| <b>Description</b>              | Multicast routing devices running PIM sparse mode often forward the same stream of multicast packets onto the same LAN through the rendezvous-point tree (RPT) and shortest-path tree (SPT). PIM assert messages help routing devices determine which routing device forwards the traffic and prunes the RPT for this group. By default, routing devices enter an assert cycle every 180 seconds. You can configure this assert timeout to be between 5 and 210 seconds. |
| <b>Options</b>                  | <b><i>seconds</i></b> —Time for routing device to wait before another assert message cycle.<br><b>Range:</b> 5 through 210 seconds<br><b>Default:</b> 180 seconds                                                                                                                                                                                                                                                                                                        |

| <b>Description</b>              | <p>Enable BFD failure detection. The BFD failure detection timers are adaptive and can be adjusted to be faster or slower. The lower the BFD failure detection timer value, the faster the failure detection and vice versa. For example, the timers can adapt to a higher value if the adjacency fails (that is, the timer detects failures more slowly). Or a neighbor can negotiate a higher value for a timer than the configured value. The timers adapt to a higher value when a BFD session flap occurs more than three times in a span of 15 seconds. A back-off algorithm increases the receive (Rx) interval by two if the local BFD instance is the reason for the session flap. The transmission (Tx) interval is increased by two if the remote BFD instance is the reason for the session flap. You can use the <b>clear bfd adaptation</b> command to return BFD interval timers to their configured values. The <b>clear bfd adaptation</b> command is hitless, meaning that the command does not affect traffic flow on the routing device.</p> <p>The remaining statement is explained separately.</p> |
| <b>Required Privilege Level</b> | <p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>Description</b>              | <p>Specify loose authentication checking on the BFD session. Use loose authentication for transitional periods only when authentication might not be configured at both ends of the BFD session.</p> <p>By default, strict authentication is enabled and authentication is checked at both ends of each BFD session. Optionally, to smooth migration from nonauthenticated sessions to authenticated sessions, you can configure <i>loose checking</i>. When loose checking is configured, packets are accepted without authentication being checked at each end of the session.</p> |

| <b>Description</b>              | Set the maximum time in milliseconds to delay sending override join messages for a multicast network that has join suppression enabled. When a router or switch sees a prune message for a join it is currently suppressing, it waits for the interval specified by the override timer before it sends an override join message.                                                                                                                                                                                                                                                               |
| <b>Options</b>                  | This is a random timer with a value in milliseconds.<br><b>Range:</b> 0 through maximum override value<br><b>Default:</b> 2000 milliseconds                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>Description</b>              | Change the value of a tracking bit (T-bit) field in the LAN prune delay hello option from the default of 1 to 0, which enables join suppression for a multicast interface. When the network starts receiving multiple identical join messages, join suppression triggers a random timer with a value of 66 through 84 milliseconds ( $1.1 \times \text{periodic}$ through $1.4 \times \text{periodic}$ , where periodic is 60 seconds). This creates an interval during which no identical join messages are sent. Eventually, only one of the identical messages is sent. Join suppression is triggered each time identical messages are sent for the same join. |

| <b>Description</b>              | Set the SPT threshold to infinity for a source-group address pair. Last-hop multicast routing devices running PIM sparse mode can forward the same stream of multicast packets onto the same LAN through an RPT rooted at the RP or an SPT rooted at the source. By default, last-hop routing devices transition to a direct SPT to the source. You can configure this routing device to set the SPT transition value to infinity to prevent this transition for any source-group address pair.<br><br>The remaining statements are explained separately. |
| <b>Required Privilege Level</b> | routing—To view this statement in the configuration.<br>routing-control—To add this statement to the configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>Description</b>              | <p>Specify the transmit interval for the <b>bfd-liveness-detection</b> statement. The negotiated transmit interval for a peer is the interval between the sending of BFD packets to peers. The receive interval for a peer is the minimum interval between receiving packets sent from its peer; the receive interval is not negotiated between peers. To determine the transmit interval, each peer compares its configured minimum transmit interval with its peer's minimum receive interval. The larger of the two numbers is accepted as the transmit interval for that peer.</p> <p>The remaining statements are explained separately.</p> |

| <b>Description</b>         | <p>Configure PIM tracing options.</p> <p>To specify more than one tracing operation, include multiple <b>flag</b> statements.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Default</b>             | The default PIM trace options are those inherited from the routing protocol's <b>traceoptions</b> statement included at the [edit routing-options] hierarchy level.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Options</b>             | <p><b>disable</b>—(Optional) Disable the tracing operation. You can use this option to disable a single operation when you have defined a broad group of tracing operations, such as <b>all</b>.</p> <p><b>file <i>filename</i></b>—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory <b>/var/log</b>. We recommend that you place tracing output in the <b>pim-log</b> file.</p> <p><b>files <i>number</i></b>—(Optional) Maximum number of trace files. When a trace file named <b>trace-file</b> reaches its maximum size, it is renamed <b>trace-file.0</b>, then <b>trace-file.1</b>, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.</p> <p>If you specify a maximum number of files, you must also include the <b>size</b> statement to specify the maximum file size.</p> <p><b>Range:</b> 2 through 1000 files</p> <p><b>Default:</b> 2 files</p> <p><b>flag <i>flag</i></b>—Tracing operation to perform. To specify more than one tracing operation, include multiple <b>flag</b> statements.</p> <p><b>PIM Tracing Flags</b></p> <ul style="list-style-type: none"><li>• <b>assert</b>—Assert messages</li><li>• <b>bidirectional-df-election</b>—Bidirectional PIM designated-forwarder (DF) election events</li></ul> |

- **bootstrap**—Bootstrap messages
- **cache**—Packets in the PIM sparse mode routing cache
- **graft**—Graft and graft acknowledgment messages
- **hello**—Hello packets
- **join**—Join messages
- **mt**—Multicast tunnel messages
- **nsr-synchronization**—Nonstop active routing (NSR) synchronization messages
- **packets**—All PIM packets
- **prune**—Prune messages
- **register**—Register and register stop messages
- **rp**—Candidate RP advertisements
- **all**—All tracing operations
- **general**—A combination of the **normal** and **route** trace operations
- **normal**—All normal operations

**Default:** If you do not specify this option, only unusual or abnormal operations are traced.

- **policy**—Policy operations and actions
- **route**—Routing table changes
- **state**—State transitions
- **task**—Interface transactions and processing
- **timer**—Timer usage

**flag-modifier**—(Optional) Modifier for the tracing flag. You can specify one or more of these modifiers:

- **detail**—Detailed trace information
- **receive**—Packets being received
- **send**—Packets being transmitted

**no-stamp**—(Optional) Do not place timestamp information at the beginning of each line in the trace file.

**Default:** If you omit this option, timestamp information is placed at the beginning of each line of the tracing output.

**no-world-readable**—(Optional) Do not allow users to read the log file.

**replace**—(Optional) Replace an existing trace file if there is one.

**Default:** If you do not include this option, tracing output is appended to an existing trace file.

**size size**—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named **trace-file** reaches this size, it is renamed **trace-file.0**. When **trace-file** again reaches this size, **trace-file.0** is renamed **trace-file.1** and **trace-file** is renamed **trace-file.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you must also include the **files** statement to specify the maximum number of trace files.

**Syntax:** **xk** to specify KB, **xm** to specify MB, or **xg** to specify GB

**Range:** 0 KB through the maximum file size supported on your system

**Default:** 1 MB

**world-readable**—(Optional) Allow any user to read the log file.

| <b>Release Information</b>      | Statement introduced in Junos OS Release 10.4.<br>Statement introduced in Junos OS Release 12.1 for the QFX Series.                                                                                                                                                                                                                        |
| <b>Description</b>              | <p>Configure a limit for the number of multicast groups (or [S,G] channels in IGMPv3) allowed on an interface. After this limit is reached, new reports are ignored and all related flows are not flooded on the interface.</p> <p>To confirm the configured group limit on the interface, use the <b>show igmp interface</b> command.</p> |
| <b>Default</b>                  | By default, there is no limit to the number of multicast groups that can join the interface.                                                                                                                                                                                                                                               |
| <b>Options</b>                  | <b>limit</b> —group limit value for the interface.<br><b>Range:</b> 1 through 32767                                                                                                                                                                                                                                                        |

**Release Information**    Statement introduced before Junos OS Release 7.4.  
                              Statement introduced in Junos OS Release 12.1 for the QFX Series.

**Description**    Enable IGMP on the router. IGMP must be enabled for the router to receive multicast packets.

The remaining statements are explained separately.

|                                 |                                                                                                                                                                                                          |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>                  | IGMP is disabled on the router. IGMP is automatically enabled on all broadcast interfaces when you configure Protocol Independent Multicast (PIM) or Distance Vector Multicast Routing Protocol (DVMRP). |
| <b>Required Privilege Level</b> | routing—To view this statement in the configuration.<br>routing-control—To add this statement to the configuration.                                                                                      |

| <b>Description</b>              | <p>The immediate leave setting is useful for minimizing the leave latency of IGMP memberships. When this setting is enabled, the routing device leaves the multicast group immediately after the last host leaves the multicast group.</p> <p>Starting in Junos OS Release 9.3, both IGMP version 2 and IGMP version 3 do host tracking when the <b>immediate-leave</b> statement is configured. This means that the multicast group leaves only when the last host leaves. The routing device keeps track of the hosts that send join messages. This allows IGMP to determine when the last host sends a leave message for the multicast group.</p> <p>When the immediate leave setting is enabled, the device removes an interface from the forwarding-table entry without first sending IGMP group-specific queries to the interface. The interface is pruned from the multicast tree for the multicast group specified in the IGMP leave message. The immediate leave setting ensures optimal bandwidth management for hosts on a switched network, even when multiple multicast groups are being used simultaneously.</p> <p>When immediate leave is disabled and one host sends a leave group message, the routing device first sends a group query to determine if another receiver responds. If no receiver responds, the routing device removes all hosts on the interface from the multicast group. Immediate leave is disabled by default for both IGMP version 2 and IGMP version 3.</p> |
|                                 | <div>  <p><b>NOTE:</b> Although host tracking is enabled for IGMPv2 and MLDv1 when you enable immediate leave, use immediate leave with these versions only when there is one host on the interface. The reason is that IGMPv2 and MLDv1 use a report suppression mechanism whereby only one host on an interface sends a group join report in response to a membership query. The other interested hosts suppress their reports. The purpose of this mechanism is to avoid a flood of reports for the same group. But it also interferes with host tracking, because the router only knows about the one interested host and does not know about the others.</p> </div>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## static (Protocols IGMP)

---

**Syntax**    static {  
              group *multicast-group-address* {  
                  exclude;  
                  group-count *number*;  
                  group-increment *increment*;  
                  source *ip-address* {  
                      source-count *number*;  
                      source-increment *increment*;  
                  }  
              }  
          }  
      }

**Hierarchy Level**    [edit logical-systems *logical-system-name* protocols **igmp** interface *interface-name*],  
                          [edit protocols **igmp** interface *interface-name*]

**Release Information**    Statement introduced before Junos OS Release 7.4.  
                              Statement introduced in Junos OS Release 9.0 for EX Series switches.  
                              Statement introduced in Junos OS Release 12.1 for the QFX Series.

**Description**    Test multicast forwarding on an interface without a receiver host.

The **static** statement simulates IGMP joins on a routing device statically on an interface without any IGMP hosts. It is supported for both IGMPv2 and IGMPv3 joins. This statement is especially useful for testing multicast forwarding on an interface without a receiver host.

.....  
**NOTE:** To prevent joining too many groups accidentally, the **static** statement is not supported with the **interface all** statement.  
.....

The remaining statements are explained separately.

**Required Privilege Level**    routing and trace—To view this statement in the configuration.  
                                  routing-control and trace-control—To add this statement to the configuration.

| <b>Description</b>         | <p>Configure IGMP tracing options.</p> <p>To specify more than one tracing operation, include multiple <b>flag</b> statements.</p> <p>To trace the paths of multicast packets, use the <b>mtrace</b> command.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Default</b>             | The default IGMP trace options are those inherited from the routing protocols <b>traceoptions</b> statement included at the [edit routing-options] hierarchy level.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Options</b>             | <p><b>disable</b>—(Optional) Disable the tracing operation. You can use this option to disable a single operation when you have defined a broad group of tracing operations, such as <b>all</b>.</p> <p><b>file <i>filename</i></b>—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory <b>/var/log</b>. We recommend that you place tracing output in the file <b>igmp-log</b>.</p> <p><b>files <i>number</i></b>—(Optional) Maximum number of trace files. When a trace file named <b>trace-file</b> reaches its maximum size, it is renamed <b>trace-file.0</b>, then <b>trace-file.1</b>, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.</p> <p>If you specify a maximum number of files, you must also include the <b>size</b> statement to specify the maximum file size.</p> <p><b>Range:</b> 2 through 1000 files</p> <p><b>Default:</b> 2 files</p> <p><b>flag</b>—Tracing operation to perform. To specify more than one tracing operation, include multiple <b>flag</b> statements.</p> <p><b>IGMP Tracing Flags</b></p> <ul style="list-style-type: none"> <li><b>leave</b>—Leave group messages (for IGMP version 2 only).</li> <li><b>mtrace</b>—Mtrace packets. Use the <b>mtrace</b> command to troubleshoot the software.</li> <li><b>packets</b>—All IGMP packets.</li> </ul> |

- **query**—IGMP membership query messages, including general and group-specific queries.
- **report**—Membership report messages.

#### Global Tracing Flags

- **all**—All tracing operations
- **general**—A combination of the **normal** and **route** trace operations
- **normal**—All normal operations

**Default:** If you do not specify this option, only unusual or abnormal operations are traced.

- **policy**—Policy operations and actions
- **route**—Routing table changes
- **state**—State transitions
- **task**—Interface transactions and processing
- **timer**—Timer usage

**flag-modifier**—(Optional) Modifier for the tracing flag. You can specify one or more of these modifiers:

- **detail**—Detailed trace information
- **receive**—Packets being received
- **send**—Packets being transmitted

**no-stamp**—(Optional) Do not place timestamp information at the beginning of each line in the trace file.

**Default:** If you omit this option, timestamp information is placed at the beginning of each line of the tracing output.

**no-world-readable**—(Optional) Do not allow users to read the log file.

**replace**—(Optional) Replace an existing trace file if there is one.

**Default:** If you do not include this option, tracing output is appended to an existing trace file.

**size size**—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named **trace-file** reaches this size, it is renamed **trace-file.0**. When **trace-file** again reaches this size, **trace-file.0** is renamed **trace-file.1** and **trace-file** is renamed **trace-file.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you must also include the **files** statement to specify the maximum number of trace files.

**Syntax:** *xk* to specify KB, *xm* to specify MB, or *xg* to specify GB

**Range:** 10 KB through the maximum file size supported on your system

**Default:** 1 MB

**world-readable**—(Optional) Allow any user to read the log file.

**Required Privilege Level** routing and trace—To view this statement in the configuration.  
routing-control and trace-control—To add this statement to the configuration.

## version (Protocols IGMP)

**Syntax** `version version;`

**Hierarchy Level** [edit logical-systems *logical-system-name* protocols **igmp interface** *interface-name*],  
[edit protocols **igmp interface** *interface-name*]

**Release Information** Statement introduced before Junos OS Release 7.4.  
Statement introduced in Junos OS Release 9.0 for EX Series switches.  
Statement introduced in Junos OS Release 12.1 for the QFX Series.

**Description** Specify the version of IGMP.

**Options** **version**—IGMP version number.

**Range:** 1, 2, or 3

**Default:** IGMP version 2

**Required Privilege Level** routing—To view this statement in the configuration.  
routing-control—To add this statement to the configuration.

| <b>Release Information</b>      | Statement introduced in Junos OS Release 12.3 for the QFX Series.                                                                                                                                                                                                                                                           |
| <b>Description</b>              | Configure the switch to be an IGMP querier. If there are any multicast routers on the same local network, make sure the source address for the IGMP querier is greater (a higher number) than the IP addresses for those routers on the network. This ensures that switch is always the IGMP querier on the network.        |
| <b>Required Privilege Level</b> | routing—To view this statement in the configuration.<br>routing-control—To add this statement to the configuration.                                                                                                                                                                                                         |

| Release Information | Statement introduced in Junos OS Release 11.1 for the QFX Series.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Description         | Define tracing operations for IGMP snooping.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Default             | The <b>traceoptions</b> feature is disabled by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Options             | <p><b>file <i>filename</i></b>—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory <b>/var/log</b>.</p> <p><b>files <i>number</i></b>—(Optional) Maximum number of trace files. When a trace file named <b>trace-file</b> reaches its maximum size, it is renamed <b>trace-file.0</b>, then <b>trace-file.1</b>, and so on, until the maximum number of trace files is reached (<b>xk</b> to specify KB, <b>xm</b> to specify MB, or <b>xg</b> to specify gigabytes), at which point the oldest trace file is overwritten. If you specify a maximum number of files, you also must specify a maximum file size with the <b>size</b> option.</p> <p><b>Range:</b> 2 through 1000</p> <p><b>Default:</b> 3 files</p> <p><b>flag <i>flag</i></b> —Tracing operation to perform. To specify more than one tracing operation, include multiple flag statements. You can include the following flags:</p> <ul style="list-style-type: none"><li>• <b>all</b>—All tracing operations.</li><li>• <b>general</b>—Trace general IGMP snooping protocol events.</li><li>• <b>krt</b>—Trace communication over routing sockets.</li><li>• <b>nexthop</b>— Trace next-hop related events.</li><li>• <b>normal</b>—Trace normal IGMP snooping protocol events.</li><li>• <b>packets</b>—Trace all IGMP packets.</li><li>• <b>policy</b>—Trace policy processing.</li><li>• <b>query</b>—Trace IGMP membership query messages.</li><li>• <b>report</b>—Trace membership report messages.</li><li>• <b>route</b>—Trace routing information.</li><li>• <b>state</b>—Trace IGMP state transitions.</li><li>• <b>task</b>—Trace routing protocol task processing.</li></ul> |

- **timer**—Trace routing protocol timer processing.
- **vlan**—Trace VLAN related events.

**no-stamp**—(Optional) Do not time stamp trace file.

**no-world-readable**—(Optional) Restrict file access to the user who created the file.

**size size** —(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named **trace-file** reaches its maximum size, it is renamed **trace-file.0**, then **trace-file.1**, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten. If you specify a maximum number of files, you also must specify a maximum file size with the **files** option. Use **xk** to specify KB, **xm** to specify MB, or **xg** to specify gigabytes.

**Range:** 10 KB through 1 gigabytes

**Default:** 128 KB

**world-readable**—(Optional) Enable unrestricted file access.

## vlan (IGMP Snooping)

---

**Syntax**    `vlan vlan-name {  
              disable {  
                  interface interface-name;  
              }  
              immediate-leave;  
              interface interface-name {  
                  multicast-router-interface;  
                  static {  
                      group ip-address;  
                  }  
              }  
              version number;  
          }`

**Hierarchy Level**    [edit protocols [igmp-snooping](#)]

**Release Information**    Statement introduced in Junos OS Release 11.1 for the QFX Series.  
                              **version** statement introduced in Junos OS Release 12.1 for the QFX Series.

**Description**    Configure IGMP snooping parameters for a VLAN.

The remaining statements are explained separately.

**TIP:** To display a list of all configured VLANs on the system, including VLANs that are configured but not committed, type ? after `vlan` or `vlangs` in your configuration mode command line. Note that only one VLAN is displayed for a VLAN range. For IGMP snooping, secondary private VLANs are not listed.

**Default**    IGMP snooping options apply to the specified VLAN.

**Options**    *vlan-name*—Name of a VLAN.

**Required Privilege Level**    routing—To view this statement in the configuration.  
                                  routing-control—To add this statement to the configuration.

| <b>Release Information</b>      | Statement introduced in Junos OS Release 11.1 for EX Series switches.<br>Statement introduced in Junos OS Release 12.1 for the QFX Series.                                                                                                                                                                                                                                                             |
| <b>Description</b>              | Specify the IGMP version for the IGMP general query that the switch sends to hosts when an interface comes up. The configured IGMP version affects only the version of the general queries sent by a switch. It does not affect the version of IGMP messages that the switch can snoop. For example, If the switch is configured for IGMP version 1 (IGMPv1), it can snoop IGMPv2 and IGMPv3 messages. |
| <b>Default</b>                  | If you do not configure the <b>version</b> statement, the default is IGMPv2.                                                                                                                                                                                                                                                                                                                           |
| <b>Options</b>                  | <b>version</b> —IGMP version number.<br><b>Range:</b> 1 through 3                                                                                                                                                                                                                                                                                                                                      |
| <b>Required Privilege Level</b> | routing—To view this statement in the configuration.<br>routing-control—To add this statement to the configuration.                                                                                                                                                                                                                                                                                    |

**Release Information** Statement introduced before Junos OS Release 7.4.  
 Statement introduced in Junos OS Release 12.1 for the QFX Series.

**Description** Define an MSDP peer group. MSDP peers within groups share common tracing options, if present and not overridden for an individual peer with the [peer](#) statement. To configure multiple MSDP groups, include multiple **group** statements.

By default, the group's options are identical to the global MSDP options. To override the global options, include group-specific options within the **group** statement.

The group must contain at least one peer.

**Options** *group-name*—Name of the MSDP group.

The remaining statements are explained separately.

**Required Privilege** routing—To view this statement in the configuration.  
**Level** routing-control—To add this statement to the configuration.

**Release Information** Statement introduced before Junos OS Release 7.4.  
Statement introduced in Junos OS Release 12.1 for the QFX Series.

**Description** Apply one or more policies to routes being imported into the routing table from MSDP.

**Options** *policy-names*—Name of one or more policies.

**Required Privilege** routing—To view this statement in the configuration.  
**Level** routing-control—To add this statement to the configuration.

| <b>Description</b>              | Configure the local end of an MSDP session. You must configure at least one peer for MSDP to function. When configuring a peer, you must include this statement. This address is used to accept incoming connections to the peer and to establish connections to the remote peer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>Description</b>         | <p>Define an MSDP peering relationship. An MSDP router must know which routers are its peers. You define the peer relationships explicitly by configuring the neighboring routers that are the MSDP peers of the local router. After peer relationships are established, the MSDP peers exchange messages to advertise active multicast sources. To configure multiple MSDP peers, include multiple <b>peer</b> statements.</p> <p>By default, the peer's options are identical to the global or group-level MSDP options. To override the global or group-level options, include peer-specific options within the <b>peer (Protocols MSDP)</b> statement.</p> <p>At least one peer must be configured for MSDP to function. You must configure <b>address</b> and <b>local-address</b>.</p> |
| <b>Options</b>             | <p><b>address</b>—Name of the MSDP peer.</p> <p>The remaining statements are explained separately.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Required Privilege</b>  | routing—To view this statement in the configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Release Information</b> | <p>Statement introduced before Junos OS Release 7.4.</p> <p>Statement introduced in Junos OS Release 12.1 for the QFX Series.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Description</b>         | <p>Configure MSDP tracing options.</p> <p>To specify more than one tracing operation, include multiple <b>flag</b> statements.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Default</b>             | <p>The default MSDP trace options are those inherited from the routing protocol's <b>traceoptions</b> statement included at the [edit routing-options] hierarchy level.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Options</b>             | <p><b>disable</b>—(Optional) Disable the tracing operation. You can use this option to disable a single operation when you have defined a broad group of tracing operations, such as <b>all</b>.</p> <p><b>file <i>filename</i></b>—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory <b>/var/log</b>. We recommend that you place tracing output in the <b>msdp-log</b> file.</p> <p><b>files <i>number</i></b>—(Optional) Maximum number of trace files. When a trace file named <b><i>trace-file</i></b> reaches its maximum size, it is renamed <b><i>trace-file.0</i></b>, then <b><i>trace-file.1</i></b>, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

If you specify a maximum number of files, you must also include the **size** statement to specify the maximum file size.

**Range:** 2 through 1000 files

**Default:** 2 files

**flag *flag***—Tracing operation to perform. To specify more than one tracing operation, include multiple **flag** statements.

#### MSDP Tracing Flags

- **keepalive**—Keepalive messages
- **packets**—All MSDP packets
- **route**—MSDP changes to the routing table
- **source-active**—Source-active packets
- **source-active-request**—Source-active request packets
- **source-active-response**—Source-active response packets

#### Global Tracing Flags

- **all**—All tracing operations
- **general**—A combination of the **normal** and **route** trace operations
- **normal**—All normal operations

**Default:** If you do not specify this option, only unusual or abnormal operations are traced.

- **policy**—Policy operations and actions
- **route**—Routing table changes
- **state**—State transitions
- **task**—Interface transactions and processing
- **timer**—Timer usage

***flag-modifier***—(Optional) Modifier for the tracing flag. You can specify one or more of these modifiers:

- **detail**—Detailed trace information

- **receive**—Packets being received

- **send**—Packets being transmitted

**no-stamp**—(Optional) Do not place timestamp information at the beginning of each line in the trace file.

**Default:** If you omit this option, timestamp information is placed at the beginning of each line of the tracing output.

**no-world-readable**—(Optional) Do not allow any user to read the log file.

**replace**—(Optional) Replace an existing trace file if there is one.

**Default:** If you do not include this option, tracing output is appended to an existing trace file.

**size size**—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named **trace-file** reaches this size, it is renamed **trace-file.0**. When **trace-file** again reaches this size, **trace-file.0** is renamed **trace-file.1** and **trace-file** is renamed **trace-file.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you must also include the **files** statement to specify the maximum number of trace files.

**Syntax:** **xk** to specify KB, **xm** to specify MB, or **xg** to specify GB

**Range:** 10 KB through the maximum file size supported on your system

**Default:** 1 MB

**world-readable**—(Optional) Allow any user to read the log file.

| <b>Description</b>              | <p>Configure source-specific multicast (SSM) groups.</p> <p>By default, the SSM group multicast address is limited to the IP address range from 232.0.0.0 through 232.255.255.255. However, you can extend SSM operations into another Class D range by including the <b>ssm-groups</b> statement in the configuration. The default SSM address range from 232.0.0.0 through 232.255.255.255 cannot be used in the <b>ssm-groups</b> statement. This statement is for adding other multicast addresses to the default SSM group addresses. This statement does not override the default SSM group address range.</p> <p>IGMPv3 supports SSM groups. By utilizing inclusion lists, only sources that are specified send to the SSM group.</p> |
| <b>Options</b>                  | <i>ip-addresses</i> —List of one or more additional SSM group addresses separated by a space.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## Routine Monitoring

- [Monitoring IGMP Snooping on page 3925](#)
- [Verifying the IGMP Snooping Group Timeout Value on page 3926](#)

## Monitoring IGMP Snooping

- Purpose** Use the monitoring feature to view status and information about the IGMP snooping configuration.
- Action** To display IGMP snooping details in the CLI, enter the following commands:
  - `show igmp-snooping vlans`
  - `show igmp-snooping statistics`
  - `show igmp-snooping route`
  - `show igmp-snooping membership`
- Meaning** [Table 243 on page 3925](#) summarizes the IGMP snooping details displayed.

Table 243: Summary of IGMP Snooping Output Fields

| Field                 | Values                                              |
|-----------------------|-----------------------------------------------------|
| IGMP Snooping Monitor |                                                     |
| VLAN                  | VLAN for which IGMP snooping is enabled.            |
| Interfaces            | Interface connected to a multicast router.          |
| Groups                | Number of the multicast groups learned by the VLAN. |
| MRouters              | Multicast router.                                   |
| Receivers             | Multicast receiver.                                 |

Table 243: Summary of IGMP Snooping Output Fields (*continued*)

| Field                  | Values                                                             |
|------------------------|--------------------------------------------------------------------|
| IGMP Route Information |                                                                    |
| VLAN                   | VLAN for which IGMP snooping is enabled.                           |
| Next-Hop               | Next hop assigned by the switch after performing the route lookup. |
| Group                  | Multicast groups learned by the VLAN.                              |

## Verifying the IGMP Snooping Group Timeout Value

**Purpose** Verify that the IGMP snooping group timeout value has been changed correctly from its default value.

**Action** Display the IGMP snooping membership information, which contains the group timeout value that was derived from the IGMP configuration:

```
user@switch> show igmp-snooping membership detail
VLAN: v43 Tag: 43 (Index: 4)
Group: 225.0.0.1
Receiver count: 1, Flags: <v2-hosts>
ge-0/0/15.0 Uptime: 00:00:05 timeout: 510
```

**Meaning** The IGMP snooping group timeout value determines how long a switch waits to receive an IGMP query from a multicast router before removing a multicast group from its multicast cache table. When you enable IGMP snooping, the default IGMP snooping group timeout value of 260 seconds is applied to all VLANs, which means that the switch waits 260 seconds to receive an IGMP query before removing a multicast group from its multicast cache table. You can change the timeout value by using the **robust-count** option.

## Sample Output

### clear igmp statistics

The following sample output displays IGMP statistics information before and after the **clear igmp statistics** command is entered:

```

user@host> show igmp statistics
IGMP packet statistics for all interfaces
IGMP Message type      Received      Sent  Rx errors
Membership Query        8883         459      0
V1 Membership Report    0            0        0
DVMRP                   19784        35476    0
PIM V1                  18310        0        0
Cisco Trace             0            0        0
V2 Membership Report    0            0        0
Group Leave             0            0        0
Mtrace Response         0            0        0
Mtrace Request          0            0        0
Domain Wide Report      0            0        0
V3 Membership Report    0            0        0
Other Unknown types     0            0        0
IGMP v3 unsupported type 0            0        0
IGMP v3 source required for SSM 0            0
IGMP v3 mode not applicable for SSM 0

IGMP Global Statistics
Bad Length              0
Bad Checksum            0
Bad Receive If          0
Rx non-local            1227

| <b>Description</b>              | Display trace information about an IP multicast path.                                                                                                                                                                                                                                                                                                                  |
| <b>Options</b>                  | <i>source</i> —Source hostname or address.<br><br><i>logical-system (logical-system-name)</i> —(Optional) Perform this operation on a logical system.<br><br><i>routing-instance routing-instance-name</i> —(Optional) Trace a particular routing instance.                                                                                                            |
| <b>Additional Information</b>   | The <b>mtrace</b> command for multicast traffic is similar to the <b>traceroute</b> command used for unicast traffic. Unlike <b>traceroute</b> , <b>mtrace</b> traces traffic backwards, from the receiver to the source.                                                                                                                                              |
| <b>Required Privilege Level</b> | view                                                                                                                                                                                                                                                                                                                                                                   |

Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                              |

**Table 244: mtrace Output Fields**

| Field Name                        | Field Description                                             |
|-----------------------------------|---------------------------------------------------------------|
| <b>Mtrace from</b>                | IP address of the receiver.                                   |
| <b>to</b>                         | IP address of the source.                                     |
| <b>via group</b>                  | IP address of the multicast group (if any).                   |
| <b>Querying full reverse path</b> | Indicates the full reverse path query has begun.              |
| <i>number-of-hops</i>             | Number of hops from the source to the named router or switch. |
| <i>router-name</i>                | Name of the router or switch for this hop.                    |
| <i>address</i>                    | Address of the router or switch for this hop.                 |

Table 244: mtrace Output Fields (*continued*)

| Field Name      | Field Description                              |
|-----------------|------------------------------------------------|
| <i>protocol</i> | Protocol used (for example, PIM).              |
| Round trip time | Average round-trip time, in milliseconds (ms). |
| total ttl of    | Time-to-live (TTL) threshold.                  |

## Sample Output

### mtrace source

```
user@host> mtrace 192.1.4.2
Mtrace from 192.1.4.2 to 192.1.1.2 via group 0.0.0.0
Querying full reverse path... * *
  0  routerA.lab.mycompany.net (192.1.1.2)
 -1  routerB.lab.mycompany.net (192.1.2.2) PIM thresh^ 1
 -2  routerC.lab.mycompany.net (192.1.3.2) PIM thresh^ 1
 -3  hostA.lab.mycompany.net (192.1.4.2)
Round trip time 2 ms; total ttl of 2 required.
```

## mtrace from-source

---

**Syntax**    `mtrace from-source source source`  
              `<brief | detail>`  
              `<extra-hops extra-hops>`  
              `<group group>`  
              `<interval interval>`  
              `<loop>`  
              `<max-hops max-hops>`  
              `<max-queries max-queries>`  
              `<multicast-response | unicast-response>`  
              `<no-resolve>`  
              `<no-router-alert>`  
              `<response response>`  
              `<routing-instance routing-instance-name>`  
              `<ttl tll>`  
              `<wait-time wait-time>`

**Release Information**    Command introduced before Junos OS Release 7.4.  
                              Command introduced in Junos OS Release 9.0 for EX Series switches.  
                              Command introduced in Junos OS Release 11.3 for the QFX Series.

**Description**    Display trace information about an IP multicast path from a source to this router or switch. If you specify a group address with this command, Junos OS returns additional information, such as packet rates and losses.

**Options**    **brief | detail**—(Optional) Display the specified level of output.

**extra-hops *extra-hops***—(Optional) Number of hops to take after reaching a nonresponsive router. You can specify a number between **0** and **255**.

**group *group***—(Optional) Group address for which to trace the path. The default group address is **0.0.0.0**.

**interval *interval***—(Optional) Number of seconds to wait before gathering statistics again. The default value is **10** seconds.

**loop**—(Optional) Loop indefinitely, displaying rate and loss statistics.

**max-hops *max-hops***—(Optional) Maximum hops to trace toward the source. The range of values is **0** through **255**. The default value is **32** hops.

**max-queries *max-queries***—(Optional) Maximum number of query attempts for any hop. The range of values is 1 through **32**. The default is **3**.

**multicast-response**—(Optional) Always request the response using multicast.

**no-resolve**—(Optional) Do not attempt to display addresses symbolically.

**no-router-alert**—(Optional) Do not use the router-alert IP option.

**response *response***—(Optional) Send trace response to a host or multicast address.

**routing-instance** *routing-instance-name*—(Optional) Trace a particular routing instance.

**source** *source*—Source hostname or address.

**ttl** *tll*—(Optional) IP time-to-live (TTL) value. You can specify a number between 0 and 255. Local queries to the multicast group use a value of 1. Otherwise, the default value is 127.

**unicast-response**—(Optional) Always request the response using unicast.

**wait-time** *wait-time*—(Optional) Number of seconds to wait for a response. The default value is 3.

| <b>Description</b>         | Display trace information about a multicast path from this router or switch to a gateway router or switch.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Options</b>             | <p><b>gateway gateway</b>—Send the trace query to a gateway multicast address.</p> <p><b>brief   detail</b>—(Optional) Display the specified level of output.</p> <p><b>extra-hops extra-hops</b>—(Optional) Number of hops to take after reaching a nonresponsive router or switch. You can specify a number between <b>0</b> and <b>255</b>.</p> <p><b>group group</b>—(Optional) Group address for which to trace the path. The default group address is <b>0.0.0.0</b>.</p> <p><b>interface interface-name</b>—(Optional) Source address for sending the trace query.</p> <p><b>interval interval</b>—(Optional) Number of seconds to wait before gathering statistics again. The default value is <b>10</b>.</p> <p><b>loop</b>—(Optional) Loop indefinitely, displaying rate and loss statistics.</p> <p><b>max-hops max-hops</b>—(Optional) Maximum hops to trace toward the source. You can specify a number between <b>0</b> and <b>255</b>. The default value is <b>32</b>.</p> <p><b>max-queries max-queries</b>—(Optional) Maximum number of query attempts for any hop. You can specify a number between <b>0</b> and <b>255</b>. The default value is <b>3</b>.</p> <p><b>multicast-response</b>—(Optional) Always request the response using multicast.</p> <p><b>no-resolve</b>—(Optional) Do not attempt to display addresses symbolically.</p> |

**no-router-alert**—(Optional) Do not use the router-alert IP option.

**response *response***—(Optional) Send trace response to a host or multicast address.

**routing-instance *routing-instance-name***—(Optional) Trace a particular routing instance.

**ttl *tll***—(Optional) IP time-to-live value. You can specify a number between 0 and 225. Local queries to the multicast group use TTL 1. Otherwise, the default value is 127.

**unicast-response**—(Optional) Always request the response using unicast.

**wait-time *wait-time***—(Optional) Number of seconds to wait for a response. The default value is 3.

List of Sample Output [mtrace to-gateway on page 3957](#)

Output Fields [Table 247 on page 3956](#) describes the output fields for the **mtrace to-gateway** command. Output fields are listed in the approximate order in which they appear.

**Table 247: mtrace to-gateway Output Fields**

| Field Name                        | Field Description                                             |
|-----------------------------------|---------------------------------------------------------------|
| <b>Mtrace from</b>                | IP address of the receiver.                                   |
| <b>to</b>                         | IP address of the source.                                     |
| <b>via group</b>                  | IP address of the multicast group (if any).                   |
| <b>Querying full reverse path</b> | Indicates the full reverse path query has begun.              |
| <b><i>number-of-hops</i></b>      | Number of hops from the source to the named router or switch. |
| <b><i>router-name</i></b>         | Name of the router or switch for this hop.                    |
| <b><i>address</i></b>             | Address of the router or switch for this hop.                 |
| <b><i>protocol</i></b>            | Protocol used (for example, PIM).                             |
| <b>Round trip time</b>            | Average round-trip time, in milliseconds (ms).                |
| <b>total ttl of</b>               | Time-to-live (TTL) threshold.                                 |

## Sample Output

```
mtrace to-gateway      user@host> mtrace to-gateway gateway 192.1.3.2 group 225.1.1.1 interface 192.1.1.73 brief

Mtrace from 192.1.1.73 to 192.1.1.2 via group 225.1.1.1
Querying full reverse path... * *
  0  routerA.lab.mycompany.net (192.1.1.2)
-1  routerA.lab.mycompany.net (192.1.1.2)  PIM  thresh^ 1
-2  routerB.lab.mycompany.net (192.1.2.2)  PIM  thresh^ 1
-3  routerC.lab.mycompany.net (192.1.3.2)  PIM  thresh^ 1
Round trip time 2 ms; total ttl of 3 required.
```

| query-interval          | Interval at which the IGMP querier sends general host-query messages to solicit membership information.  | All levels      |
| query-response-interval | How long the IGMP querier waits to receive a response from a query message before sending another query. | All levels      |
| src-address             | Source address of IGMP queries.                                                                          |                 |
| version                 | IGMP version.                                                                                            | All levels      |

## Sample Output

show configuration  
protocols igmp

```
user@switch> show configuration protocols igmp
query-interval 150;
query-response-interval 50;
accounting;
interface vlan.43 {
  version 2;
}
igmp-querier {
  src-address 10.0.0.2;
}
```

## show igmp group

|                                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                  |

Table 249: show igmp group Output Fields (*continued*)

| Field Name       | Field Description                                                                                                                                                                                                         | Level of Output |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| Source timeout   | Time remaining until the group traffic is no longer forwarded. The timer is refreshed when a listener in include mode sends a report. A group in exclude mode or configured as a static group displays a zero timer.      | detail          |
| Last reported by | Address of the host that last reported membership in this group.                                                                                                                                                          | All levels      |
| Timeout          | Time remaining until the group membership is removed.                                                                                                                                                                     | brief none      |
| Group timeout    | Time remaining until a group in exclude mode moves to include mode. The timer is refreshed when a listener in exclude mode sends a report. A group in include mode or configured as a static group displays a zero timer. | detail          |
| Type             | Type of group membership: <ul style="list-style-type: none"> <li>• <b>Dynamic</b>—Host reported the membership.</li> <li>• <b>Static</b>—Membership is configured.</li> </ul>                                             | All levels      |

## Sample Output

### show igmp group (Include Mode)

```
user@host> show igmp group
Interface: t1-0/1/0.0
  Group: 232.1.1.1
    Group mode: Include
    Source: 10.0.0.2
    Last reported by: 10.9.5.2
    Timeout: 24 Type: Dynamic
  Group: 232.1.1.1
    Group mode: Include
    Source: 10.0.0.3
    Last reported by: 10.9.5.2
    Timeout: 24 Type: Dynamic
  Group: 232.1.1.1
    Group mode: Include
    Source: 10.0.0.4
    Last reported by: 10.9.5.2
    Timeout: 24 Type: Dynamic
  Group: 232.1.1.2
    Group mode: Include
    Source: 10.0.0.4
    Last reported by: 10.9.5.2
    Timeout: 24 Type: Dynamic
Interface: t1-0/1/1.0
Interface: ge-0/2/2.0
Interface: ge-0/2/0.0
Interface: local
  Group: 224.0.0.2
    Source: 0.0.0.0
    Last reported by: Local
    Timeout: 0 Type: Dynamic
  Group: 224.0.0.22
    Source: 0.0.0.0
    Last reported by: Local
    Timeout: 0 Type: Dynamic
```

### show igmp group (Exclude Mode)

```
user@host> show igmp group
Interface: t1-0/1/0.0
Interface: t1-0/1/1.0
Interface: ge-0/2/2.0
Interface: ge-0/2/0.0
Interface: local
  Group: 224.0.0.2
    Source: 0.0.0.0
    Last reported by: Local
    Timeout: 0 Type: Dynamic
  Group: 224.0.0.22
    Source: 0.0.0.0
    Last reported by: Local
    Timeout: 0 Type: Dynamic
```

### show igmp group brief

The output for the **show igmp group brief** command is identical to that for the **show igmp group** command.

### show igmp group detail

```
user@host> show igmp group detail
```

```

| <b>SSM Map Policy</b>     | Name of the source-specific multicast (SSM) map policy that has been applied to the IGMP interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | All levels      |
| <b>Timeout</b>            | How long until the IGMP querier is declared to be unreachable, in seconds.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | All levels      |
| <b>Version</b>            | IGMP version being used on the interface: 1 , 2 , or 3.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | All levels      |
| <b>Groups</b>             | Number of groups on the interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | All levels      |
| <b>Group limit</b>        | Maximum number of groups allowed on the interface. Any joins requested after the limit is reached are rejected.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | All levels      |
| <b>Group threshold</b>    | Configured threshold at which a warning message is generated.<br><br>This threshold is based on a percentage of groups received on the interface. If the number of groups received reaches the configured threshold, the device generates a warning message.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | All levels      |
| <b>Group log-interval</b> | Time (in seconds) between consecutive log messages.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | All levels      |
| <b>Immediate Leave</b>    | State of the immediate leave option: <ul style="list-style-type: none"> <li>• <b>On</b>—Indicates that the router removes a host from the multicast group as soon as the router receives a leave group message from a host associated with the interface.</li> <li>• <b>Off</b>—Indicates that after receiving a leave group message, instead of removing a host from the multicast group immediately, the router sends a group query to determine if another receiver responds.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                         | All levels      |
| <b>Promiscuous Mode</b>   | State of the promiscuous mode option: <ul style="list-style-type: none"> <li>• <b>On</b>—Indicates that the router can accept IGMP reports from subnetworks that are not associated with its interfaces.</li> <li>• <b>Off</b>—Indicates that the router can accept IGMP reports only from subnetworks that are associated with its interfaces.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | All levels      |
| <b>Passive</b>            | State of the passive mode option: <ul style="list-style-type: none"> <li>• <b>On</b>—Indicates that the router can run IGMP on the interface but not send or receive control traffic such as IGMP reports, queries, and leaves.</li> <li>• <b>Off</b>—Indicates that the router can run IGMP on the interface and send or receive control traffic such as IGMP reports, queries, and leaves.</li> </ul> <p>The <b>passive</b> statement enables you to selectively activate up to two out of a possible three available query or control traffic options. When enabled, the following options appear after the <b>on</b> state declaration:</p> <ul style="list-style-type: none"> <li>• <b>send-general-query</b>—The interface sends general queries.</li> <li>• <b>send-group-query</b>—The interface sends group-specific and group-source-specific queries.</li> <li>• <b>allow-receive</b>—The interface receives control traffic.</li> </ul> | All levels      |
| <b>OIF map</b>            | Name of the OIF map (if configured) associated with the interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | All levels      |

Table 250: show igmp interface Output Fields (*continued*)

| Field Name                   | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Level of Output |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| <b>SSM map</b>               | Name of the source-specific multicast (SSM) map (if configured) used on the interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | All levels      |
| <b>Configured Parameters</b> | Information configured by the user: <ul style="list-style-type: none"> <li>• <b>IGMP Query Interval</b>—Interval (in seconds) at which this router sends membership queries when it is the querier.</li> <li>• <b>IGMP Query Response Interval</b>—Time (in seconds) that the router waits for a report in response to a general query.</li> <li>• <b>IGMP Last Member Query Interval</b>—Time (in seconds) that the router waits for a report in response to a group-specific query.</li> <li>• <b>IGMP Robustness Count</b>—Number of times the router retries a query.</li> </ul> | All levels      |
| <b>Derived Parameters</b>    | Derived information: <ul style="list-style-type: none"> <li>• <b>IGMP Membership Timeout</b>—Timeout period (in seconds) for group membership. If no report is received for these groups before the timeout expires, the group membership is removed.</li> <li>• <b>IGMP Other Querier Present Timeout</b>—Time (in seconds) that the router waits for the IGMP querier to send a query.</li> </ul>                                                                                                                                                                                  | All levels      |

## Sample Output

### show igmp interface

```
user@host> show igmp interface
Interface: at-0/3/1.0
  Querier: 10.111.30.1
  State:      Up Timeout:   None Version:  2 Groups:      4
  SSM Map Policy: ssm-policy-A
Interface: so-1/0/0.0
  Querier: 10.111.10.1
  State:      Up Timeout:   None Version:  2 Groups:      2
  SSM Map Policy: ssm-policy-B
Interface: so-1/0/1.0
  Querier: 10.111.20.1
  State:      Up Timeout:   None Version:  2 Groups:      4
  SSM Map Policy: ssm-policy-C
Immediate Leave: On
Promiscuous Mode: Off

Configured Parameters:
IGMP Query Interval: 125.0
IGMP Query Response Interval: 10.0
IGMP Last Member Query Interval: 1.0
IGMP Robustness Count: 2

Derived Parameters:
IGMP Membership Timeout: 260.0
IGMP Other Querier Present Timeout: 255.0
```

### show igmp interface brief

The output for the **show igmp interface brief** command is identical to that for the **show igmp interface** command. For sample output, see [show igmp interface on page 3967](#).

### show igmp interface detail

The output for the **show igmp interface detail** command is identical to that for the **show igmp interface** command. For sample output, see [show igmp interface on page 3967](#).

### show igmp interface <interface-name>

```
user@host# show igmp interface ge-3/2/0.0
Interface: ge-3/2/0.0
  Querier: 20.1.1.1
  State: Up Timeout:   None Version:  3 Groups:      1
  Group limit: 8
  Group threshold: 60
  Group log-interval: 10
  Immediate leave: Off
  Promiscuous mode: Off
```

**Table 252: show igmp-snooping membership Output Fields**

| Field Name | Field Description                 | Level of Output |
|------------|-----------------------------------|-----------------|
| VLAN       | Name of the VLAN.                 | All             |
| Interfaces | Interfaces assigned to the VLAN.  | All             |
| Tag        | Numerical identifier of the VLAN. | <b>detail</b>   |

Table 252: show igmp-snooping membership Output Fields (*continued*)

| Field Name          | Field Description                                                                                                                                                                                     | Level of Output |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| Router interfaces   | Names of multicast router interfaces.                                                                                                                                                                 | detail          |
| • static or dynamic | Whether the multicast router interface is <b>static</b> or <b>dynamic</b> .                                                                                                                           | detail          |
| • Uptime            | For static interfaces, length of time since the interface was configured as a multicast router interface; for dynamic interfaces, length of time since the first query was received on the interface. | detail          |
| • timeout           | Query timeout in seconds.                                                                                                                                                                             | detail          |
| Group               | IP multicast address of the multicast group.                                                                                                                                                          | detail          |
| Receiver count      | Number of interfaces that have membership in a multicast group.                                                                                                                                       | detail          |
| Flags               | IGMP version of the host sending a join message.                                                                                                                                                      | detail          |
| Uptime              | Length of time a multicast group has been active on the interface.                                                                                                                                    | detail          |
| timeout             | Time (in seconds) left until the entry for the multicast group is removed.                                                                                                                            | All             |
| Last reporter       | Last host to report membership for the multicast group.                                                                                                                                               | detail          |
| Include source      | Source addresses from which multicast streams are allowed based on IGMPv3 reports.                                                                                                                    | detail          |

## Sample Output

### show igmp-snooping membership

```
user@switch> show igmp-snooping membership
VLAN: v1
  224.1.1.1      *           258 secs
    Interfaces: ge-0/0/0.0
  224.1.1.3      *           258 secs
    Interfaces: ge-0/0/0.0
  224.1.1.5      *           258 secs
    Interfaces: ge-0/0/0.0
  224.1.1.7      *           258 secs
    Interfaces: ge-0/0/0.0
  224.1.1.9      *           258 secs
    Interfaces: ge-0/0/0.0
  224.1.1.11     *           258 secs
    Interfaces: ge-0/0/0.0
```

### show igmp-snooping membership detail

```
user@switch> show igmp-snooping membership detail

| <b>Output Fields</b>            | <a href="#">Table 254 on page 3976</a> lists the output fields for the <b>show igmp-snooping statistics</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                  |

**Table 254: show igmp-snooping statistics Output Fields**

| Field Name        | Field Description                                                                           |
|-------------------|---------------------------------------------------------------------------------------------|
| Bad length        | IGMP packet has illegal or bad length.                                                      |
| Bad checksum      | IGMP or IP checksum is incorrect.                                                           |
| Invalid interface | Packet was received through an invalid interface.                                           |
| Not local         | Number of packets received from senders that are not local.                                 |
| Receive unknown   | Unknown IGMP type.                                                                          |
| Timed out         | Number of timeouts for all multicast groups.                                                |
| IGMP Type         | Type of IGMP message ( <b>Queries</b> , <b>Reports</b> , <b>Leaves</b> , or <b>Other</b> ). |
| Received          | Number of IGMP packets received.                                                            |
| Transmitted       | Number of IGMP packets transmitted.                                                         |
| Recv Errors       | Number of general receive errors.                                                           |

## Sample Output

| <b>Output Fields</b>            | <a href="#">Table 256 on page 3980</a> describes the output fields for the <b>show msdp</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                                |

**Table 256: show msdp Output Fields**

| Field Name    | Field Description                                                                        | Level of Output |
|---------------|------------------------------------------------------------------------------------------|-----------------|
| Peer address  | IP address of the peer.                                                                  | All levels      |
| Local address | Local address of the peer.                                                               | All levels      |
| State         | Status of the MSDP connection: <b>Listen</b> , <b>Established</b> , or <b>Inactive</b> . | All levels      |
| Last up/down  | Time at which the most recent peer-state change occurred.                                | All levels      |

Table 256: show msdp Output Fields (*continued*)

| Field Name           | Field Description                                                                                                                                                                   | Level of Output |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| Peer-Group           | Peer group name.                                                                                                                                                                    | All levels      |
| SA Count             | Number of source-active cache entries advertised by each peer that were accepted, compared to the number that were received, in the format <i>number-accepted/number-received</i> . | All levels      |
| Peer Connect Retries | Number of peer connection retries.                                                                                                                                                  | detail          |
| State timer expires  | Number of seconds before another message is sent to a peer.                                                                                                                         | detail          |
| Peer Times out       | Number of seconds to wait for a response from the peer before the peer is declared unavailable.                                                                                     | detail          |
| SA accepted          | Number of entries in the source-active cache accepted from the peer.                                                                                                                | detail          |
| SA received          | Number of entries in the source-active cache received by the peer.                                                                                                                  | detail          |

## Sample Output

### show msdp

```

user@host> show msdp
Peer address    Local address  State          Last up/down  Peer-Group  SA Count
198.32.8.193    198.32.8.195  Established    5d 19:25:44   North23     120/150
198.32.8.194    198.32.8.195  Established    3d 19:27:27   North23     300/345
198.32.8.196    198.32.8.195  Established    5d 19:39:36   North23     10/13
198.32.8.197    198.32.8.195  Established    5d 19:32:27   North23     5/6
198.32.8.198    198.32.8.195  Established    3d 19:33:04   North23     2305/3000

```

### show msdp brief

The output for the **show msdp brief** command is identical to that for the **show msdp** command. For sample output, see [show msdp on page 3981](#).

### show msdp detail

```

user@host> show msdp detail
Peer: 10.255.70.15
Local address: 10.255.70.19
State: Established
Peer Connect Retries: 0
State timer expires: 22
Peer Times out: 49
SA accepted: 0
SA received: 0

```

## show msdp source

**Output Fields** Table 257 on page 3983 describes the output fields for the **show msdp source** command. Output fields are listed in the approximate order in which they appear.

**Table 257: show msdp source Output Fields**

| Field Name     | Field Description                                                                                                                                                                                                                                                       |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Source address | IP address of the source.                                                                                                                                                                                                                                               |
| /Len           | Length of the prefix for this IP address.                                                                                                                                                                                                                               |
| Type           | Discovery method for this multicast source: <ul style="list-style-type: none"> <li>• <b>Configured</b>—Source-active limit explicitly configured for this source.</li> <li>• <b>Dynamic</b>—Source-active limit established when this source was discovered.</li> </ul> |
| Maximum        | Source-active limit applied to this source.                                                                                                                                                                                                                             |
| Threshold      | Source-active threshold applied to this source.                                                                                                                                                                                                                         |
| Exceeded       | Number of source-active messages received from this source exceeding the established maximum.                                                                                                                                                                           |

## Sample Output

**show msdp source**

```

user@host> show msdp source
Source address /Len  Type      Maximum  Threshold  Exceeded
0.0.0.0        /0    Configured    5        none       0
10.1.0.0       /16   Configured   500      none       0
10.1.1.1       /32   Configured  10000    none       0
10.1.1.2       /32   Dynamic     6936     none       0
10.1.5.5       /32   Dynamic     500      none      123
10.2.1.1       /32   Dynamic      2        none       0

```

## show msdp source-active

| <b>Output Fields</b>            | <a href="#">Table 258 on page 3985</a> describes the output fields for the <b>show msdp source-active</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

Table 258: show msdp source-active Output Fields

| Field Name                              | Field Description                                                                                                                                          |
|-----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Global active source limit exceeded     | Number of times all peers have exceeded configured active source limits.                                                                                   |
| Global active source limit maximum      | Configured number of active source messages accepted by the device.                                                                                        |
| Global active source limit threshold    | Configured threshold for applying random early discard (RED) to drop some but not all MSDP active source messages.                                         |
| Global active source limit log-warning  | Threshold at which a warning message is logged (percentage of the number of active source messages accepted by the device).                                |
| Global active source limit log interval | Time (in seconds) between consecutive log messages.                                                                                                        |
| Group address                           | Multicast address of the group.                                                                                                                            |
| Source address                          | IP address of the source.                                                                                                                                  |
| Peer address                            | IP address of the peer.                                                                                                                                    |
| Originator                              | Router ID configured on the source of the rendezvous point (RP) that originated the message, or the loopback address when the router ID is not configured. |
| Flags                                   | Flags: <b>Accept</b> , <b>Reject</b> , or <b>Filtered</b> .                                                                                                |

## Sample Output

### `show msdp source-active`

```
user@host> show msdp source-active
Group address  Source address  Peer address  Originator  Flags
230.0.0.0      192.168.195.46  local        10.255.14.30 Accept
230.0.0.1      192.168.195.46  local        10.255.14.30 Accept

### `show msdp source-active brief`

The output for the **show msdp source-active brief** command is identical to that for the **show msdp source-active** command. For sample output, see [show msdp source-active on page 3986](#).

### `show msdp source-active detail`

The output for the **show msdp source-active detail** command is identical to that for the **show msdp source-active** command. For sample output, see [show msdp source-active on page 3986](#).

### `show msdp source-active source`

```
user@host> show msdp source-active source 192.168.215.246
Global active source limit exceeded: 0
Global active source limit maximum: 25000
Global active source limit threshold: 24000
Global active source limit log-warning: 100
Global active source limit log interval: 0

Group address  Source address  Peer address  Originator  Flags

Output fields are listed in the approximate order in which they appear.</p>                                                                                                                                                                                                                                                                 |

**Table 259: show msdp statistics Output Fields**

| Field Name                              | Field Description                                                                                                           |
|-----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| Global active source limit exceeded     | Number of times all peers have exceeded configured active source limits.                                                    |
| Global active source limit maximum      | Configured number of active source messages accepted by the device.                                                         |
| Global active source limit threshold    | Configured threshold for applying random early discard (RED) to drop some but not all MSDP active source messages.          |
| Global active source limit log-warning  | Threshold at which a warning message is logged (percentage of the number of active source messages accepted by the device). |
| Global active source limit log interval | Time (in seconds) between consecutive log messages.                                                                         |
| Peer                                    | Address of peer.                                                                                                            |

Table 259: show msdp statistics Output Fields (*continued*)

| Field Name                          | Field Description                                                                                                                                   |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| Last State Change                   | How long ago the peer state changed.                                                                                                                |
| Last message received from the peer | How long ago the last message was received from the peer.                                                                                           |
| RPF Failures                        | Number of reverse path forwarding (RPF) failures.                                                                                                   |
| Remote Closes                       | Number of times the remote peer closed.                                                                                                             |
| Peer Timeouts                       | Number of peer timeouts.                                                                                                                            |
| SA messages sent                    | Number of source-active messages sent.                                                                                                              |
| SA messages received                | Number of source-active messages received.                                                                                                          |
| SA request messages sent            | Number of source-active request messages sent.                                                                                                      |
| SA request messages received        | Number of source-active request messages received.                                                                                                  |
| SA response messages sent           | Number of source-active response messages sent.                                                                                                     |
| SA response messages received       | Number of source-active response messages received.                                                                                                 |
| Active source exceeded              | Number of times this peer has exceeded configured source-active limits.                                                                             |
| Active source Maximum               | Configured number of active source messages accepted by this peer.                                                                                  |
| Active source threshold             | Configured threshold on this peer for applying random early discard (RED) to drop some but not all MSDP active source messages.                     |
| Active source log-warning           | Configured threshold on this peer at which a warning message is logged (percentage of the number of active source messages accepted by the device). |
| Active source log-interval          | Time (in seconds) between consecutive log messages on this peer.                                                                                    |
| Keepalive messages sent             | Number of keepalive messages sent.                                                                                                                  |
| Keepalive messages received         | Number of keepalive messages received.                                                                                                              |
| Unknown messages received           | Number of unknown messages received.                                                                                                                |

Table 259: show msdp statistics Output Fields (*continued*)

| Field Name              | Field Description                  |
|-------------------------|------------------------------------|
| Error messages received | Number of error messages received. |

## Sample Output

**show msdp statistics**

```
user@host> show msdp statistics
Global active source limit exceeded: 0
Global active source limit maximum: 10
Global active source limit threshold: 8
Global active source limit log-warning: 60
Global active source limit log interval: 60

Peer: 10.255.245.39
Last State Change: 11:54:49 (00:24:59)
Last message received from peer: 11:53:32 (00:26:16)
RPF Failures: 0
Remote Closes: 0
Peer Timeouts: 0
SA messages sent: 376
SA messages received: 459
SA request messages sent: 0
SA request messages received: 0
SA response messages sent: 0
SA response messages received: 0
Active source exceeded: 0
Active source Maximum: 10
Active source threshold: 8
Active source log-warning: 60
Active source log-interval: 120
Keepalive messages sent: 17
Keepalive messages received: 19
Unknown messages received: 0
Error messages received: 0
```

**show msdp statistics  
peer**

```
user@host> show msdp statistics peer 10.255.182.140
Peer: 10.255.182.140
Last State Change: 8:19:23 (00:01:08)

| <b>Output Fields</b>                                | <a href="#">Table 260 on page 3991</a> describes the output fields for the <b>show multicast flow-map</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                               |

**Table 260: show multicast flow-map Output Fields**

| Field Name                | Field Description                                         | Levels of Output |
|---------------------------|-----------------------------------------------------------|------------------|
| <b>Name</b>               | Name of the flow map.                                     | All levels       |
| <b>Policy</b>             | Name of the policy associated with the flow map.          | All levels       |
| <b>Cache-timeout</b>      | Cache timeout value assigned to the flow map.             | All levels       |
| <b>Bandwidth</b>          | Bandwidth setting associated with the flow map.           | All levels       |
| <b>Adaptive</b>           | Whether or not adaptive mode is enabled for the flow map. | none             |
| <b>Flow-map</b>           | Name of the flow map.                                     | <b>detail</b>    |
| <b>Adaptive Bandwidth</b> | Whether or not adaptive mode is enabled for the flow map. | <b>detail</b>    |
| <b>Redundant Sources</b>  | Redundant sources defined for the same destination group. | <b>detail</b>    |

## Sample Output

**show multicast  
flow-map**

```
user@host> show multicast flow-map
Instance: master
Name      Policy      Cache timeout      Bandwidth Adaptive
map2      policy2      never              2000000 no
map1      policy1      60 seconds        2000000 no
```

## Sample Output

**show multicast  
flow-map detail**

```
user@host> show multicast flow-map detail
Instance: master
Flow-map: map1
  Policy:      policy1
  Cache Timeout: 600 seconds
  Bandwidth:   2000000
  Adaptive Bandwidth: yes
  Redundant Sources: 11.11.11.11
  Redundant Sources: 11.11.11.12
  Redundant Sources: 11.11.11.13
```

## show multicast interface

|                                                     |                                                                                                                                                                                                                                  |

| <b>Output Fields</b>                                | <p><a href="#">Table 263 on page 3998</a> describes the output fields for the <b>show multicast next-hops</b> command. Output fields are listed in the approximate order in which they appear.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

**Table 263: show multicast next-hops Output Fields**

| Field Name                     | Field Description                                                                                                                                      |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Family</b>                  | Protocol family (such as <b>INET</b> ).                                                                                                                |
| <b>ID</b>                      | Next-hop identifier of the prefix. The identifier is returned by the routing device's Packet Forwarding Engine.                                        |
| <b>RefCount</b>                | Number of cache entries that are using this next hop.                                                                                                  |
| <b>KRefCount</b>               | Kernel reference count for the next hop.                                                                                                               |
| <b>Downstream interface</b>    | Interface names associated with each multicast next-hop ID.                                                                                            |
| <b>Incoming interface list</b> | List of interfaces that accept incoming traffic. Only shown for routes that do not use strict RPF-based forwarding, for example for bidirectional PIM. |

## Sample Output

### show multicast next-hops

```
user@host> show multicast next-hops
Family: INET
ID      Refcount  KRefCount Downstream interface
262142      4          2 so-1/0/0.0
262143      2          1 mt-1/1/0.49152
262148      2          1 mt-1/1/0.32769
```

### show multicast next-hops (Bidirectional PIM)

```
user@host> show multicast next-hops
Family: INET
ID      Refcount  KRefCount Downstream interface
2097151      8          4 ge-0/0/1.0

Family: INET6
ID      Refcount  KRefCount Downstream interface
2097157      2          1 ge-0/0/1.0

Family: Incoming interface list
ID      Refcount  KRefCount Downstream interface
513      5          2 lo0.0
           ge-0/0/1.0
514      5          2 lo0.0
           ge-0/0/1.0
           xe-4/1/0.0
515      3          1 lo0.0
           ge-0/0/1.0
           xe-4/1/0.0
544      1          0 lo0.0
           xe-4/1/0.0
```

### show multicast next-hops brief

The output for the **show multicast next-hops brief** command is identical to that for the **show multicast next-hops** command. For sample output, see [show multicast next-hops on page 3999](#).

### show multicast next-hops detail

```
user@host> show multicast next-hops detail
Family: INET
ID      Refcount  KRefCount Downstream interface
1048577      2          1 fe-0/1/2.0-(1048574)
           ge-0/2/3.0-(1048576)
```

## show multicast pim-to-igmp-proxy

| <b>Description</b>                                  | Display the entries in the IP multicast forwarding table. You can display similar information with the <b>show route table inet.1</b> command.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Options</b>                                      | <p><b>none</b>—Display standard information about all entries in the multicast forwarding table for all routing instances.</p> <p><b>brief   detail   extensive   summary</b>—(Optional) Display the specified level of output.</p> <p><b>active   all   inactive</b>—(Optional) Display all active entries, all entries, or all inactive entries, respectively, in the multicast forwarding table.</p> <p><b>group group</b>—(Optional) Display the cache entries for a particular group.</p> <p><b>inet   inet6</b>—(Optional) Display multicast forwarding table entries for IPv4 or IPv6 family addresses, respectively.</p> <p><b>instance instance-name</b>—(Optional) Display entries in the multicast forwarding table for a specific multicast instance.</p> <p><b>logical-system (all   logical-system-name)</b>—(Optional) Perform this operation on all logical systems or on a particular logical system.</p> <p><b>regular-expression</b>—(Optional) Display information about the multicast forwarding table entries that match a UNIX OS-style regular expression.</p> |

**source-prefix** *source-prefix*—(Optional) Display the cache entries for a particular source prefix.

**Output Fields** [Table 266 on page 4005](#) describes the output fields for the **show multicast route** command. Output fields are listed in the approximate order in which they appear.

**Table 266: show multicast route Output Fields**

| Field Name                           | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                     | Level of Output         |
|--------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------|
| <b>family</b>                        | IPv4 address family ( <b>INET</b> ) or IPv6 address family ( <b>INET6</b> ).                                                                                                                                                                                                                                                                                                                                                          | All levels              |
| <b>Group</b>                         | Group address.<br><br>For any-source multicast routes, for example for bidirectional PIM, the group address includes the prefix length.                                                                                                                                                                                                                                                                                               | All levels              |
| <b>Source</b>                        | Prefix and length of the source as it is in the multicast forwarding table.                                                                                                                                                                                                                                                                                                                                                           | All levels              |
| <b>Incoming interface list</b>       | List of interfaces that accept incoming traffic. Only shown for routes that do not use strict RPF-based forwarding, for example for bidirectional PIM.                                                                                                                                                                                                                                                                                | All levels              |
| <b>Upstream interface</b>            | Name of the interface on which the packet with this source prefix is expected to arrive.                                                                                                                                                                                                                                                                                                                                              | All levels              |
| <b>Downstream interface list</b>     | List of interface names to which the packet with this source prefix is forwarded.                                                                                                                                                                                                                                                                                                                                                     | All levels              |
| <b>Number of outgoing interfaces</b> | Total number of outgoing interfaces for each (S,G) entry.                                                                                                                                                                                                                                                                                                                                                                             | <b>extensive</b>        |
| <b>Session description</b>           | Name of the multicast session.                                                                                                                                                                                                                                                                                                                                                                                                        | <b>detail extensive</b> |
| <b>Statistics</b>                    | Rate at which packets are being forwarded for this source and group entry (in Kbps and pps), and number of packets that have been forwarded to this prefix. If one or more of the kilobits per second packet forwarding statistic queries fails or times out, the statistics field displays <b>Forwarding statistics are not available</b> .<br><br><b>NOTE:</b> On QFX Series switches, this field does not report valid statistics. | <b>detail extensive</b> |
| <b>Next-hop ID</b>                   | Next-hop identifier of the prefix. The identifier is returned by the routing device's Packet Forwarding Engine and is also displayed in the output of the <b>show multicast nexthops</b> command.                                                                                                                                                                                                                                     | <b>detail extensive</b> |

Table 266: show multicast route Output Fields (*continued*)

| Field Name                                    | Field Description                                                                                                                                                                                                                | Level of Output          |
|-----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------|
| <b>Incoming interface list ID</b>             | For bidirectional PIM, incoming interface list identifier.<br><br>Identifiers for interfaces that accept incoming traffic. Only shown for routes that do not use strict RPF-based forwarding, for example for bidirectional PIM. | <b>detail extensive</b>  |
| <b>Upstream protocol</b>                      | Protocol running on the interface on which the packet with this source prefix is expected to arrive.                                                                                                                             | <b>detail extensive</b>  |
| <b>Route type</b>                             | Type of multicast route. Values can be (S,G) or (*,G).                                                                                                                                                                           | <b>summary</b>           |
| <b>Route state</b>                            | Whether the group is <b>Active</b> or <b>Inactive</b> .                                                                                                                                                                          | <b>summary extensive</b> |
| <b>Route count</b>                            | Number of multicast routes.                                                                                                                                                                                                      | <b>summary</b>           |
| <b>Forwarding state</b>                       | Whether the prefix is pruned or forwarding.                                                                                                                                                                                      | <b>extensive</b>         |
| <b>Cache lifetime/timeout</b>                 | Number of seconds until the prefix is removed from the multicast forwarding table. A value of <b>never</b> indicates a permanent forwarding entry. A value of <b>forever</b> indicates routes that do not have keepalive times.  | <b>extensive</b>         |
| <b>Wrong incoming interface notifications</b> | Number of times that the upstream interface was not available.                                                                                                                                                                   | <b>extensive</b>         |
| <b>Uptime</b>                                 | Time since the creation of a multicast route.                                                                                                                                                                                    | <b>extensive</b>         |

## Sample Output

```

show multicast route  user@host> show multicast route
Family: INET

Group: 228.0.0.0
  Source: 10.255.14.144/32
  Upstream interface: local
  Downstream interface list:
    so-1/0/0.0

Group: 239.1.1.1
  Source: 10.255.14.144/32
  Upstream interface: local
  Downstream interface list:
    so-1/0/0.0

Group: 239.1.1.1
  Source: 10.255.70.15/32
  Upstream interface: so-1/0/0.0
  Downstream interface list:
    mt-1/1/0.49152

Family: INET6

```

```

show multicast route  user@host> show multicast route
(Bidirectional PIM)  Family: INET

Group: 224.1.1.0/24
  Source: *
  Incoming interface list:
    lo0.0 ge-0/0/1.0
  Downstream interface list:

```

The output for the **show multicast route brief** command is identical to that for the **show**

**show multicast route  
brief**

**multicast route** command. For sample output, see [show multicast route on page 4007](#) or [show multicast route \(Bidirectional PIM\) on page 4007](#).

**show multicast route  
detail**

```
user@host> show multicast route detail
Family: INET

**Output Fields** Table 267 on page 4011 describes the output fields for the **show multicast rpf** command. Output fields are listed in the approximate order in which they appear.

**Table 267: show multicast rpf Output Fields**

| Field Name    | Field Description                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Instance      | Name of the routing instance. (Displayed when multicast is configured within a routing instance.)                                                                                                                                                                                                                                                                                                             |
| Source prefix | Prefix and length of the source as it exists in the multicast forwarding table.                                                                                                                                                                                                                                                                                                                               |
| Protocol      | How the route was learned.                                                                                                                                                                                                                                                                                                                                                                                    |
| Interface     | Upstream RPF interface.<br><br><b>NOTE:</b> The displayed interface information does not apply to bidirectional PIM RP addresses. This is because the <b>show multicast rpf</b> command does not take into account equal-cost paths or the designated forwarder. For accurate upstream RPF interface information, always use the <b>show pim join extensive</b> command when bidirectional PIM is configured. |
| Neighbor      | Upstream RPF neighbor.<br><br><b>NOTE:</b> The displayed neighbor information does not apply to bidirectional PIM. This is because the <b>show multicast rpf</b> command does not take into account equal-cost paths or the designated forwarder. For accurate upstream RPF neighbor information, always use the <b>show pim join extensive</b> command when bidirectional PIM is configured.                 |

## Sample Output

```
show multicast rpf      user@host> show multicast rpf

| <b>Output Fields</b>                                | Table 268 on page 4014 describes the output fields for the <b>show multicast scope</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                                                                                        |

**Table 268: show multicast scope Output Fields**

| Field Name      | Field Description                                           |
|-----------------|-------------------------------------------------------------|
| Scope name      | Name of the multicast scope.                                |
| Group Prefix    | Range of multicast groups that are scoped.                  |
| Interface       | Interface that is the boundary of the administrative scope. |
| Resolve Rejects | Number of kernel resolve rejects.                           |

## Sample Output

```
show multicast scope user@host> show multicast scope
```

| Scope name | Group Prefix   | Interface  | Resolve<br>Rejects |
|------------|----------------|------------|--------------------|
| 232-net    | 232.232.0.0/16 | fe-0/0/0.1 | 0                  |
| local      | 239.255.0.0/16 | fe-0/0/0.1 | 0                  |
| local      | ff05::/16      | fe-0/0/0.1 | 0                  |
| larry      | ff05::1234/128 | fe-0/0/0.1 | 0                  |

```
show multicast scope user@host> show multicast scope inet
inet
```

| Scope name | Group Prefix   | Interface  | Resolve<br>Rejects |
|------------|----------------|------------|--------------------|
| 232-net    | 232.232.0.0/16 | fe-0/0/0.1 | 0                  |
| local      | 239.255.0.0/16 | fe-0/0/0.1 | 0                  |

```
show multicast scope user@host> show multicast scope inet6
inet6
```

| Scope name | Group Prefix   | Interface  | Resolve<br>Rejects |
|------------|----------------|------------|--------------------|
| local      | ff05::/16      | fe-0/0/0.1 | 0                  |
| larry      | ff05::1234/128 | fe-0/0/0.1 | 0                  |

## show multicast sessions

| <b>Output Fields</b>                                | Table 271 on page 4022 describes the output fields for the <b>show pim bootstrap</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                              |

**Table 271: show pim bootstrap Output Fields**

| Field Name           | Field Description                                                                               |
|----------------------|-------------------------------------------------------------------------------------------------|
| <b>Instance</b>      | Name of the routing instance.                                                                   |
| <b>BSR</b>           | Bootstrap router.                                                                               |
| <b>Pri</b>           | Priority of the routing device as elected to be the bootstrap router.                           |
| <b>Local address</b> | Local routing device address.                                                                   |
| <b>Pri</b>           | Local routing device address priority to be elected as the bootstrap router.                    |
| <b>State</b>         | Local routing device election state: <b>Candidate</b> , <b>Elected</b> , or <b>Ineligible</b> . |

Table 271: show pim bootstrap Output Fields (*continued*)

| Field Name | Field Description                                                                                    |
|------------|------------------------------------------------------------------------------------------------------|
| Timeout    | How long until the local routing device declares the bootstrap router to be unreachable, in seconds. |

## Sample Output

### show pim bootstrap

```
user@host> show pim bootstrap
Instance: PIM.master
```

| BSR                        | Pri                     | Local address | Pri        | State      | Timeout |
|----------------------------|-------------------------|---------------|------------|------------|---------|
| None                       | 0                       | 10.255.71.46  | 0          | InEligible | 0       |
| feco:1:1:1:1:0:aff:785c 34 | feco:1:1:1:1:0:aff:7c12 | 0             | InEligible | 0          |         |

### show pim bootstrap instance

```
user@host> show pim bootstrap instance VPN-A
Instance: PIM.VPN-A
```

| BSR  | Pri | Local address   | Pri | State      | Timeout |
|------|-----|-----------------|-----|------------|---------|
| None | 0   | 192.168.196.105 | 0   | InEligible | 0       |

| Field Name          | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Mode</b>         | <p>PIM mode running on the interface:</p> <ul style="list-style-type: none"> <li>• <b>B</b>—In bidirectional mode, multicast groups are carried across the network over bidirectional shared trees. This type of tree minimizes PIM routing state, which is especially important in networks with numerous and dispersed senders and receivers.</li> <li>• <b>S</b>—In sparse mode, routing devices must join and leave multicast groups explicitly. Upstream routing devices do not forward multicast traffic to this routing device unless this device has sent an explicit request (using a join message) to receive multicast traffic.</li> <li>• <b>Dense</b>—Unlike sparse mode, where data is forwarded only to routing devices sending an explicit request, dense mode implements a flood-and-prune mechanism, similar to DVMRP (the first multicast protocol used to support the multicast backbone). (Not supported on QFX Series.)</li> <li>• <b>Sparse-Dense</b>—Sparse-dense mode allows the interface to operate on a per-group basis in either sparse or dense mode. A group specified as <b>dense</b> is not mapped to a rendezvous point (RP). Instead, data packets destined for that group are forwarded using PIM-Dense Mode (PIM-DM) rules. A group specified as <b>sparse</b> is mapped to an RP, and data packets are forwarded using PIM-Sparse Mode (PIM-SM) rules. (Not supported on QFX Series.)</li> </ul> <p>When sparse-dense mode is configured, the output includes both <b>S</b> and <b>D</b>. When bidirectional-sparse mode is configured, the output includes <b>S</b> and <b>B</b>. When bidirectional-sparse-dense mode is configured, the output includes <b>B</b>, <b>S</b>, and <b>D</b>.</p> |
| <b>IP</b>           | Version number of the address family on the interface: <b>4</b> (IPv4) or <b>6</b> (IPv6).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>V</b>            | PIM version running on the interface: 1 or 2.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>State</b>        | <p>State of PIM on the interface:</p> <ul style="list-style-type: none"> <li>• <b>Active</b>—Bidirectional mode is enabled on the interface and on all PIM neighbors.</li> <li>• <b>DR</b>—Designated router.</li> <li>• <b>NotCap</b>—Bidirectional mode is not enabled on the interface. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

Table 274: show pim neighbors Output Fields

| Field Name                                       | Field Description                                                                                                                                                                                                                                                                                              | Level of Output   |
|--------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| <b>Instance</b>                                  | Name of the routing instance.                                                                                                                                                                                                                                                                                  | All levels        |
| <b>Interface</b>                                 | Interface through which the neighbor is reachable.                                                                                                                                                                                                                                                             | All levels        |
| <b>Neighbor addr</b>                             | Address of the neighboring PIM routing device.                                                                                                                                                                                                                                                                 | All levels        |
| <b>IP</b>                                        | IP version: 4 or 6.                                                                                                                                                                                                                                                                                            | All levels        |
| <b>V</b>                                         | PIM version running on the neighbor: 1 or 2.                                                                                                                                                                                                                                                                   | All levels        |
| <b>Mode</b>                                      | PIM mode of the neighbor: <b>Sparse</b> , <b>Dense</b> , <b>SparseDense</b> , or <b>Unknown</b> . When the neighbor is running PIM version 2, this mode is always <b>Unknown</b> .                                                                                                                             | All levels        |
| <b>Option</b>                                    | Can be one or more of the following: <ul style="list-style-type: none"> <li>• <b>B</b>—Bidirectional Capable.</li> <li>• <b>H</b>—Hello Option Holdtime.</li> <li>• <b>G</b>—Generation Identifier.</li> <li>• <b>P</b>—Hello Option DR Priority.</li> <li>• <b>L</b>—Hello Option LAN Prune Delay.</li> </ul> | <b>brief</b> none |
| <b>Uptime</b>                                    | Time the neighbor has been operational since the PIM process was last initialized, in the format <b>dd:hh:mm:ss ago</b> for less than a week and <b>nwnd:hh:mm:ss ago</b> for more than a week.                                                                                                                | All levels        |
| <b>Address</b>                                   | Address of the neighboring PIM router.                                                                                                                                                                                                                                                                         | <b>detail</b>     |
| <b>BFD</b>                                       | Status and operational state of the Bidirectional Forwarding Detection (BFD) protocol on the interface: <b>Enabled</b> , <b>Operational state is up</b> , or <b>Disabled</b> .                                                                                                                                 | <b>detail</b>     |
| <b>Hello Option Holdtime</b>                     | Time for which the neighbor is available, in seconds. The range of values is 0 through 65,535.                                                                                                                                                                                                                 | <b>detail</b>     |
| <b>Hello Default Holdtime</b>                    | Default holdtime and the time remaining if the <b>holdtime</b> option is not in the received hello message.                                                                                                                                                                                                    | <b>detail</b>     |
| <b>Hello Option DR Priority</b>                  | Designated router election priority. The range of values is 0 through 255.                                                                                                                                                                                                                                     | <b>detail</b>     |
| <b>Hello Option Generation ID</b>                | 9-digit or 10-digit number used to tag hello messages.                                                                                                                                                                                                                                                         | <b>detail</b>     |
| <b>Hello Option Bi-Directional PIM supported</b> | Neighbor can process bidirectional PIM messages.                                                                                                                                                                                                                                                               | <b>detail</b>     |
| <b>Hello Option LAN Prune Delay</b>              | Time to wait before the neighbor receives prune messages, in the format <b>delay nnn ms override nnnn ms</b> .                                                                                                                                                                                                 | <b>detail</b>     |

Table 274: show pim neighbors Output Fields (*continued*)

| Field Name                 | Field Description                                                                                                                                                                                                                                                                     | Level of Output |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| Join Suppression supported | Neighbor is capable of join suppression.                                                                                                                                                                                                                                              | detail          |
| Rx Join                    | Information about joins received from the neighbor. <ul style="list-style-type: none"><li>• <b>Group</b>—Group addresses in the join message.</li><li>• <b>Source</b>—Address of the source in the join message.</li><li>• <b>Timeout</b>—Time for which the join is valid.</li></ul> | detail          |

## Sample Output

### show pim neighbors

```
user@host> show pim neighbors
Instance: PIM.master
B = Bidirectional Capable, G = Generation Identifier,
H = Hello Option Holdtime, L = Hello Option LAN Prune Delay,
P = Hello Option DR Priority

Interface          IP V Mode      Option      Uptime Neighbor addr
so-1/0/0.0         4 2           HPLG        00:07:10 10.111.10.2
```

### show pim neighbors brief

The output for the **show pim neighbors brief** command is identical to that for the **show pim neighbors** command. For sample output, see [show pim neighbors on page 4039](#).

### show pim neighbors instance

```
user@host> show pim neighbors instance VPN-A
Instance: PIM.VPN-A
B = Bidirectional Capable, G = Generation Identifier,
H = Hello Option Holdtime, L = Hello Option LAN Prune Delay,
P = Hello Option DR Priority

Interface          IP V Mode      Option      Uptime Neighbor addr
at-0/3/1.0         4 2           HPLG        00:07:54 10.111.30.2
mt-1/1/0.32768     4 2           HPLG        00:07:22 10.10.47.101
so-1/0/1.0         4 2           HPLG        00:07:50 10.111.20.2
```

### show pim neighbors detail

```
user@host> show pim neighbors detail
Instance: PIM.master
Interface: ge-0/0/1.0

    Address: 10.10.1.1, IPv4, PIM v2, Mode: SparseDense, sg Join Count: 0, ts
Join Count: 2
    Hello Option Holdtime: 65535 seconds
    Hello Option DR Priority: 1
    Hello Option Generation ID: 2053759302
    Hello Option Bi-Directional PIM supported
    Hello Option LAN Prune Delay: delay 500 ms override 2000 ms
                                Join Suppression supported

    Address: 10.10.1.2, IPv4, PIM v2, sg Join Count: 0, ts
Join Count: 2
    BFD: Disabled
    Hello Option Holdtime: 105 seconds 93 remaining
    Hello Option DR Priority: 1
    Hello Option Generation ID: 1734018161
    Hello Option Bi-Directional PIM supported
    Hello Option LAN Prune Delay: delay 500 ms override 2000 ms
                                Join Suppression supported

Interface: lo0.0

    Address: 10.255.179.246, IPv4, PIM v2, Mode: SparseDense, sg Join Count:
0, ts
Join Count: 0
    Hello Option Holdtime: 65535 seconds
    Hello Option DR Priority: 1

| <b>RP selected</b>                | For sparse mode and bidirectional mode, the identity of the RP for the specified group address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | <i>group-address</i> |

## Sample Output

### show pim rps

```

user@host> show pim rps
Instance: PIM.master
Address family INET
RP address      Type      Mode   Holdtime Timeout Groups  Group prefixes
10.10.1.3        static    bidir   150      None      2  224.1.3.0/24
                  225.1.3.0/24
10.10.13.2       static    bidir   150      None      2  224.1.1.0/24
                  225.1.1.0/24

```

### show pim rps brief

The output for the **show pim rps brief** command is identical to that for the **show pim rps** command. For sample output, see [show pim rps on page 4044](#).

### show pim rps <group-address> (Bidirectional PIM)

```

user@host> show pim rps 224.1.1.1
Instance: PIM.master

224.1.0.0/16
  11.4.12.75 (Bidirectional)

RP selected: 11.4.12.75

```

### show pim rps <group-address> (PIM Dense Mode)

```

user@host> show pim rps 224.1.1.1
Instance: PIM.master

Dense Mode active for group 224.1.1.1

```

### show pim rps <group-address> (SSM Range Without

```

user@host> show pim rps 224.1.1.1
Instance: PIM.master

Source-specific Mode (SSM) active for group 224.1.1.1

```

### asm-override-ssm Configured)

show pim rps  
<group-address>  
(SSM Range With  
asm-override-ssm  
Configured and a  
Sparse-Mode RP)

```
user@host> show pim rps 224.1.1.1
```

```
Instance: PIM.master
```

```
Source-specific Mode (SSM) active with Sparse Mode ASM override for group 224.1.1.1
```

```
224.1.0.0/16
```

```
11.4.12.75
```

```
RP selected: 11.4.12.75
```

show pim rps  
<group-address>  
(SSM Range With  
asm-override-ssm

```
user@host> show pim rps 224.1.1.1
```

```
Instance: PIM.master
```

```
Source-specific Mode (SSM) active with Sparse Mode ASM override for group 224.1.1.1
```

Configured and a  
Bidirectional RP)

224.1.0.0/16  
11.4.12.75 (Bidirectional)

| <b>Output Fields</b>                                | <a href="#">Table 276 on page 4049</a> describes the output fields for the <b>show pim source</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

Table 276: show pim source Output Fields

| Field Name         | Field Description                                                     |
|--------------------|-----------------------------------------------------------------------|
| Instance           | Name of the routing instance.                                         |
| Source             | Address of the source or reverse path.                                |
| Prefix/length      | Prefix and prefix length for the route used to reach the RPF address. |
| Upstream interface | RPF interface toward the source address.                              |
| Upstream Neighbor  | Address of the RPF neighbor used to reach the source address.         |

## Sample Output

### show pim source

```

user@host> show pim source
Instance: PIM.master Family: INET

Source 10.255.14.144
  Prefix 10.255.14.144/32
  Upstream interface Local
  Upstream neighbor Local

Source 10.255.70.15
  Prefix 10.255.70.15/32
  Upstream interface so-1/0/0.0
  Upstream neighbor 10.111.10.2

Instance: PIM.master Family: INET6

```

### show pim source brief

The output for the **show pim source brief** command is identical to that for the **show pim source** command. For sample output, see [show pim source on page 4049](#).

### show pim source detail

```

user@host> show pim source detail
Instance: PIM.master Family: INET

Source 10.255.14.144
  Prefix 10.255.14.144/32
  Upstream interface Local
  Upstream neighbor Local
  Active groups:228.0.0.0
    239.1.1.1
    239.1.1.1

Source 10.255.70.15
  Prefix 10.255.70.15/32
  Upstream interface so-1/0/0.0
  Upstream neighbor 10.111.10.2
  Active groups:239.1.1.1

Instance: PIM.master Family: INET6

```

## show pim statistics

---

| <b>V2 Assert</b>        | PIM version 2 assert packets.                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>V2 Graft</b>         | PIM version 2 graft packets.                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>V2 Graft Ack</b>     | PIM version 2 graft acknowledgment packets.                                                                                                                                                                                                                                                                                                                                                                             |
| <b>V2 Candidate RP</b>  | PIM version 2 candidate RP packets.                                                                                                                                                                                                                                                                                                                                                                                     |

Table 277: show pim statistics Output Fields (*continued*)

| Field Name                              | Field Description                                                                                                                                              |
|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>V2 State Refresh</b>                 | PIM version 2 control messages related to PIM dense mode (PIM-DM) state refresh.<br><br>State refresh is an extension to PIM-DM. It not supported in Junos OS. |
| <b>V2 DF Election</b>                   | PIM version 2 send and receive messages associated with bidirectional PIM designated forwarder election.                                                       |
| <b>V1 Query</b>                         | PIM version 1 query packets.                                                                                                                                   |
| <b>V1 Register</b>                      | PIM version 1 register packets.                                                                                                                                |
| <b>V1 Register Stop</b>                 | PIM version 1 register stop packets.                                                                                                                           |
| <b>V1 Join Prune</b>                    | PIM version 1 join and prune packets.                                                                                                                          |
| <b>V1 RP Reachability</b>               | PIM version 1 RP reachability packets.                                                                                                                         |
| <b>V1 Assert</b>                        | PIM version 1 assert packets.                                                                                                                                  |
| <b>V1 Graft</b>                         | PIM version 1 graft packets.                                                                                                                                   |
| <b>V1 Graft Ack</b>                     | PIM version 1 graft acknowledgment packets.                                                                                                                    |
| <b>AutoRP Announce</b>                  | Auto-RP announce packets.                                                                                                                                      |
| <b>AutoRP Mapping</b>                   | Auto-RP mapping packets.                                                                                                                                       |
| <b>AutoRP Unknown type</b>              | Auto-RP packets with an unknown type.                                                                                                                          |
| <b>Anycast Register</b>                 | Auto-RP announce packets.                                                                                                                                      |
| <b>Anycast Register Stop</b>            | Auto-RP announce packets.                                                                                                                                      |
| <b>Global Statistics</b>                | Summary of PIM statistics for all interfaces.                                                                                                                  |
| <b>Hello dropped on neighbor policy</b> | Number of hello packets dropped because of a configured neighbor policy.                                                                                       |
| <b>Unknown type</b>                     | Number of PIM control packets received with an unknown type.                                                                                                   |
| <b>V1 Unknown type</b>                  | Number of PIM version 1 control packets received with an unknown type.                                                                                         |
| <b>Unknown Version</b>                  | Number of PIM control packets received with an unknown version. The version is not version 1 or version 2.                                                     |

Table 277: show pim statistics Output Fields (*continued*)

| Field Name                             | Field Description                                                                                                         |
|----------------------------------------|---------------------------------------------------------------------------------------------------------------------------|
| <b>Neighbor unknown</b>                | Number of PIM control packets received (excluding PIM hello) without first receiving the hello packet.                    |
| <b>Bad Length</b>                      | Number of PIM control packets received for which the packet size does not match the PIM length field in the packet.       |
| <b>Bad Checksum</b>                    | Number of PIM control packets received for which the calculated checksum does not match the checksum field in the packet. |
| <b>Bad Receive If</b>                  | Number of PIM control packets received on an interface that does not have PIM configured.                                 |
| <b>Rx Bad Data</b>                     | Number of PIM control packets received that contain data for TCP Bad register packets.                                    |
| <b>Rx Intf disabled</b>                | Number of PIM control packets received on an interface that has PIM disabled.                                             |
| <b>Rx V1 Require V2</b>                | Number of PIM version 1 control packets received on an interface configured for PIM version 2.                            |
| <b>Rx V2 Require V1</b>                | Number of PIM version 2 control packets received on an interface configured for PIM version 1.                            |
| <b>Rx Register not RP</b>              | Number of PIM register packets received when the router is not the RP for the group.                                      |
| <b>Rx Register no route</b>            | Number of PIM register packets received when the RP does not have a unicast route back to the source.                     |
| <b>Rx Register no decap if</b>         | Number of PIM register packets received when the RP does not have a de-encapsulation interface.                           |
| <b>Null Register Timeout</b>           | Number of NULL register timeout packets.                                                                                  |
| <b>RP Filtered Source</b>              | Number of PIM packets received when the router has a source address filter configured for the RP.                         |
| <b>Rx Unknown Reg Stop</b>             | Number of register stop messages received with an unknown type.                                                           |
| <b>Rx Join/Prune no state</b>          | Number of join and prune messages received for which the router has no state.                                             |
| <b>Rx Join/Prune on upstream if</b>    | Number of join and prune messages received on the interface used to reach the upstream router, toward the RP.             |
| <b>Rx Join/Prune for invalid group</b> | Number of join or prune messages received for invalid multicast group addresses.                                          |

Table 277: show pim statistics Output Fields (*continued*)

| Field Name                            | Field Description                                                                                                                                           |
|---------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Rx Join/Prune messages dropped</b> | Number of join and prune messages received and dropped.                                                                                                     |
| <b>Rx sparse join for dense group</b> | Number of PIM sparse mode join messages received for a group that is configured for dense mode.                                                             |
| <b>Rx Graft/Graft Ack no state</b>    | Number of graft and graft acknowledgment messages received for which the router or switch has no state.                                                     |
| <b>Rx Graft on upstream if</b>        | Number of graft messages received on the interface used to reach the upstream router, toward the RP.                                                        |
| <b>Rx CRP not BSR</b>                 | Number of BSR messages received in which the PIM message type is Candidate-RP-Advertisement, not Bootstrap.                                                 |
| <b>Rx BSR when BSR</b>                | Number of BSR messages received in which the PIM message type is Bootstrap.                                                                                 |
| <b>Rx BSR not RPF if</b>              | Number of BSR messages received on an interface that is not the RPF interface.                                                                              |
| <b>Rx unknown hello opt</b>           | Number of PIM hello packets received with options that Junos OS does not support.                                                                           |
| <b>Rx data no state</b>               | Number of PIM control packets received for which the router has no state for the data type.                                                                 |
| <b>Rx RP no state</b>                 | Number of PIM control packets received for which the router has no state for the RP.                                                                        |
| <b>Rx aggregate</b>                   | Number of PIM aggregate MDT packets received.                                                                                                               |
| <b>Rx malformed packet</b>            | Number of PIM control packets received with a malformed IP unicast or multicast address family.                                                             |
| <b>No RP</b>                          | Number of PIM control packets received with no RP address.                                                                                                  |
| <b>No register encaps if</b>          | Number of PIM register packets received when the first-hop router does not have an encapsulation interface.                                                 |
| <b>No route upstream</b>              | Number of PIM control packets received when the router does not have a unicast route to the the interface used to reach the upstream router, toward the RP. |
| <b>Nexthop Unusable</b>               | Number of PIM control packets with an unusable nexthop. A path can be unusable if the route is hidden or the link is down.                                  |
| <b>RP mismatch</b>                    | Number of PIM control packets received for which the router has an RP mismatch.                                                                             |

Table 277: show pim statistics Output Fields (*continued*)

| Field Name                                 | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>RP mode mismatch</b>                    | RP mode (sparse or bidirectional) mismatches encountered when processing join and prune messages.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>RPF neighbor unknown</b>                | Number of PIM control packets received for which the router has an unknown RPF neighbor for the source.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Rx Joins/Prunes filtered</b>            | The number of join and prune messages filtered because of configured route filters and source address filters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Tx Joins/Prunes filtered</b>            | The number of join and prune messages filtered because of configured route filters and source address filters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Embedded-RP invalid addr</b>            | Number of packets received with an invalid embedded RP address in PIM join messages and other types of messages sent between routing domains.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Embedded-RP limit exceed</b>            | Number of times the limit configured with the <b>maximum-rps</b> statement is exceeded. The <b>maximum-rps</b> statement limits the number of embedded RPs created in a specific routing instance. The range is from 1 through 500. The default is 100.                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Embedded-RP added</b>                   | <p>Number of packets in which the embedded RP for IPv6 is added.</p> <p>The following receive events trigger extraction of an IPv6 embedded RP address on the router:</p> <ul style="list-style-type: none"> <li>• Multicast Listener Discovery (MLD) report for an embedded RP multicast group address</li> <li>• PIM join message with an embedded RP multicast group address</li> <li>• Static embedded RP multicast group address associated with an interface</li> <li>• Packets sent to an embedded RP multicast group address received on the DR</li> </ul> <p>An embedded RP node discovered through these receive events is added if it does not already exist on the routing platform.</p> |
| <b>Embedded-RP removed</b>                 | Number of packets in which the embedded RP for IPv6 is removed. The embedded RP is removed whenever all PIM join states using this RP are removed or the configuration changes to remove the embedded RP feature.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Rx Register msgs filtering drop</b>     | Number of received register messages dropped because of a filter configured for PIM register messages.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Tx Register msgs filtering drop</b>     | Number of register messages dropped because of a filter configured for PIM register messages.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Rx Bidir Join/Prune on non-Bidir if</b> | Error counter for join and prune messages received on non-bidirectional PIM interfaces.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

Table 277: show pim statistics Output Fields (*continued*)

| Field Name                              | Field Description                                                                                                                                                                   |
|-----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Rx Bidir Join/Prune on non-DF if</b> | Error counter for join and prune messages received on non-designated forwarder interfaces.                                                                                          |
| <b>V4 (S,G) Maximum</b>                 | Maximum number of (S,G) IPv4 multicast routes accepted for the VPN routing and forwarding (VRF) routing instance. If this number is met, additional (S,G) entries are not accepted. |
| <b>V4 (S,G) Accepted</b>                | Number of accepted (S,G) IPv4 multicast routes.                                                                                                                                     |
| <b>V4 (S,G) Threshold</b>               | Threshold at which a warning message is logged (percentage of the maximum number of (S,G) IPv4 multicast routes accepted by the device).                                            |
| <b>V4 (S,G) Log Interval</b>            | Time (in seconds) between consecutive log messages.                                                                                                                                 |
| <b>V6 (S,G) Maximum</b>                 | Maximum number of (S,G) IPv6 multicast routes accepted for the VPN routing and forwarding (VRF) routing instance. If this number is met, additional (S,G) entries are not accepted. |
| <b>V6 (S,G) Accepted</b>                | Number of accepted (S,G) IPv6 multicast routes.                                                                                                                                     |
| <b>V6 (S,G) Threshold</b>               | Threshold at which a warning message is logged (percentage of the maximum number of (S,G) IPv6 multicast routes accepted by the device).                                            |
| <b>V6 (S,G) Log Interval</b>            | Time (in seconds) between consecutive log messages.                                                                                                                                 |
| <b>V4 (grp-prefix, RP) Maximum</b>      | Maximum number of group-to-rendezvous point (RP) IPv4 multicast mappings accepted for the VRF routing instance. If this number is met, additional mappings are not accepted.        |
| <b>V4 (grp-prefix, RP) Accepted</b>     | Number of accepted group-to-RP IPv4 multicast mappings.                                                                                                                             |
| <b>V4 (grp-prefix, RP) Threshold</b>    | Threshold at which a warning message is logged (percentage of the maximum number of group-to-RP IPv4 multicast mappings accepted by the device).                                    |
| <b>V4 (grp-prefix, RP) Log Interval</b> | Time (in seconds) between consecutive log messages.                                                                                                                                 |
| <b>V6 (grp-prefix, RP) Maximum</b>      | Maximum number of group-to RP IPv6 multicast mappings accepted for the VRF routing instance. If this number is met, additional mappings are not accepted.                           |
| <b>V6 (grp-prefix, RP) Accepted</b>     | Number of accepted group-to-RP IPv6 multicast mappings.                                                                                                                             |

Table 277: show pim statistics Output Fields (*continued*)

| Field Name                              | Field Description                                                                                                                                                                                 |
|-----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>V6 (grp-prefix, RP) Threshold</b>    | Threshold at which a warning message is logged (percentage of the maximum number of group-to-RP IPv6 multicast mappings accepted by the device).                                                  |
| <b>V6 (grp-prefix, RP) Log Interval</b> | Time (in seconds) between consecutive log messages.                                                                                                                                               |
| <b>V4 Register Maximum</b>              | Maximum number of IPv4 PIM registers accepted for the VRF routing instance. If this number is met, additional PIM registers are not accepted.<br><br>You configure the register limits on the RP. |
| <b>V4 Register Accepted</b>             | Number of accepted IPv4 PIM registers.                                                                                                                                                            |
| <b>V4 Register Threshold</b>            | Threshold at which a warning message is logged (percentage of the maximum number of IPv4 PIM registers accepted by the device).                                                                   |
| <b>V4 Register Log Interval</b>         | Time (in seconds) between consecutive log messages.                                                                                                                                               |
| <b>V6 Register Maximum</b>              | Maximum number of IPv6 PIM registers accepted for the VRF routing instance. If this number is met, additional PIM registers are not accepted.<br><br>You configure the register limits on the RP. |
| <b>V6 Register Accepted</b>             | Number of accepted IPv6 PIM registers.                                                                                                                                                            |
| <b>V6 Register Threshold</b>            | Threshold at which a warning message is logged (percentage of the maximum number of IPv6 PIM registers accepted by the device).                                                                   |
| <b>V6 Register Log Interval</b>         | Time (in seconds) between consecutive log messages.                                                                                                                                               |

| <b>Description</b>                    | Display system-wide Internet Group Management Protocol (IGMP) statistics.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Options</b>                        | <p><b>none</b>—Display system statistics for IGMP.</p> <p><b>all-chassis</b>—(TX Matrix and TX Matrix Plus routers only) (Optional) Display system statistics for IGMP for all the routers in the chassis.</p> <p><b>all-lcc</b>—(TX Matrix and TX Matrix Plus routers only) (Optional) On a TX Matrix router, display system statistics for IGMP for all T640 routers (or line-card chassis) connected to the TX Matrix router. On a TX Matrix Plus router, display system statistics for IGMP for all T1600 routers (or line-card chassis) connected to the TX Matrix Plus router.</p> <p><b>all-members</b>—(EX4200 switches only) (Optional) Display IGMP statistics for all members of the Virtual Chassis configuration.</p> <p><b>lcc <i>number</i></b>—(TX Matrix and TX Matrix Plus routers only) (Optional) On a TX Matrix router, display system statistics for IGMP for a specific T640 router that is connected to the TX Matrix router. On a TX Matrix Plus router, display system statistics for IGMP for a specific T1600 router that is connected to the TX Matrix Plus router. Replace <i>number</i> with a value from 0 through 3.</p> <p><b>local</b>—(EX4200 switches only) (Optional) Display IGMP statistics for the local Virtual Chassis member.</p> <p><b>member <i>member-id</i></b>—(EX4200 switches only) (Optional) Display IGMP statistics for the specified member of the Virtual Chassis configuration. Replace <i>member-id</i> with a value from 0 through 9.</p> <p><b>scc</b>—(TX Matrix routers only) (Optional) Display system statistics for IGMP for the TX Matrix router (or switch-card chassis).</p> |

**sfc number**—(TX Matrix Plus routers only) (Optional) Display system statistics for IGMP for the TX Matrix Plus router (or switch-fabric chassis). Replace *number* with 0.

**Additional Information** By default, when you issue the **show system statistics igmp** command on a TX Matrix or TX Matrix Plus master Routing Engine, the command is broadcast to all the T640 (in a routing matrix based on a TX Matrix router) or T1600 (in a routing matrix based on a TX Matrix Plus router) master Routing Engines connected to it. Likewise, if you issue the same command on the TX Matrix or TX Matrix Plus backup Routing Engine, the command is broadcast to all the T640 (in a routing matrix based on a TX Matrix router) or T1600 (in a routing matrix based on a TX Matrix Plus router) backup Routing Engines that are connected to it.

## Sample Output

show system statistics  
igmp

```
user@host> show system statistics igmp
igmp:
  17178 messages received
  0 messages received with too few bytes
  0 messages received with bad checksum
  0 membership queries received
  0 membership queries received with invalid field(s)
  0 membership reports received
  0 membership reports received with invalid field(s)
  0 membership reports received for groups to which we belong
  0 membership reports sent
```

show system statistics  
igmp (EX Series  
Switches)

```
user@host> show system statistics igmp
igmp:
  0 messages received
  0 messages received with too few bytes
  0 messages received with bad checksum
  0 membership queries received
  0 membership queries received with invalid fields
  0 membership reports received
  0 membership reports received with invalid fields
  0 membership reports received for groups to which we belong
  0 Membership reports sent
```

show system statistics  
igmp (TX Matrix Plus  
Router)

```
user@host> show system statistics igmp

## Overview of Firewall Filters

Firewall filters provide rules that define whether to accept or discard packets that are transiting an interface on a QFX Series product. If a packet is accepted, you can configure additional actions to perform on the packet, such as class-of-service (CoS) marking (grouping similar types of traffic together and treating each type of traffic as a class with its own level of service priority) and traffic policing (controlling the maximum rate of traffic sent or received). You configure firewall filters to determine whether to accept or discard a packet before it enters or exits any of these:

- Port
- VLAN

- Layer 3 (routed) interface
- Routed VLAN interface (RVI)

An *ingress* firewall filter is applied to packets that are entering an interface or VLAN, and an *egress* firewall filter is applied to packets that are exiting an interface or VLAN.

**NOTE:** Firewall filters are sometimes called *access control lists (ACLs)*.

- [Firewall Filter Types on page 4072](#)
- [Firewall Filter Components on page 4072](#)
- [Firewall Filter Processing on page 4073](#)

---

### Firewall Filter Types

The following firewall filter types are supported on the QFX Series:

- Port (Layer 2) firewall filter—Port firewall filters apply to Layer 2 traffic transiting system ports.
- VLAN firewall filter—VLAN firewall filters provide access control for packets that enter a VLAN, are bridged within a VLAN, or leave a VLAN.
- Router (Layer 3) firewall filter—You can apply a router firewall filter on IPv4 or IPv6 Layer 3 (routed) interfaces and routed VLAN interfaces (RVI). You can also apply a router firewall filter in the ingress direction (only) on a loopback interface, which filters traffic sent to the switch itself.

**NOTE:** You can apply a firewall filter to a management interface (for example, `me0`) on a QFX3500 device. You cannot apply a firewall filter to a management interface on a QFX3000-G or QFX3000-M system.

To apply a firewall filter:

1. Configure the firewall filter.
2. Apply the firewall filter to a port, VLAN, or router interface.

**NOTE:** You can apply only one firewall filter to a port, VLAN, or interface for a given direction. For example, for interface `ge-0/0/6.0`, you can apply one filter for the ingress direction and one for the egress direction.

---

### Firewall Filter Components

In a firewall filter, you first define the family address type (ethernet-switching or inet) and then define one or more terms that specify the filtering criteria and the action to take if a match occurs.

Each term consists of the following components:

- **Match conditions**—Specify values that a packet must contain to be considered a match. You can specify values for most fields in the IP, TCP, UDP, or ICMP headers. You can also match on interface names.
- **Action**—Specifies what to do if a packet matches the match conditions. A filter can accept, discard, or reject a matching packet and then perform additional actions, such as counting, classifying, and policing. If no action is specified for a term, the default is to accept the matching packet.

### Firewall Filter Processing

If there are multiple terms in a filter, the order of the terms is important. If a packet matches the first term, the switch executes the action defined by that term, and no other terms are evaluated. If the switch does not find a match between the packet and the first term, it compares the packet to the next term. If no match occurs between the packet and the second term, the system continues to compare the packet to each successive term in the filter until a match is found. If the packet does not match any terms in the filter, the switch discards the packet by default.

### Understanding Filter-Based Forwarding

You can use firewall filters in conjunction with virtual routing instances to specify different routes for packets to travel in their networks. To set up this feature—called filter-based forwarding—you specify a filter and match criteria and then specify the virtual routing instance to send packets to.

You might want to use filter-based forwarding to route specific types of traffic through a firewall or other security device before the traffic continues on its path. You can also use filter-based forwarding to give certain types of traffic preferential treatment. For example, you might want to ensure that the highest-priority traffic is forwarded over a 40-Gigabit Ethernet link. You might also use filter-based forwarding to obtain more control over load balancing than dynamic routing protocols provide.

**NOTE:** You can create as many as 128 filters or terms that direct packets to a given virtual routing instance.

## Understanding How Firewall Filters Are Evaluated

A firewall filter consists of one or more terms, and the order of the terms within a filter is important. Before you configure firewall filters, you should understand how the QFX Series products evaluate the terms within a filter and how packets are evaluated against the terms.

When a firewall filter consists of a single term, the filter is evaluated as follows:

- If the packet matches all the conditions, the action in the **then** statement is taken.
- If the packet matches all the conditions, and no action is specified in the **then** statement, the default action **accept** is taken.
- If the packet does not match all the conditions, the switch discards it.

When a firewall filter consists of more than one term, the filter is evaluated sequentially:

1. The packet is evaluated against the conditions in the **from** statement in the first term.
2. If the packet matches all the conditions in the term, the action in the **then** statement is taken and the evaluation ends. Subsequent terms in the filter are not evaluated.
3. If the packet does not match all the conditions in the term, the packet is evaluated against the conditions in the **from** statement in the second term.

This process continues until the packet matches all the conditions in the **from** statement in one of the subsequent terms or there are no more terms in the filter.

4. If a packet passes through all the terms in the filter without a match, the switch discards it.

**NOTE:** The order of conditions in a **from** statement is not important because a packet must match all the conditions to be considered a match.

---

Figure 145 on page 4075 shows how QFX Series products evaluate the terms within a firewall filter.

Figure 145: Evaluation of Terms Within a Firewall Filter

If you do not include a **from** statement in a term, all packets will match the term and be processed by the **then** statement. If a term does not contain a **then** statement or if an action has not been configured in the **then** statement, the term accepts any matching packets.

Every firewall filter contains an implicit **deny** statement at the end of the filter, which is equivalent to the following explicit filter term:

```
term implicit-rule {
  then discard;
}
```

Consequently, a packet that does not match any of the terms in a firewall filter is discarded. If you configure a filter that has no terms, all packets that pass through the filter are discarded.

**NOTE:** Firewall filtering is supported on packets that are at least 64 bytes long.

## Understanding How Firewall Filters Control Packet Flows

A switch supports firewall filters that allow you to control flows of data packets and local packets. *Data packets* transit a switch as they are forwarded from a source to a destination. *Local packets* are destined for or sent by a Routing Engine (they do not transit a switch). Local packets usually contain routing protocol data, data for IP services such as Telnet or SSH, or data for administrative protocols such as the Internet Control Message Protocol (ICMP).

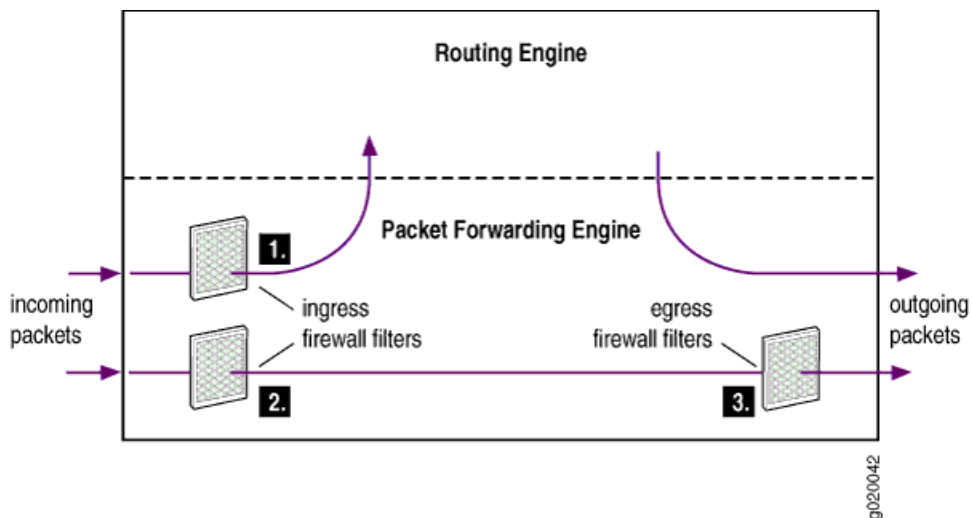

Firewall filters affect packet flows entering into or exiting from a switch as follows:

- Ingress firewall filters affect the flow of data packets that are received on switch interfaces. When a switch receives a data packet, the Packet Forwarding Engine in the system that contains the ingress interface determines where to forward the packet by looking in its Layer 2 or Layer 3 forwarding table for the best route to the destination. Data packets are forwarded to an egress interface. Locally destined packets are forwarded to the Routing Engine.
- Egress firewall filters affect data packets that are transiting a switch but do not affect packets sent by the Routing Engine. These filters are applied by the Packet Forwarding Engine in the system that contains the egress interface.

Figure 146 on page 4076 illustrates the application of ingress and egress firewall filters to control the flow of packets through a switch:

1. Ingress firewall filter applied to locally destined packets that are received on switch interfaces and are destined for the Routing Engine.
2. Ingress firewall filter applied to data packets that are received on switch interfaces and will transit the switch.
3. Egress firewall filter applied to data packets that are transiting the switch.

Figure 146: Application of Firewall Filters to Control Packet Flow

## Understanding Firewall Filter Match Conditions

Before you define terms for firewall filters, you must understand how the conditions in a term are handled and how to specify interface, numeric, address, and bit-field filter match conditions to achieve the desired filter results.

- [Filter Match Conditions on page 4077](#)
- [Numeric Filter Match Conditions on page 4077](#)
- [Interface Filter Match Conditions on page 4078](#)
- [IP Address Filter Match Conditions on page 4078](#)
- [MAC Address Filter Match Conditions on page 4079](#)
- [Bit-Field Filter Match Conditions on page 4079](#)

### Filter Match Conditions

In the **from** statement of a firewall filter term, you specify the conditions that the packet must match for the action in the **then** statement to be taken. All conditions must match for the action to be implemented. The order in which you specify match conditions is not important, because a packet must match all the conditions in a term for a match to occur.

If you specify multiple values for the same condition, a match on any one of those values matches that condition. For example, if you specify multiple IP source addresses using the **source-address** statement, a packet that contains any one of those IP source addresses matches the condition. In some cases you can specify multiple values for the same condition by enclosing the possible values in square brackets, as in:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set protocol (icmp | udp)
```

In other cases you must enter multiple statements, as in:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set source-address 10.1.1.1
user@switch# set source-address 10.1.1.2
```

If you specify no match conditions in a term, that term matches all packets.

**NOTE:** Unlike traditional Junos OS firewall filters, you cannot use **except** in a condition statement to negate the condition.

### Numeric Filter Match Conditions

You can specify numeric filter match conditions that are identified by a numeric value, such as port and protocol numbers. For numeric filter match conditions, you specify the

condition and a single value that a field in a packet must contain to be considered a match.

You can specify the numeric value in one of the following ways:

- Single number—A match occurs if the value of the field matches the number. For example, to match Telnet traffic:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set source-port 23
```

- Text synonym for a single number—A match occurs if the value of the field matches the number that corresponds to the synonym. For example, to match Telnet traffic:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set source-port telnet
```

- To specify multiple values for the same match condition in a filter term, enter each value in its own match statement. For example, a match occurs in the following term if the value of the source port in the packet is 22 or 23.

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set source-port 22
user@switch# set source-port 23
```

---

### Interface Filter Match Conditions

You can specify an interface filter match condition to match an interface on which a packet is received or transmitted. For example, if you apply a filter to a VLAN you might want the filter to match on some interfaces that participate in the VLAN and not match on other interfaces in the VLAN. When you specify the name of the interface, you must include a logical unit.

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set interface ge-0/0/6.0
```

In this example, the final character (0) specifies the logical unit. You can include the wildcard (\*) as part of the interface name. For example:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set interface ge-0/*/6.0
user@switch# set interface ge-0/1/*0
user@switch# set interface ge-0/0/6.*
```

Note that you must specify a value or a wildcard for the logical unit.

---

### IP Address Filter Match Conditions

You can specify an address filter match condition to match an IP source or destination address or prefix in a packet. Specify the address or prefix type and the address or prefix itself. For example:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set destination-address 10.2.1.0/24;
```

If you omit the prefix length, it defaults to /32. For example:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set destination-address 10
[edit firewall family family-name filter filter-name term term-name from]
user@switch# show
destination-address {
```

```
10.0.0.0/32;
}
```

To specify more than one IP address or prefix in a filter term, enter each address or prefix in its own match statement. For example, a match occurs in the following term if the source address of a packet matches either of the following prefixes:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set source-address 10.1.0.0/16
user@switch# set source-address 10.2.0.0/16
```

### MAC Address Filter Match Conditions

You can specify a MAC address filter match condition to match a source or destination MAC address. You specify the address type and value that a packet must contain to be considered a match.

You can specify the MAC address as six hexadecimal bytes in any of the following formats:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set destination-mac-address 00:11:22:33:44:55
```

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set destination-mac-address 0011.2233.4455
```

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set destination-mac-address 001122334455
```

Regardless of the formats you use, the system resolves the address to the standard format, in this case 00:11:22:33:44:55.

To specify more than one MAC address in a filter term, enter each MAC address in its own match statement. For example, a match occurs in the following term if the value of the MAC source address matches either of the following addresses:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set source-mac-address 00:11:22:33:44:55
user@switch# set source-mac-address 00:11:22:33:20:15
```

### Bit-Field Filter Match Conditions

You can specify bit-field filter match conditions to match particular bits within certain fields in Ethernet frames and IP, TCP, UDP, and ICMP headers. You usually specify the field and the bit within the field that must be set in a packet to be considered a match.

In most cases you can use a keyword to specify the bit you want to match on. For example, to match on a TCP SYN packet you can enter **syn**, as in:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set tcp-flags syn
```

You can also enter **0x02** because the SYN bit is the third least-significant bit of the 8-bit tcp-flags field:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set tcp-flags 0x02
```

To match multiple bit-field values, use the logical operators, which are described in [Table 278 on page 4080](#). The operators are listed in order from highest precedence to lowest precedence. Operations are evaluated from left to right.

Table 278: Actions for Firewall Filters

| Logical Operators | Description |
|-------------------|-------------|
| !                 | Negation    |
| &                 | Logical AND |
|                   | Logical OR  |

If you use a logical operator, enclose the values in quotation marks and do not include any spaces. For example, the following statement matches the second packet of a TCP handshake:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set tcp-flags "syn&ack"
```

To negate a match, precede the value with an exclamation point. For example, the following statement matches only the initial packet of a TCP handshake:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set tcp-flags "syn!ack"
```

You can use text synonyms to specify some common bit-field matches. For example, the following statement also matches the initial packet of a TCP handshake:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set tcp-initial
```

## Firewall Filter Match Conditions and Actions

Each term in a firewall filter consists of *match conditions* and an *action*. Match conditions are the fields and values that a packet must contain to be considered a match. You can define single or multiple match conditions in *match statements*. You can also include no match statement, in which case the term matches all packets.

When a packet matches a filter, a switch takes the action specified in the term. In addition, you can specify action modifiers to count, mirror, rate-limit, and classify packets. If no match conditions are specified for the term, the switch accepts the packet by default.

This topic describes the various match conditions, actions, and action modifiers that you can define in a firewall filter.

- [Table 279 on page 4081](#) describes the match conditions you can specify when configuring a firewall filter. Some of the numeric range and bit-field match conditions allow you to specify a text synonym. To see a list of all the synonyms for a match condition, type ? at the appropriate place in a statement.

- [Table 280 on page 4088](#) shows the actions that you can specify in a term.
- [Table 281 on page 4088](#) shows the action modifiers you can use to count, mirror, rate-limit, and classify packets.

Table 279: Supported Match Conditions for Firewall Filters

| Match Condition                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Direction and Interface                                                                                                                       |
|---------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <b>destination-address</b><br><i>ip-address</i>   | IP destination address field, which is the address of the final destination node.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Ingress ports, VLANs, IPv4 (inet) interfaces, and IPv6 (inet6) interfaces.<br><br>Egress IPv4 (inet) interfaces, and IPv6 (inet6) interfaces. |
| <b>destination-mac-address</b> <i>mac-address</i> | Destination media access control (MAC) address of the packet.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Ingress ports, VLANs and IPv4 (inet) interfaces.<br><br>Egress ports and VLANs.                                                               |
| <b>destination-port</b> <i>value</i>              | TCP or UDP destination port field. Typically, you specify this match in conjunction with the <b>protocol</b> match statement. For the following well-known ports you can specify text synonyms (the port numbers are also listed):<br><br><b>afs</b> (1483), <b>bgp</b> (179), <b>biff</b> (512), <b>bootpc</b> (68), <b>bootps</b> (67),<br><br><b>cmd</b> (514), <b>cvspserver</b> (2401),<br><br><b>dhcp</b> (67), <b>domain</b> (53),<br><br><b>eklogin</b> (2105), <b>ekshell</b> (2106), <b>exec</b> (512),<br><br><b>finger</b> (79), <b>ftp</b> (21), <b>ftp-data</b> (20), | Ingress ports, VLANs, IPv4 (inet) interfaces, and IPv6 (inet6) interfaces.<br><br>Egress IPv4 (inet) interfaces.                              |

Table 279: Supported Match Conditions for Firewall Filters (*continued*)

| Match Condition                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Direction and Interface                                                                                                                             |
|---------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                   | <p>http (80), https (443),</p> <p>ident (113), imap (143),</p> <p>kerberos-sec (88), klogin (543), kpasswd (761), krb-prop (754), krbupdate (760), kshell (544),</p> <p>ldap (389), login (513),</p> <p>mobileip-agent (434), mobilip-mn (435), msdp (639),</p> <p>netbios-dgm (138), netbios-ns (137), netbios-ssn (139), nfsd (2049), nntp (119), ntalk (518), ntp (123),</p> <p>pop3 (110), pptp (1723), printer (515),</p> <p>radacct (1813), radius (1812), rip (520), rkinit (2108),</p> <p>smtp (25), snmp (161), snmptrap (162), snpp (444), socks (1080), ssh (22), sunrpc (111), syslog (514),</p> <p>tacacs-ds (65), talk (517), telnet (23), tftp (69), timed (525),</p> <p>who (513),</p> <p>xdmcp (177),</p> <p>zephyr-clt (2103), zephyr-hm (2104)</p> |                                                                                                                                                     |
| <b>destination-prefix-list</b> <i>prefix-list</i> | IP destination prefix list field. You can define a list of IP address prefixes under a prefix-list alias for frequent use. Define this list at the [edit policy-options] hierarchy level.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | <p>Ingress ports, VLANs, IPv4 (inet) interfaces, and IPv6 (inet6) interfaces.</p> <p>Egress IPv4 (inet) interfaces and IPv6 (inet6) interfaces.</p> |
| <b>dot1q-tag</b> <i>number</i>                    | 802.1Q VLAN ID field in the Ethernet frame. The tag values can be 1–4094.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | <p>Ingress ports and VLANs.</p> <p>Egress ports and VLANs (<i>Number</i> must be the VLAN ID of the VLAN you want to match).</p>                    |

Table 279: Supported Match Conditions for Firewall Filters (*continued*)

| Match Condition                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Direction and Interface                                                                        |
|------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------|
| <b>dot1q-user-priority <i>number</i></b> | <p>802.1Q priority field in the Ethernet frame (used for class-of-service priorities). Values can be 0–7.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed):</p> <ul style="list-style-type: none"> <li>• <b>best-effort (0)</b>—Best effort</li> <li>• <b>background (1)</b>—Background</li> <li>• <b>standard (2)</b>—Standard or spare</li> <li>• <b>excellent-load (3)</b>—Excellent load</li> <li>• <b>controlled-load (4)</b>—Controlled load</li> <li>• <b>video (5)</b>—Video</li> <li>• <b>voice (6)</b>—Voice</li> <li>• <b>network-control (7)</b>—Network control reserved traffic</li> </ul>                                                                                                                                                                                      | <p>Ingress ports and VLANs.</p> <p>Egress ports and VLANs.</p>                                 |
| <b>dscp <i>value</i></b>                 | <p>Differentiated Services code point (DSCP). The DiffServ protocol uses the type-of-service (ToS) byte in the IP header. The most-significant 6 bits of this byte form the DSCP.</p> <p>You can specify DSCP in hexadecimal, binary, or decimal form.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed):</p> <ul style="list-style-type: none"> <li>• <b>ef (46)</b>—as defined in <a href="#">RFC 3246</a>, <i>An Expedited Forwarding PHB</i>.</li> <li>• <b>af11 (10), af12 (12), af13 (14); af21 (18), af22 (20), af23 (22); af31 (26), af32 (28), af33 (30); af41 (34), af42 (36), af43 (38)</b></li> </ul> <p>These four classes, with three drop precedences in each class, for a total of 12 code points, are defined in <a href="#">RFC 2597</a>, <i>Assured Forwarding PHB</i>.</p> | <p>Ingress ports, VLANs, and IPv4 (inet) interfaces.</p> <p>Egress IPv4 (inet) interfaces.</p> |

Table 279: Supported Match Conditions for Firewall Filters (*continued*)

| Match Condition                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Direction and Interface  |

| <b>ether-type value</b>          | Ethernet type field of a packet. The EtherType value specifies what protocol is being transported in the Ethernet frame. In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): <ul style="list-style-type: none"> <li>• <b>aarp (0x80F3)</b>—EtherType value AARP</li> <li>• <b>appletalk (0x809B)</b>—EtherType value AppleTalk</li> <li>• <b>arp (0x0806)</b>—EtherType value ARP</li> <li>• <b>fcoe (0x8906)</b>—EtherType value FCoE</li> <li>• <b>fip (0x8914)</b>—EtherType value FIP</li> <li>• <b>ipv4 (0x0800)</b>—EtherType value IPv4</li> <li>• <b>mpls-multicast (0x8848)</b>—EtherType value MPLS multicast</li> <li>• <b>mpls-unicast (0x8847)</b>—EtherType value MPLS unicast</li> <li>• <b>oam (0x88A8)</b>—EtherType value OAM</li> <li>• <b>ppp (0x880B)</b>—EtherType value PPP</li> <li>• <b>pppoe-discovery (0x8863)</b>—EtherType value PPPoE Discovery Stage</li> <li>• <b>pppoe-session (0x8864)</b>—EtherType value PPPoE Session Stage</li> <li>• <b>sna (0x80D5)</b>—EtherType value SNA</li> </ul> | Ingress ports and VLANs. |
| <b>ether-type list-of-values</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Egress ports and VLANs.  |
| <b>fragment-flags value</b>      | IP fragmentation flags. In place of the numeric value, you can specify one of the following text synonyms (the hexadecimal values are also listed): <ul style="list-style-type: none"> <li>• <b>is-fragment</b></li> <li>• <b>dont-fragment (0x4000)</b></li> <li>• <b>more-fragments (0x2000)</b></li> <li>• <b>reserved (0x8000)</b></li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Ingress ports and VLANs. |

Table 279: Supported Match Conditions for Firewall Filters (*continued*)

| Match Condition        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Direction and Interface                                                                                                 |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <b>icmp-code value</b> | <p>ICMP code field. Because the meaning of the value depends upon the associated <b>icmp-type</b>, you must specify a value for <b>icmp-type</b> along with a value for <b>icmp-code</b>. In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed). The keywords are grouped by the ICMP type with which they are associated:</p> <ul style="list-style-type: none"> <li>parameter-problem—ip-header-bad (0), required-option-missing (1)</li> <li>redirect—redirect-for-network (0), redirect-for-host (1), redirect-for-tos-and-net (2), redirect-for-tos-and-host (3)</li> <li>time-exceeded—ttl-eq-zero-during-reassembly (1), ttl-eq-zero-during-transit (0)</li> <li>unreachable—network-unreachable (0), host-unreachable (1), protocol-unreachable (2), port-unreachable (3), fragmentation-needed (4), source-route-failed (5), destination-network-unknown (6), destination-host-unknown (7), source-host-isolated (8), destination-network-prohibited (9), destination-host-prohibited (10), network-unreachable-for-TOS (11), host-unreachable-for-TOS (12), communication-prohibited-by-filtering (13), host-precedence-violation (14), precedence-cutoff-in-effect (15)</li> </ul> | <p>Ingress ports, VLANs, IPv4 (inet) interfaces, and IPv6 (inet6) interfaces.</p> <p>Egress IPv4 (inet) interfaces.</p> |
| <b>icmp-type value</b> | <p>ICMP message type field. Typically, you specify this match in conjunction with the <b>protocol</b> match statement to determine which protocol is being used on the port. In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed):</p> <p>echo-reply (0), destination unreachable (3), source-quench (4), redirect (5), echo-request (8), IPv4 (inet)-advertisement (9), IPv4 (inet)-solicit (10), time-exceeded (11), parameter-problem (12), timestamp (13), timestamp-reply (14), info-request (15), info-reply (16), mask-request (17), mask-reply (18)</p> <p>See also <b>icmp-code variable</b>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | <p>Ingress ports, VLANs, IPv4 (inet) interfaces, and IPv6 (inet6) interfaces.</p> <p>Egress IPv4 (inet) interfaces.</p> |

Table 279: Supported Match Conditions for Firewall Filters (*continued*)

| Match Condition                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Direction and Interface                                                                                                                      |

| <b>interface</b> <i>interface-name</i>     | Interface on which the packet is received, including the logical unit. You can include the wildcard character (*) as part of an interface name or logical unit.<br><br><b>NOTE:</b> An interface from which a packet is sent cannot be used as a match condition.                                                                                                                                                                                                                                                                                                            | Ingress ports, VLANs, IPv4 (inet) interfaces, and IPv6 (inet6) interfaces.<br><br>Egress IPv4 (inet) interfaces and IPv6 (inet6) interfaces. |
| <b>ip-options</b>                          | Specify <b>any</b> to create a match if anything is specified in the options field in the IP header.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Ingress ports, VLANs, and IPv4 (inet) interfaces.<br><br>Egress IPv4 (inet) interfaces.                                                      |
| <b>is-fragment</b>                         | Using this condition causes a match if the More Fragments flag is enabled in the IP header or if the fragment offset is not zero.                                                                                                                                                                                                                                                                                                                                                                                                                                            | Ingress ports, VLANs, and IPv4 (inet) interfaces.<br><br>Egress IPv4 (inet) interfaces.                                                      |
| <b>l2-encap-type llc-non-snap</b>          | Match on logical link control (LLC) layer packets for non-Subnet Access Protocol (SNAP) Ethernet Encapsulation type.                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Ingress ports and VLANs.<br><br>Egress ports and VLANs.                                                                                      |
| <b>precedence value</b>                    | IP precedence bits in the type-of-service (ToS) byte in the IP header. (This byte can also be used for the DiffServ DSCP.) In place of the numeric value, you can specify one of the following text synonyms (the numeric values are also listed):<br><br><ul style="list-style-type: none"> <li>• <b>routine</b> (0)</li> <li>• <b>priority</b> (1)</li> <li>• <b>immediate</b> (2)</li> <li>• <b>flash</b> (3)</li> <li>• <b>flash-override</b> (4)</li> <li>• <b>critical-ecp</b> (5)</li> <li>• <b>internet-control</b> (6)</li> <li>• <b>net-control</b> (7)</li> </ul> | Ingress ports, VLANs, and IPv4 (inet) interfaces.<br><br>Egress IPv4 (inet) interfaces.                                                      |
| <b>protocol type</b>                       | IPv4 protocol value. In place of the numeric value, you can specify one of the following text synonyms (the numeric values are also listed):<br><br><b>icmp (1), igmp (2), ipip (4), tcp (6), egp (8), udp (17), rsvp (46), gre (47), esp (50), ah (51), ospf (89), pim (103), vrrp (112), sctp (132)</b>                                                                                                                                                                                                                                                                    | Ingress ports, VLANs, and IPv4 (inet) interfaces.<br><br>Egress IPv4 (inet) interfaces.                                                      |
| <b>source-address</b><br><b>ip-address</b> | IP source address field, which is the address of the node that sent the packet.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Ingress ports, VLANs, IPv4 (inet) interfaces, and IPv6 (inet6) interfaces..<br><br>Egress IPv4 (inet) interfaces.                            |

Table 279: Supported Match Conditions for Firewall Filters (*continued*)

| Match Condition                                   | Description                                                                                                                                                                                                                                                                                                                                                         | Direction and Interface                                                                                      |
|---------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------|
| <b>source-mac-address</b> <i>mac-address</i>      | Source media access control (MAC) address of the packet.                                                                                                                                                                                                                                                                                                            | Ingress ports and VLANs.<br>Egress ports and VLANs.                                                          |
| <b>source-port</b> <i>value</i>                   | TCP or UDP source port. Typically, you specify this match in conjunction with the <b>protocol</b> match statement. In place of the numeric field, you can specify one of the text synonyms listed under <b>destination-port</b> .                                                                                                                                   | Ingress ports, VLANs, IPv4 (inet) interfaces, and IPv6 (inet6) interfaces.<br>Egress IPv4 (inet) interfaces. |
| <b>source-prefix-list</b> <i>prefix-list</i>      | IP source prefix list. You can define a list of IP address prefixes under a prefix-list alias for frequent use. Define this list at the <b>[edit policy-options]</b> hierarchy level.                                                                                                                                                                               | Ingress ports, VLANs, IPv4 (inet) interfaces, and IPv6 (inet6) interfaces.<br>Egress IPv4 (inet) interfaces. |
| <b>tcp-established</b>                            | Match packets of an established TCP connection. This condition matches packets other than those used to set up a TCP connection—that is, three-way handshake packets are not matched.<br><br>When you specify <b>tcp-established</b> , a switch does not implicitly verify that the protocol is TCP. You must also specify the <b>protocol tcp</b> match condition. | Ingress ports, VLANs, IPv4 (inet) interfaces, and IPv6 (inet6) interfaces.<br>Egress IPv4 (inet) interfaces. |
| <b>tcp-flags</b> <i>value</i>                     | One or more TCP flags:<br><ul style="list-style-type: none"> <li>• <b>ack</b> (0x10)</li> <li>• <b>fin</b> (0x01)</li> <li>• <b>push</b> (0x08)</li> <li>• <b>rst</b> (0x04)</li> <li>• <b>syn</b> (0x02)</li> <li>• <b>urgent</b> (0x20)</li> </ul>                                                                                                                | Ingress ports, VLANs, IPv4 (inet) interfaces, and IPv6 (inet6) interfaces.<br>Egress IPv4 (inet) interfaces. |
| <b>tcp-initial</b>                                | Match the first TCP packet of a connection. A match occurs when the TCP flag <b>SYN</b> is set and the TCP flag <b>ACK</b> is not set.<br><br>When you specify <b>tcp-initial</b> , a switch does not implicitly verify that the protocol is TCP. You must also specify the <b>protocol tcp</b> match condition.                                                    | Ingress ports, VLANs, IPv4 (inet) interfaces, and IPv6 (inet6) interfaces.<br>Egress IPv4 (inet) interfaces. |
| <b>ttl</b> <i>value</i>                           | IP Time-to-live (TTL) field in decimal. The value can be 1-255.                                                                                                                                                                                                                                                                                                     | Ingress IPv4 (inet) interfaces.<br>Egress IPv4 (inet) interfaces.                                            |
| <b>vlan</b> ( <i>vlan-name</i>   <i>vlan-id</i> ) | VLAN names or ID.                                                                                                                                                                                                                                                                                                                                                   | Ingress ports and VLANs.<br>Egress ports and VLANs.                                                          |

Use **then** statements to define actions that should occur if a packet matches all conditions in a **from** statement. [Table 280 on page 4088](#) shows the actions that you can specify in a term. (If you do not include a **then** statement, the system accepts packets that match the filter.)

Table 280: Actions for Firewall Filters

| Action                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>accept</b>                         | Accept a packet. This is the default action for packets that match a term.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>discard</b>                        | Discard a packet silently without sending an Internet Control Message Protocol (ICMP) message.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>reject message-type</b>            | <p>Discard a packet and send a “destination unreachable” ICMPv4 message (type 3). To log rejected packets, configure the <b>syslog</b> action modifier.</p> <p>You can specify one of the following message types: <b>administratively-prohibited</b> (default), <b>bad-host-tos</b>, <b>bad-network-tos</b>, <b>host-prohibited</b>, <b>host-unknown</b>, <b>host-unreachable</b>, <b>network-prohibited</b>, <b>network-unknown</b>, <b>network-unreachable</b>, <b>port-unreachable</b>, <b>precedence-cutoff</b>, <b>precedence-violation</b>, <b>protocol-unreachable</b>, <b>source-host-isolated</b>, <b>source-route-failed</b>, or <b>tcp-reset</b>.</p> <p>If you specify <b>tcp-reset</b>, the system sends a TCP reset if the packet is a TCP packet; otherwise nothing is sent.</p> <p>If you do not specify a message type, the ICMP notification “destination unreachable” is sent with the default message “communication administratively filtered.”</p> <p><b>NOTE:</b> The <b>reject</b> action is supported on ingress interfaces only.</p> |
| <b>routing-instance instance-name</b> | Forward matched packets to a virtual routing instance.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>routing-instance instance-name</b> | Forward matched packets to a virtual routing instance.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>vlan VLAN-name</b>                 | <p>Forward matched packets to a specific VLAN.</p> <p><b>NOTE:</b> The <b>vlan</b> action is supported on ingress interfaces only.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

You can also specify the action modifiers listed in [Table 281 on page 4088](#) to count, mirror, rate-limit, and classify packets.

Table 281: Action Modifiers for Firewall Filters

| Action Modifier               | Description                                                                                                                                                                                                                                   |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>analyzer analyzer-name</b> | <p>Mirror traffic (copy packets) to an analyzer configured at the <b>[edit ethernet-switching-options analyzer]</b> hierarchy level.</p> <p>You can specify port mirroring for ingress port, VLAN, and IPv4 (inet) firewall filters only.</p> |
| <b>count counter-name</b>     | Count the number of packets that match the term.                                                                                                                                                                                              |

Table 281: Action Modifiers for Firewall Filters (*continued*)

| Action Modifier                                              | Description                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>forwarding-class</b> <i>class</i>                         | <p>Classify the packet in one of the following forwarding classes:</p> <ul style="list-style-type: none"> <li>• <b>assured-forwarding</b></li> <li>• <b>best-effort</b></li> <li>• <b>expedited-forwarding</b></li> <li>• <b>network-control</b></li> </ul> <p><b>NOTE:</b> The <b>forwarding-class</b> action modifier is supported on ingress interfaces only.</p> |
| <b>log</b>                                                   | <p>Log the packet's header information in the Routing Engine. To view this information, enter the <b>show firewall log</b> operational mode command.</p> <p><b>NOTE:</b> The <b>log</b> action modifier is supported on ingress interfaces only.</p>                                                                                                                 |
| <b>loss-priority</b> (low   medium-low   medium-high   high) | <p>Set the packet loss priority (PLP).</p> <p><b>NOTE:</b> The <b>loss-priority</b> action modifier is supported on ingress interfaces only.</p> <p><b>NOTE:</b> The <b>loss-priority</b> action modifier is not supported in combination with the <b>policer</b> action.</p>                                                                                        |
| <b>policer</b> <i>policer-name</i>                           | <p>Send packets to a policer (for the purpose of applying rate limiting).</p> <p>You can specify a policer for ingress port, VLAN, and IPv4 (inet) firewall filters only.</p> <p><b>NOTE:</b> The <b>policer</b> action modifier is not supported in combination with the <b>loss-priority</b> action.</p>                                                           |
| <b>syslog</b>                                                | <p>Log an alert for this packet.</p> <p><b>NOTE:</b> The <b>syslog</b> action modifier is supported on ingress interfaces only.</p>                                                                                                                                                                                                                                  |
| <b>three-color-policer</b> <i>three-color-policer-name</i>   | <p>Send packets to a three-color policer (for the purpose of applying rate limiting).</p> <p>You can specify a three-color policer for ingress and egress port, VLAN, and IPv4 (inet) firewall filters.</p> <p><b>NOTE:</b> The <b>policer</b> action modifier is not supported in combination with the <b>loss-priority</b> action.</p>                             |

## Understanding How a Firewall Filter Tests a Protocol

When examining match conditions in a firewall filter, a switch tests only the fields that you specify. It does not implicitly test any fields that you do not explicitly configure. For example, if you specify a match condition of **source-port ssh**, there is no implied test to determine if the protocol is TCP. In this case, the switch considers any packet that has a value of **22** (decimal) in the 2-byte field that follows a *presumed* IP header to be a match. To ensure that the term matches on TCP packets, you also specify a **protocol tcp** match condition.

For the following match conditions, you should explicitly specify the protocol match condition in the same term:

- **destination-port**—Specify **protocol tcp** or **protocol udp**.
- **icmp-code**—Specify **protocol icmp** and **icmp-type**.
- **icmp-type**—Specify **protocol tcp** or **protocol udp**.
- **source-port**—Specify **protocol tcp** or **protocol udp**.
- **tcp-flags**—Specify **protocol tcp**.

## Understanding Firewall Filter Planning

Before you create a firewall filter and apply it, determine what you want the filter to accomplish and how to use its match conditions and actions to achieve your goals. It is important that you understand how packets are matched, the default and configured actions of the firewall filter, and where to apply the firewall filter.

You can apply no more than one firewall filter per port, VLAN, or router interface per direction (input and output). For example, for a given port you can apply at most one filter in the input direction and one filter in the output direction. You should try to be conservative in the number of terms (rules) that you include in each firewall filter, because a large number of terms requires longer processing time during a commit operation and can make testing and troubleshooting more difficult.

Before you configure and apply firewall filters, answer the following questions for each of them:

1. What is the purpose of the filter?

For example, the system can drop packets based on header information, rate-limit traffic, classify packets into forwarding classes, log and count packets, or prevent denial-of-service attacks.

2. What are the appropriate match conditions? Determine the packet header fields that the packet must contain for a match. Possible fields include:

- Layer 2 header fields—Source and destination MAC addresses, 802.1Q tag, Ethernet type, or VLAN.
- Layer 3 header fields—Source and destination IP addresses, protocols, and IP options (IP precedence, IP fragmentation flags, or TTL type).
- TCP header fields—Source and destination ports and flags.
- ICMP header fields—Packet type and code.

3. What are the appropriate actions to take if a match occurs?

The system can accept, discard, or reject packets.

4. What additional action modifiers might be required?

For example, you can configure the system to mirror (copy) packets to a specified port, count matching packets, apply traffic management, or police packets.

5. On what port, router interface, or VLAN should the firewall filter be applied?

Start with the following basic guidelines:

- If packets entering or leaving a Layer 2 interface (port) need to be filtered, apply the filter at the **[edit family ethernet switching filter]** hierarchy level. This is a port filter.
- If packets entering or leaving any port in a specific VLAN need to be filtered, use a VLAN filter.

- If packets entering or leaving a Layer 3 (routed) interface or routed VLAN interface (RVI) need to be filtered, use a router firewall filter. Apply the filter to the interface at the **[edit family inet]** hierarchy level. You can also apply a router firewall filter on a loopback interface in the ingress direction.

Before you choose the interface or VLAN on which to apply a firewall filter, understand how that placement can affect traffic flow to other interfaces. In general, apply a filter close to the source device if the filter matches on source or destination IP addresses, IP protocols, or protocol information—such as ICMP message types, and TCP or UDP port numbers. However, you should apply a filter close to the destination device if the filter matches *only* on a source IP address. When you apply a filter too close to the source device, the filter could prevent that source device from accessing other services that are available on the network.

**NOTE:** Egress firewall filters do not affect the flow of locally generated control packets from the Routing Engine.

6. In which direction should the firewall filter be applied?

You typically configure different actions for traffic entering an interface than you configure for traffic exiting an interface.

7. How many filters should I create?

See “[Planning the Number of Firewall Filters to Create](#)” on page 4092 for information about how many firewall filters you can apply.

### Understanding How Many Firewall Filters Are Supported

---

QFX3500 and QFX3600 switches and Node devices support the following maximum number of firewall filter terms per type of attachment point:

- 768 terms for ingress filters
- 1024 terms for egress filters

These totals are applied in aggregate. That is, you can apply a total of 768 port filters, Layer 3 filters, and VLAN filters in the input direction and 1024 port filters, Layer 3 filters, and VLAN filters in the output direction. These maximum values also assume that each filter has only one term. If you create filters with multiple terms (including implicit terms), the maximum numbers of filters is reduced.

**NOTE:** If you want to create more than 512 egress VLAN filters, your first VLAN ID should be 6 and the subsequent VLAN IDs should increase by 1. For example, to create 1024 egress VLAN filters, the first VLAN ID would be 6, the second ID would be 7, and the sequence would continue through VLAN ID 1029. Similarly, if you want to create fewer than 512 egress VLAN filters but want the total number of terms in those filters to exceed 512, you should number your VLAN IDs in the same manner. If you do not use this approach to create your VLAN IDs, the total number of allowed terms or filters will be less than 1024 and might be 512.

The memory for filters is divided into slices that accommodate 256 filters (again assuming that there is one term per filter), and all the filters in a memory slice must be of the same type and applied in the same direction. A memory slice is reserved as soon as you apply a filter. For example, if you create a port filter and apply it in the input direction, a memory slice is reserved that will only store ingress port filters. If you create and apply only one ingress port filter, the rest of this slice is unused and is unavailable for other filter types.

Continuing with the above example, assume that you create and apply 256 ingress port filters with one term each so that one memory slice is filled. This leaves two more memory slices available for ingress filters. (Remember that the maximum number of ingress filters is 768.) If you then create and apply an ingress Layer 3 filter, another memory slice is reserved for ingress Layer 3 filters. As before, the rest of the slice is unused and is unavailable for different filter types. At this point there is one memory slice available for any ingress filter type.

Now assume that you create and apply a VLAN ingress filter. The final memory slice is reserved for VLAN ingress filters. Memory allocation for ingress filters (once again assuming one term per filter) is as follows:

- Slice 1: Filled with 256 ingress port filters. You cannot apply any more ingress port filters.
- Slice 2: Contains one ingress Layer 3 filter. You can apply 255 more ingress Layer 3 filters.
- Slice 3: Contains one ingress VLAN filter. You can apply 255 more ingress VLAN filters.

Here is another example. Assume that you create 257 ingress port filters with one term per filter—that is, you create one more term than a single memory slice can accommodate. When you apply the filters and commit the configuration, the filter memory allocation is:

- Slice 1: Filled with 256 ingress port filters. You cannot apply any more ingress port filters.
- Slice 2: Contains one ingress port filter. You can apply 255 more ingress port filters.

- Slice 3: This slice is unassigned. You can create and apply 256 ingress filters of any type (port, Layer 3, or VLAN), but all the filters must be of the same type.

### Egress Filters

---

All of the preceding principles also apply to egress filters, but four memory slices are used because IPv4 Layer 3 filters and IPv6 Layer 3 filters are stored in separate slices. The memory slices for egress filters are the same size as those for ingress filters, so the maximum number of egress filter terms is therefore 1024.

### Avoid Configuring too Many Filters

---

If you violate any of these restrictions and commit a configuration that is not in compliance, Junos OS rejects the excessive filters. For example, if you configure 300 ingress port filters and 300 ingress Layer 3 filters and try to commit the configuration, Junos OS does the following (again assuming one term per filter):

- Accepts the 300 ingress port filters (storing them in two memory slices).
- Accepts the first 256 ingress Layer 3 filters it processes (storing them in the third memory slice).
- Rejects the remaining 44 ingress Layer 3 filters.

**NOTE:** In this situation, be sure to delete excessive filters (for example, the remaining 44 ingress Layer 3 filters) from the configuration before you reboot the device. If you reboot a device that has a noncompliant configuration, you cannot predict which filters are installed after the reboot. Using the example above, the 44 ingress Layer 3 filters that were originally rejected might be installed, and 44 of the port filters that were originally accepted might be rejected.

## Understanding Firewall Filter Processing Points for Bridged and Routed Packets

You apply firewall filters at multiple processing points in the forwarding path. At each processing point, the action to be taken on a packet is determined by the configuration of the filter and the results of the lookup in the forwarding or routing table.

For both bridged (Layer 2) unicast packets and routed (Layer 3) unicast packets, firewall filters are applied in the prescribed order shown below (assuming that each filter is present and a packet is accepted by each one).

Bridged packets:

1. Ingress port filter
2. Ingress VLAN filter
3. Egress VLAN filter
4. Egress port filter

Routed packets:

1. Ingress port firewall filter
2. Ingress VLAN firewall filter (Layer 2 CoS)
3. Ingress router firewall filter (Layer 3 CoS)
4. Egress router firewall filter
5. Egress VLAN firewall filter
6. Egress port filter

**NOTE:** MAC learning occurs before filters are applied, so QFX Series products learn the MAC addresses of packets that are dropped by ingress filters.

## Applying Firewall Filters to Interfaces

For a firewall filter to work, you must apply it to at least one interface. To do this, include the **filter** statement when configuring a logical interface at the **[edit interfaces]** hierarchy level:

```
[edit interfaces]
user@switch# set interface-name unit logical-unit-number family family-name filter (input |
output) filter-name
```

In the **input** statement, specify a firewall filter to be evaluated when packets are received on the interface. Input filters applied to a loopback interface affect only traffic destined for the Routing Engine.

In the **output** statement, specify a filter to be evaluated when packets exit the interface. (You cannot apply an output filter to a loopback interface.)

**NOTE:** When you create a loopback interface, it is important to apply a filter to it so the Routing Engine is protected. We recommend that when you apply a filter to the loopback interface lo0, you include the `apply-groups` statement. Doing so ensures that the filter is automatically inherited on every loopback interface, including lo0 and other loopback interfaces.

### Overview of Policers

A switch polices traffic by limiting the input or output transmission rate of a class of traffic according to user-defined criteria. Policing (or rate-limiting) traffic allows you to control the maximum rate of traffic sent or received on an interface and to provide multiple priority levels or classes of service.

---

### Policer Overview

---

You use policers to apply limits to traffic flow and set consequences for packets that exceed these limits—usually applying a higher loss priority—so that if packets encounter downstream congestion, they can be discarded first. Policers apply only to unicast packets.

Policers provide two functions: metering and marking. A policer meters (measures) each packet against traffic rates and burst sizes that you configure. It then passes the packet and the metering result to the marker, which assigns a packet loss priority that corresponds to the metering result. [Figure 147 on page 4097](#) illustrates this process.

Figure 147: Flow of Tricolor Marking Policer Operation

9017049

After you name and configure a policer, you use it by specifying it as an action in one or more firewall filters.

### Policer Types

A switch supports three types of policers:

- **Single-rate two-color marker**—A two-color policer (or “policer” when used without qualification) meters the traffic stream and classifies packets into two categories of packet loss priority (PLP) according to a configured bandwidth and burst-size limit. You can mark packets that exceed the bandwidth and burst-size limit with a specified PLP or simply discard them.

You can specify this type of policer in an ingress or egress firewall.

**NOTE:** A two-color policer is most useful for metering traffic at the port (physical interface) level.

- **Single-rate three-color marker**—This type of policer is defined in RFC 2697, *A Single Rate Three Color Marker*, as part of an assured forwarding (AF) per-hop-behavior (PHB) classification system for a Differentiated Services (DiffServ) environment. This type of policer meters traffic based on one rate—the configured committed information rate (CIR) as well as the committed burst size (CBS) and the excess burst size (EBS). The CIR specifies the average rate at which bits are admitted to the switch. The CBS specifies the usual burst size in bytes and the EBS specifies the maximum burst size in bytes. The EBS must be greater than or equal to the CBS, and neither can be 0.

You can specify this type of policer in an ingress or egress firewall.

**NOTE:** A single-rate three-color marker (TCM) is most useful when a service is structured according to packet length and not peak arrival rate.

- **Two-rate three-color marker**—This type of policer is defined in RFC 2698, *A Two Rate Three Color Marker*, as part of an assured forwarding per-hop-behavior classification system for a Differentiated Services environment. This type of policer meters traffic based on two rates—the CIR and peak information rate (PIR) along with their associated burst sizes, the CBS and peak burst size (PBS). The PIR specifies the maximum rate at which bits are admitted to the network and must be greater than or equal to the CIR.

You can specify this type of policer in an ingress or egress firewall.

**NOTE:** A two-rate three-color policer is most useful when a service is structured according to arrival rates and not necessarily packet length.

See [Table 282 on page 4098](#) for information about how metering results are applied for each of these policer types.

### Policer Actions

Policer actions are implicit or explicit and vary by policer type. *Implicit* means that Junos OS assigns the loss priority automatically. [Table 282 on page 4098](#) describes the policer actions.

**Table 282: Policer Actions**

| Policer                 | Marking                        | Implicit Action                  | Configurable Action |
|-------------------------|--------------------------------|----------------------------------|---------------------|
| Single-rate two-color   | Green (conforming)             | Assign low loss priority         | None                |
|                         | Red (nonconforming)            | None                             | Discard             |
| Single-rate three-color | Green (conforming)             | Assign low loss priority         | None                |
|                         | Yellow (above the CIR and CBS) | Assign medium-high loss priority | None                |
|                         | Red (above the EBS)            | Assign high loss priority        | Discard             |
| Two-rate three-color    | Green (conforming)             | Assign low loss priority         | None                |
|                         | Yellow (above the CIR and CBS) | Assign medium-high loss priority | None                |
|                         | Red (above the PIR and PBS)    | Assign high loss priority        | Discard             |

**NOTE:** If you specify a policer in an egress firewall filter, the only supported action is discard.

### Policer Colors

Single-rate and two-rate three-color policers can operate in two modes:

- **Color-blind**—In color-blind mode, the three-color policer assumes that all packets examined have not been previously marked or metered. In other words, the three-color policer is “blind” to any previous coloring a packet might have had.
- **Color-aware**—In color-aware mode, the three-color policer assumes that all packets examined have been previously marked or metered. In other words, the three-color policer is “aware” of the previous coloring a packet might have had. In color-aware mode, the three-color policer can increase the PLP of a packet but cannot decrease it. For example, if a color-aware three-color policer meters a packet with a medium PLP marking, it can raise the PLP level to high but cannot reduce the PLP level to low.

### Suggested Naming Convention for Policers

We recommend that you use the naming convention ***policertypeTCM#-color type*** when configuring three-color policers and ***policer#*** when configuring two-color policers. TCM stands for three-color marker. Because policers can be numerous and must be applied correctly to work, a simple naming convention makes it easier to apply the policers properly. For example, the first single-rate, color-aware three-color policer configured would be named **srTCM1-ca**. The second two-rate, color-blind three-color configured would be named **trTCM2-cb**. The elements of this naming convention are explained below:

- sr (single-rate)
- tr (two-rate)
- TCM (tricolor marking)
- 1 or 2 (number of marker)
- ca (color-aware)
- cb (color-blind)

### Policer Counters

Each policer that you configure includes an implicit counter that counts the number of packets that exceed the rate limits that are specified for the policer. If you use the same policer in multiple terms—either within the same filter or in different filters—the implicit counter counts all the packets that are policed in all of these terms. If you want to obtain separate packet counts for each term, use these options:

- Configure a unique policer for each term.
- Configure only one policer, but use a unique, explicit counter in each term.

### Policer Algorithms

Policing uses the *token-bucket algorithm*, which enforces a limit on average bandwidth while allowing bursts up to a specified maximum value. It offers more flexibility than the *leaky bucket algorithm* in allowing a certain amount of bursty traffic before it starts discarding packets.

### How Many Policers are Supported?

---

You can configure and commit the following numbers of policers on QFX3500 and QFX3600 devices when they are operating as standalone switches:

- Two-color policers used in ingress firewall filters: 768
- Three-color policers used in ingress firewall filters: 768
- Two-color policers used in egress firewall filters: 510
- Three-color policers used in egress firewall filters: 255

### Understanding Policers with Link Aggregation Groups

If you apply a policer to a link aggregation group (LAG) on a QFX3500 switch or node, the policer applies to all the interfaces in the LAG in aggregate. For example, if you configure a policer to rate-limit at 1 Gbps and apply the policer (by using a firewall filter) to a LAG that has two member interfaces on a single switch or node, the total allowed throughput for both members is 1 Gbps.

If you apply a policer to a LAG that has members on different nodes in a QFabric network Node group or redundant server Node group, the configured rate applies to the interface on each node. For example, if you configure a policer to rate-limit at 1 Gbps and apply the policer to a LAG that has one member on server node A and one member on server node B, the allowed throughput for each member is 1 Gbps, for a total allowed throughput of 2 Gbps.

### Understanding Color-Blind Mode for Single-Rate Tricolor Marking

With the color-blind mode of single-rate tricolor marking, all packets are evaluated against the CBS. If a packet exceeds the CBS, it is evaluated against the EBS. In color-blind mode, the policer supports three loss priorities only: low, medium-high, and high.

Packets that exceed the CBS but are below the EBS are marked yellow (medium-high). Packets that exceed the EBS are marked red (high), as shown in [Table 283 on page 4101](#).

Table 283: Color-Blind Mode TCM Color-to-PLP Mapping

| Color  | PLP         | Meaning                                                     |
|--------|-------------|-------------------------------------------------------------|
| Green  | low         | Conforming.                                                 |
| Yellow | medium-high | Packet exceeds the CIR and CBS but does not exceed the EBS. |
| Red    | high        | Packet exceeds the EBS.                                     |

  - [Configuring Color-Blind Egress Policers for Medium-Low PLP on page 4182](#)

## Understanding Color-Aware Mode for Single-Rate Tricolor Marking

In color-aware mode, the treatment the packet receives depends on its classification. Marking can increase a preassigned PLP but cannot decrease it.

### Summary of PLP Changes

Table 284 on page 4101 shows how a packet's incoming priority can be modified with single-rate marking.

Table 284: Color-Aware Mode Single-Rate PLP Mapping

| Incoming PLP | Packet Metered Against      | Possible Cases                                              | Outgoing PLP |
|--------------|-----------------------------|-------------------------------------------------------------|--------------|
| low          | CIR, CBS, and EBS           | Conforming                                                  | low          |
|              |                             | Packet exceeds the CIR and CBS but does not exceed the EBS. | medium-high  |
|              |                             | Packet exceeds the EBS.                                     | high         |
| medium-low   | EBS only                    | Packet does not exceed the EBS.                             | medium-low   |
|              |                             | Packet exceeds the EBS.                                     | high         |
| medium-high  | EBS only                    | Packet does not exceed the EBS.                             | medium-high  |
|              |                             | Packet exceeds the EBS.                                     | high         |
| high         | Not metered by the policer. | All cases.                                                  | high         |

The following sections describe single-rate color-aware PLP mapping in more detail.

### Effect on Green Packets (Low PLP)

Packets belonging to the green class have already been marked by a classifier with low PLP. The marking policer can leave the PLP unchanged or increase it to medium-high or

high, so these packets are therefore metered against both the CBS and the EBS. For example, if a behavior aggregate or multifield classifier marks a packet with low PLP and the two-rate TCM policer is in color-aware mode, the output loss priority is as follows:

- If the rate of traffic flow is less than the CIR, packets remain marked as low PLP.
- If bursts exceed the CBS but not the EBS, some of the packets are marked as medium-high PLP, and some of the packets remain marked as low PLP.
- If bursts exceed the EBS, some of the packets are marked as high PLP, and some of the packets remain marked as low PLP.

#### ***Effect on Yellow Packets (Medium PLP)***

Packets belonging to the yellow class have already been marked by a classifier with medium-low or medium-high PLP. The marking policer can leave the PLP unchanged or increase it to high, so these packets are therefore metered against the EBS only. For example, if a behavior aggregate or multifield classifier marks a packet with medium-low PLP and the two-rate TCM policer is in color-aware mode, the output loss priority is as follows:

- If the rate of traffic flow is less than the CBS, the packets remain marked as medium-low PLP.
- If the rate of traffic flow is greater than the CBS but less than the EBS, the packets remain marked as medium-low PLP.
- If the rate of traffic flow is greater than the EBS, some of the packets are marked as high PLP and some remain marked as medium-low PLP.

If a BA or multifield classifier marks a packet with medium-high PLP and the two-rate TCM policer is in color-aware mode, the policer assigns output loss priority as follows:

- If the rate of traffic flow is less than the CBS, the packets remain marked as medium-high PLP.
- If the rate of traffic flow is greater than the CBS but less than the EBS, the packets remain marked as medium-high PLP.
- If the rate of traffic flow is greater than the EBS, some of the packets are marked as high PLP and some remain marked as medium-high PLP.

#### ***Effect on Red Packets (High PLP)***

Packets belonging to the red class have already been marked by a classifier with high PLP. Because the policer cannot decrease the PLP, it does not change it, and these packets are not metered against the CBS or the EBS.

## Understanding Color-Blind Mode for Two-Rate Tricolor Marking

With the color-blind mode of two-rate tricolor marking, all packets are evaluated against the committed information rate (CIR). If a packet exceeds the CIR, it is evaluated against the peak information rate (PIR). Packets that exceed the CIR but are below the PIR are marked yellow (medium-high). Packets that exceed the PIR are marked red (high).

**Table 285: Color-Blind Mode TCM Color-to-PLP Mapping**

| Color  | PLP                | Meaning                                             |
|--------|--------------------|-----------------------------------------------------|
| Green  | <b>low</b>         | Packet does not exceed the CIR.                     |
| Yellow | <b>medium-high</b> | Packet exceeds the CIR but does not exceed the PIR. |
| Red    | <b>high</b>        | Packet exceeds the PIR.                             |

## Understanding Color-Aware Mode for Two-Rate Tricolor Marking

In color-aware mode, the treatment the packet receives depends on its classification. Marking can increase the preassigned PLP but cannot decrease it

### Summary of PLP Changes

Table 286 on page 4103 shows how a packet's incoming priority can be modified with two-rate marking.

**Table 286: Color-Aware Mode Two-Rate PLP Mapping**

| Incoming PLP       | Packet Metered Against | Possible Cases                          | Outgoing PLP       |
|--------------------|------------------------|-----------------------------------------|--------------------|
| <b>low</b>         | CIR and PIR            | Packet does not exceed the CIR.         | <b>low</b>         |
|                    |                        | Packet exceeds the CIR but not the PIR. | <b>medium-high</b> |
|                    |                        | Packet exceeds the PIR.                 | <b>high</b>        |
| <b>medium-low</b>  | PIR only               | Packet does not exceed the PIR.         | <b>medium-low</b>  |
|                    |                        | Packet exceeds the PIR.                 | <b>high</b>        |
| <b>medium-high</b> | PIR only               | Packet does not exceed the PIR.         | <b>medium-high</b> |
|                    |                        | Packet exceeds the PIR.                 | <b>high</b>        |

Table 286: Color-Aware Mode Two-Rate PLP Mapping (*continued*)

| Incoming PLP | Packet Metered Against      | Possible Cases | Outgoing PLP |
|--------------|-----------------------------|----------------|--------------|
| high         | Not metered by the policer. | All cases.     | high         |

The following sections describe color-aware two-rate PLP mapping in more detail.

#### Effect on Green Packets (Low PLP)

Packets belonging to the green class have already been marked by a classifier with low PLP. The marking policer can leave the packet's PLP unchanged or increase the PLP to medium-high or high. These packets are therefore metered against both the CIR and the PIR. For example, if a behavior aggregate or multifield classifier marks a packet with low PLP and the two-rate TCM policer is in color-aware mode, the output loss priority is as follows:

- If the rate of traffic flow is less than the CIR, the packets remain marked as low PLP.
- If the rate of traffic flow is greater than the CIR but less than the PIR, some of the packets are marked as medium-high PLP and some of the packets remain marked as low PLP.
- If the rate of traffic flow is greater than the PIR, some of the packets are marked as high PLP and some of the packets remain marked as low PLP.

#### Effect on Yellow Packets (Medium PLP)

Packets belonging to the yellow class have already been marked by a classifier with medium-low or medium-high PLP. The marking policer can leave the PLP unchanged or increase it to high. These packets are therefore metered against the PIR only. For example, if a behavior aggregate (BA) or multifield classifier marks a packet with medium-low PLP and the two-rate TCM policer is in color-aware mode, the policer assigns output loss priority as follows:

- If the rate of traffic flow is less than the CIR, the packets remain marked as medium-low PLP.
- If the rate of traffic flow is greater than the CIR but less than the PIR, the packets remain marked as medium-low PLP.
- If the rate of traffic flow is greater than the PIR, some of the packets are marked as high PLP and some of the packets remain marked as medium-low PLP.

If a BA or multifield classifier marks a packet with medium-high PLP and the two-rate TCM policer is in color-aware mode, the policer assigns output loss priority as follows:

- If the rate of traffic flow is less than the CIR, the packets remain marked as medium-high PLP.
- If the rate of traffic flow is greater than the CIR but less than the PIR, the packets remain marked as medium-high PLP.

- If the rate of traffic flow is greater than the PIR, some of the packets are marked as high PLP and some of the packets remain marked as medium-high PLP.

---

### Effect on Red Packets (High PLP)

Packets belonging to the red class have already been marked by a classifier with high PLP. Because the policer cannot decrease the PLP, it does not change it, and these packets are not metered against the CIR or the PIR.

- [Understanding DHCP Option 82 for Port Security on page 4122](#)
- [Understanding Static ARP Entries on page 4124](#)

### Overview of Access Port Protection

Port security features can protect a switch against various types of attacks. Protection methods against some common attacks are:

- [Mitigation of Ethernet Switching Table Overflow Attacks on page 4105](#)
- [Mitigation of Rogue DHCP Server Attacks on page 4106](#)
- [Protection Against ARP Spoofing Attacks on page 4106](#)
- [Protection Against DHCP Snooping Database Alteration Attacks on page 4107](#)
- [Protection Against DHCP Starvation Attacks on page 4107](#)

---

### Mitigation of Ethernet Switching Table Overflow Attacks

In an overflow attack on an Ethernet switching table, an intruder sends so many requests from new MAC addresses that the table cannot learn all the addresses. The attack forces the switch to send broadcast messages when it needs to send traffic to addresses for which it lacks MAC addresses. In addition to generating unnecessary traffic, the attacker might be able to sniff the broadcast packets.

To mitigate such attacks, you can configure a limit for learned MAC addresses or allow only specific MAC addresses. Use the MAC limit feature to control the total number of MAC addresses that can be added to the Ethernet switching table for the specified

interface or interfaces. By setting the MAC addresses that are explicitly allowed, you ensure that the addresses of network devices whose network access is critical are guaranteed to be included in the Ethernet switching table.

### Mitigation of Rogue DHCP Server Attacks

---

By default, all access ports are untrusted, and all trunk ports are trusted with regard to DHCP. Trusted ports allow DHCP servers to provide IP addresses and other information to requesting devices. If someone connects an unauthorized DHCP server to a trusted port, the unauthorized server can start issuing IP addresses and configuration information to the network's DHCP clients. The information provided to the clients by this server can disrupt their network access. The unauthorized server might also assign itself as the default gateway device for the network. An attacker can then sniff the network traffic and perpetrate a man-in-the-middle attack—that is, it misdirects traffic intended for a legitimate network device to a device of its choice.

To mitigate this problem, set the interface to which the unauthorized server is connected as untrusted. That action blocks all ingress DHCP server messages from that interface.

**NOTE:** The switch logs all DHCP server packets that are received on untrusted ports. For example:

```
5 untrusted DHCPOFFER received, interface xe-0/0/2.0[65], vlan v1[10] server
ip/mac 12.12.12.1/00:00:00:00:01:12 offer ip/client mac
12.12.12.253/00:AA:BB:CC:DD:01
```

You can use these messages to detect unauthorized DHCP servers on the network.

**NOTE:** If you attach a DHCP server to an access port, you must configure the port as trusted.

---

### Protection Against ARP Spoofing Attacks

---

In ARP spoofing, an attacker sends faked ARP messages on the network. The attacker associates its own MAC address with the IP address of a network device connected to the switch. Any traffic sent to that IP address is instead sent to the attacker. Now the attacker can create various types of problems, including sniffing the packets that were meant for another host and perpetrating man-in-the-middle attacks. (In a man-in-the-middle attack, the attacker intercepts messages between two hosts, reads them, and perhaps alters them, all without the original hosts knowing that their communications have been compromised.)

To protect against ARP spoofing on your switch, enable both DHCP snooping and dynamic ARP inspection (DAI). DHCP snooping builds and maintains the DHCP snooping table. That table contains the MAC addresses, IP addresses, lease times, binding types, VLAN information, and interface information for the untrusted interfaces on the switch. DAI

uses the information in the DHCP snooping table to validate ARP packets. Invalid ARP packets are blocked, and when they are blocked, a system log message is recorded that includes the type of ARP packet and the sender's IP address and MAC address.

See [“Example: Configuring DHCP Snooping and DAI to Protect the Switch from ARP Spoofing Attacks”](#) on page 4162.

### Protection Against DHCP Snooping Database Alteration Attacks

In an attack designed to alter the DHCP snooping database, an intruder introduces a DHCP client on one of the switch's untrusted access interfaces that has a MAC address identical to that of a client on another untrusted port. The intruder acquires the DHCP lease, which results in changes to the entries in the DHCP snooping table. Subsequently, what would have been valid ARP requests from the legitimate client are blocked.

To protect against this type of alteration of the DHCP snooping database, configure MAC addresses that are explicitly allowed on the interface. See [“Example: Configuring Allowed MAC Addresses to Protect the Switch from DHCP Snooping Database Alteration Attacks”](#) on page 4167.

### Protection Against DHCP Starvation Attacks

In a DHCP starvation attack, an attacker floods an Ethernet LAN with DHCP requests from spoofed (counterfeit) MAC addresses so that trusted DHCP servers cannot keep up with requests from legitimate DHCP clients. The address space of those servers is completely used up, so they can no longer assign IP addresses and lease times to clients. DHCP requests from those clients are either dropped—that is, the result is a denial of service (DoS)—or directed to a rogue DHCP server set up by the attacker to imitate a legitimate DHCP server.

To protect the switch from DHCP starvation attacks, use the MAC limiting feature. Specify the maximum number of MAC addresses that the switch can learn on the access interfaces to which DHCP clients connect. The DHCP server or servers can then supply only the specified number of IP addresses over each of those interfaces. If a DHCP starvation attack occurs after the maximum number of IP addresses has been assigned, the attack fails.

## Port Security Overview

Ethernet LANs are vulnerable to attacks such as address spoofing (forging) and Layer 2 denial of service (DoS) on network devices. Port security features help protect the access ports on your switch against the loss of information and productivity that can result from such attacks.

Juniper Networks Junos operating system (Junos OS) provides features to help secure ports on the switch. Ports can be categorized as either trusted or untrusted. You apply policies appropriate to each category to protect ports against various types of attacks.

Basic port security features are enabled in the switch's default configuration. You can configure additional features with minimal configuration steps.

Depending on the particular feature, you can configure the feature either on:

- VLANs—A specific VLAN or all VLANs
- Interfaces—A specific interface or all interfaces

**NOTE:** If you configure one of the port security features on all VLANs or all interfaces, those port security features are thereby enabled on all VLANs or all interfaces that are not explicitly configured with other port security features.

However, if you explicitly configure one of the port security features on a specific VLAN or on a specific interface, you must explicitly configure any additional port security features that you want to apply to that VLAN or interface. Otherwise, the switch software automatically applies the default values for the other port security features.

For example, if you enable DHCP snooping on all VLANs and enable IP source guard (not supported on the QFX Series switch) only on a specific VLAN, you must also explicitly enable DHCP snooping on that specific VLAN. If you do not explicitly enable DHCP snooping on that VLAN, the default value of no DHCP snooping applies to it.

---

Port security features on switches are:

- DHCP option 82—Also known as the DHCP relay agent information option. This feature helps protect the switch against attacks such as spoofing of IP addresses and media access control (MAC) addresses and DHCP IP address starvation. Option 82 provides information about the network location of a DHCP client, and the DHCP server uses this information to implement IP addresses or other parameters for the client.
- DHCP snooping—Filters and blocks ingress DHCP server messages on untrusted ports; builds and maintains an IP address/MAC address binding database (called the DHCP snooping database). You enable this feature on VLANs.

- Dynamic ARP inspection (DAI)—Prevents ARP spoofing attacks. ARP requests and replies are compared against entries in the DHCP snooping database, and filtering decisions are made based on the results of those comparisons. You enable this feature on VLANs.
- IP source guard—Mitigates the effects of IP address spoofing attacks on the Ethernet LAN. With IP source guard enabled, the source IP address in the packet sent from an untrusted access interface is validated against the source MAC address in the DHCP snooping database. The packet is forwarded if the source IP address to source MAC address binding is valid; if the binding is not valid, the packet is discarded. You enable this feature on VLANs.

**NOTE:** IP source guard is not supported on the QFX Series.

- MAC limiting—Protects against flooding of the Ethernet switching table (also known as the MAC forwarding table or Layer 2 forwarding table). You can enable this feature on:
  - Access interfaces (ports)
  - Access interface based on its membership within a specific VLAN

**NOTE:** You can configure a MAC limit on a VLAN in the [edit vlans] hierarchy. However, configuring the MAC limit on a VLAN does not provide protection against flooding of the Ethernet switching table. When incoming packets exceed the MAC limit on a VLAN, the event is logged, but the packets are not dropped. No other action can be configured. Therefore, setting the MAC limit on a VLAN is not considered a port security feature.

- MAC move limiting—Tracks MAC movement and detects MAC spoofing on access ports. You enable this feature on VLANs.
- Persistent MAC learning—Also known as sticky MAC. Persistent MAC learning allows dynamically learned MAC addresses to persist through switch reboots. You enable this feature on interfaces.
- Trusted DHCP server—Configuring the DHCP server on a trusted port protects against rogue DHCP servers sending leases. You enable this feature on interfaces (ports). By default, access ports are untrusted, and trunk ports are trusted. (Access ports are the switch ports that connect to Ethernet endpoints such as user PCs and laptops, servers, and printers. Trunk ports are the switch ports that connect to other Ethernet switches or to routers.)

## Understanding DHCP Snooping for Port Security

DHCP snooping allows a switch to monitor and control DHCP messages received from untrusted devices connected to the switch. When DHCP snooping is enabled, the system snoops the DHCP messages to view DHCP lease information and build and maintain a database of valid IP address to MAC address (IP-MAC) bindings. This database is called the DHCP snooping database. Only clients with valid bindings are allowed access to the network.

---

### DHCP Snooping Basics

Dynamic Host Configuration Protocol (DHCP) allocates IP addresses dynamically, “leasing” addresses to devices so that the addresses can be reused when no longer needed. Hosts and end devices that require IP addresses obtained through DHCP must communicate with a DHCP server across the LAN.

DHCP snooping acts as a guardian of network security by keeping track of valid IP addresses assigned to downstream network devices by a trusted DHCP server (the server is connected to a trusted network port). By default, all trunk ports on the switch are trusted (**dhcp-trusted**) and all access ports are untrusted (**no-dhcp-trusted**) for DHCP snooping. You can modify these DHCP defaults on each of the switch's interfaces. See **dhcp-trusted**.

When DHCP snooping is enabled, the lease information from the switch (which is a DHCP client) is used to create the DHCP snooping database, which is a mapping of IP address to VLAN–MAC–address pairs. For each VLAN–MAC–address pair, the database stores the corresponding IP address.

Entries in the DHCP database are updated in the following events:

- When a DHCP client releases an IP address (sends a DHCPRELEASE message), the associated mapping entry is deleted from the database.
- When you move a network device from one VLAN to another, typically the device has to acquire a new IP address. So its entry in the database, including the VLAN ID, is updated.
- When the lease time (timeout value) assigned by the DHCP server expires, the associated entry is deleted from the database.

**TIP:** By default, the IP-MAC bindings are lost when the switch is rebooted and DHCP clients (the network devices, or hosts) must reacquire bindings. However, you can configure the bindings to persist by setting the `dhcp-snooping-file` statement to store the database file either locally or remotely.

You can configure the switch to snoop DHCP server responses only from particular VLANs. Doing this prevents spoofing of DHCP server messages.

You configure DHCP snooping per VLAN, not per interface (port). By default, DHCP snooping is disabled for all VLANs. You can enable DHCP snooping on all VLANs or on specific VLANs.

**NOTE:** If you configure DHCP for all VLANs and you enable a different port security feature on a specific VLAN, you must also explicitly enable DHCP on that VLAN. Otherwise, the default behavior of no DHCP snooping applies to that VLAN.

**TIP:** For private VLANs, enable DHCP snooping on the primary VLAN. If you enable DHCP snooping only on a community VLAN, DHCP messages coming from private VLAN trunk ports are not snooped.

## DHCP Snooping Process

The process of DHCP snooping entails the following steps:

1. The network device sends a DHCPDISCOVER packet to request an IP address.
2. The switch forwards the packet to the DHCP server.
3. The server sends a DHCPOFFER packet to offer an address. If the DHCPOFFER packet is from a trusted interface, switch forwards the packet to the DHCP client.
4. The network device sends a DHCPREQUEST packet to accept the IP address. The switch snoops this packet and adds an IP-MAC placeholder binding to the database.

The entry is considered a placeholder until a DHCPACK packet is received from the server. Until then, the IP address could still be assigned to some other host.

5. The server sends a DHCPACK packet to assign the IP address or a DHCPNAK packet to deny the address request.
6. The switch updates the DHCP database in accordance with the type of packet received:
  - Upon receipt of a DHCPACK packet, the switch updates lease information for the IP-MAC binding in its database.
  - Upon receipt of a DHCPNACK packet, the switch deletes the placeholder.

**NOTE:** DHCPDISCOVER and DHCPOFFER packets are not snooped. The DHCP database is updated only after the DHCPREQUEST packet has been sent.

---

For general information about the messages that the DHCP client and DHCP server exchange during the assignment of an IP address for the client, see the [Junos OS System Basics Configuration Guide](#).

### DHCP Server Access

---

Switch access to the DHCP server can be configured in three ways:

- [Switch, DHCP Clients, and DHCP Server Are All on the Same VLAN on page 4112](#)
- [Switch Acts as DHCP Server on page 4113](#)
- [Switch Acts as Relay Agent on page 4114](#)

#### **Switch, DHCP Clients, and DHCP Server Are All on the Same VLAN**

When the switch, DHCP clients, and DHCP server are all members of the same VLAN, the DHCP server can be connected to the switch in one of two ways:

- The server is directly connected to the same switch as the one connected to the DHCP clients (the hosts, or network devices, that are requesting IP addresses from the server). You must configure the port that connects the server to the switch as a trusted port. See [Figure 148 on page 4113](#).
- The server is directly connected to a switch that is itself directly connected through a trunk port to the switch that the DHCP clients are connected to. The trunk port is configured by default as a trusted port. The switch that the DHCP server is connected to is not configured for DHCP snooping. See [Figure 149 on page 4113](#)—in the figure, ge-0/0/11 is a trusted trunk port.

Figure 148: DHCP Server Connected Directly to Switch

Figure 149: DHCP Server Connected Directly to Switch 2, with Switch 2 Connected to Switch 1 Through a Trusted Trunk Port

**Switch Acts as DHCP Server**

**NOTE:** This is not supported on the QFX Series.

The switch itself is configured as a DHCP server; this is known as a *local configuration*. See [Figure 150 on page 4114](#).

**Figure 150: Switch Is the DHCP Server**

#### ***Switch Acts as Relay Agent***

The switch functions as a relay agent when the DHCP clients or the DHCP server is connected to the switch through a Layer 3 interface (on the switch, these interfaces are configured as routed VLAN interfaces, or RVIs). These trunk interfaces are trusted by default.

These two scenarios illustrate the switch acting as a relay agent:

- The DHCP server and clients are in different VLANs.
- The switch is connected to a router that is in turn connected to the DHCP server. See [Figure 151 on page 4115](#).

Figure 151: Switch Acting as Relay Agent Through Router to DHCP Server

### DHCP Snooping Table

Juniper Networks Junos operating system (Junos OS) creates a DHCP snooping information table that displays the content of the DHCP snooping database. The table shows the current IP-MAC bindings, the lease time, type of binding, names of associated VLANs, and associated interfaces. To view the table, type the **show dhcp snooping binding** operational mode command:

```
user@switch> show dhcp snooping binding
```

DHCP Snooping Information:

| MAC address       | IP address | Lease (seconds) | Type    | VLAN     | Interface  |
|-------------------|------------|-----------------|---------|----------|------------|
| 00:05:85:3A:82:77 | 192.0.2.17 | 600             | dynamic | employee | ge-0/0/1.0 |
| 00:05:85:3A:82:79 | 192.0.2.18 | 653             | dynamic | employee | ge-0/0/1.0 |
| 00:05:85:3A:82:80 | 192.0.2.19 | 720             | dynamic | employee | ge-0/0/2.0 |

### Static IP Address Additions to the DHCP Snooping Database

You can add specific static IP addresses to the database and have the addresses dynamically assigned through DHCP snooping. To add static IP addresses, you supply the IP address, the MAC address of the device, the interface on which the device is connected, and the VLAN with which the interface is associated. No lease time is assigned to the entry. The statically configured entry never expires.

### Snooping DHCP Packets That Have Invalid IP Addresses

If you enable DHCP snooping on a VLAN and then devices on that VLAN send DHCP packets that request invalid IP addresses, these invalid IP addresses are stored in the DHCP snooping database until they are deleted when their default timeout is reached. To eliminate this unnecessary consumption of space in the DHCP snooping database,

the switch drops the DHCP packets that request invalid IP addresses, preventing the snooping of these packets. The invalid IP addresses are:

- 0.0.0.0
- 128.0.x.x
- 191.255.x.x
- 192.0.0.x
- 223.255.255.x
- 224.x.x.x
- 240.x.x.x to 255.255.255.255

---

### Prioritizing Snooped Packets

---

**NOTE:** Prioritizing DHCP snooped packets is not supported on the QFX Series.

---

You can use CoS forwarding classes and queues to prioritize DHCP snooped packets for a specified VLAN. This type of configuration places the DHCP snooped packets for that VLAN in the desired egress queue, so that the security procedure does not interfere with the transmittal of high-priority traffic.

## Understanding DAI for Port Security

Dynamic ARP inspection (DAI) protects switches against ARP spoofing.

DAI inspects ARP packets on the LAN and uses the information in the DHCP snooping database on the switch to validate ARP packets and to protect against ARP cache poisoning. ARP requests and replies are compared against entries in the DHCP snooping database, and filtering decisions are made based on the results of those comparisons. When an attacker tries to use a forged ARP packet to spoof an address, the switch compares the address to entries in the database. If the MAC address or IP address in an ARP packet does not match a valid entry in the DHCP snooping database, the packet is dropped.

ARP packets are sent to the Routing Engine and are rate-limited to protect the switch from CPU overload.

- [Address Resolution Protocol on page 4117](#)
- [ARP Spoofing on page 4117](#)
- [Dynamic ARP Inspection \(DAI\) on page 4118](#)
- [Prioritizing Inspected Packets on page 4118](#)

### Address Resolution Protocol

Sending IP packets on a multiaccess network requires mapping an IP address to an Ethernet media access control (MAC) address.

Ethernet LANs use Address Resolution Protocol (ARP) to map MAC addresses to IP addresses.

The switch maintains this mapping in a cache that it consults when forwarding packets to network devices. If the ARP cache does not contain an entry for the destination device, the host (the DHCP client) broadcasts an ARP request for that device's address and stores the response in the cache.

### ARP Spoofing

ARP spoofing (also known as ARP poisoning or ARP cache poisoning) is one way to initiate man-in-the-middle attacks. The attacker sends an ARP packet that spoofs the MAC address of another device on the LAN. Instead of the switch sending traffic to the proper network device, it sends it to the device with the spoofed address that is impersonating the proper device. If the impersonating device is the attacker's machine, the attacker receives all the traffic from the switch that should have gone to another device. The result is that traffic from the switch is misdirected and cannot reach its proper destination.

One type of ARP spoofing is gratuitous ARP, which is when a network device sends an ARP request to resolve its own IP address. In normal LAN operation, gratuitous ARP messages indicate that two devices have the same MAC address. They are also broadcast when a network interface card (NIC) in a device is changed and the device is rebooted, so that other devices on the LAN update their ARP caches. In malicious situations, an attacker can poison the ARP cache of a network device by sending an ARP response to

the device that directs all packets destined for a certain IP address to go to a different MAC address instead.

To prevent MAC spoofing through gratuitous ARP and through other types of spoofing, the switches examine ARP responses through DAI.

### Dynamic ARP Inspection (DAI)

---

DAI examines ARP requests and responses on the LAN and validates ARP packets. The switch intercepts ARP packets from an access port and validates them against the DHCP snooping database. If no IP-MAC entry in the database corresponds to the information in the ARP packet, DAI drops the ARP packet and the local ARP cache is not updated with the information in that packet. DAI also drops ARP packets when the IP address in the packet is invalid.

Junos OS for EX Series switches and the QFX Series uses DAI for ARP packets received on access ports because these ports are untrusted by default. Trunk ports are trusted by default, so ARP packets bypass DAI on them.

You configure DAI for each VLAN, not for each interface (port). By default, DAI is disabled for all VLANs. You can set an interface to be trusted for ARP packets by setting **dhcp-trusted** on that port.

For packets directed to the switch to which a network device is connected, ARP queries are broadcast on the VLAN. The ARP responses to those queries are subjected to the DAI check.

For DAI, all ARP packets are trapped to the Routing Engine. To prevent CPU overloading, ARP packets destined for the Routing Engine are rate-limited.

If the DHCP server goes down and the lease time for an IP-MAC entry for a previously valid ARP packet runs out, that packet is blocked.

### Prioritizing Inspected Packets

---

**NOTE:** This is not supported on the QFX Series.

---

You can use CoS forwarding classes and queues to prioritize DAI packets for a specified VLAN. This type of configuration places inspected packets for that VLAN in the desired egress queue, ensuring that the security procedure does not interfere with the transmittal of high-priority traffic.

## Understanding MAC Limiting and MAC Move Limiting for Port Security

MAC limiting protects against flooding of the Ethernet switching table (also known as the MAC forwarding table or Layer 2 forwarding table). You enable this feature on Layer 2 interfaces (ports). MAC move limiting detects MAC movement and MAC spoofing on access interfaces. You enable this feature on VLANs.

- [MAC Limiting on page 4119](#)
- [MAC Move Limiting on page 4120](#)
- [Actions for MAC Limiting on page 4120](#)
- [MAC Addresses That Exceed the MAC Limit or MAC Move Limit on page 4120](#)

### MAC Limiting

MAC limiting sets a limit on the number of MAC addresses that can be learned on a single Layer 2 access interface or on all the Layer 2 access interfaces on the switch. Junos OS provides two MAC limiting methods:

- Maximum number of MAC addresses—You configure the maximum number of dynamic MAC addresses allowed per interface. When the limit is exceeded, incoming packets with new MAC addresses can be ignored, dropped, or logged. You can also specify that the interface be shut down or temporarily disabled.
- Allowed MAC addresses—You configure specific “allowed” MAC addresses for the access interface. Any MAC address that is not in the list of configured addresses is not learned, and the switch logs an appropriate message. Allowed MAC binds MAC addresses to a VLAN so that the address does not get registered outside the VLAN. If an allowed MAC setting conflicts with a dynamic MAC setting, the allowed MAC setting takes precedence.

**NOTE:** If you do not want the system to log messages about invalid MAC addresses received by an interface that has been configured for allowed MAC addresses, disable the logging by configuring the [no-allowed-mac-log](#) statement.

You configure MAC limiting per interface, not per VLAN. You can specify the maximum number of dynamic MAC addresses that can be learned on a single Layer 2 access interface (including tagged-access interfaces) or on all Layer 2 access interfaces.

## MAC Move Limiting

---

MAC move limiting causes the switch to track the number of times a MAC address can move to a new interface (port). It can help to prevent MAC spoofing, and it can also detect and prevent loops.

If a MAC address moves more than the configured number of times within 1 second, the switch performs the configured action. You can configure MAC move limiting to apply to all VLANs or to a specific VLAN.

## Actions for MAC Limiting

---

You can choose to have one of the following actions performed when the limit of MAC addresses or the limit of MAC moves is exceeded:

- **drop**—Drop the packet and generate a system log entry. This is the default.
- **log**—Do not drop the packet but generate a system log entry.
- **none**—Take no action.
- **shutdown**—Disable the interface and generate an alarm. If you configure the switch with the **port-error-disable** statement, the disabled interface recovers automatically upon expiration of the specified timeout. If this is not configured, you can bring up the disabled interfaces by running the **clear ethernet-switching port-error** command.

See descriptions of results of these various action settings in “[Verifying That MAC Limiting Is Working Correctly](#)” on page 4280.

If you set a MAC limit to apply to all interfaces on the switch, you can override that setting for a particular interface by specifying action **none**. See “[Configuring the none Action to Override a MAC Limit Applied to All Interfaces \(CLI Procedure\)](#)” on page 4192

## MAC Addresses That Exceed the MAC Limit or MAC Move Limit

---

If you have configured the **port-error-disable** statement, you can view which interfaces are temporarily disabled because the MAC limit or MAC move limit was exceeded. Use the **show ethernet-switching interfaces** command.

The log messages that indicate the MAC limit or MAC move limit has been exceeded include the offending MAC addresses.

## Understanding Trusted and Untrusted Ports

By default, all access ports are untrusted and all trunk ports are trusted in regard to DHCP. Trusted ports allow DHCP servers to provide IP addresses and other information to requesting devices. Untrusted ports drop traffic from DHCP servers to prevent unauthorized servers from providing any configuration information to clients.

If you attach a DHCP server to an access port, you must configure the port as trusted. Before you do so, ensure that the server is physically secure—that is, that access to the server is monitored and controlled.

## Understanding Trusted DHCP Servers for Port Security

Any interface on the switch that connects to a DHCP server can be configured as a trusted port. Configuring a DHCP server on a trusted port protects against rogue DHCP servers sending leases.

Ensure that the DHCP server interface is physically secure—that is, that access to the server is monitored and controlled at the site—before you configure the port as trusted.

## Understanding DHCP Option 82 for Port Security

You can use DHCP option 82, also known as the DHCP relay agent information option, to help protect the switch against attacks such as spoofing (forging) of IP addresses and MAC addresses, and DHCP IP address starvation. Hosts on untrusted access interfaces on Ethernet LAN switches send requests for IP addresses in order to access the Internet. The switch forwards or relays these requests to DHCP servers, and the servers send offers for IP address leases in response. Attackers can use these messages to perpetrate address spoofing and starvation.

Option 82 provides information about the network location of a DHCP client, and the DHCP server uses this information to implement IP addresses or other parameters for the client. The Juniper Networks Junos operating system (Junos OS) implementation of DHCP option 82 supports RFC 3046, *DHCP Relay Agent Information Option*, at <http://tools.ietf.org/html/rfc3046>.

This topic covers:

- [DHCP Option 82 Processing on page 4122](#)
- [Suboption Components of Option 82 on page 4123](#)
- [Configurations That Support Option 82 on page 4123](#)

---

### DHCP Option 82 Processing

If DHCP option 82 is enabled on the switch, then when a DHCP client that is connected to the switch on an untrusted interface sends a DHCP request, the switch inserts information about the client's network location into the packet header of that request. The switch then sends the request to the DHCP server. The DHCP server reads the option 82 information in the packet header and uses it to implement the IP address or another parameter for the client. See “[Suboption Components of Option 82](#)” on page 4123 for details about option 82 information.

You can enable DHCP option 82 on a single VLAN or on all VLANs on the switch. You can also configure it on Layer 3 interfaces (in routed VLAN interfaces, or RVIs) when the switch is functioning as a relay agent.

When option 82 is enabled on the switch, then this sequence of events occurs when a DHCP client sends a DHCP request:

1. The switch receives the request and inserts the option 82 information in the packet header.
2. The switch forwards or relays the request to the DHCP server.
3. The server uses the DHCP option 82 information to formulate its reply and sends a response back to the switch. It does not alter the option 82 information.
4. The switch strips the option 82 information from the response packet.
5. The switch forwards the response packet to the client.

**NOTE:** To use the DHCP option 82 feature, you must ensure that the DHCP server is configured to accept option 82. If it is not configured to accept option 82, then when it receives requests containing option 82 information, it does not use the information in setting parameters and it does not echo the information in its response message.

### Suboption Components of Option 82

When configuring DHCP option 82, you can use the following suboptions:

- **circuit ID**—Identifies the circuit (interface and/or VLAN) on the switch on which the request was received. The circuit ID contains the interface name and/or VLAN name, with the two elements separated by a colon—for example, **xe-0/0/10:vlan1**. If the request packet is received on a Layer 3 interface, the circuit ID is just the interface name—for example, **xe-0/0/10**.

Use the **prefix** option to add an optional prefix to the circuit ID. If you enable the **prefix** option, the hostname for the switch is used as the prefix; for example, **switch1:xe-0/0/10:vlan1**.

You can also specify that the interface description be used rather than the interface name and that the VLAN ID be used rather than the VLAN name.

- **remote ID**—Identifies the host. By default, the remote ID is the MAC address of the switch. You can specify that the remote ID be the hostname of the switch, the interface description, or a character string of your choice. You can also add an optional prefix to the remote ID.
- **vendor ID**—Identifies the vendor of the host. If you specify the **vendor-id** option but do not enter a value, the default value **Juniper** is used. To specify a value, you type a character string.

### Configurations That Support Option 82

You can use option 82 with the following configurations:

- The DHCP client and the DHCP server are on the same VLAN. In this case the switch forwards the requests from the clients on untrusted access interfaces to the server on a trusted interface. For this configuration, you set DHCP option 82 at the **[edit ethernet-switching-options secure-access-port vlan]** hierarchy level.
- The DHCP client or the DHCP server is connected to the switch through a Layer 3 interface and the switch is configured to relay DHCP requests. [Figure 152 on page 4124](#) illustrates a scenario for the switch-as-relay-agent; in this instance, the switch relays requests through a router to the server.

Figure 152: Switch Relays DHCP Requests to Server

For the configuration shown in [Figure 152 on page 4124](#), you set DHCP option 82 at the `[edit forwarding-options helpers bootp]` hierarchy level.

## Understanding Static ARP Entries

You can create explicit mappings between IP addresses and MAC addresses, which are called static ARP table entries. Unlike dynamically learned ARP entries, static entries do not age out. You might want to create static ARP entries in a troubleshooting situation or if your device is unable to learn a MAC address dynamically for any reason.

## Device Security

---

- [Understanding Storm Control on page 4125](#)
- [Understanding Unknown Unicast Forwarding on page 4126](#)

### Understanding Storm Control

A traffic storm occurs when broadcast packets prompt receiving devices to broadcast packets in response. This prompts further responses, creating a snowball effect. The switch is flooded with packets, which creates unnecessary traffic that leads to poor performance or even a complete loss of service by some clients. Storm control causes a device to monitor traffic levels and take a specified action when a specified traffic level—called the *storm control level*—is exceeded, thus preventing packets from proliferating and degrading service. You can configure devices to drop broadcast and unknown unicast packets, shut down interfaces, or temporarily disable interfaces when the storm control level is exceeded.

By default, storm control is enabled on all interfaces at a level of 80 percent of the available bandwidth. You can change the storm control level by configuring it as a specific bandwidth value. (The **level** configuration statement, which allows you to configure the storm control level as a percentage of the combined broadcast and unknown unicast streams, is deprecated and might be removed from future releases. We recommend that you phase out its use and replace it with the **bandwidth** statement.)

**NOTE:** When you configure storm control bandwidth, the value you configure is rounded off internally to the closest multiple of 64 Kbps, and the rounded-off value represents the bandwidth that is actually enforced. For example, if you configure a bandwidth limit of 150 Kbps, storm control enforces a bandwidth limit of 128 Kbps.

**NOTE:** Storm control must be disabled on all Ethernet interfaces that belong to the FCoE VLAN to prevent FCoE traffic from being dropped. Configuring storm control on an Ethernet interface and including that interface in an FCoE-FC gateway may have undesirable effects, including FCoE packet loss. After disabling storm control on all interfaces, enable storm control on any interfaces that are not part of an FCoE-FC gateway on which you want to use storm control.

**CAUTION:** The Junos OS allows you to configure a storm control value that exceeds the bandwidth of the interface. If you configure an interface this way, storm control does not drop broadcast or unknown unicast packets even if they consume all the available bandwidth.

Broadcast, multicast, and unicast packets are sent as part of normal operations, so to recognize a storm, you must be able to identify when traffic has reached an abnormal level. Suspect a storm when operations begin timing out and network response times slow down. Users might be unable to access expected services. Monitor the percentage of broadcast and unknown unicast traffic in the network when it is operating normally. This data can then be used as a benchmark to determine when traffic levels are too high. You can then configure storm control to set the level at which you want to drop broadcast and unknown unicast traffic.

- [storm-control on page 1641](#)

## Understanding Unknown Unicast Forwarding

Unknown unicast packets have unknown destination MAC addresses. By default, these packets are flooded out all the ports in the VLAN, which can trigger a traffic storm and cause security issues and performance degradation. To prevent storms, you can configure a VLAN to forward unknown unicast traffic to a trunk port, which prevents the packets from being flooded.

### Firewall and Policer Configuration Examples

---

- [Example: Using Filter-Based Forwarding to Route Application Traffic to a Security Device on page 4127](#)
- [Example: Using Two-Color Policers and Prefix Lists on page 4131](#)
- [Example: Using Policers to Manage Oversubscription on page 4134](#)

### Example: Using Filter-Based Forwarding to Route Application Traffic to a Security Device

You can configure filter-based forwarding by using a firewall filter to forward matched traffic to a specific virtual routing instance.

This example describes how to set up filter-based forwarding:

- [Requirements on page 4127](#)
- [Overview and Topology on page 4128](#)
- [Configuration on page 4128](#)
- [Verification on page 4130](#)

#### Requirements

---

This example requires Junos OS Release 12.2X50-D20 or later.

## Overview and Topology

In this example, traffic from one application server that is destined for a different application server is matched by a firewall filter based on the IP address of the source application server. Any matching packets are routed to a virtual routing instance that sends the traffic to a security device. In this case, the security device must be able to forward the traffic to the destination application server. For this example, assume that the address of the destination application server is 192.168.0.1.

## Configuration

To configure filter-based forwarding:

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste them into the CLI at the **[edit]** hierarchy level.

```
[edit]
set interfaces xe-0/0/0 unit 0 family inet address 10.1.0.1/24
set interfaces xe-0/0/3 unit 0 family inet address 10.1.3.1/24
set firewall family inet filter f1 term t1 from source-address 10.1.0.50/32
set firewall family inet filter f1 term t1 from protocol tcp
set interfaces xe-0/0/0 unit 0 family inet filter input f1
set routing-instances vrf01 instance-type virtual-router
set routing-instances vrf01 interface xe-0/0/3.0
set routing-instances vrf01 routing-options static route 192.168.0.1/24 next-hop 10.1.3.254
set firewall family inet filter f1 term t1 then routing-instance vrf01
```

### Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the CLI User Guide. To configure filter-based forwarding:

1. Configure an interface to connect to the application server:  

```
[edit interfaces]
user@switch# set xe-0/0/0 unit 0 family inet address 10.1.0.1/24
```
2. Configure an interface to connect to the security device:  

```
[edit interfaces]
user@switch# set xe-0/0/3 unit 0 family inet address 10.1.3.1/24
```
3. Create a firewall filter that matches packets based on the address of the application server that the traffic will be sent from. Also configure the filter so that it matches only TCP packets:  

```
[edit firewall]
user@switch# set family inet filter f1 term t1 from source-address 10.1.0.50/32
user@switch# set firewall family inet filter f1 term t1 from protocol tcp
```
4. Apply the filter to the interface that connects to the source application server and configure it to match incoming packets:  

```
[edit interfaces]
user@switch# set xe-0/0/0 unit 0 family inet filter input f1
```
5. Create a virtual router:  

```
[edit]
user@switch# set routing-instances vrf01 instance-type virtual-router
```
6. Associate the virtual router with the interface that connects to the security device:

- ```
[edit routing-instances]
user@switch# set vrf01 interface xe-0/0/3.0
```
7. Configure the routing information for the virtual routing instance:
- ```
[edit routing-instances]
user@switch# set vrf01 routing-options static route 192.168.0.1/24 next-hop 10.1.3.254
```
8. Set the filter to forward packets to the virtual router:
- ```
[edit firewall]
user@switch# set family inet filter f1 term t1 then routing-instance vrf01
```

### Results

Check the results of the configuration:

```
user@switch> show configuration
interfaces {
  xe-0/0/0 {
    unit 0 {
      family inet {
        filter {
          input f1;
        }
        address 10.1.0.1/24;
      }
    }
  }
  xe-0/0/3 {
    unit 0 {
      family inet {
        address 10.1.3.1/24;
      }
    }
  }
}
firewall {
  family inet {
    filter f1 {
      term t1 {
        from {
          source-address {
            10.1.0.50/32;
          }
          protocol tcp;
        }
        then {
          routing-instance vrf01;
        }
      }
    }
  }
}
routing-instances {
  vrf01 {
    instance-type virtual-router;
    interface xe-0/0/1.0;
    routing-options {
```

```

static {
    route 12.34.56.0/24 next-hop 10.1.3.254;
}
}
}
}

```

## Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying That Filter-Based Forwarding Was Configured on page 4130](#)

### Verifying That Filter-Based Forwarding Was Configured

**Purpose** Verify that filter-based forwarding was properly enabled on the switch.

**Action** 1. Use the `show interfaces filters` command:

```

user@switch> show interfaces filters xe-0/0/0.0
Interface      Admin Link Proto Input Filter      Output Filter
xe-0/0/0.0      up    down inet f1

```

2. Use the `show route forwarding-table` command:

```

user@switch> show route forwarding-table

Routing table: default.inet
Internet:
Destination      Type RtRef Next hop      Type Index NhRef Netif
default          user  1 0:12:f2:21:cf:0 ucst  331  4 me0.0
default          perm  0                rjct  36   3

## Example: Using Two-Color Policers and Prefix Lists

If you provide specific amounts of bandwidth to internal or external customers, you can use policing to make sure that customers do not consume more bandwidth than they should receive. For example, you might connect many customers to one 10-Gbps interface and want to ensure that none of them congest the interface by using more bandwidth than they have been allotted.

You could accomplish this by creating a two-color policer similar to the following for each customer:

```

firewall {
  policer Limit-Customer-1 {
    if-exceeding {
      bandwidth-limit 100m;
      burst-size-limit 150m;
    }
    then discard;
  }
}

```

Creating a policer for each customer is clearly not a scalable solution, however. As an alternative, you can create prefix lists that group classes of customers and then create policers for each prefix list. For example, you could create prefix lists such as **Class-A-Customer-Prefixes**, **Class-B-Customer-Prefixes**, and **Class-C-Customer-Prefixes** (at the **[edit policy-options]** hierarchy level) and create the following corresponding policers:

```

firewall {
  policer Class-A {
    if-exceeding {
      bandwidth-limit 100m;
      burst-size-limit 150m;
    }
  }
}

```

```
    }
    then discard;
  }
  policer Class-B {
    if-exceeding {
      bandwidth-limit 75m;
      burst-size-limit 100m;
    }
    then discard;
  }
  policer Class-C {
    if-exceeding {
      bandwidth-limit 50m;
      burst-size-limit 75m;
    }
    then discard;
  }
}
```

You must create filter terms that specify the prefix lists in their **from** statements and the corresponding policers in their **then** statements similar to the following:

```
firewall
family inet {
  filter Class-A-Customers {
    term term-1 {
      from {
        destination-prefix-list {
          Class-A-Customer-Prefixes;
        }
      }
      then policer Class-A;
    }
  }
  filter Class-B-Customers {
    term term-1 {
      from {
        destination-prefix-list {
          Class-B-Customer-Prefixes;
        }
      }
      then policer Class-B;
    }
  }
  filter Class-C-Customers {
    term term-1 {
      from {
        destination-prefix-list {
          Class-C-Customer-Prefixes;
        }
      }
      then policer Class-C;
    }
  }
}
```

Here are the steps to create this firewall configuration:

1. Create the first policer:

```
[edit firewall]
user@switch# set policer Class-A if-exceeding bandwidth-limit 100m burst-size-limit 150m
user@switch# set policer Class-A then discard
```

2. Create the second policer:

```
[edit firewall]
user@switch# set policer Class-B if-exceeding bandwidth-limit 75m burst-size-limit 100m
user@switch# set policer Class-B then discard
```

3. Create the third policer:

```
[edit firewall]
user@switch# set policer Class-C if-exceeding bandwidth-limit 50m burst-size-limit 75m
user@switch# set policer Class-C then discard
```

4. Create a filter for class A customers:

```
[edit firewall]
user@switch# edit family inet filter Class-A-Customers
```

5. Configure the filter to send packets matching the Class-A-Customer-Prefixes prefix list to the Class-A policer:

```
[edit firewall family inet filter Class-A-Customers]
user@switch# set term term-1 from source-prefix-list Class-A-Customers
user@switch# set term term-1 then policer Class-A
```

6. Create a filter for class B customers:

```
[edit firewall]
user@switch# edit family inet filter Class-B-Customers
```

7. Configure the filter to send packets matching the Class-B-Customer-Prefixes prefix list to the Class-B policer:

```
[edit firewall family inet filter Class-B-Customers]
user@switch# set term term-1 from source-prefix-list Class-B-Customers
user@switch# set term term-1 then policer Class-B
```

8. Create a filter for class C customers:

```
[edit firewall]
user@switch# edit family inet filter Class-C-Customers
```

9. Configure the filter to send packets matching the Class-C-Customer-Prefixes prefix list to the Class-C policer:

```
[edit firewall family inet filter Class-C-Customers]
user@switch# set term term-1 from source-prefix-list Class-C-Customers
user@switch# set term term-1 then policer Class-C
```

10. Apply the filters you created to the appropriate interfaces in the output direction.

**NOTE:** Note that the implicit deny statement in this filter will block traffic from any source that does not match one of the prefix lists. If you want the filter to allow this traffic, you must include an explicit term for this purpose.

- [Applying Firewall Filters to Interfaces on page 4095](#)

- prefix-list

### Example: Using Policers to Manage Oversubscription

You might want to use a policer when an interface is oversubscribed and you want to control what will happen if congestion occurs. For example, you might have servers connected to a switch as listed in [Table 287 on page 4134](#).

**Table 287: Servers Connected to Switch**

Server Type	Connection	IP Address
Network application server	1-gigabit interface	10.0.0.1
Authentication server	1-gigabit interface	10.0.0.2
Database server	10-gigabit interface	10.0.0.3

In this example, users access services provided by the network application server, which requests information from the database server as appropriate. When it receives a request from a user, the network application server first contacts the authentication server to verify the user's credentials. When a user is authenticated and the network application server provides the requested service, all the packets sent from the database server to the application server must transit the 1-Gigabit Ethernet interface connected to the application server twice—once on ingress to the application server and again on egress to the user.

The sequence of events for a user session is as follows:

1. A user connects to the application server and requests a service.
2. The application server requests the user's credentials and relays them to the authentication server.
3. If the authentication server verifies the credentials, the application server initiates the requested service.
4. The application server requests the files necessary to meet the user's request from the database server.
5. The database server sends the requested files to the application server.
6. The application server includes the requested files in its response to the user.

Traffic from the database server to the application server might congest the 1-gigabit interface to which that the application server is connected. This congestion might prevent the server from responding to requests from users and creating new sessions for them. You can use policing to make sure that this does not occur.

To create this firewall configuration, perform the following steps on the database server:

1. Create a policer to drop traffic from the database server to the application server if it exceeds certain limits:

```
[edit firewall]
user@switch# set policer Database-Egress-Policer if-exceeding bandwidth-limit 400
burst-size-limit 500m
user@switch# set policer Database-Egress-Policer then discard
```

2. Create a filter to examine traffic from the database server to the application server:

```
[edit firewall]
user@switch# edit family inet filter Database-Egress-Filter
```

3. Configure the filter to apply the policer to traffic egressing the database server and destined for the application server:

```
[edit firewall family inet filter Database-Egress-Filter]
user@switch# set term term-1 from destination-address 10.0.0.1
user@switch# set term term-1 then policer Database-Egress-Policer
```

4. If required, configure a term to allow traffic from the database server to other destinations (otherwise the traffic will be dropped by the implicit deny statement):

```
[edit firewall family inet filter Database-Egress-Filter]
user@switch# set term term-2 then accept
```

Note that omitting a **from** statement causes the term to match all packets, which is the desired behavior.

5. Install the egress filter as an output filter on the database server interface that is connected the application server:

```
[edit interfaces]
user@switch# set xe-0/0/3 unit 0 family inet filter output Database-Egress-Filter
```

Here is how the final configuration would appear:

```
firewall {
  policer Database-Egress-Policer {
    if-exceeding {
      bandwidth-limit 400;
      burst-size-limit 500m;
    }
    then discard;
  }
  family inet {
    filter Database-Egress-Filter {
      term term-1 {
        from {
          destination-address {
            10.0.0.1/24;
          }
        }
        then policer Database-Egress-Policer;
      }
      term term-2 { # If required, include this term so that traffic from the database server
                    # to other destinations is allowed.
        then accept;
      }
    }
  }
}
```

```
}  
]
```

### Example: Configuring Basic Port Security Features

You can configure DHCP snooping, dynamic ARP inspection (DAI), MAC limiting, persistent MAC learning, and MAC move limiting on the access ports of switches to protect the switches and the Ethernet LAN against address spoofing and Layer 2 denial-of-service (DoS) attacks. You can also configure a trusted DHCP server and specific (allowed) MAC addresses for the switch interfaces.

This example describes how to configure basic port security features on a switch:

- [Requirements on page 4136](#)
- [Overview and Topology on page 4137](#)
- [Configuration on page 4139](#)
- [Verification on page 4140](#)

---

#### Requirements

---

This example uses the following hardware and software components:

- One EX Series switch or one QFX3500 switch

- Junos OS Release 11.4 or later for EX Series switches or Junos OS Release 12.1 or later for the QFX Series
- A DHCP server to provide IP addresses to network devices on the switch

Before you configure basic port security features, be sure you have:

- Connected the DHCP server to the switch.
- Configured a VLAN on the switch. See the task for your platform:
  - [Configuring VLANs for EX Series Switches \(CLI Procedure\)](#)
  - [“Configuring VLANs” on page 1553](#) for the QFX Series

**NOTE:** In this example, the DHCP server and its clients are all members of a single VLAN on the switch.

### Overview and Topology

Ethernet LANs are vulnerable to address spoofing and DoS attacks on network devices. To protect the devices from such attacks, you can configure:

- DHCP snooping to validate DHCP server messages
- DAI to protect against MAC spoofing
- MAC limiting to constrain the number of MAC addresses the switch adds to its MAC address cache
- MAC move limiting to help prevent MAC spoofing
- Persistent MAC learning (sticky MAC) to constrain the MAC addresses that can be learned on an interface to the first ones learned, even after a reboot of the switch
- Trusted DHCP server configured on a trusted port to protect against rogue DHCP servers sending leases

This example shows how to configure these security features on a switch connected to a DHCP server.

The setup for this example includes the VLAN **employee-vlan** on the switch. [Figure 153 on page 4138](#) illustrates the topology for this example.

Figure 153: Network Topology for Basic Port Security

The components of the topology for this example are shown in [Table 288 on page 4138](#).

Table 288: Components of the Port Security Topology

Properties	Settings
Switch hardware	One EX Series switch or one QFX3500 switch
VLAN name and ID	<b>employee-vlan</b> , tag 20
VLAN subnets	192.0.2.16/28 192.0.2.17 through 192.0.2.30 192.0.2.31 is subnet's broadcast address
Interfaces in <b>employee-vlan</b>	ge-0/0/1, ge-0/0/2, ge-0/0/3, ge-0/0/8
Interface for DHCP server	ge-0/0/8

In this example, the switch is initially configured with the default port security setup. In the default switch configuration:

- Secure port access is activated on the switch.
- DHCP snooping and DAI are disabled on all VLANs.
- All access ports are untrusted, and all trunk ports are trusted for DHCP snooping.

In the configuration tasks for this example, you set the DHCP server as trusted; you enable DHCP snooping, DAI, and MAC move limiting on a VLAN; you set a value for a MAC limit on some interfaces; you configure some specific (allowed) MAC addresses on an interface; and you configure persistent MAC learning on an interface.

## Configuration

To configure basic port security on a switch whose DHCP server and client ports are in a single VLAN:

### CLI Quick Configuration

To quickly configure basic port security on the switch, copy the following commands and paste them into the switch terminal window:

```
[edit ethernet-switching-options secure-access-port]
set interface ge-0/0/1 mac-limit 4
set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:80
set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:81
set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:83
set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:85
set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:88
set interface ge-0/0/2 mac-limit 4
set interface ge-0/0/1 persistent-learning
set interface ge-0/0/8 dhcp-trusted
set vlan employee-vlan arp-inspection
set vlan employee-vlan examine-dhcp
set vlan employee-vlan mac-move-limit 5
```

### Step-by-Step Procedure

Configure basic port security on the switch:

1. Enable DHCP snooping on the VLAN:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee-vlan examine-dhcp
```

2. Specify the interface (port) from which DHCP responses are allowed:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface ge-0/0/8 dhcp-trusted
```

3. Enable dynamic ARP inspection (DAI) on the VLAN:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee-vlan arp-inspection
```

4. Configure a MAC limit of 4 and use the default action, **drop**. (Packets are dropped, and the MAC address is not added to the Ethernet switching table if the MAC limit is exceeded on the interfaces):

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface ge-0/0/1 mac-limit 4
user@switch# set interface ge-0/0/2 mac-limit 4
```

5. Allow learned MAC addresses for a particular interface to persist across restarts of the switch and interface-down events by enabling persistent MAC learning:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface ge-0/0/1 persistent-learning
```

6. Configure a MAC move limit of 5 and use the default action, **drop**. (Packets are dropped, and the MAC address is not added to the Ethernet switching table if a MAC address has exceeded the MAC move limit):

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee-vlan mac-move-limit 5
```

7. Configure allowed MAC addresses:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:80
user@switch# set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:81
user@switch# set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:83
```

```
user@switch# set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:85
user@switch# set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:88
```

### Results

Check the results of the configuration:

```
[edit ethernet-switching-options secure-access-port]
user@switch# show
interface ge-0/0/1.0 {
    mac-limit 4;
    persistent-learning;
}
interface ge-0/0/2.0 {
    allowed-mac [ 00:05:85:3a:82:80 00:05:85:3a:82:81 00:05:85:3a:82:83
    00:05:85:3a:82:85 00:05:85:3a:82:88 ];
    mac-limit 4;
}
interface ge-0/0/8.0 {
    dhcp-trusted;
}
vlan employee-vlan {
    arp-inspection
    examine-dhcp;
    mac-move-limit 5;
}
```

### Verification

---

To confirm that the configuration is working properly:

- [Verifying That DHCP Snooping Is Working Correctly on the Switch on page 4140](#)
- [Verifying That DAI Is Working Correctly on the Switch on page 4141](#)
- [Verifying That MAC Limiting, MAC Move Limiting, and Persistent MAC Learning Are Working Correctly on the Switch on page 4141](#)
- [Verifying That Allowed MAC Addresses Are Working Correctly on the Switch on page 4142](#)

#### ***Verifying That DHCP Snooping Is Working Correctly on the Switch***

**Purpose** Verify that DHCP snooping is working on the switch.

**Action** Send some DHCP requests from network devices (here they are DHCP clients) connected to the switch.

Display the DHCP snooping information when the interface on which the DHCP server connects to the switch is trusted. The following output results when requests are sent from the MAC addresses and the server has provided the IP addresses and leases:

```
user@switch> show dhcp snooping binding
```

DHCP Snooping Information:

MAC Address	IP Address	Lease	Type	VLAN	Interface
00:05:85:3A:82:77	192.0.2.17	600	dynamic	employee-vlan	ge-0/0/1.0
00:05:85:3A:82:79	192.0.2.18	653	dynamic	employee-vlan	ge-0/0/1.0
00:05:85:3A:82:80	192.0.2.19	720	dynamic	employee-vlan	ge-0/0/2.0
00:05:85:3A:82:81	192.0.2.20	932	dynamic	employee-vlan	ge-0/0/2.0
00:05:85:3A:82:83	192.0.2.21	1230	dynamic	employee-vlan	ge-0/0/2.0
00:05:85:27:32:88	192.0.2.22	3200	dynamic	employee-vlan	ge-0/0/2.0

**Meaning** When the interface on which the DHCP server connects to the switch has been set to trusted, the output (see preceding sample) shows, for each MAC address, the assigned IP address and lease time—that is, the time, in seconds, remaining before the lease expires.

If the DHCP server had been configured as untrusted, no entries would be added to the DHCP snooping database, and nothing would be shown in the output of the **show dhcp snooping binding** command.

#### *Verifying That DAI Is Working Correctly on the Switch*

**Purpose** Verify that DAI is working on the switch.

**Action** Send some ARP requests from network devices connected to the switch.

Display the DAI information:

```
user@switch> show arp inspection statistics
```

ARP inspection statistics:

Interface	Packets received	ARP inspection pass	ARP inspection failed
ge-0/0/1.0	7	5	2
ge-0/0/2.0	10	10	0
ge-0/0/3.0	12	12	0

**Meaning** The sample output shows the number of ARP packets received and inspected per interface, with a listing of how many packets passed and how many failed the inspection on each interface. The switch compares the ARP requests and replies against the entries in the DHCP snooping database. If a MAC address or IP address in the ARP packet does not match a valid entry in the database, the packet is dropped.

#### *Verifying That MAC Limiting, MAC Move Limiting, and Persistent MAC Learning Are Working Correctly on the Switch*

**Purpose** Verify that MAC limiting, MAC move limiting, and persistent MAC learning are working on the switch.

**Action** Suppose that two packets have been sent from hosts on **ge-0/0/1** and five packets from hosts on **ge-0/0/2**, with both interfaces set to a MAC limit of 4 with the default action **drop** and **ge-0/0/1** enabled for persistent MAC learning.

Display the MAC addresses learned:

```
user@switch> show ethernet-switching table
Ethernet-switching table: 7 entries, 4 learned, 2 persistent entries
  VLAN          MAC address      Type      Age      Interfaces
  ---          -
employee-vlan   *                Flood     -        All-members
employee-vlan   00:05:85:3A:82:77 Persistent    0        ge-0/0/1.0
employee-vlan   00:05:85:3A:82:79 Persistent    0        ge-0/0/1.0
employee-vlan   00:05:85:3A:82:80 Learn        0        ge-0/0/2.0
employee-vlan   00:05:85:3A:82:81 Learn        0        ge-0/0/2.0
employee-vlan   00:05:85:3A:82:83 Learn        0        ge-0/0/2.0
employee-vlan   00:05:85:3A:82:85 Learn        0        ge-0/0/2.0
```

Now suppose packets have been sent from two of the hosts on **ge-0/0/2** after they have been moved to other interfaces more than five times in 1 second, with **employee-vlan** set to a MAC move limit of 5 with the default action **drop**.

Display the MAC addresses in the table:

```
user@switch> show ethernet-switching table
Ethernet-switching table: 7 entries, 2 learned, 2 persistent entries
  VLAN          MAC address      Type      Age      Interfaces
  ---          -
employee-vlan   *                Flood     -        All-members
employee-vlan   00:05:85:3A:82:77 Persistent    0        ge-0/0/1.0
employee-vlan   00:05:85:3A:82:79 Persistent    0        ge-0/0/1.0
employee-vlan   00:05:85:3A:82:80 Learn        0        ge-0/0/2.0
employee-vlan   00:05:85:3A:82:81 Learn        0        ge-0/0/2.0
employee-vlan   *                Flood     -        ge-0/0/2.0
employee-vlan   *                Flood     -        ge-0/0/2.0
```

**Meaning** The first sample output shows that with a MAC limit of 4 for each interface, the fifth MAC address on **ge-0/0/2** was not learned because it exceeded the MAC limit. The second sample output shows that MAC addresses for three of the hosts on **ge-0/0/2** were not learned, because the hosts had been moved back more than five times in 1 second.

Interface **ge-0/0/1.0** was enabled for persistent MAC learning, so the MAC addresses associated with this interface are of the type **persistent**.

#### **Verifying That Allowed MAC Addresses Are Working Correctly on the Switch**

**Purpose** Verify that allowed MAC addresses are working on the switch.

**Action** Display the MAC cache information after five allowed MAC addresses have been configured on interface **ge-0/0/2**:

```
user@switch> show ethernet-switching table
Ethernet-switching table: 5 entries, 4 learned
```

VLAN	MAC address	Type	Age	Interfaces
employee-vlan	00:05:85:3A:82:80	Learn	0	ge-0/0/2.0
employee-vlan	00:05:85:3A:82:81	Learn	0	ge-0/0/2.0
employee-vlan	00:05:85:3A:82:83	Learn	0	ge-0/0/2.0
employee-vlan	00:05:85:3A:82:85	Learn	0	ge-0/0/2.0
employee-vlan	*	Flood	-	ge-0/0/2.0

**Meaning** Because the MAC limit value for this interface has been set to 4, only four of the five configured allowed addresses are learned.

## Example: Configuring Storm Control

Using storm control can prevent problems caused by broadcast storms. You can configure storm control to rate-limit broadcast traffic and unknown unicast traffic at a specified level and to drop packets when the specified traffic level is exceeded, which prevents packets from proliferating and degrading service or causing a security issue. You can also

configure the switch to shut down or temporarily disable an interface when the storm control limit is exceeded.

This example shows how to configure storm control:

- [Requirements on page 4144](#)
- [Overview and Topology on page 4144](#)
- [Configuration on page 4144](#)

---

## Requirements

This example uses the following hardware and software components:

- A switch
- Junos OS Release 11.1 or later

---

## Overview and Topology

A traffic storm occurs when broadcast packets prompt receiving devices to broadcast packets in response. This prompts further responses, creating a snowball effect. The switch is flooded with packets, and the resulting unnecessary traffic leads to poor performance or even a complete loss of service by some clients. Storm control causes a device to monitor traffic levels and take a specified action when a specified traffic level—called the *storm control level*—is exceeded, thus preventing packets from proliferating and degrading service.

Storm control monitors the incoming broadcast traffic and unknown unicast traffic and compares it with the level that you specify. If broadcast traffic and unknown unicast traffic exceed the specified level, the switch drops packets for the controlled traffic types. Storm control is enabled by default on all interfaces, and the default level is 80 percent of the available bandwidth.

This example shows how to configure the storm control level on interface **xe-0/0/0** by setting the level to a traffic rate of 5000000 Kbps, based on the total of the combined broadcast and unknown unicast streams. If broadcast traffic and unknown unicast traffic exceed these levels, the switch drops packets for the controlled traffic types.

---

## Configuration

### Step-by-Step Procedure

To configure storm control for a 10-Gigabit Ethernet interface to the equivalent of 50 percent of the available bandwidth:

- Specify the level of allowed broadcast traffic and unknown unicast traffic on a specific interface:

```
[edit ethernet-switching-options]  
user@switch# set storm-control interface xe-0/0/0 bandwidth 5000000
```

**Results** Display the results of the configuration:

```
[edit ethernet-switching-options]  
user@switch# show storm-control  
interface xe-0/0/0 {
```

```
    bandwidth 5000000;
}
```

## Example: Configuring MAC Limiting to Protect the Switch from DHCP Starvation Attacks

In a DHCP starvation attack, an attacker floods an Ethernet LAN with DHCP requests from spoofed (counterfeit) MAC addresses. The switch's trusted DHCP server or servers cannot keep up with the requests and can no longer assign IP addresses and lease times to legitimate DHCP clients on the switch. Requests from those clients are either dropped or directed to a rogue DHCP server set up by the attacker.

This example describes how to configure MAC limiting, a port security feature, to protect the switch against DHCP starvation attacks:

- [Requirements on page 4145](#)
- [Overview and Topology on page 4145](#)
- [Configuration on page 4146](#)
- [Verification on page 4147](#)

### Requirements

This example uses the following hardware and software components:

- One QFX3500 switch
- Junos OS Release 12.1 or later for the QFX Series
- A DHCP server to provide IP addresses to network devices on the switch

Before you configure MAC limiting, a port security feature, to mitigate DHCP starvation attacks, be sure you have:

- Connected the DHCP server to the switch.
- Configured the VLAN **employee-vlan** on the switch. See [“Example: Setting Up Bridging with Multiple VLANs” on page 1476](#).

### Overview and Topology

Ethernet LANs are vulnerable to address spoofing and DoS attacks on network devices. This example describes how to protect the switch against one common type of attack, a DHCP starvation attack.

This example shows how to configure port security features on a switch that is connected to a DHCP server.

The setup for this example includes the VLAN **employee-vlan** on the switch. [Figure 154 on page 4146](#) illustrates the topology for this example.

Figure 154: Network Topology for Basic Port Security

The components of the topology for this example are shown in [Table 289 on page 4146](#).

Table 289: Components of the Port Security Topology

Properties	Settings
Switch hardware	One QFX3500 switch
VLAN name and ID	<b>employee-vlan</b>
Interfaces in <b>employee-vlan</b>	<b>ge-0/0/1, ge-0/0/2, ge-0/0/3, ge-0/0/8</b>
Interface for DHCP server	<b>ge-0/0/8</b>

In this example, the switch has already been configured as follows:

- Secure port access is activated on the switch.
- No MAC limit is set on any of the interfaces.
- DHCP snooping is disabled on the VLAN **employee-vlan**.
- All access interfaces are untrusted, which is the default setting.

### Configuration

To configure the MAC limiting port security feature to protect the switch against DHCP starvation attacks:

**CLI Quick Configuration** To quickly configure MAC limiting, copy the following commands and paste them into the switch terminal window:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface ge-0/0/1 mac-limit 3 action drop
user@switch# set interface ge-0/0/2 mac-limit 3 action drop
```

**Step-by-Step Procedure** Configure MAC limiting:

1. Configure a MAC limit of **3** on **ge-0/0/1** and specify that packets with new addresses be dropped if the limit has been exceeded on the interface:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface ge-0/0/1 mac-limit (Access Port Security) 3 action drop
```

2. Configure a MAC limit of **3** on **ge-0/0/2** and specify that packets with new addresses be dropped if the limit has been exceeded on the interface:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface ge-0/0/2 mac-limit 3 action drop
```

**Results** Check the results of the configuration:

```
[edit ethernet-switching-options secure-access-port]
user@switch# show
interface ge-0/0/1.0 {
    mac-limit 3 action drop;
}
interface ge-0/0/2.0 {
    mac-limit 3 action drop;
}
```

### Verification

Confirm that the configuration is working properly.

#### *Verifying That MAC Limiting Is Working Correctly on the Switch*

**Purpose** Verify that MAC limiting is working on the switch.

**Action** Send some DHCP requests from network devices (here they are DHCP clients) connected to the switch.

Display the MAC addresses learned when DHCP requests are sent from hosts on **ge-0/0/1** and from hosts on **ge-0/0/2**, with both interfaces set to a MAC limit of **3** with the action **drop**:

```
user@switch> show ethernet-switching table
Ethernet-switching table: 7 entries, 6 learned
```

VLAN	MAC address	Type	Age	Interfaces
default	*	Flood	-	ge-0/0/2.0
default	00:05:85:3A:82:77	Learn	0	ge-0/0/1.0
default	00:05:85:3A:82:79	Learn	0	ge-0/0/1.0
default	00:05:85:3A:82:80	Learn	0	ge-0/0/1.0
default	00:05:85:3A:82:81	Learn	0	ge-0/0/2.0
default	00:05:85:3A:82:83	Learn	0	ge-0/0/2.0
default	00:05:85:3A:82:85	Learn	0	ge-0/0/2.0

**Meaning** The sample output shows that with a MAC limit of **3** for each interface, the DHCP request for a fourth MAC address on **ge-0/0/2** was dropped because it exceeded the MAC limit.

Because only 3 MAC addresses can be learned on each of the two interfaces, attempted DHCP starvation attacks fail.

  - [Configuring MAC Limiting on page 4188](#)

## Example: Configuring MAC Limiting, Including Dynamic and Allowed MAC Addresses, to Protect the Switch from Ethernet Switching Table Overflow Attacks

In an Ethernet switching table overflow attack, an intruder sends so many requests from new MAC addresses that the Ethernet switching table fills up and then overflows, forcing the switch to broadcast all messages.

This example describes how to configure MAC limiting and allowed MAC addresses, two port security features, to protect the switch from Ethernet switching table attacks:

- [Requirements on page 4148](#)
- [Overview and Topology on page 4149](#)
- [Configuration on page 4150](#)
- [Verification on page 4151](#)

### Requirements

This example uses the following hardware and software components:

- One EX Series switch or QFX3500 switch
- Junos OS Release 9.0 or later for EX Series switches or Junos OS 12.1 or later for the QFX Series.

- A DHCP server to provide IP addresses to network devices on the switch

Before you configure specific port security features to mitigate common access-interface attacks, be sure you have:

- Connected the DHCP server to the switch.
- Configured a VLAN on the switch. See the task for your platform:

### Overview and Topology

Ethernet LANs are vulnerable to address spoofing and DoS attacks on network devices. This example describes how to protect the switch from an attack on the Ethernet switching table that causes the table to overflow and thus forces the switch to broadcast all messages.

This example shows how to configure port security features on a switch connected to a DHCP server.

The setup for this example includes the VLAN **employee-vlan** on the switch. The procedure for creating that VLAN is described in the topic [Example: Setting Up Bridging with Multiple VLANs for EX Series Switches](#) and [“Example: Setting Up Bridging with Multiple VLANs” on page 1476](#) for the QFX Series. That procedure is not repeated here. [Figure 155 on page 4149](#) illustrates the topology for this example.

**Figure 155: Network Topology for Basic Port Security**

The components of the topology for this example are shown in [Table 290 on page 4150](#).

Table 290: Components of the Port Security Topology

Properties	Settings
Switch hardware	One EX Series switch or one QFX3500 switch
VLAN name and ID	<b>employee-vlan</b> , tag 20
VLAN subnets	192.0.2.16/28 192.0.2.17 through 192.0.2.30 192.0.2.31 is subnet's broadcast address
Interfaces in <b>employee-vlan</b>	ge-0/0/1, ge-0/0/2, ge-0/0/3, ge-0/0/8
Interface for DHCP server	ge-0/0/8

In this example, use the MAC limit feature to control the total number of MAC addresses that can be added to the Ethernet switching table for the specified interface. Use the allowed MAC addresses feature to ensure that the addresses of network devices whose network access is critical are guaranteed to be included in the Ethernet switching table.

In this example, the switch has already been configured as follows:

- Secure port access is activated on the switch.
- No MAC limit is set on any of the interfaces.
- All access interfaces are untrusted, which is the default setting.

### Configuration

To configure MAC limiting and some allowed MAC addresses to protect the switch against Ethernet switching table overflow attacks:

#### CLI Quick Configuration

To quickly configure MAC limiting, clear the MAC forwarding table, and configure some allowed MAC addresses, copy the following commands and paste them into the switch terminal window:

```
[edit ethernet-switching-options secure-access-port]
set interface ge-0/0/1 mac-limit 4 action drop
set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:80
set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:81
set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:83
set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:85
exit
exit
clear ethernet-switching-table interface ge-0/0/1
```

#### Step-by-Step Procedure

Configure MAC limiting and some allowed MAC addresses:

1. Configure a MAC limit of 4 on **ge-0/0/1** and specify that incoming packets with different addresses be dropped once the limit is exceeded on the interface:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface ge-0/0/1 mac-limit (Access Port Security) 4 action drop
```

2. Clear the current entries for interface ge-0/0/1 from the MAC address forwarding table :

```
user@switch# clear ethernet-switching-table interface ge-0/0/1
```

3. Configure the allowed MAC addresses on ge-0/0/2:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:80
user@switch# set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:81
user@switch# set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:83
user@switch# set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:85
```

**Results** Check the results of the configuration:

```
[edit ethernet-switching-options secure-access-port]
user@switch# show
interface ge-0/0/1.0 {
  mac-limit 4 action drop;
}
interface ge-0/0/2.0 {
  allowed-mac [ 00:05:85:3a:82:80 00:05:85:3a:82:81 00:05:85:3a:82:83 00:05:85:3a:82:85 ];
}
```

### Verification

To confirm that the configuration is working properly:

- [Verifying That MAC Limiting Is Working Correctly on the Switch on page 4151](#)

#### *Verifying That MAC Limiting Is Working Correctly on the Switch*

**Purpose** Verify that MAC limiting is working on the switch.

**Action** Display the MAC cache information after DHCP requests have been sent from hosts on **ge-0/0/1**, with the interface set to a MAC limit of 4 with the action **drop**, and after four allowed MAC addresses have been configured on interface **ge-0/0/2**:

```
user@switch> show ethernet-switching table
Ethernet-switching table: 5 entries, 4 learned
```

VLAN	MAC address	Type	Age	Interfaces
employee-vlan	00:05:85:3A:82:71	Learn	0	ge-0/0/1.0
employee-vlan	00:05:85:3A:82:74	Learn	0	ge-0/0/1.0
employee-vlan	00:05:85:3A:82:77	Learn	0	ge-0/0/1.0
employee-vlan	00:05:85:3A:82:79	Learn	0	ge-0/0/1.0
employee-vlan	*	Flood	0	ge-0/0/1.0
employee-vlan	00:05:85:3A:82:80	Learn	0	ge-0/0/2.0
employee-vlan	00:05:85:3A:82:81	Learn	0	ge-0/0/2.0
employee-vlan	00:05:85:3A:82:83	Learn	0	ge-0/0/2.0
employee-vlan	00:05:85:3A:82:85	Learn	0	ge-0/0/2.0
employee-vlan	*	Flood	-	ge-0/0/2.0

**Meaning** The sample output shows that with a MAC limit of 4 for the interface, the DHCP request for a fifth MAC address on **ge-0/0/1** was dropped because it exceeded the MAC limit and that only the specified allowed MAC addresses have been learned on the **ge-0/0/2** interface.

## Example: Configuring a DHCP Server Interface as Untrusted to Protect the Switch from Rogue DHCP Server Attacks

In a rogue DHCP server attack, an attacker has introduced a rogue server into the network, allowing it to give IP address leases to the network's DHCP clients and to assign itself as the gateway device.

This example describes how to configure a DHCP server interface as untrusted to protect the switch from a rogue DHCP server:

- [Requirements on page 4152](#)
- [Overview and Topology on page 4152](#)
- [Configuration on page 4154](#)
- [Verification on page 4154](#)

### Requirements

---

This example uses the following hardware and software components:

- One EX Series switch or one QFX3500 switch
- Junos OS Release 9.0 or later for EX Series switches or Junos OS Release 12.1 or later for the QFX Series
- A DHCP server to provide IP addresses to network devices on the switch

Before you configure an untrusted DHCP server interface to mitigate rogue DHCP server attacks, be sure you have:

- Connected the DHCP server to the switch.
- Enabled DHCP snooping on the VLAN.
- Configured a VLAN on the switch. See the task for your platform:
  - [Example: Setting Up Bridging with Multiple VLANs for EX Series Switches](#)
  - ["Example: Setting Up Bridging with Multiple VLANs" on page 1476](#) for the QFX Series

### Overview and Topology

---

Ethernet LANs are vulnerable to address spoofing and DoS attacks on network devices. This example describes how to protect the switch from rogue DHCP server attacks.

This example shows how to explicitly configure an untrusted interface on an EX3200-24P switch and a QFX3500 switch. [Figure 156 on page 4153](#) illustrates the topology for this example.

**Figure 156: Network Topology for Basic Port Security**

The components of the topology for this example are shown in [Table 291 on page 4153](#).

**Table 291: Components of the Port Security Topology**

Properties	Settings
Switch hardware	One EX3200-24P, 24 ports (8 PoE ports) or one QFX3500 switch
VLAN name and ID	<b>employee-vlan</b> , tag 20
VLAN subnets	192.0.2.16/28 192.0.2.17 through 192.0.2.30 192.0.2.31 is the subnet's broadcast address
Interfaces in <b>employee-vlan</b>	<b>ge-0/0/1</b> , <b>ge-0/0/2</b> , <b>ge-0/0/3</b> , <b>ge-0/0/8</b>
Interface for DHCP server	<b>ge-0/0/8</b>

In this example, the switch has already been configured as follows:

- Secure port access is activated on the switch.
- DHCP snooping is enabled on the VLAN **employee-vlan**.
- The interface (port) where the rogue DHCP server has connected to the switch is currently trusted.

## Configuration

---

To configure the DHCP server interface as untrusted because the interface is being used by a rogue DHCP server:

**CLI Quick Configuration** To quickly set the rogue DHCP server interface as untrusted, copy the following command and paste it into the switch terminal window:

```
[edit ethernet-switching-options secure-access-port]
set interface ge-0/0/8 no-dhcp-trusted
```

**Step-by-Step Procedure** To set the DHCP server interface as untrusted:

- Specify the interface (port) from which DHCP responses are not allowed:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface ge-0/0/8 no-dhcp-trusted
```

**Results** Check the results of the configuration:

```
[edit ethernet-switching-options secure-access-port]
user@switch# show
interface ge-0/0/8.0 {
  no-dhcp-trusted;
}
```

## Verification

---

Confirm that the configuration is working properly.

### *Verifying That the DHCP Server Interface Is Untrusted*

**Purpose** Verify that the DHCP server is untrusted.

- Action**
1. Send some DHCP requests from network devices (here they are DHCP clients) connected to the switch.
  2. Display the DHCP snooping information when the port on which the DHCP server connects to the switch is not trusted.

**Meaning** There is no output from the command because no entries are added to the DHCP snooping database.

**Related Documentation**

- [Example: Configuring Basic Port Security Features on page 4136](#)
- [Enabling a Trusted DHCP Server \(CLI Procedure\) on page 4199](#)

- [show dhcp snooping binding on page 4293](#)

## Example: Configuring DHCP Snooping, DAI, and MAC Limiting on a Switch with Access to a DHCP Server Through a Second Switch

You can configure DHCP snooping, dynamic ARP inspection (DAI), and MAC limiting on the access interfaces of switches to protect the switch and the Ethernet LAN against address spoofing and Layer 2 denial-of-service (DoS) attacks. To obtain those basic settings, you can use the switch's default configuration for port security, configure the MAC limit, and enable DHCP snooping and DAI on a VLAN. You can configure those features when the DHCP server is connected to a different switch from the one to which the DHCP clients (network devices) are connected.

This example describes how to configure port security features on a switch whose hosts obtain IP addresses and lease times from a DHCP server connected to a second switch:

- [Requirements on page 4155](#)
- [Overview and Topology on page 4155](#)
- [Configuring a VLAN, Interfaces, and Port Security Features on Switch 1 on page 4157](#)
- [Configuring a VLAN and Interfaces on Switch 2 on page 4159](#)
- [Verification on page 4160](#)

### Requirements

This example uses the following hardware and software components:

- One EX Series switch or QFX3500 switch—"Switch 1" in this example.
- An additional EX Series switch or QFX3500 switch—"Switch 2" in this example. You do not configure port security on this second switch.
- Junos OS Release 9.0 or later for EX Series switches or Junos OS Release 12.1 or later for the QFX Series.
- A DHCP server connected to Switch 2. You use the server to provide IP addresses to network devices connected to Switch 1.
- At least two network devices (hosts) that you connect to access interfaces on Switch 1. These devices are DHCP clients.

Before you configure DHCP snooping, DAI, and MAC limiting port security features, be sure you have:

- Connected the DHCP server to Switch 2.
- Configured a VLAN on the switch. See the task for your platform:
  - [Example: Setting Up Bridging with Multiple VLANs for EX Series Switches](#)
  - ["Example: Setting Up Bridging with Multiple VLANs" on page 1476](#) for the QFX Series

### Overview and Topology

Ethernet LANs are vulnerable to address spoofing and DoS attacks on network devices. To protect the devices from such attacks, you can configure:

- DHCP snooping to validate DHCP server messages
- DAI to protect against ARP spoofing
- MAC limiting to constrain the number of MAC addresses the switch adds to its MAC address cache

This example shows how to configure these port security features on Switch 1. Switch 1 is connected to another switch (Switch 2) that is not configured with port security features. That second switch is connected to a DHCP server. (See [Figure 157 on page 4156](#).) Network devices (hosts) that are connected to Switch 1 send requests for IP addresses (that is, the devices are DHCP clients). Those requests are transmitted from Switch 1 to Switch 2 and then to the DHCP server connected to Switch 2. Responses to the requests are transmitted along the reverse path of the one followed by the requests.

The setup for this example includes the VLAN **employee-vlan** on both switches.

[Figure 157 on page 4156](#) shows the network topology for the example.

**Figure 157: Network Topology for Port Security Setup with Two Switches on the Same VLAN**

The components of the topology for this example are shown in [Table 292 on page 4156](#).

**Table 292: Components of Port Security Setup on Switch 1 with a DHCP Server Connected to Switch 2**

Properties	Settings
Switch hardware	One EX Series switch or one QFX3500 switch (Switch 1), and an additional EX Series switch or QFX3500 switch (Switch 2)
VLAN name and ID	<b>employee-vlan, tag 20</b>

**Table 292: Components of Port Security Setup on Switch 1 with a DHCP Server Connected to Switch 2** (*continued*)

Properties	Settings
VLAN subnets	192.0.2.16/28 192.0.2.17 through 192.0.2.30 192.0.2.31 is subnet's broadcast address
Trunk interface on both switches	ge-0/0/11
Access interfaces on Switch 1	ge-0/0/1, ge-0/0/2, and ge-0/0/3
Access interface on Switch 2	ge-0/0/1
Interface for DHCP server	ge-0/0/1 on Switch 2

Switch 1 is initially configured with the default port security setup. In the default configuration on the switch:

- Secure port access is activated on the switch.
- The switch does not drop any packets, which is the default setting.
- DHCP snooping and dynamic ARP inspection (DAI) are disabled on all VLANs.
- All access interfaces are untrusted and trunk interfaces are trusted; these are the default settings.

In the configuration tasks for this example, you configure a VLAN on both switches.

In addition to configuring the VLAN, you enable DHCP snooping on Switch 1. In this example, you also enable DAI and a MAC limit of 5 on Switch 1.

Because the interface that connects Switch 2 to Switch 1 is a trunk interface, you do not have to configure this interface to be trusted. As noted above, trunk interfaces are automatically trusted, so DHCP messages coming from the DHCP server to Switch 2 and then on to Switch 1 are trusted.

### Configuring a VLAN, Interfaces, and Port Security Features on Switch 1

#### CLI Quick Configuration

To quickly configure a VLAN, interfaces, and port security features, copy the following commands and paste them into the switch terminal window:

```
[edit]
set ethernet-switching-options secure-access-port interface ge-0/0/1 mac-limit 5 action drop
clear ethernet-switching table interface ge-0/0/1
set ethernet-switching-options secure-access-port vlan employee-vlan arp-inspection
set ethernet-switching-options secure-access-port vlan employee-vlan examine-dhcp
set interfaces ge-0/0/1 unit 0 family ethernet-switching vlan members 20
set interfaces ge-0/0/2 unit 0 family ethernet-switching vlan members 20
set interfaces ge-0/0/3 unit 0 family ethernet-switching vlan members 20
set interfaces ge-0/0/11 unit 0 family ethernet-switching port-mode trunk
set interfaces ge-0/0/11 unit 0 family ethernet-switching vlan members 20
set vlans employee-vlan vlan-id 20
```

**Step-by-Step Procedure** To configure MAC limiting, a VLAN, and interfaces on Switch 1 and enable DAI and DHCP on the VLAN:

1. Configure the VLAN **employee-vlan** with VLAN ID 20:  

```
[edit vlans]
user@switch1# set employee-vlan vlan-id 20
```
2. Configure an interface on Switch 1 as a trunk interface:  

```
[edit interfaces]
user@switch1# set ge-0/0/11 unit 0 family ethernet-switching port-mode trunk
```
3. Associate the VLAN with interfaces **ge-0/0/1**, **ge-0/0/2**, **ge-0/0/3**, and **ge-0/0/11**:  

```
[edit interfaces]
user@switch1# set ge-0/0/1 unit 0 family ethernet-switching vlan members 20
user@switch1# set ge-0/0/2 unit 0 family ethernet-switching vlan members 20
user@switch1# set ge-0/0/3 unit 0 family ethernet-switching vlan members 20
user@switch1# set ge-0/0/11 unit 0 family ethernet-switching vlan members 20
```
4. Enable DHCP snooping on the VLAN:  

```
[edit ethernet-switching-options secure-access-port]
user@switch1# set vlan employee-vlan examine-dhcp
```
5. Enable DAI on the VLAN:  

```
[edit ethernet-switching-options secure-access-port]
user@switch1# set vlan employee-vlan arp-inspection
```
6. Configure a MAC limit of 5 on **ge-0/0/1** and use the default action, drop (packets with new addresses are dropped if the limit has been exceeded):  

```
[edit ethernet-switching-options secure-access-port]
user@switch1# set interface ge-0/0/1 mac-limit 5 drop
```
7. Clear the existing MAC address table entries from interface **ge-0/0/1**:  

```
user@switch1# clear ethernet-switching table interface ge-0/0/1
```

**Results** Display the results of the configuration:

```
[edit]
user@switch1# show
ethernet-switching-options {
  secure-access-port {
    interface ge-0/0/1.0 {
      mac-limit 5 action drop;
    }
    vlan employee-vlan {
      arp-inspection;
      examine-dhcp;
    }
  }
}
interfaces {
  ge-0/0/1 {
    unit 0 {
      family ethernet-switching {
        vlan {
          members 20;
        }
      }
    }
  }
}
```

```

}
ge-0/0/2 {
  unit 0 {
    family ethernet-switching {
      vlan {
        members 20;
      }
    }
  }
}
ge-0/0/3 {
  unit 0 {
    family ethernet-switching {
      vlan {
        members 20;
      }
    }
  }
}
ge-0/0/11 {
  unit 0 {
    family ethernet-switching {
      port-mode trunk;
      vlan {
        members 20;
      }
    }
  }
}
vpls {
  employee-vlan {
    vlan-id 20;
  }
}

```

### Configuring a VLAN and Interfaces on Switch 2

To configure the VLAN and interfaces on Switch 2:

**CLI Quick Configuration** To quickly configure the VLAN and interfaces on Switch 2, copy the following commands and paste them into the switch terminal window:

```

[edit]
set interfaces ge-0/0/1 unit 0 family ethernet-switching port-mode trunk
set interfaces ge-0/0/11 unit 0 family ethernet-switching port-mode trunk
set vpls employee-vlan vlan-id 20

```

**Step-by-Step Procedure** To configure the VLAN and interfaces on Switch 2:

1. Configure an interface on Switch 2 as a trunk interface:
 

```

[edit interfaces]
user@switch2# set ge-0/0/11 unit 0 ethernet-switching port-mode trunk

```
2. Associate the VLAN with interfaces **ge-0/0/1** and **ge-0/0/11**:
 

```

[edit interfaces]
user@switch2# set ge-0/0/1 unit 0 family ethernet-switching vlan members 20

```

```
user@switch2# set ge-0/0/11 unit 0 family ethernet-switching vlan members 20
```

**Results** Display the results of the configuration:

```
[edit]
user@switch2# show
interfaces {
  ge-0/0/1 {
    unit 0 {
      family ethernet-switching {
        vlan {
          members 20;
        }
      }
    }
  }
  ge-0/0/11 {
    unit 0 {
      family ethernet-switching {
        port-mode trunk;
        vlan {
          members 20;
        }
      }
    }
  }
}
vlangs {
  employee-vlan {
    vlan-id 20;
  }
}
```

---

### Verification

To confirm that the configuration is working properly.

- [Verifying That DHCP Snooping Is Working Correctly on Switch 1 on page 4160](#)
- [Verifying That DAI Is Working Correctly on Switch 1 on page 4161](#)
- [Verifying That MAC Limiting Is Working Correctly on Switch 1 on page 4161](#)

#### ***Verifying That DHCP Snooping Is Working Correctly on Switch 1***

**Purpose** Verify that DHCP snooping is working on Switch 1.

**Action** Send some DHCP requests from network devices (here they are DHCP clients) connected to the switch.

Display the DHCP snooping information when the interface through which Switch 2 sends the DHCP server replies to clients connected to Switch 1 is trusted. The server has provided the IP addresses and leases:

```
user@switch1> show dhcp snooping binding
```

DHCP Snooping Information:

MAC Address	IP Address	Lease	Type	VLAN	Interface
00:05:85:3A:82:77	192.0.2.17	600	dynamic	employee-vlan	ge-0/0/1.0
00:05:85:3A:82:79	192.0.2.18	653	dynamic	employee-vlan	ge-0/0/1.0
00:05:85:3A:82:80	192.0.2.19	720	dynamic	employee-vlan	ge-0/0/1.0
00:05:85:3A:82:81	192.0.2.20	932	dynamic	employee-vlan	ge-0/0/1.0
00:05:85:3A:82:83	192.0.2.21	1230	dynamic	employee-vlan	ge-0/0/1.0
00:05:85:3A:82:90	192.0.2.20	932	dynamic	employee-vlan	ge-0/0/2.0
00:05:85:3A:82:91	192.0.2.21	1230	dynamic	employee-vlan	ge-0/0/3.0

**Meaning** The output shows, for each MAC address, the assigned IP address and lease time—that is, the time, in seconds, remaining before the lease expires.

#### *Verifying That DAI Is Working Correctly on Switch 1*

**Purpose** Verify that DAI is working on Switch 1.

**Action** Send some ARP requests from network devices connected to the switch.

Display the DAI information:

```
user@switch1> show arp inspection statistics
```

ARP inspection statistics:

Interface	Packets received	ARP inspection pass	ARP inspection failed
ge-0/0/1.0	7	5	2
ge-0/0/2.0	10	10	0
ge-0/0/3.0	18	15	3

**Meaning** The sample output shows the number of ARP packets received and inspected per interface, with a listing of how many packets passed and how many failed the inspection on each interface. The switch compares the ARP requests and replies against the entries in the DHCP snooping database. If a MAC address or IP address in the ARP packet does not match a valid entry in the database, the packet is dropped.

#### *Verifying That MAC Limiting Is Working Correctly on Switch 1*

**Purpose** Verify that MAC limiting is working on Switch 1.

**Action** Display the MAC addresses that are learned when DHCP requests are sent from hosts on **ge-0/0/1**:

```
user@switch1> show ethernet-switching table
```

Ethernet-switching table: 6 entries, 5 learned

VLAN	MAC address	Type	Age	Interfaces
employee-vlan	00:05:85:3A:82:77	Learn	0	ge-0/0/1.0
employee-vlan	00:05:85:3A:82:79	Learn	0	ge-0/0/1.0
employee-vlan	00:05:85:3A:82:80	Learn	0	ge-0/0/1.0
employee-vlan	00:05:85:3A:82:81	Learn	0	ge-0/0/1.0
employee-vlan	00:05:85:3A:82:83	Learn	0	ge-0/0/1.0
employee-vlan	*	Flood	-	ge-0/0/1.0

**Meaning** The sample output shows that five MAC addresses have been learned for interface **ge-0/0/1**, which corresponds to the MAC limit of **5** set in the configuration. The last line of the output shows that a sixth MAC address request was dropped, as indicated by the asterisk (\*) in the **MAC address** column.

## Example: Configuring DHCP Snooping and DAI to Protect the Switch from ARP Spoofing Attacks

In an ARP spoofing attack, the attacker associates its own MAC address with the IP address of a network device connected to the switch. Traffic intended for that IP address is now sent to the attacker instead of being sent to the intended destination. The attacker can send faked, or “spoofed,” ARP messages on the LAN.

**NOTE:** When dynamic ARP inspection (DAI) is enabled, the switch logs the number of invalid ARP packets that it receives on each interface, along with the sender's IP and MAC addresses. You can use these log messages to discover ARP spoofing on the network.

This example describes how to configure DHCP snooping and dynamic ARP inspection (DAI), two port security features, to protect the switch against ARP spoofing attacks:

- [Requirements on page 4163](#)
- [Overview and Topology on page 4163](#)
- [Configuration on page 4164](#)
- [Verification on page 4165](#)

---

## Requirements

This example uses the following hardware and software components:

- One EX Series switch or one QFX3500 switch
- Junos OS Release 11.4 or later for EX Series switches or Junos OS Release 12.1 or later for the QFX Series
- A DHCP server to provide IP addresses to network devices on the switch

Before you configure DHCP snooping and DAI (two port security features) to mitigate ARP spoofing attacks, be sure you have:

- Connected the DHCP server to the switch.
- Configured a VLAN on the switch. See the task for your platform:
  - [Example: Setting Up Bridging with Multiple VLANs for EX Series Switches](#)
  - [“Example: Setting Up Bridging with Multiple VLANs” on page 1476](#) for the QFX Series

---

## Overview and Topology

Ethernet LANs are vulnerable to address spoofing and DoS attacks on network devices. This example describes how to protect the switch against one common type of attack, an ARP spoofing attack.

In an ARP spoofing attack, the attacker sends faked ARP messages, thus creating various types of problems on the LAN—for example, the attacker might launch a man-in-the-middle attack.

This example shows how to configure port security features on a switch that is connected to a DHCP server. The setup for this example includes the VLAN **employee-vlan** on the switch. The procedure for creating that VLAN is described in the topic [Example: Setting Up Bridging with Multiple VLANs for EX Series Switches](#) and [“Example: Setting Up Bridging with Multiple VLANs” on page 1476](#) for the QFX Series. That procedure is not repeated here. [Figure 158 on page 4164](#) illustrates the topology for this example.

Figure 158: Network Topology for Basic Port Security

The components of the topology for this example are shown in [Table 293 on page 4164](#).

Table 293: Components of the Port Security Topology

Properties	Settings
Switch hardware	One EX3200-24P, 24 ports (8 PoE ports) or one QFX3500 switch
VLAN name and ID	<b>employee-vlan</b> , tag 20
VLAN subnets	192.0.2.16/28 192.0.2.17 through 192.0.2.30 192.0.2.31 is the subnet's broadcast address
Interfaces in <b>employee-vlan</b>	<code>ge-0/0/1</code> , <code>ge-0/0/2</code> , <code>ge-0/0/3</code> , <code>ge-0/0/8</code>
Interface for DHCP server	<code>ge-0/0/8</code>

In this example, the switch has already been configured as follows:

- Secure port access is activated on the switch.
- DHCP snooping is disabled on the VLAN **employee-vlan**.
- All access ports are untrusted, which is the default setting.

### Configuration

To configure DHCP snooping and dynamic ARP inspection (DAI) to protect the switch against ARP attacks:

**CLI Quick Configuration** To quickly configure DHCP snooping and dynamic ARP inspection (DAI), copy the following commands and paste them into the switch terminal window:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface ge-0/0/8 dhcp-trusted
user@switch# set vlan employee-vlan examine-dhcp
user@switch# set vlan employee-vlan arp-inspection
```

**Step-by-Step Procedure** Configure DHCP snooping and dynamic ARP inspection (DAI) on the VLAN:

1. Set the **ge-0/0/8** interface as trusted:  

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface ge-0/0/8 dhcp-trusted
```
2. Enable DHCP snooping on the VLAN:  

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee-vlan examine-dhcp
```
3. Enable DAI on the VLAN:  

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee-vlan arp-inspection
```

**Results** Check the results of the configuration:

```
[edit ethernet-switching-options secure-access-port]
user@switch# show
interface ge-0/0/8.0 {
  dhcp-trusted;
}
vlan employee-vlan {
  arp-inspection;
  examine-dhcp;
}
```

### Verification

Confirm that the configuration is working properly.

- [Verifying That DHCP Snooping Is Working Correctly on the Switch on page 4165](#)
- [Verifying That DAI Is Working Correctly on the Switch on page 4166](#)

### *Verifying That DHCP Snooping Is Working Correctly on the Switch*

**Purpose** Verify that DHCP snooping is working on the switch.

**Action** Send some DHCP requests from network devices (here they are DHCP clients) connected to the switch.

Display the DHCP snooping information when the port on which the DHCP server connects to the switch is trusted. The following output results when requests are sent from the MAC addresses and the server has provided the IP addresses and leases:

```
user@switch> show dhcp-snooping binding
DHCP Snooping Information:
MAC Address      IP Address      Lease      Type      VLAN      Interface
-----
00:05:85:3A:82:77 192.0.2.17      600      dynamic  employee-vlan ge-0/0/1.0
00:05:85:3A:82:79 192.0.2.18      653      dynamic  employee-vlan ge-0/0/1.0
00:05:85:3A:82:80 192.0.2.19      720      dynamic  employee-vlan ge-0/0/2.0
00:05:85:3A:82:81 192.0.2.20      932      dynamic  employee-vlan ge-0/0/2.0
00:05:85:3A:82:83 192.0.2.21      1230     dynamic  employee-vlan ge-0/0/2.0
00:05:85:27:32:88 192.0.2.22      3200     dynamic  employee-vlan ge-0/0/3.0
```

**Meaning** When the interface on which the DHCP server connects to the switch has been set to trusted, the output (see preceding sample) shows, for each MAC address, the assigned IP address and lease time—that is, the time, in seconds, remaining before the lease expires.

#### *Verifying That DAI Is Working Correctly on the Switch*

**Purpose** Verify that DAI is working on the switch.

**Action** Send some ARP requests from network devices connected to the switch.

Display the DAI information:

```
user@switch> show arp inspection statistics
ARP inspection statistics:
Interface      Packets received  ARP inspection pass  ARP inspection failed
-----
ge-0/0/1.0      7                 5                     2
ge-0/0/2.0     10                10                    0
ge-0/0/3.0     12                12                    0
```

**Meaning** The sample output shows the number of ARP packets received and inspected per interface, with a listing of how many packets passed and how many failed the inspection on each interface. The switch compares the ARP requests and replies against the entries in the DHCP snooping database. If a MAC address or IP address in the ARP packet does not match a valid entry in the database, the packet is dropped.

## Example: Configuring Allowed MAC Addresses to Protect the Switch from DHCP Snooping Database Alteration Attacks

In one type of attack on the DHCP snooping database, an intruder introduces a DHCP client on an untrusted access interface with a MAC address identical to that of a client on another untrusted interface. The intruder then acquires the DHCP lease of that other client, thus changing the entries in the DHCP snooping table. Subsequently, what would have been valid ARP requests from the legitimate client are blocked.

This example describes how to configure allowed MAC addresses, a port security feature, to protect the switch from DHCP snooping database alteration attacks:

- [Requirements on page 4167](#)
- [Overview and Topology on page 4167](#)
- [Configuration on page 4169](#)
- [Verification on page 4169](#)

### Requirements

This example uses the following hardware and software components:

- One EX Series switch or one QFX3500 switch
- Junos OS Release 11.4 or later for EX Series switches or Junos OS Release 12.1 or later for the QFX Series
- A DHCP server to provide IP addresses to network devices on the switch

Before you configure specific port security features to mitigate common access-interface attacks, be sure you have:

- Connected the DHCP server to the switch.
- Configured a VLAN on the switch. See the task for your platform:
  - [Example: Setting Up Bridging with Multiple VLANs for EX Series Switches](#)
  - [“Example: Setting Up Bridging with Multiple VLANs” on page 1476](#) for the QFX Series

### Overview and Topology

Ethernet LANs are vulnerable to address spoofing and DoS attacks on network devices. This example describes how to protect the switch from an attack on the DHCP snooping database that alters the MAC addresses assigned to some clients.

This example shows how to configure port security features on a switch that is connected to a DHCP server.

The setup for this example includes the VLAN **employee-vlan** on the switch. [Figure 159 on page 4168](#) illustrates the topology for this example.

**Figure 159: Network Topology for Basic Port Security**

The components of the topology for this example are shown in [Table 294 on page 4168](#).

**Table 294: Components of the Port Security Topology**

Properties	Settings
Switch hardware	One EX3200-24P, 24 ports (8 PoE ports) or one QFX3500 switch
VLAN name and ID	<b>employee-vlan</b> , tag 20
VLAN subnets	192.0.2.16/28 192.0.2.17 through 192.0.2.30 192.0.2.31 is the subnet's broadcast address
Interfaces in <b>employee-vlan</b>	ge-0/0/1, ge-0/0/2, ge-0/0/3, ge-0/0/8
Interface for DHCP server	ge-0/0/8

In this example, the switch has already been configured as follows:

- Secure port access is activated on the switch.
- DHCP snooping is enabled on the VLAN **employee-vlan**.
- All access ports are untrusted, which is the default setting.

## Configuration

To configure allowed MAC addresses to protect the switch against DHCP snooping database alteration attacks:

**CLI Quick Configuration** To quickly configure some allowed MAC addresses on an interface, copy the following commands and paste them into the switch terminal window:

```
[edit ethernet-switching-options secure-access-port]
set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:80
set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:81
set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:83
set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:85
set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:88
```

**Step-by-Step Procedure** To configure some allowed MAC addresses on an interface:  
Configure the five allowed MAC addresses on an interface:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:80
user@switch# set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:81
user@switch# set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:83
user@switch# set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:85
user@switch# set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:88
```

**Results** Check the results of the configuration:

```
[edit ethernet-switching-options secure-access-port]
user@switch# show
interface ge-0/0/2.0 {
    allowed-mac [ 00:05:85:3a:82:80 00:05:85:3a:82:81 00:05:85:3a:82:83 00:05:85:
:3a:82:85 00:05:85:3a:82:88 ];
}
```

## Verification

Confirm that the configuration is working properly.

- [Verifying That Allowed MAC Addresses Are Working Correctly on the Switch on page 4169](#)

*Verifying That Allowed MAC Addresses Are Working Correctly on the Switch*

**Purpose** Verify that allowed MAC addresses are working on the switch.

**Action** Display the MAC cache information:

```
user@switch> show ethernet-switching table
Ethernet-switching table: 6 entries, 5 learned
```

VLAN	MAC address	Type	Age	Interfaces
employee-vlan	00:05:85:3A:82:80	Learn	0	ge-0/0/2.0
employee-vlan	00:05:85:3A:82:81	Learn	0	ge-0/0/2.0
employee-vlan	00:05:85:3A:82:83	Learn	0	ge-0/0/2.0
employee-vlan	00:05:85:3A:82:85	Learn	0	ge-0/0/2.0
employee-vlan	00:05:85:3A:82:88	Learn	0	ge-0/0/2.0
employee-vlan	*	Flood	-	ge-0/0/2.0

**Meaning** The output shows that the five MAC addresses configured as allowed MAC addresses have been learned and are displayed in the MAC cache. The last MAC address in the list, one that had not been configured as allowed, has not been added to the list of learned addresses.

## Example: Setting Up DHCP Option 82 with a Switch with No Relay Agent Between Clients and a DHCP Server

You can use DHCP option 82, also known as the DHCP relay agent information option, to help protect the switch against attacks such as spoofing (forging) of IP addresses and MAC addresses, and DHCP IP address starvation. Option 82 provides information about the network location of a DHCP client, and the DHCP server uses this information to implement IP addresses or other parameters for the client.

This example describes how to configure DHCP option 82 on a switch with DHCP clients, DHCP server, and switch all on the same VLAN:

- [Requirements on page 4170](#)
- [Overview and Topology on page 4171](#)
- [Configuration on page 4172](#)

### Requirements

This example uses the following hardware and software components:

- One EX Series switch or one QFX3500 switch

- Junos OS Release 9.3 or later for EX Series switches or Junos OS Release 12.1 or later for the QFX Series
- A DHCP server to provide IP addresses to network devices on the switch

Before you configure DHCP option 82 on the switch, be sure you have:

- Connected and configured the DHCP server.

**NOTE:** Your DHCP server must be configured to accept DHCP option 82. If it is not configured for DHCP option 82, it does not use the DHCP option 82 information in the requests sent to it when it formulates its reply messages.

- Configured the **employee** VLAN on the switch and associated the interfaces on which the clients and the server connect to the switch with that VLAN. See the task for your platform:
  - [Configuring VLANs for EX Series Switches \(CLI Procedure\)](#)
  - [“Configuring VLANs” on page 1553](#) for the QFX Series

### Overview and Topology

If DHCP option 82 is enabled on the switch, then when a network device—a DHCP client—that is connected to the switch on an untrusted interface sends a DHCP request, the switch inserts information about the client's network location into the packet header of that request. The switch then sends the request to the DHCP server. The DHCP server reads the option 82 information in the packet header and uses it to implement the IP address or other parameter for the client.

DHCP option 82 is enabled on an individual VLAN or on all VLANs on the switch.

When option 82 is enabled on the switch, then this sequence of events occurs when a DHCP client sends a DHCP request:

1. The switch receives the request and inserts the option 82 information in the packet header.
2. The switch forwards the request to the DHCP server.
3. The server uses the DHCP option 82 information to formulate its reply and sends a response back to the switch. It does not alter the option 82 information.
4. The switch strips the option 82 information from the response packet.
5. The switch forwards the response packet to the client.

[Figure 160 on page 4172](#) illustrates the topology for this example.

**Figure 160: Network Topology for Configuring DHCP Option 82 on a Switch That Is on the Same VLAN as the DHCP Clients and the DHCP Server**

In this example, you configure DHCP option 82 on the switch. The switch connects to the DHCP server on interface `ge-0/0/8`. The DHCP clients connect to the switch on interfaces `ge-0/0/1`, `ge-0/0/2`, and `ge-0/0/3`. The switch, server, and clients are all members of the **employee** VLAN.

### Configuration

#### CLI Quick Configuration

To quickly configure DHCP option 82, copy the following commands and paste them into the switch terminal window:

```
set ethernet-switching-options secure-access-port vlan employee dhcp-option82
set ethernet-switching-options secure-access-port vlan employee dhcp-option82 circuit-id prefix
hostname
set ethernet-switching-options secure-access-port vlan employee dhcp-option82 circuit-id
use-vlan-id
set ethernet-switching-options secure-access-port vlan employee dhcp-option82 remote-id
set ethernet-switching-options secure-access-port vlan employee dhcp-option82 remote-id
prefix mac
set ethernet-switching-options secure-access-port vlan employee dhcp-option82 remote-id
use-string employee-switch1
set ethernet-switching-options secure-access-port vlan employee dhcp-option82 vendor-id
```

#### Step-by-Step Procedure

To configure DHCP option 82:

1. Specify DHCP option 82 for the **employee** VLAN:  

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee dhcp-option82
```
2. Configure a prefix for the circuit ID suboption (the prefix is always the hostname of the switch):  

```
[edit ethernet-switching-options secure-access-port]
```

- ```
user@switch# set vlan employee dhcp-option82 circuit-id prefix hostname
```
3. Specify that the circuit ID suboption value contains the VLAN ID rather than the VLAN name (the default):
 

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee dhcp-option82 circuit-id use-vlan-id
```
  4. Specify that the remote ID suboption be included in the DHCP option 82 information:
 

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee dhcp-option82 remote-id
```
  5. Configure a prefix for the remote ID suboption (here, the prefix is the MAC address of the switch):
 

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee dhcp-option82 remote-id prefix mac
```
  6. Specify that the remote ID suboption value contain a character string (here, the string is **employee-switch1**):
 

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee dhcp-option82 remote-id use-string employee-switch1
```
  7. Configure a vendor ID suboption value, and use the default value. To use the default value, do not type a character string after the **vendor-id** option keyword:
 

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee dhcp-option82 vendor-id
```

**Results** Check the results of the configuration:

```
[edit ethernet-switching-options secure-access-port]
user@switch# show
vlan employee {
  dhcp-option82 {
    circuit-id {
      prefix hostname;
      use-vlan-id;
    }
    remote-id {
      prefix mac;
      use-string employee-switch1;
    }
    vendor-id;
  }
}
```

**Related Documentation**

- [Example: Setting Up DHCP Option 82 with a Switch as a Relay Agent Between Clients and a DHCP Server on page 4174](#)
- [Setting Up DHCP Option 82 on the Switch with No Relay Agent Between Clients and DHCP Server \(CLI Procedure\) on page 4201](#)
- RFC 3046, *DHCP Relay Agent Information Option*, at <http://tools.ietf.org/html/rfc3046>.
- [secure-access-port](#)
- [secure-access-port on page 4256](#)

## Example: Setting Up DHCP Option 82 with a Switch as a Relay Agent Between Clients and a DHCP Server

You can use DHCP option 82, also known as the DHCP relay agent information option, to help protect the switch against attacks such as spoofing (forging) of IP addresses and MAC addresses, and DHCP IP address starvation. Option 82 provides information about the network location of a DHCP client, and the DHCP server uses this information to implement IP addresses or other parameters for the client.

This example describes how to configure DHCP option 82 on a switch that is on the same VLAN with the DHCP clients but on a different VLAN from the DHCP server. In this example, the switch acts as a relay agent:

- [Requirements on page 4174](#)
- [Overview and Topology on page 4175](#)
- [Configuration on page 4175](#)

### Requirements

---

This example uses the following hardware and software components:

- One EX4200-24P switch or one QFX3500 switch
- Junos OS Release 9.3 or later for EX Series switches or Junos OS Release 12.1 or later for the QFX Series
- A DHCP server to provide IP addresses to network devices on the switch

Before you configure DHCP option 82 on the switch, be sure you have:

- Connected and configured the DHCP server.

**NOTE:** Your DHCP server must be configured to accept DHCP option 82. If it is not configured for DHCP option 82, it does not use the DHCP option 82 information in the requests sent to it when it formulates its reply messages.

- Configured the **employee** VLAN on the switch and associated the interfaces on which the clients connect to the switch with that VLAN. See the task for your platform:
  - [Configuring VLANs for EX Series Switches \(CLI Procedure\)](#)
  - [“Configuring VLANs” on page 1553](#) for the QFX Series
- Configured the **corporate** VLAN for the DHCP server.
- Configured the switch as a BOOTP relay agent. See [DHCP/BOOTP Relay for Switches Overview](#).
- Configured the routed VLAN interface (RVI) to allow the switch to relay packets to the server and receive packets from the server. See [Configuring Routed VLAN Interfaces \(CLI Procedure\)](#) or [“Configuring Routed VLAN Interfaces” on page 1551](#) for the QFX Series.

## Overview and Topology

If DHCP option 82 is enabled on the switch, then when a network device—a DHCP client—that is connected to the switch on an untrusted interface sends a DHCP request, the switch inserts information about the client's network location into the packet header of that request. The switch then sends the request (in this setting, it relays the request) to the DHCP server. The DHCP server reads the option 82 information in the packet header and uses it to implement the IP address or other parameter for the client.

When option 82 is enabled on the switch, then this sequence of events occurs when a DHCP client sends a DHCP request:

1. The switch receives the request and inserts the option 82 information in the packet header.
2. The switch relays the request to the DHCP server.
3. The server uses the DHCP option 82 information to formulate its reply and sends a response back to the switch. It does not alter the option 82 information.
4. The switch strips the option 82 information from the response packet.
5. The switch forwards the response packet to the client.

In this example, you configure option 82 on the switch. The switch is configured as a BOOTP relay agent. The switch connects to the DHCP server through the routed VLAN interface (RVI) that you configured. The switch and clients are members of the **employee** VLAN. The DHCP server is a member of the **corporate** VLAN.

## Configuration

To configure DHCP option 82:

### CLI Quick Configuration

To quickly configure DHCP option 82, copy the following commands and paste them into the switch terminal window:

```
set forwarding-options helpers bootp dhcp-option82
set forwarding-options helpers bootp dhcp-option82 circuit-id prefix hostname
set forwarding-options helpers bootp dhcp-option82 circuit-id use-vlan-id
set forwarding-options helpers bootp dhcp-option82 remote-id
set forwarding-options helpers bootp dhcp-option82 remote-id prefix mac
set forwarding-options helpers bootp dhcp-option82 remote-id use-string employee-switch1
set forwarding-options helpers bootp dhcp-option82 vendor-id
```

### Step-by-Step Procedure

To configure DHCP option 82:

1. Specify DHCP option 82 for the **employee** VLAN:  

```
[edit forwarding-options helpers bootp]
user@switch# set dhcp-option82
```
2. Configure a prefix for the circuit ID suboption (the prefix is always the hostname of the switch):  

```
[edit forwarding-options helpers bootp]
user@switch# set dhcp-option82 circuit-id prefix hostname
```
3. Specify that the circuit ID suboption value contains the VLAN ID rather than the VLAN name (the default):

- ```
[edit forwarding-options helpers bootp]
user@switch# set dhcp-option82 circuit-id use-vlan-id
```
4. Specify that the remote ID suboption be included in the DHCP option 82 information:
- ```
[edit forwarding-options helpers bootp]
user@switch# set dhcp-option82 remote-id
```
5. Configure a prefix for the remote ID suboption (here, the prefix is the MAC address of the switch):
- ```
[edit forwarding-options helpers bootp]
user@switch# set dhcp-option82 remote-id prefix mac
```
6. Specify that the remote ID suboption value contains a character string (here, the string is **employee-switch1**):
- ```
[edit forwarding-options helpers bootp]
user@switch# set dhcp-option82 remote-id use-string employee-switch1
```
7. Configure a vendor ID suboption value, and use the default value. To use the default value, do not type a character string after the **vendor-id** option keyword:
- ```
[edit forwarding-options helpers bootp]
user@switch# set dhcp-option82 vendor-id
```

**Results** Check the results of the configuration:

```
[edit forwarding-options helpers bootp]
user@switch# show
dhcp-option82 {
  circuit-id {
    prefix hostname;
    use-vlan-id;
  }
  remote-id {
    prefix mac;
    use-string employee-switch1;
  }
  vendor-id;
}
```

## Configuring Firewall Filters

You can configure firewall filters in a switch to control traffic that enters switch ports or enters and exits VLANs and Layer 3 (routed) interfaces. To use a firewall filter, you must configure the filter and then apply it to a port, VLAN, or Layer 3 interface.

- [Configuring a Firewall Filter on page 4177](#)
- [Applying a Firewall Filter to a Port on page 4179](#)
- [Applying a Firewall Filter to a VLAN on page 4179](#)
- [Applying a Firewall Filter to a Layer 3 \(Routed\) Interface on page 4179](#)

### Configuring a Firewall Filter

To configure a firewall filter:

1. Configure the family address type, filter name, term name, and at least one match condition—for example, match on packets that contain a specific source address:

```
[edit]
user@switch# set firewall family ethernet-switching filter ingress-port-filter term term-one
from source-address 192.0.2.14
```

For a firewall filter that is applied to a port or VLAN, specify the family address type **ethernet-switching**. For a firewall filter that is applied to a Layer 3 (routed) interface, specify the family address type **inet**.

The filter and term names can contain letters, numbers, and hyphens (-) and can be up to 64 characters long. Each filter name must be unique. A filter can contain one or more terms, and each term name must be unique within a filter.

2. Configure additional match conditions. For example, match on packets that contain a specific source port:

```
[edit firewall family ethernet-switching filter ingress-port-filter term
term-one from]
user@switch# set source-port 80
```

You can specify one or more match conditions in a single **from** statement. For a match to occur, the packet must match all the conditions in the term. The **from** statement is optional, but if included in a term, it cannot be empty. If you omit the **from** statement, all packets are considered to match.

3. If you want to apply a firewall filter to multiple interfaces and be able to see counters specific to each interface, configure the **interface-specific** option:

```
[edit firewall family ethernet-switching filter ingress-port-filter]
user@switch# set interface-specific
```

4. In each firewall filter term, specify the actions to take if the packet matches all the conditions in that term. You can specify an action and action modifiers:

- To specify a filter action, for example, to discard packets that match the conditions of the filter term:

```
[edit firewall] family ethernet-switching filter ingress-port-filter term
term-one then]
```

```
user@switch# set discard
```

You can specify no more than one action (**accept**, **discard**, **reject**, **routing-instance**, or **vlan**) per term.

- To specify action modifiers, for example, to count and classify packets to a forwarding class:

```
[edit firewall] family ethernet-switching filter ingress-port-filter term
term-one then]
```

```
user@switch# set count counter-one
```

```
user@switch# set forwarding-class expedited-forwarding
```

```
user@switch# set loss-priority high
```

You can specify any of the following action modifiers in a **then** statement:

- **analyzer *analyzer-name***—Mirror port traffic to a specified analyzer, which you must configure at the **[ethernet-switching-options]** level.
- **count *counter-name***—Count the number of packets that pass this filter term.

**NOTE:** We recommend that you configure a counter for each term in a firewall filter, so that you can monitor the number of packets that match the conditions specified in each filter term.

**NOTE:** On the QFX Series, filters automatically count packets that have been dropped on ingress because of cyclic redundancy check (CRC) errors.

- **forwarding-class *class***—Assign packets to a forwarding class.
- **log**—Log the packet header information in the Routing Engine.
- **loss-priority *priority***—Set the priority of dropping a packet.
- **policer *policer-name***—Apply rate-limiting to the traffic.
- **syslog**—Log an alert for this packet.

If you omit the **then** statement or do not specify an action, packets that match all the conditions in the **from** statement are accepted. However, you should always explicitly configure an action in the **then** statement. You can include no more than one action statement, but you can use any combination of action modifiers. For an action or action modifier to take effect, all conditions in the **from** statement must match.

**NOTE:** Implicit discard is also applicable to a firewall filter applied to the loopback interface, lo0.

### Applying a Firewall Filter to a Port

To apply a firewall filter to an ingress port:

1. Provide a meaningful description of the firewall filter in the configuration of the port to which the filter will be applied:

```
[edit]
user@switch# set interfaces ge-0/0/6 description "filter to limit tcp traffic at trunk port for employee-vlan"
```

2. Apply the filter to the interface, specifying the unit number, family address type, the direction of the filter (for packets entering the port), and the filter name:

```
[edit]
user@switch# set ge-0/0/6 unit 0 family ethernet-switching filter input ingress-port-filter
```

For firewall filters that are applied to ports, the family address type must be **ethernet-switching**.

**NOTE:** You can apply only one filter to a port for a given direction (ingress or egress).

### Applying a Firewall Filter to a VLAN

To apply a firewall filter to a VLAN:

1. Provide a meaningful description of the firewall filter in the configuration of the VLAN to which the filter will be applied:

```
[edit]
user@switch# set vlans employee-vlan vlan-id 20 description "filter to block rogue devices on employee-vlan"
```

2. Apply firewall filters to filter packets that are entering or exiting the VLAN:

- To apply a filter to match packets that are entering the VLAN:

```
[edit]
user@switch# set vlans employee-vlan vlan-id 20 filter input ingress-vlan-rogue-block
```

- To apply a firewall filter to match packets that are exiting the VLAN:

```
[edit]
user@switch# set vlans employee-vlan vlan-id 20 filter output egress-vlan-filter
```

**NOTE:** You can apply only one filter to a VLAN for a given direction (ingress or egress).

### Applying a Firewall Filter to a Layer 3 (Routed) Interface

To apply a firewall filter to a Layer 3 routed interface:

1. Provide a meaningful description of the firewall filter in the configuration of the interface to which the filter will be applied:

```
[edit]
```

```
user@switch# set interfaces ge-0/1/6 description "filter to count and monitor traffic on layer 3 interface"
```

2. You can apply firewall filters to filter packets that enter or exit a Layer 3 routed interface:

- To apply a firewall filter to filter packets that enter a Layer 3 interface:

```
[edit]
```

```
user@switch# set interfaces ge-0/1/6 unit 0 family inet filter input ingress-router-filter
```

- To apply a firewall filter to filter packets that exit a Layer 3 interface:

```
[edit]
```

```
user@switch# set interfaces ge-0/1/6 unit 0 family inet filter output egress-router-filter
```

For firewall filters applied to Layer 3 routed interfaces, the family address type must be **inet**.

**NOTE:** You can apply only one filter to an interface for a given direction (ingress or egress).

## Applying Firewall Filters to Interfaces

For a firewall filter to work, you must apply it to at least one interface. To do this, include the **filter** statement when configuring a logical interface at the **[edit interfaces]** hierarchy level:

```
[edit interfaces]
```

```
user@switch# set interface-name unit logical-unit-number family family-name filter (input | output) filter-name
```

In the **input** statement, specify a firewall filter to be evaluated when packets are received on the interface. Input filters applied to a loopback interface affect only traffic destined for the Routing Engine.

In the **output** statement, specify a filter to be evaluated when packets exit the interface. (You cannot apply an output filter to a loopback interface.)

**NOTE:** When you create a loopback interface, it is important to apply a filter to it so the Routing Engine is protected. We recommend that when you apply a filter to the loopback interface lo0, you include the **apply-groups** statement. Doing so ensures that the filter is automatically inherited on every loopback interface, including lo0 and other loopback interfaces.

**Related Documentation** • [Configuring Firewall Filters on page 4177](#)

## Assigning Forwarding Classes and Loss Priority

You can configure firewall filters to assign packet loss priority (PLP) and forwarding classes so that if congestion occurs, the marked packets can be dropped according to the priority you set. The valid match conditions are one or more of the six packet header fields: destination address, source address, IP protocol, source port, destination port, and DSCP. In other words, you can set the forwarding class and the PLP for each packet entering or an interface with a specific destination address, source address, IP protocol, source port, destination port, or DSCP.

**NOTE:** Junos OS assigns forwarding classes and PLP on ingress only. Do not use a filter that assigns forwarding classes or PLP as an egress filter.

When tricolor marking is enabled, a switch supports four PLP designations: **low**, **medium-low**, **medium-high**, and **high**. You can also specify any of the forwarding classes listed in [Table 295 on page 4181](#)

**Table 295: Unicast Forwarding Classes**

Unicast Forwarding Class	For CoS Traffic Type
be	Best-effort traffic
no-loss	Guaranteed delivery for TCP traffic
fcoe	Guaranteed delivery for Fibre Channel over Ethernet (FCoE) traffic
nc	Network-control traffic

To assign forwarding classes in firewall filters:

1. Configure the family address type and filter name:

```
[edit]
user@switch# edit firewall family ethernet-switching filter ingress-filter
```

2. Configure the terms of the filter as appropriate, including the **forwarding-class** and **loss-priority** action modifiers. For example, each of the following terms in the filter examines various packet header fields and assigns the appropriate forwarding class and packet loss priority:

- The term **corp-traffic** matches all IPv4 packets with a **10.1.1.0/24** source address and assigns the packets to forwarding class **no-loss** with a loss priority of **low**:

```
[edit firewall family ethernet-switching filter ingress-filter]
user@switch# set term corp-traffic from source-address 10.1.1.0/24;
user@switch# set term corp-traffic then forwarding-class no-loss
user@switch# set term corp-traffic then loss-priority low
```

- The term **data-traffic** matches all IPv4 packets with a **10.1.2.0/24** source address and assigns the packets to forwarding class **be** (best effort) with a loss priority of **medium-high**:

```
[edit firewall family ethernet-switching filter ingress-filter]
user@switch# set term data-traffic from source-address 10.1.2.0/24;
user@switch# set term data-traffic then forwarding-class be
user@switch# set term data-traffic then loss-priority medium-high
```

- Because the loss of network-generated packets can jeopardize proper network operation, the delay of these packets is preferable to discarding these packets. The term **network-traffic** assigns the packets with an IP precedence of **net-control** to forwarding class **nc** (network control) with a loss priority of **low**:

```
[edit firewall family ethernet-switching filter ingress-filter]
user@switch# set term network-traffic from precedence net-control
user@switch# set term network-traffic then forwarding-class nc
user@switch# set term network-traffic then loss-priority low
```

- The last term **accept-traffic** matches any packets that did not match on any of the preceding terms and assigns the packets to forwarding class **be** with a loss priority of **high**:

```
[edit firewall family ethernet-switching filter ingress-filter]
user@switch# set term accept-traffic then forwarding-class be
user@switch# set term accept-traffic then loss-priority high
```

3. Apply the filter **ingress-filter** to a port, VLAN, or Layer 3 interface. For information about applying the filter, see [“Configuring Firewall Filters” on page 4177](#). (Assigning forwarding classes and PLP is supported only on ingress filters.)

## Configuring Color-Blind Egress Policers for Medium-Low PLP

If you use color-blind mode and want to configure an egress policer that marks packets to have medium-low PLP, you must configure a single-rate two-color policer at the **[edit firewall policer *policer-name*]** hierarchy level, because color-blind mode does not support medium-low priority. For example:

1. Specify the name of the policer, the bandwidth limit in bits per second (bps) to control the traffic rate on an interface, and the maximum allowed burst size to control the amount of traffic bursting:

```
[edit]
user@switch# set firewall policer policer-name if-exceeding bandwidth-limit bytes
burst-size-limit bytes
```

2. Specify medium-low loss priority for matching packets:

```
[edit]
```

```
user@switch# set firewall policer policer-name then loss-priority medium-low;
```

3. Apply the filter to a port, VLAN, or Layer 3 interface.

#### Related Documentation

- [Overview of Policers on page 4096](#)

- [Configuring Firewall Filters on page 4177](#)
- [Configuring Two-Color and Three-Color Policers to Control Traffic Rates on page 4183](#)

## Configuring Two-Color and Three-Color Policers to Control Traffic Rates

You can rate-limit traffic by configuring a policer and specifying it as an action modifier for a term in a firewall filter. By default, if you specify the same policer in multiple terms, Junos OS creates a separate policer instance for each term and applies rate limiting separately for each instance. For example, if you configure a policer to discard traffic that exceeds 1 Gbps and reference that policer in three different terms, each policer instance enforces a 1-Gbps limit. In this case, the total bandwidth allowed by the filter is 3 Gbps.

You can also configure a policer to be filter-specific, which means that Junos OS creates only one policer instance regardless of how many times the policer is referenced. When you do this, rate limiting is applied in aggregate, so if you configure a policer to discard traffic that exceeds 1 Gbps and reference that policer in three different terms, the total bandwidth allowed by the filter is 1 Gbps.

**NOTE:** You can include two-color policer actions on ingress firewall filters only. You can include three-color policer actions on ingress and egress filters.

1. [Configuring Two-Color Policers on page 4183](#)
2. [Configuring Three-Color Policers on page 4184](#)
3. [Specifying Policers in a Firewall Filter Configuration on page 4184](#)
4. [Applying a Firewall Filter That Includes a Policer on page 4185](#)

### Configuring Two-Color Policers

To configure a two-color policer:

1. Specify the name of the policer, the bandwidth limit to control the traffic rate on an interface, and the maximum allowed burst size to control the amount of traffic bursting:

```
[edit firewall]
```

```
user@switch# set policer policer-name <filter-specific> if-exceeding bandwidth-limit bps  
burst-size-limit bytes
```

The policer name can contain letters, numbers, and hyphens (-) and can have as many as 64 characters.

The range for the bandwidth limit is 32000 (32k) through 102,300,000,000 (102300m) bps.

To determine the value for the burst-size limit, multiply the bandwidth of the interface on which the filter is applied by the amount of time to allow a burst of traffic at that bandwidth to occur and divide the result by 8:

**maximum burst size = (interface bandwidth) X (allowable time for burst) / (8 bits/byte)**

The range for the burst-size limit is 1 through 2,147,450,880 bytes.

2. Specify the policer action to discard or assign a loss priority to packets that exceed the rate limits:

```
[edit firewall policer policer-name]  
user@switch# set then (discard | loss-priority low | loss-priority high)
```

---

### Configuring Three-Color Policers

To configure a three-color policer:

1. Specify the name of the policer and (optionally) whether to automatically discard packets with high loss priority (PLP):

```
[edit firewall]  
user@switch# set three-color-policer policer-name  
user@switch# set three-color-policer policer-name action loss-priority high then discard
```

2. Specify whether the three-color policer should be single-rate or two-rate and whether it should be color-aware or color-blind:

```
[edit firewall three-color-policer policer-name]  
user@switch# set (single-rate | two-rate) (color-aware | color-blind)
```

3. For single-rate three-color policers, configure the CIR, CBS, and EBS:

```
[edit firewall three-color-policer policer-name single-rate]  
user@switch# set committed-information-rate bps  
user@switch# set committed-burst-size bytes  
user@switch# set excess-burst-size bytes
```

4. For two-rate three-color policers, configure the CIR, CBS, PIR, and PBS:

```
[edit firewall three-color-policer policer-name single-rate]  
user@switch# set committed-information-rate bps  
user@switch# set committed-burst-size bytes  
user@switch# set peak-information-rate bps  
user@switch# set peak-burst-size bytes
```

---

### Specifying Policers in a Firewall Filter Configuration

To use a two-color policer, configure a filter term that includes the action **policer**:

```
[edit firewall family family-name]  
user@switch# set filter filter-name term name then name
```

For example, the following commands apply a two-color policer to all packets sent from 192.0.2.0/24.

```
[edit firewall family family-name]  
user@switch# set filter limit—hosts term term1 from source-address 192.0.2.0/24  
user@switch# set filter limit—hosts term term1 then policer policer1
```

To use a three-color policer, configure a filter term that includes the action **three-color-policer**:

```
[edit firewall family name]
user@switch# set filter name term name from match-condition
user@switch# set filter name term name then three-color-policer (single-rate | two-rate) name
```

For example, the following commands apply a single-rate three-color policer to all packets received or sent by interface **ge-0/0/6** (depending on whether the filter is an ingress or egress filter).

```
[edit firewall family name]
user@switch# set filter srTCM term term-one from interface ge-0/0/6
user@switch# set filter srTCM term term-one then three-color-policer single-rate srTCM1-ca
```

You must specify whether the three-color policer is single-rate or two-rate, and this must match the policer itself. Otherwise, the configuration listing includes an error message indicating that the three-color policer you referenced in the filter does not exist.

### Applying a Firewall Filter That Includes a Policer

A firewall filter that includes one or more policer action modifiers must be applied to a port, VLAN, or Layer 3 interface like any other filter. For information about applying firewall filters, see “Configuring Firewall Filters” on page 4177.

**NOTE:** You can include two-color policer actions on ingress firewall filters only. You can include three-color policer actions on ingress and egress filters.

## Configuring Port Security (CLI Procedure)

Ethernet LANs are vulnerable to attacks such as address spoofing and Layer 2 denial of service (DoS) on network devices. Port security features such as DHCP snooping, DAI (dynamic ARP inspection), MAC limiting, MAC move limiting, and persistent MAC learning, as well as trusted DHCP server, help protect the access ports on the switch against the losses of information and productivity that can result from such attacks.

Depending on the particular feature, you can configure the port security feature either on:

- VLANs—A specific VLAN or all VLANs
- Interfaces—A specific interface or all interfaces

**NOTE:** If you configure one of the port security features on all VLANs or all interfaces, the switch software enables that port security feature on all VLANs and all interfaces that are not explicitly configured with other port security features.

However, if you do explicitly configure one of the port security features on a specific VLAN or on a specific interface, you must explicitly configure any additional port security features that you want to apply to that VLAN or interface. Otherwise, the switch software automatically applies the default values for the feature.

For example, if you enable DHCP snooping on all VLANs and decide to explicitly enable IP source guard only on a specific VLAN, you must also explicitly enable DHCP snooping on that specific VLAN. Otherwise, the default value of no DHCP snooping applies to that VLAN.

---

To configure port security features using the CLI:

- [Enabling DHCP Snooping on page 4187](#)
- [Enabling Dynamic ARP Inspection \(DAI\) on page 4187](#)
- [Limiting Dynamic MAC Addresses on an Interface on page 4187](#)
- [Enabling Persistent MAC Learning on an Interface on page 4187](#)

- [Limiting MAC Address Movement on page 4188](#)
- [Configuring Trusted DHCP Servers on an Interface on page 4188](#)

### Enabling DHCP Snooping

You can configure DHCP snooping to allow the device to monitor DHCP messages received, ensure that hosts only use the IP addresses assigned to them, and allow access only to authorized DHCP servers.

To enable DHCP snooping:

- On a specific VLAN:
 

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan default examine-dhcp
```
- On all VLANs:
 

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan all examine-dhcp
```

### Enabling Dynamic ARP Inspection (DAI)

You can enable DAI to protect against ARP spoofing. To enable DAI:

- On a single VLAN (here, the VLAN is **employee-vlan**):
 

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee-vlan arp-inspection
```
- On all VLANs:
 

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan all arp-inspection
```

### Limiting Dynamic MAC Addresses on an Interface

Limit the number of dynamic MAC addresses allowed on an interface and specify the action to take if the limit is exceeded—for example, set a MAC limit of **5** with an action of **drop**:

- On a single interface:
 

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface ge-0/0/1 mac-limit 5 action drop
```
- On all interfaces:
 

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface all mac-limit 5 action drop
```

You can also specify the actions **log** (do not drop the packet but generate an alarm, an SNMP trap, or a system log entry), **none** (no action), or **shutdown** (disable the interface and generate an alarm) to occur if the number of dynamic MAC addresses is exceeded.

### Enabling Persistent MAC Learning on an Interface

You can configure learned MAC addresses to persist on an interface across restarts of the switch:

```
[edit ethernet-switching-options secure-access-port]
```

```
user@switch# set interface ge-0/0/1 persistent-learning
```

### Limiting MAC Address Movement

---

You can limit the number of times a MAC address can move from its original interface in 1 second—for example, set a MAC move limit of 5 with an action of **drop** if the limit is exceeded:

- On a single VLAN (here, the VLAN is **employee-vlan**):  

```
[edit ethernet-switching-options secure-access-port]  
user@switch# set vlan employee-vlan mac-move-limit 5 action drop
```
- On all VLANs:  

```
[edit ethernet-switching-options secure-access-port]  
user@switch# set vlan all mac-move-limit 5 action drop
```

You can also specify the actions **log** (do not drop the packet but generate an alarm, an SNMP trap, or a system log entry), **none** (no action), or **shutdown** (disable the interface or VLAN and generate an alarm) to occur if the MAC address moves more than the specified number of times in 1 second.

### Configuring Trusted DHCP Servers on an Interface

---

Configure a trusted DHCP server on an interface:

```
[edit ethernet-switching-options secure-access-port]  
user@switch# set interface ge-0/0/1 dhcp-trusted
```

## Configuring MAC Limiting

To configure MAC limiting on a specific interface or on all interfaces:

1. To limit the number of dynamic MAC addresses, set a MAC limit of 5.

The action is not specified, so the switch performs the default action **drop** if the limit is exceeded:

- On a single interface (here, the interface is **xe-0/0/1**):  

```
[edit ethernet-switching-options secure-access-port]
```

```
user@switch# set interface xe-0/0/1 mac-limit (Access Port Security) 5
```

- On all interfaces:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface all mac-limit 5
```

**CAUTION:** Do not set the MAC limit to 1. The first learned MAC address is often inserted into the forwarding database automatically. (For instance, the first MAC address inserted into the forwarding database for routed VLAN interfaces is the MAC address of the RVI. For Aggregated Ethernet bundles using LACP, the first MAC address inserted into the forwarding database in the forwarding table is the source address of the protocol packet.) The switch therefore fails to learn MAC addresses other than the automatic addresses when the MAC limit is set to 1, and this causes problems with MAC learning and forwarding.

2. To specify allowed MAC addresses:

- On a single interface (here, the interface is `xe-0/0/2`):

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface xe-0/0/2 allowed-mac 00:05:85:3A:82:80
user@switch# set interface xe-0/0/2 allowed-mac 00:05:85:3A:82:81
user@switch# set interface xe-0/0/2 allowed-mac 00:05:85:3A:82:83
```

- On all interfaces:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface all allowed-mac 00:05:85:3A:82:80
user@switch# set interface all allowed-mac 00:05:85:3A:82:81
user@switch# set interface all allowed-mac 00:05:85:3A:82:83
```

## Configuring MAC Move Limiting (CLI Procedure)

When MAC move limiting is configured, MAC address movements are tracked by the switch and, if a MAC address changes more than the configured number of times within 1 second, the changes to MAC addresses are dropped, logged, ignored, or the interface is shut down.

**NOTE:** Although you enable this feature on VLANs, the MAC move limitation pertains to the number of movements for each individual MAC address rather than the total number of MAC address moves in the VLAN. For example, if the MAC move limit is set to 1, the switch allows an unlimited number of MAC address movements within the VLAN as long as the same MAC address does not change more than once.

You configure MAC move limiting per VLAN, not per interface (port). In the default configuration, the number of MAC moves permitted is unlimited.

You can choose to have one of the following actions performed when the MAC move limit is exceeded:

- **drop**—Drop the packet and generate a system log entry. This is the default.
- **log**—Do not drop the packet but generate a system log entry.
- **none**—Take no action.
- **shutdown**—Disable the interfaces in the VLAN and generate a system log entry. If you have configured the switch with the **port-error-disable** statement, the disabled interfaces recover automatically upon expiration of the specified disable timeout. If you have not configured the switch for autorecovery from port error disabled conditions, you can bring up the disabled interfaces by running the **clear ethernet-switching port-error** command.

To configure a MAC move limit for MAC addresses within a specific VLAN or for MAC addresses within all VLANs, using the CLI:

- On a single VLAN: To limit the number of MAC address movements that can be made by an individual MAC address within the VLAN **employee-vlan**, set a MAC move limit of 5:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee-vlan mac-move-limit 5
```

The action is not specified, so the switch performs the default action **drop** if it tracks that an individual MAC address within the **employee-vlan** has moved more than 5 times within one second.

- On all VLANs: To limit the number of MAC movements that can be made by individual MAC addresses within all VLANs, set a MAC move limit of 5:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan all mac-move-limit 5
```

The action is not specified, so the switch performs the default action **drop** if it tracks that an individual MAC address within any of the VLANs has moved more than 5 times within 1 second.

## Configuring Autorecovery for MAC Limited or Storm Control Interfaces (CLI Procedure)

An Ethernet access interface might shut down or be disabled as a result of one of the following configurations:

- MAC limiting—**mac-limit** statement is configured with action **shutdown**.
- MAC move limiting—**mac-move-limit** statement is configured with action **shutdown**.
- Storm control—**storm-control** statement is configured with the action **shutdown**.

You can configure a device to automatically restore the disabled interfaces to service after a specified period of time. Autorecovery applies to all the interfaces that have been disabled due to MAC limiting, MAC move limiting, or storm control errors.

To configure autorecovery from the disabled state due to MAC limiting, MAC move limiting, or storm control shutdown actions:

```
[edit ethernet-switching-options]
user@switch# set port-error-disable disable-timeout seconds
```

**NOTE:** You must specify the disable timeout value—there is no default disable timeout period. If you do not specify a timeout value, you must use the [clear ethernet-switching port-error](#) command to clear the errors and restore the interfaces to service.

## Configuring the none Action to Override a MAC Limit Applied to All Interfaces (CLI Procedure)

If you set a MAC limit in your port security settings to apply to all interfaces, you can override that setting for a particular interface by specifying the action **none**.

To use the **none** action to override a MAC limit setting:

1. Set the MAC limit for all interfaces—for example, a limit of **5** with action **drop**:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface all mac-limit (Access Port Security) 5 action drop
```

2. Change the action for one interface with this command.

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface xe-0/0/2 mac-limit action none
```

## Configuring Static ARP Entries

You can create static ARP table entries, which are explicit mappings between IP addresses and MAC addresses.

- To configure a static ARP entry:

```
[edit interfaces interface-name unit logical-unit-number family inet address
address]
user@switch# set arp ip-address (mac | multicast-mac) mac-address
```

The IP address that you specify must be part of the subnet defined in the enclosing **address** statement.

To associate a multicast MAC address with a unicast IP address, use the **multicast-mac** statement.

Specify the MAC address as 6 hexadecimal bytes in one of the following formats: *nnnn.nnnn.nnnn* or *nn:nn:nn:nn:nn:nn*; for example, 0011.2233.4455 or 00:11:22:33:44:55.

### Related Documentation

## Configuring Static IP Addresses for DHCP Bindings on Access Ports (CLI Procedure)

You can add static (fixed) IP addresses and bind them to fixed MAC addresses in the DHCP snooping database. These bindings are labeled as “static” in the database, while those bindings that have been added through the process of DHCP snooping are labeled “dynamic.”

To configure a static IP address/MAC address binding in the DHCP snooping database (replace **ge-0/0/2**, **10.0.10.12**, **data-vlan**, and **00:05:85:3A:82:80** with values for your configuration):

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface ge-0/0/2 static-ip 10.0.10.12 vlan data-vlan mac 00:05:85:3A:82:80
```

To view results of the configuration steps before committing the configuration, type the **show** command at the user prompt.

To commit these changes to the active configuration, type the **commit** command at the user prompt.

## Configuring Unknown Unicast Forwarding

Unknown unicast packets have unknown destination MAC addresses. By default, these packets are flooded out all the ports in the VLAN, which can trigger a traffic storm and cause security issues and performance degradation.

To prevent storms, configure a VLAN to forward unknown unicast traffic to a trunk port. The destination MAC address can be learned from the trunk port and added to the Ethernet switching table. You can configure different VLANs to forward unknown unicast traffic to different trunk interfaces or use one trunk interface for multiple VLANs.

To configure unknown unicast forwarding options using the CLI:

**NOTE:** Before you can configure unknown unicast forwarding within a VLAN, you must first configure that VLAN.

1. Configure unknown unicast forwarding for a specific VLAN:

```
[edit ethernet-switching-options]
user@switch# set unknown-unicast-forwarding vlan VLAN-name
```

2. Specify the trunk interface to which unknown unicast traffic will be forwarded:

```
[edit ethernet-switching-options ]
user@switch# set unknown-unicast-forwarding vlan VLAN-name interface (Unknown Unicast Forwarding) interface-name
```

### Related Documentation

## Enabling DHCP Snooping (CLI Procedure)

DHCP snooping allows the switch to monitor and control DHCP messages received from untrusted devices connected to the switch. It builds and maintains a database of valid IP-address/MAC-address (IP-MAC) bindings called the DHCP snooping database.

.....

**NOTE:** If you configure DHCP snooping for all VLANs and you enable a different port security feature on a specific VLAN, you must also explicitly enable DHCP snooping on that VLAN. Otherwise, the default value of no DHCP snooping applies to that VLAN.

.....

This topic describes:

- [Enabling DHCP Snooping on page 4196](#)
- [Applying CoS Forwarding Classes to Prioritize Snooped Packets on page 4196](#)

## Enabling DHCP Snooping

You configure DHCP snooping per VLAN, not per interface (port). By default, DHCP snooping is disabled for all VLANs. You can enable DHCP snooping on all VLANs or on specific VLANs.

To enable DHCP snooping on a VLAN or all VLANs:

- On a specific VLAN:

```
[edit ethernet-switching-options secure-access port]
user@switch# set vlan vlan-name examine-dhcp
```

- On all VLANs:

```
[edit ethernet-switching-options secure-access port]
user@switch# set vlan all examine-dhcp
```

**TIP:** By default, the IP-MAC bindings are lost when the switch is rebooted and DHCP clients (the network devices, or hosts) must reacquire bindings. However, you can configure the bindings to persist by setting the `dhcp-snooping-file` statement to store the database file either locally or remotely.

**TIP:** For private VLANs (PVLANS), enable DHCP snooping on the primary VLAN. If you enable DHCP snooping only on a community VLAN, DHCP messages coming from PVLAN trunk ports are not snooped.

## Applying CoS Forwarding Classes to Prioritize Snooped Packets

On EX Series switches you might need to use class of service (CoS) to protect packets from critical applications from being dropped during periods of network congestion and delay and you might also need the port security features of DHCP snooping on the same ports through which those critical packets are entering and leaving.

**NOTE:** This is not supported on the QFX Series switch.

To apply CoS forwarding classes and queues to snooped packets:

1. Create a user-defined forwarding class to be used for prioritizing snooped packets:

```
[edit class-of-service]
user@switch# set forwarding-classes class class-name queue queue-number
```

2. Enable DHCP snooping on a specific VLAN or on all VLANs and apply the desired forwarding class on the snooped packets:

- On a specific VLAN:

```
[edit ethernet-switching-options secure-access port]
user@switch# set vlan vlan-name examine-dhcp forwarding-class class-name
```

- On all VLANs:

```
[edit ethernet-switching-options secure-access port]
user@switch# set vlan all examine-dhcp forwarding-class class-name
```

#### Related Documentation

- [Enabling DHCP Snooping \(J-Web Procedure\)](#)
- [Example: Configuring Basic Port Security Features on page 4136](#)

- [secure-access-port on page 4256](#)

### Enabling Dynamic ARP Inspection (CLI Procedure)

Dynamic ARP inspection (DAI) protects switches against ARP spoofing. DAI inspects ARP packets on the LAN and uses the information in the DHCP snooping database on the switch to validate ARP packets and to protect against ARP cache poisoning.

This topic describes:

- [Enabling DAI on page 4198](#)
- [Applying CoS Forwarding Classes to Prioritize Inspected Packets on page 4198](#)

## Enabling DAI

---

You configure DAI for each VLAN, not for each interface (port). By default, DAI is disabled for all VLANs.

To enable DAI on a VLAN or all VLANs:

- On a single VLAN:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan vlan-name arp-inspection
```

- On all VLANs:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan all arp-inspection
```

## Applying CoS Forwarding Classes to Prioritize Inspected Packets

---

You might need to use class of service (CoS) to protect packets from critical applications from being dropped during periods of network congestion and delay and you might also need the port security features of DHCP snooping on the same ports through which those critical packets are entering and leaving.

To apply CoS forwarding classes and queues to DAI packets:

1. Create a user-defined forwarding class to be used for prioritizing DAI packets:

```
[edit class-of-service]
user@switch# set forwarding-classes class class-name queue queue-number
```

2. Enable DAI on a specific VLAN or on all VLANs and apply the desired forwarding class on the DAI packets:

- On a specific VLAN:

```
[edit ethernet-switching-options secure-access port]
user@switch# set vlan vlan-name arp-inspection forwarding-class class-name
```

- On all VLANs:

```
[edit ethernet-switching-options secure-access port]
user@switch# set vlan all arp-inspection forwarding-class class-name
```

## Enabling a Trusted DHCP Server (CLI Procedure)

You can configure any interface on a switch that connects to a DHCP server as a trusted interface (port). Configuring a DHCP server on a trusted interface protects against rogue DHCP servers sending leases.

You configure a trusted DHCP server on an interface, not on a VLAN. By default, all access interfaces are untrusted, and all trunk interfaces are trusted.

To configure a trusted interface for a DHCP server by using the CLI (here, the interface is **ge-0/0/8**):

```
[edit ethernet-switching-options secure-access port]
user@switch# set interface ge-0/0/8 dhcp-trusted
```

### Related Documentation

- [Understanding Trusted DHCP Servers for Port Security on page 4121](#)
- [secure-access-port](#)
- [secure-access-port on page 4256](#)

## Enabling a Trusted Port for DHCP

By default, all access ports are untrusted and all trunk ports are trusted with regard to DHCP. Trusted ports allow DHCP servers to provide IP addresses and other information to requesting devices. Untrusted ports drop traffic from DHCP servers to prevent unauthorized servers from providing any configuration information to clients.

If you attach a DHCP server to an access port, you must configure it as trusted. You configure a trusted DHCP server on an interface, not on a VLAN.

**NOTE:** Before you attach a DHCP server to a trusted access port, ensure that the server is physically secure—that is, that access to the server is monitored and controlled.

- To configure a trusted interface for a DHCP server by using the CLI (here, the interface is **xe-0/0/8**):

```
[edit ethernet-switching-options secure-access port]
user@switch# set interface xe-0/0/8 dhcp-trusted
```

### Related Documentation

## Setting Up DHCP Option 82 on the Switch with No Relay Agent Between Clients and DHCP Server (CLI Procedure)

You can use DHCP option 82, also known as the DHCP relay agent information option, to help protect the switch against attacks such as spoofing (forging) of IP addresses and MAC addresses, and DHCP IP address starvation. Option 82 provides information about the network location of a DHCP client, and the DHCP server uses this information to implement IP addresses or other parameters for the client.

You can configure the DHCP option 82 feature in two topologies:

- The switch, DHCP clients, and DHCP server are all on the same VLAN. The switch forwards the clients' requests to the server and forwards the server's replies to the clients. This topic describes this configuration.
- The switch functions as a relay agent when the DHCP clients or the DHCP server is connected to the switch through a Layer 3 interface. On the switch, these interfaces are configured as routed VLAN interfaces, or RVIs. The switch relays the clients' requests to the server and then forwards the server's replies to the clients. This configuration is described in [“Setting Up DHCP Option 82 with the Switch as a Relay Agent Between Clients and DHCP Server \(CLI Procedure\)”](#) on page 4204.

Before you configure DHCP option 82 on the switch, perform these tasks:

- Connect and configure the DHCP server.

**NOTE:** Your DHCP server must be configured to accept DHCP option 82. If the server is not configured for DHCP option 82, the server does not use the DHCP option 82 information in the requests sent to it when it formulates its reply messages.

- Configure a VLAN on the switch and associate the interfaces on which the clients and the server connect to the switch with that VLAN.

To configure DHCP option 82:

**NOTE:** Replace values displayed in *italics* with values for your configuration.

1. Specify DHCP option 82 for all VLANs associated with the switch or for a specified VLAN. (You can also configure the feature for a VLAN range.)

- On a specific VLAN:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee dhcp-option82
```

- On all VLANs:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan all dhcp-option82
```

The remaining steps are optional.

2. To configure a prefix for the circuit ID suboption (the prefix is always the hostname of the switch):

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee dhcp-option82 circuit-id prefix hostname
```

3. To specify that the circuit ID suboption value should contain the interface description rather than the interface name (the default):

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee dhcp-option82 circuit-id use-interface-description
```

4. To specify that the circuit ID suboption value should contain the VLAN ID rather than the VLAN name (the default):

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee dhcp-option82 circuit-id use-vlan-id
```

5. To specify that the remote ID suboption be included in the DHCP option 82 information:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee dhcp-option82 remote-id
```

6. To configure a prefix for the remote ID suboption (here, the prefix is the MAC address of the switch):

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee dhcp-option82 remote-id prefix mac
```

7. To specify that the prefix for the remote ID suboption be the hostname of the switch rather than the MAC address of the switch (the default):

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee dhcp-option82 remote-id prefix hostname
```

8. To specify that the remote ID suboption value should contain the interface description:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee dhcp-option82 remote-id use-interface-description
```

9. To specify that the remote ID suboption value should contain a character string:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee dhcp-option82 remote-id use-string mystring
```

10. To configure a vendor ID suboption and use the default value (the default value is **Juniper**), do not type a character string after the **vendor-id** option keyword:

```
[edit ethernet-switching-options secure-access-port]
```

```
user@switch# set vlan employee dhcp-option82 vendor-id
```

11. To specify that the vendor ID suboption value should contain a character string value that you specify rather than **Juniper** (the default):

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee dhcp-option82 vendor-id mystring
```

To view results of the configuration steps before committing the configuration, type the **show** command at the user prompt.

To commit these changes to the active configuration, type the **commit** command at the user prompt.

- [RFC 3046, DHCP Relay Agent Information Option](#), at <http://tools.ietf.org/html/rfc3046>.

## Setting Up DHCP Option 82 with the Switch as a Relay Agent Between Clients and DHCP Server (CLI Procedure)

You can use DHCP option 82, also known as the DHCP relay agent information option, to help switches against attacks such as spoofing (forging) of IP addresses and MAC addresses, and DHCP IP address starvation. Option 82 provides information about the network location of a DHCP client, and the DHCP server uses this information to implement IP addresses or other parameters for the client.

You can configure the DHCP option 82 feature in two topologies:

- The switch functions as a relay agent when the DHCP clients or the DHCP server is connected to the switch through a Layer 3 interface. On the switch, these interfaces are configured as routed VLAN interfaces, or RVIs. The switch relays the clients' requests to the server and then forwards the server's replies to the clients. This topic describes this configuration.
- The switch, DHCP clients, and DHCP server are all on the same VLAN. The switch forwards the clients' requests to the server and forwards the server's replies to the clients. This configuration is described in [“Setting Up DHCP Option 82 on the Switch with No Relay Agent Between Clients and DHCP Server \(CLI Procedure\)” on page 4201](#).

Before you configure DHCP option 82 on the switch, perform these tasks:

- Connect and configure the DHCP server.

.....  
**NOTE:** Your DHCP server must be configured to accept DHCP option 82. If the server is not configured for DHCP option 82, the server does not use the DHCP option 82 information in the requests sent to it when it formulates its reply messages.  
.....

- Configure the VLAN on the switch and associate the interfaces on which the clients connect to the switch with that VLAN.
- Configure the routed VLAN interface (RVI) to allow the switch to relay packets to the server and receive packets from the server. See [Configuring Routed VLAN Interfaces \(CLI Procedure\)](#) or [“Configuring Routed VLAN Interfaces” on page 1551](#) for the QFX Series.
- Configure the switch as a BOOTP relay agent. See [DHCP/BOOTP Relay for Switches Overview](#).

To configure DHCP option 82:

**NOTE:** Replace values displayed in *italics* with values for your configuration.

1. Specify DHCP option 82 for the BOOTP server:

- On all interfaces that connect to the server:

```
[edit forwarding-options helpers bootp]
user@switch# set dhcp-option82
```

- On a specific interface that connects to the server:

```
[edit forwarding-options helpers bootp]
user@switch# set interface ge-0/0/10 dhcp-option82
```

The remaining steps are optional. They show configurations for all interfaces; include the specific interface designation to configure any of the following options on a specific interface:

2. To configure a prefix for the circuit ID suboption (the prefix is always the hostname of the switch):

```
[edit forwarding-options helpers bootp]
user@switch# set dhcp-option82 circuit-id prefix hostname
```

3. To specify that the circuit ID suboption value should contain the interface description rather than the interface name (the default):

```
[edit forwarding-options helpers bootp]
user@switch# set dhcp-option82 circuit-id use-interface-description
```

4. To specify that the circuit ID suboption value should contain the VLAN ID rather than the VLAN name (the default):

```
[edit forwarding-options helpers bootp]
user@switch# set dhcp-option82 circuit-id use-vlan-id
```

5. To specify that the remote ID suboption be included in the DHCP option 82 information:

```
[edit forwarding-options helpers bootp]
user@switch# set dhcp-option82 remote-id
```

6. To configure a prefix for the remote ID suboption (here, the prefix is the MAC address of the switch):

```
[edit forwarding-options helpers bootp]
user@switch# set dhcp-option82 remote-id prefix mac
```

7. To specify that the prefix for the remote ID suboption be the hostname of the switch rather than the MAC address of the switch (the default):

```
[edit forwarding-options helpers bootp]
user@switch# set dhcp-option82 remote-id prefix hostname
```

8. To specify that the remote ID suboption value should contain the interface description:

```
[edit forwarding-options helpers bootp]
user@switch# set dhcp-option82 remote-id use-interface-description
```

9. To specify that the remote ID suboption value should contain a character string:

```
[edit forwarding-options helpers bootp]
user@switch# set dhcp-option82 remote-id use-string mystring
```

10. To configure a vendor ID suboption and use the default value (the default value is **Juniper**), do not type a character string after the **vendor-id** option keyword:

```
[edit forwarding-options helpers bootp]
user@switch# set dhcp-option82 vendor-id
```

11. To specify that the vendor ID suboption value contains a character string value that you specify rather than **Juniper** (the default):

```
[edit forwarding-options helpers bootp]
user@switch# set dhcp-option82 vendor-id mystring
```

To view results of the configuration steps before committing the configuration, type the **show** command at the user prompt.

To commit these changes to the active configuration, type the **commit** command at the user prompt.

## Configuration Statements for Firewall Filters

### family

**Syntax**

```
family family-name {
  filter filter-name {
    interface-specific;
    term term-name {
      from {
        match-conditions;
      }
      then {
        action;
        action-modifiers;
      }
    }
  }
}
```

**Hierarchy Level** [edit [firewall](#)]

**Release Information** Statement introduced in Junos OS Release 11.1 for the QFX Series.

**Description** Configure a firewall filter for IP version 4 or IP version 6.

**Options** *family-name*—Type of addressing protocol:

- **ethernet-switching**—Filter Layer 2 Ethernet packets and Layer 3 (IP) packets (allows some Layer 3 filtering).
- **inet**—Filter Layer 3 IPv4 packets (provides additional Layer 3 filter options).
- **inet6**—Filter Layer 3 IPv6 packets (provides additional Layer 3 filter options).

The remaining statements are explained separately.

**Required Privilege Level** interface—To view this statement in the configuration.  
interface-control—To add this statement to the configuration.

**Related Documentation**

## filter

---

**Syntax**    `filter filter-name {  
                  interface-specific;  
                  term term-name {  
                    from {  
                      match-conditions;  
                    }  
                    then {  
                      action;  
                      action-modifiers;  
                    }  
                  }  
                }`

**Hierarchy Level**    [edit `firewall family family-name`]

**Release Information**    Statement introduced in Junos OS Release 11.1 for the QFX Series.

**Description**    Configure firewall filters.

**Options**    *filter-name*—Name that identifies the filter. The name can contain letters, numbers, and hyphens (-), and can be up to 64 characters long. To include spaces in the name, enclose it in quotation marks.

The remaining statements are explained separately.

**Required Privilege Level**    firewall—To view this statement in the configuration.  
                                  firewall-control—To add this statement to the configuration.

Hierarchy Level [\[edit\]](#)

**Release Information** Statement introduced in Junos OS Release 11.1 for the QFX Series.

**Description** Configure firewall filters and policers.

The remaining statements are explained separately.

<b>Required Privilege Level</b>	firewall—To view this statement in the configuration. firewall-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Firewall Filter Match Conditions and Actions on page 4080</a></li><li>• <a href="#">Configuring Firewall Filters on page 4177</a></li><li>• <a href="#">Configuring Two-Color and Three-Color Policers to Control Traffic Rates on page 4183</a></li><li>• <a href="#">Overview of Firewall Filters on page 4071</a></li></ul>

---

## from

---

<b>Syntax</b>	<pre>from {     match-conditions; }</pre>
<b>Hierarchy Level</b>	[edit <b>firewall family</b> <i>family-name</i> <b>filter</b> <i>filter-name</i> <b>term</b> <i>term-name</i> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Match packet fields to values specified in a match condition. If the <b>from</b> statement is not included in a firewall filter configuration, all packets are considered to match and the actions and action modifiers in the <b>then</b> statement are implemented.
<b>Options</b>	<b>match-conditions</b> —Conditions that define the values or fields that the incoming or outgoing packets must contain for a match. You can specify one or more match conditions. If you specify more than one, they all must match for a match to occur and for the action in the <b>then</b> statement to be implemented.
<b>Required Privilege Level</b>	firewall—To view this statement in the configuration. firewall-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Firewall Filter Match Conditions and Actions on page 4080</a></li><li>• <a href="#">Configuring Firewall Filters on page 4177</a></li><li>• <a href="#">Understanding Firewall Filter Match Conditions on page 4077</a></li></ul>

## interface-specific

---

<b>Syntax</b>	interface-specific;
<b>Hierarchy Level</b>	[edit <b>firewall</b> family <i>family-name</i> <b>filter</b> <i>filter-name</i> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Configure separate counters for each interface to which a filter is applied.
<b>Required Privilege Level</b>	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Firewall Filter Match Conditions and Actions on page 4080</a></li> <li>• <a href="#">Configuring Firewall Filters on page 4177</a></li> <li>• <a href="#">Overview of Firewall Filters on page 4071</a></li> </ul>

## term

---

<b>Syntax</b>	<pre>term <i>term-name</i> {     from {         <i>match-conditions</i>;     }     then {         <i>action</i>;         <i>action-modifiers</i>;     } }</pre>
<b>Hierarchy Level</b>	[edit <b>firewall</b> family <i>family-name</i> <b>filter</b> <i>filter-name</i> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Define a firewall filter term.
<b>Options</b>	<p><b><i>term-name</i></b>—Name that identifies the term. The name can contain letters, numbers, and hyphens (-), and can be up to 64 characters long. To include spaces in the name, enclose it in quotation marks.</p> <p>The remaining statements are explained separately.</p>
<b>Required Privilege Level</b>	firewall—To view this statement in the configuration. firewall-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Firewall Filter Match Conditions and Actions on page 4080</a></li> <li>• <a href="#">Configuring Firewall Filters on page 4177</a></li> <li>• <a href="#">Overview of Firewall Filters on page 4071</a></li> </ul>

## then (Filters)

---

<b>Syntax</b>	<pre>then {     action;     action-modifiers; }</pre>
<b>Hierarchy Level</b>	[edit <b>firewall family</b> <i>family-name</i> <b>filter</b> <i>filter-name</i> <b>term</b> <i>term-name</i> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Configure a firewall filter action.
<b>Options</b>	<p><b>action</b>—Actions to accept, discard, or forward packets that match all conditions specified in a filter term.</p> <p><b>action-modifiers</b>—Additional actions to analyze, classify, count, or police packets that match all conditions specified in a filter term.</p>
<b>Required Privilege Level</b>	<p>firewall—To view this statement in the configuration.</p> <p>firewall-control—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Firewall Filter Match Conditions and Actions on page 4080</a></li><li>• <a href="#">Configuring Firewall Filters on page 4177</a></li><li>• <a href="#">Understanding Firewall Filter Match Conditions on page 4077</a></li></ul>

## Configuration Statements for Policers

---

### action

---

<b>Syntax</b>	<pre>action {     loss-priority high then discard; }</pre>
<b>Hierarchy Level</b>	[edit <b>firewall three-color-policer</b> <i>name</i> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Discard traffic on a logical interface using tricolor marking policing.
<b>Options</b>	The statements are explained separately.
<b>Required Privilege Level</b>	<p>firewall—To view this statement in the configuration.</p> <p>firewall-control—To add this statement to the configuration.</p>

## bandwidth-limit

---

<b>Syntax</b>	<code>bandwidth-limit <i>bps</i>;</code>
<b>Hierarchy Level</b>	[edit <code>firewall policer <i>policer-name</i> if-exceeding</code> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Specify the traffic rate in bits per second.
<b>Options</b>	<p><b><i>bps</i></b>—Traffic rate in bits per second. Specify <i>bps</i> as a decimal value or as a decimal number followed by one of the abbreviation <b>k</b> (1000), <b>m</b> (1,000,000), or <b>g</b> (1,000,000,000).</p> <p><b>Range:</b> 32000 bps (32 Kbps) through 10,000,000,000 bps (10 Gbps)</p>
<b>Required Privilege Level</b>	<p>firewall—To view this statement in the configuration.</p> <p>firewall-control—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Configuring Two-Color and Three-Color Policers to Control Traffic Rates on page 4183</a></li> <li>• <a href="#">Overview of Policers on page 4096</a></li> </ul>

## burst-size-limit

---

<b>Syntax</b>	<code>burst-size-limit <i>bytes</i>;</code>
<b>Hierarchy Level</b>	[edit <code>firewall policer <i>policer-name</i> if-exceeding</code> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Specify the maximum allowed burst size to control the amount of traffic bursting.
<b>Options</b>	<p><b><i>bytes</i></b>—Decimal value or a decimal number followed by <b>k</b> (thousand), <b>m</b> (million), or <b>g</b> (giga).</p> <p><b>Range:</b> 1 through 2,147,450,880 bytes (2147 MB)</p>
<b>Required Privilege Level</b>	<p>firewall—To view this statement in the configuration.</p> <p>firewall-control—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Configuring Two-Color and Three-Color Policers to Control Traffic Rates on page 4183</a></li> <li>• <a href="#">Overview of Policers on page 4096</a></li> </ul>

## color-aware

---

<b>Syntax</b>	color-aware;
<b>Hierarchy Level</b>	[edit <b>firewall three-color-policer</b> <i>policer-name</i> single-rate], [edit <b>firewall three-color-policer</b> <i>policer-name</i> two-rate]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Configure the way preclassified packets are metered. In color-aware mode, the switch can assign a higher packet-loss priority, but cannot assign a lower packet loss priority (PLP). For example, suppose an upstream device assigns medium-high PLP to a packet because the packet exceeded its committed information rate (CIR). The switch cannot change the PLP to low even if the packet conforms to the configured CIR of the appropriate interface. On the other hand, if an upstream device assigns low PLP to a packet but the packet exceeds the CIR and committed burst size (CBS) of the switch interface, the switch can increase the PLP to medium-high.
<b>Default</b>	If you omit the <b>color-aware</b> statement, the default behavior is color-aware mode.
<b>Required Privilege Level</b>	firewall—To view this statement in the configuration. firewall-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Overview of Policers on page 4096</a></li><li>• <a href="#">Understanding Color-Aware Mode for Single-Rate Tricolor Marking on page 4101</a></li><li>• <a href="#">Understanding Color-Aware Mode for Two-Rate Tricolor Marking on page 4103</a></li><li>• <a href="#">color-blind on page 4217</a></li></ul>

## color-blind

---

<b>Syntax</b>	color-blind;
<b>Hierarchy Level</b>	[edit <a href="#">firewall three-color-policer</a> <i>policer-name</i> single-rate], [edit <a href="#">firewall three-color-policer</a> <i>policer-name</i> two-rate]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Configure the way preclassified packets are metered. In color-blind mode, the switch ignores any preclassification of packets and can assign a higher or lower packet loss priority (PLP). For example, suppose an upstream device assigns medium-high PLP to a packet because the packet exceeded the CIR on the upstream device. The switch can change the PLP to low if the packet conforms to the CIR of the appropriate interface.
<b>Default</b>	If you omit the <b>color-blind</b> statement, the default behavior is color-aware mode.
<b>Required Privilege Level</b>	firewall—To view this statement in the configuration. firewall-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Overview of Policers on page 4096</a></li> <li>• <a href="#">Understanding Color-Blind Mode for Single-Rate Tricolor Marking on page 4100</a></li> <li>• <a href="#">Understanding Color-Blind Mode for Two-Rate Tricolor Marking on page 4103</a></li> <li>• <a href="#">Configuring Color-Blind Egress Policers for Medium-Low PLP on page 4182</a></li> <li>• <a href="#">color-aware on page 4216</a></li> </ul>

## committed-burst-size

---

<b>Syntax</b>	<code>committed-burst-size bytes;</code>
<b>Hierarchy Level</b>	[edit <a href="#">firewall three-color-policer</a> <i>policer-name</i> single-rate], [edit <a href="#">firewall three-color-policer</a> <i>policer-name</i> two-rate]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Configure the maximum number of bytes allowed for incoming traffic to burst above the committed information rate and still be marked with low packet loss priority (green).
	<div> <b>NOTE:</b> When you include the <code>committed-burst-size</code> statement in the configuration, you must also include the <code>committed-information-rate</code> statement at the same hierarchy level.</div>
<b>Options</b>	<b>bytes</b> —Number of bytes. You can specify a value in bytes either as a complete decimal number or as a decimal number followed by the abbreviation <b>k</b> (1000), <b>m</b> (1,000,000), or <b>g</b> (1,000,000,000). <b>Range:</b> 512 bytes through 268435456 bytes (268 MB)
<b>Required Privilege Level</b>	<b>firewall</b> —To view this statement in the configuration. <b>firewall-control</b> —To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Configuring Two-Color and Three-Color Policers to Control Traffic Rates on page 4183</a></li><li>• <a href="#">Overview of Policers on page 4096</a></li></ul>

## committed-information-rate

<b>Syntax</b>	<code>committed-information-rate <i>bits-per-second</i>;</code>
<b>Hierarchy Level</b>	[edit <code>firewall three-color-policer <i>policer-name</i> single-rate</code> ], [edit <code>firewall three-color-policer <i>policer-name</i> two-rate</code> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Configure the guaranteed bandwidth under normal line conditions and the average rate up to which packets are marked with low packet loss priority (green).
	<div>  <p><b>NOTE:</b> When you include the <code>committed-information-rate</code> statement in the configuration, you must also include the <code>committed-burst-size</code> statement at the same hierarchy level.</p> </div>
<b>Options</b>	<p><b><i>bits-per-second</i></b>—Number of bits per second. You can specify a value in bits per second either as a complete decimal number or as a decimal number followed by the abbreviation <b>k</b> (1000), <b>m</b> (1,000,000), or <b>g</b> (1,000,000,000).</p> <p><b>Range:</b> 32,000 bps through 10,000,000,000 bps (10 gbps)</p>
<b>Required Privilege Level</b>	<p><code>firewall</code>—To view this statement in the configuration.</p> <p><code>firewall-control</code>—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Configuring Two-Color and Three-Color Policers to Control Traffic Rates on page 4183</a></li> <li>• <a href="#">Overview of Policers on page 4096</a></li> </ul>

## excess-burst-size

---

<b>Syntax</b>	<code>excess-burst-size bytes;</code>
<b>Hierarchy Level</b>	[edit <a href="#">firewall three-color-policer</a> <i>policer-name</i> single-rate]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Configure the maximum number of bytes allowed for incoming traffic to burst above the committed information rate and still be marked with medium-high packet loss priority (yellow). Packets that exceed the excess burst size (EBS) are marked with high packet loss priority (red).
	<div> <b>NOTE:</b> When you include the <code>excess-burst-size</code> statement in the configuration, you must also include the <code>committed-burst-size</code> and <code>committed-information-rate</code> statements at the same hierarchy level.</div>
<b>Options</b>	<p><b>bytes</b>—Number of bytes. You can specify a value in bytes either as a complete decimal number or as a decimal number followed by the abbreviation <b>k</b> (1000), <b>m</b> (1,000,000), or <b>g</b> (1,000,000,000).</p> <p><b>Range:</b> 512 bytes through 268435456 bytes (268 MB)</p>
<b>Required Privilege Level</b>	<p><b>firewall</b>—To view this statement in the configuration.</p> <p><b>firewall-control</b>—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Configuring Two-Color and Three-Color Policers to Control Traffic Rates on page 4183</a></li><li>• <a href="#">Overview of Policers on page 4096</a></li></ul>

## filter-specific

---

<b>Syntax</b>	filter-specific;
<b>Hierarchy Level</b>	[edit <a href="#">firewall policer</a> <i>policer-name</i> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	<p>Configure a policer to be filter-specific, which means that Junos OS creates only one policer instance regardless of how many times the policer is referenced. If you use a filter-specific policer in multiple terms, both of the following are true:</p> <ul style="list-style-type: none"> <li>• Traffic is policed at the aggregate rate. For example, if you create a policer that has a bandwidth limit of 100 Mbps and use the policer in two terms, the total allowed bandwidth for both terms is 100 Mbps—not 100 Mbps for each term.</li> <li>• The implicit counter counts all the packets are that matched by any of the terms. For example, if you reference the same filter-specific policer in term1 and term2, and term1 matches 1000 packets and term2 matches 500 packets, the implicit counter shows 1500 matches for the policer.</li> </ul>
<b>Required Privilege Level</b>	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Configuring Two-Color and Three-Color Policers to Control Traffic Rates on page 4183</a></li> <li>• <a href="#">Overview of Policers on page 4096</a></li> </ul>

## firewall

---

```
Syntax  firewall {

## peak-burst-size

<b>Syntax</b>	<code>peak-burst-size bytes;</code>
<b>Hierarchy Level</b>	[edit <a href="#">firewall three-color-policer</a> <i>policer-name</i> two-rate]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Configure the maximum number of bytes allowed for incoming packets to burst above the peak information rate (PIR) and still be marked with medium-high packet loss priority (yellow). Packets that exceed the peak burst size (PBS) are marked with high packet loss priority (red).
	<div>  <p><b>NOTE:</b> When you include the <code>peak-burst-size</code> statement in the configuration, you must also include the <code>committed-burst-size</code> and <code>peak-information-rate</code> statements at the same hierarchy level.</p> </div>
<b>Options</b>	<p><b>bytes</b>—Number of bytes. You can specify a value in bytes either as a complete decimal number or as a decimal number followed by the abbreviation <b>k</b> (1000), <b>m</b> (1,000,000), or <b>g</b> (1,000,000,000).</p> <p><b>Range:</b> 1500 bytes through 100,000,000,000 bytes (100 GB)</p>
<b>Required Privilege Level</b>	<p><b>firewall</b>—To view this statement in the configuration.</p> <p><b>firewall-control</b>—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Configuring Two-Color and Three-Color Policers to Control Traffic Rates on page 4183</a></li> <li>• <a href="#">Overview of Policers on page 4096</a></li> </ul>

## peak-information-rate

---

<b>Syntax</b>	<code>peak-information-rate <i>bits-per-second</i>;</code>
<b>Hierarchy Level</b>	[edit <code>firewall three-color-policer <i>policer-name</i> two-rate</code> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Configure the maximum achievable rate. Packets that exceed the committed information rate (CIR) but are below the peak information rate (PIR) are marked with medium-high packet loss priority (yellow). Packets that exceed the PIR are marked with high packet loss priority (red). You can configure a discard action for packets that exceed the PIR.
	<div><p><b>NOTE:</b> When you include the <code>peak-information-rate</code> statement in the configuration, you must also include the <code>committed-information-rate</code> and <code>peak-burst-size</code> statements at the same hierarchy level.</p></div>
<b>Options</b>	<p><b><i>bits-per-second</i></b>—Number of bits per second. You can specify a value in bits per second either as a complete decimal number or as a decimal number followed by the abbreviation <b>k</b> (1000), <b>m</b> (1,000,000), or <b>g</b> (1,000,000,000).</p> <p><b>Range:</b> 32,000 bps through 10,000,000,000 bps (10 gbps)</p>
<b>Required Privilege Level</b>	<p><code>firewall</code>—To view this statement in the configuration.</p> <p><code>firewall-control</code>—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Configuring Two-Color and Three-Color Policers to Control Traffic Rates on page 4183</a></li><li>• <a href="#">Overview of Policers on page 4096</a></li></ul>

## policer

<b>Syntax</b>	<pre> policer <i>policer-name</i> {   filter-specific;   if-exceeding {     bandwidth-limit <i>bps</i>;     burst-size-limit <i>bytes</i>;   }   then {     <i>policer-action</i>;   } } </pre>
<b>Hierarchy Level</b>	[edit <a href="#">firewall</a> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	<p>Configure policer rate limits and actions. To activate a policer, you must include the <b>policer</b> action modifier in the <b>then</b> statement in a firewall filter term.</p> <p>Each policer that you configure includes an implicit counter that counts the number of packets that exceed the rate limits that are specified for the policer. If you use the same policer in multiple terms—either within the same filter or across filters—the policer's implicit counter is used to count packets that are policed in all of these terms. If you want to obtain separate packet counts for each term, use these approaches:</p> <ul style="list-style-type: none"> <li>• Configure a unique policer for each term.</li> <li>• Configure only one policer, but use a unique, explicit counter in each term.</li> </ul>
<b>Options</b>	<p><b><i>policer-name</i></b>—Name that identifies the policer. The name can contain letters, numbers, hyphens (-), and can be up to 64 characters long.</p> <p>The remaining statements are explained separately.</p>
<b>Required Privilege Level</b>	<p>firewall—To view this statement in the configuration.</p> <p>firewall-control—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Configuring Two-Color and Three-Color Policers to Control Traffic Rates on page 4183</a></li> <li>• <a href="#">Configuring Firewall Filters on page 4177</a></li> <li>• <a href="#">Overview of Policers on page 4096</a></li> </ul>

## single-rate

---

<b>Syntax</b>	<pre>single-rate {   (color-aware   color-blind);   committed-information-rate <i>bps</i>;   committed-burst-size <i>bytes</i>;   excess-burst-size <i>bytes</i>; }</pre>
<b>Hierarchy Level</b>	[edit <a href="#">firewall three-color-policer</a> <i>policer-name</i> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	<p>Configure a single-rate three-color policer in which marking is based on the committed information rate (CIR), committed burst size (CBS), and excess burst size (EBS).</p> <p>Packets that conform to the CIR or the CBS are assigned low loss priority (green). Packets that exceed the CIR and the CBS but are within the EBS are assigned medium-high loss priority (yellow). Packets that exceed the EBS are assigned high loss priority (red).</p> <p>Green and yellow packets are always forwarded; this action is not configurable. You can configure red packets to be discarded. By default, red packets are forwarded.</p> <p>The remaining statements are explained separately.</p>
<b>Options</b>	<b><i>policer-name</i></b> —Name of the three-color policer. Use this name when you apply the policer to an interface.
<b>Required Privilege Level</b>	<b>firewall</b> —To view this statement in the configuration. <b>firewall-control</b> —To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Configuring Two-Color and Three-Color Policers to Control Traffic Rates on page 4183</a></li><li>• <a href="#">Overview of Policers on page 4096</a></li></ul>

## then (Policers)

---

Syntax	then { <i>policer-action</i> ; }
Hierarchy Level	[edit <b>firewall</b> <b>policer</b> <i>policer-name</i> ]
Release Information	Statement introduced in Junos OS Release 11.1 for the QFX Series.
Description	Configure a policer action.
Options	<i>policer-action</i> —Allowed policer actions are <b>discard</b> , <b>loss-priority high</b> , and <b>loss-priority low</b> . <b>discard</b> causes the system to drop traffic that exceeds the rate limits defined by the policer. Use <b>loss-priority high</b> to allow the system to forward matching traffic in some cases.
<div>  <p><b>NOTE:</b> If you specify a policer in an egress firewall filter, the only supported action is <b>discard</b>.</p> </div>	
Required Privilege Level	firewall—To view this statement in the configuration. firewall-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> <li>• <a href="#">Configuring Two-Color and Three-Color Policers to Control Traffic Rates on page 4183</a></li> <li>• <a href="#">Configuring Firewall Filters on page 4177</a></li> <li>• <a href="#">Overview of Policers on page 4096</a></li> </ul>

## three-color-policer

---

Syntax	<pre>three-color-policer <i>policer-name</i> {   action {     loss-priority high then discard;   }   single-rate {     (color-aware   color-blind);     committed-information-rate <i>bps</i>;     committed-burst-size <i>bytes</i>;     excess-burst-size <i>bytes</i>;   }   two-rate {     (color-aware   color-blind);     committed-information-rate <i>bps</i>;     committed-burst-size <i>bytes</i>;     peak-information-rate <i>bps</i>;     peak-burst-size <i>bytes</i>;   } }</pre>
Hierarchy Level	[edit <a href="#">firewall</a> ], [edit logical-systems <i>logical-system-name</i> firewall]
Release Information	Statement introduced in Junos OS Release 11.1 for the QFX Series.
Description	Configure a three-color policer.
Options	<p><b><i>policer-name</i></b>—Name of the three-color policer. Use this name when you apply the policer to an interface.</p> <p>The remaining statements are explained separately.</p>
Required Privilege Level	firewall—To view this statement in the configuration. firewall-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"><li>• <a href="#">Configuring Two-Color and Three-Color Policers to Control Traffic Rates on page 4183</a></li><li>• <a href="#">Overview of Policers on page 4096</a></li></ul>

## two-rate

<b>Syntax</b>	<pre>two-rate {   (color-aware   color-blind);   committed-information-rate <i>bps</i>;   committed-burst-size <i>bytes</i>;   peak-information-rate <i>bps</i>;   peak-burst-size <i>bytes</i>; }</pre>
<b>Hierarchy Level</b>	[edit <b>firewall three-color-policer</b> <i>policer-name</i> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	<p>Configure a two-rate three-color policer in which marking is based on the committed information rate (CIR), committed burst size (CBS), peak information rate (PIR), and peak burst size (PBS).</p> <p>Packets that conform to the CIR or the CBS are assigned low loss priority (green). Packets that exceed the CIR and the CBS but are within the PIR or the PBS are assigned medium-high loss priority (yellow). Packets that exceed the PIR and the PBS are assigned high loss priority (red).</p> <p>Green and yellow packets are always forwarded; this action is not configurable. You can configure red packets to be discarded. By default, red packets are forwarded.</p> <p>The remaining statements are explained separately.</p>
<b>Required Privilege Level</b>	<p>firewall—To view this statement in the configuration.</p> <p>firewall-control—To add this statement to the configuration.</p>

## Configuration Statements for Port Security

---

### allowed-mac

---

Syntax	allowed-mac <i>mac-address-list</i>
Hierarchy Level	[edit <a href="#">ethernet-switching-options secure-access-port interface</a> (all   <i>interface-name</i> )]
Release Information	Statement introduced in Junos OS Release 11.1 for the QFX Series.
Description	Specify particular MAC addresses to be added to the MAC address cache.
	<div> <b>NOTE:</b> Although this configuration restricts the addresses that can be added to the MAC address cache, it does not block the switch from receiving Layer 2 control packets—such as Link Layer Discovery Protocol (LLDP) packets—transmitted from MAC addresses that are not specified in the list of allowed MAC addresses. Control packets do not undergo the MAC address check, and they are therefore included in the statistics of packets received, though, they are not forwarded to another destination.</div>
Default	Allowed MAC addresses take precedence over dynamic MAC values. For example, if the <b>mac-limit</b> statement is set to four and three allowed MACs are configured, only one dynamic MAC can be learned on that interface.
Options	<b>mac-address-list</b> —One or more MAC addresses configured as allowed MAC addresses for a specified interface or all interfaces.
Required Privilege Level	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"><li>• <a href="#">Understanding MAC Limiting and MAC Move Limiting for Port Security on page 4119</a></li><li>• <a href="#">Configuring MAC Limiting on page 4188</a></li><li>• <a href="#">Configuring MAC Move Limiting (CLI Procedure) on page 4190</a></li><li>• <a href="#">mac-limit on page 4249</a></li><li>• <a href="#">no-allowed-mac-log on page 4251</a></li></ul>

## arp-inspection

<b>Syntax</b>	(arp-inspection   no-arp-inspection) { forwarding-class (for DHCP Snooping or DAI Packets) <i>class-name</i> ; }
<b>Hierarchy Level</b>	[edit] <a href="#">ethernet-switching-options secure-access-port vlan</a> (all   <i>vlan-name</i> )]
<b>Release Information</b>	Statement introduced in Junos OS Release 12.1 for the QFX Series.
<b>Description</b>	Perform dynamic ARP inspection on all VLANs or on the specified VLAN. <ul style="list-style-type: none"> <li>• <b>arp-inspection</b>—Enable ARP inspection.</li> </ul> <div style="border: 1px solid #ccc; padding: 10px; margin: 10px 0;">  <p><b>NOTE:</b> When ARP inspection is enabled, the switch logs ARP request packets that it rejects.</p> </div> <ul style="list-style-type: none"> <li>• <b>no-arp-inspection</b>—Disable ARP inspection.</li> </ul>
<b>Default</b>	Disabled.
<b>Required Privilege Level</b>	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Enabling Dynamic ARP Inspection (CLI Procedure) on page 4197</a></li> <li>• <a href="#">Example: Configuring Basic Port Security Features on page 4136</a><a href="#">Example: Configuring DHCP Snooping, DAI , and MAC Limiting on a Switch with Access to a DHCP Server Through a Second Switch on page 4155</a></li> <li>• <a href="#">Example: Configuring DHCP Snooping and DAI to Protect the Switch from ARP Spoofing Attacks on page 4162</a></li> </ul>

## circuit-id

---

<b>Syntax</b>	<pre>circuit-id {     prefix hostname;     use-interface-description;     use-vlan-id; }</pre>
<b>Hierarchy Level</b>	<pre>[edit ethernet-switching-options secure-access-port vlan (all   <i>vlan-name</i>) dhcp-option82] [edit forwarding-options helpers bootp <i>dhcp-option82</i>] [edit forwarding-options helpers bootp interface <i>interface-name</i> dhcp-option82]</pre>
<b>Release Information</b>	Statement introduced in Junos OS Release 9.3 for EX Series switches. Statement introduced in Junos OS Release 11.3 for the QFX Series.
<b>Description</b>	<p>Configure the <b>circuit-id</b> suboption (suboption 1) of DHCP option 82 (the DHCP relay agent information option) in DHCP packets destined for a DHCP server. This suboption identifies the circuit (interface and/or VLAN) on which the DHCP request arrived.</p> <p>The format of the <b>circuit-id</b> information for Gigabit Ethernet interfaces that use VLANs is <b><i>interface-name:vlan-name</i></b> . On a Layer 3 interface, the format is just <b><i>interface-name</i></b> .</p> <p>The remaining statements are explained separately.</p>
<b>Default</b>	If DHCP option 82 is enabled on the switch, the circuit ID is supplied by default in the format <b><i>interface-name:vlan-name</i></b> or, on a Layer 3 interface, just <b><i>interface-name</i></b> .
<b>Required Privilege Level</b>	system—To view this statement in the configuration. system-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Example: Setting Up DHCP Option 82 with a Switch with No Relay Agent Between Clients and a DHCP Server on page 4170</a></li><li>• <a href="#">Example: Setting Up DHCP Option 82 with a Switch as a Relay Agent Between Clients and a DHCP Server on page 4174</a></li><li>• <a href="#">Setting Up DHCP Option 82 on the Switch with No Relay Agent Between Clients and DHCP Server (CLI Procedure) on page 4201</a></li><li>• <a href="#">Setting Up DHCP Option 82 with the Switch as a Relay Agent Between Clients and DHCP Server (CLI Procedure) on page 4204</a></li><li>• <a href="#">[edit forwarding-options] Configuration Statement Hierarchy on EX Series Switches</a></li><li>• <a href="#">RFC 3046, DHCP Relay Agent Information Option</a>, at <a href="http://tools.ietf.org/html/rfc3046">http://tools.ietf.org/html/rfc3046</a>.</li></ul>

---

## dhcp-trusted

---

<b>Syntax</b>	(dhcp-trusted   no-dhcp-trusted);
<b>Hierarchy Level</b>	[edit ethernet-switching-options secure-access-port interface (Access Port Security) (all   <i>interface-name</i> )]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Allow or deny DHCP responses from the specified interfaces (ports) or all interfaces. <ul style="list-style-type: none"><li>• <b>dhcp-trusted</b>—Allow DHCP responses.</li><li>• <b>no-dhcp-trusted</b>—Deny DHCP responses.</li></ul>
<b>Default</b>	Trusted for trunk ports, untrusted for access ports.
<b>Required Privilege Level</b>	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Overview of Access Port Protection on page 4105</a></li><li>• <a href="#">Enabling a Trusted Port for DHCP on page 4200</a></li></ul>

## dhcp-option82

<b>Syntax</b>	<pre> dhcp-option82 {   circuit-id {     prefix hostname;     use-interface-description;     use-vlan-id;   }   remote-id {     prefix hostname   mac   none;     use-interface-description;     use-string <i>string</i>;   }   vendor-id &lt;<i>string</i>&gt;; } </pre>
<b>Hierarchy Level</b>	<p>[edit ethernet-switching-options secure-access-port vlan (all   <i>vlan-name</i>)]</p> <p>[edit forwarding-options helpers bootp]</p> <p>[edit forwarding-options helpers bootp interface <i>interface-name</i>]</p>
<b>Release Information</b>	<p>Statement introduced in Junos OS Release 9.3 for EX Series switches.</p> <p>Statement introduced in Junos OS Release 11.3 for the QFX Series.</p>
<b>Description</b>	<p>When the switch receives a DHCP request from a DHCP client connected on one of the switch's interfaces, have the switch insert DHCP option 82 (also known as the DHCP relay agent information option) information in the DHCP request packet header before it forwards or relays the request to a DHCP server. The server uses the option 82 information, which provides details about the circuit and host the request came from, in formulating the reply; the server does not, however, make any changes to the option 82 information in the packet header. The switch receives the reply and then removes the DHCP option 82 information before forwarding the reply to the client.</p> <p>The remaining statements are explained separately.</p>
<b>Default</b>	Insertion of DHCP option 82 information is not enabled.
<b>Required Privilege Level</b>	<p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>

## dhcp-snooping-file

<b>Syntax</b>	<code>dhcp-snooping-file {     location <i>local_pathname</i>   <i>remote_URL</i>;     timeout <i>seconds</i>;     write-interval <i>seconds</i>; }</code>
<b>Hierarchy Level</b>	[edit <a href="#">ethernet-switching-options secure-access-port</a> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 12.1 for the QFX Series.
<b>Description</b>	Specify a local pathname or remote URL for the DHCP snooping database file to maintain persistence of IP-MAC bindings.  The remaining statements are explained separately.
<b>Default</b>	The IP-MAC bindings in the DHCP snooping database file are not persistent. If the switch is rebooted, the bindings are lost.
<b>Required Privilege Level</b>	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Understanding DHCP Snooping for Port Security on page 4110</a></li> </ul>

## dhcp-trusted

<b>Syntax</b>	<code>(dhcp-trusted   no-dhcp-trusted);</code>
<b>Hierarchy Level</b>	[edit <a href="#">ethernet-switching-options secure-access-port interface</a> (Access Port Security) (all   <i>interface-name</i> )]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Allow or deny DHCP responses from the specified interfaces (ports) or all interfaces. <ul style="list-style-type: none"> <li>• <b>dhcp-trusted</b>—Allow DHCP responses.</li> <li>• <b>no-dhcp-trusted</b>—Deny DHCP responses.</li> </ul>
<b>Default</b>	Trusted for trunk ports, untrusted for access ports.
<b>Required Privilege Level</b>	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Overview of Access Port Protection on page 4105</a></li> <li>• <a href="#">Enabling a Trusted Port for DHCP on page 4200</a></li> </ul>

## disable-timeout (Port Error Disable)

---

<b>Syntax</b>	disable-timeout <i>timeout</i> ;
<b>Hierarchy Level</b>	[edit <a href="#">ethernet-switching-options port-error-disable</a> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Specify how long Ethernet switching interfaces remain in a disabled state due to MAC limiting, MAC move limiting, or storm control errors.
	<div><p><b>NOTE:</b> If you modify an existing timeout value, the new timeout value does not affect currently disabled interfaces are configured for automatic recovery. The new timeout value applies only to subsequent port errors. Run the <a href="#">clear ethernet-switching port-error</a> command to restore currently disabled interfaces.</p></div>
<b>Default</b>	The disable timeout statement is not enabled.
<b>Options</b>	<p><b>timeout</b>—Time, in seconds, that an interface remains disabled. The disabled interface automatically returns to service when the specified time expires.</p> <p><b>Range:</b> 10 through 3600 seconds</p>
<b>Required Privilege Level</b>	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Understanding MAC Limiting and MAC Move Limiting for Port Security on page 4119</a></li><li>• <a href="#">Understanding Storm Control on page 4125</a></li><li>• <a href="#">Example: Configuring Storm Control on page 4143</a></li><li>• <a href="#">Configuring Autorecovery for MAC Limited or Storm Control Interfaces (CLI Procedure) on page 4192</a></li><li>• <a href="#">action-shutdown on page 4266</a></li></ul>

## examine-dhcp

<b>Syntax</b>	(examine-dhcp   no-examine-dhcp);
<b>Hierarchy Level</b>	[edit <a href="#">ethernet-switching-options secure-access-port vlan</a> (all   <i>vlan-name</i> )]
<b>Release Information</b>	Statement introduced in Junos OS Release 12.1 for the QFX Series
<b>Description</b>	<p>Enable DHCP snooping on all VLANs or on the specified VLAN.</p> <ul style="list-style-type: none"> <li>• examine-dhcp—Enable DHCP snooping.</li> </ul> <div style="border: 1px solid #ccc; padding: 10px; margin: 10px 0;">  <p><b>NOTE:</b> When DHCP snooping is enabled, the switch logs DHCPDISCOVER packets that it rejects.</p> </div> <ul style="list-style-type: none"> <li>• no-examine-dhcp—Disable DHCP snooping.</li> </ul>
<b>Default</b>	Disabled.
<b>Required Privilege Level</b>	<p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Example: Configuring Basic Port Security Features on page 4136</a></li> <li>• <a href="#">Example: Configuring DHCP Snooping, DAI, and MAC Limiting on a Switch with Access to a DHCP Server Through a Second Switch on page 4155</a></li> <li>• <a href="#">Example: Configuring DHCP Snooping and DAI to Protect the Switch from ARP Spoofing Attacks on page 4162</a></li> <li>• <a href="#">Enabling DHCP Snooping (CLI Procedure) on page 4194</a></li> </ul>

## examine-fip

---

<b>Syntax</b>	<pre>examine-fip {     examine-vn2vn {         beacon-period <i>milliseconds</i>;     }     fc-map <i>fc-map-value</i>; }</pre>
<b>Hierarchy Level</b>	[edit ethernet-switching-options secure-access-port vlan (all   <i>vlan-name</i> )]
<b>Release Information</b>	<p>Statement introduced in Junos OS Release 10.4 for EX Series switches.</p> <p>Statement introduced in Junos OS Release 11.1 for the QFX Series.</p> <p>Statement <b>examine-vn2vn</b> introduced in Junos OS Release 12.2 for the QFX Series.</p>
<b>Description</b>	<p>Enable FIP snooping on a specified VLAN. Ensure that the VLAN is a dedicated FCoE VLAN that transports only FCoE traffic.</p> <p>(QFX Series only) Enable VN_Port to VN_Port (VN2VN_Port) FIP snooping on a specified VLAN. The VLAN must be a dedicated FCoE VLAN that transports only VN2VN_Port traffic. One FCoE VLAN cannot support both VN_Port to VF_Port (VN2VF_Port) FIP snooping and VN2VN_Port FIP snooping. Configure separate, dedicated FCoE VLANs for VN2VN_Port FIP snooping and VN2VN_Port FIP snooping.</p> <p>The remaining statements are explained separately.</p>
<b>Required Privilege Level</b>	<p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">vlan</a></li><li>• <a href="#">Example: Configuring an FCoE Transit Switch</a></li><li>• <a href="#">Configuring VN2VF_Port FIP Snooping on an FCoE Transit Switch on page 4596</a></li></ul>

## fc-map

<b>Syntax</b>	<code>fc-map <i>fc-map-value</i>;</code>
<b>Hierarchy Level</b>	<p>[edit ethernet-switching options secure-access-port vlan (all   <i>vlan-name</i>) <a href="#">examine-fip</a>]</p> <p>For the QFX Series only:</p> <p>[edit <a href="#">fc-fabrics</a> <i>fc-fabric-name</i> <a href="#">protocols fip</a>]</p>
<b>Release Information</b>	<p>Statement introduced in Junos OS Release 10.4 for EX Series switches.</p> <p>Statement introduced in Junos OS Release 11.1 for the QFX Series.</p>
<b>Description</b>	<p>Set the FCoE mapped address prefix (FC-MAP) value for the FCoE VLAN to match the FC switch (or FCoE forwarder) FC-MAP value for the FC fabric. The FC-MAP value is a unique MAC address prefix an FC switch uses to identify FCoE traffic for a given FC fabric (traffic on a particular FCoE VLAN).</p> <p>You can configure the FC-MAP value or use the default value. The FC switch provides the FC-MAP value to FCoE nodes (ENodes) in the FIP discovery advertisement message. If the EX Series switch or the QFX Series FCoE VLAN FC-MAP value does not match the FC switch FC-MAP value, neither device discovers the FC switch on that VLAN, and the ENodes on that VLAN cannot access the FC switch. The FC switch accepts only FCoE traffic that uses the correct FC-MAP value as part of the VN_Port MAC address.</p> <p>When the QFX Series acts as an FCoE-FC gateway, the FC-MAP value for the gateway and the FCoE devices must match the FC switch FC-MAP value in order to communicate with the FC switch.</p>
	<div>  <p><b>NOTE:</b> Changing the FC-MAP value causes all logins to drop and forces the ENodes to log in again.</p> </div>
<b>Options</b>	<p><b><i>fc-map-value</i></b>—FC-MAP value, hexadecimal value preceded by “0x”.</p> <p><b>Range:</b> 0x0EFC00 through 0x0EFCFF</p> <p><b>Default:</b> 0xEFC00</p>
<b>Required Privilege Level</b>	<p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">examine-fip on page 4242</a></li> <li>• <a href="#">show fip snooping on page 4770</a></li> <li>• Example: Configuring an FCoE Transit Switch</li> <li>• <a href="#">Configuring VN2VF_Port FIP Snooping on an FCoE Transit Switch on page 4596</a></li> </ul>

## fcoe-trusted

---

<b>Syntax</b>	fcoe-trusted;
<b>Hierarchy Level</b>	[edit ethernet-switching-options secure-access-port interface <i>interface-name</i> ]  For the QFX Series only:  [edit fc-fabrics <i>fc-fabric-name</i> protocols fip]
<b>Release Information</b>	Statement introduced in Junos OS Release 10.4 for EX Series switches. Statement introduced in Junos OS Release 11.1 for the QFX Series. Statement introduced for the FC fabric in Junos OS Release 11.3 for the QFX Series.
<b>Description</b>	<p>Configure the specified 10-Gigabit Ethernet interface to trust Fibre Channel over Ethernet (FCoE) traffic. If an interface is connected to another switch such as an FCoE forwarder (FCF) or a transit switch, you can configure the interface as trusted so that the interface forwards FCoE traffic from the switch to the FCoE devices without installing FIP snooping filters.</p> <p>(QFX Series only) Configure the specified local Fibre Channel fabric to trust FCoE traffic on all ports in the fabric. Changing the fabric ports from untrusted to trusted removes any existing FIP snooping filters from the ports. Changing the fabric ports from trusted to untrusted by removing the <b>fcoe-trusted</b> configuration from the fabric forces all of the FCoE sessions on those ports to log out so that when the ENodes and VN_Ports log in again, the switch can build the appropriate FIP snooping filters.</p>
<b>Required Privilege Level</b>	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">show fip snooping on page 4770</a></li><li>• Example: Configuring an FCoE Transit Switch</li><li>• <a href="#">Configuring VN2VF_Port FIP Snooping on an FCoE Transit Switch on page 4596</a></li></ul>

## forwarding-class (for DHCP Snooping or DAI Packets)

<b>Syntax</b>	forwarding-class class <i>class-name</i> ;
<b>Hierarchy Level</b>	[edit ethernet-switching-options secure-access-port vlan (all   <i>vlan-name</i> ) (examine-dhcp   arp-inspection)]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.2 for EX Series switches. Statement introduced in Junos OS Release 12.1 for the QFX Series.
<b>Description</b>	Assign a user-defined or a predefined forwarding class to the packets that have been checked for DHCP snooping or dynamic ARP inspection (DAI).
<div>  <p><b>NOTE:</b> To assign a user-defined class, you must first configure the user-defined class by using the forwarding-classes configuration statement at the [edit class-of-service] hierarchy level.</p> </div>	
<b>Default</b>	Disabled.
<b>Options</b>	<i>class-name</i> —Name of the forwarding class. The forwarding class can be one of the predefined forwarding classes (best-effort, assured-forwarding, expedited-forwarding, network-control) or it can be a user-defined forwarding class.
<b>Required Privilege Level</b>	system—To view this statement in the configuration. system-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• Example: Using CoS Forwarding Classes to Prioritize Snooped Packets in Heavy Network Traffic</li> <li>• Understanding Junos OS CoS Components for EX Series Switches</li> <li>• <a href="#">Understanding DHCP Snooping for Port Security on page 4110</a></li> <li>• <a href="#">Understanding DAI for Port Security on page 4117</a></li> </ul>

## interface (Secure Access Port)

---

<b>Syntax</b>	<pre>interface (all   <i>interface-name</i>) {     <b>allowed-mac</b> <i>mac-address-list</i>;     (<b>dhcp-trusted</b>   <b>no-dhcp-trusted</b>);     <b>mac-limit</b> <i>limit</i> action <i>action</i>;     <b>no-allowed-mac-log</b>;     <b>static-ip</b> <i>ip-address</i> {         <b>vlan</b> <i>vlan-name</i>;         <b>mac</b> <i>mac-address</i>;     } }</pre>
<b>Hierarchy Level</b>	[edit <a href="#">ethernet-switching-options secure-access-port</a> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	<p>Apply port security features to all interfaces or to the specified interface.</p> <p>The remaining statements are explained separately.</p>
<b>Options</b>	<p><b>all</b>—Apply port security features to all interfaces. Does not apply to QFabric systems.</p> <p><b><i>interface-name</i></b>—Apply port security features to the specified interface.</p>
<b>Required Privilege Level</b>	<p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Overview of Access Port Protection on page 4105</a></li><li>• <a href="#">Understanding MAC Limiting and MAC Move Limiting for Port Security on page 4119</a></li><li>• <a href="#">Understanding Trusted and Untrusted Ports on page 4121</a></li><li>• <a href="#">Configuring MAC Limiting on page 4188</a></li><li>• <a href="#">Enabling a Trusted Port for DHCP on page 4200</a></li></ul>

## interface (Unknown Unicast Forwarding)

---

<b>Syntax</b>	<code>interface <i>interface-name</i>;</code>
<b>Hierarchy Level</b>	[edit <a href="#">ethernet-switching-options unknown-unicast-forwarding</a> <code>vlan</code> (all [ <i>vlan-name</i> ])]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Specify the interface to which unknown unicast packets are forwarded.
<b>Required Privilege Level</b>	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Understanding Unknown Unicast Forwarding on page 4126</a></li> <li>• <a href="#">Configuring Unknown Unicast Forwarding on page 4194</a></li> <li>• <a href="#">show vlans on page 1752</a></li> </ul>

## location

---

<b>Syntax</b>	<code>location <i>local_pathname</i>   <i>remote_URL</i>;</code>
<b>Hierarchy Level</b>	[edit <a href="#">ethernet-switching-options secure-access-port dhcp-snooping-file</a> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 12.1 for the QFX Series.
<b>Description</b>	Specify either a local pathname or a remote URL as the location in which to store the DHCP snooping database.
<b>Options</b>	<p><code><i>local_pathname</i>   <i>remote_URL</i></code> —Location for storing the DHCP snooping database.</p> <ul style="list-style-type: none"> <li>• <code><i>local_pathname</i></code> —Use <code>/path</code> to store the database on a local switch.</li> <li>• <code><i>remote_URL</i></code> —Use <code>ftp://ip-address</code> or <code>ftp://hostname/path</code> to store the database at a remote location.</li> </ul>
<b>Required Privilege Level</b>	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.

## mac

---

<b>Syntax</b>	<code>mac mac-address;</code>
<b>Hierarchy Level</b>	[edit <a href="#">ethernet-switching-options secure-access-port</a> interface (Access Port Security) (all   <i>interface-name</i> ) static-ip <i>ip-address</i> vlan (DHCP Bindings on Access Ports) <i>vlan-name</i> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 on the QFX Series switches.
<b>Description</b>	Specify a media access control (MAC) address (hardware address) for the specified static IP address.
<b>Options</b>	<i>mac-address</i> —Value in hexadecimal format.
<b>Required Privilege Level</b>	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.

## mac-limit

<b>Syntax</b>	<code>mac-limit <i>limit</i> {     &lt;action <i>action</i>&gt;; }</code>
<b>Hierarchy Level</b>	[edit <a href="#">ethernet-switching-options secure-access-port interface</a> (all   <i>interface-name</i> )]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Specify the number of MAC addresses that can be dynamically added to the MAC address cache for this access interface (port) and the action to be taken if the limit is exceeded.
<b>Default</b>	The default action is <b>drop</b> .
<b>Options</b>	<p><i>limit</i>—Maximum number of MAC addresses.</p> <p><i>action action</i>—(Optional) Action to take when the MAC address limit is exceeded:</p> <ul style="list-style-type: none"> <li>• <b>drop</b>—Drop the packet and generate a system log entry. This is the default.</li> <li>• <b>log</b>—Do not drop the packet but generate a system log entry.</li> <li>• <b>none</b>—No action.</li> <li>• <b>shutdown</b>—Disable the interface and generate an alarm. If you configure the switch with the <a href="#">port-error-disable</a> statement, the disabled interface recovers automatically upon expiration of the specified timeout. If this statement is not configured, you can bring up the disabled interfaces by running the <a href="#">clear ethernet-switching port-error</a> command.</li> </ul>
<b>Required Privilege Level</b>	<p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Understanding MAC Limiting and MAC Move Limiting for Port Security on page 4119</a></li> <li>• <a href="#">Configuring MAC Limiting on page 4188</a></li> <li>• <a href="#">allowed-mac on page 4232</a></li> </ul>

## mac-move-limit

---

<b>Syntax</b>	<code>mac-move-limit <i>limit</i> &lt;fabric-limit <i>limit</i>&gt; action <i>action</i>;</code>
<b>Hierarchy Level</b>	[edit <a href="#">ethernet-switching-options secure-access-port</a> (all   <i>vlan-name</i> )]
<b>Release Information</b>	Statement introduced in Junos OS Release 12.1 for the QFX Series.
<b>Description</b>	Specify the number of times a MAC address can move to a new interface (port) in 1 second and the action to be taken by the switch if the MAC address move limit is exceeded.
<b>Default</b>	The default move limit is unlimited. The default action is <b>drop</b> .
<b>Options</b>	<p><b>fabric-limit</b>—Specify the maximum number of moves in a QFabric system. If you do not specify a fabric limit, the value for <b>mac-move-limit</b> applies to the QFabric system.</p> <p><b>limit</b>—Maximum number of moves to a new interface per second.</p> <p><b>action <i>action</i></b>—(Optional) Action to take when the MAC address move limit is reached:</p> <ul style="list-style-type: none"><li>• <b>drop</b>—Drop the packet and generate an alarm, an SNMP trap, or a system log entry. This is the default.</li><li>• <b>log</b>—Do not drop the packet but generate an alarm, an SNMP trap, or a system log entry.</li><li>• <b>none</b>—No action.</li><li>• <b>shutdown</b>—Disable the interface and generate an alarm. If you have configured the switch with the <b>port-error-disable</b> statement, the disabled interfaces recover automatically upon expiration of the specified disable timeout. If you have not configured the switch for autorecovery from port error disabled conditions, you can bring up the disabled interfaces by running the <b>clear-ethernet-switch-port</b> command.</li></ul>
<b>Required Privilege Level</b>	<p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">mac-limit on page 4249</a></li><li>• <a href="#">Example: Configuring Basic Port Security Features on page 4136</a></li><li>• <a href="#">Configuring MAC Move Limiting (CLI Procedure) on page 4190</a></li><li>• <a href="#">Configuring Autorecovery From the Disabled State on Secure or Storm Control Interfaces (CLI Procedure)</a></li></ul>

## no-allowed-mac-log

<b>Syntax</b>	no-allowed-mac-log;
<b>Hierarchy Level</b>	[edit <a href="#">ethernet-switching-options secure-access-port interface</a> (all   <i>interface-name</i> )]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Specify that the switch should not log messages when it receives packets from invalid MAC addresses on an interface that has been configured for allowed MAC addresses.
<b>Default</b>	The switch logs messages when it receives packets from invalid MAC addresses on an interface that has been configured for particular allowed (specific) MAC addresses.
<b>Required Privilege Level</b>	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Understanding MAC Limiting and MAC Move Limiting for Port Security on page 4119</a></li> <li>• <a href="#">Configuring MAC Limiting on page 4188</a></li> <li>• <a href="#">allowed-mac on page 4232</a></li> <li>• <a href="#">mac-limit on page 4249</a></li> </ul>

## no-dhcp-trusted

<b>Syntax</b>	(dhcp-trusted   no-dhcp-trusted);
<b>Hierarchy Level</b>	[edit <a href="#">ethernet-switching-options secure-access-port interface</a> (Access Port Security) (all   <i>interface-name</i> )]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	<p>Port security features, such as DHCP snooping and dynamic ARP inspection inspect packets only on untrusted interfaces.</p> <p>Allow or deny DHCP responses from the specified interfaces (ports) or all interfaces.</p> <ul style="list-style-type: none"> <li>• <b>dhcp-trusted</b>—Allow DHCP responses.</li> <li>• <b>no-dhcp-trusted</b>—Deny DHCP responses.</li> </ul>
<b>Default</b>	Trusted for trunk ports, untrusted for access ports.
<b>Required Privilege Level</b>	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Overview of Access Port Protection on page 4105</a></li> <li>• <a href="#">Enabling a Trusted Port for DHCP on page 4200</a></li> </ul>

## no-gratuitous-arp-request

---

<b>Syntax</b>	no-gratuitous-arp-request;
<b>Hierarchy Level</b>	[edit <a href="#">interfaces</a> <i>interface-name</i> ], [edit <a href="#">interfaces</a> <i>interface-range</i> <i>interface-name</i> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Configure the switch not to respond to gratuitous ARP requests. You can disable responses to gratuitous ARP requests on both Layer 2 Ethernet switching interfaces and routed VLAN interfaces (RVIs).
<b>Default</b>	Gratuitous ARP responses are enabled on all Ethernet switching interfaces and RVIs.
<b>Required Privilege Level</b>	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Configuring Routed VLAN Interfaces on page 1551</a></li></ul>

## persistent-learning

---

<b>Syntax</b>	persistent-learning;
<b>Hierarchy Level</b>	[edit ethernet-switching-options secure-access-port interface (all   <i>interface-name</i> )]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.4 for EX Series switches. Statement introduced in Junos OS Release 12.1 for the QFX Series.
<b>Description</b>	Specify that learned MAC addresses persist on the specified interfaces across restarts of the switch and link-down conditions. This feature is also known as sticky MAC.
<b>Required Privilege Level</b>	system—To view this statement in the configuration. system-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Example: Configuring Basic Port Security Features on page 4136</a></li><li>• <a href="#">Configuring Persistent MAC Learning (CLI Procedure)</a></li></ul>

## port-error-disable

<b>Syntax</b>	<code>port-error-disable {     disable-timeout <i>timeout</i>; }</code>
<b>Hierarchy Level</b>	[edit <a href="#">ethernet-switching-options</a> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 on the QFX Series.
<b>Description</b>	Disable rather than block an interface when enforcing MAC limiting, MAC move limiting, and storm control, and allow the interface to recover automatically from the error condition after a specified period of time:
	<div>  <p><b>NOTE:</b> The <code>port-error-disable</code> configuration does not apply to preexisting error conditions. It affects only error conditions that are detected after you enable and commit the <code>port-error-disable</code> statement. To clear a preexisting error condition and restore the interface to service, use the <code>clear ethernet-switching port-error</code> command.</p> </div>
	<ul style="list-style-type: none"> <li>If you enable the <code>mac-limit</code> statement with the <code>shutdown</code> option and also enable the <code>port-error-disable</code> statement, the switch disables (rather than shuts down) the interface when the MAC address limit is reached.</li> <li>If you have enabled the <code>mac-move-limit</code> statement with the <code>shutdown</code> option and you enable the <code>port-error-disable</code> statement, the switch disables (rather than shuts down) the interface when the maximum number of moves to a new interface is reached.</li> <li>If you enable the <code>storm-control</code> statement with the <code>action-shutdown</code> option and you also enable <code>port-error-disable</code>, the switch disables (rather than shuts down) the interface when broadcast traffic and unknown unicast traffic exceed the specified levels.</li> </ul>
<b>Default</b>	Not enabled.
<b>Required Privilege Level</b>	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li><a href="#">Understanding MAC Limiting and MAC Move Limiting for Port Security on page 4119</a></li> <li><a href="#">Understanding Storm Control on page 4125</a></li> <li><a href="#">Example: Configuring Storm Control on page 4143</a></li> <li><a href="#">Configuring Autorecovery for MAC Limited or Storm Control Interfaces (CLI Procedure) on page 4192</a></li> <li><a href="#">action-shutdown on page 4266</a></li> <li><a href="#">disable-timeout on page 4238</a></li> </ul>

- [clear ethernet-switching port-error on page 4290](#)

## prefix (Remote ID for Option 82)

---

<b>Syntax</b>	prefix hostname   mac   none;
<b>Hierarchy Level</b>	[edit ethernet-switching-options secure-access-port vlan (all   <i>vlan-name</i> ) dhcp-option82 remote-id] [edit forwarding-options helpers bootp dhcp-option82 remote-id] [edit forwarding-options helpers bootp interface <i>interface-name</i> dhcp-option82 remote-id]
<b>Release Information</b>	Statement introduced in Junos OS Release 9.3 for EX Series switches. Statement introduced in Junos OS Release 12.1 for the QFX Series.
<b>Description</b>	Configure an optional prefix for the remote ID suboption in the DHCP option 82 information that is inserted by the switch into the packet header of a DHCP request before it forwards or relays the request to a DHCP server.
<b>Default</b>	If <b>prefix</b> is not explicitly specified, no prefix is appended to the remote ID.
<b>Options</b>	<b>hostname</b> —Name of the host system (the switch) that is forwarding or relaying the DHCP request from the DHCP client to the DHCP server.  <b>mac</b> —MAC address of the host system (the switch) that is forwarding or relaying the DHCP request from the DHCP client to the DHCP server.  <b>none</b> —No prefix is applied to the remote ID.
<b>Required Privilege Level</b>	system—To view this statement in the configuration. system-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Example: Setting Up DHCP Option 82 with a Switch with No Relay Agent Between Clients and a DHCP Server on page 4170</a></li><li>• <a href="#">Example: Setting Up DHCP Option 82 with a Switch as a Relay Agent Between Clients and a DHCP Server on page 4174</a></li><li>• <a href="#">Setting Up DHCP Option 82 on the Switch with No Relay Agent Between Clients and DHCP Server (CLI Procedure) on page 4201</a></li><li>• <a href="#">Setting Up DHCP Option 82 with the Switch as a Relay Agent Between Clients and DHCP Server (CLI Procedure) on page 4204</a></li><li>• [edit forwarding-options] Configuration Statement Hierarchy on EX Series Switches</li><li>• RFC 3046, <i>DHCP Relay Agent Information Option</i>, at <a href="http://tools.ietf.org/html/rfc3046">http://tools.ietf.org/html/rfc3046</a>.</li></ul>

## remote-id

<b>Syntax</b>	<pre>remote-id {     prefix hostname   mac   none;     use-interface-description;     use-string string; }</pre>
<b>Hierarchy Level</b>	<p>[edit ethernet-switching-options secure-access-port vlan (all   <i>vlan-name</i>) <b>dhcp-option82</b>]</p> <p>[edit forwarding-options helpers bootp <b>dhcp-option82</b>]</p> <p>[edit forwarding-options helpers bootp interface <i>interface-name</i> <b>dhcp-option82</b>]</p>
<b>Release Information</b>	<p>Statement introduced in Junos OS Release 9.3 for EX Series switches.</p> <p>Statement introduced in Junos OS Release 11.3 for the QFX Series.</p>
<b>Description</b>	<p>Insert the <b>remote-id</b> suboption of DHCP option 82 (also known as the DHCP relay agent information option) in DHCP request packet headers before forwarding or relaying requests to a DHCP server. This suboption provides a trusted identifier for the host system that has forwarded or relayed requests to the server.</p> <p>The remaining statements are explained separately.</p>
<b>Default</b>	<p>If <b>remote-id</b> is not explicitly set, no remote ID value is inserted in the DHCP request packet header. If the <b>remote-id</b> option is specified but is not qualified by a keyword, the MAC address of the host device (the switch) is used as the remote ID.</p>
<b>Required Privilege Level</b>	<p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Example: Setting Up DHCP Option 82 with a Switch with No Relay Agent Between Clients and a DHCP Server on page 4170</a></li> <li>• <a href="#">Example: Setting Up DHCP Option 82 with a Switch as a Relay Agent Between Clients and a DHCP Server on page 4174</a></li> <li>• <a href="#">Setting Up DHCP Option 82 on the Switch with No Relay Agent Between Clients and DHCP Server (CLI Procedure) on page 4201</a></li> <li>• <a href="#">Setting Up DHCP Option 82 with the Switch as a Relay Agent Between Clients and DHCP Server (CLI Procedure) on page 4204</a></li> <li>• [edit forwarding-options] Configuration Statement Hierarchy on EX Series Switches</li> <li>• RFC 3046, <i>DHCP Relay Agent Information Option</i>, at <a href="http://tools.ietf.org/html/rfc3046">http://tools.ietf.org/html/rfc3046</a>.</li> </ul>

## secure-access-port

```
Syntax  secure-access-port {
    deactivate;
    dhcp-snooping-file {
        location (local_pathname | remote_URL);
        timeout seconds;
        write-interval seconds;
    }
    interface (all | interface-name) {
        allowed-mac mac-address-list;
        (dhcp-trusted | no-dhcp-trusted);
        fcoe-trusted;
        mac-limit limit {
            <action action>;
        }
        no-allowed-mac-log;
        persistent-learning;
        static-ip ip-address {
            vlan vlan-name;
            mac mac-address;
        }
    }
    vlan (all | vlan-name) {
        (arp-inspection | no-arp-inspection) [
            forwarding-class (for DHCP Snooping or DAI Packets) class-name;
        ]
        dhcp-option82 {
            circuit-id {
                prefix (Circuit ID for Option 82) hostname;
                use-interface-description;
                use-vlan-id;
            }
            remote-id {
                prefix (Remote ID for Option 82) hostname | mac | none;
                use-interface-description;
                use-string string;
            }
            vendor-id <string>;
        }
        (examine-dhcp | no-examine-dhcp) {
            forwarding-class (for DHCP Snooping or DAI Packets) class-name;
        }
        examine-fip {
            examine-vn2vn {
                beacon-period milliseconds;
            }
            fc-map fc-map-value;
        }
        mac-move-limit limit action action;
    }
}
```

Hierarchy Level [edit [ethernet-switching-options](#)]

<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Configure port security features, including MAC limiting and whether interfaces can receive DHCP responses, and apply dynamic ARP inspection, DHCP snooping, DHCP option 82, and MAC move limiting on no VLANs, specific VLANs, or all VLANs.  The remaining statements are explained separately.
<b>Required Privilege Level</b>	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Overview of Access Port Protection on page 4105</a></li> <li>• <a href="#">Understanding MAC Limiting and MAC Move Limiting for Port Security on page 4119</a></li> <li>• <a href="#">Understanding Trusted and Untrusted Ports on page 4121</a></li> <li>• <a href="#">Configuring MAC Limiting on page 4188</a></li> <li>• <a href="#">Enabling a Trusted Port for DHCP on page 4200</a></li> </ul>

## static-ip

<b>Syntax</b>	<pre>static-ip <i>ip-address</i>;       mac <i>mac-address</i>;       vlan <i>vlan-name</i>; }</pre>
<b>Hierarchy Level</b>	[edit <a href="#">ethernet-switching-optionssecure-access-port interface</a> (all   <i>interface-name</i> )]
<b>Release Information</b>	Statement introduced in Junos OS Release 12.1 on the QFX Series.
<b>Description</b>	Bind a static IP address to a MAC address in the DHCP snooping database.
<b>Options</b>	<p><i>ip-address</i>—IP address assigned to the device connected on the specified interface.</p> <p>The remaining statements are explained separately.</p>
<b>Required Privilege Level</b>	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Configuring Static IP Addresses for DHCP Bindings on Access Ports (CLI Procedure) on page 4193</a></li> </ul>

## timeout (DHCP Snooping)

---

<b>Syntax</b>	timeout <i>seconds</i> ;
<b>Hierarchy Level</b>	[edit <a href="#">ethernet-switching-options secure-access-port dhcp-snooping-file</a> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Specify a timeout value for remote read and write operations. This value determines the amount of time that the switch waits for a remote system to respond when the DHCP snooping database is stored on a remote FTP site.
<b>Default</b>	None
<b>Options</b>	<i>seconds</i> —Value in seconds. <b>Range:</b> 10 through 3600
<b>Required Privilege Level</b>	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Understanding DHCP Snooping for Port Security on page 4110</a></li></ul>

## use-interface-description

<b>Syntax</b>	<code>use-interface-description;</code>
<b>Hierarchy Level</b>	<p>[edit ethernet-switching-options secure-access-port vlan (all   <i>vlan-name</i>) <b>dhcp-option82</b> <b>circuit-id</b>],</p> <p>[edit forwarding-options helpers bootp <b>dhcp-option82</b> <b>circuit-id</b>],</p> <p>[edit forwarding-options helpers bootp interface <i>interface-name</i> <b>dhcp-option82</b> <b>circuit-id</b>]</p> <p>[edit ethernet-switching-options secure-access-port vlan (all   <i>vlan-name</i>) <b>dhcp-option82</b> <b>remote-id</b>]</p> <p>[edit forwarding-options helpers bootp <b>dhcp-option82</b> <b>remote-id</b>]</p> <p>[edit forwarding-options helpers bootp interface <i>interface-name</i> <b>dhcp-option82</b> <b>remote-id</b>]</p>
<b>Release Information</b>	<p>Statement introduced in Junos OS Release 9.3 for EX Series switches.</p> <p>Statement introduced in Junos OS Release 11.3 for the QFX Series.</p>
<b>Description</b>	Use the interface description rather than the interface name (the default) in the circuit ID or remote ID value in the DHCP option 82 information.
<b>Required Privilege Level</b>	<p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Example: Setting Up DHCP Option 82 with a Switch with No Relay Agent Between Clients and a DHCP Server on page 4170</a></li> <li>• <a href="#">Example: Setting Up DHCP Option 82 with a Switch as a Relay Agent Between Clients and a DHCP Server on page 4174</a></li> <li>• <a href="#">Setting Up DHCP Option 82 on the Switch with No Relay Agent Between Clients and DHCP Server (CLI Procedure) on page 4201</a></li> <li>• <a href="#">Setting Up DHCP Option 82 with the Switch as a Relay Agent Between Clients and DHCP Server (CLI Procedure) on page 4204</a></li> <li>• <a href="#">[edit forwarding-options] Configuration Statement Hierarchy on EX Series Switches</a></li> <li>• <a href="#">RFC 3046, DHCP Relay Agent Information Option</a>, at <a href="http://tools.ietf.org/html/rfc3046">http://tools.ietf.org/html/rfc3046</a>.</li> </ul>

## use-string

---

<b>Syntax</b>	<code>use-string <i>string</i>;</code>
<b>Hierarchy Level</b>	<code>[edit ethernet-switching-options secure-access-port vlan (all   <i>vlan-name</i>) dhcp-option82 <i>remote-id</i>]</code> <code>[edit forwarding-options helpers bootp dhcp-option82 <i>remote-id</i>]</code> <code>[edit forwarding-options helpers bootp interface <i>interface-name</i> dhcp-option82 <i>remote-id</i>]</code>
<b>Release Information</b>	Statement introduced in Junos OS Release 9.3 for EX Series switches. Statement introduced in Junos OS Release 11.3 for the QFX Series.
<b>Description</b>	Use a string rather than the MAC address of the host system (the default) in the remote ID value in the DHCP option 82 information.
<b>Options</b>	<b><i>string</i></b> —Character string used as the remote ID value.  <b>Range:</b> 1–255 characters
<b>Required Privilege Level</b>	<b>system</b> —To view this statement in the configuration. <b>system-control</b> —To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Example: Setting Up DHCP Option 82 with a Switch with No Relay Agent Between Clients and a DHCP Server on page 4170</a></li><li>• <a href="#">Example: Setting Up DHCP Option 82 with a Switch as a Relay Agent Between Clients and a DHCP Server on page 4174</a></li><li>• <a href="#">Setting Up DHCP Option 82 on the Switch with No Relay Agent Between Clients and DHCP Server (CLI Procedure) on page 4201</a></li><li>• <a href="#">Setting Up DHCP Option 82 with the Switch as a Relay Agent Between Clients and DHCP Server (CLI Procedure) on page 4204</a></li><li>• <a href="#">[edit forwarding-options] Configuration Statement Hierarchy on EX Series Switches</a></li><li>• <a href="#">RFC 3046, DHCP Relay Agent Information Option</a>, at <a href="http://tools.ietf.org/html/rfc3046">http://tools.ietf.org/html/rfc3046</a>.</li></ul>

## use-vlan-id

---

<b>Syntax</b>	use-vlan-id;
<b>Hierarchy Level</b>	[edit forwarding-options helpers bootp dhcp-option82-circuit-id] [edit forwarding-options helpers bootp interface <i>interface-name</i> dhcp-option82-circuit-id]
<b>Release Information</b>	Statement introduced in Junos OS Release 9.3 for EX Series switches. Statement introduced in Junos OS Release 11.3 for the QFX Series.
<b>Description</b>	Use the VLAN ID rather than the VLAN name (the default) in the circuit ID value in the DHCP option 82 information.
<b>Required Privilege Level</b>	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Example: Setting Up DHCP Option 82 with a Switch with No Relay Agent Between Clients and a DHCP Server on page 4170</a></li> <li>• <a href="#">Example: Setting Up DHCP Option 82 with a Switch as a Relay Agent Between Clients and a DHCP Server on page 4174</a></li> <li>• <a href="#">Setting Up DHCP Option 82 on the Switch with No Relay Agent Between Clients and DHCP Server (CLI Procedure) on page 4201</a></li> <li>• <a href="#">Setting Up DHCP Option 82 with the Switch as a Relay Agent Between Clients and DHCP Server (CLI Procedure) on page 4204</a></li> <li>• [edit forwarding-options] Configuration Statement Hierarchy on EX Series Switches</li> <li>• RFC 3046, <i>DHCP Relay Agent Information Option</i>, at <a href="http://tools.ietf.org/html/rfc3046">http://tools.ietf.org/html/rfc3046</a>.</li> </ul>

## vendor-id

---

<b>Syntax</b>	<code>vendor-id &lt;string&gt;;</code>
<b>Hierarchy Level</b>	[edit ethernet-switching-options secure-access-port vlan (all   <i>vlan-name</i> ) <a href="#">dhcp-option82</a> ] [edit forwarding-options helpers bootp <a href="#">dhcp-option82</a> ] [edit forwarding-options helpers bootp interface <i>interface-name</i> <a href="#">dhcp-option82</a> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 9.3 for EX Series switches. Statement introduced in Junos OS Release 11.3 for the QFX Series.
<b>Description</b>	Insert a vendor ID in the DHCP option 82 information in a DHCP request packet header before forwarding or relaying the request to a DHCP server.
<b>Default</b>	If <b>vendor-id</b> is not explicitly configured for DHCP option 82, no vendor ID is set.
<b>Options</b>	<b>string</b> —(Optional) A single string that designates the vendor ID.  <b>Range:</b> 1–255 characters  <b>Default:</b> If you specify <b>vendor-id</b> with no <b>string</b> value, the default vendor ID <b>Juniper</b> is configured.
<b>Required Privilege Level</b>	system—To view this statement in the configuration. system-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Example: Setting Up DHCP Option 82 with a Switch with No Relay Agent Between Clients and a DHCP Server on page 4170</a></li><li>• <a href="#">Example: Setting Up DHCP Option 82 with a Switch as a Relay Agent Between Clients and a DHCP Server on page 4174</a></li><li>• <a href="#">Setting Up DHCP Option 82 on the Switch with No Relay Agent Between Clients and DHCP Server (CLI Procedure) on page 4201</a></li><li>• <a href="#">Setting Up DHCP Option 82 with the Switch as a Relay Agent Between Clients and DHCP Server (CLI Procedure) on page 4204</a></li><li>• <a href="#">[edit forwarding-options] Configuration Statement Hierarchy on EX Series Switches</a></li></ul>

## vlan (Secure Access Port)

```
Syntax  vlan (all | vlan-name) {
    examine-fip {
        examine-vn2vn {
            beacon-period milliseconds;
        }
        fc-map fc-map-value;
    }
    dhcp-option82
    circuit-id {
        prefix (Circuit ID for Option 82) hostname;
        use-interface-description;
        use-vlan-id;
    }
    remote-id {
        prefix (Remote ID for Option 82) hostname | mac | none;
        use-interface-description;
        use-string string;
    }
    vendor-id <string>;
}
(arp-inspection | no-arp-inspection);
circuit-id {
    prefix (Circuit ID for Option 82) hostname;
    use-interface-description;
    use-vlan-id;
}
remote-id {
    prefix (Remote ID for Option 82) hostname | mac | none;
    use-interface-description;
    use-string string;
}
vendor-id <string>;
}
(examine-dhcp | no-examine-dhcp);
mac-move-limit limit action action;
}
```

**Hierarchy Level** [edit [ethernet-switching-options secure-access-port](#)]

**Release Information** Statement introduced in Junos OS Release 11.1 for the QFX Series.

**Description** Apply DHCP snooping, dynamic ARP inspection (DAI), DHCP option 82, and MAC move limiting.

**TIP:** To display a list of all configured VLANs on the system, including VLANs that are configured but not committed, type ? after vlan or vlans in your configuration mode command line. Note that only one VLAN is displayed for a VLAN range.

The remaining statements are explained separately.

<b>Options</b>	<b>all</b> —Apply DHCP snooping, DAI, DHCP option 82, and MAC move limiting to all VLANs.  <b>vlan-name</b> —Apply DHCP snooping, DAI, DHCP option 82, and MAC move limiting to the specified VLAN.
<b>Required Privilege Level</b>	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Overview of Access Port Protection on page 4105</a></li><li>• <a href="#">Understanding MAC Limiting and MAC Move Limiting for Port Security on page 4119</a></li><li>• <a href="#">Understanding Trusted and Untrusted Ports on page 4121</a></li><li>• <a href="#">Configuring MAC Limiting on page 4188</a></li><li>• <a href="#">Enabling a Trusted Port for DHCP on page 4200</a></li></ul>

## vlan (Static IP)

---

<b>Syntax</b>	<code>vlan <i>vlan-name</i>;</code>
<b>Hierarchy Level</b>	[edit <a href="#">ethernet-switching-options secure-access-port interface</a> (all   <i>interface-name</i> ) <a href="#">static-ip ip-address</a> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 12.1 for the QFX Series switches.
<b>Description</b>	Associate a static IP address with the specified VLAN.
<b>Options</b>	<b>vlan-name</b> —Name of a VLAN associated with the specified interface.
<b>Required Privilege Level</b>	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Configuring Static IP Addresses for DHCP Bindings on Access Ports (CLI Procedure) on page 4193</a></li></ul>

---

## write-interval

---

<b>Syntax</b>	<code>write-interval <i>seconds</i>;</code>
<b>Hierarchy Level</b>	[edit <a href="#">ethernet-switching-options secure-access-port dhcp-snooping-file</a> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 12.1 for the QFX Series.
<b>Description</b>	Specify how frequently the switch writes the database entries from memory into the specified DHCP snooping database file.
<b>Default</b>	None
<b>Options</b>	<i>seconds</i> —Value in seconds. <b>Range:</b> 60 through 86400
<b>Required Privilege Level</b>	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Understanding DHCP Snooping for Port Security on page 4110</a></li></ul>

## Configuration Statements for Device Security

---

### action-shutdown

---

<b>Syntax</b>	action-shutdown;
<b>Hierarchy Level</b>	[edit <a href="#">ethernet-switching-options storm-control</a> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	<p>Shut down or disable interfaces when the storm control level is exceeded, as follows:</p> <ul style="list-style-type: none"><li>• If you set both the <b>action-shutdown</b> and the <b>port-error-disable</b> statements, the affected interfaces are disabled temporarily and recover automatically when the disable timeout expires.</li><li>• If you set the <b>action-shutdown</b> statement and do not set the <b>port-error-disable</b> statement, the affected interfaces are shut down when the storm control level is exceeded, and they do not recover automatically. You must issue the <b>clear ethernet-switching port-error</b> command to clear the port error and restore the interfaces to service.</li></ul>
<b>Default</b>	The <b>action-shutdown</b> feature is disabled. If the storm control level is exceeded, the switch drops broadcast and unknown unicast messages on the specified interfaces.
<b>Required Privilege Level</b>	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Understanding Storm Control on page 4125</a></li><li>• <a href="#">Example: Configuring Storm Control on page 4143</a></li><li>• <a href="#">port-error-disable on page 4253</a></li><li>• <a href="#">disable-timeout on page 4238</a></li><li>• <a href="#">clear ethernet-switching port-error on page 4290</a></li></ul>

## bandwidth

<b>Syntax</b>	<code>bandwidth <i>bandwidth</i>;</code>
<b>Hierarchy Level</b>	[edit <code>ethernet-switching-options storm-control interface</code> (all   <i>interface-name</i> )]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	For interfaces configured for storm control, configure the storm control level as the bandwidth in kilobits per second (Kbps). If the combination of broadcast and unknown unicast traffic exceeds this level, the switch performs the appropriate action.
<b>Default</b>	None.
<b>Options</b>	<b>bandwidth</b> —Broadcast and unknown unicast traffic rate in Kbps. <b>Range:</b> 100 through 10000000 Kbps <b>Default:</b> None

**NOTE:** When you configure storm control bandwidth, the value you configure is rounded off internally to the closest multiple of 64 Kbps, and the rounded-off value represents the bandwidth that is actually enforced. For example, if you configure a bandwidth limit of 150 Kbps, storm control enforces a bandwidth limit of 128 Kbps.

**CAUTION:** Junos OS allows you to configure a storm control value that exceeds the bandwidth of the interface. If you configure an interface with such a value, storm control does not drop broadcast or unknown unicast packets even if they consume all the available bandwidth.

<b>Required Privilege Level</b>	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
---------------------------------	---

<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Understanding Storm Control on page 4125</a></li> <li>• <a href="#">Example: Configuring Storm Control on page 4143</a></li> <li>• <a href="#">action-shutdown on page 4266</a></li> <li>• <a href="#">port-error-disable on page 4253</a></li> <li>• <a href="#">disable-timeout on page 4238</a></li> <li>• <a href="#">clear ethernet-switching port-error on page 4290</a></li> </ul>

## interface (Storm Control)

---

<b>Syntax</b>	<pre>interface (all   <i>interface-name</i>) {     bandwidth <i>bandwidth</i>;     no-broadcast;     no-multicast;     no-unknown-unicast; }</pre>
<b>Hierarchy Level</b>	[edit <a href="#">ethernet-switching-options storm-control</a> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Apply storm control to all interfaces or to the specified interface.  The remaining statement is explained separately.
<b>Default</b>	Storm control is disabled.
<b>Options</b>	<b>all</b> —Apply storm control to all interfaces.  <b><i>interface-name</i></b> —Apply storm control to the specified interface.
<b>Required Privilege Level</b>	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Understanding Storm Control on page 4125</a></li><li>• <a href="#">Example: Configuring Storm Control on page 4143</a></li></ul>

## no-broadcast

---

<b>Syntax</b>	no-broadcast;
<b>Hierarchy Level</b>	[edit <a href="#">ethernet-switching-options storm-control interface</a> (all   <i>interface-name</i> )]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	For interfaces configured for storm control, disable broadcast traffic storm control on the interface.
<b>Default</b>	When storm control is enabled on an interface, it is enabled for both unknown unicast traffic and broadcast traffic.
<b>Required Privilege Level</b>	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Understanding Storm Control on page 4125</a></li> <li>• <a href="#">Example: Configuring Storm Control on page 4143</a></li> </ul>

## no-multicast

---

<b>Syntax</b>	no-multicast;
<b>Hierarchy Level</b>	[edit <a href="#">ethernet-switching-options storm-control interface</a> (all   <i>interface-name</i> )]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Disable storm control for all multicast traffic (both registered multicast and unregistered multicast) for the specified interface or for all interfaces.
<b>Default</b>	Storm control is enabled for unknown unicast traffic, multicast traffic, and broadcast traffic.
<b>Required Privilege Level</b>	system—To view this statement in the configuration. system-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Understanding Storm Control on page 4125</a></li> <li>• <a href="#">Example: Configuring Storm Control on page 4143</a></li> </ul>

## no-unknown-unicast

---

<b>Syntax</b>	no-unknown-unicast;
<b>Hierarchy Level</b>	[edit <a href="#">ethernet-switching-options storm-control interface</a> (all   <i>interface-name</i> )]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	For interfaces configured for storm control, disable unknown unicast traffic storm control on the interface.
<b>Default</b>	When storm control is enabled on an interface, it is enabled for both unknown unicast traffic and broadcast traffic.
<b>Required Privilege Level</b>	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Understanding Storm Control on page 4125</a></li><li>• <a href="#">Example: Configuring Storm Control on page 4143</a></li></ul>

## storm-control

**Syntax**

```
storm-control {
  action-shutdown;
  interface (all | interface-name) {
    bandwidth bandwidth;
    no-broadcast;
    no-multicast;
    no-unknown-unicast;
  }
}
```

**Hierarchy Level** [edit [ethernet-switching-options](#)]

**Release Information** Statement introduced in Junos OS Release 11.1 for the QFX Series.

**Description** Apply storm control to all interfaces or to the specified interfaces.

The statements are explained separately.

**NOTE:** The **no-multicast** option is not supported on QFabric systems.

**Default** By default, storm control is enabled on all switch interfaces at a level of 80 percent of the combined broadcast and unknown unicast streams. You can change the storm control level by configuring it as a specific bandwidth value.

When you configure storm control bandwidth on an aggregated Ethernet interface, each member of the aggregated interface is assigned that bandwidth. For example, if you configure 7000000 Kbps on aggregated interface **ae1**, and **ae1** has two members, **xe-2:0/0/0** and **xe-2:0/0/1**, each member is allowed a bandwidth level of 7000000 Kbps. Thus, the storm control bandwidth on **ae1** could be as much as 14000000 Kbps of combined broadcast and unknown unicast traffic.

**Required Privilege Level**

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

- [Verifying That Two-Color Policers Are Operational on page 4286](#)
- [Verifying That Unknown Unicast Packets Are Forwarded to a Trunk Interface on page 4286](#)

### Monitoring Firewall Filter Traffic

You can use operational mode commands to monitor firewall filter traffic.

- [Monitoring Traffic for All Firewall Filters and Policers That Are Configured on page 4275](#)
- [Monitoring Traffic for a Specific Firewall Filter on page 4276](#)
- [Monitoring Traffic for a Specific Policer on page 4276](#)

#### Monitoring Traffic for All Firewall Filters and Policers That Are Configured

**Purpose** Monitor the number of packets and bytes that matched the firewall filters and monitor the number of packets that exceeded policer rate limits:

**Action** Use the **show firewall** operational mode command:

```
user@switch> show firewall
```

```
Filter: egress-vlan-watch-employee
Counters:
Name                               Bytes          Packets
counter-employee-web              3348           27
Filter: ingress-port-limit-tcp-icmp
Counters:
Name                               Bytes          Packets
icmp-counter                      560            10
Policers:
Name                               Packets
icmp-connection-policer          10
tcp-connection-policer           0
Filter: ingress-vlan-rogue-block
Filter: ingress-vlan-limit-guest
```

**Meaning** The **show firewall** command displays the names of all firewall filters, counters, and policers that are configured. For each counter that is specified in a filter configuration, the output field shows the byte count and packet count for the term in which the counter is specified. For each policer that is specified in a filter configuration, the output field shows the packet count for packets that exceed the specified rate limits.

---

#### Monitoring Traffic for a Specific Firewall Filter

**Purpose** Monitor the number of packets and bytes that matched a firewall filter and monitor the number of packets that exceeded policer rate limits.

**Action** Use the **show firewall filter *filter-name*** operational mode command:

```
user@switch> show firewall filter ingress-port-limit-tcp-icmp
Filter: ingress-port-limit-tcp-icmp
Counters:
Name                               Bytes          Packets
icmp-counter                      560            10
```

**Meaning** The **show firewall filter *filter-name*** command limits the display information to the counters and policers that are defined for the specified filter.

---

#### Monitoring Traffic for a Specific Policer

**Purpose** Monitor the number of packets that exceeded the rate limits of a policer:

**Action** Use the **show firewall policer *policer-name*** operational mode command:

```
user@switch> show firewall policer icmp-connection-policer
Filter: ingress-port-limit-tcp-icmp
Policers:
Name                               Packets
icmp-connection-policer           10
```

**Meaning** The **show firewall policer *policer-name*** command displays the number of packets that exceeded the rate limits for the specified policer.

- Related Documentation**

## Monitoring Port Security

**Purpose** Use the monitoring functionality to view these port security details:

- DHCP snooping database for a VLAN or all VLANs
- ARP inspection details for all interfaces

**Action** To monitor port security in the J-Web interface, select **Monitor > Security > Port Security**.

To monitor and manipulate the DHCP snooping database and ARP inspection statistics in the CLI, enter the following commands:

- **show dhcp snooping binding**
- **clear dhcp snooping binding**—In addition to clearing the whole database, you can clear database entries for specified VLANs or MAC addresses.
- **show arp inspection statistics**
- **clear arp inspection statistics**

**Meaning** The J-Web Port Security Monitoring page comprises two sections:

- **DHCP Snooping**—Displays the DHCP snooping database for all the VLANs for which DHCP snooping is enabled. To view the DHCP snooping database for a specific VLAN, select the specific VLAN from the list.
- **ARP Inspection**—Displays the ARP inspection details for all interfaces. The information includes details of the number of packets that passed ARP inspection and the number of packets that failed the inspection. The pie chart graphically represents these statistics when you select an interface. To view ARP inspection statistics for a specific interface, select the interface from the list.

You have the following options on the page:

- **Clear ALL**—Clears the DHCP snooping database, either for all VLANs if the option **ALL** has been selected in the Select VLANs list or for the specific VLAN that has been selected in that list.
- **Clear**—Deletes a specific IP address from the DHCP snooping database.

To clear ARP statistics on the page, click **Clear All** in the ARP Statistics section.

Use the CLI commands to show and clear DHCP snooping database and ARP inspection statistics details.

  - [Configuring Port Security \(J-Web Procedure\)](#)
  - [Example: Configuring Basic Port Security Features on page 4136](#)

## Verifying That Firewall Filters Are Operational

**Purpose** Verify that firewall filters are working properly after you apply them to ports, VLANs, or Layer 3 interfaces.

**Action** Use the **show firewall** operational mode command to verify that the firewall filters are working properly:

```
user@switch> show firewall
Filter: egress-vlan-watch-employee
Counters:
Name                               Bytes      Packets
counter-employee-web              0           0
Filter: ingress-port-limit-tcp-icmp
Counters:
Name                               Bytes      Packets
icmp-counter                      560        10
Policers:
Name                               Packets
icmp-connection-policer          10
tcp-connection-policer           0
Filter: ingress-vlan-rogue-block
Filter: ingress-vlan-limit-guest
```

**Meaning** The **show firewall** command displays the names of all firewall filters, counters, and policers that are configured. For each counter that is specified in a filter configuration, the output field shows the byte count and packet count for the term in which the counter is specified. In the above example, the **icmp-counter** in the filter **ingress-port-limit-tcp-icmp** shows that the filter matched 10 packets. For each policer that is specified in a filter configuration, the output field shows the packet count for packets that exceed the specified rate limits. The policer **icmp-connection-policer** shows that 10 ICMP packets were policed.

- Related Documentation**

## Verifying That DAI Is Working Correctly

**Purpose** Verify that dynamic ARP inspection (DAI) is working on the switch.

**Action** Send some ARP requests from network devices connected to the switch.

Display the DAI information:

```
user@switch> show arp inspection statistics
```

## ARP inspection statistics:

Interface	Packets received	ARP inspection pass	ARP inspection failed
ge-0/0/1.0	7	5	2
ge-0/0/2.0	10	10	0
ge-0/0/3.0	12	12	0

**Meaning** The sample output shows the number of ARP packets received and inspected per interface, with a listing of how many packets passed and how many failed the inspection on each interface. The switch compares the ARP requests and replies against the entries in the DHCP snooping database. If a MAC address or IP address in the ARP packet does not match a valid entry in the database, the packet is dropped.

- Related Documentation**
- [Enabling Dynamic ARP Inspection \(CLI Procedure\) on page 4197](#)

  - [Example: Configuring DHCP Snooping and DAI to Protect the Switch from ARP Spoofing Attacks on page 4162](#)
  - [Monitoring Port Security on page 4277](#)

## Verifying That DHCP Snooping Is Working Correctly

**Purpose** Verify that DHCP snooping is working on the switch and that the DHCP snooping database is correctly populated with both dynamic and static bindings.

**Action** Send some DHCP requests from network devices (here they are DHCP clients) connected to the switch.

Display the DHCP snooping information when the interface on which the DHCP server connects to the switch is trusted. The following output results when requests are sent from the MAC addresses and the server has provided the IP addresses and leases:

```
user@switch> show dhcp snooping binding
```

## DHCP Snooping Information:

MAC address	IP address	Lease (seconds)	Type	VLAN	Interface
00:05:85:3A:82:77	192.0.2.17	600	dynamic	employee	ge-0/0/1.0
00:05:85:3A:82:79	192.0.2.18	653	dynamic	employee	ge-0/0/1.0
00:05:85:3A:82:80	192.0.2.19	720	dynamic	employee	ge-0/0/2.0
00:05:85:3A:82:81	192.0.2.20	932	dynamic	employee	ge-0/0/2.0
00:05:85:3A:82:83	192.0.2.21	1230	dynamic	employee	ge-0/0/2.0
00:05:85:27:32:88	192.0.2.22	–	static	data	ge-0/0/4.0

**Meaning** When the interface on which the DHCP server connects to the switch has been set to trusted, the output (see preceding sample) shows, for each MAC address, the assigned IP address and lease time—that is, the time, in seconds, remaining before the lease

expires. Static IP addresses have no assigned lease time. The statically configured entry never expires.

If the DHCP server had been configured as untrusted, no entries would be added to the DHCP snooping database and nothing would be shown in the output of the **show dhcp snooping binding** command.

## Verifying That MAC Limiting Is Working Correctly

MAC limiting protects against flooding of the Ethernet switching table by setting a limit on the number of MAC addresses that can be learned on a single Layer 2 access interface (port).

Junos OS provides two MAC limiting methods:

- **Maximum number of MAC addresses**—You configure the maximum number of dynamic MAC addresses allowed per interface. When the limit is exceeded, incoming packets with new MAC addresses can be ignored, dropped, or logged. You can also specify that the interface be shut down or temporarily disabled.
- **Allowed MAC addresses**—You configure specific “allowed” MAC addresses for the access interface. Any MAC address that is not in the list of configured addresses is not learned, and the switch logs an appropriate message. The allowed MAC method binds MAC addresses to a VLAN so that the address is not registered outside the VLAN. If an allowed MAC setting conflicts with a dynamic MAC setting, the allowed MAC setting takes precedence.

This topic includes the following tasks:

1. [Verifying That MAC Limiting for Dynamic MAC Addresses Is Working Correctly on page 4281](#)
2. [Verifying That Allowed MAC Addresses Are Working Correctly on page 4281](#)

3. [Verifying That Interfaces Are Shut Down on page 4282](#)
4. [Customizing the Ethernet Switching Table Display to View Information for a Specific Interface on page 4282](#)

### Verifying That MAC Limiting for Dynamic MAC Addresses Is Working Correctly

**Purpose** Verify that MAC limiting for dynamic MAC addresses is working.

**Action** Display the MAC addresses that have been learned. The following sample output shows the results of sending two packets from hosts connected to **xe-1:0/0/1** and five packets from hosts connected to **xe-1:0/0/2**, with both interfaces configured with a MAC limit of **4** and the action **drop**:

```
user@switch> show ethernet-switching table
Ethernet-switching table: 7 entries, 6 learned
```

VLAN	MAC address	Type	Age	Interfaces
employee-vlan	*	Flood	-	xe-1:0/0/2.0
employee-vlan	00:05:85:3A:82:77	Learn	0	xe-1:0/0/1.0
employee-vlan	00:05:85:3A:82:79	Learn	0	xe-1:0/0/1.0
employee-vlan	00:05:85:3A:82:80	Learn	0	xe-1:0/0/2.0
employee-vlan	00:05:85:3A:82:81	Learn	0	xe-1:0/0/2.0
employee-vlan	00:05:85:3A:82:83	Learn	0	xe-1:0/0/2.0
employee-vlan	00:05:85:3A:82:85	Learn	0	xe-1:0/0/2.0

**Meaning** The output shows that the fifth packet received on the **xe-1:0/0/2** interface was dropped because it exceeded the MAC limit for that interface. The address was not learned, and thus an asterisk (\*) rather than an address appears in the MAC address column in the first line of the sample output.

### Verifying That Allowed MAC Addresses Are Working Correctly

**Purpose** Verify that allowed MAC addresses are working.

**Action** Display the MAC cache information after allowed MAC addresses have been configured on an interface. The following sample shows the MAC cache after four allowed MAC addresses had been configured on interface **xe-1:0/0/2** and a fifth MAC address appeared on the interface.

```
user@switch> show ethernet-switching table
Ethernet-switching table: 5 entries, 4 learned
```

VLAN	MAC address	Type	Age	Interfaces
employee-vlan	00:05:85:3A:82:80	Learn	0	xe-1:0/0/2.0
employee-vlan	00:05:85:3A:82:81	Learn	0	xe-1:0/0/2.0
employee-vlan	00:05:85:3A:82:83	Learn	0	xe-1:0/0/2.0
employee-vlan	00:05:85:3A:82:85	Learn	0	xe-1:0/0/2.0
employee-vlan	*	Flood	-	xe-1:0/0/2.0

**Meaning** Because the fifth address was not allowed it was not learned, and an asterisk (\*) rather than an address appears in the MAC address column in the last line of the sample output.

### Verifying That Interfaces Are Shut Down

**Purpose** Verify that an interface is shut down when the MAC limit is exceeded.

**Action** For more information about interfaces that have been shut down because the MAC limit was exceeded, use the **show ethernet-switching interfaces** command.

```
user@switch> show ethernet-switching interfaces
```

Interface	State	VLAN members	Tag	Tagging	Blocking
bme0.32770	down	mgmt	untagged	unblocked	
xe-0/0/0.0	down	v1	untagged	MAC limit exceeded	
xe-0/0/1.0	up	v1	untagged	unblocked	
xe-0/0/2.0	up	v1	untagged	unblocked	
me0.0	up	mgmt	untagged	unblocked	

**NOTE:** You can configure interfaces to recover automatically when the MAC limit has been exceeded by specifying the **port-error-disable** statement with a **disable timeout** value. The switch automatically restores the disabled interface to service when the disable timeout expires. The **port-error-disable** configuration does not apply to preexisting error conditions—it affects only error conditions that are detected after the **port-error-disable** statement has been enabled and the configuration has been committed. To clear a preexisting error condition and restore the interface to service, use the **clear ethernet-switching port-error** command.

### Customizing the Ethernet Switching Table Display to View Information for a Specific Interface

**Purpose** You can use the **show ethernet-switching table** command to view information for a specific interface.

**Action** For example, to display the MAC addresses that have been learned on the **xe-0/0/2** interface, enter:

```
user@switch> show ethernet-switching table interface xe-0/0/2.0
```

Ethernet-switching table: 1 unicast entries

VLAN	MAC address	Type	Age	Interfaces
v1	*	Flood	-	All-members
v1	00:00:06:00:00:00	Learn	0	xe-0/0/2.0

**Meaning** The MAC limit value for the **xe-0/0/2** interface had been set to **1**, and the output shows that only one MAC address was learned and added to the MAC cache.

- Related Documentation**
- [Configuring MAC Limiting on page 4188](#)
  - [Monitoring Port Security on page 4277](#)
  - [Configuring Autorecovery From the Disabled State on Secure or Storm Control Interfaces \(CLI Procedure\)](#)
  - [Example: Configuring Allowed MAC Addresses to Protect the Switch from DHCP Snooping Database Alteration Attacks on page 4167](#)
  - [Example: Configuring MAC Limiting, Including Dynamic and Allowed MAC Addresses, to Protect the DCF from Ethernet Switching Table Overflow Attacks](#)
  - [Example: Configuring MAC Limiting to Protect the Switch from DHCP Starvation Attacks on page 4145](#)

## Verifying That MAC Move Limiting Is Working Correctly

**Purpose** Verify that MAC move limiting is working on the switch.

**Action** Display the MAC addresses in the Ethernet switching table when MAC move limiting has been configured for a VLAN. The following sample shows the results after two of the hosts on **ge-0/0/2** sent packets after the MAC addresses for those hosts had moved to other interfaces more than five times in 1 second. The VLAN, **employee-vlan**, was set to a MAC move limit of **5** with the action **drop**:

```
user@switch> show ethernet-switching table
```

```
Ethernet-switching table: 7 entries, 4 learned
```

VLAN	MAC address	Type	Age	Interfaces
employee-vlan	00:05:85:3A:82:77	Learn	0	ge-0/0/1.0
employee-vlan	00:05:85:3A:82:79	Learn	0	ge-0/0/1.0
employee-vlan	00:05:85:3A:82:80	Learn	0	ge-0/0/2.0
employee-vlan	00:05:85:3A:82:81	Learn	0	ge-0/0/2.0
employee-vlan	*	Flood	-	ge-0/0/2.0
employee-vlan	*	Flood	-	ge-0/0/2.0

**Meaning** The last two lines of the sample output show that MAC addresses for two hosts on **ge-0/0/2** were not learned, because the hosts had been moved back and forth from the original interfaces more than five times in 1 second.

- Related Documentation**
- [Configuring MAC Move Limiting \(CLI Procedure\) on page 4190](#)
  - [Configuring MAC Move Limiting \(J-Web Procedure\)](#)
  - [Configuring Autorecovery From the Disabled State on Secure or Storm Control Interfaces \(CLI Procedure\)](#)
  - [Example: Configuring Basic Port Security Features on page 4136](#)

- [Monitoring Port Security on page 4277](#)

## Verifying That the Port Error Disable Setting Is Working Correctly

**Purpose** Verify that the port error disable setting is working as expected for MAC limited and storm control interfaces.

**Action** Display information about interfaces:

```
user@switch> show ethernet-switching interfaces
Interface      State    VLAN members      Blocking
xe-2:0/0/0.0   up       T1122              unblocked
xe-2:0/0/1.0   down     default            MAC limit exceeded
xe-2:0/0/2.0   down     default            Storm control in effect
xe-2:0/0/3.0   down     default            unblocked
xe-2:0/0/4.0   down     default            unblocked
xe-2:0/0/5.0   down     default            unblocked
xe-2:0/0/6.0   down     default            unblocked
```

**Meaning** For interfaces disabled by port security features, the sample output from the **show ethernet-switching interfaces** command specifies the reasons that the interfaces are disabled:

- **MAC limit exceeded**—The interface is temporarily disabled because of a [mac-limit](#) error. The disabled interface is automatically restored to service when the [disable-timeout \(Port Error Disable\)](#) expires.
- **MAC move limit exceeded**—The interface is temporarily disabled because of a [mac-move-limit](#) error. The disabled interface is automatically restored to service when the [disable-timeout](#) expires.
- **Storm control in effect**—The interface is temporarily disabled because of a [storm-control](#) error. The disabled interface is automatically restored to service when the [disable-timeout \(Port Error Disable\)](#) expires.

- Related Documentation**

  - [Configuring Autorecovery for MAC Limited or Storm Control Interfaces \(CLI Procedure\) on page 4192](#)

## Verifying That a Trusted DHCP Server Is Working Correctly

**Purpose** Verify that a DHCP trusted server is working on the switch. See what happens when the DHCP server is trusted and then untrusted.

**Action** Send some DHCP requests from network devices (here they are DHCP clients) connected to the switch.

Display the DHCP snooping information when the interface on which the DHCP server connects to the switch is trusted. The following output results when requests are sent from the MAC addresses and the server has provided the IP addresses and leases:

```
user@switch> show dhcp snooping binding
```

DHCP Snooping Information:

MAC Address	IP Address	Lease	Type	VLAN	Interface
00:05:85:3A:82:77	192.0.2.17	600	dynamic	employee-vlan	ge-0/0/1.0
00:05:85:3A:82:79	192.0.2.18	653	dynamic	employee-vlan	ge-0/0/1.0
00:05:85:3A:82:80	192.0.2.19	720	dynamic	employee-vlan	ge-0/0/2.0
00:05:85:3A:82:81	192.0.2.20	932	dynamic	employee-vlan	ge-0/0/2.0
00:05:85:3A:82:83	192.0.2.21	1230	dynamic	employee-vlan	ge-0/0/2.0
00:05:85:27:32:88	192.0.2.22	3200	dynamic	employee-vlan	ge-0/0/2.0

**Meaning** When the interface on which the DHCP server connects to the switch has been set to trusted, the output (see preceding sample) shows, for each MAC address, the assigned IP address and lease time—that is, the time, in seconds, remaining before the lease expires.

If the DHCP server had been configured as untrusted, no entries would be added to the DHCP snooping database and nothing would be shown in the output of the **show dhcp snooping binding** command.

## Verifying That Three-Color Policers Are Operational

**Purpose** Verify that three-color policers in firewall filter configurations are working properly.

**Action** Use the following operational mode commands to verify that a three-color policer is working properly:

- **show class-of-service forwarding-table classifiers**
- **show interfaces *interface-name* extensive**
- **show interfaces queue *interface-name***

- Related Documentation**
- [Overview of Policers on page 4096](#)
  - [Configuring Two-Color and Three-Color Policers to Control Traffic Rates on page 4183](#)

## Verifying That Two-Color Policers Are Operational

**Purpose** Verify that two-color policers in firewall filter configurations are working properly.

**Action** Use the **show firewall policer** operational mode command to verify that the policers are working properly:

```
user@switch> show firewall policer
Filter: egress-vlan-watch-employee
Filter: ingress-port-filter
Filter: ingress-port-limit-tcp-icmp
Policies:
Name                                     Packets
icmp-connection-policer                  10
tcp-connection-policer                   539
Filter: ingress-vlan-rogue-block
Filter: ingress-vlan-limit-guest
```

**Meaning** The **show firewall policer** command displays the names of all firewall filters and policers that are configured. For each policer that is specified in a filter configuration, the output field shows the current packet count for all packets that exceed the specified rate limits.

- Related Documentation**
- [Configuring Two-Color and Three-Color Policers to Control Traffic Rates on page 4183](#)
  - [Configuring Firewall Filters on page 4177](#)
  - [Monitoring Firewall Filter Traffic on page 4275](#)

## Verifying That Unknown Unicast Packets Are Forwarded to a Trunk Interface

**Purpose** Verify that a VLAN is forwarding all unknown unicast packets (those with unknown destination MAC addresses) to a single trunk port instead of flooding them out all the ports in the VLAN.

**Action** 1. Display the forwarding interface for unknown unicast packets for a VLAN (here, the VLAN name is **v1**):

```
user@switch> show configuration ethernet-switching-options

unknown-unicast-forwarding {
    vlan v1 {
        interface xe-2:0/0/7.0;
    }
}
```

2. Display the Ethernet switching table:

```
user@switch> show ethernet-switching table vlan v1
Ethernet-switching table: 3 unicast entries
VLAN    MAC address    Type    Age    Interfaces
v1      *              Flood   -      - All-members
v1      00:01:09:00:00:00 Learn      24    xe-2:0/0/7.0
```

v1                      00:11:09:00:01:00 Learn                      37 xe-2:0/0/3.0

**Meaning**    The sample output from the **show configuration ethernet-switching-options** command shows that the unknown unicast forwarding interface for VLAN **v1** is interface **xe-2:0/0/7**. The output of the **show ethernet-switching table** command shows that an unknown unicast packet is received on interface **xe-0/0/3** with the source MAC address (SMAC) of **00:11:09:00:01:00**. This shows that the SMAC of the packet is learned in the normal way (through the interface **xe-0/0/3.0**). The destination MAC address (DMAC) **00:01:09:00:00:00** is learned on interface **xe-0/0/7**.

## Monitoring Commands

## clear arp inspection statistics

---

<b>Syntax</b>	clear arp inspection statistics <interface <i>interface</i> >
<b>Release Information</b>	Command introduced in Junos OS Release 9.0 for EX Series switches. Command introduced in Junos OS Release 12.1 for the QFX Series.
<b>Description</b>	Clear ARP inspection statistics.
<b>Options</b>	<b>none</b> —Clears ARP statistics on all interfaces.  <b>interface <i>interface-names</i></b> —(Optional) Clear ARP statistics on one or more interfaces.
<b>Required Privilege Level</b>	clear
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">show arp inspection statistics on page 4292</a></li><li>• <a href="#">Example: Configuring Basic Port Security Features on page 4136</a></li><li>• <a href="#">Verifying That DAI Is Working Correctly on page 4278</a></li></ul>
<b>List of Sample Output</b>	<a href="#">clear arp inspection statistics on page 4288</a>
<b>Output Fields</b>	This command produces no output.

## Sample Output

**clear arp inspection statistics**      user@switch> clear arp inspection statistics

## clear dhcp snooping binding

---

<b>Syntax</b>	clear dhcp snooping binding <mac (all   <i>mac-address</i> )> <vlan (all   <i>vlan-name</i> )> <vlan (all   <i>vlan-name</i> ) mac (all   <i>mac-address</i> )>
<b>Release Information</b>	Command introduced in Junos OS Release 12.1 for the QFX Series.
<b>Description</b>	Clear the DHCP snooping database information.
<b>Options</b>	<p><b>mac (all   <i>mac-address</i>)</b>—(Optional) Clear DHCP snooping information for the specified MAC address or all MAC addresses.</p> <p><b>vlan (all   <i>vlan-name</i>)</b>—(Optional) Clear DHCP snooping information for the specified VLAN or all VLANs.</p>
<b>Required Privilege Level</b>	clear
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Example: Configuring Basic Port Security Features on page 4136</a></li> <li>• <a href="#">show dhcp snooping binding on page 4293</a></li> </ul>
<b>List of Sample Output</b>	<a href="#">clear dhcp snooping binding on page 4289</a>
<b>Output Fields</b>	This command produces no output.

### Sample Output

```
clear dhcp snooping binding    user@switch> clear dhcp snooping binding
```

## clear ethernet-switching port-error

---

<b>Syntax</b>	clear ethernet-switching port-error <interface <i>interface-name</i> >
<b>Release Information</b>	Command introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Clear all MAC limiting, MAC move limiting, and storm control errors from all the Ethernet switching interfaces on the switch or from the specified interface, and restore the interfaces or the specified interface to service.
<b>Options</b>	<b>none</b> —Clear all MAC limiting, MAC move limiting, and storm control errors from all the Ethernet switching interfaces on the switch and restore the interfaces to service.  <b>interface <i>interface-name</i></b> —(Optional) Clear all MAC limiting, MAC move limiting, and storm control errors from the specified interface and restore the interface to service.
<b>Required Privilege Level</b>	clear
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Configuring MAC Limiting on page 4188</a></li><li>• <a href="#">Example: Configuring Storm Control on page 4143</a></li><li>• <a href="#">Configuring Port Security (CLI Procedure) on page 4186</a></li><li>• <a href="#">port-error-disable on page 4253</a></li><li>• <a href="#">Configuring Autorecovery for MAC Limited or Storm Control Interfaces (CLI Procedure) on page 4192</a></li></ul>
<b>Output Fields</b>	This command produces no output.

## clear firewall

---

<b>Syntax</b>	<code>clear firewall (all   counter <i>counter-name</i>   filter <i>filter-name</i>)</code>
<b>Release Information</b>	Command introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	<p>Clear statistics provided by firewall filters.</p> <p>When you clear the counters of a filter, this not only impacts the counters shown by the CLI, but also the ones tracked by SNMP 2.</p>
<b>Options</b>	<p><b>all</b>—Clear the packet and byte counts for all firewall filter counters and clear the packet counts for all policer counters.</p> <p><b>counter <i>counter-name</i></b>—Clear the packet and byte counts for the specified firewall filter counter.</p> <p><b>filter <i>filter-name</i></b>—Clear the packet and byte counts for the specified firewall filter.</p>
<b>Required Privilege Level</b>	clear
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Verifying That Firewall Filters Are Operational on page 4278</a></li> <li>• <a href="#">Verifying That Two-Color Policers Are Operational on page 4286</a></li> <li>• <a href="#">Overview of Firewall Filters on page 4071</a></li> <li>• <a href="#">Overview of Policers on page 4096</a></li> </ul>

## Sample Output

<b>clear firewall all</b>	<code>user@switch&gt; clear firewall all</code>
<b>clear firewall counter</b>	<code>user@switch&gt; clear firewall counter port-filter-counter</code>
<b>clear firewall filter</b>	<code>user@switch&gt; clear firewall filter ingress-port-filter</code>

## show arp inspection statistics

<b>Syntax</b>	show arp inspection statistics
<b>Release Information</b>	Command introduced in Junos OS Release 9.0 for EX Series switches. Command introduced in Junos OS Release 12.1 for the QFX Series.
<b>Description</b>	Display ARP inspection statistics.
<b>Required Privilege Level</b>	view
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">clear arp inspection statistics on page 4288</a></li> <li>• <a href="#">Example: Configuring Basic Port Security Features on page 4136</a></li> <li>• <a href="#">Verifying That DAI Is Working Correctly on page 4278</a></li> </ul>
<b>List of Sample Output</b>	<a href="#">show arp inspection statistics on page 4292</a>
<b>Output Fields</b>	<a href="#">Table 296 on page 4292</a> lists the output fields for the <b>show arp inspection statistics</b> command. Output fields are listed in the approximate order in which they appear.

**Table 296: show arp inspection statistics Output Fields**

Field Name	Field Description	Level of Output
Interface	Interface on which ARP inspection has been applied.	All levels
Packets received	Total number of packets total that underwent ARP inspection.	All levels
ARP inspection pass	Total number of packets that passed ARP inspection.	All levels
ARP inspection failed	Total number of packets that failed ARP inspection.	All levels

## Sample Output

### show arp inspection statistics

```
user@switch> show arp inspection statistics
```

Interface	Packets received	ARP inspection pass	ARP inspection failed
ge-0/0/0	0	0	0
ge-0/0/1	0	0	0
ge-0/0/2	0	0	0
ge-0/0/3	0	0	0
ge-0/0/4	0	0	0
ge-0/0/5	0	0	0
ge-0/0/6	0	0	0
ge-0/0/7	703	701	2

## show dhcp snooping binding

<b>Syntax</b>	<b>show dhcp snooping binding</b> <b>&lt;interface <i>interface-name</i>&gt;</b> <b>&lt;vlan <i>vlan-name</i>&gt;</b>
<b>Release Information</b>	Command introduced in Junos OS Release 9.0 for EX Series switches. Command introduced in Junos OS Release 12.1 for the QFX Series.
<b>Description</b>	Display the DHCP snooping database information.
<b>Options</b>	<b>interface <i>interface-name</i></b> —(Optional) Display the DHCP snooping database information for an interface.  <b>vlan <i>vlan-name</i></b> —(Optional) Display the DHCP snooping database information for a VLAN.
<b>Required Privilege Level</b>	view
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">clear dhcp snooping binding</a></li> <li>• <a href="#">Example: Configuring Basic Port Security Features on page 4136</a></li> <li>• <a href="#">Verifying That DHCP Snooping Is Working Correctly on page 4279</a></li> </ul>
<b>List of Sample Output</b>	<a href="#">show dhcp snooping binding on page 4294</a>
<b>Output Fields</b>	<a href="#">Table 297 on page 4293</a> lists the output fields for the <b>show dhcp snooping binding</b> command. Output fields are listed in the approximate order in which they appear.

**Table 297: show dhcp snooping binding Output Fields**

Field Name	Field Description	Level of Output
MAC Address	MAC address of the network device; bound to the IP address.	All levels
IP Address	IP address of the network device; bound to the MAC address.	All levels
Lease	Lease granted to the IP address.	All levels
Type	How the MAC address was acquired.	All levels
VLAN	VLAN name of the network device whose MAC address is shown.	All levels
Interface	Interface address (port).	All levels

## Sample Output

`show dhcp snooping  
binding`

`user@switch> show dhcp snooping binding`

DHCP Snooping Information:

MAC Address	IP Address	Lease	Type	VLAN	Interface
00:00:01:00:00:03	192.0.2.0	640	dynamic	guest	ge-0/0/12.0
00:00:01:00:00:04	192.0.2.1	720	dynamic	guest	ge-0/0/12.0
00:00:01:00:00:05	192.0.2.5	800	dynamic	guest	ge-0/0/13.0

## show firewall

<b>Syntax</b>	<pre>show firewall   &lt;counter <i>counter-name</i>&gt;   &lt;filter <i>filter-name</i>&gt;   &lt;log &lt;detail   interface <i>interface-name</i>&gt;&gt;   &lt;terse&gt;</pre>
<b>Release Information</b>	Command introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Display statistics about configured firewall filters.
<b>Options</b>	<p><b>counter <i>counter-name</i></b>—(Optional) Display statistics about a particular firewall filter counter.</p> <p><b>filter <i>filter-name</i></b>—(Optional) Display statistics about a particular firewall filter.</p> <p><b>log</b>—(Optional) Display log entries for all firewall filter activity.</p> <p><b>terse</b>—(Optional) Display firewall filter names only.</p>
<b>Required Privilege Level</b>	view
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Verifying That Firewall Filters Are Operational on page 4278</a></li> <li>• <a href="#">Verifying That Two-Color Policers Are Operational on page 4286</a></li> <li>• <a href="#">Overview of Firewall Filters on page 4071</a></li> <li>• <a href="#">Overview of Policers on page 4096</a></li> </ul>
<b>List of Sample Output</b>	<p><a href="#">show firewall on page 4297</a></p> <p><a href="#">show firewall filter <i>filter-name</i> on page 4297</a></p> <p><a href="#">show firewall counter <i>counter-name</i> on page 4297</a></p> <p><a href="#">show firewall log on page 4297</a></p> <p><a href="#">show firewall log detail on page 4297</a></p>
<b>Output Fields</b>	Table 298 on page 4295 lists the output fields for the <b>show firewall</b> command. Output fields are listed in the approximate order in which they appear.

**Table 298: show firewall Output Fields**

Field Name	Field Description	Level of Output
Filter	Name of the filter that is configured at the <code>[edit firewall family <i>family-name</i> filter]</code> hierarchy level.	All levels

Table 298: show firewall Output Fields (*continued*)

Field Name	Field Description	Level of Output
<b>Counters</b>	Display filter counter information: <ul style="list-style-type: none"> <li>• Name—Name of a filter counter that has been configured with the <b>count</b> firewall filter action modifier.</li> <li>• Bytes—Number of bytes that match the filter term where the <b>count</b> action modifier was specified.</li> <li>• Packets—Number of packets that matched the filter term where the <b>count</b> action modifier was specified.</li> </ul>	All levels
<b>Policers</b>	Display policer information: <ul style="list-style-type: none"> <li>• Name—Name of the policer that is configured at the <b>[edit firewall policer]</b> hierarchy level.</li> <li>• Packets—Number of packets that matched the filter term where the <b>policer</b> action modifier was specified. This is the number of packets that exceeded the rate limits that the policer specifies.</li> </ul>	All levels
<b>Action</b>	Filter action: <ul style="list-style-type: none"> <li>• <b>A</b>—Accept</li> <li>• <b>D</b>—Discard</li> </ul>	All levels
<b>Interface</b>	Interface on which the firewall filter is applied.	All levels
<b>Protocol</b>	Name of the packet protocol.	All levels
<b>Packet Length</b>	Length of the packet.	All levels
<b>Src Addr</b>	Source address of the packet.	All levels
<b>Dest Addr</b>	Destination address of the packet.	All levels

## Sample Output

### show firewall

```

user@switch> show firewall
Filter: egress-vlan-watch-employee
Counters:
Name                                     Bytes      Packets
counter-employee-web                     0           0
Filter: ingress-port-limit-tcp-icmp
Counters:
Name                                     Bytes      Packets
icmp-counter                             560         10
Policers:
Name                                     Packets
icmp-connection-policer                  10
tcp-connection-policer                   0
Filter: ingress-vlan-rogue-block
Filter: ingress-vlan-limit-guest

```

### show firewall filter filter-name

```

user@switch> show firewall filter ingress-port-limit-tcp-icmp
Filter: ingress-port-limit-tcp-icmp
Counters:
Name                                     Bytes      Packets
icmp-counter                             560         10
Policers:
Name                                     Packets
icmp-connection-policer                  10
tcp-connection-policer                   0

```

### show firewall counter counter-name

```

user@switch> show firewall counter icmp-counter
Filter: ingress-port-voip-class-filter
Counters:
Name                                     Bytes      Packets
icmp-counter                             560         10

```

### show firewall log

```

user@switch> show firewall log
Log :

Time      Filter  Action Interface  Protocol  Src Addr
      Dest Addr
08:00:53  pfe      R      ge-1/0/6.0   ICMP      192.168.3.5
          192.168.3.4

<b>Output Fields</b>	Table 299 on page 4299 lists the output fields for the <b>show firewall policer</b> command. Output fields are listed in the approximate order in which they appear.

**Table 299: show firewall policer Output Fields**

Field Name	Field Description	Level of Output
<b>Filter</b>	Name of the filter that is configured at the <b>[edit firewall family <i>family-name</i> filter]</b> hierarchy level.	All levels
<b>Policers</b>	Display policer information: <ul style="list-style-type: none"> <li>• <b>Filter</b>—Name of filter that specifies the <b>policer</b> action modifier.</li> <li>• <b>Name</b>—Name of policer.</li> <li>• <b>Packets</b>—Number of packets that matched the filter term in which the <b>policer</b> action modifier is specified. This is the number of packets that exceed the rate limits that the policer specifies.</li> </ul>	All levels

## Sample Output

```
show firewall policer      user@switch> show firewall policer
                           Filter: egress-vlan-filter
                           Filter: ingress-port-filter
                           Policers:
                           Name                               Packets
                           icmp-connection-policer             0
                           tcp-connection-policer               0
                           Filter: ingress-vlan-rogue-block
```

```
show firewall policer      user@switch> show firewall policer tcp-connection-policer
policer-name              Filter: ingress-port-filter
                           Policers:
                           Name                               Packets
                           tcp-connection-policer               0
```

## show interfaces filters

<b>Syntax</b>	show interfaces filters <interface-name>
<b>Release Information</b>	Command introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Display firewall filters that are configured on each interface in a switch.
<b>Options</b>	<b>none</b> —Display firewall filter information about all interfaces.  <b>interface-name</b> —(Optional) Display firewall filter information about a particular interface.
<b>Required Privilege Level</b>	view
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">show firewall on page 4295</a></li> </ul>
<b>List of Sample Output</b>	<a href="#">show interfaces filters on page 4302</a> <a href="#">show interfaces filters interface-name on page 4302</a>
<b>Output Fields</b>	Table 300 on page 4301 lists the output fields for the <b>show interfaces filters</b> command. Output fields are listed in the approximate order in which they appear.

Table 300: show interfaces filters Output Fields

Field Name	Field Description	Level of Output
<b>Interface</b>	Name of the physical interface.	All levels
<b>Admin</b>	Interface state: <b>up</b> or <b>down</b> .	All levels
<b>Link</b>	Link state: <b>up</b> or <b>down</b> .	All levels
<b>Proto</b>	Protocol that is configured on the interface.	All levels
<b>Input Filter</b>	Name of the firewall filter to be evaluated when packets are received on the interface.	All levels
<b>Output Filter</b>	Name of the firewall filter to be evaluated when packets are transmitted on the interface.	All levels

## Sample Output

```
show interfaces filters user@switch> show interfaces filters
Interface      Admin Link Proto Input Filter      Output Filter

- [Cannot Egress Filter Certain Traffic Originating on QFX Switch on page 4306](#)
- [Firewall Filter Match Condition Not Working with Q-in-Q Tunneling on page 4307](#)
- [Egress Firewall Filters with Private VLANs on page 4307](#)
- [Egress Filtering of L2PT Traffic Not Supported on page 4308](#)
- [Cannot Drop BGP Packets in Certain Circumstances on page 4308](#)
- [Invalid Statistics for Policer on page 4308](#)

### Firewall Filter Configuration Returns a No Space Available in TCAM Message

---

**Problem** When a firewall filter configuration exceeds the amount of available Ternary Content Addressable Memory (TCAM) space, the system returns the following **syslogd** message:

```
No space available in tcam.  
Rules for filter filter-name will not be installed.
```

A switch returns this message during the commit operation if the firewall filter that has been applied to a port, VLAN, or Layer 3 interface exceeds the amount of space available in the TCAM table. The filter is not applied, but the commit operation for the firewall filter configuration is completed in the CLI module.

**Solution** When a firewall filter configuration exceeds the amount of available TCAM table space, you must configure a new firewall filter with fewer filter terms so that the space requirements for the filter do not exceed the available space in the TCAM table.

You can perform either of the following procedures to correct the problem:

To delete the filter and its binding and apply the new smaller firewall filter to the same binding:

1. Delete the filter and its binding to ports, VLANs, or Layer 3 interfaces. For example:

```
[edit]
user@switch# delete firewall family ethernet-switching filter ingress-vlan-rogue-block
user@switch# delete vlans employee-vlan description "filter to block rogue devices on
employee-vlan"
user@switch# delete vlans employee-vlan filter input ingress-vlan-rogue-block
```

2. Commit the changes:

```
[edit]
user@switch# commit
```

3. Configure a smaller filter with fewer terms that does not exceed the amount of available TCAM space. For example:

```
[edit]
user@switch# set firewall family ethernet-switching filter new-ingress-vlan-rogue-block ...
```

4. Apply (bind) the new firewall filter to a port, VLAN, or Layer 3 interface. For example:

```
[edit]
user@switch# set vlans employee-vlan description "filter to block rogue devices on
employee-vlan"
user@switch# set vlans employee-vlan filter input new-ingress-vlan-rogue-block
```

5. Commit the changes:

```
[edit]
user@switch# commit
```

To apply a new firewall filter and overwrite the existing binding but not delete the original filter:

1. Configure a firewall filter with fewer terms than the original filter:

```
[edit]
user@switch# set firewall family ethernet-switching filter new-ingress-vlan-rogue-block...
```

2. Apply the firewall filter to the port, VLAN, or Layer 3 interfaces to overwrite the binding of the original filter—for example:

```
[edit]
user@switch# set vlans employee-vlan description "smaller filter to block rogue devices on
employee-vlan"
user@switch# set vlans employee-vlan filter input new-ingress-vlan-rogue-block
```

Because you can apply no more than one firewall filter per VLAN per direction, the binding of the original firewall filter to the VLAN is overwritten with the new firewall filter **new-ingress-vlan-rogue-block**.

3. Commit the changes:

```
[edit]
user@switch# commit
```

**NOTE:** The original filter is not deleted and is still available in the configuration.

### Filter Counts Previously Dropped Packet

**Problem** If you configure two or more filters in the same direction for a physical interface and one of the filters includes a counter, the counter will be incorrect if the following circumstances apply:

- You configure the filter that is applied to packets first to discard certain packets. For example, imagine that you have a VLAN filter that accepts packets sent to 10.10.1.0/24 addresses and implicitly discards packets sent to any other addresses. You apply the filter to the **admin** VLAN in the output direction, and interface xe-0/0/1 is a member of that VLAN.
- You configure a subsequent filter to accept and count packets that are dropped by the first filter. In this example, you have a port filter that accepts and counts packets sent to 192.168.1.0/24 addresses that is also applied to xe-0/0/1 in the output direction.

The egress VLAN filter is applied first and correctly discards packets sent to 192.168.1.0/24 addresses. The egress port filter is applied next and counts the discarded packets as matched packets. The packets are not forwarded, but the counter displayed by the egress port filter is incorrect.

Remember that the order in which filters are applied depends on the direction in which they are applied, as indicated here:

Ingress filters:

1. Port (Layer 2) filter
2. VLAN filter
3. Router (Layer 3) filter

Egress filters:

1. Router (Layer 3) filter
2. VLAN filter
3. Port (Layer 2) filter

**Solution** This is expected behavior.

### Matching Packets Not Counted

**Problem** If you configure two egress filters with counters for a physical interface and a packet matches both of the filters, only one of the counters includes that packet.

For example:

- You configure an egress port filter with a counter for interface xe-0/0/1.
- You configure an egress VLAN filter with a counter for the **adminVLAN**, and interface xe-0/0/1 is a member of that VLAN.
- A packet matches both filters.

In this case, the packet is counted by only one of the counters even though it matched both filters.

**Solution** This is expected behavior.

---

#### Counter Reset When Editing Filter

**Problem** If you edit a firewall filter term, the value of any counter associated with any term in the same filter is set to 0, including the implicit counter for any policer referenced by the filter. Consider the following examples:

- Assume that your filter has **term1**, **term2**, and **term3**, and each term has a counter that has already counted matching packets. If you edit any of the terms in any way, the counters for all the terms are reset to 0.
- Assume that your filter has **term1** and **term2**. Also assume that **term2** has a **policer** action modifier and the implicit counter of the policer has already counted 1000 matching packets. If you edit **term1** or **term2** in any way, the counter for the policer referenced by **term2** is reset to 0.

**Solution** This is expected behavior.

---

#### Cannot Include loss-priority and policer Actions in Same Term

**Problem** You cannot include both of the following actions in the same firewall filter term in a QFX Series switch:

- **loss-priority**
- **policer**

If you do so, you see the following error message when you attempt to commit the configuration: "cannot support policer action if loss-priority is configured."

**Solution** This is expected behavior.

---

#### Cannot Egress Filter Certain Traffic Originating on QFX Switch

**Problem** On a QFX Series switch, you cannot filter certain traffic with a firewall filter applied in the output direction if the traffic originates on the QFX switch. This limitation applies to control traffic for protocols such as ICMP (ping), STP, LACP, and so on.

**Solution** This is expected behavior.

### Firewall Filter Match Condition Not Working with Q-in-Q Tunneling

**Problem** If you create a firewall filter that includes a match condition of **dot1q-tag** or **dot1q-user-priority** and apply the filter on input to a trunk port that participates in a service VLAN, the match condition does not work if the Q-in-Q EtherType is not 0x8100. (When Q-in-Q tunneling is enabled, trunk interfaces are assumed to be part of the service provider or data center network and therefore participate in service VLANs.)

**Solution** This is expected behavior. To set the Q-in-Q EtherType to 0x8100, enter the **set dot1q-tunneling ethertype 0x8100** statement at the **[edit ethernet-switching-options]** hierarchy level. You must also configure the other end of the link to use the same EtherType.

### Egress Firewall Filters with Private VLANs

**Problem** If you apply a firewall filter in the output direction to a primary VLAN, the filter also applies to the secondary VLANs that are members of the primary VLAN when the traffic egresses with the primary VLAN tag or isolated VLAN tag, as listed below:

- Traffic forwarded from a secondary VLAN trunk port to a promiscuous port (trunk or access)
- Traffic forwarded from a secondary VLAN trunk port that carries an isolated VLAN to a PVLAN trunk port.
- Traffic forwarded from a promiscuous port (trunk or access) to a secondary VLAN trunk port
- Traffic forwarded from a PVLAN trunk port. to a secondary VLAN trunk port
- Traffic forwarded from a community port to a promiscuous port (trunk or access)

If you apply a firewall filter in the output direction to a primary VLAN, the filter does *not* apply to traffic that egresses with a community VLAN tag, as listed below:

- Traffic forwarded from a community trunk port to a PVLAN trunk port
- Traffic forwarded from a secondary VLAN trunk port that carries a community VLAN to a PVLAN trunk port
- Traffic forwarded from a promiscuous port (trunk or access) to a community trunk port
- Traffic forwarded from a PVLAN trunk port. to a community trunk port

If you apply a firewall filter in the output direction to a community VLAN, the following behaviors apply:

- The filter is applied to traffic forwarded from a promiscuous port (trunk or access) to a community trunk port (because the traffic egresses with the community VLAN tag).
- The filter is applied to traffic forwarded from a community port to a PVLAN trunk port (because the traffic egresses with the community VLAN tag).

- The filter is *not* applied to traffic forwarded from a community port to a promiscuous port (because the traffic egresses with the primary VLAN tag or untagged).

**Solution** These are expected behaviors. They occur only if you apply a firewall filter to a private VLAN in the output direction and do not occur if you apply a firewall filter to a private VLAN in the input direction.

---

#### Egress Filtering of L2PT Traffic Not Supported

**Problem** Egress filtering of L2PT traffic is not supported on the QFX3500 switch. That is, if you configure L2PT to tunnel a protocol on an interface, you cannot also use a firewall filter to filter traffic for that protocol on that interface in the output direction. If you commit a configuration for this purpose, the firewall filter is not applied to the L2PT-tunneled traffic.

**Solution** This is expected behavior.

---

#### Cannot Drop BGP Packets in Certain Circumstances

**Problem** BGP packets with a time-to-live (TTL) value greater than 1 cannot be discarded using a firewall filter applied to a loopback interface or applied on input to a Layer 3 interface. BGP packets with TTL value of 1 or 0 can be discarded using a firewall filter applied to a loopback interface or applied on input to a Layer 3 interface.

**Solution** This is expected behavior.

---

#### Invalid Statistics for Policer

**Problem** If you apply a single-rate two-color policer in more than 128 terms in a firewall filter, the output of the **show firewall** command displays incorrect data for the policer.

**Solution** This is expected behavior.

---

#### Incomplete Count of Packet Drops

**Problem** Under certain circumstances, Junos OS might display a misleading number of packets dropped by an ingress policer.

If packets are dropped because of ingress admission control, policer statistics might not show the number of packet drops you would expect by calculating the difference between ingress and egress packet counts. This might happen if you apply an ingress policer to multiple interfaces, and the aggregate ingress rate of those interfaces exceeds the line rate of a common egress interface. In this case, packets might be dropped from the ingress buffer. These drops are not included in the count of packets dropped by the policer, which causes policer statistics to underreport the total number of drops.

**Solution** This is expected behavior.

### Counter Reset When Editing Filter

**Problem** If you edit a firewall filter term, the value of any counter associated with any term in the same filter is set to 0, including the implicit counter for any policer referenced by the filter. Consider the following examples:

- Assume that your filter has **term1**, **term2**, and **term3**, and each term has a counter that has already counted matching packets. If you edit any of the terms in any way, the counters for all the terms are reset to 0.
- Assume that your filter has **term1** and **term2**. Also assume that **term2** has a **policer** action modifier and the implicit counter of the policer has already counted 1000 matching packets. If you edit **term1** or **term2** in any way, the counter for the policer referenced by **term2** is reset to 0.

**Solution** This is expected behavior.

### Invalid Statistics for Policer

**Problem** If you apply a single-rate two-color policer in more than 128 terms in a firewall filter, the output of the **show firewall** command displays incorrect data for the policer.

**Solution** This is expected behavior.

### Egress Policers on QFX3500 Might Allow More Throughput Than is Configured

**Problem** If you configure a policer to rate-limit throughput and apply it on egress to multiple interfaces on a QFX3500 switch or node, the measured aggregate policed rate might be twice the configured rate, depending on which interfaces you apply the policer to. This occurs if you apply a policer to multiple interfaces and *both* of the following are true:

- There is at least one policed interface in the range xe-0/0/0 to xe-0/0/23 or the range xe-0/1/1 to xe-0/1/7
- There is at least one policed interface in the range xe-0/0/24 to xe-0/0/47 or the range xe-0/1/8 to xe-0/1/15

For example, if you configure a policer to rate-limit at 1 Gbps and apply the policer (by using a firewall filter) to xe-0/0/0 and xe-0/0/24 in the output direction, each interface is rate-limited at 1 Gbps, for a total allowed throughput of 2 Gbps. The same behavior

occurs if you apply the policer to xe-0/1/1 and xe-0/0/24—each interface is rate-limited at 1 Gbps.

If you apply the same policer on egress to multiple interfaces in these groups, each group is rate-limited at 1 Gbps. For example, if you apply the policer to xe-0/0/0 through xe-0/0/4 (five interfaces) and xe-0/0/24 through xe-0/0/33 (ten interfaces), each group is rate-limited at 1 Gbps, for a total allowed throughput of 2 Gbps.

Here is another example: If you apply the policer to xe-0/0/0 through xe-0/0/4 and xe-0/1/1 through xe-0/1/5 (a total of ten interfaces), that group is rate-limited at 1 Gbps in aggregate. If you also apply the policer to xe-0/0/24, that one interface is rate-limited at 1 Gbps while the other ten are still rate-limited at 1 Gbps in aggregate.

Interfaces xe-0/1/1 through xe-0/1/15 are physically located on the QSFP+ uplink ports, according to the following scheme:

- xe-0/1/1 through xe-0/1/3 are on Q0.
- xe-0/1/4 through xe-0/1/7 are on Q1.
- xe-0/1/8 through xe-0/1/11 are on Q2.
- xe-0/1/12 through xe-0/1/15 are on Q3.

This behavior occurs only if the policer is applied in the output direction. If you configure a policer as described above but apply it in the input direction, the total allowed throughput for all interfaces is 1 Gbps.

**Solution** This is expected behavior.

### Understanding Port Mirroring

- [Port Mirroring Overview on page 4313](#)
- [Port-Mirroring Terminology on page 4314](#)
- [Port Mirroring Constraints and Limitations on page 4315](#)

#### Port Mirroring Overview

---

Port mirroring copies packets entering or exiting a port or entering a VLAN and sends the copies to a local interface for local monitoring or to a VLAN for remote monitoring. Use port mirroring to send traffic to applications that analyze traffic for purposes such as monitoring compliance, enforcing policies, detecting intrusions, monitoring and predicting traffic patterns, correlating events, and so on.

Port mirroring is needed for traffic analysis on a switch because a switch normally sends packets only to the port to which the destination device is connected. You configure port mirroring on the switch to send copies of unicast traffic to a local interface or a VLAN and run an analyzer application on a device connected to the interface or VLAN. You configure port mirroring by using the **analyzer** statement.

Keep performance in mind when configuring port mirroring. For example, If you mirror traffic from multiple ports, the mirrored traffic may exceed the capacity of the output interface. We recommend that you limit the amount of copied traffic by selecting specific interfaces instead of using the **all** keyword. You can also limit the amount of mirrored traffic by using a firewall filter. Mirroring only the necessary packets reduces the possibility of a performance impact.

You can use port mirroring to copy any of the following:

- All packets entering or exiting an interface (in any combination)—For example, you can send copies of the packets entering some interfaces and the packets exiting other

interfaces to the same local interface or VLAN. If you configure port mirroring to copy packets exiting an interface, traffic that originates on that switch or Node device (in a QFabric system) is not copied when it egresses. Only switched traffic is copied on egress. (See the limitation on egress mirroring below.)

- All packets entering a VLAN—You cannot use port mirroring to copy packets exiting a VLAN.
- Firewall-filtered sample—Sample of packets entering a port or VLAN. Configure a firewall filter to select certain packets for mirroring.

**NOTE:** Firewall filters are not supported on egress ports; therefore, you cannot specify policy-based sampling of packets exiting an interface.

### Port-Mirroring Terminology

Table 301 on page 4314 lists the terms used in the documentation about port mirroring and provides definitions.

**Table 301: Port Mirroring Terms and Definitions**

Term	Description
Analyzer	Port-mirroring configuration. The analyzer includes a name, source interfaces or source VLAN, and a destination for mirrored packets (either a local access interface or a VLAN).
Output interface (also known as monitor interface)	<p>Access interface to which packet copies are sent and to which a device running an analyzer application is connected.</p> <p>The following limitations apply to an output interface:</p> <ul style="list-style-type: none"> <li>• Cannot also be a source port.</li> <li>• Cannot be used for switching.</li> <li>• Cannot be an aggregated Ethernet interface (LAG).</li> <li>• Does not participate in Layer 2 protocols, such as Spanning Tree Protocol (STP).</li> <li>• Loses any existing VLAN associations when you configure it as an analyzer output interface.</li> </ul> <p>If the capacity of the output interface is insufficient to handle the traffic from the source ports, overflow packets are dropped.</p>
Output IP address	<p>IP address of the device running an analyzer application. The device can be on a remote network. When you use this feature, the mirrored packets are GRE-encapsulated. The analyzer device must be able to de-encapsulate GRE-encapsulated packets, or the GRE-encapsulated packets must be de-encapsulated before reaching the analyzer device. (You can use a network sniffer to de-encapsulate the packets.)</p> <ul style="list-style-type: none"> <li>• An output IP address cannot be in the same subnetwork as any of the switch's management interfaces.</li> <li>• If you create virtual routing instances and also create an analyzer configuration that includes an output IP address, the output address belongs to the default virtual routing instance (inet.0 routing table).</li> </ul>

Table 301: Port Mirroring Terms and Definitions (*continued*)

Output VLAN (also known as monitor or analyzer VLAN)	<p>VLAN to which copies are sent and to which a device running an analyzer application is connected. The analyzer VLAN can span multiple switches.</p> <p>The following limitations apply to an output VLAN:</p> <ul style="list-style-type: none"> <li>• Cannot be a private VLAN or VLAN range.</li> <li>• Cannot be shared by multiple <b>analyzer</b> statements.</li> <li>• An output VLAN interface cannot be a member of any other VLAN.</li> <li>• An output VLAN interface cannot be an aggregated Ethernet interface (LAG).</li> <li>• On the source (monitored) switch, only one interface can be a member of the analyzer VLAN.</li> </ul>
Input interface (also known as mirrored or monitored interface)	Interface that provides traffic to be mirrored. This traffic can be entering or exiting the interface. (Ingress or egress traffic can be mirrored.) An input interface cannot also be an output interface for an analyzer.
Monitoring station	Computer running an analyzer application.
Remote port mirroring	Flooding of packet copies (mirrored packets) to an analyzer VLAN that you create specifically for the purpose of receiving mirror traffic instead of sending it to an access interface.
Policy-based mirroring	Mirroring of packets that match the match a firewall filter term. The action <b>analyzer analyzer-name</b> is used in the firewall filter to send the packets to the analyzer.

### Port Mirroring Constraints and Limitations

- [Local and Remote Port Mirroring on page 4315](#)
- [Remote Port Mirroring Only on page 4316](#)

#### Local and Remote Port Mirroring

The following constraints and limitations apply to local and remote port mirroring with the QFX Series:

- You can create a total of four port-mirroring configurations on the QFX Series (standalone switches and QFabric systems), subject to the following limits:
  - There can be no more than two configurations that mirror ingress traffic.
  - There can be no more than two configurations that mirror egress traffic.
- You can configure no more than one type of output in one port-mirroring configuration. That is, you can use no more than one of the following to complete a **set analyzer name output** statement:
  - **interface**
  - **ip-address**
  - **vlan**
- If you configure Junos OS to mirror egress packets, do not configure more than 2000 VLANs on a QFX3500 device or QFabric system. If you do so, some VLAN packets

might contain incorrect VLAN IDs. This applies to any VLAN packets—not only the mirrored copies.

- The **ratio** and **loss-priority** options are not supported.
- Packets with physical layer errors are filtered out and are not sent to the output port or VLAN.
- If you use sFlow monitoring to sample traffic, it does not sample the mirror copies when they exit from the output interface.
- You cannot mirror packets exiting or entering the following ports:
  - Dedicated Virtual Chassis interfaces
  - Management interfaces (me0 or vme0)
  - Fibre Channel interfaces
  - Routed VLAN interfaces
- Do not include an 802.1Q subinterface that has a unit number other than 0 in a port mirroring configuration. Port mirroring does not work with subinterfaces if their unit number is not 0. (You configure 802.1Q subinterfaces using the **vlan-tagging** statement.)
- When packet copies are sent out the output interface, they are not modified for any changes that are normally applied on egress, such as CoS rewriting.
- An interface can be the input interface for only one mirroring configuration. Do not use the same interface as the input interface for multiple mirroring configurations.
- (QFabric systems only) If you configure a QFabric analyzer to mirror egress traffic and the input and output interfaces are on different Node devices, the mirrored copies have incorrect VLAN IDs. This limitation does not apply if you configure a QFabric analyzer to mirror egress traffic and the input and output interfaces are on the *same* Node device. In this case the mirrored copies have the correct VLAN IDs (as long as you do not configure more than 2000 VLANs on the QFabric system).

#### ***Remote Port Mirroring Only***

The following constraints and limitations apply to remote port mirroring with the QFX Series:

- If you configure an output IP address, the address cannot be in the same subnetwork as any of the switch's management interfaces.
- If you create virtual routing instances and also create an analyzer configuration that includes an output IP address, the output address belongs to the default virtual routing instance (inet.0 routing table).
- An output VLAN cannot be a private VLAN or VLAN range.
- An output VLAN cannot be shared by multiple **analyzer** statements.
- An output VLAN interface cannot be a member of any other VLAN.

- An output VLAN interface cannot be an aggregated Ethernet interface.
- On the source (monitored) switch, only one interface can be a member of the analyzer VLAN.

## DHCP Relay

- [DHCP and BOOTP Relay Overview on page 4317](#)

### DHCP and BOOTP Relay Overview

You can configure a Juniper Networks switch to act as a Dynamic Host Configuration Protocol (DHCP) or Bootstrap Protocol (BOOTP) relay agent. This means that if the switch receives a broadcast DHCP or BOOTP request from a locally attached host (client), it relays the message to a specified DHCP or BOOTP server. You should configure the switch to be a DHCP/BOOTP relay agent if you have locally attached hosts and a distant DHCP or BOOTP server.

If you configure a switch to be a DHCP relay agent, you can also enable smart DHCP relay, which enables you to configure alternative gateway addresses for a DHCP server so that if the server fails to reply to the requests sent to the primary gateway address, the switch can resend the requests to the alternative gateway addresses. To use this feature, you must configure a routed VLAN interface or Layer 3 subinterface with multiple IP addresses and configure that interface to be a relay agent.

**NOTE:** Because DHCP and BOOTP messages are broadcast and are not directed to a specific server, switch, or router, Juniper switches cannot function as both a DHCP server and a DHCP/BOOTP relay agent at the same time. The Junos operating system (Junos OS) generates a commit error if both options are configured at the same time, and the commit operation does not succeed until one of the options is removed.

### Configuration Examples

---

- [Example: Configuring Port Mirroring for Local Analysis on page 4319](#)
- [Example: Configuring Port Mirroring for Remote Analysis on page 4324](#)

#### Example: Configuring Port Mirroring for Local Analysis

Use port mirroring to send traffic to applications that analyze traffic for purposes such as monitoring compliance, enforcing policies, detecting intrusions, monitoring and predicting traffic patterns, correlating events, and so on. Port mirroring copies packets entering or exiting an interface or entering a VLAN and sends the copies to a local interface for local monitoring.

This example describes how to configure port mirroring to copy traffic sent by employee computers to a switch to an access interface on the same switch.

- [Requirements on page 4319](#)
- [Overview and Topology on page 4320](#)
- [Mirroring All Employee Traffic for Local Analysis on page 4320](#)
- [Mirroring Employee-to-Web Traffic for Local Analysis on page 4321](#)
- [Verification on page 4323](#)

#### Requirements

---

This example uses the following hardware and software components:

- Junos OS Release 11.1
- A switch

## Overview and Topology

This topic includes two related examples that describe how to mirror traffic entering interfaces on the switch to an access interface on the same switch. The first example shows how to mirror all traffic sent by employee computers to the switch. The second example includes a filter to mirror only the employee traffic going to the Web.

In this example, **xe-0/0/0** and **xe-0/0/6** serve as connections for employee computers. Interface **xe-0/0/47** is connected to a device running an analyzer application.

**NOTE:** Multiple ports mirrored to one interface can cause buffer overflow and dropped packets.

Figure 161 on page 4320 shows the network topology for this example.

Figure 161: Network Topology for Local Port Mirroring Example

## Mirroring All Employee Traffic for Local Analysis

To configure port mirroring for all traffic sent by employee computers for local analysis, perform the tasks explained in this section.

### CLI Quick Configuration

To quickly configure local port mirroring for ingress traffic to the two ports connected to employee computers, copy the following commands and paste them into a switch terminal window:

```
[edit]
set interfaces xe-0/0/0 unit 0 family ethernet-switching
set interfaces xe-0/0/6 unit 0 family ethernet-switching
set interfaces xe-0/0/47 unit 0 family ethernet-switching
set ethernet-switching options analyzer employee-monitor input ingress interface xe-0/0/0.0
set ethernet-switching options analyzer employee-monitor input ingress interface xe-0/0/6.0
set ethernet-switching options analyzer employee-monitor output interface xe-0/0/47.0
```

### Step-by-Step Procedure

To configure an analyzer called **employee-monitor** and specify the input (source) interfaces and the output interface:

1. Configure the interfaces connected to employee computers as input interfaces for the port-mirror analyzer **employee-monitor**:

```
[edit ethernet-switching-options]
user@switch# set analyzer employee-monitor input ingress interface xe-0/0/0.0
user@switch# set analyzer employee-monitor input ingress interface xe-0/0/6.0
2. Configure the output analyzer interface for the employee-monitor analyzer. This will
be the destination interface for the mirrored packets:

[edit ethernet-switching-options]
user@switch# set analyzer employee-monitor output interface xe-0/0/47.0
```

**Results** Check the results of the configuration:

```
[edit]
user@switch# show ethernet-switching-options
analyzer employee-monitor {
  input {
    ingress {
      interface xe-0/0/0.0;
      interface xe-0/0/6.0;
    }
  }
  output {
    interface {
      xe-0/0/47.0;
    }
  }
}
```

### Mirroring Employee-to-Web Traffic for Local Analysis

To mirror only traffic sent by employees to the Web for local analysis, perform the tasks explained in this section.

#### CLI Quick Configuration

To quickly configure local port mirroring of traffic from employee computers that is destined for the Web, copy the following commands and paste them into a switch terminal window:

```
[edit]
set ethernet-switching-options analyzer employee-web-monitor output interface xe-0/0/47.0
set firewall family ethernet-switching filter watch-employee term employee-to-corp from
destination-address 192.0.2.16/28
set firewall family ethernet-switching filter watch-employee term employee-to-corp from
source-address 192.0.2.16/28
set firewall family ethernet-switching filter watch-employee term employee-to-corp then accept
set firewall family ethernet-switching filter watch-employee term employee-to-web from
destination-port 80
set firewall family ethernet-switching filter watch-employee term employee-to-web then analyzer
employee-web-monitor
set interfaces xe-0/0/0 unit 0 family ethernet-switching filter input watch-employee
set interfaces xe-0/0/6 unit 0 family ethernet-switching filter input watch-employee
```

**Step-by-Step Procedure** To configure local port mirroring of employee-to-web traffic from the two ports connected to employee computers:

1. Configure the output interface:

```
[edit interfaces]
user@switch# set xe-0/0/47 unit 0 family ethernet-switching
```

2. Configure the **employee-web-monitor** analyzer output. (Configure only the output—the input comes from the filter.)

```
[edit ethernet-switching-options]
user@switch# set analyzer employee-web-monitor output interface xe-0/0/47.0
```

3. Configure a firewall filter called **watch-employee** that includes a term to match traffic sent to the Web and send it to the analyzer **employee-web-monitor**. Traffic to and from the corporate subnet (destination or source address of **192.0.2.16/28**) does not need to be copied, so create another term to accept that traffic before it reaches the term that sends Web traffic to the analyzer:

```
[edit firewall family ethernet-switching]
user@switch# set filter watch-employee term employee-to-corp from destination-address 192.0.2.16/28
user@switch# set filter watch-employee term employee-to-corp from source-address 192.0.2.16/28
user@switch# set filter watch-employee term employee-to-corp then accept
user@switch# set filter watch-employee term employee-to-web from destination-port 80
user@switch# set filter watch-employee term employee-to-web then analyzer employee-web-monitor
```

4. Apply the firewall filter to the appropriate interfaces as an ingress filter (egress filters do not allow analyzers):

```
[edit interfaces]
user@switch# set xe-0/0/0 unit 0 family ethernet-switching filter input watch-employee
user@switch# set xe-0/0/6 unit 0 family ethernet-switching filter input watch-employee
```

**Results** Check the results of the configuration:

```
[edit]
user@switch# show ethernet-switching-options
  analyzer employee-web-monitor {
    output {
      interface xe-0/0/47.0;
    }
  }
...
firewall family ethernet-switching {
  filter watch-employee {
    term employee-to-web {
      from {
        destination-port 80;
      }
      then analyzer employee-web-monitor;
    }
  }
}
...
interfaces {
```

```

xe-0/0/0 {
  unit 0 {
    family ethernet-switching {
      filter {
        input watch-employee;
      }
    }
  }
}
xe-0/0/6 {
  family ethernet-switching {
    filter {
      input watch-employee;
    }
  }
}

```

## Verification

### *Verifying That the Analyzer Has Been Correctly Created*

**Purpose** Verify that the analyzer named **employee-monitor** or **employee-web-monitor** has been created on the switch with the appropriate input interfaces and appropriate output interface.

**Action** You can verify that the port mirror analyzer has been configured as expected using the **show analyzer** command.

```

user@switch> show analyzer
Analyzer name           : employee-monitor
Output interface        : xe-0/0/47.0
Mirror ratio            : 1
Loss priority           : Low
Ingress monitored interfaces : xe-0/0/0.0
Ingress monitored interfaces : xe-0/0/6.0
Egress monitored interfaces  : None

```

**Meaning** This output shows that the **employee-monitor** analyzer:

- Has a ratio of 1 (mirroring every packet, the default setting)
- Has a loss priority of low (set this option to high only when the analyzer output is to a VLAN)
- Is mirroring the traffic entering the **xe-0/0/0** and **xe-0/0/6** interfaces
- Is sending the mirrored traffic to the **xe-0/0/47** interface

## Example: Configuring Port Mirroring for Remote Analysis

Use port mirroring to send traffic to applications that analyze traffic for purposes such as monitoring compliance, enforcing policies, detecting intrusions, monitoring and predicting traffic patterns, correlating events, and so on. Port mirroring copies packets entering or exiting an interface or entering a VLAN and sends the copies either to a local interface for local monitoring or to a VLAN for remote monitoring. This example describes how to configure port mirroring for remote analysis.

- [Requirements on page 4324](#)
- [Overview and Topology on page 4324](#)
- [Mirroring All Employee Traffic for Remote Analysis on page 4325](#)
- [Mirroring Employee-to-Web Traffic for Remote Analysis on page 4326](#)
- [Verification on page 4328](#)

---

### Requirements

This example uses the following hardware and software components:

- Junos OS Release 12.1 for the QFX Series
- A switch

---

### Overview and Topology

This topic includes two related examples that describe how to mirror traffic entering ports on the switch to an analyzer VLAN so that you can perform analysis using a remote device. The first example shows how to mirror all traffic sent by employee computers to the switch. The second example includes a filter to mirror only the employee traffic going to the Web.

In this example:

- Interfaces **ge-0/0/0** and **ge-0/0/1** are Layer 2 interfaces that connect to employee computers.
- Interface **ge-0/0/10** is a Layer 2 interface that connects to another switch.
- VLAN **remote-analyzer** is configured on all switches in the topology to carry the mirrored traffic.

**NOTE:** In addition to performing the configuration steps described here, you must also configure the analyzer VLAN (**remote-analyzer** in this example) on the other switches that are used to connect the source switch (the one in this configuration) to the one that the monitoring station is connected to.

---

### Mirroring All Employee Traffic for Remote Analysis

**CLI Quick Configuration** To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **edit** hierarchy level:

```
[edit]
set vlans remote-analyzer vlan-id 999
set interfaces ge-0/0/10 unit 0 family ethernet-switching port-mode trunk
set interfaces ge-0/0/10 unit 0 family ethernet-switching vlan members 999
set ethernet-switching-options analyzer employee-monitor input ingress interface ge-0/0/0.0
set ethernet-switching-options analyzer employee-monitor input ingress interface ge-0/0/1.0
set ethernet-switching-options analyzer employee-monitor output vlan remote-analyzer
```

**Step-by-Step Procedure** To configure basic remote port mirroring:

1. Configure the analyzer VLAN (called **remote-analyzer** in this example):  

```
[edit vlans]
user@switch# set vlans remote-analyzer vlan-id 999
```
2. Configure the interface connected to another switch for trunk mode and associate it with the **remote-analyzer** VLAN:  

```
[edit interfaces]
user@switch# set ge-0/0/10 unit 0 family ethernet-switching port-mode trunk
user@switch# set ge-0/0/10 unit 0 family ethernet-switching vlan members 999
```
3. Configure the **employee-monitor** analyzer:  

```
[edit ethernet-switching-options]
user@switch# set analyzer employee-monitor
user@switch# set analyzer employee-monitor input ingress interface ge-0/0/0.0
user@switch# set analyzer employee-monitor input ingress interface ge-0/0/1.0
user@switch# set analyzer employee-monitor output vlan remote-analyzer
```
4. Configure the **remote-analyzer** VLAN on the switches that connect this switch to the monitoring workstation.

**Results** Check the results of the configuration:

```
[edit]
user@switch# show
ethernet-switching-options {
  analyzer employee-monitor {
    input {
      ingress {
        interface ge-0/0/0.0;
        interface ge-0/0/1.0;
      }
    }
    output {
      vlan {
        remote-analyzer;
      }
    }
  }
}
```

## Mirroring Employee-to-Web Traffic for Remote Analysis

**CLI Quick Configuration** To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **edit** hierarchy level:

```
[edit]
set vlans remote-analyzer vlan-id 999
set interfaces ge-0/0/10 unit 0 family ethernet-switching port mode trunk
set interfaces ge-0/0/10 unit 0 family ethernet-switching vlan members 999
set ethernet-switching-options analyzer employee-web-monitor loss-priority high output vlan 999
set firewall family ethernet-switching filter watch-employee term employee-to-web from destination-port 80
set firewall family ethernet-switching filter watch-employee term employee-to-web then analyzer employee-web-monitor
set ge-0/0/0 unit 0 family ethernet-switching filter input watch-employee
set interfaces ge-0/0/1 unit 0 family ethernet-switching filter input watch-employee
```

**Step-by-Step Procedure**

1. Configure the analyzer VLAN (called **remote-analyzer** in this example):  

```
[edit vlans]
user@switch# set remote-analyzer vlan-id 999
```
2. Configure an interface to associate it with the **remote-analyzer** VLAN:  

```
[edit interfaces]
user@switch# set interfaces ge-0/0/10 unit 0 family ethernet-switching port mode trunk
user@switch# set ge-0/0/10 unit 0 family ethernet-switching vlan members 999
```
3. Configure the **employee-web-monitor** analyzer. (Configure only the output—the input comes from the filter.)  

```
[edit ethernet-switching-options]
user@switch# set ethernet-switching-options analyzer employee-web-monitor output vlan 999
```
4. Configure a firewall filter called **watch-employee** to match traffic sent to the Web and send it to the analyzer **employee-web-monitor**:  

```
[edit firewall family ethernet-switching]
user@switch# set filter watch-employee term employee-to-web from destination-port 80
user@switch# set filter watch-employee term employee-to-web then analyzer employee-web-monitor
```
5. Apply the firewall filter to the appropriate interfaces as an ingress filter:  

```
[edit interfaces]
user@switch# set ge-0/0/0 unit 0 family ethernet-switching filter input watch-employee
user@switch# set ge-0/0/1 unit 0 family ethernet-switching filter input watch-employee
```
6. Configure the **remote-analyzer** VLAN on the switches that connect this switch to the monitoring workstation.

**Results** Check the results of the configuration:

```
[edit]
user@switch# show
interfaces {
  ...
  ge-0/0/10 {
    unit 0 {
      family ethernet-switching {
```

```

        port-mode trunk;
        vlan {
            members remote-analyzer;
        }
    }
}
ge-0/0/0 {
    unit 0 {
        family ethernet-switching {
            filter {
                input watch-employee;
            }
        }
    }
}
ge-0/0/1 {
    unit 0 {
        family ethernet-switching {
            filter {
                input watch-employee;
            }
        }
    }
}
...
firewall {
    family ethernet-switching {
        ...
        filter watch-employee {
            term employee-to-web {
                from {
                    destination-port 80;
                }
                then analyzer employee-web-monitor;
            }
        }
    }
}
ethernet-switching-options {
    analyzer employee-web-monitor {
        output {
            vlan {
                999;
            }
        }
    }
}
vpls {
    remote-analyzer {
        vlan-id 999;
    }
}

```

## Verification

---

### *Verifying That the Analyzer Has Been Correctly Created*

- Purpose** Verify that the analyzer named **employee-monitor** or **employee-web-monitor** has been created on the switch with the appropriate input interfaces and appropriate output interface.
- Action** You can verify the port mirror analyzer is configured as expected using the **show analyzer** command.
- ```
user@switch> show analyzer
Analyzer name       : employee-monitor
Output VLAN        : remote-analyzer
Ingress monitored interfaces : ge-0/0/0.0
Ingress monitored interfaces : ge-0/0/1.0
```
- Meaning** This output shows that the **employee-monitor** analyzer is mirroring the traffic entering **ge-0/0/0** and **ge-0/0/1** and is sending the mirror traffic to the analyzer **remote-analyzer**.
- Related Documentation**
- [Understanding Port Mirroring on page 4313](#)
  - [Configuring Port Mirroring on page 4328](#)
  - [Example: Configuring Port Mirroring for Local Analysis on page 4319](#)
  - [Overview of Firewall Filters on page 4071](#)

## Configuration Tasks

---

- [Configuring Port Mirroring on page 4328](#)
- [Configuring DHCP and BOOTP Relay on page 4331](#)

### Configuring Port Mirroring

You use port mirroring to copy packets and send the copies to a device running an application such as a network analyzer or intrusion detection application so that you can analyze traffic without delaying it. You can mirror traffic entering or exiting a port or entering a VLAN, and you can send the copies to a local access interface or to a VLAN through a trunk interface.

We recommend that you disable port mirroring when you are not using it. To avoid creating a performance issue. If you do enable port mirroring, we recommend that you select specific input interfaces instead of using the **all** keyword. You can also limit the amount of mirrored traffic by using a firewall filter.

**NOTE:** If you want to create additional analyzers without deleting an existing analyzer, first disable the existing analyzer using the **disable analyzer analyzer-name** command.

---

**NOTE:** You must configure port mirroring output interfaces as family `ethernet-switching`.

- [Configuring Port Mirroring for Local Analysis on page 4329](#)
- [Configuring Port Mirroring for Remote Analysis on page 4329](#)
- [Filtering the Traffic Entering an Analyzer on page 4330](#)

### Configuring Port Mirroring for Local Analysis

To mirror interface traffic to a local interface on the switch:

1. If you want to mirror traffic that is ingressing or egressing specific interfaces, choose a name for the port-mirroring configuration and configure what traffic should be mirrored by specifying the interfaces and direction of traffic:

```
[edit ethernet-switching-options]
user@switch# set analyzer analyzer-name input (ingress | egress) interface interface-name
```

**NOTE:** If you configure Junos OS to mirror egress packets, do not configure more than 2000 VLANs. If you do so, some VLAN packets might contain incorrect VLAN IDs.

**NOTE:** If you configure mirroring for packets that egress an access interface, the original packets lose any VLAN tags when they exit the access interface, but the mirrored (copied) packets retain the VLAN tags when they are sent to the analyzer system.

2. If you want to specify that all traffic entering a VLAN should be mirrored, choose a name for the port-mirroring configuration and specify the VLAN:

```
[edit ethernet-switching-options]
user@switch# set analyzer analyzer-name input ingress vlan vlan-name
```

**NOTE:** You cannot configure port mirroring to copy traffic that egresses a VLAN.

3. Configure the destination interface for the mirrored packets:

```
[edit ethernet-switching-options]
user@switch# set analyzer analyzer-name output interface interface-name
```

### Configuring Port Mirroring for Remote Analysis

To mirror traffic to a VLAN for analysis at a remote location:

1. Configure a VLAN to carry the mirrored traffic:

```
[edit]
```

```
user@switch# set vlans vlan-name vlan-id number
```

2. Configure the interface that connects to another switch (the uplink interface) to trunk mode and associate it with the appropriate VLAN:

```
[edit]
```

```
user@switch# set interfaces interface-name unit 0 family ethernet-switching port-mode  
trunk vlan members (vlan-name | vlan-id)
```

3. Configure the analyzer:

- a. Choose a name for the analyzer:

```
[edit ethernet-switching-options]  
user@switch# set analyzer analyzer-name
```

- b. Specify the interface to be mirrored and whether the traffic should be mirrored on ingress or egress:

```
[edit ethernet-switching-options]  
user@switch# set analyzer analyzer-name input (ingress | egress) interface interface-name
```

- c. Specify the appropriate IP address or VLAN as the output (a VLAN is specified in this example:

```
[edit ethernet-switching-options]  
user@switch# set analyzer analyzer-name output vlan (vlan-name | vlan-id)
```

If you specify an IP address as the output, note the following constraints:

- The address cannot be in the same subnet as any of the switch's management interfaces.
- If you create virtual routing instances and also create an analyzer configuration that includes an output IP address, the output address belongs to the default virtual routing instance (**inet.0** routing table).
- The analyzer device must be able to de-encapsulate GRE-encapsulated packets, or the GRE-encapsulated packets must be de-encapsulated before reaching the analyzer device. (You can use a network sniffer to de-encapsulate the packets.)

### Filtering the Traffic Entering an Analyzer

---

In addition to specifying which traffic to mirror by configuring an analyzer, you can also use a firewall filter to exercise more control over which packets are copied. For example, you might use a filter to specify that only traffic from certain applications be mirrored. The filter can use any of the available match conditions and must have an action of **analyzer *analyzer-name***. If you use the same analyzer in multiple filters or terms, the output packets are copied only once.

**NOTE:** You can include the action **analyzer** in ingress firewall filters only. You can apply ingress filters with this action to ports (Layer 2 interfaces), Layer 3 interfaces, and VLANs.

When you use a firewall filter as the input to an analyzer, you output the copied traffic to a local interface or a VLAN just as you do when a firewall is not involved.

To configure port mirroring with filters:

1. Configure an analyzer for local or remote analysis. Configure only the output. For example, for local analysis enter:

```
[edit ethernet-switching-options]
user@switch# set analyzer analyzer-name output interface interface-name
```

**NOTE:** Do not configure input to this analyzer.

2. Create a firewall filter using any of the available match conditions and specify the action as **analyzer *analyzer-name***.
3. Apply the firewall filter to the interfaces or VLAN that should provide the input to the analyzer:

```
[edit]
user@switch# set interfaces interface-name unit 0 family ethernet-switching filter input
filter-name
[edit]
user@switch# set vlan (vlan-name | vlan-id) filter input filter-name
```

## Configuring DHCP and BOOTP Relay

You can configure the QFX Series to act as a Dynamic Host Configuration Protocol (DHCP) and Bootstrap Protocol (BOOTP) relay agent. This means that if a locally attached host can issue a DHCP or BOOTP request as a broadcast message and the switch relays the message to a specified DHCP or BOOTP server. You should configure a switch to be a DHCP and BOOTP relay agent if you have locally attached hosts and a remote DHCP or BOOTP server.

If you configure a switch to be a DHCP relay agent, you can also enable smart DHCP relay, which allows you to configure alternative gateway addresses for a DHCP server so that if the server fails to reply to the requests sent using the primary gateway address, the switch can resend the requests via the alternative gateway addresses. To use this feature, you must configure a routed VLAN interface or Layer 3 logical interface with multiple IP addresses and configure that interface to be a relay agent.

- [Configuring a DHCP and BOOTP Relay Agent on page 4331](#)
- [Configuring DHCP Smart Relay on page 4333](#)

### Configuring a DHCP and BOOTP Relay Agent

To configure a switch to act as a DHCP and BOOTP relay agent, include the **bootp** statement at the **[edit forwarding-options helpers]** hierarchy level:

```
[edit forwarding-options helpers]
bootp {
  apply-secondary-as-giaddr text-description;
  client-response-ttl number;
  description text-description;
  interface (interface-name | interface-group) {
    client-response-ttl number;
    description text-description;
    maximum-hop-count number;
    minimum-wait-time seconds;
    no-listen;
    server address
    apply-secondary-as-giaddr
  }
  maximum-hop-count number;
  minimum-wait-time seconds;
  relay-agent-option;
  server server-identifier
}
```

To include a description of the BOOTP service, DHCP service, or interface, use the **description** statement.

To configure a logical interface or a group of logical interfaces with a specific DHCP relay or BOOTP configuration, include the **interface** statement.

To stop packets from being forwarded, include the **no-listen** statement.

To set the maximum allowed number in the hops field of the BOOTP message, include the **maximum-hop-count** statement. BOOTP messages that have a larger number in the hops field than the maximum allowed are not forwarded. If you omit the **maximum-hop-count** statement, the default maximum number of hops is four.

To set the minimum allowed number of seconds in the **secs** field of the BOOTP message, include the **minimum-wait-time** statement. This setting configures a minimum number of seconds since the client sent its first BOOTP request. BOOTP messages that have a smaller number in the **secs** field than the allowed minimum are not forwarded. The default value for the minimum wait time is zero (0).

To set the IP address that specify the DHCP or BOOTP server for the router, switch, or interface, include the **server** statement. You can include multiple **server** statements.

To set an IP time-to-live (TTL) value for DHCP response packets sent to a DHCP client, include the **client-response-ttl** statement.

The following example demonstrates a BOOTP relay agent configuration.

```
user@host# show forwarding-options
helpers {
  bootp {
    description "dhcp relay agent global parameters";
    server 192.168.55.44;
    server 172.16.0.3 routing-instance c3;
    maximum-hop-count 10;
    minimum-wait-time 8;
```

```

interface {
  xe-0/0/1 {
    description "use this info for this interface";
    server 10.10.10.10;
    server 192.168.14.14;
    maximum-hop-count 11;
    minimum-wait-time 3;
  }
  xe-0/0/2 {
    no-listen; ###ignore DHCPDISCOVER messages on this interface
  }
  all {
    description "globals apply to all other interfaces";
  }
}
}

```

### Configuring DHCP Smart Relay

You can use DHCP smart relay to provide redundancy and resiliency to your DHCP relay configuration. Smart relay provides additional relay functionality and requires all of the configuration settings required by DHCP relay. To use DHCP smart relay, you also need an interface with multiple IP addresses assigned to it. You can achieve this by doing either of the following tasks:

- Create a routed VLAN interface and assign at least two IP addresses to it. See [“Configuring Routed VLAN Interfaces” on page 1551](#) and [“Example: Configuring Routing Between VLANs on One Switch” on page 1481](#) for information about this approach.
- Create a Layer 3 logical interface (by using VLAN tagging) and assign at least two IP addresses to it. See [“Understanding Layer 3 Logical Interfaces” on page 1930](#) and [“Configuring a Layer 3 Logical Interface” on page 2033](#) for information about this approach.

Once you have created an interface with multiple IP addresses, complete the smart relay configuration by entering one of the following statements:

- **set forwarding-options helpers bootp smart-relay-global:** Use this statement to enable smart relay on all the interfaces that are configured as relay agents.
- **set forwarding-options helpers bootp interface *interface-name* smart-relay-agent:** Use this statement to enable smart relay on a specific interface.

When smart relay is configured for an interface, the switch initially sends DHCP request (discover) messages out of that interface using the primary address of the interface as the gateway IP address (in the giaddr field) for the DHCP message. If no DHCP offer message is received from a server in reply, the switch allows the client to send as many as three more discover messages using the same gateway IP address. If no DHCP offer message is received after three retries, the switch resends the discover message using the alternate IP address as the gateway IP address. If you configure more than two IP addresses on the relay agent interface, the switch repeats this process until a DHCP offer message is received or all of the IP addresses have been used without success.

## Configuration Statements for Port Mirroring

---

## analyzer

```
Syntax analyzer {
    name {
        input {
            egress {
                interface (all | interface-name);
            }
            ingress {
                interface (all | interface-name);
                vlan (vlan-id | vlan-name);
            }
        }
        output {
            interface interface-name;
            ip-address ip-address;
            vlan (vlan-id | vlan-name);
        }
    }
}
```

**Hierarchy Level** [edit [ethernet-switching-options](#)]

**Release Information** Statement introduced in Junos OS Release 11.1 for the QFX Series.  
Option **output** **vlan** added in Junos OS Release 12.1 for the QFX Series.  
Option **output** **ip-address** added in Junos OS Release 12.3 for the QFX Series.

**Description** Configure port mirroring. You can create a total of four port-mirroring configurations on the QFX Series, subject to the following limits:

- There can be no more than two configurations that mirror ingress traffic.
- There can be no more than two configurations that mirror egress traffic.

**Default** Port mirroring is disabled, and Junos OS creates no default analyzers.

**Options** **all**—Mirror all the access interfaces. Using this option does not cause the QSFP+ or management interfaces to be mirrored.

**CAUTION:** Configuring the **all** option in a QFabric system causes all the access interfaces on all the nodes to be mirrored. Be cautious about using this option on a QFabric system.

**name**—Name of the analyzer. The name can include as many as 125 characters; must begin with a letter; and can include uppercase letters, lowercase letters, numbers, dashes, and underscores. No other special characters are allowed.

The remaining statements are explained separately.

**Required Privilege Level** routing—To view this statement in the configuration.  
routing-control—To add this statement to the configuration.

---

## egress

---

**Syntax** egress {  
    **interface** (all | *interface-name*);  
}

**Hierarchy Level** [edit **ethernet-switching-options analyzer name input**]

**Release Information** Statement introduced in Junos OS Release 11.2 for the QFX Series.

**Description** Specify interfaces for which egressing traffic is mirrored.

The statement is explained separately.

.....

**NOTE:** If you configure Junos OS to mirror egress packets, do not configure more than 2000 VLANs. If you do so, some of the mirrored packets might contain incorrect VLAN IDs.

.....

**Required Privilege Level** routing—To view this statement in the configuration.  
routing-control—To add this statement to the configuration.

| <b>Release Information</b>      | Statement introduced in Junos OS Release 12.3 for the QFX Series.                                                                                                                                                                                                                                                                                                                   |
| <b>Description</b>              | Specify the IP address to which traffic should be mirrored (the IP address of the analyzer system). The device can be on a remote network. The analyzer device must be able to de-encapsulate GRE-encapsulated packets, or the GRE-encapsulated packets must be de-encapsulated before reaching the analyzer device. (You can use a network sniffer to de-encapsulate the packets.) |
| <b>Required Privilege Level</b> | routing—To view this statement in the configuration.<br>routing-control—To add this statement to the configuration.                                                                                                                                                                                                                                                                 |

| <b>Release Information</b>      | <p>Statement introduced in Junos OS Release 7.6.</p> <p>Statement introduced in Junos OS Release 9.0 for EX Series switches.</p> <p>Support for the BFD protocol introduced in Junos OS Release 9.6.</p> <p>Support for the BFD protocol introduced in Junos OS Release 9.6 for EX Series switches.</p> <p>Support for IS-IS introduced in JUNOS OS Release 11.2.</p> <p>Statement introduced in Junos OS Release 11.3 for the QFX Series.</p>                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Description</b>              | <p>Configure authentication key updates for the Border Gateway Protocol (BGP), the Label Distribution Protocol (LDP) routing protocols, the Bidirectional Forwarding Detection (BFD) protocol, and the Intermediate System-to-Intermediate System (IS-IS) protocol. When the <b>authentication-key-chains</b> statement is configured at the <b>[edit security]</b> hierarchy level, and is associated with the BGP, LDP, or IS-IS protocols at the <b>[edit protocols]</b> hierarchy level or with the BFD protocol using the <b>bfd-liveness-detection</b> statement, authentication key updates can occur without interrupting routing and signaling protocols such as Open Shortest Path First (OSPF) and Resource Reservation Setup Protocol (RSVP).</p> <p>The remaining statements are explained separately.</p> |
| <b>Required Privilege Level</b> | <p>admin—To view this statement in the configuration.</p> <p>admin-control—To add this statement to the configuration.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## ssh-known-hosts

---

**Syntax**    ssh-known-hosts {  
              host *host-name* {  
                  fetch-from-server *host-name*;  
                  load-key-file *file-name*;  
              }  
          }

**Hierarchy Level**    [edit security ssh-known-hosts]

**Release Information**    Statement introduced in Junos OS Release 11.1 for the QFX Series.

**Description**    Configure SSH support for known hosts and for administering SSH host key updates.

**Options**    **host *host-name***—Hostname of the SSH known host entry. This option has the following suboptions:

- **fetch-from-server *host-name***—Retrieve SSH public host key information from a specified server.
- **load-key-file *filename***—Import SSH host key information from the `/var/tmp/ssh-known-hosts` file.

**Required Privilege Level**    admin—To view this statement in the configuration.  
                                  admin-control—To add this statement to the configuration.

| <b>Description</b>              | <p>Specify a start time for key transmission. You do not need to specify an end time for the key. If a new key is present with a new start time, the keychain rolls over to the new one. The start time must be unique within the keychain.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Options</b>                  | <p><b>now</b>—Start time as the current year, month, day, hour, minute, and second.</p> <p><b>daydays</b>—Start time as the specified number of days after the current day. For example, if the current day is the 12th and you configure <b>start-time 2day</b>, the start time will be on the 14th, exactly two days after the configuration is entered.</p> <p><b>hourhours</b>—Start time as the specified number of hours after the current hour. For example, if the current hour is 9:00 and you configure <b>start-time 3hour</b>, the start time will be in 12:00, exactly three hours after the configuration is entered.</p> <p><b>minuteminutes</b>—Start time as the specified number of minutes after the current minute. For example, if the current minute is 27 minutes after the hour and you configure <b>start-time 5min</b>, the start time will be in 32 minutes after the hour, exactly five minutes after the configuration is entered.</p> <p><b>monthmonths</b>—Start time as the specified number of months after the current month. For example, if the current month is March and you configure <b>start-time 4month</b>, the start time will be in July, exactly four months after the configuration is entered.</p> <p><b>secondseconds</b>—Start time as the specified number of seconds after the current second. For example, if the current second is 10:20:40 and you configure <b>start-time 10seconds</b>, the start time will be 10:20:50, exactly 10 seconds after the configuration is entered.</p> <p><b>yearyears</b>—Start time as the specified number of years after the current year. For example, if the current year is 2011 and you configure <b>start-time 1year</b>, the start time will be in 2012, exactly one year after the configuration is entered.</p> <p><b>yyyy-mm-dd.hh:mm:ss</b>—Start time in UTC (Coordinated Universal Time). The start time must be unique within the keychain.</p> |
| <b>Required Privilege Level</b> | <p>admin—To view this statement in the configuration.</p> <p>admin-control—To add this statement to the configuration.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## traceoptions

**Syntax** traceoptions {  
     file *filename* <files *number*> <size *size*>;  
     flag all;  
     flag certificates;  
     flag database;  
     flag general;  
     flag ike;  
     flag parse;  
     flag policy-manager;  
     flag routing-socket;  
     flag timer;  
     level  
     no-remote-trace  
 }

**Hierarchy Level** [edit security],  
 [edit services ipsec-vpn]

Trace options can be configured at either the [edit security] or the [edit services ipsec-vpn] hierarchy level, but not at both levels.

**Release Information** Statement introduced before Junos OS Release 7.4.  
 Statement introduced in Junos OS Release 9.0 for EX Series switches.  
 Statement introduced in Junos OS Release 11.1 for the QFX Series.

**Description** Configure security trace options.

To specify more than one trace option, include multiple **flag** statements. Trace option output is recorded in the `/var/log/kmd` file.

**NOTE:** The `traceoptions` statement is not supported on QFabric systems.

**Options** **files *number***—(Optional) Maximum number of trace files. When a trace file (for example, **kmd**) reaches its maximum size, it is renamed **kmd.0**, then **kmd.1**, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum number of files, you must also specify a maximum file size with the **size** option.

**Range:** 2 through 1000 files

**Default:** 0 files

**size *size***—(Optional) Maximum size of each trace file, in kilobytes (KB). When a trace file (for example, **kmd**) reaches this size, it is renamed, **kmd.0**, then **kmd.1** and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

**Default:** 1024 KB

**flag *flag***—Trace operation to perform. To specify more than one trace operation, include multiple **flag** statements.

- **all**—Trace all security events.
- **certificates**—Trace certificate events.
- **database**—Trace database events.
- **general**—Trace general events.
- **ike**—Trace IKE module processing.
- **parse**—Trace configuration processing.
- **policy-manager**—Trace policy manager processing.
- **routing-socket**—Trace routing socket messages.
- **timer**—Trace internal timer events.

**level *level***—(Optional) Set traceoptions level.

- **all**—match all levels.
- **error**—Match error conditions.
- **info**—Match informational messages.
- **notice**—Match conditions that should be handled specially.
- **verbose**—Match verbose messages.
- **warning**—Match warning messages.

**no-remote-trace**—(Optional) Disable remote tracing

## show analyzer

|                                 |                                                                                                                                                                                  |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>                   | <b>show analyzer</b> < <i>analyzer-name</i> >                                                                                                                                    |
| <b>Release Information</b>      | Command introduced in Junos OS Release 11.1 for the QFX Series.                                                                                                                  |
| <b>Description</b>              | Display information about port mirroring.                                                                                                                                        |
| <b>Options</b>                  | <i>analyzer-name</i> —(Optional) Displays the status of a specific analyzer (port-mirroring configuration).                                                                      |
| <b>Required Privilege Level</b> | view                                                                                                                                                                             |
| <b>List of Sample Output</b>    | <a href="#">show analyzer on page 4372</a>                                                                                                                                       |
| <b>Output Fields</b>            | <a href="#">Table 302 on page 4372</a> describes the output fields for the <b>show analyzer</b> command. Output fields are listed in the approximate order in which they appear. |

**Table 302: show analyzer Output Fields**

| Field Name                          | Field Description                                                                                                                 |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <b>Analyzer name</b>                | Name of the analyzer.                                                                                                             |
| <b>Output interface</b>             | Local interface to which mirror packets are sent. If you configure an output interface, you cannot also configure an output VLAN. |
| <b>Output VLAN</b>                  | VLAN to which mirror packets are sent. If you configure an output VLAN, you cannot also configure an output interface.            |
| <b>Egress monitored interfaces</b>  | Interfaces for which egress traffic is mirrored.                                                                                  |
| <b>Ingress monitored interfaces</b> | Interfaces for which ingress traffic is mirrored.                                                                                 |
| <b>Ingress monitored VLANs</b>      | VLANs for which ingress traffic is mirrored.                                                                                      |

## Sample Output

```

show analyzer
user@switch> show analyzer
Analyzer name       : employee-monitor
Output interface    : ge-0/0/10.0
Output VLAN         : remote-analyzer
Egress monitored interfaces : ge-0/0/7.0
Ingress monitored interfaces : ge-0/0/8.0
Ingress monitored interfaces : ge-0/0/9.0

```

### Port Mirroring Constraints and Limitations

---

- [Local and Remote Port Mirroring on page 4373](#)
- [Remote Port Mirroring Only on page 4374](#)

#### ***Local and Remote Port Mirroring***

The following constraints and limitations apply to local and remote port mirroring with the QFX Series:

- You can create a total of four port-mirroring configurations on the QFX Series (standalone switches and QFabric systems), subject to the following limits:
  - There can be no more than two configurations that mirror ingress traffic.
  - There can be no more than two configurations that mirror egress traffic.
- You can configure no more than one type of output in one port-mirroring configuration. That is, you can use no more than one of the following to complete a **set analyzer name output** statement:
  - **interface**
  - **ip-address**
  - **vlan**
- If you configure Junos OS to mirror egress packets, do not configure more than 2000 VLANs on a QFX3500 device or QFabric system. If you do so, some VLAN packets might contain incorrect VLAN IDs. This applies to any VLAN packets—not only the mirrored copies.

- The **ratio** and **loss-priority** options are not supported.
- Packets with physical layer errors are filtered out and are not sent to the output port or VLAN.
- If you use sFlow monitoring to sample traffic, it does not sample the mirror copies when they exit from the output interface.
- You cannot mirror packets exiting or entering the following ports:
  - Dedicated Virtual Chassis interfaces
  - Management interfaces (me0 or vme0)
  - Fibre Channel interfaces
  - Routed VLAN interfaces
- Do not include an 802.1Q subinterface that has a unit number other than 0 in a port mirroring configuration. Port mirroring does not work with subinterfaces if their unit number is not 0. (You configure 802.1Q subinterfaces using the **vlan-tagging** statement.)
- When packet copies are sent out the output interface, they are not modified for any changes that are normally applied on egress, such as CoS rewriting.
- An interface can be the input interface for only one mirroring configuration. Do not use the same interface as the input interface for multiple mirroring configurations.
- (QFabric systems only) If you configure a QFabric analyzer to mirror egress traffic and the input and output interfaces are on different Node devices, the mirrored copies have incorrect VLAN IDs. This limitation does not apply if you configure a QFabric analyzer to mirror egress traffic and the input and output interfaces are on the *same* Node device. In this case the mirrored copies have the correct VLAN IDs (as long as you do not configure more than 2000 VLANs on the QFabric system).

#### ***Remote Port Mirroring Only***

The following constraints and limitations apply to remote port mirroring with the QFX Series:

- If you configure an output IP address, the address cannot be in the same subnetwork as any of the switch's management interfaces.
- If you create virtual routing instances and also create an analyzer configuration that includes an output IP address, the output address belongs to the default virtual routing instance (inet.0 routing table).
- An output VLAN cannot be a private VLAN or VLAN range.
- An output VLAN cannot be shared by multiple **analyzer** statements.
- An output VLAN interface cannot be a member of any other VLAN.
- An output VLAN interface cannot be an aggregated Ethernet interface.
- On the source (monitored) switch, only one interface can be a member of the analyzer VLAN.

### Egress Port Mirroring with VLAN Translation

**Problem** If you create a port-mirroring configuration that mirrors customer VLAN (CVLAN) traffic on egress and the traffic undergoes VLAN translation before being mirrored, the VLAN translation does not apply to the mirrored packets. That is, the mirrored packets retain the service VLAN (SVLAN) tag that should be replaced by the CVLAN tag on egress. The original packets are unaffected—on these packets VLAN translation works properly, and the SVLAN tag is replaced with the CVLAN tag on egress.

**Solution** This is expected behavior.

## Overview of Fibre Channel on the QFX Series

Fibre Channel (FC) is a high-speed network technology that interconnects network elements and allows them to communicate with one another. The International Committee for Information Technology Standards (INCITS) T11 Technical Committee sets FC standards.

FC networks provide high-performance characteristics such as lossless transport combined with flexible network topology. FC is primarily used in storage area networks (SANs) because it provides reliable, lossless, in-order frame transport between initiators and targets. FC components include initiators, targets, and FC-capable switches that interconnect FC devices and may also interconnect FC devices with Fibre Channel over Ethernet (FCoE) devices. Initiators originate I/O commands. Targets receive I/O commands. For example, a server can initiate an I/O request to a storage device target.

Juniper Networks QFX Series can function as an FCoE-FC gateway or as an FCoE transit switch.

FCoE transports native FC frames over an Ethernet network by encapsulating the unmodified frames in Ethernet. It also provides protocol extensions to discover FCoE devices through the Ethernet network. FCoE requires that the Ethernet network support data center bridging (DCB) extensions that ensure lossless transport and allow the Layer 2 Ethernet domain to meet the requirements of FC transport.

The FCoE-FC gateway functionality is a licensed feature on the QFX Series. As an FCoE-FC gateway, the switch connects FCoE devices on an Ethernet network to a SAN FC switch.

You do not need a license to use the switch as an FCoE transit switch. As an FCoE transit switch, the switch:

- Is a Layer 2 data center bridging (DCB) switch that can transport FCoE frames.
- Implements FCoE Initialization Protocol (FIP) snooping.
- Connects multiple FCoE endpoints to the FC network.

**NOTE:** The QFX3600 device does not support FC or FCoE features.

---

This topic describes:

### Fibre Channel Transport Protocol

---

The Fibre Channel Protocol is a transport protocol that consists of five layers as shown in [Table 303 on page 4381](#):

Table 303: Fibre Channel Protocol Layers

| FC Protocol Layer | Description                                |
|-------------------|--------------------------------------------|
| FC-0              | Physical (cabling, connectors, and so on)  |
| FC-1              | Data link layer                            |
| FC-2              | Network layer (defines the main protocols) |
| FC-3              | Common services                            |
| FC-4              | Protocol mapping                           |

The FC protocol layers are generally split into three groups:

- FC-0 and FC-1 are the physical layers.
- FC-2 is the protocol layer, similar to OSI Layer 3.
- FC-3 and FC-4 are the services layers.

The FCoE-FC gateway operates the physical layers and the protocol layer, and provides FIP and service redirection at the services layer.

#### How FC Works on the QFX Series

The switch connects devices that support FC and Ethernet (such as FCoE servers on an Ethernet network) to an FC SAN, thus converging the Ethernet and FC networks on a single physical network infrastructure. The switch provides the class-of-service (CoS) features needed to handle the different types of traffic appropriately.

To converge FC and Ethernet networks, you can configure the switch as an:

- [FCoE-FC Gateway on page 4381](#)
- [FCoE Transit Switch on page 4382](#)
- [FCoE VLANs on page 4382](#)

#### **FCoE-FC Gateway**

When the switch functions as an FCoE-FC gateway, the switch aggregates FCoE traffic and performs the encapsulation and de-encapsulation of native FC frames in Ethernet as it transports the frames between FCoE devices in the Ethernet network and the FC switch. In effect, the switch translates Ethernet to FC and FC to Ethernet.

The gateway receives FC frames encapsulated in Ethernet from FCoE devices through an FCoE VLAN interface composed of one or more 10-Gigabit Ethernet interfaces. The gateway removes the Ethernet encapsulation from the FC frames, and then sends the native FC frames to the FC switch through a native FC interface.

The gateway receives native FC frames from the FC switch on the gateway's native FC interfaces. The gateway encapsulates the native FC frames in Ethernet, and then sends the encapsulated frames to the appropriate FCoE device through the FCoE VLAN interface.

To FCoE devices, the gateway behaves like an FC switch and can present multiple virtual F\_Ports (VF\_Ports) on a single interface. To an FC switch, the gateway behaves like an FC node that is doing N\_Port ID virtualization (NPIV).

### **FCoE Transit Switch**

When the switch functions as an FCoE transit switch, it forwards traffic (including FCoE traffic) based on Layer 2 media access control (MAC) forwarding and is a normal DCB-enabled Layer 2 switch that also performs FIP snooping. The switch aggregates FCoE traffic and passes it through to an FCF. The switch does not remove the Ethernet encapsulation from the FC frames, but it does preserve the class of service (CoS) required to transport FC frames.

The switch inspects (snoops) FIP information in order to create filters that permit only valid FCoE traffic to flow through the switch between FCoE devices and the FCF. The switch does not use native FC ports because the FC frames are encapsulated in Ethernet when they flow between the FCoE devices and the FCF. Virtual point-to-point links between each FCoE device and the FCF pass transparently through the switch, so the switch is not seen as a terminating point or an intermediate point by FCoE devices or by the FCF.

### **FCoE VLANs**

On the QFX Series, all FCoE traffic must travel in a VLAN dedicated to transporting only FCoE traffic. Only FCoE interfaces should be members of an FCoE VLAN. Ethernet traffic that is not FCoE or FIP traffic must travel in a different VLAN.

**NOTE:** On a QFX3500 or QFabric system Node device, the same VLAN cannot be used in both transit switch mode and FCoE-FC gateway mode.

---

**NOTE:** FCoE VLANs (any VLAN that carries FCoE traffic) support only Spanning Tree Protocol (STP) and link aggregation group (LAG) Layer 2 features. IGMP snooping is enabled by default on all VLANs; be sure to disable IGMP snooping on FCoE VLANs.

---

You can configure more than one FCoE VLAN, but any given virtual link must be in only one FCoE VLAN.

**NOTE:** All 10-Gigabit Ethernet interfaces that connect to FCoE devices must have a native VLAN configured in order to transport FIP traffic, because FIP VLAN discovery and notification frames are exchanged as untagged packets.

---

**BEST PRACTICE:** Only FCoE traffic is permitted on the FCoE VLAN. A native VLAN might need to carry untagged traffic of different types and protocols.

Therefore, it is a good practice to keep the native VLAN separate from FCoE VLANs.

---

### Supported FC Features and Functions

---

QFX Series supports the following features and functionality:

- As an FCoE-FC gateway:
  - DCB, including Data Center Bridging Capability Exchange protocol (DCBX), priority-based flow control (PFC), enhanced transmission service (ETS), and 10-Gigabit Ethernet interfaces
  - FCoE Initialization Protocol (FIP)
  - Proxy for FCoE devices when communicating with FC switches and acts as a proxy for FC switches when communicating with FCoE devices
  - Up to 12 native FC interfaces per QFX3500 switch (each interface can be configured as a 2-Gigabit, 4-Gigabit, or 8-Gigabit Ethernet interface)
- As an FCoE transit switch:
  - DCB functions
  - FIP snooping
  - Transparent Layer 2 MAC forwarding of FCoE frames

### Lossless Transport Support

---

The QFX Series supports up to six lossless forwarding classes. For lossless transport, you must enable PFC on the IEEE 802.1p code point of lossless forwarding classes. The following limitations apply to support lossless transport:

- The external cable length from the QFX3500 or QFabric system Node device to other devices cannot exceed 300 meters.
- The internal cable length from the QFabric system Node device to the QFabric system Interconnect device cannot exceed 150 meters.
- For FCoE traffic, the interface maximum transmission unit (MTU) must be at least 2180 bytes to accommodate the packet payload, headers, and checks.

## Overview of FIP

Fibre Channel over Ethernet (FCoE) Initialization Protocol (FIP) is a Layer 2 protocol that establishes and maintains Fibre Channel (FC) virtual links between pairs of FCoE devices such as server FCoE Nodes (ENodes) and FC switches. FIP can also establish and maintain virtual links between FCoE devices and an FCoE-FC gateway such as the QFX Series, where the gateway acts on behalf of the FC switch.

FIP enables FCoE devices to discover one another and to initialize and maintain virtual links over a physical Ethernet network. This allows FCoE devices in the Ethernet network to access storage devices in the FC storage area network (SAN).

FIP solves the problem presented by the FC requirement for point-to-point connections (FC does not permit point-to-multipoint connections) by creating a unique virtual link for each connection between an ENode VN\_Port and an FC switch VF\_Port. Multiple virtual links can use a single physical link and virtual links can traverse Ethernet transit (passthrough) switches while appearing to be direct point-to-point connections to the FC switch.

FIP has its own EtherType (0x8914) to distinguish its traffic from payload-carrying FCoE traffic and other Ethernet traffic. FIP operations occur on a per-VLAN basis.

For more details about FIP, see the Technical Committee T11 organization document *Fibre Channel Backbone - 5 (FC-BB-5) Rev 2.00* available at <http://www.t11.org/ftp/t11/pub/fc/bb-5/09-056v5.pdf>.

### Understanding Fibre Channel

Fibre Channel (FC) is a serial I/O interconnect network technology capable of supporting multiple protocols. It is used primarily for storage area networks (SANs). The committee standardizing FC is the International Committee for Information Technology Standards (INCITS).

When configured as a Fibre Channel over Ethernet (FCoE)-FC gateway, the QFX Series supports the transport of native FC traffic between FC switches and the gateway's native FC interfaces.

FC concepts include:

- [FC Fabrics on page 4386](#)
- [FC Port Types on page 4386](#)
- [FC Switches on page 4386](#)
- [Adapters on page 4387](#)

- [N\\_Port ID Virtualization \(NPIV\) on page 4387](#)
- [FC Services on page 4387](#)

---

## FC Fabrics

An FC fabric is a switched network topology that interconnects FC devices using FC switches, usually to create a SAN. An FC switch is a Layer 3 network switch that is compatible with the FC protocol, forwards FC traffic, and provides FC services to the components of the FC fabric. FC devices are usually servers or storage devices such as disk arrays.

Switches called FCoE forwarders (FCFs) perform a subset of FC switch functions. An FCF is a Layer 3 network switch that is compatible with the FC protocol and forwards FC traffic, but does not provide network services.

When configured as an FCoE-FC gateway, the QFX Series acts as a proxy for the FCF functionality of an FC switch. The gateway provides FCoE devices on the Ethernet network access to the FC network without requiring the FC switches in the SAN to support Ethernet interfaces. The gateway is not an FCF and does not provide FC services.

FC network design often uses two fabrics (dual-rail topology) for redundancy. The two fabrics connect to edge devices but are otherwise unconnected, so that if one fabric goes down, the other fabric can continue to provide connectivity.

---

## FC Port Types

The QFX Series supports the following FC port types:

- **N\_Port**—An N\_Port is a port on the node of an FC device such as a server or a storage device and is also known as a node port.
- **F\_Port**—An F\_Port is a port on an FC switch that connects to an FC device N\_Port in a point-to-point connection. F\_Ports are also known as fabric ports.

These port types are a subset of the existing FC port types that can be supported in an FC fabric.

---

## FC Switches

FC switches provide FC services to the FC network. FC switches forward Layer 3 traffic. They may transport a combination of native FC traffic and other traffic, such as Internet Small Computer Systems Interface (iSCSI) or FCoE, or they may transport only native FC traffic. When an FC switch supports FCoE, it combines FCoE termination functions with the FC stack on an FC switching element. This is also known as a dual-stack switch.

When FC switches support FCoE, they present virtual FC interfaces in the form of virtual F\_Ports (VF\_Ports) to the FCoE nodes (ENodes) on FCoE devices. A VF\_Port is an endpoint in a virtual point-to-point connection with an ENode virtual N\_Port (VN\_Port). A VF\_Port emulates a native FC F\_Port and performs similar functions. A VF\_Port is an intermediate port in a connection between an FCoE device such as a server in the Ethernet network and a storage device in the FC SAN.

FC switches that support FCoE contain at least one lossless Ethernet media access controller (MAC) paired with an FCoE controller. The lossless Ethernet MAC implements Ethernet extensions to avoid frame loss due to congestion. The FCoE controller instantiates and terminates virtual port instances as they are needed. Each VF\_Port instance has one unique virtual link to an ENode VN\_Port.

FCoE support also requires one FCoE Link End Point (LEP) for each VF\_Port connection. An FCoE LEP is a virtual FC interface mapped onto the physical Ethernet interface. It transmits and receives FCoE frames on the virtual link, and handles FC frame encapsulation for traffic going from the FC switch to the FCoE device and frame de-encapsulation of traffic received from the FCoE device.

When you configure the QFX Series as an FCoE-FC gateway, the gateway performs these FC-to-Ethernet and Ethernet-to-FC conversion functions so that the FC switch does not need Ethernet (FCoE) ports.

---

### Adapters

FC host bus adapters (HBAs) in FC switches and devices perform functions similar to those of Ethernet adapters in Ethernet switches and devices. Switches that perform FCoE functions and FCoE devices have converged network adapters (CNAs) that support both native FC and Ethernet functionality.

---

### N\_Port ID Virtualization (NPIV)

FC requires a unique point-to-point link between the FC switch (F\_Port) and each host N\_Port. In order to avoid using one physical link for each F\_Port to N\_Port connection, the port connections must be virtualized so that they can share a physical link while maintaining logical separation.

FC accomplishes this by enabling you to create an independent virtual link for each FC session by mapping each session to a virtualized N\_Port. This process is called N\_Port ID virtualization (NPIV).

NPIV makes each virtual link look like a dedicated point-to-point link. In this way, multiple FC devices and multiple applications or virtual machines (VMs) on a single FC device can connect to an FC switch using one physical port instead of using a physical port for each connection. The virtual link creates a secure boundary between traffic from different sources on a single physical connection.

NPIV works by creating a unique virtual port identifier for each logical connection on a physical port. Conceptually, this is similar to splitting a single physical interface into multiple logical interfaces or subinterfaces. A virtual port identifier consists of the port's unique worldwide name (WWN) combined with a Fibre Channel ID (FCID) that the FC switch assigns to the virtual connection. This creates a virtual host bus adapter (HBA) for each virtual link that uniquely identifies the link to the FC switch.

---

### FC Services

When you configure the QFX Series as an FCoE-FC gateway, the gateway connects FCoE devices in the Ethernet network to the FC fabric. The gateway does not provide FC services

directly. The gateway logs in to the FC fabric and obtains FC services from the FC fabric, including:

- Management servers
  - Zone server—Defines which devices can connect to each other in the FC fabric.
  - Fabric configuration server—Discovers FC fabric topology and attributes.
  - Policy server—Distributes the rules for administering, managing, and controlling access to FC fabric resources.
  - HBA management server—Registers HBA information with the FC fabric.
- Domain manager—Allocates domain IDs to virtual switches.
- Fabric login server—Provides login services to the gateway so that the native FC ports on the gateway can perform initial fabric login (FLOGI) to the FC fabric and subsequent fabric discovery (FDISC) logins for the physical and virtual ports on the FCoE devices in the Ethernet network. This includes allocating Fibre Channel IDs (FCIDs) to ports.
- Name server—Discovers, registers, and unregisters N\_Port attributes, including the attributes of the native FC ports on the gateway that connect to the FC fabric.
- Event server—Validates incoming events to ensure transaction integrity.
- Time server—Maintains a common time for devices in the FC fabric.
- Fabric controller
  - Fabric Shortest Path First (FSPF)—The FC fabric provides link-state path selection to the gateway.
  - State change notification (SCN) / registered state change notification server (RSCN)—Notifies the appropriate nodes when new devices come online, when other nodes fail, or when changes on an online node affect system operation.

## Understanding DCB Features and Requirements

Data center bridging (DCB) is a set of enhancements to the IEEE 802.1 bridge specifications. DCB modifies and extends Ethernet behavior to support I/O convergence in the data center. I/O convergence includes but is not limited to the transport of Ethernet LAN traffic and Fibre Channel (FC) storage area network (SAN) traffic on the same physical Ethernet network infrastructure.

A converged architecture saves cost by reducing the number of networks and switches required to support both types of traffic, reducing the number of interfaces required, reducing cable complexity, and reducing administration activities.

The Juniper Networks QFX Series supports the DCB features required to transport converged Ethernet and FC traffic while providing the class-of-service (CoS) and other characteristics FC requires for transmitting storage traffic. To accommodate FC traffic, DCB specifications provide:

- A flow control mechanism called priority-based flow control (PFC, described in IEEE 802.1Qbb) to help provide lossless transport.
- A discovery and exchange protocol for conveying configuration and capabilities among neighbors to ensure consistent configuration across the network, called Data Center Bridging Capability Exchange protocol (DCBX), which is an extension of Link Layer Data Protocol (LLDP, described in IEEE 802.1AB).
- A bandwidth management mechanism called enhanced transmission selection (ETS, described in IEEE 802.1Qaz).
- A congestion management mechanism called quantized congestion notification (QCN, described in IEEE 802.1Qau).

The switch supports the PFC, DCBX, and ETS standards but does not support QCN. The switch also provides the high-bandwidth interfaces (10-Gbps minimum) required to support DCB and converged traffic.

This topic describes the DCB standards and requirements the switch supports:

- [Lossless Transport on page 4389](#)
- [ETS on page 4390](#)
- [DCBX on page 4391](#)

### Lossless Transport

FC traffic requires lossless transport (defined as no frames dropped because of congestion). Standard Ethernet does not support lossless transport, but the DCB extensions to Ethernet along with proper buffer management enable an Ethernet network to provide the level of class of service (CoS) necessary to transport FC frames encapsulated in Ethernet over an Ethernet network.

This section describes these factors in creating lossless transport over Ethernet:

- [PFC on page 4390](#)
- [Buffer Management on page 4390](#)
- [Physical Interfaces on page 4390](#)

### **PFC**

PFC is a link-level flow control mechanism similar to Ethernet PAUSE (described in IEEE 802.3x). Ethernet PAUSE stops all traffic on a link for a period of time. PFC enables you to divide traffic on a link into eight priorities and stop the traffic of a selected priority without stopping the traffic assigned to other priorities on the link.

Pausing the traffic of a selected priority enables you to provide lossless transport for traffic assigned that priority and at the same time use standard lossy Ethernet transport for the rest of the link traffic.

### **Buffer Management**

Buffer management is critical to the proper functioning of PFC, because if buffers are allowed to overflow, frames are dropped and transport is not lossless.

For each lossless flow priority, the switch requires sufficient buffer space to:

- Store frames sent during the time it takes to send the PFC pause frame across the cable between devices.
- Store the frames that are already on the wire when the sender receives the PFC pause frame.

The propagation delay due to cable length and speed, as well as processing speed, determines the amount of buffer space needed to prevent frame loss due to congestion.

The switch automatically sets the threshold for sending PFC pause frames to accommodate delay from cables as long as 150 meters (492 feet) and to accommodate large frames that might be on the wire when the switch sends the pause frame. This ensures that the switch sends pause frames early enough to allow the sender to stop transmitting before the receive buffers on the switch overflow.

### **Physical Interfaces**

The switch supports 10-Gbps, full-duplex interfaces. The switch enables DCB capability only on 10-Gbps (or faster) Ethernet interfaces.

### **ETS**

---

PFC divides traffic into up to eight separate streams (priorities, configured on the switch as forwarding classes) on a physical link. ETS enables you to manage the link bandwidth by:

- Grouping the priorities into priority groups (configured on the switch as forwarding class sets).
- Specifying the bandwidth available to each of the priority groups as a percentage of the total available link bandwidth.

- Allocating the bandwidth to the individual priorities in the priority group.

The available link bandwidth is the bandwidth remaining after servicing strict priority flows.

Managing link bandwidth with ETS provides several advantages:

- There is uniform management of all types of traffic on the link, both congestion-managed traffic and standard Ethernet traffic.
- When a priority group does not use all of its allocated bandwidth, other priority groups on the link can use that bandwidth as needed.

When a priority in a priority group does not use all of its allocated bandwidth, other priorities in the group can use that bandwidth.

The result is better bandwidth utilization, because priorities that consist of bursty traffic can share bandwidth during periods of low traffic transmission instead of consuming their entire bandwidth allocation when traffic loads are light.

- You can assign traffic types with different service needs to different priorities so that each traffic type receives appropriate treatment.
- Strict priority traffic retains its allocated bandwidth.

## DCBX

DCB devices use DCBX to exchange configuration information with directly connected peers (switches and endpoints such as servers). DCBX is an extension of LLDP. If you disable LLDP on an interface, that interface cannot run DCBX. If you attempt to enable DCBX on an interface on which LLDP is disabled, the configuration commit fails.

DCBX can:

- Discover the DCB capabilities of peers.
- Detect DCB feature misconfiguration or mismatches between peers.
- Configure DCB features on peers.

You can configure DCBX operation for PFC, ETS, and for Layer 2 and Layer 4 applications such as FCoE and iSCSI. DCBX is enabled or disabled on a per-interface basis.

## Understanding FCoE

Fibre Channel over Ethernet (FCoE) is a method of supporting converged Fibre Channel (FC) and Ethernet traffic on a data center bridging (DCB) network. FCoE encapsulates unmodified FC frames in Ethernet to transport the FC frames over a physical Ethernet network. The T11 Technical Committee, which is the International Committee for Information Technology Standards (INCITS) committee responsible for FC interfaces, developed the FCoE standard to provide a method for transporting FC frames over a DCB network. The T11 document *Fibre Channel Backbone - 5 (FC-BB-5) Rev 2.00* at <http://www.t11.org/ftp/t11/pub/fc/bb-5/09-056v5.pdf> provides details about the FCoE version 1 standard.

**NOTE:** The switch does not support T11 Annex F *FCoE Pre-FIP Virtual Link Instantiation Protocol*.

To the Ethernet network, an FCoE frame is the same as any other Ethernet frame because the Ethernet encapsulation provides the header information needed to forward the frames. However, to achieve the lossless behavior that FC transport requires, the Ethernet network must conform to DCB standards.

DCB standards create an environment over which FCoE can transport native FC traffic encapsulated in Ethernet while preserving the mandatory class of service (CoS) and other characteristics that FC traffic requires.

Supporting FCoE in a DCB network requires that the FCoE devices in the Ethernet network and the FC switches at the edge of the SAN network handle both Ethernet and native FC traffic. To handle Ethernet traffic, an FC switch does one of two things:

- Incorporates FCoE interfaces.
- Uses an FCoE-FC gateway such as a QFX Series to de-encapsulate FCoE traffic from FCoE devices into native FC and to encapsulate native FC traffic from the FC switch into FCoE and forward it to FCoE devices through the Ethernet network.

FCoE concepts include:

- [FCoE Devices on page 4392](#)
- [FCoE Frames on page 4394](#)
- [Virtual Links on page 4394](#)
- [FCoE VLANs on page 4395](#)

---

### FCoE Devices

Each FCoE device has a converged network adapter (CNA) that combines the functions of an FC host bus adapter (HBA) and a lossless Ethernet network interface card (NIC) with 10-Gbps Ethernet ports. The portion of the CNA that handles FCoE traffic is called an FCoE Node (ENode). An ENode combines FCoE termination functions and the client part of the FC stack on the CNA.

ENodes present virtual FC interfaces to FC switches in the form of virtual N\_Ports (VN\_Ports). A VN\_Port is an endpoint in a virtual point-to-point connection called a virtual link. The other endpoint of the virtual link is an FC switch (or FCF) port. A VN\_Port emulates a native FC N\_Port and performs similar functions: handling the creation, detection, and flow of messages to and from the FC switch. A single ENode can host multiple VN\_Ports. Each VN\_Port has a separate, unique virtual link with a FC switch.

ENodes contain at least one lossless Ethernet media access controller (MAC). Each Ethernet MAC is paired with an FCoE controller. The lossless Ethernet MAC is a full-duplex Ethernet MAC that implements Ethernet extensions to avoid frame loss due to congestion and supports frames of at least 2500 bytes. The FCoE controller instantiates and terminates VN\_Port instances dynamically as they are needed for FCoE sessions. Each VN\_Port instance has a unique virtual link to an FC switch.

**NOTE:** A *session* is a fabric login (FLOGI) or fabric discovery (FDISC) login to the FC SAN fabric. Session does not refer to end-to-end server-to-storage sessions.

ENodes also contain one FCoE link end point (LEP) for each VN\_Port connection. An FCoE LEP is a virtual FC interface mapped onto the physical Ethernet interface.

An FCoE LEP:

- Transmits and receives FCoE frames on the virtual link.
- Handles FC frame encapsulation for traffic going from the server to the FC switch.
- Performs frame de-encapsulation of traffic received from the FC switch.

Figure 162 on page 4393 shows a block diagram of the major ENode components.

**Figure 162: ENode Components**

## FCoE Frames

---

The FCoE protocol specification replaces the FC0 and FC1 layers of the FC stack with Ethernet, but retains the FC frame header. Retaining the FC frame header enables the FC frame to pass directly to a native FC SAN after de-encapsulation. The FCoE header carries the FC start of file (SOF) bits and end of file (EOF) bits in an encoded format. FCoE supports two frame types, control frames and data frames. FCoE Initialization Protocol (FIP) carries all of the discovery and fabric login frames.

FIP control frames handle FCoE device discovery, initializing communication, and maintaining communication. They do not carry a data payload. FIP has its own EtherType (0x8914) to distinguish FIP traffic from FCoE traffic and other Ethernet traffic. To establish communication, the ENode uses the globally unique MAC address assigned to it by the CNA manufacturer.

After FIP establishes a connection between FCoE devices, the FCoE data frames handle the transport of the FC frames encapsulated in Ethernet. FCoE also has its own EtherType (0x8906) to distinguish FCoE frames from other Ethernet traffic and ensure the in-order frame handling that FC requires. FCoE frames include:

- 2112 bytes FC payload
- 24 bytes FC header
- 14 bytes standard Ethernet header
- 14 bytes FCoE header
- 8 bytes cyclic redundancy check (CRC) plus EOF
- 4 bytes VLAN header
- 4 bytes frame check sequence (FCS)

The payload, headers, and checks add up to 2180 bytes. Therefore, interfaces that carry FCoE traffic should have a configured maximum transmission unit (MTU) of 2180 or larger. An MTU size of 2180 bytes is the minimum size; some network administrators prefer an MTU of 2240 or 2500 bytes.

## Virtual Links

---

Native FC uses point-to-point physical links between FC devices. In FCoE, virtual links replace the physical links. A virtual link emulates a point-to-point link between two FCoE device endpoints, such as a server VN\_Port and an FC switch (or FCF) VF\_Port.

Each FCoE interface can support multiple virtual links. The MAC addresses of the FCoE endpoints (the VN\_Port and the VF\_Port) uniquely identify each virtual link and allow traffic for multiple virtual links to share the same physical link while maintaining data separation and security.

A virtual link exists in one FCoE VLAN and cannot belong to more than one VLAN. Although the FC switch and the FCoE device detect a virtual link as a point-to-point connection, virtual links do not need to be direct connections between a VF\_Port and a VN\_Port. A virtual link can traverse one or more transit switches, also known as passthrough switches.

A transit switch can transparently aggregate virtual links while still appearing and functioning as a point-to-point connection to the FCoE devices. However, a virtual link must remain within a single Layer 2 domain.

### FCoE VLANs

On the QFX Series, all FCoE traffic must travel in a VLAN dedicated to transporting only FCoE traffic. Only FCoE interfaces should be members of an FCoE VLAN. Ethernet traffic that is not FCoE or FIP traffic must travel in a different VLAN.

**NOTE:** On a QFX3500 or QFabric system Node device, the same VLAN cannot be used in both transit switch mode and FCoE-FC gateway mode.

**NOTE:** FCoE VLANs (any VLAN that carries FCoE traffic) support only Spanning Tree Protocol (STP) and link aggregation group (LAG) Layer 2 features. IGMP snooping is enabled by default on all VLANs; be sure to disable IGMP snooping on FCoE VLANs.

You can configure more than one FCoE VLAN, but any given virtual link must be in only one FCoE VLAN.

**NOTE:** All 10-Gigabit Ethernet interfaces that connect to FCoE devices must have a native VLAN configured in order to transport FIP traffic, because FIP VLAN discovery and notification frames are exchanged as untagged packets.

**BEST PRACTICE:** Only FCoE traffic is permitted on the FCoE VLAN. A native VLAN might need to carry untagged traffic of different types and protocols. Therefore, it is a good practice to keep the native VLAN separate from FCoE VLANs.

## Understanding FCoE Transit Switch Functionality

You can use the QFX Series as a Fibre Channel over Ethernet (FCoE) transit switch. An FCoE transit switch is a Layer 2 data center bridging (DCB) switch that can transport FCoE frames and implements FCoE Initialization Protocol (FIP) snooping. A DCB switch transports both FCoE and Ethernet LAN traffic over the same network infrastructure while preserving the class of service (CoS) that Fibre Channel (FC) traffic requires.

An FCoE transit switch does not encapsulate or de-encapsulate FC frames in Ethernet. It is an access switch that transports FC frames that have already been encapsulated in Ethernet between FCoE initiators such as servers and a storage area network (SAN) FC switch that supports both Ethernet and native FC traffic on its interfaces. The transit switch acts as a passthrough switch and is transparent to the FC switch, which detects each connection to an FCoE device as a direct point-to-point link.

When a QFX Series acts as a transit switch, the VLANs you configure for FCoE traffic can use any of the switch ports on the device (QFX3500 switch or QFabric system Node device) because the traffic in both directions is standard Ethernet traffic, not native FC traffic.

**NOTE:** The Ethernet interfaces that connect to FCoE devices must include a native VLAN to transport FIP traffic, because FIP VLAN discovery and notification frames are exchanged as untagged packets. It is a good practice to keep the native VLAN separate from the VLANs that carry FCoE traffic. FCoE VLANs should carry only FCoE traffic, but other types of untagged traffic might use the native VLAN.

FCoE traffic should use a VLAN dedicated only to FCoE traffic. Do not mix FCoE traffic with standard Ethernet traffic on a VLAN on the switch.

**NOTE:** FCoE VLANs (any VLAN that carries FCoE traffic) support only Spanning Tree Protocol (STP) and link aggregation group (LAG) Layer 2 features. IGMP snooping is enabled by default on all VLANs; be sure to disable IGMP snooping on FCoE VLANs.

**NOTE:** On a QFX3500 switch or on a QFabric system Node device, the same VLAN cannot be used in both transit switch mode and FCoE-FC gateway mode. If you configure both a transit switch and an FCoE-FC gateway on the same QFX3500 switch or QFabric system Node device, configure different FCoE VLANs for the transit switch and the FCoE-FC gateway.

Transit switch architecture differs from FCoE-FC gateway architecture. As an FCoE-FC gateway, the system transports traffic to the FC SAN as native FC frames, and the VLAN must use an FCoE VLAN interface and native FC interfaces to transport that traffic. As a transit switch, the system forwards Ethernet traffic, and requires DCB configuration for

lossless transport of that traffic and FIP snooping at FCoE device access ports, but not the FCoE-FC gateway features necessary for transporting FC traffic.

The QFX Series complies with DCB standards for ensuring lossless transport and low latency, and provides 10-Gbps ports for FCoE traffic. For lossless transport to function correctly, you must use priority-based flow control (PFC, described in IEEE 802.1Qbb) to create bandwidth reservations and ensure proper CoS for FCoE traffic.

FIP snooping adds security by filtering access so that only traffic from servers that have successfully logged in to the FC network passes through the transit switch and reaches the FC network. The Technical Committee T11 organization specifications describe two types of FIP snooping:

- The FC-BB-5 specification describes VN\_Port to VF\_Port (VN2VF\_Port) FIP snooping, which provides security for communication between FCoE device VN\_Ports on the Ethernet network and FCF or FC switch VF\_Ports.
- The FC-BB-6 specification describes VN\_Port to VN\_Port (VN2VN\_Port) FIP snooping, which provides security for communication between FCoE device VN\_Ports on the Ethernet network.

To accommodate the larger size of Ethernet-encapsulated frames, FCoE interfaces should be configured with a maximum transmission unit (MTU) size of at least 2180 bytes.

The transit switch transparently connects FCoE-capable devices such as servers in an Ethernet LAN to an FC switch or to a gateway switch (hereafter referred to as the FC switch), as shown in [Figure 163 on page 4397](#). The transit switch acts as a transparent DCB access layer between FCoE servers and the FC switch.

**Figure 163: FCoE Transit Switch Connecting FCoE Devices to an FC Switch**

The transit switch performs FIP snooping at the ports connected to the FCoE devices. For VN2VF\_Port FIP snooping, at the SAN edge, the FC switch must be able to convert the FCoE traffic to native FC traffic. (VN2VN\_Port FIP snooping switches traffic between VN\_Ports directly through the transit switch, without going through the FC switch, so no conversion of FCoE traffic to native FC traffic is needed.)

Encapsulated FCoE traffic flows through the transit switch to the FCoE ports on the FC switch. The FC switch removes the Ethernet encapsulation from the FCoE frames to restore the native FC frames. Native FC traffic travels out native FC ports to storage devices in the FC SAN.

Native FC traffic from storage devices flows to the FC switch FC ports, and the FC switch encapsulates that traffic in Ethernet as FCoE traffic. The FCoE traffic flows through the transit switch to the appropriate FCoE device.

**NOTE:** The FC switch and FC fabric apply appropriate zoning checks on traffic to and from each ENode and provide FC services (for example, name server, fabric login server, or event server).

---

**NOTE:** The QFX3500 switch supports VN\_Port to VN\_Port FIP snooping to allow FCoE initiators and targets to communicate directly through the switch without going through an FCoE forwarder (FCF) or an FC switch. An FCoE VLAN can support either VN2VF\_Port FIP snooping (FC-BB-5) or VN2VN\_Port FIP snooping (FC-BB-6), but not both. The same QFX3500 switch can have multiple FCoE VLANs configured, some FCoE VLANs for VN2VF FIP snooping traffic and others for VN2VN FIP snooping traffic.

---

For load balancing, increasing available bandwidth, and port failover protection, you can configure the 10-Gigabit Ethernet interfaces that belong to an FCoE VLAN as a link aggregation group (LAG). In addition, creating a LAG prevents spanning tree algorithms from blocking physical links and wasting bandwidth.

## Understanding an FCoE-FC Gateway

A Fibre Channel over Ethernet (FCoE)-Fibre Channel (FC) gateway connects FCoE devices on an Ethernet network to an FC switch in an FC storage area network (SAN) as shown in [Figure 164 on page 4399](#). To FCoE devices such as servers, the FCoE-FC gateway presents virtual fabric ports (VF\_Ports) and appears to be an FCoE forwarder (FCF). To the FC switch, the FCoE-FC gateway presents a proxy node port (NP\_Port) and appears to be an FC device.

**Figure 164: FCoE-FC Gateway Topology**

The FCoE-FC gateway handles FCoE Initialization Protocol (FIP) and FCoE traffic on the interfaces connected to FCoE devices. The gateway forwards native FC traffic on the interfaces to the FC switch. The gateway does not provide FC services (such as fabric login server or name server). It is a proxy for an FCF, not an FCF or an FC switch. The gateway transparently substitutes for the FC switch when communicating with FCoE devices and transparently substitutes for FCoE devices when communicating with the FC switch.

The gateway does not use an FC domain ID, so it extends the SAN fabric while saving domain resources. Using the gateway also means that the FC switch does not have to handle FCoE traffic (and therefore requires no FCoE blades or ports). The gateway converges Ethernet and FC backbones to leverage existing resources.

- [Gateway FC Fabric on page 4400](#)
- [Fabric Services on page 4401](#)
- [FCoE-FC Gateway Traffic Switching on page 4401](#)

## Gateway FC Fabric

---

A gateway FC fabric is a QFX Series configuration construct. It is not the same thing as an FC fabric in the SAN; the gateway FC fabric is local to the switch. It creates associations that connect FCoE devices with converged network adapters (CNAs) on the Ethernet network to an FC switch on the Fibre Channel network. A gateway FC fabric consists of:

- A unique fabric name.
- A unique fabric ID.
- At least one dedicated VLAN for FCoE traffic. VLANs that carry FCoE traffic should not carry any other type of traffic.

**NOTE:** On a QFX3500 or QFabric system Node device, the same VLAN cannot be used in both transit switch mode and FCoE-FC gateway mode.

- At least one FCoE VLAN interface (Layer 3 VLAN interface) that includes one or more 10-Gigabit Ethernet interfaces connected to FCoE devices. The FCoE VLANs transport traffic between the FCoE servers and the FCoE-FC gateway. Each FCoE VLAN must carry only FCoE traffic. You cannot mix FCoE traffic and standard Ethernet traffic on the same VLAN.

The 10-Gigabit Ethernet interfaces that connect to FCoE devices must include a native VLAN to transport FIP traffic because FIP VLAN discovery and notification frames are exchanged as untagged packets.

Each FCoE VLAN interface can present multiple VF\_Port interfaces to the FCoE network.

**NOTE:** Storm control must be disabled on all Ethernet interfaces that belong to the FCoE VLAN to prevent FCoE traffic from being dropped.

- One or more native FC interfaces. The native FC interfaces transport traffic between the gateway and the FC switch.

**TIP:** If the network does not use a dual-rail architecture for redundancy, configure more than one native FC interface for each FC fabric to create redundant connections between the FCoE devices and the FC switch. If one physical link goes down, any sessions it carried can log in again and connect to the FC switch on a different interface. Even in dual-rail architecture networks, creating redundant connections between the QFabric system and the FC switch is the best practice.

You can also configure FIP parameters for the fabric or accept the default FIP parameters. VN\_Port to VF\_Port (VN2VF\_Port) FIP snooping is automatically enabled on all server-facing ports because all ports are untrusted by default. You can disable VN2VF\_Port FIP snooping on a port-by-port basis by marking a port as an FCoE trusted interface. You

can disable VN2VF\_Port FIP snooping on all Ethernet ports in an FC fabric by configuring the fabric as FCoE trusted.

Because the switch has 12 native FC ports and each FC fabric requires a minimum of one native FC port, the switch supports a maximum of 12 FC fabrics. However, as a best practice for redundancy, we recommend that you assign at least two native FC interfaces to each FC fabric.

On a QFabric system, all of the FC and FCoE traffic that belongs to a particular gateway FC fabric must ingress and egress the same gateway Node device. Gateway FC fabrics do not span across Node devices. All of the native FC interfaces and the Ethernet interfaces that belong to the FCoE VLAN must reside on the same gateway Node device to be included in an FC fabric on that Node device.

Traffic from FC and FCoE devices that are not in the same FC fabric remain separate and cannot communicate with each other through the gateway.

### **Fabric Services**

---

The FC switch provides all FC services (domain manager, name server, fabric login server, and so on) except FIP to the FCoE devices. The FC switch assigns all FCIDs (through N\_Port ID virtualization) and fabric attributes to FCoE device VN\_Ports.

The FCoE-FC gateway does not provide FC services (except FIP). The gateway relays communication between the FC switch and the FCoE devices, encapsulates and de-encapsulates native FC frames, converges Ethernet and FC backbones, and aggregates FCoE device VN\_Port sessions.

### **FCoE-FC Gateway Traffic Switching**

---

All traffic that flows through the gateway FC fabric is switched through the FC switch. Even if two hosts on the Ethernet FCoE network connect directly to the gateway, FCoE communication between them goes through the FC switch, as shown in [Figure 165 on page 4402](#).

**Figure 165: Traffic Switching Between FCoE Hosts Connected to the FC Network by an FCoE-FC Gateway**

For example, FCoE host server *Host1* sends frames destined for FCoE host server *Host2*. Both *Host1* and *Host2* are directly connected to the gateway. The communication path looks like this:

1. *Host1* sends FCoE frames destined for *Host2* to the gateway.
2. The gateway de-encapsulates the FCoE frames from *Host1* into native FC frames and switches them to the FC switch.
3. The FC switch processes the native FC frames and sends them back to the gateway destined for *Host2*.
4. The gateway encapsulates the FC frames in Ethernet and sends the resulting FCoE frames to *Host2*.
5. When *Host2* replies, the FCoE reply goes to the gateway. The gateway de-encapsulates the reply and switches it to the FC switch for processing. The FC switch then sends it back to the gateway, which encapsulates the FC frames and sends them to *Host1*.

## Understanding FCoE-FC Gateway Functions

When it functions as a Fibre Channel over Ethernet (FCoE)-Fibre Channel (FC) gateway, the QFX Series provides the following functions:

- [Login and Logout on page 4403](#)
- [FCoE and FC Frame Handling on page 4403](#)
- [Data Center Bridging on page 4403](#)
- [Disabling the Fabric WWN Verification Check on page 4404](#)
- [Load Balancing on page 4405](#)

### Login and Logout

---

Each of the native FC interfaces on the gateway performs a fabric login (FLOGI) to the FC switch when each interface initializes. This establishes the link between each gateway FC interface and the FC switch.

When FCoE devices on the Ethernet network send an FCoE Initialization Protocol (FIP) login (FIP FLOGI) or FIP discovery (FIP FDISC) request to the gateway, the gateway acts on behalf of those devices and converts their FIP FLOGI and FIP FDISC requests to FC FDISC requests. The gateway then sends the FC FDISC requests to the FC switch. When the FC switch responds to an FDISC request, the gateway converts the FC response into a FIP response and sends it to the appropriate FCoE device.

The gateway also converts FIP logout (LOGO) requests from FCoE devices into FC LOGO requests to the FC switch, and converts the FC switch response into a FIP response for the FCoE device.

### FCoE and FC Frame Handling

---

When it receives FCoE frames from FCoE devices, the gateway strips away the Ethernet encapsulation from the FC frame before sending the native FC frame to the FC switch.

When it receives native FC frames from the FC switch, the gateway encapsulates the native FC frames in Ethernet before sending the resulting FCoE frames to the appropriate VN\_Port.

### Data Center Bridging

---

The Ethernet ports connected to the FCoE devices are 10-Gbps Ethernet ports and support data center bridging (DCB) specifications:

- Priority-based flow control (PFC, described in IEEE 802.1Qbb)
- Data Center Bridging Capability Exchange protocol (DCBX), which is an extension of Link Layer Data Protocol (LLDP, described in IEEE 802.1AB)
- Enhanced transmission selection (ETS, described in IEEE 802.1Qaz)
- 10-Gigabit Ethernet ports

### Disabling the Fabric WWN Verification Check

---

The gateway connects to a SAN fabric using the gateway NP\_Ports (native FC ports). When the NP\_Ports initialize, each port sends a FLOGI to the FC switch to which it is connected in the SAN fabric. The FC switch sends a FLOGI accept (FLOGI-ACC) message back to each NP\_Port. The FLOGI-ACC message includes the SAN fabric worldwide name (WWN). The gateway uses the SAN fabric WWN in the multicast discovery advertisement (MDA) that the gateway sends to the ENodes in the FCoE network.

Some FC switches substitute their own WWN (often the FC switch's virtual WWN) for the SAN fabric WWN in the FLOGI-ACC message. When the FC switch substitutes its own WWN for the fabric WWN, gateway NP\_Ports that log in to the same SAN fabric might receive different fabric WWNs in the FLOGI-ACC messages if the NP\_Ports are connected to different FC switches in that SAN fabric. This creates a problem, because different fabric WWNs indicate different SAN fabrics. But in this scenario, the different fabric WWNs come from different FC switches in the same SAN fabric.

If the gateway receives different fabric WWNs on NP\_Ports that are connected to the same SAN fabric, the gateway uses the first fabric WWN it receives in the MDA it sends to the ENodes. The gateway isolates the NP\_Ports connected to that fabric that receive a different fabric WWN in the FLOGI-ACC message. No ENode sessions are assigned to the isolated NP\_Ports. FC traffic is assigned only to NP\_Ports that receive a fabric WWN that matches the fabric WWN received by the first NP\_Port to log in to the FC fabric. (If an NP\_Port receives a fabric WWN that does not match the fabric WWN received by the first NP\_Port to log in to the FC fabric, it does not carry traffic to the SAN fabric.)

In summary, the scenario is:

1. The gateway has multiple NP\_Ports connected to more than one FC switch in a SAN fabric.
2. When the NP\_Ports initialize, each NP\_Port sends a FLOGI to the FC switch to which it is connected.
3. The FC switches substitute their own WWNs for the fabric WWN in the FLOGI-ACC message, so different NP\_Ports receive different fabric WWNs.
4. In the MDA the gateway sends to FCoE devices, the gateway uses the fabric WWN that the first NP\_Port to log in to the fabric receives in the FLOGI-ACC message. If other NP\_Ports receive a different fabric WWN from other FC switches in the SAN fabric, that fabric WWN is not advertised.
5. NP\_Ports that receive a fabric WWN that does not match the first received fabric WWN are isolated, and the ENode sessions cannot use those ports.

To prevent this from happening, you can disable the gateway fabric WWN verification check so that all NP\_Ports connected to a SAN fabric are used to carry traffic between the gateway and the FC switch, regardless of the fabric WWN the NP\_Port receives in the FLOGI-ACC message.

**NOTE:** Disabling or enabling the fabric WWN verification check logs out all FCoE sessions.

### Load Balancing

The switch performs automatic link load balancing for the connections between the gateway and the FC SAN and can also perform load balancing for the connections between the gateway and the FCoE devices in the Ethernet network. On the native FC links (NP\_Ports) between the gateway and the FC SAN, the gateway can use one of the following two load-balancing algorithms:

- Simple load balancing—Each ENode FLOGI session and VN\_Port FDISC session is assigned to the least-loaded link. This is the default load-balancing algorithm.
- ENode-based load balancing—When an ENode logs in to the fabric, all subsequent DISC sessions associated with that ENode are placed on the same link as the ENode FLOGI session, regardless of the link load. New ENode FLOGIs are placed on the least-loaded link.

**NOTE:** Changing the load-balancing algorithm when FCoE sessions are running forces the FCoE sessions to log out, then log in again.

You can balance the load on the Ethernet ports facing the FCoE devices by configuring those ports as a link aggregation group (LAG).

### Understanding FCoE and FIP Session High Availability

The QFX Series provides high availability features to maintain storage network sessions when a system process is terminated and during certain types of upgrades:

- [Fibre Channel Process Termination High Availability \(FCoE-FC Gateway Mode\) on page 4406](#)
- [FIP Snooping High Availability on page 4406](#)
- [Nonstop Software Upgrade \(QFabric Systems\) on page 4407](#)

### Fibre Channel Process Termination High Availability (FCoE-FC Gateway Mode)

In FCoE-FC gateway mode, the QFX3500 switch provides high availability to restore the FCoE sessions running on the switch in case the Fibre Channel (FC) process is terminated. A session is a fabric login (FLOGI) or fabric discovery (FDISC) login to the FC SAN fabric, not an end-to-end server-to-storage session.

The switch stores FCoE session data in a persistent storage module. If the FC process terminates, the switch restores the existing FCoE sessions on the same interfaces that they were on before the FC process terminated. Data traffic for existing sessions is not affected during session restoration.

For a brief time, the system does not process control traffic because of the FC process restart and session restoration. During this brief time, no new FCoE sessions can be established, and no existing sessions can log out.

**NOTE:** During the restoration process, if the FC process does not receive an “interface up” notification from a particular interface within a certain time, the switch times out the restore operation and discards the data on that interface. The previously existing FCoE sessions on that interface are not restored, and the ENodes must log in again.

**NOTE:** An FC process restart and session restoration resets the Fibre Channel statistics.

If the FC process terminates repeatedly, the operating system disables the process until you manually restart it. To restart the FC process manually, issue the **restart fibre-channel** command.

### FIP Snooping High Availability

You can configure the system to perform FIP snooping on Ethernet interfaces that are connected to FCoE devices that have ENodes. The QFX Series provides high availability to restore running FIP snooping sessions in case the Ethernet switching process is terminated.

The Ethernet switching process stores the FIP snooping state in a persistent storage module. If the Ethernet switching process terminates, the QFX Series restores the existing FIP snooping sessions on the same interfaces that they were on before the Ethernet switching process terminated. The high availability features preserve:

- Logged in ENodes
- Discovered FCFs
- Existing sessions
- Existing FIP snooping filters

In the event of an Ethernet switching process termination, ENodes remain logged in and existing sessions are not interrupted.

**NOTE:** An Ethernet switching process restart and session restoration resets the FIP snooping statistics.

### Nonstop Software Upgrade (QFabric Systems)

On QFabric system Node groups that have more than one Node device, nonstop software upgrade (NSSU) enables you to upgrade the Node devices with minimal packet loss and maximum uptime. NSSU automates software upgrades on the QFabric system components in an orderly and consistent manner to maximize system uptime.

The system upgrades components with redundant architectures, such as redundant server Node groups and network Node groups that have two or more members, in stages. While the system upgrades one component, the redundant component continues to function.

For example, while one member of a redundant server Node group is upgraded, the other member continues to forward traffic. When the first Node group member completes the upgrade, it comes online while the system upgrades the second member.

NSSU provides high availability for the lossless traffic forwarding required to support storage networks. If your system design includes redundancy (redundant Node devices in Node groups, LAGs, etc.) so that an alternate traffic path is available, when you upgrade a Node device, traffic is not impacted.

In fully redundant topologies, NSSU preserves FIP session, FIP snooping filter, VN2VF\_Port session, and VN2VN\_Port session information and prevents traffic loss in most cases. An exception is that Node devices that are directly connected to ENodes experience momentary traffic loss when the Node device reboots.

## Understanding FIP Functions

Fibre Channel over Ethernet (FCoE) Initialization Protocol (FIP) performs four major functions:

- FIP VLAN discovery: FCoE device FCoE nodes (ENodes) discover the FCoE VLANs on which to transmit and receive FIP and FCoE traffic.
- FIP discovery: FCoE devices discover Fibre Channel (FC) switches to which they can connect.
- Initialization: FCoE devices perform fabric login (FLOGI) and fabric discovery (FDISC) to create a virtual link with an FC switch.
- Maintenance: The QFX Series ensures that the virtual link between the FCoE device and the FC switch remains valid, and also that the link termination logout (LOGO) functions properly.

When you configure the switch as an FCoE-FC gateway, it converts FIP requests and information from FCoE devices into FC requests and information and relays them to the FC switch. To FCoE devices, the gateway appears to be an FCoE forwarder (FCF) and presents virtual fabric port (VF\_Port) interfaces to the server ENode. To FC switches, the gateway appears to be an FC device that supports N\_Port ID virtualization (NPIV) and presents an N\_Port interface to the FC switch F\_Port interface. When you configure the QFX Series as an FCoE transit switch, you do not configure FIP parameters on the switch.

FIP FLOGI, FDISC, and LOGO are similar to the same processes in the native FC protocol.

This topic describes:

- [FIP VLAN Discovery on page 4408](#)
- [FIP Discovery on page 4409](#)
- [FIP FLOGI on page 4410](#)

- [FIP LOGO on page 4411](#)

---

### FIP VLAN Discovery

The gateway supports FIP VLAN discovery. Host ENodes use FIP VLAN discovery to discover the FCoE VLANs on which they will send and receive FIP and FCoE traffic and on which they will establish a virtual link with the FC switch. This means FCoE devices do not need manually configured FCoE VLANs.

FIP VLAN discovery and notification takes place on the native VLAN that the FCoE device uses for Ethernet traffic:

1. The ENode sends a FIP VLAN discovery request to a multicast address called *ALL-FCF-MACs* to which all FC switches and FCFs on the VLAN listen.
2. The FC switches and FCFs respond on the native VLAN with a list of the FCoE VLANs that are available for login.

3. The ENode selects an FCoE VLAN and continues the FIP process on that VLAN.

Except for FIP VLAN discovery, all other FIP and FCoE traffic runs on an FCoE VLAN.

**BEST PRACTICE:** Only FCoE traffic is permitted on the FCoE VLAN. A native VLAN might need to carry untagged traffic of different types and protocols. Therefore, it is a good practice to keep the native VLAN separate from FCoE VLANs.

### FIP Discovery

The FIP discovery process allows an FCoE device ENode MAC to locate (discover) the FC switches in the FCoE VLAN to which it belongs. The ENode selects an FC switch to log in to from the available FC switches. Either the ENode MAC or the FC switch can initiate the FIP discovery process.

Server ENode MACs initiate FIP discovery:

1. When an ENode MAC comes online, it sends a multicast discovery solicitation message on its FCoE VLAN to a multicast address called *ALL-FCF-MACs* to which all FCFs (including the FCF functionality of FC switches) on the VLAN listen. The discovery solicitation message includes the ENode's addressing mode and the maximum protocol data unit (PDU) size the ENode MAC uses for FCoE traffic.

The ENode uses the globally unique ENode MAC address assigned to it by the converged network adapter (CNA) manufacturer as an identifier in the FIP frame header.

2. The FCFs on the VLAN that have a similar supported addressing mode, match the maximum FCoE size, and can accept a login from the ENode reply to the discovery solicitation message by sending a solicited unicast discovery advertisement message to the soliciting ENode MAC.
3. The ENode MAC compiles a list of FCFs that are available for login, selects an FCF (the FCF with the highest priority setting), and is then ready to log in to the FCF.

The FIP discovery process is similar when the FC switch or FCF initiates discovery:

1. FCF MACs periodically send unsolicited multicast discovery advertisements on the FCoE VLAN to the *ALL-ENode-MACs* multicast address, to which all ENode MACs on the VLAN listen. The FIP keepalive advertisement period timer (FKA\_ADV\_PERIOD) controls the interval between multicast discovery advertisements. The multicast discovery advertisements inform ENodes on the VLAN that FCF VF\_Ports are available for establishing virtual links with ENode VN\_Ports.
2. ENodes on the FCoE VLAN create an entry for the FCF-MAC in their FCF-MAC lists.
3. An ENode can respond to the unsolicited multicast discovery advertisement with a unicast discovery solicitation message to the FCF.
4. Upon receiving the ENode's unicast discovery solicitation, the FCF replies with a unicast discovery advertisement sent to the ENode MAC.

After the ENode MAC selects an FCF to log in to, FIP initialization begins. To proceed from discovery to initialization, the server ENode addressing mode must match the FCF addressing mode and maximum FCoE size. In addition, the FCF must be configured to allow FIP FLOGI from that ENode.

### FIP FLOGI

---

FIP initialization is the server ENode login process to the FCF after the ENode discovers the FCFs (including FC switches) on the FCoE VLAN:

1. The ENode sends a fabric login (FLOGI) request message to the FCF.
2. The FCF replies to confirm the ENode login and provides the ENode a locally unique MAC address to use for FCoE frame transactions. The locally unique MAC address identifies the VN\_Port interface of the ENode for the session the login establishes. (The ENode continues to use the globally unique ENode MAC address for FIP frame transactions.)

The locally unique ENode MAC address for FCoE operations depends on whether the ENode address mode is configured as a fabric-provided MAC address (FPMA) or as a server-provided MAC address (SPMA; the gateway does not support ENodes in SPMA mode and rejects login attempts from ENodes in SPMA mode):

- For FPMA mode, the FCF provides a MAC address to the ENode during the FIP FLOGI exchange. The FPMA MAC address is a 48-bit value that is unique to the local fabric and consists of a 24-bit FCoE mapped address prefix (FC-MAP) and a 24-bit FC identifier (FCID). You can configure the FC-MAP value on the FCF or use the default value of 0EFC00h. The FCoE device must use the same FC-MAP value as the FCF, or else discovery and login fail.
- For SPMA mode, the server provides its MAC address to the FCF. The FCF compares the server MAC address to a list of addresses approved for FCoE access. The gateway does not support ENodes in SPMA mode.

Successful login instantiates a secure virtual link between the ENode and the FCF and terminates the FIP virtual link instantiation phase. The initiating server behind the ENode can exchange FC payloads with storage devices in the FC SAN by sending FCoE frames over the virtual link.

### FIP FDISC

---

After an ENode successfully logs in to an FCF and establishes a virtual link, the ENode can request more virtual links (sessions) over the same physical link by sending a FIP fabric discovery (FDISC) request. FDISC allows the creation of multiple separate secure VN\_Port virtual links on one physical link. Each virtual link receives a locally unique identifier from the FCF to enable security and separation between the VN\_Port virtual links sharing a physical ENode port. This is called N\_Port ID virtualization (NPIV).

FDISC is similar to FLOGI in that it requests a login and a unique ID from the FCF. The difference is that FLOGI obtains the initial login and ID for the physical link, whereas FDISC obtains additional logins and IDs so that multiple virtual links can share one physical link securely.

After a VN\_Port FDISC is complete, the application using that VN\_Port can send FCoE frames over the virtual link.

### FIP Maintenance (Keepalive Messages)

Although FCoE protocol handles the payload communication between the initiating ENode and the target FC device, FIP continues to run in the background. FIP constantly updates ENode FCF lists by listening to the periodic FCF multicast discovery advertisements, and it verifies the ability to reach the FCF by transmitting periodic FIP keepalive advertisements.

The ENode sends periodic ENode FIP keepalive advertisements to the FCF with the ENode MAC address as the identifier. The ENode also sends periodic VN\_Port FIP keepalive advertisements on behalf of each VN\_Port on the ENode, using the VN\_Port MAC address as the source MAC. The VN\_Port FIP keepalive advertisements occur every 90 seconds. The keepalive advertisements reset the session timer for the virtual link connection to the FCF. If the FCF does not receive a keepalive advertisement for a logged-in ENode or VN\_Port before the session timer expires, the virtual link is terminated.

The periodic unsolicited multicast discovery advertisements the FCF sends to the *ALL-ENode-MACs* address continuously verify that the FCF is still reachable. The ENode and the FCF periodic unsolicited multicast discovery advertisements occur at the configured FIP keepalive advertisement period interval (FKA\_ADV\_PERIOD) plus or minus a random offset to prevent a flood of simultaneous keepalive advertisements.

If the FCF does not receive the ENode keepalive advertisements before the FCF's FIP keepalive timer expires, the FCF considers the virtual link to the ENode as "down" and terminates the virtual link to the ENode. The keepalive timer expires in 2.5 times the configured timer value. This also terminates any VN\_Port virtual links instantiated by that ENode.

If the FCF does not receive a VN\_Port keepalive advertisement before the FCF's FIP keepalive timer expires, the FCF considers the virtual link to the VN\_Port as "down" and terminates the virtual link to that VN\_Port. The VN\_Port keepalive timer expires in 2.5 times the configured timer value.

If the ENode does not receive the FCF unsolicited multicast discovery advertisement before the ENode's FIP keepalive timer expires, the ENode considers the virtual link to the FCF as "down" and all of the VN\_Port virtual links to that FCF on the ENode are terminated.

### FIP LOGO

FIP handles ENode and VN\_Port logout when a session is finished.

## Understanding FIP Implementation

In a network that converges Fibre Channel (FC) and Ethernet traffic, when you configure the QFX Series as a Fibre Channel over Ethernet (FCoE)-FC gateway, it translates FCoE Initialization Protocol (FIP) frames from FCoE nodes (ENodes) into native FC frames for FC switches and translates native FC frames from FC switches into FIP frames for ENodes. To an FCoE device, the gateway appears to be an FCoE forwarder (FCF) and presents a fabric port (F\_Port) interface to the FCoE device ENode. To an FC switch, the gateway appears to be an FC host capable of N\_Port ID virtualization (NPIV) and presents a node port (N\_Port) interface to the FC switch F\_Port interface.

**NOTE:** The N\_Ports that the gateway presents to the FC switch are called proxy N\_Ports (NP\_Ports). To the FC switch, the gateway NP\_Ports appear to be native FC N\_Ports that are capable of performing NPIV. The NP\_Ports are proxies for the FCoE devices in the Ethernet network. The NP\_Ports convert FCoE traffic from the FCoE devices into native FC traffic for the FC switch. The NP\_Ports also convert native FC traffic from the FC switch into FCoE traffic for the FCoE devices on the Ethernet network.

---

### FIP Basics

FIP is enabled by default on all VLAN interfaces that belong to each FC fabric configured on the gateway. You can configure FIP parameters at a global level or on an individual interface. When you configure a parameter on an interface, it overrides the global configuration only for that interface. If you do not explicitly configure a FIP parameter, the gateway uses the default value.

In order for the gateway to connect FCoE devices with FCFs, the FIP parameters you configure on the gateway must be compatible with the parameters configured on the FC switch (for example, the FC-MAP values of the FC switch and of the FC fabric FIP configuration on the gateway must match, or the FC switch drops the frames).

When the NP\_Ports on the gateway come up, they perform an FC FLOGI to the connected FC switch. Successful login establishes communication between the gateway and the FC switch, and gateway NP\_Ports are marked for sending FDISC messages. Successful login also creates a next-hop entry in the gateway for the FC switch. If the FC switch rejects the FLOGI request, no link is established. The gateway maintains a list of valid FCF-MACs with which ENodes can connect.

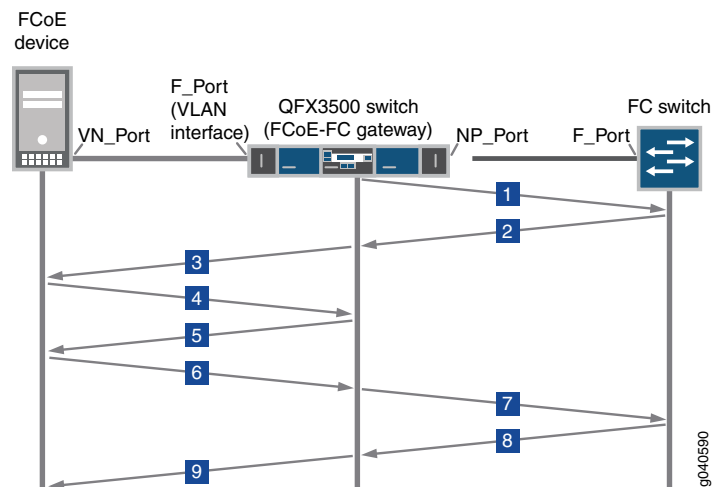

After establishing communication with an FC switch, the gateway can connect FCoE devices in the Ethernet network to the FC switch. All of the subsequent connections the gateway makes with FC switches as a proxy for ENodes (on behalf of ENodes) are virtualized (NPIV) connections.

### Fabric Login and FIP Login Overview

Figure 166 on page 4413 provides a brief overview of the FCoE-FC gateway fabric login to the FC switch and the FCoE device FIP login to the gateway.

**Figure 166: FCoE-FC Gateway Fabric Login and FIP Login**

The numbers in the following list correspond to the numbers in Figure 166 on page 4413 and briefly describe each step of the login process:

1. The FCoE-FC gateway NP\_Port sends an FC fabric login (FLOGI) request to the FC switch F\_Port.
2. The FC switch accepts the gateway FLOGI.
3. The gateway sends FIP multicast discovery advertisements on the FCoE VLAN (the gateway F\_Port interface) to all connected FCoE device ENodes.
4. The FCoE device ENode sends a discovery solicitation message to the gateway.
5. The gateway responds with a unicast discovery advertisement to the ENode.

**NOTE:** The gateway limits the number of discovery solicitations it accepts from FCoE devices to a maximum of 100 outstanding requests at any given time. If the gateway has 100 discovery solicitations outstanding, the gateway does not respond to new discovery solicitations. Instead, the gateway drops new discovery solicitations and reports the number of dropped discovery solicitations in the **Dropped** field of the `show fibre-channel fip statistics` command output. When there are fewer than 100 outstanding discovery solicitations, the system responds to new requests as usual with a discovery advertisement.

6. The FCoE device sends a FIP FLOGI or FIP FDISC message to the gateway.
7. The gateway converts the FIP FLOGI or FIP FDISC to an FC FDISC and forwards it to the FC switch to obtain a login for the FCoE device.
8. The FC switch responds to the FC FDISC by sending a new ID for the NPIV session to the gateway.
9. The gateway converts the FC FDISC response from the FC switch to a FIP FDISC response and forwards it to the FCoE device.

The following sections describe some of these steps in greater detail.

### Proxy FIP Discovery

---

After the gateway establishes a connection with an FC switch:

1. The gateway sends periodic FIP multicast discovery advertisements on the FCoE VLAN so that ENodes can add the gateway to their FCF lists.
2. The ENode initializes and sends a multicast discovery solicitation message on the FCoE VLAN. If the ENode has already initialized and has a list of FCFs, it can send a unicast discovery solicitation message to a particular FCF such as the gateway.

.....

**NOTE:** The gateway limits the number of discovery solicitations it accepts from FCoE devices to a maximum of 100 outstanding requests at any given time. If the gateway has 100 discovery solicitations outstanding, the gateway does not accept new discovery solicitations until there are fewer than 100 discovery solicitations outstanding.

.....

3. When the gateway receives a multicast discovery solicitation from an ENode, it responds by sending a unicast discovery advertisement to that ENode.

When the gateway receives a unicast discovery solicitation from an ENode, it also responds with a unicast discovery advertisement to the ENode.

To the ENode, the gateway appears to be an FCF.

The FIP discovery process adds the ENode to the gateway ENode database.

### Proxy FIP Initialization

---

1. If the ENode chooses to log in to the gateway, it responds to the gateway's unicast discovery advertisement by sending a login request in the form of a FIP FLOGI if it is the initial connection to the gateway. If the ENode already has an established session with the gateway and another application or virtual machine wants to connect to the gateway, the ENode sends a FIP FDISC to the gateway.
2. The gateway receives the FIP FLOGI or FIP FDISC from the ENode, converts it into an FC FDISC, and sends it through the least-loaded NP\_Port to the FC switch on behalf of the ENode. The FC FDISC message requests an FCID for the new virtual link.

**NOTE:** The gateway converts both ENode FIP FLOGI and FIP FDISC messages into FC FDISC messages, because the gateway has already performed FC FLOGI with the FC switch, so all subsequent connection requests on the gateway NP\_Port are FDISC requests for virtual (NPIV) connections. FDISC messages request a virtual N\_Port connection over an existing physical N\_Port connection.

3. The FC switch processes the request, accepts it, assigns a unique FCID for the connection, and then sends the response to the gateway. If the FC switch rejects the FDISC request, no virtual link is established.
4. The gateway maps the FC switch response to the ENode VN\_Port, converts the FC acceptance message to a FIP FLOGI or FIP FDISC response, and sends it to the ENode VN\_Port.
5. The ENode VN\_Port accepts the FCID, and the virtual link is established.

If an ENode sends an FDISC, the proxy gateway switch checks whether the ENode has already performed a FLOGI to create the initial connection. If the ENode has not performed a FLOGI, the FDISC request is dropped.

The FC protocol does not recognize multipoint-to-point connections. Although the gateway can aggregate traffic from multiple FCoE servers on one NP\_Port, each virtual link appears to be an individual point-to-point link between an FCoE ENode VN\_Port and the FC switch, not as an aggregated multipoint-to-point link. The gateway is essentially invisible to the FC protocol, so the virtual link looks and acts like a point-to-point link from the FCoE device to the FC switch.

### Proxy FIP Maintenance

The gateway sends and receives periodic FIP keepalive messages to and from ENode VN\_Ports to maintain the connection between the gateway and the ENodes.

### Proxy FIP Logout

As with FIP discovery and FIP FLOGI, the gateway represents the FCoE device in transactions with the FC switch and represents the FC switch in transactions with the FCoE device:

1. An ENode VN\_Port sends a FIP LOGO message to log off and terminate the virtual link connection.
2. The gateway converts the FIP LOGO to an FC LOGO and relays it to the FC switch.
3. The FC switch responds to the LOGO request.
4. The gateway converts the FC LOGO response to a FIP LOGO response and relays it to the VN\_Port, completing the logout and terminating the virtual link.

## Understanding FIP Parameters on an FCoE-FC Gateway

By default, FIP is enabled, and the default FIP settings are valid on all FCoE interfaces that are part of the gateway FC fabric. You can configure some FIP parameters at a global level or on a specific interface. Some FIP parameters can be configured only at the global level or only at the individual interface level. When you configure a parameter at the interface level, the configuration overrides the global setting for that interface only.

- [Priority on page 4418](#)

### FIP Keepalive Advertisement Period

---

The FIP keepalive advertisement period (fka-adv-period) is the time interval between messages that verify the connection is still valid and the device at the other end of the virtual link is still reachable. The ENode sends an ENode FIP keepalive advertisement to the gateway with the ENode MAC address as the source address to verify its reachability. The ENode also sends VN\_Port FIP keepalive messages for every VN\_Port on the ENode that is logged in to the gateway, with the VN\_Port MAC address as the source address.

The FIP keepalive advertisement period also determines the time interval between unsolicited multicast discovery advertisements from the gateway to the *ALL-ENode-MACs* multicast address. Unsolicited multicast discovery advertisements serve as keepalive messages from the gateway to the ENodes and also advertise the gateway's presence on the network.

The gateway sends the periodic unsolicited multicast discovery advertisements to the ENodes. On the gateway, you can configure a global FIP keepalive advertisement period for an FC fabric and you can configure a FIP keepalive advertisement period for individual interfaces to override the global setting.

### Addressing Mode

---

For FIP transactions, the ENode identifies itself using the globally unique MAC address assigned to the CNA by the manufacturer. After FIP has established a virtual link between an ENode VN\_Port and the gateway, for FCoE transactions, the VN\_Port identifies itself using a locally unique MAC address. The format of the locally unique MAC address depends on the addressing mode the fabric supports and the addressing mode the ENode is programmed to use.

The addressing mode is not a configurable parameter on the gateway. FC fabrics on the gateway support only the fabric provided MAC address (FPMA) addressing mode for FCoE transactions. The gateway does not support the server provided MAC address (SPMA) addressing mode. ENodes that use SPMA cannot log in to the gateway.

The FC switch assigns a locally unique FPMA to an ENode MAC through the FLOGI or FDISC process:

1. During the FIP discovery process, the ENode compiles a list of compatible FCFs (including the gateway) in the fabric. A compatible addressing mode is one of the criteria an FCF must meet to be added to an ENode's compatible FCFs list.
2. The ENode MAC transmits a FLOGI or FDISC to the FCF that includes the addressing modes the ENode supports.
3. If the FCF supports an addressing mode the ENode uses, the FCF accepts the FLOGI or FDISC and assigns the FPMA in the accept message (FIP FLOGI LS\_ACC or FIP NPIV FDISC LS\_ACC). If the ENode uses an addressing mode that is incompatible with the FCF, the FLOGI or FDISC is rejected.

The FPMA uniquely identifies a single VN\_Port at that ENode MAC in FCoE transactions with the FCF. Each VN\_Port connection receives its own unique FPMA to identify its virtual link connection. When an ENode uses NPIV to create multiple VN\_Ports, each VN\_Port virtual link receives its own unique FPMA to identify its traffic.

An FPMA consists of two concatenated 24-bit values:

1. The upper 24 bits are the FCF's FC-MAP value, which is a MAC address prefix that is unique to the fabric.
2. The lower 24 bits are the locally unique FCID that the FCF (FC switch) assigns to the VN\_Port.

The combination of these values guarantees that each FPMA is unique within a fabric.

### FC-MAP

The FCoE mapped address prefix (FC-MAP) value is a MAC address prefix used by the FCF that is unique within a given fabric. The FCF uses the FC-MAP for FCoE traffic within that fabric. The FCF rejects FCoE traffic that uses an FC-MAP value that does not match the FCF's FC-MAP value. In most cases, the FCF uses the default FC-MAP value (0EFC00), but a pool of 256 values is available (0EFC00 through 0EFCFF).

The gateway learns FC switches in the fabric that match the gateway fabric's FC-MAP value. To learn and communicate with an FC switch, the FC-MAP value for a fabric (or for the fabric's FCoE VLAN) on the gateway must match the FC switch's FC-MAP value. If the FC-MAP values do not match, no connection is established.

**NOTE:** Changing the FC-MAP value causes all logins to drop and forces the ENodes to log in again.

## FCoE Trusted Fabric

---

By default, all interfaces are untrusted interfaces. You can globally configure all of the ports in a specified gateway FC fabric to be FCoE trusted. This reduces system overhead by eliminating the need for filters. The total number of FCoE sessions (ENode to FCF sessions) the system can support is 2500 sessions. Sessions are defined as the combined number of VN\_Port to VF\_Port sessions and VN\_Port to VN\_Port sessions. (Although VN2VF and VN2VN sessions run in different FCoE VLANs, the session limit is a system limit, not a per-VLAN limit.)

**NOTE:** A session is a FLOGI or FDISC login to the FC SAN fabric. Session does not refer to end-to-end server-to-storage sessions. There is no limit to the number of end-to-end server-to-storage sessions.

**NOTE:** Changing the fabric ports from untrusted to trusted removes any existing FIP snooping filters from the ports and terminates the existing sessions. Changing the fabric ports from trusted to untrusted forces all of the FCoE sessions on those ports to log out so that when the ENodes and VN\_Ports log in again, the switch can build the appropriate FIP snooping filters.

## Maximum Number of FCoE Sessions Per ENode

---

You can configure the maximum number of FCoE session logins from each ENode that are permitted on the gateway FC fabric. The number of sessions is the ENode FLOGI session plus the VN\_Port FDISC sessions on that ENode. Regardless of whether the fabric is trusted or untrusted, the maximum number of FCoE sessions per ENode is 2500 sessions. The total number of sessions cannot exceed the gateway fabric's maximum limit of 2500 sessions.

The maximum number of FCoE sessions per ENode is a global configuration for all members of the gateway FC fabric and cannot be configured on a per-interface basis.

**NOTE:** Session does not refer to end-to-end server-to-storage sessions. There is no limit to the number of end-to-end server-to-storage sessions.

## Priority

---

When the FIP discovery process offers an ENode the choice of more than one FCF-MAC on a given FCF to use for login, the ENode chooses the FCF-MAC to which to send a login request based on the FCF-MAC priority. The lower the priority number, the higher the FCF-MAC's priority. The ENode selects the highest-priority (lowest priority number) FCF-MAC for the login request.

An ENode can receive multiple FCF-MAC advertisements from the same FCF in two ways:

- During the FIP discovery process, an FCF can receive an ENode MAC's multicast discovery solicitation on multiple FCF-MACs. Each FCF-MAC replies with a unicast discovery advertisement to the ENode. The ENode determines that the advertisements are from the same FCF, because the value in the Name\_Identifier descriptor is the same in each advertisement.
- During the FIP discovery process, an ENode MAC can receive unsolicited multicast discovery advertisements from multiple FCF-MACs on the same FCF. The ENode determines that the advertisements are from the same FCF, because the value in the Name\_Identifier descriptor is the same in each advertisement.

On the gateway, you can configure the priority value for an entire fabric or for an individual interface. The default value for both the fabric and the individual interfaces is 128 (the highest priority is 0; the lowest priority is 255).

## Understanding Fibre Channel Virtual Links

A virtual link emulates a secure point-to-point connection between the virtual node port (VN\_Port) of a Fibre Channel over Ethernet (FCoE) node (ENode) and the virtual fabric port (VF\_Port) of an FCoE forwarder (FCF). The combination of the FCF media access control (MAC) address and the VN\_Port MAC address uniquely identifies each virtual link. Uniquely identifying each virtual link enables the logical separation of traffic that belongs to each virtual link. A single physical link between an ENode and an FCF can carry multiple virtual links and maintain secure, separate transport of traffic on the different virtual links.

Virtual links are necessary because Fibre Channel protocol does not recognize multipoint-to-point connections. Even when multiple connections are aggregated on one physical port, FCoE Initialization Protocol (FIP) presents each virtual link as an individual point-to-point link between an ENode VN\_Port and an FCF VF\_Port.

## Understanding Interfaces on an FCoE-FC Gateway

When the QFX Series functions as an FCoE-FC gateway to connect FCoE devices on an Ethernet network to a Fibre Channel (FC) switch in a storage area network (SAN), it handles FCoE traffic from hosts and native FC traffic from the FC switch. To support this architecture, each local FC fabric configured on the gateway (in the **fc-fabrics** configuration hierarchy) must have:

- An Ethernet-network-facing F\_Port interface for the FCoE VLAN to connect to FCoE device VN\_Ports in the form of an FCoE VLAN interface. Multiple VF\_Ports are initiated on the F\_Port interface, one VF\_Port for each ENode that logs in to the FC network.
- One or two blocks of six proxy N\_Port (NP\_Port) interfaces to connect to FC switch fabric ports (F\_Ports).

Each FC fabric is local to the gateway on which you configure it. This means that both the FC switch and the FCoE devices must be connected to the same gateway (QFX3500 switch or QFabric system Node device), and that all of the interfaces configured for the local fabric also must be on that gateway. FC fabric traffic does not flow between different Node devices in a QFabric system.

This topic describes:

- [Native FC Interfaces to the FC Switch on page 4420](#)
- [FIP Login Session Limits on page 4422](#)
- [Trusted and Untrusted Interfaces on page 4425](#)
- [Buffer-to-Buffer Credit Recovery on page 4426](#)
- [FCoE VLAN Interface to FCoE Devices on page 4427](#)
- [Assigning Interfaces to a Fibre Channel Fabric on page 4430](#)
- [Deleting a Fibre Channel Interface on page 4430](#)

---

### Native FC Interfaces to the FC Switch

You must configure either 6 or 12 of the physical interfaces on the gateway as native FC NP\_Port interfaces to connect to FC switch F\_Port interfaces. By default, all of the gateway interfaces are Ethernet interfaces, so you must explicitly configure the interfaces that you want to use as FC interfaces.

You can configure the FC-capable ports xe-0/0/0 through xe-0/0/5 as fc-0/0/0 through fc-0/0/5, and ports xe-0/0/42 through xe-0/0/47 as fc-0/0/42 through fc-0/0/47 to create blocks of native FC interfaces. You cannot individually configure a single port as a native FC interface. Within these port blocks, you cannot mix FC interfaces with Ethernet interfaces. All of the ports in a block must be either native FC interfaces or Ethernet interfaces.

You cannot configure ports xe-0/0/6 through xe-0/0/41 and ports xe-0/1/1 through xe-0/1/15 as native FC ports; they can only be Ethernet ports. Native FC ports do not handle Ethernet traffic (including FCoE traffic); they handle only native FC traffic and must connect to native FC ports.

You can configure:

- Six native FC interfaces by configuring either ports xe-0/0/0 through xe-0/0/5 as fc-0/0/0 through fc-0/0/5 or ports xe-0/0/42 through xe-0/0/47 as fc-0/0/42 through fc-0/0/47.
- Twelve native FC interfaces by configuring ports xe-0/0/0 through xe-0/0/5 as fc-0/0/0 through fc-0/0/5 and ports xe-0/0/42 through xe-0/0/47 as fc-0/0/42 through fc-0/0/47.
- No native FC interfaces by leaving ports xe-0/0/0 through xe-0/0/5 and ports xe-0/0/42 through xe-0/0/47 in their default state as Ethernet interfaces.

Each native FC interface can belong to only one local FC fabric configured on the gateway. You can configure up to 12 FC fabrics on a gateway, but each FC fabric must use different native FC interfaces to connect to an FCF. (Although the native FC ports are configured in blocks, each individual port can belong to a different FC fabric.) Native FC interfaces can be configured as loopback interfaces.

- [Port Mode on page 4421](#)
- [NPIV on page 4421](#)
- [Port Speed on page 4422](#)

### **Port Mode**

The gateway presents a proxy N\_Port (NP\_Port) interface to the FC switch. An NP\_Port connects to a single FC switch F\_Port using a point-to-point link (in other architectures an N\_Port can also connect in a point-to-point link to another N\_Port, but that is not a valid configuration on the gateway).

You must explicitly configure each native FC interface connected to an FC switch as an NP\_Port. The gateway NP\_Ports act as a proxy for the FCoE device virtual N\_Ports (VN\_Ports) when the VN\_Ports attempt to connect to the FC switch.

When the FC switch is a trusted switch, configure the fabric as **fcoe-trusted** to reduce overhead caused by the VN\_Port to VF\_Port (VN2VF\_Port) FIP snooping filters that are automatically installed on untrusted ports.

### **NPIV**

FC requires a unique point-to-point link between the FC switch and each host N\_Port. The gateway creates an independent virtual link for each FCoE device session by mapping each FCoE device to a virtualized N\_Port through the gateway's proxy function. This process is called N\_Port ID virtualization (NPIV).

NPIV makes each virtual link look like a dedicated point-to-point link to the FC switch. In this way, multiple FCoE devices, multiple applications, and multiple virtual machines on an FCoE device can connect to an FC switch using one physical port instead of using a physical port for each host connection. The virtual link creates a secure boundary between traffic from different sources that are on a single physical port.

FCoE-FC gateway mode implements NPIV as follows:

1. An NP\_Port on the gateway comes up and logs in to the attached F\_Port on the FC switch. The FC switch sees the gateway port as a physical FC device N\_Port and assigns it a unique FCID. This establishes the physical point-to-point link between the gateway and the FC switch.
2. The gateway receives a FIP discovery message from an FCoE device that seeks to log in to the FC network. To the FCoE device, the gateway presents a virtual F\_Port (VF\_Port) interface and appears to be an FCF.
3. The gateway converts the FCoE device's message into an FC fabric discovery (FDISC) message and sends it through the least-loaded physical NP\_Port to the FC switch. The FDISC message requests an FCID for the new virtual link.
4. The FC switch processes the request, accepts it, assigns a unique FCID for the connection, and sends the response.
5. The gateway maps the FC switch response to the host FCoE device's VN\_Port and sends a FIP acceptance advertisement to the FCoE device.
6. The FCoE device accepts the FCID.

If the FC switch rejects the FDISC, the gateway relays the rejection to the FCoE device VN\_Port.

### **Port Speed**

The gateway supports configuring FC port speeds of 2 Gbps, 4 Gbps, or 8 Gbps. FC ports can also autonegotiate the port speed to 2, 4, or 8 Gbps.

### **FIP Login Session Limits**

---

A FIP login session is a fabric login (FLOGI) or fabric discovery (FDISC) login to the FC SAN fabric. (A session here does not refer to an end-to-end server-to-storage session; there is no limit to the number of end-to-end server-to-storage sessions.) You can limit the maximum number of FIP login sessions on each gateway Node device (QFX3500 switch or QFabric system Node device configured in FCoE-FC gateway mode), on each local gateway FC fabric, and on each individual NP\_Port interface in a local FC fabric:

- Gateway Node devices and Node groups—The total number of FIP login sessions on the gateway Node or Node group (the sum of the sessions on all of the NP\_Port interfaces in all of the local FC fabrics on the gateway Node or Nodes) cannot exceed the limit. When a gateway reaches the maximum session limit, the gateway sends subsequent multicast discovery advertisements (MDAs) with the availability bit set to 0 (zero) to prevent additional ENode login attempts. If the maximum number of sessions is running on the gateway, ENodes cannot use the gateway to log in new sessions to the FC switch. When the number of sessions falls below the maximum, the gateway sets the availability bit in MDAs to 1 so that ENodes can again log in new sessions. When a session slot becomes available, the system accepts the first session request to fill the slot.
- FC fabric—The total number of FIP login sessions on an FC fabric (the sum of the sessions on all of the NP\_Port interfaces that belong to the fabric) cannot exceed the

limit. When a fabric reaches the maximum session limit, the gateway sends MDAs associated with that fabric with the availability bit set to 0 to prevent additional ENode login attempts.

**NOTE:** Other FC fabrics on the same gateway can still accept ENode logins as long as the maximum session limit for those fabrics and the maximum session limit for the gateway (the Node device) have not been met.

- **NP\_Port interfaces**—The total number of FIP login sessions cannot exceed the interface's limit. When an interface reaches the maximum session limit, the gateway removes it from the load-balancing list for that FC fabric to prevent the gateway from attempting to assign new sessions to the interface. Other interfaces in the FC fabric can still accept logins until the FC fabric or gateway reaches its maximum session limit. However, the interface that reached the maximum session limit cannot be assigned new sessions until the number of sessions on the interface falls below the limit.

**BEST PRACTICE:** Configure a maximum session limit for each NP\_Port interface that is less than or equal to the number of FIP sessions the directly connected FC switch port is configured to support. This prevents the gateway from attempting to assign new login sessions to an interface when the connected FC switch port reaches its maximum number of sessions.

- [FCoE Trusted and Untrusted Interface Session Limits on page 4423](#)
- [Configuring Consistent Session Limits on page 4423](#)
- [Decreasing Session Limits on page 4424](#)
- [Increasing Session Limits on page 4425](#)
- [Effect of Deactivating and Then Reactivating the Configuration on Session Limits on page 4425](#)

### ***FCoE Trusted and Untrusted Interface Session Limits***

The maximum number of VN2VF\_Port FCoE login sessions that each gateway can support is 2500 sessions, regardless of whether interfaces are trusted or untrusted. (In software releases earlier than Junos OS Release 12.3, the session limit on untrusted interfaces and untrusted fabrics was 376 sessions.)

### ***Configuring Consistent Session Limits***

The system does not perform commit checks to enforce consistent session limit configuration. For example, the system does not prevent you from configuring a higher limit for ENode sessions than the total session limit for the gateway Node device, or from configuring a higher limit on an interface than on the fabric to which the interface belongs.

To prevent unexpected FIP login rejections, you should configure consistent Node device, fabric, and interface session limits. For example:

- The session limit of an interface should not exceed the session limit of the fabric to which it belongs.
- For interfaces that belong to the same fabric, the sum of the interface session limits should not exceed the fabric session limit.
- The fabric session limit should not exceed the session limit of the gateway Node device.
- For fabrics that belong to the same gateway Node device, the sum of the fabric session limits should not exceed the Node device session limit.

Session limit configuration considerations include:

- The fabric session limit restricts how many sessions can run on the NP\_Port interfaces that belong to that fabric. If the combined session limits of the interfaces exceed the fabric session limit, the total number of sessions on the interfaces is the fabric limit.

For example, if a fabric has three NP\_Port interfaces, and each NP\_Port interface has a limit of 500 sessions (total of 1500 sessions for the three interfaces), but the fabric has a limit of 1000 sessions, the combined number of sessions on the three interfaces is limited to 1000 sessions.

- The gateway Node device session limit restricts how many sessions can run on the fabrics that belong to that gateway. If the combined session limits of the fabrics exceed the gateway Node device session limit, the total number of sessions on the fabrics is the gateway Node device limit.

For example, if a gateway has two fabrics, and each fabric has a limit of 1000 sessions (total of 2000 sessions for the two fabrics), but the gateway has a limit of 1500 sessions, the combined number of sessions on the two fabrics is limited to 1500 sessions.

Hierarchically, the gateway Node device session limit is the maximum limit for all sessions on the gateway, regardless of fabric and interface session limits. In the same way, the fabric session limit supersedes the interface session limit.

When session limits are exceeded, no new logins are accepted until a session slot becomes free.

### ***Decreasing Session Limits***

If you decrease the session limit, the currently logged in sessions are terminated as follows:

- Gateway Node devices and Node groups—Decreasing the session limit terminates all of the sessions on the Node device (all sessions on all interfaces on all fabrics). If the gateway Node device is part of a Node group, all sessions on all members of the Node group are terminated.
- Fabric—Decreasing the session limit terminates all of the sessions on all of the interfaces that belong to the fabric.
- NP\_Port interfaces—Decreasing the session limit terminates all of the sessions on the interface and also terminates all of the sessions on any other interfaces that belong to the same fabric.

After you decrease a session limit, the sessions are terminated even if the new session limit is greater than the number of currently active sessions. For example:

- An interface has 300 active sessions.
- The current session limit is 1000 sessions.
- You decrease the session limit to 500 sessions and commit the new configuration.
- All 300 sessions are logged out, even though the new session limit is greater than the number of sessions running.

After the session limit change takes effect, the ENodes log in again and establish new sessions, up to the new session limits.

### ***Increasing Session Limits***

Increasing the session limits does not disrupt logged in sessions.

### ***Effect of Deactivating and Then Reactivating the Configuration on Session Limits***

If you decrease session limits, all ENodes are logged out. Deactivating and then reactivating the configuration can have the same effect as decreasing the session limit, which results in the ENodes being logged out.

The ENode logouts occur because when you deactivate the configuration, the system reverts to the default session limit of 2500 sessions (the maximum number of sessions). When you reactivate the configuration, the system uses the configured session limit. Unless the configured session limit is equal to the maximum session limit, reactivating the configuration decreases the session limit, which causes the ENodes to be logged out.

For example, if you:

1. Configure and commit a limit of 400 sessions.
2. Allow ENodes to log in and start sessions.
3. Deactivate the configuration.
4. Reactivate the configuration.
5. The ENode sessions are logged out because deactivating the session increased the session limit from 400 to 2500.

Because an increase in the session limit does not affect existing sessions, the running ENode sessions are not affected. However, reactivating the configuration decreased the session limit from 2500 back to 400. The session limit decrease causes the ENode sessions to be logged out.

### ***Trusted and Untrusted Interfaces***

---

By default, gateway fabric interfaces are untrusted interfaces. If you do not configure a gateway fabric as an FCoE trusted fabric to set all of the gateway fabric interfaces as trusted interfaces, the gateway installs VN2VF\_Port FIP snooping filters on the fabric ports.

If you configure a gateway fabric as an FCoE trusted fabric, the gateway does not install VN2VF\_Port FIP snooping filters on the fabric interfaces. This is usually done when the gateway is connected to an FCoE transit switch that has VN2VF\_Port FIP snooping enabled.

Regardless of whether an interface is trusted or untrusted, the maximum session limit is 2500 sessions.

**NOTE:** The session limit for a Node group is the same as the session limit for an individual Node device, 2500 sessions. Even if more than one Node device in a Node group is acting as an FCoE-FC gateway, the total maximum number of sessions on all Node devices in the Node group is 2500 sessions.

The default maximum login session value for Node devices (on QFabric systems, the maximum applies to each Node device), trusted fabrics, and interfaces in trusted fabrics is 2500 sessions.

### Buffer-to-Buffer Credit Recovery

---

Buffer-to-buffer credits represent the number of receive buffers an interface can use to store FC frames. Buffer-to-buffer credit determines buffer-to-buffer flow control. When an interface transmits a frame, it decrements its buffer-to-buffer credit count by one. When the destination interface forwards the frame and frees a buffer, it sends a receiver ready (R\_RDY) primitive to the transmitting interface. Each R\_RDY primitive the transmitting interface receives increments its buffer-to-buffer credit count by one.

Both interfaces on an FC link track buffer-to-buffer credits. As long as buffer-to-buffer credits are available, the transmitter continues to send frames. If the number of buffer-to-buffer credits reaches zero (0), transmission stops until buffer-to-buffer credits are available, as indicated by the reception of an R\_RDY primitive. Buffer-to-buffer credits can compensate for long cable distances to limit throughput and prevent buffer overflow.

However, if frame corruption or errors transmitting R\_RDY primitives occur, the buffer-to-buffer credit counters on the sending and receiving interfaces do not have the same values. This causes the permanent loss of buffer-to-buffer credits. When credits are lost, the buffer credit count can decrement to zero and indicate that there is no available buffer space even if buffer space is actually available. This can result in unnecessary link idle time.

To recover lost buffer-to-buffer credits, you can configure a buffer-to-buffer credit state change number (BB\_SC\_N). BB\_SC\_N must be configured on both ends of the connection. If only one end of the connection is configured for BB\_SC\_N, the feature is disabled. The two directly connected FC interfaces communicate the BB\_SC\_N value during fabric login (FLOGI).

When you enable BB\_SC\_N on the interfaces on both ends of an FC link, the interfaces exchange buffer-to-buffer state change send (BB\_SCs) and buffer-to-buffer state change receive (BB\_SCr) primitives to track the number of frames sent and the number of R\_RDY primitives received. The state change number determines the number of frames and R\_RDY primitives the interfaces exchange between consecutive BB\_SCn primitives and

between consecutive BB\_SCr primitives. The state change primitives inform each interface of the other interface's frame count and R\_RDY count states.

The state counters should match so that each interface knows and agrees with the other interface's state. If the interface at either end of the link detects a discrepancy, it knows that a frame or an R\_RDY primitive was corrupted or dropped.

For example, if a receiving interface has sent two R\_RDY primitives but the BB\_SCr that the interface receives from the sending interface only counts one R\_RDY primitive received, it reveals that one R\_RDY primitive was not delivered successfully and that one buffer-to-buffer credit was lost. When one of the interfaces on the link detects a discrepancy, the interfaces can take corrective action and recover the lost buffer-to-buffer credits.

Enabling the buffer-to-buffer credit recovery feature does not impact buffer resources and has an insignificant impact on processing resources.

If buffer-to-buffer credit recovery is not used, then when there is no buffer credit on a port, a timeout and recovery mechanism prevents buffer overflow.

### FCoE VLAN Interface to FCoE Devices

Each FC fabric configured on the gateway includes at least one FCoE VLAN interface to connect the FCoE devices on the FCoE VLAN to the FC switch. (Including the FCoE VLAN interface and the native FC interfaces in the FC fabric configuration connects them.) FCoE VLANs can include any Ethernet interface on the switch that is in tagged-access or trunk mode. The best practice is to configure Ethernet interfaces that belong to FCoE VLANs in **tagged-access** port mode.

**NOTE:** The Ethernet interfaces that connect to FCoE devices must include a native VLAN to transport FIP traffic, because FIP VLAN discovery and notification frames are exchanged as untagged packets.

FCoE VLANs should carry only FCoE traffic. You should not mix FCoE traffic and standard Ethernet traffic on the same VLAN.

**NOTE:** FCoE VLANs (any VLAN that carries FCoE traffic) support only Spanning Tree Protocol (STP) and link aggregation group (LAG) Layer 2 features.

Each FCoE VLAN interface can belong to only one FC fabric configured on the gateway. A gateway FC fabric can have more than one FCoE VLAN, but each FCoE VLAN in the FC fabric must belong only to that FC fabric. You can configure more than one FC fabric on a gateway; each FC fabric must use different FCoE VLAN interfaces to connect to FCoE devices.

**NOTE:** Storm control must be disabled on all Ethernet interfaces that belong to the FCoE VLAN to prevent FCoE traffic from being dropped.

- [Port Mode on page 4428](#)
- [Disabling Storm Control on FCoE Interfaces on page 4429](#)
- [NPIV Support on page 4430](#)
- [VN2VF\\_Port FIP Snooping on page 4430](#)

### **Port Mode**

You must explicitly configure the FCoE VLAN interface in F\_Port mode. All members of the FCoE VLAN use the FCoE VLAN interface as the connection to the gateway NP\_Port interfaces and ultimately to the FC switch.

All of the 10-Gigabit Ethernet interfaces that are members of an FCoE VLAN should be configured as **tagged-access** port mode interfaces. However, the system also supports configuring these interfaces in **trunk** port mode.

**BEST PRACTICE:** Use **tagged-access** port mode for Ethernet interfaces that are connected to converged network adapters (CNAs) in FCoE access devices.

Use trunk port mode when an Ethernet interface is an interswitch link (ISL)—that is, when the port is connected to another switch. For example, if a port is connected to a transit switch that is performing VN2VF\_Port FIP snooping, configure the port in trunk mode and as an FCoE trusted port.

The **tagged-access** port mode was not available in Junos OS Release 11.3 and earlier releases. In Release 11.3 and earlier, only trunk port mode was used for Ethernet interfaces that belong to an FCoE VLAN. Because **tagged-access** mode is now available, using trunk mode for interfaces connected to FCoE CNAs is not recommended.

If an existing configuration uses trunk mode for ports connected to FCoE CNAs, you can change the port mode to **tagged-access** without disrupting traffic. Although we recommend changing the port mode of these ports from trunk mode to **tagged-access** mode as a best practice, it is not mandatory. New configurations should use **tagged-access** mode for interfaces that connect to FCoE devices.

There are several advantages of configuring Ethernet ports connected to FCoE devices in **tagged-access** mode instead of in **trunk** mode:

- It is standard practice to configure ISL ports as trunk ports.
- It is standard practice not to configure ports that connect to servers as trunk ports.
- When an interface goes down, if that interface is in **trunk** mode, then the FCoE sessions on that interface are terminated only after the gateway stops receiving FIP keepalive

messages from the ENode and exceeds 2.5 times the FIP keepalive timeout advertisement value. If the interface is in **tagged-access** mode and the interface goes down, the gateway sends a FIP message to terminate the sessions on the interface.

- Similarly, if an ENode session moves from one interface to another interface, if the original interface is in **trunk** mode, the session is not removed from the interface until the gateway stops receiving FIP keepalive messages and exceeds 2.5 times the FIP keepalive advertisement timeout value. But if the interface is in **tagged-access** mode, the gateway detects that the session is no longer on the interface, does not refresh the FIP keepalive timer, and thus ages out the session.

**NOTE:** FIP is enabled on the FCoE VLAN, which is a Layer 3 interface. As with other Layer 3 interfaces under Junos OS, when the last member (10-Gigabit Ethernet interface) of the FCoE VLAN is deleted, the FCoE VLAN interface is internally marked as “down.” When the Layer 3 FCoE VLAN interface is marked as “down”, FIP stops running on it. When the last member interface is deleted from an FCoE VLAN and FIP stops running, the result could be an immediate timeout for the VN\_Ports that were connected on that interface, regardless of whether the port mode is **tagged-access** or **trunk**.

### ***Disabling Storm Control on FCoE Interfaces***

Storm control is enabled by default on all interfaces. When a QFX3500 switch or a QFX3500 Node device is acting as an FCoE-FC gateway, disable storm control on the QFX3500 switch or QFX3500 Node device, and if desired, enabled it on ports that are not part of an FCoE-FC gateway VLAN. Storm control is not supported on the FCoE interfaces of an FCoE-FC gateway VLAN. Configuring storm control on an Ethernet interface and including that interface in an FCoE-FC gateway may have undesirable effects, including FCoE packet loss.

You can disable storm control in either of two ways:

- Disable storm control on all interfaces, then enable storm control on the interfaces you want to use storm control. (From the default configuration, you cannot disable storm control on individual interfaces because the default configuration enables storm control on **all** interfaces, not on individual interfaces.)

For example, if you want interfaces xe-0/0/20, xe-0/0/21, and xe-0/0/22 to use storm control, disable storm control on all interfaces, then enable storm control on those three interfaces:

1. Disable storm control on all interfaces:

```
user@switch# delete ethernet-switching-options storm-control interface all
```

2. Enable storm control on interfaces xe-0/0/20, xe-0/0/21, and xe-0/0/22:

```
user@switch# set ethernet-switching-options storm-control interface xe-0/0/20
user@switch# set ethernet-switching-options storm-control interface xe-0/0/21
user@switch# set ethernet-switching-options storm-control interface xe-0/0/22
```

- Disable storm control for all unknown unicast traffic on all interfaces by including the following statement in your configuration:

```
user@switch# set ethernet-switching-options storm-control interface all no-unknown-unicast
```

### ***NPIV Support***

The gateway supports FCoE device NPIV. For example, a single physical FCoE device can have multiple virtual machines running on it. Each virtual machine can instantiate a separate virtual connection to the gateway, which results in its own virtual link to the FC switch. In this way, an FCoE device can have multiple separate connections to the FC SAN on a single physical port.

This is similar to the NPIV function the gateway performs with the FC switch to support multiple virtual FCoE device connections on one physical NP\_Port.

The gateway presents multiple VF\_Port interfaces on each FCoE VLAN interface to support the requirement for unique, secure virtual links.

### ***VN2VF\_Port FIP Snooping***

The FCoE-facing ports that belong to an FCoE VLAN on a gateway are enabled for VN2VF\_Port FIP snooping automatically. You can disable VN2VF\_Port FIP snooping on any individual interface by configuring it as a trusted interface.

### ***Assigning Interfaces to a Fibre Channel Fabric***

---

You assign at least one FCoE VLAN interface and at least one native FC interface to each FC fabric you configure on the gateway. All of the interfaces that belong to an FC fabric must reside on the same gateway device. Interfaces on different gateways cannot belong to the same FC fabric, because an FC fabric is local to a single gateway device.

### ***Deleting a Fibre Channel Interface***

---

To delete an FC interface or an FCoE VLAN interface, you must delete the interface from the fabric first and then delete the interface from the switch.

## Understanding Load Balancing in an FCoE-FC Gateway Proxy Fabric

You can balance or rebalance the load on the ports in an FCoE-FC gateway proxy fabric in order to avoid overutilizing or underutilizing the links. Load balancing is distributing sessions across the available native Fibre Channel (FC) interfaces (NP\_Ports) that belong to a local gateway FC fabric to create a relatively equal load on all the fabric links. Load rebalancing is redistributing the existing sessions across the available NP\_Port links on a local gateway FC fabric.

**NOTE:** A session is a fabric login (FLOGI) or fabric discovery (FDISC) login to the FC SAN fabric. Session does not refer to end-to-end server-to-storage sessions.

The fabric-facing NP\_Port links of an FCoE-FC gateway use different load-balancing methods than the FCoE-network-facing Ethernet links. You can balance the load on the FCoE-network facing Ethernet port members of the FCoE-FC gateway by configuring the ports in a link aggregation group (LAG). This topic focuses on NP\_Port load balancing.

Balancing the load on FCoE-FC gateway NP\_Port links consists of two steps:

1. Choosing the algorithm used to balance and rebalance the link load
2. Choosing whether to rebalance link loads automatically or only when you explicitly request a rebalance (load-rebalancing method)

You can configure a different load-balancing algorithm and use a different rebalancing method for each local FC fabric on the FCoE-FC gateway. The load-balancing algorithm and automated rebalancing, if configured, apply to all NP\_Port interfaces in the local FC fabric.

This topic describes:

### Load-Balancing Algorithms

---

You can choose one of three load-balancing algorithms to configure the way the switch balances the link loads. The switch uses the configured algorithm to balance the link loads when NP\_Ports are initialized and whenever link loads are rebalanced. Regardless of whether you configure automated load rebalancing or use on-demand load rebalancing, the switch uses the configured algorithm to balance the link load:

- **Simple load balancing**—The switch assigns each ENode FLOGI session and VN\_Port FDISC session to the least-loaded link. The switch can place FDISC sessions on a different link than the parent FLOGI session (an ENode FLOGI session and its subsequent FDISC sessions can be placed on different links). Simple load balancing is the default load-balancing algorithm. Rebalancing the link load disrupts only selected sessions to minimize the impact (the switch uses an algorithm to log out only the sessions that need to be moved to other links to balance the load when those sessions log in again).
- **ENode-based load balancing**—When an ENode logs in to the fabric, the switch places all subsequent VN\_Port FDISC sessions associated with that ENode on the same link as the ENode FLOGI session, regardless of the link load. New ENode FLOGIs are placed on the least-loaded link. The switch calculates the link load based on the combined total of FLOGIs and FDISCs on each NP\_Port link. Rebalancing the link load disrupts all sessions (all sessions log out and then log in again).
- **FLOGI-based load balancing**—Similar to ENode-based load balancing; when an ENode logs in to the fabric, the switch places all subsequent VN\_Port FDISC sessions associated with that ENode on the same link as the ENode FLOGI session, regardless of the link load. New ENode FLOGIs are placed on the least-loaded link.

One difference between ENode-based load balancing and FLOGI-based load balancing is that the switch calculates the link load based only on the number of FLOGIs on each NP\_Port link. The algorithm does not count FDISCs. Another difference is that instead of disrupting all sessions on a link load rebalance, the system disrupts only selected sessions to minimize the impact (the switch uses an algorithm to log out only the sessions that need to be moved to other links to balance the load when those sessions log in again).

**NOTE:** Changing the load-balancing algorithm when FCoE sessions are running forces the FCoE sessions to log out and then log in again.

---

If you do not explicitly configure the load-balancing algorithm, the switch uses simple load balancing by default on the all NP\_Port interfaces that belong to a given local FC fabric.

The following sections describe how each algorithm works, its advantages and disadvantages, and what happens when NP\_Port links come up for the first time, when an NP\_Port link is added to existing links, and when you rebalance the link load:

- [Simple Load Balancing on page 4433](#)
- [ENode-Based Load Balancing on page 4434](#)
- [FLOGI-Based Load Balancing on page 4434](#)
- [Load-Balancing Algorithm Comparison on page 4435](#)

### **Simple Load Balancing**

Simple load balancing provides the most equal load balancing across links because each VN\_Port FDISC session can be assigned to the least-loaded link, regardless of whether the parent ENode FLOGI session is on that link. (The parent ENode is the ENode that originates the logins to the fabric. After the parent ENode logs in, the VN\_Ports on that ENode can log in to the fabric using FDISC.)

The FCoE-FC gateway performs simple load balancing by default on the NP\_Ports that connect the gateway to the FC SAN. When an ENode sends a FLOGI request to the gateway, the gateway checks the NP\_Ports that connect it to the FC SAN and assigns the new session to the least-loaded link.

Every time an ENode sends a FLOGI or an FDISC request, the gateway assigns the new session to the least-loaded NP\_Port link. After the gateway assigns an ENode FLOGI session to an NP\_Port, subsequent FDISC requests by the same ENode can result in sessions being assigned to different NP\_Ports, because the gateway always assigns the new session to the least-loaded interface.

**NOTE:** Because VN\_Port sessions might be placed on a different link than their parent ENode, if the link that contains the ENode goes down, only the ENode session and any of its VN\_Port sessions that are on that link go down. VN\_Port sessions on other links remain active as long as the link is up and the VN\_Port is not logged out.
