About This Guide

Use this guide to understand and configure class of service (CoS) features in Junos OS to define service levels that provide different delay, jitter, and packet loss characteristics to particular applications served by specific traffic flows. Applying CoS features to each device in your network ensures quality of service (QoS) for traffic throughout your entire network. This guide applies to all EX Series switches except the [EX4600](#) and the [EX9200](#) lines of switches.

Junos OS CoS for EX Series Switches Overview

IN THIS SECTION

- How Junos OS CoS Works | 3
- Default CoS Behavior on EX Series Switches | 4

When a network experiences congestion and delay, some packets must be dropped. Junos operating system (Junos OS) *class of service* (CoS) divides traffic into classes to which you can apply different levels of throughput and packet loss when congestion occurs. This allows packet loss to happen according to rules that you configure.

For interfaces that carry IPv4, IPv6, and MPLS traffic, you can configure Junos OS CoS features to provide multiple classes of service for different applications. CoS also allows you to rewrite the Differentiated Services code point (DSCP), IP precedence, 802.1p, or EXP CoS bits of packets egressing out of an interface, thus allowing you to tailor packets for the remote peers' network requirements. See *Understanding Using CoS with MPLS Networks on EX Series Switches* for more information about CoS for MPLS networks.

CoS provides multiple classes of service for different applications. You can configure multiple forwarding classes for transmitting packets, define which packets are placed into each output queue, and schedule the transmission service level for each queue.

In designing CoS applications, you must give careful consideration to your service needs and thoroughly plan and design your CoS configuration to ensure consistency and interoperability across all platforms in a CoS domain.

Because Juniper Networks EX Series Ethernet Switches implement CoS in hardware rather than in software, you can experiment with and deploy CoS features without affecting packet-forwarding and switching performance.

NOTE: CoS policies can be enabled or disabled on each interface of an EX Series switch. Also, each physical and *logical interface* on the switch can have custom CoS rules associated with it. When CoS is used in an MPLS network, there are some additional restrictions. See *Understanding Using CoS with MPLS Networks on EX Series Switches*.

How Junos OS CoS Works

Junos OS CoS works by examining traffic entering at the edge of your network. The switches classify traffic into defined service groups to provide the special treatment of traffic across the network. For example, voice traffic can be sent across certain links, and data traffic can use other links. In addition, the data traffic streams can be serviced differently along the network path. As the traffic leaves the network at the far edge, you can rewrite the traffic to meet the policies of the targeted peer.

To support CoS, you must configure each switch in the network. Generally, each switch examines the packets that enter it to determine their CoS settings. These settings then dictate which packets are transmitted first to the next downstream switch. Switches at the edges of the network might be required to alter the CoS settings of the packets that enter the network to classify the packets into the appropriate service groups.

[Figure 1 on page 4](#) represents the network scenario of an enterprise. Switch A is receiving traffic from various network nodes such as desktop computers, servers, surveillance cameras, and VoIP telephones. As each packet enters, Switch A examines the packet's CoS settings and classifies the traffic into one of the groupings defined by the enterprise. This definition allows Switch A to prioritize resources for servicing the traffic streams it receives. Switch A might alter the CoS settings of the packets to better match the enterprise's traffic groups.

When Switch B receives the packets, it examines the CoS settings, determines the appropriate traffic groups, and processes the packets according to those settings. It then transmits the packets to Switch C, which performs the same actions. Switch D also examines the packets and determines the appropriate groups. Because Switch D sits at the far end of the network, it can rewrite the CoS bits of the packets before transmitting them.

Figure 1: Packet Flow Across the Network

Default CoS Behavior on EX Series Switches

If you do not configure any CoS settings on the switch, the software still ensures that user traffic and protocol packets are forwarded with minimum delay when the network is experiencing congestion. Some CoS settings, such as classifiers, are automatically applied to each logical interface that you configure. Other settings, such as *rewrite rules*, are applied only if you explicitly associate them with an interface.

Example: Combining CoS with MPLS on EX Series Switches

Configuring CoS on EX Series Switches

The topics in this guide describe how to configure the Junos OS class-of-service (CoS) components. Junos CoS provides a flexible set of tools that enable you to fine tune control over the traffic on your network.

- Define classifiers that classify incoming traffic into forwarding classes to place traffic in groups for transmission.
- Map forwarding classes to output queues to define the type of traffic on each output queue.

- Configure schedulers for each output queue to control the service level (priority, bandwidth characteristics) of each type of traffic.
- Provide different service levels for the same forwarding classes on different interfaces.
- Provide congestion management with tail drop profiles, queue shaping, and congestion notification.
- Configure CoS on MPLS networks.
- Configure various CoS components individually or in combination to define CoS services.

NOTE: When you change the CoS configuration or when you deactivate and then reactivate the CoS configuration, the system experiences packet drops because the system momentarily blocks traffic to change the mapping of incoming traffic to input queues.

[Table 1 on page 6](#) lists the primary CoS configuration tasks, includes platform limitations, and provides links to those tasks.

Table 1: CoS Configuration Tasks

CoS Configuration Task	Links
<p>Basic CoS Configuration:</p> <ul style="list-style-type: none"> • Configure CoS using EZQoS with templates for key traffic classes, or a browser and the J-Web interface. • Configure code-point aliases to assign a name to a pattern of code-point bits that you can use instead of the bit pattern when you configure CoS components such as classifiers and rewrite rules. • Configure classifiers and multdestination classifiers. <ul style="list-style-type: none"> • Configure rewrite rules to alter code-point bit values in outgoing packets on the outbound interfaces of a switch so that the CoS treatment matches the policies of a targeted peer. • Set the forwarding class and loss priority of a packet based on the incoming CoS value and assign packets to output queues based on the associated forwarding class. • Configure forwarding classes. • Configure priority-based flow control to apply link-level flow control on a specific traffic class so that different types of traffic can efficiently use the same network interface card (NIC). • Configure CoS schedulers to define the properties of output queues on EX Series switches. These properties include the amount of interface bandwidth assigned to the queue, the size of the memory buffer allocated for storing packets, the priority of the queue, and the drop profiles associated with the queue. • Assign the following CoS components to physical or logical interfaces: <ul style="list-style-type: none"> • Classifiers (logical interfaces only) • Forwarding classes (logical interfaces only) 	<ul style="list-style-type: none"> • "Configuring Junos OS EZQoS for CoS (CLI Procedure)" on page 48 • "Configuring CoS (J-Web Procedure)" on page 49 • "Defining CoS Code-Point Aliases (CLI Procedure)" on page 61 • "Defining CoS Classifiers (CLI Procedure)" on page 70 • "Example: Configuring Multidestination (Multicast, Broadcast, DLF) Classifiers" on page 75 • "Defining CoS Rewrite Rules (CLI Procedure)" on page 90 • "Defining CoS Forwarding Classes (CLI Procedure)" on page 107 • "Configuring Priority-Based Flow Control for an EX Series Switch (CLI Procedure)" on page 116 • "Defining CoS Schedulers and Scheduler Maps (CLI Procedure)" on page 126 • "Assigning CoS Components to Interfaces (CLI Procedure)" on page 51

Understanding Junos OS CoS Components for EX Series Switches

IN THIS SECTION

- [Code-Point Aliases | 8](#)
- [Policers | 8](#)
- [Classifiers | 9](#)
- [Forwarding Classes | 9](#)
- [Tail Drop Profiles | 9](#)
- [Schedulers | 9](#)
- [Rewrite Rules | 10](#)

This topic describes the Juniper Networks Junos operating system (Junos OS) class-of-service (CoS) components for Juniper Networks EX Series Ethernet Switches:

Code-Point Aliases

A code-point alias assigns a name to a pattern of code-point bits. You can use this name instead of the bit pattern when you configure other CoS components such as classifiers, drop-profile maps, and *rewrite rules*.

Policers

Policers limit traffic of a certain class to a specified bandwidth and *burst size*. Packets exceeding the policer limits can be discarded. You define policers with filters that can be associated with input interfaces.

For more information about policers, see *Understanding the Use of Policers in Firewall Filters*.

NOTE: You can configure policers to discard packets that exceed the rate limits. If you want to configure CoS parameters such as **loss-priority** and **forwarding-class**, you must use firewall filters.

Classifiers

Packet classification associates incoming packets with a particular CoS servicing level. In Juniper Networks Junos operating system (Junos OS), *classifiers* associate packets with a forwarding class and loss priority and assign packets to output queues based on the associated forwarding class. Junos OS supports two general types of classifiers:

- Behavior aggregate or CoS value traffic classifiers—Examines the CoS value in the packet header. The value in this single field determines the CoS settings applied to the packet. BA classifiers allow you to set the forwarding class and loss priority of a packet based on the Differentiated Services code point (DSCP) value, IP precedence value, and IEEE 802.1p value.
- Multifield traffic classifiers—Examines multiple fields in the packet such as source and destination addresses and source and destination port numbers of the packet. With multifield classifiers, you set the forwarding class and loss priority of a packet based on *firewall filter* rules.

Forwarding Classes

Forwarding classes group the packets for transmission. Based on forwarding classes, you assign packets to output queues. Forwarding classes affect the forwarding, scheduling, and marking policies applied to packets as they transit a switch. By default, four categories of forwarding classes are defined: best effort, assured forwarding, expedited forwarding, and network control. For EX Series switches, 16 forwarding classes are supported, providing granular classification capability.

Tail Drop Profiles

Drop profile is a mechanism that defines parameters that allow packets to be dropped from the network. Drop profiles define the meanings of the loss priorities. When you configure drop profiles you are essentially setting the value for queue fullness. The queue fullness represents a percentage of the queue used to store packets in relation to the total amount that has been allocated for that specific queue.

Loss priorities set the priority of dropping a packet. Loss priority affects the scheduling of a packet without affecting the packet's relative ordering. You can use the loss priority setting to identify packets that have experienced congestion. Typically you mark packets exceeding some service level with a high loss priority.

Schedulers

Each switch interface has multiple queues assigned to store packets. The switch determines which queue to service based on a particular method of scheduling. This process often involves determining which type of packet should be transmitted before another. You can define the priority, bandwidth, delay buffer size, and tail drop profiles to be applied to a particular queue for packet transmission.

A scheduler map associates a specified forwarding class with a scheduler configuration. You can associate up to four user-defined scheduler maps with the interfaces.

Rewrite Rules

A *rewrite rule* sets the appropriate CoS bits in the outgoing packet, thus allowing the next downstream device to classify the packet into the appropriate service group. Rewriting, or marking, outbound packets is useful when the switch is at the border of a network and must alter the CoS values to meet the policies of the targeted peer.

NOTE: Egress firewall filters can also assign forwarding class and loss priority so that the packets are rewritten based on forwarding class and loss priority.

[Understanding CoS Two-Color Marking | 10](#)

[Understanding CoS Rewrite Rules | 88](#)

[Example: Configuring CoS on EX Series Switches | 11](#)

Understanding CoS Two-Color Marking

Networks police traffic by limiting the input or output transmission rate of a class of traffic on the basis of user-defined criteria. Policing traffic allows you to control the maximum rate of traffic sent or received on an interface and to partition a network into multiple priority levels or classes of service.

Policers require you to apply limits to the traffic flow and set a consequence for packets that exceed these limits—usually a higher loss priority, so that packets exceeding the policer limits are discarded first.

Juniper Networks EX Series Ethernet Switches support a single-rate two-color marking type of policer, which is a simplified version of Single-Rate-Three-Color marking, defined in RFC 2697, *A Single Rate Three Color Marker*. This type of policer meters traffic based on the configured committed information rate (CIR) and committed burst size (CBS).

The single-rate two-color marker meters traffic and marks incoming packets depending on whether they are smaller than the committed burst size (CBS)—marked green—or exceed it—marked red.

The single-rate two-color marking policer operates in color-blind mode. In this mode, the policer's actions are not affected by any previous marking or metering of the examined packets. In other words, the policer is “blind” to any previous coloring a packet might have had.

Example: Configuring CoS on EX Series Switches

IN THIS SECTION

- [Requirements | 11](#)
- [Overview and Topology | 12](#)
- [Configuration | 15](#)
- [Verification | 32](#)

Configure class of service (CoS) on your switch to manage traffic so that when the network experiences congestion and delay, critical applications are protected. Using CoS, you can divide traffic on your switch into classes and provide various levels of throughput and packet loss. This is especially important for traffic that is sensitive to jitter and delay, such as voice traffic.

This example shows how to configure CoS on a single EX Series switch in the network.

Requirements

This example uses the following hardware and software components:

- EX Series switches
- Junos OS Release 9.0 or later for EX Series switches

Overview and Topology

This example uses the topology shown in [Figure 2 on page 13](#).

Figure 2: Topology for Configuring CoS

The topology for this configuration example consists of EX switches at the access layer.

The EX Series access switches are configured to support VLAN membership. On the access layer switch, interfaces ge-0/0/0 and ge-0/0/1 are assigned to the voice VLAN (voice-vlan) for two VoIP IP phones. Switch interface ge-0/0/2 is assigned to the camera VLAN (camera-vlan) for the surveillance camera. Switch interfaces ge-0/0/3, ge-0/0/4, ge-0/0/5, and ge-0/0/6 are assigned to the server VLAN (server-vlan) for the servers hosting various applications such as those provided by Citrix, Microsoft, Oracle, and SAP. The trunk ports, ge-0/0/20 and ge-0/0/21, are assigned to the server, voice, employee, and camera VLANs and used as uplink ports to connect the distribution layer switches.

[Table 2 on page 14](#) shows the VLAN configuration components.

Table 2: Configuration Components: VLANs

VLAN Name	VLAN ID	VLAN Subnet and Available IP Addresses	VLAN Description
voice-vlan	10	192.168.1.0/28 192.168.1.1 through 192.168.1.14 192.168.1.15 is the subnet's broadcast address.	Voice VLAN used for employee VoIP communication.
camera-vlan	20	192.168.1.16/28 192.168.1.17 through 192.168.1.30 192.168.1.31 is the subnet's broadcast address.	VLAN for the surveillance cameras.
server-vlan	30	192.168.1.32/28 192.168.1.33 through 192.168.1.46 192.168.1.47 is the subnet's broadcast address.	VLAN for the servers hosting enterprise applications.

PoE-capable ports on EX Series switches support Power over Ethernet (PoE) to provide both network connectivity and power for VoIP telephones connecting to the ports. [Table 3 on page 15](#) shows the

switch interfaces that are assigned to the VLANs and the IP addresses for devices connected to the switch ports on a 48-port switch, all ports of which are PoE-capable.

Table 3: Configuration Components: Switch Interfaces Assigned to VLANs and Devices on a 48-Port All-PoE Switch

Interfaces	VLAN Membership	IP Addresses	Port Devices
ge-0/0/0, ge-0/0/1	voice-vlan	192.168.1.1/28 through 192.168.1.2/28	Two VoIP telephones.
ge-0/0/2	camera-vlan	192.168.1.17/28	Surveillance camera.
ge-0/0/3, ge-0/0/4, ge-0/0/5, ge-0/0/6	server-vlan	192.168.1.33/28 through 192.168.1.36/28	Four servers hosting applications such as those provided by Citrix, Microsoft, Oracle, and SAP.

NOTE: This example shows how to configure CoS on a standalone EX Series switch. This example does not consider across-the-network applications of CoS in which you might implement different configurations on ingress and egress switches to provide differentiated treatment to different classes across a set of nodes in a network.

NOTE: Although you will sometimes see schedulers configured for strict-high priority with a transmit-rate configured, that configuration is misleading because strict-high priority schedulers get unlimited bandwidth and the transmit-rate parameter has no effect on them. With this configuration, lower priority queues can suffer starvation if there is congestion. It is better that schedulers with strict-high priority have shaping-rate parameters configured, which is the correct way to limit their bandwidth.

set class-of-service scheduler-maps ethernet-cos-map forwarding-class best-effort scheduler be-
sched
set class-of-service interfaces ge-0/0/20 scheduler-map ethernet-cos-map
set class-of-service interfaces ge-0/0/21 scheduler-map ethernet-cos-map
set class-of-service schedulers voice-sched-queue-shap shaping-rate 30m
set class-of-service scheduler-maps sched-map-be forwarding-class best-effort scheduler voice-
sched-queue-shap
set class-of-service interfaces ge-0/0/2 scheduler-map sched-map-be

```

Step-by-Step Procedure

To configure and apply CoS:

1. Configure one-to-one mappings between eight forwarding classes and eight queues:

```
[edit class-of-service]
user@switch# set forwarding-classes class app queue-num 5
user@switch# set forwarding-classes class mail queue-num 1
user@switch# set forwarding-classes class db queue-num 2
user@switch# set forwarding-classes class erp queue-num 3
user@switch# set forwarding-classes class video queue-num 4
user@switch# set forwarding-classes class best-effort queue-num 0
user@switch# set forwarding-classes class voice queue-num 6
user@switch# set forwarding-classes class network-control queue-num 7
```

2. Define the firewall filter voip_class to classify the VoIP traffic:

```
[edit firewall]
user@switch# set family ethernet-switching filter voip_class
```

3. Define the term voip:

```
[edit firewall]
user@switch# set family ethernet-switching filter voip_class term voip from source-address
192.168.1.1/28
user@switch# set family ethernet-switching filter voip_class term voip from source-address
192.168.1.2/28
user@switch# set family ethernet-switching filter voip_class term voip protocol udp
user@switch# set family ethernet-switching filter voip_class term voip source-port 2698
user@switch# set family ethernet-switching filter voip_class term voip then forwarding-
class voice loss-priority low
```

4. Define the term network_control (for the voip_class filter):

```
[edit firewall]
user@switch# set family ethernet-switching filter voip_class term network_control from
precedence [net-control internet-control]
```

```
user@switch# set family ethernet-switching filter voip_class term network_control then
forwarding-class network-control loss-priority low
```

5. Define the term `best_effort_traffic` with no match conditions (for the `voip_class` filter):

```
[edit firewall]
user@switch# set family ethernet-switching filter voip_class term best_effort_traffic then
forwarding-class best-effort loss-priority low
```

6. Apply the firewall filter `voip_class` as an input filter to the interfaces for the VoIP phones:

```
[edit interfaces]
user@switch# set ge-0/0/0 description phone1-voip-ingress-port
user@switch# set ge-0/0/0 unit 0 family ethernet-switching filter input voip_class
user@switch# set ge-0/0/1 description phone2-voip-ingress-port
user@switch# set ge-0/0/1 unit 0 family ethernet-switching filter input voip_class
```

7. Apply port shaping on the interface `ge-0/0/0`:

```
[edit]
user@switch# set class-of-service interfaces ge-0/0/0 shaping-rate 100m
```

8. Define the firewall filter `video_class` to classify the video traffic:

```
[edit firewall]
user@switch# set family ethernet-switching filter video_class
```

9. Define the term `video`:

```
[edit firewall]
user@switch# set family ethernet-switching filter video_class term video from source-
address 192.168.1.17/28
user@switch# set family ethernet-switching filter video_class term video protocol udp
user@switch# set family ethernet-switching filter video_class term video source-port 2979
user@switch# set family ethernet-switching filter video_class term video then forwarding-
class video loss-priority low
```

10. Define the term `network_control` (for the `video_class` filter):

```
[edit firewall]
user@switch# set family ethernet-switching filter video_class term network_control from
precedence [net-control internet-control]
user@switch# set family ethernet-switching filter video_class term network_control then
forwarding-class network-control loss-priority low
```

11. Define the term `best_effort_traffic` with no match conditions (for the `video_class` filter):

```
[edit firewall]
user@switch# set family ethernet-switching filter video_class term best_effort_traffic then
forwarding-class best-effort loss-priority low
```

12. Apply the firewall filter `video_class` as an input filter to the interface for the surveillance camera:

```
[edit interfaces]
user@switch# set ge-0/0/2 description video-ingress-port
user@switch# set ge-0/0/2 unit 0 family ethernet-switching filter input video_class
```

13. Define the firewall filter `app_class` to classify the application server traffic:

```
[edit firewall]
user@switch# set family ethernet-switching filter app_class
```

14. Define the term `app` (for the `app_class` filter):

```
[edit firewall]
user@switch# set family ethernet-switching filter app_class term app from source-address
192.168.1.33/28
user@switch# set family ethernet-switching filter app_class term app protocol tcp
user@switch# set family ethernet-switching filter app_class term app source-port [1494 2512
2513 2598 2897]
user@switch# set family ethernet-switching filter app_class term app then forwarding-class
app loss-priority low
```

15. Define the term mail (for the app_class filter):

```
[edit firewall]
user@switch# set family ethernet-switching filter app_class term mail from source-address
192.168.1.34/28
user@switch# set family ethernet-switching filter app_class term mail protocol tcp
user@switch# set family ethernet-switching filter app_class term mail source-port [25 143
389 691 993 3268 3269]
user@switch# set family ethernet-switching filter app_class term mail then forwarding-class
mail loss-priority low
```

16. Define the term db (for the app_class filter):

```
[edit firewall]
user@switch# set family ethernet-switching filter app_class term db from source-address
192.168.1.35/28
user@switch# set family ethernet-switching filter app_class term db protocol tcp
user@switch# set family ethernet-switching filter app_class term db source-port [1521 1525
1527 1571 1810 2481]
user@switch# set family ethernet-switching filter app_class term db then forwarding-class
db loss-priority low
```

17. Define the term erp (for the app_class filter):

```
[edit firewall]
user@switch# set family ethernet-switching filter app_class term erp from source-address
192.168.1.36/28
user@switch# set family ethernet-switching filter app_class term erp protocol tcp
user@switch# set family ethernet-switching filter app_class term erp source-port [3200 3300
3301 3600]
user@switch# set family ethernet-switching filter app_class term erp then forwarding-class
erp loss-priority low
```

18. Define the term network_control (for the app_class filter):

```
[edit firewall]
user@switch# set family ethernet-switching filter app_class term network_control from
precedence [net-control internet-control]
```

```
user@switch# set family ethernet-switching filter app_class term network_control then
forwarding-class network-control loss-priority low
```

19. Define the term `best_effort_traffic` (for the `app_class` filter):

```
[edit firewall]
user@switch# set family ethernet-switching filter app_class term best_effort_traffic then
forwarding-class best-effort loss-priority low
```

20. Apply the firewall filter `app_class` as an input filter to the interfaces for the servers hosting applications:

```
[edit interfaces]
user@switch# set ge-0/0/3 unit 0 family ethernet-switching filter input app_class
user@switch# set ge-0/0/4 unit 0 family ethernet-switching filter input app_class
user@switch# set ge-0/0/5 unit 0 family ethernet-switching filter input app_class
user@switch# set ge-0/0/6 unit 0 family ethernet-switching filter input app_class
```

21. Configure schedulers:

```
[edit class-of-service]
user@switch# set schedulers voice-sched shaping-rate percent 10
user@switch# set schedulers voice-sched buffer-size percent 10
user@switch# set schedulers voice-sched priority strict-high
user@switch# set schedulers video-sched priority low
user@switch# set schedulers video-sched transmit-rate percent 15
user@switch# set schedulers app-sched buffer-size percent 10
user@switch# set schedulers app-sched priority low
user@switch# set schedulers app-sched transmit-rate percent 10
user@switch# set schedulers mail-sched buffer-size percent 5
user@switch# set schedulers mail-sched priority low
user@switch# set schedulers mail-sched transmit-rate percent 5
user@switch# set schedulers db-sched buffer-size percent 10
user@switch# set schedulers db-sched priority low
user@switch# set schedulers db-sched transmit-rate percent 10
user@switch# set schedulers erp-sched buffer-size percent 10
user@switch# set schedulers erp-sched priority low
user@switch# set schedulers erp-sched transmit-rate percent 10
user@switch# set schedulers nc-sched shaping-rate percent 5
user@switch# set schedulers nc-sched buffer-size percent 5
```

```

user@switch# set schedulers nc-sched priority strict-high
user@switch# set schedulers nc-sched transmit-rate percent 5
user@switch# set schedulers be-sched buffer-size percent 35
user@switch# set schedulers be-sched priority low
user@switch# set schedulers be-sched transmit-rate percent 35

```

22. Assign the forwarding classes to schedulers with the scheduler map ethernet-cos-map:

```

[edit class-of-service]
user@switch# set scheduler-maps ethernet-cos-map forwarding-class voice scheduler voice-
sched
user@switch# set scheduler-maps ethernet-cos-map forwarding-class video scheduler video-
sched
user@switch# set scheduler-maps ethernet-cos-map forwarding-class app scheduler app-sched
user@switch# set scheduler-maps ethernet-cos-map forwarding-class mail scheduler mail-sched
user@switch# set scheduler-maps ethernet-cos-map forwarding-class db scheduler db-sched
user@switch# set scheduler-maps ethernet-cos-map forwarding-class erp scheduler erp-sched
user@switch# set scheduler-maps ethernet-cos-map forwarding-class network-control scheduler
nc-sched
user@switch# set scheduler-maps ethernet-cos-map forwarding-class best-effort scheduler be-
sched

```

23. Associate the scheduler map with the outgoing interfaces:

```

[edit class-of-service interfaces]
user@switch# set ge-0/0/20 scheduler-map ethernet-cos-map
user@switch# set ge-0/0/21 scheduler-map ethernet-cos-map

```

24. Apply queue shaping for the best-effort queue:

```

[edit]
user@switch# set class-of-service schedulers voice-sched-queue-shap shaping-rate 30m
user@switch# set class-of-service scheduler-maps sched-map-be forwarding-class best-effort
scheduler voice-sched-queue-shap
user@switch# set class-of-service interfaces ge-0/0/2 scheduler-map sched-map-be

```

Results

Display the results of the configuration:

```
user@switch> show firewall
```

```
firewall family ethernet-switching {
  filter voip_class {
    term voip {

Verification

IN THIS SECTION

- [Verifying That the Defined Forwarding Classes Exist and Are Mapped to Queues | 32](#)
- [Verifying That the Forwarding Classes Have Been Assigned to Schedulers | 33](#)
- [Verifying That the Scheduler Map Has Been Applied to the Interfaces | 35](#)
- [Verifying That Port Shaping Has Been Applied | 35](#)
- [Verifying That Queue Shaping Has Been Applied | 40](#)

To confirm that the configuration is working properly, perform these tasks:

Verifying That the Defined Forwarding Classes Exist and Are Mapped to Queues

Purpose

Verify that the forwarding classes app, best-effort, db, erp, mail, network-control, video, and voice have been defined and mapped to queues.

Action

```
user@switch> show class-of-service forwarding-class
```

Forwarding class	ID	Queue
app	0	5
db	1	2
erp	2	3

video	6	4
network-control	7	7

Meaning

This output shows that the forwarding classes have been defined and mapped to appropriate queues.

Verifying That the Forwarding Classes Have Been Assigned to Schedulers

Purpose

Verify that the forwarding classes have been assigned to schedulers.

Action

```

user@switch> show class-of-service scheduler-map
Scheduler map: ethernet-cos-map, Index: 2
  Scheduler: voice-sched, Forwarding class: voice, Index: 22
    Shaping rate: 10 percent, Rate Limit: none, Buffer size: 10 percent,
    Priority: Strict-high
    Drop profiles:
      Loss priority  Protocol  Index  Name
      High          non-TCP    1      <default-drop-profile>
      High          TCP       1      <default-drop-profile>

  Scheduler: video-sched, Forwarding class: video, Index: 22
    Transmit rate: 10 percent, Rate Limit: none, Buffer size: 10 percent,
    Priority: low
    Drop profiles:
      Loss priority  Protocol  Index  Name
      High          non-TCP    1      <default-drop-profile>
      High          TCP       1      <default-drop-profile>

  Scheduler: app-sched, Forwarding class: app, Index: 22
    Transmit rate: 10 percent, Rate Limit: none, Buffer size: 10 percent,
    Priority: low
    Drop profiles:
      Loss priority  Protocol  Index  Name
      High          non-TCP    1      <default-drop-profile>
      High          TCP       1      <default-drop-profile>

  Scheduler: mail-sched, Forwarding class: mail, Index: 22
    Transmit rate: 5 percent, Rate Limit: none, Buffer size: 5 percent,
    Priority: low
    Drop profiles:
      Loss priority  Protocol  Index  Name
      High          non-TCP    1      <default-drop-profile>
      High          TCP       1      <default-drop-profile>

```

Scheduler: db-sched, Forwarding class: db, Index: 22

Transmit rate: 10 percent, Rate Limit: none, Buffer size: 10 percent,

Priority: low

Drop profiles:

Loss priority	Protocol	Index	Name
High	non-TCP	1	<default-drop-profile>
High	TCP	1	<default-drop-profile>

Scheduler: erp-sched, Forwarding class: erp, Index: 22

Transmit rate: 10 percent, Rate Limit: none, Buffer size: 10 percent,

Priority: low

Drop profiles:

Loss priority	Protocol	Index	Name
High	non-TCP	1	<default-drop-profile>
High	TCP	1	<default-drop-profile>

Scheduler: be-sched, Forwarding class: best-effort, Index: 20

Transmit rate: 35 percent, Rate Limit: none, Buffer size: 35 percent,

Priority: low

Drop profiles:

Loss priority	Protocol	Index	Name
High	non-TCP	1	<default-drop-profile>
High	TCP	1	<default-drop-profile>

Scheduler: nc-sched, Forwarding class: network-control, Index: 22

Shaping rate: 5 percent, Rate Limit: none, Buffer size: 5 percent,

Priority: Strict-high

Drop profiles:

Loss priority	Protocol	Index	Name
High	non-TCP	1	<default-drop-profile>
High	TCP	1	<default-drop-profile>

Meaning

This output shows that the forwarding classes have been assigned to schedulers.

Verifying That the Scheduler Map Has Been Applied to the Interfaces

Purpose

Verify that the scheduler map has been applied to the interfaces.

Action

```
user@switch> show class-of-service interface
...
Physical interface: ge-0/0/20, Index: 149
Queues supported: 8, Queues in use: 8
  Scheduler map: ethernet-cos-map, Index: 43366
  Input scheduler map: <default>, Index: 3
...
Physical interface: ge-0/0/21, Index: 150
Queues supported: 8, Queues in use: 8
  Scheduler map: ethernet-cos-map, Index: 15103
  Input scheduler map: <default>, Index: 5
...
```

Meaning

This output includes details of the interfaces to which the scheduler map (ethernet-cos-map) has been applied (ge-0/0/20 and ge-0/0/21).

Verifying That Port Shaping Has Been Applied

Purpose

Verify that the port shaping has been applied to an interface.

Action

Following is the output before port shaping is applied to the interface ge-0/0/0, when there is egress traffic of 400 Mbps exiting on that interface:

```
user@switch> show interfaces ge-0/0/0 extensive
Physical interface: ge-0/0/0, Enabled, Physical link is Up
  Interface index: 239, SNMP ifIndex: 548, Generation: 242
```

Link-level type: Ethernet, MTU: 1514, Speed: Auto, Duplex: Auto, BPDU Error: None, MAC-REWRITE Error: None, Loopback: Disabled, Source filtering: Disabled, Flow control: Enabled, Auto-negotiation: Enabled, Remote fault: Online,

Media type: Copper

Device flags : Present Running

Interface flags: SNMP-Traps Internal: 0x0

Link flags : None

CoS queues : 8 supported, 8 maximum usable queues

Hold-times : Up 0 ms, Down 0 ms

Current address: 00:23:9c:0b:ae:8d, Hardware address: 00:23:9c:0b:ae:8d

Last flapped : 2012-07-07 03:21:52 UTC (1d 18:02 ago)

    Output packets:          0           0 pps
  Protocol eth-switch, Generation: 163, Route table: 0
  Flags: Trunk-Mode

```

```

user@switch> show class-of-service interface ge-0/0/0
Physical interface: ge-0/0/0, Index: 165
Queues supported: 8, Queues in use: 4
Shaping rate: 100000000 bps
...
...

```

Meaning

In the output for the `show interfaces ge-0/0/0 statistics` command, the `Traffic statistics:` field shows that egress traffic is ~100 Mbps (100,223,104 bps). The output for the `show class-of-service interface ge-0/0/0` command shows that the shaping rate is 100,000,000 bps, which indicates that a port shaping of 100 Mbps is applied to the ge-0/0/0 interface.

Verifying That Queue Shaping Has Been Applied

Purpose

Verify that the queue shaping has been applied to the best-effort queue.

Action

Following is the output before queue shaping is applied to the best-effort queue when there is egress traffic of 400 Mbps exiting on that interface:

```

user@switch> show interfaces ge-0/0/2 extensive
Physical interface: ge-0/0/2, Enabled, Physical link is Up
  Interface index: 239, SNMP ifIndex: 548, Generation: 242
  Link-level type: Ethernet, MTU: 1514, Speed: Auto, Duplex: Auto, BPDU Error: None, MAC-REWRITE
Error: None, Loopback: Disabled, Source filtering: Disabled, Flow control: Enabled, Auto-
negotiation: Enabled, Remote fault: Online,
  Media type: Copper
  Device flags   : Present Running
  Interface flags: SNMP-Traps Internal: 0x0
  Link flags    : None
  CoS queues    : 8 supported, 8 maximum usable queues
  Hold-times    : Up 0 ms, Down 0 ms
  Current address: 00:23:9c:0b:ae:8d, Hardware address: 00:23:9c:0b:ae:8d
  Last flapped  : 2012-07-07 03:21:52 UTC (1d 18:02 ago)
  Statistics last cleared: 2012-07-07 23:54:34 UTC (21:29:59 ago)
  Traffic statistics:

Understanding Junos OS EZQoS for CoS Configurations on EX Series Switches

Junos operating system (Junos OS) EZQoS on Juniper Networks EX Series Ethernet Switches eliminates the complexities involved in configuring *class of service* (CoS) across the network. EZQoS offers templates for key traffic classes.

Junos OS CoS allows you to divide traffic into classes and offer various levels of throughput and packet loss when congestion occurs. You can use CoS to ensure that different types of traffic (voice, video, and data) get the bandwidth and consideration they need to meet user expectations and business objectives.

Configuring CoS requires careful consideration of your service needs and thorough planning and design to ensure consistency across all switches in a CoS domain. To configure CoS manually, you must define and fine-tune all CoS components such as classifiers, *rewrite rules*, forwarding classes, schedulers, and scheduler-maps and then apply these components to the interfaces. Therefore, configuring CoS can be a fairly complex and time-consuming task.

EZQoS works by automatically assigning preconfigured values to all CoS parameters based on the typical application requirements. These preconfigured values are stored in a template with a unique name. You can change the preconfigured values of these parameters to suit your particular application needs.

For using EZQoS, you must identify which switch ports are being used for a specific application (such as VoIP, video, and data) and manually apply the corresponding application-specific EZQoS template to these switch ports.

NOTE: Currently, we provide an EZQoS template for configuring CoS for VoIP.

NOTE: We recommend that you do not use the term **EZQoS** for defining a classifier.

RELATED DOCUMENTATION

[Configuring Junos OS EZQoS for CoS \(CLI Procedure\)](#) | 48

Configuring Junos OS EZQoS for CoS (CLI Procedure)

You use Junos OS EZQoS on EX Series switches to eliminate the complexities involved in configuring class of service (CoS) across the network. EZQoS offers templates for key traffic classes.

When you configure EZQoS on EX Series switches, preconfigured values are assigned to all CoS parameters based on the typical application requirements. These preconfigured values are stored in a template with a unique name.

NOTE: Currently, we provide an EZQoS template for configuring CoS for VoIP applications. The EZQoS VoIP template is stored in `/etc/config/ezqos-voip.conf`.

To configure EZQoS using the CLI:

1. Load the EZQoS configuration file (`/etc/config/ezqos-voip.conf`):

```
[edit]
user@switch# load merge /etc/config/ezqos-voip.conf
```

2. Apply the EZQoS group (`ezqos-voip`):

```
[edit]
user@switch# set apply-groups ezqos-voip
```

3. Apply the DSCP classifier (**ezqos-dscp-classifier**) to a Gigabit Ethernet interface (**ge-0/0/0**):

```
[edit class-of-service interfaces]
user@switch# set ge-0/0/0 unit 0 classifiers dscp ezqos-dscp-classifier
```

4. Apply the scheduler map (**ezqos-voip-sched-maps**) to a Gigabit Ethernet interface (**ge-0/0/1**):

```
[edit class-of-service interfaces]
user@switch# set ge-0/0/1 scheduler-map ezqos-voip-sched-maps
```

Configuring CoS (J-Web Procedure)

The Class of Service Configuration pages allow you to configure the Junos CoS components. You can configure forwarding classes for transmitting packets, define which packets are placed into each output queue, and schedule the transmission service level for each queue. After defining the CoS components you must assign classifiers to the required physical and logical interfaces.

Using the Class of Service Configuration pages, you can configure various CoS components individually or in combination to define particular CoS services.

To configure CoS components :

1. In the J-Web interface, select **Configure>Class of Service**.
2. On the Class of Service Configuration page, select one of the following options depending on the CoS component that you want to define. Enter information into the pages as described in the respective table:
 - To define or edit CoS value aliases, select **CoS Value Aliases** .
 - To define or edit forwarding classes and assign queues, select **Forwarding Classes**.
 - To define or edit classifiers, select **Classifiers** .
 - To define or edit rewrite rules, select **Rewrite Rules**.

- To define or edit schedulers, select **Schedulers**.
 - To define or edit virtual channel groups, select **Interface Associations**.
3. Click **Apply** after completing configuration on any Configuration page.

- [Assigning CoS Components to Interfaces \(J-Web Procedure\) | 52](#)
- [Monitoring Interfaces That Have CoS Components | 54](#)

Assigning CoS Components to Interfaces (CLI Procedure)

After you have defined the following CoS components, you must assign them to logical or physical interfaces.

- Forwarding classes—Assign only to logical interfaces.
- Classifiers—Assign only to logical interfaces.
- Scheduler maps—Assign to either physical or logical interfaces.
- Rewrite rules—Assign to either physical or logical interfaces.

You can assign a CoS component to a single interface or to multiple interfaces using wild cards.

To assign CoS components to interfaces:

- To assign CoS components to a single interface, associate a CoS component (for example a scheduler map named `ethernet-cos-map`) with an interface:

```
[edit class-of-service interfaces]  
user@switch# set ge-0/0/20 scheduler-map ethernet-cos-map
```

- To assign a CoS component to multiple interfaces, associate a CoS component (for example, a rewrite rule named `customup-rw`) to all Gigabit Ethernet interfaces on the switch, use wild characters for the interface name and logical-interface (unit) number:

```
[edit class-of-service interfaces]
user@switch# set ge-* unit * rewrite-rules ieee-802.1 customup-rw
```

Assigning CoS Components to Interfaces (J-Web Procedure)

NOTE: This topic applies only to the J-Web Application package.

After you have defined CoS components on an EX Series switch, you must assign them to logical or physical interfaces. You can use the J-Web interface to assign scheduler maps to physical or logical interfaces and to assign forwarding classes or classifiers to logical interfaces.

To assign CoS components to interfaces:

1. Select **Configure** > **Class of Service** > **Assign to Interface**.

NOTE: After you make changes to the configuration on this page, you must commit the changes immediately for them to take effect. To commit all changes to the active configuration, select **Commit Options** > **Commit**. See [Using the Commit Options to Commit Configuration Changes \(J-Web Procedure\)](#) for details about all commit options.

2. To configure an interface association, select an interface from the list and click **Edit**.
3. Select one of the following:
 - **Associate system default scheduler map**—Associates the interface with the default scheduler map.

- **Select the scheduler map**—Associates the interface with a configured scheduler map. Select the scheduler map from the list.

4. Click **OK**.

5. To manage a CoS assignment on a logical interface, Click one of the following options:

- **Add**—Adds a CoS service to a logical interface on a specified physical interface. Enter information as described in [Table 4 on page 53](#).
- **Edit**—Modifies a CoS service assignment to a logical interface. Enter information as described in [Table 4 on page 53](#).
- **Delete**—Deletes the CoS service assignment to a logical interface.

Table 4: Assigning CoS Components to Logical Interfaces

Field	Function	Your Action
Unit	Specifies the name of a logical interface. Enables you to assign CoS components when you configure a logical interface on a physical interface.	Type the interface name. To assign CoS to all logical interfaces configured on this physical interface, type the wildcard character (*).
Forwarding Class	Assigns a predefined forwarding class to incoming packets on a logical interface.	To assign a forwarding class to an interface, select the forwarding class.
Classifiers	Enables you to apply classification maps to a logical interface. Classifiers assign a forwarding class and loss priority to an incoming packet based on its CoS value.	To assign a classification map to an interface, select an appropriate classifier for each CoS value type used on the interface.
Rewrite Rules	Enables you to alter the CoS values in outgoing packets to meet the requirements of the targeted peer. A rewrite rule examines the forwarding class and loss priority of a packet and sets its bits to a corresponding value specified in the rule.	To assign rewrite rules to the interface, select the appropriate rewrite rule for each CoS value type used on the interface.

CoS Code-Point Aliases

IN THIS CHAPTER

- Understanding CoS Code-Point Aliases | 57
- Defining CoS Code-Point Aliases (CLI Procedure) | 61
- Defining CoS Code-Point Aliases (J-Web Procedure) | 62
- Monitoring CoS Value Aliases | 63

Understanding CoS Code-Point Aliases

IN THIS SECTION

- Default Code-Point Aliases | 58

A code-point alias assigns a name to a pattern of code-point bits. You can use this name instead of the bit pattern when you configure other CoS components such as classifiers, drop-profile maps, and *rewrite rules*.

NOTE: This topic applies to all EX Series switches except the EX4600. Because the EX4600 uses a different chipset than other EX Series switches, the code-point aliases on EX4600 match those on QFX Series switches. For EX4600 code-point aliases, see *Understanding CoS Code-Point Aliases*.

Behavior aggregate classifiers use class-of-service (CoS) values such as Differentiated Services code points (DSCPs), IP precedence, and IEEE 802.1p bits to associate incoming packets with a particular CoS servicing level. On a switch, you can assign a meaningful name or alias to the CoS values and use this alias instead of bits when configuring CoS components. These aliases are not part of the specifications

but are well known through usage. For example, the alias for DSCP 101110 is widely accepted as ef (expedited forwarding).

When you configure classes and define classifiers, you can refer to the markers by alias names. You can configure user-defined classifiers in terms of alias names. If the value of an alias changes, it alters the behavior of any classifier that references it.

This topic covers:

Default Code-Point Aliases

Table 6 on page 58 shows the default mappings between the bit values and standard aliases.

[Defining CoS Code-Point Aliases \(CLI Procedure\) | 61](#)

[Defining CoS Code-Point Aliases \(J-Web Procedure\) | 62](#)

Defining CoS Code-Point Aliases (CLI Procedure)

You can use code-point aliases to streamline the process of configuring CoS features on your EX Series switch. A code-point alias assigns a name to a pattern of code-point bits. You can use this name instead of the bit pattern when you configure other CoS components such as classifiers, drop-profile maps, and rewrite rules.

You can configure code-point aliases for the following CoS marker types:

- **dscp** and **dscp-ipv6**—Handles incoming IPv4 and IPv6 packets, respectively.
- **ieee-802.1**—Handles Layer 2 CoS.
- **inet-precedence**—Handles incoming IPv4 packets. IP precedence mapping requires only the higher order three bits of the DSCP field.

To configure a code-point alias for a specified CoS marker type (**dscp**), assign an alias (**my1**) to the code-point (**110001**):

```
[edit class-of-service code-point-aliases]
user@switch# set dscp my1 110001
```

The **my1** alias will be applicable for incoming IPv4 packets.

Understanding CoS Classifiers

IN THIS SECTION

- [Behavior Aggregate Classifiers | 67](#)
- [Multifield Classifiers | 69](#)

Packet classification associates incoming packets with a particular class-of-service (CoS) servicing level. Classifiers associate packets with a forwarding class and loss priority, and packets are associated to an output queue based on the forwarding class. You can define classifiers for the following interfaces:

- IPv4 and IPv6 traffic to network interfaces, aggregated Ethernet interfaces (also known as link aggregation groups (LAGs))

- On switches that support the ELS configuration style, inter-VLAN routing functions use an integrated routing and bridging (IRB) interface named `irb`
- On switches that do not support the ELS configuration style, inter-VLAN routing functions use a routed VLAN interface (RVI) named `vlan`

There are two general types of classifiers:

- Behavior aggregate (BA) classifiers
- Multifield (MF) classifiers

You can configure both a BA classifier and an MF classifier on an interface. If you do this, the BA classification is performed first and then the MF classification. If the two classification results conflict, the MF classification result overrides the BA classification result.

Behavior Aggregate Classifiers

BA classifiers are based on fixed-length fields in the packet header, which makes them computationally more efficient than MF classifiers. Therefore core devices that handle high traffic volumes are normally configured to perform BA classification. The BA classifier maps packets to a forwarding class and a loss priority. The forwarding class determines the output queue for a packet. The loss priority is used by a scheduler to control packet discard during periods of congestion.

These are the following types of BA classifiers:

- `dscp`—Differentiated Services Code Point (DSCP) for IP DiffServ. Handles incoming IPv4 packets.
- `dscp-ipv6`—Handles incoming IPv6 packets.
- `ieee-802.1`—Handles Layer 2 CoS (IEEE 802.1p).
- `inet-precedence`—Handles incoming IPv4 packets. IP precedence mapping requires only the upper three bits of the DSCP field.

A BA classifier takes a specified CoS value as either the literal bit pattern or as a defined alias and attempts to match it to the type of packet arriving on the interface. If the information in the packet's header matches the specified pattern, the packet is sent to the appropriate queue, defined by the forwarding class associated with the classifier.

Default Behavior Aggregate Classification

Juniper Networks Junos operating system (Junos OS) automatically assigns implicit default BA classifiers to logical interfaces based on the type of interface. [Table 9 on page 68](#) lists different types of interfaces and the corresponding implicit default BA classification.

Table 9: Default BA Classification

Type of Interface	Default BA Classification
Trunk interfaces	ieee8021p-default
Layer 3 interface (IPv4)	dscp-default
Layer 3 interface (IPv6)	dscp-ipv6-default
Access interface	Untrusted
<i>Routed VLAN interface (RVI)</i>	No default classification

When you explicitly associate a BA classifier with a *logical interface*, you are overriding the implicit (default) BA classifier with an explicit BA classifier.

[Table 10 on page 68](#) describes the BA classifier types you can configure on Layer 2 and Layer 3 interfaces.

Table 10: Allowed BA Classification

Type of Interface	Allowed BA Classification
Layer 2 interface	IEEE 802.1p, IP precedence, DSCP, DSCP IPv6
Layer 3 interface (IPv4)	IEEE 802.1p, IP precedence, DSCP
Layer 3 interface (IPv6)	IEEE 802.1p, IP precedence, DSCP IPv6

You cannot apply DSCP and IP precedence classifiers to the same interface. You also cannot apply IEEE 802.1p classifiers to an interface with classifiers of any other type. DSCP IPv6 classifiers can be applied to an interface with either DSCP or IP precedence classifiers, because they apply to different types of packets.

NOTE: On EX4300 switches, the three classifiers (DSCP, DSCP IPv6, and IEEE 802.1p) can co-exist on an L2 interface along with a fixed classifier. BA classification takes precedence over fixed classification.

If you have not explicitly configured a classifier on a logical interface, the default classifiers are assigned and classification works as follows:

- To a logical interface configured with an IPv4 address, a DSCP classifier is assigned by default, and IPv4 and IPv6 packets are classified using the DSCP classifier.
- To logical interface configured with an IPv6 address, a DSCP IPv6 classifier is assigned by default, and IPv4 and IPv6 packets are classified using the DSCP IPv6 classifier.

NOTE: On EX8200 switches, you can configure either one classifier of type DSCP or IEEE802.1p, or you can configure one classifier each of type DSCP and IEEE802.1p.

You can configure IRB interfaces on switches that support the ELS configuration style, or routed VLAN interfaces on switches that do not support the ELS configuration style. After you do this, the User Priority (UP) bits in the incoming packets are rewritten according to the default IEEE 802.1p rewrite rule.

NOTE: By default, all BA classifiers classify traffic into either the best-effort forwarding class or the network-control forwarding class.

Multifield Classifiers

Multifield (MF) classifiers examine multiple fields in a packet such as source and destination addresses and source and destination port numbers of the packet. With MF classifiers, you set the forwarding class and loss priority of a packet based on *firewall filter* rules.

MF classification is normally performed at the network edge because of the general lack of support for DSCP or IP precedence classifiers in end-user applications. On an edge switch, an MF classifier provides the filtering functionality that scans through a variety of packet fields to determine the forwarding class for a packet. Typically, any classifier performs matching operations on the selected fields against a configured value.

[Example: Configuring CoS on EX Series Switches | 11](#)

[Defining CoS Classifiers \(CLI Procedure\) | 70](#)

[Defining CoS Classifiers \(J-Web Procedure\) | 72](#)

Defining CoS Classifiers (CLI Procedure)

Packet classification associates incoming packets with a particular CoS servicing level. Classifiers associate packets with a forwarding class and loss priority and assign packets to output queues based on the associated forwarding class. Junos OS supports two general types of classifiers:

- **Behavior aggregate (BA) classifier**—Examine the CoS value in the packet header. The value in this single field determines the CoS settings applied to the packet. BA classifiers allow you to set the forwarding class and loss priority of a packet based on the Differentiated Services code point (DSCP) value, IP precedence value, or IEEE 802.1p value. EX Series switches except EX4300 switches support two types of loss priorities: `high` and `low`. EX4300 switches support three types of loss priorities: `high`, `medium-high`, and `low`.

You can configure BA classifiers for the following CoS marker types:

- **dscp** and **dscp-ipv6**—Handles incoming IPv4 and IPv6 packets, respectively.
- **ieee-802.1**—Handles Layer 2 CoS.
- **inet-precedence**—Handles incoming IPv4 packets. IP precedence mapping requires only the higher order three bits of the DSCP field.
- **Multifield (MF) classifier**—Examine multiple fields in the packet such as source and destination addresses and source and destination port numbers of the packet. With MF classifiers, you set the forwarding class and loss priority of a packet based on firewall filter rules.

The following example describes how to configure a BA classifier (**ba-classifier**) as the default DSCP map for handling IPv4 traffic and to apply the BA classifier to either a specific Gigabit Ethernet interface or to all the Gigabit Ethernet interfaces on the switch. The BA classifier assigns loss priorities, as shown in [Table 11 on page 71](#), to incoming packets in the four forwarding classes.

You can use the same procedure to set MF classifiers (except that you would use firewall filter rules).

Table 11: BA-classifier Loss Priority Assignments

Forwarding Class	For CoS Traffic Type	ba-classifier Assignment
be	Best-effort traffic	High-priority code point: 000001
ef	Expedited-forwarding traffic	High-priority code point: 101110
af	Assured-forwarding traffic	High-priority code point: 001100
nc	Network-control traffic	High-priority code point: 110001

To configure a DSCP BA classifier named **ba-classifier** as the default DSCP map:

- Associate code point **000001** with forwarding class **be** and loss priority **high**:

```
[edit class-of-service classifiers]
user@switch# set dscp ba-classifier import default forwarding-class be loss-priority high
code-points 000001
```

- Associate code point **101110** with forwarding class **ef** and loss priority **high**:

```
[edit class-of-service classifiers]
user@switch# set dscp ba-classifier forwarding-class ef loss-priority high code-points 101110
```

- Associate code point **001100** with forwarding class **af** and loss priority **high**:

```
[edit class-of-service classifiers]
user@switch# set dscp ba-classifier forwarding-class af loss-priority high code-points 001100
```

- Associate code point **110001** with forwarding class **nc** and loss priority **high**:

```
[edit class-of-service classifiers]
user@switch# set dscp ba-classifier forwarding-class nc loss-priority high code-points 110001
```

- Apply the classifier to a specific interface or to all Gigabit Ethernet interfaces on the switch.

- To apply the classifier to a specific interface:

```
[edit class-of-service interfaces]
user@switch# set ge-0/0/0 unit 0 classifiers dscp ba-classifier
```

- To apply the classifier to all Gigabit Ethernet interfaces on the switch, use wildcards for the interface name and the logical-interface (unit) number:

```
[edit class-of-service interfaces]
user@switch# set ge-* unit * classifiers dscp ba-classifier
```

Defining CoS Classifiers (J-Web Procedure)

NOTE: This topic applies only to the J-Web Application package.

You can use the J-Web interface to define CoS classifiers on an EX Series switch. Classifiers examine the CoS value or alias of an incoming packet and assign the packet a level of service by setting its forwarding class and loss priority.

To define CoS classifiers:

1. Select **Configure > Class of Service > Classifiers**.

NOTE: After you make changes to the configuration on this page, you must commit the changes immediately for them to take effect. To commit all changes to the active configuration, select **Commit Options > Commit**. See [Using the Commit Options to Commit Configuration Changes \(J-Web Procedure\)](#) for details about all commit options.

2. Click one of the following options:
- **Add**—Adds a classifier. Enter information into the classifier page as described in [Table 12 on page 73](#).
 - **Edit**—Modifies an existing classifier. Enter information into the classifier page as described in [Table 12 on page 73](#).
 - **Delete**—Deletes an existing classifier.

Table 12: Classifiers Configuration Fields

Field	Function	Your Action
Classifier Name	Specifies the name for a classifier.	To name a classifier, type the name—for example, ba-classifier .
Classifier Type	Specifies the type of classifier: dscp , ieee-802.1 , or inet-precedence .	Select a value from the list.

Table 12: Classifiers Configuration Fields *(Continued)*

Field	Function	Your Action
Code Point Mapping	Sets the forwarding classes and the packet loss priorities (PLPs) for specific CoS values and aliases.	<p>To add a code point mapping:</p> <ol style="list-style-type: none"> 1. Click Add. 2. Select the code point. 3. Select a forwarding class from the following list: <ul style="list-style-type: none"> • expedited-forwarding—Provides low loss, low delay, low jitter, assured bandwidth, and end-to-end service. Packets can be forwarded out of sequence or dropped. • best-effort—Provides no special CoS handling of packets. Typically, RED drop profile is aggressive and no loss priority is defined. • assured-forwarding—Provides high assurance for packets within the specified service profile. Excess packets are dropped. • network-control—Packets can be delayed but not dropped. 4. Select the loss priority. <p>To assign a loss priority, select one:</p> <ul style="list-style-type: none"> • high—Packet has a high loss priority. • low—Packet has a low loss priority.

[Example: Configuring CoS on EX Series Switches | 11](#)

[Monitoring CoS Classifiers | 82](#)

Example: Configuring Multidestination (Multicast, Broadcast, DLF) Classifiers

IN THIS SECTION

- [Requirements | 76](#)
- [Overview | 76](#)
- [Verification | 77](#)

Packet classification associates incoming packets with a particular CoS servicing level. Behavior aggregate (BA) classifiers examine the CoS value in the packet header to determine the CoS settings applied to the packet. BA classifiers allow you to set the forwarding class and loss priority of a packet based on the incoming CoS value.

Beginning with Junos OS Release 17.1, EX4300 switches support multidestination classifiers. On EX4300 switches, you can apply multidestination classifiers globally or to a specific interface. If you apply multidestination classifiers both globally and to a specific interface, the classifications on the interface take precedence.

Multidestination classifiers apply to all of the switch interfaces and handle multicast, broadcast, and destination lookup fail (DLF) traffic. You cannot apply a multidestination classifier to a single interface or to a range of interfaces, except on an EX4300 switch.

Unicast and multidestination traffic must use different classifiers.

Configuring Multidestination Classifiers

Step-by-Step Procedure

To configure a multicast IEEE 802.1 BA classifier named `ba-mcast-classifier`:

1. Associate code point 000 with forwarding class `mcast` and loss priority `low`:

```
[edit class-of-service classifiers]
user@switch# set ieee-802.1 ba-mcast-classifier forwarding-class mcast loss-priority low code-points 000
```

2. Configure the classifier as a multidestination classifier:

```
[edit class-of-service]
user@switch# set multi-destination classifiers ieee-802.1 ba-mcast-classifier
```

Requirements

This example uses the following hardware and software components:

- One switch (this example was tested on a Juniper Networks QFX3500 Switch)
- Junos OS Release 11.1 or later for the QFX Series.

Overview

Junos OS supports three general types of classifiers:

- Behavior aggregate or CoS value traffic classifiers—Examine the CoS value in the packet header. The value in this single field determines the CoS settings applied to the packet. BA classifiers allow you to set the forwarding class and loss priority of a packet based on the CoS value.
- Fixed classifiers. Fixed classifiers classify all ingress traffic on a physical interface into one forwarding class, regardless of the CoS bits in the VLAN header or the DSCP bits in the packet header.
- Multifield traffic classifiers—Examine multiple fields in the packet such as source and destination addresses and source and destination port numbers of the packet. With multifield classifiers, you set the forwarding class and loss priority of a packet based on firewall filter rules.

Multidestination classifiers apply to all of the switch interfaces and handle multicast, broadcast, and destination lookup fail (DLF) traffic. You cannot apply a multidestination classifier to a single interface or to a range of interfaces.

NOTE: You must assign unicast traffic and multicast traffic to different classifiers. One classifier cannot include both unicast and multicast forwarding classes. A multidestination classifier can include only forwarding classes for multicast traffic.

The following example describes how to configure a BA classifier called `ba-mcast-classifier`, which is applied to all of the switch interfaces. The BA classifier assigns loss priorities, as shown in [Table 13 on page 77](#), to incoming packets in the multdestination forwarding class.

You can also use firewall filters to set multifield classifiers.

Table 13: BA-mcast-classifier Loss Priority Assignments

Multicast Forwarding Class	Traffic Type	ba-mcast-classifier Assignment
mcast	Best-effort multicast traffic	Low loss priority code point: 000

Verification

IN THIS SECTION

- [Verifying the IEEE 802.1 Multidestination Classifier | 77](#)
- [Verifying the Multidestination Classifier Configuration | 78](#)

To verify the multidestination classifier configuration, perform these tasks:

Verifying the IEEE 802.1 Multidestination Classifier

Purpose

Verify that the classifier `ba-mcast-classifier` is configured as the IEEE 802.1 multidestination classifier:

Action

Verify the results of the classifier configuration using the operational mode command `show configuration class-of-service multi-destination classifiers ieee-802.1`:

```
user@switch> show configuration class-of-service multi-destination classifiers ieee-802.1
ba-mcast-classifier;
```

Verifying the Multidestination Classifier Configuration

Purpose

Verify that you configured the multidestination classifier with the correct forwarding classes, loss priorities, and code points.

Action

List the classifier configuration using the operational mode command `show configuration class-of-service classifiers ieee-802.1 ba-mcast-classifier`:

```
user@switch> show configuration class-of-service classifiers ieee-802.1 ba-mcast-classifier
  forwarding-class mcast {
    loss-priority low code-points 000;
  }
```

Release History Table

Release	Description
17.1	Beginning with Junos OS Release 17.1, EX4300 switches support multidestination classifiers.

Configuring and Applying IEEE 802.1ad Classifiers

If you apply an IEEE 802.1 classifier to a logical interface, this classifier takes precedence and is not compatible with any other classifier type. For Juniper Networks MX Series 5G Universal Routing Platform interfaces or IQ2 PICs with IEEE 802.1ad frame formats or EX Series switches, you can set the

forwarding class and loss priority for traffic on the basis of the three IEEE 802.1p bits (three bits in either the inner virtual LAN (VLAN) tag or the outer VLAN tag) and the drop eligible indicator (DEI) bit. You can apply the default map or customize one or more of the default values.

You then apply the classifier to the interface on which you configure IEEE 802.1ad frame formats.

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the [CLI User Guide](#).

1. Define the custom IEEE 802.1ad map:

- a. Create the classifier by specifying a name for it and defining it as an IEEE-802.1ad (DEI) classifier.

```
[edit]
user@host# edit class-of-service classifiers ieee-802.1ad dot1p_dei_class
```

- b. Assign the forwarding class and loss priority to the code-point alias.

```
[edit class-of-service classifiers ieee-802.1ad dot1p_dei_class]
user@host# set forwarding-class best-effort loss-priority low code-points [0000 1101]
```

2. Apply the classifier to the logical interface:

- a. Specify the interface to which you want to apply the classifier.

```
[edit]
user@host# edit class-of-service interfaces ge-2/0/0 unit 0
```

- b. Specify the name of the classifier you want to apply to the interface.

```
[edit class-of-service interfaces ge-2/0/0 unit 0]
user@host# set classifiers ieee-802.1ad dot1p_dei_class
```

3. Verify the custom IEEE 802.1ad map configuration:

```
[edit]
user@host# show
```

```
class-of-service {
  classifiers {
```

```

ieee-802.1ad dot1p_dei_class {
    forwarding-class best-effort {
        loss-priority low code-points [ 0000 1101 ];
    }
}

```

```

class-of-service {
    interfaces {
        ge-2/0/0 {
            unit 0 {
                classifiers {
                    ieee-802.1ad dot1p_dei_class;
                }
            }
        }
    }
}

```

Understanding How Behavior Aggregate Classifiers Prioritize Trusted Traffic

Applying Behavior Aggregate Classifiers to Logical Interfaces

Configuring the IEEE 802.1p Field for CoS Host Outbound Traffic

This topic provides a summary of the configuration for setting the IEEE 802.1p field in the Ethernet frame header for host outbound traffic (control plane traffic). You can set a global value for the priority code point that applies to all host outbound traffic. Additionally, or alternatively, you can specify that rewrite rules are applied to all host outbound traffic on egress logical interfaces. These are rules that have been previously configured to set the IEEE 802.1p field for data traffic on those interfaces.

Configuration of 802.1p bits is supported only on the following hardware and software components:

- EX Series switches
- MX Series 5G Universal Routing Platforms

- Enhanced Queuing DPCs
- MPCs
- Junos OS Release 12.3 or later

To configure the IEEE 802.1p field settings:

1. (Optional) Specify a global default value for the IEEE 802.1p field for all host outbound traffic.
See [Configuring a Global Default IEEE 802.1p Value for All Host Outbound Traffic](#).
2. (Optional) Specify that the IEEE 802.1p rewrite rules for the egress logical interfaces are applied to all host outbound traffic on those interfaces.
See [Applying Egress Interface Rewrite Rules to the IEEE 802.1p Field for All Host Outbound Traffic on the Interface](#).

Configuring a Global Default IEEE 802.1p Value for All Host Outbound Traffic

This topic describes how to configure a global default value for the IEEE 802.1p field for all host outbound traffic on MX Series routers and EX Series switches.

To configure a global default value for the IEEE 802.1p field:

- Specify the value.

```
[edit class-of-service host-outbound-traffic ieee-802.1]
user@host# set default value
```

For example, specify that a value of 010 is applied to all host outbound traffic:

```
[edit class-of-service host-outbound-traffic ieee-802.1]
user@host# set default 010
```

Monitoring CoS Classifiers

IN THIS SECTION

- Purpose | 82
- Action | 82
- Meaning | 82

Purpose

NOTE: This topic applies only to the J-Web Application package.

Use the monitoring functionality to display the mapping of incoming CoS values to the forwarding class and loss priority for each classifier.

Action

To monitor CoS classifiers in the J-Web interface, select **Monitor > Class of Service > Classifiers**.

To monitor CoS classifiers in the CLI, enter the following CLI command:

```
show class-of-service classifier
```

Meaning

[Table 14 on page 83](#) summarizes key output fields for CoS classifiers.

Table 14: Summary of Key CoS Classifier Output Fields

Field	Values	Additional Information
Classifier Name	Name of a classifier.	To display classifier assignments, click the plus sign (+).
CoS Value Type	<p>The classifiers are displayed by type:</p> <ul style="list-style-type: none"> • dscp—All classifiers of the DSCP type. • ieee-802.1—All classifiers of the IEEE 802.1 type. • inet-precedence—All classifiers of the IP precedence type. 	
Index	Internal index of the classifier.	
Incoming CoS Value	CoS value of the incoming packets, in bits. These values are used for classification.	
Assign to Forwarding Class	Forwarding class that the classifier assigns to an incoming packet. This class affects the forwarding and scheduling policies that are applied to the packet as it transits the switch.	
Assign to Loss Priority	Loss priority value that the classifier assigns to the incoming packet based on its CoS value.

Troubleshooting a CoS Classifier Configuration for a TCAM Space Error

IN THIS SECTION

- Problem | 84
- Solution | 84

Problem

Description

When a CoS classifier configuration exceeds the amount of available ternary content addressable memory (TCAM) space, the switch returns the following system log message:

```
<number_of_rules_being_added> rules for <filter_name> class <filter_class> will not be  
installed, key: <bind_point>. no space in tcam db(<shared_pool_information>)
```

The switch returns this message during the commit operation if the number of classifiers defined in the CoS configuration or the number of bind points (interfaces) to which classifiers are bound causes the CoS configuration to exceed the amount of available TCAM space. However, the commit operation for the CoS configuration is completed in the CLI module.

Solution

When a CoS configuration exceeds the amount of available TCAM table space, you must either define fewer classifiers or bind them to fewer interfaces, or both, so that the space requirements for the CoS configuration do not exceed the available space in TCAM.

To delete classifier definitions and bind points in a CoS configuration, and to apply a new CoS classifier definition to fewer bind points:

1. Delete either the CoS classifier definition or the bind points:
 - To delete the CoS classifier definition:

- For behavioral classifiers:

```
[edit class-of-service]
user@switch# delete classifier dscp d1
```

- For multifield classifiers:

```
[edit]
user@switch# delete interfaces ge-3/0/2 unit 0 family ethernet-switching filter input ipacl
```

This command deletes a multifield classifier defined for a port. Similarly, you can delete a multifield classifier defined for a VLAN or router.

You can also delete terms defined in a single multifield classifier:

```
[edit]
user@switch# delete firewall family inet filter f1 term t1
```

In both these examples (for behavioral and multifield classifiers), the assumption is that too many classifier definitions resulted in the error message.

- To delete the bind points:

```
[edit class-of-service]
user@switch# delete class-of-service interfaces ge-0/0/0
user@switch# delete class-of-service interfaces ge-0/0/1
user@switch# delete class-of-service interfaces ge-0/0/2
user@switch# delete class-of-service interfaces ge-0/0/3
user@switch# delete class-of-service interfaces ge-0/0/4
user@switch# delete class-of-service interfaces ge-0/0/5
user@switch# delete class-of-service interfaces ge-0/0/6
user@switch# delete class-of-service interfaces ge-0/0/7
user@switch# delete class-of-service interfaces ge-0/0/8
```

Here the assumption is that too many bind points (nine) in the configuration resulted in the error message.

2. Commit the operation:

```
[edit]
user@switch# commit
```

3. Define fewer classifiers in the CoS configuration or bind classifiers to fewer interfaces, or both, so that the CoS classifier configuration does not exceed the amount of available TCAM space on the switch:

- To define CoS classifiers:
 - For behavioral classifiers:

```
[edit]
user@switch# set class-of-service classifiers dscp d2 forwarding-class fc1 loss-
priority low code-points 000001
user@switch# set class-of-service classifiers dscp d2 forwarding-class fc2 loss-
priority low code-points 000010
user@switch# set class-of-service classifiers dscp d2 forwarding-class fc3 loss-
priority low code-points 000011
user@switch# set class-of-service classifiers dscp d2 forwarding-class fc4 loss-
priority low code-points 000100
user@switch# set class-of-service classifiers dscp d2 forwarding-class fc5 loss-
priority low code-points 000101
user@switch# set class-of-service classifiers dscp d2 forwarding-class fc6 loss-
priority low code-points 000110
user@switch# set class-of-service classifiers dscp d2 forwarding-class fc7 loss-
priority low code-points 000111
```

- For multifield Classifiers:

```
[edit]
user@switch# set firewall family inet filter f1 term t1 from protocol tcp
user@switch# set firewall family inet filter f1 term t1 then loss-priority high
user@switch# set firewall family inet filter f1 term t1 then forwarding-class best-
effort
user@switch# set firewall family inet filter f1 term t2 from protocol udp
user@switch# set firewall family inet filter f1 term t2 then loss-priority high
user@switch# set firewall family inet filter f1 term t2 then forwarding-class assured-
forwarding
user@switch# set firewall family inet filter f1 term t3 from source-port ssh
```

```

user@switch# set firewall family inet filter f1 term t3 then loss-priority low
user@switch# set firewall family inet filter f1 term t3 then forwarding-class fc8
user@switch# set class-of-service forwarding-classes best-effort, assured-forwarding,
fc8

```

- To bind classifiers to fewer interfaces:

```

[edit]
user@switch# set class-of-service interfaces ge-0/0/0 unit 0 classifiers dscp d2
user@switch# set class-of-service interfaces ge-0/0/1 unit 0 classifiers dscp d2
user@switch# set class-of-service interfaces ge-0/0/2 unit 0 forwarding-class best-effort
user@switch# set class-of-service interfaces ge-0/0/3 unit 0 forwarding-class assured-
forwarding
user@switch# set class-of-service interfaces ge-0/0/4 unit 0 forwarding-class fc8

```

4. Commit the operation:

```

[edit]
user@switch# commit

```

5. Check system log for an error message. If an error message is not logged, then your classifier configuration has not exceeded the TCAM space limit.

If an error message is logged, then repeat this procedure by defining fewer classifiers or binding classifiers to fewer bind points.

Understanding CoS Rewrite Rules

IN THIS SECTION

- How Rewrite Rules Work | 88
- Default Rewrite Rule | 89

As packets enter or exit a network, edge switches might be required to alter the class-of-service (CoS) settings of the packets. This topic describes how to use *rewrite rules* to alter the CoS settings. It covers:

This topic covers:

How Rewrite Rules Work

Rewrite rules set the value of the CoS bits within a packet's header. Each rewrite rule reads the current forwarding class and loss priority associated with the packet, locates the chosen CoS value from a table,

and writes this CoS value into the packet header. For rewrites to occur, rewrite rules must be explicitly assigned to an interface.

On EX Series switches, you can define rewrite rules for IPv4 and IPv6 traffic to network interfaces, aggregated Ethernet interfaces (also known as link aggregation groups (LAGs)), routed VLAN interfaces (RVIs), Layer 3 interfaces, and Layer 3 VLAN-tagged sub-interfaces. Multiple rewrite rules of different types can be assigned to a single interface.

On EX4300 switches, you cannot configure separate DSCPv4 and DSCPv6 rewrite rules on network interfaces, aggregated Ethernet interfaces, Layer 3 interfaces, and integrated routing and bridging (IRB) interfaces. If you configure a DSCPv4 rewrite rule on an interface to rewrite IPv4 traffic, then the same rewrite rule is applied to IPv6 traffic also on that interface, and vice versa. You can define only DSCPv4 rewrite rules on integrated routing and bridging (IRB) interfaces and Layer 3 VLAN-tagged logical interfaces.

In effect, the rewrite rule performs the reverse function of the behavior aggregate (BA) classifier, which is used when the packet enters the switch. As the packet leaves the switch, the final CoS action is generally the application of a rewrite rule.

You configure rewrite rules to alter CoS values in outgoing packets on the outbound interfaces of an edge switch to meet the policies of a targeted peer. This allows the downstream switch in a neighboring network to classify each packet into the appropriate service group.

NOTE: When an IP precedence rewrite rule is active, bits 3, 4, and 5 of the type-of-service (ToS) byte are always reset to zero when code points are rewritten.

Default Rewrite Rule

To define a rewrite rule on an interface, you can either create your own rewrite rule and enable it on the interface or enable a default rewrite rule. See ["Defining CoS Rewrite Rules \(CLI Procedure\)" on page 90](#).

[Table 15 on page 90](#) shows the default rewrite-rule mappings. These are based on the default bit definitions of Differentiated Services code point (DSCP), IEEE 802.1p, and IP precedence values and the default forwarding classes. You can configure multiple CoS rewrite rules for DSCP, IP precedence and IEEE 802.1p.

NOTE: By default, rewrite rules are not assigned to an interface. You must explicitly assign a user-defined or system-defined rewrite rule to an interface for the rewrites to occur.

When the CoS values of a packet match the forwarding class and packet-loss-priority (PLP) values, the switch rewrites markings on the packet based on the rewrite table.

Table 15: Default Packet Header Rewrite Mappings

Map from Forwarding Class	PLP Value	Map to DSCP/IEEE 802.1p/IP Precedence Value
expedited-forwarding	low	ef
expedited-forwarding	high	ef
assured-forwarding	low	af11
assured-forwarding	high	af12 (DSCP)
best-effort	low	be
best-effort	high	be
network-control	low	nc1/cs6
network-control	high	nc2/cs7

RELATED DOCUMENTATION

[Understanding Junos OS CoS Components for EX Series Switches | 8](#)

[Example: Configuring CoS on EX Series Switches | 11](#)

[Defining CoS Rewrite Rules \(CLI Procedure\) | 90](#)

[Defining CoS Rewrite Rules \(J-Web Procedure\) | 93](#)

Defining CoS Rewrite Rules (CLI Procedure)

You configure rewrite rules to alter CoS values in outgoing packets on the outbound interfaces of an EX Series switch to match the policies of a targeted peer. Policy matching allows the downstream routing platform or switch in a neighboring network to classify each packet into the appropriate service group.

To configure a CoS rewrite rule, create the rule by giving it a name and associating it with a forwarding class, loss priority, and a code point, thus creating a rewrite table, and you can enable the rewrite rule on an interface. On EX Series switches except EX4300 switches, you can also enable a rewrite rule on routed VLAN interfaces (RVIs). On EX4300 switches, you can also enable rewrite rules on integrated routing and bridging (IRB) interfaces. If you need to customize a rewrite rule, you can create a customized rewrite rule using a firewall filter configuration. You can configure CoS rewrite rules for DSCP, IP precedence and IEEE 802.1p.

You can configure rewrite rules for the following CoS marker types:

- **dscp** and **dscp-ipv6**—Handles incoming IPv4 and IPv6 packets, respectively. On EX4300 switches, you cannot configure DSCP IPv4 and DSCP IPv6 rewrite rules on the same interface. If you configure a DSCP IPv4 rewrite rule on an interface to rewrite IPv4 traffic, then the same rewrite rule is applied to IPv6 traffic also on that interface, and vice versa.
- **ieee-802.1**—Handles Layer 2 CoS.
- **inet-precedence**—Handles incoming IPv4 packets. IP precedence mapping requires only the higher order three bits of the DSCP field.

NOTE: To replace an existing rewrite rule on the interface with a new rewrite rule of the same type, first explicitly remove the rewrite rule and then apply the new rule.

To create IEEE 802.1p rewrite rules and enable them on Layer 2 interfaces:

- To create an IEEE 802.1p rewrite rule named `customup-rw` in the rewrite table for all Layer 2 interfaces:

```
[edit class-of-service rewrite-rules]
user@switch# set ieee-802.1 customup-rw forwarding-class be loss-priority low code-point 000
user@switch# set ieee-802.1 customup-rw forwarding-class be loss-priority high code-point 001
user@switch# set ieee-802.1 customup-rw forwarding-class af loss-priority low code-point 010
user@switch# set ieee-802.1 customup-rw forwarding-class af loss-priority high code-point 011
user@switch# set ieee-802.1 customup-rw forwarding-class ef loss-priority low code-point 100
user@switch# set ieee-802.1 customup-rw forwarding-class ef loss-priority high code-point 101
user@switch# set ieee-802.1 customup-rw forwarding-class nc loss-priority low code-point 110
user@switch# set ieee-802.1 customup-rw forwarding-class nc loss-priority high code-point 111
```

- To enable an IEEE 802.1p rewrite rule named customup-rw on a Layer 2 interface:

```
[edit]
user@switch# set class-of-service interfaces ge-0/0/0 unit 0 rewrite-rules ieee-802.1
customup-rw
```

(On EX4300 switches) To enable an IEEE 802.1p rewrite rule named customup-rw on a Layer 2 interface:

```
[edit]
user@switch# set class-of-service interfaces ge-0/0/0 rewrite-rules ieee-802.1 customup-rw
```

- To enable an IEEE 802.1p rewrite rule named customup-rw on all Gigabit Ethernet interfaces on the switch, use wildcards for the interface name and logical-interface (unit) number:

```
[edit]
user@switch# set class-of-service interfaces ge-* unit * rewrite-rules customup-rw
```

(On EX4300 switches) To enable an IEEE 802.1p rewrite rule named customup-rw on all Gigabit Ethernet interfaces on the switch, use wildcards for the interface name:

```
[edit]
user@switch# set class-of-service interfaces ge-* rewrite-rules customup-rw
```

Defining CoS Rewrite Rules (J-Web Procedure)

NOTE: This topic applies only to the J-Web Application package.

You can use the J-Web interface to define CoS rewrite rules. Use the rewrite rules to alter the CoS values in outgoing packets to meet the requirements of the targeted peer. A rewrite rule examines the forwarding class and loss priority of a packet and sets its bits to a corresponding value specified in the rule.

To define rewrite rules:

1. Select **Configure > Class of Service > Rewrite Rules**.

NOTE: After you make changes to the configuration on this page, you must commit the changes immediately for them to take effect. To commit all changes to the active configuration, select **Commit Options > Commit**. See [Using the Commit Options to Commit Configuration Changes \(J-Web Procedure\)](#) for details about all commit options.

2. Select one of the following options:

- **Add**—Adds a rewrite rule. Enter information into the rewrite rule page as described in [Table 16 on page 93](#).
- **Edit**—Modifies an existing rewrite rule. Enter information into the rewrite rule page as described in [Table 16 on page 93](#).
- **Delete**—Deletes an existing rewrite rule.

Table 16: Rewrite Rules Configuration Page Summary

Field	Function	Your Action
Rewrite Rule Name	Specifies the name for the rewrite rule.	To name a rule, type the name—for example, rewrite-dscps .
Rewrite rule type	Specifies the type of rewrite rule: dscp , ieee-802.1 , or inet-precedence .	Select a value from the list.

Table 16: Rewrite Rules Configuration Page Summary (*Continued*)

Field	Function	Your Action
Code Point Mapping	<p>Rewrites outgoing CoS values of a packet based on the forwarding class and loss priority.</p> <p>Allows you to remove a code point mapping entry.</p>	<p>To configure a CoS value assignment, follow these steps:</p> <p>To add a code point mapping:</p> <ol style="list-style-type: none"> 1. Click Add. 2. Select the code point. 3. Select a forwarding class from the following list: <ul style="list-style-type: none"> • expedited-forwarding—Provides low loss, low delay, low jitter, assured bandwidth, and end-to-end service. Packets can be forwarded out of sequence or dropped. • best-effort—Provides no special CoS handling of packets. Typically, RED drop profile is aggressive and no loss priority is defined. • assured-forwarding—Provides high assurance for packets within the specified service profile. Excess packets are dropped. • network-control—Packets can be delayed but not dropped. 4. Select the loss priority. <p>To assign a loss priority, select one:</p> <ul style="list-style-type: none"> • high—Packet has a high loss priority. • low—Packet has a low loss priority. <p>To edit an existing code point mapping, select it and click Edit.</p> <p>To remove a code point mapping entry, select it and click Remove.</p>

[Example: Configuring CoS on EX Series Switches | 11](#)

Classifiers and Rewrite Rules at the Global, Physical, and Logical Interface Levels Overview

On most ACX Series Universal Metro Routers and EX Series switches, CoS supports classification and rewrite at the global level and physical interface levels.

NOTE: The ACX6360 router does not support rewrite rules or Layer 2 (IEEE802.1p and IEEE802.1ad) classifiers.

NOTE: ACX7100 routers support classification and rewrite rules of all types (Inet-Prec/DSCP/DSCP-v6/EXP/IEEE-802.1p/IEEE-802.1ad) at the logical interface level.

At a global level, you can define EXP classification.

At a physical interface level, you can define the following features:

- DSCP, DSCP-IPV6, and IPv4 precedence classifiers
- DSCP, DSCP-IPV6, and IPv4 precedence rewrites
- IEEE 802.1p and IEEE 802.1ad classifiers (inner and outer)
- IEEE 802.1p and IEEE 802.1ad rewrites (outer)

The IEEE 802.1ad classifier uses IEEE 802.1p and DEI bits together.

NOTE: You cannot configure both IEEE 802.1p and IEEE 802.1ad classifiers together at the physical interface level.

At a logical interface level, you can define the fixed classification and EXP rewrites.

To configure global EXP classifiers, include the **classifiers exp *classifier-name*** statement at the **[edit class-of-service system-defaults]** hierarchy level.

To configure classifiers or *rewrite rules* at the physical interface, include either the **classifiers** statement or the **rewrite-rules** statement at the **[edit class-of-service interfaces *interface-name*]** hierarchy level.

To configure fixed classifiers at the logical interface, include the **forwarding-class *fc*** or the **rewrite-rules** statement at the **[edit class-of-service interfaces *interface-name* unit *number*]** hierarchy level.

To configure EXP rewrite at the logical interface, include the **[edit class-of-service interfaces *interface-name* unit *number* rewrite-rules exp *rewrite-rule*]** statement.

To display classifiers configured under **system-defaults**, enter the **show class-of-service system-defaults** command.

To display classifiers and rewrite rules bound to physical interfaces, enter the **show class-of-service interfaces *interface-name*** command.

| *Configuring Classifiers and Rewrite Rules at the Global and Physical Interface Levels*

Configuring Classifiers and Rewrite Rules at the Global and Physical Interface Levels

On ACX Series Universal Metro Routers and EX Series switches, CoS supports classification and rewrite at the global and physical interface levels.

To configure the global EXP classifier, include the following statements at the **[edit class-of-service] system-defaults** hierarchy level.

```
[edit class-of-service]
{
  system-defaults {
    classifiers exp classifier-name
  }
}
```

CoS supports one global system default classifier of the EXP type, as shown in the following example:

```
[edit class-of-service]
{
  system-defaults {
    classifiers {
      exp exp-classf-core;
    }
  }
}
```

To configure classifiers and rewrite rules at the physical interface level, include the following statements at the **[edit class-of-service] interfaces** hierarchy level.

```
[edit class-of-service]
interfaces {
  interface-name
    classifiers dscp classifier-name
    classifiers inet-precedence classifier-name
    classifiers ieee-802.1 [vlan-tag (outer | inner)] classifier-name
    rewrite-rules dscp rewrite-name
    rewrite-rules inet-prec rewrite-name
    rewrite-rules ieee-802.1 rewrite-name
}
```

The following example shows classifiers and rewrite rules configured on physical interfaces:

```
ge-0/1/0 {
  unit 0 {
    rewrite-rules {
      exp custom-exp;
    }
  }
  classifiers {
    dscp d1;
    ieee-802.1 ci;
  }
  rewrite-rules {
    dscp default;
  }
}
```

```

ge-0/1/2 {
  classifiers {
    ieee-802.1 ci;
  }
  rewrite-rules {
    ieee-802.1 ri;
  }
}
ge-0/1/3 {
  unit 0 {
    rewrite-rules {
      exp custom-exp2;
    }
  }
}
ge-0/1/7 {
  classifiers {
    dscp d1;
  }
}
ge-0/1/8 {
  classifiers {
    dscp d1;
  }
}

```

RELATED DOCUMENTATION

Classifiers and Rewrite Rules at the Global, Physical and Logical Interface Levels Overview

Applying Egress Interface Rewrite Rules to the IEEE 802.1p Field for All Host Outbound Traffic on the Interface

This topic describes how to apply rewrite rules for egress logical interfaces to the IEEE 802.1p field for all host outbound traffic on those interfaces on MX Series routers and EX Series switches.

This task requires separately configured rewrite rules that map packet loss priority information to the code point value in the 802.1p field for data traffic on egress logical interfaces. See *Rewriting Packet Headers to Ensure Forwarding Behavior*.

To configure the rewrite rules:

1. Configure the CoS rewrite rules to map the forwarding class to the desired value for the 802.1p field.

See *Configuring Rewrite Rules*.

2. Associate the rewrite rules to the desired egress logical interfaces.

See *Applying Rewrite Rules to Output Logical Interfaces*.

3. (Optional) Configure the forwarding class for host outbound traffic. Do not configure this forwarding class if you want to use the default forwarding class assignment (input classification).

See *Overriding the Input Classification*.

To configure the rewrite rules to apply to the host outbound traffic IEEE 802.1p field:

- Configure the rewrite rules.

```
[edit class-of-service host-outbound-traffic ieee-802.1]
user@host# set rewrite-rules
```

NOTE: Enabling IEEE 802.1p rewrite rules for host outbound traffic on a DPC installed on an MX Series device without creating any corresponding IEEE 802.1p rewrite rules on a logical interface on the DPC causes the IEEE 802.1p code point to be automatically set to 000 for all host generated traffic that exits that logical interface.

```
[edit class-of-service]
rewrite-rules {
  ieee-802.1 rewrite_foo {
    forwarding-class network-control {
      loss-priority low code-point 101;
    }
  }
}
interfaces {
  ge-1/0/0 {
    unit 100 {
      rewrite-rules {
        ieee-802.1 rewrite_foo vlan-tag outer-and-inner;
      }
    }
  }
}
```

```

    }
}
host-outbound-traffic {
    forwarding-class network-control;
}
host-outbound-traffic {
    ieee-802.1 {
        rewrite-rules;
    }
}

```

Understanding CoS Forwarding Classes

IN THIS SECTION

- Default Forwarding Classes | 104

Class-of-Service (CoS) forwarding classes can be thought of as output queues. In effect, the result of classifying packets is the identification of an output queue for a particular packet. For a classifier to assign an output queue to a packet, it must associate the packet with one of the following forwarding classes:

- best-effort (be)—Provides no service profile. Loss priority is typically not carried in a CoS value.
- expedited-forwarding (ef)—Provides a low loss, low latency, low *jitter*, assured bandwidth, end-to-end service.
- assured-forwarding (af)—Provides a group of values you can define and includes four subclasses: AF1, AF2, AF3, and AF4, each with two drop probabilities: low and high.
- network-control (nc)—Supports protocol control and thus is typically high priority.
- multicast best-effort (mcast-be)—Provides no service profile for multicast packets.

- multicast expedited forwarding (mcast-ef)—Supports high-priority multicast packets.
- multicast assured-forwarding (mcast-af)—Provides two drop profiles; high, and low, for multicast packets.
- multicast network-control (mcast-nc)—Supports high-priority multicast packets that are not delay-sensitive.

NOTE: The forwarding classes multicast expedited-forwarding, multicast assured-forwarding, multicast network-control, and multicast best-effort are applicable only to Juniper Networks EX4300 Ethernet Switches.

Juniper Networks EX Series Ethernet Switches support up to 16 forwarding classes, thus allowing granular packet classification. For example, you can configure multiple classes of expedited forwarding (EF) traffic such as EF, EF1, and EF2.

EX Series switches support up to eight output queues, except EX4300 switches, which support 12 output queues. Therefore, if you configure more forwarding classes than the number of queues supported, you must map multiple forwarding classes to one or more output queues.

This topic describes:

Default Forwarding Classes

[Table 18 on page 105](#) shows the four default forwarding classes defined for unicast traffic, and [Table 19 on page 105](#) shows the default forwarding classes defined for multicast traffic.

NOTE: The default forwarding classes for multicast traffic are applicable only to EX4300 switches.

You can rename the forwarding classes associated with the queues supported on your switch. Assigning a new class name to an output queue does not alter the default classification or scheduling that is applicable to that queue. However, because CoS configurations can be quite complicated, we recommend that you avoid altering the default class names or queue number associations.

Table 18: Default Forwarding Classes for Unicast Traffic

Forwarding Class Name	Comments
best-effort (be)	The software does not apply any special CoS handling to packets with 000000 in the DiffServ field. This is a backward compatibility feature. These packets are usually dropped under congested network conditions.
expedited-forwarding (ef)	The software delivers assured bandwidth, low loss, low delay, and low delay variation (jitter) end-to-end for packets in this service class. The software accepts excess traffic in this class, but in contrast to the assured forwarding class, the out-of-profile expedited-forwarding class packets can be forwarded out of sequence or dropped.
assured-forwarding (af)	<p>The software offers a high level of assurance that the packets are delivered as long as the packet flow from the customer stays within a certain service profile that you define.</p> <p>The software accepts excess traffic, but it applies a tail drop profile to determine that excess packets are dropped, and not forwarded.</p> <p>Two drop probabilities (low and high) are defined for this service class.</p>
network-control (nc)	<p>The software delivers packets in this service class with a high priority. (These packets are not delay-sensitive.)</p> <p>Typically, these packets represent routing protocol hello or keep alive messages. Because loss of these packets jeopardizes proper network operation, packet delay is preferable to packet discard for these packets.</p>

Table 19: Default Forwarding Classes for Multicast Traffic on EX4300 Switches

Forwarding Class Name	Comments
multicast best-effort (mcast-be)	The software does not apply any special CoS handling to multicast packets. These packets are usually dropped under congested network conditions.

Table 19: Default Forwarding Classes for Multicast Traffic on EX4300 Switches (Continued)

Forwarding Class Name	Comments
multicast expedited-forwarding (mcast-ef)	The software delivers assured bandwidth, low loss, low delay, and low delay variation (jitter) end-to-end for multicast packets in this service class. The software accepts excess traffic in this class, but in contrast to the multicast assured forwarding class, out-of-profile multicast expedited-forwarding class packets can be forwarded out of sequence or dropped.
multicast assured-forwarding (mcast-af)	<p>The software offers a high level of assurance that the multicast packets are delivered as long as the packet flow from the customer stays within a certain service profile that you define.</p> <p>The software accepts excess traffic, but it applies a tail drop profile to determine if the excess packets are dropped and not forwarded.</p> <p>Two drop probabilities (low and high) are defined for this service class.</p>
multicast network-control (mcast-nc)	<p>The software delivers packets in this service class with a high priority. (These packets are not delay-sensitive.)</p> <p>Typically, these packets represent routing protocol hello or keep alive messages. Because loss of these packets jeopardizes proper network operation, packet delay is preferable to packet discard for these packets.</p>

The following rules govern queue assignment:

- CoS configurations that specify more queues than the switch can support are not accepted. If you commit such a configuration, the commit fails and a message displays that states the number of queues available.
- All default CoS configurations are based on queue number. The name of the forwarding class that is displayed in the default configuration for a queue number is that of the forwarding class currently associated with that queue.

[Defining CoS Forwarding Classes \(CLI Procedure\) | 107](#)

Defining CoS Forwarding Classes (CLI Procedure)

Forwarding classes allow you to group packets for transmission. Based on forwarding classes, you assign packets to output queues.

By default, four categories of forwarding classes are defined: best effort, assured forwarding, expedited forwarding, and network control. EX Series switches support up to 16 forwarding classes.

You can configure forwarding classes in one of the following ways:

- Using class statement—You can configure up to 16 forwarding classes and you can map multiple forwarding classes to single queue.
- Using queue statement—You can configure up to 8 forwarding classes and you can map one forwarding class to one queue.

This example uses the class statement to configure forwarding classes.

To configure CoS forwarding classes, map the forwarding classes to queues:

```
[edit class-of-service forwarding-classes]
user@switch# set class be queue-num 0
user@switch# set class ef queue-num 1
user@switch# set class af queue-num 2
user@switch# set class nc queue-num 3
user@switch# set class ef1 queue-num 4
user@switch# set class ef2 queue-num 5
user@switch# set class af1 queue-num 6
user@switch# set class nc1 queue-num 7
```

Defining CoS Forwarding Classes (J-Web Procedure)

NOTE: This topic applies only to the J-Web Application package.

You can define CoS forwarding classes on an EX Series switch using the J-Web interface. Assigning a forwarding class to a queue number affects the scheduling and marking of a packet as it transits a switch.

To define forwarding classes:

1. Select **Configure > Class of Service > Forwarding Classes**.

NOTE: After you make changes to the configuration on this page, you must commit the changes immediately for them to take effect. To commit all changes to the active configuration, select **Commit Options > Commit**. See [Using the Commit Options to Commit Configuration Changes \(J-Web Procedure\)](#) for details about all commit options.

2. Select one of the following options:
 - **Add**—Adds a forwarding class. Enter information into the forwarding class page as described in [Table 20 on page 108](#).
 - **Edit**—Modifies an existing forwarding class. Enter information into the forwarding class page as described in [Table 20 on page 108](#).
 - **Delete**—Deletes an existing forwarding class.

Table 20: Forwarding Classes Configuration Fields

Field	Function	Your Action
Forwarding Class Summary		

Table 20: Forwarding Classes Configuration Fields (*Continued*)

Field	Function	Your Action
Queue #	<p>Specifies the internal queue numbers to which forwarding classes are assigned.</p> <p>By default, if a packet is not classified, it is assigned to the class associated with queue 0. You can have more than one forwarding class to a queue number.</p>	<p>To specify an internal queue number, select an integer from 0 through 11, appropriate for your platform as follows:</p> <p>NOTE: For EX2300 and EX2300-C switches, a maximum of eight egress queues are supported per port. To specify an internal queue number select an integer from 0 through 7.</p>
Forwarding Class Name	<p>Specifies the forwarding class names assigned to specific internal queue numbers.</p> <p>By default, four forwarding classes are assigned to queue numbers 0 (best-effort), 1 (assured-forwarding), 5 (expedited-forwarding), and 7 (network-connect).</p>	Type the name—for example, be-class.

Flow Control

IN THIS CHAPTER

- [Understanding Priority-Based Flow Control | 113](#)
- [Configuring Priority-Based Flow Control for an EX Series Switch \(CLI Procedure\) | 116](#)

Understanding Priority-Based Flow Control

IN THIS SECTION

- [Reliability of Packet Delivery in Standard Ethernet Networks and in Layer 2 Networks | 113](#)
- [Calculations for Buffer Requirements When Using PFC PAUSE | 114](#)
- [How PFC and Congestion Notification Profiles Work With or Without DCBX | 114](#)

Priority-based flow control (PFC), IEEE standard 802.1Qbb, is a link-level flow control mechanism. The flow control mechanism is similar to that used by IEEE 802.3x Ethernet PAUSE, but it operates on individual priorities. Instead of pausing all traffic on a link, PFC allows you to selectively pause traffic according to its class.

This topic describes:

Reliability of Packet Delivery in Standard Ethernet Networks and in Layer 2 Networks

Standard Ethernet does not guarantee that a packet injected into the network will arrive at its intended destination. Reliability is provided by upper-layer protocols. Generally, a network path consists of multiple hops between the source and destination. A problem arises when transmitters send packets faster than receivers can accept them. When receivers run out of available buffer space to hold incoming flows, they silently drop additional incoming packets. This problem is generally resolved by upper-layer protocols that detect the drops and request retransmission.

Applications that require reliability in Layer 2 must have flow control that includes feedback from a receiver to a sender regarding buffer availability. Using IEEE 802.3x Ethernet PAUSE control frames, a receiver can generate a MAC control frame and send a PAUSE request to a sender when a specified threshold of receiver buffer has been filled to prevent buffer overflow. Upon receiving a PAUSE request, the sender stops transmission of any new packets until the receiver notifies the sender that it has sufficient buffer space to accept them again. The disadvantage of using Ethernet PAUSE is that it operates on the entire link, which might be carrying multiple traffic flows. Some traffic flows do not need flow control in Layer 2, because they are carrying applications that rely on upper-layer protocols for reliability. PFC enables you to configure Layer 2 flow control selectively for the traffic that requires it, such as Fibre Channel over Ethernet (FCoE) traffic, without impacting other traffic on the link. You can also enable PFC for other traffic types, such as iSCSI.

Calculations for Buffer Requirements When Using PFC PAUSE

The receive buffer must be large enough to accommodate all data that is received while the system is responding to a PFC PAUSE frame.

When you calculate buffer requirements, consider the following factors:

- Processing and queuing delay of the PFC PAUSE—In general, the time to detect the lack of sufficient buffer space and to transmit the PFC PAUSE is negligible. However, delays can occur if the switch detects a reduction in buffer space just as the transmitter is beginning to transmit a maximum length frame.
- Propagation delay across the media—The delay amount depends on the length and speed of the physical link.
- Response time to the PFC PAUSE frame
- Propagation delay across the media on the return path

NOTE: We recommend that you configure at least 20 percent of the buffer size for the queue that is using PFC and that you do not specify the **exact** option.

Because it is mandatory to explicitly configure a certain percentage of buffer size for PFC, you must also explicitly configure some buffer size for any other forwarding classes that you are planning to use (including the default forwarding classes and the user-defined forwarding classes). The percentage that you allocate depends on the usage of the respective classes.

How PFC and Congestion Notification Profiles Work With or Without DCBX

PFC can be applied to an interface regardless of whether the Data Center Bridging Capability Exchange protocol (DCBX) is enabled.

However, automatic control and advertisement of PFC requires DCBX:

- When DCBX is enabled—DCBX detects the data center bridging (DCB) neighbor's PFC configuration, uses autonegotiation to advertise local and peer PFC configuration, and then enables or disables PFC depending on whether the configurations are compatible or not. When PFC is enabled, it uses the congestion notification profile, which you have configured and applied to the interface.
- When DCBX is not enabled—*Class of service* (CoS) triggers PFC when the incoming frame has a User Priority (UP) field that matches the three-bit pattern specified for the congestion notification profile.

To manually control the use of PFC on the interface regardless of the configuration of the peer data center devices, you can explicitly change the configuration of DCBX on the interface to disable PFC autonegotiation. See *Disabling DCBX to Disable PFC Autonegotiation on EX Series Switches (CLI Procedure)*. When PFC autonegotiation is disabled, PFC is triggered by the congestion notification profile for PFC regardless of the configuration of the DCB peer.

NOTE: PFC functions effectively only when the peer devices connected to the local interface are also using PFC and are configured compatibly with the local interface. PFC must be symmetrical—if PFC is not configured to use the same traffic class (code point) on both the local and the peer interface, it does not have any impact on the traffic.

Table 22 on page 115 shows the one-to-one mapping between the UP field of an IEEE 802.1Q tagged frame, the traffic class, and the egress queue. In addition to setting a PFC congestion notification profile on an ingress port, you must set a forwarding class to match the priority specified in the PFC congestion notification profile and to forward the frame to the appropriate queue.

Juniper Networks EX Series Ethernet Switches support up to six traffic classes and allow you to associate those classes with six different congestion notification profiles. (The switches support up to 16 forwarding classes.)

Configuring Priority-Based Flow Control for an EX Series Switch (CLI Procedure)

You can configure priority-based flow control (PFC) to apply link-level flow control on a specific traffic class so that different types of traffic can efficiently use the same network interface card (NIC). You must configure PFC for all interfaces carrying Fibre Channel over Ethernet (FCoE) traffic. You can also configure PFC on interfaces carrying other traffic types, such as Internet small computer system interface (iSCSI) traffic. Using PFC is optional for traffic types other than FCoE.

NOTE:

- PFC is supported only on 10-Gigabit Ethernet interfaces.

- If you are using PFC for a non-FCoE DCBX application, use the same 802.1p code points for the PFC congestion notification profile and for the application map that is carrying that application traffic.

Data Center Bridging Capability Exchange protocol (DCBX) is enabled by default on all 10-Gigabit Ethernet interfaces. DCBX enables or disables PFC on the local interface depending on whether the PFC configuration on that interface is the same as the PFC configuration of the connected interface on the data center bridging (DCB) peer.

NOTE: When you configure PFC, we recommend that you:

- Configure at least 20 percent of the buffer for the queue that is using PFC.
- Configure an appropriate percent of the buffer for any other forwarding classes (default forwarding classes and the user-defined forwarding classes) that you are using.
- Do not specify the exact option when configuring the buffer for the queue that is using PFC.
- Configure the `loss-priority` statement to `low` for a traffic class that is using PFC.
- Verify that the PFC configurations of the local interfaces are the same as the PFC configurations of the connected interfaces on the DCB peer. See *show dcbx neighbors*.

EX Series switches support up to six congestion notification profiles for PFC.

To configure PFC:

1. Configure a congestion notification profile, specifying the name of the profile and specifying the three-bit pattern of the User Priority bits in an incoming frame that will trigger the priority-based flow control on that traffic class:

```
[edit class-of-service]
user@switch# set congestion-notification-profile profile-name input ieee-802.1 code-point
up-bits pfc
```

2. Disable standard Ethernet flow control on the interfaces that will be used for the traffic class that you have selected for PFC:

```
[edit interfaces]
user@switch# set interface-name ether-options no-flow-control
```

NOTE: You cannot apply PFC to interfaces that are using standard Ethernet flow control. You must first disable flow control on those interfaces.

3. Bind the congestion notification profile to the interfaces that will be used for the traffic class that you have selected for PFC:

```
[edit class-of-service]
user@switch# set interfaces interface-name congestion-notification-profile profile-name
```

4. Create a CoS classifier for a traffic class that will use PFC:

```
[edit class-of-service]
user@switch# set classifiers ieee-802.1 classifier-name import default
```

5. Configure this traffic class (*classifier-name*) to use a user-defined or default forwarding class with a low loss priority value and specify the 802.1p code points::

```
[edit class-of-service]
user@switch# set classifiers ieee-802.1 classifier-name forwarding-class class-name loss-
priority low code-points 3 bit-patterns
```

6. Bind the *classifier-name* classifier to all interfaces that require PFC:

```
[edit class-of-service]
user@switch# set interfaces interface-name unit logical-unit-number classifiers ieee-802.1
classifier-name
```

7. Assign the specified forwarding-class to an egress queue:

```
[edit class-of-service]
user@switch# set forwarding-classes class-name queue-number
```

8. Set a scheduler for this queue, allocating at least 20 percent of the buffer to be used for FCoE traffic:

```
[edit class-of-service]
user@switch# set schedulers scheduler-name buffer-size percent
```

9. Set a scheduler to allocate buffer space for forwarding classes carrying other traffic:

NOTE: You must explicitly allocate some buffer space for the other forwarding classes. The default allocation of buffer space for forwarding classes is overridden when you manually configure the requisite amount of buffer space for the FCoE traffic.

```
[edit class-of-service]
user@switch# set scheduler-name buffer-size percent
```

10. Configure a scheduler map that associates the specified scheduler with the specified forwarding class:

```
[edit class-of-service]
user@switch# set scheduler-maps map-name forwarding-class class-name scheduler scheduler-name
```

For example:

```
[edit class-of-service]
user@switch# set scheduler-maps pfc-map forwarding-class af2 scheduler pfc-sched
user@switch# set scheduler-maps pfc-map forwarding-class best-effort scheduler default-sched
user@switch# set scheduler-maps pfc-map forwarding-class network-control scheduler default-sched
user@switch# set scheduler-maps pfc-map forwarding-class expedited-forwarding scheduler default-sched
```

11. Assign the scheduler map to the egress interface:

```
[edit class-of-service]
user@switch# set interfaces interface-name scheduler-map pfc-map
```

Understanding CoS Schedulers

IN THIS SECTION

- Default Schedulers | 121
- Excess Rate | 121
- Transmission Rate | 122
- Scheduler Buffer Size | 122
- Priority Scheduling | 122
- Scheduler Drop-Profile Maps | 123
- Scheduler Maps | 123

You use class-of-service (CoS) schedulers to define the properties of output queues on Juniper Networks EX Series Ethernet Switches. These properties include the amount of interface bandwidth assigned to the queue, the size of the memory buffer allocated for storing packets, the priority of the queue, and the drop profiles associated with the queue.

You associate the schedulers with forwarding classes by means of scheduler maps. You can then associate each scheduler map with an interface, thereby configuring the queues, packet schedulers, and tail drop processes that operate according to this mapping.

Default Schedulers

Each forwarding class has an associated scheduler priority. On EX Series switches other than Juniper Networks EX4300 and EX3400 Ethernet Switches, only two forwarding classes—best-effort (queue 0) and network-control (queue 7)—are used in the default configuration. By default on these switches, the best-effort forwarding class (queue 0) receives 95 percent of the bandwidth and the buffer space for the output link, and the network-control forwarding class (queue 7) receives 5 percent. The default drop profile causes the buffer to fill completely and then to discard all incoming packets until it has free space.

On EX4300 and EX 3400 switches, four forwarding classes—best-effort (queue 0), multicast best-effort (queue 8), network-control (queue 3), and multicast network-control (queue 11)—are used in the default configuration. By default, all the multicast traffic flows through the multicast best-effort queue. EX4300 and EX3400 switches support 12 queues (0–11), and the default scheduler transmission rates for queues 0 through 11 are 75, 0, 0, 5, 0, 0, 0, 0, 15, 0, 0 and 5 percent, respectively, of the total available bandwidth.

On EX Series switches other than EX4300 switches, the expedited-forwarding (queue 5) and assured-forwarding (queue 1) classes have no scheduler because no resources are assigned to queue 5 or queue 1, by default. However, you can manually configure resources to be assigned to the expedited-forwarding and assured-forwarding classes. On EX4300 switches, the expedited-forwarding (queue 1) and assured-forwarding (queue 2) classes have no scheduler because no resources are assigned to queue 1 or queue 2, by default. However, you can manually configure resources to be assigned to the expedited-forwarding and assured-forwarding classes.

Also by default, any queue can exceed the assigned bandwidth if additional bandwidth is available from other queues. When a forwarding class does not fully use the allocated transmission bandwidth, the remaining bandwidth can be used by other forwarding classes if they have a traffic load that exceeds their allocated bandwidth.

Excess Rate

Excess rate traffic determines the percentage of the excess bandwidth to share when a queue receives traffic in excess of its bandwidth allocation. By default, the excess bandwidth is shared in the ratio of the transmit rates. You can control this distribution by configuring the excess-rate statement at the [edit class-of-service schedulers *scheduler-name*] hierarchy. You can specify the excess rate sharing in percentage.

NOTE: Only EX4300 switches support the excess-rate option.

Transmission Rate

Transmission-rate control determines the actual traffic bandwidth for each forwarding class you configure. The transmission rate is specified in bits per second. Each queue is allocated some portion of the bandwidth of the interface. This bandwidth can be a fixed value, such as 1 megabit per second (Mbps), a percentage of the total available bandwidth, or the rest of the available bandwidth. In case of congestion, the configured transmission rate is guaranteed for the queue. Transmission-rate control allows you to ensure that each queue receives the bandwidth appropriate for its level of service.

Scheduler Buffer Size

To control congestion at the output stage, you can configure the delay-buffer bandwidth by using the [buffer-size configuration statement](#). The delay-buffer bandwidth provides packet buffer space to absorb burst traffic up to the specified duration of delay. When the specified delay buffer becomes full, packets with 100 percent drop probability are dropped from the tail of the buffer.

On EX Series switches other than EX4300 and EX3400 switches, the default scheduler transmission rates for queues 0 through 7 are 95, 0, 0, 0, 0, 0, 0, and 5 percent, respectively, of the total available bandwidth. The default buffer-size percentages for queues 0 through 7 are 95, 0, 0, 0, 0, 0, 0, and 5 percent, respectively, of the total available buffer.

On EX4300 and EX3400 switches, the default scheduler transmission rates for queues 0 through 11 are 75, 0, 0, 5, 0, 0, 0, 0, 15, 0, 0 and 5 percent, respectively, of the total available buffer. The default buffer-size percentages for queues 0 through 11 are 75, 0, 0, 5, 0, 0, 0, 0, 15, 0, 0 and 5 percent, respectively, of the total available buffer.

For each scheduler on EX Series switches, you can configure the buffer size as one of the following:

- The exact buffer size.
- A percentage of the total buffer.
- The remaining buffer available. The remainder is the buffer percentage that is not assigned to other queues. For example, if you assign 40 percent of the delay buffer to queue 0, allow queue 2 to keep the default allotment of 20 percent, allow queue 7 to keep the default allotment of 5 percent, and assign the remainder to queue 3, then queue 3 uses 35 percent of the delay buffer.

You can configure the buffer size as a temporal value on Juniper Networks EX4300 Ethernet Switches also.

Priority Scheduling

Priority scheduling determines the order in which an interface transmits traffic from queues, thus ensuring that queues containing important traffic are provided faster access.

Priority scheduling is accomplished through a procedure in which the scheduler examines the priority of the queue. Juniper Networks Junos operating system (Junos OS) supports two levels of transmission priority:

- **Low**—The scheduler determines whether the individual queue is within its defined bandwidth profile or not. This binary decision, which is re-evaluated on a regular time cycle, involves comparing the amount of data transmitted by the queue against the bandwidth allocated to it by the scheduler. If the transmitted amount is less than the allocated amount, the queue is considered to be in profile. A queue is out of profile when the amount of traffic that it transmits is larger than the queue's allocated limit. An out-of-profile queue is transmitted only if bandwidth is available. Otherwise, it is buffered.

On EX Series switches other than EX4300 switches, a queue from a set of queues is selected based on the shaped deficit weighted round robin (SDWRR) algorithm, which operates within the set. On EX4300 switches, the weighted deficit round-robin (WDRR) algorithm is used to select a queue from a set of queues.

- **Strict-high**—A strict-high priority queue receives preferential treatment over a low-priority queue. Unlimited bandwidth is assigned to a strict-high priority queue. On EX Series switches other than EX4300 switches, queues are scheduled according to the queue number, starting with the highest queue, 7, with decreasing priority down through queue 0. Traffic in higher-numbered queues is always scheduled prior to traffic in lower-numbered queues. In other words, if there are two high-priority queues, the queue with the higher queue number is processed first. On EX4300 switches, you can configure multiple strict-high priority queues on an interface and an EX4300 switch processes these queues in a round-robin method.

Packets in low-priority queues are transmitted only when strict-high priority queues are empty.

Scheduler Drop-Profile Maps

Drop-profile maps associate drop profiles with a scheduler. A drop-profile map sets the drop profile for a specific packet loss priority (PLP) and protocol type. The inputs for a drop-profile map are the PLP and the protocol type. The output is the drop profile.

Scheduler Maps

A scheduler map associates a specified forwarding class with a scheduler configuration. After configuring a scheduler, you must include it in a scheduler map and then associate the scheduler map with an output interface.

On EX Series switches, if you configure more than the supported number of scheduler maps on a switch or for a port group in a line card, an error is logged in the system log. On any interface in a port group on a line card or on a switch, if you configure a scheduler map that causes the number of scheduler maps for that port group to exceed the maximum number supported, the default scheduler map is bound to

that interface. We recommend that you check the system log for errors after the commit operation to verify that you have not configured more than the maximum permitted number of scheduler maps.

NOTE: On EX Series switches, you cannot configure a scheduler map on an individual interface that is a member of a link aggregation group (LAG). Instead, you must configure the scheduler map on the LAG itself (that is, on the aggregated Ethernet (ae) interface).

Table 23 on page 124 shows the number of scheduler maps supported for each port group in a switch or line card.

Table 23: Support for Scheduler Maps on Switches and Line Cards

Switch/Line Card	Number of Port Groups	Port Grouping Details	Number of Scheduler Maps Supported for Each Port Group

Defining CoS Schedulers and Scheduler Maps (CLI Procedure)

IN THIS SECTION

- [Configuring a Scheduler and a Scheduler Map | 126](#)
- [Assigning a Scheduler Map to Interfaces | 127](#)

You use schedulers to define the class-of-service (CoS) properties of output queues. These properties include the amount of interface bandwidth assigned to the queue, the size of the memory buffer allocated for storing packets, the priority of the queue, and the drop profiles associated with the queue.

You associate the schedulers with forwarding classes by means of scheduler maps. You can then associate each scheduler map with an interface, thereby configuring the queues and packet schedulers that operate according to this mapping.

NOTE: On EX Series switches, you cannot configure a scheduler map on an individual interface that is a member of a link aggregation group (LAG). Instead, you must configure the scheduler map on the LAG itself (that is, on the aggregated Ethernet (ae) interface).

You can associate up to four user-defined scheduler maps with an interface.

This topic describes:

Configuring a Scheduler and a Scheduler Map

You can define the properties for an output queue by configuring a scheduler. You can then define a scheduler map to associate a forwarding class with a scheduler.

To configure a scheduler and a scheduler map:

1. Create a scheduler, and assign one or more output queue properties to it:

```
[edit class-of-service]
user@switch# set schedulers scheduler-name output-queue-properties
```

For various properties that you can define for an output queue, see the *schedulers* hierarchy.

2. Configure a scheduler map that associates the scheduler with the forwarding class:

```
[edit class-of-service]
user@switch# set scheduler-maps map-name forwarding-class class-name scheduler scheduler-name
```

Assigning a Scheduler Map to Interfaces

After defining a scheduler map, you can assign the scheduler map to one or more interfaces. You can also assign the scheduler map to multiple interfaces by using a wildcard representation of the interface or Virtual Chassis Ports (VCPs).

Following are sample syntaxes and examples for assigning a scheduler map to a single or to multiple interfaces:

- To assign the scheduler map to one interface:

```
[edit class-of-service interfaces]
user@switch# set interface-name scheduler-map map-name
```

- To assign the scheduler map to more than one interface, you can use a wildcard representation of the interface:

```
[edit class-of-service interfaces]
user@switch# set wild-card-representation-of-interface-name scheduler-map map-name
```

For example, following is the configuration to assign the `be-map` scheduler map to all Gigabit Ethernet interfaces (`ge-*`):

```
[edit class-of-service interfaces]
user@switch# set ge-* scheduler-map be-map
```

- To assign the scheduler map to all VCPs:

```
[edit class-of-service interfaces]
user@switch# set wild-card-representation-of-vcp scheduler-map map-name
```

For example, following is the configuration to assign the be-map scheduler map to all VCPs:

```
[edit class-of-service interfaces]
user@switch# set vcp-* scheduler-map be-map
```

[Understanding CoS Schedulers | 120](#)

Defining CoS Schedulers (J-Web Procedure)

NOTE: This topic applies only to the J-Web Application package.

You can use the J-Web interface to define CoS schedulers on an EX Series switch. Using schedulers, you can assign attributes to queues and thereby provide congestion control for a particular class of traffic. These attributes include the amount of interface bandwidth, memory buffer size, transmit rate, and schedule priority.

To configure schedulers:

1. Select **Configure > Class of Service > Schedulers**.

NOTE: After you make changes to the configuration on this page, you must commit the changes immediately for them to take effect. To commit all changes to the active

configuration, select **Commit Options > Commit**. See [Using the Commit Options to Commit Configuration Changes \(J-Web Procedure\)](#) for details about all commit options.

2. Select one of the following options:

- **Add**—Adds a scheduler. Enter information into the Schedulers page as described in [Table 24 on page 129](#).
- **Edit**—Modifies an existing scheduler. Enter information into the Schedulers page as described in [Table 24 on page 129](#).
- **Delete**—Deletes an existing scheduler.

Table 24: Schedulers Configuration Page

Field	Function	Your Action

- [Meaning | 135](#)

Purpose

NOTE: This topic applies only to the J-Web Application package.

Use the monitoring functionality to display assignments of CoS forwarding classes to schedulers.

Action

To monitor CoS scheduler maps in the J-Web interface, select **Monitor > Class of Service > Scheduler Maps**.

To monitor CoS scheduler maps in the CLI, enter the following CLI command:

```
show class-of-service scheduler-map
```

Meaning

[Table 26 on page 135](#) summarizes key output fields for CoS scheduler maps.

Table 26: Summary of Key CoS Scheduler Maps Output Fields

Field	Values	Additional Information
Scheduler Map	Name of a scheduler map.	For details, click the plus sign (+).
Index	Index of a specific object—scheduler maps, schedulers, or drop profiles.	
Scheduler Name	Name of a scheduler.	
Forwarding Class	Forwarding classes this scheduler is assigned to.	
Transmit Rate	<div>Configured transmit rate of the scheduler in bits per second (bps). The rate value can be either of the following:</div> <ul style="list-style-type: none">A percentage—The scheduler receives the specified percentage of the total interface bandwidth.remainder—The scheduler receives the remaining bandwidth of the interface after bandwidth allocation to other schedulers.	

Table 26: Summary of Key CoS Scheduler Maps Output Fields *(Continued)*

Field	Values	Additional Information
Buffer Size	<p>Delay buffer size in the queue or the amount of transmit delay (in milliseconds). The buffer size can be either of the following:</p> <ul style="list-style-type: none"> • A percentage—The buffer is a percentage of the total buffer allocation. • remainder—The buffer is sized according to what remains after other scheduler buffer allocations. 	
Priority	<p>Scheduling priority of a queue:</p> <ul style="list-style-type: none"> • strict-high—Packets in this queue are transmitted first. • low—Packets in this queue are transmitted last. 	
Excess rate	The percentage of excess bandwidth traffic to share.	
Drop Profiles	Name and index of a drop profile that is assigned to a specific loss priority and protocol pair.	
Loss Priority	Packet loss priority corresponding to a drop profile.	
Protocol	Transport protocol corresponding to a drop profile.	
Drop Profile Name	Name of the drop profile.	

Table 26: Summary of Key CoS Scheduler Maps Output Fields *(Continued)*

Field	Values	Additional Information
Index	Index of a specific object—scheduler maps, schedulers, or drop profiles.

Understanding CoS Congestion Management

IN THIS SECTION

- [Weighted Tail Drop Congestion Management | 139](#)
- [Weighted Random Early Detection Congestion Management | 140](#)

A congestion in a network occurs because of various parameters and some packets must be dropped to avoid congestion and to facilitate easy flow of traffic in the network. On Juniper Networks EX Series Ethernet Switches, *class of service* (CoS) provides congestion management mechanisms for a switch to drop arriving packets based on certain parameters when a queue is full. Based on the EX Series switch that you are using, packets are dropped depending on the priority of a packet or on both priority and drop probability of a packet.

You can specify parameters at the [edit class-of-service drop-profiles] hierarchy level for dropping packets and reference the parameters in a scheduler configuration.

Weighted Tail Drop Congestion Management

A weighted tail drop (WTD) is a congestion management mechanism for packets to be dropped from the tail of the queue when the queue reaches a certain buffer capacity (that is, the fill level), and hence the name weighted tail drop. The packets that are dropped are based on priority and are those marked with a packet loss priority (PLP) of *high*. You can configure a WTD profile (a WTD mechanism) usually on edge devices in a network.

When you configure a WTD profile, you are essentially setting the value for queue fullness. The queue fullness represents a percentage of the memory, known as delay-buffer bandwidth, that is used to store packets in relation to the total amount of memory that has been allocated for that specific queue. The delay-buffer bandwidth provides packet buffer space to absorb burst traffic up to the specified duration of delay. When the specified delay buffer becomes full, packets are dropped from the tail of the buffer.

By default, if you do not configure any drop profile, WTD profile is in effect and functions as the primary mechanism for managing congestion.

NOTE: The default WTD profile associated with the packets whose PLP is *low* cannot be modified. You can configure custom drop profile only for those packets whose PLP is *high*.

Weighted Random Early Detection Congestion Management

In a weighted random early detection (WRED) congestion management mechanism, random packets with a PLP of low or high are gradually dropped (based on drop probability) when the queue reaches a certain buffer capacity (that is, fill level).

NOTE: The WRED mechanism is supported only on Juniper Networks EX4300 standalone switches, EX4300 Virtual Chassis, EX4600 standalone switches, and EX9200 standalone switches.

Following are the different implementations of WRED:

- Segmented Drop Profile
- Interpolated Drop Profile

From a high level, segmented drop profile is a stair-step-like drop profile, whereas interpolated drop profile is a smother (curve) drop profile. [Figure 3 on page 141](#) and [Figure 4 on page 142](#) show a graphical representation of segmented and interpolated drop profiles. Regardless of the implementation, a drop profile represents a graph where the x-axis represents the percentage of fill level (l) and the y-axis represents the percentage of drop probability (p). The origin (0,0) represents the drop profile in which the drop probability is 0 percent when the queue fullness is 0 percent, and the point (100,100) represents that the drop probability is 100 percent when the queue fullness is 100 percent. Although the formation of graph lines in [Figure 3 on page 141](#) and [Figure 4 on page 142](#) is different, the application of the profile is the same. When a packet reaches the head of the queue, a random number between 0 and 100 is calculated. This random number is plotted against the drop profile graph using the current queue fullness of that particular queue. When the random number falls above the graph line, the packet is transmitted. When the number falls below the graph line, the packet is dropped from the network.

The following sections discuss the WRED drop profile implementations and parameters.

Segmented Drop Profile

In a segmented drop profile configuration, you can define multiple data points for fill level and drop probability. [Figure 3 on page 141](#) shows a graphical representation of a segmented drop profile.

Figure 3: Graphical Representation of a Segmented Drop Profile

To create the profile's graph line, the software begins at the bottom-left corner of the graph, representing a 0 percent fill level and a 0 percent drop probability (that is the point (0,0)). The configuration draws a line directly to the right until it reaches the first defined fill level (that is, 25 percent represented in the graph on the x-axis). The software then continues the line vertically until the first drop probability is reached (that is, 25 percent represented in the graph in the y-axis). This process is repeated for all of the defined fill levels and drop probabilities until the top-right corner of the graph is reached (that is point (100,100) in the graph).

Interpolated Drop Profile

An interpolated drop profile configuration forms a smoother graph line compared to the graph in a segmented drop profile configuration. In this method of congestion management also, a switch uses multiple drop profile values to drop incoming packets to reduce congestion in the output queue.

Following are interpolated drop profile configurations on EX Series switches:

Interpolated Drop Profile Configuration on EX Series Switches Except EX4300 Switches

An interpolated drop profile on all EX Series switches except EX4300 switches automatically generates 64 pairs of data points on the graph beginning at (0, 0) and ending at (100, 100). Along the way, the graph line intersects specific data points that you define for fullness and drop probability.

[Figure 4 on page 142](#) shows a graphical representation of an interpolated drop profile.

Figure 4: Graphical Representation of an Interpolated Drop Profile on EX Series Switches Except EX4300 Switches

Interpolated Drop Profile Configuration on EX4300 Switches

On EX4300 switches, you can set two queue fill levels and two drop probabilities in each drop profile. The two fill levels and the two drop probabilities create two pairs of values. The first fill level and the first drop probability create one value pair and the second fill level and the second drop probability create the second value pair.

NOTE: You can configure a maximum of 64 drop profiles on EX4300 switches.

The first fill level value specifies the percentage of queue fullness at which packets begin to drop, known as the drop start point. Until the queue reaches this level of fullness, no packets are dropped. The second fill level value specifies the percentage of queue fullness at which all packets are dropped, known as the drop end point.

The first drop probability value is always 0 (zero). This pairs with the drop start point and specifies that until the queue fullness level reaches the first fill level, no packets drop. When the queue fullness exceeds the drop start point, packets begin to drop until the queue exceeds the second fill level, when all packets drop. The second drop probability value, known as the maximum drop rate, specifies the likelihood of dropping packets when the queue fullness reaches the drop end point. As the queue fills from the drop start point to the drop end point, packets drop in a smooth, linear pattern (called an interpolated graph) as shown in [Figure 5 on page 143](#). After the drop end point, all packets drop.

Figure 5: Tail-Drop Profile Packet Drop on EX4300 Switches

The thick line in [Figure 5 on page 143](#) shows the packet drop characteristics for a sample tail drop profile. At the drop start point, the queue reaches a fill level of 30 percent. At the drop end point, the queue fill level reaches 50 percent, and the maximum drop rate is 80 percent.

No packets drop until the queue fill level reaches the drop start point of 30 percent. When the queue reaches the 30 percent fill level, packets begin to drop. As the queue fills, the percentage of packets dropped increases in a linear fashion. When the queue fills to the drop end point of 50 percent, the rate of packet drop has increased to the maximum drop rate of 80 percent. When the queue fill level exceeds the drop end point of 50 percent, all of the packets drop until the queue fill level drops below 50 percent.

Drop Profile Parameters

You can specify the following two values in drop profile configuration:

- Fill level—The queue fullness value, which represents a percentage of the memory used to store packets in relation to the total amount of memory allocated to the queue.
- Drop probability—The percentage value that corresponds to the likelihood that an individual packet is dropped.

[Configuring CoS Congestion Management \(CLI Procedure\) | 144](#)

Configuring CoS Congestion Management (CLI Procedure)

IN THIS SECTION

- [Configuring a Weighted Tail Drop Profile | 145](#)
- [Configuring a Weighted Random Early Detection Drop Profile | 145](#)

An effective congestion management mechanism is imperative to ensure smooth flow of traffic in a network and also to ensure minimum packet drops in the network. Class of service (CoS) provides

congestion management methods that allow you to define parameters based on which packets can be dropped when the output queue is full. These parameters vary depending on the EX Series switch that you are using in a network.

You can specify parameters for dropping packets at the [edit class-of-service drop-profiles] hierarchy level and reference them in a scheduler configuration. The parameters that you can specify are fill-level and drop-probability. The first parameter defines the delay-buffer bandwidth, which provides packet buffer space to absorb burst traffic up to the specified duration of delay. When the specified delay buffer becomes full, packets with 100 percent drop probability are dropped from the head of the buffer. The second parameter represents a percentage value that correlates to the likelihood that an individual packet is dropped from the network.

Depending on the switch on which you are configuring a drop profile, you can configure either a weighted tail drop (WTD) profile or a weighted random early detection (WRED) profile.

Configuring a Weighted Tail Drop Profile

A weighted tail drop (WTD) is a congestion management mechanism in which packets are dropped from the tail of the queue when the queue reaches a certain buffer capacity (that is, the fill level), and hence the name weighted tail drop. When that level is reached, packets marked with a packet loss priority (PLP) of high are prevented from entering the queue (that is, they are discarded).

To configure a WTD profile, create a drop profile name and assign a fill level:

```
[edit class-of-service drop-profiles]
user@switch# set profile-name fill-level percentage
```

Following is a sample WTD profile in which the fill level is set to 80 percent:

```
[edit class-of-service drop-profiles]
user@switch# set wtd-profile fill-level 80
```

Configuring a Weighted Random Early Detection Drop Profile

A WRED drop profile enables you to define multiple data points for fill level and drop probability so that packets are dropped at various levels of queue fullness, and for various drop probabilities. Unlike the WTD drop profile that can be defined only for packets with a PLP of high, WRED can be defined for packets with a PLP of high and also for packets with a PLP of low.

NOTE: The WRED drop profile is supported only on EX4300 standalone switches and EX4300 Virtual Chassis.

WRED has two implementations: segmented and interpolated. From a high level, segmented is a stair-step-like drop profile, whereas interpolated is a smother (curve) drop profile. For a graphical representation of both these implementations, see ["Understanding CoS Congestion Management" on page 139](#). Although the formation of graph lines is different for both these implementations, the application of the profile is the same. On EX Series switches except EX4300 switches, when a packet reaches the head of the queue, a random number between 0 and 100 is calculated. This random number is plotted against the drop profile using the current queue fullness of that particular queue. When the random number falls above the graph line, the packet is transmitted. When the number falls below the graph line, the packet is dropped from the network.

For information about congestion management on EX4300 switches, see ["Understanding CoS Congestion Management" on page 139](#).

NOTE: On EX4300 switches, you cannot enable WRED on multidestination (multicast) queues. You can enable WRED only on unicast queues.

Following is the procedure to define a segmented and an interpolated drop profiles:

- To configure a segmented drop profile, specify multiple data points for fill level (l) and drop probability (p) as follows:

```
[edit class-of-service drop-profiles]
user@switch# set profile-name fill-level percentage-l1 drop-probability percentage-p1
user@switch# set profile-name fill-level percentage-l2 drop-probability percentage-p2
user@switch# set profile-name fill-level percentage-l3 drop-probability percentage-p3
user@switch# set profile-name fill-level percentage-l4 drop-probability percentage-p4
```

Following is a sample segmented drop profile:

```
[edit class-of-service drop-profiles]
user@switch# set seg-prof fill-level 20 drop-probability 25
user@switch# set seg-prof fill-level 40 drop-probability 50
user@switch# set seg-prof fill-level 60 drop-probability 75
user@switch# set seg-prof fill-level 80 drop-probability 100
```

- To configure an interpolated drop profile on EX Series switches except EX4300 switches, specify multiple data points for fill level (l) and drop probability (p) using the `interpolate` statement as follows:

```
[edit class-of-service drop-profiles ]
user@switch# set profile-name interpolate fill-level percentage-l1 drop-probability
percentage-l1
user@switch# set profile-name interpolate fill-level percentage-l2 drop-probability
percentage-l2
user@switch# set profile-name interpolate fill-level percentage-l3 drop-probability
percentage-p3
user@switch# set profile-name interpolate fill-level percentage-l4 drop-probability
percentage-p4
```

Following is a sample interpolated drop profile:

```
[edit class-of-service drop-profiles]
user@switch# set inter-prof interpolate fill-level 20 drop-probability 25
user@switch# set inter-prof interpolate fill-level 40 drop-probability 50
user@switch# set inter-prof interpolate fill-level 60 drop-probability 75
user@switch# set inter-prof interpolate fill-level 80 drop-probability 100
```

- To configure an interpolated drop profile EX4300 switches, specify two data points for fill level (l) and drop probability (p) by using the `interpolate` statement as follows:

```
[edit class-of-service drop-profiles ]
user@switch# set profile-name interpolate fill-level percentage-l1 fill-level percentage-l2
drop-probability percentage-l1 percentage-l2
```

Following is a sample interpolated drop profile:

```
[edit class-of-service drop-profiles]
user@switch# set inter-prof interpolate fill-level 20 fill-level 80 drop-probability 25 drop-
probability 100
```

Understanding CoS Tail Drop Profiles

Tail drop profile is a congestion management mechanism that allows switch to drop arriving packets when queue buffers become full or begin to overflow.

Tail drop profiles define the meanings of the loss priorities. When you configure tail drop profiles you are essentially setting the value for queue fullness. The queue fullness represents a percentage of the memory used to store packets in relation to the total amount that has been allocated for that specific queue.

The queue fullness defines the delay-buffer bandwidth, which provides packet buffer space to absorb burst traffic up to the specified duration of delay. Once the specified delay buffer becomes full, packets with 100 percent drop probability are dropped from the tail of the buffer.

You specify drop probabilities in the drop profile section of the CoS configuration hierarchy and reference them in each scheduler configuration.

By default, if you do not configure any drop profile, tail drop profile is in effect and functions as the primary mechanism for managing congestion. In the default tail drop profile, when the fill level is 0 percent, the drop probability is 0 percent. When the fill level is 100 percent, the drop probability is 100 percent.

NOTE: The default drop profile associated with the packets whose loss priority is low cannot be modified. You can configure custom drop profile only for those packets whose loss priority is high.

Understanding Port Shaping and Queue Shaping for CoS

IN THIS SECTION

- [Port Shaping | 153](#)
- [Queue Shaping | 154](#)

When the amount of traffic on a switch's network exceeds the maximum bandwidth, packets are lost because of congestion in the network. The excess traffic in the network must be handled carefully to ensure minimum or no data loss in the network. A class-of-service (CoS) configuration includes several parameters that classify traffic into different queues and also define packet loss priorities (PLPs) to ensure smooth transmission of data in the network. You can use these configuration parameters to control or shape traffic for a specific port on a switch or for a specific CoS queue. While port shaping defines the maximum bandwidth allocated to an interface, queue shaping defines a limit on excess-bandwidth usage for each queue.

Port Shaping

Port shaping enables you to shape the aggregate traffic through a port or channel to a rate that is less than the line rate. You can configure interfaces to shape traffic based on the rate-limited bandwidth of the total interface bandwidth. This allows you to shape the output of the interface so that the interface

transmits less traffic than it is capable of transmitting. For port shaping, you specify the shaping rate as the peak rate at which traffic can pass through the interface. You specify the rate as a value in bits per second (bps) either as a decimal number or as a decimal number followed by the abbreviation k (1000), m (1,000,000), or g (1,000,000,000) and the value can range from 1000 through 160,000,000,000 bps.

By default, shaping is not configured on an interface. If you do not configure a shaping rate on an interface, the default shaping rate is 100 percent, which is the equivalent to no shaping configured for that interface.

On modern EX series switches that support Enhanced Layer 2 Software (ELS), when you configure a shaping rate on an ae interface, the traffic is equally divided among the members of the ae interface. For example, consider an interface, ae0, that consists of three interfaces: ge-0/0/0, ge-0/0/1, and ge-0/0/2. If you configure a shaping rate of X Mbps on ae0, traffic up to the rate of X/3 Mbps flows through each of the three interfaces. This is known as scale mode.

NOTE: On older EX switches that don't support ELS, when you configure a shaping rate on an aggregated Ethernet (ae) interface, all members of the ae interface are shaped at the configured shaping rate. For example, consider an interface ae0 that consists of three interfaces: ge-0/0/0, ge-0/0/1, and ge-0/0/2. If you configure a shaping rate of X Mbps on ae0, traffic up to the rate of X Mbps flows through each of the three interfaces. Therefore, the total traffic flowing through ae0 can be at the rate of 3X Mbps. This is replicate mode.

Queue Shaping

Queue shaping throttles the rate at which queues transmit packets. For example, using queue shaping, you can rate-limit a strict-priority queue so that the strict-priority queue does not lock out (or starve) low-priority queues. Similarly, for any queue, you can configure queue shaping.

You can specify queue shaping as the maximum rate at which traffic can pass through the queue or as a percentage of the available bandwidth. On EX Series switches except EX4300 switches, you can specify the rate as a value between 3200 and 160,000,000,000 bps and the percentage as a value from 0 to 100 percent. On EX4300 switches, you can specify the rate as a value between 8000 and 160,000,000,000 bps and the percentage as a value from 0 to 100 percent.

RELATED DOCUMENTATION

[Understanding CoS Schedulers](#) | 120

[Defining CoS Schedulers and Scheduler Maps \(CLI Procedure\)](#) | 126

Configuring Shaping for CoS (CLI Procedure)

IN THIS SECTION

- [Configuring Port Shaping for CoS on an EX Series Switch | 155](#)
- [Configuring Queue Shaping for CoS on an EX Series Switch | 155](#)

Port shaping and queue shaping enable you to limit traffic on an interface or queue, respectively, so that you can control the amount of traffic passing through the interface or the queue. Port shaping enables you to shape the aggregate traffic through an interface to a rate that is less than the line rate for that interface. When you configure port shaping on an interface, you are essentially specifying a value that indicates the maximum amount of traffic that can pass through the interface. This value must be less than the maximum bandwidth for that interface. Queue shaping enables you to throttle the rate at which a queue transmits packets. When you configure queue shaping, you can specify either as the maximum rate at which traffic can pass through the queue or as a percentage of the available bandwidth.

Configuring Port Shaping for CoS on an EX Series Switch

You can configure port shaping on network interfaces, aggregated Ethernet interfaces (also known as link aggregation groups (LAGs)), and loopback interfaces.

To configure port shaping on an interface:

1. Ensure that the interface on which you want to configure port shaping is up and running.
2. Assign a shaping rate for the interface:

[edit]

```
user@switch# set class-of-service interfaces interface-name shaping-rate value
```

The value indicates the maximum amount of traffic (in bps) that can pass through the interface. This value must be less than the maximum bandwidth for that interface.

Configuring Queue Shaping for CoS on an EX Series Switch

Queue shaping enables you to restrict the rate at which queues transmit traffic. You can configure queue shaping on any queue supported by CoS on an EX Series switch that supports up to eight output queues and 16 forwarding classes. Forwarding classes can be thought of as output queues. In effect, the result of classifying packets into forwarding classes is the identification of an output queue for a particular

packet. For a classifier to assign an output queue to a packet, it must associate the packet with one of the forwarding classes discussed in ["Understanding CoS Forwarding Classes" on page 103](#).

To configure queue shaping:

1. Ensure that the interface on which you want to configure queue shaping is up and running.
2. Configure queue shaping:
 - a. Define a scheduler and assign a shaping rate to the scheduler:

```
[edit]
user@switch# set class-of-service schedulers scheduler-name shaping-rate (rate | percent
percentage)
```

You can assign a *rate* (a value in bits per second (bps)) or a percentage value for shaping-rate.

- b. Define a scheduler map and assign a forwarding class and scheduler (that you defined in the previous step) to the scheduler map:

```
[edit]
user@switch# set class-of-service scheduler-maps scheduler-map-name forwarding-class
class-name scheduler scheduler-name
```

- c. Assign the scheduler map to an interface:

```
[edit]
user@switch# set class-of-service interfaces interface-name scheduler-map scheduler-map-
name
```

RELATED DOCUMENTATION

Applying a Shaping Rate to Physical Interfaces Overview

On T4000 routers with Type 5 FPCs and on EX Series switches, you can configure physical interfaces to shape traffic based on the rate-limited bandwidth of the total interface bandwidth. This allows you to shape the output of the physical interface, so that the interface transmits less traffic than it is physically capable of carrying.

If you do not configure a shaping rate on the physical interface, the default physical interface bandwidth is based on the channel bandwidth and the time slot allocation.

In general, the physical interface speed is the basis for calculating the various queue parameters for a physical interface such as delay buffer size, weighted round-robin (WRR) weight, drop profile, and so forth. However, when you apply a shaping rate by including the `shaping-rate` statement, the shaping rate on that physical interface becomes the basis for calculating all the queue parameters for that physical interface.

On T4000 routers with Type 5 FPCs, the shaping rate value for the physical interface must be a minimum of 292 Kbps. The maximum value of shaping rate is limited by the maximum transmission rate of the interface.

RELATED DOCUMENTATION

Configuring the Shaping Rate for Physical Interfaces

Configuring the Shaping Rate for Physical Interfaces

To configure the shaping rate on the physical interface, either include the `shaping-rate` statement at the `[edit class-of-service interfaces interface-name]` hierarchy level or include the `output-traffic-control-profile` statement at the `[edit class-of-service interfaces interface-name]` hierarchy level.

You can specify a peak bandwidth rate in bps, either as a complete decimal number or as a decimal number followed by the abbreviation k (1000), m (1,000,000), or g (1,000,000,000). For physical interfaces, the range is from 1000 through 6,400,000,000,000 bps.

For physical interfaces on T4000 routers with Type 5 FPCs, the shaping rate value for the physical interface must be a minimum of 292 Kbps. The maximum value of `shaping-rate` is limited by the maximum transmission rate of the interface.

The following are two example configurations for applying a shaping rate of 5 Gbps on a T4000 12x10 Gbps physical interface (xe-4/0/0):

Applying a shaping rate at the [edit class-of-service interfaces *interface-name*] hierarchy:

```
[edit class-of-service]
interfaces {
  xe-4/0/0 {
    shaping-rate 5g;
  }
}
```

Applying a shaping rate using traffic-control-profiles:

```
[edit class-of-service]
traffic-control-profiles {
  output {
    shaping-rate 5g;
  }
}
interfaces {
  xe-4/0/0 {
    output-traffic-control-profile output;
  }
}
```

To view the results of your configuration, issue the following `show` commands:

- `show class-of-service interface interface-name`
- `show interfaces interface-name extensive`

- [Support, Limitations, and Notes | 168](#)

Explicit congestion notification (ECN) enables end-to-end congestion notification between two endpoints on TCP/IP based networks. The two endpoints are an ECN-enabled sender and an ECN-enabled receiver. ECN must be enabled on both endpoints and on all of the intermediate devices between the endpoints for ECN to work properly. Any device in the transmission path that does not support ECN breaks the end-to-end ECN functionality.

ECN notifies networks about congestion with the goal of reducing packet loss and delay by making the sending device decrease the transmission rate until the congestion clears, without dropping packets. RFC 3168, *The Addition of Explicit Congestion Notification (ECN) to IP*, defines ECN.

ECN is disabled by default. Normally, you enable ECN only on queues that handle best-effort traffic because other traffic types use different methods of congestion notification—lossless traffic uses priority-based flow control (PFC) and strict-high priority traffic receives all of the port bandwidth it requires up to the point of a configured maximum rate.

You enable ECN on individual output queues (as represented by forwarding classes) by enabling ECN in the queue scheduler configuration, mapping the scheduler to forwarding classes (queues), and then applying the scheduler to interfaces.

NOTE: For ECN to work on a queue, you must also apply a weighted random early detection (WRED) packet drop profile to the queue.

How ECN Works

Without ECN, switches respond to network congestion by dropping TCP/IP packets. Dropped packets signal the network that congestion is occurring. Devices on the IP network respond to TCP packet drops by reducing the packet transmission rate to allow the congestion to clear. However, the packet drop method of congestion notification and management has some disadvantages. For example, packets are dropped and must be retransmitted. Also, bursty traffic can cause the network to reduce the transmission rate too much, resulting in inefficient bandwidth utilization.

Instead of dropping packets to signal network congestion, ECN marks packets to signal network congestion, without dropping the packets. For ECN to work, all of the switches in the path between two ECN-enabled endpoints must have ECN enabled. ECN is negotiated during the establishment of the TCP connection between the endpoints.

ECN-enabled switches determine the queue congestion state based on the WRED packet drop profile configuration applied to the queue, so each ECN-enabled queue must also have a WRED drop profile. If a queue fills to the level at which the WRED drop profile has a packet drop probability greater than zero (0), the switch might mark a packet as experiencing congestion. Whether or not a switch marks a packet as experiencing congestion is the same probability as the drop probability of the queue at that fill level.

ECN communicates whether or not congestion is experienced by marking the two least-significant bits in the differentiated services (DiffServ) field in the IP header. The most significant six bits in the DiffServ field contain the Differentiated Services Code Point (DSCP) bits. The state of the two ECN bits signals whether or not the packet is an ECN-capable packet and whether or not congestion has been experienced.

ECN-capable senders mark packets as ECN-capable. If a sender is not ECN-capable, it marks packets as not ECN-capable. If an ECN-capable packet experiences congestion at the egress queue of a switch, the switch marks the packet as experiencing congestion. When the packet reaches the ECN-capable receiver (destination endpoint), the receiver echoes the congestion indicator to the sender (source endpoint) by sending a packet marked to indicate congestion.

After receiving the congestion indicator from the receiver, the source endpoint reduces the transmission rate to relieve the congestion. This is similar to the result of TCP congestion notification and management, but instead of dropping the packet to signal network congestion, ECN marks the packet

and the receiver echoes the congestion notification to the sender. Because the packet is not dropped, the packet does not need to be retransmitted.

ECN Bits in the DiffServ Field

The two ECN bits in the DiffServ field provide four codes that determine if a packet is marked as an ECN-capable transport (ECT) packet, meaning that both endpoints of the transport protocol are ECN-capable, and if there is congestion experienced (CE), as shown in [Table 29 on page 161](#):

Table 29: ECN Bit Codes

ECN Bits (Code)	Meaning
00	Non-ECT—Packet is marked as not ECN-capable
01	ECT(1)—Endpoints of the transport protocol are ECN-capable
10	ECT(0)—Endpoints of the transport protocol are ECN-capable
11	CE—Congestion experienced

Codes 01 and 10 have the same meaning: the sending and receiving endpoints of the transport protocol are ECN-capable. There is no difference between these codes.

End-to-End ECN Behavior

After the sending and receiving endpoints negotiate ECN, the sending endpoint marks packets as ECN-capable by setting the DiffServ ECN field to ECT(1) (01) or ECT(0) (10). Every intermediate switch between the endpoints must have ECN enabled or it does not work.

When a packet traverses a switch and experiences congestion at an output queue that uses the WRED packet drop mechanism, the switch marks the packet as experiencing congestion by setting the DiffServ ECN field to CE (11). Instead of dropping the packet (as with TCP congestion notification), the switch forwards the packet.

NOTE: At the egress queue, the WRED algorithm determines whether or not a packet is drop eligible based on the queue fill level (how full the queue is). If a packet is drop eligible and marked as ECN-capable, the packet can be marked CE and forwarded. If a packet is drop eligible and is

not marked as ECN-capable, it might be dropped. See ["WRED Drop Profile Control of ECN Thresholds"](#) on page 165 for more information about the WRED algorithm.

When the packet reaches the receiver endpoint, the CE mark tells the receiver that there is network congestion. The receiver then sends (echoes) a message to the sender that indicates there is congestion on the network. The sender acknowledges the congestion notification message and reduces its transmission rate. [Figure 6 on page 162](#) summarizes how ECN works to mitigate network congestion:

Figure 6: Explicit Congestion Notification

End-to-end ECN behavior includes:

1. The ECN-capable sender and receiver negotiate ECN capability during the establishment of their connection.
2. After successful negotiation of ECN capability, the ECN-capable sender sends IP packets with the ECT field set to the receiver.

NOTE: All of the intermediate devices in the path between the sender and the receiver must be ECN-enabled.

3. If the WRED algorithm on a switch egress queue determines that the queue is experiencing congestion and the packet is drop eligible, the switch can mark the packet as "congestion experienced" (CE) to indicate to the receiver that there is congestion on the network. If the packet has already been marked CE (congestion has already been experienced at the egress of another switch), the switch forwards the packet with CE marked.

If there is no congestion at the switch egress queue, the switch forwards the packet and does not change the ECT-enabled marking of the ECN bits, so the packet is still marked as ECN-capable but not as experiencing congestion.

On QFX5210, QFX5200, QFX5100, EX4600, QFX3500, and QFX3600 switches, and on QFabric systems, packets that are not marked as ECN-capable (ECT, 00) are treated according to the WRED drop profile configuration and might be dropped during periods of congestion.

On QFX10000 switches, the switch uses the tail-drop algorithm to drop packets that are marked ECT (00) during periods of congestion. (When a queue fills to its maximum level of fullness, tail-drop simply drops all subsequently arriving packets until there is space in the queue to buffer more packets. All non-ECN-capable packets are treated the same.)

4. The receiver receives a packet marked CE to indicate that congestion was experienced along the congestion path.
5. The receiver echoes (sends) a packet back to the sender with the ECE bit (bit 9) marked in the flag field of the TCP header. The ECE bit is the ECN echo flag bit, which notifies the sender that there is congestion on the network.
6. The sender reduces the data transmission rate and sends a packet to the receiver with the CWR bit (bit 8) marked in the flag field of the TCP header. The CWR bit is the congestion window reduced flag bit, which acknowledges to the receiver that the congestion experienced notification was received.
7. When the receiver receives the CWR flag, the receiver stops setting the ECE bit in replies to the sender.

Table 30 on page 163 summarizes the behavior of traffic on ECN-enabled queues.

Table 30: Traffic Behavior on ECN-Enabled Queues

Incoming IP Packet Marking of ECN Bits	ECN Configuration on the Output Queue	Action if WRED Algorithm Determines Packet is Drop Eligible	Outgoing Packet Marking of ECN Bits
Non-ECT (00)	Does not matter	Drop (QFX5210, QFX5200, QFX5100, EX4600, QFX3500, QFX3600, QFabric systems). Tail drop occurs when queue reaches maximum fullness because no WRED drop probability is applied (QFX10000 switches).	No ECN bits marked

Table 30: Traffic Behavior on ECN-Enabled Queues (Continued)

Incoming IP Packet Marking of ECN Bits	ECN Configuration on the Output Queue	Action if WRED Algorithm Determines Packet is Drop Eligible	Outgoing Packet Marking of ECN Bits
ECT (10 or 01)	ECN disabled	Drop	Packet dropped—no ECN bits marked
ECT (10 or 01)	ECN enabled	Do not drop. Mark packet as experiencing congestion (CE, bits 11).	Packet marked ECT (11) to indicate congestion
CE (11)	ECN disabled	Drop	Packet dropped—no ECN bits marked
CE (11)	ECN enabled	Do not drop. Packet is already marked as experiencing congestion, forward packet without changing the ECN marking.	Packet marked ECT (11) to indicate congestion

When an output queue is not experiencing congestion as defined by the WRED drop profile mapped to the queue, all packets are forwarded, and no packets are dropped.

ECN Compared to PFC and Ethernet PAUSE

ECN is an end-to-end network congestion notification mechanism for IP traffic. Priority-based flow control (PFC) (IEEE 802.1Qbb) and Ethernet PAUSE (IEEE 802.3X) are different types of congestion management mechanisms.

ECN requires that an output queue must also have an associated WRED packet drop profile. Output queues used for traffic on which PFC is enabled should not have an associated WRED drop profile. Interfaces on which Ethernet PAUSE is enabled should not have an associated WRED drop profile.

PFC is a peer-to-peer flow control mechanism to support lossless traffic. PFC enables connected peer devices to pause flow transmission during periods of congestion. PFC enables you to pause traffic on a specified type of flow on a link instead of on all traffic on a link. For example, you can (and should) enable PFC on lossless traffic classes such as the `fcoe` forwarding class. Ethernet PAUSE is also a peer-to-peer flow control mechanism, but instead of pausing only specified traffic flows, Ethernet PAUSE pauses all traffic on a physical link.

With PFC and Ethernet PAUSE, the sending and receiving endpoints of a flow do not communicate congestion information to each other across the intermediate switches. Instead, PFC controls flows

between two PFC-enabled peer devices (for example, switches) that support data center bridging (DCB) standards. PFC works by sending a pause message to the connected peer when the flow output queue becomes congested. Ethernet PAUSE simply pauses all traffic on a link during periods of congestion and does not require DCB.

PFC works this way: if a switch output queue fills to a certain threshold, the switch sends a PFC pause message to the connected peer device that is transmitting data. The pause message tells the transmitting switch to pause transmission of the flow. When the congestion clears, the switch sends another PFC message to tell the connected peer to resume transmission. (If the output queue of the transmitting switch also reaches a certain threshold, that switch can in turn send a PFC pause message to the connected peer that is transmitting to it. In this way, PFC can propagate a transmission pause back through the network.)

See *Understanding CoS Flow Control (Ethernet PAUSE and PFC)* for more information. For QFX5100 and EX4600 switches only, you can also refer to *Understanding PFC Functionality Across Layer 3 Interfaces*.

WRED Drop Profile Control of ECN Thresholds

You apply WRED drop profiles to forwarding classes (which are mapped to output queues) to control how the switch marks ECN-capable packets. A scheduler map associates a drop profile with a scheduler and a forwarding class, and then you apply the scheduler map to interfaces to implement the scheduling properties for the forwarding class on those interfaces.

Drop profiles define queue fill level (the percentage of queue fullness) and drop probability (the percentage probability that a packet is dropped) pairs. When a queue fills to a specified level, traffic that matches the drop profile has the drop probability paired with that fill level. When you configure a drop profile, you configure pairs of fill levels and drop probabilities to control how packets drop at different levels of queue fullness.

The first fill level and drop probability pair is the drop start point. Until the queue reaches the first fill level, packets are not dropped. When the queue reaches the first fill level, packets that exceed the fill level have a probability of being dropped that equals the drop probability paired with the fill level.

The last fill level and drop probability pair is the drop end point. When the queue reaches the last fill level, all packets are dropped unless they are configured for ECN.

NOTE: Lossless queues (forwarding class configured with the `no-loss` packet drop attribute) and strict-high priority queues do not use drop profiles. Lossless queues use PFC to control the flow of traffic. Strict-high priority queues receive all of the port bandwidth they require up to the configured maximum bandwidth limit (scheduler `transmit-rate` on QFX10000 switches, and

shaping-rate on QFX5210, QFX5200, QFX5100, QFX3500, QFX3600, and EX4600 switches, and QFabric systems).

Different switches support different amounts of fill level/drop probability pairs in drop profiles. For example, QFX10000 switches support 32 fill level/drop probability pairs, so there can be as many as 30 intermediate fill level/drop probability pairs between the drop start and drop endpoints. QFX5210, QFX5200, QFX5100, QFX3500, QFX3600, and EX4600 switches, and QFabric systems support two fill level/drop probability pairs—by definition, the two pairs you configure on these switches are the drop start and drop end points.

NOTE: Do not configure the last fill level as 100 percent.

The drop profile configuration affects ECN packets as follows:

- Drop start point—ECN-capable packets might be marked as congestion experienced (CE).
- Drop end point—ECN-capable packets are always marked CE.

As a queue fills from the drop start point to the drop end point, the probability that an ECN packet is marked CE is the same as the probability that a non-ECN packet is dropped if you apply the drop profile to best-effort traffic. As the queue fills, the probability of an ECN packet being marked CE increases, just as the probability of a non-ECN packet being dropped increases when you apply the drop profile to best-effort traffic.

At the drop end point, all ECN packets are marked CE, but the ECN packets are not dropped. When the queue fill level exceeds the drop end point, all ECN packets are marked CE. (At this point on QFX5210, QFX5200, QFX5100, EX4600, QFX3500, and QFX3600 switches, and on QFabric systems, all non-ECN packets are dropped.) ECN packets (and all other packets) are tail-dropped if the queue fills completely.

To configure a WRED packet drop profile and apply it to an output queue (using hierarchical scheduling on switches that support ETS):

1. Configure a drop profile using the statement `set class-of-service drop-profiles profile-name interpolate fill-level drop-start-point fill-level drop-end-point drop-probability 0 drop-probability percentage`.
2. Map the drop profile to a queue scheduler using the statement `set class-of-service schedulers scheduler-name drop-profile-map loss-priority (low | medium-high | high) protocol any drop-profile profile-name`. The name of the drop-profile is the name of the WRED profile configured in Step 1.
3. Map the scheduler, which Step 2 associates with the drop profile, to the output queue using the statement `set class-of-service scheduler-maps map-name forwarding-class forwarding-class-name scheduler scheduler-name`. The forwarding class identifies the output queue. Forwarding classes are mapped to

output queues by default, and can be remapped to different queues by explicit user configuration. The scheduler name is the scheduler configured in Step 2.

4. Associate the scheduler map with a traffic control profile using the statement `set class-of-service traffic-control-profiles tcp-name scheduler-map map-name`. The scheduler map name is the name configured in Step 3.
5. Associate the traffic control profile with an interface using the statement `set class-of-service interface interface-name forwarding-class-set forwarding-class-set-name output-traffic-control-profile tcp-name`. The output traffic control profile name is the name of the traffic control profile configured in Step 4.

The interface uses the scheduler map in the traffic control profile to apply the drop profile (and other attributes, including the enable ECN attribute) to the output queue (forwarding class) on that interface. Because you can use different traffic control profiles to map different schedulers to different interfaces, the same queue number on different interfaces can handle traffic in different ways.

Starting in Release 15.1, you can configure a WRED packet drop profile and apply it to an output queue on switches that support port scheduling (ETS hierarchical scheduling is either not supported or not used). To configure a WRED packet drop profile and apply it to an output queue on switches that support port scheduling (ETS hierarchical scheduling is either not supported or not used):

1. Configure a drop profile using the statement `set class-of-service drop-profiles profile-name interpolate fill-level level1 level2 ... level32 drop-probability probability1 probability2 ... probability32`. You can specify as few as two fill level/drop probability pairs or as many as 32 pairs.
2. Map the drop profile to a queue scheduler using the statement `set class-of-service schedulers scheduler-name drop-profile-map loss-priority (low | medium-high | high) drop-profile profile-name`. The name of the drop-profile is the name of the WRED profile configured in Step 1.
3. Map the scheduler, which Step 2 associates with the drop profile, to the output queue using the statement `set class-of-service scheduler-maps map-name forwarding-class forwarding-class-name scheduler scheduler-name`. The forwarding class identifies the output queue. Forwarding classes are mapped to output queues by default, and can be remapped to different queues by explicit user configuration. The scheduler name is the scheduler configured in Step 2.
4. Associate the scheduler map with an interface using the statement `set class-of-service interfaces interface-name scheduler-map scheduler-map-name`.

The interface uses the scheduler map to apply the drop profile (and other attributes) to the output queue mapped to the forwarding class on that interface. Because you can use different scheduler maps on different interfaces, the same queue number on different interfaces can handle traffic in different ways.

Support, Limitations, and Notes

If the WRED algorithm that is mapped to a queue does not find a packet drop eligible, then the ECN configuration and ECN bits marking does not matter. The packet transport behavior is the same as when ECN is not enabled.

ECN is disabled by default. Normally, you enable ECN only on queues that handle best-effort traffic, and you do not enable ECN on queues that handle lossless traffic or strict-high priority traffic.

ECN supports the following:

- IPv4 and IPv6 packets
- Untagged, single-tagged, and double-tagged packets
- The outer IP header of IP tunneled packets (but not the inner IP header)

ECN does not support the following:

- IP packets with MPLS encapsulation
- The inner IP header of IP tunneled packets (however, ECN works on the outer IP header)
- Multicast, broadcast, and destination lookup fail (DLF) traffic
- Non-IP traffic

NOTE: On QFX10000 switches, when you enable a queue for ECN and apply a WRED drop profile to the queue, the WRED drop profile only sets the thresholds for marking ECN traffic as experiencing congestion (CE, 11). On ECN-enabled queues, the WRED drop profile does not set drop thresholds for non-ECT (00) traffic (traffic that is not ECN-capable). Instead, the switch uses the tail-drop algorithm on traffic that is marked non-ECT on ECN-enabled queues during periods of congestion.

To apply a WRED drop profile to non-ECT traffic, configure a multifield (MF) classifier to assign non-ECT traffic to a different output queue that is not ECN-enabled, and then apply the WRED drop profile to that queue.

Release History Table

Release	Description
15.1	Starting in Release 15.1, you can configure a WRED packet drop profile and apply it to an output queue on switches that support port scheduling (ETS hierarchical scheduling is either not supported or not used).

RELATED DOCUMENTATION

| *Example: Configuring ECN*

Example: Configuring ECN

IN THIS SECTION

- [Requirements | 169](#)
- [Overview | 169](#)
- [Configuration | 172](#)
- [Verification | 175](#)

This example shows how to enable explicit congestion notification (ECN) on an output queue.

Requirements

This example uses the following hardware and software components:

- One switch.
- Junos OS Release 13.2X51-D25 or later for the QFX Series or Junos OS Release 14.1X53-D20 for the OCX Series

Overview

ECN enables end-to-end congestion notification between two endpoints on TCP/IP based networks. The two endpoints are an ECN-enabled sender and an ECN-enabled receiver. ECN must be enabled on both endpoints and on all of the intermediate devices between the endpoints for ECN to work properly. Any device in the transmission path that does not support ECN breaks the end-to-end ECN functionality.

A weighted random early detection (WRED) packet drop profile must be applied to the output queues on which ECN is enabled. ECN uses the WRED drop profile thresholds to mark packets when the output queue experiences congestion.

ECN reduces packet loss by forwarding ECN-capable packets during periods of network congestion instead of dropping those packets. (TCP notifies the network about congestion by dropping packets.) During periods of congestion, ECN marks ECN-capable packets that egress from congested queues. When the receiver receives an ECN packet that is marked as experiencing congestion, the receiver

echoes the congestion state back to the sender. The sender then reduces its transmission rate to clear the congestion.

ECN is disabled by default. You can enable ECN on best-effort traffic. ECN should not be enabled on lossless traffic queues, which uses priority-based flow control (PFC) for congestion notification, and ECN should not be enabled on strict-high priority traffic queues.

To enable ECN on an output queue, you not only need to enable ECN in the queue scheduler, you also need to:

- Configure a WRED packet drop profile.
- Configure a queue scheduler that includes the WRED drop profile and enables ECN. (This example shows only ECN and drop profile configuration; you can also configure bandwidth, priority, and buffer settings in a scheduler.)
- Map the queue scheduler to a forwarding class (output queue) in a scheduler map.
- Starting in Junos OS 15.1, enhanced transmission selection (ETS) hierarchical scheduling is supported. If you are using enhanced transmission selection (ETS) hierarchical scheduling, add the forwarding class to a forwarding class set (priority group).
- If you are using ETS, associate the queue scheduler map with a traffic control profile (priority group scheduler for hierarchical scheduling).
- If you are using ETS, apply the traffic control profile and the forwarding class set to an interface. On that interface, the output queue uses the scheduler mapped to the forwarding class, as specified by the scheduler map attached to the traffic control profile. This enables ECN on the queue and applies the WRED drop profile to the queue.

If you are using port scheduling, apply the scheduler map to an interface. On that interface, the output queue uses the scheduler mapped to the forwarding class in the scheduler map, which enables ECN on the queue and applies the WRED drop profile to the queue.

[Table 31 on page 170](#) shows the configuration components for this example.

Table 31: Components of the ECN Configuration Example

Component	Settings
Hardware	QFX Series switch

Table 31: Components of the ECN Configuration Example (*Continued*)

Component	Settings
Drop profile (with two fill level/ drop probability pairs)	Name: be-dp Drop start fill level: 30 percent Drop end fill level: 75 percent Drop probability at drop start (minimum drop rate): 0 percent Drop probability at drop end (maximum drop rate): 80 percent
Scheduler	Name: be-sched ECN: enabled Drop profile: be-dp Transmit rate: 25% Buffer size: 25% Priority: low
Scheduler map	Name: be-map Forwarding class: best-effort Scheduler: be-sched NOTE: By default, the best-effort forwarding class is mapped to output queue 0.
Forwarding class set (ETS only)	Name: be-pg Forwarding class: best-effort (queue 0)
Traffic control profile (ETS only)	Name: be-tcp Scheduler map: be-map
Interface (ETS only)	Name: xe-0/0/20 Forwarding class set: be-pg (Output) traffic control profile: be-tcp
Interface (port scheduling only)	Name: xe-0/0/20

NOTE: Only switches that support ETS hierarchical scheduling support forwarding class set and traffic control profile configuration. Direct port scheduling does not use the hierarchical scheduling structure.

NOTE: On QFX5100, EX4600, QFX3500, and QFX3600 switches, and on QFabric systems, the WRED drop profile also controls packet drop behavior for traffic that is not ECN-capable (packets marked non-ECT, ECN bit code 00).

On QFX10000 switches, when ECN is enabled on a queue, the WRED drop profile only sets the ECN thresholds, it does not control packet drop on non-ECN packets. On ECN-enabled queues, QFX10000 switches use the tail-drop algorithm on non-ECN packets during periods of congestion. If you do not enable ECN, then the queue uses the WRED packet drop mechanism.

Configuration

IN THIS SECTION

● [CLI Quick Configuration | 172](#)

● [Configuring ECN | 173](#)

CLI Quick Configuration

To quickly configure the drop profile, scheduler with ECN enabled, and to map the scheduler to an output queue on an interface, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level.

ETS Quick Configuration

```
[edit class-of-service]
set drop-profile be-dp interpolate fill-level 30 fill-level 75 drop-probability 0 drop-
probability 80
set schedulers be-sched explicit-congestion-notification
set schedulers be-sched drop-profile-map loss-priority low protocol any drop-profile be-dp
set schedulers be-sched transmit-rate percent 25
set schedulers be-sched buffer-size percent 25
```

```

set schedulers be-sched priority low
set scheduler-maps be-map forwarding-class best-effort scheduler be-sched
set forwarding-class-sets be-pg class best-effort
set traffic-control-profiles be-tcp scheduler-map be-map
set interfaces xe-0/0/20 forwarding-class-set be-pg output-traffic-control-profile be-tcp

```

Port Scheduling Quick Configuration (QFX10000 Switches)

```

[edit class-of-service]
set drop-profile be-dp interpolate fill-level 30 fill-level 75 drop-probability 0 drop-
probability 80
set schedulers be-sched explicit-congestion-notification
set schedulers be-sched drop-profile-map loss-priority low protocol any drop-profile be-dp
set schedulers be-sched transmit-rate percent 25
set schedulers be-sched buffer-size percent 25
set schedulers be-sched priority low
set scheduler-maps be-map forwarding-class best-effort scheduler be-sched
set interfaces xe-0/0/20 scheduler-map be-map

```

Configuring ECN

Step-by-Step Procedure

To configure ECN:

1. Configure the WRED packet drop profile be-dp. This example uses a drop start point of 30 percent, a drop end point of 75 percent, a minimum drop rate of 0 percent, and a maximum drop rate of 80 percent:

```

[edit class-of-service]
user@switch# set drop-profile be-dp interpolate fill-level 30 fill-level 75 drop-probability
0 drop-probability 80

```

2. Create the scheduler be-sched with ECN enabled and associate the drop profile be-dp with the scheduler:

```

[edit class-of-service]
user@switch# set schedulers be-sched explicit-congestion-notification
user@switch# set schedulers be-sched drop-profile-map loss-priority low protocol any drop-

```

```

profile be-dp
user@switch# set be-sched transmit-rate percent 25
user be-sched transmit-rate percent 25
user@switch# set be-sched buffer-size percent 25
user@switch# set be-sched buffer-size percent 25
user@switch# set be-sched priority low

```

3. Map the scheduler be-sched to the best-effort forwarding class (output queue 0) using scheduler map be-map:

```

[edit class-of-service]
user@switch# set scheduler-maps be-map forwarding-class best-effort scheduler be-sched

```

4. If you are using ETS, add the forwarding class best-effort to the forwarding class set be-pg; if you are using direct port scheduling, skip this step:

```

[edit class-of-service]
user@switch# set forwarding-class-sets be-pg class best-effort

```

5. If you are using ETS, associate the scheduler map be-map with the traffic control profile be-tcp; if you are using direct port scheduling, skip this step:

```

[edit class-of-service]
user@switch# set traffic-control-profiles be-tcp scheduler-map be-map

```

6. If you are using ETS, associate the traffic control profile be-tcp and the forwarding class set be-pg with the interface on which you want to enable ECN on the best-effort queue:

```

[edit class-of-service]
user@switch# set interfaces xe-0/0/20 forwarding-class-set be-pg output-traffic-control-
profile be-tcp

```

If you are using direct port scheduling, associate the scheduler map `be-map` with the interface on which you want to enable ECN on the best-effort queue:

```
[edit class-of-service]
user@switch# set interfaces xe-0/0/20 scheduler-map be-map
```

Verification

IN THIS SECTION

- [Verifying That ECN Is Enabled | 175](#)

Verifying That ECN Is Enabled

Purpose

Verify that ECN is enabled in the scheduler `be-sched` by showing the configuration for the scheduler map `be-map`.

Action

Display the scheduler map configuration using the operational mode command `show class-of-service scheduler-map be-map`:

```
user@switch> show class-of-service scheduler-map be-map
Scheduler map: be-map, Index: 12240

Scheduler:be-sched, Forwarding class: best-effort, Index: 115
  Transmit rate: 25 percent, Rate Limit: none, Buffer size: 25 percent,
  Buffer Limit: none, Priority: low
  Excess Priority: unspecified, Explicit Congestion Notification: enable
  Drop profiles:
    Loss priority  Protocol  Index  Name
    Low           any       3312   be-dp
    Medium-high   any       1       <default-drop-profile>
    High          any       1       <default-drop-profile>
```

Meaning

The `show class-of-service scheduler-map` operational command shows the configuration of the scheduler associated with the scheduler map and the forwarding class mapped to that scheduler. The output shows that:

- The scheduler associated with the scheduler map is `be-sched`.
- The scheduler map applies to the forwarding class `best-effort` (output queue 0).
- The scheduler `be-sched` has a transmit rate of 25 percent, a queue buffer size of 25 percent, and a drop priority of `low`.
- Explicit congestion notification state is `enable`.
- The WRED drop profile used for low drop priority traffic is `be-dp`.

Release History Table

Release	Description
15.1	Starting in Junos OS 15.1, enhanced transmission selection (ETS) hierarchical scheduling is supported.

You can use *class of service* (CoS) within MPLS networks to prioritize certain types of traffic during periods of congestion. See [EX Series Switch Software Features Overview](#) for a complete list of the Junos OS MPLS features that are supported on specific EX Series switches.

Juniper Networks EX Series Ethernet Switches support Differentiated Service Code Point (DSCP) or IP precedence and IEEE 802.1p CoS classifiers on the customer-edge interfaces of the ingress provider

edge (PE) switch. DSCP or IP precedence classifiers are used for Layer 3 packets. IEEE 802.1p is used for Layer 2 packets.

When a packet enters a customer-edge interface of the ingress PE switch, the switch associates the packet with a particular CoS servicing level before putting the packet onto the label-switched path (LSP). The switches within the LSP utilize the CoS value set at the ingress PE switch. The CoS value that was embedded in the classifier is translated and encoded in the MPLS header by means of the EXP or experimental bits. EX Series switches enable a default EXP classifier and a default EXP rewrite rule. For more information about EXP classifiers and EXP *rewrite rules*, see EXP Classifiers and EXP rewrite Rules.

This topic includes:

EXP Classifiers and EXP rewrite Rules

EX Series switches enable a default EXP classifier and a default EXP rewrite rule. You can configure a custom EXP classifier and a custom EXP rewrite rule if you prefer. However, the switch supports only one type of EXP classifier (default or custom) and only one EXP rewrite rule (default or custom).

You do not bind the EXP classifier or the EXP rewrite rule to individual interfaces. The switch automatically and implicitly applies the default or the custom EXP classifier and the default or the custom EXP rewrite rule to the appropriate MPLS-enabled interfaces. Because rewrite rules affect only egress interfaces, the switch applies the EXP rewrite rule only to those MPLS interfaces that are transmitting MPLS packets (not to the MPLS interfaces that are receiving the packets).

After traversing the MPLS tunnel, the traffic flows out from the egress provider edge (PE) switch. Before the traffic leaves the egress interface, the egress PE switch copies the EXP bits from the MPLS header to the most significant bits in the original IP packet--- that is, to the IP precedence bits.

Guidelines for Using CoS Classifiers on CCCs

When you are configuring CoS for MPLS over circuit cross-connect (CCC), there are some additional guidelines, as follows:

- You *must* explicitly bind a CoS classifier to the CCC interface on the ingress PE switch.
- You *must* use the same DSCP, IP precedence, or IEEE 802.1p classifier on CCC interfaces. However, if the CCC interfaces are on the same switch, you cannot configure both a DSCP and an IP precedence classifier on these interfaces. Thus, if you configure one CCC interface to use a DSCP classifier DSCP1, you cannot configure another CCC interface to use another DSCP classifier DSCP2. All the CCC interfaces on the switch must use the same DSCP (or IP precedence) classifier and the same IEEE 802.1p classifier.
- You *cannot* configure one CCC interface to use a DSCP classifier and another CCC interface to use an IP precedence classifier, because these classifier types overlap.

- You *can* configure one CCC interface to use a DSCP classifier and another CCC interface to use IEEE 802.1p classifier.
- You *can* configure one CCC interface to use both a DSCP and an IEEE 802.1p classifier. If you configure a CCC interface to use both these classifiers, the DSCP classifier is used for routing Layer 3 packets and the IEEE 802.1p classifier is used for routing Layer 2 packets.
- You *can* configure one CCC interface to use both an IP precedence and an IEEE 802.1p classifier. If you configure a CCC interface to use both these classifiers, the IP precedence classifier is used for routing Layer 3 packets and the IEEE 802.1p classifier is used for routing Layer 2 packets.

You can define multiple DSCP, IP precedence, and IEEE 802.1p classifiers for the non-CCC interfaces on a switch.

Using CoS Classifiers with IP over MPLS

When you are configuring CoS for IP over MPLS, the customer-edge interface uses the CoS configuration for the switch as the default. You do not have to bind a classifier to the customer-edge interface in this case. There are no restrictions on using multiple DSCP, IP precedence, and IEEE 802.1p classifiers on the same switch.

- You can modify the CoS classifier for a particular interface, but it is not required.
- You can configure a DSCP classifier, DSCP1 on the first interface, another DSCP classifier, DSCP2 on the second interface, and an IP precedence classifier on a third interface, and so forth.

Setting CoS Bits in an MPLS Header

When traffic enters an LSP tunnel, the CoS bits in the MPLS header are set in one of two ways:

- The number of the output queue into which the packet was buffered and the packet loss priority (PLP) bit are written into the MPLS header and are used as the packet's CoS value. This behavior is the default, and no configuration is required. The [Junos OS Class of Service User Guide for Routing Devices](#) explains the IP CoS values, and summarizes how the CoS bits are treated.
- You set a fixed CoS value on all packets entering the LSP tunnel. A fixed CoS value means that all packets entering the LSP receive the same class of service.

The CoS value can be a decimal number from 0 through 7. This number corresponds to a 3-bit binary number. The high-order 2 bits of the CoS value select which transmit queue to use on the outbound interface card.

The low-order bit of the CoS value is treated as the PLP bit and is used to select the RED drop profile to use on the output queue. If the low-order bit is 0, the non-PLP drop profile is used, and if the low-order bit is 1, the PLP drop profile is used. It is generally expected that random early detection (RED) will more

aggressively drop packets that have the PLP bit set. For more information about RED and drop profiles, see the [Junos OS Class of Service User Guide for Routing Devices](#).

NOTE: Configuring the PLP drop profile to drop packets more aggressively (for example, setting the CoS value from 6 to 7) decreases the likelihood of traffic getting through.

Table 32 on page 181 summarizes how MPLS CoS values correspond to the transmit queue and PLP bit. Note that in MPLS, the mapping between the CoS bit value and the output queue is hard-coded. You cannot configure the mapping for MPLS; you can configure it only for IPv4 traffic flows, as described in the [Junos OS Class of Service User Guide for Routing Devices](#).

Table 32: MPLS CoS Values

MPLS CoS Value	Bits	Transmit Queue	PLP Bit
0	000	0	Not set
1	001	0	Set
2	010	1	Not set
3	011	1	Set
4	100	2	Not set
5	101	2	Set
6	110	3	Not set
7	111	3	Set

Because the CoS value is part of the MPLS header, the value is associated with the packets only while they travel through the LSP tunnel. The value is not copied back to the IP header when the packets exit from the LSP tunnel.

EXP Rewrite Rules

When traffic passes from the customer-edge interface to an MPLS interface, the DSCP, IP precedence, or IEEE 802.1p CoS classifier is translated into the EXP bits within the MPLS header. You cannot disable the default EXP rewrite rule, but you can configure your own custom EXP classifier and a custom EXP rewrite rule. You cannot bind the EXP classifier to individual MPLS interfaces; the switch applies it globally to all the MPLS-enabled interfaces on the switch.

Only one EXP rewrite rule (either default or custom) is supported on a switch. The switch applies it to all the egress interfaces on which MPLS is enabled.

Policer

Policing helps to ensure that the amount of traffic forwarded through an LSP never exceeds the requested bandwidth allocation. During periods of congestion (when the total rate of queuing packets exceeds the rate of transmission), any new packets being sent to an interface can be dropped because there is no place to store them. You can configure a policer on the ingress PE switch to prevent this:

- If you are using MPLS over CCC, you bind the policer to the LSP. You cannot bind a policer to a CCC interface.
- If you are using IP over MPLS, you bind the policer to the **inet-family** customer-edge interface. You cannot bind a policer to the LSP when you are using IP over MPLS.

Schedulers

The schedulers for using CoS with MPLS are the same as for the other CoS configurations on EX Series switches. Default schedulers are provided for best-effort and network-control forwarding classes. If you are using assured-forwarding, expedited-forwarding, or any custom forwarding class, we recommend that you configure a scheduler to support that forwarding class. See ["Understanding CoS Schedulers" on page 120](#).

Example: Combining CoS with MPLS on EX Series Switches

IN THIS SECTION

- [Requirements | 183](#)
- [Overview and Topology | 183](#)

- [Configuring the Local PE Switch | 187](#)
- [Configuring the Remote PE Switch | 190](#)
- [Configuring the Provider Switch | 192](#)
- [Verification | 194](#)

You can use class of service (CoS) within MPLS networks to prioritize certain types of traffic during periods of congestion. The CoS value is included within the MPLS label, which is passed through the network, enabling end-to-end CoS across the network.

MPLS services are often used to ensure better performance for low-latency applications such as VoIP and other business-critical functions. These applications place specific demands on a network for successful transmission. CoS gives you the ability to control the mix of bandwidth, delay, jitter, and packet loss while taking advantage of the MPLS labeling mechanism.

This example shows how to configure CoS on an MPLS network that is using a unidirectional circuit cross-connect (CCC) from the ingress provider edge (PE) switch to the egress PE switch. for the customer-edge interface of the ingress provider edge (PE) switch. It describes adding the configuration of CoS components to the ingress PE switch, the egress PE switch, and the core provider switches of the existing MPLS network. Because of the unidirectional configuration, the DSCP classifier needs to be configured only on the ingress PE switch.

Requirements

This example uses the following hardware and software components:

- Junos OS Release 10.1 or later for EX Series switches
- Three EX Series switches

Before you configure CoS with MPLS, be sure you have:

Configured an MPLS network with two PE switches and one provider switch. See *Basic MPLS Configuration*. This example assumes that an MPLS network has been configured using a cross circuit-connect (CCC).

Overview and Topology

IN THIS SECTION

- [Topology | 187](#)

This example describes adding custom classifiers and custom rewrite rules to switches in an MPLS network that is using MPLS over CCC.

It is a unidirectional configuration. Therefore, you need to configure custom classifiers and custom rewrite rules as follows:

- On the ingress PE switch: custom DSCP classifier and custom EXP rewrite rule
- On the egress PE switch: custom EXP classifier
- On the provider switch: customer EXP classifier and custom EXP rewrite rule

NOTE: You can also configure schedulers and shapers as needed. If you are using **assured-forwarding**, **expedited-forwarding**, or other custom forwarding classes, we recommend that you configure a scheduler to support that forwarding class. See ["Defining CoS Schedulers and Scheduler Maps \(CLI Procedure\)" on page 126](#).

The example creates a custom DSCP classifier (**dscp1**) on the ingress PE switch and binds this classifier to the CCC interface. It includes configuration of a policer on the ingress PE switch. The policer is applied as a filter on the label-switched path (LSP) **lsp_to_pe2_ge1** to ensure that the amount of traffic forwarded through the LSP never exceeds the requested bandwidth allocation.

This example creates a custom EXP rewrite rule (**exp1**) on the ingress PE switch, specifying a loss-priority and code point to be used for the expedited-forwarding class as the packet travels through the LSP. The switch applies this custom rewrite rule on the core interfaces **ge-0/0/5.0** and **ge-0/0/6.0**, which are the egress interfaces for this switch.

[Table 33 on page 184](#) shows the CoS configuration components added to the ingress PE switch.

Table 33: CoS Configuration Components on the Ingress PE Switch

Property	Settings	Description
Local PE switch hardware	EX Series switch	PE-1
Policing filter configured and applied to the LSP.	policing filter mypolicer filter myfilter	Name of the rate-limiting policer. Name of the filter, which refers to the policer
Custom DSCP classifier	dscp1	Specifies the name of the custom DSCP classifier

Table 33: CoS Configuration Components on the Ingress PE Switch (Continued)

Property	Settings	Description
Custom EXP rewrite rule	e1	Name of the custom EXP rewrite rule.
Customer-edge interface	ge-0/0/1.0	Interface that receives packets from devices outside the network. The custom DSCP classifier must be specified on this CCC interface.
Core interfaces	ge-0/0/5.0 and ge-0/0/6.0	Interfaces that transmit MPLS packets to other switches within the MPLS network. The EXP rewrite rule is applied implicitly to these interfaces.

[Table 34 on page 185](#) shows the CoS configuration components added to the egress PE switch in this example.

Table 34: CoS Configuration Components of the Egress PE Switch

Property	Settings	Description
Remote provider edge switch hardware	EX Series switch	PE-2
Custom EXP classifier	exp1	Name of custom EXP classifier
Customer-edge interface	ge-0/0/1.0	Interface that transmits packets from this network to devices outside the network. No CoS classifier is specified for this interface. A scheduler can be specified.

Table 34: CoS Configuration Components of the Egress PE Switch (Continued)

Property	Settings	Description
Core interfaces	ge-0/0/7.0 and ge-0/0/8.0	Core interfaces on PE-2 that receive MPLS packets from the provider switch. The EXP classifier is enabled by default on the switch and applied implicitly to these interfaces.

[Table 35 on page 186](#) shows the MPLS configuration components used for the provider switch in this example.

Table 35: CoS Configuration Components of the Provider Switch

Property	Settings	Description
Provider switch hardware	EX Series switch	Transit switch within the MPLS network configuration.
Custom EXP classifier	exp1	Name of the custom EXP classifier.
Custom EXP rewrite rule	e1	Name of the custom EXP rewrite rule.
Core interfaces receiving packets from other MPLS switches.	ge-0/0/5.0 and ge-0/0/6.0	Interfaces that connect the provider switch to the ingress PE switch (PE-1). The EXP classifier is enabled by default on the switch and applied implicitly to these interfaces.
Core interfaces transmitting packets to other switches within the MPLS network.	ge-0/0/7.0 and ge-0/0/8.0	Interfaces that transmit packets to the egress PE (PE-2). The EXP rewrite rule is applied implicitly on these interfaces. Schedulers can also be specified and will be applied to these interfaces.

Topology

Configuring the Local PE Switch

IN THIS SECTION

- [Procedure | 187](#)

Procedure

CLI Quick Configuration

To quickly configure a custom DSCP classifier, custom EXP rewrite rule, and a policer on the local PE switch, copy the following commands and paste them into the switch terminal window of PE-1:

[edit]

```
set class-of-service classifiers dscp set class-of-service classifiers dscp dscp1 import default
set class-of-service classifiers dscp dscp1 forwarding-class expedited-forwarding loss-priority
low code-points 000111
set class-of-service rewrite-rules exp e1 forwarding-class expedited-forwarding loss-priority
low code-point 111
set class-of-service interfaces ge-0/0/1 unit 0 classifier dscp1
set firewall policer mypolicer if-exceeding bandwidth-limit 500m
set firewall policer mypolicer if-exceeding burst-size-limit 33553920
set firewall policer mypolicer then discard
set firewall family any filter myfilter term t1 then policer mypolicer
set protocols mpls label-switched-path lsp_to_pe2_ge1 to 127.1.1.3 policing filter myfilter
```

Step-by-Step Procedure

To configure a custom DSCP classifier, custom EXP rewrite rule, and a policer on the ingress PE switch:

1. Import the default DSCP classifier classes to the custom DSCP classifier that you are creating:

```
[edit class-of-service]
user@switch# set classifiers dscp dscp1 import default
```

2. Add the expedited-forwarding class to this custom DSCP classifier, specifying a loss priority and code point:

```
[edit class-of-service]
user@switch# set classifiers dscp dscp1 forwarding-class expedited-forwarding loss-priority
low code-points 000111
```

3. Specify the values for the custom EXP rewrite rule, **e1**:

```
[edit class-of-service]
user@switch# set rewrite-rules exp e1 forwarding-class expedited-forwarding loss-priority low
code-point 111
```

4. Bind the DSCP classifier to the CCC interface:

```
[edit class-of-service]
user@switch# set class-of-service interfaces ge-0/0/1 unit 0 classifier dscp1
```

5. Specify the number of bits per second permitted, on average, for the firewall policer, which will later be applied to the LSP:

```
[edit firewall]
set policer mypolicer if-exceeding bandwidth-limit 500m
```

6. Specify the maximum size permitted for bursts of data that exceed the given bandwidth limit for this policer:

```
[edit firewall policer]
set mypolicer if-exceeding burst-size-limit 33553920
```

7. Discard traffic that exceeds the rate limits for this policer:

```
[edit firewall policer]
set mypolicer then discard
```

8. To reference the policer, configure a filter term that includes the policer action:

```
[edit firewall]
user@switch# set family any filter myfilter term t1 then policer
mypolicer
```

9. Apply the filter to the LSP:

```
[edit protocols mpls]
set label-switched-path lsp_to_pe2_ge1 policing filter myfilter
```

Results

Display the results of the configuration:

```
[edit]
user@switch# show
class-of-service {
  classifiers {
    dscp dscp1 {
      import default;
      forwarding-class expedited-forwarding {
        loss-priority low code-points 000111;
      }
    }
  }
}
interfaces {
  ge-0/0/1 {
    unit 0 {
      classifiers {
        dscp dscp1;
      }
    }
  }
}
```

```
}
rewrite-rules {
  exp e1 {
    forwarding-class expedited-forwarding {
      loss-priority low code-point 111;
    }
  }
}
}
firewall {
  family any {
    filter myfilter {
      term t1 {
        then policer mypolicer;
      }
    }
  }
  policer mypolicer {
    if-exceeding {
      bandwidth-limit 500m;
      burst-size-limit 33553920;
    }
    then discard;
  }
}
}
```

Configuring the Remote PE Switch

IN THIS SECTION

- Procedure | 191

Procedure

CLI Quick Configuration

To quickly configure a custom EXP classifier on the remote PE switch, copy the following commands and paste them into the switch terminal window of PE-2:

```
[edit]
set class-of-service classifiers exp exp1 import default
set class-of-service classifiers exp exp1 forwarding-class expedited-forwarding loss-priority
low code-points 010
```

Step-by-Step Procedure

To configure a custom EXP classifier on the egress PE switch:

1. Import the default EXP classifier classes to the custom EXP classifier that you are creating:

```
[edit class-of-service]
user@switch# set classifiers exp exp1 import default
```

2. Add the expedited-forwarding class to this custom EXP classifier, specifying a loss priority and code point:

```
[edit class-of-service]
user@switch# set classifiers exp exp1 forwarding-class expedited-forwarding loss-priority low
code-points 010
```

Results

Display the results of the configuration:

```
[edit]
user@switch# show
class-of-service {
  classifiers {
    exp exp1 {
```

```

        import default;
        forwarding-class expedited-forwarding {
            loss-priority low code-points 010;
        }
    }
}

```

Configuring the Provider Switch

IN THIS SECTION

- [Procedure | 192](#)

Procedure

CLI Quick Configuration

To quickly configure a custom EXP classifier and a custom EXP rewrite rule on the provider switch, copy the following commands and paste them into the switch terminal window of the provider switch:

```

[edit]
set class-of-service classifiers exp exp1 import default
set class-of-service classifiers exp exp1 forwarding-class expedited-forwarding loss-priority
low code-points 010
set class-of-service rewrite-rules exp e1 forwarding-class expedited-forwarding loss-priority
low code-point 111

```

Step-by-Step Procedure

To configure a custom EXP classifier and a custom EXP rewrite rule on the provider switch:

1. Import the default EXP classifier classes to the custom EXP classifier that you are creating:

```

[edit class-of-service]
user@switch# set classifiers exp exp1 import default

```

2. Add the expedited-forwarding class to this custom EXP classifier, specifying a loss priority and code point:

```
[edit class-of-service]
user@switch# set classifiers exp exp1 forwarding-class expedited-forwarding loss-priority low
code-points 010
```

3. Specify the values for the custom EXP rewrite rule, **e1**:

```
[edit class-of-service]
user@switch# set rewrite-rules exp e1 forwarding-class expedited-forwarding loss-priority low
code-point 111
```

Results

Display the results of the configuration:

```
[edit]
user@switch# show
class-of-service {
  classifiers {
    exp exp1 {
      import default;
      forwarding-class expedited-forwarding {
        loss-priority low code-points 010;
      }
    }
  }
  rewrite-rules {
    exp e1 {
      forwarding-class expedited-forwarding {
        loss-priority low code-point 111;
      }
    }
  }
}
```

Verification

IN THIS SECTION

- [Verifying That the Policer Firewall Filter Is Operational | 194](#)
- [Verifying That the CoS Classifiers Are Going to the Right Queue | 194](#)
- [Verifying the CoS Forwarding Table Mapping | 199](#)
- [Verifying the Rewrite Rules | 199](#)

To confirm that the configuration is working properly, perform these tasks:

Verifying That the Policer Firewall Filter Is Operational

Purpose

Verify the operational state of the policer that is configured on the ingress PE switch.

Action

```
user@switch> show firewall
```

```
Filter: myfilter
```

```
Policers:
```

Name	Packets
mypolicer-t1	0

Meaning

This output shows that the firewall filter **mypolicer** has been created.

Verifying That the CoS Classifiers Are Going to the Right Queue

Purpose

Verify that the CoS classifiers are going to the right queue.

Action

```
user@switch> show class-of-service forwarding-table classifier
```

```
63      111111      3      0
```

Meaning

This output shows that a new DSCP classifier has been created, index **9346**, on the ingress PE switch (PE-1).

Verifying the CoS Forwarding Table Mapping

Purpose

For each logical interface, display either the table index of the classifier for a given code point type or the queue number (if it is a fixed classification) in the forwarding table.

Action

```
user@switch> show class-of-service forwarding-table classifier mapping
```

Interface	Index	Table Index/	
		Q num	Table type
ge-0/0/1.0	92	9346	DSCP

Meaning

The results show that the new DSCP classifier, index number **9346**, is bound to interface **ge-0/0/1.0**.

Verifying the Rewrite Rules

Purpose

Display mapping of the queue number and loss priority to code point value for each rewrite rule as it exists in the forwarding table.

Action

```
user@switch>show class-of-service forwarding-table rewrite-rule
```

```
Rewrite table index: 31, # entries: 4, Table type: DSCP
```

FC#	Low bits	State	High bits	State
0	000000	Enabled	000000	Enabled
1	101110	Enabled	101110	Enabled
2	001010	Enabled	001100	Enabled
3	110000	Enabled	111000	Enabled

Rewrite table index: 34, # entries: 4, Table type: IEEE 802.1

FC#	Low bits	State	High bits	State
0	000	Enabled	001	Enabled
1	010	Enabled	011	Enabled
2	100	Enabled	101	Enabled
3	110	Enabled	111	Enabled

Rewrite table index: 35, # entries: 4, Table type: IPv4 precedence

FC#	Low bits	State	High bits	State
0	000	Enabled	000	Enabled
1	101	Enabled	101	Enabled
2	001	Enabled	001	Enabled
3	110	Enabled	111	Enabled

Rewrite table index: 9281, # entries: 1, Table type: EXP

FC#	Low bits	State	High bits	State
1	111	Enabled	000	Disabled

Meaning

This output shows that a new EXP classifier with the index number **9281** has been created.

Configuring CoS on an MPLS Provider Edge Switch Using IP Over MPLS

IN THIS SECTION

- [Configuring CoS | 201](#)
- [Configuring an LSP Policer | 201](#)

You can use class of service (CoS) within MPLS networks to prioritize certain types of traffic during periods of congestion. This topic describes configuring CoS components on a provider edge (PE) switch that is using IP Over MPLS.

This task describes how to create a custom DSCP classifier and a custom EXP rewrite rule on the ingress PE switch. It includes configuring a policer firewall filter and applying it to the customer-edge interface of the ingress PE switch. The policer firewall filter ensures that the amount of traffic forwarded through the MPLS tunnel never exceeds the requested bandwidth allocation.

Before you begin, configure the basic components for an MPLS network:

- Configure two PE switches. See *Basic MPLS Configuration*.
- Configure one or more provider switches.

Configuring CoS

To configure CoS on a provider edge switch:

1. Import the default DSCP classifier classes to the custom DSCP classifier that you are creating:

```
[edit class-of-service]
user@switch# set classifiers dscp classifier-name import default
```

2. Add a forwarding class to this custom DSCP classifier and specify a loss priority and code point:

```
[edit class-of-service]
user@switch# set classifiers dscp classifier-name forwarding-class forwarding-class loss-
priority loss-priority code-points code-point
```

3. Specify the values for the custom EXP rewrite rule, e1:

```
[edit class-of-service]
user@switch# set rewrite-rules exp e1 forwarding-class forwarding-class loss-priority loss-
priority code-points code-point
```

Configuring an LSP Policer

To configure an LSP policer:

1. Specify the number of bits per second permitted, on average, for the firewall policer, which will later be applied to the customer-edge-interface:

```
[edit firewall]
user@switch# set policer mypolicer if-exceeding bandwidth-limit 500m
```

2. Specify the maximum size permitted for bursts of data that exceed the given bandwidth limit for this policer:

```
[edit firewall policer]
user@switch# set mypolicer if-exceeding burst-size-limit 33553920
```

3. Discard traffic that exceeds the rate limits for this policer:

```
[edit firewall policer]
user@switch# set mypolicer then discard
```

4. To reference the policer, configure a filter term that includes the policer action:

```
[edit firewall]
user@switch# set family inet filter myfilter term t1 then policer mypolicer
```

5. Apply the filter to the customer-edge interface:

```
[edit interfaces]
user@switch# set ge-2/0/3 unit 0 family inet address 192.168.121.1/16 policing filter myfilter
```

NOTE: You can also configure schedulers and shapers as needed. See ["Defining CoS Schedulers and Scheduler Maps \(CLI Procedure\)" on page 126](#).

Configuring CoS on an MPLS Provider Edge Switch Using Circuit Cross-Connect

IN THIS SECTION

- [Configuring CoS | 203](#)
- [Configuring an LSP Policer | 204](#)

You can use class of service (CoS) within MPLS networks to prioritize certain types of traffic during periods of congestion. This topic describes configuring CoS components on a provider edge (PE) switch that is using MPLS over circuit-cross connect (CCC).

NOTE: If you are using MPLS over CCC, you can use only one DSCP or IP precedence classifier and only one IEEE 802.1p classifier on the CCC interfaces.

This procedure is for creating a custom DSCP classifier and a custom EXP rewrite rule on the ingress PE. It also includes enabling a policer on the label-switched path (LSP) of the ingress PE to ensure that the amount of traffic forwarded through the LSP never exceeds the requested bandwidth allocation.

This topic includes:

Configuring CoS

To configure CoS on a provider edge switch:

1. Import the default DSCP classifier classes to the custom DSCP classifier that you are creating:

```
[edit class-of-service]
user@switch# set classifiers dscp classifier-name import default
```

2. Add the expedited-forwarding class to this custom DSCP classifier, specifying a loss priority and code point:

```
[edit class-of-service]
user@switch# set classifiers dscp classifier-name forwarding-class forwarding-class loss-
priority loss-priority code-points code-point
```

3. Specify the values for the custom EXP rewrite rule, e1:

```
[edit class-of-service]
user@switch# set rewrite-rules exp e1 forwarding-class forwarding-class loss-priority loss-
priority code-point code-point
```

4. Bind the DSCP classifier to the CCC interface:

```
[edit ]
user@switch# set class-of-service interfaces interface unit unit classifier classifier-
name
```

Configuring an LSP Policer

To configure an LSP policer:

1. Specify the number of bits per second permitted, on average, for the policer, which will later be applied to the LSP:

```
[edit firewall]
set policer mypolicer if-exceeding bandwidth-limit 500m
```

2. Specify the maximum size permitted for bursts of data that exceed the given bandwidth limit for this policer:

```
[edit firewall policer]
set mypolicer if-exceeding burst-size-limit 33553920
```

3. Discard traffic that exceeds the rate limits for this policer:

```
[edit firewall policer]
set mypolicer then discard
```

4. To reference the policer, configure a filter term that includes the policer action:

```
[edit firewall]
user@switch# set family any filter myfilter term t1 then policer
mypolicer
```

5. Apply the filter to the LSP:

```
[edit protocols mpls]
set label-switched-path lsp_to_pe2_ge1 policing filter myfilter
```

NOTE: You can also configure schedulers and shapers as needed. See ["Defining CoS Schedulers and Scheduler Maps \(CLI Procedure\)" on page 126](#).

Configuring CoS on Provider Switches of an MPLS Network

You can add class-of-service (CoS) components to your MPLS networks on EX Series switches to achieve end-to-end Differentiated Services to match your specific business requirements. The configuration of CoS components on the provider switches is the same regardless of whether the provider edge (PE) switches are using MPLS over CCC or IP over MPLS.

This task shows how to configure a custom EXP classifier and custom EXP rewrite rule on the provider switch.

1. Import the default EXP classifier classes to the custom EXP classifier that you are creating:

```
[edit class-of-service]
user@switch# set classifiers exp exp1 import default
```

2. Add the expedited-forwarding class to this custom EXP classifier, specifying a loss priority and code point:

```
[edit class-of-service]
user@switch# set classifiers exp exp1 forwarding-class expedited-forwarding loss-priority low
code-points 010
```

3. Specify the values for the custom EXP rewrite rule, **e1**:

```
[edit class-of-service]
user@switch# set rewrite-rules exp e1 forwarding-class expedited-forwarding loss-priority low
code-point 111
```

NOTE: You can also configure schedulers and shapers as needed. See "[Defining CoS Schedulers and Scheduler Maps \(CLI Procedure\)](#)" on page 126.

CHAPTER 15

CoS on EVPN VXLANs

IN THIS CHAPTER

- [CoS Support on EVPN VXLANs | 207](#)

CoS Support on EVPN VXLANs

IN THIS SECTION

- [Understanding CoS on VXLAN Interfaces | 207](#)
- [Configuring CoS on VXLAN Interfaces | 209](#)
- [Implementing CoS on VXLAN Interfaces \(Junos OS Evolved\) | 212](#)
- [CoS Limitations on VXLANs | 213](#)

You can configure class of service (CoS) features on VXLAN interfaces. VXLAN traffic from different tenants traverses network boundaries over the same physical underlay network. To ensure fairness in the treatment of traffic for all tenants in the VXLAN, and to prioritize higher priority traffic, apply CoS features to the VXLAN interfaces.

Understanding CoS on VXLAN Interfaces

This section describes how classification and rewrite rules are applied to packets in a VXLAN instance. [Figure 7 on page 208](#) shows a simple VXLAN with two leaf nodes and one spine node.

Figure 7: Classifiers and Rewrite Rules on VXLANs

Refer to [Figure 7 on page 208](#) to understand the packet flow with DSCP/ToS fields in a VXLAN:

1. CE 1 sends a packet with Layer3 DSCP/ToS bit programmed to the Leaf 1 node.
2. Leaf 1 receives the original packet and appends the VXLAN header on top of the original packet. The outer VXLAN Layer3 header uses the original packet DSCP/ToS bit. You can create classifiers based on the original packet DSCP/802.1p bit. The ingress interface on the ingress leaf supports DSCP and 802.1p classifiers.
3. If rewrite is configured on Leaf 1, the inner header will have the DSCP/802.1p bit set by CE 1 and the outer header will have the rewrite bit. Only DSCP rewrite rules are supported, except on QFX10000 switches where 802.1p rewrite is also supported if the underlay is tagged.
4. The Spine node receives the VXLAN packet and can use ingress classification using these DSCP bits and forward the packet to the egress interface with the appropriate forwarding class.
5. The Spine egress interface can rewrite these bits using rewrite rules. These Spine rewrite rules only affects the outer Layer3 DSCP field. The inner/original packet still holds the DSCP/802.1p bit that was set by CE 1.
6. Leaf 2 receives the packet, processes the tunnel termination, and remove the outer VXLAN header.
7. Leaf 2 classification and rewrite functionality works on the inner header.
8. The original packet arrives on CE 2.

NOTE: On the leaf nodes, if the packet is multicast, you can use multi-destination classification to create appropriate multicast classification and rewrite rules.

Configuring CoS on VXLAN Interfaces

This section shows sample configurations of classifiers and rewrite rules for the leaf and spine nodes in VXLAN using [Figure 7 on page 208](#) as a reference. You can create schedulers as normal for the classifiers on each node.

Sample configuration of classifiers and rewrite rules on Leaf 1.

1. Create a classifier based on the *original*/DSCP/ToS bits:

```
[edit class-of-service classifiers]
user@leaf1#set dscp dscp_cf forwarding-class best-effort loss-priority low code-points 100000
user@leaf1#set dscp dscp_cf forwarding-class network-control loss-priority high code-points 110000
user@leaf1#set dscp dscp_cf forwarding-class expedited-forwarding loss-priority low code-points 011010
user@leaf1#set dscp dscp_cf forwarding-class assured-forwarding loss-priority high code-points 001010
```

2. Apply the classifier to the ingress interface:

```
[edit class-of-service interfaces]
user@leaf1#set ge-0/0/0 unit 0 classifiers dscp dscp_cf
```

3. Create a rewrite rule for the *outer* VXLAN DSCP/ToS bits:

```
[edit class-of-service rewrite-rules]
user@leaf1#set dscp dscp_rw forwarding-class best-effort loss-priority low code-points af22
user@leaf1#set dscp dscp_rw forwarding-class network-control loss-priority high code-points af31
user@leaf1#set dscp dscp_rw forwarding-class expedited-forwarding loss-priority low code-points af13
user@leaf1#set dscp dscp_rw forwarding-class assured-forwarding loss-priority high code-points cs3
```

4. Apply the rewrite rule to the egress Leaf 1 interfaces:

```
[edit class-of-service interfaces]
user@leaf1#set ge-0/0/1 unit 0 rewrite-rules dscp dscp_rw
user@leaf1#set ge-0/0/2 unit 0 rewrite-rules dscp dscp_rw
```

Sample configuration of classifiers and rewrite rules on the Spine.

1. Create a classifier based on the outer VXLAN DSCP/ToS bits:

```
[edit class-of-service classifiers]
user@spine#set dscp dscp_cf forwarding-class best-effort loss-priority low code-points af22
user@spine#set dscp dscp_cf forwarding-class network-control loss-priority high code-points af31
user@spine#set dscp dscp_cf forwarding-class expedited-forwarding loss-priority low code-points af13
user@spine#set dscp dscp_cf forwarding-class assured-forwarding loss-priority high code-points cs3
```

2. Apply the classifier to the ingress Spine interfaces:

```
[edit class-of-service interfaces]
user@spine#set ge-0/0/3 unit 0 classifiers dscp dscp_cf
user@spine#set ge-0/0/5 unit 0 classifiers dscp dscp_cf
```

3. Create a rewrite rule for the outer VXLAN DSCP/ToS bits:

```
[edit class-of-service rewrite-rules]
user@spine#set dscp dscp_rw forwarding-class best-effort loss-priority low code-points af22
user@spine#set dscp dscp_rw forwarding-class network-control loss-priority high code-points af31
user@spine#set dscp dscp_rw forwarding-class expedited-forwarding loss-priority low code-points af13
user@spine#set dscp dscp_rw forwarding-class assured-forwarding loss-priority high code-points cs3
```

4. Apply the rewrite rule to the egress Spine interfaces:

```
[edit class-of-service interfaces]
user@spine#set ge-0/0/4 unit 0 rewrite-rules dscp dscp_rw
user@spine#set ge-0/0/6 unit 0 rewrite-rules dscp dscp_rw
```

Sample configuration of classifiers and rewrite rules on Leaf 2.

1. Create a classifier based on the *original*/DSCP/ToS bits, as the VXLAN header is removed at tunnel termination *before* forwarding classes are applied:

```
[edit class-of-service classifiers]
user@leaf2#set dscp dscp_cf forwarding-class best-effort loss-priority low code-points 100000
user@leaf2#set dscp dscp_cf forwarding-class network-control loss-priority high code-points 110000
user@leaf2#set dscp dscp_cf forwarding-class expedited-forwarding loss-priority low code-points 011010
user@leaf2#set dscp dscp_cf forwarding-class assured-forwarding loss-priority high code-points 001010
```

2. Apply the classifier to the ingress Leaf 2 interfaces:

```
[edit class-of-service interfaces]
user@leaf2#set ge-0/0/7 unit 0 classifiers dscp dscp_cf
user@leaf2#set ge-0/0/8 unit 0 classifiers dscp dscp_cf
```

3. Create a rewrite rule for the *original*/DSCP/ToS bits:

```
[edit class-of-service rewrite-rules]
user@leaf2#set dscp dscp_rw forwarding-class best-effort loss-priority low code-points 100000
user@leaf2#set dscp dscp_rw forwarding-class network-control loss-priority high code-points 110000
user@leaf2#set dscp dscp_rw forwarding-class expedited-forwarding loss-priority low code-points 011010
user@leaf2#set dscp dscp_rw forwarding-class assured-forwarding loss-priority high code-points 001010
```

4. Apply the rewrite rule to the egress Leaf 2 interface:

```
[edit class-of-service interfaces]
user@leaf2#set ge-0/0/9 unit 0 rewrite-rules dscp dscp_rw
```

To check the CoS configuration on one of the interfaces:

```
user@node#show class-of-service interface interface-name
```

To check the queue statistics on one of the interfaces:

```
user@node#show interfaces queue interface-name
```

Implementing CoS on VXLAN Interfaces (Junos OS Evolved)

CoS for EVPN VXLAN traffic is supported using a combination of classifiers, schedulers, and rewrite rules. This section describes how these components are implemented across different nodes on devices running Junos OS Evolved to apply CoS on the EVPN VXLAN traffic.

- **Classification at User Network Interface (UNI)/Ingress PE** — Traffic classification based on IEEE 802.1p and Differentiated Services code point (DSCP) are supported on the ingress PE where the EVPN VXLAN tunnel is initiated. BA and MF classifiers can be applied to Enterprise style (EP) or Service Provider (SP) style access interfaces.
- **Classification at Network Node Interface (NNI)/Egress PE** — Traffic classification based on IEEE 802.1p and Differentiated Services code point (DSCP) are supported on the egress PE where the EVPN VXLAN tunnel is terminated. BA classifiers can be applied to the underlying logical interface or unit. MF classifiers are not supported in tunnel terminations.
- **Rewrite at NNI** — After the encapsulation of the VXLAN tunnel, the rewrites on the outer/tunnel header are configured using the rewrite rules on the underlying logical interface or unit. Based on the configured rewrite rules, the VXLAN traffic is classified in the Spine/Network. DSCP rewrites on the outer/tunnel header of VXLAN packets is supported on the NNI interface.

Rewrite rules are supported in the following EVPN VXLAN scenarios:

- Intra-VNI L2 gateway — Rewrite rules are applied to both unicast and broadcast, unknown unicast, and multicast (BUM) traffic.
- Inter-VNI L3 gateway — Centrally-routed bridging (CRB) and edge-routed bridging (ERB).
- EVPN Type 5 routes.
- **Rewrite at UNI** — After the termination of the VXLAN tunnel, the rewrites on the inner headers are configured using rewrite rules on the Enterprise style (EP) or Service Provider (SP) style access interfaces. Based on the configured rewrite rules, the decapsulated packets are classified in the CE side network. The following rewrite rules are supported on the UNI interface for the decapsulated packets:
 - DSCP rewrites on the inner IPv4/IPv6 header
 - IEEE 802.1p rewrites on the inner Ethernet header (if tagged)

Rewrite rules are supported in the following EVPN VXLAN scenarios:

- Intra-VNI L2 gateway — Rewrite rules are applied to both unicast and broadcast, unknown unicast, and multicast (BUM) traffic.
- Inter-VNI L3 gateway — Centrally-routed bridging (CRB) and edge-routed bridging (ERB).
- EVPN Type 5 routes.
- **Scheduling** — Traffic prioritization and bandwidth reservation are achieved by using schedulers. The schedulers are associated with a forwarding class set via classifiers.

CoS Limitations on VXLANs

The following limitations apply to PTX routers:

- DSCP rewrite rules are not supported on Integrated Routing and Bridging (IRB) (L3 gateway scenarios).
- IEEE 802.1p rewrite rules are not supported on the NNI interface.
- Explicit congestion notification (ECN) rewrites are not supported on either UNI or NNI interfaces.
- Priority-based flow control (PFC) is not supported.
- No support for CoS classification and rewrite mechanism for IPv6 or IRB underlay.

The CoS functionality on EVPN VXLAN is the same as on QFX5K platforms. All VXLAN CoS features already supported on the QFX5120 are also supported on the QFX5130 and QFX5700 platforms.

The following limitations apply to the QFX5130 and QFX5700 platforms:

- HQoS is not supported due to hardware limitations.
- Classifier, rewrite and scheduler on IRB interface is not supported.
- DOT1P rewrite and classifier on the NNI port is not supported.
- DOT1P and DSCP rewrite on the UNI port is not supported.
- DSCP rewrite on the NNI port is supported with the following limitations:
 - DSCP rewrite takes effect only after you disable TOS copy (set `vxlan-disable-copy-tos-encap` at [edit forwarding-options] hierarchy level) on the VXLAN encapsulation node. When TOS copy is disabled, ECN bits are not copied from the inner to the outer header, so the packet outer header will have the defined rewrite DSCP value and an ECN value of 00.
 - DSCP rewrite rewrites both the outer and the inner header. So the inner header DSCP value cannot be preserved.
- PFC configuration will cause momentary traffic drops of up to 10ms.

- DSCP IPV6 classifiers and rewrites are not supported. Use DSCP classifier and rewrite instead.
- TOS copy feature does not work for Type-5 EVPN VXLANs.

The following limitation applies to QFX10000 platforms:

- Because IRB interfaces do not support dscp rewrite rules, you can apply rewrite rules on underlying L2 interfaces. 802.1p/dscp values in a VXLAN tunneled packet are written using underlying L2 interface rules.
