUS server.

	<ul style="list-style-type: none"> <li>• <b>Range:</b> 1 through 65,335</li> <li>• <b>Default:</b> 1813 (as specified in RFC 2866)</li> </ul>
<b>accounting-retry number</b>	<p>Configure the number of accounting retry attempts.</p> <ul style="list-style-type: none"> <li>• <b>Range:</b> 0 through 100 attempts</li> <li>• <b>Default:</b> 0</li> </ul>
<b>accounting-timeout seconds</b>	<p>Configure the accounting request timeout period.</p> <ul style="list-style-type: none"> <li>• <b>Range:</b> 0 through 1000 seconds</li> <li>• <b>Default:</b> 0</li> </ul>
<b>dynamic-request-port number</b>	<p>Configure the RADIUS client dynamic request port number</p> <ul style="list-style-type: none"> <li>• <b>Range:</b> 1 through 65535</li> <li>• <b>Default:</b> 3799</li> </ul>
<b>max-outstanding- requests value</b>	<p>Configure the maximum number of outstanding requests in flight to the server.</p> <ul style="list-style-type: none"> <li>• <b>Range:</b> 0 through 2000 requests</li> <li>• <b>Default:</b> 1000 requests</li> </ul>
<b>port port-number</b>	<p>Configure the port number on which to contact the RADIUS server.</p> <ul style="list-style-type: none"> <li>• <b>Range:</b> 1 through 65,335</li> <li>• <b>Default:</b> 1812 (as specified in RFC 2865)</li> </ul>
<b>preauthentication-port number</b>	<p>Configure the RADIUS server preauthentication-port number.</p> <ul style="list-style-type: none"> <li>• <b>Range:</b> 1 through 65535</li> </ul>
<b>preauthentication-secret secret</b>	<p>Configure the shared secret with the RADIUS server; it can include spaces if the character string is enclosed in quotation marks. The secret used by the local device must match that used by the RADIUS server.</p>
<b>retry value</b>	<p>Configure the number of times that the device is allowed to try to contact a RADIUS authentication server.</p> <ul style="list-style-type: none"> <li>• <b>Range:</b> 1 through 100</li> </ul>

- **Default:** 3

**routing-instance**  
*routing-instance-name*

Configure the routing instance name for the management routing instance. In the case of configuring the non-default management instance, use the value `mgmt_junos`. that is `mgmt_junos`. Configuring this option along with the `management-instance` statement enables authentication processes (for example, RADIUS and TACACS+) to use the non-default management routing instance for packet traffic.

**NOTE:** You must also define the `mgmt_junos` routing instance under the `[edit routing-instances]` hierarchy level.

If you do not configure the `mgmt_junos` instance under the `[edit routing-instances]` hierarchy level and configure it only under `tacplus-server` or `radius-server`, the commit will fail.

**secret** *password*

(Required) Configure the password (shared secret) to use with the RADIUS server; it can include spaces if the character string is enclosed in quotation marks. The secret password used by the local device must match that used by the RADIUS server.

**source-address** *source-address*

Configure a valid IPv4 or IPv6 address configured on one of the device's interfaces.

**timeout** *seconds*

Configure the amount of time the local device waits to receive a response from a RADIUS server.

- **Range:** 1 through 1000 seconds
- **Default:** 3 seconds

## Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

## Release Information

Statement introduced before Junos OS Release 7.4.

}

```

## Hierarchy Level

[edit access]

## Description

Configure RADIUS over TLS, also known as RADSEC, to redirect regular RADIUS traffic to remote RADIUS servers connected over TLS. The TLS connection provides encryption, authentication, and data integrity for the exchange of RADIUS messages.

To configure RADIUS over TLS, you need to configure the RADSEC server as a destination for RADIUS traffic. Traffic that is destined for a RADIUS server can then be redirected to the RADSEC destination. RADSEC destinations are identified by a unique numeric ID. You can configure multiple RADSEC destinations with different parameters pointing to the same RADSEC server.

TLS relies on certificates and private-public key exchange pairs to secure the transmission of data between the RADSEC client and server. The RADSEC destination uses local certificates that are dynamically acquired from the Junos PKI infrastructure.

To enable RADSEC, you must specify the name of the local certificate. If a certificate is not available, or if the certificate was revoked, the RADSEC destination attempts to retrieve it every 300 seconds.

## Default

RADSEC is not enabled by default.

## Options

<b>destination <i>id-number</i></b>	Globally unique ID number for the RADSEC destination. <ul style="list-style-type: none"> <li>• <b>Range:</b> 1 through 65535</li> </ul>
<b>address <i>ip-address</i></b>	Specify the IP address of the RADSEC server.
<b>id-reuse-timeout <i>seconds</i></b>	Configure the number of seconds after which the RADIUS ID field value can be reused. <ul style="list-style-type: none"> <li>• <b>Default:</b> 120 seconds</li> <li>• <b>Range:</b> 60 to 3600 seconds</li> </ul>
<b>logical-system <i>ls-name</i> routing-instance <i>ri-name</i></b>	Specify the logical system or the routing instance for transport. <p><b>Default:</b> If you do not explicitly configure the logical system or routing instance, the default is used. You can specify the logical system, the routing instance, or both.</p> <ul style="list-style-type: none"> <li>• No configuration specifies default:default.</li> <li>• Configuring only the routing instance specifies default:<i>ri-name</i>.</li> <li>• Configuring only the logical system specifies <i>ls-name</i>:default.</li> <li>• Configuring both the logical system and the routing instance specifies <i>ls-name</i>:<i>ri-name</i>.</li> </ul>
<b>max-tx-buffers <i>number</i></b>	Configure the maximum number of packets buffered on transmission.

**NOTE:** The buffer allocation should be able to accommodate the `max-outstanding-requests` for mapped RADIUS servers configured at the `[edit access radius-server]` hierarchy level.

- **Default:** 100
- **Range:** 32 to 3200

**port** *port-number* (Optional) Configure the port number of the RADSEC server.

- **Default:** 2083
- **Range:** 1 through 65535

**source-address** *ip-address* Configure the source IP address, which is the IP address of the RADSEC server. If the source address is not configured for dynamic requests, dynamic requests will be rejected.

**tls-certificate** *certificate-name* Specify the name of the local certificate.

**tls-force-ciphers** [medium | low] (Optional) Allow lower-grade ciphers than the default.

- Values:
  - low—Add medium and low grade ciphers.
  - medium—Add medium grade ciphers.

**NOTE:** The "tls-force-ciphers" option is not applicable. Strong cipher suites are always used by default.

**tls-min-version** [v1.1 | v1.2] (Optional) Configure the TLS version to limit the lowest supported versions of TLS that are enabled for SSL connections.

- Values:
  - v1.1—Require TLS 1.1 and 1.2.
  - v1.2—Require TLS 1.2.
- **Default:** v1.2

<b>tls-peer-name</b> <i>name</i>	Certified name of the RADSEC server.
<b>tls-timeout</b> <i>seconds</i>	Specify a limit on TLS negotiation. <ul style="list-style-type: none"> <li>• <b>Default:</b> 5 seconds</li> <li>• <b>Range:</b> 3 through 90 seconds</li> </ul>

## Syntax

```
rate-limit limit;
```

## Hierarchy Level

```
[edit system services netconf ssh],  
[edit system services ssh],  
[edit system services tftp-server],
```

## Description

Configure the maximum number of connections attempts per minute, per protocol (either IPv6 or IPv4) on an access service. For example, a rate limit of 10 allows 10 IPv6 ssh session connection attempts per minute and 10 IPv4 ssh session connection attempts per minute.

## Default

150 connections

## Options

`rate-limit limit`—(Optional) Maximum number of connection attempts allowed per minute, per IP protocol (either IPv4 or IPv6).

- Junos OS
  - **Range:** 1 through 250
  - **Default:** 150
- Junos OS Evolved
  - **Range:** 1 through 250
  - **Default:** 150

**NOTE:** For certain Junos OS Evolved releases, the `rate-limit` option was specified as the number of connection attempts allowed per second, and had various default values.

**Table 43: Releases with Connection Attempts Allowed per Second**

Release	Range	Default
Junos OS Evolved Release 20.4R1	1 through 5	3
Junos OS Evolved Release 20.4R2	1 through 5	(unlimited - no rate-limit enforced)
Junos OS Evolved Release 21.1R1	1 through 5	3

# regex-additive-logic

## IN THIS SECTION

- [Syntax | 1309](#)
- [Hierarchy Level | 1309](#)
- [Description | 1309](#)
- [Default | 1310](#)
- [Required Privilege Level | 1310](#)
- [Release Information | 1310](#)

## Syntax

```
regex-additive-logic;
```

## Hierarchy Level

```
[edit system]
```

## Description

Enable additive logic (that is, deny by default / allow some as specified) to be used in regular expressions in the `allow-configuration-regexps` and `deny-configuration-regexps` statements at the `[edit system login class class-name]` hierarchy level.

When you enable additive logic, the `allow-configuration-regexps` statement takes precedence over the `deny-configuration-regexps` statement. Thus, if you configure the `regex-additive-logic` statement and the same configuration hierarchy is referenced in both the `allow-configuration-regexps` statement and the `deny-configuration-regexps` statement, then the configuration hierarchy is allowed. If you do not configure the

regex-additive-logic, then the same hierarchy would be denied in this case because the deny-configuration-regexps statement takes precedence by default.

## Default

By default, this statement is disabled; the deny-configuration-regexps statement takes precedence over the allow-configuration-regexps statement.

## Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

## Release Information

Statement introduced in Junos OS Release 16.1.

# root-authentication

### IN THIS SECTION

- [Syntax | 1318](#)
- [Hierarchy Level | 1318](#)
- [Description | 1318](#)
- [Options | 1319](#)

- Required Privilege Level | 1319
- Release Information | 1319

## Syntax

```
root-authentication {  
    encrypted-password "password";  
    no-public-keys  
    ssh-ecdsa name {  
        from from;  
    }  
    ssh-ed25519 name {  
        from from;  
    }  
    ssh-rsa name {  
        from from;  
    }  
}
```

## Hierarchy Level

[edit system]

## Description

Configure the authentication methods for the root-level user, whose username is root.

You can use the `ssh-ecdsa`, `ssh-ed25519`, or `ssh-rsa` statements to directly configure SSH ECDSA, ED25519, or RSA keys to authenticate root logins. You can configure more than one public key for SSH authentication of root logins as well as for user accounts. When a user logs in as root, the public keys are referenced to determine whether the private key matches any of them.

## Options

<b>encrypted-password</b> <i>"password"</i>	Specify the MD5 or other password. You can specify only one encrypted password. You cannot configure a blank password using blank quotation marks (" "). You must configure a password whose number of characters range from 1 through 128 characters and enclose the password in quotation marks.
<b>no-public-keys</b>	Disable SSH public key-based authentication.
<b>ssh-ecdsa</b> <i>name from from</i>	Use an SSH ECDSA public key. You can specify one or more public keys.
<b>ssh-ed25519</b> <i>name from from</i>	Use an SSH ED25519 public key. You can specify one or more public keys.
<b>ssh-rsa</b> <i>name from from</i>	Use an SSH RSA public key. You can specify one or more public keys.

## Syntax

```
server address <logical-system logical-system-name> <routing-instance routing-instance-name>;
```

## Hierarchy Level

```
[edit forwarding-options helpers domain],  
[edit forwarding-options helpers domain interface interface-name],  
[edit forwarding-options helpers port port-number],  
[edit forwarding-options helpers port port-number interface interface-name],  
[edit forwarding-options helpers tftp],  
[edit forwarding-options helpers tftp interface interface-name]
```

## Description

Specify the DNS or TFTP server for forwarding DNS or TFTP requests, or specify a destination server address for forwarding LAN broadcast packets as unicast traffic for a custom-configured UDP port.

When configuring port helpers, in releases prior to Junos OS Release 17.2, only one server can be specified for a given port. For Junos OS Release 17.2 and later, multiple servers can be specified for a given port at the global or interface-specific level. When multiple servers are specified, the same packet, with the originator IP address and port requests, is forwarded to the different configured servers; the payload of the UDP packet is not modified.

## Options

**address**—IP address of the server.

**logical-system** *logical-system-name*—(Optional) Logical system name of the server.

**routing-instance** [ *routing-instance-names* ]—(Optional) Set the routing instance name or names that belong to the DNS server or TFTP server.

## Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

## Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced for port helpers in Junos OS Release 17.2R1 for EX4300 switches.

Support for multiple server instances for a given port introduced in Junos OS Release 17.2 for MX Series routers.

Support for multiple server instances for a given port introduced in Junos OS Release 17.3R1 for EX9200 switches.

        routing-instance routing-instance-name;  
        secret password;  
        source-address source-address;  
        timeout seconds;  
    }  
}
```

## Hierarchy Level

[edit system accounting destination [radius](#)]

## Description

Configure RADIUS accounting.

To configure multiple RADIUS accounting servers, include multiple `server server-address` statements. The servers are tried in order and in a round-robin fashion until a valid response is received from one of the servers or until all the configured retry limits are reached.

**NOTE:** The [edit system accounting] hierarchy is not available on QFabric systems.

## Options

<i>server-address</i>	Specify the IPv4 or IPv6 address of the RADIUS authentication server.
<i>accounting-port <i>port-number</i></i>	<p>Configure the accounting port number on which to contact the RADIUS server.</p> <ul style="list-style-type: none"><li>• <b>Range:</b> 1 through 65,335</li><li>• <b>Default:</b> 1813</li></ul>
<i>accounting-retry <i>number</i></i>	<p>Configure the number of accounting retry attempts.</p> <ul style="list-style-type: none"><li>• <b>Range:</b> 0 through 100 attempts</li><li>• <b>Default:</b> 0</li></ul>
<i>accounting-timeout <i>seconds</i></i>	<p>Configure the accounting request timeout period.</p> <ul style="list-style-type: none"><li>• <b>Range:</b> 0 through 1000 seconds</li><li>• <b>Default:</b> 0</li></ul>

<b>dynamic-request-port</b> <i>number</i>	<p>Configure the RADIUS client dynamic request port number</p> <ul style="list-style-type: none"> <li>• <b>Range:</b> 1 through 65535</li> <li>• <b>Default:</b> 3799</li> </ul>
<b>max-outstanding-requests</b> <i>value</i>	<p>Configure the maximum number of outstanding requests in flight to the server.</p> <ul style="list-style-type: none"> <li>• <b>Range:</b> 0 through 2000 requests</li> <li>• <b>Default:</b> 1000 requests</li> </ul>
<b>port</b> <i>port-number</i>	<p>Configure the port number on which to contact the RADIUS server.</p> <ul style="list-style-type: none"> <li>• <b>Range:</b> 1 through 65,335</li> <li>• <b>Default:</b> 1812 (as specified in RFC 2865)</li> </ul>
<b>preauthentication-port</b> <i>number</i>	<p>Configure the RADIUS server preauthentication-port number.</p> <ul style="list-style-type: none"> <li>• <b>Range:</b> 1 through 65535</li> </ul>
<b>preauthentication-secret</b> <i>secret</i>	<p>Configure the shared secret with the RADIUS server; it can include spaces if the character string is enclosed in quotation marks. The secret used by the local device must match that used by the RADIUS server.</p>
<b>retry</b> <i>value</i>	<p>Configure the number of times that the device is allowed to try to contact a RADIUS authentication server.</p> <ul style="list-style-type: none"> <li>• <b>Range:</b> 1 through 100</li> <li>• <b>Default:</b> 3</li> </ul>
<b>routing-instance</b> <i>routing-instance-name</i>	<p>Configure the routing instance name for the management routing instance. In the case of configuring the non-default management instance, use the value <code>mgmt_junos</code>. that is <code>mgmt_junos</code>. Configuring this option along with the <code>management-instance</code> statement enables authentication processes (for example, RADIUS and TACACS+) to use the non-default management routing instance for packet traffic.</p>

**NOTE:** You must also define the `mgmt_junos` routing instance under the `[edit routing-instances]` hierarchy level.

If you do not configure the `mgmt_junos` instance under the `[edit routing-instances]` hierarchy level and configure it only under `tacplus-server` or `radius-server`, the commit will fail.

<b><code>secret</code></b> <i>password</i>	(Required) Configure the password (shared secret) to use with the RADIUS server; it can include spaces if the character string is enclosed in quotation marks. The secret password used by the local device must match that used by the RADIUS server.
<b><code>source-address</code></b> <i>source-address</i>	Configure a valid IPv4 or IPv6 address configured on one of the device's interfaces.
<b><code>timeout</code></b> <i>seconds</i>	Configure the amount of time the local device waits to receive a response from a RADIUS server. <ul style="list-style-type: none"> <li>• <b>Range:</b> 1 through 1000 seconds</li> <li>• <b>Default:</b> 3 seconds</li> </ul>

## Required Privilege Level

`admin`—To view this statement in the configuration.

`admin-control`—To add this statement to the configuration.

## Release Information

- [Description | 1327](#)
- [Options | 1327](#)
- [Required Privilege Level | 1328](#)
- [Release Information | 1328](#)

## Syntax

```
server {  
    server-address {  
        port port-number;  
        routing-instance routing-instance;  
        secret password;  
        single-connection;  
        source-address address  
        timeout seconds;  
    }  
}
```

## Hierarchy Level

```
[edit system accounting destination tacplus]
```

## Description

Configure TACACS+ logging.

## Options

*server-  
address*

Address of the IPv4 or IPv6 TACACS+ authentication server.

**NOTE:** Wildcard characters cannot be used in the TACACS+ server address or source address. This is because the TACACS+ server and source can accept both IPv4 and IPv6 addresses and, if you use wildcard characters for these addresses, Junos OS cannot validate mismatching server and source address families.

*port port-  
number*

Configure the port number on which to contact the TACACS+ authentication server.

- **Default:** 49

*routing-  
instance  
routing-  
instance*

Configure the routing instance name for the management routing instance, that is `mgmt_junos`. Configuring this parameter along with the `management-instance` statement enables authentication processes (for example, RADIUS and TACACS+) to use the non-default management routing instance for packet traffic.

**NOTE:** You must also define the `mgmt_junos` routing instance under the `[edit routing-instances]` hierarchy level.

If you do not configure the `mgmt_junos` instance under the `[edit routing-instances]` hierarchy level and configure it only under `tacplus-server` or `radius-server`, the commit will fail.

*secret  
password*

Configure the password to use with the RADIUS or TACACS+ server. The secret password used by the local router or switch must match that used by the server. The password can include spaces included in quotation marks.

**NOTE:** To ensure better security, we recommend you configure the TACACS+ secret password with a minimum of 14 characters.

<b>single-connection</b>	Optimize attempts to connect to a TACACS+ server. The software maintains one open TCP connection to the server for multiple requests rather than opening a connection for each connection attempt.
<b>source-address</b> <i>source-address</i>	Specify a source address for each configured TACACS+ server to record in system log messages that are directed to a remote machine. Configure a valid IP address on one of the device interfaces. For system logging, the address is recorded as the message source in messages sent to the remote machines specified in all <code>host hostname</code> statements at the <code>[edit system syslog]</code> hierarchy level. <ul style="list-style-type: none"> <li>• <b>Default:</b> The primary address of the interface.</li> </ul>
<b>timeout</b> <i>seconds</i>	The amount of time that the local device waits to receive a response from a TACACS+ server. <ul style="list-style-type: none"> <li>• <b>Default:</b> 3 seconds</li> <li>• <b>Range:</b> 1 through 90 seconds</li> </ul>

interface (all | [interface-names])],
[edit protocols dot1x authenticator interface (all | [interface-names])]
```

## Description

For a device configured for 802.1X authentication, specify that when the device receives an Extensible Authentication Protocol Over LAN (EAPoL) Access-Reject message during the authentication process between the device and the RADIUS authentication server, supplicants attempting to access the LAN are granted access and moved to a specific bridge domain or VLAN. Any bridge domain, VLAN name or VLAN ID sent by a RADIUS server as part of the EAPoL Access-Reject message is ignored.

When you specify the bridge domain, VLAN ID, or VLAN name, bridge domain or VLAN must already be configured on the device.

## Default

None

## Options

<b>server-reject-bridge-domain</b> <i>bridge-domain</i>	(MX Series only) Move the supplicant on the interface to the bridge domain specified by this name or numeric identifier.
<b>server-reject-vlan</b> <i>(vlan-id) vlan-name</i>	(MX Series in enhanced LAN mode, EX, QFX, and SRX Series only) Move the supplicant on the interface to the VLAN specified by this name or numeric identifier.
<b>block-interval</b> <i>seconds</i>	Specify the number of seconds that the 802.1X interface ignores Extensible Authentication Protocol (EAP) start messages from the client when an EAPoL block has been enabled on the 802.1X interface. <ul style="list-style-type: none"> <li>• <b>Range:</b> 120 through 65,535 seconds</li> </ul>

The remaining statements are explained separately. Search for a statement in [CLI Explorer](#) or click a linked statement in the Syntax section for details.

rate-limit number;
rekey {
    data-limit bytes;
    time-limit minutes;
}
root-login (allow | deny | deny-password);
sftp-server;
}

```

## Hierarchy Level

[edit system services]

## Description

Allow SSH requests from remote systems to access the local device.

## Options

**authentication-order** [*method1 method2...*]

Configure the order in which the software tries different user authentication methods when attempting to authenticate a user. For each login attempt, the software tries the authentication methods in order, starting with the first one, until the password matches.

- **Default:** If you do not include the `authentication-order` statement, users are verified based on their configured passwords.

- **Syntax:** Specify one or more of the following authentication methods listed in the order in which they must be tried:
  - `ldaps`—Use LDAP authentication services.
  - `password`—Use the password configured for the user with the authentication statement at the `[edit system login user]` hierarchy level.
  - `radius`—Use RADIUS authentication services.
  - `tacplus`—Use TACACS+ authentication services.

**authorized-keys-command**

Specify a command string to be used to look up the user's public keys.

**authorized-keys-command-user**

Specify the user under whose account the `authorized-keys-command` is run.

**ciphers [ *cipher-1*  
*cipher-2*  
*cipher-3* ...]**

Specify the set of ciphers the SSH server can use to perform encryption and decryption functions.

**NOTE:** Ciphers represent a set. To configure SSH ciphers use the set command as shown in the following example:

```
user@host#set system services ssh ciphers [ aes256-cbc aes192-cbc ]
```

- **Values:** Specify one or more of the following ciphers:
  - `3des-cbc`—Triple Data Encryption Standard (DES) in Cipher Block Chaining (CBC) mode.
  - `aes128-cbc`—128-bit Advanced Encryption Standard (AES) in CBC mode.
  - `aes128-ctr`—128-bit AES in counter mode.
  - `aes128-gcm@openssh.com`—128-bit AES in Galois/Counter Mode.
  - `aes192-cbc`—192-bit AES in CBC mode.
  - `aes192-ctr`—192-bit AES in counter mode.
  - `aes256-cbc`—256-bit AES in CBC mode.
  - `aes256-ctr`—256-bit AES in counter mode.

- `aes256-gcm@openssh.com`—256-bit AES in Galois/Counter Mode.
- `arcfour`—128-bit RC4-stream cipher in CBC mode.
- `arcfour128`—128-bit RC4-stream cipher in CBC mode.
- `arcfour256`—256-bit RC4-stream cipher in CBC mode.
- `blowfish-cbc`—128-bit blowfish-symmetric block cipher in CBC mode.
- `cast128-cbc`—128-bit cast in CBC mode.
- `chacha20-poly1305@openssh.com`—ChaCha20 stream cipher and Poly1305 MAC.

**client-alive-count-  
max *number***

Configure the number of client alive messages that can be sent without `sshd` receiving any messages back from the client. If this threshold is reached while client alive messages are being sent, `sshd` will disconnect the client, terminating the session. Client alive messages are sent through the encrypted channel. Use in conjunction with the `client-alive-interval` statement to disconnect unresponsive SSH clients.

- **Default:** 3 messages
- **Range:** 0 through 255 messages

**client-alive-interval  
*seconds***

Configure a timeout interval in seconds, after which if no data has been received from the client, `sshd` will send a message through the encrypted channel to request a response from the client. This option applies to SSH protocol version 2 only. Use in conjunction with the `client-alive-count-max` statement to disconnect unresponsive SSH clients.

- **Default:** 0 seconds
- **Range:** 1 through 65535 seconds

**fingerprint-hash  
(md5 | sha2-256)**

Specify the hash algorithm used by the SSH server when it displays key fingerprints.

**NOTE:** The FIPS image does not permit the use of MD5 fingerprints. On systems in FIPS mode, `sha2-256` is the only available option.

- **Values:** Specify one of the following:

- md5—Enable the SSH server to use the MD5 algorithm.
- sha2-256—Enable the SSH server to use the sha2-256 algorithm.
- **Default:** sha2-256

**log-key-changes**  
**log-key-changes**

Enable Junos OS to log the authorized SSH keys. When the `log-key-changes` statement is configured and committed, Junos OS logs the changes to the set of authorized SSH keys for each user (including the keys that were added or removed). Junos OS logs the differences since the last time the `log-key-changes` statement was configured. If the `log-key-changes` statement was never configured, then Junos OS logs all the authorized SSH keys.

- **Default:** Junos OS logs all the authorized SSH keys.

**macs [algorithm1  
algorithm2...]**

Specify the set of message authentication code (MAC) algorithms that the SSH server can use to authenticate messages.

**NOTE:** The *macs* configuration statement represents a set. Therefore, it must be configured as follows:

```
user@host#set system services ssh macs [hmac-md5 hmac-sha1]
```

- **Values:** Specify one or more of the following MAC algorithms to authenticate messages:
  - hmac-md5—Hash-based MAC using Message-Digest 5 (MD5)
  - hmac-md5-96—96-bits of hash-based MAC using MD5
  - hmac-md5-96-etm@openssh.com—96-bits of hash-based Encrypt-then-MAC using MD5
  - hmac-md5-etm@openssh.com—Hash-based Encrypt-then-MAC using MMD5
  - hmac-ripemd160—Hash-based MAC using RIPEMD
  - hmac-ripemd160-etm@openssh.com—Hash-based Encrypt-then-MAC using RIPEMD
  - hmac-sha1—Hash-based MAC using secure hash algorithm-1 (SHA-1)
  - hmac-sha1-96—96-bits of hash-based MAC using SHA-1

- `hmac-sha1-96-etm@openssh.com`—96-bits of hash-based Encrypt-then-MAC using SHA-1
- `hmac-sha1-etm@openssh.com`—Hash-based Encrypt-then-MAC using SHA-1
- `hmac-sha2-256`—256-bits of hash-based MAC using secure hash algorithm-2 (SHA-2)
- `hmac-sha2-256-etm@openssh.com`—Hash-based Encrypt-then-Mac using SHA-2
- `hmac-sha2-512`—512-bits of hash-based MAC using SHA-2
- `hmac-sha2-512-etm@openssh.com`—Hash-based Encrypt-then-Mac using SHA-2
- `umac-128-etm@openssh.com`—Encrypt-then-MAC using UMAC-128 algorithm specified in RFC4418
- `umac-128@openssh.com`—UMAC-128 algorithm specified in RFC4418
- `umac-64-etm@openssh.com`—Encrypt-then-MAC using UMAC-64 algorithm specified in RFC4418
- `umac-64@openssh.com`—UMAC-64 algorithm specified in RFC4418

**max-pre-authentication-packets** *number*

Define the maximum number of pre-authentication SSH packets that the SSH server will accept prior to user authentication.

- **Range:** 20 through 2147483647 packets
- **Default:** 128 packets

**max-sessions-per-connection** *number*

Specify the maximum number of ssh sessions allowed per single SSH connection.

- **Range:** 1 through 65535 sessions
- **Default:** 10 sessions

**no-challenge-response**

Disable SSH challenge-response-based authentication methods.

**NOTE:** Configuring this statement under the `[edit system services ssh]` hierarchy affects both the **SSH** login service and the **NETCONF** over SSH service.

**no-password-authentication**

Disable SSH password-based authentication methods.

**NOTE:** Configuring this statement under the [edit system services ssh] hierarchy affects both the **SSH** login service and the **NETCONF** over SSH service.

**no-passwords**

Disable both password-based and challenge-response-based authentication for SSH.

**NOTE:** Configuring this statement under the [edit system services ssh] hierarchy affects both the **SSH** login service and the **NETCONF** over SSH service.

**no-public-keys**

Disable public key authentication system wide. If you specify the no-public-keys statement at the [edit system login user *user-name* authentication] hierarchy level, you disable public key authentication for a specific user.

**port *port-number***

Specify the port number on which to accept incoming SSH connections.

- **Default:** 22
- **Range:** 1 through 65535

**protocol-version [v2]**

Specify the Secure Shell (SSH) protocol version.

Starting in Junos OS Release 19.3R1 and Junos OS Release 18.3R3, on all SRX Series devices, we've removed the nonsecure SSH protocol version 1 (v1) option from the [edit system services ssh protocol-version] hierarchy level. You can use the SSH protocol version 2 (v2) as the default option to remotely manage systems and applications. With the v1 option deprecated, Junos OS is compatible with OpenSSH 7.4 and later versions.

Junos OS releases before 19.3R1 and 18.3R3 continue to support the v1 option to remotely manage systems and applications.

- **Default:** v2—SSH protocol version 2 is the default, introduced in Junos OS Release 11.4.

**rate-limit *number***

Configure the maximum number of connection attempts per minute, per protocol (either IPv6 or IPv4) on an access service. For example, a rate limit of 10 allows 10 IPv6 SSH session connection attempts per minute and 10 IPv4 SSH session connection attempts per minute.

- **Range:** 1 through 250 connections
- **Default:** 150 connections

**rekey**

Specify limits before the session keys are renegotiated.

**data-limit *bytes*** Specify the data limit before renegotiating the session keys.

**time-limit *minutes*** Specify the time limit before renegotiating the session keys.

- **Range:** 1 through 1440 minutes

**root-login (allow | deny | deny-password)**

Control user access through SSH.

- **allow**—Allow users to log in to the device as root through SSH.
- **deny**—Disable users from logging in to the device as root through SSH.
- **deny-password**—Allow users to log in to the device as root through SSH when the authentication method (for example, RSA authentication) does not require a password.
- **Default:** deny-password is the default for most systems.

Starting in Junos release 17.4R1 for MX Series routers, the default for root-login is **deny**. In previous Junos OS releases, the default setting for the MX240, MX480, MX960, MX2010 and MX2020 was **allow**.

**sftp-server**

Globally enable incoming SSH File Transfer Protocol (SFTP) connections. By configuring the sftp-server statement, you enable authorized devices to connect to the device through SFTP. If the sftp-server statement is not present in the configuration, then SFTP is globally disabled and no devices can connect to the device through SFTP.

**allow-tcp-forwarding**

Enable a user to create an SSH tunnel over a CLI session to a disaggregated Junos OS platform by using SSH.

Starting in Junos OS Release 22.2R1, we've disabled the TCP forwarding feature by default to enhance security. To enable the TCP forwarding feature, you can configure the allow-tcp-forwarding statement at the [edit system services ssh] hierarchy level. In addition, we've deprecated the tcp-forwarding and no-tcp-forwarding statements at the [edit system services ssh] hierarchy level.

The remaining statements are explained separately. Search for a statement in [CLI Explorer](#) or click a linked statement in the Syntax section for details.

## Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

## Release Information

Statement introduced before Junos OS Release 7.4.

ciphers, hostkey-algorithm, key-exchange, and macs statements introduced in Junos OS Release 11.2.

max-sessions-per-connection and no-tcp-forwarding statements introduced in Junos OS Release 11.4.

SHA-2 options introduced in Junos OS Release 12.1.

Support for the curve25519-sha256 option on the key-exchange statement added in Junos OS Release 12.1X47-D10.

client-alive-interval and client-alive-count-max statements introduced in Junos OS Release 12.2.

max-pre-authentication-packets statement introduced in Junos OS Release 12.3X48-D10.

no-passwords statement introduced in Junos OS Release 13.3.

no-public-keys statement introduced in Junos OS release 15.1.

tcp-forwarding statement introduced in Junos OS Release 15.1X53-D50 for the NFX250 Network Services Platform.

fingerprint-hash statement introduced in Junos OS Release 16.1.

log-key-changes statement introduced in Junos OS Release 17.4R1.

sftp-server statement introduced in Junos OS Release 19.1R1.

no-challenge-response and no-password-authentication statements introduced in Junos OS Release 19.4R1.

Option ldaps introduced in Junos OS Release 20.2R1.

allow-tcp-forwarding option added in Junos OS Release 22.2R1.

## Syntax

```
ssh-known-hosts {  
    fetch-from-server server;  
    host hostname {  
        dsa-key key;  
        ecdsa-sha2-nistp256-key key;  
        ecdsa-sha2-nistp384-key key;  
        ecdsa-sha2-nistp521-key key;  
        ed25519-key key;  
        rsa-key key;  
        rsa1-key key;  
    }  
    load-key-file filename;  
}
```

## Hierarchy Level

[edit security]

## Description

Configure SSH support for known hosts and for administering SSH host key updates.

## Options

- fetch-from-server *server*

Retrieve SSH public host key information from the specified server. Specify by server name or IP address.
- host *host-name*

Hostname of the SSH known host entry. This option has the following suboptions:
  - dsa-key *key*—Base64-encoded Digital Signature Algorithm (DSA) key for SSH version 2.
  - ecdsa-sha2-nistp256-key *key*—Base64-encoded ECDSA-SHA2-NIST256 key.
  - ecdsa-sha2-nistp384-key *key*—Base64-encoded ECDSA-SHA2-NIST384 key.
  - ecdsa-sha2-nistp521-key *key*—Base64-encoded ECDSA-SHA2-NIST521 key.
  - ed25519-key *key*—Base64-encoded ED25519 key.
  - rsa-key *key*—Base64-encoded public key algorithm that supports encryption and digital signatures for SSH version 1 and SSH version 2.
  - rsa1-key *key*—Base64-encoded RSA public key algorithm, which supports encryption and digital signatures for SSH version 1.
- load-key-file *filename*

Import SSH host key information from the named file. If the file is in a directory other than the home directory of the device, specify pathname as well. The default filename is /var/tmp/ssh-known-hosts.

[Configuring SSH Host Keys for Secure Copying of Data](#)

# static (802.1X)

### IN THIS SECTION

- [Syntax | 1354](#)
- [Hierarchy Level | 1355](#)
- [Description | 1355](#)
- [Options | 1355](#)
- [Required Privilege Level | 1356](#)
- [Release Information | 1356](#)

## Syntax

```
static mac-address {  
    bridge-domain-assignment bridge-domain-assignment;  
    interface [interface-names];  
}
```

```
vlan-assignment (vlan-id | vlan-name );
}
```

## Hierarchy Level

[edit protocols [dot1x](#) [authenticator](#)]

## Description

Configure MAC addresses to exclude from 802.1X authentication. The static MAC list provides an authentication bypass mechanism for supplicants connecting to a port, permitting devices such as printers that are not 802.1X-enabled to be connected to the network on 802.1X-enabled ports.

Using this 802.1X authentication-bypass mechanism, the supplicant connected to the MAC address is assumed to be successfully authenticated and the port is opened for it. No further authentication is done for the supplicant.

You can optionally configure the VLAN so that the supplicant is moved to or the interfaces on which the MAC address can gain access from.

## Options

<b><i>mac-address</i></b>	The MAC address of the device for which 802.1X authentication should be bypassed and the device permitted access to the port.
<b>bridge-domain-assignment <i>bridge-domain-assignment</i></b>	(MX Series only) Specify the bridge-domain name or 802.1q tag identifier for the MAC address that should be allowed to bypass RADIUS authentication.
<b>interface [<i>interface-names</i>]</b>	Specify a list of interfaces on which the specified MAC addresses are allowed to bypass RADIUS authentication and allowed to connect to the LAN without authentication.
<b>vlan-assignment (<i>vlan-id</i>   <i>vlan-name</i>)</b>	(EX, QFX, and SRX Series only) Specify the VLAN 802.1q tag identifier or VLAN name associated with the list of MAC addresses that should be allowed to bypass RADIUS authentication.

## Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

## Release Information

## Syntax

```
tacplus-options {  
    (exclude-cmd-attribute | no-cmd-attribute-value);  
    authorization-time-interval minutes;  
    enhanced-accounting;  
    (strict-authorization | no-strict-authorization);  
    service-name service-name;  
    timestamp-and-timezone;  
}
```

## Hierarchy Level

```
[edit system]
```

## Description

Configure TACACS+ options for authentication and accounting.

## Options

### **authorization-time-interval** *minutes*

Configure the time interval at which the authorization profile that is configured on the TACACS+ server is fetched by the Junos OS device during a TACACS+ authentication session. The TACACS+ server sends the authorization profile once by default after the user is successfully authenticated, and the authorization profile is stored locally on the Junos OS device. The authorization-time-interval option enables the Junos OS device to periodically check the authorization profile configured remotely on the TACACS+ server at the configured time interval.

If there is a change in the remote authorization profile, the device fetches the authorization profile from the TACACS+ server and the authorization profile configured locally under the [edit system login class class-name] hierarchy. The device refreshes the authorization profile stored locally by combining the remote and locally-configured authorization profiles. This ensures that any changes made to the authorization profile configuration on the TACACS+ server are reflected on the Junos OS device without the user having to restart the authentication process.

To enable the periodic refresh of the authorization profile, you must set the authorization time interval at which the Junos OS device fetches the authorization profile configuration from the TACACS+ server and refreshes the authorization profile stored locally. The time interval can be configured directly on the TACACS+ server or locally on the Junos OS device using the CLI. Use the following guidelines to determine which time interval configuration takes precedence:

- If there is no time interval configured on the TACACS+ server for periodic refresh, the Junos OS device does not receive the time interval value in the authorization response. In this case, the value configured locally on the Junos OS device will take effect.
- If the time interval is configured on the TACACS+ server and there is no authorization time interval configured locally on the Junos OS device, the value configured on the TACACS+ server will take effect.

- If the periodic refresh time interval is configured on the TACACS+ server and also locally on the Junos OS device, the value configured on the TACACS+ server will take precedence.
- If there is no periodic refresh time interval configured on the TACACS+ server and there is no authorization time interval configured on the Junos OS device, there will be no periodic refresh.
- If the periodic refresh time interval configured on the TACACS+ server is out of range or invalid, the authorization time interval value configured locally will take effect.
- If the periodic refresh time interval configured on the TACACS+ server is out of range or invalid and there is no authorization time interval configured locally, there will be no periodic refresh.

After the periodic authorization time interval is set, if the user changes the interval before the authorization request is sent from the Junos OS device, the updated interval takes effect after the next immediate periodic refresh.

- **Default:** If the authorization time interval is not configured, the authorization profile is not refreshed during a TACACS+ authentication session.
- **Range:** 15 through 1440 minutes

#### **enhanced-accounting**

Configure the audit of TACACS+ authentication events, such as access method, remote port, and access privileges.

#### **exclude-cmd-attribute**

Exclude the `cmd` attribute value completely from start and stop accounting records to enable logging of accounting records in the correct log file on a TACACS+ server.

#### **no-cmd-attribute-value**

Set the `cmd` attribute value to an empty string in the TACACS+ accounting start and stop requests to enable logging of accounting records in the correct log file on a TACACS+ server.

#### **no-strict-authorization**

Don't deny login if the authorization request fails. When a user is logging in, Junos OS issues two TACACS+ requests—first the authentication request followed by the authorization request.

- **Default:** By default, when the authorization request is rejected by the TACACS+ server, Junos OS ignores this and allows full access to the user. Specifying `no-strict-authorization` restores this default behavior.

#### **service-name service-name**

Name of the authentication service used when you configure multiple TACACS+ servers to use the same authentication service.

- **Default:** junos-exec

#### strict-authorization

Deny login if the authorization request fails. When a user is logging in, Junos OS issues two TACACS+ requests—first the authentication request followed by the authorization request. When the strict-authorization option is specified, Junos OS denies access to the user even when the TACACS+ authorization request fails.

- **Default:** By default, when the authorization request is rejected by the TACACS+ server, Junos OS ignores this and allows full access to the user.

#### timestamp-and-timezone

Include this statement if you want start time, stop time, and time zone attributes included in the start and stop accounting records.

## Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

## Release Information

Statement introduced before Junos OS Release 7.4.

no-cmd-attribute-value and exclude-cmd-attribute options introduced in Junos OS Release 9.3.

timestamp-and-timezone option introduced in Junos OS Release 12.2.

strict-authorization and no-strict-authorization options introduced in Junos OS Release 13.3 for EX Series, M Series, MX Series, PTX Series, and T Series. Support for these options was added to Junos OS Evolved starting in Release 21.1.

enhanced-accounting option introduced in Junos OS Release 14.1.

authorization-time-interval option introduced in Junos OS Release 17.4.

## RELATED DOCUMENTATION

## Syntax

```
tacplus-server server-address {  
    port port-number;  
    routing-instance routing-instance;  
    secret password;  
    single-connection;  
    source-address source-address;  
    timeout seconds;  
}
```

## Hierarchy Level

```
[edit system]
```

## Description

Configure the IPv4 or IPv6 TACACS+ server.

## Options

*server-  
address*

Address of the IPv4 or IPv6 TACACS+ authentication server.

**NOTE:** Wildcard characters cannot be used in the TACACS+ server address or source address. This is because the TACACS+ server and source can accept both IPv4 and IPv6 addresses and, if you use wildcard characters for these addresses, Junos OS cannot validate mismatching server and source address families.

*port port-  
number*

Configure the port number on which to contact the TACACS+ authentication server.

- **Default:** 49

*routing-  
instance  
routing-  
instance*

Configure the routing instance name for the management routing instance, that is `mgmt_junos`. Configuring this parameter along with the `management-instance` statement enables authentication processes (for example, RADIUS and TACACS+) to use the non-default management routing instance for packet traffic.

**NOTE:** You must also define the `mgmt_junos` routing instance under the `[edit routing-instances]` hierarchy level.

If you do not configure the `mgmt_junos` instance under the `[edit routing-instances]` hierarchy level and configure it only under `tacplus-server` or `radius-server`, the commit will fail.

*secret  
password*

Configure the password to use with the RADIUS or TACACS+ server. The secret password used by the local router or switch must match that used by the server. The password can include spaces included in quotation marks.

**NOTE:** To ensure better security, we recommend you configure the TACACS+ secret password with a minimum of 14 characters.

<b>single-connection</b>	Optimize attempts to connect to a TACACS+ server. The software maintains one open TCP connection to the server for multiple requests rather than opening a connection for each connection attempt.
<b>source-address</b> <i>source-address</i>	Specify a source address for each configured TACACS+ server to record in system log messages that are directed to a remote machine. Configure a valid IP address on one of the device interfaces. For system logging, the address is recorded as the message source in messages sent to the remote machines specified in all <code>host hostname</code> statements at the <code>[edit system syslog]</code> hierarchy level. <ul style="list-style-type: none"> <li>• <b>Default:</b> The primary address of the interface.</li> </ul>
<b>timeout</b> <i>seconds</i>	The amount of time that the local device waits to receive a response from a TACACS+ server. <ul style="list-style-type: none"> <li>• <b>Default:</b> 3 seconds</li> <li>• <b>Range:</b> 1 through 90 seconds</li> </ul>

## Required Privilege Level

admin—To view this statement in the configuration.

# telnet

## IN THIS SECTION

- [Syntax | 1370](#)
- [Hierarchy Level | 1370](#)
- [Description | 1370](#)
- [Options | 1371](#)
- [Required Privilege Level | 1372](#)
- [Release Information | 1372](#)

## Syntax

```
telnet {  
    authentication-order [authentication-methods];  
    connection-limit limit;  
    rate-limit limit;  
}
```

## Hierarchy Level

```
[edit system services]
```

## Description

Provide Telnet connections from remote systems to the local device.

## Options

### authentication-order [*authentication-methods*]

Configure the order in which the software tries different user authentication methods when attempting to authenticate a user. For each login attempt, the software tries the authentication methods in order, starting with the first one, until the password matches.

- **Values:** Specify one or more of the following authentication methods listed in the order in which they must be tried:
  - `ldaps`—Use LDAP authentication services.
  - `password`—Use the password configured for the user with the authentication statement at the [edit system login user] hierarchy level.
  - `radius`—Use RADIUS authentication services.
  - `tacplus`—Use TACACS+ authentication services.
- **Default:** If you do not include the authentication-order statement, users are verified based on their configured passwords.

### connection-limit *limit*

Configure the maximum number of connections sessions for the telnet service per protocol (either IPv6 or IPv4).

**NOTE:** The actual number of maximum connections depends on the availability of system resources, and might be fewer than the configured connection-limit value if the system resources are limited.

- **Range:** 1 through 250 connections
- **Default:** 75 connections

### rate-limit *limit*

Configure the maximum number of connections attempts per minute, per protocol (either IPv6 or IPv4) on an access service. For example, a rate limit of 10 allows 10 IPv6 telnet session connection attempts per minute and 10 IPv4 telnet session connection attempts per minute.

- **Range:** 1 through 250 connections
- **Default:** 150 connections

## Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

## Description

Select the type, length, and value (TLV) messages that should not be advertised by the Link Layer Discovery Protocol (LLDP) or LLDP Media Endpoint Discovery (LLDP-MED) protocol. LLDP-capable devices transmit information in type, length, and value (TLV) messages to neighbor devices. Device information can include information such as chassis and port identification and system name and system capabilities.

In multi-vendor networks, it might not be desirable to send TLV messages because they can contain sensitive information about a network device. You can configure LLDP or LLDP-MED to disable any non-mandatory TLV message. (These mandatory TLVs are always advertised: chassis-id, port-id, and time-to-live.)

When you configure the `tlv-filter` statement, you specify the TLVs that you want to disable. This is useful when you want to allow most, but not all, TLVs.

You can also disable TLVs using the `tlv-select` statement. When you configure the `tlv-select` statement, you specify the TLVs that you want to be advertised by LLDP or LLDP-MED. All other non-mandatory TLVs are disabled.

**NOTE:** The `tlv-select` and `tlv-filter` statements are mutually exclusive and cannot be used on the same configuration stanza at the same time.

## Default

All TLVs for LLDP and LLDP-MED are enabled by default.

## Options

**tlv-name** Specify the non-mandatory TLV message that you want to disable.

- **Values:** You can disable the following TLV messages for LLDP:
  - `cloud-reach-event-tlv`—Use to have cloud-ready EX4400 Series switches stop sending cloud-reach-events. By default, once an EX4400 connects to the Juniper Mist Cloud Service via its phone-home routine, subsequent TLV messages are automatically halted.
  - `jnpr-chassis-serial`—The chassis serial number.
  - `jnpr-vcp`—Juniper virtual chassis port.
  - `link-aggregation`—Advertises whether the port is aggregated and its aggregated port ID.
  - `mac-phy-config-status`—Advertises information about the physical interface, such as autonegotiation status and support and MAU (medium attachment unit) type.
  - `management-address`— The IP management address of the local system.
  - `maximum-frame-size`—The maximum transmission unit (MTU) of the interface sending LLDP frames.
  - `port-description`—The user-configured port description.
  - `port-vid`—Indicates the port VLAN ID that will be associated with an untagged or priority tagged data frame received on the VLAN port.
  - `power-vi-mdi`—Advertises MDI (media dependent interface) power support, PSE (power sourcing equipment) power pair, and power class information.
  - `system-capabilities`—The primary function performed by the system. The capabilities that system supports are defined; for example, bridge or router. This information cannot be configured, but is based on the model of the product.
  - `system-description`—The user-configured name of the local system.
  - `system-name`—The user-configured name of the local system.
  - `vlan-name`—Indicates the assigned name of any VLAN at the device.

You can disable the following TLV messages for LLDP-MED:

- `ext-power-via-mdi`—The power type, power source, power priority, and power value of the port. It is the responsibility of the PSE device (network connectivity device) to advertise the power priority on a port.
- `location-id`—The physical location of the endpoint.

- `med-capabilities`—The primary function of the port.
- `network-policy`—The port VLAN configuration and associated Layer 2 and Layer 3 attributes. Attributes include the policy identifier, application types, such as voice or streaming video, 802.1Q VLAN tagging, and 802.1p priority bits and Diffserv code points.

## Required Privilege Level

`routing`—To view this statement in the configuration.

`routing-control`—To add this statement to the configuration.

## Release Information

Statement introduced in Junos OS Release 18.3.

## Description

Select the type, length, and value (TLV) messages that should be advertised by Link Layer Discovery Protocol (LLDP) or LLDP Media Endpoint Discovery (LLDP-MED) protocol. LLDP-capable devices transmit information in type, length, and value (TLV) messages to neighbor devices. Device information can include information such as chassis and port identification and system name and system capabilities.

In multi-vendor networks, it might not be desirable to send TLV messages because they can contain sensitive information about a network device. You can configure LLDP or LLDP-MED to choose which non-mandatory TLV messages to advertise. (These mandatory TLVs are always advertised: chassis-id, port-id, and time-to-live.)

When you configure the `tlv-select` statement, you specify the TLVs that LLDP or LLDP-MED should advertise. All other non-mandatory TLVs are disabled. This is useful when you want to disable most, but not all, TLVs.

You can also disable TLVs using the `tlv-filter` statement. When you configure the `tlv-filter` statement, you specify the TLVs that should be disabled.

**NOTE:** The `tlv-select` and `tlv-filter` statements are mutually exclusive and cannot be used on the same configuration stanza at the same time.

## Default

All TLVs for LLDP and LLDP-MED are enabled by default.

## Options

- tlv-name** Specify the non-mandatory TLV message that you want to advertise.
- **Values:** You can advertise the following TLV messages for LLDP:
    - `jnpr-chassis-serial`—The chassis serial number.
    - `jnpr-vcp`—Juniper virtual chassis port.
    - `link-aggregation`—Advertises whether the port is aggregated and its aggregated port ID.
    - `mac-phy-config-status`—Advertises information about the physical interface, such as autonegotiation status and support and MAU (medium attachment unit) type.
    - `management-address`— The IP management address of the local system.
    - `maximum-frame-size`—The maximum transmission unit (MTU) of the interface sending LLDP frames.
    - `port-description`—The user-configured port description.
    - `port-vid`—Indicates the port VLAN ID that will be associated with an untagged or priority tagged data frame received on the VLAN port.
    - `power-vi-mdi`—Advertises MDI (media dependent interface) power support, PSE (power sourcing equipment) power pair, and power class information.

- `system-capabilities`—The primary function performed by the system. The capabilities that system supports are defined; for example, bridge or router. This information cannot be configured, but is based on the model of the product.
- `system-description`—The user-configured name of the local system.
- `system-name`—The user-configured name of the local system.
- `vlan-name`—Indicates the assigned name of any VLAN at the device.

You can advertise the following TLV messages for LLDP-MED:

- `ext-power-via-mdi`—The power type, power source, power priority, and power value of the port. It is the responsibility of the PSE device (network connectivity device) to advertise the power priority on a port.
- `location-id`—The physical location of the endpoint.
- `med-capabilities`—The primary function of the port.
- `network-policy`—The port VLAN configuration and associated Layer 2 and Layer 3 attributes. Attributes include the policy identifier, application types, such as voice or streaming video, 802.1Q VLAN tagging, and 802.1p priority bits and Diffserv code points.

# traceoptions (802.1X)

## IN THIS SECTION

- [Syntax | 1381](#)
- [Hierarchy Level | 1381](#)
- [Description | 1382](#)
- [Default | 1382](#)
- [Options | 1382](#)
- [Required Privilege Level | 1383](#)
- [Release Information | 1383](#)

## Syntax

```
traceoptions {  
    file filename <files number> <size size> <world-readable | no-world-readable> <match regex>;  
    flag flag;  
}
```

## Hierarchy Level

[edit protocols [dot1x](#)]

## Description

Define tracing operations for the 802.1X protocol.

## Default

Tracing operations are disabled.

## Options

**file** *filename*—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory **/var/log**.

**files** *number*—(Optional) Maximum number of trace files. When a trace file named **trace-file** reaches its maximum size, it is renamed **trace-file.0**, then **trace-file.1**, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten. If you specify a maximum number of files, you also must specify a maximum file size by using the **size** option.

- **Range:** 2 through 1000
- **Default:** 3 files

**flag** *flag*—Tracing operation to perform. To specify more than one tracing operation, include multiple flag statements. You can include the following flags:

- **all**—All tracing operations.
- **config-internal**—Trace internal configuration operations.
- **dot1x-event**—(Switches with ELS only) Trace 802.1x events.
- **dot1x-debug**—(Switches without ELS) Trace 802.1x events.
- **dot1x-ipc**—(Switches with ELS only) Trace IPC interactions.
- **eapol**—Trace EAPOL packets transmitted and received.
- **esw-if**—(Switches without ELS) Trace ESW interactions.
- **general**—Trace general operations.
- **normal**—Trace normal operations.

- **parse**—Trace reading of the configuration.
- **regex-parse**—Trace regular-expression parsing operations.
- **state**—Trace protocol state changes.
- **task**—Trace protocol task operations.
- **timer**—Trace protocol timer operations.
- **vlan**—Trace VLAN transactions.

**match** *regex*—(Optional) Refine the output to include lines that contain the regular expression.

**no-world-readable**—(Optional) Restrict file access to the user who created the file.

**size** *size*—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named **trace-file** reaches its maximum size, it is renamed **trace-file.0**, then **trace-file.1**, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten. If you specify a maximum number of files with the **files** option, you also must specify a maximum file size.

- **Syntax:** **yk** to specify KB, **ym** to specify MB, or **yg** to specify GB
- **Range:** 10 KB through 1 GB
- **Default:** 128 KB

**world-readable**—(Optional) Enable unrestricted file access.

## Required Privilege Level

**routing**—To view this statement in the configuration.

**routing-control**—To add this statement to the configuration.

## Release Information

Statement introduced in Junos OS Release 9.0.

Support for the **dot1x-event** and **dot1x-ipc** options introduced in Junos OS Release 13.2X50 for EX Series switches.

## RELATED DOCUMENTATION

## traceoptions (DNS, Port, and TFTP Packet Forwarding)

## IN THIS SECTION

- [Syntax | 1384](#)
- [Hierarchy Level | 1385](#)
- [Description | 1385](#)
- [Default | 1385](#)
- [Options | 1385](#)
- [Required Privilege Level | 1387](#)
- [Release Information | 1387](#)

### Syntax

```
traceoptions {  
    file filename <files number> <match regular-expression> <size bytes> <world-readable | no-  
world-readable>;  
    flag flag;  
    level level;  
    <no-remote-trace>;  
}
```

## Hierarchy Level

```
[edit forwarding-options helpers]
```

## Description

Configure tracing operations for BOOTP, DNS, TFTP, or custom UDP port packet forwarding.

## Default

If you do not include this statement, no tracing operations are performed.

## Options

**file *filename***—Name of the file to receive the output of the tracing operation. Enclose the name in quotation marks (" "). All files are placed in a file named **fud** in the directory **/var/log**. If you include the file statement, you must specify a filename.

**files *number***—(Optional) Maximum number of trace files. When a trace file named **trace-file** reaches its maximum size, it is renamed **trace-file.0**, then **trace-file.1**, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum number of files, you also must specify a maximum file size with the **size** option and a filename.

- **Range:** 2 through 1000
- **Default:** 3 files

**flag *flag***—Tracing operation to perform. To specify more than one tracing operation, include multiple flag statements. You can include the following flags:

- **address**—Trace address management events
- **all**—Trace all events
- **bootp**—Trace BOOTP or DHCP services events

- **config**—Trace configuration events
- **domain**—Trace DNS service events
- **ifdb**—Trace interface database operations
- **io**—Trace I/O operations
- **main**—Trace main loop events
- **port**—Trace arbitrary protocol events
- **rtsock**—Trace routing socket operations
- **tftp**—Trace TFTP service events
- **trace**—Trace tracing operations
- **ui**—Trace user interface operations
- **util**—Trace miscellaneous utility operations

**match *regular-expression***—(Optional) Refine the output to include lines that contain the regular expression.

**no-remote-trace**—(Optional) Disable remote tracing globally or for a specific tracing operation.

**no-world-readable**—(Optional) Restrict file access to the owner.

**size *size***—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named **trace-file** reaches this size, it is renamed **trace-file.0**. When the **trace-file** file again reaches its maximum size, **trace-file.0** is renamed **trace-file.1** and **trace-file** is renamed **trace-file.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you also must specify a maximum number of trace files with the **files** option and filename.

- **Syntax:** ***xk*** to specify KB, ***xm*** to specify MB, or ***xg*** to specify GB
- **Range:** 0 bytes through 4,294,967,295 KB
- **Default:** 128 KB

**world-readable**—(Optional) Enable unrestricted file access.

## Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

## Release Information

Statement introduced before Junos OS Release 7.4.

Statement standardized and **match** option introduced in Junos OS Release 8.0.

### RELATED DOCUMENTATION

*Tracing BOOTP, DNS, and TFTP Forwarding Operations*

# traceoptions (LLDP)

## IN THIS SECTION

- [Syntax | 1388](#)
- [Hierarchy Level | 1388](#)
- [Description | 1388](#)
- [Default | 1388](#)
- [Options | 1388](#)
- [Required Privilege Level | 1390](#)
- [Release Information | 1391](#)

## Syntax

```
traceoptions {  
    file filename <files number> <size maximum-file-size> <world-readable | no-world-readable>;  
    flag flag <disable>;  
}
```

## Hierarchy Level

```
[edit protocols lldp],  
[edit routing-instances routing-instance-name protocols lldp]
```

## Description

Define tracing operations for the Link Layer Discovery Protocol (LLDP). You can trace messages under LLDP for LLDP and physical topology SNMP MIBs.

**NOTE:** The traceoptions statement is not supported on the QFX3000 QFabric system.

## Default

The default LLDP protocol-level trace options are inherited from the global traceoptions statement.

## Options

**disable** (Optional) Disable the tracing operation. One use of this option is to disable a single operation when you have defined a broad group of tracing operations, such as all.

**file *filename*** Name of the file to receive the output of the tracing operation. Enclose the name in quotation marks. All files are placed in the directory `/var/log`. We recommend that you place spanning-tree protocol tracing output in the file `/var/log/stp-log`.

**files *number*** (Optional) Maximum number of trace files. When a trace file named *trace-file* reaches its maximum size, it is renamed *trace-file.0*, then *trace-file.1*, and so on, until the maximum number of trace files is reached. Then, the oldest trace file is overwritten.

If you specify a maximum number of files, you must also specify a maximum file size with the `size` option.

- **Range:** 2 through 1000 files
- **Default:** 1 trace file only

**flag** Specify a tracing operation to perform. To specify more than one tracing operation, include multiple `flag` statements.

- **Values:** The following are the LLDP-specific tracing options:
  - `all`—Trace all operations.
  - `configuration`—Log configuration events.
  - `interface`—Trace interface update events.
  - `packet`—Trace packet events.
  - `protocol`—Trace protocol information.
  - `rtsock`—Trace socket events.
  - `snmp`—Trace SNMP configuration operations.
  - `vlan`—Trace VLAN update events.

The following are the global tracing options:

- `all`—All tracing operations.
- `config-internal`—Trace configuration internals.
- `general`—Trace general events.
- `normal`—All normal events. This is the default. If you do not specify this option, only unusual or abnormal operations are traced.

- `parse`—Trace configuration parsing.
- `policy`—Trace policy operations and actions.
- `regex-parse`—Trace regular-expression parsing.
- `route`—Trace routing table changes.
- `state`—Trace state transitions.
- `task`—Trace protocol task processing.
- `timer`—Trace protocol task timer processing.

**no-world-readable**

(Optional) Prevent any user from reading the log file. This is the default. If you do not include this option, tracing output is appended to an existing trace file.

**size  
maximum-  
file-size**

(Optional) Maximum size of each trace file, in kilobytes (KB) or megabytes (MB). When a trace file named *trace-file* reaches this size, it is renamed *trace-file.0*. When the *trace-file* again reaches its maximum size, *trace-file.0* is renamed *trace-file.1* and *trace-file* is renamed *trace-file.0*. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you must also specify a maximum number of trace files with the `files` option.

- **Syntax:** *xk* to specify KB, *xm* to specify MB, or *xg* to specify GB
- **Range:** 10 KB through the maximum file size supported on your system
- **Default:** 1 MB

**world-readable**

(Optional) Allow any user to read the log file.

## Required Privilege Level

`routing`—To view this statement in the configuration.

`routing-control`—To add this statement to the configuration.

## Release Information

Statement introduced in Junos OS Release 9.0.

# traceoptions (Outbound SSH)

## IN THIS SECTION

- [Syntax | 1391](#)
- [Hierarchy Level | 1392](#)
- [Description | 1392](#)
- [Options | 1392](#)
- [Required Privilege Level | 1393](#)
- [Release Information | 1393](#)

## Syntax

```
traceoptions {  
    file <filename> <files number> <match regular-expression> <size size> <(world-readable | no-  
world-readable)>;  
    flag flag;  
    no-remote-trace;  
}
```

## Hierarchy Level

```
[edit system services outbound-ssh]
```

## Description

Set the trace options for the outbound SSH service. By default, tracing operations are disabled.

## Options

- `file`—Configure the trace file information.
  - `filename`—(Optional) By default, the name of the file is the name of the process being traced. Use this option to override the default file name and specify a file to receive the output of the tracing operation. Enclose the name within quotation marks. All trace files are placed in the directory `/var/log`.
  - `files number`—(Optional) Specify the maximum number of trace files to create before overwriting the oldest one. If you specify a maximum number of files, you also must specify a maximum file size with the `size` option and a file name with the `filename` option.

Range: 2 through 1000 files

Default: 3 files

- `match regular-expression`—(Optional) When configured, the system adds only those lines to the trace file that match the regular expression. For example, if the regular expression is set to `=error`, the system only adds lines to the trace file that include the string `error`.
- `size maximum-file-size`—(Optional) Specify the maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named `trace-file` reaches this size, it is renamed `trace-file.0`. When `trace-file` again reaches its maximum size, `trace-file.0` is renamed `trace-file.1` and `trace-file` is renamed `trace-file.0`. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you also must specify a maximum number of trace files by using the `files` option and a filename by using the `file` option.

Syntax: x K to specify KB, x m to specify MB, or x g to specify GB

Range: 10 KB through 1 GB

Default: 128 KB

- `world-readable` | `no-world-readable`—(Optional) By default, access to the trace files is restricted to the user who configured the tracing operation. The `world-readable` option enables any user to read the file. To explicitly set the default behavior, configure the `no-world-readable` option.
- `flag`—Specify the tracing operation to perform. To specify more than one tracing operation, include multiple `flag` statements. You can include the following flags:
  - `all`—Trace all events.
  - `configuration`—Trace configuration events.
  - `connectivity`—Trace TCP connection handling between the management application and the device.
- `no-remote-trace`—(Optional) Disable remote tracing and logging operations that track normal operations, error conditions, and packets that are generated by or passed through the device.

## Required Privilege Level

`trace`—To view this statement in the configuration.

`trace-control`—To add this statement to the configuration.

## Release Information

Statement introduced in Junos OS Release 10.4.

- **Range:** 2 through 1000
- **Default:** 3 files
- **match *regex***—(Optional) Refine the output to include lines that contain the regular expression.
- **no-world-readable**—(Optional) Disable unrestricted file access.
- **size *size***—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named **trace-file** reaches this size, it is renamed **trace-file.0**. When the trace-file again reaches its maximum size, **trace-file.0** is renamed **trace-file.1** and **trace-file** is renamed **trace-file.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten. If you specify a maximum file size, you also must specify a maximum number of trace files with the **files** option and filename.
- **Syntax:** *kk* to specify KB, *mm* to specify MB, or *gg* to specify GB.
- **Range:** 10 KB through 1 GB
- **Default:** 128 KB
- **world-readable**—(Optional) Enable unrestricted file access.

**flag *flag***—Tracing operation to perform. To specify more than one tracing operation, include multiple **flag** statements. You can include the following flags:

- **all *trace-level***—Trace all SBC process operations.
- **common *trace-level***—Trace common events.
- **configuration *trace-level***—Trace configuration events.
- **device-monitor *trace-level***—Trace device monitor events.
- **ipc *trace-level***—Trace IPC events.

- `memory-pool trace-level`—Trace memory pool events.
- `trace-level`—Trace level options are related to the severity of the event being traced. When you choose a trace level, messages at that level and higher levels are captured. Enter one of the following trace levels as the `trace-level`:
  - `debug`—Log all code flow of control.
  - `error`—Log failures with a short-term effect.
  - `info`—Log summary for normal operations, such as the policy decisions made for a call.
  - `trace`—Log program trace START and EXIT macros.
  - `warning`—Log failure recovery events or failure of an external entity.
- `ui trace-level`—Trace user interface operations.

## Required Privilege Level

`system`—To view this statement in the configuration.

`system-control`—To add this statement to the configuration.

## Release Information

Statement introduced in Junos OS Release 9.5.

# traceoptions (Security)

### IN THIS SECTION

- [Syntax | 1397](#)
- [Hierarchy Level | 1397](#)
- [Description | 1397](#)

- [Options | 1398](#)
- [Required Privilege Level | 1399](#)
- [Release Information | 1399](#)

## Syntax

```
tracoptions {  
    file filename <files number> <size size>;  
    flag all;  
    flag certificates;  
    flag database;  
    flag general;  
    flag ike;  
    flag parse;  
    flag policy-manager;  
    flag routing-socket;  
    flag timer;  
    level  
    no-remote-trace  
}
```

## Hierarchy Level

```
[edit security],  
[edit services ipsec-vpn]
```

Trace options can be configured at either the [edit security] or the [edit services ipsec-vpn] hierarchy level, but not at both levels.

## Description

Configure security trace options.

To specify more than one trace option, include multiple `flag` statements. Trace option output is recorded in the `/var/log/kmd` file.

**NOTE:** The `traceoptions` statement is not supported on QFabric systems.

## Options

`files number`—(Optional) Maximum number of trace files. When a trace file (for example, `kmd`) reaches its maximum size, it is renamed `kmd.0`, then `kmd.1`, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum number of files, you must also specify a maximum file size with the `size` option.

- **Range:** 2 through 1000 files
- **Default:** 0 files

`size size`—(Optional) Maximum size of each trace file, in kilobytes (KB). When a trace file (for example, `kmd`) reaches this size, it is renamed, `kmd.0`, then `kmd.1` and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

- **Default:** 1024 KB

`flag flag`—Trace operation to perform. To specify more than one trace operation, include multiple `flag` statements.

- `all`—Trace all security events.
- `certificates`—Trace certificate events.
- `database`—Trace database events.
- `general`—Trace general events.
- `ike`—Trace IKE module processing.
- `parse`—Trace configuration processing.
- `policy-manager`—Trace policy manager processing.
- `routing-socket`—Trace routing socket messages.
- `timer`—Trace internal timer events.

`level level`—(Optional) Set traceoptions level.

- `all`—match all levels.
- `error`—Match error conditions.
- `info`—Match informational messages.
- `notice`—Match conditions that should be handled specially.
- `verbose`—Match verbose messages.
- `warning`—Match warning messages.

`no-remote-trace`—(Optional) Disable remote tracing

## Required Privilege Level

`admin`—To view the configuration.

`admin-control`—To add this statement to the configuration.

## Release Information

Statement introduced before Junos OS Release 7.4.

- [Required Privilege Level | 1402](#)
- [Release Information | 1402](#)

## Syntax

```
unattended-boot;
```

## Hierarchy Level

```
[edit system]
```

## Description

Set the switch to unattended mode for U-Boot to prevent unauthorized access to the system before the JUNOS OS login prompt appears. In unattended mode, access to the loader CLI is blocked, as well as recovery mechanisms such as password recovery by using single-user mode and booting the switch by using a USB flash drive. In order to access the CLI in U-Boot mode, the user must enter a boot-loader password that has been previously configured.

**NOTE:** If the root password is lost while the switch is in unattended mode, the switch must be reset to the factory default configuration using the LCD panel. For more information see *Reverting to the Default Factory Configuration for the EX Series Switch*.

## Default

Unattended mode is not enabled by default.

## Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

## Release Information

Statement introduced in Junos OS Release 13.2X51-D20.

- [Description | 1405](#)
- [Options | 1406](#)
- [Required Privilege Level | 1407](#)
- [Release Information | 1407](#)

## Syntax

```
user user-name {  
    authentication {  
        encrypted-password encrypted-password;  
        no-public-keys;  
        ssh-ecdsa name {  
            from host-list;  
        }  
        ssh-ed25519 name {  
            from host-list;  
        }  
        ssh-rsa name {  
            from host-list;  
        }  
    }  
    class class-name;  
    cli {  
        prompt prompt;  
    }  
    full-name complete-name;  
    uid uid;  
}
```

## Hierarchy Level

```
[edit system login]
```

## Description

Configure access permission for individual users. Starting in Junos OS Release 18.3, the `ssh-dsa` hostkey algorithm is deprecated— rather than immediately removed—to provide backward compatibility and a chance to bring your configuration into compliance with the new configuration.

## Options

### authentication

Specify one or more authentication methods that a user can use to log in to the router or switch. You can assign multiple authentication methods to a single user.

### encrypted-password

Message Digest 5 (MD5) or other encrypted authentication. Specify the MD5 or other password. You can specify only one encrypted password for each user.

**CAUTION:** Do not use the encrypted-password option unless the password is *already* encrypted, and you are entering the encrypted version of the password.

If you accidentally configure the encrypted-password statement with a plain-text password or with blank quotation marks (" "), you will not be able to log in to the device as this user.

- **Range:** You cannot configure a blank password for encrypted-password using blank quotation marks (" "). You must configure a password whose number of characters range from 1 through 128 characters and enclose the password in quotation marks.

### no-public-keys

Disables ssh public key authentication for the user specified. If the no-public-keys statement is specified at the [edit system services ssh] hierarchy level, public key authentication is disabled for all users on the device.

### ssh-ecdsa public-key

SSH version 2 authentication. Specify the ECDSA public key. You can specify one or more public keys for each user.

**from *host-list*** Specify a pattern-list of allowed hosts.

### ssh-ed25519 public-key

SSH version 2 authentication. Specify the ED25519 public key. You can specify one or more public keys for each user.

**from *host-list*** Specify a pattern-list of allowed hosts.

### ssh-rsa public-key

SSH version 2 authentication. Specify the RSA public key. You can specify one or more public keys for each user.

**from *host-list*** Specify a pattern-list of allowed hosts.

<b>class</b> <i>class-name</i>	Assign a user to a login class. You must assign each user to a login class. Specify one of the classes defined at the [edit system login class] hierarchy level.
<b>cli</b>	Set the CLI prompt specified for a specified login user or specified login class. The prompt set for the login user has precedence.
<b>prompt</b> <i>prompt</i>	Specify the prompt string you want to see displayed in the CLI prompt.
<b>full-name</b> <b>complete-name</b>	Specify the user's complete name. If the name contains spaces, enclose it in quotation marks. Do not include colons or commas.
<b>uid</b> <i>uid-value</i>	<p>Numeric identifier associated with the user account, either assigned by an administrator or assigned automatically when you commit the user configuration. It is used by applications that request numeric identifiers, such as some RADIUS queries, or secure applications, such as flow-tap monitoring. This value must be unique on the router or switch.</p> <ul style="list-style-type: none"> <li>• <b>Default:</b> If you do not assign a UID to a user, the software assigns one when you commit the configuration, preferring the lowest available number.</li> <li>• <b>Range:</b> 100 through 64000</li> </ul>

## Required Privilege Level

            (no-world-readable | world-readable);
        }
        flag flag level level;
        no-remote-trace;
    }
}

```

## Hierarchy Level

[edit system services]

## Description

Configure settings for HTTP or HTTPS access. HTTP access allows management of the device using the browser-based J-Web graphical user interface. HTTPS access allows secure management of the device using the J-Web interface. With HTTPS access, communication between the device's Web server and your browser is encrypted.

**NOTE:** On SRX340, SRX345, and SRX380 devices, the factory-default configuration has a generic HTTP configuration. To use Gigabit Ethernet (ge) and fxp0 ports as management ports, you must use the **set system services web-management http interface** command to configure HTTP access for those interfaces. The Web management HTTP and HTTPS interfaces are changed to fxp0.0 and from ge-0/0/1.0 through ge-0/0/7.0.

vSRX 3.0 on Hyper-V does not support the web management https configuration.

## Options

<b>control max-threads <i>max-threads</i></b>	Configure the maximum number of simultaneous threads to handle access requests. <ul style="list-style-type: none"> <li>• <b>Range:</b> 0 through 16</li> </ul>
<b>management-url</b>	Configure the URL path for Web management access.
<b>traceoptions</b>	Set the trace options. <ul style="list-style-type: none"> <li>• <b>file</b>—Configure the trace file information. <ul style="list-style-type: none"> <li>• <i>filename</i>—Name of the file to receive the output of the tracing operation. Enclose the name in quotation marks. All files are placed in the directory <b>/var/log</b>. By default, the name of the file is the name of the process being traced.</li> <li>• <i>files number</i>— Maximum number of trace files. When a trace file named <b>trace-file</b> reaches its maximum size, it is renamed <b>trace-file.0</b>, then <b>trace-file.1</b>, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.</li> </ul> </li> </ul>

If you specify a maximum number of files, you also must specify a maximum file size with the size *maximum file-size* option.

**Range:** 2 through 1000 files

**Default:** 10 files

- *match regular-expression*—Refine the output to include lines that contain the regular expression.
- *size maximum-file-size*—Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB).

**Range:** 10 KB through 1 GB

**Default:** 128 KB

If you specify a maximum file size, you also must specify a maximum number of trace files with the files *number* option.

- *(world-readable | no-world-readable)*— By default, log files can be accessed only by the user who configures the tracing operation. The *world-readable* option enables any user to read the file. To explicitly set the default behavior, use the *no-world-readable* option.
- *flag flag*—Specify which tracing operation to perform. To specify more than one tracing operation, include multiple *flag* statements. You can include the following flags.
  - *all*—Trace all areas.
  - *configuration*—Trace configuration.
  - *dynamic-vpn*—Trace dynamic VPN events.
  - *init*—Trace the daemon init process.
  - *mgd*—Trace MGD requests.
  - *webauth*—Trace Web authentication requests.
- *level level* —Specify the level of debugging output.
  - *all*—Match all levels.
  - *error*—Match error conditions.

- `info`—Match informational messages.
- `notice`—Match conditions that should be handled specially.
- `verbose`—Match verbose messages.
- `warning`—Match warning messages.
- `no-remote-trace`—Disable remote tracing.

The remaining statements are explained separately. Search for a statement in [CLI Explorer](#) or click a linked statement in the Syntax section for details.

## Required Privilege Level

`system`—To view this statement in the configuration.

`system-control`—To add this statement to the configuration.

## Release Information

Statement introduced before Junos OS Release 7.4.

Support for `https` introduced for SRX5400, SRX5600, and SRX5800 devices starting from Junos OS Release 12.1X44-D10 and on vSRX, SRX300, SRX320, SRX340, SRX345, SRX380, SRX550M, and SRX1500 devices starting from Junos OS Release 15.1X49-D40.

# xnm-clear-text

### IN THIS SECTION

- [Syntax | 1418](#)
- [Hierarchy Level | 1418](#)
- [Description | 1418](#)
- [Options | 1418](#)
- [Required Privilege Level | 1419](#)

## Syntax

```
xnm-clear-text {  
    connection-limit limit;  
    rate-limit limit;  
}
```

## Hierarchy Level

```
[edit system services]
```

## Description

Allow Junos XML protocol clear-text requests from remote systems to the local router.

**NOTE:** Junos OS Evolved does not support the `xnm-clear-text` statement.

## Options

<b>connection-limit</b> <i>limit</i>	Configure the maximum number of connections sessions for the xnm-clear-text service per protocol (either IPv6 or IPv4).
--------------------------------------	---

**NOTE:** The actual number of maximum connections depends on the availability of system resources, and might be fewer than the configured `connection-limit` value if the system resources are limited.

- **Range:** 1 through 250 connections
- **Default:** 75 connections

**rate-limit *limit*** Configure the maximum number of connections attempts per minute, per protocol (either IPv6 or IPv4) on an access service. For example, a rate limit of 10 allows 10 IPv6 xnm-clear-text session connection attempts per minute and 10 IPv4 xnm-clear-text session connection attempts per minute.

- **Range:** 1 through 250 connections
- **Default:** 150 connections

## Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

## Release Information

# xnm-ssl

## IN THIS SECTION

- [Syntax | 1420](#)
- [Hierarchy Level | 1420](#)
- [Description | 1420](#)
- [Options | 1421](#)
- [Required Privilege Level | 1422](#)
- [Release Information | 1422](#)

## Syntax

```
xnm-ssl {  
    connection-limit limit;  
    local-certificate name;  
    rate-limit limit;  
    ssl-renegotiation ;  
}
```

## Hierarchy Level

```
[edit system services]
```

## Description

Allow Junos XML protocol SSL requests from remote systems to the local router.

**WARNING:** Starting with Junos OS Release 15.1, the `ssl3-support` option is not available for configuration with the `set system services xnm-ssl` and `file copy` commands. SSLv3 is no longer supported and available.

For all releases prior to and including Junos OS Release 14.2, SSLv3 is disabled by default at runtime. The `ssl3-support` option is hidden and deprecated in Junos OS Release 14.2 and earlier releases. However, you can use the `set system services xnm-ssl ssl3-support` command to enable SSLv3 for a Junos XML protocol client application to use as the protocol to connect to the Junos XML protocol server on a router, and you can use the `file copy source destination ssl3-support` command to enable the copying of files from an SSLv3 URL.

Using SSLv3 presents a potential security vulnerability, and we recommend that you not use SSLv3. For more details about this security vulnerability, go to <https://kb.juniper.net/InfoCenter/index?page=content&id=JSA10656>.

**NOTE:** When FIPS mode is enabled on the device, the `xnm-ssl` service does not support TLS 1.0. For a device in FIPS mode, the clients must communicate with the `xnm-ssl` service using TLS 1.1 or later. In non-FIPS mode, clients can communicate with the `xnm-ssl` service using TLS 1.0 or later. The `xnm-ssl` service never negotiates with the SSLv2 or SSLv3 (the predecessors to TLS 1.0) even if the FIPS mode is enabled or disabled.

## Options

### **connection-limit limit**

Configure the maximum number of connections sessions for the ftp service per protocol (either IPv6 or IPv4).

**NOTE:** The actual number of maximum connections depends on the availability of system resources, and might be fewer than the configured `connection-limit` value if the system resources are limited.

- **Range:** 1 through 250 connections
- **Default:** 75 connections

### **local-certificate name**

Import or reference an SSL certificate by specifying the name of the local certificate to use.

There is no default. The value for `local-certificate` should be the same as the name provided during the import of the certificate using the CLI configuration statement `local` at the `[edit security certificates]` hierarchy level.

- rate-limit *limit*** Configure the maximum number of connections attempts per minute, per protocol (either IPv6 or IPv4) on an access service. For example, a rate limit of 10 allows 10 IPv6 ftp session connection attempts per minute and 10 IPv4 ftp session connection attempts per minute.
- **Range:** 1 through 250 connections
  - **Default:** 150 connections
- ssl-renegotiation** Enable SSL re-negotiation for xnm-ssl service.
- **Default:** Disabled

## Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

# clear accounting server statistics archival-transfer

## IN THIS SECTION

- [Syntax | 1427](#)
- [Description | 1427](#)
- [Options | 1427](#)
- [Required Privilege Level | 1428](#)
- [Output Fields | 1428](#)
- [Sample Output | 1428](#)
- [Release Information | 1428](#)

## Syntax

```
clear accounting server statistics archival-transfer
```

## Description

Clears the statistics of transfer attempted, succeeded, and failed for accounting statistics files and router configuration archives.

## Options

This command has no options.

## Required Privilege Level

clear

## Output Fields

When you enter this command, the transfer statistics are cleared.

## Sample Output

clear accounting server statistics archival-transfer

```
user@host> clear accounting server statistics archival-transfer
```

## Release Information

Command introduced in Junos OS Release 19.2.

# clear captive-portal

### IN THIS SECTION

- [Syntax | 1429](#)
- [Description | 1429](#)
- [Options | 1429](#)
- [Required Privilege Level | 1429](#)
- [Output Fields | 1430](#)
- [Sample Output | 1430](#)

## Syntax

```
clear captive-portal (firewall [interface-names] | interface (802.1X) (all | [interface-names])  
| mac-address [mac-addresses])
```

## Description

Reset the authentication state of a captive portal interface or captive portal firewall statistics on one or more interfaces.

## Options

<b>firewall</b> [ <i>interface-names</i> ]	Resets captive portal statistics on all interfaces or on the specified interface.
<b>interface</b> (all   <i>interface-names</i> )	Resets the authentication state of users connected to all interfaces or the specified interfaces.
<b>mac-address</b> <i>mac-addresses</i>	Resets the authentication state for the specified MAC addresses.

## Required Privilege Level

view

## Output Fields

Table 44 on page 1430 lists the output fields for the `clear captive-portal interface` command. (The `clear captive-portal firewall` and `clear captive-portal mac-address` commands have no output). Output fields are listed in the approximate order in which they appear.

**Table 44: clear captive-portal interface Output Fields**

Field Name	Field Description
<b>Interface</b>	Interface on which captive portal has been configured.
<b>State</b>	<p>The state of the port:</p> <ul style="list-style-type: none"> <li>• <b>Authenticated</b>—The client has been authenticated through the RADIUS server or has been permitted access through server fail fallback.</li> <li>• <b>Authenticating</b>—The client is authenticating through the RADIUS server.</li> <li>• <b>Connecting</b>—Switch is attempting to contact the RADIUS server.</li> <li>• <b>Initialize</b>—The interface link is down.</li> <li>• <b>Held</b>—An action has been triggered through server fail fallback during a RADIUS server timeout. A supplicant is denied access, permitted access through a specified VLAN, or maintains the authenticated state granted to it before the RADIUS server timeout occurred.</li> </ul>
<b>MAC address</b>	The MAC address of the connected client on the interface.
<b>User</b>	Users connected to the captive portal interface.

## Sample Output

`clear captive-portal interface`

```
user@switch> clear captive-portal interface
ge-0/0/3.0
```

## clear captive-portal interface

```
user@switch> clear captive-portal interface
Captive Portal Information:
Interface      State           MAC address     User
ge-0/0/3.0     Authenticated   00:03:47:e1:ba:b9  aclallow
ge-0/0/5.0     Connecting
ge-0/0/7.0     Connecting
ge-0/0/9.0     Connecting
```

## clear captive-portal mac-address

```
user@switch> clear captive-portal mac-address 00:03:47:e1:ba:b9
```

This command has no output.

## clear captive-portal firewall

```
user@switch> clear captive-portal firewall
```

This command has no output.

## Release Information

Command introduced in Junos OS Release 10.1.

### RELATED DOCUMENTATION

# clear dot1x

## IN THIS SECTION

- [Syntax | 1432](#)
- [Description | 1432](#)
- [Options | 1433](#)
- [Required Privilege Level | 1433](#)
- [Sample Output | 1434](#)
- [Release Information | 1434](#)

## Syntax

```
clear dot1x (firewall <counter-name> | interface <[interface-name]> | mac-address [mac-addresses] | statistics <interface interface-name>)
```

## Description

Reset the authentication state of an interface or delete 802.1X statistics from the switch. When you reset an interface using the **interface** or **mac-address** options, reauthentication on the interface is also triggered. The switch sends out a multicast message on the interface to restart the authentication of all connected supplicants. If a MAC address is reset, then the switch sends out a unicast message to that specific MAC address to restart authentication.

If a supplicant is sending traffic when the `clear dot1x interface` command is issued, the authenticator immediately initiates reauthentication. This process happens quickly, and it might seem that reauthentication did not occur. To verify that reauthentication has happened, issue the `show dot1x interface detail` command. The values for **Reauthentication due** and **Reauthentication interval** will be about the same.

**CAUTION:** When you clear the learned MAC addresses from an interface using the `clear dot1x interface` command, all MAC addresses are cleared, including those in static MAC bypass list.

If you have enabled Media Access Control Security (MACsec) using static secure association key (SAK) security mode on an EX Series switch, the SAKs are rotated when the `clear dot1x` command is entered. The `clear dot1x` command has no impact on MACsec when MACsec is enabled using static connectivity association keys (CAK) or any other security mode.

## Options

<b>eapol-block</b>	Clear EAPOL block on the interface and allow the switch to receive EAPOL messages from a supplicant connected to that interface.
<b>firewall &lt;counter-name&gt;</b>	Clear 802.1X firewall counter statistics. If the <i>counter-name</i> option is specified, clear 802.1X firewall statistics for that counter.
<b>interface &lt;[interface-name]&gt;</b>	Reset the authentication state of all the supplicants (also, clears all the authentication bypassed clients) connected to the specified interface (when the interface is an authenticator) or reset the authentication state for the interface itself (when the interface is a supplicant).
<b>mac-address [mac-addresses]</b>	Reset the authentication state of the specified MAC addresses.
<b>statistics &lt;interface interface-name&gt;</b>	Clear 802.1X statistics on all 802.1X-enabled interfaces. If the <b>interface</b> option is specified, clear 802.1X firewall statistics for that interface or interfaces.

## Required Privilege Level

view

## Sample Output

### clear dot1x firewall

```
user@switch> clear dot1x firewall c1
```

### clear dot1x interface (Specific Interfaces)

```
user@switch> clear dot1x interface ge-1/0/0 ge-2/0/0 ge-2/0/0 ge5/0/0
```

### clear dot1x mac-address (Specific MAC Address)

```
user@switch> clear dot1x mac-address 00:04:ae:cd:23:5f
```

### clear dot1x statistics interface (Specific Interface)

```
user@switch> clear dot1x statistics interface ge-1/0/1
```

### clear dot1x eapol-block

```
user@switch> clear dot1x eapol-block
```

## Release Information

Command introduced in Junos OS Release 9.0.

**firewall** option added in Junos OS Release 9.5 for EX Series switches.

Support for **eapol-block** introduced in Junos OS Releases 14.1X53-D40 and 15.1X53-D51 for EX Series switches.

## Syntax

```
request message all message "text"  
request message message "text" (terminal terminal-name | user user-name)
```

## Description

Display a message on the screens of all users who are logged in to the router or switch or on specific screens.

## Options

<b>all</b>	Display a message on the terminal of all users who are currently logged in.
<b>message</b> <i>"text"</i>	Message to display.
<b>terminal</b> <i>terminal-name</i>	Name of the terminal on which to display the message.
<b>user</b> <i>user-name</i>	Name of the user to whom to direct the message.

## Required Privilege Level

maintenance

## Output Fields

When you enter this command, you are provided feedback on the status of your request.

## Sample Output

**request message message**

```
user@host> request message message "Maintenance window in 10 minutes" user maria
Message from user@host on tty0 at 20:27 ...
Maintenance window in 10 minutes
EOF
```

## Syntax

```
request security certificate enroll filename filename subject subject  
alternative-subject alternative-subject certification-authority certification-authority  
encoding (binary | pem) key-file key-file domain-name domain-name
```

## Description

(Encryption interface on M Series and T Series routers and EX Series switches only) Obtain a signed certificate from a certificate authority (CA). The signed certificate validates the CA and the owner of the certificate. The results are saved in a specified file to the **/var/etc/ikecert** directory.

**NOTE:** For FIPS mode, the digital security certificates must be compliant with the National Institute of Standards and Technology (NIST) SP 800-131A standard. The `request security key-pair` command is deprecated and not available with Junos in FIPS mode because it generates RSA and DSA keys with sizes of 512 and 1024 bits that are not compliant with the NIST SP 800-131A standard.

## Options

<b>filename</b> <i>filename</i>	File that stores the certificate.
<b>subject</b> <i>subject</i>	Distinguished name ( <b>dn</b> ), which consists of a set of components—for example, an organization ( <b>o</b> ), an organization unit ( <b>ou</b> ), a country ( <b>c</b> ), and a locality ( <b>l</b> ).
<b>alternative-subject</b> <i>alternative-subject</i>	Tunnel source address.
<b>certification-authority</b> <i>certification-authority</i>	Name of the certificate authority profile in the configuration.
<b>encoding</b> (binary   pem)	File format used for the certificate. The format can be a binary file or privacy-enhanced mail (PEM), an ASCII base64-encoded format. The default format is binary.
<b>key-file</b> <i>key-file</i>	File containing a local private key.
<b>domain-name</b> <i>domain-name</i>	Fully qualified domain name.

## Required Privilege Level

maintenance

## Output Fields

When you enter this command, you are provided feedback on the status of your request.

## Sample Output

**request security certificate enroll filename subject alternative-subject certification-authority key-file domain-name (Signed)**

```
user@host> request security certificate enroll filename host.crt subject c=uk,o=london
alternative-subject 10.50.1.4 certification-authority verisign key-file
```

```

host-1.prv domain-name host.example.com
CA name: example.com CA file: ca_verisign
local pub/private key pair: host.prv
subject: c=uk,o=london domain name: host.example.com
alternative subject: 10.50.1.4
Encoding: binary
Certificate enrollment has started. To view the status of your enrollment, check the key
management process (kmd) log file at /var/log/kmd. <-----

```

## Release Information

Command introduced before Junos OS Release 7.4.

## Syntax

```
request security key-pair filename
<size key-size>
<type (rsa | dsa)>
```

## Description

(Encryption interface on M Series and T Series routers and EX Series switches only) Generate a public and private key pair for a digital certificate.

**NOTE:** The `request security-certificates` command is deprecated and are not available with Junos in FIPS mode because security certificates are not compliant with the NIST SP 800-131A standard.

## Options

- filename***      Name of a file in which to store the key pair.
- size key-size***      (Optional) Key size, in bits. The key size can be **512**, **1024**, or **2048**. The default value is **1024**.
- type***      (Optional) Algorithm used to encrypt the key:
- **rsa**—RSA algorithm. This is the default.
  - **dsa**—Digital signature algorithm with Secure Hash Algorithm (SHA).

## Required Privilege Level

maintenance

## Output Fields

When you enter this command, you are provided feedback on the status of your request.

## Sample Output

**request security key-pair**

```
user@host> request security key-pair security-key-file
```

## Release Information

Command introduced before Junos OS Release 7.4.

# request security pki generate-key-pair

### IN THIS SECTION

- [Syntax | 1463](#)

## Syntax

```
request security pki generate-key-pair certificate-id certificate-id-name  
<size (512 | 1024 | 2048)>  
<type (dsa | rsa)>
```

## Description

Generate a public key infrastructure (PKI) public/private key pair for a local digital certificate.

## Options

<b>certificate-id</b> <i>certificate-id-name</i>	Name of the local digital certificate and the public/private key pair.
<b>size</b>	(Optional) Key pair size. The key pair size can be <b>512</b> , <b>1024</b> , or <b>2048</b> bits. If a key pair size is not specified, the default value, <b>1024</b> bits, is applied.
<b>type</b>	(Optional) The algorithm to be used for encrypting the public/private key pair. The encryption algorithm can be <b>dsa</b> or <b>rsa</b> . If an encryption algorithm is not specified, the default value, <b>rsa</b> , is applied.

## Required Privilege Level

maintenance

## Output Fields

When you enter this command, you are provided feedback on the status of your request.

## Sample Output

**request security pki generate-key-pair**

```
user@switch> request security pki generate-key-pair certificate-id billy size 2048
Generated key pair billy, key size 2048 bits
```

## Release Information

Command introduced in Junos OS Release 11.1.

# request security ssh key-pair-identity generate

### IN THIS SECTION

- [Syntax | 1468](#)
- [Description | 1468](#)
- [Options | 1468](#)
- [Required Privilege Level | 1468](#)
- [Output Fields | 1469](#)
- [Sample Output | 1469](#)
- [Release Information | 1469](#)

## Syntax

```
request security ssh key-pair-identity generate <identity-name> passphrase passphrase
```

## Description

Generate the SSH private and public key pair for a specified identity. The private and public key files are stored in the `/var/db` directory, which is accessible through root only. Filenames are based on the `identity-name` with extensions. The files are similar to the certificate files that are stored in Junos OS.

## Options

- `identity-name`—Identity name.
- `passphrase passphrase`— An SSH identity generated with a passphrase. The passphrase is used to protect the private key file stored in the file system. This option does not allow the user to enter a weak passphrase, which ensures stronger security. A private key is used to connect to a remote server and is never displayed or transferred between servers, even if the system is compromised. The private key cannot be used to connect to a remote server if the passphrase is not known.

**NOTE:** By default, the passphrase uses Advanced Encryption Standard (AES) 128 in cipher block chaining (CBC) mode to encrypt a private key. All generated keys are stored in the `/var/db/ssh_key` directory.

## Required Privilege Level

maintenance

## Output Fields

When you enter this command, you are provided feedback on the status of your request.

## Sample Output

**request security ssh key-pair-identity with passphrase**

```
user@host> request security ssh key-pair-identity generate myident passphrase 1q2w3e
Created SSH key myident
```

## Release Information

Command introduced in Junos OS Release 15.1X49-D70.

# request system autorecovery state

## IN THIS SECTION

- [Syntax | 1472](#)
- [Description | 1472](#)
- [Options | 1472](#)
- [Required Privilege Level | 1473](#)
- [Output Fields | 1473](#)
- [Sample Output | 1473](#)
- [Sample Output | 1474](#)
- [Sample Output | 1474](#)
- [Release Information | 1475](#)

## Syntax

```
request system autorecovery state (save | recover | clear)
```

## Description

Use this command to prepare the system for autorecovery of configuration, licenses, and disk information.

## Options

**save**      Save the current state of the disk partitioning, configuration, and licenses for autorecovery.

The active Junos OS configuration is saved as the Junos rescue configuration, after which the rescue configuration, licenses, and disk partitioning information is saved for autorecovery. Autorecovery information must be initially saved using this command for the autorecovery feature to verify integrity of data on every bootup.

Any recovery performed at a later stage will restore the data to the same state as it was when the save command was executed.

A fresh rescue configuration is generated when the command is executed. Any existing rescue configuration will be overwritten.

**recover** Recover the disk partitioning, configuration, and licenses.

After autorecovery data has been saved, the integrity of saved items is always checked automatically on every bootup. The recovery command allows you to forcibly re-run the tests at any time if required.

**clear** Clear all saved autorecovery information.

Only the autorecovery information is deleted; the original copies of the data used by the router are not affected. Clearing the autorecovery information also disables all autorecovery integrity checks performed during bootup.

## Required Privilege Level

maintenance

## Output Fields

When you enter this command, you are provided feedback on the status of your request.

## Sample Output

**request system autorecovery state save**

```
user@host> request system autorecovery state save
Saving config recovery information
```

```
Saving license recovery information
Saving bsdlable recovery information
```

## Sample Output

### request system autorecovery state recover

```

## Syntax

```
request system download resume download-id <max-rate>
```

## Description

Use this command to resume a download that has been paused. You can resume the downloaded instances that are not in progress because of an error or that have been explicitly paused. The file will continue downloading from the point where it paused. By default, the download resumes with the same bandwidth specified with the `request system download start` command. You can specify a new (maximum) bandwidth with the `request system download resume` command.

Downloads in the paused and error states can be resumed.

## Options

`download-id`—(Required) The ID number of the download to be resumed.

`max-rate`—(Optional) The maximum bandwidth for the download.

## Required Privilege Level

maintenance

## Output Fields

When you enter this command, you are provided feedback on the status of your request.

## Sample Output

`request system download resume`

```

## Syntax

```
request system download start (sftp-url / delay / identity-file / login / max-rate / passphrase  
/ save as )
```

## Description

Use this command to create a download instance and identify it with a unique integer called the download ID.

## Options

`sftp-url`—(Required) The FTP or HTTP URL location of the file to be downloaded securely.

`delay`—(Optional) The number of hours after which the download should start. Ranges from 1 through 48 hours.

`identity-file`—(Required) The name of the file requesting a Secure FTP (SFTP) download. The SFTP in smart download leverages public key authentication to authenticate a download request. You must generate a private or public key pair before starting a download, and then upload a public key to an SFTP server.

`login`—(Optional) The username and password for the server in the format `username:password`.

`max-rate`—(Optional) The maximum average bandwidth for the download. Numbers with the suffix k or K, m or M, and g or G are interpreted as Kbps, Mbps, or Gbps, respectively.

`passphrase`—(Required) The passphrase to protect the private key file stored on the file system. This option does not allow the user to enter a weak passphrase, which ensures stronger security.

`save-as`—(Optional) The filename to be used for saving the file in the `/var/tmp` location.

## Required Privilege Level

maintenance

## Output Fields

When you enter this command, you are provided feedback on the status of your request.

- [Syntax | 1489](#)
- [Prerequisites | 1489](#)
- [Description | 1489](#)
- [Required Privilege Level | 1489](#)
- [Sample Output | 1490](#)
- [Release Information | 1492](#)

## Syntax

```
request system filesystem encryption enable
```

## Prerequisites

Following are the prerequisites to enable file-system encryption:

- System contains a TPM2.0 with IDevID provisioned.
- System having single or redundant disk are supported.
- Take data backup of configurations and log files.

## Description

When you enable encryption process on the file-system, the conversion process starts with the backup routing engine followed by the active routing engine. In the case of redundant disks, the conversion starts with the primary disk followed by the secondary disk to avoid loss of data.

Once enabled, the encryption cannot be disabled and all the software image versions that does not support file-system encryption are deleted.

## Required Privilege Level

maintenance

## Sample Output

**request system filesystem encryption enable**

```
user@host> request system filesystem encryption enable
```

You are about to encrypt LVM partitions on "/dev/sda5 and /dev/sdb5"

LVM volumes currently on /dev/sda5

```
jvg_P-jlvmjunos
jvg_P-jlvmrootrw
jvg_P-jlvmspare
jvg_P-jlvmmvm
```

The swap partition on /dev/sda6 will be deleted and added to VG jvg\_P

LVM volumes currently on /dev/sdb5

```
jvg_S-jlvmjunos
jvg_S-jlvmrootrw
jvg_S-jlvmspare
jvg_S-jlvmmvm
```

The swap partition on /dev/sdb6 will be deleted and added to VG jvg\_S

Type YES to continue: ? YES

Preparing partition /dev/sda5 for encryption

Fixing PV device size

Physical volume "/dev/sda5" changed

1 physical volume(s) resized or updated / 0 physical volume(s) not resized

Logical volume "jlvmswap" created.

Setting up swapspace version 1, size = 108 MiB (113242112 bytes)

no label, UUID=72162649-0bdd-4827-bc83-0e18278f5aac

Preparing partition /dev/sdb5 for encryption

Fixing PV device size

Physical volume "/dev/sdb5" changed

1 physical volume(s) resized or updated / 0 physical volume(s) not resized

Logical volume "jlvmswap" created.

Setting up swapspace version 1, size = 108 MiB (113242112 bytes)

no label, UUID=d89d3741-feb7-4152-8883-de5a9a2d1e5d

During the conversion process, the vmhost reboot using request `vmhost reboot` is required to start file-system encryption and to reflect the changes.

```
user@host> request vmhost reboot
```

```
error: no suitable video mode found.

## Syntax

```
request system filesystem encryption keys  
<delete>
```

## Description

Key slots are the Keys used to encrypt an area or slot on the hard disk. You must enable file-system encryption on the disk before deleting the key slots. After deleting the key slots, reboot the vmhost to reflect the changes.

## Options

<b>delete</b>	Erase all keyslots.
---------------	---------------------

## Required Privilege Level

maintenance

## Sample Output

**request system filesystem encryption keys delete**

```
user@host> request system filesystem encryption keys delete
```

```
You are about to erase all keyslots on /dev/sda5 and /dev/sdb5, this  
is potentially dangerous, you will not be able to unlock encrypted  
filesystems after this step. Only continue if you sure of what you  
are doing.
```

```
Type YES to continue: ? YES
```

```
Erasing keyslots on LUKS2 device /dev/sda5
```

```
Erasing keyslots on LUKS2 device /dev/sdb5
```

```
All keyslots erased, a vmhost reboot is needed for changes to take effect
```

```
user@host> request vmhost reboot
```

## Release Information

Command introduced in Junos OS Release 22.3R1.

## Syntax

```
request system firmware upgrade
<cb>
<fpc>
<fpm>
<ftc slot (0 | 1)>
<pem slot slot-number mcu (primary | secondary)>
<poe fpc-slot slot-number> <psm>
<psm>
<re>
<sfb slot slot-number tag tag-number>
<vcpu>
<optics [fpc-slot fpc-slot-number | pic-slot pic-slot-number | port port-number]>
```

## Description

Use this command to upgrade firmware and optics module on a system running either Junos OS or Junos OS Evolved.

## Options

- |            |   |
|------------|---|
| <b>cb</b>  | (ACX7100 Series routers, MX10004, and MX10008 routers) Upgrade baseboard FPGA. <ul style="list-style-type: none"><li>• <b>fancpld</b>—(Optional) Upgrade fanboard CPLD.</li><li>• <b>optics</b>—(Optional) Upgrade optics CPLD.</li></ul> |
| <b>fpc</b> | Upgrade FPC ROM monitor.  |

- `bcm-pfe`—(Optional) Upgrade BCM PFE chip.
- `slot slot-number`—(Optional) Upgrade all devices in a particular FPC slot.

After you upgrade the firmware on the LC9600 line card, the line card may go offline. If this happens, use the `request chassis fpc slot-number restart` command to restart the line card.

<code>fpm</code>	(MX10004 and MX10008 routers) Upgrade front panel module firmware.
<code>ftc slot (0   1)</code>	(MX10004 and MX10008 routers) Upgrade fan tray controller firmware.
<code>pic</code>	(Junos OS only) Upgrade PIC firmware.
<code>pem slot slot-number mcu (primary   secondary)</code>	(Junos OS only—PTX10008, PTX10016, QFX10008, QFX10016, MX10004, MX10008, MX10016, and MX304 devices) Upgrade PEM firmware. The <code>mcu</code> option upgrades the firmware on one micro controller unit at a time, applies only to the MX304 router, and is required for the MX304 PEM firmware upgrade.
<code>poe fpc-slot slot-number</code>	Upgrade Power over Ethernet (PoE) firmware.
<code>psm</code>	Upgrade power supply module firmware. <ul style="list-style-type: none"> <li>• <code>slot slot-number</code>—(Optional) Upgrade a particular power supply module.</li> </ul>
<code>re</code>	Upgrade baseboard BIOS/FPGA. There is an active BIOS image and a backup BIOS image. <ul style="list-style-type: none"> <li>• <code>bios</code>—(Optional) Upgrade BIOS.</li> <li>• <code>fpga</code>—(Optional) Upgrade baseboard FPGA.</li> <li>• <code>i210</code>—(Optional) Upgrade baseboard i210 GbE NIC.</li> <li>• <code>i40nvm</code>—(Optional) Upgrade baseboard i40. <p>Starting in Junos OS Release 19.3R1, you can upgrade the i40e NVM firmware on routers with VM Host support.</p> </li> <li>• <code>ssd</code>—(Optional) Upgrade Routing Engine solid-state drive (SSD) firmware. <ul style="list-style-type: none"> <li>• <code>disk1</code>—Upgrade SSD disk1 firmware.</li> <li>• <code>disk2</code>—Upgrade SSD disk2 firmware.</li> </ul> <p>Starting in Junos OS Release 17.2R1, you can upgrade the SSD firmware on routers with the VM Host support.</p> </li> </ul>

- xmcfgpga—(Optional) Upgrade XMC FPGA.

**sfb slot**  
**slot-number**  
**tag tag-**  
**number**

(MX10004 and MX10008 routers) Upgrade the SF2 and SFB2 switch fabric firmware. *slot-number* can be 0 to 5. For tag *tag-number* option, specify the tag number that indicates you want to update the FPGA. To find out what number you should use for the tag option, issue the show system firmware command. For example, on the MX10004 router, the show system firmware command shows the tag numbers in the third column as follows:

user@host> show system firmware

Part	Type	Tag	Current version	Available version	Status
[output truncated]					
...					
SFB 0	FPGA PRIM	0	0.13.0	0.13.0	
OK					
SFB 1	FPGA PRIM	0	0.13.0	0.13.0	
OK					
SFB 2	FPGA PRIM	0	0.13.0	0.13.0	
OK					
SFB 3	FPGA PRIM	0	0.13.0	0.13.0	
OK					
SFB 4	FPGA PRIM	0	0.13.0	0.13.0	
OK					
SFB 5	FPGA PRIM	0	0.13.0	0.13.0	
OK					
...					
[output truncated]					

After you upgrade the firmware on the SFB, you must take the SFB offline by using the request chassis sfb slot *slot-number* offline command. Once the SFB is offline, bring the SFB back online and make the new firmware take effect by using the request chassis sfb slot *slot-number* online-reload command.

**vcpu**  
**optics**

- Upgrade VCPU ROM monitor.
- Upgrade optics firmware.
- fpc-slot *fpc-slot-number*—Upgrade optics firmware for a specific FPC slot.
  - pic-slot *pic-slot-number*—Upgrade optics firmware for a specific PIC slot.
  - port *port-number*—Upgrade optics firmware for a specific port.

## Required Privilege Level

maintenance

## Output Fields

When you enter this command, you are provided feedback on the status of your request.

## Sample Output

**request system firmware upgrade**

```

user@host> request system firmware upgrade re bios
Part          Type          Tag Current  Available Status
              version      version
Routing Engine 0 RE BIOS      0   1.5      1.9      OK
Routing Engine 0 RE BIOS Backup 1  1.7      1.9      OK
Perform indicated firmware upgrade ? [yes,no] (no) yes
user@host> request system firmware upgrade re bios backup
Part          Type          Tag Current  Available Status
              version      version
Routing Engine 0 RE BIOS      0   1.5      1.9      OK
Routing Engine 0 RE BIOS Backup 1  1.7      1.9      OK
Perform indicated firmware upgrade ? [yes,no] (no) yes

user@host> request system firmware upgrade re ssd disk1
Part  Type  Tag          Current  Available  Status
              version  version
Routing Engine 0 RE SSD1    4    12028    12029    OK
Perform indicated firmware upgrade ? [yes,no] (no) yes

Firmware upgrade initiated, use "show system firmware" to monitor status.

user@host> request system firmware upgrade pem slot 0
...
...
Firmware upgrade initiated, use "show system firmware" to monitor status.

```

```
user@host> request system firmware upgrade optics fpc-slot 0
...
...
Firmware optics upgrade initiated, use "show system firmware" to monitor status.
```

### **request system firmware upgrade fpc slot**

```
user@host> request system firmware upgrade fpc slot 0
...
...
FPC may go offline after the upgrade, Please restart FPC post upgrade.

"request chassis fpc <slot> restart" command can be used for restarting the fpc.
```

### **request system firmware upgrade sfb**

```
user@host> request system firmware upgrade sfb slot 0 tag 0
...
...
"Firmware upgrade initiated, use "show system firmware" to monitor status. After upgrade, do
"request chassis sfb slot <slot> offline" and "request chassis sfb slot <slot> online-reload"
for new firmware to take effect.
```

## **Release Information**

Command introduced in Junos OS Release 10.2.

cb option added in Junos OS Evolved Releases 21.1R2 and 21.2R1. Support for the MX10004 router added in Junos OS Release 22.3R1.

pem option introduced in Junos OS Release 21.2R1.

optics option introduced in Junos OS Release 21.2R2.

sfb option introduced in Junos OS Release 21.4R1 for the MX10008 router. Support for the MX10004 router added in Junos OS Release 22.3R1.

mcu option introduced in Junos OS Release 22.2R1-S1 and 22.3R1 for the MX304 router.

## Syntax

```
request system license update
```

## Description

Starts autoupdating license keys from the license portal.

- The **request system license update** command always uses the default Juniper license server: **<https://ae1.juniper.net/>**.
- The **request system license update** command is supported only on SRX, vSRX, and QFX Series devices.

The products supported by the [Juniper Agile Licensing](#) (JAL) portal includes: QFX series, SRX Series, EX Series, NFX, vBNG, vMX, vSRX, and ACX. For other Juniper products (SPACE, JSA, SBR Carrier, Screen OS and so on) access the [License Management System](#) (LMS).

## Options

**trial**—Immediately updates trial license keys from the license portal.

## Required Privilege Level

maintenance

## Output Fields

When you enter this command, you are provided feedback on the status of your request.

## Sample Output

**request system license update**

```
user@host> request system license update
```

```
Trying to update license keys from https://ae1.juniper.net has been sent, use show system  
license to check status.
```

**request system license update trial**

```
user@host> request system license update trial
```

```
Request to automatically update trial license keys from https://ae1.juniper.net has been sent,  
use show system license to check status.
```

## Release Information

Command introduced in Junos OS Release 9.5.

# request system reboot (Junos OS)

```

## Description

Use this command to reboot the device software.

This command can be used on standalone devices and on devices supported in a Virtual Chassis, Virtual Chassis Fabric, or QFabric system.

Starting with Junos OS Release 15.1F3, the `request system reboot` command reboots only the guest operating system on the PTX5000 with RE-PTX-X8-64G and, MX240, MX480, and MX960 with RE-S-X6-64G.

Starting with Junos OS Release 15.1F5, the `request system reboot` command reboots only the guest operating system on the MX2010, and MX2020 with REMX2K-X8-64G.

Starting from Junos OS Release 17.2R1, PTX10008 routers do not support the `request system reboot` command. Starting from Junos OS Release 17.4R1, PTX10016 routers do not support the `request system reboot` command. Use the `request vmhost reboot` command instead of the `request system reboot` command on the PTX10008 and PTX10016 routers to reboot the Junos OS software package or bundle on the router. See [request vmhost reboot](#).

Starting from Junos OS Release 19.1R1, the PTX10002-60C router and the QFX10002-60C switch do not support the `request system reboot` command. Use the `request vmhost reboot` command instead of the `request system reboot` command on these devices to reboot the Junos OS software package or bundle on the device. See [request vmhost reboot](#).

On a QFabric system, to avoid traffic loss on the network Node group, switch mastership of the Routing Engine to the backup Routing Engine, and then reboot.

## Options

The options described here are not all supported on every platform or release of Junos OS. Refer to the Syntax sections for the options commonly available on each type of platform.

<b>none</b>	Reboot the software immediately.
<b>all-chassis</b>	(Optional) On a TX Matrix router or TX Matrix Plus router, reboot all routers connected to the TX Matrix or TX Matrix Plus router, respectively.
<b>all-lcc</b>	(Optional) On a TX Matrix router or TX Matrix Plus router, reboot all line card chassis connected to the TX Matrix or TX Matrix Plus router, respectively.
<b>all-members   local   member member-id</b>	<p>(Optional) Specify which member of the Virtual Chassis to reboot:</p> <ul style="list-style-type: none"> <li>• <b>all-members</b>—Reboots each switch that is a member of the Virtual Chassis.</li> <li>• <b>local</b>—Reboots only the local switch (switch where you are logged in).</li> <li>• <b>member member-id</b>—Reboots the specified member switch of the Virtual Chassis</li> </ul>
<b>at time</b>	<p>(Optional) Time at which to reboot the software, specified in one of the following ways:</p> <ul style="list-style-type: none"> <li>• <b>now</b>—Stop or reboot the software immediately. This is the default.</li> <li>• <b>+minutes</b>—Number of minutes from now to reboot the software.</li> <li>• <b>yymmddhhmm</b>—Absolute time at which to reboot the software, specified as year, month, day, hour, and minute.</li> <li>• <b>hh:mm</b>—Absolute time on the current day at which to stop the software, specified in 24-hour time.</li> </ul>
<b>both-routing-engines</b>	(Optional) Reboot both Routing Engines at the same time.
<b>fast-boot</b>	(Optional, QFX Series) Minimizes traffic loss and downtime of network ports by leaving the network ports up during the system reboot.
<b>hypervisor</b>	(Optional) Reboot Junos OS, host OS, and any installed guest VMs.
<b>in minutes</b>	(Optional) Number of minutes from now to reboot the software. The minimum value is 1. This option is an alias for the <b>at +minutes</b> option.

<b>in-service</b>	(Optional) Enables you to reset the software state (no software version change) of the system with minimal disruption in data and control traffic.
<b>junos</b>	(Optional) Reboot from the Junos OS (main) volume.
<b>lcc <i>number</i></b>	<p>—(Optional) Line-card chassis (LLC) number.</p> <p>Replace <i>number</i> with the following values depending on the LCC configuration:</p> <ul style="list-style-type: none"> <li>• 0 through 3, when T640 routers are connected to a TX Matrix router in a routing matrix.</li> <li>• 0 through 3, when T1600 routers are connected to a TX Matrix Plus router in a routing matrix.</li> <li>• 0 through 7, when T1600 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix.</li> <li>• 0, 2, 4, or 6, when T4000 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix.</li> </ul>
<b>media (compact-flash   disk   removable- compact-flash   usb)</b>	(Optional) Use the indicated boot medium for the next boot.
<b>media (external   internal)</b>	<p>(Optional) Use the indicated boot medium for the next boot:</p> <ul style="list-style-type: none"> <li>• <b>external</b>—Reboot the device using a software package stored on an external boot source, such as a USB flash drive.</li> <li>• <b>internal</b>—Reboot the device using a software package stored in an internal memory source.</li> </ul>
<b>message "<i>text</i>"</b>	(Optional) Message to display to all system users before stopping or rebooting the software.
<b>network</b>	(Optional) Reboot using the Preboot Execution Environment (PXE) boot method over the network.
<b>oam</b>	(Optional) Reboot from the maintenance volume (OAM volume, usually the compact flash drive).
<b>other-routing- engine</b>	(Optional) Reboot the other Routing Engine from which the command is issued. For example, if you issue the command from the primary Routing Engine, the backup

Routing Engine is rebooted. Similarly, if you issue the command from the backup Routing Engine, the primary Routing Engine is rebooted.

**partition**  
***partition***

(Optional) Reboot using the specified partition on the boot media. This option is equivalent to the `slice` option that is supported on some devices. Specify one of the following *partition* values:

- 1—Reboot from partition 1.
- 2—Reboot from partition 2.
- alternate—Reboot from the alternate partition.

**scc**

(Optional) Reboot the Routing Engine on the TX Matrix switch-card chassis. If you issue the command from re0, re0 is rebooted. If you issue the command from re1, re1 is rebooted.

**sfc number**

(Optional) Reboot the Routing Engine on the TX Matrix Plus switch-fabric chassis. If you issue the command from re0, re0 is rebooted. If you issue the command from re1, re1 is rebooted. Replace *number* with 0.

**slice *slice***

(Optional) Reboot using the specified partition on the boot media. This option was originally the `partition` option but was renamed to `slice` on EX Series and QFX Series switches. Specify one of the following *slice* values:

- 1—Reboot from partition 1.
- 2—Reboot from partition 2.
- alternate—Reboot from the alternate partition (which did not boot the switch at the last bootup).

**NOTE:** The `slice` option is not supported on QFX Series switches that have no alternate slice when Junos OS boots as a Virtual Machine (VM). To switch to the previous version of Junos OS, issue the `request system software rollback` command.

**usb**

(Optional) Reboot from a USB device.

The following options are available only on QFabric Systems:

<b>all</b>	(Optional) Reboots the software on the Director group, fabric control Routing Engines, fabric manager Routing Engines, Interconnect devices, and network and server Node groups.
<b>director-device name</b>	(Optional) Reboots the software on the Director device and the default partition (QFabric CLI).
<b>director-group</b>	(Optional) Reboots the software on the Director group and the default partition (QFabric CLI).
<b>fabric</b>	(Optional) Reboots the fabric control Routing Engines and the Interconnect devices.
<b>node-group name</b>	(Optional) Reboots the software on a server Node group or a network Node group.
<b>graceful</b>	(Optional) Enables the QFabric component to reboot with minimal impact to network traffic. This sub-option is only available for the <code>all</code> , <code>fabric</code> , and <code>director-group</code> options.

## Additional Information

Reboot requests are recorded in the system log files, which you can view with the `show log` command (see *show log*). Also, the names of any running processes that are scheduled to be shut down are changed. You can view the process names with the `show system processes` command (see *show system processes*).

On a TX Matrix or TX Matrix Plus router, if you issue the `request system reboot` command on the primary Routing Engine, all the primary Routing Engines connected to the routing matrix are rebooted. If you issue this command on the backup Routing Engine, all the backup Routing Engines connected to the routing matrix are rebooted.

**NOTE:** Before issuing the `request system reboot` command on a TX Matrix Plus router with no options or the `all-chassis`, `all-lcc`, `lcc number`, or `sfc` options, verify that primary Routing Engine for all routers in the routing matrix are in the same slot number. If the primary Routing Engine for a line-card chassis is in a different slot number than the primary Routing Engine for a TX Matrix Plus router, the line-card chassis might become logically disconnected from the routing matrix after the `request system reboot` command.

**NOTE:** To reboot a router that has two Routing Engines, reboot the backup Routing Engine (if you have upgraded it) first, and then reboot the primary Routing Engine.

## Required Privilege Level

maintenance

## Output Fields

When you enter this command, you are provided feedback on the status of your request.

## Sample Output

### **request system reboot**

```
user@host> request system reboot
Reboot the system ? [yes,no] (no)
```

### **request system reboot (at 2300)**

```
user@host> request system reboot at 2300 message ?Maintenance time!?
Reboot the system ? [yes,no] (no) yes

shutdown: [pid 186]
*** System shutdown message from root@test.example.net ***
System going down at 23:00
```

### **request system reboot (in 2 Hours)**

The following example, which assumes that the time is 5 PM (17:00), illustrates three different ways to request the system to reboot in two hours:

```
user@host> request system reboot at +120
user@host> request system reboot in 120
user@host> request system reboot at 19:00
```

## request system reboot (Immediately)

```
user@host> request system reboot at now
```

## request system reboot (at 1:20 AM)

To reboot the system at 1:20 AM, enter the following command. Because 1:20 AM is the next day, you must specify the absolute time.

```
user@host> request system reboot at 06060120
request system reboot at 120
Reboot the system at 120? [yes,no] (no) yes
```

## request system reboot in-service

```
user@switch> request system reboot in-service
Reboot the system ? [yes,no] yes

- [Description | 1514](#)
- [Options | 1514](#)
- [Required Privilege Level | 1514](#)
- [Release Information | 1515](#)

## Syntax

```
request system reboot <at time> <in minutes><media><message "text">
```

## Description

Reboot the software.

## Options

- **at *time*** (Optional)— Specify the time at which to reboot the device. You can specify time in one of the following ways:
  - **now**— Reboot the device immediately. This is the default.
  - **+*minutes***— Reboot the device in the number of minutes from now that you specify.
  - ***yymmddhhmm***— Reboot the device at the absolute time on the date you specify. Enter the year, month, day, hour (in 24-hour format), and minute.
  - ***hh:mm***— Reboot the device at the absolute time you specify, on the current day. Enter the time in 24-hour format, using a colon (:) to separate hours from minutes.
- **in *minutes*** (Optional)— Specify the number of minutes from now to reboot the device. This option is a synonym for the **at +minutes** option
- **media *type*** (Optional)— Specify the boot device to boot the device from:
  - **disk/internal**— Reboot from the internal media. This is the default.
  - **usb**— Reboot from the USB storage device.
  - **compact flash**— Reboot from the external CompactFlash card.

**NOTE:** The `media` command option is not available on vSRX.

- **message "*text*"** (Optional)— Provide a message to display to all system users before the device reboots.

Example: **request system reboot at 5 in 50 media internal message stop**

- [Description | 1515](#)
- [Options | 1516](#)
- [Required Privilege Level | 1516](#)
- [Release Information | 1516](#)

## Syntax

```
request system reboot usb <yes|no>
```

## Description

Use this command to boot from the USB, without power cycling the SRX device. This command helps to detect USB with a soft reboot and provides the user with control over the boot sequence for soft reboot without turning off the device.

## Options

- yes – Reboot system
- No – Do not reboot system

## Required Privilege Level

maintenance

## Release Information

Command introduced in Junos OS Release 21.2R1.

# request system snapshot (Maintenance)

### IN THIS SECTION

- [Syntax | 1517](#)
- [Description | 1517](#)
- [Options | 1517](#)
- [Required Privilege Level | 1518](#)
- [Output Fields | 1518](#)
- [Sample Output | 1519](#)
- [Release Information | 1520](#)

## Syntax

```
request system snapshot
<config-partition>
<media (compact-flash | hard-disk | internal | usb)>
<partition>
<root-partition>
<factory>
<node (all | local | node-id | primary)>
<slice (alternate) >
```

## Description

Use this command to back up the currently running and active file system partitions on the device.

## Options

- **config-partition**— Creates a snapshot of the configuration partition only and stores it onto the default **/altconfig** on the hard disk device or an **/altconfig** on a USB device.
- **root-partition**— Creates a snapshot of the root partition only and stores it onto the default **/altroot** on the hard disk device or an **/altroot** on a USB device.
- **factory**— (Optional) Specifies that only the files shipped from the factory are included in the snapshot.
- **media**—(Optional) Specify the boot device the software is copied to:
  - **compact-flash**—Copy software to the primary compact flash drive.
  - **hard-disk**— Copy software to the hard disk.
  - **usb**— Copy software to the device connected to the USB port.
  - **internal**— Copy software to an internal flash drive. This is the default option.

USB option is available on all SRX series devices; hard disk and compact-flash options are available only on SRX5800, SRX5600, and SRX5400 devices; media internal option is available only on SRX300, SRX320, SRX340, SRX345, SRX380, and SRX550M devices.

- **external**— Copies software to an external storage device. This option is available for the compact flash on the SRX650 Services Gateway.
- **node**—(Optional) Specify the archive data and executable areas of a specific node. If you do not specify the node option, the device considers the current node as default option.
  - **node-id**—Specify for node (0, 1).
  - **all**—Specify for all nodes.
  - **local**—Specify for local nodes.
  - **primary**— Specify for primary nodes.
- **partition**—(Default) Specify that the target media should be repartitioned before the backup is saved to it.

The target media is partitioned whether or not it is specified in the command, because this is a mandatory option.

Example: **request system snapshot media usb partition**

Example: **request system snapshot media usb partition factory**

- **slice**—(Optional) Take a snapshot of the root partition the system has currently booted from to another slice in the same media.
  - **alternate**—(Optional) Store the snapshot on the other root partition in the system.

The slice option cannot be used along with the other `request system snapshot` options, because the options are mutually exclusive. If you use the `factory`, `media`, or `partition` option, you cannot use the `slice` option; if you use the `slice` option, you cannot use any of the other options.

## Required Privilege Level

The following filesystems were archived: / /config
```

## Release Information

Command introduced in Junos OS Release 10.2.

# request system software abort in-service-upgrade (ICU)

### IN THIS SECTION

- [Syntax | 1521](#)
- [Description | 1521](#)
- [Options | 1521](#)

- [Required Privilege Level | 1521](#)
- [Output Fields | 1522](#)
- [Sample Output | 1522](#)
- [Release Information | 1522](#)

## Syntax

```
request system software abort in-service-upgrade
```

## Description

Use this command to terminate an in-band cluster upgrade (ICU).

This command must be issued from a router session other than the one on which you issued the `request system in-service-upgrade` command that launched the ICU. If an ICU is in progress, this command terminates it. If the node is being upgraded, this command will cancel the upgrade. This command is also helpful in recovering the node in case of a failed ICU.

We recommend that you use the command only when there is an issue with the ongoing session of ISSU. You may need to manually intervene to bring the system to sane state if after issuing the command the system does not recover from the terminate.

## Options

This command has no options.

## Required Privilege Level

view

## Output Fields

When you enter this command, you are provided feedback on the status of your request.

## Sample Output

**request system software abort in-service-upgrade**

```
user@host> request system software abort in-service-upgrade
In-Service-Upgrade aborted
```

## Release Information

Command introduced in Junos OS Release 15.1X49-D35.

### RELATED DOCUMENTATION

- [Description | 1523](#)
- [Options | 1523](#)
- [Required Privilege Level | 1523](#)
- [Release Information | 1523](#)

## Syntax

```
request system software add package-name
```

## Description

Use this command to install new software package on the device, for example: **request system software add junos-srxsme-10.0R2-domestic.tgz no-copy no-validate partition reboot**.

## Options

- **delay-restart**—Install the software package but does not restart the software process.
- **best-effort-load**—Activate a partial load and treat parsing errors as warnings instead of errors.
- **no-copy**—Install the software package but does not saves the copies of package files.
- **no-validate**—Do not check the compatibility with current configuration before installation starts.
- **partition**—Format and re-partition the media before installation.
- **reboot**—Reboot the device after installation is completed.
- **unlink**—Remove the software package after successful installation.
- **validate**—Check the compatibility with current configuration before installation starts.

## Required Privilege Level

maintenance

## Release Information

Partition option introduced in the command in Junos OS Release 10.1.

# request system software rollback (SRX Series)

## IN THIS SECTION

- [Syntax | 1524](#)
- [Description | 1524](#)
- [Options | 1524](#)
- [Required Privilege Level | 1525](#)
- [Release Information | 1525](#)

## Syntax

```
request system software rollback <node-id>
```

## Description

Use this command to revert to the software that was loaded at the last successful `request system software add` command. The upgraded FreeBSD 11.x (supported in Junos OS Release 17.4R1) Junos OS image provides an option to save a recovery image in an Operation, Administration, and Maintenance (OAM) partition, but that option will save only the Junos OS image, not the Linux image. If a user saves the Junos OS image and recovers it later, it might not be compatible with the Linux software loaded on the system.

## Options

*node-id*—Identification number of the chassis cluster node. It can be 0 or 1.

## Required Privilege Level

maintenance

## Release Information

Command introduced in Junos OS Release 10.1.

# request system zeroize

### IN THIS SECTION

- [Syntax | 1525](#)
- [Description | 1526](#)
- [Options | 1526](#)
- [Required Privilege Level | 1526](#)
- [Sample Output | 1527](#)

## Syntax

```
request system zeroize <media>
```

## Description

Erases all configuration information and resets all key values. The command removes all data files, including customized configuration and log files, by unlinking the files from their directories.

The command removes all user-created files from the system including all plain-text passwords, secrets, and private keys for SSH, local encryption, local authentication, IPsec, RADIUS, TACACS+, and SNMP.

This command reboots the device and sets it to the factory default configuration. After the reboot, you cannot access the device through the management Ethernet interface. Log in through the console as root and start the Junos OS CLI by typing `cli` at the prompt.

## Options

**media** (Optional) In addition to removing all configuration and log files, the `media` option causes memory and the media to be scrubbed, removing all traces of any user-created files. Every storage device attached to the system is scrubbed, including disks, flash drives, removable USBs, and the like. The duration of the scrubbing process is dependent on the size of the media being erased. As a result, the request system zeroize media operation can take considerably more time than the request system zeroize operation. However, the critical security parameters are all removed at the beginning of the process.

**NOTE:** The `media` option is not supported on SRX5000 line devices.

## Required Privilege Level

Not applicable.

## Sample Output

### request system zeroize

```

user@host> request system zeroize
warning: System will be rebooted and may not boot without configuration
Erase all data, including configuration and log files? [yes,no] (no) yes

- [Release Information | 1540](#)

## Syntax

```
show captive-portal interface  
  <interface-name>  
  detail
```

## Description

Display the current operational state of all captive portal interfaces with the list of connected users and the configured values of captive portal attributes on the interfaces.

## Options

<b>none</b>	Display all captive portal interfaces.
<b><i>interface-name</i></b>	(Optional) Display the state for the specified captive portal interface and lists the MAC address and user names of any clients authenticated on the interface.
<b><i>interface-name</i> detail</b>	(Optional) Display the configured values of captive portal attributes on the specified captive portal interface.

## Required Privilege Level

view

## Output Fields

[Table 46 on page 1536](#) lists the output fields for the `show captive-portal interface` command. Output fields are listed in the approximate order in which they appear.

**Table 46: show captive-portal interface Output Fields**

Field Name	Field Description	Level of Output
Interface	Interface on which captive portal has been configured.	All levels

Table 46: show captive-portal interface Output Fields (*Continued*)

Field Name	Field Description	Level of Output
State	<p>The state of the interface:</p> <ul style="list-style-type: none"> <li>• <b>Authenticated</b>—The client has been authenticated through the RADIUS server or has been permitted access through server fail fallback.</li> <li>• <b>Authenticating</b>—The client is authenticating through the RADIUS server.</li> <li>• <b>Connecting</b>—Switch is attempting to contact the RADIUS server.</li> <li>• <b>Initialize</b>—The interface link is down.</li> <li>• <b>Held</b>—An action has been triggered through server fail fallback during a RADIUS server timeout. A supplicant is denied access, permitted access through a specified VLAN, or maintains the authenticated state granted to it before the RADIUS server timeout occurred.</li> </ul>	All levels
MAC address	The MAC address of the connected client on the interface..	brief
User	Users connected to the captive portal interface.	brief
Fallen back	<p>Indicates when 802.1X authentication and captive portal are both enabled on an interface:</p> <ul style="list-style-type: none"> <li>• If 802.1X authentication and captive portal are both enabled, <b>CP fallen back</b> status is <b>Yes</b>.</li> <li>• If 802.1X authentication and captive portal are not both enabled, <b>CP fallen back</b> status is <b>No</b>.</li> </ul>	
Supplicant mode	Mode used to authenticate clients—multiple, single, or single-supplicant.	detail
Number of retries	Number of times the user can attempt to submit authentication information.	detail
Quiet period	Time, in seconds, after a user exceeds the maximum number of retries before they can attempt to authenticate.	detail

**Table 46: show captive-portal interface Output Fields (Continued)**

Field Name	Field Description	Level of Output
Configured CP session timeout	Time, in seconds, that a client can be idle before the session expires.	detail
Server timeout	Time, in seconds, that an interface will wait for a reply when relaying a response from the client to the authentication server before timing out and invoking the server-fail action.	detail
Configured CP User-keepalive timeout	Time, in minutes, that a captive portal authentication session is extended after the MAC aging timer expires.	detail
Number of connected supplicants	<p>Number of users connecting through the captive portal interface. Information for each user includes:</p> <ul style="list-style-type: none"> <li>• Supplicant—User name and MAC address.</li> <li>• Operational state—See State (above).</li> <li>• Dynamic CP session timeout—Timeout value dynamically downloaded from the RADIUS server for this user, if any.</li> <li>• CP Session expiration due in—Time remaining in session.</li> <li>• Eapol-Block—Shows whether EAPOL block is in effect or not.</li> <li>• CP Session User-keepalive Expiration due in—Time, in seconds, remaining in the keep-alive period.</li> </ul>	detail

## Sample Output

### show captive-portal interface (Only Captive Portal Enabled)

```
user@switch> show captive-portal interface
```

```
Captive Portal Information:
```

```
Interface      State          MAC address    User          Fallen back
```

ge-0/0/1.0	Connecting			
ge-0/0/10.0	Connecting	00:30:48:8c:66:bd	No User	
ge-6/0/5.0	Authenticated	00:30:48:8d:7a:9b	abcdeX	No

### show captive-portal interface (802.1X Authentication and Captive Portal Enabled)

```
user@switch> show captive-portal interface
```

Captive Portal Information:

Interface	State	MAC address	User	Fallen back
ge-0/0/1.0	Connecting			
ge-0/0/10.0	Connecting	00:30:48:8c:66:bd	No User	
ge-6/0/5.0	Authenticated	00:30:48:8d:7a:9b	abcdeX	Yes

### show captive-portal interface detail (Only Captive Portal Enabled)

```
user@switch> show captive-portal interface detail ge-6/0/5.0
```

Supplicant mode: Multiple  
Number of retries: 3  
Quiet period: 60 seconds  
Configured CP session timeout: 3600 seconds  
Server timeout: 15 seconds  
Configured CP User-keepalive timeout: 7 minutes  
CP fallen back: No  
Number of connected supplicants: 1  
    Supplicant: abcdeX, 00:30:48:8d:7a:9b  
        Operational state: Authenticated  
        Dynamic CP Session Timeout: 3600 seconds  
        CP Session Expiration due in: 3583 seconds  
            Eapol-Block: In Effect  
        CP session User-keepalive Expiration due in: 420 seconds

### show captive-portal interface detail (802.1X Authentication and Captive Portal Enabled)

```
user@switch> show captive-portal interface detail ge-6/0/5.0
```

Supplicant mode: Multiple

```

Number of retries: 3
Quiet period: 60 seconds
Configured CP session timeout: 3600 seconds
Server timeout: 15 seconds
CP fallen back: Yes
Number of connected supplicants: 1
    Supplicant: abcdeX, 00:30:48:8d:7a:9b
        Operational state: Authenticated
        Dynamic CP Session Timeout: 3600 seconds
        CP Session Expiration due in: 3583 seconds
        Eapol-Block: In Effect

```

## Output Fields

[Table 47 on page 1542](#) lists the output fields for the `show chassis routing-engine` command. Output fields are listed in the approximate order in which they appear.

**Table 47: show chassis routing-engine Output Fields**

Field Name	Field Description
Temperature	Routing Engine temperature. (Not available for vSRX deployments.)
CPU temperature	CPU temperature. (Not available for vSRX deployments.)
Total memory	<p>Total memory available on the system.</p> <p><b>NOTE:</b> Starting with Junos OS Release 15.1x49-D70 and Junos OS Release 17.3R1, there is a change in the method for calculating the memory utilization by a Routing Engine. The inactive memory is now subtracted from the total available memory. There is thus, a decrease in the reported value for used memory; as the inactive memory is now considered as free.</p>
Control plane memory	Memory available for the control plane.
Data plane memory	Memory reserved for data plane processing.
CPU utilization	Current CPU utilization statistics on the control plane core.
User	Current CPU utilization in user mode on the control plane core.
Background	Current CPU utilization in nice mode on the control plane core.
Kernel	Current CPU utilization in kernel mode on the control plane core.
Interrupt	Current CPU utilization in interrupt mode on the control plane core.
Idle	Current CPU utilization in idle mode on the control plane core.
Model	Routing Engine model.
Start time	Routing Engine start time.

**Table 47: show chassis routing-engine Output Fields (Continued)**

Field Name	Field Description
Uptime	Length of time the Routing Engine has been up (running) since the last start.
Last reboot reason	Reason for the last reboot of the Routing Engine.
Load averages	The average number of threads waiting in the run queue or currently executing over 1-, 5-, and 15-minute periods.

## Sample Output

### show chassis routing-engine (Sample 1 - SRX550M)

```

user@host> show chassis routing-engine
Routing Engine status:
  Temperature           38 degrees C / 100 degrees F
  CPU temperature       36 degrees C / 96 degrees F
  Total memory          512 MB Max   435 MB used ( 85 percent)
    Control plane memory 344 MB Max   296 MB used ( 86 percent)
    Data plane memory    168 MB Max   138 MB used ( 82 percent)
CPU utilization:
  User                  8 percent
  Background            0 percent
  Kernel                4 percent
  Interrupt             0 percent
  Idle                  88 percent
Model                  RE-SRX5500-LOWMEM
Serial ID              AAP8652
Start time             2009-09-21 00:04:54 PDT
Uptime                 52 minutes, 47 seconds
Last reboot reason     0x200:chassis control reset
Load averages:         1 minute   5 minute   15 minute
                      0.12       0.15       0.10

```

## Sample Output

### show chassis routing-engine (Sample 2 - vSRX)

```

user@host> show chassis routing-engine
Routing Engine status:
  Total memory          1024 MB Max   358 MB used ( 35 percent)
  Control plane memory  1024 MB Max   358 MB used ( 35 percent)
  5 sec CPU utilization:
    User                 2 percent
    Background           0 percent
    Kernel               4 percent
    Interrupt            6 percent
    Idle                 88 percent
  Model                 VSRX RE
  Start time            2015-03-03 07:04:18 UTC
  Uptime                2 days, 11 hours, 51 minutes, 11 seconds
  Last reboot reason    Router rebooted after a normal shutdown.
  Load averages:       1 minute   5 minute  15 minute
                       0.07       0.04     0.06

```

## Sample Output

### show chassis routing-engine (Sample 3- SRX5400)

```

user@host> show chassis routing-engine
Routing Engine status:
  Slot 0:
    Current state        Master
    Election priority    Master (default)
    Temperature          31 degrees C / 87 degrees F
    CPU temperature      31 degrees C / 87 degrees F
    DRAM                 16323 MB (16384 MB installed)
    Memory utilization    10 percent
    5 sec CPU utilization:
      User               2 percent
      Background         0 percent
      Kernel             12 percent

```

Interrupt	1 percent
Idle	85 percent
Model	RE-S-1800x4
Serial ID	9016272401
Start time	2019-07-08 01:17:10 PDT
Uptime	2 minutes, 43 seconds
Last reboot reason	Router rebooted after a normal shutdown.
Load averages:	1 minute    5 minute    15 minute
	0.63            0.52            0.24

## Sample Output

### show chassis routing-engine (Sample 4- SRX4100)

```

user@host> show chassis routing-engine
Routing Engine status:
  Temperature                29 degrees C / 84 degrees F
  CPU temperature             29 degrees C / 84 degrees F
  Total memory                1954 MB Max   567 MB used ( 29 percent)
  Memory utilization          24 percent
  5 sec CPU utilization:
    User                      0 percent
    Background                0 percent
    Kernel                    0 percent
    Interrupt                  0 percent
    Idle                       100 percent

Serial ID            BUILTIN
Uptime               17 days, 5 hours, 1 minute, 52 seconds
Last reboot reason   0x4000:VJUNOS reboot
Load averages:      1 minute   5 minute   15 minute
                    0.00       0.00       0.00

```

The Total memory 64 GB is distributed between the routing engine in the form of virtual machine for the TVP platforms (SRX1500, SRX4100, SRX4200) and the rest for the packet forwarding engine (PFE). TVP has a different architecture differentiating PFE from Junos and additional API compatibility. The above mentioned devices are the only ones with this TVP architecture in SRX. The `show chassis routing-engine` command displays only the Routing Engine memory.

## Sample Output

### `show chassis routing-engine` (Sample 5- SRX1500)

```

user@host> show chassis routing-engine
Routing Engine status:

## Syntax

```
show dot1x  
<brief | detail>  
<interface interface-name>
```

## Description

Display the current operational state of all ports with the list of connected users.

This command displays the list of connected supplicants received from the RADIUS authentication server regardless of the session state—that is, for both authenticated supplicants and for supplicants that attempted authentication.

## Options

<b>none</b>	Display information for all authenticator ports.
<b>brief   detail</b>	(Optional) Display the specified level of output.
<b>interface <i>interface-name</i></b>	(Optional) Display information for the specified port with a list of connected supplicants.

## Output Fields

Table 48 on page 1549 lists the output fields for the `show dot1x` command. Output fields are listed in the approximate order in which they appear.

**Table 48: show dot1x Output Fields**

Field Name	Field Description	Level of Output
Interface	Name of a port.	All levels
MAC address	The MAC address of the connected supplicant on the port.	All levels
Role	The 802.1X authentication role of the interface. When 802.1X is enabled on an interface, the role is <b>Authenticator</b> . As <b>Authenticator</b> , the interface blocks LAN access until a supplicant is authenticated through 802.1X or MAC RADIUS authentication.	brief, detail
State	<p>The state of the port:</p> <ul style="list-style-type: none"> <li>• <b>Authenticated</b>—The supplicant has been authenticated through the RADIUS server or has been permitted access through server fail fallback.</li> <li>• <b>Authenticating</b>—The supplicant is authenticating through the RADIUS server.</li> <li>• <b>Held</b>—An action has been triggered through server fail fallback during a RADIUS server timeout. A supplicant is denied access, permitted access through a specified VLAN, or maintains the authenticated state granted to it before the RADIUS server timeout occurred.</li> </ul>	brief
User	The username of the connected supplicant.	brief

Table 48: show dot1x Output Fields (*Continued*)

Field Name	Field Description	Level of Output
Administrative state	<p>The administrative state of the port:</p> <ul style="list-style-type: none"> <li>• <b>auto</b>—Traffic is allowed through the port based on the authentication result (by default).</li> <li>• <b>force-authorize</b>—All traffic flows through the port irrespective of the authentication result. This state is not allowed on an interface whose VLAN membership has been set to <b>dynamic</b>.</li> <li>• <b>force-unauthorize</b>—All traffic drops on the port irrespective of the authentication result. This state is not allowed on an interface whose VLAN membership has been set to <b>dynamic</b>.</li> </ul>	detail
Supplicant	<p>The mode for the supplicant:</p> <ul style="list-style-type: none"> <li>• <b>single</b>—Only the first supplicant is authenticated. All other supplicants who connect later to the port are allowed full access without any further authentication. They effectively “piggyback” on the first supplicant’s authentication.</li> <li>• <b>single-secure</b>—Only one supplicant is allowed to connect to the port. No other supplicant is allowed to connect until the first supplicant logs out.</li> <li>• <b>multiple</b>—Multiple supplicants are allowed to connect to the port. Each supplicant is authenticated individually.</li> </ul>	detail
Quiet period	<p>The number of seconds the port waits following a failed authentication exchange with the supplicant before reattempting the authentication. The default value is 60 seconds. The range is 0 through 65,535 seconds.</p>	detail
Transmit period	<p>The number of seconds the port waits before retransmitting the initial EAPOL PDUs to the supplicant. The default value is 30 seconds. The range is 1 through 65,535 seconds.</p>	detail

Table 48: show dot1x Output Fields (Continued)

Field Name	Field Description	Level of Output
MAC radius	<p>MAC RADIUS authentication:</p> <ul style="list-style-type: none"> <li>• <b>enabled</b>—The switch sends an EAPOL request to the connecting host to attempt 802.1X authentication and if the connecting host is unresponsive, the switch tries to authenticate the host by using the MAC address.</li> <li>• <b>disabled</b>—The default. The switch does not attempt to authenticate the MAC address of the connecting host.</li> </ul>	detail
MAC radius authentication protocol	<p>MAC RADIUS authentication protocol:</p> <ul style="list-style-type: none"> <li>• <b>EAP-MD5</b>—The EAP-MD5 protocol is used for MAC RADIUS authentication. EAP-MD5 is an authentication method belonging to the Extensible Authentication Protocol (EAP) authentication framework. EAP-MD5 is the default authentication protocol.</li> <li>• <b>PAP</b>—The Password Authentication Protocol (PAP) authentication protocol is used for MAC RADIUS authentication.</li> </ul>	detail
MAC radius restrict	The authentication method is restricted to MAC RADIUS only. 802.1X authentication is not enabled.	detail
Reauthentication	<p>The reauthentication state:</p> <ul style="list-style-type: none"> <li>• <b>disable</b>—Periodic reauthentication of the client is disabled.</li> <li>• <b>interval</b>—Sets the periodic reauthentication time interval. The default value is 3600 seconds. The range is 1 through 65,535 seconds.</li> </ul>	detail
Supplicant timeout	The number of seconds the port waits for a response when relaying a request from the authentication server to the supplicant before resending the request. The default value is 30 seconds. The range is 1 through 60 seconds.	detail

Table 48: show dot1x Output Fields (*Continued*)

Field Name	Field Description	Level of Output
Server timeout	The number of seconds the port waits for a reply when relaying a response from the supplicant to the authentication server before timing out. The default value is 30 seconds. The range is 1 through 60 seconds.	detail
Maximum EAPOL requests	The maximum number of times an EAPOL request packet is retransmitted to the supplicant before the authentication session times out. The default value is 2. The range is 1 through 10.	detail
Number of clients bypassed because of authentication	The number of non-802.1X clients granted access to the LAN by means of static MAC bypass. The following fields are displayed: <ul style="list-style-type: none"> <li>• <b>Client</b>—MAC address of the client.</li> <li>• <b>vlan</b> —The name of the VLAN to which the client is connected.</li> </ul>	detail
Guest VLAN member	The VLAN to which a supplicant is connected when the supplicant is authenticated using a guest VLAN. If a guest VLAN is not configured on the interface, this field displays <not configured>.	detail
Multi domain data session count	The number of data sessions that have been authenticated on a multi-domain authentication interface.	detail
Number of connected supplicants	The number of supplicants connected to a port.	detail
Supplicant	The username and MAC address of the connected supplicant.	detail

Table 48: show dot1x Output Fields *(Continued)*

Field Name	Field Description	Level of Output
Authentication method	<p>The authentication method used for a supplicant:</p> <ul style="list-style-type: none"> <li>• CWA Authentication—A supplicant is authenticated by the central Web authentication (CWA) server.</li> <li>• Fail—Authentication failed and supplicant is in Held state.</li> <li>• Guest VLAN—A supplicant is connected to the LAN through the guest VLAN.</li> <li>• MAC RADIUS—A nonresponsive host is authenticated based on its MAC address. The MAC address is configured as permitted on the RADIUS server, the RADIUS server lets the switch know that the MAC address is a permitted address, and the switch opens LAN access to the nonresponsive host on the interface to which it is connected.</li> <li>• RADIUS—A supplicant is configured on the RADIUS server, the RADIUS server communicates this to the switch, and the switch opens LAN access on the interface to which the supplicant is connected.</li> <li>• Server-fail—One of the following fallback actions is in effect because the RADIUS server is unreachable. Indicates whether EAPOL block is in effect, and the amount of time remaining for EAPOL block (in seconds). <ul style="list-style-type: none"> <li>• deny—The supplicant is denied access to the LAN, preventing traffic from flowing from the supplicant through the interface. This is the default server fail fallback action.</li> <li>• permit—The supplicant is permitted access to the LAN as if the supplicant had been successfully authenticated by the RADIUS server.</li> <li>• use-cache—In the event that the RADIUS server times out when the supplicant is attempting reauthentication, the supplicant is reauthenticated only if it was previously authenticated; otherwise, the supplicant is denied LAN access.</li> </ul> </li> </ul>	detail

**Table 48: show dot1x Output Fields (Continued)**

Field Name	Field Description	Level of Output
	<ul style="list-style-type: none"> <li>VLAN—The supplicant is configured to be moved to a specified VLAN if the RADIUS server is unavailable to reauthenticate the supplicant. (The VLAN must already exist on the switch.)</li> <li>Server-reject VLAN—The supplicant received a RADIUS access-reject message from the authentication server and was moved to a server-reject VLAN, a specified VLAN already configured on the switch.</li> </ul>	
Authenticated VLAN	The VLAN to which the supplicant is connected.	detail
Dynamic filter	User policy filter sent by the RADIUS server.	detail
Session Reauth interval	The configured reauthentication interval.	detail
Reauthentication due in	The number of seconds in which reauthentication will occur again for the connected supplicant.	detail
Session Accounting Interim Interval	The number of seconds between interim RADIUS accounting messages.	detail
Accounting Update due in	The number of seconds until the next interim RADIUS accounting update is due.	detail
CWA Redirect URL	The URL used to redirect the supplicant to a central Web server for authentication.	detail
Eapol Block	Shows whether EAPOL block is in effect or not in effect.	detail

## Sample Output

### show dot1x interface brief

```
user@switch> show dot1x interface brief
802.1X Information:
Interface      Role           State           MAC address     User
ge-0/0/1       Authenticator  Authenticated   00:a0:d2:18:1a:c8  user1
ge-0/0/2       Authenticator  Connecting
ge-0/0/3       Authenticator  Held            00:a6:55:f2:94:ae  user3
```

### show dot1x interface detail

- [Release Information | 1559](#)

## Syntax

```
show dot1x accounting attribute
```

## Description

Display the RADIUS accounting attributes sent by the switch, operating as the network access server (NAS), to the RADIUS accounting server. RADIUS accounting attributes convey information that is used to account for a service provided to an authenticated user. The user session statistics are recorded by the accounting server in an accounting log file.

RADIUS accounting attributes are included in Accounting-Request messages sent from the switch to the accounting server. Attribute information is created only if the data for the attribute is available.

## Required Privilege Level

view

## Output Fields

[Table 49 on page 1558](#) lists the output fields for the `show dot1x accounting-attributes` command. Output fields are listed in the approximate order in which they appear.

**Table 49: show dot1x accounting attribute Output Fields**

Field Name	Field Description
Accounting attributes	<p>Shows the value for the RADIUS accounting attributes sent from the NAS to the server. An attribute is displayed only if data is available for that attribute value. The following RADIUS accounting attributes are supported:</p> <ul style="list-style-type: none"> <li>• User-Name—The name of the authenticated user.</li> <li>• NAS-Port—The physical port number of the NAS which is authenticating the user.</li> <li>• Framed-IP-Address—The IP address of the authenticated user.</li> <li>• Filter-ID—The name of the filter list for the authenticated user.</li> <li>• Framed-MTU—The maximum transmission unit that can be configured for user.</li> <li>• Client-System-Name—This is a vendor-specific attribute (VSA) used to indicate the client host name. Supported for LLDP-capable devices only.</li> <li>• Session-Timeout—The maximum number of seconds that a session will stay active before termination of the session or prompt.</li> <li>• Called-Station-ID—Allows the NAS to send the phone number that the user called, using Dialed Number Identification (DNIS) or similar technology.</li> <li>• Calling-Station-ID—Allows the NAS to send the phone number that the call came from, using Dialed Number Identification (DNIS) or similar technology.</li> <li>• NAS-Identifier—Contains a string identifying the NAS originating the Accounting-Request.</li> <li>• Acct-Status-Type—Indicates whether this Accounting-Request marks the beginning of the user session (Start) or the end (Stop). Can also be used for an interim update (Interim-Update).</li> <li>• Acct-Authentic—Indicates whether the user was authenticated locally (Local), by the RADIUS server (RADIUS), or by another remote authentication protocol (Remote).</li> <li>• Acct-Session-ID—A unique ID for a specific accounting session that can be used to match start and stop records for a session in the log file.</li> <li>• Event-Timestamp—Records the time an event occurred.</li> <li>• NAS-Port-ID—The port of the NAS that is authenticating the user.</li> <li>• Framed-IPv6-Address—The IPv6 address of the authenticated user.</li> </ul>

## Sample Output

### show dot1x accounting-attributes

```
user@switch> show dot1x accounting-attributes

Accounting Attribute:
  Calling Station Id:      88-e0-f3-1f-c5-e0
  Called station Id:      00-10-94-00-00-02
  Framed Ipv6 Address      :2001:db8:0:1:2a0:a514:0:24d
  Accounting Session ID:   802.1x812f00250002dcc6

## Output Fields

Table 52 on page 1568 lists the output fields for the `show dot1x statistics` command. Output fields are listed in the approximate order in which they appear.

**Table 52: show dot1x statistics Output Fields**

Field Name	Field Description
TxReqId	The number of EAP-Request/Identity messages transmitted on the interface.
TxReq	The number of transmitted EAP-Request frames that were not EAP-Request/Identity.
TxTotal	The total number of EAPOL messages transmitted on the interface.
RxStart	The number of EAPOL-Start messages received on the interface.
RxLogoff	The number of EAP-Logoff messages received on the interface.
RxRespld	The number of EAP-Response/Identity frames received on the interface.
RxResp	The number of EAP-Response messages received that were not EAP-Response/Identity.
CoA-Request	The number of Change of Authorization (CoA) Request messages received on the interface.
CoA-Ack	The number of CoA-Ack messages transmitted on the interface.
CoA-Nak	The number of CoA-Nak messages transmitted on the interface.
RxInvalid	The number of invalid EAPOL messages received on the interface.

**Table 52: show dot1x statistics Output Fields (Continued)**

Field Name	Field Description
RxLenErr	The number of EAPOL messages with incorrect length received on the interface.
RxTotal	The total number of EAPOL messages received on the interface.
LastRxVersion	The version number of the last EAPOL message received on the interface.
LastRxSrcMac	The source MAC address in the last EAPOL message received on the interface.
PortBounceReqRx	The number of port bounce requests received on the port.

## Sample Output

### show dot1x statistics interface

```

user@host> show dot1x statistics interface ge-0/0/0

Interface: ge-0/0/0.0
  TxReqId = 4 TxReq = 0 TxTotal = 4

show ethernet-switching interfaces  
<brief | detail | summary>  
<interface interface-name>
```

## Description

Display information about switched Ethernet interfaces.

## Options

- none** (Optional) Display brief information for Ethernet-switching interfaces.
- brief | detail | summary** (Optional) Display the specified level of output.
- interface *interface-name*** (Optional) Display Ethernet-switching information for a specific interface.

## Required Privilege Level

view

## Output Fields

For QFX Series, QFabric, NFX Series, EX4600 and OCX1100:

[Table 54 on page 1577](#) lists the output fields for the `show ethernet-switching interfaces` command on QFX Series, QFabric, NFX Series, EX4600 and OCX1100. Output fields are listed in the approximate order in which they appear.

Table 54: show ethernet-switching interfaces Output Fields

Field Name	Field Description	Level of Output
<b>Interface</b>	Name of a switching interface.	All levels
<b>State</b>	Interface state. Values are <b>up</b> or <b>down</b> .	none, <b>brief</b> , <b>detail</b> , <b>summary</b>
<b>VLAN members</b>	Name of a VLAN.	none, <b>brief</b> , <b>detail</b> , <b>summary</b>
<b>Blocking</b>	<p>Forwarding state of the interface:</p> <ul style="list-style-type: none"> <li>• <b>blocked</b>—Traffic is not being forwarded on the interface.</li> <li>• <b>unblocked</b>—Traffic is forwarded on the interface.</li> <li>• <b>MAC limit exceeded</b>—The interface is temporarily disabled because of a MAC limiting error. The disabled interface is automatically restored to service when the disable timeout expires.</li> <li>• <b>MAC move limit exceeded</b>—The interface is temporarily disabled because of a MAC move limiting error. The disabled interface is automatically restored to service when the disable timeout expires.</li> <li>• <b>Storm control in effect</b> —The interface is temporarily disabled because of a storm control error. The disabled interface is automatically restored to service when the disable timeout expires.</li> <li>• <b>Storm control shutdown in effect</b> —The interface is temporarily disabled because of a storm control shutdown error. The disabled interface is automatically restored to service when the disable timeout expires.</li> </ul>	none, <b>brief</b> , <b>detail</b> , <b>summary</b>
<b>Index</b>	VLAN index internal to Junos OS software.	<b>detail</b>
<b>untagged   tagged</b>	Specifies whether the interface forwards IEEE802.1Q-tagged or untagged traffic.	<b>detail</b>

Output fields for EX Series:

Table 55 on page 1578 lists the output fields for the `show ethernet-switching interfaces` command on EX Series switches. Output fields are listed in the approximate order in which they appear.

**Table 55: show ethernet-switching interfaces Output Fields**

Field Name	Field Description	Level of Output
<b>Interface</b>	Name of a switching interface.	none, <b>brief</b> , <b>detail</b> , <b>summary</b>
<b>Index</b>	VLAN index internal to Junos OS.	<b>detail</b>
<b>State</b>	Interface state. Values are <b>up</b> and <b>down</b> .	none, <b>brief</b> , <b>detail</b>
<b>Port mode</b>	The <b>access</b> mode is the port mode default and works with a single VLAN. Port mode can also be <b>trunk</b> , which accepts tagged packets from multiple VLANs on other switches. The third port mode value is <b>tagged-access</b> , which accepts tagged packets from access devices.	<b>detail</b>
<b>Reflective Relay Status</b>	Reflective relay allows packets to use the same interface for both upstream and downstream traffic. When reflective relay has been configured, the status displayed is always <b>enabled</b> . When reflective relay is not configured, this entry does not appear in the command output.	<b>detail</b>
<b>Ether type for the interface</b>	Ether type is a two-octet field in an Ethernet frame used to indicate which protocol is encapsulated in the payload of an incoming Ethernet packet. Both 802.1Q packets and Q-in-Q packets use this field. The output displayed for this particular field indicates the interface's Ether type, which is used to match the Ether type of incoming 802.1Q packets and Q-in-Q packets. The indicated Ether type field is also added to the interface's outgoing 802.1Q and Q-in-Q packets.	<b>detail</b>
<b>VLAN membership</b>	Names of VLANs that belong to this interface.	none, <b>brief</b> , <b>detail</b> ,
<b>Tag</b>	Number of the 802.1Q tag.	none, <b>brief</b> , <b>detail</b> ,

Table 55: show ethernet-switching interfaces Output Fields *(Continued)*

Field Name	Field Description	Level of Output
<b>Tagging</b>	Specifies whether the interface forwards 802.1Q <b>tagged</b> or <b>untagged</b> traffic.	none, <b>brief</b> , <b>detail</b> ,
<b>Blocking</b>	<p>The forwarding state of the interface:</p> <ul style="list-style-type: none"> <li>• <b>unblocked</b>—Traffic is forwarded on the interface.</li> <li>• <b>blocked</b>—Traffic is not being forwarded on the interface.</li> <li>• <b>Disabled by bpdu control</b>—The interface is disabled due to receiving BPDUs on a protected interface. If the disable-timeout statement has been included in the BPDU configuration, the interface automatically returns to service after the timer expires.</li> <li>• <b>blocked by RTG</b>—The specified redundant trunk group is disabled.</li> <li>• <b>blocked by STP</b>—The interface is disabled due to a spanning-tree protocol error.</li> <li>• <b>MAC limit exceeded</b>—The interface is temporarily disabled due to a MAC limit error. The disabled interface is automatically restored to service when the disable timeout expires.</li> <li>• <b>MAC move limit exceeded</b>—The interface is temporarily disabled due to a MAC move limit error. The disabled interface is automatically restored to service when the disable timeout expires.</li> <li>• <b>Storm control in effect</b>—The interface is temporarily disabled due to a storm control error. The disabled interface is automatically restored to service when the disable timeout expires.</li> </ul>	none, <b>brief</b> , <b>detail</b> ,
<b>Number of MACs learned on IFL</b>	Number of MAC addresses learned by this interface.	<b>detail</b>

Table 55: show ethernet-switching interfaces Output Fields (Continued)

Field Name	Field Description	Level of Output
<b>mapping</b>	<p>When mapping is configured, the status is one of the following C-VLAN to S-VLAN mapping types:</p> <ul style="list-style-type: none"> <li>• <b>dot1q-tunneled</b>—The interface maps all traffic to the S-VLAN (all-in-one bundling).</li> <li>• <b>native</b>—The interface maps untagged and priority tagged packets to the S-VLAN.</li> <li>• <b>push</b>—The interface maps packets to a firewall filter to an S-VLAN.</li> <li>• <b>policy-mapped</b>—The interface maps packets to a specifically defined S-VLAN.</li> <li>• <i>integer</i>—The interface maps packets to the specified S-VLAN.</li> </ul> <p>When mapping is not configured, this entry does not appear in the command output.</p>	<b>detail</b>

## Sample Output for QFX Series Switches, QFabric, NFX Series, EX4600 and OCX1100

### show ethernet-switching interfaces

```
user@switch> show ethernet-switching interfaces
```

```

Interface	State	VLAN members	Tag	Tagging	Blocking
-----------	-------	--------------	-----	---------	----------

ge-0/0/15.0	up	vlan100	100	tagged	blocked by STP
		vlan200	200	tagged	blocked by STP

### show ethernet-switching interfaces ge-0/0/2 detail (Blocked by RTG rtggroup)

```
user@switch> show ethernet-switching interfaces ge-0/0/2 detail
```

Interface: ge-0/0/2.0, Index: 65, State: up, Port mode: Access

Ether type for the interface: 0X8100

VLAN membership:

vlan300, 802.1Q Tag: 300, untagged, msti-id: 0, blocked by RTG(rtggroup)

Number of MACs learned on IFL: 0

### show ethernet-switching interfaces ge-0/0/15 detail (Blocked by STP)

```
user@switch> show ethernet-switching interfaces ge-0/0/15 detail
```

Interface: ge-0/0/15.0, Index: 70, State: up, Port mode: Trunk

Ether type for the interface: 0X8100

VLAN membership:

vlan100, 802.1Q Tag: 100, tagged, msti-id: 0, blocked by STP

vlan200, 802.1Q Tag: 200, tagged, msti-id: 0, blocked by STP

Number of MACs learned on IFL: 0

### show ethernet-switching interfaces ge-0/0/17 detail (Disabled by bpdu-control)

```
user@switch> show ethernet-switching interfaces ge-0/0/17 detail
```

Interface: ge-0/0/17.0, Index: 71, State: down, Port mode: Trunk

Ether type for the interface: 0X8100

VLAN membership:

vlan100, 802.1Q Tag: 100, tagged, msti-id: 1, Disabled by bpdu-control

vlan200, 802.1Q Tag: 200, tagged, msti-id: 2, Disabled by bpdu-control

Number of MACs learned on IFL: 0

## show ethernet-switching interfaces detail (C-VLAN to S-VLAN Mapping)

```
user@switch>show ethernet-switching interfaces ge-0/0/6.0 detail
Interface: ge-0/0/6.0, Index: 73, State: up, Port mode: Access
Ether type for the interface: 0X8100
VLAN membership:
    map, 802.1Q Tag: 134, Mapped Tag: native, push, dot1q-tunneled, unblocked
    map, 802.1Q Tag: 134, Mapped Tag: 20, push, dot1q-tunneled, unblocked
```

## show ethernet-switching interfaces detail (Reflective Relay Is Configured)

```
user@switch1> show ethernet-switching interfaces ge-7/0/2 detail
Interface: ge-7/0/2, Index: 66, State: down, Port mode: Tagged-access
Ether type for the interface: 0X8100
Reflective Relay Status: Enabled
Ether type for the interface: 0x8100
VLAN membership:
    VLAN_Purple VLAN_Orange VLAN_Blue, 802.1Q Tag: 450, tagged, unblocked
Number of MACs learned on IFL: 0
```

## Release Information

Command introduced in Junos OS Release 9.0.

In Junos OS Release 9.6 for EX Series switches, the following updates were made:

- **Blocking** field output was updated.
- The default view was updated to include information about 802.1Q tags.
- The **detail** view was updated to include information on VLAN mapping.

In Junos OS Release 11.1 for EX Series switches, the **detail** view was updated to include reflective relay information.

## Output Fields

[Table 56 on page 1588](#) lists the output fields for the `show firewall` command. Output fields are listed in the approximate order in which they appear.

**Table 56: show firewall Output Fields**

Field Name	Field Description
Filter	<p>Name of a filter that has been configured with the filter at the [edit firewall] hierarchy level.</p> <p>When an interface-specific filter is displayed, the name of the filter is followed by the full interface name and by either -i for an input filter or -o for an output filter.</p> <p>When dynamic filters are displayed, the name of the filter is followed by the full interface name and by either -in for an input filter or -out for an output filter. When a logical system-specific filter is displayed, the name of the filter is prefixed with two underscore (__) characters and the name of the logical system (for example, __ls1/filter1).</p>
Counters	<p>Display filter counter information:</p> <ul style="list-style-type: none"> <li>• Name—Name of a filter counter that has been configured with the counter firewall filter action.</li> <li>• Bytes—Number of bytes that match the filter term under which the counter action is specified.</li> <li>• Packets—Number of packets that matched the filter term under which the counter action is specified.</li> </ul>
Policers	<p>Display policer information:</p> <ul style="list-style-type: none"> <li>• Name—Name of policer.</li> <li>• Bytes—Number of bytes that match the filter term under which the policer action is specified. This is only the number out-of-specification (out-of-spec) byte counts, not all the bytes in all packets policed by the policer.</li> <li>• Packets—Number of packets that matched the filter term under which the policer action is specified. This is only the number of out-of-specification (out-of-spec) packet counts, not all packets policed by the policer.</li> </ul>

## Sample Output

### show firewall

```
user@host> show firewall
Filter: ef_path
Counters:
Name          Bytes      Packets
def-count     0          0
video-count   0          0
voice-count   0          0

Filter: __default_bpdu_filter__

Filter: deep
Counters:
Name          Bytes      Packets
deep2         302076     5031

Filter: deep-flood
Counters:
Name          Bytes      Packets
deep_flood_def 302136     5032
deep1         0          0
Policers:
Name          Packets
deep-pol-op-first 0
```

## Release Information

## Output Fields

Table 57 on page 1591 lists the output fields for the `show lldp` command. Output fields are listed in the approximate order in which they appear.

**Table 57: show lldp Output Fields**

Field Name	Field Description	Level of Output
<b>LLDP</b>	<p>LLDP operating state. The state can be <b>enabled</b> or <b>disabled</b>.</p> <p><b>NOTE:</b> If a VLAN that has been configured for untagged packets on an interface also has Layer 2 protocol tunneling (L2PT) enabled for LLDP, the LLDP operating state for that interface is displayed as <b>disabled</b>.</p>	All levels
<b>Advertisement interval</b>	<p>Frequency, in seconds, at which LLDP advertisements are sent.</p> <p>This value is set by the <b>advertisement-interval</b> configuration statement.</p>	All levels
<b>Transmit delay</b>	<p>Seconds of delay before advertisements are sent to neighbors following a change to a TLV (type, length, or value) element in the LLDP protocol or to the state of the local system, such as a change in hostname or management address. You can set this value to reduce the delay in notifying neighbors of a change in the local system.</p> <p>This value is set by the <b>transmit-delay</b> configuration statement.</p>	All levels
<b>Hold timer</b>	<p>On EX4300 switches, the hold timer shows the length of time LLDP information is held before it is discarded. The hold timer value is equal to the advertisement interval multiplied by the hold multiplier.</p> <p>On all other switches, the hold timer shows the value of the hold multiplier.</p> <p>The hold multiplier value is set by the <b>hold-multiplier</b> configuration statement.</p>	All levels

Table 57: show lldp Output Fields (*Continued*)

Field Name	Field Description	Level of Output
<b>Notification interval</b>	<p>How often LLDP trap notifications are generated as a result of LLDP database changes. If the interval value is 0, LLDP trap notifications on database changes are disabled.</p> <p>This value is set by the <b>lldp-configuration-notification-interval</b> configuration statement.</p>	All levels
<b>Config Trap Interval</b>	<p>How often LLDP trap notifications are generated as a result of changes in topology—for example, when an endpoint connects or disconnects. If the interval value is 0, LLDP trap notifications on topology changes are disabled.</p> <p>This value is set by the <b>ptopo-configuration-trap-interval</b> configuration statement.</p>	All levels
<b>Connection Hold timer</b>	<p>Amount of time the system maintains dynamic topology entries.</p> <p>This value is set by the <b>ptopo-configuration-maximum-hold-time</b> configuration statement.</p>	All levels
<b>LLDP-MED</b>	LLDP-MED operating state. The state can be Enabled or Disabled.	All levels
<b>MED fast start count</b>	<p>Number of advertisements sent from a switch to a device, such as a VoIP telephone, when the device is first detected by the switch. These increased advertisements are temporary. After a device and a switch exchange information and can communicate, advertisements are reduced to one per second.</p> <p>This value is set by using the <b>fast-start</b> configuration statement.</p>	All levels
<b>Interface</b>	Name of the interface for which LLDP configuration information is being reported.	All levels
<b>Parent Interface</b>	Name of the aggregated Ethernet interface, if any, to which the interface belongs.	All levels
<b>LLDP</b>	LLDP operating state. The state can be Enabled or Disabled.	All levels

Table 57: show lldp Output Fields (*Continued*)

Field Name	Field Description	Level of Output
<b>Power Negotiation</b>	LLDP power negotiation operating state. The state can be <b>Enabled</b> or <b>Disabled</b> .	All levels
<b>Neighbor count</b>	Total number of new LLDP neighbors detected since the last switch reboot.	<b>detail</b>
<b>Interface</b>	Name of the interface that is advertising VLAN information.	All levels
<b>Vlan-id</b>	VLAN tag associated with the interface sending LLDP frames. If the interface is not a member of a VLAN, the VLAN ID is advertised as 0.	<b>detail</b>
<b>Vlan-name</b>	<p>VLAN name associated with the VLAN ID.</p> <p>For switches running Junos OS releases with Enhanced Layer 2 Software (ELS), this column displays the string <code>vlan-<i>vlan-id</i></code> by default. Starting in Junos OS Release 15.1X53-D59 and 18.2R1, you can configure the <code>vlan-name-tlv-option name</code> option at the <code>[edit protocols lldp]</code> hierarchy level to transmit the VLAN name in the LLDP VLAN name TLV in place of the VLAN ID, and display the actual VLAN name in this output field instead.</p>	<b>detail</b>

Table 57: show lldp Output Fields (*Continued*)

Field Name	Field Description	Level of Output
<b>LLDP basic TLVs supported</b>	<p>Basic TLVs supported on the switch:</p> <ul style="list-style-type: none"> <li>• <b>Chassis identifier</b>—TLV that advertises the MAC address associated with the local system.</li> <li>• <b>Port identifier</b>—TLV that advertises the port identification for the specified port in the local system.</li> <li>• <b>Port description</b>—Interface name for the port.</li> <li>• <b>System name</b>—TLV that advertises the user-configured name of the local system.</li> <li>• <b>System description</b>—TLV that advertises the system description containing information about the software and current image running on the system. This information is taken from the software and is not configurable.</li> <li>• <b>System capabilities</b>—TLV that advertises the primary functions performed by the system—for example, bridge or router.</li> <li>• <b>Management address</b>—TLV that advertises the IP management address of the local system.</li> </ul>	<b>detail</b>

Table 57: show lldp Output Fields (*Continued*)

Field Name	Field Description	Level of Output
<b>Supported LLDP 802 TLVs</b>	<p>802.3 TLVs supported on the switch:</p> <ul style="list-style-type: none"> <li>• <b>MAC/PHY configuration status</b>—TLV that advertises information about the physical interface, such as autonegotiation status and support and MAU type. The information is based on the physical interface structure and is not configurable.</li> <li>• <b>Power via MDI</b>—TLV that advertises MDI power support, PSE power pair, and power class information.</li> <li>• <b>Link aggregation</b>—TLV that advertises if the interface is aggregated and its aggregated interface ID.</li> <li>• <b>Maximum frame size</b>—TLV that advertises the maximum transmission unit (MTU) of the interface sending LLDP frames.</li> <li>• <b>Port VLAN tag</b>—TLV that advertises the VLAN tag configured on the interface.</li> <li>• <b>Port VLAN name</b>—TLV that advertises the VLAN name configured on the interface.</li> </ul>	<b>detail</b>

Table 57: show lldp Output Fields (*Continued*)

Field Name	Field Description	Level of Output
<b>Supported LLDP MED TLVs</b>	<p>LLDP-MED TLVs supported on the switch:</p> <ul style="list-style-type: none"> <li>• <b>LLDP MED capabilities</b>—TLV that advertises the primary function of the port. The capabilities values range from 0 through 15: <ul style="list-style-type: none"> <li>• <b>0</b>—Capabilities</li> <li>• <b>1</b>—Network Policy</li> <li>• <b>2</b>—Location Identification</li> <li>• <b>3</b>—Extended Power via MDI-PSE</li> <li>• <b>4</b>—Inventory</li> <li>• <b>5–15</b>—Reserved</li> </ul> </li> <li>• <b>Network policy</b>—TLV that advertises the port VLAN configuration and associated Layer 2 and Layer 3 attributes. Attributes include the policy identifier, application types—such as voice or streaming video—802.1Q VLAN tagging, and 802.1p priority bits and DiffServ code points.</li> <li>• <b>Endpoint location</b>—TLV that advertises the physical location of the endpoint.</li> <li>• <b>Extended power Via MDI</b>—TLV that advertises the power type, power source, power priority, and power value of the port. It is the responsibility of the PSE device (network connectivity device) to advertise the power priority on a port.</li> </ul>	<b>detail</b>

## Sample Output

### show lldp (EX3200 switches)

```

user@switch> show lldp
LLDP                  : Enabled
Advertisement interval : 30 seconds

```

```

Transmit delay      : 2 seconds
Hold timer          : 4 seconds
Notification interval : 0 Second(s)
Config Trap Interval : 0 seconds
Connection Hold timer : 300 seconds

```

```

LLDP MED            : Disabled
MED fast start count : 3 Packets

```

Interface	Parent Interface	LLDP	LLDP-MED	Power Negotiation
all	-	Enabled	Enabled	Enabled

### show lldp (EX4300 switches)

```

user@switch> show lldp
LLDP                : Enabled
Advertisement interval : 30 seconds
Transmit delay       : 2 seconds
Hold timer           : 120 seconds
Notification interval : 0 Second(s)
Config Trap Interval : 0 seconds
Connection Hold timer : 300 seconds

```

```

LLDP MED            : Disabled
MED fast start count : 3 Packets

```

Interface	Parent Interface	LLDP	LLDP-MED	Power Negotiation
all	-	Enabled	Enabled	Enabled

### show lldp detail (EX4300 switches)

```

user@switch> show lldp detail
LLDP                : Enabled
Advertisement interval : 30 seconds
Transmit delay       : 2 seconds
Hold timer           : 120 seconds
Notification interval : 0 Second(s)
Config Trap Interval : 0 seconds

- [Release Information | 1610](#)

## Syntax

```
<show lldp neighbors>  
<interface interface-ids>
```

## Description

Display learned information about Link Layer Discovery Protocol (LLDP) on all neighboring interfaces or on selected interfaces.

## Options

<b>none</b>	Display learned LLDP information on all neighboring interfaces and devices.
<b>interface <i>interface-ids</i></b>	(Optional) Display learned LLDP information on the selected interfaces or devices.

**NOTE:** When a port with DCBX enabled begins to exchange type, length, and value (TLV) entries, optional LLDP TLVs on that port are not advertised to neighbors in order to interoperate with a wider variety of converged network adapters (CNAs). As a result, information for those ports will not be listed in the output for this command.

## Required Privilege Level

## Output Fields

[Table 59 on page 1604](#) lists the output fields for the `show lldp neighbors` command. Output fields are listed in the approximate order in which they appear.

**Table 59: show lldp neighbors Output Fields**

Field Name	Field Description
<b>Local Interface</b>	List of local interfaces for which neighbor information is available.
<b>Parent Interface</b>	List of aggregated Ethernet interfaces, if any, to which the local interfaces belong.
<b>Chassis ID</b>	List of chassis identifiers for neighbors.

Table 59: show lldp neighbors Output Fields (*Continued*)

Field Name	Field Description
<b>Port info</b>	List of port information gathered from neighbors. This could be the port identifier or port description.
<b>System name</b>	List of system names gathered from neighbors.
<b>LLDP Neighbor Information</b>	Information about both the local system (the switch) and a neighbor system on the interface (appears when the <b>interface</b> option is used).
<b>Local Information</b>	Information about the local system (appears when the <b>interface</b> option is used).
<b>Index</b>	Local interface index (appears when the <b>interface</b> option is used).
<b>Time to live</b>	Number of seconds for which this information is valid (appears when the <b>interface</b> option is used).
<b>Time mark</b>	Date and timestamp of information (appears when the <b>interface</b> option is used).
<b>Local Interface</b>	Name of the local physical interface (appears when the <b>interface</b> option is used).
<b>Parent Interface</b>	Name of the aggregated Ethernet interface, if any, to which the interface belongs (appears when the <b>interface</b> option is used).
<b>Local Port ID</b>	Local interface SNMP index (appears when the interface option is used).
<b>Ageout Count</b>	Number of times the complete set of information advertised by the neighbor has been deleted from LLDP neighbor information maintained by the local system because the information timeliness interval has expired (appears when the <b>interface</b> option is used).

Table 59: show lldp neighbors Output Fields (*Continued*)

Field Name	Field Description
<b>Neighbor Information</b>	Information about a neighbor system on the interface (appears when the <b>interface</b> option is used).
<b>Chassis type</b>	Type of chassis identifier supplied, such as <b>MAC address</b> (appears when the <b>interface</b> option is used).
<b>Chassis ID</b>	Chassis identifier of the chassis type listed (appears when the <b>interface</b> option is used).
<b>Port type</b>	Type of port identifier supplied, such as <b>locally assigned</b> (appears when the <b>interface</b> option is used).
<b>Port ID</b>	Port identifier of the port type listed (appears when the <b>interface</b> option is used).
<b>Port description</b>	Port description (appears when the <b>interface</b> option is used).
<b>System name</b>	Name supplied by the system on the interface (appears when the <b>interface</b> option is used).
<b>System Description</b>	Description supplied by the system on the interface (appears when the <b>interface</b> option is used).
<b>System capabilities</b>	Capabilities (such as <b>Bridge</b> , <b>Router</b> , and <b>Telephone</b> ) that are supported or enabled by the system on the interface (appears when the <b>interface</b> option is used).

Table 59: show lldp neighbors Output Fields *(Continued)*

Field Name	Field Description
<b>Management Info</b>	<p>Details of management information: <b>Type</b> (such as <b>ipv4</b> or <b>ipv6</b>), <b>Address</b> (such as <b>10.204.34.35</b>), <b>Port ID</b>, <b>Subtype</b>, <b>Interface Subtype</b>, and organization identifier (<b>OID</b>) (appears when the <b>interface</b> option is used).</p> <p>The <b>Interface Subtype</b> displays:</p> <ul style="list-style-type: none"> <li>• <b>ifIndex(2)</b>— IP address of the neighbor's management Ethernet interface (<b>me0</b>) or virtual management Ethernet (<b>VME</b>) interface address (for a virtual chassis) is used to manage the switch.</li> <li>• <b>unknown(1)</b>—Neighbor's IP management address has been configured with set <b>protocols lldp management-address</b>.</li> </ul>
<b>Media Info</b>	<p>Additional details about the endpoint device appear when a device that supports LLDP-MED is attached to the interface. The specific details depend upon the capabilities of the device. Details might include <b>Media endpoint class</b> (such as Class 3 for communication devices such as IP phones), <b>MED Hardware revision</b>, <b>MED Firmware revision</b>, <b>MED Software revision</b>, <b>MED Serial number</b>, <b>MED Manufacturer name</b>, or <b>MED Model name</b>.</p>
<b>Organization Info</b>	<p>One or more entries listing remote information by organizationally unique identifier (<b>OUI</b>), <b>Subtype</b>, <b>Index</b>, and <b>Info</b> (appears when the <b>interface</b> option is used).</p>
<b>Age</b>	<p>How long the neighbor has been identified (appears when the <b>interface</b> option is used and NetBIOS snooping is enabled on the switch).</p>
<b>Local Interface</b>	<p>Name of the local physical interface (appears when the <b>interface</b> option is used and NetBIOS snooping is enabled on the switch).</p>
<b>Parent Interface</b>	<p>Name of the aggregated Ethernet interface, if any, to which the interface belongs (appears when the <b>interface</b> option is used and NetBIOS snooping is enabled on the switch).</p>
<b>Chassis ID</b>	<p>Chassis identifier of the chassis type listed (appears when the <b>interface</b> option is used and NetBIOS snooping is enabled on the switch).</p>

Table 59: show lldp neighbors Output Fields (*Continued*)

Field Name	Field Description
<b>Port description</b>	Port description (appears when the <b>interface</b> option is used and NetBIOS snooping is enabled on the switch).
<b>System name</b>	NetBIOS name of the host (appears when the <b>interface</b> option is used and NetBIOS snooping is enabled on the switch).

## Syntax

```
show lldp neighbors  
<interface interface>
```

## Description

Display the information about neighboring devices learned by the switch by using the Link Layer Discovery Protocol (LLDP).

**NOTE:** The Chassis ID TLV has a subtype for Network Address Family. The supported network address families are IPv4 and IPv6. LLDP frames are validated only if the Network Address subtype of the Chassis ID TLV has a value of 1 (IPv4) or 2 (IPv6). For any other value, the transmitting device is detected by LLDP as a neighbor and displayed in the output of the `show lldp neighbors` command, but is not assigned to the VLAN.

## Options

`interface interface` (Optional) Display LLDP neighbor information for a selected interface.

## Required Privilege Level

view

## Output Fields

[Table 60 on page 1611](#) lists the output fields for the `show lldp neighbors` command. Output fields are listed in the approximate order in which they appear.

**Table 60: show lldp neighbors Output Fields**

Field Name	Field Description
Local Interface	List of local interfaces for which neighbor information is available.
Parent Interface	List of aggregated Ethernet interfaces, if any, to which the local interfaces belong.
Chassis ID	List of chassis identifiers for neighbors.

Table 60: show lldp neighbors Output Fields (*Continued*)

Field Name	Field Description
<b>Port info</b>	This field displays the port information received from neighbors.
<b>System name</b>	List of system names gathered from neighbors. Includes the host name and the domain name.
<b>LLDP Neighbor Information</b>	Information about both the local system (the switch) and a neighbor system on the interface (appears when the <b>interface</b> option is used).
<b>Local Information</b>	Information about the local system (appears when the <b>interface</b> option is used).
<b>Index</b>	Local interface index (appears when the <b>interface</b> option is used).
<b>Time to live</b>	Number of seconds for which this information is valid (appears when the <b>interface</b> option is used).
<b>Time mark</b>	Date and timestamp of information (appears when the <b>interface</b> option is used).
<b>Local Interface</b>	Name of the local physical interface (appears when the <b>interface</b> option is used).
<b>Parent Interface</b>	Name of the aggregated Ethernet interface, if any, to which the interface belongs (appears when the <b>interface</b> option is used).
<b>Local Port ID</b>	Local interface SNMP index (appears when the interface option is used).
<b>Ageout Count</b>	Number of times the complete set of information advertised by the neighbor has been deleted from LLDP neighbor information maintained by the local system because the information timeliness interval expired (appears when the interface option is used).

Table 60: show lldp neighbors Output Fields (*Continued*)

Field Name	Field Description
<b>Neighbor Information</b>	Information about a neighbor system on the interface (appears when the <b>interface</b> option is used).
<b>Chassis type</b>	Type of chassis identifier supplied, such as <b>Mac address</b> (appears when the <b>interface</b> option is used).

System Description : Juniper Networks, Inc. ex4300-24p Ethernet Switch, kernel JUNOS 14.1I20151125\_0548\_rajjs, Build date: 2015-11-25 06:06:58 UTC Copyright (c) 1996-2015 Juniper Networks, Inc.

## System capabilities

Supported: Bridge Router

Enabled : Bridge Router

## Management address

Address Type : IPv4(1)

Address : 10.204.39.232

Interface Number : 33

Interface Subtype : ifIndex(2)

OID : 1.3.6.1.2.1.31.1.1.1.1.33.

Media endpoint class: Network Connectivity

## Organization Info

OUI : IEEE 802.3 Private (0x00120f)

Subtype : MAC/PHY Configuration/Status (1)

Info : Autonegotiation [supported, enabled (0x3)], PMD Autonegotiation Capability (0x1), MAU Type (0x0)

Index : 1

## Organization Info

OUI : IEEE 802.3 Private (0x00120f)

Subtype : MDI Power (2)

Info : MDI Power Support [PSE bit set, supported, disabled, CONTROL bit not set (0x3)], MDI Power Pair [signal], MDI Power Class [Unknown (7)]

Index : 2

## Organization Info

OUI : IEEE 802.3 Private (0x00120f)

Subtype : Link Aggregation (3)

Info : Aggregation Status [supported, disabled (0x1)], Aggregation Port ID (0)

Index : 3

## Organization Info

OUI : IEEE 802.3 Private (0x00120f)

Subtype : Maximum Frame Size (4)

Info : MTU Size (1514)

Index : 4

## Organization Info

OUI : Juniper Specific (0x009069)

Subtype : Chassis Serial Type (1)

```

Info      : Juniper Slot Serial [MS3112240009]

## Output Fields

[Table 61 on page 1622](#) describes the output fields for the `show lldp remote-global-statistics` command. Output fields are listed in the approximate order in which they appear.

**Table 61: show lldp remote-global-statistics Output Fields**

Field Name	Field Description
LLDP Remote Database Table Counters	Information about remote database table counters.
LastchangeTime	Time elapsed between LLDP agent startup and the last change to the remote database table information.

Table 61: show lldp remote-global-statistics Output Fields (*Continued*)

Field Name	Field Description
<b>Inserts</b>	Number of insertions made in the remote database table.
<b>Deletes</b>	Number of deletions made in the remote database table.
<b>Drops</b>	Number of LLDP frames dropped from the remote database table because of errors.
<b>Ageouts</b>	Number of remote database table entries that have aged out of the table.

## Sample Output

### show lldp remote-global-statistics

```

user@host> show lldp remote-global-statistics
user@host> show lldp remote-global-statistics
  LLDP Remote Database Table Counters
  LastchangeTime      Inserts   Deletes   Drops    Ageouts
  00:00:76 (76 sec)   192      0         0        0

```

## Release Information

Command introduced in Junos OS Release 10.0.

- [Release Information | 1639](#)

## Syntax

```
show network-access radsec local-certificate  
<state>  
<statistics [brief | detail | extensive]>  
<certificate-name>
```

## Description

Display the state and statistics of local certificate acquisition. RADSEC uses local certificates dynamically acquired from the public key infrastructure to establish a TLS connection.

If a certificate is not available, or if it was revoked, the RADSEC client will try to retrieve it every 300 seconds. Response timeout is 10 seconds, and failures are retried in 10 seconds.

## Options

<b>state</b>	Display the state of acquisition for the local certificate.
<b>statistics</b>	Display acquisition statistics for the local certificate.
<b>brief   detail   extensive</b>	(Optional) Display the specified level of output.
<b><i>certificate-name</i></b>	(Optional) Display detailed information about the specified certificate.

## Syntax

```
show network-access radsec state
<destination destination-id>
```

## Description

Display the connection state of RADSEC destinations.

## Options

`destination destination-id` (Optional) Display detailed information about the request specified by this RADSEC destination.

## Required Privilege Level

view

## Output Fields

[Table 69 on page 1645](#) lists the output fields for the `show network-access state` command. Output fields are listed in the approximate order in which they appear.

Table 69: show network-access radsec state Output Fields

Field Name	Field Description	Level of Output
Radsec state	State information for the RADSEC destination.	all
state	<p>State of the RADSEC connection.</p> <ul style="list-style-type: none"> <li>• <b>connecting</b>—Establishing TCP connection.</li> <li>• <b>ssl-handshake</b>—SSL negotiation in progress.</li> <li>• <b>open</b>—RADSEC session is established for exchange of RADIUS messages.</li> <li>• <b>pause</b>—Pause for restart of connection process. The length of the pause is determined by the reason for restarting.</li> <li>• <b>local-cert-wait</b>—Connection initiated but waiting for local certificate to complete negotiation.</li> </ul>	all
secs-in-state	Length of time in seconds of the current state.	all
remaining-secs	Length of time in seconds remaining for the current state.	all
pause-reason	The reason for restarting the connection, which triggers the pause state. The pause reason determines the length of the pause until reattempting the connection.	all
acct-support	<p>Shows whether the remote server supports accounting.</p> <ul style="list-style-type: none"> <li>• Y—Remote server supports accounting. This is the default value.</li> <li>• N—If the client receives a NAK response to an accounting request, all accounting requests will be dropped.</li> </ul>	all
remote-failures	Number of consecutive failures on the remote side.	all
tx-requests	Number of RADIUS request messages transmitted.	all

Table 69: show network-access radsec state Output Fields *(Continued)*

Field Name	Field Description	Level of Output
tx-responses	Number of RADIUS response messages transmitted.	all

## Sample Output

**show network-access radsec state**

```
user@host> show network-access radsec state
Radsec state:
  destination          895
  state                open
  secs-in-state        66
  remaining-secs       4294967295
  pause-reason         none
  acct-support         Y
  remote-failures      0
  tx-requests          0
  tx-responses         0
```

## Release Information

Command introduced in Junos OS Release 19.1R1.

## Syntax

```
show route extensive  
<destination-prefix>  
<logical-system (all | logical-system-name)>
```

## Syntax (EX Series Switches)

```
show route extensive  
<destination-prefix>
```

## Description

Display extensive information about the active entries in the routing tables.

## Options

<b>none</b>	Display all active entries in the routing table.
<b><i>destination-prefix</i></b>	(Optional) Display active entries for the specified address or range of addresses.
<b>logical-system (all   <i>logical-system-name</i>)</b>	(Optional) Perform this operation on all logical systems or on a particular logical system.

## Output Fields

Table 70 on page 1648 describes the output fields for the `show route extensive` command. Output fields are listed in the approximate order in which they appear.

**Table 70: show route extensive Output Fields**

Field Name	Field Description
<i>routing-table-name</i>	Name of the routing table (for example, inet.0).
<i>number</i> destinations	Number of destinations for which there are routes in the routing table.
<i>number</i> routes	Number of routes in the routing table and total number of routes in the following states: <ul style="list-style-type: none"> <li>• active (routes that are active).</li> <li>• holddown (routes that are in the pending state before being declared inactive).</li> <li>• hidden (routes that are not used because of a routing policy).</li> </ul>

Table 70: show route extensive Output Fields (*Continued*)

Field Name	Field Description
<i>route-destination</i> (entry, announced)	<p>Route destination (for example: 10.0.0.1/24). The entry value is the number of route for this destination, and the announced value is the number of routes being announced for this destination. Sometimes the route destination is presented in another format, such as:</p> <ul style="list-style-type: none"> <li>• <i>MPLS-label</i> (for example, 80001 ).</li> <li>• <i>interface-name</i> (for example, ge-1/0/2).</li> <li>• <i>neighbor-address: control-word-status: encapsulation type: vc-id: source</i> (Layer 2 circuit only; for example, 10.1.1.195:NoCtrlWord:1:1:Local/96).</li> <li>• <i>neighbor-address</i>—Address of the neighbor.</li> <li>• <i>control-word-status</i>—Whether the use of the control word has been negotiated for this virtual circuit: NoCtrlWord or CtrlWord.</li> <li>• <i>encapsulation type</i>—Type of encapsulation, represented by a number: (1) Frame Relay DLCI, (2) ATM AAL5 VCC transport, (3) ATM transparent cell transport, (4) Ethernet, (5) VLAN Ethernet, (6) HDLC, (7) PPP, (8) ATM VCC cell transport, (10) ATM VPC cell transport.</li> <li>• <i>vc-id</i>—Virtual circuit identifier.</li> <li>• <i>source</i>—Source of the advertisement: Local or Remote.</li> </ul>
TSI	Protocol header information.
label stacking	<p>(Next-to-the-last-hop routing device for MPLS only) Depth of the MPLS label stack, where the label-popping operation is needed to remove one or more labels from the top of the stack. A pair of routes is displayed, because the pop operation is performed only when the stack depth is two or more labels.</p> <ul style="list-style-type: none"> <li>• S=0 route indicates that a packet with an incoming label stack depth of two or more exits this router with one fewer label (the label-popping operation is performed).</li> <li>• If there is no S= information, the route is a normal MPLS route, which has a stack depth of 1 (the label-popping operation is not performed).</li> </ul>

Table 70: show route extensive Output Fields (*Continued*)

Field Name	Field Description
[ <i>protocol, preference</i> ]	<p>Protocol from which the route was learned and the preference value for the route.</p> <ul style="list-style-type: none"> <li>• +—A plus sign indicates the active route, which is the route installed from the routing table into the forwarding table.</li> <li>• - —A hyphen indicates the last active route.</li> <li>• *—An asterisk indicates that the route is both the active and the last active route. An asterisk before a to line indicates the best subpath to the route.</li> </ul> <p>In every routing metric except for the BGP LocalPref attribute, a lesser value is preferred. In order to use common comparison routines, Junos OS stores the 1's complement of the LocalPref value in the Preference2 field. For example, if the LocalPref value for Route 1 is 100, the Preference2 value is -101. If the LocalPref value for Route 2 is 155, the Preference2 value is -156. Route 2 is preferred because it has a higher LocalPref value and a lower Preference2 value.</p>
Level	(IS-IS only). In IS-IS, a single autonomous system (AS) can be divided into smaller groups called areas. Routing between areas is organized hierarchically, allowing a domain to be administratively divided into smaller areas. This organization is accomplished by configuring Level 1 and Level 2 intermediate systems. Level 1 systems route within an area. When the destination is outside an area, they route toward a Level 2 system. Level 2 intermediate systems route between areas and toward other ASs.
Route Distinguisher	IP subnet augmented with a 64-bit prefix.
PMSI	Provider multicast service interface (MVPN routing table).
Next-hop type	Type of next hop.
Next-hop reference count	Number of references made to the next hop.
Flood nexthop branches exceed maximum message	Indicates that the number of flood next-hop branches exceeded the system limit of 32 branches, and only a subset of the flood next-hop branches were installed in the kernel.

Table 70: show route extensive Output Fields (*Continued*)

Field Name	Field Description
Source	IP address of the route source.
Next hop	Network layer address of the directly reachable neighboring system.
via	<p>Interface used to reach the next hop. If there is more than one interface available to the next hop, the name of the interface that is actually used is followed by the word Selected. This field can also contain the following information:</p> <ul style="list-style-type: none"> <li>• Weight—Value used to distinguish primary, secondary, and fast reroute backup routes. Weight information is available when MPLS label-switched path (LSP) link protection, node-link protection, or fast reroute is enabled, or when the standby state is enabled for secondary paths. A lower weight value is preferred. Among routes with the same weight value, load balancing is possible.</li> <li>• Balance—Balance coefficient indicating how traffic of unequal cost is distributed among next hops when a routing device is performing unequal-cost load balancing. This information is available when you enable BGP multipath load balancing.</li> </ul>
Label-switched-path <i>lsp-path-name</i>	Name of the LSP used to reach the next hop.
Label operation	MPLS label and operation occurring at this routing device. The operation can be pop (where a label is removed from the top of the stack), push (where another label is added to the label stack), or swap (where a label is replaced by another label).
Offset	Whether the metric has been increased or decreased by an offset value.
Interface	(Local only) Local interface name.
Protocol next hop	Network layer address of the remote routing device that advertised the prefix. This address is used to recursively derive a forwarding next hop.
<i>label-operation</i>	MPLS label and operation occurring at this routing device. The operation can be pop (where a label is removed from the top of the stack), push (where another label is added to the label stack), or swap (where a label is replaced by another label).

**Table 70: show route extensive Output Fields (Continued)**

Field Name	Field Description
Indirect next hops	<p>When present, a list of nodes that are used to resolve the path to the next-hop destination, in the order that they are resolved.</p> <p>When BGP PIC Edge is enabled, the output lines that contain Indirect next hop: weight follow next hops that the software can use to repair paths where a link failure occurs. The next-hop weight has one of the following values:</p> <ul style="list-style-type: none"> <li>• 0x1 indicates active next hops.</li> <li>• 0x4000 indicates passive next hops.</li> </ul>
State	State of the route (a route can be in more than one state).
Session ID	The BFD session ID number that represents the protection using MPLS fast reroute (FRR) and loop-free alternate (LFA).
Weight	Weight for the backup path. If the weight of an indirect next hop is larger than zero, the weight value is shown.

Table 70: show route extensive Output Fields (*Continued*)

Field Name	Field Description
Inactive reason	<p>If the route is inactive, the reason for its current state is indicated. Typical reasons include:</p> <ul style="list-style-type: none"> <li>• Active preferred—Currently active route was selected over this route.</li> <li>• Always compare MED—Path with a lower multiple exit discriminator (MED) is available.</li> <li>• AS path—Shorter AS path is available.</li> <li>• Cisco Non-deterministic MED selection—Cisco nondeterministic MED is enabled and a path with a lower MED is available.</li> <li>• Cluster list length—Path with a shorter cluster list length is available.</li> <li>• Forwarding use only—Path is only available for forwarding purposes.</li> <li>• IGP metric—Path through the next hop with a lower IGP metric is available.</li> <li>• IGP metric type—Path with a lower OSPF link-state advertisement type is available.</li> <li>• Interior &gt; Exterior &gt; Exterior via Interior—Direct, static, IGP, or EBGp path is available.</li> <li>• Local preference—Path with a higher local preference value is available.</li> <li>• Next hop address—Path with a lower metric next hop is available.</li> <li>• No difference—Path from a neighbor with a lower IP address is available.</li> <li>• Not Best in its group—Occurs when multiple peers of the same external AS advertise the same prefix and are grouped together in the selection process. When this reason is displayed, an additional reason is provided (typically one of the other reasons listed).</li> <li>• Number of gateways—Path with a higher number of next hops is available.</li> <li>• Origin—Path with a lower origin code is available.</li> <li>• OSPF version—Path does not support the indicated OSPF version.</li> <li>• RIB preference—Route from a higher-numbered routing table is available.</li> <li>• Route distinguisher—64-bit prefix added to IP subnets to make them unique.</li> <li>• Route metric or MED comparison—Route with a lower metric or MED is available.</li> </ul>

Table 70: show route extensive Output Fields (*Continued*)

Field Name	Field Description
	<ul style="list-style-type: none"> <li>Route preference—Route with a lower preference value is available.</li> <li>Router ID—Path through a neighbor with a lower ID is available.</li> <li>Unusable path—Path is not usable because of one of the following conditions: the route is damped, the route is rejected by an import policy, or the route is unresolved.</li> <li>Update source—Last tiebreaker is the lowest IP address value.</li> </ul>
Local AS	Autonomous system (AS) number of the local routing device.
Age	How long the route has been known.
AI GP	Accumulated interior gateway protocol (AI GP) BGP attribute.
Metric	Cost value of the indicated route. For routes within an AS, the cost is determined by IGP and the individual protocol metrics. For external routes, destinations, or routing domains, the cost is determined by a preference value.
MED-plus-IGP	Metric value for BGP path selection to which the IGP cost to the next-hop destination has been added.
TTL-Action	For MPLS LSPs, state of the TTL propagation attribute. Can be enabled or disabled for all RSVP-signaled and LDP-signaled LSPs or for specific VRF routing instances.
Task	Name of the protocol that has added the route.
Announcement bits	<p>List of protocols that are consumers of the route. Using the following output as an example, Announcement bits (3): 0-KRT 5-Resolve tree 2 8-BGP RT Background there are (3) announcement bits to reflect the three clients (protocols) that have state for this route: Kernel (0-KRT), 5 (resolution tree process 2), and 8 (BGP).</p> <p>The notation <i>n</i>-Resolve inet indicates that the route is used for route resolution for next hops found in the routing table. <i>n</i> is an index used by Juniper Networks customer support only.</p>

Table 70: show route extensive Output Fields (*Continued*)

Field Name	Field Description
AS path	<p>AS path through which the route was learned. The letters at the end of the AS path indicate the path origin, providing an indication of the state of the route at the point at which the AS path originated:</p> <ul style="list-style-type: none"> <li>• I—IGP.</li> <li>• E—EGP.</li> <li>• Recorded—The AS path is recorded by the sample process (sampled).</li> <li>• ?—Incomplete; typically, the AS path was aggregated.</li> </ul> <p>When AS path numbers are included in the route, the format is as follows:</p> <ul style="list-style-type: none"> <li>• [ ]—Brackets enclose the local AS number associated with the AS path if more than one AS number is configured on the routing device, or if AS path prepending is configured.</li> <li>• { }—Braces enclose AS sets, which are groups of AS numbers in which the order does not matter. A set commonly results from route aggregation. The numbers in each AS set are displayed in ascending order.</li> <li>• ( )—Parentheses enclose a confederation.</li> <li>• ( [ ] )—Parentheses and brackets enclose a confederation set.</li> </ul> <p><b>NOTE:</b> In Junos OS Release 10.3 and later, the AS path field displays an unrecognized attribute and associated hexadecimal value if BGP receives attribute 128 (attribute set) and you have not configured an independent domain in any routing instance.</p>
validation-state	<p>(BGP-learned routes) Validation status of the route:</p> <ul style="list-style-type: none"> <li>• Invalid—Indicates that the prefix is found, but either the corresponding AS received from the EBGp peer is not the AS that appears in the database, or the prefix length in the BGP update message is longer than the maximum length permitted in the database.</li> <li>• Unknown—Indicates that the prefix is not among the prefixes or prefix ranges in the database.</li> <li>• Unverified—Indicates that origin validation is not enabled for the BGP peers.</li> <li>• Valid—Indicates that the prefix and autonomous system pair are found in the database.</li> </ul>

**Table 70: show route extensive Output Fields (Continued)**

Field Name	Field Description
FECs bound to route	Point-to-multipoint root address, multicast source address, and multicast group address when multipoint LDP (M-LDP) inband signaling is configured.
AS path: I <Originator>	(For route reflected output only) Originator ID attribute set by the route reflector.
route status	<p>Indicates the status of a BGP route:</p> <ul style="list-style-type: none"> <li>Accepted—The specified BGP route is imported by the default BGP policy.</li> <li>Import—The route is imported into a Layer 3 VPN routing instance.</li> <li>Import-Protect—A remote instance egress that is protected.</li> <li>Multipath—A BGP multipath active route.</li> <li>MultipathContrib—The route is not active but contributes to the BGP multipath.</li> <li>Protect—An egress route that is protected.</li> <li>Stale—A route that is marked stale due to graceful restart.</li> </ul>
Primary Upstream	When multipoint LDP with multicast-only fast reroute (MoFRR) is configured, the primary upstream path. MoFRR transmits a multicast join message from a receiver toward a source on a primary path, while also transmitting a secondary multicast join message from the receiver toward the source on a backup path.
RPF Nexthops	When multipoint LDP with MoFRR is configured, the reverse-path forwarding (RPF) next-hop information. Data packets are received from both the primary path and the secondary paths. The redundant packets are discarded at topology merge points due to the RPF checks.
Label	Multiple MPLS labels are used to control MoFRR stream selection. Each label represents a separate route, but each references the same interface list check. Only the primary label is forwarded while all others are dropped. Multiple interfaces can receive packets using the same label.

**Table 70: show route extensive Output Fields (Continued)**

Field Name	Field Description
weight	Value used to distinguish MoFRR primary and backup routes. A lower weight value is preferred. Among routes with the same weight value, load balancing is possible.
VC Label	MPLS label assigned to the Layer 2 circuit virtual connection.
MTU	Maximum transmission unit (MTU) of the Layer 2 circuit.
VLAN ID	VLAN identifier of the Layer 2 circuit.
Cluster list	(For route reflected output only) Cluster ID sent by the route reflector.
Originator ID	(For route reflected output only) Address of router that originally sent the route to the route reflector.
Prefixes bound to route	Forwarding Equivalent Class (FEC) bound to this route. Applicable only to routes installed by LDP.
Communities	Community path attribute for the route.
DeletePending	The DeletePending flag indicates that a BGP route needs to be processed due to a BGP peer down event.
Layer2-info: encaps	Layer 2 encapsulation (for example, VPLS).
control flags	Control flags: none or Site Down.
mtu	Maximum transmission unit (MTU) information.
Label-Base, range	First label in a block of labels and label block size. A remote PE routing device uses this first label when sending traffic toward the advertising PE routing device.
status vector	Layer 2 VPN and VPLS network layer reachability information (NLRI).

**Table 70: show route extensive Output Fields (Continued)**

Field Name	Field Description
Localpref	Local preference value included in the route.
Router ID	BGP router ID as advertised by the neighbor in the open message.
Primary Routing Table	In a routing table group, the name of the primary routing table in which the route resides.
Secondary Tables	In a routing table group, the name of one or more secondary tables in which the route resides.
Originating RIB	Name of the routing table whose active route was used to determine the forwarding next-hop entry in the resolution database. For example, in the case of inet.0 resolving through inet.0 and inet.3, this field indicates which routing table, inet.0 or inet.3, provided the best path for a particular prefix.
Node path count	Number of nodes in the path.
Forwarding nexthops	Number of forwarding next hops. The forwarding next hop is the network layer address of the directly reachable neighboring system (if applicable) and the interface used to reach it.
Statistics ID Group	Indicates the Kernel ID number and Statistics ID number.
Statistics	Indicates the number of packets and data transferred.

## Sample Output

### show route extensive

```

user@host> show route extensive
inet.0: 22 destinations, 23 routes (21 active, 0 holddown, 1 hidden)
203.0.113.10/16 (1 entry, 1 announced)

## Release Information

Command introduced before Junos OS Release 7.4.

DeletePending flag added to the command output in Junos OS Release 19.4R1.

## show route instance

### IN THIS SECTION

- [Syntax | 1673](#)
- [Description | 1673](#)
- [Options | 1673](#)
- [Required Privilege Level | 1673](#)
- [Output Fields | 1674](#)

- [Sample Output | 1675](#)
- [Release Information | 1678](#)

## Syntax

```
show route instance  
<brief | detail | summary>  
<instance-name>  
<operational>
```

## Description

(QFabric systems only) Display routing instance information.

## Options

<b>none</b>	(Same as <b>brief</b> ) Display standard information about all routing instances.
<b>brief   detail   summary</b>	(Optional) Display the specified level of output. If you do not specify a level of output, the system defaults to <b>brief</b> . (These options are not available with the <b>operational</b> keyword.)
<i>instance-name</i>	(Optional) Display information for a specified routing instance.
<b>operational</b>	(Optional) Display operational routing instances.

## Required Privilege Level

view

## Output Fields

Table 71 on page 1674 lists the output fields for the `show route instance` command. Output fields are listed in the approximate order in which they appear.

**Table 71: show route instance Output Fields**

Field Name	Field Description	Level of Output
<b>Instance or <i>instance-name</i></b>	Name of the routing instance.	All levels
<b>Operational Routing Instances</b>	( <b>operational</b> keyword only) Names of all operational routing instances.	—
<b>Type</b>	Type of routing instance: <b>forwarding</b> or <b>virtual-router</b> .	All levels
<b>State</b>	State of the routing instance: <b>active</b> or <b>inactive</b> .	<b>detail</b>
<b>Interfaces</b>	Name of interfaces belonging to this routing instance.	<b>detail</b>
<b>Tables</b>	Tables (and number of routes) associated with this routing instance.	<b>detail</b>
<b>Router ID</b>	Identifier for the router.	<b>detail</b>
<b>Primary RIB</b>	Primary table for this routing instance.	<b>brief none summary</b>
<b>Active/holddown/hidden</b>	Number of active, hold-down, and hidden routes.	All levels

## Sample Output

### show route instance

```

user@switch> show route instance

## Release Information

Command introduced in Junos OS Release 14.1X53-D20.

# show security ssh key-pair-identity

### IN THIS SECTION

- [Syntax | 1678](#)
- [Description | 1678](#)
- [Options | 1679](#)
- [Required Privilege Level | 1679](#)
- [Output Fields | 1679](#)
- [Sample Output | 1679](#)
- [Release Information | 1680](#)

## Syntax

```
show security ssh key-pair-identity  
  ( brief <identity-name> | public identity-name )
```

## Description

Display the SSH key pair identity information.

## Options

- `brief identity-name`—Display the brief information for a specified identity. The *identity-name* variable is optional, if an identity is not specified, the command will list brief information of all identities.
- `public identity-name`—Display the public key for a specified identity.

**NOTE:** The `public` and `brief` options are mutually exclusive

## Required Privilege Level

view

## Output Fields

When you enter this command, you are provided feedback on the status of your request.

## Sample Output

**show security ssh key-pair-identity brief**

```
user@host> show security ssh key-pair-identity brief
SSH Key Pair Identity Information:
  Name           Create Time      Encrypted
  sample         Dec 28, 17:40    yes
  identity-name  Dec 28, 17:26    yes
```

**show security ssh key-pair-identity brief sample**

```
user@host> show security ssh key-pair-identity brief sample
SSH Key Pair Identity Information:
```

Name	Create Time	Encrypted
sample	Dec 28, 17:34	yes

## Release Information

Command introduced in Junos OS Release 15.1X49-D70.

## Output Fields

[Table 72 on page 1682](#) lists the output fields for the `show security pki local-certificate` command. Output fields are listed in the approximate order in which they appear.

Table 72: show security pki local-certificate Output Fields

Field Name	Field Description	Level of Output
<b>Certificate identifier</b>	Name of the digital certificate.	All levels
<b>Certificate version</b>	Revision number of the digital certificate.	<b>detail</b>
<b>Serial number</b>	Unique serial number of the digital certificate.	<b>detail</b>
<b>Issued by</b>	Authority that issued the digital certificate.	none <b>brief</b>
<b>Issued to</b>	Device that was issued the digital certificate.	none <b>brief</b>
<b>Issuer</b>	<p>Authority that issued the digital certificate, including details of the authority organized using the distinguished name format. Possible subfields are:</p> <ul style="list-style-type: none"> <li>• <b>Common name</b>—Name of the authority.</li> <li>• <b>Organization</b>—Organization of origin.</li> <li>• <b>Organizational unit</b>—Department within an organization.</li> <li>• <b>State</b>—State of origin.</li> <li>• <b>Country</b>—Country of origin.</li> </ul>	<b>detail</b>
<b>Subject</b>	<p>Details of the digital certificate holder organized using the distinguished name format. Possible subfields are:</p> <ul style="list-style-type: none"> <li>• <b>Common name</b>—Name of the authority.</li> <li>• <b>Organization</b>—Organization of origin.</li> <li>• <b>Organizational unit</b>—Department within an organization.</li> <li>• <b>State</b>—State of origin.</li> <li>• <b>Country</b>—Country of origin.</li> </ul>	<b>detail</b>

Table 72: show security pki local-certificate Output Fields (*Continued*)

Field Name	Field Description	Level of Output
<b>Alternate subject</b>	Domain name or IP address of the device related to the digital certificate.	<b>detail</b>
<b>Validity</b>	Time period when the digital certificate is valid. Values are: <ul style="list-style-type: none"> <li>• <b>Not before</b>—Start time when the digital certificate becomes valid.</li> <li>• <b>Not after</b>—End time when the digital certificate becomes invalid.</li> </ul>	All levels
<b>Public key algorithm</b>	Encryption algorithm used with the private key, such as <b>rsaEncryption (1024 bits)</b> .	All levels
<b>Public key verification status</b>	Public key verification status: <b>Failed</b> or <b>Passed</b> . The <b>detail</b> output also provides the verification hash.	All levels
<b>Signature algorithm</b>	Encryption algorithm that the CA used to sign the digital certificate, such as <b>sha1WithRSAEncryption</b> .	<b>detail</b>
<b>Fingerprint</b>	Secure Hash Algorithm (SHA1) and Message Digest 5 (MD5) hashes used to identify the digital certificate.	<b>detail</b>
<b>Distribution CRL</b>	Distinguished name information and URL for the certificate revocation list (CRL) server.	<b>detail</b>
<b>Use for key</b>	Use of the public key, such as <b>Certificate signing</b> , <b>CRL signing</b> , <b>Digital signature</b> , or <b>Key encipherment</b> .	<b>detail</b>

# show security tpm status

## IN THIS SECTION

- [Syntax | 1685](#)
- [Description | 1686](#)
- [Options | 1686](#)
- [Required Privilege Level | 1686](#)
- [Output Fields | 1686](#)
- [Sample Output | 1687](#)
- [Release Information | 1687](#)

## Syntax

```
show security tpm status
```

## Description

Display the current status of the Trusted Platform Module (TPM). You can use this `show security tpm status` command to check the status of TPM ownership, master binding key, master encryption password, family version, and firmware version.

## Options

This command has no options.

## Required Privilege Level

security

## Output Fields

[Table 73 on page 1686](#) lists the output fields for the `show security tpm status` command.

**Table 73: show security tpm status Output Fields**

Field Name	Field Description
Enabled	Specifies whether TPM is enabled or disabled.
Owned	Specifies the TPM ownership. TPM can be owned even if the Master Encryption Key and Master Encryption Key are not created/configured.
Master Binding Key	Displays the TPM's Master Binding Key status whether it is created or not created. TPM generates cryptographic keys and encrypts them so that those can only be decrypted by the TPM. This process is know as binding. Each TPM has a master binding key, which is also know as storage root key.

**Table 73: show security tpm status Output Fields (Continued)**

Field Name	Field Description
Master Encryption Key	Displays Master Encryption Password status whether it is set or not set. The encrypted data and the hash of the configuration is protected by the TPM module using the master encryption password.
TPM Family	Displays Trusted Computing Group's (TCG) TPM family version.
TPM Firmware version	Displays the firmware version loaded in TPM.

## Sample Output

### show security tpm status

```

user@host> show security tpm status
TPM Status:
  Enabled: yes
  Owned: yes
  Master Binding Key: not-created
  Master Encryption Key: not-configured
  TPM Family: 1.2
  TPM Firmware version: 4.43

```

## Release Information

Command introduced in Junos OS Release 15.1X49-D80.

Command introduced in Junos OS Release 20.1R1 for SRX5400, SRX5600, and SRX5800 devices with SRX5K-RE3-128G Routing Engine (RE3).

TPM family and TPM firmware version details are introduced in Junos OS Release 15.1X49-D120.

# show services unified-access-control authentication-table

## IN THIS SECTION

- [Syntax](#) | 1688
- [Description](#) | 1688
- [Options](#) | 1689
- [Required Privilege Level](#) | 1689
- [Sample Output](#) | 1689
- [Release Information](#) | 1691

## Syntax

```
show services unified-access-control authentication-table
```

## Description

Display a summary of the authentication table entries configured from the IC Series UAC Appliance. Authentication tables store mappings between traffic sessions and Unified Access Control (UAC) roles. The IC Series appliance uses the roles specified in the mappings to help determine which UAC policies to apply to a session.

Use this command when you have configured the SRX Series device to act as a Junos OS Enforcer in a UAC deployment. When deployed as a Junos OS Enforcer, the SRX Series device enforces the policies that are defined on the UAC's IC Series appliance.

You can also use this command to display the content of the authentication table in a user role firewall implementation. The table, pushed from a supporting UAC device, provides the user roles associated with incoming traffic.

## Options

- `detail`—Display a detailed view of all authentication table entries.
- `extended`—Display a view of all authentication table entries with the user roles listed.
- `identifier id`—Display all authentication table entries with the specified identifier number.
- `ip source-ip-address`—Display any authentication table entry for the specified IP address.
- `role role-name`—Display all authentication table entries for the specified role name.
- `user username`—Display all authentication table entries for the specified user.

*Firewall User Authentication Overview*

## show snmp

There are several commands that you can access in Junos OS operational mode to monitor SNMP information. Some of the commands are:

- `show snmp health-monitor`, which displays the health monitor log and alarm information.
- `show snmp mib`, which displays information from the MIBs, such as device and system information.
- `show snmp statistics`, which displays SNMP statistics such as the number of packets, silent drops, and invalid output values.
- `show snmp rmon`, which displays the RMON alarm, event, history, and log information

The following example provides sample output from the `show snmp health-monitor` command:

```
user@switch> show snmp health-monitor
Alarm
Index  Variable description                               Value State
-----
32768  Health Monitor: root file system utilization
      jnxHrStoragePercentUsed.1                      58 active
32769  Health Monitor: /config file system utilization
      jnxHrStoragePercentUsed.2                      0 active
32770  Health Monitor: RE 0 CPU utilization
      jnxOperatingCPU.9.1.0.0                        0 active
32773  Health Monitor: RE 0 Memory utilization
      jnxOperatingBuffer.9.1.0.0                    35 active
```

```

32775 Health Monitor: jkernel daemon CPU utilization
    Init daemon                      0 active
    Chassis daemon                   50 active
    Firewall daemon                  0 active
    Interface daemon                 5 active
    SNMP daemon                      11 active
    MIB2 daemon                      42 active
    ...

```

The following example provides sample output from the `show snmp mib` command:

```

user@switch> show snmp mib walk system

```

```

sysDescr.0    = Juniper Networks, Inc. qfx3500s internet router, kernel

## Output Fields

[Table 74 on page 1700](#) describes the output fields for the `show snmp statistics` command. Output fields are listed in the approximate order in which they appear.

Table 74: show snmp statistics Output Fields

Field Name	Field Description
<b>Input</b>	<p>Information about received packets:</p> <ul style="list-style-type: none"> <li>• <b>Packets(snmplnPkts)</b>—Total number of messages delivered to the SNMP entity from the transport service.</li> <li>• <b>Bad versions—(snmplnBadVersions)</b> Total number of messages delivered to the SNMP entity that were for an unsupported SNMP version.</li> <li>• <b>Bad community names—(snmplnBadCommunityNames)</b> Total number of messages delivered to the SNMP entity that used an SNMP community name not known to the entity.</li> <li>• <b>Bad community uses—(snmplnBadCommunityUses)</b> Total number of messages delivered to the SNMP entity that represented an SNMP operation that was not allowed by the SNMP community named in the message.</li> <li>• <b>ASN parse errors—(snmplnASNParseErrs)</b> Total number of ASN.1 or BER errors encountered by the SNMP entity when decoding received SNMP messages.</li> <li>• <b>Too big—(snmplnTooBigs)</b> Total number of SNMP PDUs delivered to the SNMP entity with an error status field of <b>tooBig</b>.</li> <li>• <b>No such names—(snmplnNoSuchNames)</b> Total number of SNMP PDUs delivered to the SNMP entity with an error status field of <b>noSuchName</b>.</li> <li>• <b>Bad values—(snmplnBadValues)</b> Total number of SNMP PDUs delivered to the SNMP entity with an error status field of <b>badValue</b>.</li> <li>• <b>Read onlys—(snmplnReadOnlys)</b> Total number of valid SNMP PDUs delivered to the SNMP entity with an error status field of <b>readOnly</b>. Only incorrect implementations of SNMP generate this error.</li> </ul>

Table 74: show snmp statistics Output Fields *(Continued)*

Field Name	Field Description
Input (continued)	<ul style="list-style-type: none"> <li>• <b>General errors—(snmplnGenErrs)</b> Total number of SNMP PDUs delivered to the SNMP entity with an error status field of <b>genErr</b>.</li> <li>• <b>Total requests varbinds—(snmplnTotalReqVars)</b> Total number of MIB objects retrieved successfully by the SNMP entity as a result of receiving valid SNMP <b>GetRequest</b> and <b>GetNext</b> PDUs.</li> <li>• <b>Total set varbinds—(snmplnSetVars)</b> Total number of MIB objects modified successfully by the SNMP entity as a result of receiving valid SNMP <b>SetRequest</b> PDUs.</li> <li>• <b>Get requests—(snmplnGetRequests)</b> Total number of SNMP <b>GetRequest</b> PDUs that have been accepted and processed by the SNMP entity.</li> <li>• <b>Get nexts—(snmplnGetNexts)</b> Total number of SNMP <b>GetNext</b> PDUs that have been accepted and processed by the SNMP entity.</li> <li>• <b>Set requests—(snmplnSetRequests)</b> Total number of SNMP <b>SetRequest</b> PDUs that have been accepted and processed by the SNMP entity.</li> <li>• <b>Get responses—(snmplnGetResponses)</b> Total number of SNMP <b>GetResponse</b> PDUs that have been accepted and processed by the SNMP entity.</li> <li>• <b>Traps—(snmplnTraps)</b> Total number of SNMP traps generated by the SNMP entity.</li> <li>• <b>Silent drops—(snmpSilentDrops)</b> Total number of <b>GetRequest</b>, <b>GetNextRequest</b>, <b>GetBulkRequest</b>, <b>SetRequests</b>, and <b>InformRequest</b> PDUs delivered to the SNMP entity that were silently dropped because the size of a reply containing an alternate response PDU with an empty variable-bindings field was greater than either a local constraint or the maximum message size associated with the originator of the requests.</li> <li>• <b>Proxy drops—(snmpProxyDrops)</b> Total number of <b>GetRequest</b>, <b>GetNextRequest</b>, <b>GetBulkRequest</b>, <b>SetRequests</b>, and <b>InformRequest</b> PDUs delivered to the SNMP entity that were silently dropped because the transmission of the message to a proxy target failed in such a way (other than a timeout) that no response PDU could be returned.</li> </ul>

Table 74: show snmp statistics Output Fields *(Continued)*

Field Name	Field Description
	<ul style="list-style-type: none"><li>• <b>Commit pending drops</b>—Number of SNMP packets for <b>Set</b> requests dropped because of a previous pending SNMP <b>Set</b> request on the committed configuration.</li><li>• <b>Throttle drops</b>—Number of SNMP packets for any requests dropped reaching the throttle limit.</li></ul>

Table 74: show snmp statistics Output Fields *(Continued)*

Field Name	Field Description
<b>V3 Input</b>	<p>Information about SNMP version 3 packets:</p> <ul style="list-style-type: none"> <li>• <b>Unknown security models—(snmpUnknownSecurityModels)</b> Total number of packets received by the SNMP engine that were dropped because they referenced a security model that was not known to or supported by the SNMP engine.</li> <li>• <b>Invalid messages—(snmpInvalidMsgs)</b> Number of packets received by the SNMP engine that were dropped because there were invalid or inconsistent components in the SNMP message.</li> <li>• <b>Unknown pdu handlers—(snmpUnknownPDUHandlers)</b> Number of packets received by the SNMP engine that were dropped because the PDU contained in the packet could not be passed to an application responsible for handling the PDU type.</li> <li>• <b>Unavailable contexts—(snmpUnavailableContexts)</b> Number of requests received for a context that is known to the SNMP engine, but is currently unavailable.</li> <li>• <b>Unknown contexts—(snmpUnknownContexts)</b> Total number of requests received for a context that is unknown to the SNMP engine.</li> <li>• <b>Unsupported security levels—(usmStatsUnsupportedSecLevels)</b> Total number of packets received by the SNMP engine that were dropped because they requested a security level unknown to the SNMP engine (or otherwise unavailable).</li> <li>• <b>Not in time windows—(usmStatsNotInTimeWindows)</b> Total number of packets received by the SNMP engine that were dropped because they appeared outside the authoritative SNMP engine's window.</li> <li>• <b>Unknown user names—(usmStatsUnknownUserNames)</b> Total number of packets received by the SNMP engine that were dropped because they referenced a user that was not known to the SNMP engine.</li> <li>• <b>Unknown engine ids—(usmStatsUnknownEngineIDs)</b> Total number of packets received by the SNMP engine that were dropped because they referenced an SNMP engine ID that was not known to the SNMP engine.</li> </ul>

Table 74: show snmp statistics Output Fields (Continued)

Field Name	Field Description
	<ul style="list-style-type: none"> <li>• <b>Wrong digests—(usmStatsWrongDigests)</b> Total number of packets received by the SNMP engine that were dropped because they did not contain the expected digest value.</li> <li>• <b>Decryption errors—(usmStatsDecryptionErrors)</b> Total number of packets received by the SNMP engine that were dropped because they could not be decrypted.</li> </ul>
<b>Output</b>	<p>Information about transmitted packets:</p> <ul style="list-style-type: none"> <li>• <b>Packets—(snmpOutPkts)</b> Total number of messages passed from the SNMP entity to the transport service.</li> <li>• <b>Too big—(snmpOutTooBig)</b> Total number of SNMP PDUs generated by the SNMP entity with an error status field of <b>tooBig</b>.</li> <li>• <b>No such names—(snmpOutNoSuchNames)</b> Total number of SNMP PDUs delivered to the SNMP entity with an error status field of <b>noSuchName</b>.</li> <li>• <b>Bad values—(snmpOutBadValues)</b> Total number of SNMP PDUs generated by the SNMP entity with an error status field of <b>badValue</b>.</li> <li>• <b>General errors—(snmpOutGenErrs)</b> Total number of SNMP PDUs generated by the SNMP entity with an error status field of <b>genErr</b>.</li> <li>• <b>Get requests—(snmpOutGetRequests)</b> Total number of SNMP <b>GetRequest</b> PDUs generated by the SNMP entity.</li> <li>• <b>Get nexts—(snmpOutGetNexts)</b> Total number of SNMP <b>GetNext</b> PDUs generated by the SNMP entity.</li> <li>• <b>Set requests—(snmpOutSetRequests)</b> Total number of SNMP <b>SetRequest</b> PDUs generated by the SNMP entity.</li> <li>• <b>Get responses—(snmpOutGetResponses)</b> Total number of SNMP <b>GetResponse</b> PDUs generated by the SNMP entity.</li> <li>• <b>Traps—(snmpOutTraps)</b> Total number of SNMP traps generated by the SNMP entity.</li> </ul>

Table 75 on page 1705 describes the output fields for the `show snmp statistics subagents` command. Output fields are listed in the approximate order in which they appear.

**Table 75: show snmp statistics subagents Output Fields**

Field Name	Field Description
Subagent	Location of the SNMP subagent.
Request PDUs	Number of PDUs requested by the SNMP manager.
Response PDUs	Number of response PDUs sent by the SNMP subagent.
Request Variables	Number of variable bindings on the PDUs requested by the SNMP manager.
Response Variables	Number of variable bindings on the PDUs sent by the SNMP subagent.
Average Response Time	Average time taken by the SNMP subagent to send statistics response.
Maximum Response Time	Maximum time taken by the SNMP subagent to send the statistics response.

## Sample Output

### show snmp statistics

```

user@host> show snmp statistics
SNMP statistics:
  Input:
    Packets: 246213, Bad versions: 12, Bad community names: 12,
    Bad community uses: 0, ASN parse errors: 96,
    Too bigs: 0, No such names: 0, Bad values: 0,
    Read onlys: 0, General errors: 0,
    Total request varbinds: 227084, Total set varbinds: 67,
    Get requests: 44942, Get nexts: 190371, Set requests: 10712,
    Get responses: 0, Traps: 0,
    Silent drops: 0, Proxy drops: 0, Commit pending drops: 0,

```

```

    Throttle drops: 0,
V3 Input:
    Unknown security models: 0, Invalid messages: 0
    Unknown pdu handlers: 0, Unavailable contexts: 0
    Unknown contexts: 0, Unsupported security levels: 1
    Not in time windows: 0, Unknown user names: 0
    Unknown engine ids: 44, Wrong digests: 23, Decryption errors: 0
Output:
    Packets: 246093, Too bigs: 0, No such names: 31561,
    Bad values: 0, General errors: 2,
    Get requests: 0, Get nexts: 0, Set requests: 0,
    Get responses: 246025, Traps: 0

```

## Release Information

Command introduced before Junos OS Release 7.4.

Option subagents introduced in Junos OS Release 14.2.

# show ssl-certificates

## IN THIS SECTION

- [Syntax | 1709](#)
- [Description | 1709](#)

- [Options | 1709](#)
- [Required Privilege Level | 1710](#)
- [Output Fields | 1710](#)
- [Sample Output | 1711](#)
- [Release Information | 1712](#)

## Syntax

```
show ssl certificates
```

## Description

Display information about the Secure Sockets Layer (SSL) certificates installed on the switch. When you configure PEAP as the authentication protocol for MAC RADIUS authentication, you must load the server-side Secure Sockets Layer (SSL) certificate on the switch. PEAP requires an SSL certificate to create a secure TLS tunnel to protect user authentication, and uses server-side public key certificates to authenticate the server. It then creates an encrypted TLS tunnel between the client and the authentication server. The key for this encryption are transported using the server's public key. The ensuing exchange of authentication information inside the tunnel to authenticate the client is then encrypted and user credentials are safe from eavesdropping.

## Options

- none**      Display information about all SSL certificates.
- detail**     Display information about SSL certificates for the specified level of output.

## Required Privilege Level

view

## Output Fields

Table 76 on page 1710 lists the output fields for the `show ssl-certificates` command. Output fields are listed in the approximate order in which they appear.

**Table 76: show ssl-certificates Output Fields**

Field Name	Field Description	Level of Output
Issuer	Authority that issued the digital certificate, including details of the authority organized using the distinguished name format. Possible subfields are: <ul style="list-style-type: none"><li>• C—Country of origin.</li><li>• ST—State or province name.</li><li>• L—Locality.</li><li>• O—Organization of origin.</li><li>• OU—Organizational unit.</li><li>• CN—Common name of the authority.</li></ul>	All levels
Valid from	Start time when the digital certificate becomes valid.	detail
Valid to	End time when the digital certificate becomes invalid.	detail
Serial number	Unique serial number of the digital certificate.	detail

**Table 76: show ssl-certificates Output Fields (Continued)**

Field Name	Field Description	Level of Output
Subject	<p>Details of the digital certificate holder organized using the distinguished name format. Possible subfields are:</p> <ul style="list-style-type: none"> <li>• C—Country of origin.</li> <li>• ST—State or province name.</li> <li>• L—Locality.</li> <li>• O—Organization of origin.</li> <li>• OU—Organizational unit.</li> <li>• CN—Common name of the authority.</li> </ul>	detail

## Sample Output

### show ssl-certificates

```
user@root> show ssl-certificates
Issuer:      /C=IN/ST=KA/L=Blr/O=JNPR/OU=CP/CN=User-Radius/emailAddress=user@juniper.net
```

### show ssl-certificates detail

```
user@root> show ssl-certificates detail

Issuer:      /C=IN/ST=KA/L=Blr/O=JNPR/OU=CP/CN=User-Radius/emailAddress=user@juniper.net
Valid From:   May 30 17:41:04 2016 GMT
Valid Till:   May 29 17:41:04 2026 GMT
Serial Number: 0
Subject:      /C=IN/ST=KA/L=Blr/O=JNPR/OU=CP/CN=User-Radius/emailAddress=user@juniper.net
```

## Release Information

## Output Fields

Table 77 on page 1713 lists the output fields for the `show system autorecovery state` command. Output fields are listed in the approximate order in which they appear.

Table 77: `show system autorecovery state` Output Fields

Field Name	Field Description
File	The name of the file on which autorecovery checks are performed.
Slice	The disk partition on which autorecovery checks are performed.
Recovery Information	Indicates whether autorecovery information for the file or slice has been saved.
Integrity Check	Displays the status of the file's integrity check (passed or failed).
Action / Status	Displays the status of the item, or the action required to be taken for that item.

## Sample Output

`show system autorecovery state`

```
user@host> show system autorecovery state

Configuration:
File           Recovery Information  Integrity Check  Action / Status
rescue.conf.gz Saved                Passed          None
```

## Licenses:

File	Recovery Information	Integrity Check	Action / Status
JUNOS282736.lic	Saved	Passed	None
JUNOS282737.lic	Not Saved	Not checked	Requires save

## BSD Labels:

Slice	Recovery Information	Integrity Check	Action / Status
s1	Saved	Passed	None
s2	Saved	Passed	None
s3	Saved	Passed	None
s4	Saved	Passed	None

## Output Fields

[Table 80 on page 1723](#) lists the output fields for the `show system license` command. Output fields are listed in the approximate order in which they appear.

**Table 80: show system license Output Fields**

Field Name	Field Description
Feature name	Name assigned to the configured feature. You use this information to verify that all the features for which you installed licenses are present.
Licenses used	Number of licenses used by the device. You use this information to verify that the number of licenses used matches the number configured. If a licensed feature is configured, the feature is considered used.
Licenses installed	Information about the installed license key: <ul style="list-style-type: none"> <li>• License identifier—Identifier associated with a license key.</li> <li>• License version—Version of a license. The version indicates how the license is validated, the type of signature, and the signer of the license key.</li> <li>• Valid for device—Device that can use a license key.</li> <li>• Features—Feature associated with a license.</li> </ul>
Licenses needed	Number of licenses required for features being used but not yet properly licensed.
Expiry	Time remaining in the grace period before a license is required for a feature being used.
Logical system license status	Displays whether a license is enabled for a logical system.

## Sample Output

### show system license

```
user@host> show system license
```

```
License usage:
```

```

Licenses    Licenses    Licenses    Expiry

## Syntax

```
show system users  
<no-resolve>
```

## Syntax (TX Matrix Router)

```
show system users  
<all-chassis | all-lcc | lccnumber | scc>  
<no-resolve>
```

## Syntax (TX Matrix Plus Router)

```
show system users  
<detail>  
<all-chassis | all-lcc | lcc number | sfc number> <no-resolve>
```

## Syntax (MX Series Router)

```
show system users
<all-members>
<local>
<member member-id>
<no-resolve>
```

## Description

List information about the users who are currently logged in to the router or switch.

**NOTE:** The `show system users` command lists the information about administrative users that are logged in to a router or switch using the CLI, J-Web, or an SSH client. The output does not list information about web users or automated users that are logged in from a remote client application using Junos XML APIs, such as NETCONF.

## Options

<b>none</b>	List information about the users who are currently logged in to the router or switch.
<b>all-chassis</b>	(TX Matrix routers and TX Matrix Plus routers only) (Optional) Show users currently logged in to all the routers in the chassis.
<b>all-lcc</b>	(TX Matrix routers and TX Matrix Plus routers only) (Optional) On a TX Matrix router, show users currently logged in to all T640 routers (or line-card chassis) connected to the TX Matrix router. On a TX Matrix Plus router, show users currently logged in to all connected T1600 or T4000 LCCs.
<b>all-members</b>	(MX Series routers only) (Optional) Display users currently logged in to all members of the Virtual Chassis configuration.
<b>lcc <i>number</i></b>	(TX Matrix routers and TX Matrix Plus routers only) (Optional) On a TX Matrix router, show users currently logged in to a specific T640 router that is connected to the TX

Matrix router. On a TX Matrix Plus router, show users currently logged in to a specific router that is connected to the TX Matrix Plus router.

Replace *number* with the following values depending on the LCC configuration:

- 0 through 3, when T640 routers are connected to a TX Matrix router in a routing matrix.
- 0 through 3, when T1600 routers are connected to a TX Matrix Plus router in a routing matrix.
- 0 through 7, when T1600 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix.
- 0, 2, 4, or 6, when T4000 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix.

<b>local</b>	(MX Series routers only) (Optional) Display users currently logged in to the local Virtual Chassis member.
<b>member</b> <i>member-id</i>	(MX Series routers only) (Optional) Display users currently logged in to the specified member of the Virtual Chassis configuration. Replace <i>member-id</i> with a value of 0 or 1.
<b>no-resolve</b>	(Optional) Do not attempt to resolve IP addresses to hostnames.
<b>scc</b>	(TX Matrix routers only) (Optional) Show users currently logged in to the TX Matrix router (or switch-card chassis).
<b>sfc number</b>	(TX Matrix Plus routers only) (Optional) Show users currently logged in to the TX Matrix Plus router. Replace <i>number</i> with 0.

## Additional Information

By default, when you issue the `show system users` command on the primary Routing Engine of a TX Matrix router or a TX Matrix Plus router, the command is broadcast to all the primary Routing Engines of the LCCs connected to it in the routing matrix. Likewise, if you issue the same command on the backup Routing Engine of a TX Matrix or a TX Matrix Plus router, the command is broadcast to all backup Routing Engines of the LCCs that are connected to it in the routing matrix.

## Output Fields

Table 85 on page 1741 describes the output fields for the `show system users` command. Output fields are listed in the approximate order in which they appear.

Table 85: show system users Output Fields

Field Name	Field Description
<i>time</i> and up	Current time, in the local time zone, and how long the router or switch has been operational.
users	Number of users logged in to the router or switch.
load averages	Load averages for the last 1 minute, 5 minutes, and 15 minutes.
USER	Username.
TTY	Terminal through which the user is logged in.
FROM	System from which the user has logged in. A hyphen indicates that the user is logged in through the console.
LOGIN@	Time when the user logged in.
IDLE	How long the user has been idle.
WHAT	Processes that the user is running.

## Sample Output

### show system users

## Syntax

```
ssh host
<bypass-routing>
<verbose>
<extensive>
<inet | inet6>
<interface interface-name>
<logical-system logical-system-name>
<tenant tenant-name>
<routing-instance routing-instance-name>
<source address>
<v2>
<port port-number>
```

## Syntax (EX Series Switch and the QFX Series)

```
ssh host
<bypass-routing>
<verbose>
<extensive>
<inet | inet6>
<interface interface-name>
```

```
<routing-instance routing-instance-name>
<source address>
<v2>
<port port-number>
```

## Description

Use the SSH program to open a connection between a local router or switch and a remote system and execute commands on the remote system. You can issue the `ssh` command from the Junos OS CLI to log in to a remote system or from a remote system to log in to the local router or switch. When executing this command, you include one or more CLI commands by enclosing them in quotation marks and separating the commands with semicolons:

```
ssh address 'cli-command1 ; cli-command2 '
```

## Options

<b><i>host</i></b>	Name or address of the remote system.
<b>bypass-routing</b>	(Optional) Bypass the normal routing tables and send ping requests directly to a system on an attached network. If the system is not on a directly attached network, an error is returned. Use this option to ping a local system through an interface that has no route through it.
<b>verbose</b>	(Optional) Display verbose messages during the SSH attempt.
<b>extensive</b>	Display an extensive level of messaging during the SSH attempt.:
<b>inet   inet6</b>	(Optional) Create an IPv4 or IPv6 connection, respectively.
<b>interface <i>interface-name</i></b>	(Optional) Interface name for the SSH session. (This option does not work when <i>default-address-selection</i> is configured at the [edit system] hierarchy level, because this configuration uses the loopback interface as the source address for all locally generated IP packets.)
<b>logical-system <i>logical-system-name</i></b>	(Optional) Name of a particular logical system for the SSH attempt.

<b>tenant</b> <i>tenant-name</i>	(Optional) Name of a particular tenant system for the SSH attempt.
<b>routing-instance</b> <i>routing-instance-name</i>	(Optional) Name of the routing instance for the SSH attempt.
<b>source</b> <i>address</i>	(Optional) Source address of the SSH connection.
<b>v2</b>	(Optional) Use SSH version 2 when connecting to a remote host.
<b>port</b> <i>port-number</i>	(Optional) Specify a port number for the SSH connection.

## Additional Information

To configure an SSH (version 2) key for your user account, include the authentication `dsa-rsa` statement at the `[edit system login user user-name]` hierarchy level.

You can limit the number of times a user can attempt to enter a password while logging in through SSH. To specify the number of times a user can attempt to enter a password to log in through SSH, include the `retry-options` statement at the `[edit system login]` hierarchy level.

## Required Privilege Level

network

## Output Fields

When you enter this command, you are provided feedback on the status of your request.

## Sample Output

**ssh**

```
user@switch> ssh user
Host key not found from the list of known hosts.
Are you sure you want to continue connecting (yes/no)? yes
```

```
Host ?user' added to the list of known hosts.
user@device's password:
Last login: Sun Jun 21 10:43:42 1998 from junos-router
% ...
```

## Release Information

Command introduced before Junos OS Release 7.4.

Command introduced in Junos OS Release 11.1 for the QFX Series.

Command introduced in Junos OS Release 14.1X53-D20 for OCX Series switches.

The command `tenant` option is introduced in Junos OS Release 19.2R1 for SRX Series.

## Syntax

```
telnet host  
<8bit>  
<inet | inet6>  
<port port-number>  
<routing-instance routing-instance-name>  
<logical-system logical-system-name>  
<tenant tenant-name>
```

## Syntax (EX Series Switches)

```
telnet host  
<8bit>  
<bypass-routing>  
<inet | inet6>  
<interface interface-name>  
<no-resolve>  
<port port-number>  
<routing-instance routing-instance-name>  
<source source-address>
```

## Syntax (Junos OS Evolved)

```
telnet host  
<8bit>  
<inet | inet6>
```

```
<port port-number>
<routing-instance routing-instance-name>
```

## Description

Open a telnet session to a remote system. Type Ctrl+] to escape from the telnet session to the telnet command level, and then type quit to exit from telnet.

**NOTE:** For Junos OS Evolved, use the routing-instance `mgmt_junos` option to access a remote system through the management interface.

## Options

<i>host</i>	Name or address of the remote system.
<b>8bit</b>	(Optional) Use an 8-bit data path.
<b>bypass-routing</b>	(Optional) Bypass the normal routing tables and send ping requests directly to a system on an attached network. If the system is not on a directly attached network, an error is returned. Use this option to ping a local system through an interface that has no route through it.
<b>inet   inet6</b>	(Optional) Open an IPv4 or IPv6 session, respectively.
<b>interface <i>interface-name</i></b>	(Optional) Interface name for the telnet session. (This option does not work when default-address-selection is configured at the [edit system] hierarchy level, because this configuration uses the loopback interface as the source address for all locally generated IP packets.)
<b>logical-system <i>logical-system-name</i></b>	(Optional) Name of a particular logical system for the telnet attempt.
<b>tenant <i>tenant-name</i></b>	(Optional) Name of a particular tenant system for the telnet attempt.
<b>no-resolve</b>	(Optional) This option is not supported for Junos OS Evolved Release 18.3R1. Do not attempt to determine the hostname that corresponds to the IP address.

<b>port</b> <i>port-number</i>	(Optional) Port number or service name on the remote system.
<b>routing-instance</b> <i>routing-instance-name</i>	(Optional) Name of the routing instance for the telnet attempt.
<b>source</b> <i>source-address</i>	(Optional) This option is not supported for Junos OS Evolved Release 18.3R1. Source address of the telnet connection.

## Additional Information

You can limit the number of times a user can attempt to enter a password while logging in through telnet. To specify the number of times a user can attempt to enter a password to log in through telnet, include the ["retry-options" on page 1313](#) statement at the [edit system login] hierarchy level.

## Required Privilege Level

network

## Output Fields

When you enter this command, you are provided feedback on the status of your request.

## Sample Output

telnet

```
user@host> telnet 192.154.1.254
Trying 192.154.169.254...
Connected to level5.company.net.
Escape character is '^]'.
ttypa
login:
```

## Release Information

Command introduced before Junos OS Release 7.4.

The following options are deprecated in Junos OS Evolved Release 18.3R1: `bypass-routing`, `interface`, `no-resolve`, and `source`.

The command `tenant` option is introduced in Junos OS Release 19.2R1 for SRX Series.

# test access profile

### IN THIS SECTION

## Syntax

```
test access profile profile-name user username password password <detail>
```

## Description

Specify a profile to use to get information from a RADIUS server, which includes all the information from the `test access radius-server` command.

## Options

<b>detail</b>	(Optional) Show the RADIUS attributes returned by the server.
<b>profile-name</b>	Access profile name configured.
<b>password</b>	Password for the username.
<b>username</b>	User name to be authenticated to the RADIUS server.

## Output Fields

[Table 86 on page 1753](#) lists the output fields for the `test access profile` command. Output fields are listed in the approximate order in which they appear.

**Table 86: test access profile Output Fields**

Field Name	Field Description
Profile Name	Name of the configured access profile.
Client Username	The user name authenticated by the RADIUS server.
Client Password	The user password authenticated by the RADIUS server.
Num Servers	Number of RADIUS servers in the configured access profile.
Server List	List of RADIUS servers in the configure access profile.
IP Address	The IP address of the RADIUS server authenticated.

**Table 86: test access profile Output Fields (Continued)**

Field Name	Field Description
UDP Port	The RADIUS server port utilized during the authentication test.
Source Address	The source IP address of the client making the RADIUS request. If no address is shown, it defaults to the address of the outgoing interface.
Timeout	The RADIUS server timeout period.
Retry Count	The number of authentication attempts allowed by the RADIUS server.
Secret	The shared secret used for authentication with the RADIUS server.
Status	The test result status (Accepted or Rejected) and the number of retransmits utilized during authentication.
Attempts	The number of authentication attempts on the RADIUS server.
Attribute List	The list of returned RADIUS attributes, sorted by the attribute name, and including parameter length and value. See your RADIUS server documentation for attribute descriptions.
(Attribute) Name	The name of the attribute.
(Attribute) Length	The attribute length in bytes.
(Attribute) Value	The attribute value.

## Sample Output

### test access profile

The following example uses the `test access profile` command to access and display basic information about the RADIUS server(s) shown in the resulting output:

```
user@host> test access profile alpha user TEST password TEST
user@host> test access profile alpha user TEST password TEST
Test Radius Profile Access
  Profile Name       : alpha
  Client Username    : TEST
  Client Password    : TEST
  Num Servers        : 5
                        Server List
  UDP                Source      Retry
  IP Address         Port        Address  Timeout Count Secret      Status    Attempts
10.1.1.1             1812    10.10.10.10    2         1    TEST      Timeout    2
10.1.3.4             1812    Default       1         2    TEST      Timeout    3
192.168.10.10        1812    Default       3         3    TEST      Accepted   1
```

### test access profile detail

The following example uses the `test access profile detail` command to access and display detailed information about the RADIUS server(s) shown in the resulting output:

```
user@host> test access profile alpha user TEST password TEST detail
user@host> test access profile alpha user TEST password TEST detail
Test Radius Profile Access Detailed
  Profile Name       : alpha
  Client Username    : TEST
  Client Password    : TEST
  Num Servers        : 5
                        Radius Server List
  IP Address         : 10.1.3.4
  UDP Port           : 1812
  Source Address     : 192.168.10.10
  Timeout            : 2
  Retry Count        : 1
```

```

Secret          : TEST
Status          : Timeout
Attempts        : 2

IP Address      : 10.1.3.5
UDP Port        : 1812
Source Address  : Default
Timeout         : 1
Retry Count     : 2
Secret          : TEST
Status          : Timeout
Attempts        : 3

IP Address      : 192.168.10.10
UDP Port        : 1812
Source Address  : Default
Timeout         : 3
Retry Count     : 3
Secret          : TEST
Status          : Accepted
Attempts        : 1

```

## Syntax

```
test access radius-server address user username password password secret secret
<authentication-port port>
<retry number>
<source-address address>
<timeout number>
```

## Description

Verify RADIUS server authentication parameters.

## Options

<i>address</i>	RADIUS server under test IP address.
<i>password</i>	Password for the user.
<i>secret</i>	Secret shared with the RADIUS server.
<i>user</i>	User name to be authenticated to the RADIUS server.
<i>authentication-port</i>	(Optional) RADIUS server authentication port number (1through 65535).
<i>retry</i>	(Optional) Retry attempts (1through 10).
<i>source-address</i>	(Optional) Use an alternate address as the source address.
<i>timeout</i>	(Optional) Request timeout period (1through 90 seconds).

## Output Fields

[Table 87 on page 1760](#) lists the output fields for the test access radius-server command. Output fields are listed in the approximate order in which they appear.

**Table 87: test access radius-server Output Fields**

Field Name	Field Description
Server	The IP address of the RADIUS server authenticated.
UDP port	The RADIUS server port utilized during the authentication test.
Source IP Address	“Default” is shown if the IP address is the same as that of the RADIUS server. Alternatively, an IP address specified for authentication is shown.
Server timeout	The RADIUS server timeout period.
Sever retry count	The number of authentication attempts allowed by the RADIUS server.
Secret	The shared secret used for authentication with the RADIUS server.
Client Username	The user name authenticated by the RADIUS server.
Client Password	The user password authenticated by the RADIUS server.
Status	The test result status (Accepted or Rejected) and the number of retransmits utilized during authentication.

## Sample Output

### test access radius-server user password secret

The following example command tests RADIUS authentication with a specific server (172.28.30.95), user (JOHNDOE), secret (No1Knows), and password (JohnPass); and displays the resulting output:

```
user@host> test access radius-server 172.28.30.95 user JOHNDOE password JohnPass secret No1Knows
Test Radius Server Access
      Server           : 172.28.30.95
```

```

UDP port           : 1812
Source IP Address  : Default
Server timeout     : 3
Sever retry count  : 3
Secret             : No1Knows
Client Username    : JOHNDOE
Client Password    : JohnPass
Status             : Accepted, retransmits: 0

```

## Release Information

Command introduced in Junos OS Release 9.1.

# request-system-integrity-attestation

### IN THIS SECTION

- [Syntax | 1761](#)
- [Description | 1762](#)
- [Options | 1762](#)
- [Required Privilege Level | 1762](#)
- [Output Fields | 1762](#)
- [Sample Output | 1762](#)
- [Release Information | 1763](#)

## Syntax

```
request system integrity attestation (pcr-index pcr number | nonce-value | tpm-name)
```

## Description

The Attester is a device on the network that provides evidence to the Verifier on demand. The first part of that evidence is a signed collection of the TPM's Platform Configuration Registers (PCRs) called a TPM Quote. To ensure the freshness of the quote, the Verifier sends a random nonce to the Attester to include in the TPM Quote.

## Options

- nonce-value** Defines a base-64 encoded 20 byte random hex value. A cryptographically generated random number which should not be predictable prior to its issuance from a random number generation function. The random number **MUST** be derived from an entropy source external to the Attester.
- pcr-index** The numbers/indexes of the PCRs. At the moment this is limited to 32 items. (0..31)
- tpm-name** Unique system generated name for a TPM on a device.

## Required Privilege Level

view

## Output Fields

When you enter this command, you are provided feedback on the status of your request.

## Sample Output

**request system integrity attestation nonce-value \$NONCE tpm-name \$SERIAL\_NUMBER**

```
user@host> request system integrity attestation nonce-value $NONCE tpm-name $SERIAL_NUMBER
```

## Release Information

Command introduced in Junos OS Release 22.4R1.

# request-system-integrity-log-retrieval

### IN THIS SECTION

- [Syntax | 1763](#)
- [Description | 1763](#)
- [Options | 1764](#)
- [Required Privilege Level | 1764](#)
- [Release Information | 1764](#)

## Syntax

```
request system integrity log-retrieval log-type
```

## Description

The remaining evidence provided to the Verifier on demand is comprised of the boot event log recorded by the TPM. The Verifier will compare this log against the TPM Quote for validity. If the log is valid, the Verifier will check each entry in the log against a known-good entry. Note that as of this release, only the bios log option is supported.

## Options

**bios** Specifies an event type associated with BIOS/UEFI.

**ima** Specifies an event type recorded in IMA.

**netequip\_boot** Specifies an event type associated with Network Equipment Boot.
