Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description

Define an MSDP peering relationship. An MSDP routing device must know which routing devices are its peers. You define the peer relationships explicitly by configuring the neighboring routing devices that are the MSDP peers of the local routing device. After peer relationships are established, the MSDP peers exchange messages to advertise active multicast sources. To configure multiple MSDP peers, include multiple **peer** statements.

By default, the peer's options are identical to the global or group-level MSDP options. To override the global or group-level options, include peer-specific options within the peer (Protocols MSDP) statement.

At least one peer must be configured for MSDP to function. You must configure ***address*** and **local-address**.

Options

address—Name of the MSDP peer.

The remaining statements are explained separately.

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

rib-group (Protocols MSDP)

Syntax rib-group *group-name*;

Hierarchy Level
[edit logical-systems *logical-system-name* protocols msdp],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols msdp],
[edit protocols msdp],
[edit routing-instances *routing-instance-name* protocols msdp]

Release Information
Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Associate a routing table group with MSDP.

Options ***group-name***—Name of the routing table group. The name must be one that you defined with the **rib-groups** statement at the **[edit routing-options]** hierarchy level.

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

source

Syntax

```
source ip-address</prefix-length> {
  active-source-limit {
    maximum number;
    threshold number;
  }
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols msdp],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols msdp],
[edit protocols msdp],
[edit routing-instances *routing-instance-name* protocols msdp]

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description

Limit the number of active source messages the routing device accepts from sources in this address range.

Default

If you do not include this statement, the routing device accepts any number of MSDP active source messages.

Options

The other statements are explained separately.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

threshold

Syntax

threshold *number*;

Hierarchy Level

[edit logical-systems *logical-system-name* protocols msdp active-source-limit],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols msdp active-source-limit],
[edit protocols msdp active-source-limit],
[edit routing-instances *routing-instance-name* protocols msdp active-source-limit]

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description

Configure the random early detection (RED) threshold for MSDP active source messages. This number must be less than the configured or default maximum.

Options

number—RED threshold for active source messages.

Range: 1 through 1,000,000

Default: 24,000

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

[edit routing-instances *routing-instance-name* protocols msdp peer *address*]

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description

Configure MSDP tracing options.

To specify more than one tracing operation, include multiple **flag** statements.

Default

The default MSDP trace options are those inherited from the routing protocol's **traceoptions** statement included at the **[edit routing-options]** hierarchy level.

Options

disable—(Optional) Disable the tracing operation. You can use this option to disable a single operation when you have defined a broad group of tracing operations, such as **all**.

file *filename*—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory **/var/log**. We recommend that you place tracing output in the **msdp-log** file.

files *number*—(Optional) Maximum number of trace files. When a trace file named ***trace-file*** reaches its maximum size, it is renamed ***trace-file*.0**, then ***trace-file*.1**, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum number of files, you must also include the **size** statement to specify the maximum file size.

Range: 2 through 1000 files

Default: 2 files

flag ***flag***—Tracing operation to perform. To specify more than one tracing operation, include multiple **flag** statements.

MSDP Tracing Flags

- **keepalive—**Keepalive messages
- **packets**—All MSDP packets
- **route**—MSDP changes to the routing table
- **source-active**—Source-active packets
- **source-active-request**—Source-active request packets
- **source-active-response**—Source-active response packets

Global Tracing Flags

- **all**—All tracing operations
- **general**—A combination of the **normal** and **route** trace operations
- **normal**—All normal operations

Default: If you do not specify this option, only unusual or abnormal operations are traced.

- **policy**—Policy operations and actions
- **route**—Routing table changes
- **state**—State transitions
- **task**—Interface transactions and processing
- **timer**—Timer usage

flag-modifier—(Optional) Modifier for the tracing flag. You can specify one or more of these modifiers:

- **detail**—Detailed trace information
- **receive**—Packets being received
- **send**—Packets being transmitted

no-stamp—(Optional) Do not place timestamp information at the beginning of each line in the trace file.

Default: If you omit this option, timestamp information is placed at the beginning of each line of the tracing output.

no-world-readable—(Optional) Do not allow any user to read the log file.

replace—(Optional) Replace an existing trace file if there is one.

Default: If you do not include this option, tracing output is appended to an existing trace file.

size ***size***—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named ***trace-file*** reaches this size, it is renamed ***trace-file*.0**. When ***trace-file*** again reaches this size, ***trace-file*.0** is renamed ***trace-file*.1** and ***trace-file*** is renamed ***trace-file*.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you must also include the **files** statement to specify the maximum number of trace files.

Syntax: ***x*k** to specify KB, ***x*m** to specify MB, or ***x*g** to specify GB

Range: 10 KB through the maximum file size supported on your system

Default: 1 MB

world-readable—(Optional) Allow any user to read the log file.

Required Privilege Level

routing and trace—To view this statement in the configuration.
routing-control and trace-control—To add this statement to the configuration.

- Tracing MSDP Protocol Traffic on page 4084

Source-Specific Multicast Configuration Statements

asm-override-ssm

Syntax asm-override-ssm;

Hierarchy Level [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* routing-options multicast],
[edit logical-systems *logical-system-name* routing-options multicast],
[edit routing-instances *routing-instance-name* routing-options multicast],
[edit routing-options multicast]

Release Information Statement introduced in Junos OS Release 9.4.
Statement introduced in Junos OS Release 9.5 for EX Series switches.
Statement introduced in Junos OS Release 12.1 for the QFX Series.
Statement introduced in Junos OS Release 12.3 for ACX Series routers.

Description Enable the routing device to accept any-source multicast join messages (*,G) for group addresses that are within the default or configured range of source-specific multicast groups.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Example: Configuring Source-Specific Multicast Groups with Any-Source Override on page 4103

policy (SSM Maps)

Syntax policy [*policy-names*];

Hierarchy Level [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* routing-options multicast ssm-map *ssm-map-name*],
[edit logical-systems *logical-system-name* routing-options multicast ssm-map *ssm-map-name*],
[edit routing-instances *routing-instance-name* routing-options multicast ssm-map *ssm-map-name*],
[edit routing-options multicast ssm-map *ssm-map-name*]

Release Information Statement introduced in Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 12.1 for the QFX Series.
Statement introduced in Junos OS Release 12.3 for ACX Series routers.

Description Apply one or more policies to an SSM map.

Options ***policy-names***—Name of one or more policies for SSM mapping.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To view this statement in the configuration.

Related Documentation

- Example: Configuring SSM Mapping on page 4100

ssm-groups

Syntax ssm-groups [*ip-addresses*];

Hierarchy Level [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* routing-options multicast],
[edit logical-systems *logical-system-name* routing-options multicast],
[edit routing-instances *routing-instance-name* routing-options multicast],
[edit routing-options multicast]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 12.1 for the QFX Series.
Statement introduced in Junos OS Release 12.3 for ACX Series routers.

Description Configure source-specific multicast (SSM) groups.

By default, the SSM group multicast address is limited to the IP address range from 232.0.0.0 through 232.255.255.255. However, you can extend SSM operations into another Class D range by including the **ssm-groups** statement in the configuration. The default SSM address range from 232.0.0.0 through 232.255.255.255 cannot be used in the **ssm-groups** statement. This statement is for adding other multicast addresses to the default SSM group addresses. This statement does not override the default SSM group address range.

IGMPv3 supports SSM groups. By utilizing inclusion lists, only sources that are specified send to the SSM group.

Options *ip-addresses*—List of one or more additional SSM group addresses separated by a space.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- Example: Configuring Source-Specific Multicast Groups with Any-Source Override on page 4103

ssm-map (Protocols IGMP)

Syntax ssm-map *ssm-map-name*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols igmp interface *interface-name*],
[edit protocols igmp interface *interface-name*]

Release Information Statement introduced in Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Apply an SSM map to an IGMP interface.

Options ***ssm-map-name***—Name of SSM map.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Example: Configuring SSM Mapping on page 4100

ssm-map (Routing Options Multicast)

Syntax

```
ssm-map ssm-map-name {
  policy [ policy-names ];
  source [ addresses ];
}
```

Hierarchy Level [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* routing-options multicast],
[edit logical-systems *logical-system-name* routing-options multicast],
[edit routing-instances *routing-instance-name* routing-options multicast],
[edit routing-options multicast]

Release Information Statement introduced in Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 12.1 for the QFX Series.
Statement introduced in Junos OS Release 12.3 for ACX Series routers.

Description Configure SSM mapping.

Options ***ssm-map-name***—Name of the SSM map.

The remaining statements are explained separately.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Example: Configuring SSM Mapping on page 4100

ssm-map-policy (IGMP)

Syntax ssm-map-policy *ssm-map-policy-name*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols igmp interface *interface-name*],
[edit protocols igmp interface *interface-name*]

Release Information Statement introduced in Junos OS Release 11.4.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Apply an SSM map policy to an IGMP interface.

Options ***ssm-map-policy-name***—Name of SSM map policy.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Example: Configuring SSM Maps for Different Groups to Different Sources on page 4106

CHAPTER 49

Administration

Routine Monitoring

Monitoring IGMP Snooping

Purpose Use the monitoring feature to view status and information about the IGMP snooping configuration.

Action To display IGMP snooping details in the CLI, enter the following commands:

- **show igmp-snooping vlans**
- **show igmp-snooping statistics**
- **show igmp-snooping route**
- **show igmp-snooping membership**

Meaning Table 306 on page 4257 summarizes the IGMP snooping details displayed.

Table 306: Summary of IGMP Snooping Output Fields

Field	Values
IGMP Snooping Monitor	
VLAN	VLAN for which IGMP snooping is enabled.
Interfaces	Interface connected to a multicast router.
Groups	Number of the multicast groups learned by the VLAN.
MRouters	Multicast router.
Receivers	Multicast receiver.

Table 306: Summary of IGMP Snooping Output Fields *(continued)*

Field	Values
IGMP Route Information	
VLAN	VLAN for which IGMP snooping is enabled.
Next-Hop	Next hop assigned by the switch after performing the route lookup.
Group	Multicast groups learned by the VLAN.

Related Documentation

- IGMP Snooping Overview on page 3962
- Example: Configuring IGMP Snooping on page 4049
- Configuring IGMP Snooping on page 4048
- Changing the IGMP Snooping Group Timeout Value on page 4051

Verifying the IGMP Snooping Group Timeout Value

Purpose Verify that the IGMP snooping group timeout value has been changed correctly from its default value.

Action Display the IGMP snooping membership information, which contains the group timeout value that was derived from the IGMP configuration:

```
user@switch> show igmp-snooping membership detail
VLAN: v43 Tag: 43 (Index: 4)
      Group: 225.0.0.1
      Receiver count: 1, Flags: <v2-hosts>
          ge-0/0/15.0 Uptime: 00:00:05 timeout: 510
```

Meaning The IGMP snooping group timeout value determines how long a switch waits to receive an IGMP query from a multicast router before removing a multicast group from its multicast cache table. When you enable IGMP snooping, the default IGMP snooping group timeout value of 260 seconds is applied to all VLANs, which means that the switch waits 260 seconds to receive an IGMP query before removing a multicast group from its multicast cache table. You can change the timeout value by using the **robust-count** option.

clear igmp membership

Syntax

clear igmp membership
<group *address-range*>
<interface *interface-name*>
<logical-system (all | *logical-system-name*)>

Syntax (EX Series Switch and the QFX Series)

clear igmp membership
<group *address-range*>
<interface *interface-name*>

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
Command introduced in Junos OS Release 11.3 for the QFX Series.

Description

Clear Internet Group Management Protocol (IGMP) group members.

Options

none—Clear all IGMP members on all interfaces and for all address ranges.

group *address-range*—(Optional) Clear all IGMP members that are in a particular address range. An example of a range is **224.2/16**. If you omit the destination prefix length, the default is **/32**.

interface *interface-name*—(Optional) Clear all IGMP group members on an interface.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Required Privilege Level

clear

clear igmp statistics

Syntax

clear igmp statistics
<interface *interface-name*>
<logical-system (all | *logical-system-name*)>

Syntax (EX Series Switches)

clear igmp statistics
<interface *interface-name*>

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
Command introduced in Junos OS Release 11.3 for the QFX Series.

Description

Clear Internet Group Management Protocol (IGMP) statistics.

Options

none—Clear IGMP statistics on all interfaces.

interface *interface-name*—(Optional) Clear IGMP statistics for the specified interface only.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Required Privilege Level

clear

clear msdp cache

Syntax

clear msdp cache
<instance *instance-name*>
<logical-system (all | *logical-system-name*)>
<peer *peer-address*>

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 12.1 for the QFX Series.

Description

Clear the entries in the Multicast Source Discovery Protocol (MSDP) source-active cache.

Options

none—Clear entries in the MSDP source-active cache for all instances, logical systems, and peers.

instance *instance-name*—(Optional) Clear entries for a specific MSDP instance.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

peer *peer-address*—(Optional) Clear the MSDP source-active cache entries learned from a specific peer.

Required Privilege Level

clear

```

clear msdp statistics

Syntax

clear msdp statistics
<instance *instance-name*>
<logical-system (all | *logical-system-name*)>
<peer *peer-address*>

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 12.1 for the QFX Series.

Description

Clear Multicast Source Discovery Protocol (MSDP) peer statistics.

Options

none—Clear MSDP statistics for all peers.

instance ***instance-name***—(Optional) Clear statistics for the specified instance.

logical-system (all | ***logical-system-name*****)**—(Optional) Perform this operation on all logical systems or on a particular logical system.

peer ***peer-address***—(Optional) Clear the statistics for the specified peer.

```
user@host> clear msdp statistics
```

clear multicast bandwidth-admission

Syntax

clear multicast bandwidth-admission
<group *group-address*>
<inet | inet6>
<instance *instance-name*>
<interface *interface-name*>
<source *source-address*>

Release Information

Command introduced in Junos OS Release 8.3.
Command introduced in Junos OS Release 9.0 for EX Series switches.
inet6 and **instance** options introduced in Junos OS Release 10.0 for EX Series switches.
Command introduced in Junos OS Release 11.3 for the QFX Series.

Description

Reapply IP multicast bandwidth admissions.

Options

none—Reapply multicast bandwidth admissions for all IPv4 forwarding entries in the master routing instance.

group *group-address*—(Optional) Reapply multicast bandwidth admissions for the specified group.

inet—(Optional) Reapply multicast bandwidth admission settings for IPv4 flows.

inet6—(Optional) Reapply multicast bandwidth admission settings for IPv6 flows.

instance *instance-name*—(Optional) Reapply multicast bandwidth admission settings for the specified instance. If you do not specify an instance, the command applies to the master routing instance.

interface *interface-name*—(Optional) Examines the corresponding outbound interface in the relevant entries and acts as follows:

- If the interface is congested, and it was admitted previously, it is removed.
- If the interface was rejected previously, the **clear multicast bandwidth-admission** command enables the interface to be admitted as long as enough bandwidth exists on the interface.
- If you do not specify an interface, issuing the **clear multicast bandwidth-admission** command readmits any previously rejected interface for the relevant entries as long as enough bandwidth exists on the interface.

To manually reject previously admitted outbound interfaces, you must specify the interface.

source *source-address*—(Optional) Use with the **group** option to reapply multicast bandwidth admission settings for the specified (source, group) entry.

Required Privilege Level

clear

Related Documentation
- show multicast interface on page 4327

```
user@host> clear multicast bandwidth-admission
```

clear multicast scope

Syntax

clear multicast scope
<inet | inet6>
<interface *interface-name*>
<logical-system (all | *logical-system-name*)>

Syntax (EX Series Switch and the QFX Series)

clear multicast scope
<inet | inet6>
<interface *interface-name*>

Release Information

Command introduced in Junos OS Release 7.6.
Command introduced in Junos OS Release 9.0 for EX Series switches.
inet6 option introduced in Junos OS Release 10.0 for EX Series switches.
Command introduced in Junos OS Release 11.3 for the QFX Series.

Description

Clear IP multicast scope statistics.

Options

none—(Same as **logical-system all**) Clear multicast scope statistics.

inet—(Optional) Clear multicast scope statistics for IPv4 family addresses.

inet6—(Optional) Clear multicast scope statistics for IPv6 family addresses.

interface *interface-name*—(Optional) Clear multicast scope statistics on a specific interface.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Required Privilege Level

clear

user@host> clear multicast scope
```

clear multicast sessions

Syntax

clear multicast sessions
<logical-system (all | *logical-system-name*)>
<*regular-expression*>

Syntax (EX Series Switch and the QFX Series)

clear multicast sessions
<*regular-expression*>

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
Command introduced in Junos OS Release 11.3 for the QFX Series.

Description

Clear IP multicast sessions.

Options

none—(Same as **logical-system all**) Clear multicast sessions.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

regular-expression—(Optional) Clear only multicast sessions that contain the specified regular expression.

Required Privilege Level

clear

user@host> **clear multicast sessions**

clear multicast statistics

Syntax

clear multicast statistics
<inet | inet6>
<instance *instance-name*>
<interface *interface-name*>
<logical-system (all | *logical-system-name*)>

Syntax (EX Series Switch and the QFX Series)

clear multicast statistics
<inet | inet6>
<instance *instance-name*>
<interface *interface-name*>

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
inet6 and **instance** options introduced in Junos OS Release 10.0 for EX Series switches.
Command introduced in Junos OS Release 11.3 for the QFX Series.

Description

Clear IP multicast statistics.

Options

none—Clear multicast statistics for all supported address families on all interfaces.

inet—(Optional) Clear multicast statistics for IPv4 family addresses.

inet6—(Optional) Clear multicast statistics for IPv6 family addresses.

instance *instance-name*—(Optional) Clear multicast statistics for the specified instance.

interface *interface-name*—(Optional) Clear multicast statistics on a specific interface.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Required Privilege Level

clear pim join

Syntax

clear pim join
<*group-address*>
<bidirectional | dense | sparse>
<exact>
<inet | inet6>
<instance *instance-name*>
<logical-system (all | *logical-system-name*)>
<rp *ip-address/prefix* | source *ip-address/prefix*>
<sg | star-g>

Syntax (EX Series Switch and the QFX Series)

clear pim join
<*group-address*>
<dense | sparse>
<exact>
<inet | inet6>
<instance *instance-name*>
<rp *ip-address/prefix* | source *ip-address/prefix*>
<sg | star-g>

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
inet6 and **instance** options introduced in Junos OS Release 10.0 for EX Series switches.
Command introduced in Junos OS Release 11.3 for the QFX Series.
Multiple new filter options introduced in Junos OS Release 13.2.

Description

Clear the Protocol Independent Multicast (PIM) join and prune states.

Options

none—Clear the PIM join and prune states for all groups, family addresses, and instances.

group-address—(Optional) Clear the PIM join and prune states for a group address.

bidirectional | dense | sparse—(Optional) Clear PIM bidirectional mode, dense mode, or sparse and source-specific multicast (SSM) mode entries.

exact—(Optional) Clear only the group that exactly matches the specified group address.

inet | inet6—(Optional) Clear the PIM entries for IPv4 or IPv6 family addresses, respectively.

instance *instance-name*—(Optional) Clear the entries for a specific PIM-enabled routing instance.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

rp *ip-address/prefix* | source *ip-address/prefix*—(Optional) Clear the PIM entries with a specified rendezvous point (RP) address and prefix or with a specified source address and prefix. You can omit the prefix.

sg | star-g—(Optional) Clear PIM (S,G) or (*,G) entries.

Additional Information The **clear pim join** command cannot be used to clear the PIM join and prune state on a backup Routing Engine when nonstop active routing is enabled.

Required Privilege Level clear

mtrace

Syntax

mtrace *source*
<logical-system *logical-system-name*>
<routing-instance *routing-instance-name*>

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
Command introduced in Junos OS Release 9.5 for SRX1400, SRX3400, SRX3600, SRX5600, and SRX5800 devices.
Command introduced in Junos OS Release 11.3 for the QFX Series.
Command introduced in Junos OS Release 12.3 for the PTX Series.

Description

Display trace information about an IP multicast path.

Options

source—Source hostname or address.

logical-system (*logical-system-name*)—(Optional) Perform this operation on a logical system.

routing-instance *routing-instance-name*—(Optional) Trace a particular routing instance.

Additional Information

The **mtrace** command for multicast traffic is similar to the **traceroute** command used for unicast traffic. Unlike **traceroute**, **mtrace** traces traffic backwards, from the receiver to the source.

Required Privilege Level

List of Sample Output

mtrace source on page 4283

Output Fields

Table 307 on page 4281 describes the output fields for the **mtrace** command. Output fields are listed in the approximate order in which they appear.

Table 307: mtrace Output Fields

Field Name	Field Description
Mtrace from	IP address of the receiver.
to	IP address of the source.
via group	IP address of the multicast group (if any).
Querying full reverse path	Indicates the full reverse path query has begun.
number-of-hops	Number of hops from the source to the named router or switch.
router-name	Name of the router or switch for this hop.
address	Address of the router or switch for this hop.

Table 307: mtrace Output Fields *(continued)*

Field Name	Field Description
protocol	Protocol used (for example, PIM).
Round trip time	Average round-trip time, in milliseconds (ms).
total ttl of	Time-to-live (TTL) threshold.

Sample Output

mtrace source

```
user@host> mtrace 192.1.4.2
Mtrace from 192.1.4.2 to 192.1.1.2 via group 0.0.0.0
Querying full reverse path... * *
  0  routerA.lab.mycompany.net (192.1.1.2)
 -1  routerB.lab.mycompany.net (192.1.2.2)  PIM  thresh^ 1
 -2  routerC.lab.mycompany.net (192.1.3.2)  PIM  thresh^ 1
 -3  hostA.lab.mycompany.net (192.1.4.2)
Round trip time 2 ms; total ttl of 2 required.
```

mtrace from-source

Syntax

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
Command introduced in Junos OS Release 11.3 for the QFX Series.

Description

Display trace information about an IP multicast path from a source to this router or switch. If you specify a group address with this command, Junos OS returns additional information, such as packet rates and losses.

Options

brief | detail—(Optional) Display the specified level of output.

extra-hops ***extra-hops***—(Optional) Number of hops to take after reaching a nonresponsive router. You can specify a number between **0** and **255**.

group ***group***—(Optional) Group address for which to trace the path. The default group address is **0.0.0.0**.

interval ***interval***—(Optional) Number of seconds to wait before gathering statistics again. The default value is **10** seconds.

loop—(Optional) Loop indefinitely, displaying rate and loss statistics.

max-hops ***max-hops***—(Optional) Maximum hops to trace toward the source. The range of values is **0** through **255**. The default value is **32** hops.

max-queries ***max-queries***—(Optional) Maximum number of query attempts for any hop. The range of values is **1** through **32**. The default is **3**.

multicast-response—(Optional) Always request the response using multicast.

no-resolve—(Optional) Do not attempt to display addresses symbolically.

no-router-alert—(Optional) Do not use the router-alert IP option.

response ***response***—(Optional) Send trace response to a host or multicast address.

routing-instance ***routing-instance-name***—(Optional) Trace a particular routing instance.

source ***source***—Source hostname or address.

ttl ***ttl***—(Optional) IP time-to-live (TTL) value. You can specify a number between **0** and **255**. Local queries to the multicast group use a value of **1**. Otherwise, the default value is **127**.

unicast-response—(Optional) Always request the response using unicast.

wait-time ***wait-time***—(Optional) Number of seconds to wait for a response. The default value is **3**.

Output Fields

Table 308 on page 4285 describes the output fields for the **mtrace from-source** command. Output fields are listed in the approximate order in which they appear.

Table 308: mtrace from-source Output Fields

Field Name	Field Description
Mtrace from	IP address of the receiver.
to	IP address of the source.
via group	IP address of the multicast group (if any).
Querying full reverse path	Indicates the full reverse path query has begun.
number-of-hops	Number of hops from the source to the named router or switch.
router-name	Name of the router or switch for this hop.
address	Address of the router or switch for this hop.
protocol	Protocol used (for example, PIM).
Round trip time	Average round-trip time, in milliseconds (ms).
total ttl of	Time-to-live (TTL) threshold.
source	Source address.
Response Dest	Response destination address.
Overall	Average packet rate for all traffic at each hop.

Table 308: mtrace from-source Output Fields *(continued)*

Field Name	Field Description
Packet Statistics for Traffic From	Number of packets lost, number of packets sent, percentage of packets lost, and average packet rate at each hop.
Receiver	IP address receiving the multicast.
Query source	IP address sending the mtrace query.

Sample Output

mtrace from-source

```
user@host> mtrace from-source source 192.1.4.2 group 225.1.1.1
Mtrace from 192.1.4.2 to 192.1.1.2 via group 225.1.1.1
Querying full reverse path... * *
  0  routerA.lab.mycompany.net (192.1.1.2)
 -1  routerB.lab.mycompany.net (192.1.2.2)  PIM  thresh^ 1
 -2  routerC.lab.mycompany.net (192.1.3.2)  PIM  thresh^ 1
 -3  hostA.lab.mycompany.net (192.1.4.2)
Round trip time 2 ms; total ttl of 2 required.

Waiting to accumulate statistics...Results after 10 seconds:

<group *group*>
<interface *interface-name*>
<interval *interval*>
<loop>
<max-hops *max-hops*>
<max-queries *max-queries*>
<multicast-response | unicast-response>
<no-resolve>
<no-router-alert>
<response *response*>
<routing-instance *routing-instance-name*>
<ttl *ttl*>
<unicast-response>
<wait-time *wait-time*>

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
Command introduced in Junos OS Release 11.3 for the QFX Series.

Description

Display trace information about a multicast path from this router or switch to a gateway router or switch.

Options

gateway *gateway*—Send the trace query to a gateway multicast address.

brief | detail—(Optional) Display the specified level of output.

extra-hops *extra-hops*—(Optional) Number of hops to take after reaching a nonresponsive router or switch. You can specify a number between **0** and **255**.

group *group*—(Optional) Group address for which to trace the path. The default group address is **0.0.0.0**.

interface *interface-name*—(Optional) Source address for sending the trace query.

interval *interval*—(Optional) Number of seconds to wait before gathering statistics again. The default value is **10**.

loop—(Optional) Loop indefinitely, displaying rate and loss statistics.

max-hops *max-hops*—(Optional) Maximum hops to trace toward the source. You can specify a number between **0** and **255**.. The default value is **32**.

max-queries *max-queries*—(Optional) Maximum number of query attempts for any hop. You can specify a number between **0** and **255**. The default value is **3**.

multicast-response—(Optional) Always request the response using multicast.

no-resolve—(Optional) Do not attempt to display addresses symbolically.

no-router-alert—(Optional) Do not use the router-alert IP option.

response ***response***—(Optional) Send trace response to a host or multicast address.

routing-instance ***routing-instance-name***—(Optional) Trace a particular routing instance.

ttl ***ttl***—(Optional) IP time-to-live value. You can specify a number between **0** and **225**. Local queries to the multicast group use TTL **1**. Otherwise, the default value is **127**.

unicast-response—(Optional) Always request the response using unicast.

wait-time ***wait-time***—(Optional) Number of seconds to wait for a response. The default value is **3**.

Command introduced in Junos OS Release 11.3 for the QFX Series.

Description

Display information about Internet Group Management Protocol (IGMP)-enabled interfaces.

Options

none—Display standard information about all IGMP-enabled interfaces.

brief | detail—(Optional) Display the specified level of output.

interface-name—(Optional) Display information about the specified IGMP-enabled interface only.

logical-system (all | ***logical-system-name*****)**—(Optional) Perform this operation on all logical systems or on a particular logical system.

Required Privilege Level

show igmp interface detail on page 4301
show igmp interface <interface-name> on page 4301

Output Fields

Table 313 on page 4298 describes the output fields for the **show igmp interface** command. Output fields are listed in the approximate order in which they appear.

Table 313: show igmp interface Output Fields

Field Name	Field Description	Level of Output
Interface	Name of the interface.	All levels
Querier	Address of the routing device that has been elected to send membership queries.	All levels
State	State of the interface: **Up** or **Down**.	All levels

Table 313: show igmp interface Output Fields *(continued)*

Field Name	Field Description	Level of Output
SSM Map Policy	Name of the source-specific multicast (SSM) map policy that has been applied to the IGMP interface.	All levels
Timeout	How long until the IGMP querier is declared to be unreachable, in seconds.	All levels
Version	IGMP version being used on the interface: **1** , **2** , or **3**.	All levels
Groups	Number of groups on the interface.	All levels
Group limit	Maximum number of groups allowed on the interface. Any joins requested after the limit is reached are rejected.	All levels
Group threshold	Configured threshold at which a warning message is generated. This threshold is based on a percentage of groups received on the interface. If the number of groups received reaches the configured threshold, the device generates a warning message.	All levels
Group log-interval	Time (in seconds) between consecutive log messages.	All levels
Immediate Leave	State of the immediate leave option: • **On**—Indicates that the router removes a host from the multicast group as soon as the router receives a leave group message from a host associated with the interface. • **Off**—Indicates that after receiving a leave group message, instead of removing a host from the multicast group immediately, the router sends a group query to determine if another receiver responds.	All levels
Promiscuous Mode	State of the promiscuous mode option: • **On**—Indicates that the router can accept IGMP reports from subnetworks that are not associated with its interfaces. • **Off**—Indicates that the router can accept IGMP reports only from subnetworks that are associated with its interfaces.	All levels
Passive	State of the passive mode option: • **On**—Indicates that the router can run IGMP on the interface but not send or receive control traffic such as IGMP reports, queries, and leaves. • **Off**—Indicates that the router can run IGMP on the interface and send or receive control traffic such as IGMP reports, queries, and leaves. The **passive** statement enables you to selectively activate up to two out of a possible three available query or control traffic options. When enabled, the following options appear after the **on** state declaration: • **send-general-query**—The interface sends general queries. • **send-group-query**—The interface sends group-specific and group-source-specific queries. • **allow-receive**—The interface receives control traffic.	All levels
OIF map	Name of the OIF map (if configured) associated with the interface.	All levels

Table 313: show igmp interface Output Fields *(continued)*

Field Name	Field Description	Level of Output
SSM map	Name of the source-specific multicast (SSM) map (if configured) used on the interface.	All levels
Configured Parameters	Information configured by the user: • **IGMP Query Interval**—Interval (in seconds) at which this router sends membership queries when it is the querier. • **IGMP Query Response Interval**—Time (in seconds) that the router waits for a report in response to a general query. • **IGMP Last Member Query Interval**—Time (in seconds) that the router waits for a report in response to a group-specific query. • **IGMP Robustness Count**—Number of times the router retries a query.	All levels
Derived Parameters	Derived information: • **IGMP Membership Timeout**—Timeout period (in seconds) for group membership. If no report is received for these groups before the timeout expires, the group membership is removed. • **IGMP Other Querier Present Timeout**—Time (in seconds) that the router waits for the IGMP querier to send a query.	All levels

Sample Output

show igmp interface

```
user@host> show igmp interface
Interface: at-0/3/1.0
    Querier: 10.111.30.1
    State:         Up Timeout:    None Version:  2 Groups:      4
    SSM Map Policy: ssm-policy-A
Interface: so-1/0/0.0
    Querier: 10.111.10.1
    State:         Up Timeout:    None Version:  2 Groups:      2
    SSM Map Policy: ssm-policy-B
Interface: so-1/0/1.0
    Querier: 10.111.20.1
    State:         Up Timeout:    None Version:  2 Groups:      4
    SSM Map Policy: ssm-policy-C
Immediate Leave: On
Promiscuous Mode: Off

Configured Parameters:
IGMP Query Interval: 125.0
IGMP Query Response Interval: 10.0
IGMP Last Member Query Interval: 1.0
IGMP Robustness Count: 2

Derived Parameters:
IGMP Membership Timeout: 260.0
IGMP Other Querier Present Timeout: 255.0
```

show igmp interface brief

The output for the **show igmp interface brief** command is identical to that for the **show igmp interface** command. For sample output, see show igmp interface on page 4300.

show igmp interface detail

The output for the **show igmp interface detail** command is identical to that for the **show igmp interface** command. For sample output, see show igmp interface on page 4300.

show igmp interface <interface-name>

```
user@host# show igmp interface ge-3/2/0.0
Interface: ge-3/2/0.0
  Querier: 20.1.1.1
  State: Up Timeout:    None Version:  3 Groups:      1
  Group limit: 8
  Group threshold: 60
  Group log-interval: 10
  Immediate leave:  Off
  Promiscuous mode:  Off
```

show igmp statistics

Syntax

show igmp statistics
<brief | detail>
<interface *interface-name*>
<logical-system (all | *logical-system-name*)>

Syntax (EX Series Switch and the QFX Series)

show igmp statistics
<brief | detail>
<interface *interface-name*>

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
Command introduced in Junos OS Release 11.3 for the QFX Series.

Description

Display Internet Group Management Protocol (IGMP) statistics.

Options

none—Display IGMP statistics for all interfaces.

brief | detail—(Optional) Display the specified level of output.

interface ***interface-name***—(Optional) Display IGMP statistics about the specified interface only.

logical-system (all | ***logical-system-name*****)**—(Optional) Perform this operation on all logical systems or on a particular logical system.

Output Fields

Table 314 on page 4302 describes the output fields for the **show igmp statistics** command. Output fields are listed in the approximate order in which they appear.

Table 314: show igmp statistics Output Fields

Field Name	Field Description
IGMP packet statistics	Heading for IGMP packet statistics for all interfaces or for the specified interface name.

Table 314: show igmp statistics Output Fields *(continued)*

Field Name	Field Description
IGMP Message type	Summary of IGMP statistics: • **Membership Query**—Number of membership queries sent and received. • **V1 Membership Report**—Number of version 1 membership reports sent and received. • **DVMRP**—Number of DVMRP messages sent or received. • **PIM V1**—Number of PIM version 1 messages sent or received. • **Cisco Trace**—Number of Cisco trace messages sent or received. • **V2 Membership Report**—Number of version 2 membership reports sent or received. • **Group Leave**—Number of group leave messages sent or received. • **Mtrace Response**—Number of Mtrace response messages sent or received. • **Mtrace Request**—Number of Mtrace request messages sent or received. • **Domain Wide Report**—Number of domain-wide reports sent or received. • **V3 Membership Report**—Number of version 3 membership reports sent or received. • **Other Unknown types**—Number of unknown message types received. • **IGMP v3 unsupported type**—Number of messages received with unknown and unsupported IGMP version 3 message types. • **IGMP v3 source required for SSM**—Number of IGMP version 3 messages received that contained no source. • **IGMP v3 mode not applicable for SSM**—Number of IGMP version 3 messages received that did not contain a mode applicable for source-specific multicast (SSM).
Received	Number of messages received.
Sent	Number of messages sent.
Rx errors	Number of received packets that contained errors.
IGMP Global Statistics	Summary of IGMP statistics for all interfaces. • **Bad Length**—Number of messages received with length errors so severe that further classification could not occur. • **Bad Checksum**—Number of messages received with a bad IP checksum. No further classification was performed. • **Bad Receive If**—Number of messages received on an interface not enabled for IGMP. • **Rx non-local**—Number of messages received from senders that are not local. • **Timed out**—Number of groups that timed out as a result of not receiving an explicit leave message. • **Rejected Report**—Number of reports dropped because of the IGMP group policy. • **Total Interfaces**—Number of interfaces configured to support IGMP.

Sample Output

show igmp statistics

```
user@host> show igmp statistics
IGMP packet statistics for all interfaces
IGMP Message type      Received       Sent  Rx errors
Membership Query           8883        459          0
V1 Membership Report          0          0          0
```

```
DVMRP                          0          0          0
PIM V1                         0          0          0
Cisco Trace                    0          0          0
V2 Membership Report           0          0          0
Group Leave                    0          0          0
Mtrace Response                0          0          0
Mtrace Request                 0          0          0
Domain Wide Report             0          0          0
V3 Membership Report           0          0          0
Other Unknown types                                  0
IGMP v3 unsupported type                             0
IGMP v3 source required for SSM                      0
IGMP v3 mode not applicable for SSM                  0

IGMP Global Statistics
Bad Length                     0
Bad Checksum                   0
Bad Receive If                 0
Rx non-local                1227
Timed out                      0
Rejected Report                0
Total Interfaces               2
```

show igmp statistics interface

```
user@host> show igmp statistics interface fe-1/0/1.0
IGMP interface packet statistics for fe-1/0/1.0
IGMP Message type      Received       Sent  Rx errors
Membership Query              0        230          0
V1 Membership Report          0          0          0
```

show igmp-snooping membership

Syntax

show igmp-snooping membership
<brief | detail>
<interface *interface-name*>
<vlan *vlan-id* | *vlan-name*>

Release Information

Command introduced in Junos OS Release 11.1 for the QFX Series.
IGMPv3 output introduced in Junos OS Release 12.1 for the QFX Series.

Description

Display IGMP snooping membership information.

Options

none—Display general parameters.

brief | detail—(Optional) Display the specified level of output.

interface *interface-name*—(Optional) Display IGMP snooping information for the specified interface.

vlan *vlan-id* | *vlan-name*—(Optional) Display IGMP snooping information for the specified VLAN.

Output Fields

Table 315 on page 4305 lists the output fields for the **show igmp-snooping membership** command. Output fields are listed in the approximate order in which they appear.

Table 315: show igmp-snooping membership Output Fields

Field Name	Field Description	Level of Output
VLAN	Name of the VLAN.	All
Interfaces	Interfaces assigned to the VLAN.	All
Tag	Numerical identifier of the VLAN.	**detail**

Table 315: show igmp-snooping membership Output Fields *(continued)*

Field Name		Field Description	Level of Output
Router interfaces		Names of multicast router interfaces.	**detail**
	• **static** or **dynamic**	Whether the multicast router interface is **static** or **dynamic**.	**detail**
	• **Uptime**	For static interfaces, length of time since the interface was configured as a multicast router interface; for dynamic interfaces, length of time since the first query was received on the interface.	**detail**
	• **timeout**	Query timeout in seconds.	**detail**
Group		IP multicast address of the multicast group.	**detail**
Receiver count		Number of interfaces that have membership in a multicast group.	**detail**
Flags		IGMP version of the host sending a join message.	**detail**
Uptime		Length of time a multicast group has been active on the interface.	**detail**
timeout		Time (in seconds) left until the entry for the multicast group is removed.	All
Last reporter		Last host to report membership for the multicast group.	**detail**
Include source		Source addresses from which multicast streams are allowed based on IGMPv3 reports.	**detail**

Sample Output

show igmp-snooping membership

```
user@switch> show igmp-snooping membership
VLAN: v1
    224.1.1.1      *             258 secs
        Interfaces: ge-0/0/0.0
    224.1.1.3      *             258 secs
        Interfaces: ge-0/0/0.0
    224.1.1.5      *             258 secs
        Interfaces: ge-0/0/0.0
    224.1.1.7      *             258 secs
```

```
    Interfaces: ge-0/0/0.0
224.1.1.9      *              258 secs
    Interfaces: ge-0/0/0.0

List of Sample Output **show igmp-snooping statistics on page 4311**

Output Fields Table 317 on page 4310 lists the output fields for the **show igmp-snooping statistics** command. Output fields are listed in the approximate order in which they appear.

Table 317: show igmp-snooping statistics Output Fields

Field Name	Field Description
Bad length	IGMP packet has illegal or bad length.
Bad checksum	IGMP or IP checksum is incorrect.
Invalid interface	Packet was received through an invalid interface.
Not local	Number of packets received from senders that are not local.
Receive unknown	Unknown IGMP type.
Timed out	Number of timeouts for all multicast groups.
IGMP Type	Type of IGMP message (**Queries**, **Reports**, **Leaves**, or **Other**).
Received	Number of IGMP packets received.
Transmitted	Number of IGMP packets transmitted.
Recv Errors	Number of general receive errors.

Sample Output

show igmp-snooping statistics

```
user@switch> show igmp-snooping statistics
Bad length: 0 Bad checksum: 0 Invalid interface: 0
Not local: 0 Receive unknown: 0 Timed out: 58

    IGMP Type           Received       Transmitted    Recv Errors
    Queries:               74295                 0              0
    Reports:            18148423                 0       16333523

Output Fields Table 318 on page 4312 lists the output fields for the **show igmp-snooping vlans** command. Output fields are listed in the approximate order in which they appear.

Table 318: show igmp-snooping vlans Output Fields

Field Name	Field Description	Level of Output
VLAN	Name of the VLAN.	All levels
IGMP-L2-Querier	Source address for IGMP snooping queries (if switch is an IGMP querier)	All levels
Interfaces	Number of interfaces in the VLAN.	All levels
Groups	Number of groups in the VLAN.	All levels
MRouters	Number of multicast routers associated with the VLAN.	All levels
Receivers	Number of host receivers in the VLAN.	All levels

Table 318: show igmp-snooping vlans Output Fields *(continued)*

Field Name	Field Description	Level of Output
Tag	Numerical identifier of the VLAN.	**detail**
tagged | untagged	Interface participates in a tagged (802.1Q) or untagged (native) VLAN.	**detail**
vlan-interface	Internal VLAN interface identifier.	**detail**
Membership timeout	Membership timeout value.	**detail**
Querier timeout	Timeout value for interfaces dynamically marked as router or switch interfaces (interfaces that receive queries). When the querier timeout is reached, the switch marks the interface as a host interface.	**detail**
Interface	Name of the interface.	**detail**
Reporters	Number of dynamic groups on an interface.	**detail**

Sample Output

show igmp-snooping vlans

```
user@switch> show igmp-snooping vlans
VLAN      Interfaces Groups MRouters Receivers
default     0           0      0         0
v1          11          50     0         0
v10         1           0      0         0
v11         1           0      0         0

IGMP-L2-Querier: Stopped, SourceAddress: 10.10.1.2
```

show msdp

Syntax

show msdp
<brief | detail>
<instance *instance-name*>
<logical-system (all | *logical-system-name*)>
<peer *peer-address*>

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 12.1 for the QFX Series.

Description

Display Multicast Source Discovery Protocol (MSDP) information.

Options

none—Display standard MSDP information for all routing instances.

brief | detail—(Optional) Display the specified level of output.

instance ***instance-name***—(Optional) Display information for the specified instance only.

logical-system (all | ***logical-system-name*****)**—(Optional) Perform this operation on all logical systems or on a particular logical system.

peer ***peer-address***—(Optional) Display information about the specified peer only,

Output Fields

Table 319 on page 4314 describes the output fields for the **show msdp** command. Output fields are listed in the approximate order in which they appear.

Table 319: show msdp Output Fields

Field Name	Field Description	Level of Output
Peer address	IP address of the peer.	All levels
Local address	Local address of the peer.	All levels
State	Status of the MSDP connection: **Listen**, **Established**, or **Inactive**.	All levels
Last up/down	Time at which the most recent peer-state change occurred.	All levels

Table 319: show msdp Output Fields *(continued)*

Field Name	Field Description	Level of Output
Peer-Group	Peer group name.	All levels
SA Count	Number of source-active cache entries advertised by each peer that were accepted, compared to the number that were received, in the format ***number-accepted/number-received***.	All levels
Peer Connect Retries	Number of peer connection retries.	**detail**
State timer expires	Number of seconds before another message is sent to a peer.	**detail**
Peer Times out	Number of seconds to wait for a response from the peer before the peer is declared unavailable.	**detail**
SA accepted	Number of entries in the source-active cache accepted from the peer.	**detail**
SA received	Number of entries in the source-active cache received by the peer.	**detail**

Sample Output

show msdp

```
user@host> show msdp
Peer address    Local address   State       Last up/down Peer-Group SA Count
198.32.8.193    198.32.8.195    Established  5d 19:25:44 North23    120/150
198.32.8.194    198.32.8.195    Established  3d 19:27:27 North23    300/345
198.32.8.196    198.32.8.195    Established  5d 19:39:36 North23    10/13

```

show msdp brief

The output for the **show msdp brief** command is identical to that for the **show msdp** command. For sample output, see show msdp on page 4315.

show msdp detail

```
user@host> show msdp detail
Peer: 10.255.70.15
Local address: 10.255.70.19
State: Established
Peer Connect Retries: 0
State timer expires: 22
Peer Times out: 49
SA accepted: 0
SA received: 0
```

show msdp source

Syntax

show msdp source
<instance *instance-name*>
<logical-system (all | *logical-system-name*)>
<*source-address*>

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 12.1 for the QFX Series.

Description

Display multicast sources learned from Multicast Source Discovery Protocol (MSDP).

Options

none—Display standard MSDP source information for all routing instances.

instance *instance-name*—(Optional) Display information for the specified instance only.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

source-address—(Optional) IP address and optional prefix length. Display information for the specified source address only.

List of Sample Output

show msdp source on page 4317

Output Fields Table 320 on page 4317 describes the output fields for the **show msdp source** command. Output fields are listed in the approximate order in which they appear.

Table 320: show msdp source Output Fields

Field Name	Field Description
Source address	IP address of the source.
/Len	Length of the prefix for this IP address.
Type	Discovery method for this multicast source: • **Configured**—Source-active limit explicitly configured for this source. • **Dynamic**—Source-active limit established when this source was discovered.
Maximum	Source-active limit applied to this source.
Threshold	Source-active threshold applied to this source.
Exceeded	Number of source-active messages received from this source exceeding the established maximum.

Sample Output

show msdp source

```
user@host> show msdp source
Source address /Len   Type       Maximum   Threshold    Exceeded
0.0.0.0        /0     Configured       5       none        0
10.1.0.0       /16    Configured     500       none        0
10.1.1.1       /32    Configured   10000       none        0
10.1.1.2       /32    Dynamic       6936       none        0
10.1.5.5       /32    Dynamic        500       none          123
10.2.1.1       /32    Dynamic          2       none        0

Output Fields

Table 321 on page 4319 describes the output fields for the **show msdp source-active** command. Output fields are listed in the approximate order in which they appear.

Table 321: show msdp source-active Output Fields

Field Name	Field Description
Global active source limit exceeded	Number of times all peers have exceeded configured active source limits.
Global active source limit maximum	Configured number of active source messages accepted by the device.
Global active source limit threshold	Configured threshold for applying random early discard (RED) to drop some but not all MSDP active source messages.
Global active source limit log-warning	Threshold at which a warning message is logged (percentage of the number of active source messages accepted by the device).
Global active source limit log interval	Time (in seconds) between consecutive log messages.
Group address	Multicast address of the group.
Source address	IP address of the source.
Peer address	IP address of the peer.
Originator	Router ID configured on the source of the rendezvous point (RP) that originated the message, or the loopback address when the router ID is not configured.
Flags	Flags: **Accept**, **Reject**, or **Filtered**.

Sample Output

show msdp source-active

```
user@host> show msdp source-active
Group address     Source address  Peer address      Originator      Flags
230.0.0.0         192.168.195.46  local             10.255.14.30    Accept

Output Fields

Table 322 on page 4321 describes the output fields for the **show msdp statistics** command. Output fields are listed in the approximate order in which they appear.

Table 322: show msdp statistics Output Fields

Field Name	Field Description
Global active source limit exceeded	Number of times all peers have exceeded configured active source limits.
Global active source limit maximum	Configured number of active source messages accepted by the device.
Global active source limit threshold	Configured threshold for applying random early discard (RED) to drop some but not all MSDP active source messages.
Global active source limit log-warning	Threshold at which a warning message is logged (percentage of the number of active source messages accepted by the device).
Global active source limit log interval	Time (in seconds) between consecutive log messages.
Peer	Address of peer.

Table 322: show msdp statistics Output Fields *(continued)*

Field Name	Field Description
Last State Change	How long ago the peer state changed.
Last message received from the peer	How long ago the last message was received from the peer.
RPF Failures	Number of reverse path forwarding (RPF) failures.
Remote Closes	Number of times the remote peer closed.
Peer Timeouts	Number of peer timeouts.
SA messages sent	Number of source-active messages sent.
SA messages received	Number of source-active messages received.
SA request messages sent	Number of source-active request messages sent.
SA request messages received	Number of source-active request messages received.
SA response messages sent	Number of source-active response messages sent.
SA response messages received	Number of source-active response messages received.
Active source exceeded	Number of times this peer has exceeded configured source-active limits.
Active source Maximum	Configured number of active source messages accepted by this peer.
Active source threshold	Configured threshold on this peer for applying random early discard (RED) to drop some but not all MSDP active source messages.
Active source log-warning	Configured threshold on this peer at which a warning message is logged (percentage of the number of active source messages accepted by the device).
Active source log-interval	Time (in seconds) between consecutive log messages on this peer.
Keepalive messages sent	Number of keepalive messages sent.
Keepalive messages received	Number of keepalive messages received.
Unknown messages received	Number of unknown messages received.

Table 322: show msdp statistics Output Fields *(continued)*

Field Name	Field Description
Error messages received	Number of error messages received.

Sample Output

Output Fields

Table 323 on page 4325 describes the output fields for the **show multicast flow-map** command. Output fields are listed in the approximate order in which they appear.

Table 323: show multicast flow-map Output Fields

Field Name	Field Description	Levels of Output
Name	Name of the flow map.	All levels
Policy	Name of the policy associated with the flow map.	All levels
Cache-timeout	Cache timeout value assigned to the flow map.	All levels
Bandwidth	Bandwidth setting associated with the flow map.	All levels
Adaptive	Whether or not adaptive mode is enabled for the flow map.	none
Flow-map	Name of the flow map.	**detail**
Adaptive Bandwidth	Whether or not adaptive mode is enabled for the flow map.	**detail**
Redundant Sources	Redundant sources defined for the same destination group.	**detail**

Sample Output

show multicast flow-map

```
user@host> show multicast flow-map
Instance: master
Name            Policy                  Cache timeout        Bandwidth Adaptive
map2            policy2                         never          2000000 no
map1            policy1                    60 seconds          2000000 no
```

Sample Output

show multicast flow-map detail

```
user@host> show multicast flow-map detail
Instance: master
Flow-map: map1
    Policy:             policy1
    Cache Timeout:      600 seconds
    Bandwidth:          2000000
    Adaptive Bandwidth: yes
    Redundant Sources:  11.11.11.11
    Redundant Sources:  11.11.11.12
    Redundant Sources:  11.11.11.13
```

show multicast interface

Syntax

show multicast interface
<logical-system (all | *logical-system-name*)>

Syntax (EX Series Switch and the QFX Series)

show multicast interface

Release Information

Command introduced in Junos OS Release 8.3.
Command introduced in Junos OS Release 9.0 for EX Series switches.
Command introduced in Junos OS Release 11.3 for the QFX Series.

Description

Display bandwidth information about IP multicast interfaces.

Options

none—Display all interfaces that have multicast configured.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Required Privilege Level

view

List of Sample Output

show multicast interface on page 4328

Output Fields

Table 324 on page 4327 describes the output fields for the **show multicast interface** command. Output fields are listed in the approximate order in which they appear.

Table 324: show multicast interface Output Fields

Field Name	Field Description
Interface	Name of the multicast interface.
Maximum bandwidth (bps)	Maximum bandwidth setting, in bits per second, for this interface.
Remaining bandwidth (bps)	Amount of bandwidth, in bits per second, remaining on the interface.
Mapped bandwidth deduction (bps)	Amount of bandwidth, in bits per second, used by any flows that are mapped to the interface. NOTE: Adding the mapped bandwidth deduction value to the local bandwidth deduction value results in the total deduction value for the interface. This field does not appear in the output when the no QoS adjustment feature is disabled.

Table 324: show multicast interface Output Fields *(continued)*

Field Name	Field Description
Local bandwidth deduction (bps)	Amount of bandwidth, in bits per second, used by any mapped flows that are traversing the interface. NOTE: Adding the mapped bandwidth deduction value to the local bandwidth deduction value results in the total deduction value for the interface. This field does not appear in the output when the no QoS adjustment feature is disabled.
Reverse OIF mapping	State of the reverse OIF mapping feature (**on** or **off**). NOTE: This field does not appear in the output when the no QoS adjustment feature is disabled.
Reverse OIF mapping no QoS adjustment	State of the no QoS adjustment feature (**on** or **off**) for interfaces that are using reverse OIF mapping. NOTE: This field does not appear in the output when the no QoS adjustment feature is disabled.
Leave timer	Amount of time a mapped interface remains active after the last mapping ends. NOTE: This field does not appear in the output when the no QoS adjustment feature is disabled.
No QoS adjustment	State (**on**) of the no QoS adjustment feature when this feature is enabled. NOTE: This field does not appear in the output when the no QoS adjustment feature is disabled.

Sample Output

show multicast interface

```
user@host> show multicast interface
Interface                Maximum bandwidth (bps) Remaining bandwidth (bps)
fe-0/0/3                                10000000                         0
fe-0/0/3.210                            10000000                  -2000000
fe-0/0/3.220                           100000000                 100000000
fe-0/0/3.230                            20000000                  18000000
fe-0/0/2.200                           100000000                 100000000
```

show multicast mrinfo

Syntax

show multicast mrinfo
<*host*>

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
Command introduced in Junos OS Release 11.3 for the QFX Series.

Description

Display configuration information about IP multicast networks, including neighboring multicast router addresses.

Options

none—Display configuration information about all multicast networks.

host—(Optional) Display configuration information about a particular host. Replace *host* with a hostname or IP address.

Required Privilege Level

view

List of Sample Output

show multicast mrinfo on page 4330

Output Fields

Table 325 on page 4329 describes the output fields for the **show multicast mrinfo** command. Output fields are listed in the approximate order in which they appear.

Table 325: show multicast mrinfo Output Fields

Field Name	Field Description
source-address	Query address, hostname (DNS name or IP address of the source address), and multicast protocol version or the software version of another vendor.
ip-address-1—>*ip-address-2*	Queried router interface address and directly attached neighbor interface address, respectively.
(*name* or *ip-address*)	Name or IP address of neighbor.

[*metric/threshold/type/flags*]	Neighbor's multicast profile:
	• *metric*—Always has a value of **1**, because **mrinfo** queries the directly connected interfaces of a device.
	• *threshold*—Multicast threshold time-to-live (TTL). The range of values is **0** through **255**.
	• *type*—Multicast connection type: **pim** or **tunnel**.
	• *flags*—Flags for this route:
	  ◦ **querier**—Queried router is the designated router for the neighboring session.
	  ◦ **leaf**—Link is a leaf in the multicast network.
	  ◦ **down**—Link status indicator.

Sample Output

show multicast mrinfo

```
user@host> show multicast mrinfo 10.35.4.1
10.35.4.1 (10.35.4.1) [version 12.0]:
  192.168.195.166 -> 0.0.0.0 (local) [1/0/pim/querier/leaf]
  10.38.20.1 -> 0.0.0.0 (local) [1/0/pim/querier/leaf]
  10.47.1.1 -> 10.47.1.2 (10.47.1.2) [1/5/pim]
  0.0.0.0 -> 0.0.0.0 (local) [1/0/pim/down]
```

show multicast next-hops

Syntax

show multicast next-hops
<brief | detail>
<*identifier-number*>
<inet | inet6>
<logical-system (all | *logical-system-name*)>

Syntax (EX Series Switch and the QFX Series)

show multicast next-hops
<brief | detail>
<*identifier-number*>
<inet | inet6>

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
inet6 option introduced in Junos OS Release 10.0 for EX Series switches.
detail option display of next-hop ID number introduced in Junos OS Release 11.1 for M Series and T Series routers and EX Series switches.
Command introduced in Junos OS Release 11.3 for the QFX Series.
Support for bidirectional PIM added in Junos OS Release 12.1.

Description

Display the entries in the IP multicast next-hop table.

Options

none—Display standard information about all entries in the multicast next-hop table for all supported address families.

brief | detail—(Optional) Display the specified level of output.

When you include the **detail** option on M Series and T Series routers and EX Series switches, the downstream interface name includes the next-hop ID number in parentheses, in the form **fe-0/1/2.0-(1048574)** where **1048574** is the next-hop ID number.

identifier-number—(Optional) Show a particular next hop by ID number. The range of values is **1** through **65,535**.

inet | inet6—(Optional) Display entries for IPv4 or IPv6 family addresses, respectively.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Output Fields

Table 326 on page 4332 describes the output fields for the **show multicast next-hops** command. Output fields are listed in the approximate order in which they appear.

Table 326: show multicast next-hops Output Fields

Field Name	Field Description
Family	Protocol family (such as **INET**).
ID	Next-hop identifier of the prefix. The identifier is returned by the routing device's Packet Forwarding Engine.
Refcount	Number of cache entries that are using this next hop.
KRefcount	Kernel reference count for the next hop.
Downstream interface	Interface names associated with each multicast next-hop ID.
Incoming interface list	List of interfaces that accept incoming traffic. Only shown for routes that do not use strict RPF-based forwarding, for example for bidirectional PIM.

Sample Output

show multicast next-hops

```
user@host> show multicast next-hops
Family: INET
ID       Refcount  KRefcount Downstream interface
262142          4          2 so-1/0/0.0
262143          2          1 mt-1/1/0.49152
262148          2          1 mt-1/1/0.32769
```

show multicast next-hops (Bidirectional PIM

```
user@host> show multicast next-hops
Family: INET
ID           Refcount KRefcount Downstream interface
2097151             8         4 ge-0/0/1.0

Family: INET6
ID           Refcount KRefcount Downstream interface
2097157             2         1 ge-0/0/1.0

Family: Incoming interface list
ID           Refcount KRefcount Downstream interface

```

show multicast pim-to-igmp-proxy

Syntax

show multicast pim-to-igmp-proxy
<instance *instance-name*>
<logical-system (all | *logical-system-name*)>

Syntax (EX Series Switch and the QFX Series)

show multicast pim-to-igmp-proxy
<instance *instance-name*>

Release Information

Command introduced in Junos OS Release 9.6.
Command introduced in Junos OS Release 9.6 for EX Series switches.
instance option introduced in Junos OS Release 10.3.
instance option introduced in Junos OS Release 10.3 for EX Series switches.
Command introduced in Junos OS Release 11.3 for the QFX Series.

Description

Display configuration information about PIM-to-IGMP message translation, also known as PIM-to-IGMP proxy.

Options

none—Display configuration information about PIM-to-IGMP message translation for all routing instances.

instance ***instance-name***—(Optional) Display configuration information about PIM-to-IGMP message translation for a specific multicast instance.

logical-system (all | ***logical-system-name*****)**—(Optional) Perform this operation on all logical systems or on a particular logical system.

Output Fields

Table 327 on page 4334 describes the output fields for the **show multicast pim-to-igmp-proxy** command. Output fields are listed in the order in which they appear.

Table 327: show multicast pim-to-igmp-proxy Output Fields

Field Name	Field Description
Instance	Routing instance. Default instance is **master** (inet.0 routing table).
Proxy state	State of PIM-to-IGMP message translation, also known as PIM-to-IGMP proxy, on the configured upstream interfaces: **enabled** or **disabled**.
interface-name	Name of upstream interface (no more than two allowed) on which PIM-to-IGMP message translation is configured.

Sample Output

show multicast pim-to-igmp-proxy

```
user@host> show multicast pim-to-igmp-proxy
Instance: master Proxy state: enabled
ge-0/1/0.1
ge-0/1/0.2
```

show multicast pim-to-igmp-proxy instance

```
user@host> show multicast pim-to-igmp-proxy instance VPN-A
Instance: VPN-A Proxy state: enabled
ge-0/1/0.1
```

show multicast pim-to-mld-proxy

Syntax

show multicast pim-to-mld-proxy
<instance *instance-name*>
<logical-system (all | *logical-system-name*)>

Syntax (EX Series Switch and the QFX Series)

show multicast pim-to-mld-proxy
<instance *instance-name*>

Release Information

Command introduced in Junos OS Release 9.6.
Command introduced in Junos OS Release 9.6 for EX Series switches.
instance option introduced in Junos OS Release 10.3.
instance option introduced in Junos OS Release 10.3 for EX Series switches.
Command introduced in Junos OS Release 11.3 for the QFX Series.

Description

Display configuration information about PIM-to-MLD message translation, also known as PIM-to-MLD proxy.

Options

none—Display configuration information about PIM-to-MLD message translation for all routing instances.

instance *instance-name*—(Optional) Display configuration information about PIM-to-MLD message translation for a specific multicast instance.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

show multicast route

Syntax

show multicast route
<brief | detail | extensive | summary>
<active | all | inactive>
<group *group*>
<inet | inet6>
<instance *instance name*>
<logical-system (all | *logical-system-name*)>
<*regular-expression*>
<source-prefix *source-prefix*>

Syntax (EX Series Switch and the QFX Series)

show multicast route
<brief | detail | extensive | summary>
<active | all | inactive>
<group *group*>
<inet | inet6>
<instance *instance name*>
<*regular-expression*>
<source-prefix *source-prefix*>

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
inet6 and **instance** options introduced in Junos OS Release 10.0 for EX Series switches.
Command introduced in Junos OS Release 11.3 for the QFX Series.
Support for bidirectional PIM added in Junos OS Release 12.1.

Description

Display the entries in the IP multicast forwarding table. You can display similar information with the **show route table inet.1** command.

Options

none—Display standard information about all entries in the multicast forwarding table for all routing instances.

brief | detail | extensive | summary—(Optional) Display the specified level of output.

active | all | inactive—(Optional) Display all active entries, all entries, or all inactive entries, respectively, in the multicast forwarding table.

group *group*—(Optional) Display the cache entries for a particular group.

inet | inet6—(Optional) Display multicast forwarding table entries for IPv4 or IPv6 family addresses, respectively.

instance *instance-name*—(Optional) Display entries in the multicast forwarding table for a specific multicast instance.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

regular-expression—(Optional) Display information about the multicast forwarding table entries that match a UNIX OS-style regular expression.

source-prefix ***source-prefix***—(Optional) Display the cache entries for a particular source prefix.

Output Fields Table 329 on page 4339 describes the output fields for the **show multicast route** command. Output fields are listed in the approximate order in which they appear.

Table 329: show multicast route Output Fields

Field Name	Field Description	Level of Output
family	IPv4 address family (**INET**) or IPv6 address family (**INET6**).	All levels
Group	Group address. For any-source multicast routes, for example for bidirectional PIM, the group address includes the prefix length.	All levels
Source	Prefix and length of the source as it is in the multicast forwarding table.	All levels
Incoming interface list	List of interfaces that accept incoming traffic. Only shown for routes that do not use strict RPF-based forwarding, for example for bidirectional PIM.	All levels
Upstream interface	Name of the interface on which the packet with this source prefix is expected to arrive.	All levels
Downstream interface list	List of interface names to which the packet with this source prefix is forwarded.	All levels
Number of outgoing interfaces	Total number of outgoing interfaces for each (S,G) entry.	**extensive**
Session description	Name of the multicast session.	**detail extensive**
Statistics	Rate at which packets are being forwarded for this source and group entry (in Kbps and pps), and number of packets that have been forwarded to this prefix. If one or more of the kilobits per second packet forwarding statistic queries fails or times out, the statistics field displays **Forwarding statistics are not available**. NOTE: On QFX Series switches, this field does not report valid statistics.	**detail extensive**
Next-hop ID	Next-hop identifier of the prefix. The identifier is returned by the routing device's Packet Forwarding Engine and is also displayed in the output of the **show multicast nexthops** command.	**detail extensive**

Table 329: show multicast route Output Fields *(continued)*

Field Name	Field Description	Level of Output
Incoming interface list ID	For bidirectional PIM, incoming interface list identifier. Identifiers for interfaces that accept incoming traffic. Only shown for routes that do not use strict RPF-based forwarding, for example for bidirectional PIM.	**detail extensive**
Upstream protocol	The protocol that maintains the active multicast forwarding route for this group or source. When the **show multicast route extensive** command is used with the **display-origin-protocol** option, the field name is only **Protocol** and not **Upstream Protocol**. However, this field also displays the protocol that installed the active route.	**detail extensive**
Route type	Type of multicast route. Values can be (S,G) or (*,G).	**summary**
Route state	Whether the group is **Active** or **Inactive**.	**summary extensive**
Route count	Number of multicast routes.	**summary**
Forwarding state	Whether the prefix is pruned or forwarding.	**extensive**
Cache lifetime/timeout	Number of seconds until the prefix is removed from the multicast forwarding table. A value of **never** indicates a permanent forwarding entry. A value of **forever** indicates routes that do not have keepalive times.	**extensive**
Wrong incoming interface notifications	Number of times that the upstream interface was not available.	**extensive**
Uptime	Time since the creation of a multicast route.	**extensive**

Sample Output

<summary>

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
inet6 and **instance** options introduced in Junos OS Release 10.0 for EX Series switches.
Command introduced in Junos OS Release 11.3 for the QFX Series.

Description

Display information about multicast reverse-path-forwarding (RPF) calculations.

Options

none—Display RPF calculation information for all supported address families.

inet | inet6—(Optional) Display the RPF calculation information for IPv4 or IPv6 family addresses, respectively.

instance *instance-name*—(Optional) Display information about multicast RPF calculations for a specific multicast instance.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

prefix—(Optional) Display the RPF calculation information for the specified prefix.

summary—(Optional) Display a summary of all multicast RPF information.

Output Fields Table 330 on page 4345 describes the output fields for the **show multicast rpf** command. Output fields are listed in the approximate order in which they appear.

Table 330: show multicast rpf Output Fields

Field Name	Field Description
Instance	Name of the routing instance. (Displayed when multicast is configured within a routing instance.)
Source prefix	Prefix and length of the source as it exists in the multicast forwarding table.
Protocol	How the route was learned.
Interface	Upstream RPF interface. NOTE: The displayed interface information does not apply to bidirectional PIM RP addresses. This is because the **show multicast rpf** command does not take into account equal-cost paths or the designated forwarder. For accurate upstream RPF interface information, always use the **show pim join extensive** command when bidirectional PIM is configured.
Neighbor	Upstream RPF neighbor. NOTE: The displayed neighbor information does not apply to bidirectional PIM. This is because the **show multicast rpf** command does not take into account equal-cost paths or the designated forwarder. For accurate upstream RPF neighbor information, always use the **show pim join extensive** command when bidirectional PIM is configured.

Sample Output

show multicast rpf

```
user@host> show multicast rpf

show multicast scope

Syntax

show multicast scope
<inet | inet6>
<instance *instance-name*>
<logical-system (all | *logical-system-name*)>

Syntax (EX Series Switch and the QFX Series)

show multicast scope
<inet | inet6>
<instance *instance-name*>

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
inet6 and **instance** options introduced in Junos OS Release 10.0 for EX Series switches.
Command introduced in Junos OS Release 11.3 for the QFX Series.

Description

Display administratively scoped IP multicast information.

Options

none—Display standard information about administratively scoped multicast information for all supported address families in all routing instances.

inet | inet6—(Optional) Display scoped multicast information for IPv4 or IPv6 family addresses, respectively.

instance *instance-name*—(Optional) Display administratively scoped information for a specific multicast instance.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Required Privilege Level

List of Sample Output

show multicast scope on page 4349
show multicast scope inet on page 4349
show multicast scope inet6 on page 4349

Output Fields

Table 331 on page 4348 describes the output fields for the **show multicast scope** command. Output fields are listed in the approximate order in which they appear.

Table 331: show multicast scope Output Fields

Field Name	Field Description
Scope name	Name of the multicast scope.
Group Prefix	Range of multicast groups that are scoped.
Interface	Interface that is the boundary of the administrative scope.
Resolve Rejects	Number of kernel resolve rejects.

Sample Output

show multicast scope

```
user@host> show multicast scope
                                                                Resolve
Scope name           Group Prefix       Interface               Rejects
232-net              232.232.0.0/16     fe-0/0/0.1                    0
local                239.255.0.0/16     fe-0/0/0.1                    0
local                ff05::/16          fe-0/0/0.1                    0
larry                ff05::1234/128     fe-0/0/0.1                    0
```

show multicast scope inet

```
user@host> show multicast scope inet
                                                                Resolve
Scope name           Group Prefix       Interface               Rejects
232-net              232.232.0.0/16     fe-0/0/0.1                    0
local                239.255.0.0/16     fe-0/0/0.1                    0
```

show multicast scope inet6

```
user@host> show multicast scope inet6
                                                                Resolve
Scope name           Group Prefix       Interface               Rejects
local                ff05::/16          fe-0/0/0.1                    0
larry                ff05::1234/128     fe-0/0/0.1                    0
```

show multicast sessions

Syntax

show multicast sessions
<brief | detail | extensive>
<logical-system (all | *logical-system-name*)>

show pim bootstrap

Syntax

show pim bootstrap
<instance *instance-name*>
<logical-system (all | *logical-system-name*)>

Syntax (EX Series Switch and the QFX Series)

show pim bootstrap
<instance *instance-name*>

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
instance option introduced in Junos OS Release 10.0 for EX Series switches.
Command introduced in Junos OS Release 11.3 for the QFX Series.

Description

For sparse mode only, display information about Protocol Independent Multicast (PIM) bootstrap routers.

Options

none—Display PIM bootstrap router information for all routing instances.

instance ***instance-name***—(Optional) Display information about bootstrap routers for a specific PIM-enabled routing instance.

logical-system (all | ***logical-system-name*****)**—(Optional) Perform this operation on all logical systems or on a particular logical system.

show pim interfaces

Syntax

show pim interfaces
<inet | inet6>
<instance (*instance-name* | all)>
<logical-system (all | *logical-system-name*)>

Syntax (EX Series Switch and the QFX Series)

show pim interfaces
<inet | inet6>
<instance (*instance-name* | all)>

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
inet6 and **instance** options introduced in Junos OS Release 10.0 for EX Series switches.
Commmand introduced in Junos OS Release 11.3 for the QFX Series.
Support for bidirectional PIM added in Junos OS Release 12.1.
Support for the **instance all** option added in Junos OS Release 12.1.

Description

Display information about the interfaces on which Protocol Independent Multicast (PIM) is configured.

Options

none—Display interface information for all family addresses for the main instance.

inet | inet6—(Optional) Display interface information for IPv4 or IPv6 family addresses, respectively.

instance (*instance-name* | all)—(Optional) Display information about interfaces for a specific PIM-enabled routing instance or for all routing instances.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

view

List of Sample Output

show pim interfaces on page 4359

Output Fields

Table 335 on page 4358 describes the output fields for the **show pim interfaces** command. Output fields are listed in the approximate order in which they appear.

Table 335: show pim interfaces Output Fields

Field Name	Field Description
Instance	Name of the routing instance.
Name	Interface name.
State	State of the interface. The state also is displayed in the **show interfaces** command.

Table 335: show pim interfaces Output Fields *(continued)*

Field Name	Field Description
Mode	PIM mode running on the interface: • **B**—In bidirectional mode, multicast groups are carried across the network over bidirectional shared trees. This type of tree minimizes PIM routing state, which is especially important in networks with numerous and dispersed senders and receivers. • **S**—In sparse mode, routing devices must join and leave multicast groups explicitly. Upstream routing devices do not forward multicast traffic to this routing device unless this device has sent an explicit request (using a join message) to receive multicast traffic. • **Dense**—Unlike sparse mode, where data is forwarded only to routing devices sending an explicit request, dense mode implements a flood-and-prune mechanism, similar to DVMRP (the first multicast protocol used to support the multicast backbone). (Not supported on QFX Series.) • **Sparse-Dense**—Sparse-dense mode allows the interface to operate on a per-group basis in either sparse or dense mode. A group specified as **dense** is not mapped to a rendezvous point (RP). Instead, data packets destined for that group are forwarded using PIM-Dense Mode (PIM-DM) rules. A group specified as **sparse** is mapped to an RP, and data packets are forwarded using PIM-Sparse Mode (PIM-SM) rules. (Not supported on QFX Series.) When sparse-dense mode is configured, the output includes both **S** and **D**. When bidirectional-sparse mode is configured, the output includes **S** and **B**. When bidirectional-sparse-dense mode is configured, the output includes **B**, **S**, and **D**.
IP	Version number of the address family on the interface: **4** (IPv4) or **6** (IPv6).
V	PIM version running on the interface: **1** or **2**.
State	State of PIM on the interface: • **Active**—Bidirectional mode is enabled on the interface and on all PIM neighbors. • **DR**—Designated router. • **NotCap**—Bidirectional mode is not enabled on the interface. This can happen when bidirectional PIM is not configured locally, when one of the neighbors is not configured for bidirectional PIM, or when one of the neighbors has not implemented the bidirectional PIM protocol. • **NotDR**—Not the designated router. • **P2P**—Point to point.
NbrCnt	Number of neighbors that have been seen on the interface.
JoinCnt(sg)	Number of (s,g) join messages that have been seen on the interface.
JointCnt(*g)	Number of (*,g) join messages that have been seen on the interface.
DR address	Address of the designated router.

Sample Output

show pim interfaces

```
user@host> show pim interfaces
Stat = Status, V = Version, NbrCnt = Neighbor Count,
S = Sparse, D = Dense, B = Bidirectional,
DR = Designated Router, P2P = Point-to-point link,
```

```

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
summary option introduced in Junos OS Release 9.6.
inet6 and **instance** options introduced in Junos OS Release 10.0 for EX Series switches.
Support for bidirectional PIM added in Junos OS Release 12.1.
Command introduced in Junos OS Release 11.3 for the QFX Series.
Multiple new filter options introduced in Junos OS Release 13.2.

Description

Display information about Protocol Independent Multicast (PIM) groups for all PIM modes.

For bidirectional PIM, display information about PIM group ranges (*,G-range) for each active bidirectional RP group range, in addition to each of the joined (*,G) routes.

Options

none—Display the standard information about PIM groups for all supported family addresses for all routing instances.

brief | detail | extensive | summary—(Optional) Display the specified level of output.

bidirectional | dense | sparse—(Optional) Display information about PIM bidirectional mode, dense mode, or sparse and source-specific multicast (SSM) mode entries.

exact—(Optional) Display information about only the group that exactly matches the specified group address.

inet | inet6—(Optional) Display PIM group information for IPv4 or IPv6 family addresses, respectively.

instance ***instance-name***—(Optional) Display information about groups for the specified PIM-enabled routing instance only.

logical-system (all | ***logical-system-name*****)**—(Optional) Perform this operation on all logical systems or on a particular logical system.

range—(Optional) Address range of the group, specified as ***prefix/prefix-length***.

rp ***ip-address/prefix*** **| source** ***ip-address/prefix***—(Optional) Display information about the PIM entries with a specified rendezvous point (RP) address and prefix or with a specified source address and prefix. You can omit the prefix.

sg | star-g—(Optional) Display information about PIM (S,G) or (*,G) entries.

List of Sample Output

show pim join summary on page 4366
show pim join (PIM Sparse Mode) on page 4366
show pim join (Bidirectional PIM) on page 4366
show pim join inet6 on page 4367
show pim join inet6 star-g on page 4367
show pim join instance <instance-name> on page 4367
show pim join detail on page 4368
show pim join extensive (PIM Sparse Mode) on page 4368
show pim join extensive (Bidirectional PIM) on page 4369
show pim join extensive (Bidirectional PIM with a Directly Connected Phantom RP) on page 4370
show pim join instance <instance-name> extensive on page 4371
show pim join extensive (Ingress Node with Multipoint LDP Inband Signaling for Point-to-Multipoint LSPs) on page 4371
show pim join extensive (Egress Node with Multipoint LDP Inband Signaling for Point-to-Multipoint LSPs) on page 4372

Output Fields

Table 336 on page 4362 describes the output fields for the **show pim join** command. Output fields are listed in the approximate order in which they appear.

Table 336: show pim join Output Fields

Field Name	Field Description	Level of Output
Instance	Name of the routing instance.	**brief detail extensive summary** none
Family	Name of the address family: **inet** (IPv4) or **inet6** (IPv6).	**brief detail extensive summary** none
Route type	Type of multicast route: (S,G) or (*,G).	**summary**
Route count	Number of (S,G) routes and number of (*,G) routes.	**summary**

Table 336: show pim join Output Fields *(continued)*

Field Name	Field Description	Level of Output
R	Rendezvous Point Tree.	**brief detail extensive** none
S	Sparse.	**brief detail extensive** none
W	Wildcard.	**brief detail extensive** none
Group	Group address.	**brief detail extensive** none
Bidirectional group prefix length	For bidirectional PIM, length of the IP prefix for RP group ranges.	All levels
Source	Multicast source: • ***** (wildcard value) • ***ipv4-address*** • ***ipv6-address***	**brief detail extensive** none
RP	Rendezvous point for the PIM group.	**brief detail extensive** none
Flags	PIM flags: • **bidirectional**—Bidirectional mode entry. • **dense**—Dense mode entry. • **rptree**—Entry is on the rendezvous point tree. • **sparse**—Sparse mode entry. • **spt**—Entry is on the shortest-path tree for the source. • **wildcard**—Entry is on the shared tree.	**brief detail extensive** none
Upstream interface	RPF interface toward the source address for the source-specific state (S,G) or toward the rendezvous point (RP) address for the non-source-specific state (*,G). For bidirectional PIM, **RP Link** means that the interface is directly connected to a subnet that contains a phantom RP address. A pseudo multipoint LDP (M-LDP) interface appears on egress nodes in M-LDP point-to-multipoint LSPs with inband signaling.	**brief detail extensive** none

Table 336: show pim join Output Fields *(continued)*

Field Name	Field Description	Level of Output
Upstream neighbor	Information about the upstream neighbor: **Direct**, **Local**, **Unknown**, or a specific IP address. For bidirectional PIM, **Direct** means that the interface is directly connected to a subnet that contains a phantom RP address. The multipoint LDP (M-LDP) root appears on egress nodes in M-LDP point-to-multipoint LSPs with inband signaling.	**extensive**
Upstream state	Information about the upstream interface: • **Join to RP**—Sending a join to the rendezvous point. • **Join to Source**—Sending a join to the source. • **Local RP**—Sending neither join messages nor prune messages toward the RP, because this routing device is the rendezvous point. • **Local Source**—Sending neither join messages nor prune messages toward the source, because the source is locally attached to this routing device. • **Prune to RP**—Sending a prune to the rendezvous point. • **Prune to Source**—Sending a prune to the source. NOTE: RP group range entries have **None** in the **Upstream state** field because RP group ranges do not trigger actual PIM join messages between routing devices.	**extensive**

Table 336: show pim join Output Fields *(continued)*

Field Name	Field Description	Level of Output
Downstream neighbors	Information about downstream interfaces: • **Interface**—Interface name for the downstream neighbor. A pseudo PIM-SM interface appears for all IGMP-only interfaces. A pseudo multipoint LDP (M-LDP) interface appears on ingress root nodes in M-LDP point-to-multipoint LSPs with inband signaling. • **Interface address**—Address of the downstream neighbor. • **State**—Information about the downstream neighbor: **join** or **prune**. • **Flags**—PIM join flags: **R (RPtree)**, **S (Sparse)**, **W (Wildcard)**, or **zero**. • **Uptime**—Time since the downstream interface joined the group. • **Time since last Join**—Time since the last join message was received from the downstream interface. • **Time since last Prune**—Time since the last prune message was received from the downstream interface.	**extensive**
Number of downstream interfaces	Total number of outgoing interfaces for each (S,G) entry.	**extensive**
Assert Timeout	Length of time between assert cycles on the downstream interface. Not displayed if the assert timer is null.	**extensive**
Keepalive timeout	Time remaining until the downstream join state is updated (in seconds). If the downstream join state is not updated before this keepalive timer reaches zero, the entry is deleted. If there is a directly connected host, **Keepalive timeout** is **Infinity**.	**extensive**
Uptime	Time since the creation of (S,G) or (*,G) state. The uptime is not refreshed every time a PIM join message is received for an existing (S,G) or (*,G) state.	**extensive**
Bidirectional accepting interfaces	Interfaces on the routing device that forward bidirectional PIM traffic. The reasons for forwarding bidirectional PIM traffic are that the interface is the winner of the designated forwarder election (**DF Winner**), or the interface is the reverse path forwarding (RPF) interface toward the RP (**RPF**).	**extensive**

Sample Output

show pim join summary

```
user@host> show pim join summary
Instance: PIM.master Family: INET

Route type            Route count
(s,g)                 2

show pim neighbors

Syntax

show pim neighbors
<brief | detail>
<inet | inet6>
<instance (*instance-name* | all)>
<logical-system (all | *logical-system-name*)>

Syntax (EX Series Switch and the QFX Series)

show pim neighbors
<brief | detail>
<inet | inet6>
<instance (*instance-name* | all)>

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
inet6 and **instance** options introduced in Junos OS Release 10.0 for EX Series switches.
Command introduced in Junos OS Release 11.3 for the QFX Series.
Support for bidirectional PIM added in Junos OS Release 12.1.
Support for the **instance all** option added in Junos OS Release 12.1.

Description

Display information about Protocol Independent Multicast (PIM) neighbors.

Options

none—(Same as **brief**) Display standard information about PIM neighbors for all supported family addresses for the main instance.

brief | detail—(Optional) Display the specified level of output.

inet | inet6—(Optional) Display information about PIM neighbors for IPv4 or IPv6 family addresses, respectively.

instance (*instance-name* | all)—(Optional) Display information about neighbors for the specified PIM-enabled routing instance or for all routing instances.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Required Privilege Level

List of Sample Output

show pim neighbors on page 4377
show pim neighbors brief on page 4377
show pim neighbors instance on page 4377
show pim neighbors detail on page 4377
show pim neighbors detail (With BFD) on page 4378

Output Fields

Table 337 on page 4376 describes the output fields for the **show pim neighbors** command. Output fields are listed in the approximate order in which they appear.

Table 337: show pim neighbors Output Fields

Field Name	Field Description	Level of Output
Instance	Name of the routing instance.	All levels
Interface	Interface through which the neighbor is reachable.	All levels
Neighbor addr	Address of the neighboring PIM routing device.	All levels
IP	IP version: **4** or **6**.	All levels
V	PIM version running on the neighbor: **1** or **2**.	All levels
Mode	PIM mode of the neighbor: **Sparse**, **Dense**, **SparseDense**, or **Unknown**. When the neighbor is running PIM version 2, this mode is always **Unknown**.	All levels
Option	Can be one or more of the following: • **B**—Bidirectional Capable. • **H**—Hello Option Holdtime. • **G**—Generation Identifier. • **P**—Hello Option DR Priority. • **L**—Hello Option LAN Prune Delay.	**brief** none
Uptime	Time the neighbor has been operational since the PIM process was last initialized, in the format ***dd:hh:mm:ss* ago** for less than a week and ***nwnd:hh:mm:ss* ago** for more than a week.	All levels
Address	Address of the neighboring PIM routing device.	**detail**
BFD	Status and operational state of the Bidirectional Forwarding Detection (BFD) protocol on the interface: **Enabled**, **Operational state is up**, or **Disabled**.	**detail**
Hello Option Holdtime	Time for which the neighbor is available, in seconds. The range of values is **0** through **65,535.**	**detail**
Hello Default Holdtime	Default holdtime and the time remaining if the **holdtime** option is not in the received hello message.	**detail**
Hello Option DR Priority	Designated router election priority. The range of values is **0** through **255**.	**detail**
Hello Option Generation ID	9-digit or 10-digit number used to tag hello messages.	**detail**
Hello Option Bi-Directional PIM supported	Neighbor can process bidirectional PIM messages.	**detail**
Hello Option LAN Prune Delay	Time to wait before the neighbor receives prune messages, in the format **delay *nnn* ms override *nnnn* ms**.	**detail**

Table 337: show pim neighbors Output Fields *(continued)*

Field Name	Field Description	Level of Output
Join Suppression supported	Neighbor is capable of join suppression.	**detail**
Rx Join	Information about joins received from the neighbor. • **Group**—Group addresses in the join message. • **Source**—Address of the source in the join message. • **Timeout**—Time for which the join is valid.	**detail**

Sample Output

show pim neighbors

```
user@host> show pim neighbors
Instance: PIM.master
B = Bidirectional Capable, G = Generation Identifier,
H = Hello Option Holdtime, L = Hello Option LAN Prune Delay,
P = Hello Option DR Priority

Interface           IP V Mode        Option      Uptime Neighbor addr
so-1/0/0.0           4 2             HPLG      00:07:10 10.111.10.2
```

show pim neighbors brief

The output for the **show pim neighbors brief** command is identical to that for the **show pim neighbors** command. For sample output, see show pim neighbors on page 4377.

show pim neighbors instance

```
user@host> show pim neighbors instance VPN-A
Instance: PIM.VPN-A
B = Bidirectional Capable, G = Generation Identifier,
H = Hello Option Holdtime, L = Hello Option LAN Prune Delay,
P = Hello Option DR Priority

Interface           IP V Mode        Option      Uptime Neighbor addr
at-0/3/1.0           4 2             HPLG      00:07:54 10.111.30.2

```

show pim rps

Syntax

show pim rps
<brief | detail | extensive>
<*group-address*>
<inet | inet6>
<instance *instance-name*>
<logical-system (all | *logical-system-name*)>

Syntax (EX Series Switch and the QFX Series)

show pim rps
<brief | detail | extensive>
<*group-address*>
<inet | inet6>
<instance *instance-name*>

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
inet6 and **instance** options introduced in Junos OS Release 10.0 for EX Series switches.
Command introduced in Junos OS Release 11.3 for the QFX Series.
Support for bidirectional PIM added in Junos OS Release 12.1.

Description

Display information about Protocol Independent Multicast (PIM) rendezvous points (RPs).

Options

none—Display standard information about PIM RPs for all groups and family addresses for all routing instances.

brief | detail | extensive—(Optional) Display the specified level of output.

group-address—(Optional) Display the RPs for a particular group. If you specify a group address, the output lists the routing device that is the RP for that group.

inet | inet6—(Optional) Display information for IPv4 or IPv6 family addresses, respectively.

instance *instance-name*—(Optional) Display information about RPs for a specific PIM-enabled routing instance.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Output Fields Table 338 on page 4380 describes the output fields for the **show pim rps** command. Output fields are listed in the approximate order in which they appear.

Table 338: show pim rps Output Fields

Field Name	Field Description	Level of Output
Instance	Name of the routing instance.	All levels
Family or Address family	Name of the address family: **inet** (IPv4) or **inet6** (IPv6).	All levels
RP address	Address of the rendezvous point.	All levels
Type	Type of RP: • **auto-rp**—Address of the RP known through the Auto-RP protocol. • **bootstrap**—Address of the RP known through the bootstrap router protocol (BSR). • **embedded**—Address of the RP known through an embedded RP (IPv6). • **static**—Address of RP known through static configuration.	**brief** none
Holdtime	How long to keep the RP active, with time remaining, in seconds.	All levels
Timeout	How long until the local routing device determines the RP to be unreachable, in seconds.	All levels
Groups	Number of groups currently using this RP.	All levels
Group prefixes	Addresses of groups that this RP can span.	**brief** none
Learned via	Address and method by which the RP was learned.	**detail extensive**
Mode	The PIM mode of the RP: bidirectional or sparse. If a sparse and bidirectional RPs are configured with the same RP address, they appear as separate entries in both formats.	All levels
Time Active	How long the RP has been active, in the format ***hh:mm:ss***.	**detail extensive**

Table 338: show pim rps Output Fields *(continued)*

Field Name	Field Description	Level of Output
Device Index	Index value of the order in which Junos OS finds and initializes the interface. For bidirectional RPs, the **Device Index** output field is omitted because bidirectional RPs do not require encapsulation and de-encapsulation interfaces.	**detail extensive**
Subunit	Logical unit number of the interface. For bidirectional RPs, the **Subunit** output field is omitted because bidirectional RPs do not require encapsulation and de-encapsulation interfaces.	**detail extensive**
Interface	Either the encapsulation or the de-encapsulation logical interface, depending on whether this routing device is a designated router (DR) facing an RP router, or is the local RP, respectively. For bidirectional RPs, the **Interface** output field is omitted because bidirectional RPs do not require encapsulation and de-encapsulation interfaces.	**detail extensive**
Group Ranges	Addresses of groups that this RP spans.	**detail extensive** *group-address*
Active groups using RP	Number of groups currently using this RP.	**detail extensive**
total	Total number of active groups for this RP.	**detail extensive**
Register State for RP	Current register state for each group: • **Group**—Multicast group address. • **Source**—Multicast source address for which the PIM register is sent or received, depending on whether this router is a designated router facing an RP router, or is the local RP, respectively: • **First Hop**—PIM-designated routing device that sent the Register message (the source address in the IP header). • **RP Address**—RP to which the Register message was sent (the destination address in the IP header). • **State**: On the designated router: ◦ **Send**—Sending Register messages. ◦ **Probe**—Sent a null register. If a Register-Stop message does not arrive in 5 seconds, the designated router resumes sending Register messages. ◦ **Suppress**—Received a Register-Stop message. The designated router is waiting for the timer to resume before changing to **Probe** state. • On the RP: ◦ **Receive**—Receiving Register messages.	**extensive**
Anycast-PIM rpset	If anycast RP is configured, the addresses of the RPs in the set.	**extensive**
Anycast-PIM local address used	If anycast RP is configured, the local address used by the RP.	**extensive**

Table 338: show pim rps Output Fields *(continued)*

Field Name	Field Description	Level of Output

Anycast-PIM Register State	If anycast RP is configured, the current register state for each group:
	• **Group**—Multicast group address.
	• **Source**—Multicast source address for which the PIM register is sent or received, depending on whether this routing device is a designated router facing an RP router, or is the local RP, respectively.
	• **Origin**—How the information was obtained:
	  • **DIRECT**—From a local attachment
	  • **MSDP**—From the Multicast Source Discovery Protocol (MSDP)
	  • **DR**—From the designated router
		extensive

RP selected	For sparse mode and bidirectional mode, the identity of the RP for the specified group address.	*group-address*

show pim source

Syntax

show pim source
<brief | detail>
<inet | inet6>
<instance *instance-name*>
<logical-system (all | *logical-system-name*)>
<*source-prefix*>

Syntax (EX Series Switch and the QFX Series)

show pim source
<brief | detail>
<inet | inet6>
<instance *instance-name*>
<*source-prefix*>

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
inet6 and **instance** options introduced in Junos OS Release 10.0 for EX Series switches.
Command introduced in Junos OS Release 11.3 for the QFX Series.

Description

Display information about the Protocol Independent Multicast (PIM) source reverse path forwarding (RPF) state.

Options

none—Display standard information about the PIM RPF state for all supported family addresses for all routing instances.

brief | detail—(Optional) Display the specified level of output.

inet | inet6—(Optional) Display information for IPv4 or IPv6 family addresses, respectively.

instance *instance-name*—(Optional) Display information about the RPF state for a specific PIM-enabled routing instance.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

source-prefix—(Optional) Display the state for source RPF states in the given range.

show pim source on page 4387
show pim source brief on page 4387
show pim source detail on page 4387
show pim source (Egress Node with Multipoint LDP Inband Signaling for Point-to-Multipoint LSPs) on page 4388

Output Fields

Table 339 on page 4387 describes the output fields for the **show pim source** command. Output fields are listed in the approximate order in which they appear.

Table 339: show pim source Output Fields

Field Name	Field Description
Instance	Name of the routing instance.
Source	Address of the source or reverse path.
Prefix/length	Prefix and prefix length for the route used to reach the RPF address.
Upstream Protocol	
Upstream interface	RPF interface toward the source address. A pseudo multipoint LDP (M-LDP) interface appears on egress nodes in M-LDP point-to-multipoint LSPs with inband signaling.
Upstream Neighbor	Address of the RPF neighbor used to reach the source address. The multipoint LDP (M-LDP) root appears on egress nodes in M-LDP point-to-multipoint LSPs with inband signaling.

Sample Output

show pim source

```
user@host> show pim source
Instance: PIM.master Family: INET

Source 10.255.14.144
    Prefix 10.255.14.144/32
    Upstream interface Local
    Upstream neighbor Local

Source 10.255.70.15
    Prefix 10.255.70.15/32
    Upstream interface so-1/0/0.0
    Upstream neighbor 10.111.10.2

Instance: PIM.master Family: INET6
```

show pim source brief

The output for the **show pim source brief** command is identical to that for the **show pim source** command. For sample output, see show pim source on page 4387.

show pim source detail

```
user@host> show pim source detail
Instance: PIM.master Family: INET

Source 10.255.14.144
    Prefix 10.255.14.144/32
    Upstream interface Local
    Upstream neighbor Local
    Active groups:228.0.0.0
        239.1.1.1
```

```
        239.1.1.1

Source 10.255.70.15
    Prefix 10.255.70.15/32
    Upstream interface so-1/0/0.0
    Upstream neighbor 10.111.10.2
    Active groups:239.1.1.1

Instance: PIM.master Family: INET6
```

show pim source (Egress Node with Multipoint LDP Inband Signaling for Point-to-Multipoint LSPs)

```
user@host> show pim source
Instance: PIM.master Family: INET

Source 1.1.1.1
    Prefix 1.1.1.1/32
    Upstream interface Local
    Upstream neighbor Local

Source 1.2.7.7
    Prefix 1.2.7.0/24
    Upstream protocol MLDP
    Upstream interface Pseudo MLDP
    Upstream neighbor MLDP LSP root <1.1.1.2>

Source 192.168.219.11
    Prefix 192.168.219.0/28
    Upstream protocol MLDP
    Upstream interface Pseudo MLDP
    Upstream neighbor MLDP LSP root <1.1.1.2>

Instance: PIM.master Family: INET6

Source abcd::1:2:7:7
    Prefix abcd::1:2:7:0/120
    Upstream protocol MLDP
    Upstream interface Pseudo MLDP
    Upstream neighbor MLDP LSP root <1.1.1.2>
```

show pim statistics

Syntax

show pim statistics
<inet |inet6)>
<instance *instance-name*>
<interface *interface-name*>
<logical-system (all | *logical-system-name*)>

Syntax (EX Series Switch and the QFX Series)

show pim statistics
<inet |inet6)>
<instance *instance-name*>
<interface *interface-name*>

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
inet6 and **instance** options introduced in Junos OS Release 10.0 for EX Series switches.
Command introduced in Junos OS Release 11.3 for the QFX Series.
Support for bidirectional PIM added in Junos OS Release 12.1.

Description

Display Protocol Independent Multicast (PIM) statistics.

Options

none—Display PIM statistics.

inet | inet6—(Optional) Display IPv4 or IPv6 PIM statistics, respectively.

instance *instance-name*—(Optional) Display statistics for a specific routing instance enabled by Protocol Independent Multicast (PIM).

interface *interface-name*—(Optional) Display statistics about the specified interface.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Output Fields

Table 340 on page 4390 describes the output fields for the **show pim statistics** command. Output fields are listed in the approximate order in which they appear.

Table 340: show pim statistics Output Fields

Field Name	Field Description
Instance	Name of the routing instance. This field only appears if you specify an interface, for example: • **inet interface** ***interface-name*** • **inet6 interface** ***interface-name*** • **interface** ***interface-name***
Family	Output is for IPv4 or IPv6 PIM statistics. **INET** indicates IPv4 statistics, and **INET6** indicates IPv6 statistics. This field only appears if you specify an interface, for example: • **inet interface** ***interface-name*** • **inet6 interface** ***interface-name*** • **interface** ***interface-name***
PIM statistics	PIM statistics for all interfaces or for the specified interface.
PIM message type	Message type for which statistics are displayed.
Received	Number of received statistics.
Sent	Number of messages sent of a certain type.
Rx errors	Number of received packets that contained errors.
V2 Hello	PIM version 2 hello packets.
V2 Register	PIM version 2 register packets.
V2 Register Stop	PIM version 2 register stop packets.
V2 Join Prune	PIM version 2 join and prune packets.
V2 Bootstrap	PIM version 2 bootstrap packets.
V2 Assert	PIM version 2 assert packets.
V2 Graft	PIM version 2 graft packets.
V2 Graft Ack	PIM version 2 graft acknowledgment packets.
V2 Candidate RP	PIM version 2 candidate RP packets.

Table 340: show pim statistics Output Fields *(continued)*

Field Name	Field Description
V2 State Refresh	PIM version 2 control messages related to PIM dense mode (PIM-DM) state refresh. State refresh is an extension to PIM-DM. It not supported in Junos OS.
V2 DF Election	PIM version 2 send and receive messages associated with bidirectional PIM designated forwarder election.
V1 Query	PIM version 1 query packets.
V1 Register	PIM version 1 register packets.
V1 Register Stop	PIM version 1 register stop packets.
V1 Join Prune	PIM version 1 join and prune packets.
V1 RP Reachability	PIM version 1 RP reachability packets.
V1 Assert	PIM version 1 assert packets.
V1 Graft	PIM version 1 graft packets.
V1 Graft Ack	PIM version 1 graft acknowledgment packets.
AutoRP Announce	Auto-RP announce packets.
AutoRP Mapping	Auto-RP mapping packets.
AutoRP Unknown type	Auto-RP packets with an unknown type.
Anycast Register	Auto-RP announce packets.
Anycast Register Stop	Auto-RP announce packets.
Global Statistics	Summary of PIM statistics for all interfaces.
Hello dropped on neighbor policy	Number of hello packets dropped because of a configured neighbor policy.
Unknown type	Number of PIM control packets received with an unknown type.
V1 Unknown type	Number of PIM version 1 control packets received with an unknown type.
Unknown Version	Number of PIM control packets received with an unknown version. The version is not version 1 or version 2.

Table 340: show pim statistics Output Fields *(continued)*

Field Name	Field Description
Neighbor unknown	Number of PIM control packets received (excluding PIM hello) without first receiving the hello packet.
Bad Length	Number of PIM control packets received for which the packet size does not match the PIM length field in the packet.
Bad Checksum	Number of PIM control packets received for which the calculated checksum does not match the checksum field in the packet.
Bad Receive If	Number of PIM control packets received on an interface that does not have PIM configured.
Rx Bad Data	Number of PIM control packets received that contain data for TCP Bad register packets.
Rx Intf disabled	Number of PIM control packets received on an interface that has PIM disabled.
Rx V1 Require V2	Number of PIM version 1 control packets received on an interface configured for PIM version 2.
Rx V2 Require V1	Number of PIM version 2 control packets received on an interface configured for PIM version 1.
Rx Register not RP	Number of PIM register packets received when the routing device is not the RP for the group.
Rx Register no route	Number of PIM register packets received when the RP does not have a unicast route back to the source.
Rx Register no decap if	Number of PIM register packets received when the RP does not have a de-encapsulation interface.
Null Register Timeout	Number of NULL register timeout packets.
RP Filtered Source	Number of PIM packets received when the routing device has a source address filter configured for the RP.
Rx Unknown Reg Stop	Number of register stop messages received with an unknown type.
Rx Join/Prune no state	Number of join and prune messages received for which the routing device has no state.
Rx Join/Prune on upstream if	Number of join and prune messages received on the interface used to reach the upstream routing device, toward the RP.
Rx Join/Prune for invalid group	Number of join or prune messages received for invalid multicast group addresses.

Table 340: show pim statistics Output Fields *(continued)*

Field Name	Field Description
Rx Join/Prune messages dropped	Number of join and prune messages received and dropped.
Rx sparse join for dense group	Number of PIM sparse mode join messages received for a group that is configured for dense mode.
Rx Graft/Graft Ack no state	Number of graft and graft acknowledgment messages received for which the router or switch has no state.
Rx Graft on upstream if	Number of graft messages received on the interface used to reach the upstream routing device, toward the RP.
Rx CRP not BSR	Number of BSR messages received in which the PIM message type is Candidate-RP-Advertisement, not Bootstrap.
Rx BSR when BSR	Number of BSR messages received in which the PIM message type is Bootstrap.
Rx BSR not RPF if	Number of BSR messages received on an interface that is not the RPF interface.
Rx unknown hello opt	Number of PIM hello packets received with options that Junos OS does not support.
Rx data no state	Number of PIM control packets received for which the routing device has no state for the data type.
Rx RP no state	Number of PIM control packets received for which the routing device has no state for the RP.
Rx aggregate	Number of PIM aggregate MDT packets received.
Rx malformed packet	Number of PIM control packets received with a malformed IP unicast or multicast address family.
No RP	Number of PIM control packets received with no RP address.
No register encap if	Number of PIM register packets received when the first-hop routing device does not have an encapsulation interface.
No route upstream	Number of PIM control packets received when the routing device does not have a unicast route to the the interface used to reach the upstream routing device, toward the RP.
Nexthop Unusable	Number of PIM control packets with an unusable nexthop. A path can be unusable if the route is hidden or the link is down.
RP mismatch	Number of PIM control packets received for which the routing device has an RP mismatch.

Table 340: show pim statistics Output Fields *(continued)*

Field Name	Field Description
RP mode mismatch	RP mode (sparse or bidirectional) mismatches encountered when processing join and prune messages.
RPF neighbor unknown	Number of PIM control packets received for which the routing device has an unknown RPF neighbor for the source.
Rx Joins/Prunes filtered	The number of join and prune messages filtered because of configured route filters and source address filters.
Tx Joins/Prunes filtered	The number of join and prune messages filtered because of configured route filters and source address filters.
Embedded-RP invalid addr	Number of packets received with an invalid embedded RP address in PIM join messages and other types of messages sent between routing domains.
Embedded-RP limit exceed	Number of times the limit configured with the **maximum-rps** statement is exceeded. The **maximum-rps** statement limits the number of embedded RPs created in a specific routing instance. The range is from 1 through 500. The default is 100.
Embedded-RP added	Number of packets in which the embedded RP for IPv6 is added. The following receive events trigger extraction of an IPv6 embedded RP address on the routing device: • Multicast Listener Discovery (MLD) report for an embedded RP multicast group address • PIM join message with an embedded RP multicast group address • Static embedded RP multicast group address associated with an interface • Packets sent to an embedded RP multicast group address received on the DR An embedded RP node discovered through these receive events is added if it does not already exist on the routing platform.
Embedded-RP removed	Number of packets in which the embedded RP for IPv6 is removed. The embedded RP is removed whenever all PIM join states using this RP are removed or the configuration changes to remove the embedded RP feature.
Rx Register msgs filtering drop	Number of received register messages dropped because of a filter configured for PIM register messages.
Tx Register msgs filtering drop	Number of register messages dropped because of a filter configured for PIM register messages.
Rx Bidir Join/Prune on non-Bidir if	Error counter for join and prune messages received on non-bidirectional PIM interfaces.

Table 340: show pim statistics Output Fields *(continued)*

Field Name	Field Description
Rx Bidir Join/Prune on non-DF if	Error counter for join and prune messages received on non-designated forwarder interfaces.
V4 (S,G) Maximum	Maximum number of (S,G) IPv4 multicast routes accepted for the VPN routing and forwarding (VRF) routing instance. If this number is met, additional (S,G) entries are not accepted.
V4 (S,G) Accepted	Number of accepted (S,G) IPv4 multicast routes.
V4 (S,G) Threshold	Threshold at which a warning message is logged (percentage of the maximum number of (S,G) IPv4 multicast routes accepted by the device).
V4 (S,G) Log Interval	Time (in seconds) between consecutive log messages.
V6 (S,G) Maximum	Maximum number of (S,G) IPv6 multicast routes accepted for the VPN routing and forwarding (VRF) routing instance. If this number is met, additional (S,G) entries are not accepted.
V6 (S,G) Accepted	Number of accepted (S,G) IPv6 multicast routes.
V6 (S,G) Threshold	Threshold at which a warning message is logged (percentage of the maximum number of (S,G) IPv6 multicast routes accepted by the device).
V6 (S,G) Log Interval	Time (in seconds) between consecutive log messages.
V4 (grp-prefix, RP) Maximum	Maximum number of group-to-rendezvous point (RP) IPv4 multicast mappings accepted for the VRF routing instance. If this number is met, additional mappings are not accepted.
V4 (grp-prefix, RP) Accepted	Number of accepted group-to-RP IPv4 multicast mappings.
V4 (grp-prefix, RP) Threshold	Threshold at which a warning message is logged (percentage of the maximum number of group-to-RP IPv4 multicast mappings accepted by the device).
V4 (grp-prefix, RP) Log Interval	Time (in seconds) between consecutive log messages.
V6 (grp-prefix, RP) Maximum	Maximum number of group-to RP IPv6 multicast mappings accepted for the VRF routing instance. If this number is met, additional mappings are not accepted.
V6 (grp-prefix, RP) Accepted	Number of accepted group-to-RP IPv6 multicast mappings.

Table 340: show pim statistics Output Fields *(continued)*

Field Name	Field Description
V6 (grp-prefix, RP) Threshold	Threshold at which a warning message is logged (percentage of the maximum number of group-to-RP IPv6 multicast mappings accepted by the device).
V6 (grp-prefix, RP) Log Interval	Time (in seconds) between consecutive log messages.
V4 Register Maximum	Maximum number of IPv4 PIM registers accepted for the VRF routing instance. If this number is met, additional PIM registers are not accepted. You configure the register limits on the RP.
V4 Register Accepted	Number of accepted IPv4 PIM registers.
V4 Register Threshold	Threshold at which a warning message is logged (percentage of the maximum number of IPv4 PIM registers accepted by the device).
V4 Register Log Interval	Time (in seconds) between consecutive log messages.
V6 Register Maximum	Maximum number of IPv6 PIM registers accepted for the VRF routing instance. If this number is met, additional PIM registers are not accepted. You configure the register limits on the RP.
V6 Register Accepted	Number of accepted IPv6 PIM registers.
V6 Register Threshold	Threshold at which a warning message is logged (percentage of the maximum number of IPv6 PIM registers accepted by the device).
V6 Register Log Interval	Time (in seconds) between consecutive log messages.

Sample Output

show pim statistics

```
user@host> show pim statistics
PIM Message type        Received       Sent  Rx errors
V2 Hello                      15         32          0
V2 Register                    0        362          0
V2 Register Stop             483          0          0
V2 Join Prune                 18        518          0

show system statistics igmp

Syntax

show system statistics igmp

Syntax (EX Series Switches)

show system statistics igmp
<all-members>
<local>
<member *member-id*>

Syntax (TX Matrix Router)

show system statistics igmp
<all-chassis | all-lcc | lcc *number* | scc>

Syntax (TX Matrix Plus Router)

show system statistics igmp
<all-chassis | all-lcc | lcc *number* | sfc *number*>

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
sfc option introduced for the TX Matrix Plus router in Junos OS Release 9.6.
Command introduced in Junos OS Release 12.1 for the QFX Series.

Description

Display system-wide Internet Group Management Protocol (IGMP) statistics.

Options

none—Display system statistics for IGMP.

all-chassis—(TX Matrix routers and TX Matrix Plus routers only) (Optional) Display system statistics for IGMP for all the routers in the chassis.

all-lcc—(TX Matrix routers and TX Matrix Plus routers only) (Optional) On a TX Matrix router, display system statistics for IGMP for all T640 routers (or line-card chassis) connected to the TX Matrix router. On a TX Matrix Plus router, display system statistics for IGMP for all connected T1600 or T4000 LCCs.

all-members—(EX4200 switches only) (Optional) Display IGMP statistics for all members of the Virtual Chassis configuration.

lcc *number*—(TX Matrix routers and TX Matrix Plus routers only) (Optional) On a TX Matrix router, display system statistics for IGMP for a specific T640 router that is connected to the TX Matrix router. On a TX Matrix Plus router, display system statistics for IGMP for a specific router that is connected to the TX Matrix Plus router.

Replace *number* with the following values depending on the LCC configuration:

- 0 through 3, when T640 routers are connected to a TX Matrix router in a routing matrix.
- 0 through 3, when T1600 routers are connected to a TX Matrix Plus router in a routing matrix.
- 0 through 7, when T1600 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix.
- 0, 2, 4, or 6, when T4000 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix.

local—(EX4200 switches only) (Optional) Display IGMP statistics for the local Virtual Chassis member.

member ***member-id***—(EX4200 switches only) (Optional) Display IGMP statistics for the specified member of the Virtual Chassis configuration. Replace *member-id* with a value from 0 through 9.

scc—(TX Matrix routers only) (Optional) Display system statistics for IGMP for the TX Matrix router (or switch-card chassis).

sfc ***number***—(TX Matrix Plus routers only) (Optional) Display system statistics for IGMP for the TX Matrix Plus router. Replace *number* with 0.

Additional Information

By default, when you issue the **show system statistics igmp** command on the master Routing Engine of a TX Matrix router or a TX Matrix Plus router, the command is broadcast to all the master Routing Engines of the LCCs connected to it in the routing matrix. Likewise, if you issue the same command on the backup Routing Engine of a TX Matrix or a TX Matrix Plus router, the command is broadcast to all backup Routing Engines of the LCCs that are connected to it in the routing matrix.

test msdp

Syntax

test msdp (dependent-peers *prefix* | rpf-peer *originator*)
<instance *instance-name*>
<logical-system (all | *logical-system-name*)>

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 12.1 for the QFX Series.

Description

Find Multicast Source Discovery Protocol (MSDP) peers.

Options

dependent-peers ***prefix***—Find downstream dependent MSDP peers.

rpf-peer ***originator***—Find the MSDP reverse-path-forwarding (RPF) peer for the originator.

instance ***instance-name***—(Optional) Find MDSP peers for the specified routing instance.

logical-system (all | ***logical-system-name*****)**—(Optional) Perform this operation on all logical systems or on a particular logical system.

Required Privilege Level

view

List of Sample Output

test msdp dependent-peers on page 4406

Output Fields

When you enter this command, you are provided feedback on the status of your request.

Sample Output

test msdp dependent-peers

```
user@host> test msdp dependent-peers 10.0.0.1/24
```

PART 16

Security

CHAPTER 50

Overview

Firewall Filters

Overview of Firewall Filters

Firewall filters provide rules that define whether to accept or discard packets that are transiting an interface on a QFX Series product. If a packet is accepted, you can configure additional actions to perform on the packet, such as class-of-service (CoS) marking (grouping similar types of traffic together and treating each type of traffic as a class with its own level of service priority) and traffic policing (controlling the maximum rate of traffic sent or received). You configure firewall filters to determine whether to accept or discard a packet before it enters or exits any of these:

- Port
- VLAN

- Layer 3 (routed) interface
- Routed VLAN interface (RVI)

An *ingress* firewall filter is applied to packets that are entering an interface or VLAN, and an *egress* firewall filter is applied to packets that are exiting an interface or VLAN.

NOTE: Firewall filters are sometimes called *access control lists* (ACLs).

Firewall Filter Types

The following firewall filter types are supported on the QFX Series:

- Port (Layer 2) firewall filter—Port firewall filters apply to Layer 2 traffic transiting system ports.
- VLAN firewall filter—VLAN firewall filters provide access control for packets that enter a VLAN, are bridged within a VLAN, or leave a VLAN.
- Router (Layer 3) firewall filter—You can apply a router firewall filter in both ingress and egress directions on IPv4 or IPv6 Layer 3 (routed) interfaces, routed VLAN interfaces (RVI) and a loopback interface, which filters traffic sent to the switch itself or generated by the switch. (You apply a filter to a loopback interface in the input direction to protect the switch from unwanted traffic. You might want to apply a filter to a loopback interface in the output direction so that you can set the forwarding class and DSCP bit value for packets that originate on the switch itself. This feature gives you very fine control over the classification of CPU generated packets. For example, you might want to assign different DSCP values and forwarding classes to traffic generated by different routing protocols so the traffic for those protocols can be treated in a differentiated manner by other devices.)

  NOTE: You can apply a firewall filter to a management interface (for example, me0) on a QFX3500 device. You cannot apply a firewall filter to a management interface on a QFX3000-G or QFX3000-M system.

- MPLS filter—You can apply a firewall filter to an MPLS interface

To apply a firewall filter:

1. Configure the firewall filter.
2. Apply the firewall filter to a port, VLAN, or router interface.

NOTE: You can apply only one firewall filter to a port, VLAN, or interface for a given direction. For example, for interface ge-0/0/6.0, you can apply one filter for the ingress direction and one for the egress direction.

Firewall Filter Components

In a firewall filter, you first define the family address type (ethernet-switching, inet (for IPv4), inet6 (for IPv6), or mpls) and then define one or more terms that specify the filtering criteria and the action to take if a match occurs.

Each term consists of the following components:

- Match conditions—Specify values that a packet must contain to be considered a match. You can specify values for most fields in the IP, TCP, UDP, or ICMP headers. You can also match on interface names.
- Action—Specifies what to do if a packet matches the match conditions. A filter can accept, discard, or reject a matching packet and then perform additional actions, such as counting, classifying, and policing. If no action is specified for a term, the default is to accept the matching packet.

Firewall Filter Processing

If there are multiple terms in a filter, the order of the terms is important. If a packet matches the first term, the switch executes the action defined by that term, and no other terms are evaluated. If the switch does not find a match between the packet and the first term, it compares the packet to the next term. If no match occurs between the packet and the second term, the system continues to compare the packet to each successive term in the filter until a match is found. If the packet does not match any terms in the filter, the switch discards the packet by default.

Understanding Filter-Based Forwarding

You can use firewall filters in conjunction with virtual routing instances to specify different routes for packets to travel in their networks. To set up this feature—called filter-based forwarding—you specify a filter and match criteria and then specify the virtual routing instance to send packets to.

You might want to use filter-based forwarding to route specific types of traffic through a firewall or other security device before the traffic continues on its path. You can also use filter-based forwarding to give certain types of traffic preferential treatment. For example, you might want to ensure that the highest-priority traffic is forwarded over a 40-Gigabit Ethernet link. You might also use filter-based forwarding to obtain more control over load balancing than dynamic routing protocols provide.

NOTE: **You can create as many as 128 filters or terms that direct packets to a given virtual routing instance.**

Filters used for filter-based forwarding consume memory in two ternary content addressable memories (TCAMs), and this affects the number of supported filters. See "Planning the Number of Firewall Filters to Create" on page 4435 and "Understanding FIP Snooping, FBF, and MVR Filter Scalability" on page 4872 for more information. The section *FBF Filter VFP TCAM Consumption* in the latter topic specifically addresses the number of supported filters when using filter-based forwarding.

Understanding How Firewall Filters Are Evaluated

A firewall filter consists of one or more terms, and the order of the terms within a filter is important. Before you configure firewall filters, you should understand how the QFX Series products evaluate the terms within a filter and how packets are evaluated against the terms.

When a firewall filter consists of a single term, the filter is evaluated as follows:

- If the packet matches all the conditions, the action in the **then** statement is taken.
- If the packet matches all the conditions, and no action is specified in the **then** statement, the default action **accept** is taken.
- If the packet does not match all the conditions, the switch discards it.

When a firewall filter consists of more than one term, the filter is evaluated sequentially:

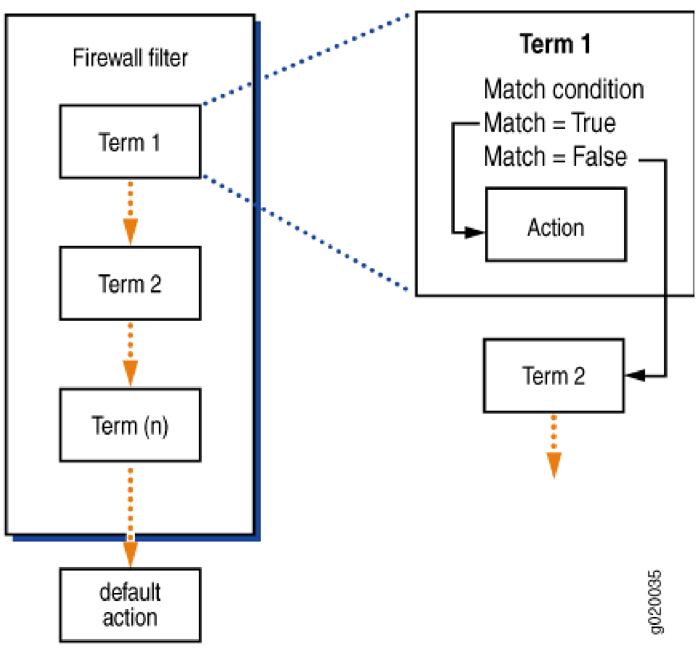
1. The packet is evaluated against the conditions in the **from** statement in the first term.
2. If the packet matches all the conditions in the term, the action in the **then** statement is taken and the evaluation ends. Subsequent terms in the filter are not evaluated.
3. If the packet does not match all the conditions in the term, the packet is evaluated against the conditions in the **from** statement in the second term.

   This process continues until the packet matches all the conditions in the **from** statement in one of the subsequent terms or there are no more terms in the filter.
4. If a packet passes through all the terms in the filter without a match, the switch discards it.

NOTE: The order of conditions in a from statement is not important because a packet must match all the conditions to be considered a match.

Figure 151 on page 4413 shows how QFX Series products evaluate the terms within a firewall filter.

Figure 151: Evaluation of Terms Within a Firewall Filter



If you do not include a **from** statement in a term, all packets will match the term and be processed by the **then** statement. If a term does not contain a **then** statement or if an action has not been configured in the **then** statement, the term accepts any matching packets.

Every firewall filter contains an implicit **deny** statement at the end of the filter, which is equivalent to the following explicit filter term:

```
term implicit-rule {
  then discard;
}
```

Consequently, a packet that does not match any of the terms in a firewall filter is discarded. If you configure a filter that has no terms, all packets that pass through the filter are discarded.

NOTE: Firewall filtering is supported on packets that are at least 64 bytes long.

Understanding How Firewall Filters Control Packet Flows

A switch supports firewall filters that allow you to control flows of data packets and local packets. *Data packets* transit a switch as they are forwarded from a source to a destination. *Local packets* are destined for or sent by a Routing Engine (they do not transit a switch). Local packets usually contain routing protocol data, data for IP services such as Telnet or SSH, or data for administrative protocols such as the Internet Control Message Protocol (ICMP).

Firewall filters affect packet flows entering into or exiting from a switch as follows:

- Ingress firewall filters affect the flow of data packets that are received on switch interfaces. When a switch receives a data packet, the Packet Forwarding Engine in the system that contains the ingress interface determines where to forward the packet by looking in its Layer 2 or Layer 3 forwarding table for the best route to the destination. Data packets are forwarded to an egress interface. Locally destined packets are forwarded to the Routing Engine.
- Egress firewall filters affect data packets that are transiting a switch but do not affect packets sent by the Routing Engine. These filters are applied by the Packet Forwarding Engine in the system that contains the egress interface.

Figure 152 on page 4415 illustrates the application of ingress and egress firewall filters to control the flow of packets through a switch:

1. Ingress firewall filter applied to locally destined packets that are received on switch interfaces and are destined for the Routing Engine.
2. Ingress firewall filter applied to data packets that are received on switch interfaces and will transit the switch.
3. Egress firewall filter applied to data packets that are transiting the switch.

Understanding Firewall Filter Match Conditions

Before you define terms for firewall filters, you must understand how the conditions in a term are handled and how to specify interface, numeric, address, and bit-field filter match conditions to achieve the desired filter results.

- Filter Match Conditions on page 4415
- Numeric Filter Match Conditions on page 4416
- Interface Filter Match Conditions on page 4416
- IP Address Filter Match Conditions on page 4417
- MAC Address Filter Match Conditions on page 4417
- Bit-Field Filter Match Conditions on page 4418

Filter Match Conditions

In the **from** statement of a firewall filter term, you specify the conditions that the packet must match for the action in the **then** statement to be taken. All conditions must match for the action to be implemented. The order in which you specify match conditions is not important, because a packet must match all the conditions in a term for a match to occur.

If you specify multiple values for the same condition, a match on any one of those values matches that condition. For example, if you specify multiple IP source addresses using the **source-address** statement, a packet that contains any one of those IP source addresses matches the condition. In some cases you can specify multiple values for the same condition by enclosing the possible values in square brackets, as in:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set protocol (icmp | udp)
```

In other cases you must enter multiple statements, as in:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set source-address 10.1.1.1
user@switch# set source-address 10.1.1.2
```

If you specify no match conditions in a term, that term matches all packets.

NOTE: **Unlike traditional Junos OS firewall filters, you cannot use except in a condition statement to negate the condition.**

Numeric Filter Match Conditions

You can specify numeric filter match conditions that are identified by a numeric value, such as port and protocol numbers. For numeric filter match conditions, you specify the condition and a single value that a field in a packet must contain to be considered a match.

You can specify the numeric value in one of the following ways:

- Single number—A match occurs if the value of the field matches the number. For example, to match Telnet traffic:

  ```
  [edit firewall family family-name filter filter-name term term-name from]
  user@switch# set source-port 23
  ```
- Text synonym for a single number—A match occurs if the value of the field matches the number that corresponds to the synonym. For example, to match Telnet traffic:

  ```
  [edit firewall family family-name filter filter-name term term-name from]
  user@switch# set source-port telnet
  ```
- To specify multiple values for the same match condition in a filter term, enter each value in its own match statement. For example, a match occurs in the following term if the value of the source port in the packet is 22 or 23.

  ```
  [edit firewall family family-name filter filter-name term term-name from]
  user@switch# set source-port 22
  user@switch# set source-port 23
  ```

Interface Filter Match Conditions

You can specify an interface filter match condition to match an interface on which a packet is received or transmitted. For example, if you apply a filter to a VLAN you might want the filter to match on some interfaces that participate in the VLAN and not match on other interfaces in the VLAN. When you specify the name of the interface, you must include a logical unit.

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set interface ge-0/0/6.0
```

In this example, the final character (0) specifies the logical unit. You can include the wildcard (*) as part of the interface name. For example:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set interface ge-0/*/6.0
user@switch# set interface ge-0/1/*.0
user@switch# set interface ge-0/0/6.*
```

Note that you must specify a value or a wildcard for the logical unit.

IP Address Filter Match Conditions

You can specify an address filter match condition to match an IP source or destination address or prefix in a packet. Specify the address or prefix type and the address or prefix itself. For example:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set destination-address 10.2.1.0/24;
```

If you omit the prefix length, it defaults to /32. For example:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set destination-address 10
[edit firewall family family-name filter filter-name term term-name from]
user@switch# show
destination-address {
10.0.0.0/32;
}
```

To specify more than one IP address or prefix in a filter term, enter each address or prefix in its own match statement. For example, a match occurs in the following term if the source address of a packet matches either of the following prefixes:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set source-address 10.1.0.0/16
user@switch# set source-address 10.2.0.0/16
```

MAC Address Filter Match Conditions

You can specify a MAC address filter match condition to match a source or destination MAC address. You specify the address type and value that a packet must contain to be considered a match.

You can specify the MAC address as six hexadecimal bytes in any of the following formats:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set destination-mac-address 00:11:22:33:44:55
```

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set destination-mac-address 0011.2233.4455
```

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set destination-mac-address 001122334455
```

Regardless of the formats you use, the system resolves the address to the standard format, in this case 00:11:22:33:44:55.

To specify more than one MAC address in a filter term, enter each MAC address in its own match statement. For example, a match occurs in the following term if the value of the MAC source address matches either of the following addresses:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set source-mac-address 00:11:22:33:44:55
```

```
user@switch# set source-mac-address 00:11:22:33:20:15
```

Bit-Field Filter Match Conditions

You can specify bit-field filter match conditions to match particular bits within certain fields in Ethernet frames and IP, TCP, UDP, and ICMP headers. You usually specify the field and the bit within the field that must be set in a packet to be considered a match.

In most cases you can use a keyword to specify the bit you want to match on. For example, to match on a TCP SYN packet you can enter **syn**, as in:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set tcp-flags syn
```

You can also enter **0x02** because the SYN bit is the third least-significant bit of the 8-bit tcp-flags field:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set tcp-flags 0x02
```

To match multiple bit-field values, use the logical operators, which are described in Table 341 on page 4418. The operators are listed in order from highest precedence to lowest precedence. Operations are evaluated from left to right.

Table 341: Actions for Firewall Filters

Logical Operators	Description
!	Negation
&	Logical AND
|	Logical OR

If you use a logical operator, enclose the values in quotation marks and do not include any spaces. For example, the following statement matches the second packet of a TCP handshake:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set tcp-flags "syn&ack"
```

To negate a match, precede the value with an exclamation point. For example, the following statement matches only the initial packet of a TCP handshake:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set tcp-flags "syn&!ack"
```

You can use text synonyms to specify some common bit-field matches. For example, the following statement also matches the initial packet of a TCP handshake:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set tcp-initial
```

Firewall Filter Match Conditions and Actions

Each term in a firewall filter consists of *match conditions* and an *action*. Match conditions are the fields and values that a packet must contain to be considered a match. You can define single or multiple match conditions in *match statements*. You can also include no match statement, in which case the term matches all packets.

When a packet matches a filter, a switch takes the action specified in the term. In addition, you can specify action modifiers to count, mirror, rate-limit, and classify packets. If no match conditions are specified for the term, the switch accepts the packet by default.

This topic describes the various match conditions, actions, and action modifiers that you can define in a firewall filter.

- Table 342 on page 4419 describes the match conditions you can specify when configuring a firewall filter. Some of the numeric range and bit-field match conditions allow you to specify a text synonym. To see a list of all the synonyms for a match condition, type **?** at the appropriate place in a statement.
- Table 343 on page 4430 shows the actions that you can specify in a term.
- Table 344 on page 4431 shows the action modifiers you can use to count, mirror, rate-limit, and classify packets.

Table 342: Supported Match Conditions for Firewall Filters

Match Condition	Description	Direction and Interface
arp-type	ARP request packet or ARP reply packet.	Egress and ingress ports.
destination-address ***ip-address***	IP destination address field, which is the address of the final destination node.	Ingress ports, VLANs, IPv4 (inet) interfaces, and IPv6 (inet6) interfaces. Egress IPv4 (inet) interfaces, and IPv6 (inet6) interfaces.
destination-mac-address ***mac-address***	Destination media access control (MAC) address of the packet.	Ingress ports, VLANs and IPv4 (inet) interfaces. Egress ports and VLANs.

Table 342: Supported Match Conditions for Firewall Filters *(continued)*

Match Condition	Description	Direction and Interface
destination-port *value*	TCP or UDP destination port field. Typically, you specify this match in conjunction with the **protocol** match statement. For the following well-known ports you can specify text synonyms (the port numbers are also listed): **afs** (1483), **bgp** (179), **biff** (512), **bootpc** (68), **bootps** (67), **cmd** (514), **cvspserver** (2401), **dhcp** (67), **domain** (53), **eklogin** (2105), **ekshell** (2106), **exec** (512), **finger** (79), **ftp** (21), **ftp-data** (20), **http** (80), **https** (443), **ident** (113), **imap** (143), **kerberos-sec** (88), **klogin** (543), **kpasswd** (761), **krb-prop** (754), **krbupdate** (760), **kshell** (544), **ldap** (389), **login** (513), **mobileip-agent** (434), **mobilip-mn** (435), **msdp** (639), **netbios-dgm** (138), **netbios-ns** (137), **netbios-ssn** (139), **nfsd** (2049), **nntp** (119), **ntalk** (518), **ntp** (123), **pop3** (110), **pptp** (1723), **printer** (515), **radacct** (1813),**radius** (1812), **rip** (520), **rkinit** (2108), **smtp** (25), **snmp** (161), **snmptrap** (162), **snpp** (444), **socks** (1080), **ssh** (22), **sunrpc** (111), **syslog** (514), **tacacs-ds** (65), **talk** (517), **telnet** (23), **tftp** (69), **timed** (525), **who** (513), **xdmcp** (177), **zephyr-clt** (2103), **zephyr-hm** (2104)	Ingress ports, VLANs, IPv4 (inet) interfaces, and IPv6 (inet6) interfaces. Egress IPv4 (inet) interfaces.

Table 342: Supported Match Conditions for Firewall Filters *(continued)*

Match Condition	Description	Direction and Interface
destination-port range-optimize *range*	Match a range of TCP or UDP port ranges while using the available memory more efficiently. Using this condition allows you to configure more firewall filters than if you configure individual destination ports.	Egress and ingress IPv4 (inet) interfaces.
destination-prefix-list *prefix-list*	IP destination prefix list field. You can define a list of IP address prefixes under a prefix-list alias for frequent use. Define this list at the **[edit policy-options]** hierarchy level.	Ingress ports, VLANs, IPv4 (inet) interfaces, and IPv6 (inet6) interfaces. Egress IPv4 (inet) interfaces and IPv6 (inet6) interfaces.
dot1q-tag *number*	802.1Q VLAN ID field in the Ethernet frame. The tag values can be 1–4094.	Ingress ports and VLANs. Egress ports and VLANs (*Number* must be the VLAN ID of the VLAN you want to match).
dot1q-user-priority *number*	802.1Q priority field in the Ethernet frame (used for class-of-service priorities). Values can be 0–7. In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): • **best-effort (0)**—Best effort • **background (1)**—Background • **standard (2)**—Standard or spare • **excellent-load (3)**—Excellent load • **controlled-load (4)**—Controlled load • **video (5)**—Video • **voice (6)**—Voice • **network-control (7)**—Network control reserved traffic	Ingress ports and VLANs. Egress ports and VLANs.

Table 342: Supported Match Conditions for Firewall Filters *(continued)*

Match Condition	Description	Direction and Interface
dscp ***value***	Differentiated Services code point (DSCP). The DiffServ protocol uses the type-of-service (ToS) byte in the IP header. The most-significant 6 bits of this byte form the DSCP. You can specify DSCP in hexadecimal, binary, or decimal form. In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): • **be**—best effort (default) • **ef (46)**—as defined in RFC 3246, *An Expedited Forwarding PHB*. • **af11 (10)**, **af12 (12)**, **af13 (14)**; **af21 (18)**, **af22 (20)**, **af23 (22)**; **af31 (26)**, **af32 (28)**, **af33 (30)**; **af41 (34)**, **af42 (36)**, **af43 (38)** These four classes, with three drop precedences in each class, for a total of 12 code points, are defined in RFC 2597, *Assured Forwarding PHB*. • **cs0**, **cs1**, **cs2**, **cs3**, **cs4**, **cs5**, **cs6**, **cs7**, **cs5**	Ingress ports, VLANs, and IPv4 (inet) interfaces. Egress IPv4 (inet) interfaces.

Table 342: Supported Match Conditions for Firewall Filters *(continued)*

Match Condition	Description	Direction and Interface
ether-type ***value***	Ethernet type field of a packet. The EtherType value specifies what protocol is being transported in the Ethernet frame. In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): • **aarp (0x80F3)**—EtherType value AARP • **appletalk (0x809B)**—EtherType value AppleTalk • **arp (0x0806)**—EtherType value ARP • **fcoe (0x8906)**—EtherType value FCoE • **fip (0x8914)**—EtherType value FIP • **ipv4 (0x0800)**—EtherType value IPv4 • **ipv6 (0x08DD)**—EtherType value IPv6 • **mpls-multicast (0x8848)**—EtherType value MPLS multicast • **mpls-unicast (0x8847)**—EtherType value MPLS unicast • **oam (0x88A8)**—EtherType value OAM • **ppp (0x880B)**—EtherType value PPP • **pppoe-discovery (0x8863)**—EtherType value PPPoE Discovery Stage • **pppoe-session (0x8864)**—EtherType value PPPoE Session Stage • **sna (0x80D5)**—EtherType value SNA	Ingress ports and VLANs. Egress ports and VLANs.
exp	Match on MPLS EXP bits.	Ingress MPLS interfaces. Egress MPLS interfaces.
fragment-flags ***value***	IP fragmentation flags. In place of the numeric value, you can specify one of the following text synonyms (the hexadecimal values are also listed): • **is-fragment** • **dont-fragment (0x4000)** • **more-fragments (0x2000)** • **reserved (0x8000)**	Ingress ports and VLANs.

Table 342: Supported Match Conditions for Firewall Filters *(continued)*

<table>
<tr><th>Match Condition</th><th>Description</th><th>Direction and Interface</th></tr>
<tr><td>icmp-code value</td><td>ICMP code field. Because the meaning of the value depends upon the associated icmp-type, you must specify a value for icmp-type along with a value for icmp-code. In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed). The keywords are grouped by the ICMP type with which they are associated:

IPv4: parameter-problem—ip-header-bad (0), required-option-missing (1)
IPv6: parameter-problem—ip6-header-bad (0), unrecognized-next-header (1), unrecognized-option (2)
redirect—redirect-for-network (0), redirect-for-host (1), redirect-for-tos-and-net (2), redirect-for-tos-and-host (3)
time-exceeded—ttl-eq-zero-during-reassembly (1), ttl-eq-zero-during-transit (0)
IPv4: unreachable—network-unreachable (0), host-unreachable (1), protocol-unreachable (2), port-unreachable (3), fragmentation-needed (4), source-route-failed (5), destination-network-unknown (6), destination-host-unknown (7), source-host-isolated (8), destination-network-prohibited (9), destination-host-prohibited (10), network-unreachable-for-TOS (11), host-unreachable-for-TOS (12), communication-prohibited-by-filtering (13), host-precedence-violation (14), precedence-cutoff-in-effect (15)
IPv6: unreachable—address-unreachable (3), administratively-prohibited (1), no-route-to-destination (0), port-unreachable (4)
</td><td>Ingress ports, VLANs, IPv4 (inet) interfaces, and IPv6 (inet6) interfaces.

Egress IPv4 (inet) interfaces.</td></tr>
</table>

Table 342: Supported Match Conditions for Firewall Filters *(continued)*

Match Condition	Description	Direction and Interface
icmp-type *value*	ICMP message type field. Typically, you specify this match in conjunction with the **protocol** match statement to determine which protocol is being used on the port. In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): *IPv4:* **echo-reply (0)**, **destination unreachable (3)**, **source-quench (4)**, **redirect (5)**, **echo-request (8)**, **IPv4 (inet)-advertisement (9)**, **IPv4 (inet)-solicit (10)**, **time-exceeded (11)**, **parameter-problem (12)**, **timestamp (13)**, **timestamp-reply (14)**, **info-request (15)**, **info-reply (16)**, **mask-request (17)**, **mask-reply (18)** *IPv6:* **destination-unreachable (1)**, **packet-too-big (2)**, **time-exceeded (3)**, **parameter-problem (4)**, **echo-request (128)**, **echo-reply (129)**, **membership-query (130)**, **membership-report (131)**, **membership-termination (132)**, **router-solicit (133)**, **router-advertisement (134)**, **neighbor-solicit (135)**, **neighbor-advertisement (136)**, **redirect (137)**, **router-renumbering (138)**, **node-information-request (139)**, **node-information-reply (140)** See also **icmp-code** ***variable***.	Ingress ports, VLANs, IPv4 (inet) interfaces, and IPv6 (inet6) interfaces. Egress IPv4 (inet) interfaces.
interface *interface-name*	Interface on which the packet is received, including the logical unit. You can include the wildcard character (*****) as part of an interface name or logical unit. NOTE: An interface from which a packet is sent cannot be used as a match condition.	Ingress ports, VLANs, IPv4 (inet) interfaces, and IPv6 (inet6) interfaces. Egress IPv4 (inet) interfaces and IPv6 (inet6) interfaces.
ip-destination-address *address*	32-bit address that is the final destination node address for the packet.	Ingress ports, VLANs, and IPv4 (inet) interfaces. Egress IPv4 (inet) interfaces.
ip-options	Specify **any** to create a match if anything is specified in the options field in the IP header.	Ingress ports, VLANs, and IPv4 (inet) interfaces. Egress IPv4 (inet) interfaces.

Table 342: Supported Match Conditions for Firewall Filters *(continued)*

Match Condition	Description	Direction and Interface
ip-precedence *ip-precedence-field*	IP precedence field. In place of the numeric field value, you can specify one of the following text synonyms (the field values are also listed): **critical-ecp** (0xa0), **flash** (0x60), **flash-override** (0x80), **immediate** (0x40), **internet-control** (0xc0), **net-control** (0xe0), **priority** (0x20), or **routine** (0x00).	Ingress ports, VLANs, and IPv4 (inet) interfaces. Egress IPv4 (inet) interfaces.
ip-protocol *number*	IP protocol field.	Ingress ports, VLANs, and IPv4 (inet) interfaces. Egress IPv4 (inet) interfaces.
ip-source-address *address*	IP address of the source node sending the packet.	Ingress ports, VLANs, and IPv4 (inet) interfaces. Egress IPv4 (inet) interfaces.
ip-version *address*	IP version of the packet.	Ingress ports, VLANs, and IPv4 (inet) interfaces. Egress IPv4 (inet) interfaces.
is-fragment	Using this condition causes a match if the More Fragments flag is enabled in the IP header or if the fragment offset is not zero.	Ingress ports, VLANs, and IPv4 (inet) interfaces. Egress IPv4 (inet) interfaces.
l2-encap-type llc-non-snap	Match on logical link control (LLC) layer packets for non-Subnet Access Protocol (SNAP) Ethernet Encapsulation type.	Ingress ports and VLANs. Egress ports and VLANs.
label	Match on MPLS label bits.	Ingress MPLS interfaces. Egress MPLS interfaces.
learn-vlan-id *number*	VLAN identifier used for MAC learning.	Ingress ports and VLANs. Egress ports and VLANs.
next-header	IPv4 or IPv6 protocol value. In place of the numeric value, you can specify one of the following text synonyms (the numeric values are also listed): **hop-by-hop (0)**,**icmp (1)**, **icmp6 (58)**, **igmp (2)**, **ipip (4)**, **tcp (6)**, **egp (8)**, **udp (17)**, **ipv6 (41)**, **routing (43)**, **fragment (44)**,**rsvp (46)**, **gre (47)**, **esp (50)**, **ah (51)**, **icmp6 (58)**, **no-next-header (59)**, **dstopts (60)**, **ospf (89)**, **pim (103)**, **vrrp (112)**, **sctp (132)**	Ingress ports, VLANs, and IPv6 (inet6) interfaces. Egress IPv6 (inet6) interfaces.

Table 342: Supported Match Conditions for Firewall Filters *(continued)*

Match Condition	Description	Direction and Interface
packet-length	Packet length in bytes. You must enter a value between 0 and 65535.	Ingress ports, VLANs, IPv4 (inet), and IPv6 (inet6) interfaces. Egress IPv4 (inet) interfaces.
payload-protocol	IPv4 or IPv6 protocol value. In place of the numeric value, you can specify one of the following text synonyms (the numeric values are also listed): **hop-by-hop** (0),**icmp** (1), **icmp6** (58), **igmp** (2), **ipip** (4), **tcp** (6), **egp** (8), **udp** (17), **ipv6** (41), **routing** (43), **fragment** (44),**rsvp** (46), **gre** (47), **esp** (50), **ah** (51), **icmp6** (58), **no-next-header** (59), **dstopts** (60), **ospf** (89), **pim** (103), **vrrp** (112), **sctp** (132)	Ingress ports, VLANs, and IPv6 (inet6) interfaces. Egress IPv6 (inet6) interfaces.
precedence *value*	IP precedence bits in the type-of-service (ToS) byte in the IP header. (This byte can also used for the DiffServ DSCP.) In place of the numeric value, you can specify one of the following text synonyms (the numeric values are also listed): • **routine** (0) • **priority** (1) • **immediate** (2) • **flash** (3) • **flash-override** (4) • **critical-ecp** (5) • **internet-control** (6) • **net-control** (7)	Ingress ports, VLANs, and IPv4 (inet) interfaces. Egress IPv4 (inet) interfaces.
protocol *type*	IPv4 or IPv6 protocol value. In place of the numeric value, you can specify one of the following text synonyms (the numeric values are also listed): **hop-by-hop** (0),**icmp** (1), **icmp6**, **igmp** (2), **ipip** (4), **tcp** (6), **egp** (8), **udp** (17), **ipv6** (41), **routing** (43), **fragment** (44),**rsvp** (46), **gre** (47), **esp** (50), **ah** (51), **icmp6** (58), **no-next-header** (59), **dstopts** (60), **ospf** (89), **pim** (103), **vrrp** (112), **sctp** (132)	Ingress ports, VLANs and IPv4 (inet) interfaces. Egress IPv4 (inet) interfaces.

Table 342: Supported Match Conditions for Firewall Filters *(continued)*

Match Condition	Description	Direction and Interface
rat-type *tech-type-value*	Match the radio-access technology (RAT) type specified in the 8-bit Tech-Type field of Proxy Mobile IPv4 (PMIPv4) access technology type extension. The technology type specifies the access technology through which the mobile device is connected to the access network. Specify a single value, a range of values, or a set of values. You can specify a technology type as a numeric value from 0 through 255 or as a system keyword. • Numeric value 1 matches IEEE 802.3. • Numeric value 2 matches IEEE 802.11a/b/g. • Numeric value 3 matches IEEE 802.16e • Numeric value 4 matches IEEE 802.16m. • Text string **eutran** matches 4G. • Text string **geran** matches 2G. • Text string **utran** matches 3G. •	Egress and ingress IPv4 (inet) interfaces.
sample	Sample the packet traffic. Apply this option only if you have enabled traffic sampling.	Egress and ingress IPv4 (inet) interfaces.
source-address *ip-address*	IP source address field, which is the address of the node that sent the packet.	Ingress ports, VLANs, IPv4 (inet) interfaces, and IPv6 (inet6) interfaces. Egress IPv4 (inet) interfaces.
source-mac-address *mac-address*	Source media access control (MAC) address of the packet.	Ingress ports and VLANs. Egress ports and VLANs.
source-port *value*	TCP or UDP source port. Typically, you specify this match in conjunction with the **protocol** match statement. In place of the numeric field, you can specify one of the text synonyms listed under **destination-port**.	Ingress ports, VLANs, IPv4 (inet) interfaces, and IPv6 (inet6) interfaces. Egress IPv4 (inet) interfaces.
source-port range-optimize *range*	Match a range of TCP or UDP port ranges while using the available memory more efficiently. Using this condition allows you to configure more firewall filters than if you configure individual source ports.	Egress and ingress IPv4 (inet) interfaces.

Table 342: Supported Match Conditions for Firewall Filters *(continued)*

Match Condition	Description	Direction and Interface
source-prefix-list ***prefix-list***	IP source prefix list. You can define a list of IP address prefixes under a prefix-list alias for frequent use. Define this list at the **[edit policy-options]** hierarchy level.	Ingress ports, VLANs, IPv4 (inet) interfaces, and IPv6 (inet6) interfaces. Egress IPv4 (inet) interfaces.
tcp-established	Match packets of an established TCP connection. This condition matches packets other than those used to set up a TCP connection—that is, three-way handshake packets are not matched. When you specify **tcp-established**, a switch does not implicitly verify that the protocol is TCP. You must also specify the **protocol tcp** match condition.	Ingress ports, VLANs, IPv4 (inet) interfaces, and IPv6 (inet6) interfaces. Egress IPv4 (inet) interfaces.
tcp-flags ***value***	One or more TCP flags: • **ack (0x10)** • **fin (0x01)** • **push (0x08)** • **rst (0x04)** • **syn (0x02)** • **urgent (0x20)**	Ingress ports, VLANs, IPv4 (inet) interfaces, and IPv6 (inet6) interfaces. Egress IPv4 (inet) interfaces.
tcp-initial	Match the first TCP packet of a connection. A match occurs when the TCP flag **SYN** is set and the TCP flag **ACK** is not set. When you specify **tcp-initial**, a switch does not implicitly verify that the protocol is TCP. You must also specify the **protocol tcp** match condition.	Ingress ports, VLANs, IPv4 (inet) interfaces, and IPv6 (inet6) interfaces. Egress IPv4 (inet) interfaces.
traffic-class	8-bit field that specifies the class-of-service (CoS) priority of the packet. The traffic-class field is used to specify a DiffServ code point (DSCP) value. This field was previously used as the type-of-service (ToS) field in IPv4, and, the semantics of this field (for example, DSCP) are identical to those of IPv4. You can specify one of the following text synonyms (the field values are also listed): **af11 (10)**, **af12 (12)**, **af13 (14)**, **af21 (18)**, **af22 (20)**, **af23 (22)**, **af31 (26)**, **af32 (28)**, **af33 (30)**, **af41 (34)**, **af42 (36)**, **af43 (38)**, **cs0 (0)**, **cs1 (8)**, **cs2 (16)**, **cs3 (24)**, **cs4 (32)**, **cs5 (40)**, **cs6 (48)**, **cs7 (56)**, **ef (46)**	Ingress ports, VLANs, and IPv6 (inet6) interfaces. Egress IPv6 (inet6) interfaces.

Table 342: Supported Match Conditions for Firewall Filters *(continued)*

Match Condition	Description	Direction and Interface
ttl ***value***	IP Time-to-live (TTL) field in decimal. The value can be 1-255.	Ingress IPv4 (inet) interfaces. Egress IPv4 (inet) interfaces.
user-vlan-1p-priority ***value***	Match on the IEEE 802.1p user priority bits in the customer VLAN tag (the inner tag in a dual-tag frame with 802.1Q VLAN tags). Specify a single value or multiple values from 0 through 7.	Ingress ports, VLANs, and IPv4 (inet) interfaces. Egress IPv4 (inet) interfaces.
user-vlan-id ***number***	Match the first VLAN identifier that is part of the payload.	Ingress ports, VLANs, and IPv4 (inet) interfaces. Egress IPv4 (inet) interfaces.
vlan (*vlan-name* | *vlan-id*)	VLAN names or ID.	Ingress ports and VLANs. Egress ports and VLANs.

Use **then** statements to define actions that should occur if a packet matches all conditions in a **from** statement. Table 343 on page 4430 shows the actions that you can specify in a term. (If you do not include a **then** statement, the system accepts packets that match the filter.)

Table 343: Actions for Firewall Filters

Action	Description
accept	Accept a packet. This is the default action for packets that match a term.
discard	Discard a packet silently without sending an Internet Control Message Protocol (ICMP) message.
reject ***message-type***	Discard a packet and send a “destination unreachable” ICMPv4 message (type 3). To log rejected packets, configure the **syslog** action modifier. You can specify one of the following message types: **administratively-prohibited (default), bad-host-tos, bad-network-tos, host-prohibited, host-unknown, host-unreachable, network-prohibited, network-unknown, network-unreachable, port-unreachable, precedence-cutoff, precedence-violation, protocol-unreachable, source-host-isolated, source-route-failed,** or **tcp-reset**. If you specify **tcp-reset**, the system sends a TCP reset if the packet is a TCP packet; otherwise nothing is sent. If you do not specify a message type, the ICMP notification “destination unreachable” is sent with the default message “communication administratively filtered.” NOTE: The **reject** action is supported on ingress interfaces only.

Table 343: Actions for Firewall Filters *(continued)*

Action	Description
routing-instance *instance-name*	Forward matched packets to a virtual routing instance.
vlan *VLAN-name*	Forward matched packets to a specific VLAN. NOTE: The **vlan** action is supported on ingress interfaces only.

You can also specify the action modifiers listed in Table 344 on page 4431 to count, mirror, rate-limit, and classify packets.

Table 344: Action Modifiers for Firewall Filters

Action Modifier	Description
analyzer ***analyzer-name***	Mirror traffic (copy packets) to an analyzer configured at the **[edit ethernet-switching-options analyzer]** hierarchy level. You can specify port mirroring for ingress port, VLAN, and IPv4 (inet) firewall filters only.
count ***counter-name***	Count the number of packets that match the term.
dscp ***value***	Differentiated Services code point (DSCP). The DiffServ protocol uses the type-of-service (ToS) byte in the IP header. The most-significant 6 bits of this byte form the DSCP. You can specify DSCP in hexadecimal, binary, or decimal form. In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): • **be**—best effort (default) • **ef (46)**—as defined in RFC 3246, *An Expedited Forwarding PHB*. • **af11 (10)**, **af12 (12)**, **af13 (14)**; **af21 (18)**, **af22 (20)**, **af23 (22)**; **af31 (26)**, **af32 (28)**, **af33 (30)**; **af41 (34)**, **af42 (36)**, **af43 (38)** These four classes, with three drop precedences in each class, for a total of 12 code points, are defined in RFC 2597, *Assured Forwarding PHB*. • **cs0**, **cs1**, **cs2**, **cs3**, **cs4**, **cs5**, **cs6**, **cs7**, **cs5**

Table 344: Action Modifiers for Firewall Filters *(continued)*

Action Modifier	Description
forwarding-class ***class***	Classify the packet in one of the following forwarding classes: • **best-effort** • **fcoe** • **mcast** • **network-control** • **no-loss** NOTE: To configure a forwarding class, you must also configure loss priority.
log	Log the packet's header information in the Routing Engine. To view this information, enter the **show firewall log** operational mode command. NOTE: The **log** action modifier is supported on ingress interfaces only.
loss-priority (low | medium-low | medium-high | high)	Set the packet loss priority (PLP). NOTE: The **loss-priority** action modifier is supported on ingress interfaces only. NOTE: The **loss-priority** action modifier is not supported in combination with the **policer** action.
policer ***policer-name***	Send packets to a policer (for the purpose of applying rate limiting). You can specify a policer for ingress port, VLAN, IPv4 (inet), IPv6 (inet6), and MPLS filters. NOTE: The **policer** action modifier is not supported in combination with the **loss-priority** action.
syslog	Log an alert for this packet. NOTE: The **syslog** action modifier is supported on ingress interfaces only.
three-color-policer ***three-color-policer-name***	Send packets to a three-color policer (for the purpose of applying rate limiting). You can specify a three-color policer for ingress and egress port, VLAN, IPv4 (inet), IPv6 (inet6), and MPLS filters. NOTE: The **policer** action modifier is not supported in combination with the **loss-priority** action.

Understanding How a Firewall Filter Tests a Protocol

When examining match conditions in a firewall filter, a switch tests only the fields that you specify. It does not implicitly test any fields that you do not explicitly configure. For example, if you specify a match condition of **source-port ssh**, there is no implied test to determine if the protocol is TCP. In this case, the switch considers any packet that has a value of **22** (decimal) in the 2-byte field that follows a *presumed* IP header to be a match. To ensure that the term matches on TCP packets, you also specify a **protocol tcp** match condition.

For the following match conditions, you should explicitly specify the protocol match condition in the same term:

- **destination-port**—Specify **protocol tcp** or **protocol udp**.
- **icmp-code**—Specify **protocol icmp** and **icmp-type**.
- **icmp-type**—Specify **protocol tcp** or **protocol udp**.
- **source-port**—Specify **protocol tcp** or **protocol udp**.
- **tcp-flags**—Specify **protocol tcp**.

Understanding Firewall Filter Planning

Before you create a firewall filter and apply it, determine what you want the filter to accomplish and how to use its match conditions and actions to achieve your goals. It is important that you understand how packets are matched, the default and configured actions of the firewall filter, and where to apply the firewall filter.

You can apply no more than one firewall filter per port, VLAN, or router interface per direction (input and output). For example, for a given port you can apply at most one filter in the input direction and one filter in the output direction. You should try to be conservative in the number of terms (rules) that you include in each firewall filter, because a large number of terms requires longer processing time during a commit operation and can make testing and troubleshooting more difficult.

Before you configure and apply firewall filters, answer the following questions for each of them:

1. What is the purpose of the filter?

   For example, the system can drop packets based on header information, rate-limit traffic, classify packets into forwarding classes, log and count packets, or prevent denial-of-service attacks.

2. What are the appropriate match conditions? Determine the packet header fields that the packet must contain for a match. Possible fields include:

   - Layer 2 header fields—Source and destination MAC addresses, 802.1Q tag, Ethernet type, or VLAN.
   - Layer 3 header fields—Source and destination IP addresses, protocols, and IP options (IP precedence, IP fragmentation flags, or TTL type).
   - TCP header fields—Source and destination ports and flags.
   - ICMP header fields—Packet type and code.

3. What are the appropriate actions to take if a match occurs?

   The system can accept, discard, or reject packets.

4. What additional action modifiers might be required?

   For example, you can configure the system to mirror (copy) packets to a specified port, count matching packets, apply traffic management, or police packets.

5. On what port, router interface, or VLAN should the firewall filter be applied?

   Start with the following basic guidelines:

   - If packets entering or leaving a Layer 2 interface (port) need to be filtered, apply the filter at the **[edit family ethernet switching filter]** hierarchy level. This is a port filter.
   - If packets entering or leaving any port in a specific VLAN need to be filtered, use a VLAN filter.

- If packets entering or leaving a Layer 3 (routed) interface or routed VLAN interface (RVI) need to be filtered, use a router firewall filter. Apply the filter to the interface at the **[edit family inet]** hierarchy level. You can also apply a router firewall filter on a loopback interface.

Before you choose the interface or VLAN on which to apply a firewall filter, understand how that placement can affect traffic flow to other interfaces. In general, apply a filter close to the source device if the filter matches on source or destination IP addresses, IP protocols, or protocol information—such as ICMP message types, and TCP or UDP port numbers. However, you should apply a filter close to the destination device if the filter matches *only* on a source IP address. When you apply a filter too close to the source device, the filter could prevent that source device from accessing other services that are available on the network.

NOTE: Egress firewall filters do not affect the flow of locally generated control packets from the Routing Engine.

6. In which direction should the firewall filter be applied?

   You typically configure different actions for traffic entering an interface than you configure for traffic exiting an interface.

7. How many filters should I create?

   See "Planning the Number of Firewall Filters to Create" on page 4435 for information about how many firewall filters you can apply.

Planning the Number of Firewall Filters to Create

Understanding How Many Firewall Filters Are Supported

QFX3500, QFX3600, and QFX5100 switches and QFabric Node devices support the maximum numbers of firewall filter terms per type of attachment point shown in Table 345 on page 4436.

Table 345: Supported Firewall Filter Numbers

Filter Type	QFX3500, QFX3600	QFX5100
Ingress	768	1536
Egress	1024	1024

These totals are applied in aggregate. For example, on the QFX3500 and QFX3600 you can apply a total of 768 terms in all your port filters, Layer 3 filters, and VLAN filters that are applied in the input direction and 1024 terms in port filters, Layer 3 filters, and VLAN filters that are applied in the output direction.

NOTE: If you want to create more than 512 egress VLAN filters, your first VLAN ID should be 6 and the subsequent VLAN IDs should increase by 1. For example, to create 1024 egress VLAN filters, the first VLAN ID would be 6, the second ID would be 7, and the sequence would continue through VLAN ID 1029. Similarly, if you want to create fewer than 512 egress VLAN filters but want the total number of terms in those filters to exceed 512, you should number your VLAN IDs in the same manner. If you do not use this approach to create your VLAN IDs, the total number of allowed terms or filters will be less than 1024 and might be 512.

The ternary content addressable memory (TCAM) for firewall filters is divided into slices that accommodate 256 terms, and all the terms in a memory slice must be in filters of the same type and applied in the same direction. A memory slice is reserved as soon as you commit a filter. For example, if you create a port filter and apply it in the input direction, a memory slice is reserved that will only store ingress port filters. If you create and apply only one ingress port filter and that filter has only one term, the rest of this slice is unused and is unavailable for other filter types.

Continuing with the above example, assume that you create and apply 256 ingress port filters with one term each so that one memory slice is filled. This leaves two more memory slices available for ingress filters. (Remember that the maximum number of ingress terms is 768.) If you then create and apply an ingress Layer 3 filter with one term, another memory slice is reserved for ingress Layer 3 filters. As before, the rest of the slice is unused and is unavailable for different filter types. At this point there is one memory slice available for any ingress filter type.

Now assume that you create and apply a VLAN ingress filter. The final memory slice is reserved for VLAN ingress filters. Memory allocation for ingress filters (once again assuming one term per filter) is as follows:

- Slice 1: Filled with 256 ingress port filters. You cannot commit any more ingress port filters.
- Slice 2: Contains one ingress Layer 3 filter with one term. You can commit 255 more terms in ingress Layer 3 filters.
- Slice 3: Contains one ingress VLAN filter with one term. You can commit 255 more terms in ingress VLAN filters.

Here is another example. Assume that you create 257 ingress port filters with one term per filter—that is, you create one more term than a single memory slice can accommodate. When you apply the filters and commit the configuration, the filter memory allocation is:

- Slice 1: Filled with 256 ingress port filters. You cannot apply any more ingress port filters.
- Slice 2: Contains one ingress port filter. You can apply 255 more terms in ingress port filters.
- Slice 3: This slice is unassigned. You can create and apply 256 terms in ingress filters of any type (port, Layer 3, or VLAN), but all the filters must be of the same type.

Egress Filters

All of the preceding principles also apply to egress filters, but four memory slices are used because IPv4 Layer 3 filters and IPv6 Layer 3 filters are stored in separate slices. The memory slices for egress filters are the same size as those for ingress filters, so the maximum number of egress filter terms is therefore 1024.

Avoid Configuring too Many Filters

If you violate any of these restrictions and commit a configuration that is not in compliance, Junos OS rejects the excessive filters. For example, if you configure 300 ingress port filters and 300 ingress Layer 3 filters and try to commit the configuration, Junos OS does the following (again assuming one term per filter):

- Accepts the 300 ingress port filters (storing them in two memory slices).
- Accepts the first 256 ingress Layer 3 filters it processes (storing them in the third memory slice).
- Rejects the remaining 44 ingress Layer 3 filters.

NOTE: In this situation, be sure to delete excessive filters (for example, the remaining 44 ingress Layer 3 filters) from the configuration before you reboot the device. If you reboot a device that has a noncompliant configuration, you cannot predict which filters are installed after the reboot. Using the example above, the 44 ingress Layer 3 filters that were originally rejected might be installed, and 44 of the port filters that were originally accepted might be rejected.

Policers can Limit Egress Filters

The number of egress policers that you configure can affect the total number of allowed egress firewall filters. Every policer has two implicit counters that consume two entries in a 1024-entry TCAM that is used for counters, including counters that are configured as action modifiers in firewall filter terms. (Policers consume two entries because one is used for green packets and one is used for nongreen packets regardless of policer type.) If the TCAM becomes full, you cannot commit any more egress firewall filters that have terms with counters. For example, if you configure and commit 512 egress policers (two-color, three-color, or a combination of both policer types), all of the memory entries for counters are used up. If later in your configuration file you insert additional egress firewall filters with terms that also include counters, *none* of the terms in those filters are committed because there is no available memory space for the counters.

Here are some additional examples:

- Assume that you configure egress filters that include a total of 512 policers and no counters. Later in your configuration file you include another egress filter with 10 terms, 1 of which has a counter action modifier. None of the terms in this filter are committed because there is not enough TCAM space for the counter.
- Assume that you configure egress filters that include a total of 500 policers, so 1000 TCAM entries are occupied. Later in your configuration file you include the following two egress filters:
  - Filter A with 20 terms and 20 counters. All the terms in this filter are committed because there is enough TCAM space for all the counters.
  - Filter B comes after Filter A and has five terms and five counters. *None* of the terms in this filter are committed because there is not enough memory space for *all* the counters. (Five TCAM entries are required but only four are available.)

You can prevent this problem from occurring by ensuring that egress firewall filter terms with counter actions are placed earlier in your configuration file than terms that include policers. In this circumstance, Junos OS commits policers even if there is not enough TCAM space for the implicit counters. For example, assume the following:

- You have 1024 egress firewall filter terms with counter actions.
- Later in your configuration file you have an egress filter with 10 terms. None of the terms have counters but one has a policer action modifier.

You can successfully commit the filter with 10 terms even though there is not enough TCAM space for the implicit counters of the policer. The policer is committed without the counters.

Planning for Filter-Specific Policers

You can configure policers to be filter-specific, which means that Junos OS creates only one policer instance regardless of how many times the policer is referenced. When you do this, rate limiting is applied in aggregate, so if you configure a policer to discard traffic that exceeds 1 Gbps and reference that policer in three different terms, the total bandwidth allowed by the filter is 1 Gbps. However, the behavior of a filter-specific policer is affected by how the firewall filter terms that reference the policer are stored in ternary content addressable memory (TCAM). If you create a filter-specific policer and reference it in multiple firewall filter terms, the policer allows more traffic than expected if the terms are stored in different TCAM slices. For example, if you configure a policer to discard traffic that exceeds 1 Gbps and reference that policer in three different terms that are stored in three separate memory slices, the total bandwidth allowed by the filter is 3 Gbps, not 1 Gbps.

To prevent this unexpected behavior from occurring, use the information about TCAM slices presented above to organize your configuration file so that all the firewall filter terms that reference a given filter-specific policer are stored in the same TCAM slice.

Planning for Filter-Based Forwarding

You can use firewall filters in conjunction with virtual routing instances to specify different routes for packets to travel in their networks. To set up this feature–called filter-based forwarding–you specify a filter and match criteria and then specify the virtual routing instance to send packets to. Filters used in this way also consume memory in an additional TCAM. See "Understanding FIP Snooping, FBF, and MVR Filter Scalability" on page 4872 for more information. The section *FBF Filter VFP TCAM Consumption* in this topic specifically addresses the number of supported filters when using filter-based forwarding.

Understanding Firewall Filter Processing Points for Bridged and Routed Packets

You apply firewall filters at multiple processing points in the forwarding path. At each processing point, the action to be taken on a packet is determined by the configuration of the filter and the results of the lookup in the forwarding or routing table.

For both bridged (Layer 2) unicast packets and routed (Layer 3) unicast packets, firewall filters are applied in the prescribed order shown below (assuming that each filter is present and a packet is accepted by each one).

Bridged packets:

1. Ingress port filter
2. Ingress VLAN filter
3. Egress VLAN filter
4. Egress port filter

Routed packets:

1. Ingress port firewall filter
2. Ingress VLAN firewall filter (Layer 2 CoS)
3. Ingress router firewall filter (Layer 3 CoS)
4. Egress router firewall filter
5. Egress VLAN firewall filter
6. Egress port filter

NOTE: MAC learning occurs before filters are applied, so QFX Series products learn the MAC addresses of packets that are dropped by ingress filters.

Applying Firewall Filters to Interfaces

For a firewall filter to work, you must apply it to at least one interface. To do this, include the **filter** statement when configuring a logical interface at the **[edit interfaces]** hierarchy level:

```
[edit interfaces]
user@switch# set interface-name unit logical-unit-number family family-name filter (input | output) filter-name
```

In the **input** statement, specify a firewall filter to be evaluated when packets are received on the interface. Input filters applied to a loopback interface affect only traffic destined for the Routing Engine.

In the **output** statement, specify a filter to be evaluated when packets exit the interface.

NOTE: When you create a loopback interface, it is important to apply an ingress filter to it so the Routing Engine is protected. We recommend that when you apply a filter to the loopback interface **lo0**, you include the **apply-groups** statement. Doing so ensures that the filter is automatically inherited on every loopback interface, including **lo0** and other loopback interfaces.

Policers

Overview of Policers

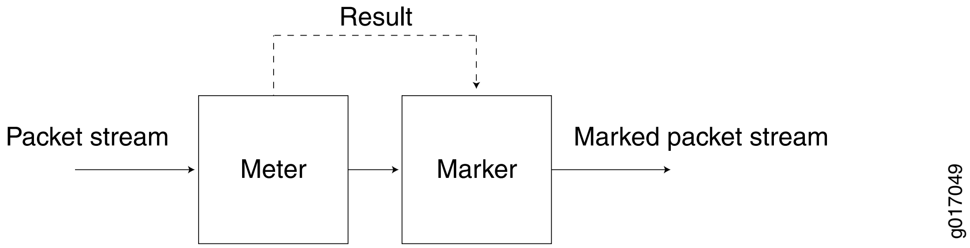
A switch polices traffic by limiting the input or output transmission rate of a class of traffic according to user-defined criteria. Policing (or rate-limiting) traffic allows you to control the maximum rate of traffic sent or received on an interface and to provide multiple priority levels or classes of service.

Policer Overview

You use policers to apply limits to traffic flow and set consequences for packets that exceed these limits—usually applying a higher loss priority—so that if packets encounter downstream congestion, they can be discarded first. Policers apply only to unicast packets.

Policers provide two functions: metering and marking. A policer meters (measures) each packet against traffic rates and burst sizes that you configure. It then passes the packet and the metering result to the marker, which assigns a packet loss priority that corresponds to the metering result. Figure 153 on page 4442 illustrates this process.

Figure 153: Flow of Tricolor Marking Policer Operation



After you name and configure a policer, you use it by specifying it as an action in one or more firewall filters.

Policer Types

A switch supports three types of policers:

- Single-rate two-color marker—A two-color policer (or "policer" when used without qualification) meters the traffic stream and classifies packets into two categories of packet loss priority (PLP) according to a configured bandwidth and burst-size limit. You can mark packets that exceed the bandwidth and burst-size limit with a specified PLP or simply discard them.

  You can specify this type of policer in an ingress or egress firewall.

  NOTE: **A two-color policer is most useful for metering traffic at the port (physical interface) level.**

- Single-rate three-color marker—This type of policer is defined in RFC 2697, *A Single Rate Three Color Marker*, as part of an assured forwarding (AF) per-hop-behavior (PHB) classification system for a Differentiated Services (DiffServ) environment. This type of policer meters traffic based on one rate—the configured committed information rate (CIR) as well as the committed burst size (CBS) and the excess burst size (EBS). The CIR specifies the average rate at which bits are admitted to the switch. The CBS specifies the usual burst size in bytes and the EBS specifies the maximum burst size in bytes. The EBS must be greater than or equal to the CBS, and neither can be 0.

  You can specify this type of policer in an ingress or egress firewall.

  NOTE: **A single-rate three-color marker (TCM) is most useful when a service is structured according to packet length and not peak arrival rate.**

- Two-rate three-color marker—This type of policer is defined in RFC 2698, *A Two Rate Three Color Marker*, as part of an assured forwarding per-hop-behavior classification system for a Differentiated Services environment. This type of policer meters traffic based on two rates—the CIR and peak information rate (PIR) along with their associated burst sizes, the CBS and peak burst size (PBS). The PIR specifies the maximum rate at which bits are admitted to the network and must be greater than or equal to the CIR.

You can specify this type of policer in an ingress or egress firewall.

NOTE: A two-rate three-color policer is most useful when a service is structured according to arrival rates and not necessarily packet length.

See Table 346 on page 4443 for information about how metering results are applied for each of these policer types.

Policer Actions

Policer actions are implicit or explicit and vary by policer type. *Implicit* means that Junos OS assigns the loss priority automatically. Table 346 on page 4443 describes the policer actions.

Table 346: Policer Actions

Policer	Marking	Implicit Action	Configurable Action
Single-rate two-color	Green (conforming)	Assign low loss priority	None
	Red (nonconforming)	None	Discard
Single-rate three-color	Green (conforming)	Assign low loss priority	None
	Yellow (above the CIR and CBS)	Assign medium-high loss priority	None
	Red (above the EBS)	Assign high loss priority	Discard
Two-rate three-color	Green (conforming)	Assign low loss priority	None
	Yellow (above the CIR and CBS)	Assign medium-high loss priority	None
	Red (above the PIR and PBS)	Assign high loss priority	Discard

NOTE: If you specify a policer in an egress firewall filter, the only supported action is discard.

Policer Colors

Single-rate and two-rate three-color policers can operate in two modes:

- Color-blind—In color-blind mode, the three-color policer assumes that all packets examined have not been previously marked or metered. In other words, the three-color policer is “blind” to any previous coloring a packet might have had.
- Color-aware—In color-aware mode, the three-color policer assumes that all packets examined have been previously marked or metered. In other words, the three-color policer is “aware” of the previous coloring a packet might have had. In color-aware mode, the three-color policer can increase the PLP of a packet but cannot decrease it. For example, if a color-aware three-color policer meters a packet with a medium PLP marking, it can raise the PLP level to high but cannot reduce the PLP level to low.

Filter-Specific Policers

You can configure policers to be filter-specific, which means that Junos OS creates only one policer instance regardless of how many times the policer is referenced. When you do this, rate limiting is applied in aggregate, so if you configure a policer to discard traffic that exceeds 1 Gbps and reference that policer in three different terms, the total bandwidth allowed by the filter is 1 Gbps. However, the behavior of a filter-specific policer is affected by how the firewall filter terms that reference the policer are stored in TCAM. If you create a filter-specific policer and reference it in multiple firewall filter terms, the policer allows more traffic than expected if the terms are stored in different TCAM slices. For example, if you configure a policer to discard traffic that exceeds 1 Gbps and reference that policer in three different terms that are stored in three separate memory slices, the total bandwidth allowed by the filter is 3 Gbps, not 1 Gbps.

To prevent this unexpected behavior from occurring, use the information about TCAM slices presented in “Planning the Number of Firewall Filters to Create” on page 4435 to organize your configuration file so that all the firewall filter terms that reference a given filter-specific policer are stored in the same TCAM slice.

Suggested Naming Convention for Policers

We recommend that you use the naming convention ***policertypeTCM#-color type*** when configuring three-color policers and ***policer#*** when configuring two-color policers. TCM stands for three-color marker. Because policers can be numerous and must be applied correctly to work, a simple naming convention makes it easier to apply the policers properly. For example, the first single-rate, color-aware three-color policer configured would be named **srTCM1-ca**. The second two-rate, color-blind three-color configured would be named **trTCM2-cb**. The elements of this naming convention are explained below:

- sr (single-rate)
- tr (two-rate)
- TCM (tricolor marking)
- 1 or 2 (number of marker)
- ca (color-aware)
- cb (color-blind)

Policer Counters

Each policer that you configure includes an implicit counter that counts the number of packets that exceed the rate limits that are specified for the policer. If you use the same policer in multiple terms—either within the same filter or in different filters—the implicit counter counts all the packets that are policed in all of these terms. If you want to obtain separate packet counts for each term, use these options:

- Configure a unique policer for each term.
- Configure only one policer, but use a unique, explicit counter in each term.

Policer Algorithms

Policing uses the *token-bucket algorithm*, which enforces a limit on average bandwidth while allowing bursts up to a specified maximum value. It offers more flexibility than the *leaky bucket algorithm* in allowing a certain amount of bursty traffic before it starts discarding packets.

How Many Policers are Supported?

You can configure and commit the following numbers of policers on QFX3500 and QFX3600 devices when they are operating as standalone switches:

- Two-color policers used in ingress firewall filters: 767
- Three-color policers used in ingress firewall filters: 767
- Two-color policers used in egress firewall filters: 1022
- Three-color policers used in egress firewall filters: 512

Policers can Limit Egress Firewall Filters

The number of egress policers that you configure can affect the total number of allowed egress firewall filters. Every policer has two implicit counters that consume two entries in a 1024-entry TCAM that is used for counters, including counters that are configured as action modifiers in firewall filter terms. (Policers consume two entries because one is used for green packets and one is used for nongreen packets regardless of policer type.) If the TCAM becomes full, you cannot commit any more egress firewall filters that have terms with counters. For example, if you configure and commit 512 egress policers (two-color, three-color, or a combination of both policer types), all of the memory entries for counters are used up. If later in your configuration file you insert additional egress firewall filters with terms that also include counters, *none* of the terms in those filters are committed because there is no available memory space for the counters.

Here are some additional examples:

- Assume that you configure egress filters that include a total of 512 policers and no counters. Later in your configuration file you include another egress filter with 10 terms, 1 of which has a counter action modifier. None of the terms in this filter are committed because there is not enough TCAM space for the counter.

- Assume that you configure egress filters that include a total of 500 policers, so 1000 TCAM entries are occupied. Later in your configuration file you include the following two egress filters:
  - Filter A with 20 terms and 20 counters. All the terms in this filter are committed because there is enough TCAM space for all the counters.
  - Filter B comes after Filter A and has five terms and five counters. *None* of the terms in this filter are committed because there is not enough memory space for *all* the counters. (Five TCAM entries are required but only four are available.)

You can prevent this problem by ensuring that egress firewall filter terms with counter actions are placed earlier in your configuration file than terms that include policers. In this circumstance, Junos OS commits policers even if there is not enough TCAM space for the implicit counters. For example, assume the following:

- You have 1024 egress firewall filter terms with counter actions.
- Later in your configuration file you have an egress filter with 10 terms. None of the terms have counters but one has a policer action modifier.

You can successfully commit the filter with 10 terms even though there is not enough TCAM space for the implicit counters of the policer. The policer is committed without the counters.

Understanding Policers with Link Aggregation Groups

If you apply a policer to a link aggregation group (LAG) on a QFX3500 switch or node, the policer applies to all the interfaces in the LAG in aggregate. For example, if you configure a policer to rate-limit at 1 Gbps and apply the policer (by using a firewall filter) to a LAG that has two member interfaces on a single switch or node, the total allowed throughput for both members is 1 Gbps.

If you apply a policer to a LAG that has members on different nodes in a QFabric network Node group or redundant server Node group, the configured rate applies to the interface on each node. For example, if you configure a policer to rate-limit at 1 Gbps and apply the policer to a LAG that has one member on server node A and one member on server node B, the allowed throughput for each member is 1 Gbps, for a total allowed throughput of 2 Gbps.

Understanding Color-Blind Mode for Single-Rate Tricolor Marking

With the color-blind mode of single-rate tricolor marking, all packets are evaluated against the CBS. If a packet exceeds the CBS, it is evaluated against the EBS. In color-blind mode, the policer supports three loss priorities only: low, medium-high, and high.

Packets that exceed the CBS but are below the EBS are marked yellow (medium-high). Packets that exceed the EBS are marked red (high), as shown in Table 347 on page 4447.

Table 347: Color-Blind Mode TCM Color-to-PLP Mapping

Color	PLP	Meaning
Green	low	Conforming.
Yellow	medium-high	Packet exceeds the CIR and CBS but does not exceed the EBS.
Red	high	Packet exceeds the EBS.

Related Documentation

Understanding Color-Aware Mode for Single-Rate Tricolor Marking

In color-aware mode, the treatment the packet receives depends on its classification. Marking can increase a preassigned PLP but cannot decrease it.

Summary of PLP Changes

Table 348 on page 4447 shows how a packet's incoming priority can be modified with single-rate marking.

Table 348: Color-Aware Mode Single-Rate PLP Mapping

Incoming PLP	Packet Metered Against	Possible Cases	Outgoing PLP
low	CIR, CBS, and EBS	Conforming	low
		Packet exceeds the CIR and CBS but does not exceed the EBS.	medium-high
		Packet exceeds the EBS.	high
medium-low	EBS only	Packet does not exceed the EBS.	medium-low
		Packet exceeds the EBS.	high
medium-high	EBS only	Packet does not exceed the EBS.	medium-high
		Packet exceeds the EBS.	high

Table 348: Color-Aware Mode Single-Rate PLP Mapping *(continued)*

Incoming PLP	Packet Metered Against	Possible Cases	Outgoing PLP
high	Not metered by the policer.	All cases.	**high**

The following sections describe single-rate color-aware PLP mapping in more detail.

Effect on Green Packets (Low PLP)

Packets belonging to the green class have already been marked by a classifier with low PLP. The marking policer can leave the PLP unchanged or increase it to medium-high or high, so these packets are therefore metered against both the CBS and the EBS. For example, if a behavior aggregate or multifield classifier marks a packet with low PLP and the two-rate TCM policer is in color-aware mode, the output loss priority is as follows:

- If the rate of traffic flow is less than the CIR, packets remain marked as low PLP.
- If bursts exceed the CBS but not the EBS, some of the packets are marked as medium-high PLP, and some of the packets remain marked as low PLP.
- If bursts exceed the EBS, some of the packets are marked as high PLP, and some of the packets remain marked as low PLP.

Effect on Yellow Packets (Medium PLP)

Packets belonging to the yellow class have already been marked by a classifier with medium-low or medium-high PLP. The marking policer can leave the PLP unchanged or increase it to high, so these packets are therefore metered against the EBS only. For example, if a behavior aggregate or multifield classifier marks a packet with medium-low PLP and the two-rate TCM policer is in color-aware mode, the output loss priority is as follows:

- If the rate of traffic flow is less than the CBS, the packets remain marked as medium-low PLP.
- If the rate of traffic flow is greater than the CBS but less than the EBS, the packets remain marked as medium-low PLP.
- If the rate of traffic flow is greater than the EBS, some of the packets are marked as high PLP and some remain marked as medium-low PLP.

If a BA or multifield classifier marks a packet with medium-high PLP and the two-rate TCM policer is in color-aware mode, the policer assigns output loss priority as follows:

- If the rate of traffic flow is less than the CBS, the packets remain marked as medium-high PLP.
- If the rate of traffic flow is greater than the CBS but less than the EBS, the packets remain marked as medium-high PLP.
- If the rate of traffic flow is greater than the EBS, some of the packets are marked as high PLP and some remain marked as medium-high PLP.

Effect on Red Packets (High PLP)

Packets belonging to the red class have already been marked by a classifier with high PLP. Because the policer cannot decrease the PLP, it does not change it, and these packets are not metered against the CBS or the EBS.

Related Documentation

- Configuring Color-Blind Egress Policers for Medium-Low PLP on page 4537

Understanding Color-Blind Mode for Two-Rate Tricolor Marking

With the color-blind mode of two-rate tricolor marking, all packets are evaluated against the committed information rate (CIR). If a packet exceeds the CIR, it is evaluated against the peak information rate (PIR). Packets that exceed the CIR but are below the PIR are marked yellow (medium-high). Packets that exceed the PIR are marked red (high).

Table 349: Color-Blind Mode TCM Color-to-PLP Mapping

Color	PLP	Meaning
Green	low	Packet does not exceed the CIR.
Yellow	medium-high	Packet exceeds the CIR but does not exceed the PIR.
Red	high	Packet exceeds the PIR.

Related Documentation

Understanding Color-Aware Mode for Two-Rate Tricolor Marking

In color-aware mode, the treatment the packet receives depends on its classification. Marking can increase the preassigned PLP but cannot decrease it

Summary of PLP Changes

Table 350 on page 4449 shows how a packet's incoming priority can be modified with two-rate marking.

Table 350: Color-Aware Mode Two-Rate PLP Mapping

Incoming PLP	Packet Metered Against	Possible Cases	Outgoing PLP
low	CIR and PIR	Packet does not exceed the CIR.	low
		Packet exceeds the CIR but not the PIR.	medium-high
		Packet exceeds the PIR.	high

Table 350: Color-Aware Mode Two-Rate PLP Mapping *(continued)*

Incoming PLP	Packet Metered Against	Possible Cases	Outgoing PLP
medium-low	PIR only	Packet does not exceed the PIR.	**medium-low**
		Packet exceeds the PIR.	**high**
medium-high	PIR only	Packet does not exceed the PIR.	**medium-high**
		Packet exceeds the PIR.	**high**
high	Not metered by the policer.	All cases.	**high**

The following sections describe color-aware two-rate PLP mapping in more detail.

Effect on Green Packets (Low PLP)

Packets belonging to the green class have already been marked by a classifier with low PLP. The marking policer can leave the packet's PLP unchanged or increase the PLP to medium-high or high. These packets are therefore metered against both the CIR and the PIR. For example, if a behavior aggregate or multifield classifier marks a packet with low PLP and the two-rate TCM policer is in color-aware mode, the output loss priority is as follows:

- If the rate of traffic flow is less than the CIR, the packets remain marked as low PLP.
- If the rate of traffic flow is greater than the CIR but less than the PIR, some of the packets are marked as medium-high PLP and some of the packets remain marked as low PLP.
- If the rate of traffic flow is greater than the PIR, some of the packets are marked as high PLP and some of the packets remain marked as low PLP.

Effect on Yellow Packets (Medium PLP)

Packets belonging to the yellow class have already been marked by a classifier with medium-low or medium-high PLP. The marking policer can leave the PLP unchanged or increase it to high. These packets are therefore metered against the PIR only. For example, if a behavior aggregate (BA) or multifield classifier marks a packet with medium-low PLP and the two-rate TCM policer is in color-aware mode, the policer assigns output loss priority as follows:

- If the rate of traffic flow is less than the CIR, the packets remain marked as medium-low PLP.
- If the rate of traffic flow is greater than the CIR but less than the PIR, the packets remain marked as medium-low PLP.
- If the rate of traffic flow is greater than the PIR, some of the packets are marked as high PLP and some of the packets remain marked as medium-low PLP.

If a BA or multifield classifier marks a packet with medium-high PLP and the two-rate TCM policer is in color-aware mode, the policer assigns output loss priority as follows:

- If the rate of traffic flow is less than the CIR, the packets remain marked as medium-high PLP.
- If the rate of traffic flow is greater than the CIR but less than the PIR, the packets remain marked as medium-high PLP.
- If the rate of traffic flow is greater than the PIR, some of the packets are marked as high PLP and some of the packets remain marked as medium-high PLP.

Effect on Red Packets (High PLP)

Packets belonging to the red class have already been marked by a classifier with high PLP. Because the policer cannot decrease the PLP, it does not change it, and these packets are not metered against the CIR or the PIR.

Port Security

Overview of Access Port Protection

Port security features can protect a switch against various types of attacks. Protection methods against some common attacks are:

Mitigation of Ethernet Switching Table Overflow Attacks

In an overflow attack on an Ethernet switching table, an intruder sends so many requests from new MAC addresses that the table cannot learn all the addresses. The attack forces the switch to send broadcast messages when it needs to send traffic to addresses for which it lacks MAC addresses. In addition to generating unnecessary traffic, the attacker might be able to sniff the broadcast packets.

To mitigate such attacks, you can configure a limit for learned MAC addresses or allow only specific MAC addresses. Use the MAC limit feature to control the total number of MAC addresses that can be added to the Ethernet switching table for the specified interface or interfaces. By setting the MAC addresses that are explicitly allowed, you ensure that the addresses of network devices whose network access is critical are guaranteed to be included in the Ethernet switching table.

Mitigation of Rogue DHCP Server Attacks

By default, all access ports are untrusted, and all trunk ports are trusted with regard to DHCP. Trusted ports allow DHCP servers to provide IP addresses and other information to requesting devices. If someone connects an unauthorized DHCP server to a trusted port, the unauthorized server can start issuing IP addresses and configuration information to the network's DHCP clients. The information provided to the clients by this server can disrupt their network access. The unauthorized server might also assign itself as the default gateway device for the network. An attacker can then sniff the network traffic and perpetrate a man-in-the-middle attack—that is, it misdirects traffic intended for a legitimate network device to a device of its choice.

To mitigate this problem, set the interface to which the unauthorized server is connected as untrusted. That action blocks all ingress DHCP server messages from that interface.

.

NOTE: The switch logs all DHCP server packets that are received on untrusted ports. For example:

5 untrusted DHCPOFFER received, interface xe-:0/0/2.0[65], vlan v1[10] server ip/mac 12.12.12.1/00:00:00:00:01:12 offer ip/client mac 12.12.12.253/00:AA:BB:CC:DD:01

You can use these messages to detect unauthorized DHCP servers on the network.

NOTE: If you attach a DHCP server to an access port, you must configure the port as trusted.

Protection Against ARP Spoofing Attacks

In ARP spoofing, an attacker sends faked ARP messages on the network. The attacker associates its own MAC address with the IP address of a network device connected to the switch. Any traffic sent to that IP address is instead sent to the attacker. Now the attacker can create various types of problems, including sniffing the packets that were meant for another host and perpetrating man-in-the middle attacks. (In a man-in-the-middle attack, the attacker intercepts messages between two hosts, reads them, and perhaps alters them, all without the original hosts knowing that their communications have been compromised.)

To protect against ARP spoofing on your switch, enable both DHCP snooping and dynamic ARP inspection (DAI). DHCP snooping builds and maintains the DHCP snooping table. That table contains the MAC addresses, IP addresses, lease times, binding types, VLAN information, and interface information for the untrusted interfaces on the switch. DAI uses the information in the DHCP snooping table to validate ARP packets. Invalid ARP packets are blocked, and when they are blocked, a system log message is recorded that includes the type of ARP packet and the sender's IP address and MAC address.

See "Example: Configuring DHCP Snooping and DAI to Protect the Switch from ARP Spoofing Attacks" on page 4513.

Protection Against DHCP Snooping Database Alteration Attacks

In an attack designed to alter the DHCP snooping database, an intruder introduces a DHCP client on one of the switch's untrusted access interfaces that has a MAC address identical to that of a client on another untrusted port. The intruder acquires the DHCP lease, which results in changes to the entries in the DHCP snooping table. Subsequently, what would have been valid ARP requests from the legitimate client are blocked.

To protect against this type of alteration of the DHCP snooping database, configure MAC addresses that are explicitly allowed on the interface. See "Example: Configuring Allowed MAC Addresses to Protect the Switch from DHCP Snooping Database Alteration Attacks" on page 4518.

Protection Against DHCP Starvation Attacks

In a DHCP starvation attack, an attacker floods an Ethernet LAN with DHCP requests from spoofed (counterfeit) MAC addresses so that trusted DHCP servers cannot keep up with requests from legitimate DHCP clients. The address space of those servers is completely used up, so they can no longer assign IP addresses and lease times to clients. DHCP requests from those clients are either dropped—that is, the result is a denial of service (DoS)—or directed to a rogue DHCP server set up by the attacker to imitate a legitimate DHCP server.

To protect the switch from DHCP starvation attacks, use the MAC limiting feature. Specify the maximum number of MAC addresses that the switch can learn on the access interfaces to which DHCP clients connect. The DHCP server or servers can then supply only the specified number of IP addresses over each of those interfaces. If a DHCP starvation attack occurs after the maximum number of IP addresses has been assigned, the attack fails.

Port Security Overview

Ethernet LANs are vulnerable to attacks such as address spoofing (forging) and Layer 2 denial of service (DoS) on network devices. Port security features help protect the access ports on your switch against the loss of information and productivity that can result from such attacks.

Juniper Networks Junos operating system (Junos OS) provides features to help secure ports on the switch. Ports can be categorized as either trusted or untrusted. You apply policies appropriate to each category to protect ports against various types of attacks.

Basic port security features are enabled in the switch's default configuration. You can configure additional features with minimal configuration steps.

Depending on the particular feature, you can configure the feature either on VLANs or interfaces.

Port security features supported on switches are:

- DHCP snooping—Filters and blocks ingress Dynamic Host Configuration Protocol (DHCP) server messages on untrusted ports; builds and maintains an IP address to MAC address binding (IP-MAC binding) database, which is called the DHCP snooping database.

  NOTE: **DHCP snooping is not enabled in the default switch configurations. DHCP snooping is enabled on a per-VLAN basis. The details of enabling DHCP snooping depend on the particular switch.**

- DHCPv6 snooping—DHCP snooping for IPv6.
- DHCP option 82—Also known as the DHCP Relay Agent information option. This DHCPv4 feature helps protect the switch against attacks such as spoofing of IP addresses and media access control (MAC) addresses and DHCP IP address starvation. Option 82 provides information about the network location of a DHCP client, and the DHCP server uses this information to implement IP addresses or other parameters for the client.
- DHCPv6 option 37—Option 37 is the DHCP for IPv6 (DHCPv6) equivalent of option 82 and is enabled by default when DHCPv6 snooping is enabled on a VLAN.
- Dynamic ARP inspection (DAI)—Prevents Address Resolution Protocol (ARP) spoofing attacks. ARP requests and replies are compared against entries in the DHCP snooping database, and filtering decisions are made on the basis of the results of those comparisons. You enable DAI on a VLAN.

- IPv6 Neighbor Discovery (ND) inspection—Prevents IPv6 address spoofing attacks. Neighbor discovery requests and replies are compared against entries in the DHCPv6 snooping database, and filtering decisions are made on the basis of the results of those comparisons. You enable ND inspection on a VLAN.
- IP source guard—Mitigates the effects of IP address spoofing attacks on the Ethernet LAN. With IP source guard enabled, the source IP address in the packet sent from an untrusted access interface is validated against the source MAC address in the DHCP snooping database. The packet is forwarded if the source IP-MAC binding is valid; if the binding is not valid, the packet is discarded. You enable IP source guard on a VLAN. EX Series switches support IPv6 source guard also.

  NOTE: IP source guard is not supported on the QFX Series.

- MAC limiting—Protects against flooding of the Ethernet switching table (also known as the MAC forwarding table or Layer 2 forwarding table). You can enable MAC limiting on an interface.
- MAC move limiting—(Not supported on EX9200) Tracks MAC movement and detects MAC spoofing on access ports. You enable this feature on a VLAN.
- Persistent MAC learning—Also known as sticky MAC. Persistent MAC learning enables interfaces to retain dynamically learned MAC addresses across switch reboots You enable this feature on an interface.
- Trusted DHCP server—Configuring the DHCP server on a trusted port protects against rogue DHCP servers sending leases. You enable this feature on an interface (port). By default, access ports are untrusted, and trunk ports are trusted. (Access ports are the switch ports that connect to Ethernet endpoints such as user PCs and laptops, servers, and printers. Trunk ports are the switch ports that connect an Ethernet switch to other switches or to routers.)

Understanding DHCP Snooping for Port Security

DHCP snooping enables the switch to monitor and control DHCP messages received from untrusted devices connected to the switch. When DHCP snooping is enabled, the system snoops the DHCP messages to view DHCP lease information and build and maintain a database of valid IP address to MAC address (IP-MAC) bindings called the DHCP snooping database. Only clients with valid bindings are allowed access to the network.

DHCP Snooping Basics

Dynamic Host Configuration Protocol (DHCP) allocates IP addresses dynamically, *leasing* addresses to devices so that the addresses can be reused when no longer needed. Hosts and end devices that require IP addresses obtained through DHCP must communicate with a DHCP server across the LAN.

DHCP snooping acts as a guardian of network security by keeping track of valid IP addresses assigned to downstream network devices by a trusted DHCP server (the server is connected to a trusted network port).

By default, all trunk ports on the switch are trusted and all access ports are untrusted for DHCP snooping.

When DHCP snooping is enabled, the lease information from the switch is used to create the DHCP snooping database, a mapping of IP address to MAC-address pairs.

NOTE: **DHCP snooping is disabled in the default switch configuration. You must explicitly enable DHCP snooping by setting examine-dhcp at the [edit ethernet-switching-options secure-access-port] hierarchy level.**

Entries in the DHCP database are updated in these events:

- When a DHCP client releases an IP address (sends a DHCPRELEASE message), the associated mapping entry is deleted from the database.
- If you move a network device from one VLAN to another, typically the device needs to acquire a new IP address. Therefore, its entry in the database, including the VLAN ID, is updated.

- When the lease time (timeout value) assigned by the DHCP server expires, the associated entry is deleted from the database.

TIP: By default, the IP-MAC bindings are lost when the switch is rebooted and DHCP clients (the network devices, or hosts) must reacquire bindings. However, you can configure the bindings to persist by setting the **dhcp-snooping-file** statement to store the database file either locally or remotely.

You can configure the switch to snoop DHCP server responses only from particular VLANs. Doing this prevents spoofing of DHCP server messages.

You configure DHCP snooping per VLAN, not per interface (port). DHCP snooping is disabled by default.

DHCP Snooping Process

The basic process of DHCP snooping consists of the following steps:

NOTE: When DHCP snooping is enabled for a VLAN, all DHCP packets sent from that network devices in that VLAN are subjected to DHCP snooping. The final IP-MAC binding occurs when the DHCP server sends DHCPACK to the DHCP client.

1. The network device sends DHCPDISCOVER packet to request IP address.
2. The switch forwards the packet to the DHCP server.
3. The server sends a DHCPOFFER packet to offer an address. If the DHCPOFFER packet is from a trusted interface, the switch forwards the packet to the DHCP client.
4. The network device sends a DHCPREQUEST packet to accept the IP address. The switch adds an IP-MAC placeholder binding to the database. The entry is considered a placeholder until a DHCPACK packet is received from the server. Until then, the IP address could still be assigned to some other host.
5. The server sends a DHCPACK packet to assign the IP address or a DHCPNAK packet to deny the address request.
6. The switch updates the DHCP database in accordance with the type of packet received:
   - Upon receipt of a DHCPACK packet, the switch updates lease information for the IP-MAC binding in its database.
   - Upon receipt of a DHCPNACK packet, the switch deletes the placeholder.

NOTE: The DHCP database is updated only after the DHCPREQUEST packet has been sent.

For general information about the messages that the DHCP client and DHCP server exchange during the assignment of an IP address for the client, see the *Junos OS System Basics Configuration Guide*.

DHCP Server Access

A switch's access to the DHCP server can be configured in three ways:

Switch, DHCP Clients, and DHCP Server Are All on the Same VLAN

When the switch, DHCP clients, and DHCP server are *all members of the same VLAN*, the DHCP server can be connected to the switch in one of two ways:

- The server is directly connected to the same switch as the one connected to the DHCP clients (the hosts, or network devices, that are requesting IP addresses from the server). The VLAN is enabled for DHCP snooping to protect the untrusted access ports. The trunk port is configured by default as a trusted port. See Figure 154 on page 4458.
- The server is connected to an intermediary switch (Switch 2) that is connected through a trunk port to the switch (Switch 1) that the DHCP clients are connected to. Switch 2 is being used as a transit switch. The VLAN is enabled for DHCP snooping to protect the untrusted access ports. The trunk port is configured by default as a trusted port. See Figure 155 on page 4459—in the figure, **ge-0/0/11** is a trusted trunk port.

Figure 154: DHCP Server Connected Directly to Switch

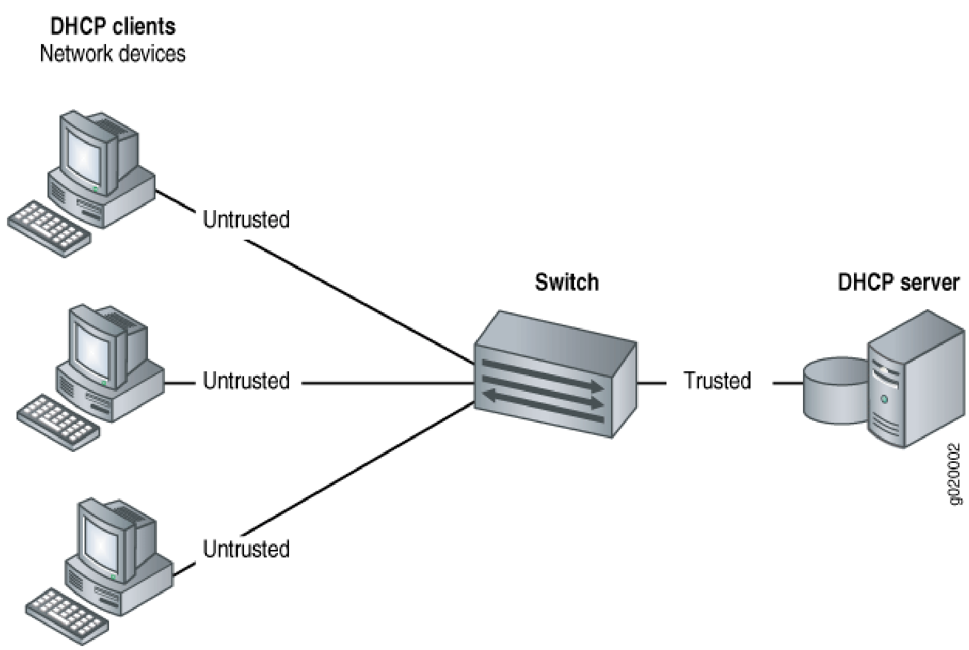

Figure 155: DHCP Server Connected Directly to Switch 2, with Switch 2 Connected to Switch 1 Through a Trusted Trunk Port

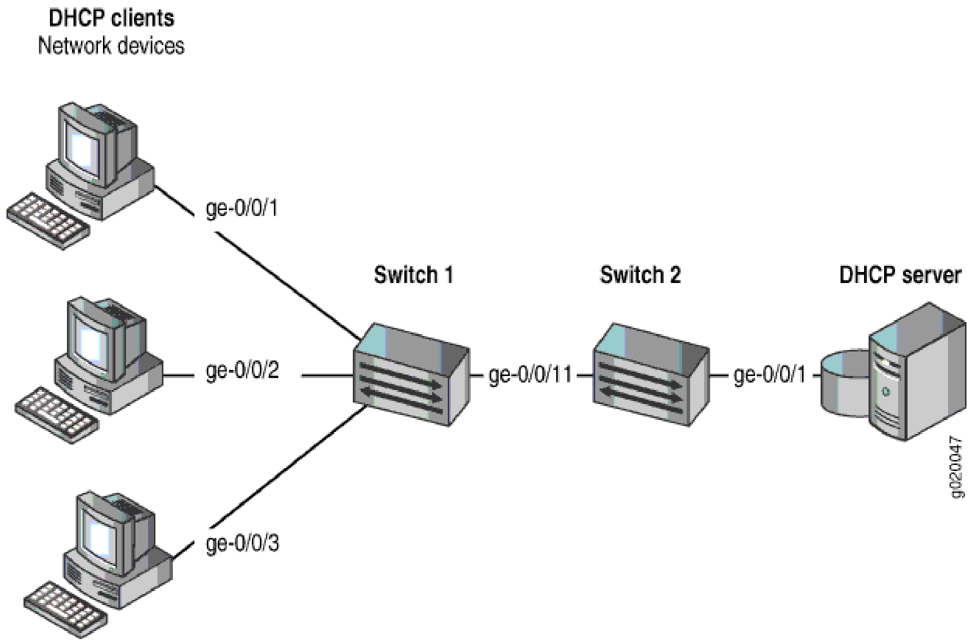
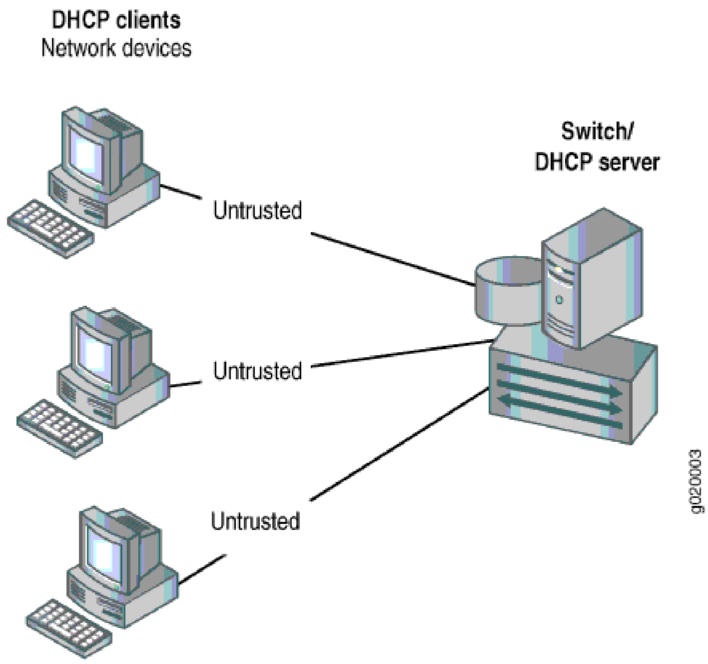


Switch Acts as DHCP Server

NOTE: The switch acting as a DHCP server is not supported on the QFX Series switch.

The switch itself is configured as a DHCP server; this is known as a “local” configuration. See Figure 156 on page 4460.

Figure 156: Switch Is the DHCP Server



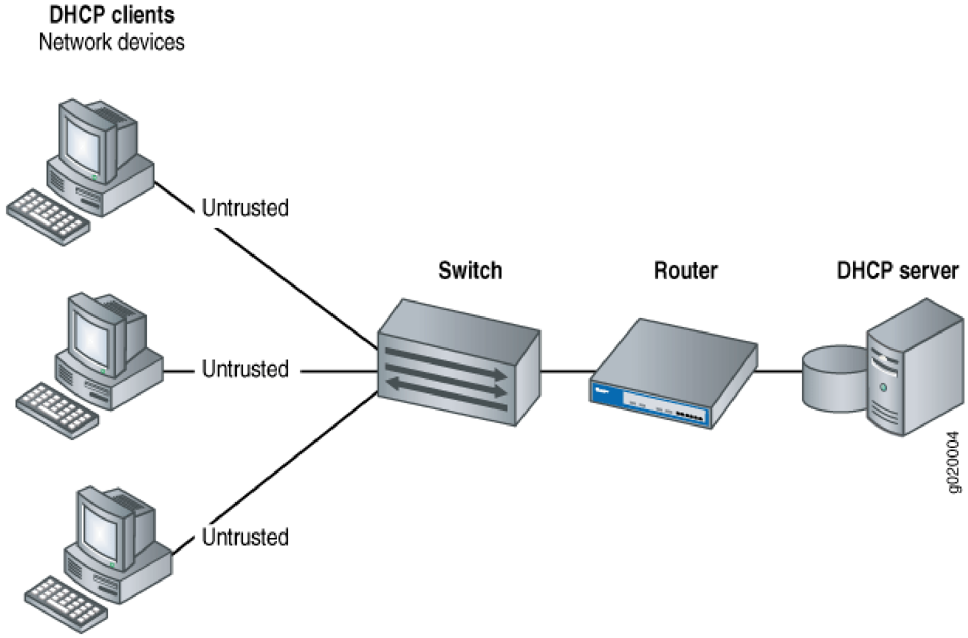
Switch Acts as Relay Agent

The switch functions as a relay agent when the DHCP clients or the DHCP server is connected to the switch through a Layer 3 interface. The Layer 3 interfaces on the switch are configured as routed VLAN interfaces (RVIs,) or integrated routing and bridging interfaces (IRBs). The trunk interfaces are trusted by default.

These two scenarios illustrate the switch acting as a relay agent:

- The DHCP server and clients are in different VLANs.
- The switch is connected to a router that is in turn connected to the DHCP server. See Figure 157 on page 4461.

Figure 157: Switch Acting as Relay Agent Through Router to DHCP Server



DHCP Snooping Table

The software creates a DHCP snooping information table that displays the content of the DHCP snooping database. The table shows current IP-MAC bindings, as well as lease time, type of binding, names of associated VLANs, and associated interface.

To display the DHCP snooping database, issue the operational mode command show dhcp snooping binding.

Static IP Address Additions to the DHCP Snooping Database

You can add specific static IP addresses to the database as well as have the addresses dynamically assigned through DHCP snooping. To add static IP addresses, you supply the IP address, the MAC address of the device, the interface on which the device is connected, and the VLAN with which the interface is associated. No lease time is assigned to the entry. The statically configured entry never expires.

Snooping DHCP Packets That Have Invalid IP Addresses

If you enable DHCP snooping on a VLAN and then devices on that VLAN send DHCP packets that request invalid IP addresses, these invalid IP addresses will be stored in the DHCP snooping database until they are deleted when their default timeout is reached. To eliminate this unnecessary consumption of space in the DHCP snooping database, the switch drops the DCHP packets that request invalid IP addresses, preventing the snooping of these packets. The invalid IP addresses are:

- 0.0.0.0
- 128.0.*x.x*
- 191.255.*x.x*

- 192.0.0.*x*
- 223.255.255.*x*
- 224.*x.x.x*
- 240.*x.x.x* to 255.255.255.255

Prioritizing Snooped Packets

NOTE: Prioritizing snooped packets is not supported on the QFX Series.

You can use class-of-service (CoS) forwarding classes and queues to prioritize DHCP snooped packets for a specified VLAN. This type of configuration places the DHCP snooped packets for that VLAN in the desired egress queue, so that the security procedure does not interfere with the transmittal of high-priority traffic. For additional information, see *Example: Using CoS Forwarding Classes to Prioritize Snooped Packets in Heavy Network Traffic*.

Understanding DAI for Port Security

Dynamic ARP inspection (DAI) protects switches against ARP spoofing.

DAI inspects Address Resolution Protocol (ARP) packets on the LAN and uses the information in the DHCP snooping database on the switch to validate ARP packets and to protect against ARP spoofing (also known as ARP poisoning or ARP cache poisoning). ARP requests and replies are compared against entries in the DHCP snooping database, and filtering decisions are made based on the results of those comparisons. When an attacker tries to use a forged ARP packet to spoof an address, the switch compares the address with entries in the database. If the media access control (MAC) address or IP address in the ARP packet does not match a valid entry in the DHCP snooping database, the packet is dropped.

ARP packets are sent to the Routing Engine and are rate-limited to protect the switch from CPU overload.

Address Resolution Protocol

Sending IP packets on a multi-access network requires mapping an IP address to an Ethernet MAC address.

Ethernet LANs use ARP to map MAC addresses to IP addresses.

The switch maintains this mapping in a cache that it consults when forwarding packets to network devices. If the ARP cache does not contain an entry for the destination device, the host (the DHCP client) broadcasts an ARP request for that device's address and stores the response in the cache.

ARP Spoofing

ARP spoofing is one way to initiate man-in-the-middle attacks. The attacker sends an ARP packet that spoofs the MAC address of another device on the LAN. Instead of the switch sending traffic to the proper network device, the switch sends the traffic to the device with the spoofed address that is impersonating the proper device. If the impersonating device is the attacker's machine, the attacker receives all the traffic from the switch that must have gone to another device. The result is that traffic from the switch is misdirected and cannot reach its proper destination.

One type of ARP spoofing is gratuitous ARP, which is when a network device sends an ARP request to resolve its own IP address. In normal LAN operation, gratuitous ARP messages indicate that two devices have the same MAC address. They are also broadcast when a network interface card (NIC) in a device is changed and the device is rebooted, so that other devices on the LAN update their ARP caches. In malicious situations, an attacker can poison the ARP cache of a network device by sending an ARP response to the device that directs all packets destined for a certain IP address to go to a different MAC address instead.

To prevent MAC spoofing through gratuitous ARP and through other types of spoofing, the switches examine ARP responses through DAI.

Dynamic ARP Inspection

DAI examines ARP requests and responses on the LAN and validates ARP packets. The switch intercepts ARP packets from an access port and validates them against the DHCP snooping database. If no IP-MAC entry in the database corresponds to the information in the ARP packet, DAI drops the ARP packet and the local ARP cache is not updated with the information in that packet. DAI also drops ARP packets when the IP address in the packet is invalid. ARP probe packets are not subjected to dynamic ARP inspection. The switch always forwards such packets.

Junos OS for EX Series switches and the QFX Series uses DAI for ARP packets received on access ports because these ports are untrusted by default. Trunk ports are trusted by default, and therefore ARP packets bypass DAI on them.

You configure DAI for each VLAN, not for each interface (port). By default, DAI is disabled for all VLANs.

If you set an interface to be a DHCP trusted port, it is also trusted for ARP packets.

NOTE:

- If your switch uses Junos OS for EX Series switches with support for the Enhanced Layer 2 Software (ELS) configuration style, see *Enabling a Trusted DHCP Server (CLI Procedure)* for information about configuring an access interface to be a DHCP trusted port. .
- If your switch is not using Junos OS for EX Series switches with support for the Enhanced Layer 2 Software (ELS) configuration style, see "Enabling a Trusted DHCP Server (CLI Procedure)" on page 4555 for information about configuring an access interface to be a DHCP trusted port.

For packets directed to the switch to which a network device is connected, ARP queries are broadcast on the VLAN. The ARP responses to those queries are subjected to the DAI check.

For DAI, all ARP packets are trapped to the PFE. To prevent CPU overloading, ARP packets destined for the Routing Engine are rate-limited.

If the DHCP server goes down and the lease time for an IP-MAC entry for a previously valid ARP packet runs out, that packet is blocked.

Prioritizing Inspected Packets

NOTE: Prioritizing inspected packets is not supported on the QFX Series.

You can use class-of-service (CoS) forwarding classes and queues to prioritize DAI packets for a specified VLAN. This type of configuration places inspected packets for that VLAN in the egress queue, that you specify, ensuring that the security procedure does not interfere with the transmission of high-priority traffic.

Understanding MAC Limiting and MAC Move Limiting for Port Security

MAC limiting protects against flooding of the Ethernet switching table (also known as the MAC forwarding table or Layer 2 forwarding table). You enable this feature on Layer 2 interfaces (ports). MAC move limiting detects MAC movement and MAC spoofing on access interfaces. You enable this feature on VLANs.

MAC Limiting

MAC limiting sets a limit on the number of MAC addresses that can be learned on a single Layer 2 access interface or on all the Layer 2 access interfaces on the switch. Junos OS provides two MAC limiting methods:

- Maximum number of MAC addresses—You configure the maximum number of dynamic MAC addresses allowed per interface. When the limit is exceeded, incoming packets with new MAC addresses can be ignored, dropped, or logged. You can also specify that the interface be shut down or temporarily disabled.
- Allowed MAC addresses—You configure specific “allowed” MAC addresses for the access interface. Any MAC address that is not in the list of configured addresses is not

learned, and the switch logs an appropriate message. Allowed MAC binds MAC addresses to a VLAN so that the address does not get registered outside the VLAN. If an allowed MAC setting conflicts with a dynamic MAC setting, the allowed MAC setting takes precedence.

NOTE: If you do not want the system to log messages about invalid MAC addresses received by an interface that has been configured for allowed MAC addresses, disable the logging by configuring the no-allowed-mac-log statement.

You configure MAC limiting per interface, not per VLAN. You can specify the maximum number of dynamic MAC addresses that can be learned on a single Layer 2 access interface (including tagged-access interfaces) or on all Layer 2 access interfaces.

MAC Move Limiting

MAC move limiting causes the switch to track the number of times a MAC address can move to a new interface (port). It can help to prevent MAC spoofing, and it can also detect and prevent loops.

If a MAC address moves more than the configured number of times within 1 second, the switch performs the configured action. You can configure MAC move limiting to apply to all VLANs or to a specific VLAN.

Actions for MAC Limiting

You can choose to have one of the following actions performed when the limit of MAC addresses or the limit of MAC moves is exceeded:

- **drop**—Drop the packet and generate a system log entry. This is the default.
- **log**—Do not drop the packet but generate a system log entry.
- **none**—Take no action.
- **shutdown**—Disable the interface and generate an alarm. If you configure the switch with the **port-error-disable** statement, the disabled interface recovers automatically upon expiration of the specified timeout. If this is not configured, you can bring up the disabled interfaces by running the **clear ethernet-switching port-error** command.

See descriptions of results of these various action settings in "Verifying That MAC Limiting Is Working Correctly" on page 4674.

If you set a MAC limit to apply to all interfaces on the switch, you can override that setting for a particular interface by specifying action **none**. See "Configuring the none Action to Override a MAC Limit Applied to All Interfaces (CLI Procedure)" on page 4549

MAC Addresses That Exceed the MAC Limit or MAC Move Limit

If you have configured the **port-error-disable** statement, you can view which interfaces are temporarily disabled because the MAC limit or MAC move limit was exceeded. Use the **show ethernet-switching interfaces** command.

The log messages that indicate the MAC limit or MAC move limit has been exceeded include the offending MAC addresses.

Understanding Trusted and Untrusted Ports

By default, all access ports are untrusted and all trunk ports are trusted in regard to DHCP. Trusted ports allow DHCP servers to provide IP addresses and other information to requesting devices. Untrusted ports drop traffic from DHCP servers to prevent unauthorized servers from providing any configuration information to clients.

If you attach a DHCP server to an access port, you must configure the port as trusted. Before you do so, ensure that the server is physically secure—that is, that access to the server is monitored and controlled.

Understanding DHCP Option 82 for Port Security

You can use DHCP option 82, also known as the DHCP relay agent information option, to help protect the switch against attacks such as spoofing (forging) of IP addresses and MAC addresses, and DHCP IP address starvation. Hosts on untrusted access interfaces on Ethernet LAN switches send requests for IP addresses in order to access the Internet. The switch forwards or relays these requests to DHCP servers, and the servers send offers for IP address leases in response. Attackers can use these messages to perpetrate address spoofing and starvation.

Option 82 provides information about the network location of a DHCP client, and the DHCP server uses this information to implement IP addresses or other parameters for the client. The Juniper Networks Junos operating system (Junos OS) implementation of DHCP option 82 supports RFC 3046, *DHCP Relay Agent Information Option*, at http://tools.ietf.org/html/rfc3046.

This topic covers:

DHCP Option 82 Processing

If DHCP option 82 is enabled on the switch, then when a DHCP client that is connected to the switch on an untrusted interface sends a DHCP request, the switch inserts information about the client's network location into the packet header of that request. The switch then sends the request to the DHCP server. The DHCP server reads the option 82 information in the packet header and uses it to implement the IP address or another parameter for the client. See “Suboption Components of Option 82” on page 4469 for details about option 82 information.

You can enable DHCP option 82 on a single VLAN or on all VLANs on the switch. You can also configure it on Layer 3 interfaces (in routed VLAN interfaces, or RVIs) when the switch is functioning as a relay agent.

When option 82 is enabled on the switch, then this sequence of events occurs when a DHCP client sends a DHCP request:

1. The switch receives the request and inserts the option 82 information in the packet header.
2. The switch forwards or relays the request to the DHCP server.
3. The server uses the DHCP option 82 information to formulate its reply and sends a response back to the switch. It does not alter the option 82 information.

4. The switch strips the option 82 information from the response packet.
5. The switch forwards the response packet to the client.

NOTE: To use the DHCP option 82 feature, you must ensure that the DHCP server is configured to accept option 82. If it is not configured to accept option 82, then when it receives requests containing option 82 information, it does not use the information in setting parameters and it does not echo the information in its response message.

Suboption Components of Option 82

When configuring DHCP option 82, you can use the following suboptions:

- circuit ID—Identifies the circuit (interface and/or VLAN) on the switch on which the request was received. The circuit ID contains the interface name and/or VLAN name, with the two elements separated by a colon—for example, **xe-0/0/10:vlan1**. If the request packet is received on a Layer 3 interface, the circuit ID is just the interface name—for example, **xe-0/0/10**.

  Use the **prefix** option to add an optional prefix to the circuit ID. If you enable the **prefix** option, the hostname for the switch is used as the prefix; for example, **switch1:xe-0/0/10:vlan1**..

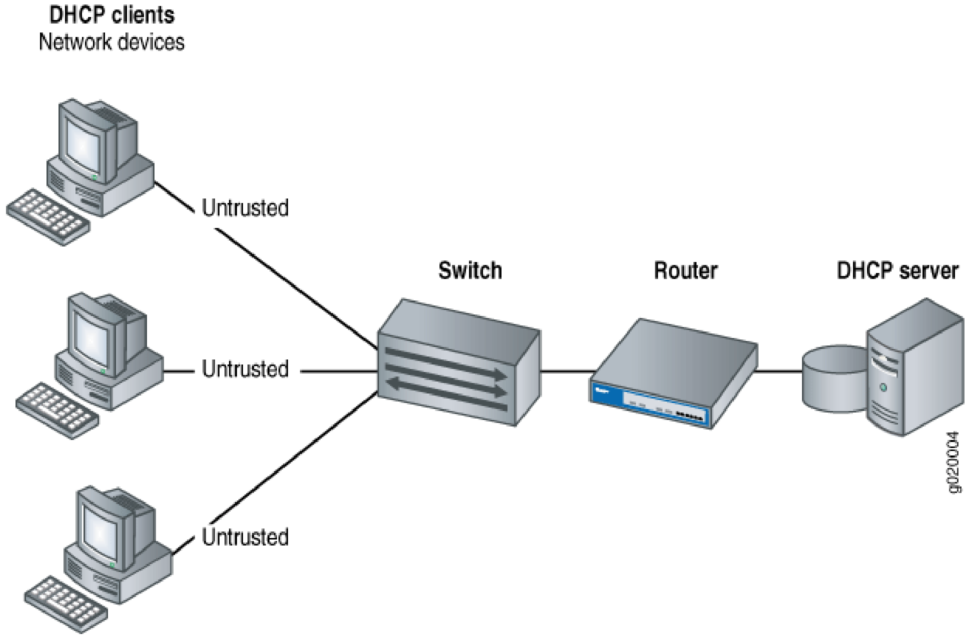
  You can also specify that the interface description be used rather than the interface name and that the VLAN ID be used rather than the VLAN name.
- remote ID—Identifies the host. By default, the remote ID is the MAC address of the switch. You can specify that the remote ID be the hostname of the switch, the interface description, or a character string of your choice. You can also add an optional prefix to the remote ID.
- vendor ID—Identifies the vendor of the host. If you specify the **vendor-id** option but do not enter a value, the default value **Juniper** is used. To specify a value, you type a character string.

Configurations That Support Option 82

You can use option 82 with the following configurations:

- The DHCP client and the DHCP server are on the same VLAN. In this case the switch forwards the requests from the clients on untrusted access interfaces to the server on a trusted interface. For this configuration, you set DHCP option 82 at the **[edit ethernet-switching-options secure-access-port vlan]** hierarchy level.
- The DHCP client or the DHCP server is connected to the switch through a Layer 3 interface and the switch is configured to relay DHCP requests. Figure 158 on page 4470 illustrates a scenario for the switch-as-relay-agent; in this instance, the switch relays requests through a router to the server.

Figure 158: Switch Relays DHCP Requests to Server



For the configuration shown in Figure 158 on page 4470, you set DHCP option 82 at the **[edit forwarding-options helpers bootp]** hierarchy level.

Understanding Static ARP Entries

You can create explicit mappings between IP addresses and MAC addresses, which are called static ARP table entries. Unlike dynamically learned ARP entries, static entries do not age out. You might want to create static ARP entries in a troubleshooting situation or if your device is unable to learn a MAC address dynamically for any reason.

Device Security

Understanding Storm Control

A traffic storm occurs when broadcast packets prompt receiving devices to broadcast packets in response. This prompts further responses, creating a snowball effect. The switch is flooded with packets, which creates unnecessary traffic that leads to poor performance or even a complete loss of service by some clients. Storm control causes a device to monitor traffic levels and take a specified action when a specified traffic level—called the *storm control level*—is exceeded, thus preventing packets from proliferating and degrading service. You can configure devices to drop broadcast and unknown unicast packets, shut down interfaces, or temporarily disable interfaces when the storm control level is exceeded.

Storm control is disabled by default. If you configure storm control and do not specify a storm control level, the default level is 80 percent of the available bandwidth for ingress traffic. You can change the storm control level by configuring it as a specific bandwidth value. (The **level** configuration statement, which allows you to configure the storm control level as a percentage of the combined broadcast and unknown unicast streams, is deprecated and might be removed from future releases. We recommend that you phase out its use and replace it with the **bandwidth** statement.)

NOTE: There is no default rate limiting of BUM traffic to 80% on MX platforms. If the storm control profile is not attached to the IFL, BUM traffic can go up to the line rate.

NOTE: When you configure storm control bandwidth, the value you configure is rounded off internally to the closest multiple of 64 Kbps, and the rounded-off value represents the bandwidth that is actually enforced. For example, if you configure a bandwidth limit of 150 Kbps, storm control enforces a bandwidth limit of 128 Kbps.

NOTE: Storm control must be disabled on all Ethernet interfaces that belong to the FCoE VLAN to prevent FCoE traffic from being dropped. Configuring storm control on an Ethernet interface and including that interface in an FCoE-FC gateway may have undesirable effects, including FCoE packet loss. After disabling storm control on all interfaces, enable storm control on any interfaces that are not part of an FCoE-FC gateway on which you want to use storm control.

CAUTION: The Junos OS allows you to configure a storm control value that exceeds the bandwidth of the interface. If you configure an interface this way, storm control does not drop broadcast or unknown unicast packets even if they consume all the available bandwidth.

Broadcast, multicast, and unicast packets are sent as part of normal operations, so to recognize a storm, you must be able to identify when traffic has reached an abnormal level. Suspect a storm when operations begin timing out and network response times slow down. Users might be unable to access expected services. Monitor the percentage of broadcast and unknown unicast traffic in the network when it is operating normally. This data can then be used as a benchmark to determine when traffic levels are too high. You can then configure storm control to set the level at which you want to drop broadcast and unknown unicast traffic.

Understanding Unicast RPF

Unicast reverse-path forwarding (RPF) helps protect the switch against denial-of-service (DoS) and distributed denial-of-service (DDoS) attacks by verifying the unicast source address of each packet that arrives on an ingress interface where unicast RPF is enabled. It also helps ensure that traffic arriving on ingress interfaces comes from a network source that the receiving interface can reach.

When you enable unicast RPF, the switch forwards a packet only if the receiving interface is the best return path to the packet's unicast source address. This is known as strict mode unicast RPF.

NOTE: On Juniper Networks EX3200, EX4200, and EX4300 Ethernet Switches, the switch applies unicast RPF *globally* to all interfaces when unicast RPF is configured on any interface. For additional information, see "Limitations of the Unicast RPF Implementation on EX3200, EX4200, and EX4300 Switches" on page 4476.

This topic covers:

Unicast RPF for Switches Overview

Unicast RPF functions as an ingress filter that reduces the forwarding of IP packets that might be spoofing an address. By default, unicast RPF is disabled on the switch interfaces.

The type of unicast RPF provided on the switches—that is, strict mode unicast RPF is especially useful on untrusted interfaces. An untrusted interface is an interface where untrusted users or processes can place packets on the network segment.

The switch supports only the active paths method of determining the best return path back to a unicast source address. The active paths method looks up the best reverse path entry in the forwarding table. It does not consider alternate routes specified using routing-protocol-specific methods when determining the best return path.

If the forwarding table lists the receiving interface as the interface to use to forward the packet back to its unicast source, it is the best return path interface.

Use strict mode unicast RPF only on symmetrically routed interfaces. (For information about symmetrically routed interfaces, see "When to Enable Unicast RPF" on page 4474.)

For more information about strict unicast RPF, see RFC 3704, *Ingress Filtering for Multihomed Networks* at http://www.ietf.org/rfc/rfc3704.txt.

Unicast RPF Implementation

This section includes:

Unicast RPF Packet Filtering

When you enable unicast RPF on the switch, the switch handles traffic in the following manner:

- If the switch receives a packet on the interface that is the best return path to the unicast source address of that packet, the switch forwards the packet.
- If the best return path from the switch to the packet's unicast source address is not the receiving interface, the switch discards the packet.
- If the switch receives a packet that has a source IP address that does not have a routing entry in the forwarding table, the switch discards the packet.

Bootstrap Protocol (BOOTP) and DHCP Requests

Bootstrap protocol (BOOTP) and DHCP request packets are sent with a broadcast MAC address and therefore the switch does not perform unicast RPF checks on them. The switch forwards all BOOTP packets and DHCP request packets without performing unicast RPF checks.

Default Route Handling

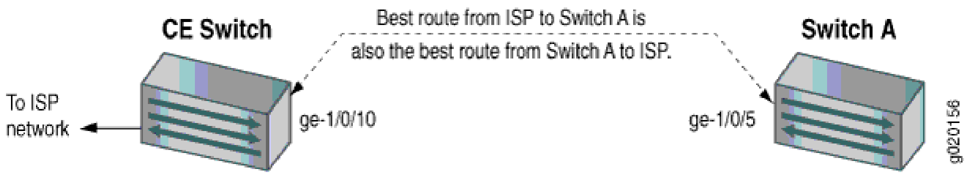
If the best return path to the source is the default route (**0.0.0.0**) and the default route points to **reject**, the switch discards the packets. If the default route points to a valid network interface, the switch performs a normal unicast RPF check on the packets.

When to Enable Unicast RPF

Enable unicast RPF when you want to ensure that traffic arriving on a network interface comes from a source that resides on a network that that interface can reach. You can enable unicast RPF on untrusted interfaces to filter spoofed packets. For example, a common application for unicast RPF is to help defend an enterprise network from DoS/DDoS attacks coming from the Internet.

Enable unicast RPF only on symmetrically routed interfaces. A symmetrically routed interface uses the same route in both directions between the source and the destination, as shown in Figure 159 on page 4475. Symmetrical routing means that if an interface receives a packet, the switch uses the same interface to send a reply to the packet source (the receiving interface matches the forwarding-table entry for the best return path to the source).

Figure 159: Symmetrically Routed Interfaces



Enabling unicast RPF on asymmetrically routed interfaces (where different interfaces receive a packet and reply to its source) results in packets from legitimate sources being filtered (discarded) because the best return path is not the same interface that received the packet.

The following switch interfaces are most likely to be symmetrically routed and thus are candidates for unicast RPF enabling:

- The service provider edge to a customer
- The customer edge to a service provider
- A single access point out of the network (usually on the network perimeter)
- A terminal network that has only one link

NOTE: Because unicast RPF is enabled globally on EX3200, EX4200, and EX4300 switches, ensure that *all* interfaces are symmetrically routed before you enable unicast RPF on these switches. Enabling unicast RPF on asymmetrically routed interfaces results in packets from legitimate sources being filtered.

TIP: Enabling unicast RPF as close as possible to the traffic source stops spoofed traffic before it can proliferate or reach interfaces that do not have unicast RPF enabled.

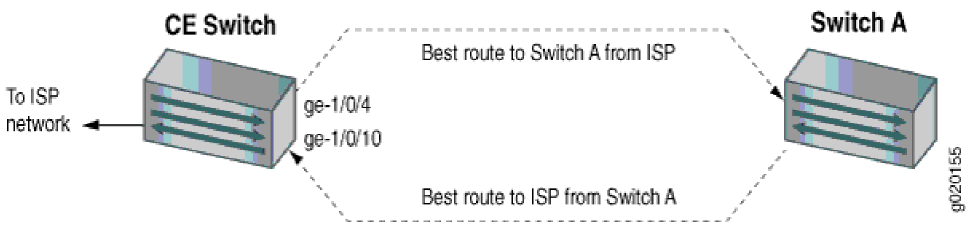
When Not to Enable Unicast RPF

Typically, you will not enable unicast RPF if:

- Switch interfaces are multihomed.
- Switch interfaces are trusted interfaces.
- BGP is carrying prefixes and some of those prefixes are not advertised or are not accepted by the ISP under its policy. (The effect in this case is the same as filtering an interface by using an incomplete access list.)
- Switch interfaces face the network core. Core-facing interfaces are usually asymmetrically routed.

An asymmetrically routed interface uses different paths to send and receive packets between the source and the destination, as shown in Figure 160 on page 4476. This means that if an interface receives a packet, that interface does not match the forwarding table entry as the best return path back to the source. If the receiving interface is not the best return path to the source of a packet, unicast RPF causes the switch to discard the packet even though it comes from a valid source.

Figure 160: Asymmetrically Routed Interfaces



NOTE: Do not enable unicast RPF on EX3200, EX4200, and EX4300 switches if any switch interfaces are asymmetrically routed, because unicast RPF is enabled globally on all interfaces of these switches. All switch interfaces must be symmetrically routed for you to enable unicast RPF without the risk of the switch discarding traffic that you want to forward.

Limitations of the Unicast RPF Implementation on EX3200, EX4200, and EX4300 Switches

On EX3200, EX4200, and EX4300 switches, the switch implements unicast RPF on a global basis. You cannot enable unicast RPF on a per-interface basis. Unicast RPF is globally disabled by default.

- When you enable unicast RPF on any interface, it is automatically enabled on all switch interfaces, including link aggregation groups (LAGs), integrated routing and bridging (IRB) interfaces, and routed VLAN interfaces (RVIs).
- When you disable unicast RPF on the interface (or interfaces) on which you enabled unicast RPF, it is automatically disabled on all switch interfaces.

NOTE: You must explicitly disable unicast RPF on every interface on which it was explicitly enabled or unicast RPF remains enabled on all switch interfaces.

QFX switches and EX3200 and EX4200 switches do not perform unicast RPF filtering on equal-cost multipath (ECMP) traffic. The unicast RPF check examines only one best return path to the packet source, but ECMP traffic employs an address block consisting of multiple paths. Using unicast RPF to filter ECMP traffic on these switches can result in the switch discarding packets that you want to forward because the unicast RPF filter does not examine the entire ECMP address block.

Understanding Unknown Unicast Forwarding

Unknown unicast traffic consists of unicast packets with unknown destination MAC addresses. By default, the switch floods these unicast packets that are traveling in a VLAN to all interfaces that are members of the VLAN. Forwarding this type of traffic can create unnecessary traffic that leads to poor network performance or even a complete loss of network service. This is known as a traffic storm.

To prevent a storm, you can disable the flooding of unknown unicast packets to all VLAN interfaces by configuring one VLAN or all VLANs to forward all unknown unicast traffic to a specific interface. This channels the unknown unicast traffic to a single interface.

CHAPTER 51

Configuration

Firewall and Policer Configuration Examples

Example: Using Filter-Based Forwarding to Route Application Traffic to a Security Device

You can configure filter-based forwarding by using a firewall filter to forward matched traffic to a specific virtual routing instance.

This example describes how to set up filter-based forwarding:

- Configuration on page 4480
- Verification on page 4482

Requirements

This example requires Junos OS Release 12.2X50-D20 or later.

Overview and Topology

In this example, traffic from one application server that is destined for a different application server is matched by a firewall filter based on the IP address of the source application server. Any matching packets are routed to a virtual routing instance that sends the traffic to a security device. In this case, the security device must be able to forward the traffic to the destination application server. For this example, assume that the address of the destination application server is 192.168.0.1.

Configuration

To configure filter-based forwarding:

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste them into the CLI at the **[edit]** hierarchy level.

```
[edit]
set interfaces xe-0/0/0 unit 0 family inet address 10.1.0.1/24
set interfaces xe-0/0/3 unit 0 family inet address 10.1.3.1/24
set firewall family inet filter f1 term t1 from source-address 10.1.0.50/32
set firewall family inet filter f1 term t1 from protocol tcp
set interfaces xe-0/0/0 unit 0 family inet filter input f1
set routing-instances vrf01 instance-type virtual-router
set routing-instances vrf01 interface xe-0/0/3.0
set routing-instances vrf01 routing-options static route 192.168.0.1/24 next-hop 10.1.3.254
set firewall family inet filter f1 term t1 then routing-instance vrf01
```

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.To configure filter-based forwarding:

1. Configure an interface to connect to the application server:

   ```
   [edit interfaces]
   user@switch# set xe-0/0/0 unit 0 family inet address 10.1.0.1/24
   ```

2. Configure an interface to connect to the security device:

   ```
   [edit interfaces]
   user@switch# set xe-0/0/3 unit 0 family inet address 10.1.3.1/24
   ```

3. Create a firewall filter that matches packets based on the address of the application server that the traffic will be sent from. Also configure the filter so that it matches only TCP packets:

   ```
   [edit firewall]
   user@switch# set family inet filter f1 term t1 from source-address 10.1.0.50/32
   user@switch# set firewall family inet filter f1 term t1 from protocol tcp
   ```

4. Apply the filter to the interface that connects to the source application server and configure it to match incoming packets:

   ```
   [edit interfaces]
   ```

```
user@switch# set xe-0/0/0 unit 0 family inet filter input f1
```

5. Create a virtual router:

```
[edit]
user@switch# set routing-instances vrf01 instance-type virtual-router
```

6. Associate the virtual router with the interface that connects to the security device:

```
[edit routing-instances]
user@switch# set vrf01 interface xe-0/0/3.0
```

7. Configure the routing information for the virtual routing instance:

```
[edit routing-instances]
user@switch# set vrf01 routing-options static route 192.168.0.1/24 next-hop 10.1.3.254
```

8. Set the filter to forward packets to the virtual router:

```
[edit firewall]
user@switch# set family inet filter f1 term t1 then routing-instance vrf01
```

Results

Check the results of the configuration:

```
user@switch> show configuration
interfaces {
  xe-0/0/0 {
    unit 0 {
      family inet {
        filter {
          input f1;
        }
        address 10.1.0.1/24;
      }
    }
  }
  xe-0/0/3 {
    unit 0 {
      family inet {
        address 10.1.3.1/24;
      }
    }
  }
}
firewall {
  family inet {
    filter f1 {
      term t1 {
        from {
          source-address {
            10.1.0.50/32;
          }
          protocol tcp;
        }
        then {
          routing-instance vrf01;
        }
      }
    }
  }
```

```
    }
    routing-instances {
        vrf01 {
            instance-type virtual-router;
            interface xe-0/0/1.0;
            routing-options {
                static {
                    route 12.34.56.0/24 next-hop 10.1.3.254;
                }
            }
        }
    }
```

Verification

To confirm that the configuration is working properly, perform these tasks:

- Verifying That Filter-Based Forwarding Was Configured on page 4482

Verifying That Filter-Based Forwarding Was Configured

Purpose Verify that filter-based forwarding was properly enabled on the switch.

Action

1. Use the **show interfaces filters** command:

```
user@switch> show interfaces filters xe-0/0/0.0
Interface       Admin Link Proto Input Filter         Output Filter
xe-0/0/0.0      up    down inet  f1
```

2. Use the **show route forwarding-table** command:

```
user@switch> show route forwarding-table

Routing table: default.inet
Internet:
Destination        Type RtRef Next hop           Type Index NhRef Netif
default            user     1 0:12:f2:21:cf:0    ucst   331     4 me0.0
default            perm     0                    rjct    36     3
0.0.0.0/32         perm     0                    dscd    34     1
10.1.0.0/24        ifdn     0                    rslv   613     1 xe-0/0/0.0
10.1.0.0/32        iddn     0 10.1.0.0           recv   611     1 xe-0/0/0.0

10.1.0.255/32      iddn     0 10.1.0.255         bcst   610     1 xe-0/0/0.0
10.1.1.0/26        ifdn     0                    rslv   583     1 vlan.0
10.1.1.0/32        iddn     0 10.1.1.0           recv   581     1 vlan.0
10.1.1.1/32        user     0                    rjct    36     3
10.1.1.1/32        intf     0 10.1.1.1           locl   582     2
10.1.1.1/32        iddn     0 10.1.1.1           locl   582     2
10.1.1.63/32       iddn     0 10.1.1.63          bcst   580     1 vlan.0
255.255.255.255/32 perm     0                    bcst    32     1

Routing table: vrf01.inet
Internet:
Destination        Type RtRef Next hop           Type Index NhRef Netif
default            perm     0                    rjct   559     2
0.0.0.0/32         perm     0                    dscd   545     1
10.1.3.0/24        ifdn     0                    rslv   617     1 xe-0/0/3.0
10.1.3.0/32        iddn     0 10.1.3.0           recv   615     1 xe-0/0/3.0
```

```
10.1.3.1/32        user     0                    rjct   559     2
192.168.0.1/24     user     0 10.1.3.254         ucst   616     2 xe-0/0/3.0
192.168.0.1/24     user     0 10.1.3.254         ucst   616     2 xe-0/0/3.0
10.1.3.255/32      iddn     0 10.1.3.255         bcst   614     1 xe-0/0/3.0
224.0.0.0/4        perm     0                    mdsc   546     1
224.0.0.1/32       perm     0 224.0.0.1          mcst   529     1
255.255.255.255/32 perm     0                    bcst   543     1

Routing table: default.iso
ISO:
Destination        Type RtRef Next hop           Type Index NhRef Netif
default            perm     0                    rjct    60     1

Routing table: vrf01.iso
ISO:
Destination        Type RtRef Next hop           Type Index NhRef Netif
default            perm     0                    rjct   600     1
```

Meaning The output indicates that the filter was created on the interface and that the virtual routing instance is forwarding matching traffic to the correct IP address.

Example: Using Two-Color Policers and Prefix Lists

If you provide specific amounts of bandwidth to internal or external customers, you can use policing to make sure that customers do not consume more bandwidth than they should receive. For example, you might connect many customers to one 10-Gbps interface and want to ensure that none of them congest the interface by using more bandwidth than they have been allotted.

You could accomplish this by creating a two-color policer similar to the following for each customer:

```
firewall {
  policer Limit-Customer-1 {
    if-exceeding {
      bandwidth-limit 100m;
      burst-size-limit 150m;
    }
    then discard;
  }
```

Creating a policer for each customer is clearly not a scalable solution, however. As an alternative, you can create prefix lists that group classes of customers and then create policers for each prefix list. For example, you could create prefix lists such as **Class-A-Customer-Prefixes**, **Class-B-Customer-Prefixes**, and **Class-C-Customer-Prefixes** (at the **[edit policy-options]** hierarchy level) and create the following corresponding policers:

```
firewall {
  policer Class-A {
    if-exceeding {
      bandwidth-limit 100m;
      burst-size-limit 150m;
    }
    then discard;
  }
  policer Class-B {
    if-exceeding {
      bandwidth-limit 75m;
      burst-size-limit 100m;
    }
    then discard;
  }
  policer Class-C {
    if-exceeding {
      bandwidth-limit 50m;
      burst-size-limit 75m;
    }
    then discard;
  }
}
```

You must create filter terms that specify the prefix lists in their **from** statements and the corresponding policers in their **then** statements similar to the following:

```
firewall
  family inet {
    filter Class-A-Customers {
      term term-1 {
        from {
          destination-prefix-list {
            Class-A-Customer-Prefixes;
          }
        }
        then policer Class-A;
      }
    }
    filter Class-B-Customers {
      term term-1 {
        from {
          destination-prefix-list {
            Class-B-Customer-Prefixes;
          }
        }
        then policer Class-B;
      }
    }
    filter Class-C-Customers {
      term term-1 {
        from {
          destination-prefix-list {
            Class-C-Customer-Prefixes;
          }
        }
```

```
            then policer Class-C;
          }
        }
      }
```

Here are the steps to create this firewall configuration:

1. Create the first policer:

   ```
   [edit firewall]
   user@switch# set policer Class-A if-exceeding bandwidth-limit 100m burst-size-limit 150m
   user@switch# set policer Class-A then discard
   ```
2. Create the second policer:

   ```
   [edit firewall]
   user@switch# set policer Class-B if-exceeding bandwidth-limit 75m burst-size-limit 100m
   user@switch# set policer Class-B then discard
   ```
3. Create the third policer:

   ```
   [edit firewall]
   user@switch# set policer Class-C if-exceeding bandwidth-limit 50m burst-size-limit 75m
   user@switch# set policer Class-C then discard
   ```
4. Create a filter for class A customers:

   ```
   [edit firewall]
   user@switch# edit family inet filter Class-A-Customers
   ```
5. Configure the filter to send packets matching the **Class-A-Customer-Prefixes** prefix list to the **Class-A** policer:

   ```
   [edit firewall family inet filter Class-A-Customers]
   user@switch# set term term-1 from source-prefix-list Class-A-Customers
   user@switch# set term term-1 then policer Class-A
   ```
6. Create a filter for class B customers:

   ```
   [edit firewall]
   user@switch# edit family inet filter Class-B-Customers
   ```
7. Configure the filter to send packets matching the **Class-B-Customer-Prefixes** prefix list to the **Class-B** policer:

   ```
   [edit firewall family inet filter Class-B-Customers]
   user@switch# set term term-1 from source-prefix-list Class-B-Customers
   user@switch# set term term-1 then policer Class-B
   ```
8. Create a filter for class C customers:

   ```
   [edit firewall]
   user@switch# edit family inet filter Class-C-Customers
   ```
9. Configure the filter to send packets matching the **Class-C-Customer-Prefixes** prefix list to the **Class-C** policer:

   ```
   [edit firewall family inet filter Class-C-Customers]
   user@switch# set term term-1 from source-prefix-list Class-C-Customers
   user@switch# set term term-1 then policer Class-C
   ```
10. Apply the filters you created to the appropriate interfaces in the output direction.

NOTE: Note that the implicit deny statement in this filter will block traffic from any source that does not match one of the prefix lists. If you want the filter to allow this traffic, you must include an explicit term for this purpose.

- *prefix-list*

Example: Using Policers to Manage Oversubscription

You might want to use a policer when an interface is oversubscribed and you want to control what will happen if congestion occurs. For example, you might have servers connected to a switch as listed in Table 351 on page 4486.

Table 351: Servers Connected to Switch

Server Type	Connection	IP Address
Network application server	1-gigabit interface	10.0.0.1
Authentication server	1-gigabit interface	10.0.0.2
Database server	10-gigabit interface	10.0.0.3

In this example, users access services provided by the network application server, which requests information from the database server as appropriate. When it receives a request from a user, the network application server first contacts the authentication server to verify the user's credentials. When a user is authenticated and the network application server provides the requested service, all the packets sent from the database server to the application server must transit the 1-Gigabit Ethernet interface connected to the application server twice—once on ingress to the application server and again on egress to the user.

The sequence of events for a user session is as follows:

1. A user connects to the application server and requests a service.
2. The application server requests the user's credentials and relays them to the authentication server.
3. If the authentication server verifies the credentials, the application server initiates the requested service.
4. The application server requests the files necessary to meet the user's request from the database server.
5. The database server sends the requested files to the application server.
6. The application server includes the requested files in its response to the user.

Traffic from the database server to the application server might congest the 1-gigabit interface to which that the application server is connected. This congestion might prevent the server from responding to requests from users and creating new sessions for them. You can use policing to make sure that this does not occur.

To create this firewall configuration, perform the following steps on the database server:

1. Create a policer to drop traffic from the database server to the application server if it exceeds certain limits:

```
[edit firewall]
user@switch# set policer Database-Egress-Policer if-exceeding bandwidth-limit 400
burst-size-limit 500m
user@switch# set policer Database-Egress-Policer then discard
```

2. Create a filter to examine traffic from the database server to the application server:

```
[edit firewall]
user@switch# edit family inet filter Database-Egress-Filter
```

3. Configure the filter to apply the policer to traffic egressing the database server and destined for the application server:

```
[edit firewall family inet filter Database-Egress-Filter]
user@switch# set term term-1 from destination-address 10.0.0.1
user@switch# set term term-1 then policer Database-Egress-Policer
```

4. If required, configure a term to allow traffic from the database server to other destinations (otherwise the traffic will be dropped by the implicit deny statement):

```
[edit firewall family inet filter Database-Egress-Filter]
user@switch# set term term-2 then accept
```

   Note that omitting a **from** statement causes the term to match all packets, which is the desired behavior.

5. Install the egress filter as an output filter on the database server interface that is connected the application server:

```
[edit interfaces]
user@switch# set xe-0/0/3 unit 0 family inet filter output Database-Egress-Filter
```

Here is how the final configuration would appear:

```
firewall {
  policer Database-Egress-Policer {
    if-exceeding {
      bandwidth-limit 400;
      burst-size-limit 500m;
    }
    then discard;
  }
  family inet {
    filter Database-Egress-Filter {
      term term-1 {
        from {
          destination-address {
            10.0.0.1/24;
          }
        }
        then policer Database-Egress-Policer;
      }
      term term-2 {  # If required, include this term so that traffic from the database server
        to other destinations is allowed.
        then accept;
      }
    }
```

```
    }
  ]
```

Port Security Configuration Examples (Original CLI Only)

Example: Configuring Basic Port Security Features

You can configure DHCP snooping, dynamic ARP inspection (DAI), MAC limiting, persistent MAC learning, and MAC move limiting on the access ports of switches to protect the switches and the Ethernet LAN against address spoofing and Layer 2 denial-of-service (DoS) attacks. You can also configure a trusted DHCP server and specific (allowed) MAC addresses for the switch interfaces.

This example describes how to configure basic port security features on a switch:

Requirements

This example uses the following hardware and software components:

- One EX Series switch or one QFX3500 switch
- Junos OS Release 11.4 or later for EX Series switches or Junos OS Release 12.1 or later for the QFX Series

- A DHCP server to provide IP addresses to network devices on the switch

Before you configure basic port security features, be sure you have:

- Connected the DHCP server to the switch.
- Configured a VLAN on the switch. See the task for your platform:
  - *Configuring VLANs for EX Series Switches (CLI Procedure)*
  - “Configuring VLANs” on page 1534 for the QFX Series

NOTE: **In this example, the DHCP server and its clients are all members of a single VLAN on the switch.**

Overview and Topology

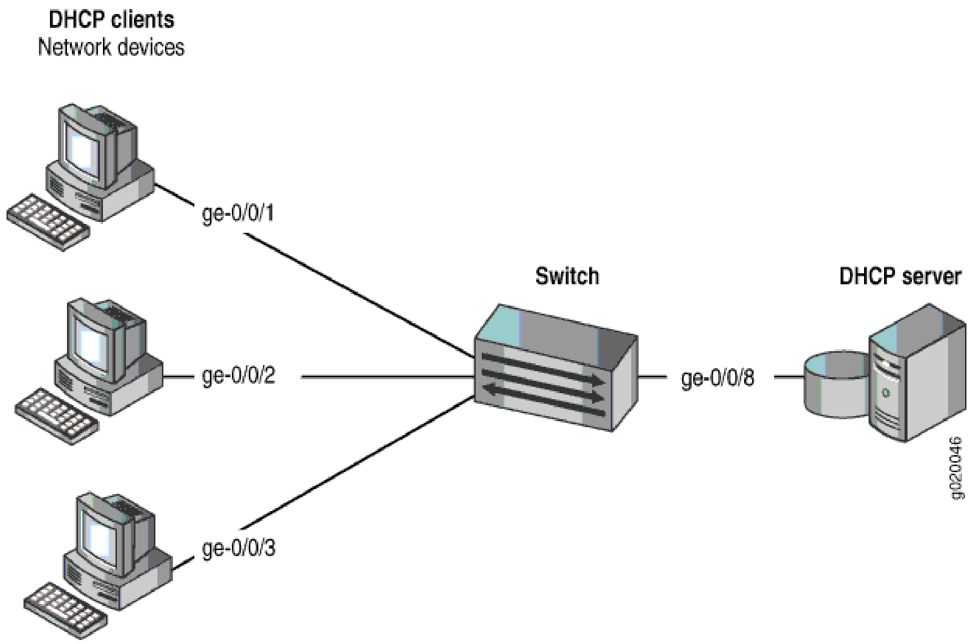
Ethernet LANs are vulnerable to address spoofing and DoS attacks on network devices. To protect the devices from such attacks, you can configure:

- DHCP snooping to validate DHCP server messages
- DAI to protect against MAC spoofing
- MAC limiting to constrain the number of MAC addresses the switch adds to its MAC address cache
- MAC move limiting to help prevent MAC spoofing
- Persistent MAC learning (sticky MAC) to constrain the MAC addresses that can be learned on an interface to the first ones learned, even after a reboot of the switch
- Trusted DHCP server configured on a trusted port to protect against rogue DHCP servers sending leases

This example shows how to configure these security features on a switch connected to a DHCP server.

The setup for this example includes the VLAN **employee-vlan** on the switch. Figure 161 on page 4490 illustrates the topology for this example.

Figure 161: Network Topology for Basic Port Security



The components of the topology for this example are shown in Table 352 on page 4490.

Table 352: Components of the Port Security Topology

Properties	Settings
Switch hardware	One EX Series switch or one QFX3500 switch
VLAN name and ID	**employee-vlan**, tag **20**
VLAN subnets	**192.0.2.16/28** **192.0.2.17** through **192.0.2.30** **192.0.2.31** is subnet's broadcast address
Interfaces in **employee-vlan**	**ge-0/0/1**, **ge-0/0/2**, **ge-0/0/3**, **ge-0/0/8**
Interface for DHCP server	**ge-0/0/8**

In this example, the switch is initially configured with the default port security setup. In the default switch configuration:

- Secure port access is activated on the switch.
- DHCP snooping and DAI are disabled on all VLANs.
- All access ports are untrusted, and all trunk ports are trusted for DHCP snooping.

In the configuration tasks for this example, you set the DHCP server as trusted; you enable DHCP snooping, DAI, and MAC move limiting on a VLAN; you set a value for a MAC limit on some interfaces; you configure some specific (allowed) MAC addresses on an interface; and you configure persistent MAC learning on an interface.

Configuration

To configure basic port security on a switch whose DHCP server and client ports are in a single VLAN:

CLI Quick Configuration

To quickly configure basic port security on the switch, copy the following commands and paste them into the switch terminal window:

```
[edit ethernet-switching-options secure-access-port]
set interface ge-0/0/1 mac-limit 4
set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:80
set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:81
set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:83
set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:85
set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:88
set interface ge-0/0/2 mac-limit 4
set interface ge-0/0/1 persistent-learning
set interface ge-0/0/8 dhcp-trusted
set vlan employee-vlan arp-inspection
set vlan employee-vlan examine-dhcp
set vlan employee-vlan mac-move-limit 5
```

Step-by-Step Procedure

Configure basic port security on the switch:

1. Enable DHCP snooping on the VLAN:

   ```
   [edit ethernet-switching-options secure-access-port]
   user@switch# set vlan employee-vlan examine-dhcp
   ```
2. Specify the interface (port) from which DHCP responses are allowed:

   ```
   [edit ethernet-switching-options secure-access-port]
   user@switch# set interface ge-0/0/8 dhcp-trusted
   ```
3. Enable dynamic ARP inspection (DAI) on the VLAN:

   ```
   [edit ethernet-switching-options secure-access-port]
   user@switch# set vlan employee-vlan arp-inspection
   ```
4. Configure a MAC limit of **4** and use the default action, **drop**. (Packets are dropped, and the MAC address is not added to the Ethernet switching table if the MAC limit is exceeded on the interfaces):

   ```
   [edit ethernet-switching-options secure-access-port]
   user@switch# set interface ge-0/0/1 mac-limit 4
   user@switch# set interface ge-0/0/2 mac-limit 4
   ```
5. Allow learned MAC addresses for a particular interface to persist across restarts of the switch and interface-down events by enabling persistent MAC learning:

   ```
   [edit ethernet-switching-options secure-access-port]
   user@switch# set interface ge-0/0/1 persistent-learning
   ```
6. Configure a MAC move limit of **5** and use the default action, **drop**. (Packets are dropped, and the MAC address is not added to the Ethernet switching table if a MAC address has exceeded the MAC move limit):

   ```
   [edit ethernet-switching-options secure-access-port]
   user@switch# set vlan employee-vlan mac-move-limit 5
   ```
7. Configure allowed MAC addresses:

   ```
   [edit ethernet-switching-options secure-access-port]
   user@switch# set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:80
   user@switch# set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:81
   user@switch# set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:83
   ```

```
user@switch# set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:85
user@switch# set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:88
```

Results

Check the results of the configuration:

```
[edit ethernet-switching-options secure-access-port]
user@switch# show
interface ge-0/0/1.0 {
  mac-limit 4;
  persistent-learning;
}
interface ge-0/0/2.0 {
  allowed-mac [ 00:05:85:3a:82:80 00:05:85:3a:82:81 00:05:85:3a:82:83
    00:05:85:3a:82:85 00:05:85:3a:82:88 ];
  mac-limit 4;
}
interface ge-0/0/8.0 {
  dhcp-trusted;
}
vlan employee-vlan {
  arp-inspection
  examine-dhcp;
  mac-move-limit 5;
}
```

Verification

To confirm that the configuration is working properly:

- Verifying That DHCP Snooping Is Working Correctly on the Switch on page 4492
- Verifying That DAI Is Working Correctly on the Switch on page 4493
- Verifying That MAC Limiting, MAC Move Limiting, and Persistent MAC Learning Are Working Correctly on the Switch on page 4494
- Verifying That Allowed MAC Addresses Are Working Correctly on the Switch on page 4494

Verifying That DHCP Snooping Is Working Correctly on the Switch

Purpose Verify that DHCP snooping is working on the switch.

Action Send some DHCP requests from network devices (here they are DHCP clients) connected to the switch.

Display the DHCP snooping information when the interface on which the DHCP server connects to the switch is trusted. The following output results when requests are sent from the MAC addresses and the server has provided the IP addresses and leases:

```
user@switch> show dhcp snooping binding
DHCP Snooping Information:
MAC Address         IP Address    Lease    Type     VLAN          Interface
-----------------   ----------    -----    ----     ----          ---------
00:05:85:3A:82:77    192.0.2.17    600    dynamic  employee-vlan   ge-0/0/1.0
00:05:85:3A:82:79    192.0.2.18    653    dynamic  employee-vlan   ge-0/0/1.0
00:05:85:3A:82:80    192.0.2.19    720    dynamic  employee-vlan   ge-0/0/2.0
00:05:85:3A:82:81    192.0.2.20    932    dynamic  employee-vlan   ge-0/0/2.0
00:05:85:3A:82:83    192.0.2.21   1230    dynamic  employee-vlan   ge-0/0/2.0
00:05:85:27:32:88    192.0.2.22   3200    dynamic  employee-vlan   ge-0/0/2.0
```

Meaning When the interface on which the DHCP server connects to the switch has been set to trusted, the output (see preceding sample) shows, for each MAC address, the assigned IP address and lease time—that is, the time, in seconds, remaining before the lease expires.

If the DHCP server had been configured as untrusted, no entries would be added to the DHCP snooping database, and nothing would be shown in the output of the **show dhcp snooping binding** command.

Verifying That DAI Is Working Correctly on the Switch

Purpose Verify that DAI is working on the switch.

Action Send some ARP requests from network devices connected to the switch.

Display the DAI information:

```
user@switch> show arp inspection statistics
ARP inspection statistics:
Interface        Packets received  ARP inspection pass   ARP inspection failed
---------------  ---------------   -------------------- ---------------------
ge-0/0/1.0                      7                     5                     2
ge-0/0/2.0                     10                    10                     0
ge-0/0/3.0                     12                    12                     0
```

Meaning The sample output shows the number of ARP packets received and inspected per interface, with a listing of how many packets passed and how many failed the inspection on each interface. The switch compares the ARP requests and replies against the entries in the DHCP snooping database. If a MAC address or IP address in the ARP packet does not match a valid entry in the database, the packet is dropped.

Verifying That MAC Limiting, MAC Move Limiting, and Persistent MAC Learning Are Working Correctly on the Switch

Purpose Verify that MAC limiting, MAC move limiting, and persistent MAC learning are working on the switch.

Action Suppose that two packets have been sent from hosts on **ge-0/0/1** and five packets from hosts on **ge-0/0/2**, with both interfaces set to a MAC limit of **4** with the default action **drop** and **ge-0/0/1** enabled for persistent MAC learning.

Display the MAC addresses learned:

```
user@switch> show ethernet-switching table
Ethernet-switching table:  7 entries, 4 learned, 2 persistent entries
  VLAN                 MAC address         Type         Age    Interfaces

  employee-vlan        *                   Flood          -    All-members
  employee-vlan        00:05:85:3A:82:77   Persistent     0    ge-0/0/1.0
  employee-vlan        00:05:85:3A:82:79   Persistent     0    ge-0/0/1.0
  employee-vlan        00:05:85:3A:82:80   Learn          0    ge-0/0/2.0
  employee-vlan        00:05:85:3A:82:81   Learn          0    ge-0/0/2.0
  employee-vlan        00:05:85:3A:82:83   Learn          0    ge-0/0/2.0
  employee-vlan        00:05:85:3A:82:85   Learn          0    ge-0/0/2.0
```

Now suppose packets have been sent from two of the hosts on **ge-0/0/2** after they have been moved to other interfaces more than five times in 1 second, with **employee-vlan** set to a MAC move limit of **5** with the default action **drop**.

Display the MAC addresses in the table:

```
user@switch> show ethernet-switching table

Ethernet-switching table:  7 entries, 2 learned, 2 persistent entries
  VLAN                 MAC address         Type         Age    Interfaces

  employee-vlan        *                   Flood          -    All-members
  employee-vlan        00:05:85:3A:82:77   Persistent     0    ge-0/0/1.0
  employee-vlan        00:05:85:3A:82:79   Persistent     0    ge-0/0/1.0
  employee-vlan        00:05:85:3A:82:80   Learn          0    ge-0/0/2.0
  employee-vlan        00:05:85:3A:82:81   Learn          0    ge-0/0/2.0
  employee-vlan        *                   Flood          -    ge-0/0/2.0
  employee-vlan        *                   Flood          -    ge-0/0/2.0
```

Meaning The first sample output shows that with a MAC limit of **4** for each interface, the fifth MAC address on **ge-0/0/2** was not learned because it exceeded the MAC limit. The second sample output shows that MAC addresses for three of the hosts on **ge-/0/0/2** were not learned, because the hosts had been moved back more than five times in 1 second.

Interface ge-0/0/1.0 was enabled for persistent MAC learning, so the MAC addresses associated with this interface are of the type **persistent**.

Verifying That Allowed MAC Addresses Are Working Correctly on the Switch

Purpose Verify that allowed MAC addresses are working on the switch.

Action Display the MAC cache information after five allowed MAC addresses have been configured on interface **ge-0/0/2**:

```
user@switch> show ethernet-switching table
Ethernet-switching table:  5 entries, 4 learned
  VLAN                 MAC address        Type         Age    Interfaces

  employee-vlan        00:05:85:3A:82:80   Learn         0     ge-0/0/2.0
  employee-vlan        00:05:85:3A:82:81   Learn         0     ge-0/0/2.0
  employee-vlan        00:05:85:3A:82:83   Learn         0     ge-0/0/2.0
  employee-vlan        00:05:85:3A:82:85   Learn         0     ge-0/0/2.0
  employee-vlan        *                   Flood         -     ge-0/0/2.0
```

Meaning Because the MAC limit value for this interface has been set to **4**, only four of the five configured allowed addresses are learned.

Example: Configuring MAC Limiting to Protect the Switch from DHCP Starvation Attacks

In a DHCP starvation attack, an attacker floods an Ethernet LAN with DHCP requests from spoofed (counterfeit) MAC addresses. The switch's trusted DHCP server or servers cannot keep up with the requests and can no longer assign IP addresses and lease times to legitimate DHCP clients on the switch. Requests from those clients are either dropped or directed to a rogue DHCP server set up by the attacker.

This example describes how to configure MAC limiting, a port security feature, to protect the switch against DHCP starvation attacks:

Requirements

This example uses the following hardware and software components:

- One QFX3500 switch
- Junos OS Release 12.1 or later for the QFX Series
- A DHCP server to provide IP addresses to network devices on the switch

Before you configure MAC limiting, a port security feature, to mitigate DHCP starvation attacks, be sure you have:

- Connected the DHCP server to the switch.
- Configured the VLAN **employee-vlan** on the switch. See “Example: Setting Up Bridging with Multiple VLANs” on page 1451.

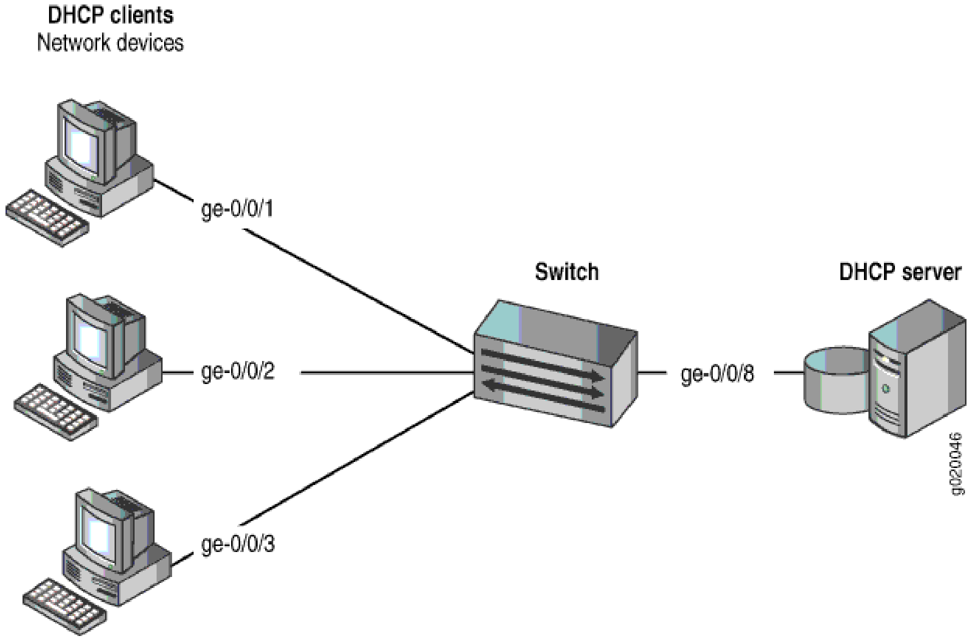
Overview and Topology

Ethernet LANs are vulnerable to address spoofing and DoS attacks on network devices. This example describes how to protect the switch against one common type of attack, a DHCP starvation attack.

This example shows how to configure port security features on a switch that is connected to a DHCP server.

The setup for this example includes the VLAN **employee-vlan** on the switch. Figure 162 on page 4497 illustrates the topology for this example.

Figure 162: Network Topology for Basic Port Security



The components of the topology for this example are shown in Table 353 on page 4497.

Table 353: Components of the Port Security Topology

Properties	Settings
Switch hardware	One QFX3500 switch
VLAN name and ID	**employee-vlan**
Interfaces in **employee-vlan**	**ge-0/0/1**, **ge-0/0/2**, **ge-0/0/3**, **ge-0/0/8**
Interface for DHCP server	**ge-0/0/8**

In this example, the switch has already been configured as follows:

- Secure port access is activated on the switch.
- No MAC limit is set on any of the interfaces.
- DHCP snooping is disabled on the VLAN **employee-vlan**.
- All access interfaces are untrusted, which is the default setting.

Configuration

To configure the MAC limiting port security feature to protect the switch against DHCP starvation attacks:

CLI Quick Configuration

To quickly configure MAC limiting, copy the following commands and paste them into the switch terminal window:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface ge-0/0/1 mac-limit 3 action drop
user@switch# set interface ge-0/0/2 mac-limit 3 action drop
```

Step-by-Step Procedure

Configure MAC limiting:

1. Configure a MAC limit of **3** on **ge-0/0/1** and specify that packets with new addresses be dropped if the limit has been exceeded on the interface:

   ```
   [edit ethernet-switching-options secure-access-port]
   user@switch# set interface ge–0/0/1 mac-limit (Access Port Security) 3 action drop
   ```
2. Configure a MAC limit of **3** on **ge-0/0/2** and specify that packets with new addresses be dropped if the limit has been exceeded on the interface:

   ```
   [edit ethernet-switching-options secure-access-port]
   user@switch# set interface ge-0/0/2 mac-limit 3 action drop
   ```

Results

Check the results of the configuration:

```
[edit ethernet-switching-options secure-access-port]
user@switch# show
interface ge-0/0/1.0 {
  mac-limit 3 action drop;
}
interface ge-0/0/2.0 {
  mac-limit 3 action drop;
}
```

Verification

Confirm that the configuration is working properly.

Verifying That MAC Limiting Is Working Correctly on the Switch

Purpose

Verify that MAC limiting is working on the switch.

Action Send some DHCP requests from network devices (here they are DHCP clients) connected to the switch.

Display the MAC addresses learned when DHCP requests are sent from hosts on **ge-0/0/1** and from hosts on **ge-0/0/2**, with both interfaces set to a MAC limit of **3** with the action **drop**:

```
user@switch>  show ethernet-switching table
Ethernet-switching table:  7 entries, 6 learned
  VLAN           MAC address         Type         Age    Interfaces

  default        *                   Flood          -    ge-0/0/2.0
  default        00:05:85:3A:82:77   Learn          0    ge-0/0/1.0
  default        00:05:85:3A:82:79   Learn          0    ge-0/0/1.0
  default        00:05:85:3A:82:80   Learn          0    ge-0/0/1.0
  default        00:05:85:3A:82:81   Learn          0    ge-0/0/2.0
  default        00:05:85:3A:82:83   Learn          0    ge-0/0/2.0
  default        00:05:85:3A:82:85   Learn          0    ge-0/0/2.0
```

Meaning The sample output shows that with a MAC limit of **3** for each interface, the DHCP request for a fourth MAC address on **ge-0/0/2** was dropped because it exceeded the MAC limit.

Because only 3 MAC addresses can be learned on each of the two interfaces, attempted DHCP starvation attacks fail.

- Understanding MAC Limiting and MAC Move Limiting for Port Security on page 4465
- Configuring MAC Limiting on page 4545

Example: Configuring MAC Limiting, Including Dynamic and Allowed MAC Addresses, to Protect the Switch from Ethernet Switching Table Overflow Attacks

In an Ethernet switching table overflow attack, an intruder sends so many requests from new MAC addresses that the Ethernet switching table fills up and then overflows, forcing the switch to broadcast all messages.

This example describes how to configure MAC limiting and allowed MAC addresses, two port security features, to protect the switch from Ethernet switching table attacks:

Requirements

This example uses the following hardware and software components:

- One EX Series switch or QFX3500 switch

- Junos OS Release 9.0 or later for EX Series switches or Junos OS 12.1 or later for the QFX Series.
- A DHCP server to provide IP addresses to network devices on the switch

Before you configure specific port security features to mitigate common access-interface attacks, be sure you have:

- Connected the DHCP server to the switch.
- Configured a VLAN on the switch. See the task for your platform:

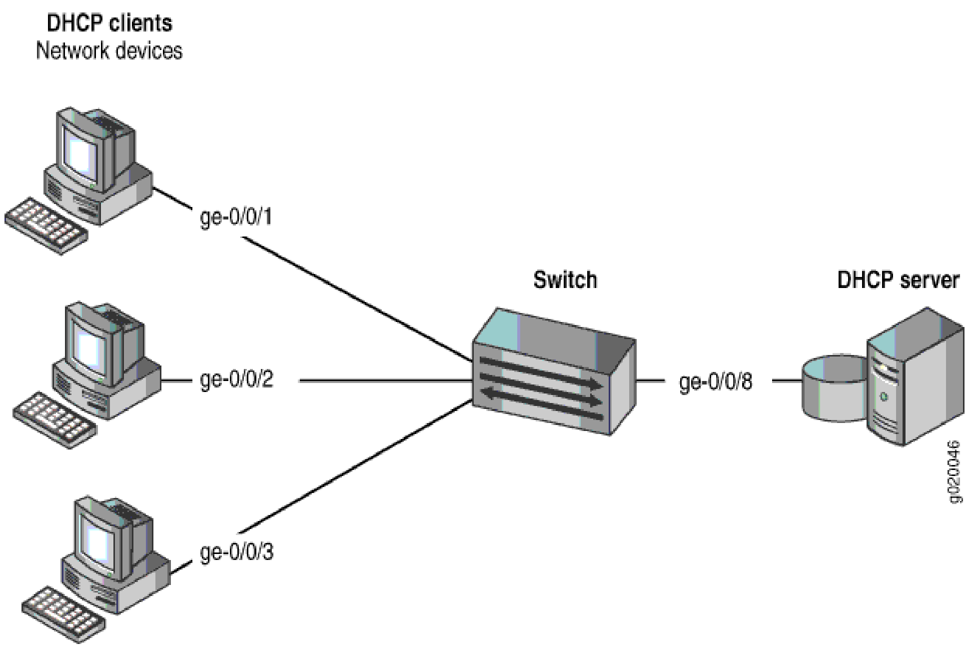
Overview and Topology

Ethernet LANs are vulnerable to address spoofing and DoS attacks on network devices. This example describes how to protect the switch from an attack on the Ethernet switching table that causes the table to overflow and thus forces the switch to broadcast all messages.

This example shows how to configure port security features on a switch connected to a DHCP server.

The setup for this example includes the VLAN **employee-vlan** on the switch. The procedure for creating that VLAN is described in the topic *Example: Setting Up Bridging with Multiple VLANs for EX Series Switches* and “Example: Setting Up Bridging with Multiple VLANs” on page 1451 for the QFX Series. That procedure is not repeated here. Figure 163 on page 4500 illustrates the topology for this example.

Figure 163: Network Topology for Basic Port Security



The components of the topology for this example are shown in Table 354 on page 4501.

Table 354: Components of the Port Security Topology

Properties	Settings
Switch hardware	One EX Series switch or one QFX3500 switch
VLAN name and ID	**employee-vlan**, tag **20**
VLAN subnets	**192.0.2.16/28** **192.0.2.17** through **192.0.2.30** **192.0.2.31** is subnet's broadcast address
Interfaces in **employee-vlan**	**ge-0/0/1**, **ge-0/0/2**, **ge-0/0/3**, **ge-0/0/8**
Interface for DHCP server	**ge-0/0/8**

In this example, use the MAC limit feature to control the total number of MAC addresses that can be added to the Ethernet switching table for the specified interface. Use the allowed MAC addresses feature to ensure that the addresses of network devices whose network access is critical are guaranteed to be included in the Ethernet switching table.

In this example, the switch has already been configured as follows:

- Secure port access is activated on the switch.
- No MAC limit is set on any of the interfaces.
- All access interfaces are untrusted, which is the default setting.

Configuration

To configure MAC limiting and some allowed MAC addresses to protect the switch against Ethernet switching table overflow attacks:

CLI Quick Configuration

To quickly configure MAC limiting, clear the MAC forwarding table, and configure some allowed MAC addresses, copy the following commands and paste them into the switch terminal window:

```
[edit ethernet-switching-options secure-access-port]
set interface ge-0/0/1 mac-limit 4 action drop
set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:80
set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:81
set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:83
set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:85
exit
exit
clear ethernet-switching-table interface ge-0/0/1
```

Step-by-Step Procedure

Configure MAC limiting and some allowed MAC addresses:

1. Configure a MAC limit of **4** on **ge-0/0/1** and specify that incoming packets with different addresses be dropped once the limit is exceeded on the interface:

   ```
   [edit ethernet-switching-options secure-access-port]
   user@switch# set interface ge-0/0/1 mac-limit (Access Port Security) 4 action drop
   ```

2. Clear the current entries for interface ge-0/0/1 from the MAC address forwarding table :

   `user@switch#` **clear ethernet-switching-table interface ge-0/0/1**

3. Configure the allowed MAC addresses on **ge-0/0/2**:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:80
user@switch# set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:81
user@switch# set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:83
user@switch# set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:85
```

Results Check the results of the configuration:

```
[edit ethernet-switching-options secure-access-port]
user@switch# show
interface ge-0/0/1.0 {
  mac-limit 4 action drop;
}
interface ge-0/0/2.0 {
  allowed-mac [ 00:05:85:3a:82:80 00:05:85:3a:82:81 00:05:85:3a:82:83 00:05:85
  :3a:82:85 ];
}
```

Verification

To confirm that the configuration is working properly:

- Verifying That MAC Limiting Is Working Correctly on the Switch on page 4502

Verifying That MAC Limiting Is Working Correctly on the Switch

Purpose Verify that MAC limiting is working on the switch.

Action Display the MAC cache information after DHCP requests have been sent from hosts on **ge-0/0/1**, with the interface set to a MAC limit of **4** with the action **drop**, and after four allowed MAC addresses have been configured on interface **ge/0/0/2**:

```
user@switch> show ethernet-switching table
Ethernet-switching table:  5 entries, 4 learned
  VLAN              MAC address       Type         Age    Interfaces

  employee-vlan     00:05:85:3A:82:71   Learn        0    ge-0/0/1.0
  employee-vlan     00:05:85:3A:82:74   Learn        0    ge-0/0/1.0
  employee-vlan     00:05:85:3A:82:77   Learn        0    ge-0/0/1.0
  employee-vlan     00:05:85:3A:82:79   Learn        0    ge-0/0/1.0
  employee-vlan     *                   Flood        0    ge-0/0/1.0
  employee-vlan     00:05:85:3A:82:80   Learn        0    ge-0/0/2.0
  employee-vlan     00:05:85:3A:82:81   Learn        0    ge-0/0/2.0
  employee-vlan     00:05:85:3A:82:83   Learn        0    ge-0/0/2.0
  employee-vlan     00:05:85:3A:82:85   Learn        0    ge-0/0/2.0
  employee-vlan     *                   Flood        -    ge-0/0/2.0
```

Meaning The sample output shows that with a MAC limit of **4** for the interface, the DHCP request for a fifth MAC address on **ge-0/0/1** was dropped because it exceeded the MAC limit and that only the specified allowed MAC addresses have been learned on the **ge-0/0/2** interface.

Example: Configuring a DHCP Server Interface as Untrusted to Protect the Switch from Rogue DHCP Server Attacks

In a rogue DHCP server attack, an attacker has introduced a rogue server into the network, allowing it to give IP address leases to the network's DHCP clients and to assign itself as the gateway device.

This example describes how to configure a DHCP server interface as untrusted to protect the switch from a rogue DHCP server:

- Requirements on page 4503
- Overview and Topology on page 4504
- Configuration on page 4505
- Verification on page 4505

Requirements

This example uses the following hardware and software components:

- One EX Series switch or one QFX3500 switch
- Junos OS Release 9.0 or later for EX Series switches or Junos OS Release 12.1 or later for the QFX Series
- A DHCP server to provide IP addresses to network devices on the switch

Before you configure an untrusted DHCP server interface to mitigate rogue DHCP server attacks, be sure you have:

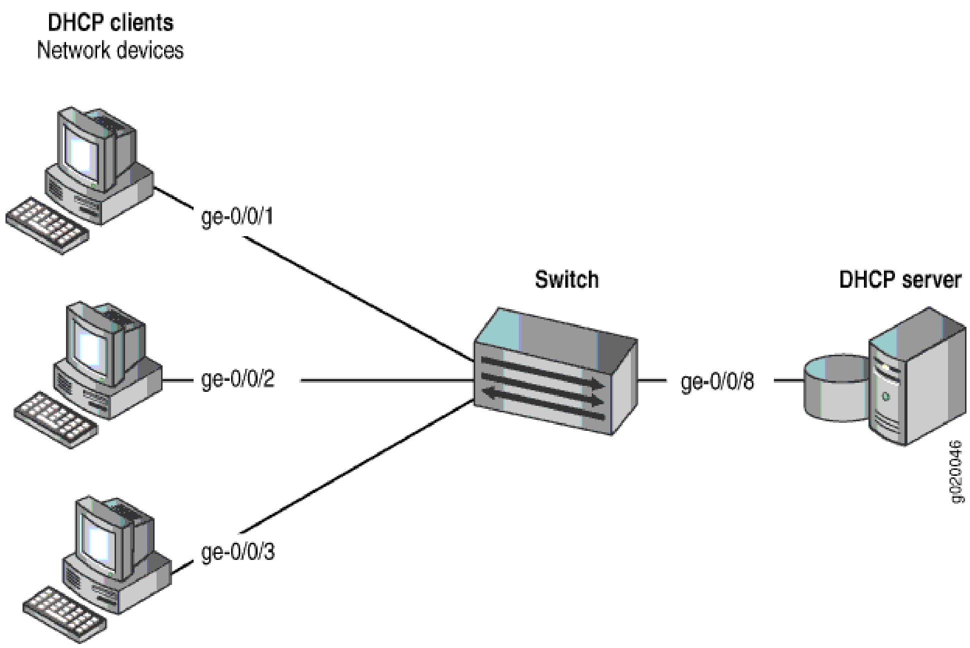
- Connected the DHCP server to the switch.
- Enabled DHCP snooping on the VLAN.
- Configured a VLAN on the switch. See the task for your platform:
  - *Example: Setting Up Bridging with Multiple VLANs for EX Series Switches*
  - “Example: Setting Up Bridging with Multiple VLANs” on page 1451 for the QFX Series

Overview and Topology

Ethernet LANs are vulnerable to address spoofing and DoS attacks on network devices. This example describes how to protect the switch from rogue DHCP server attacks.

This example shows how to explicitly configure an untrusted interface on an EX3200-24P switch and a QFX3500 switch. Figure 164 on page 4504 illustrates the topology for this example.

Figure 164: Network Topology for Basic Port Security



The components of the topology for this example are shown in Table 355 on page 4504.

Table 355: Components of the Port Security Topology

Properties	Settings
Switch hardware	One EX3200-24P, 24 ports (8 PoE ports) or one QFX3500 switch
VLAN name and ID	**employee-vlan**, tag **20**
VLAN subnets	**192.0.2.16/28** **192.0.2.17** through **192.0.2.30** **192.0.2.31** is the subnet's broadcast address
Interfaces in **employee-vlan**	**ge-0/0/1**, **ge-0/0/2**, **ge-0/0/3**, **ge-0/0/8**
Interface for DHCP server	**ge-0/0/8**

In this example, the switch has already been configured as follows:

- Secure port access is activated on the switch.

- DHCP snooping is enabled on the VLAN **employee-vlan**.
- The interface (port) where the rogue DHCP server has connected to the switch is currently trusted.

Configuration

To configure the DHCP server interface as untrusted because the interface is being used by a rogue DHCP server:

CLI Quick Configuration

To quickly set the rogue DHCP server interface as untrusted, copy the following command and paste it into the switch terminal window:

```
[edit ethernet-switching-options secure-access-port]
set interface ge-0/0/8 no-dhcp-trusted
```

Step-by-Step Procedure

To set the DHCP server interface as untrusted:

- Specify the interface (port) from which DHCP responses are not allowed:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface ge-0/0/8 no-dhcp-trusted
```

Results

Check the results of the configuration:

```
[edit ethernet-switching-options secure-access-port]
user@switch# show
interface ge-0/0/8.0 {
  no-dhcp-trusted;
}
```

Verification

Confirm that the configuration is working properly.

Verifying That the DHCP Server Interface Is Untrusted

Purpose

Verify that the DHCP server is untrusted.

Action

1. Send some DHCP requests from network devices (here they are DHCP clients) connected to the switch.
2. Display the DHCP snooping information when the port on which the DHCP server connects to the switch is not trusted.

Meaning

There is no output from the command because no entries are added to the DHCP snooping database.

Example: Configuring DHCP Snooping, DAI , and MAC Limiting on a Switch with Access to a DHCP Server Through a Second Switch

You can configure DHCP snooping, dynamic ARP inspection (DAI), and MAC limiting on the access interfaces of switches to protect the switch and the Ethernet LAN against address spoofing and Layer 2 denial-of-service (DoS) attacks. To obtain those basic settings, you can use the switch's default configuration for port security, configure the MAC limit, and enable DHCP snooping and DAI on a VLAN. You can configure those features when the DHCP server is connected to a different switch from the one to which the DHCP clients (network devices) are connected.

This example describes how to configure port security features on a switch whose hosts obtain IP addresses and lease times from a DHCP server connected to a second switch:

Requirements

This example uses the following hardware and software components:

- One EX Series switch or QFX3500 switch—“Switch 1” in this example.
- An additional EX Series switch or QFX3500 switch—”Switch 2” in this example. You do not configure port security on this second switch.
- Junos OS Release 9.0 or later for EX Series switches or Junos OS Release 12.1 or later for the QFX Series.
- A DHCP server connected to Switch 2. You use the server to provide IP addresses to network devices connected to Switch 1.
- At least two network devices (hosts) that you connect to access interfaces on Switch 1. These devices are DHCP clients.

Before you configure DHCP snooping, DAI, and MAC limiting port security features, be sure you have:

- Connected the DHCP server to Switch 2.
- Configured a VLAN on the switch. See the task for your platform:
  - *Example: Setting Up Bridging with Multiple VLANs for EX Series Switches*
  - “Example: Setting Up Bridging with Multiple VLANs” on page 1451 for the QFX Series

Overview and Topology

Ethernet LANs are vulnerable to address spoofing and DoS attacks on network devices. To protect the devices from such attacks, you can configure:

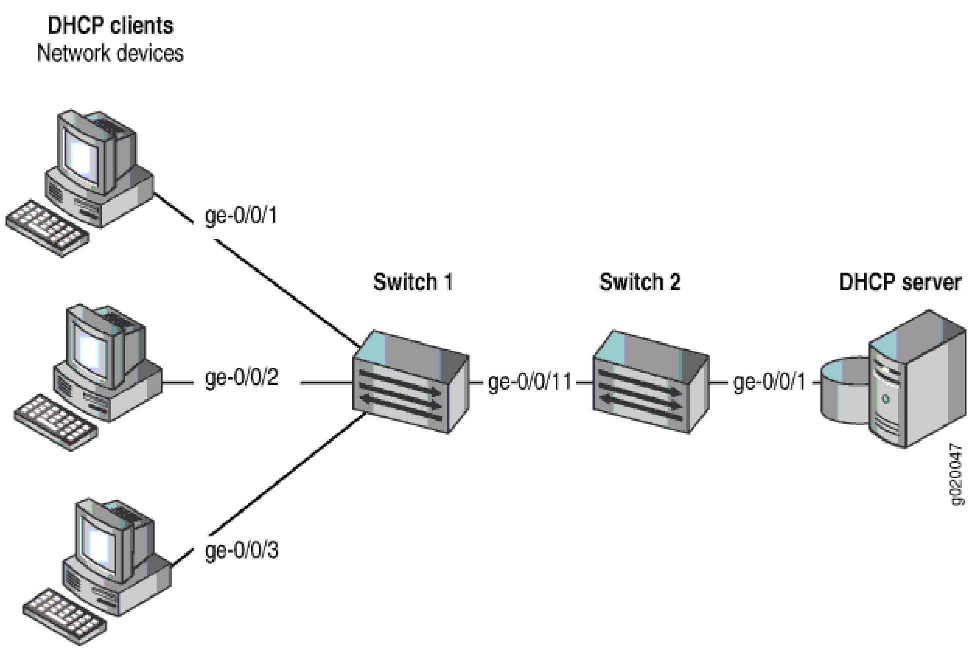
- DHCP snooping to validate DHCP server messages
- DAI to protect against ARP spoofing
- MAC limiting to constrain the number of MAC addresses the switch adds to its MAC address cache

This example shows how to configure these port security features on Switch 1. Switch 1 is connected to another switch (Switch 2) that is not configured with port security features. That second switch is connected to a DHCP server. (See Figure 165 on page 4507.) Network devices (hosts) that are connected to Switch 1 send requests for IP addresses (that is, the devices are DHCP clients). Those requests are transmitted from Switch 1 to Switch 2 and then to the DHCP server connected to Switch 2. Responses to the requests are transmitted along the reverse path of the one followed by the requests.

The setup for this example includes the VLAN **employee-vlan** on both switches.

Figure 165 on page 4507 shows the network topology for the example.

Figure 165: Network Topology for Port Security Setup with Two Switches on the Same VLAN



The components of the topology for this example are shown in Table 356 on page 4508.

Table 356: Components of Port Security Setup on Switch 1 with a DHCP Server Connected to Switch 2

Properties	Settings
Switch hardware	One EX Series switch or one QFX3500 switch (Switch 1), and an additional EX Series switch or QFX3500 switch (Switch 2)
VLAN name and ID	**employee-vlan**, tag **20**
VLAN subnets	**192.0.2.16/28** **192.0.2.17** through **192.0.2.30** **192.0.2.31** is subnet's broadcast address
Trunk interface on both switches	**ge-0/0/11**
Access interfaces on Switch 1	**ge-0/0/1**, **ge-0/0/2**, and **ge-0/0/3**
Access interface on Switch 2	**ge-0/0/1**
Interface for DHCP server	**ge-0/0/1** on Switch 2

Switch 1 is initially configured with the default port security setup. In the default configuration on the switch:

- Secure port access is activated on the switch.
- The switch does not drop any packets, which is the default setting.
- DHCP snooping and dynamic ARP inspection (DAI) are disabled on all VLANs.
- All access interfaces are untrusted and trunk interfaces are trusted; these are the default settings.

In the configuration tasks for this example, you configure a VLAN on both switches.

In addition to configuring the VLAN, you enable DHCP snooping on Switch 1. In this example, you also enable DAI and a MAC limit of **5** on Switch 1.

Because the interface that connects Switch 2 to Switch 1 is a trunk interface, you do not have to configure this interface to be trusted. As noted above, trunk interfaces are automatically trusted, so DHCP messages coming from the DHCP server to Switch 2 and then on to Switch 1 are trusted.

Configuring a VLAN, Interfaces, and Port Security Features on Switch 1

CLI Quick Configuration

To quickly configure a VLAN, interfaces, and port security features, copy the following commands and paste them into the switch terminal window:

```
[edit]
set ethernet-switching-options secure-access-port interface ge-0/0/1 mac-limit 5 action drop
clear ethernet-switching table interface ge-0/0/1
set ethernet-switching-options secure-access-port vlan employee-vlan arp-inspection
set ethernet-switching-options secure-access-port vlan employee-vlan examine-dhcp
set interfaces ge-0/0/1 unit 0 family ethernet-switching vlan members 20
set interfaces ge-0/0/2 unit 0 family ethernet-switching vlan members 20
```

set interfaces ge-0/0/3 unit 0 family ethernet-switching vlan members 20
set interfaces ge-0/0/11 unit 0 family ethernet-switching port-mode trunk
set interfaces ge-0/0/11 unit 0 family ethernet-switching vlan members 20
set vlans employee-vlan vlan-id 20

Step-by-Step Procedure

To configure MAC limiting, a VLAN, and interfaces on Switch 1 and enable DAI and DHCP on the VLAN:

1. Configure the VLAN **employee-vlan** with VLAN ID **20**:

   ```
   [edit vlans]
   user@switch1# set employee-vlan vlan-id 20
   ```
2. Configure an interface on Switch 1 as a trunk interface:

   ```
   [edit interfaces]
   user@switch1# set ge-0/0/11 unit 0 family ethernet-switching port-mode trunk
   ```
3. Associate the VLAN with interfaces **ge-0/0/1**, **ge-0/0/2**, **ge-0/0/3**, and **ge-0/0/11**:

   ```
   [edit interfaces]
   user@switch1# set ge-0/0/1 unit 0 family ethernet-switching vlan members 20
   user@switch1# set ge-0/0/2 unit 0 family ethernet-switching vlan members 20
   user@switch1# set ge-0/0/3 unit 0 family ethernet-switching vlan members 20
   user@switch1# set ge-0/0/11 unit 0 family ethernet-switching vlan members 20
   ```
4. Enable DHCP snooping on the VLAN:

   ```
   [edit ethernet-switching-options secure-access-port]
   user@switch1# set vlan employee-vlan examine-dhcp
   ```
5. Enable DAI on the VLAN:

   ```
   [edit ethernet-switching-options secure-access-port]
   user@switch1# set vlan employee-vlan arp-inspection
   ```
6. Configure a MAC limit of **5** on **ge-0/0/1** and use the default action, drop (packets with new addresses are dropped if the limit has been exceeded):

   ```
   [edit ethernet-switching-options secure-access-port]
   user@switch1# set interface ge-0/0/1 mac-limit 5 drop
   ```
7. Clear the existing MAC address table entries from interface ge-0/0/1:

   ```
   user@switch1# clear ethernet-switching table interface ge-0/0/1
   ```

Results

Display the results of the configuration:

```
[edit]
user@switch1# show
ethernet-switching-options {
   secure-access-port {
      interface ge-0/0/1.0{
         mac-limit 5 action drop;
      }
      vlan employee-vlan {
         arp-inspection;
         examine-dhcp;
      }
   }
}
interfaces {
   ge-0/0/1 {
      unit 0 {
         family ethernet-switching {
            vlan {
```

```
                members 20;
              }
            }
          }
        }
        ge-0/0/2 {
          unit 0 {
            family ethernet-switching {
              vlan {
                members 20;
              }
            }
          }
        }
        ge-0/0/3 {
          unit 0 {
            family ethernet-switching {
              vlan {
                members 20;
              }
            }
          }
        }
        ge-0/0/11 {
          unit 0 {
            family ethernet-switching {
              port-mode trunk;
              vlan {
                members 20;
              }
            }
          }
        }
      }
      vlans {
        employee-vlan {
          vlan-id 20;
        }
      }
```

Configuring a VLAN and Interfaces on Switch 2

To configure the VLAN and interfaces on Switch 2:

CLI Quick Configuration

To quickly configure the VLAN and interfaces on Switch 2, copy the following commands and paste them into the switch terminal window:

```
[edit]
set interfaces ge-0/0/1 unit 0 family ethernet-switching port-mode trunk
set interfaces ge-0/0/11 unit 0 family ethernet-switching port-mode trunk
set vlans employee-vlan vlan-id 20
```

Step-by-Step Procedure

To configure the VLAN and interfaces on Switch 2:

1. Configure an interface on Switch 2 as a trunk interface:

   ```
   [edit interfaces]
   ```

```
user@switch2# set ge-0/0/11 unit 0 ethernet-switching port-mode trunk
```

2. Associate the VLAN with interfaces **ge-0/0/1** and **ge-0/0/11**:

```
[edit interfaces]
user@switch2# set ge-0/0/1 unit 0 family ethernet-switching vlan members 20
user@switch2# set ge-0/0/11 unit 0 family ethernet-switching vlan members 20
```

Results Display the results of the configuration:

```
[edit]
user@switch2# show
interfaces {
  ge-0/0/1 {
    unit 0 {
      family ethernet-switching {
        vlan {
          members 20;
        }
      }
    }
  }
  ge-0/0/11 {
    unit 0 {
      family ethernet-switching {
        port-mode trunk;
        vlan {
          members 20;
        }
      }
    }
  }
}
vlans {
  employee-vlan {
    vlan-id 20;
  }
}
```

Verification

To confirm that the configuration is working properly.

- Verifying That DHCP Snooping Is Working Correctly on Switch 1 on page 4511
- Verifying That DAI Is Working Correctly on Switch 1 on page 4512
- Verifying That MAC Limiting Is Working Correctly on Switch 1 on page 4512

Verifying That DHCP Snooping Is Working Correctly on Switch 1

Purpose Verify that DHCP snooping is working on Switch 1.

Action Send some DHCP requests from network devices (here they are DHCP clients) connected to the switch.

Display the DHCP snooping information when the interface through which Switch 2 sends the DHCP server replies to clients connected to Switch 1 is trusted. The server has provided the IP addresses and leases:

```
user@switch1> show dhcp snooping binding
DHCP Snooping Information:
MAC Address        IP Address    Lease    Type     VLAN          Interface
-----------------  ----------    -----    ----     ----          ---------
00:05:85:3A:82:77   192.0.2.17    600    dynamic  employee—vlan   ge-0/0/1.0
00:05:85:3A:82:79   192.0.2.18    653    dynamic  employee—vlan   ge-0/0/1.0
00:05:85:3A:82:80   192.0.2.19    720    dynamic  employee—vlan   ge-0/0/1.0
00:05:85:3A:82:81   192.0.2.20    932    dynamic  employee—vlan   ge-0/0/1.0
00:05:85:3A:82:83   192.0.2.21   1230    dynamic  employee—vlan   ge-0/0/1.0
00:05:85:3A:82:90   192.0.2.20    932    dynamic  employee—vlan   ge-0/0/2.0
00:05:85:3A:82:91   192.0.2.21   1230    dynamic  employee—vlan   ge-0/0/3.0
```

Meaning The output shows, for each MAC address, the assigned IP address and lease time—that is, the time, in seconds, remaining before the lease expires.

Verifying That DAI Is Working Correctly on Switch 1

Purpose Verify that DAI is working on Switch 1.

Action Send some ARP requests from network devices connected to the switch.

Display the DAI information:

```
user@switch1> show arp inspection statistics
ARP inspection statistics:
Interface    Packets received  ARP inspection pass  ARP inspection failed
----------   ---------------–  -------------------  ---------------------
ge-0/0/1.0                  7                    5                      2
ge-0/0/2.0                 10                   10                      0
ge-0/0/3.0                 18                   15                      3
```

Meaning The sample output shows the number of ARP packets received and inspected per interface, with a listing of how many packets passed and how many failed the inspection on each interface. The switch compares the ARP requests and replies against the entries in the DHCP snooping database. If a MAC address or IP address in the ARP packet does not match a valid entry in the database, the packet is dropped.

Verifying That MAC Limiting Is Working Correctly on Switch 1

Purpose Verify that MAC limiting is working on Switch 1.

Action Display the MAC addresses that are learned when DHCP requests are sent from hosts on **ge-0/0/1**:

```
user@switch1> show ethernet-switching table

Ethernet-switching table:  6 entries, 5 learned
  VLAN              MAC address       Type         Age    Interfaces

  employee-vlan     00:05:85:3A:82:77   Learn          0    ge-0/0/1.0
  employee-vlan     00:05:85:3A:82:79   Learn          0    ge-0/0/1.0
  employee-vlan     00:05:85:3A:82:80   Learn          0    ge-0/0/1.0
  employee-vlan     00:05:85:3A:82:81   Learn          0    ge-0/0/1.0
  employee-vlan     00:05:85:3A:82:83   Learn          0    ge-0/0/1.0
  employee-vlan     *                   Flood          -    ge-0/0/1.0
```

Meaning The sample output shows that five MAC addresses have been learned for interface **ge-0/0/1**, which corresponds to the MAC limit of **5** set in the configuration. The last line of the output shows that a sixth MAC address request was dropped, as indicated by the asterisk (*) in the **MAC address** column.

Example: Configuring DHCP Snooping and DAI to Protect the Switch from ARP Spoofing Attacks

In an ARP spoofing attack, the attacker associates its own MAC address with the IP address of a network device connected to the switch. Traffic intended for that IP address is now sent to the attacker instead of being sent to the intended destination. The attacker can send faked, or "spoofed," ARP messages on the LAN.

NOTE: When dynamic ARP inspection (DAI) is enabled, the switch logs the number of invalid ARP packets that it receives on each interface, along with the sender's IP and MAC addresses. You can use these log messages to discover ARP spoofing on the network. ARP probe packets are not subjected to dynamic ARP inspection. The switch always forwards such packets.

This example describes how to configure DHCP snooping and dynamic ARP inspection (DAI), two port security features, to protect the switch against ARP spoofing attacks:

- Requirements on page 4514
- Overview and Topology on page 4514
- Configuration on page 4515
- Verification on page 4516

Requirements

This example uses the following hardware and software components:

- One EX Series switch or one QFX3500 switch
- Junos OS Release 11.4 or later for EX Series switches or Junos OS Release 12.1 or later for the QFX Series
- A DHCP server to provide IP addresses to network devices on the switch

Before you configure DHCP snooping and DAI (two port security features) to mitigate ARP spoofing attacks, be sure you have:

- Connected the DHCP server to the switch.
- Configured a VLAN on the switch. See the task for your platform:
  - *Example: Setting Up Bridging with Multiple VLANs for EX Series Switches*
  - "Example: Setting Up Bridging with Multiple VLANs" on page 1451 for the QFX Series

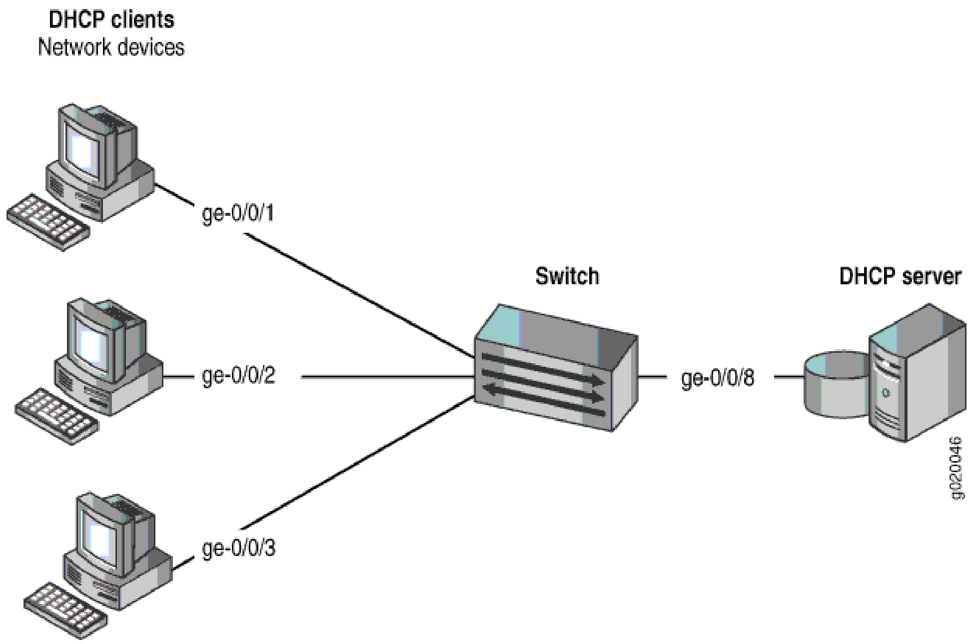
Overview and Topology

Ethernet LANs are vulnerable to address spoofing and DoS attacks on network devices. This example describes how to protect the switch against one common type of attack, an ARP spoofing attack.

In an ARP spoofing attack, the attacker sends faked ARP messages, thus creating various types of problems on the LAN—for example, the attacker might launch a man-in-the middle attack.

This example shows how to configure port security features on a switch that is connected to a DHCP server. The setup for this example includes the VLAN **employee-vlan** on the switch. The procedure for creating that VLAN is described in the topic *Example: Setting Up Bridging with Multiple VLANs for EX Series Switches* and "Example: Setting Up Bridging with Multiple VLANs" on page 1451 for the QFX Series. That procedure is not repeated here. Figure 166 on page 4515 illustrates the topology for this example.

Figure 166: Network Topology for Basic Port Security



The components of the topology for this example are shown in Table 357 on page 4515.

Table 357: Components of the Port Security Topology

Properties	Settings
Switch hardware	One EX3200-24P, 24 ports (8 PoE ports) or one QFX3500 switch
VLAN name and ID	**employee-vlan**, tag **20**
VLAN subnets	**192.0.2.16/28** **192.0.2.17** through **192.0.2.30** **192.0.2.31** is the subnet's broadcast address
Interfaces in **employee-vlan**	**ge-0/0/1**,**ge-0/0/2**, **ge-0/0/3**, **ge-0/0/8**
Interface for DHCP server	**ge-0/0/8**

In this example, the switch has already been configured as follows:

- Secure port access is activated on the switch.
- DHCP snooping is disabled on the VLAN **employee-vlan**.
- All access ports are untrusted, which is the default setting.

Configuration

To configure DHCP snooping and dynamic ARP inspection (DAI) to protect the switch against ARP attacks:

CLI Quick Configuration

To quickly configure DHCP snooping and dynamic ARP inspection (DAI), copy the following commands and paste them into the switch terminal window:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface ge-0/0/8 dhcp-trusted
user@switch# set vlan employee-vlan examine-dhcp
user@switch# set vlan employee-vlan arp-inspection
```

Step-by-Step Procedure

Configure DHCP snooping and dynamic ARP inspection (DAI) on the VLAN:

1. Set the **ge-0/0/8** interface as trusted:

   ```
   [edit ethernet-switching-options secure-access-port]
   user@switch# set interface ge-0/0/8 dhcp-trusted
   ```
2. Enable DHCP snooping on the VLAN:

   ```
   [edit ethernet-switching-options secure-access-port]
   user@switch# set vlan employee-vlan examine-dhcp
   ```
3. Enable DAI on the VLAN:

   ```
   [edit ethernet-switching-options secure-access-port]
   user@switch# set vlan employee-vlan arp-inspection
   ```

Results

Check the results of the configuration:

```
[edit ethernet-switching-options secure-access-port]
user@switch# show
interface ge-0/0/8.0 {
  dhcp-trusted;
}
vlan employee-vlan {
  arp-inspection;
  examine-dhcp;
}
```

Verification

Confirm that the configuration is working properly.

- Verifying That DHCP Snooping Is Working Correctly on the Switch on page 4516
- Verifying That DAI Is Working Correctly on the Switch on page 4517

Verifying That DHCP Snooping Is Working Correctly on the Switch

Purpose

Verify that DHCP snooping is working on the switch.

Action Send some DHCP requests from network devices (here they are DHCP clients) connected to the switch.

Display the DHCP snooping information when the port on which the DHCP server connects to the switch is trusted. The following output results when requests are sent from the MAC addresses and the server has provided the IP addresses and leases:

```
user@switch> show dhcp-snooping binding
DHCP Snooping Information:
MAC Address        IP Address    Lease    Type     VLAN            Interface
-----------------  ----------    -----    ----     ----            ---------
00:05:85:3A:82:77   192.0.2.17    600    dynamic  employee-vlan   ge-0/0/1.0
00:05:85:3A:82:79   192.0.2.18    653    dynamic  employee-vlan   ge-0/0/1.0
00:05:85:3A:82:80   192.0.2.19    720    dynamic  employee-vlan   ge-0/0/2.0
00:05:85:3A:82:81   192.0.2.20    932    dynamic  employee-vlan   ge-0/0/2.0
00:05:85:3A:82:83   192.0.2.21   1230    dynamic  employee-vlan   ge-0/0/2.0
00:05:85:27:32:88   192.0.2.22   3200    dynamic  employee-vlan   ge-0/0/3.0
```

Meaning When the interface on which the DHCP server connects to the switch has been set to trusted, the output (see preceding sample) shows, for each MAC address, the assigned IP address and lease time—that is, the time, in seconds, remaining before the lease expires.

Verifying That DAI Is Working Correctly on the Switch

Purpose Verify that DAI is working on the switch.

Action Send some ARP requests from network devices connected to the switch.

Display the DAI information:

```
user@switch> show arp inspection statistics
ARP inspection statistics:
Interface        Packets received  ARP inspection pass   ARP inspection failed
---------------  ---------------   --------------------  ---------------------
ge-0/0/1.0                      7                     5                      2
ge-0/0/2.0                     10                    10                      0
ge-0/0/3.0                     12                    12                      0
```

Meaning The sample output shows the number of ARP packets received and inspected per interface, with a listing of how many packets passed and how many failed the inspection on each interface. The switch compares the ARP requests and replies against the entries in the DHCP snooping database. If a MAC address or IP address in the ARP packet does not match a valid entry in the database, the packet is dropped.

Example: Configuring Allowed MAC Addresses to Protect the Switch from DHCP Snooping Database Alteration Attacks

In one type of attack on the DHCP snooping database, an intruder introduces a DHCP client on an untrusted access interface with a MAC address identical to that of a client on another untrusted interface. The intruder then acquires the DHCP lease of that other client, thus changing the entries in the DHCP snooping table. Subsequently, what would have been valid ARP requests from the legitimate client are blocked.

This example describes how to configure allowed MAC addresses, a port security feature, to protect the switch from DHCP snooping database alteration attacks:

Requirements

This example uses the following hardware and software components:

- One EX Series switch or one QFX3500 switch
- Junos OS Release 11.4 or later for EX Series switches or Junos OS Release 12.1 or later for the QFX Series
- A DHCP server to provide IP addresses to network devices on the switch

Before you configure specific port security features to mitigate common access-inteface attacks, be sure you have:

- Connected the DHCP server to the switch.
- Configured a VLAN on the switch. See the task for your platform:
  - *Example: Setting Up Bridging with Multiple VLANs for EX Series Switches*
  - "Example: Setting Up Bridging with Multiple VLANs" on page 1451 for the QFX Series

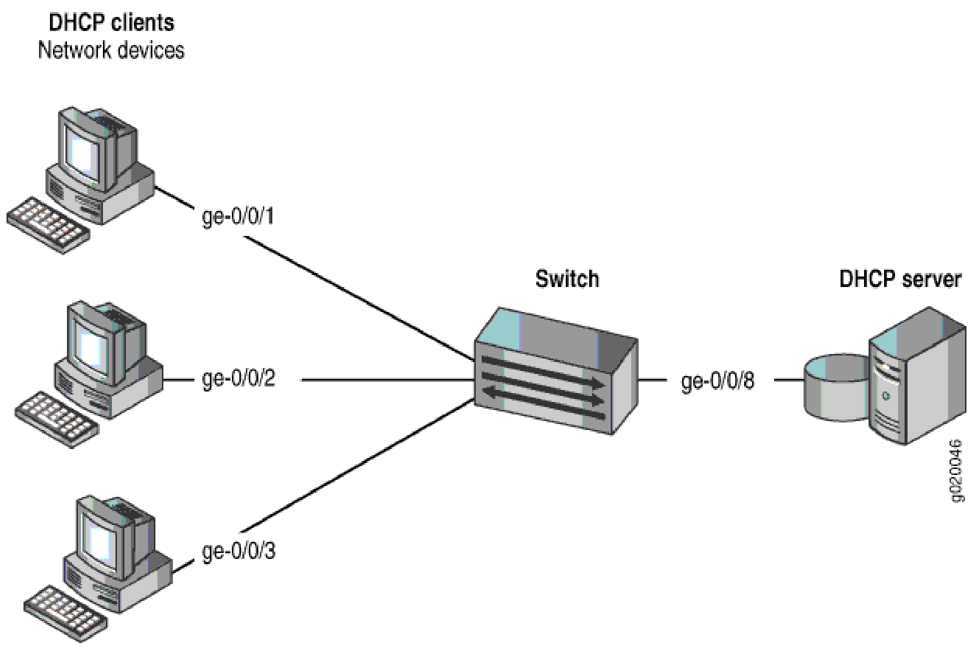
Overview and Topology

Ethernet LANs are vulnerable to address spoofing and DoS attacks on network devices. This example describes how to protect the switch from an attack on the DHCP snooping database that alters the MAC addresses assigned to some clients.

This example shows how to configure port security features on a switch that is connected to a DHCP server.

The setup for this example includes the VLAN **employee-vlan** on the switch. Figure 167 on page 4519 illustrates the topology for this example.

Figure 167: Network Topology for Basic Port Security



The components of the topology for this example are shown in Table 358 on page 4519.

Table 358: Components of the Port Security Topology

Properties	Settings
Switch hardware	One EX3200-24P, 24 ports (8 PoE ports) or one QFX3500 switch
VLAN name and ID	**employee-vlan**, tag **20**
VLAN subnets	**192.0.2.16/28** **192.0.2.17** through **192.0.2.30** **192.0.2.31** is the subnet's broadcast address
Interfaces in **employee-vlan**	**ge-0/0/1**, **ge-0/0/2**, **ge-0/0/3**, **ge-0/0/8**
Interface for DHCP server	**ge-0/0/8**

In this example, the switch has already been configured as follows:

- Secure port access is activated on the switch.
- DHCP snooping is enabled on the VLAN **employee-vlan**.
- All access ports are untrusted, which is the default setting.

Configuration

To configure allowed MAC addresses to protect the switch against DHCP snooping database alteration attacks:

CLI Quick Configuration

To quickly configure some allowed MAC addresses on an interface, copy the following commands and paste them into the switch terminal window:

```
[edit ethernet-switching-options secure-access-port]
set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:80
set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:81
set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:83
set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:85
set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:88
```

Step-by-Step Procedure

To configure some allowed MAC addresses on an interface:

Configure the five allowed MAC addresses on an interface:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:80
user@switch# set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:81
user@switch# set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:83
user@switch# set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:85
user@switch# set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:88
```

Results

Check the results of the configuration:

```
[edit ethernet-switching-options secure-access-port]
user@switch# show
interface ge-0/0/2.0 {
  allowed-mac [ 00:05:85:3a:82:80 00:05:85:3a:82:81 00:05:85:3a:82:83 00:05:85
  :3a:82:85 00:05:85:3a:82:88 ];
}
```

Verification

Confirm that the configuration is working properly.

- Verifying That Allowed MAC Addresses Are Working Correctly on the Switch on page 4520

Verifying That Allowed MAC Addresses Are Working Correctly on the Switch

Purpose

Verify that allowed MAC addresses are working on the switch.

Action Display the MAC cache information:

```
user@switch> show ethernet-switching table
Ethernet-switching table:  6 entries, 5 learned
  VLAN                 MAC address        Type         Age    Interfaces

  employee-vlan        00:05:85:3A:82:80  Learn          0    ge-0/0/2.0
  employee-vlan        00:05:85:3A:82:81  Learn          0    ge-0/0/2.0
  employee-vlan        00:05:85:3A:82:83  Learn          0    ge-0/0/2.0
  employee-vlan        00:05:85:3A:82:85  Learn          0    ge-0/0/2.0
  employee-vlan        00:05:85:3A:82:88  Learn          0    ge-0/0/2.0
  employee-vlan        *                  Flood          -    ge-0/0/2.0
```

Meaning The output shows that the five MAC addresses configured as allowed MAC addresses have been learned and are displayed in the MAC cache. The last MAC address in the list, one that had not been configured as allowed, has not been added to the list of learned addresses.

Example: Setting Up DHCP Option 82 with a Switch with No Relay Agent Between Clients and a DHCP Server

You can use DHCP option 82, also known as the DHCP relay agent information option, to help protect the switch against attacks such as spoofing (forging) of IP addresses and MAC addresses, and DHCP IP address starvation. Option 82 provides information about the network location of a DHCP client, and the DHCP server uses this information to implement IP addresses or other parameters for the client.

This example describes how to configure DHCP option 82 on a switch with DHCP clients, DHCP server, and switch all on the same VLAN:

- Requirements on page 4521
- Overview and Topology on page 4522
- Configuration on page 4523

Requirements

This example uses the following hardware and software components:

- One EX Series switch or one QFX3500 switch

- Junos OS Release 9.3 or later for EX Series switches or Junos OS Release 12.1 or later for the QFX Series
- A DHCP server to provide IP addresses to network devices on the switch

Before you configure DHCP option 82 on the switch, be sure you have:

- Connected and configured the DHCP server.

NOTE: **Your DHCP server must be configured to accept DHCP option 82. If it is not configured for DHCP option 82, it does not use the DHCP option 82 information in the requests sent to it when it formulates its reply messages.**

- Configured the **employee** VLAN on the switch and associated the interfaces on which the clients and the server connect to the switch with that VLAN. See the task for your platform:
  - *Configuring VLANs for EX Series Switches (CLI Procedure)*
  - “Configuring VLANs” on page 1534 for the QFX Series

Overview and Topology

If DHCP option 82 is enabled on the switch, then when a network device—a DHCP client—that is connected to the switch on an untrusted interface sends a DHCP request, the switch inserts information about the client's network location into the packet header of that request. The switch then sends the request to the DHCP server. The DHCP server reads the option 82 information in the packet header and uses it to implement the IP address or other parameter for the client.

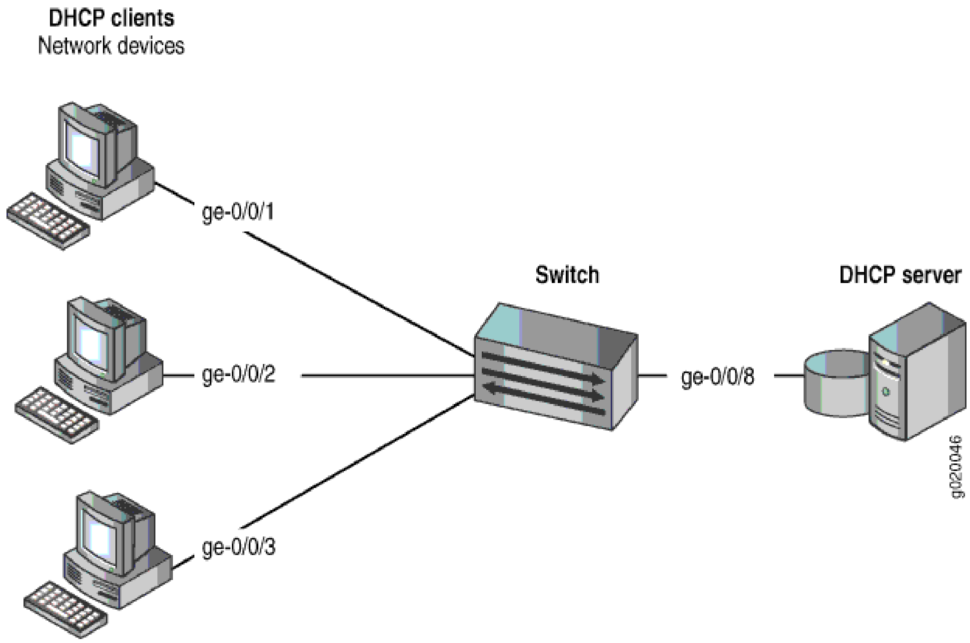
DHCP option 82 is enabled on an individual VLAN or on all VLANs on the switch.

When option 82 is enabled on the switch, then this sequence of events occurs when a DHCP client sends a DHCP request:

1. The switch receives the request and inserts the option 82 information in the packet header.
2. The switch forwards the request to the DHCP server.
3. The server uses the DHCP option 82 information to formulate its reply and sends a response back to the switch. It does not alter the option 82 information.
4. The switch strips the option 82 information from the response packet.
5. The switch forwards the response packet to the client.

Figure 168 on page 4523 illustrates the topology for this example.

Figure 168: Network Topology for Configuring DHCP Option 82 on a Switch That Is on the Same VLAN as the DHCP Clients and the DHCP Server



In this example, you configure DHCP option 82 on the switch. The switch connects to the DHCP server on interface **ge-0/0/8**. The DHCP clients connect to the switch on interfaces **ge-0/0/1**, **ge-0/0/2**, and **ge-0/0/3**. The switch, server, and clients are all members of the **employee** VLAN.

Configuration

CLI Quick Configuration

To quickly configure DHCP option 82, copy the following commands and paste them into the switch terminal window:

set ethernet-switching-options secure-access-port vlan employee dhcp-option82
set ethernet-switching-options secure-access-port vlan employee dhcp-option82 circuit-id prefix hostname
set ethernet-switching-options secure-access-port vlan employee dhcp-option82 circuit-id use-vlan-id
set ethernet-switching-options secure-access-port vlan employee dhcp-option82 remote-id
set ethernet-switching-options secure-access-port vlan employee dhcp-option82 remote-id prefix mac
set ethernet-switching-options secure-access-port vlan employee dhcp-option82 remote-id use-string employee-switch1
set ethernet-switching-options secure-access-port vlan employee dhcp-option82 vendor-id

Step-by-Step Procedure

To configure DHCP option 82:

1. Specify DHCP option 82 for the **employee** VLAN:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee dhcp-option82
```

2. Configure a prefix for the circuit ID suboption (the prefix is always the hostname of the switch):

```
[edit ethernet-switching-options secure-access-port]
```

```
user@switch# set vlan employee dhcp-option82 circuit-id prefix hostname
```

3. Specify that the circuit ID suboption value contains the VLAN ID rather than the VLAN name (the default):

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee dhcp-option82 circuit-id use-vlan-id
```

4. Specify that the remote ID suboption be included in the DHCP option 82 information:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee dhcp-option82 remote-id
```

5. Configure a prefix for the remote ID suboption (here, the prefix is the MAC address of the switch):

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee dhcp-option82 remote-id prefix mac
```

6. Specify that the remote ID suboption value contain a character string (here, the string is **employee-switch1**):

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee dhcp-option82 remote-id use-string employee-switch1
```

7. Configure a vendor ID suboption value, and use the default value. To use the default value, do not type a character string after the **vendor-id** option keyword:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee dhcp-option82 vendor-id
```

Results Check the results of the configuration:

```
[edit ethernet-switching-options secure-access-port]
user@switch# show
vlan employee {
  dhcp-option82 {
    circuit-id {
      prefix hostname;
      use-vlan-id;
    }
    remote-id {
      prefix mac;
      use-string employee-switch1;
    }
    vendor-id;
  }
}
```

Related Documentation

- Example: Setting Up DHCP Option 82 with a Switch as a Relay Agent Between Clients and a DHCP Server on page 4525
- Setting Up DHCP Option 82 on the Switch with No Relay Agent Between Clients and DHCP Server (CLI Procedure) on page 4557

- RFC 3046, *DHCP Relay Agent Information Option*, at http://tools.ietf.org/html/rfc3046.
- *secure-access-port*
- **secure-access-port on page 4622**

Example: Setting Up DHCP Option 82 with a Switch as a Relay Agent Between Clients and a DHCP Server

You can use DHCP option 82, also known as the DHCP relay agent information option, to help protect the switch against attacks such as spoofing (forging) of IP addresses and MAC addresses, and DHCP IP address starvation. Option 82 provides information about the network location of a DHCP client, and the DHCP server uses this information to implement IP addresses or other parameters for the client.

This example describes how to configure DHCP option 82 on a switch that is on the same VLAN with the DHCP clients but on a different VLAN from the DHCP server. in this example, the switch acts as a relay agent:

Requirements

This example uses the following hardware and software components:

- One EX4200-24P switch or one QFX3500 switch
- Junos OS Release 9.3 or later for EX Series switches or Junos OS Release 12.1 or later for the QFX Series
- A DHCP server to provide IP addresses to network devices on the switch

Before you configure DHCP option 82 on the switch, be sure you have:

- Connected and configured the DHCP server.

NOTE: Your DHCP server must be configured to accept DHCP option 82. If it is not configured for DHCP option 82, it does not use the DHCP option 82 information in the requests sent to it when it formulates its reply messages.

- Configured the **employee** VLAN on the switch and associated the interfaces on which the clients connect to the switch with that VLAN. See the task for your platform:
  - *Configuring VLANs for EX Series Switches (CLI Procedure)*
  - “Configuring VLANs” on page 1534 for the QFX Series
- Configured the **corporate** VLAN for the DHCP server.
- Configured the switch as a BOOTP relay agent. See *DHCP/BOOTP Relay for Switches Overview*.
- Configured the routed VLAN interface (RVI) to allow the switch to relay packets to the server and receive packets from the server. See *Configuring Routed VLAN Interfaces (CLI Procedure)* or “Configuring Routed VLAN Interfaces” on page 1532 for the QFX Series.

Overview and Topology

If DHCP option 82 is enabled on the switch, then when a network device—a DHCP client—that is connected to the switch on an untrusted interface sends a DHCP request, the switch inserts information about the client's network location into the packet header of that request. The switch then sends the request (in this setting, it relays the request) to the DHCP server. The DHCP server reads the option 82 information in the packet header and uses it to implement the IP address or other parameter for the client.

When option 82 is enabled on the switch, then this sequence of events occurs when a DHCP client sends a DHCP request:

1. The switch receives the request and inserts the option 82 information in the packet header.
2. The switch relays the request to the DHCP server.
3. The server uses the DHCP option 82 information to formulate its reply and sends a response back to the switch. It does not alter the option 82 information.
4. The switch strips the option 82 information from the response packet.
5. The switch forwards the response packet to the client.

In this example, you configure option 82 on the switch. The switch is configured as a BOOTP relay agent. The switch connects to the DHCP server through the routed VLAN interface (RVI) that you configured. The switch and clients are members of the **employee** VLAN. The DHCP server is a member of the **corporate** VLAN.

Configuration

To configure DHCP option 82:

CLI Quick Configuration

To quickly configure DHCP option 82, copy the following commands and paste them into the switch terminal window:

```
set forwarding-options helpers bootp dhcp-option82
set forwarding-options helpers bootp dhcp-option82 circuit-id prefix hostname
set forwarding-options helpers bootp dhcp-option82 circuit-id use-vlan-id
set forwarding-options helpers bootp dhcp-option82 remote-id
set forwarding-options helpers bootp dhcp-option82 remote-id prefix mac
set forwarding-options helpers bootp dhcp-option82 remote-id use-string employee-switch1
set forwarding-options helpers bootp dhcp-option82 vendor-id
```

Step-by-Step Procedure

To configure DHCP option 82:

1. Specify DHCP option 82 for the **employee** VLAN:

   ```
   [edit forwarding-options helpers bootp]
   user@switch# set dhcp-option82
   ```
2. Configure a prefix for the circuit ID suboption (the prefix is always the hostname of the switch):

   ```
   [edit forwarding-options helpers bootp]
   user@switch# set dhcp-option82 circuit-id prefix hostname
   ```
3. Specify that the circuit ID suboption value contains the VLAN ID rather than the VLAN name (the default):

```
[edit forwarding-options helpers bootp]
user@switch# set dhcp-option82 circuit-id use-vlan-id
```

4. Specify that the remote ID suboption be included in the DHCP option 82 information:

```
[edit forwarding-options helpers bootp]
user@switch# set dhcp-option82 remote-id
```

5. Configure a prefix for the remote ID suboption (here, the prefix is the MAC address of the switch):

```
[edit forwarding-options helpers bootp]
user@switch# set dhcp-option82 remote-id prefix mac
```

6. Specify that the remote ID suboption value contains a character string (here, the string is **employee-switch1**):

```
[edit forwarding-options helpers bootp]
user@switch# set dhcp-option82 remote-id use-string employee-switch1
```

7. Configure a vendor ID suboption value, and use the default value. To use the default value, do not type a character string after the **vendor-id** option keyword:

```
[edit forwarding-options helpers bootp]
user@switch# set dhcp-option82 vendor-id
```

Results Check the results of the configuration:

```
[edit forwarding-options helpers bootp]
user@switch# show
dhcp-option82 {
  circuit-id {
    prefix hostname;
    use-vlan-id;
  }
  remote-id {
    prefix mac;
    use-string employee-switch1;
  }
  vendor-id;
}
```

Device Security Configuration Example (Original CLI Only)

Example: Configuring Storm Control to Prevent Network Outages

Using storm control can prevent problems caused by broadcast storms. You can configure storm control to rate-limit broadcast traffic and unknown unicast traffic at a specified level and to drop packets when the specified traffic level is exceeded, which prevents packets from proliferating and degrading service or causing a security issue. You can also configure the switch to shut down or temporarily disable an interface when the storm control limit is exceeded.

This example shows how to configure storm control:

NOTE: **This example uses a Junos OS release that does not supports the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that supports ELS, see** “Example: Configuring Storm Control to Prevent Network Outages” on page 4529.

Requirements

This example uses the following hardware and software components:

- A switch
- Junos OS Release 11.1 or later

Overview and Topology

A traffic storm occurs when broadcast packets prompt receiving devices to broadcast packets in response. This prompts further responses, creating a snowball effect. The switch is flooded with packets, and the resulting unnecessary traffic leads to poor performance or even a complete loss of service by some clients. Storm control causes a device to monitor traffic levels and take a specified action when a specified traffic level—called the *storm control level*—is exceeded, thus preventing packets from proliferating and degrading service.

Storm control monitors the incoming broadcast traffic and unknown unicast traffic and compares it with the level that you specify. If broadcast traffic and unknown unicast traffic exceed the specified level, the switch drops packets for the controlled traffic types. Storm control is enabled by default on all interfaces, and the default level is 80 percent of the available bandwidth.

This example shows how to configure the storm control level on interface **xe-0/0/0** by setting the level to a traffic rate of 5000000 Kbps, based on the total of the combined broadcast and unknown unicast streams. If broadcast traffic and unknown unicast traffic exceed these levels, the switch drops packets for the controlled traffic types.

Configuration

Step-by-Step Procedure

To configure storm control for a 10-Gigabit Ethernet interface to the equivalent of 50 percent of the available bandwidth:

- Specify the level of allowed broadcast traffic and unknown unicast traffic on a specific interface:

```
[edit ethernet-switching-options]
user@switch# set storm-control interface xe-0/0/0 bandwidth 5000000
```

Results

Display the results of the configuration:

```
[edit ethernet-switching-options]
user@switch# show storm-control
interface xe-0/0/0 {
  bandwidth 5000000;
}
```

Device Security Configuration Example (ELS CLI Only)

Example: Configuring Storm Control to Prevent Network Outages

Storm control enables you to prevent network outages caused by broadcast storms on the LAN. You can configure storm control on to rate-limit broadcast traffic, multicast traffic, and unknown unicast traffic at a specified level and to have packets dropped when the specified traffic level is exceeded, thereby preventing packets from proliferating and degrading the LAN.

NOTE: This example uses a Junos OS release that supports the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that does not support ELS, see "Example: Configuring Storm Control to Prevent Network Outages" on page 4527. .

Requirements

This example uses the following hardware and software components:

- One QFX Series switch running Junos OS with ELS
- Junos OS Release 13.2 or later

Overview and Topology

A storm is generated when messages are broadcast on a network and each message prompts a receiving node to respond by broadcasting its own messages on the network. This, in turn, prompts further responses, creating a snowball effect and resulting in a broadcast storm that can cause network outages.

You can use storm control to prevent broadcast storms by specifying the amount, also known as the *storm control level*, of broadcast traffic, multicast traffic, and unknown unicast traffic to be allowed on an interface. You specify the storm control level as the traffic rate in kilobits per second (Kbps) of the combined applicable traffic streams or as the percentage of available bandwidth used by the combined applicable traffic streams. By default, storm control is enabled on all interfaces at a level of 80 percent of the available bandwidth.

Storm control monitors the level of applicable incoming traffic and compares it with the level that you specify. If the combined level of the applicable traffic exceeds the specified level, the switch drops packets for the controlled traffic types. As an alternative to having the switch drop packets, you can configure storm control to shut down interfaces or temporarily disable interfaces (see the **action-shutdown** statement or the recovery-timeout statement) when the storm control level is exceeded.

The topology used in this example consists of one switch connected to various network devices. This example shows how to configure the storm control level on interface xe-0/0/0 by setting the level to a traffic rate of 15,000 Kbps, based on the traffic rate of the combined applicable traffic streams. If the combined traffic exceeds this level, the switch drops packets for the controlled traffic types to prevent a network outage.

Configuration

CLI Quick Configuration

To quickly configure storm control based on the traffic rate in kilobits per second of the combined traffic streams, copy the following command and paste it into the switch terminal window:

```
[edit]
set forwarding-options storm-control-profiles sc-profile all bandwidth-level 15000
set interfaces xe-0/0/0 unit 0 family ethernet-switching storm-control sc-profile
```

Step-by-Step Procedure

To configure storm control:

1. Configure a storm control profile, **sc-profile**, and specify the traffic rate in kilobits per second of the combined traffic streams:

   ```
   [edit]
   user@switch> set forwarding-options storm-control-profiles sc-profile all bandwidth-level 15000
   ```

2. Bind the storm control profile, **sc**, to a logical interface:

```
[edit]
user@switch> set interfaces xe-0/0/0 unit 0 family ethernet-switching storm-control
sc-profile
```

Results Display the results of the configuration:

```
[edit forwarding-options]
user@switch> show storm-control-profiles sc-profile
all {
  bandwidth 15000;
}
```

```
[edit]
user@switch> show interfaces xe-0/0/0
unit 0 {
  family ethernet-switching {
    vlan {
      members default;
    }
    storm-control sc-profile;
  }
}
```

Firewall and Policer Configuration Tasks

Configuring Firewall Filters

You can configure firewall filters in a switch to control traffic that enters switch ports or enters and exits VLANs and Layer 3 (routed) interfaces. To use a firewall filter, you must configure the filter and then apply it to a port, VLAN, or Layer 3 interface.

Configuring a Firewall Filter

To configure a firewall filter:

1. Configure the family address type, filter name, term name, and at least one match condition—for example, match on packets that contain a specific source address:

   ```
   [edit]
   user@switch# set firewall family ethernet-switching filter ingress-port-filter term term-one from source-address 192.0.2.14
   ```

   For a firewall filter that is applied to a port or VLAN, specify the family address type **ethernet-switching**. For a firewall filter that is applied to a Layer 3 (routed) interface, specify the family address type **inet**.

   The filter and term names can contain letters, numbers, and hyphens (-) and can be up to 64 characters long. Each filter name must be unique. A filter can contain one or more terms, and each term name must be unique within a filter.

2. Configure additional match conditions. For example, match on packets that contain a specific source port:

   ```
   [edit firewall family ethernet-switching filter ingress-port-filter term term-one from]
   user@switch# set source-port 80
   ```

   You can specify one or more match conditions in a single **from** statement. For a match to occur, the packet must match all the conditions in the term. The **from** statement is optional, but if included in a term, it cannot be empty. If you omit the **from** statement, all packets are considered to match.

3. If you want to apply a firewall filter to multiple interfaces and be able to see counters specific to each interface, configure the **interface-specific** option:

   ```
   [edit firewall family ethernet-switching filter ingress-port-filter]
   user@switch# set interface-specific
   ```

4. In each firewall filter term, specify the actions to take if the packet matches all the conditions in that term. You can specify an action and action modifiers:

   - To specify a filter action, for example, to discard packets that match the conditions of the filter term:

     ```
     [edit firewall family ethernet-switching filter ingress-port-filter term term-one then]
     user@switch# set discard
     ```

     You can specify no more than one action (**accept**, **discard**, **reject**, **routing-instance**, or **vlan**) per term.

   - To specify action modifiers, for example, to count and classify packets to a forwarding class:

     ```
     [edit firewall family ethernet-switching filter ingress-port-filter term term-one then]
     user@switch# set count counter-one
     user@switch# set forwarding-class expedited-forwarding
     user@switch# set loss-priority high
     ```

You can specify any of the following action modifiers in a **then** statement:

- **analyzer** ***analyzer-name***—Mirror port traffic to a specified analyzer, which you must configure at the **[ethernet-switching-options]** level.
- **count** ***counter-name***—Count the number of packets that pass this filter term.

NOTE: We recommend that you configure a counter for each term in a firewall filter, so that you can monitor the number of packets that match the conditions specified in each filter term.

NOTE: On the QFX Series, filters automatically count packets that have been dropped on ingress because of cyclic redundancy check (CRC) errors.

- **forwarding-class** ***class***—Assign packets to a forwarding class.
- **log**—Log the packet header information in the Routing Engine.
- **loss-priority** ***priority***—Set the priority of dropping a packet.
- **policer** ***policer-name***—Apply rate-limiting to the traffic.
- **syslog**—Log an alert for this packet.

If you omit the **then** statement or do not specify an action, packets that match all the conditions in the **from** statement are accepted. However, you should always explicitly configure an action in the **then** statement. You can include no more than one action statement, but you can use any combination of action modifiers. For an action or action modifier to take effect, all conditions in the **from** statement must match.

NOTE: Implicit discard is also applicable to a firewall filter applied to the loopback interface, lo0.

Applying a Firewall Filter to a Port

To apply a firewall filter to an ingress port:

1. Provide a meaningful description of the firewall filter in the configuration of the port to which the filter will be applied:

```
[edit]
user@switch# set interfaces ge-0/0/6 description "filter to limit tcp traffic at trunk port for employee-vlan"
```

2. Apply the filter to the interface, specifying the unit number, family address type, the direction of the filter (for packets entering the port), and the filter name:

```
[edit]
user@switch# set ge-0/0/6 unit 0 family ethernet-switching filter input ingress-port-filter
```

For firewall filters that are applied to ports, the family address type must be **ethernet-switching**.

NOTE: You can apply only one filter to a port for a given direction (ingress or egress).

Applying a Firewall Filter to a VLAN

To apply a firewall filter to a VLAN:

1. Provide a meaningful description of the firewall filter in the configuration of the VLAN to which the filter will be applied:

   ```
   [edit]
   user@switch# set vlans employee-vlan vlan-id 20 description "filter to block rogue devices on employee-vlan"
   ```
2. Apply firewall filters to filter packets that are entering or exiting the VLAN:

   - To apply a filter to match packets that are entering the VLAN:

     ```
     [edit]
     user@switch# set vlans employee-vlan vlan-id 20 filter input ingress-vlan-rogue-block
     ```
   - To apply a firewall filter to match packets that are exiting the VLAN:

     ```
     [edit]
     user@switch# set vlans employee-vlan vlan-id 20 filter output egress-vlan-filter
     ```

NOTE: You can apply only one filter to a VLAN for a given direction (ingress or egress).

Applying a Firewall Filter to a Layer 3 (Routed) Interface

To apply a firewall filter to a Layer 3 routed interface:

1. Provide a meaningful description of the firewall filter in the configuration of the interface to which the filter will be applied:

   ```
   [edit]
   user@switch# set interfaces ge-0/1/6 description "filter to count and monitor traffic on layer 3 interface"
   ```
2. You can apply firewall filters to filter packets that enter or exit a Layer 3 routed interface:

   - To apply a firewall filter to filter packets that enter a Layer 3 interface:

     ```
     [edit]
     user@switch# set interfaces ge-0/1/6 unit 0 family inet filter input ingress-router-filter
     ```
   - To apply a firewall filter to filter packets that exit a Layer 3 interface:

     ```
     [edit]
     user@switch# set interfaces ge-0/1/6 unit 0 family inet filter output egress-router-filter
     ```

For firewall filters applied to Layer 3 routed interfaces, the family address type must be **inet**.

NOTE: You can apply only one filter to an interface for a given direction (ingress or egress).

- Verifying That Firewall Filters Are Operational on page 4672
- Monitoring Firewall Filter Traffic on page 4669
- Configuring Port Mirroring on page 4730

Applying Firewall Filters to Interfaces

For a firewall filter to work, you must apply it to at least one interface. To do this, include the **filter** statement when configuring a logical interface at the **[edit interfaces]** hierarchy level:

```
[edit interfaces]
user@switch# set interface-name unit logical-unit-number family family-name filter (input | output) filter-name
```

In the **input** statement, specify a firewall filter to be evaluated when packets are received on the interface. Input filters applied to a loopback interface affect only traffic destined for the Routing Engine.

In the **output** statement, specify a filter to be evaluated when packets exit the interface.

NOTE: When you create a loopback interface, it is important to apply an ingress filter to it so the Routing Engine is protected. We recommend that when you apply a filter to the loopback interface lo0, you include the **apply-groups** statement. Doing so ensures that the filter is automatically inherited on every loopback interface, including lo0 and other loopback interfaces.

Related Documentation

- Configuring Firewall Filters on page 4531

Assigning Forwarding Classes and Loss Priority

You can configure firewall filters to assign packet loss priority (PLP) and forwarding classes so that if congestion occurs, the marked packets can be dropped according to the priority you set. The valid match conditions are one or more of the six packet header fields: destination address, source address, IP protocol, source port, destination port, and DSCP. In other words, you can set the forwarding class and the PLP for each packet entering or an interface with a specific destination address, source address, IP protocol, source port, destination port, or DSCP.

NOTE: Junos OS assigns forwarding classes and PLP on ingress only. Do not use a filter that assigns forwarding classes or PLP as an egress filter.

When tricolor marking is enabled, a switch supports four PLP designations: **low**, **medium-low**, **medium-high**, and **high**. You can also specify any of the forwarding classes listed in Table 359 on page 4536

Table 359: Unicast Forwarding Classes

Unicast Forwarding Class	For CoS Traffic Type
be	Best-effort traffic
no-loss	Guaranteed delivery for TCP traffic
fcoe	Guaranteed delivery for Fibre Channel over Ethernet (FCoE) traffic
nc	Network-control traffic

To assign forwarding classes in firewall filters:

1. Configure the family address type and filter name:

```
[edit]
user@switch# edit firewall family ethernet-switching filter ingress-filter
```

2. Configure the terms of the filter as appropriate, including the **forwarding-class** and **loss-priority** action modifiers. For example, each of the following terms in the filter examines various packet header fields and assigns the appropriate forwarding class and packet loss priority:

   - The term **corp-traffic** matches all IPv4 packets with a **10.1.1.0/24** source address and assigns the packets to forwarding class **no-loss** with a loss priority of **low**:

```
[edit firewall family ethernet-switching filter ingress-filter]
user@switch# set term corp-traffic from source-address 10.1.1.0/24;
user@switch# set term corp-traffic then forwarding-class no-loss
user@switch# set term corp-traffic then loss-priority low
```

   - The term **data-traffic** matches all IPv4 packets with a **10.1.2.0/24** source address and assigns the packets to forwarding class **be** (best effort) with a loss priority of **medium-high**:

```
[edit firewall family ethernet-switching filter ingress-filter]
user@switch# set term data-traffic from source-address 10.1.2.0/24;
user@switch# set term data-traffic then forwarding-class be
user@switch# set term data-traffic then loss-priority medium-high
```

- Because the loss of network-generated packets can jeopardize proper network operation, the delay of these packets is preferable to discarding these packets. The term **network-traffic** assigns the packets with an IP precedence of **net-control** to forwarding class **nc** (network control) with a loss priority of **low**:

```
[edit firewall family ethernet-switching filter ingress-filter]
user@switch# set term network-traffic from precedence net-control
user@switch# set term network-traffic then forwarding-class nc
user@switch# set term network-traffic then loss-priority low
```

- The last term **accept-traffic** matches any packets that did not match on any of the preceding terms and assigns the packets to forwarding class **be** with a loss priority of **high**:

```
[edit firewall family ethernet-switching filter ingress-filter]
user@switch# set term accept-traffic then forwarding-class be
user@switch# set term accept-traffic then loss-priority high
```

3. Apply the filter **ingress-filter** to a port, VLAN, or Layer 3 interface. For information about applying the filter, see "Configuring Firewall Filters" on page 4531. (Assigning forwarding classes and PLP is supported only on ingress filters.)

Configuring Color-Blind Egress Policers for Medium-Low PLP

If you use color-blind mode and want to configure an egress policer that marks packets to have medium-low PLP, you must configure a single-rate two-color policer at the **[edit firewall policer *policer-name*]** hierarchy level, because color-blind mode does not support medium-low priority. For example:

1. Specify the name of the policer, the bandwidth limit in bits per second (bps) to control the traffic rate on an interface, and the maximum allowed burst size to control the amount of traffic bursting:

```
[edit]
user@switch# set firewall policer policer-name if-exceeding bandwidth-limit bytes
burst-size-limit bytes
```

2. Specify medium-low loss priority for matching packets:

```
[edit]
user@switch# set firewall policer policer-name then loss-priority medium-low;
```

3. Apply the filter to a port, VLAN, or Layer 3 interface.

Related Documentation

- Overview of Policers on page 4441
- Understanding Color-Blind Mode for Single-Rate Tricolor Marking on page 4447
- Understanding Color-Blind Mode for Two-Rate Tricolor Marking on page 4449
- Configuring Firewall Filters on page 4531
- Configuring Two-Color and Three-Color Policers to Control Traffic Rates on page 4538

Configuring Two-Color and Three-Color Policers to Control Traffic Rates

You can rate-limit traffic by configuring a policer and specifying it as an action modifier for a term in a firewall filter. By default, if you specify the same policer in multiple terms, Junos OS creates a separate policer instance for each term and applies rate limiting separately for each instance. For example, if you configure a policer to discard traffic that exceeds 1 Gbps and reference that policer in three different terms, each policer instance enforces a 1-Gbps limit. In this case, the total bandwidth allowed by the filter is 3 Gbps.

You can also configure a policer to be filter-specific, which means that Junos OS creates only one policer instance regardless of how many times the policer is referenced. When you do this, rate limiting is applied in aggregate, so if you configure a policer to discard traffic that exceeds 1 Gbps and reference that policer in three different terms, the total bandwidth allowed by the filter is 1 Gbps.

NOTE: You can include two-color policer actions on ingress firewall filters only. You can include three-color policer actions on ingress and egress filters.

1. Configuring Two-Color Policers on page 4538
2. Configuring Three-Color Policers on page 4539
3. Specifying Policers in a Firewall Filter Configuration on page 4539
4. Applying a Firewall Filter That Includes a Policer on page 4540

Configuring Two-Color Policers

To configure a two-color policer:

1. Specify the name of the policer, the bandwidth limit to control the traffic rate on an interface, and the maximum allowed burst size to control the amount of traffic bursting:

   ```
   [edit firewall]
   user@switch# set policer policer-name <filter-specific> if-exceeding bandwidth-limit bps burst-size-limit bytes
   ```

   The policer name can contain letters, numbers, and hyphens (-) and can have as many as 64 characters.

   The range for the bandwidth limit is 32000 (32k) through 102,300,000,000 (102300m) bps.

To determine the value for the burst-size limit, multiply the bandwidth of the interface on which the filter is applied by the amount of time to allow a burst of traffic at that bandwidth to occur and divide the result by 8:

maximum burst size = (interface bandwidth) X (allowable time for burst) / (8 bits/byte)

The range for the burst-size limit is 1 through 2,147,450,880 bytes.

2. Specify the policer action to discard or assign a loss priority to packets that exceed the rate limits:

```
[edit firewall policer policer-name]
user@switch# set then (discard | loss-priority low | loss-priority high)
```

Configuring Three-Color Policers

To configure a three-color policer:

1. Specify the name of the policer and (optionally) whether to automatically discard packets with high loss priority (PLP):

```
[edit firewall]
user@switch# set three-color-policer policer-name
user@switch# set three-color-policer policer-name action loss-priority high then discard
```

2. Specify whether the three-color policer should be single-rate or two-rate and whether it should be color-aware or color-blind:

```
[edit firewall three-color-policer policer-name]
user@switch# set (single-rate | two-rate) (color-aware | color-blind)
```

3. For single-rate three-color policers, configure the CIR, CBS, and EBS:

```
[edit firewall three-color-policer policer-name single-rate]
user@switch# set committed-information-rate bps
user@switch# set committed-burst-size bytes
user@switch# set excess-burst-size bytes
```

4. For two-rate three-color policers, configure the CIR, CBS, PIR, and PBS:

```
[edit firewall three-color-policer policer-name single-rate]
user@switch# set committed-information-rate bps
user@switch# set committed-burst-size bytes
user@switch# set peak-information-rate bps
user@switch# set peak-burst-size bytes
```

Specifying Policers in a Firewall Filter Configuration

To use a two-color policer, configure a filter term that includes the action **policer**:

```
[edit firewall family family-name]
user@switch# set filter filter-name term name then name
```

For example, the following commands apply a two-color policer to all packets sent from 192.0.2.0/24.

```
[edit firewall family family-name]
user@switch# set filter limit—hosts term term1 from source-address 192.0.2.0/24
user@switch# set filter limit—hosts term term1 then policer policer1
```

To use a three-color policer, configure a filter term that includes the action **three-color-policer**:

```
[edit firewall family name]
user@switch# set filter name term name from match-condition
```

user@switch# **set filter *name* term *name* then three-color-policer (single-rate | two-rate) *name***

For example, the following commands apply a single-rate three-color policer to all packets received or sent by interface **ge-0/0/6** (depending on whether the filter is an ingress or egress filter).

```
[edit firewall family name]
user@switch# set filter srTCM term term-one from interface ge-0/0/6
user@switch# set filter srTCM term term-one then three-color-policer single-rate srTCM1-ca
```

You must specify whether the three-color policer is single-rate or two-rate, and this must match the policer itself. Otherwise, the configuration listing includes an error message indicating that the three-color policer you referenced in the filter does not exist.

Applying a Firewall Filter That Includes a Policer

A firewall filter that includes one or more policer action modifiers must be applied to a port, VLAN, or Layer 3 interface like any other filter. For information about applying firewall filters, see "Configuring Firewall Filters" on page 4531.

NOTE: You can include two-color policer actions on ingress firewall filters only. You can include three-color policer actions on ingress and egress filters.

Related Documentation

Configuring MPLS Firewall Filters and Policers

You can configure an MPLS firewall filter to count packets based on the EXP bits for the top-level MPLS label in a packet. You can also configure policers for MPLS LSPs.

The following sections discuss MPLS firewall filters and policers:

- Configuring MPLS Firewall Filters on page 4540
- Examples: Configuring MPLS Firewall Filters on page 4541
- Configuring Policers for LSPs on page 4542

Configuring MPLS Firewall Filters

You can configure an MPLS firewall filter to count packets based on the EXP bits for the top-level MPLS label in a packet. You can then apply this filter to a specific interface on input or output. You can also configure a policer for the MPLS filter to police (that is, rate-limit) the traffic on the interface to which the filter is attached. You cannot apply MPLS firewall filters to loopback interfaces.

You can configure the following match conditions for MPLS filters at the **[edit firewall family mpls filter *filter-name* term *term-name* from]** hierarchy level:

- **exp**
- **label**

These **exp** match condition can accept EXP bits in the range 0 through 7. You can configure the following choices:

- A single EXP bit—for example, **exp 3;**
- Several EXP bits—for example, **exp 0, 4;**
- A range of EXP bits—for example, **exp [0-5];**

The **label** match condition can accept a range of values from 0 to 1048575.

If you do not specify a match criterion (that is, you do not configure the **from** statement and use only the **then** statement with the **count** action keyword), all the MPLS packets passing through the interface on which the filter is applied will be counted.

You also can configure any of the following action keywords at the **[edit firewall family mpls filter *filter-name* term *term-name* then]** hierarchy level:

- **accept**
- **count**
- **discard**
- **policer**
- **three-color-policer**

Examples: Configuring MPLS Firewall Filters

The following examples illustrate how you might configure an MPLS firewall filter and then apply the filter to an interface. This filter is configured to count MPLS packets with EXP bits set to either 0 or 4.

The following shows a configuration for an MPLS firewall filter:

```
[edit firewall]
family mpls {
  filter expf {
    term expt0 {
      from {
        exp 0,4;
      }
      then {
        count counter0;
        accept;
      }
    }
  }
}
```

Configuring Policers for LSPs

MPLS LSP policing allows you to control the amount of traffic forwarded through a particular LSP. Policing helps to ensure that the amount of traffic forwarded through an LSP never exceeds the requested bandwidth allocation. LSP policing is supported on regular LSPs, LSPs configured with DiffServ-aware traffic engineering, and multiclass LSPs. You can configure multiple policers for each multiclass LSP. For regular LSPs, each LSP policer is applied to all of the traffic traversing the LSP. The policer's bandwidth limitations become effective as soon as the total sum of traffic traversing the LSP exceeds the configured limit.

You configure the multiclass LSP and DiffServ-aware traffic engineering LSP policers in a filter. The filter can be configured to distinguish between the different class types and apply the relevant policer to each class type. The policers distinguish between class types based on the EXP bits.

You configure LSP policers under the **family any** filter. The **family any** filter is used because the policer is applied to traffic entering the LSP. This traffic might be from different families: IPv6, MPLS, and so on. You do not need to know what sort of traffic is entering the LSP, as long as the match conditions apply to all types of traffic.

LSP Policer Limitations

When configuring MPLS LSP policers, be aware of the following limitations:

- LSP policers are supported for packet LSPs only.
- LSP policers are supported for unicast next hops only. Multicast next hops are not supported.
- LSP policers are not supported on aggregated interfaces.
- The LSP policer runs before any output filters.
- Traffic sourced from the Routing Engine (for example, ping traffic) does not take the same forwarding path as transit traffic. This type of traffic cannot be policed.

Related Documentation

- Overview of Policers on page 4441

Port Security Configuration Tasks (Original CLI Only)

Configuring Port Security (CLI Procedure)

Ethernet LANs are vulnerable to attacks such as address spoofing and Layer 2 denial of service (DoS) on network devices. Port security features such as DHCP snooping, DAI (dynamic ARP inspection), MAC limiting, MAC move limiting, and persistent MAC learning, as well as trusted DHCP server, help protect the access ports on the switch against the losses of information and productivity that can result from such attacks.

Depending on the particular feature, you can configure the port security feature either on:

- VLANs—A specific VLAN or all VLANs
- Interfaces—A specific interface or all interfaces

NOTE: If you configure one of the port security features on all VLANs or all interfaces, the switch software enables that port security feature on all VLANs and all interfaces that are not explicitly configured with other port security features.

However, if you do explicitly configure one of the port security features on a specific VLAN or on a specific interface, you must explicitly configure any additional port security features that you want to apply to that VLAN or interface. Otherwise, the switch software automatically applies the default values for the feature.

For example, if you disable DHCP snooping on all VLANs and decide to explicitly enable IP source guard only on a specific VLAN, you must also explicitly enable DHCP snooping on that specific VLAN. Otherwise, the default value of no DHCP snooping applies to that VLAN.

To configure port security features using the CLI:

- Enabling Persistent MAC Learning on an Interface on page 4545
- Limiting MAC Address Movement on page 4545
- Configuring Trusted DHCP Servers on an Interface on page 4545

Enabling DHCP Snooping

You can configure DHCP snooping to allow the device to monitor DHCP messages received, ensure that hosts only use the IP addresses assigned to them, and allow access only to authorized DHCP servers.

To enable DHCP snooping:

- On a specific VLAN:

```
[edit vlans forwarding-options dhcp-security]
user@switch# set vlan default examine-dhcp
```

- On all VLANs:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan all examine-dhcp
```

Enabling Dynamic ARP Inspection (DAI)

You can enable DAI to protect against ARP snooping. To enable DAI:

- On a single VLAN (here, the VLAN is **employee-vlan**):

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee-vlan arp-inspection
```

- On all VLANs:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan all arp-inspection
```

Limiting Dynamic MAC Addresses on an Interface

Limit the number of dynamic MAC addresses allowed on an interface and specify the action to take if the limit is exceeded—for example, set a MAC limit of **5** with an action of **drop**:

- On a single interface:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface ge-0/0/1 mac-limit 5 action drop
```

- On all interfaces:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface all mac-limit 5 action drop
```

You can also specify the actions **log** (do not drop the packet but generate an alarm, an SNMP trap, or a system log entry), **none** (no action), or **shutdown** (disable the interface and generate an alarm) to occur if the number of dynamic MAC addresses is exceeded.

Enabling Persistent MAC Learning on an Interface

You can configure learned MAC addresses to persist on an interface across restarts of the switch:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface ge-0/0/1 persistent-learning
```

Limiting MAC Address Movement

You can limit the number of times a MAC address can move from its original interface in 1 second—for example, set a MAC move limit of **5** with an action of **drop** if the limit is exceeded:

- On a single VLAN (here, the VLAN is **employee-vlan**):

  ```
  [edit ethernet-switching-options secure-access-port]
  user@switch# set vlan employee-vlan mac-move-limit 5 action drop
  ```

- On all VLANs:

  ```
  [edit ethernet-switching-options secure-access-port]
  user@switch# set vlan all mac-move-limit 5 action drop
  ```

You can also specify the actions **log** (do not drop the packet but generate an alarm, an SNMP trap, or a system log entry), **none** (no action), or **shutdown** (disable the interface or VLAN and generate an alarm) to occur if the MAC address moves more than the specified number of times in 1 second.

Configuring Trusted DHCP Servers on an Interface

Configure a trusted DHCP server on an interface:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface ge-0/0/1 dhcp-trusted
```

- **secure-access-port on page 4622**

Configuring MAC Limiting

To configure MAC limiting on a specific interface or on all interfaces:

1. To limit the number of dynamic MAC addresses, set a MAC limit of **5**.

The action is not specified, so the switch performs the default action **drop** if the limit is exceeded:

- On a single interface (here, the interface is **xe-0/0/1**):

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface xe-0/0/1 mac-limit (Access Port Security) 5
```

- On all interfaces:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface all mac-limit 5
```

CAUTION: Do not set the MAC limit to 1. The first learned MAC address is often inserted into the forwarding database automatically. (For instance, the first MAC address inserted into the forwarding database for routed VLAN interfaces is the MAC address of the RVI. For Aggregated Ethernet bundles using LACP, the first MAC address inserted into the forwarding database in the forwarding table is the source address of the protocol packet.) The switch therefore fails to learn MAC addresses other than the automatic addresses when the MAC limit is set to 1, and this causes problems with MAC learning and forwarding.

2. To specify allowed MAC addresses:

- On a single interface (here, the interface is **xe-0/0/2**):

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface xe-0/0/2 allowed-mac 00:05:85:3A:82:80
user@switch# set interface xe-0/0/2 allowed-mac 00:05:85:3A:82:81
user@switch# set interface xe-0/0/2 allowed-mac 00:05:85:3A:82:83
```

- On all interfaces:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface all allowed-mac 00:05:85:3A:82:80
user@switch# set interface all allowed-mac 00:05:85:3A:82:81
user@switch# set interface all allowed-mac 00:05:85:3A:82:83
```

Configuring MAC Move Limiting (CLI Procedure)

When MAC move limiting is configured, MAC address movements are tracked by the switch and, if a MAC address changes more than the configured number of times within 1 second, the changes to MAC addresses are dropped, logged, ignored, or the interface is shut down.

NOTE: Although you enable this feature on VLANs, the MAC move limitation pertains to the number of movements for each individual MAC address rather than the total number of MAC address moves in the VLAN. For example, If the MAC move limit is set to 1, the switch allows an unlimited number of MAC address movements within the VLAN as long as the same MAC address does not change more than once.

You configure MAC move limiting per VLAN, not per interface (port). In the default configuration, the number of MAC moves permitted is unlimited.

You can choose to have one of the following actions performed when the MAC move limit is exceeded:

- **drop**—Drop the packet and generate a system log entry. This is the default.
- **log**—Do not drop the packet but generate a system log entry.
- **none**—Take no action.
- **shutdown**—Disable the interfaces in the VLAN and generate a system log entry. If you have configured the switch with the **port-error-disable** statement, the disabled interfaces recover automatically upon expiration of the specified disable timeout. If you have not configured the switch for autorecovery from port error disabled conditions, you can bring up the disabled interfaces by running the **clear ethernet-switching port-error** command.

To configure a MAC move limit for MAC addresses within a specific VLAN or for MAC addresses within all VLANs, using the CLI:

- On a single VLAN: To limit the number of MAC address movements that can be made by an individual MAC address within the VLAN **employee-vlan**, set a MAC move limit of **5**:

  ```
  [edit ethernet-switching-options secure-access-port]
  user@switch# set vlan employee-vlan mac-move-limit 5
  ```

  The action is not specified, so the switch performs the default action **drop** if it tracks that an individual MAC address within the **employee-vlan** has moved more than 5 times within one second.

- On all VLANs: To limit the number of MAC movements that can be made by individual MAC addresses within all VLANs, set a MAC move limit of **5**:

  ```
  [edit ethernet-switching-options secure-access-port]
  user@switch# set vlan all mac-move-limit 5
  ```

  The action is not specified, so the switch performs the default action **drop** if it tracks that an individual MAC address within any of the VLANs has moved more than 5 times within 1 second.

Configuring Autorecovery for MAC Limited or Storm Control Interfaces (CLI Procedure)

An Ethernet access interface might shut down or be disabled as a result of one of the following configurations:

- MAC limiting—**mac-limit** statement is configured with action **shutdown**.
- MAC move limiting—**mac-move-limit** statement is configured with action **shutdown**.
- Storm control—**storm-control** statement is configured with the action **shutdown**.

You can configure a device to automatically restore the disabled interfaces to service after a specified period of time. Autorecovery applies to all the interfaces that have been disabled due to MAC limiting, MAC move limiting, or storm control errors.

To configure autorecovery from the disabled state due to MAC limiting, MAC move limiting, or storm control shutdown actions:

```
[edit ethernet-switching-options]
user@switch# set port-error-disable disable-timeout seconds
```

NOTE: You must specify the disable timeout value—there is no default disable timeout period. If you do not specify a timeout value, you must use the clear ethernet-switching port-error command to clear the errors and restore the interfaces to service.

Related Documentation

Configuring the none Action to Override a MAC Limit Applied to All Interfaces (CLI Procedure)

If you set a MAC limit in your port security settings to apply to all interfaces, you can override that setting for a particular interface by specifying the action **none**.

To use the **none** action to override a MAC limit setting:

1. Set the MAC limit for all interfaces—for example, a limit of **5** with action **drop**:

   ```
   [edit ethernet-switching-options secure-access-port]
   user@switch# set interface all mac-limit (Access Port Security) 5 action drop
   ```
2. Change the action for one interface with this command.

   ```
   [edit ethernet-switching-options secure-access-port]
   user@switch# set interface xe-0/0/2 mac-limit action none
   ```

Configuring Static ARP Entries

You can create static ARP table entries, which are explicit mappings between IP addresses and MAC addresses.

- To configure a static ARP entry:

```
[edit interfaces interface-name unit logical-unit-number family inet address address]
user@switch# set arp ip-address (mac | multicast-mac) mac-address
```

The IP address that you specify must be part of the subnet defined in the enclosing **address** statement.

To associate a multicast MAC address with a unicast IP address, use the **multicast-mac** statement.

Specify the MAC address as 6 hexadecimal bytes in one of the following formats: ***nnnn.nnnn.nnnn*** or ***nn:nn:nn:nn:nn:nn***; for example, **0011.2233.4455** or **00:11:22:33:44:55**.

Related Documentation

Configuring Static IP Addresses for DHCP Bindings on Access Ports (CLI Procedure)

You can add static (fixed) IP addresses and bind them to fixed MAC addresses in the DHCP snooping database. These bindings are labeled as “static” in the database, while those bindings that have been added through the process of DHCP snooping are labeled “dynamic.”

To configure a static IP address/MAC address binding in the DHCP snooping database (replace **ge-0/0/2**, **10.0.10.12**, **data-vlan**, and **00:05:85:3A:82:80** with values for your configuration):

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface ge-0/0/2 static-ip 10.0.10.12 vlan data-vlan mac 00:05:85:3A:82:80
```

To view results of the configuration steps before committing the configuration, type the **show** command at the user prompt.

To commit these changes to the active configuration, type the **commit** command at the user prompt.

Related Documentation

- *secure-access-port*

- secure-access-port on page 4622

Enabling DHCP Snooping (CLI Procedure)

DHCP snooping allows the switch to monitor and control DHCP messages received from untrusted devices connected to the switch. It builds and maintains a database of valid IP-address/MAC-address (IP-MAC) bindings called the DHCP snooping database.

NOTE: If you configure DHCP snooping for all VLANs and you enable a different port security feature on a specific VLAN, you must also explicitly enable DHCP snooping on that VLAN. Otherwise, the default value of no DHCP snooping applies to that VLAN.

This topic describes:

Enabling DHCP Snooping

You configure DHCP snooping per VLAN, not per interface (port). By default, DHCP snooping is disabled for all VLANs. You can enable DHCP snooping on all VLANs or on specific VLANs.

To enable DHCP snooping on a VLAN or all VLANs:

- On a specific VLAN:

  ```
  [edit ethernet-switching-options secure-access port]
  user@switch# set vlan vlan-name examine-dhcp
  ```

- On all VLANs:

  ```
  [edit ethernet-switching-options secure-access port]
  user@switch# set vlan all examine-dhcp
  ```

TIP: By default, the IP-MAC bindings are lost when the switch is rebooted and DHCP clients (the network devices, or hosts) must reacquire bindings. However, you can configure the bindings to persist by setting the **dhcp-snooping-file** statement to store the database file either locally or remotely.

TIP: For private VLANs (PVLANs), enable DHCP snooping on the primary VLAN. If you enable DHCP snooping only on a community VLAN, DHCP messages coming from PVLAN trunk ports are not snooped.

Applying CoS Forwarding Classes to Prioritize Snooped Packets

On EX Series switches you might need to use class of service (CoS) to protect packets from critical applications from being dropped during periods of network congestion and delay and you might also need the port security features of DHCP snooping on the same ports through which those critical packets are entering and leaving.

NOTE: This is not supported on the QFX Series switch.

To apply CoS forwarding classes and queues to snooped packets:

1. Create a user-defined forwarding class to be used for prioritizing snooped packets:

   ```
   [edit class-of-service]
   user@switch# set forwarding-classes class class-name queue queue-number
   ```

2. Enable DHCP snooping on a specific VLAN or on all VLANs and apply the desired forwarding class on the snooped packets:

   - On a specific VLAN:

     ```
     [edit ethernet-switching-options secure-access port]
     user@switch# set vlan vlan-name examine-dhcp forwarding-class class-name
     ```

- On all VLANs:

```
[edit ethernet-switching-options secure-access port]
user@switch# set vlan all examine-dhcp forwarding-class class-name
```

Enabling Dynamic ARP Inspection (CLI Procedure)

Dynamic ARP inspection (DAI) protects switches against ARP spoofing. DAI inspects ARP packets on the LAN and uses the information in the DHCP snooping database on the switch to validate ARP packets and to protect against ARP cache poisoning.

This topic describes:

- Enabling DAI on page 4554
- Applying CoS Forwarding Classes to Prioritize Inspected Packets on page 4554

Enabling DAI

You configure DAI for each VLAN, not for each interface (port). By default, DAI is disabled for all VLANs.

To enable DAI on a VLAN or all VLANs:

- On a single VLAN:

  ```
  [edit ethernet-switching-options secure-access-port]
  user@switch# set vlan vlan-name arp-inspection
  ```

- On all VLANs:

  ```
  [edit ethernet-switching-options secure-access-port]
  user@switch# set vlan all arp-inspection
  ```

Applying CoS Forwarding Classes to Prioritize Inspected Packets

You might need to use class of service (CoS) to protect packets from critical applications from being dropped during periods of network congestion and delay and you might also need the port security features of DHCP snooping on the same ports through which those critical packets are entering and leaving.

To apply CoS forwarding classes and queues to DAI packets:

1. Create a user-defined forwarding class to be used for prioritizing DAI packets:

   ```
   [edit class-of-service]
   user@switch# set forwarding-classes class class-name queue queue-number
   ```

2. Enable DAI on a specific VLAN or on all VLANs and apply the desired forwarding class on the DAI packets:

   - On a specific VLAN:

     ```
     [edit ethernet-switching-options secure-access port]
     user@switch# set vlan vlan-name arp-inspection forwarding-class class-name
     ```

   - On all VLANs:

     ```
     [edit ethernet-switching-options secure-access port]
     user@switch# set vlan all arp-inspection forwarding-class class-name
     ```

Enabling a Trusted DHCP Server (CLI Procedure)

You can configure any interface on a switch that connects to a DHCP server as a trusted interface (port). Configuring a DHCP server on a trusted interface protects against rogue DHCP servers sending leases.

You configure a trusted DHCP server on an interface, not on a VLAN. By default, all access interfaces are untrusted, and all trunk interfaces are trusted.

To configure a trusted interface for a DHCP server by using the CLI (here, the interface is **ge-0/0/8**):

```
[edit ethernet-switching-options secure-access port]
user@switch# set interface ge-0/0/8 dhcp-trusted
```

Related Documentation

- Monitoring Port Security on page 4671
- Understanding Trusted DHCP Servers for Port Security on page 4467
- *secure-access-port*
- **secure-access-port on page 4622**

Enabling a Trusted Port for DHCP

By default, all access ports are untrusted and all trunk ports are trusted with regard to DHCP. Trusted ports allow DHCP servers to provide IP addresses and other information to requesting devices. Untrusted ports drop traffic from DHCP servers to prevent unauthorized servers from providing any configuration information to clients.

If you attach a DHCP server to an access port, you must configure it as trusted. You configure a trusted DHCP server on an interface, not on a VLAN.

NOTE: **Before you attach a DHCP server to a trusted access port, ensure that the server is physically secure—that is, that access to the server is monitored and controlled.**

- To configure a trusted interface for a DHCP server by using the CLI (here, the interface is **xe-0/0/8**):

```
[edit ethernet-switching-options secure-access port]
user@switch# set interface xe-0/0/8 dhcp-trusted
```

Setting Up DHCP Option 82 on the Switch with No Relay Agent Between Clients and DHCP Server (CLI Procedure)

You can use DHCP option 82, also known as the DHCP relay agent information option, to help protect the switch against attacks such as spoofing (forging) of IP addresses and MAC addresses, and DHCP IP address starvation. Option 82 provides information about the network location of a DHCP client, and the DHCP server uses this information to implement IP addresses or other parameters for the client.

You can configure the DHCP option 82 feature in two topologies:

- The switch, DHCP clients, and DHCP server are all on the same VLAN. The switch forwards the clients' requests to the server and forwards the server's replies to the clients. This topic describes this configuration.
- The switch functions as a relay agent when the DHCP clients or the DHCP server is connected to the switch through a Layer 3 interface. On the switch, these interfaces are configured as routed VLAN interfaces, or RVIs. The switch relays the clients' requests to the server and then forwards the server's replies to the clients. This configuration is described in "Setting Up DHCP Option 82 with the Switch as a Relay Agent Between Clients and DHCP Server (CLI Procedure)" on page 4560.

Before you configure DHCP option 82 on the switch, perform these tasks:

- Connect and configure the DHCP server.

  NOTE: Your DHCP server must be configured to accept DHCP option 82. If the server is not configured for DHCP option 82, the server does not use the DHCP option 82 information in the requests sent to it when it formulates its reply messages.

- Configure a VLAN on the switch and associate the interfaces on which the clients and the server connect to the switch with that VLAN.

To configure DHCP option 82:

NOTE: Replace values displayed in italics with values for your configuration.

1. Specify DHCP option 82 for all VLANs associated with the switch or for a specified VLAN. (You can also configure the feature for a VLAN range.)
   - On a specific VLAN:

     ```
     [edit ethernet-switching-options secure-access-port]
     user@switch# set vlan employee dhcp-option82
     ```
   - On all VLANs:

     ```
     [edit ethernet-switching-options secure-access-port]
     user@switch# set vlan all dhcp-option82
     ```

   The remaining steps are optional.
2. To configure a prefix for the circuit ID suboption (the prefix is always the hostname of the switch):

   ```
   [edit ethernet-switching-options secure-access-port]
   user@switch# set vlan employee dhcp-option82 circuit-id prefix hostname
   ```
3. To specify that the circuit ID suboption value should contain the interface description rather than the interface name (the default):

   ```
   [edit ethernet-switching-options secure-access-port]
   user@switch# set vlan employee dhcp-option82 circuit-id use-interface-description
   ```
4. To specify that the circuit ID suboption value should contain the VLAN ID rather than the VLAN name (the default):

   ```
   [edit ethernet-switching-options secure-access-port]
   user@switch# set vlan employee dhcp-option82 circuit-id use-vlan-id
   ```
5. To specify that the remote ID suboption be included in the DHCP option 82 information:

   ```
   [edit ethernet-switching-options secure-access-port]
   user@switch# set vlan employee dhcp-option82 remote-id
   ```
6. To configure a prefix for the remote ID suboption (here, the prefix is the MAC address of the switch):

   ```
   [edit ethernet-switching-options secure-access-port]
   user@switch# set vlan employee dhcp-option82 remote-id prefix mac
   ```
7. To specify that the prefix for the remote ID suboption be the hostname of the switch rather than the MAC address of the switch (the default):

   ```
   [edit ethernet-switching-options secure-access-port]
   user@switch# set vlan employee dhcp-option82 remote-id prefix hostname
   ```
8. To specify that the remote ID suboption value should contain the interface description:

   ```
   [edit ethernet-switching-options secure-access-port]
   user@switch# set vlan employee dhcp-option82 remote-id use-interface-description
   ```
9. To specify that the remote ID suboption value should contain a character string:

   ```
   [edit ethernet-switching-options secure-access-port]
   user@switch# set vlan employee dhcp-option82 remote-id use-string mystring
   ```
10. To configure a vendor ID suboption and use the default value (the default value is **Juniper**), do not type a character string after the **vendor-id** option keyword:

    ```
    [edit ethernet-switching-options secure-access-port]
    ```

```
user@switch# set vlan employee dhcp-option82 vendor-id
```

11. To specify that the vendor ID suboption value should contain a character string value that you specify rather than **Juniper** (the default):

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee dhcp-option82 vendor-id mystring
```

To view results of the configuration steps before committing the configuration, type the **show** command at the user prompt.

To commit these changes to the active configuration, type the **commit** command at the user prompt.

Setting Up DHCP Option 82 with the Switch as a Relay Agent Between Clients and DHCP Server (CLI Procedure)

You can use DHCP option 82, also known as the DHCP relay agent information option, to help switches against attacks such as spoofing (forging) of IP addresses and MAC addresses, and DHCP IP address starvation. Option 82 provides information about the network location of a DHCP client, and the DHCP server uses this information to implement IP addresses or other parameters for the client.

You can configure the DHCP option 82 feature in two topologies:

- The switch functions as a relay agent when the DHCP clients or the DHCP server is connected to the switch through a Layer 3 interface. On the switch, these interfaces are configured as routed VLAN interfaces, or RVIs. The switch relays the clients' requests to the server and then forwards the server's replies to the clients. This topic describes this configuration. The configuration for this topology is the same regardless of whether your switch is running Junos OS for EX Series switches with support for the Enhanced Layer 2 Software (ELS) configuration style or not.
- The switch, DHCP clients, and DHCP server are all on the same VLAN. The switch forwards the clients' requests to the server and forwards the server's replies to the clients. This configuration for this topology differs if your switch is running Junos OS for EX Series switches with support for the Enhanced Layer 2 Software (ELS) configuration style.
  - If your switch is running Junos OS for EX Series switches with support for the Enhanced Layer 2 Software (ELS) configuration style. see *Setting Up DHCP Option 82 on the Switch with No Relay Agent Between Clients and DHCP Server (CLI Procedure)*.
  - If your switch is running Junos OS for EX Series switches without support for ELS, see "Setting Up DHCP Option 82 on the Switch with No Relay Agent Between Clients and DHCP Server (CLI Procedure)" on page 4557.

Before you configure DHCP option 82 on the switch, perform these tasks:

- Connect and configure the DHCP server.

  NOTE: **Your DHCP server must be configured to accept DHCP option 82. If the server is not configured for DHCP option 82, the server does not use the DHCP option 82 information in the requests sent to it when it formulates its reply messages.**

- Configure the VLAN on the switch and associate the interfaces on which the clients connect to the switch with that VLAN.
- Configure the routed VLAN interface (RVI) to allow the switch to relay packets to the server and receive packets from the server. See *Configuring Routed VLAN Interfaces (CLI Procedure)* or "Configuring Routed VLAN Interfaces" on page 1532 for the QFX Series.
- Configure the switch as a BOOTP relay agent. See *DHCP/BOOTP Relay for Switches Overview*.

To configure DHCP option 82:

NOTE: Replace values displayed in italics with values for your configuration.

1. Specify DHCP option 82 for the BOOTP server:
   - On all interfaces that connect to the server:

     ```
     [edit forwarding-options helpers bootp]
     user@switch# set dhcp-option82
     ```
   - On a specific interface that connects to the server:

     ```
     [edit forwarding-options helpers bootp]
     user@switch# set interface ge-0/0/10 dhcp-option82
     ```

     The remaining steps are optional. They show configurations for all interfaces; include the specific interface designation to configure any of the following options on a specific interface:
2. To configure a prefix for the circuit ID suboption (the prefix is always the hostname of the switch):

   ```
   [edit forwarding-options helpers bootp]
   user@switch# set dhcp-option82 circuit-id prefix hostname
   ```
3. To specify that the circuit ID suboption value should contain the interface description rather than the interface name (the default):

   ```
   [edit forwarding-options helpers bootp]
   user@switch# set dhcp-option82 circuit-id use-interface-description
   ```
4. To specify that the circuit ID suboption value should contain the VLAN ID rather than the VLAN name (the default):

   ```
   [edit forwarding-options helpers bootp]
   user@switch# set dhcp-option82 circuit-id use-vlan-id
   ```
5. To specify that the remote ID suboption be included in the DHCP option 82 information:

   ```
   [edit forwarding-options helpers bootp]
   user@switch# set dhcp-option82 remote-id
   ```
6. To configure a prefix for the remote ID suboption (here, the prefix is the MAC address of the switch):

   ```
   [edit forwarding-options helpers bootp]
   user@switch# set dhcp-option82 remote-id prefix mac
   ```
7. To specify that the prefix for the remote ID suboption be the hostname of the switch rather than the MAC address of the switch (the default):

   ```
   [edit forwarding-options helpers bootp]
   user@switch# set dhcp-option82 remote-id prefix hostname
   ```
8. To specify that the remote ID suboption value should contain the interface description:

   ```
   [edit forwarding-options helpers bootp]
   user@switch# set dhcp-option82 remote-id use-interface-description
   ```
9. To specify that the remote ID suboption value should contain a character string:

   ```
   [edit forwarding-options helpers bootp]
   user@switch# set dhcp-option82 remote-id use-string mystring
   ```
10. To configure a vendor ID suboption and use the default value (the default value is **Juniper**), do not type a character string after the **vendor-id** option keyword:

```
[edit forwarding-options helpers bootp]
user@switch# set dhcp-option82 vendor-id
```

11. To specify that the vendor ID suboption value contains a character string value that you specify rather than **Juniper** (the default):

```
[edit forwarding-options helpers bootp]
user@switch# set dhcp-option82 vendor-id mystring
```

To view results of the configuration steps before committing the configuration, type the **show** command at the user prompt.

To commit these changes to the active configuration, type the **commit** command at the user prompt.

Device Security Configuration Tasks

Configuring Unicast RPF (CLI Procedure)

Unicast reverse-path forwarding (RPF) can help protect your LAN from denial-of-service (DoS) and distributed denial-of-service (DDoS) attacks on untrusted interfaces. Enabling unicast RPF on the switch interfaces filters traffic with source addresses that do not use the incoming interface as the best return path back to the source. When a packet comes into an interface, if that interface is not the best return path to the source, the switch discards the packet. If the incoming interface is the best return path to the source, the switch forwards the packet.

NOTE: On EX3200, EX4200, and EX4300 switches, you can enable unicast RPF only globally—that is, on all switch interfaces. You cannot enable unicast RPF on a per-interface basis.

Before you begin:

- On an EX8200, EX6200, or QFX Series switch, ensure that the selected switch interface is symmetrically routed before you enable unicast RPF. A symmetrically routed interface is an interface that uses the same route in both directions between the source and the destination. Do not enable unicast RPF on asymmetrically routed interfaces. An asymmetrically routed interface uses different paths to send and receive packets between the source and the destination.

- On an EX3200, EX4200, or EX4300 switch, ensure that *all* switch interfaces are symmetrically routed before you enable unicast RPF on an interface. When you enable unicast RPF on any interface, it is enabled globally on all switch interfaces. Do not enable unicast RPF on asymmetrically routed interfaces. An asymmetrically routed interface uses different paths to send and receive packets between the source and the destination.

To enable unicast RPF, configure it explicitly on a selected customer-edge interface:

[edit interfaces]
user@switch# **set ge-1/0/10 unit 0 family inet rpf-check**

BEST PRACTICE: On EX3200, EX4200, and EX4300 switches, unicast RPF is enabled globally on *all* switch interfaces, regardless of whether you configure it explicitly on only one interface or only on some interfaces.

On EX3200, EX4200, and EX4300 switches, we recommend that you enable unicast RPF explicitly on either all interfaces or only one interface. To avoid possible confusion, do not enable it on only some interfaces:

- Enabling unicast RPF explicitly on only one interface makes it easier if you choose to disable it in the future because you must explicitly disable unicast RPF on every interface on which you explicitly enabled it. If you explicitly enable unicast RPF on two interfaces and you disable it on only one interface, unicast RPF is still implicitly enabled globally on the switch. The drawback of this approach is that the switch displays the flag that indicates that unicast RPF is enabled only on interfaces on which unicast RPF is explicitly enabled, so even though unicast RPF is enabled on all interfaces, this status is not displayed.
- Enabling unicast RPF explicitly on all interfaces makes it easier to know whether unicast RPF is enabled on the switch because every interface shows the correct status. (Only interfaces on which you explicitly enable unicast RPF display the flag that indicates that unicast RPF is enabled.) The drawback of this approach is that if you want to disable unicast RPF, you must explicitly disable it on every interface. If unicast RPF is enabled on any interface, it is implicitly enabled on all interfaces.

Related Documentation

- *Troubleshooting Unicast RPF*
- Understanding Unicast RPF on page 4473

Disabling Unicast RPF (CLI Procedure)

Unicast reverse-path forwarding (RPF) can help protect your LAN from denial-of-service (DoS) and distributed denial-of-service (DDoS) attacks on untrusted interfaces. Unicast RPF filters traffic with source addresses that do not use the incoming interface as the best return path back to the source. If the network configuration changes so that an interface that has unicast RPF enabled becomes a trusted interface or becomes asymmetrically routed (the interface that receives a packet is not the best return path to the packet's source), disable unicast RPF.

To disable unicast RPF on an EX3200, EX4200, or EX4300 switch, you must delete it from every interface on which you explicitly configured it. If you do not disable unicast RPF on every interface on which you explicitly enabled it, it remains implicitly enabled on all interfaces. If you attempt to delete unicast RPF from an interface on which it was not explicitly enabled, the **warning: statement not found** message appears. If you do not disable unicast RPF on every interface on which you explicitly enabled it, unicast RPF remains implicitly enabled on all interfaces of the EX3200, EX4200, or EX4300 switch.

On EX8200, EX6200, and QFX Series switches, the switch does not apply unicast RPF to an interface unless you explicitly enable that interface for unicast RPF.

To disable unicast RPF, delete its configuration from the interface:

[edit interfaces]
user@switch# **delete ge-1/0/10 unit 0 family inet** rpf-check

NOTE: On EX3200, EX4200, and EX4300 switches, if you do not disable unicast RPF on every interface on which you explicitly enabled it, unicast RPF remains implicitly enabled on all interfaces.

Configuring Unknown Unicast Forwarding (CLI Procedure)

NOTE: This task uses Junos OS for EX Series switches or QFX Series with support for the Enhanced Layer 2 Software (ELS) configuration style. If your EX Series switch runs software that does not support ELS, see *Configuring Unknown Unicast Forwarding (CLI Procedure)*. For ELS details, see "Getting Started with Enhanced Layer 2 Software" on page 58

Unknown unicast traffic consists of packets with unknown destination MAC addresses. By default, the switch floods these packets to all interfaces associated with a VLAN. Forwarding such traffic to interfaces on the switch can create a security issue.

To prevent flooding unknown unicast traffic across the switch, configure unknown unicast forwarding to direct all unknown unicast packets within a VLAN out to a specific interface. You can configure each VLAN to divert unknown unicast traffic to different interfaces or use one interface for multiple VLANs.

To configure unknown unicast forwarding options:

- Configure unknown unicast forwarding for a specific VLAN (here, the VLAN name is employee), and specify the interface to which all unknown unicast traffic will be forwarded:

  ```
  [edit switch-options]
  user@switch# set unknown-unicast-forwarding vlan vlan-name interface ge-x/y/z.0
  ```

Configuration Statements for Firewall Filters

family

Syntax

```
family family-name {
  filter filter-name {
    interface-specific;
    term term-name {
      from {
        match-conditions;
      }
      then {
        action;
        action-modifiers;
      }
    }
  }
}
```

Hierarchy Level [edit firewall]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Configure a firewall filter for IP version 4 or IP version 6.

Options *family-name*—Type of addressing protocol:

- **ethernet-switching**—Filter Layer 2 Ethernet packets and Layer 3 (IP) packets (allows some Layer 3 filtering).
- **inet**—Filter Layer 3 IPv4 packets (provides additional Layer 3 filter options).
- **inet6**—Filter Layer 3 IPv6 packets (provides additional Layer 3 filter options).

The remaining statements are explained separately.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

filter

Syntax

```
filter filter-name {
  interface-specific;
  term term-name {
    from {
      match-conditions;
    }
    then {
      action;
      action-modifiers;
    }
  }
}
```

Hierarchy Level [edit firewall family *family-name*]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Configure firewall filters.

Options ***filter-name***—Name that identifies the filter. The name can contain letters, numbers, and hyphens (-), and can be up to 64 characters long. To include spaces in the name, enclose it in quotation marks.

The remaining statements are explained separately.

Required Privilege Level firewall—To view this statement in the configuration.
firewall-control—To add this statement to the configuration.

Related Documentation

filter (Layer 2 and Layer 3 Interfaces)

Syntax filter (input | output) *filter-name*;

Hierarchy Level [edit interfaces *interface-name* unit *logical-unit-number* family *family-name*]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Apply a firewall filter to traffic transiting a port or Layer 3 interface.

Default All incoming traffic is accepted unmodified on the port or Layer 3 interface, and all outgoing traffic is sent unmodified from the port or Layer 3 interface.

Options *filter-name*—Name of a firewall filter defined at the **[edit firewall family *family-name* filter]** hierarchy level.

input—Apply a firewall filter to traffic entering the port or Layer 3 interface.

output—Apply a firewall filter to traffic exiting the port or Layer 3 interface.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

filter (VLANs)

Syntax filter (input | output) *filter-name*;

Hierarchy Level [edit vlans *vlan-name*]
[edit vlans *vlan-name* forwarding-options]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Apply a firewall filter to traffic ingressing or egressing a VLAN.

Default All incoming traffic is accepted unmodified to a VLAN, and all outgoing traffic is sent unmodified from a VLAN.

Options *filter-name*—Name of a firewall filter defined at the **[edit firewall family *family-name* filter]** hierarchy level.

input—Apply a firewall filter to VLAN ingress traffic.

output—Apply a firewall filter to VLAN egress traffic.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

from

Syntax

```
from {
  match-conditions;
}
```

Hierarchy Level [edit **firewall family** *family-name* **filter** *filter-name* **term** *term-name*]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Match packet fields to values specified in a match condition. If the **from** statement is not included in a firewall filter configuration, all packets are considered to match and the actions and action modifiers in the **then** statement are implemented.

Options *match-conditions*—Conditions that define the values or fields that the incoming or outgoing packets must contain for a match. You can specify one or more match conditions. If you specify more than one, they all must match for a match to occur and for the action in the **then** statement to be implemented.

Required Privilege Level
firewall—To view this statement in the configuration.
firewall-control—To add this statement to the configuration.

Configuration Statements for Policers

- single-rate on page 4588
- then (Policers) on page 4589
- three-color-policer on page 4590
- two-rate on page 4591

action

Syntax

```
action {
  loss-priority high then discard;
}
```

Hierarchy Level [edit firewall three-color-policer *name*]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Discard traffic on a logical interface using tricolor marking policing.

Options The statements are explained separately.

Required Privilege Level firewall—To view this statement in the configuration.
firewall-control—To add this statement to the configuration.

bandwidth-limit

Syntax bandwidth-limit *bps*;

Hierarchy Level [edit firewall policer *policer-name* if-exceeding]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Specify the traffic rate in bits per second.

Options *bps*—Traffic rate in bits per second. Specify *bps* as a decimal value or as a decimal number followed by one of the abbreviation **k** (1000), **m** (1,000,000), or **g** (1,000,000,000).

Range: 32000 bps (32 Kbps) through 10,000,000,000 bps (10 Gbps)

Required Privilege Level firewall—To view this statement in the configuration.
firewall-control—To add this statement to the configuration.

Related Documentation

color-aware

Syntax color-aware;

Hierarchy Level [edit firewall three-color-policer *policer-name* single-rate],
[edit firewall three-color-policer *policer-name* two-rate]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Configure the way preclassified packets are metered. In color-aware mode, the switch can assign a higher packet-loss priority, but cannot assign a lower packet loss priority (PLP). For example, suppose an upstream device assigns medium-high PLP to a packet because the packet exceeded its committed information rate (CIR). The switch cannot change the PLP to low even if the packet conforms to the configured CIR of the appropriate interface. On the other hand, if an upstream device assigns low PLP to a packet but the packet exceeds the CIR and committed burst size (CBS) of the switch interface, the switch can increase the PLP to medium-high.

Default If you omit the **color-aware** statement, the default behavior is color-aware mode.

Required Privilege Level firewall—To view this statement in the configuration.
firewall-control—To add this statement to the configuration.

Related Documentation

- **color-aware on page 4576**

committed-burst-size

Syntax committed-burst-size *bytes*;

Hierarchy Level [edit firewall three-color-policer *policer-name* single-rate],
[edit firewall three-color-policer *policer-name* two-rate]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Configure the maximum number of bytes allowed for incoming traffic to burst above the committed information rate and still be marked with low packet loss priority (green).

NOTE: When you include the **committed-burst-size** statement in the configuration, you must also include the **committed-information-rate** statement at the same hierarchy level.

Options *bytes*—Number of bytes. You can specify a value in bytes either as a complete decimal number or as a decimal number followed by the abbreviation **k** (1000), **m** (1,000,000), or **g** (1,000,000,000).

Range: 512 bytes through 268435456 bytes (268 MB)

Required Privilege Level firewall—To view this statement in the configuration.
firewall-control—To add this statement to the configuration.

Related Documentation

committed-information-rate

Syntax committed-information-rate *bits-per-second*;

Hierarchy Level [edit firewall three-color-policer *policer-name* single-rate],
[edit firewall three-color-policer *policer-name* two-rate]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Configure the guaranteed bandwidth under normal line conditions and the average rate up to which packets are marked with low packet loss priority (green).

NOTE: When you include the **committed-information-rate** statement in the configuration, you must also include the **committed-burst-size** statement at the same hierarchy level.

Options *bits-per-second*—Number of bits per second. You can specify a value in bits per second either as a complete decimal number or as a decimal number followed by the abbreviation **k** (1000), **m** (1,000,000), or **g** (1,000,000,000).

Range: 32,000 bps through 10,000,000,000 bps (10 gbps)

Required Privilege Level firewall—To view this statement in the configuration.
firewall-control—To add this statement to the configuration.

Related Documentation

excess-burst-size

Syntax excess-burst-size *bytes*;

Hierarchy Level [edit firewall three-color-policer *policer-name* single-rate]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Configure the maximum number of bytes allowed for incoming traffic to burst above the committed information rate and still be marked with medium-high packet loss priority (yellow). Packets that exceed the excess burst size (EBS) are marked with high packet loss priority (red).

NOTE: When you include the **excess-burst-size** statement in the configuration, you must also include the **committed-burst-size** and **committed-information-rate** statements at the same hierarchy level.

Options *bytes*—Number of bytes. You can specify a value in bytes either as a complete decimal number or as a decimal number followed by the abbreviation **k** (1000), **m** (1,000,000), or **g** (1,000,000,000).

Range: 512 bytes through 268435456 bytes (268 MB)

Required Privilege Level firewall—To view this statement in the configuration.
firewall-control—To add this statement to the configuration.

Related Documentation

- Overview of Policers on page 4441

filter-specific

Syntax filter-specific;

Hierarchy Level [edit firewall policer *policer-name*]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Configure a policer to be filter-specific, which means that Junos OS creates only one policer instance regardless of how many times the policer is referenced. If you use a filter-specific policer in multiple terms, both of the following are true:

- Traffic is policed at the aggregate rate. For example, if you create a policer that has a bandwidth limit of 100 Mbps and use the policer in two terms, the total allowed bandwidth for both terms is 100 Mbps—not 100 Mbps for each term.
- The implicit counter counts all the packets are that matched by any of the terms. For example, if you reference the same filter-specific policer in term1 and term2, and term1 matches 1000 packets and term2 matches 500 packets, the implicit counter shows 1500 matches for the policer.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration

Related Documentation

loss-priority high then discard (Three-Color Policer)

Syntax loss-priority high then discard;

Hierarchy Level [edit firewall three-color-policer *policer-name* action]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description For packets with high loss priority, discard the packets. The loss priority setting is not configurable. Include this statement if you do not want the switch to forward packets that have high packet-loss priority.

For single-rate three-color policers, Junos OS assigns high loss priority to packets that exceed the committed information rate and the excess burst size.

For two-rate three-color policers, Junos OS assigns high loss priority to packets that exceed the peak information rate and the peak burst size.

Required Privilege Level firewall—To view this statement in the configuration.
firewall-control—To add this statement to the configuration.

peak-information-rate

Syntax peak-information-rate *bits-per-second*;

Hierarchy Level [edit firewall three-color-policer *policer-name* two-rate]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Configure the maximum achievable rate. Packets that exceed the committed information rate (CIR) but are below the peak information rate (PIR) are marked with medium-high packet loss priority (yellow). Packets that exceed the PIR are marked with high packet loss priority (red). You can configure a discard action for packets that exceed the PIR.

NOTE: When you include the **peak-information-rate** statement in the configuration, you must also include the **committed-information-rate** and **peak-burst-size** statements at the same hierarchy level.

Options *bits-per-second*—Number of bits per second. You can specify a value in bits per second either as a complete decimal number or as a decimal number followed by the abbreviation **k** (1000), **m** (1,000,000), or **g** (1,000,000,000).

Range: 32,000 bps through 10,000,000,000 bps (10 gbps)

Required Privilege Level firewall—To view this statement in the configuration.
firewall-control—To add this statement to the configuration.

Related Documentation

policer

Syntax

```
policer policer-name {
  filter-specific;
  if-exceeding {
    bandwidth-limit bps;
    burst-size-limit bytes;
  }
  then {
    policer-action;
  }
}
```

Hierarchy Level [edit firewall]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Configure policer rate limits and actions. To activate a policer, you must include the **policer** action modifier in the **then** statement in a firewall filter term.

Each policer that you configure includes an implicit counter that counts the number of packets that exceed the rate limits that are specified for the policer. If you use the same policer in multiple terms—either within the same filter or across filters—the policer's implicit counter is used to count packets that are policed in all of these terms. If you want to obtain separate packet counts for each term, use these approaches:

- Configure a unique policer for each term.
- Configure only one policer, but use a unique, explicit counter in each term.

Options ***policer-name***—Name that identifies the policer. The name can contain letters, numbers, hyphens (-), and can be up to 64 characters long.

The remaining statements are explained separately.

Required Privilege Level firewall—To view this statement in the configuration.
firewall-control—To add this statement to the configuration.

Related Documentation

- Configuring Two-Color and Three-Color Policers to Control Traffic Rates on page 4538

single-rate

Syntax

```
single-rate {
  (color-aware | color-blind);
  committed-information-rate bps;
  committed-burst-size bytes;
  excess-burst-size bytes;
}
```

Hierarchy Level [edit firewall three-color-policer *policer-name*]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Configure a single-rate three-color policer in which marking is based on the committed information rate (CIR), committed burst size (CBS), and excess burst size (EBS).

Packets that conform to the CIR or the CBS are assigned low loss priority (green). Packets that exceed the CIR and the CBS but are within the EBS are assigned medium-high loss priority (yellow). Packets that exceed the EBS are assigned high loss priority (red).

Green and yellow packets are always forwarded; this action is not configurable. You can configure red packets to be discarded. By default, red packets are forwarded.

The remaining statements are explained separately.

Options *policer-name*—Name of the three-color policer. Use this name when you apply the policer to an interface.

Required Privilege Level firewall—To view this statement in the configuration.
firewall-control—To add this statement to the configuration.

Related Documentation

then (Policers)

Syntax

```
then {
  policer-action;
}
```

Hierarchy Level [edit firewall policer *policer-name*]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Configure a policer action.

Options *policer-action*—Allowed policer actions are **discard**, **loss-priority high**, and **loss-priority low**. **discard** causes the system to drop traffic that exceeds the rate limits defined by the policer. Use **loss-priority high** to allow the system to forward matching traffic in some cases.

NOTE: **If you specify a policer in an egress firewall filter, the only supported action is discard.**

Required Privilege Level firewall—To view this statement in the configuration.
firewall-control—To add this statement to the configuration.

Configuration Statements for Port Security

circuit-id

Syntax

```
circuit-id {
  prefix hostname;
  use-interface-description;
  use-vlan-id;
}
```

Hierarchy Level

- For platforms with ELS:

  [edit vlans *vlan-name* forwarding-options dhcp-security option-82]

- For platforms without ELS:

  [edit ethernet-switching-options secure-access-port vlan (all | *vlan-name*) dhcp-option82],
  [edit forwarding-options helpers bootp dhcp-option82] ,
  [edit forwarding-options helpers bootp interface *interface-name* dhcp-option82]

Release Information

Statement introduced in Junos OS Release 9.3 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.
Hierarchy level **[edit vlans *vlan-name* forwarding-options dhcp-security]** introduced in Junos OS Release 13.2X50-D10. (See "Getting Started with Enhanced Layer 2 Software" on page 58 for information about ELS.)

Description

Configure the **circuit-id** suboption (suboption 1) of DHCP option 82 (the DHCP relay agent information option) in DHCP packets destined for a DHCP server. This suboption identifies the circuit (the interface, the VLAN, or both) on which the DHCP request arrived.

The remaining statements are explained separately.

Default

If DCHP option 82 is enabled on the switch, the circuit ID is supplied by default in the format ***interface-name*:*vlan-name*** or, on a Layer 3 interface, just ***interface-name***.

Required Privilege Level

system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

dhcp-snooping-file

Syntax

```
dhcp-snooping-file {
  location local_pathname | remote_URL;
  timeout seconds;
  write-interval seconds;
}
```

Hierarchy Level

For platforms without ELS:

[edit ethernet-switching-options secure-access-port]

For platforms with ELS:

[edit system processes] dhcp-service]

Release Information

Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description

Specify a local pathname or remote URL for the DHCP snooping database file to maintain persistence of IP-MAC bindings.

The remaining statements are explained separately.

Default

The IP-MAC bindings in the DHCP snooping database file are not persistent. If the switch is rebooted, the bindings are lost.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

fc-map

Syntax fc-map *fc-map-value*;

Hierarchy Level Original CLI

[edit ethernet-switching options secure-access-port vlan (all | *vlan-name*) examine-fip]

ELS CLI for Platforms that Support FCoE

[edit vlans *vlan-name* forwarding-options fip-security]

NOTE: The fc-map configuration statement is in a different hierarchy on the original CLI than on the Enhanced Layer 2 Software (ELS) CLI.

QFX Series that Support FCoE-FC Gateway Configuration

[edit fc-fabrics *fc-fabric-name* protocols fip]

Release Information Statement introduced in Junos OS Release 10.4 for EX Series switches.
Statement introduced in Junos OS Release 11.1 for the QFX Series.
Statement introduced for the ELS CLI in Junos OS Release 13.2 for the QFX Series.

Description Set the FCoE mapped address prefix (FC-MAP) value for the FCoE VLAN to match the FC switch (or FCoE forwarder) FC-MAP value for the FC fabric. The FC-MAP value is a unique MAC address prefix an FC switch uses to identify FCoE traffic for a given FC fabric (traffic on a particular FCoE VLAN).

You can configure the FC-MAP value or use the default value. The default FC-MAP value is different for VN_Port to VF_Port (VN2VF_Port) FIP snooping (0x0EFC00) than for VN_Port to VN_Port (VN2VN_Port) FIP snooping.

The FC switch provides the FC-MAP value to FCoE nodes (ENodes) in the FIP discovery advertisement message. If the EX Series switch or the QFX Series FCoE VLAN FC-MAP value does not match the FC switch FC-MAP value, neither device discovers the FC switch on that VLAN, and the ENodes on that VLAN cannot access the FC switch. The FC switch accepts only FCoE traffic that uses the correct FC-MAP value as part of the VN_Port MAC address.

When the QFX Series acts as an FCoE-FC gateway, the FC-MAP value for the gateway and the FCoE devices must match the FC switch FC-MAP value in order to communicate with the FC switch.

NOTE: Changing the FC-MAP value causes all logins to drop and forces the ENodes to log in again.

Options *fc-map-value*—FC-MAP value, hexadecimal value preceded by “0x”.

Range: 0x0EFC00 through 0x0EFCFF

Default: 0x0EFC00 for VN2VF_Port FIP snooping0x0EFD00 for VN2VN_Port FIP snooping

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

fcoe-trusted

Syntax

fcoe-trusted;

Hierarchy Level

Original CLI

[edit ethernet-switching-options secure-access-port interface *interface-name*]

ELS CLI for Platforms that Support FCoE

[edit vlans *vlan-name* forwarding-options fip-security interface *interface-name*]

NOTE: The **fcoe-trusted** configuration statement is in a different hierarchy on the original CLI than on the Enhanced Layer 2 Software (ELS) CLI.

QFX Series that Support FCoE-FC Gateway Configuration

[edit fc-fabrics *fc-fabric-name* protocols fip]

Release Information

Statement introduced in Junos OS Release 10.4 for EX Series switches.
Statement introduced in Junos OS Release 11.1 for the QFX Series.
Statement introduced for the FC fabric in Junos OS Release 11.3 for the QFX Series.
Statement introduced for the ELS CLI in Junos OS Release 13.2 for the QFX Series.

Description

Configure the specified 10-Gigabit Ethernet interface to trust Fibre Channel over Ethernet (FCoE) traffic. If an interface is connected to another switch such as an FCoE forwarder (FCF) or a transit switch, you can configure the interface as trusted so that the interface forwards FCoE traffic from the switch to the FCoE devices without installing FIP snooping filters.

(QFX Series FCoE-FC gateway) Configure the specified local Fibre Channel fabric to trust FCoE traffic on all ports in the fabric. Changing the fabric ports from untrusted to trusted removes any existing FIP snooping filters from the ports. Changing the fabric ports from trusted to untrusted by removing the **fcoe-trusted** configuration from the fabric forces all of the FCoE sessions on those ports to log out so that when the ENodes and VN_Ports log in again, the switch can build the appropriate FIP snooping filters.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

mac-move-limit

Syntax mac-move-limit *limit* <fabric-limit *limit*> action *action*;

Hierarchy Level For platforms without ELS:

[edit ethernet-switching-options secure-access-port (all | *vlan-name*)]

For platforms with ELS:

[edit vlans *vlan-name* switch-options],

Release Information Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Specify the number of times a MAC address can move to a new interface (port) in 1 second and the action to be taken by the switch if the MAC address move limit is exceeded.

Default The default move limit is unlimited. The default action is **drop**.

Options **fabric-limit**—Specify the maximum number of moves in a QFabric system. If you do not specify a fabric limit, the value for **mac-move-limit** applies to the QFabric system.

limit—Maximum number of moves to a new interface per second.

action ***action***—(Optional) Action to take when the MAC address move limit is reached:

- **drop**—Drop the packet and generate an alarm, an SNMP trap, or a system log entry. This is the default.
- **log**—Do not drop the packet but generate an alarm, an SNMP trap, or a system log entry.
- **none**—No action.
- **shutdown**—Disable the interface and generate an alarm. If you have configured the switch with the **port-error-disable** statement, the disabled interfaces recover automatically upon expiration of the specified disable timeout. If you have not configured the switch for autorecovery from port error disabled conditions, you can bring up the disabled interfaces by running the **clear-ethernet-switch-port** command.

Required Privilege Level system—To view this statement in the configuration.
system–control—To add this statement to the configuration.

Related Documentation

port-error-disable

Syntax

```
port-error-disable {
  (disable-timeout seconds | recovery-timeout seconds);
}
```

Hierarchy Level

- For platforms without ELS:

  [edit ethernet-switching-options]

- For platforms with ELS:

  [edit switch-options]

Release Information Statement introduced in Junos OS Release 11.1 on the QFX Series.

Description Disable rather than block an interface when enforcing MAC limiting, MAC move limiting, and storm control, and allow the interface to recover automatically from the error condition after a specified period of time:

NOTE: The **port-error-disable** configuration does not apply to preexisting error conditions. It affects only error conditions that are detected after you enable and commit the **port-error-disable** statement. To clear a preexisting error condition and restore the interface to service, use the clear ethernet-switching port-error command.

- If you enable the mac-limit statement with the **shutdown** option and also enable the **port-error-disable** statement, the switch disables (rather than shuts down) the interface when the MAC address limit is reached.
- If you have enabled the mac-move-limit statement with the **shutdown** option and you enable the **port-error-disable** statement, the switch disables (rather than shuts down) the interface when the maximum number of moves to a new interface is reached.
- If you enable the storm-control statement with the **action-shutdown** option and you also enable **port-error-disable**, the switch disables (rather than shuts down) the interface when broadcast traffic and unknown unicast traffic exceed the specified levels.

Default Not enabled.

Required Privilege Level routing—To view this statement in the configuration.
routing–control—To add this statement to the configuration.

vendor-id

Syntax vendor-id <*string*>;

Hierarchy Level

- For platforms with ELS:

  [edit vlans *vlan-name* forwarding-options dhcp-security option-82]

- For platforms without ELS:

  [edit ethernet-switching-options secure-access-port vlan (all | *vlan-name*) dhcp-option82],
  [edit forwarding-options helpers bootp dhcp-option82],
  [edit forwarding-options helpers bootp interface *interface-name* dhcp-option82]

Release Information Statement introduced in Junos OS Release 9.3 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.
Hierarchy level **[edit vlans *vlan-name* forwarding-options dhcp-security]** introduced in Junos OS Release 13.2X50-D10. (See "Getting Started with Enhanced Layer 2 Software" on page 58 for information about ELS.)

Description Insert a vendor ID in the DHCP option 82 information in a DHCP request packet header before forwarding or relaying the request to a DHCP server.

Default If **vendor-id** is not explicitly configured for DHCP option 82, then no vendor ID is set.

Options ***string***—(Optional) A single string that designates the vendor ID.

Range: 1–255 characters

Default: If you specify **vendor-id** with no ***string*** value, then the default vendor ID **Juniper Networks** is configured.

Required Privilege Level system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

write-interval

Syntax write-interval *seconds*;

Hierarchy Level For platforms without ELS:

[edit ethernet-switching-options secure-access-port dhcp-snooping-file]

For platforms with ELS:

[edit system processes] dhcp-service dhcp-snooping-file]

Release Information Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Specify how frequently the switch writes the database entries from memory into the specified DHCP snooping database file.

Default None

Options *seconds*—Value in seconds.

Range: 60 through 86400

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Understanding DHCP Snooping for Port Security on page 4456

Configuration Statements for Port Security (Original CLI Only)

allowed-mac

Syntax allowed-mac *mac-address-list*

Hierarchy Level [edit ethernet-switching-options secure-access-port interface (all | *interface-name*)]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Specify particular MAC addresses to be added to the MAC address cache.

NOTE: Although this configuration restricts the addresses that can be added to the MAC address cache, it does not block the switch from receiving Layer 2 control packets—such as Link Layer Discovery Protocol (LLDP) packets—transmitted from MAC addresses that are not specified in the list of allowed MAC addresses. Control packets do not undergo the MAC address check, and they are therefore included in the statistics of packets received, though, they are not forwarded to another destination.

Default Allowed MAC addresses take precedence over dynamic MAC values. For example, if the **mac-limit** statement is set to four and three allowed MACs are configured, only one dynamic MAC can be learned on that interface.

Options *mac-address-list*—One or more MAC addresses configured as allowed MAC addresses for a specified interface or all interfaces.

Required Privilege Level routing—To view this statement in the configuration.
routing–control—To add this statement to the configuration.

arp-inspection

Syntax

```
(arp-inspection | no-arp-inspection) {
  forwarding-class (for DHCP Snooping or DAI Packets) class-name;
}
```

Hierarchy Level [editethernet-switching-options secure-access-port vlan (all | *vlan-name*)]

Release Information Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Perform dynamic ARP inspection on all VLANs or on the specified VLAN.

- **arp-inspection**—Enable ARP inspection.

NOTE: When ARP inspection is enabled, the switch logs ARP request packets that it rejects.

- **no-arp-inspection**—Disable ARP inspection.

Default Disabled.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

dhcp-trusted

Syntax (dhcp-trusted | no-dhcp-trusted);

Hierarchy Level [edit ethernet-switching-options secure-access-port interface (Access Port Security) (all | *interface-name*)]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Allow or deny DHCP responses from the specified interfaces (ports) or all interfaces.

- **dhcp-trusted**—Allow DHCP responses.
- **no-dhcp-trusted**—Deny DHCP responses.

Default Trusted for trunk ports, untrusted for access ports.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

dhcp-option82

Syntax

```
dhcp-option82 {
  circuit-id {
    prefix hostname;
    use-interface-description;
    use-vlan-id;
  }
  remote-id {
    prefix hostname | mac | none;
    use-interface-description;
    use-string string;
  }
  vendor-id <string>;
}
```

Hierarchy Level

[edit ethernet-switching-options secure-access-port vlan (all | *vlan-name*)]
[edit forwarding-options helpers bootp]
[edit forwarding-options helpers bootp interface *interface-name*]

Release Information

Statement introduced in Junos OS Release 9.3 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.

Description

When the switch receives a DHCP request from a DHCP client connected on one of the switch's interfaces, have the switch insert DHCP option 82 (also known as the DHCP relay agent information option) information in the DHCP request packet header before it forwards or relays the request to a DHCP server. The server uses the option 82 information, which provides details about the circuit and host the request came from, in formulating the reply; the server does not, however, make any changes to the option 82 information in the packet header. The switch receives the reply and then removes the DHCP option 82 information before forwarding the reply to the client.

The remaining statements are explained separately.

Default

Insertion of DHCP option 82 information is not enabled.

Required Privilege Level

system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

Related Documentation

- RFC 3046, *DHCP Relay Agent Information Option*, at http://tools.ietf.org/html/rfc3046.

disable-timeout (Port Error Disable)

Syntax disable-timeout *timeout*;

Hierarchy Level [edit ethernet-switching-options port-error-disable]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Specify how long Ethernet switching interfaces remain in a disabled state due to MAC limiting, MAC move limiting, or storm control errors.

NOTE: If you modify an existing timeout value, the new timeout value does not affect currently disabled interfaces are configured for automatic recovery. The new timeout value applies only to subsequent port errors. Run the clear ethernet-switching port-error command to restore currently disabled interfaces.

Default The disable timeout statement is not enabled.

Options *timeout*—Time, in seconds, that an interface remains disabled. The disabled interface automatically returns to service when the specified time expires.

Range: 10 through 3600 seconds

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

examine-dhcp

Syntax (examine-dhcp | no-examine-dhcp);

Hierarchy Level [edit ethernet-switching-options secure-access-port vlan (all | *vlan-name*)]

Release Information Statement introduced in Junos OS Release 12.1 for the QFX Series

Description Enable DHCP snooping on all VLANs or on the specified VLAN.

- examine-dhcp—Enable DHCP snooping.

NOTE: When DHCP snooping is enabled, the switch logs DHCPDISCOVER packets that it rejects.

- no-examine-dhcp—Disable DHCP snooping.

Default Disabled.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

examine-fip

Syntax

```
examine-fip {
  examine-vn2vn {
    beacon-period milliseconds;
  }
  fc-map fc-map-value;
}
```

Hierarchy Level [edit ethernet-switching-options secure-access-port vlan (all | *vlan-name*)]

Release Information

Statement introduced in Junos OS Release 10.4 for EX Series switches.
Statement introduced in Junos OS Release 11.1 for the QFX Series.
Statement **examine-vn2vn** introduced in Junos OS Release 12.2 for the QFX Series.

Description

NOTE: This statement supports the original CLI. If your switch runs the Enhanced Layer 2 Software (ELS) CLI, see examine-vn2vf for VN_Port to VF_Port (VN2VF_Port) FIP snooping, and see examine-vn2vn for VN_Port to VN_Port (VN2VN_Port) FIP snooping. For ELS details, see "Getting Started with Enhanced Layer 2 Software" on page 58.

Enable FIP snooping on a specified VLAN. Ensure that the VLAN is a dedicated FCoE VLAN that transports only FCoE traffic.

(QFX Series only) Enable VN2VN_Port FIP snooping on the specified VLAN. The VLAN must be a dedicated FCoE VLAN that transports only VN2VN_Port traffic. One FCoE VLAN cannot support both VN2VF_Port FIP snooping and VN2VN_Port FIP snooping. Configure separate, dedicated FCoE VLANs for VN2VN_Port FIP snooping and VN2VN_Port FIP snooping.

The remaining statements are explained separately.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

forwarding-class (for DHCP Snooping or DAI Packets)

Syntax forwarding-class class *class-name*;

Hierarchy Level [edit ethernet-switching-options secure-access-port vlan (all | *vlan-name*) (examine-dhcp | arp-inspection)]

Release Information Statement introduced in Junos OS Release 11.2 for EX Series switches.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Assign a user-defined or a predefined forwarding class to the packets that have been checked for DHCP snooping or dynamic ARP inspection (DAI).

NOTE: To assign a user-defined class, you must first configure the user-defined class by using the *forwarding-classes* configuration statement at the [edit *class-of-service*] hierarchy level.

Default Disabled.

Options ***class-name***—Name of the forwarding class. The forwarding class can be one of the predefined forwarding classes (best-effort, assured-forwarding, expedited-forwarding, network-control) or it can be a user-defined forwarding class.

Required Privilege Level system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

interface (Secure Access Port)

Syntax

```
interface (all | interface-name) {
  allowed-mac mac-address-list;
  (dhcp-trusted | no-dhcp-trusted);
  mac-limit limit action action;
  no-allowed-mac-log;
  static-ip  ip-address {
    vlan vlan-name;
    mac mac-address;
  }
}
```

Hierarchy Level

[edit ethernet-switching-options secure-access-port]

Release Information

Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description

Apply port security features to all interfaces or to the specified interface.

The remaining statements are explained separately.

Options

all—Apply port security features to all interfaces. Does not apply to QFabric systems.

interface-name—Apply port security features to the specified interface.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

location

Syntax location *local_pathname* | *remote_URL*;

Hierarchy Level [edit ethernet-switching-options secure-access-port dhcp-snooping-file]

Release Information Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Specify either a local pathname or a remote URL as the location in which to store the DHCP snooping database.

Options ***local_pathname* | *remote_URL*** —Location for storing the DHCP snooping database.

- ***local_pathname*** —Use ***/path*** to store the database on a local switch.
- ***remote_URL*** —Use **ftp://*ip-address*** or **ftp:// *hostname*/*path*** to store the database at a remote location.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

mac

Syntax mac *mac-address*;

Hierarchy Level [edit ethernet-switching-options secure-access-port interface (Access Port Security) (all | *interface-name*) static-ip *ip-address* vlan (DHCP Bindings on Access Ports) *vlan-name*]
[edit vlans *vlan-name* forwarding-options dhcp-security group *group-name* interface *interface-name* static-ip *ip-address*]

Release Information Statement introduced in Junos OS Release 11.1 on the QFX Series switches.

Description Specify a media access control (MAC) address (hardware address) for the specified static IP address.

Options ***mac-address***—Value in hexadecimal format.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

mac-limit

Syntax

```
mac-limit limit {
  <action action>;
}
```

Hierarchy Level [edit ethernet-switching-options secure-access-port interface (all | *interface-name*)]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Specify the number of MAC addresses that can be dynamically added to the MAC address cache for this access interface (port) and the action to be taken if the limit is exceeded.

Default The default action is **drop**.

Options *limit*—Maximum number of MAC addresses.

action ***action***—(Optional) Action to take when the MAC address limit is exceeded:

- **drop**—Drop the packet and generate a system log entry. This is the default.
- **log**—Do not drop the packet but generate a system log entry.
- **none**—No action.
- **shutdown**—Disable the interface and generate an alarm. If you configure the switch with the port-error-disable statement, the disabled interface recovers automatically upon expiration of the specified timeout. If this statement is not configured, you can bring up the disabled interfaces by running the clear ethernet-switching port-error command.

Required Privilege Level routing—To view this statement in the configuration.
routing–control—To add this statement to the configuration.

no-dhcp-trusted

Syntax (dhcp-trusted | no-dhcp-trusted);

Hierarchy Level [edit ethernet-switching-options secure-access-port interface (Access Port Security) (all | *interface-name*)]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Port security features, such as DHCP snooping and dynamic ARP inspection inspect packets only on untrusted interfaces.

Allow or deny DHCP responses from the specified interfaces (ports) or all interfaces.

- **dhcp-trusted**—Allow DHCP responses.
- **no-dhcp-trusted**—Deny DHCP responses.

Default Trusted for trunk ports, untrusted for access ports.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

prefix (Remote ID for Option 82)

Syntax prefix hostname | mac | none;

Hierarchy Level [edit ethernet-switching-options secure-access-port vlan (all | *vlan-name*) dhcp-option82 remote-id]
[edit forwarding-options helpers bootp dhcp-option82 remote-id]
[edit forwarding-options helpers bootp interface *interface-name* dhcp-option82 remote-id]

Release Information Statement introduced in Junos OS Release 9.3 for EX Series switches.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Configure an optional prefix for the remote ID suboption in the DHCP option 82 information that is inserted by the switch into the packet header of a DHCP request before it forwards or relays the request to a DHCP server.

Default If **prefix** is not explicitly specified, no prefix is appended to the remote ID.

Options **hostname**—Name of the host system (the switch) that is forwarding or relaying the DHCP request from the DHCP client to the DHCP server.

mac—MAC address of the host system (the switch) that is forwarding or relaying the DHCP request from the DHCP client to the DHCP server.

none—No prefix is applied to the remote ID.

Required Privilege Level system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

remote-id

Syntax

```
remote-id {
  host-name host-name;
  prefix hostname | mac | none; | host
  use-interface-description;
  use-string string;
}
```

Hierarchy Level

- For platforms with ELS:

  [edit vlans *vlan-name* forwarding-options dhcp-security option-82]

- For platforms without ELS:

  [edit ethernet-switching-options secure-access-port vlan (all | *vlan-name*) dhcp-option82],
  [edit forwarding-options helpers bootp dhcp-option82],
  [edit forwarding-options helpers bootp interface *interface-name* dhcp-option82]

Release Information

Statement introduced in Junos OS Release 9.3 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.
Hierarchy level **[edit vlans *vlan-name* forwarding-options dhcp-security option-82]** introduced in Junos OS Release 13.2X50-D10. (See "Getting Started with Enhanced Layer 2 Software" on page 58 for information about ELS.)

Description

Insert the **remote-id** suboption of DHCP option 82 (also known as the DHCP relay agent information option) in DHCP request packet headers before forwarding or relaying requests to a DHCP server. This suboption provides a trusted identifier for the host system that has forwarded or relayed requests to the server.

The remaining statements are explained separately, and their availability depends on the hierarchy level at which **remote-id** is specified, as follows:

- The statement prefix is *not* supported at the **[edit vlans *vlan-name* forwarding-options dhcp-security option-82]** hierarchy level.
- The statement **host-name** is supported *only* at the **[edit vlans *vlan-name* forwarding-options dhcp-security option-82]** hierarchy level.

Default

If **remote-id** is not explicitly set, no remote ID value is inserted in the DHCP request packet header.

If **remote-id** is explicitly set, but is not qualified by a keyword:

- At the **[edit vlans *vlan-name* forwarding-options dhcp-security]** hierarchy level, the default keyword value is *interface-name*.
- At all other hierarchy levels, the **remote-id** default keyword value of is the MAC address of the switch.

Required Privilege Level

system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

secure-access-port

Syntax

```
secure-access-port {
  deactivate;
    dhcp-snooping-file {
    location (local_pathname | remote_URL);
    timeout seconds;
    write-interval seconds;
  }
  interface (all | interface-name) {
    allowed-mac mac-address-list;
    (dhcp-trusted | no-dhcp-trusted);
    fcoe-trusted;
    mac-limit limit {
      <action action>;
    }
    no-allowed-mac-log;
    persistent-learning;
    static-ip  ip-address {
      vlan vlan-name;
      mac mac-address;
    }
  }
  vlan (all | vlan-name) {
    (arp-inspection | no-arp-inspection) [
      forwarding-class (for DHCP Snooping or DAI Packets) class-name;
    }
    dhcp-option82 {
      circuit-id {
        prefix (Circuit ID for Option 82) hostname;
        use-interface-description;
        use-vlan-id;
      }
      remote-id {
        prefix (Remote ID for Option 82) hostname | mac | none;
        use-interface-description;
        use-string string;
      }
      vendor-id <string>;
    }
    (examine-dhcp | no-examine-dhcp) {
      forwarding-class (for DHCP Snooping or DAI Packets) class-name;
    }
    examine-fip {
      examine-vn2vn {
        beacon-period milliseconds;
      }
      fc-map fc-map-value;
    }
    mac-move-limit limit action action;
  }
```

Hierarchy Level [edit ethernet-switching-options]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Configure port security features, including MAC limiting and whether interfaces can receive DHCP responses, and apply dynamic ARP inspection, DHCP snooping, DHCP option 82, and MAC move limiting on no VLANs, specific VLANs, or all VLANs.

The remaining statements are explained separately.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

static-ip

Syntax

```
static-ip ip-address;
  mac mac-address;
  vlan vlan-name;
}
```

Hierarchy Level [edit ethernet-switching-optionssecure-access-port interface (all | *interface-name*)]
[edit vlans *vlan-name* forwarding-options dhcp-security group *group-name* interface *interface-name*]

Release Information Statement introduced in Junos OS Release 12.1 on the QFX Series.

Description Bind a static IP address to a MAC address in the DHCP snooping database.

Options *ip-address*—IP address assigned to the device connected on the specified interface.

The remaining statements are explained separately.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Configuring Static IP Addresses for DHCP Bindings on Access Ports (CLI Procedure) on page 4550

timeout (DHCP Snooping)

Syntax timeout *seconds*;

Hierarchy Level [edit ethernet-switching-options secure-access-port dhcp-snooping-file]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Specify a timeout value for remote read and write operations. This value determines the amount of time that the switch waits for a remote system to respond when the DHCP snooping database is stored on a remote FTP site.

Default None

Options ***seconds*** —Value in seconds.

Range: 10 through 3600

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Understanding DHCP Snooping for Port Security on page 4456

use-interface-description

Syntax use-interface-description;

Hierarchy Level

- For platforms with ELS:

  [edit vlans *vlan-name* forwarding-options dhcp-security option-82 circuit-id]

- For platforms without ELS:

  [edit ethernet-switching-options secure-access-port vlan (all | *vlan-name*) dhcp-option82 circuit-id],
  [edit forwarding-options helpers bootp dhcp-option82 circuit-id],
  [edit forwarding-options helpers bootp interface *interface-name* dhcp-option82 circuit-id],
  [edit ethernet-switching-options secure-access-port vlan (all | *vlan-name*) dhcp-option82 remote-id],
  [edit forwarding-options helpers bootp dhcp-option82 remote-id],
  [edit forwarding-options helpers bootp interface *interface-name* dhcp-option82 remote-id]

Release Information Statement introduced in Junos OS Release 9.3 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.
Hierarchy level **[edit vlans *vlan-name* forwarding-options dhcp-security]** introduced in Junos OS Release 13.2X50-D10. (See "Getting Started with Enhanced Layer 2 Software" on page 58 for information about ELS.)

Description Use the interface description rather than the interface name (which is the default value) in the circuit ID or remote ID value in the DHCP option 82 information.

Required Privilege Level system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

Related Documentation

vlan (Static IP)

Syntax vlan *vlan-name*;

Hierarchy Level [edit ethernet-switching-options secure-access-port interface (all | *interface-name*) static-ip *ip-address*]

Release Information Statement introduced in Junos OS Release 12.1 for the QFX Series switches.

Description Associate a static IP address with the specified VLAN.

Options ***vlan-name***—Name of a VLAN associated with the specified interface.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Configuring Static IP Addresses for DHCP Bindings on Access Ports (CLI Procedure) on page 4550

vlan (Secure Access Port)

Syntax

```
vlan (all | vlan-name) {
  examine-fip {
    examine-vn2vn {
      beacon-period milliseconds;
    }
    fc-map fc-map-value;
  }
  dhcp-option82
    circuit-id {
      prefix (Circuit ID for Option 82) hostname;
      use-interface-description;
      use-vlan-id;
    }
    remote-id {
      prefix (Remote ID for Option 82) hostname | mac | none;
      use-interface-description;
      use-string string;
    }
    vendor-id <string>;
  }
  (arp-inspection | no-arp-inspection);
    circuit-id {
      prefix (Circuit ID for Option 82) hostname;
      use-interface-description;
      use-vlan-id;
    }
    remote-id {
      prefix (Remote ID for Option 82) hostname | mac | none;
      use-interface-description;
      use-string string;
    }
  vendor-id <string>;
  }
  (examine-dhcp | no-examine-dhcp);
  mac-move-limitlimit action action;
}
```

Hierarchy Level [edit ethernet-switching-options secure-access-port]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Apply DHCP snooping, dynamic ARP inspection (DAI), DHCP option 82, and MAC move limiting.

TIP: To display a list of all configured VLANs on the system, including VLANs that are configured but not committed, type **?** after **vlan** or **vlans** in your configuration mode command line. Note that only one VLAN is displayed for a VLAN range.

The remaining statements are explained separately.

Options **all**—Apply DHCP snooping, DAI, DHCP option 82, and MAC move limiting to all VLANs.

vlan-name —Apply DHCP snooping, DAI, DHCP option 82, and MAC move limiting to the specified VLAN.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Configuration Statements for Port Security (ELS CLI Only)

accept-source-mac

Syntax

```
accept-source-mac {
  mac-address mac-address {
    policer {
      input cos-policer-name;
      output cos-policer-name;
    }
  }
}
```

Hierarchy Level [edit interfaces *interface-name* unit *logical-unit-number*],
[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.1X48 for PTX Packet Transport Routers.
Statement introduced in Junos OS Release 13.2 for the QFX Series.

Description For Gigabit Ethernet intelligent queuing (IQ) interfaces only, accept traffic from and to the specified remote media access control (MAC) address.

The **accept-source-mac** statement is equivalent to the **source-address-filter** statement, which is valid for aggregated Ethernet, Fast Ethernet, and Gigabit Ethernet interfaces only. To allow the interface to receive packets from specific MAC addresses, include the **accept-source-mac** statement.

On untagged Gigabit Ethernet interfaces, you should not configure the **source-address-filter** statement and the **accept-source-mac** statement simultaneously. On tagged Gigabit Ethernet interfaces, you should not configure the **source-address-filter** statement and the **accept-source-mac** statement with an identical MAC address specified in both filters.

The statements are explained separately.

NOTE: The policer statement is not supported on PTX Series Packet Transport Routers.

NOTE: On QFX platforms, if you configure source MAC addresses for an interface using the static-mac or persistent-learning statements and later configure a different MAC address for the same interface using the **accept-source-mac** statement, the MAC addresses that you previously configured for the interface remain in the ethernet-switching table and can still be used to send packets to the interface.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

arp-inspection

Syntax

```
arp-inspection {
  forwarding-class class-name;
}
```

Hierarchy Level

- For platforms with ELS:

  [edit vlans *vlan-name* forwarding-options dhcp-security],
  [edit forwarding-options dhcp-relay]

- For platforms without ELS:

  [edit ethernet-switching-options secure-access-port vlan (all | *vlan-name*)],
  [edit forwarding-options dhcp-relay]

Release Information

Statement introduced in Junos OS Release 9.0 for EX Series switches.
Hierarchy level **[edit vlans *vlan-name* forwarding-options dhcp-security]** introduced in Junos OS Release 13.2X50-D10. (See "Getting Started with Enhanced Layer 2 Software" on page 58 for information about ELS.)
Statement introduced in Junos OS Release 13.2 for the QFX series.

Description

Perform dynamic ARP inspection (DAI) on all VLANs or on the specified VLAN.

When DAI is enabled, the switch logs invalid ARP packets that it receives on each interface, along with the sender's IP and MAC addresses. ARP probe packets are not subjected to dynamic ARP inspection. The switch always forwards such packets.

NOTE: If you configure DAI at the **[edit vlans *vlan-name* forwarding-options dhcp-security]** hierarchy level:

- DAI can be configured only for a specific VLAN, not for a list or a range of VLAN IDs.
- DHCP snooping is automatically enabled on the specified VLAN.
- The **forwarding-class** statement is not available at the **[edit vlans *vlan-name* forwarding-options dhcp-security]** hierarchy level.

See *Enabling Dynamic ARP Inspection (CLI Procedure)* for more information about this configuration.

NOTE: On EX9200 switches, DAI is not supported in an MC-LAG scenario.

The remaining statement is explained separately.

Default

Disabled.

Required Privilege Level

system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

        logical-system-name;
        routing-instance-name;
      }
      use-interface-description (device | logical);
      use-vlan-id;
    }
    remote-id {
      host-name hostname;
      use-interface-description (device | logical);
      use-string string;
    }
    vendor-id {
      use-string string;
    }
  }
}
```

Hierarchy Level [edit vlans *vlan-name* forwarding-options]

Release Information Statement introduced in Junos OS Release 13.2X50-D10 for EX Series switches.
Statement introduced in Junos OS Release 13.2 for the QFX series.

Description Configure port security features on the switch. DHCP snooping is enabled automatically if you configure any of the following port security features within this hierarchy:

- Dynamic ARP inspection (DAI)
- IP source guard
- DHCP option 82

- Static IP

For switches that support DHCPv6, both DHCP snooping and DHCPv6 snooping are enabled automatically if you configure any of the features listed above or any of the following IPv6 features:

- IPv6 Neighbor Discovery inspection
- IPv6 source guard
- Static IPv6

NOTE: On EX9200 switches, DHCP snooping, DAI, and IP source guard are not supported in an MC-LAG scenario.

The remaining statements are explained separately.

Required Privilege Level

interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

dhcp-service

Syntax

```
dhcp-service {
  dhcp-snooping-file (local_pathname | remote_URL);
    write-interval interval;
  }
```

Hierarchy Level [edit system processes]

Release Information Statement introduced in Junos OS Release 13.2X50-D10 for EX Series switches.
Statement introduced in Junos OS Release 13.2 for the QFX Series.

Description Enable DHCP services on the switch. DHCP services automate network-parameter assignment to network devices. The DHCP service process is enabled by default on your switch. However, by default, IP-MAC bindings in the DHCP snooping database do not persist. You can configure the IP-MAC bindings in the DHCP database to persist through switch reboots by configuring a storage location for the DHCP database file. When specifying the location for the DHCP database, you must also specify how frequently the switch writes the database entries into the DHCP snooping database file.

The remaining statements are explained separately.

Required Privilege Level admin—To view this statement in the configuration.
admin-control—To add this statement to the configuration.

Related Documentation

- *Configuring Persistent Bindings in the DHCP or DHCPv6 Snooping Database (CLI Procedure)*

group (DHCP Security)

Syntax

```
group group-name {
  interface interface-name {
    static-ip ip-address {
      mac mac-address;
    }
    static-ipv6 ip-address {
      mac mac-address;
    }
  }
  overrides {
    no-option37;
    no-option-82;
    trusted;
    untrusted;
  }
}
```

Hierarchy Level [edit vlans *vlan-name* forwarding-options dhcp-security]

Release Information Statement introduced in Junos OS Release 13.2X50-D10 for EX Series switches.
Statement introduced in Junos OS Release 13.2 for the QFX series.
Support for the **static-ipv6** and **no-option37** statements introduced in Junos OS Release 13.2X51-D20 for EX Series switches.

Description Specify the name of a group of access interfaces that you want to configure for DHCP security attributes that are different from the attributes set for other interfaces in the VLAN. A group must contain at least one interface. The remaining statements are explained separately.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 8.4.
Support for the **switch-options** statement added in Junos OS Release 9.2.
Support for top-level configuration for the **virtual-switch** type of routing instance added in Junos OS Release 9.2. In Junos OS Release 9.1 and earlier, the routing instances hierarchy supported this statement only for a VPLS instance or a bridge domain configured within a virtual switch.
Support for logical systems added in Junos OS Release 9.6.
Support at [edit switch-options], [edit switch-options interface *interface-name*], [edit vlans *vlan-name* switch-options], and [edit vlans *vlan-name* switch-options interface *interface-name*] hierarchy levels introduced in Junos OS Release 12.3R2 for EX Series switches.
Support at hierarchy levels under **[edit vlans *vlan-name*]** introduced in Junos OS Release 13.2X50-D10 for EX Series switches.
Statement introduced in Junos OS Release 13.2 for the QFX Series.

Description (MX Series routers, EX Series switches, and the QFX Series) Configure a limit to the number of MAC addresses that can be learned from a bridge domain or VLAN, virtual switch, or set of bridge domains or VLANs.

Default All devices except the EX Series switches: 1024 MAC addresses for each logical interface; EX Series switches: 65,536 MAC addresses for each interface and VLAN.

Options ***limit***—Maximum number of MAC addresses learned from an interface.

Range: 1 through 131,071 MAC addresses per interface, or 1 through 65,535 MAC addresses per interface

The remaining statement is explained separately.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

no-dhcp-snooping

Syntax no-dhcp-snooping;

Hierarchy Level [edit vlans *vlan-name* forwarding-options dhcp-security]

Release Information Statement introduced in Junos OS Release 13.2X50-D10 for EX Series switches.
Statement introduced in Junos OS Release 13.2 for the QFX series.

Description Disable DHCP snooping for the specified VLAN.

NOTE: Explicitly disabling DHCP snooping also disables any other port security features that you have enabled under **[edit vlans *vlan-name* forwarding-options dhcp-security]**, including dynamic ARP inspection (DAI) and IP source guard for the specified VLAN.

There is no configuration statement that explicitly enables DHCP snooping.

Default DHCP snooping is not enabled.

NOTE: Junos OS for EX Series switches with support for the Enhanced Layer 2 Software (ELS) configuration style does not have a configuration statement that explicitly enables DHCP snooping.

DHCP snooping is enabled automatically by Junos OS if any of the following is configured at the **[edit vlans *vlan-name* forwarding-options dhcp-security]** hierarchy level:

- DAI
- IP source guard
- Static IP
- DHCP option 82

Required Privilege Level system—To view this statement in the configuration.

no-option-82

Syntax

no-option-82;

Hierarchy Level

[edit vlans *vlan-name* forwarding-options dhcp-security group *group-name* overrides]

Release Information

Statement introduced in Junos OS Release 13.2X50-D10 for EX Series switches.
Statement introduced in Junos OS Release 13.2 for the QFX series.

Description

Configure a specific group of one or more access interfaces within the VLAN *not* to transmit DHCP option 82 information, even if the VLAN is configured to use option 82.

Required Privilege Level

interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

option-82

Syntax

```
option-82 {
  circuit-id {
    prefix (host-name | routing-instance-name);
    use-interface-description;
    use-vlan-id;
  }
  remote-id {
    host-name;
    use-interface-description;
    use-string string;
  }
  vendor-id;
    use-string string;
  }
```

Hierarchy Level

[edit vlans *vlan-name* forwarding-options dhcp-security]

Release Information

Statement introduced in Junos OS Release 13.2X50-D10 for EX Series switches.
Statement introduced in Junos OS Release 13.2 for the QFX series.

Description

When the switch receives a DHCP request from a DHCP client connected on one of the switch's interfaces, have the switch insert DHCP option 82 (also known as the DHCP relay agent information option) information in the DHCP request packet header before it forwards or relays the request to a DHCP server. The server uses the option 82 information, which provides details about the circuit and host the request came from, in formulating the reply; the server does not, however, make any changes to the option 82 information in the packet header. The switch receives the reply and then removes the DHCP option 82 information before forwarding the reply to the client.

The remaining statements are explained separately.

Default

Insertion of DHCP option 82 information is not enabled.

Required Privilege Level

system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

overrides (DHCP Security)

Syntax overrides (trusted | untrusted |no-option37 | no-option-82);

Hierarchy Level [edit vlans *vlan-name* forwarding-options dhcp-security group *group-name*]

Release Information Statement introduced in Junos OS Release 13.2X50-D10 for EX Series switches.
Statement introduced in Junos OS Release 13.2 for the QFX series.
Support for the **no-option37** option introduced in Junos OS Release 13.2X51-D20 for EX Series switches.

Description Modify selected attributes of a specific interface within a group of interfaces that is configured within a specified VLAN.

Options **no-option37**—The interface specified in this group does not support DHCPv6 option 37.

no-option82—The interface specified in this group does not support DHCP option 82.

trusted—The interface specified in this group is trusted. DHCP snooping does not apply to the trusted interface. Likewise, DAI and IP source guard—even if they are enabled for the VLAN—do not apply to the interface that is configured with the **overrides** and the **trusted** options. Access interfaces are untrusted by default.

untrusted—(Only for EX9200) The interface specified in this group is untrusted. Trunk interface are trusted by default. Access interfaces are untrusted by default.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

recovery-timeout

Syntax recovery-timeout *seconds*;

Hierarchy Level [edit interfaces *interface-name* family ethernet-switching]

Release Information Statement introduced in Junos OS Release 13.2X50-D10 for EX Series switches.
Statement introduced in Junos OS Release 13.2 for the QFX Series.

Description Disable rather than block an interface when enforcing MAC limiting, MAC move limiting, or rate-limiting configuration options for shutting down the interface, and allow the interface to recover automatically from the error condition after the specified period of time:

- If you have enabled MAC limiting with the **shutdown** option and you enable **recovery-timeout**, the switch disables (rather than shuts down) the interface when the MAC address limit is reached.
- If you have enabled MAC move limiting (Not supported on EX9200) with the **shutdown** option and you enable **recovery-timeout**, the switch disables (rather than shuts down) the interface when the maximum number of moves to a new interface is reached.
- If you have enabled storm control with the **action-shutdown** option and you enable **recovery-timeout** the switch disables (rather than shuts down) the interface when applicable traffic exceeds the specified levels. Depending upon the configuration, applicable traffic could include broadcast, unknown unicast, and multicast traffic.

NOTE: The recovery-timeout configuration does not apply to pre-existing error conditions. It impacts only error conditions that are detected after recovery-timeout has been enabled and committed. To clear a pre-existing error condition and restore the interface to service, use the operational mode command clear ethernet-switching recovery-timeout.

Default Not enabled.

Options *seconds*— Number of seconds that the interface remains in a disabled state due to a port error prior to automatic recovery.

Range: **10** through **3600**

Required Privilege Level system—To view this statement in the configuration.
system–control—To add this statement to the configuration.

static-ip

Syntax

```
static-ip ip-address {
  vlan  vlan-name;
  mac mac-address;
}
```

Hierarchy Level

- For platforms with ELS:

  [edit vlans *vlan-name* forwarding-options dhcp-security group *group-name* interface *interface-name*]

- For platforms without ELS:

  [edit ethernet-switching-options secure-access-port interface (all | *interface-name*)]

Release Information

Statement introduced in Junos OS Release 9.2 for EX Series switches.
Hierarchy level **[edit vlans *vlan-name* forwarding-options dhcp-security]** introduced in Junos OS Release 13.2X50-D10. (See "Getting Started with Enhanced Layer 2 Software" on page 58 for information about ELS.)

Description

Configure a static IP address to MAC address (IP-MAC) binding to be added to the DHCP snooping database.

NOTE: The VLAN is specified at the higher hierarchy level when **static-ip** is configured at **[edit vlans *vlan-name* forwarding-options dhcp-security group *group-name* interface *interface-name*]**.

Options

ip-address—Static IP address assigned to a device connected on the specified interface.

mac*mac-address*—Static MAC address assigned to a device connected on the specified interface.

The remaining statements are explained separately.

Required Privilege Level

system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

action-shutdown

Syntax action-shutdown;

Hierarchy Level For platforms without ELS:

[edit ethernet-switching-options storm-control]

For platforms with ELS:

[edit forwarding-options storm-control-profiles]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Shut down or disable interfaces when the storm control level is exceeded, as follows:

- If you set both the **action-shutdown** and the **port-error-disable** statements, the affected interfaces are disabled temporarily and recover automatically when the disable timeout expires.
- If you set the **action-shutdown** statement and do not set the **port-error-disable** statement, the affected interfaces are shut down when the storm control level is exceeded, and they do not recover automatically. You must issue the **clear ethernet-switching port-error** command to clear the port error and restore the interfaces to service.

Default The **action-shutdown** feature is disabled. If the storm control level is exceeded, the switch drops broadcast and unknown unicast messages on the specified interfaces.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

rpf-check

Syntax rpf-check;

Hierarchy Level [edit interfaces *interface-name* unit *logical-unit-number* family inet],
[edit interfaces *interface-name* unit *logical-unit-number* family inet6]

Release Information Statement introduced in Junos OS Release 9.3 for EX Series switches.
Statement introduced in Junos OS Release 13.2 for the QFX Series.

Description On EX3200 and EX4200 switches, enable a reverse-path forwarding (RPF) check on unicast traffic (except ECMP packets) on all ingress interfaces.

On EX4300 switches, enable a reverse-path forwarding (RPF) check on unicast traffic, including ECMP packets, on all ingress interfaces.

On EX8200 and EX6200 switches, enable an RPF check on unicast traffic, including ECMP packets, on the selected ingress interfaces.

On QFX Series switches, enable an RPF check on unicast traffic (except ECMP packets) on the selected ingress interfaces.

Default Unicast RPF is disabled on all interfaces.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Configuration Statements for Device Security (ELS CLI Only)

bandwidth-level

Syntax bandwidth-level *kbps*;

Hierarchy Level [edit forwarding-options storm-control-profiles *profile-name* all]

Release Information Statement introduced in Junos OS Release 13.2X50-D10 for EX Series switches.
Statement introduced in Junos OS Release 13.2 for the QFX series.

Description Configure the storm control level as the bandwidth in kilobits per second of the available bandwidth used by the combined broadcast, multicast, and unknown unicast traffic streams.

NOTE: When you configure storm control level on an aggregated Ethernet interface, the storm control level for each member of the aggregated Ethernet interface is set to that bandwidth. For example, if you configure a storm control level of 15,000 Kbps on ae1, and ae1 has two members, ge-0/0/0 and ge-0/0/1, each member has a storm control level of 15,000 Kbps. Thus, the storm control level on ae1 allows a traffic rate of up to 30,000 Kbps of combined broadcast, multicast, and unknown unicast traffic.

Default On EX4300 switches—If you do not specify the storm control level using either the **bandwidth-level** or the **bandwidth-percentage** statements, the storm control level defaults to 80 percent of the available bandwidth used by the combined broadcast, unknown unicast, and multicast traffic streams.

On EX9200 switches—Storm control is not enabled by default.

Options **bandwidth-level** ***kbps***—Traffic rate in kilobits per second of the combined broadcast, multicast, and unknown unicast traffic streams.

Range: 100 through 10,000,000

Default: None

Required Privilege Level system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

Related Documentation

- bandwidth-percentage on page 4658
- *Example: Configuring Storm Control to Prevent Network Outages on EX Series Switches*
- *Configuring or Disabling Storm Control (CLI Procedure)*

bandwidth-percentage

Syntax bandwidth-percentage *percentage*;

Hierarchy Level [edit forwarding-options storm-control-profiles *profile-name* all]

Release Information Statement introduced in Junos OS Release 13.2X50-D10 for EX Series switches.
Statement introduced in Junos OS Release 13.2 for the QFX series.

Description Configure the storm control level as the percentage of available bandwidth used by the combined broadcast, multicast, and unknown unicast traffic streams on an interface. The storm control level is configured as part of the storm control profile.

NOTE: When you configure storm control level on an aggregated Ethernet interface, the storm control level for each member of the aggregated Ethernet interface is set to that bandwidth. For example, if you configure a storm control level of 15,000 Kbps on ae1, and ae1 has two members, ge-0/0/0 and ge-0/0/1, each member has a storm control level of 15,000 Kbps. Thus, the storm control level on ae1 allows a traffic rate of up to 30,000 Kbps of combined broadcast, multicast, and unknown unicast traffic.

Default On EX4300 switches—The storm control level is 80 percent of the available bandwidth used by the combined broadcast, unknown unicast, and multicast traffic streams.

On EX9200 switches—Storm control is not enabled by default.

Required Privilege Level system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

Configuration Statements for Device Security (Original CLI Only)

bandwidth

Syntax bandwidth *bandwidth*;

Hierarchy Level [edit ethernet-switching-options storm-control interface (all | *interface-name*)]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description For interfaces configured for storm control, configure the storm control level as the bandwidth in kilobits per second (Kbps). If the combination of broadcast and unknown unicast traffic exceeds this level, the switch performs the appropriate action.

Default None.

Options **bandwith**—Broadcast and unknown unicast traffic rate in Kbps.

Range: 100 through 10000000 Kbps

Default: None

NOTE: When you configure storm control bandwidth, the value you configure is rounded off internally to the closest multiple of 64 Kbps, and the rounded-off value represents the bandwidth that is actually enforced. For example, if you configure a bandwidth limit of 150 Kbps, storm control enforces a bandwidth limit of 128 Kbps.

CAUTION: Junos OS allows you to configure a storm control value that exceeds the bandwidth of the interface. If you configure an interface with such a value, storm control does not drop broadcast or unknown unicast packets even if they consume all the available bandwidth.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

          }
          remote-id {
            prefix (Remote ID for Option 82) hostname | mac | none;
            use-interface-description;
            use-string string;
          }
          vendor-id <string>;
        }
        (examine-dhcp | no-examine-dhcp) {
          forwarding-class (for DHCP Snooping or DAI Packets) class-name;
        }
        examine-fip {
          examine-vn2vn {
            beacon-period milliseconds;
          }
          fc-map fc-map-value;
        }
        mac-move-limit limit <fabric-limit limit action action;
      }
    }
    static {
      vlan vlan-id {
        mac mac-address next-hop interface-name;
      }
    }
    storm-control {
      interface (all | interface-name) {
        bandwidth bandwidth;
        no-broadcast;
        no-multicast;
        no-unknown-unicast;
      }
    }
    traceoptions {
      file filename <files number> <no-stamp> <replace> <size size> <world-readable |
        no-world-readable>;
      flag flag <disable>;
    }
    unknown-unicast-forwarding {
      vlan (all | vlan-name) {
        interface interface-name;
      }
    }
  }
```

Hierarchy Level [edit]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Configure Ethernet switching options.

The remaining statements are explained separately.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

storm-control

Syntax

```
storm-control {
  action-shutdown;
  interface (all | interface-name) {
    bandwidth bandwidth;
    no-broadcast;
    no-multicast;
    no-unknown-unicast;
  }
}
```

Hierarchy Level [edit ethernet-switching-options]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Apply storm control to all interfaces or to the specified interfaces.

The statements are explained separately.

NOTE: **The no-multicast option is not supported on QFabric systems.**

Default By default, storm control is enabled on all switch interfaces at a level of 80 percent of the combined broadcast, multicast, and unknown unicast streams. You can change the storm control level by configuring it as a specific bandwidth value.

When you configure storm control bandwidth on an aggregated Ethernet interface, each member of the aggregated interface is assigned that bandwidth. For example, if you configure 7000000 Kbps on aggregated interface **ae1**, and **ae1** has two members, **xe-2:0/0/0** and **xe-2:0/0/1**, each member is allowed a bandwidth level of 7000000 Kbps. Thus, the storm control bandwidth on **ae1** could be as much as 14000000 Kbps of combined broadcast and unknown unicast traffic.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

CHAPTER 52

Administration

Routine Monitoring

Monitoring Firewall Filter Traffic

You can use operational mode commands to monitor firewall filter traffic.

Monitoring Traffic for All Firewall Filters and Policers That Are Configured

Purpose Monitor the number of packets and bytes that matched the firewall filters and monitor the number of packets that exceeded policer rate limits:

Action Use the **show firewall** operational mode command:

```
user@switch> show firewall
```

```
Filter: egress-vlan-watch-employee
Counters:
Name                                                  Bytes              Packets
counter-employee-web                                   3348                   27
Filter: ingress-port-limit-tcp-icmp
Counters:
Name                                                  Bytes              Packets
icmp-counter                                            560                   10
Policers:
Name                                                Packets
icmp-connection-policer                                  10
tcp-connection-policer                                    0
Filter: ingress-vlan-rogue-block
Filter: ingress-vlan-limit-guest
```

Meaning The **show firewall** command displays the names of all firewall filters, counters, and policers that are configured. For each counter that is specified in a filter configuration, the output field shows the byte count and packet count for the term in which the counter is specified. For each policer that is specified in a filter configuration, the output field shows the packet count for packets that exceed the specified rate limits.

Monitoring Traffic for a Specific Firewall Filter

Purpose Monitor the number of packets and bytes that matched a firewall filter and monitor the number of packets that exceeded policer rate limits.

Action Use the **show firewall filter *filter-name*** operational mode command:

```
user@switch> show firewall filter ingress-port-limit-tcp-icmp
Filter: ingress-port-limit-tcp-icmp
Counters:
Name                                                  Bytes              Packets
icmp-counter                                            560                   10
```

Meaning The **show firewall filter *filter-name*** command limits the display information to the counters and policers that are defined for the specified filter.

Monitoring Traffic for a Specific Policer

Purpose Monitor the number of packets that exceeded the rate limits of a policer:

Action Use the **show firewall policer *policer-name*** operational mode command:

```
user@switch> show firewall policer icmp-connection-policer
Filter: ingress-port-limit-tcp-icmp
Policers:
Name                                                Packets
icmp-connection-policer                                  10
```

Meaning The **show firewall policer *policer-name*** command displays the number of packets that exceeded the rate limits for the specified policer.

Related Documentation

- Verifying That Firewall Filters Are Operational on page 4672

Monitoring Port Security

Purpose Use the monitoring functionality to view these port security details:

- DHCP snooping database for a VLAN or all VLANs
- ARP inspection details for all interfaces

Action To monitor port security in the J-Web interface, select **Monitor** > **Security** > **Port Security**.

To monitor and manipulate the DHCP snooping database and ARP inspection statistics in the CLI, enter the following commands:

- **show dhcp snooping binding**
- **clear dhcp snooping binding**—In addition to clearing the whole database, you can clear database entries for specified VLANs or MAC addresses.
- **show arp inspection statistics**
- **clear arp inspection statistics**

NOTE: On EX4300 switches, to monitor and manipulate the DHCP snooping database and ARP inspection statistics in the CLI, enter the following commands:

- **show dhcp-security binding**
- **clear dhcp-security binding**—In addition to clearing the whole database, you can clear database entries for specified VLANs or IP Address.
- **show dhcp-security arp inspection statistics**
- **clear arp inspection statistics**

Meaning The J-Web Port Security Monitoring page comprises two sections:

- DHCP Snooping Details—Displays the DHCP snooping database for all the VLANs for which DHCP snooping is enabled. To view the DHCP snooping database for a specific VLAN, select the specific VLAN from the list.
- ARP Inspection Details—Displays the ARP inspection details for all interfaces. The information includes details of the number of packets that passed ARP inspection and the number of packets that failed the inspection. The pie chart graphically represents these statistics when you select an interface. To view ARP inspection statistics for a specific interface, select the interface from the list.

You can use the following options on the page to clear DHCP snooping and ARP inspection details:

- Clear All—Clears the DHCP snooping database, either for all VLANs if the option **ALL** has been selected in the Select VLANs list or for the specific VLAN that has been selected in that list.
- Clear—Deletes a specific IP address from the DHCP snooping database.

To clear ARP inspection details on the page, click **Clear All** in the ARP inspection details section.

NOTE: **Clear All button in the ARP inspection details section is not supported on EX4300 switches.**

Use the CLI commands to show and clear DHCP snooping database and ARP inspection statistics details.

Verifying That Firewall Filters Are Operational

Purpose Verify that firewall filters are working properly after you apply them to ports, VLANs, or Layer 3 interfaces.

Action Use the **show firewall** operational mode command to verify that the firewall filters are working properly:

```
user@switch> show firewall
Filter: egress-vlan-watch-employee
Counters:
Name                                                 Bytes                Packets
counter-employee-web                                     0                      0
Filter: ingress-port-limit-tcp-icmp
Counters:
Name                                                 Bytes                Packets
icmp-counter                                           560                     10
Policers:
Name                                               Packets
icmp-connection-policer                                 10
tcp-connection-policer                                   0
Filter: ingress-vlan-rogue-block
Filter: ingress-vlan-limit-guest
```

Meaning The **show firewall** command displays the names of all firewall filters, counters, and policers that are configured. For each counter that is specified in a filter configuration, the output field shows the byte count and packet count for the term in which the counter is specified. In the above example, the **icmp-counter** in the filter **ingress-port-limit-tcp-icmp** shows that the filter matched 10 packets. For each policer that is specified in a filter configuration, the output field shows the packet count for packets that exceed the specified rate limits. The policer **icmp-connection-policer** shows that 10 ICMP packets were policed.

Verifying That DAI Is Working Correctly

Purpose Verify that dynamic ARP inspection (DAI) is working on the switch.

Action Send some ARP requests from network devices connected to the switch.

Display the DAI information:

```
user@switch> show arp inspection statistics
ARP inspection statistics:
Interface        Packets received  ARP inspection pass   ARP inspection failed
---------------  ---------------   --------------------  ---------------------
ge-0/0/1.0                     7                      5                      2
ge-0/0/2.0                    10                     10                      0
ge-0/0/3.0                    12                     12                      0
```

Meaning The sample output shows the number of ARP packets received and inspected per interface, with a listing of how many packets passed and how many failed the inspection on each interface. The switch compares the ARP requests and replies against the entries in the DHCP snooping database. If a MAC address or IP address in the ARP packet does not match a valid entry in the database, the packet is dropped.

Related Documentation

Verifying That DHCP Snooping Is Working Correctly

Purpose Verify that DHCP snooping is working on the switch and that the DHCP snooping database is correctly populated with both dynamic and static bindings.

Action Send some DHCP requests from network devices (here they are DHCP clients) connected to the switch.

Display the DHCP snooping information when the interface on which the DHCP server connects to the switch is trusted. The following output results when requests are sent from the MAC addresses and the server has provided the IP addresses and leases:

```
user@switch>  show dhcp snooping binding
DHCP Snooping Information:
MAC address        IP address  Lease (seconds) Type     VLAN      Interface

00:05:85:3A:82:77  192.0.2.17  600             dynamic  employee  ge-0/0/1.0
00:05:85:3A:82:79  192.0.2.18  653             dynamic  employee  ge-0/0/1.0
00:05:85:3A:82:80  192.0.2.19  720             dynamic  employee  ge-0/0/2.0
00:05:85:3A:82:81  192.0.2.20  932             dynamic  employee  ge-0/0/2.0
00:05:85:3A:82:83  192.0.2.21  1230            dynamic  employee  ge-0/0/2.0
00:05:85:27:32:88  192.0.2.22  –               static   data      ge-0/0/4.0
```

Meaning When the interface on which the DHCP server connects to the switch has been set to trusted, the output (see preceding sample) shows, for each MAC address, the assigned IP address and lease time—that is, the time, in seconds, remaining before the lease expires. Static IP addresses have no assigned lease time. The statically configured entry never expires.

If the DHCP server had been configured as untrusted, no entries would be added to the DHCP snooping database and nothing would be shown in the output of the **show dhcp snooping binding** command.

Verifying That MAC Limiting Is Working Correctly

MAC limiting protects against flooding of the Ethernet switching table by setting a limit on the number of MAC addresses that can be learned on a single Layer 2 access interface (port).

Junos OS provides two MAC limiting methods:

- Maximum number of MAC addresses—You configure the maximum number of dynamic MAC addresses allowed per interface. When the limit is exceeded, incoming packets with new MAC addresses can be ignored, dropped, or logged. You can also specify that the interface be shut down or temporarily disabled.
- Allowed MAC addresses—You configure specific “allowed” MAC addresses for the access interface. Any MAC address that is not in the list of configured addresses is not learned, and the switch logs an appropriate message. The allowed MAC method binds MAC addresses to a VLAN so that the address is not registered outside the VLAN. If an allowed MAC setting conflicts with a dynamic MAC setting, the allowed MAC setting takes precedence.

This topic includes the following tasks:

Verifying That MAC Limiting for Dynamic MAC Addresses Is Working Correctly

Purpose Verify that MAC limiting for dynamic MAC addresses is working.

Action Display the MAC addresses that have been learned. The following sample output shows the results of sending two packets from hosts connected to **xe-1:0/0/1** and five packets from hosts connected to **xe-1:0/0/2**, with both interfaces configured with a MAC limit of **4** and the action **drop**:

```
user@switch> show ethernet-switching table
Ethernet-switching table:  7 entries, 6 learned
  VLAN                    MAC address         Type         Age    Interfaces

  employee-vlan           *                   Flood          -    xe-1:0/0/2.0
  employee-vlan           00:05:85:3A:82:77   Learn          0    xe-1:0/0/1.0
  employee-vlan           00:05:85:3A:82:79   Learn          0    xe-1:0/0/1.0
  employee-vlan           00:05:85:3A:82:80   Learn          0    xe-1:0/0/2.0
  employee-vlan           00:05:85:3A:82:81   Learn          0    xe-1:0/0/2.0
  employee-vlan           00:05:85:3A:82:83   Learn          0    xe-1:0/0/2.0
  employee-vlan           00:05:85:3A:82:85   Learn          0    xe-1:0/0/2.0
```

Meaning The output shows that the fifth packet received on the **xe-1:0/0/2** interface was dropped because it exceeded the MAC limit for that interface. The address was not learned, and thus an asterisk (*) rather than an address appears in the MAC address column in the first line of the sample output.

Verifying That Allowed MAC Addresses Are Working Correctly

Purpose Verify that allowed MAC addresses are working.

Action Display the MAC cache information after allowed MAC addresses have been configured on an interface. The following sample shows the MAC cache after four allowed MAC addresses had been configured on interface **xe-1:0/0/2** and a fifth MAC address appeared on the interface.

```
user@switch> show ethernet-switching table
Ethernet-switching table:  5 entries, 4 learned
  VLAN                 MAC address        Type         Age    Interfaces

  employee-vlan        00:05:85:3A:82:80  Learn          0    xe-1:0/0/2.0
  employee-vlan        00:05:85:3A:82:81  Learn          0    xe-1:0/0/2.0
  employee-vlan        00:05:85:3A:82:83  Learn          0    xe-1:0/0/2.0
  employee-vlan        00:05:85:3A:82:85  Learn          0    xe-1:0/0/2.0
  employee-vlan        *                  Flood          -    xe-1:0/0/2.0
```

Meaning Because the fifth address was not allowed it was not learned, and an asterisk (*) rather than an address appears in the MAC address column in the last line of the sample output.

Verifying That Interfaces Are Shut Down

Purpose Verify that an interface is shut down when the MAC limit is exceeded.

Action For more information about interfaces that have been shut down because the MAC limit was exceeded, use the **show ethernet-switching interfaces** command.

```
user@switch> show ethernet-switching interfaces
Interface     State   VLAN members       Tag    Tagging  Blocking

bme0.32770      down    mgmt      untagged unblocked

xe-0/0/0.0      down    v1        untagged MAC limit exceeded

xe- 0/0/1.0       up      v1        untagged unblocked

xe-0/0/2.0       up      v1        untagged unblocked

me0.0           up      mgmt      untagged unblocked
```

NOTE: You can configure interfaces to recover automatically when the MAC limit has been exceeded by specifying the **port-error-disable** statement with a **disable timeout** value. The switch automatically restores the disabled interface to service when the disable timeout expires. The **port-error-disable** configuration does not apply to preexisting error conditions—it affects only error conditions that are detected after the **port-error-disable** statement has been enabled and the configuration has been committed. To clear a preexisting error condition and restore the interface to service, use the clear ethernet-switching port-error command.

Customizing the Ethernet Switching Table Display to View Information for a Specific Interface

Purpose You can use the **show ethernet-switching table** command to view information for a specific interface.

Action For example, to display the MAC addresses that have been learned on the **xe-0/0/2** interface, enter:

```
user@switch> show ethernet-switching table interface xe-0/0/2.0
Ethernet-switching table: 1 unicast entries

  VLAN              MAC address       Type         Age Interfaces

  v1                *                 Flood          - All-members

  v1                00:00:06:00:00:00 Learn          0 xe-0/0/2.0
```

Meaning The MAC limit value for the **xe-0/0/2** interface had been set to **1**, and the output shows that only one MAC address was learned and added to the MAC cache.

Related Documentation

- Configuring MAC Limiting on page 4545
- Monitoring Port Security on page 4671

- Example: Configuring Allowed MAC Addresses to Protect the Switch from DHCP Snooping Database Alteration Attacks on page 4518
- Example: Configuring MAC Limiting to Protect the Switch from DHCP Starvation Attacks on page 4495

Verifying That MAC Move Limiting Is Working Correctly

Purpose Verify that MAC move limiting is working on the switch.

Action Display the MAC addresses in the Ethernet switching table when MAC move limiting has been configured for a VLAN. The following sample shows the results after two of the hosts on **ge-0/0/2** sent packets after the MAC addresses for those hosts had moved to other interfaces more than five times in 1 second. The VLAN, **employee-vlan**, was set to a MAC move limit of **5** with the action **drop**:

```
user@switch> show ethernet-switching table

Ethernet-switching table:  7 entries, 4 learned
  VLAN                  MAC address         Type          Age    Interfaces

  employee-vlan         00:05:85:3A:82:77   Learn           0    ge-0/0/1.0
  employee-vlan         00:05:85:3A:82:79   Learn           0    ge-0/0/1.0
  employee-vlan         00:05:85:3A:82:80   Learn           0    ge-0/0/2.0
  employee-vlan         00:05:85:3A:82:81   Learn           0    ge-0/0/2.0
  employee-vlan         *                   Flood           -    ge-0/0/2.0
  employee-vlan         *                   Flood           -    ge-0/0/2.0
```

Meaning The last two lines of the sample output show that MAC addresses for two hosts on **ge-0/0/2** were not learned, because the hosts had been moved back and forth from the original interfaces more than five times in 1 second.

Related Documentation

Verifying That the Port Error Disable Setting Is Working Correctly

Purpose Verify that the port error disable setting is working as expected for MAC limited and storm control interfaces.

Action Display information about interfaces:

```
user@switch> show ethernet-switching interfaces
Interface        State     VLAN members          Blocking
xe-2:0/0/0.0  up       T1122                  unblocked
xe-2:0/0/1.0  down     default                MAC limit exceeded
xe-2:0/0/2.0  down     default                Storm control in effect
xe-2:0/0/3.0  down     default                unblocked
xe-2:0/0/4.0  down     default                unblocked
xe-2:0/0/5.0  down     default                unblocked
xe-2:0/0/6.0  down     default                unblocked
```

Meaning For interfaces disabled by port security features, the sample output from the **show ethernet-switching interfaces** command specifies the reasons that the interfaces are disabled:

- **MAC limit exceeded**—The interface is temporarily disabled because of a **mac-limit** error. The disabled interface is automatically restored to service when the **disable-timeout (Port Error Disable)** expires.
- **MAC move limit exceeded**—The interface is temporarily disabled because of a *mac-move-limit* error. The disabled interface is automatically restored to service when the *disable-timeout* expires.
- **Storm control in effect**—The interface is temporarily disabled because of a **storm-control** error. The disabled interface is automatically restored to service when the **disable-timeout (Port Error Disable)** expires.

Verifying Unicast RPF Status

Purpose Verify that unicast reverse-path forwarding (RPF) is enabled and is working on the interface.

Action Use one of the **show interfaces** ***interface-name*** commands with either the **extensive** or **detail** options to verify that unicast RPF is enabled and working on the switch. The following example displays output from the **show interfaces ge- extensive** command.

```
user@switch> show interfaces ge-1/0/10 extensive
Physical interface: ge-1/0/10, Enabled, Physical link is Down
  Interface index: 139, SNMP ifIndex: 58, Generation: 140
  Link-level type: Ethernet, MTU: 1514, Speed: Auto, MAC-REWRITE Error: None,
  Loopback: Disabled, Source filtering: Disabled, Flow control: Enabled,
  Auto-negotiation: Enabled, Remote fault: Online
  Device flags   : Present Running
  Interface flags: Hardware-Down SNMP-Traps Internal: 0x0
  Link flags     : None
  CoS queues     : 8 supported, 8 maximum usable queues
  Hold-times     : Up 0 ms, Down 0 ms
  Current address: 00:19:e2:50:95:ab, Hardware address: 00:19:e2:50:95:ab

```
 Input  packets:                   0
 Output packets:                   0
Transit statistics:
 Input  bytes  :                   0                    0 bps
 Output bytes  :                   0                    0 bps
 Input  packets:                   0                    0 pps
 Output packets:                   0                    0 pps
 IPv6 transit statistics:
  Input  bytes  :                  0
  Output bytes  :                  0
  Input  packets:                  0
  Output packets:                  0
    Protocol inet, Generation: 144, Route table: 0
  Flags: uRPF
  Addresses, Flags: Is-Preferred Is-Primary
```

Meaning The **show interfaces ge-1/0/10 extensive** command (and the **show interfaces ge-1/0/10 detail** command) displays in-depth information about the interface. The **Flags:** output field near the bottom of the display reports the unicast RPF status. If unicast RPF has not been enabled, the **uRPF** flag is not displayed.

On EX3200, EX4200, and EX4300 switches, unicast RPF is implicitly enabled on *all* switch interfaces, including aggregated Ethernet interfaces (also referred to as link aggregation groups or LAGs), integrated routing and bridging (IRB) interfaces, and routed VLAN interfaces (RVIs) when you enable unicast RPF on a single interface. However, the unicast RPF status is shown as enabled only on interfaces for which you have explicitly configured unicast RPF. Thus, the **uRPF** flag is not displayed on interfaces for which you have not explicitly configured unicast RPF even though unicast RPF is implicitly enabled on all interfaces on EX3200 and EX4200 switches.

Verifying That a Trusted DHCP Server Is Working Correctly

Purpose Verify that a DHCP trusted server is working on the switch. See what happens when the DHCP server is trusted and then untrusted.

Action Send some DHCP requests from network devices (here they are DHCP clients) connected to the switch.

Display the DHCP snooping information when the interface on which the DHCP server connects to the switch is trusted. The following output results when requests are sent from the MAC addresses and the server has provided the IP addresses and leases:

```
user@switch> show dhcp snooping binding
DHCP Snooping Information:
MAC Address        IP Address    Lease    Type      VLAN            Interface
-----------------  ----------    -----    ----      ----            ---------
00:05:85:3A:82:77   192.0.2.17    600    dynamic  employee—vlan    ge-0/0/1.0
00:05:85:3A:82:79   192.0.2.18    653    dynamic  employee—vlan    ge-0/0/1.0
00:05:85:3A:82:80   192.0.2.19    720    dynamic  employee—vlan    ge-0/0/2.0
00:05:85:3A:82:81   192.0.2.20    932    dynamic  employee—vlan    ge-0/0/2.0
00:05:85:3A:82:83   192.0.2.21   1230    dynamic  employee—vlan    ge-0/0/2.0
00:05:85:27:32:88   192.0.2.22   3200    dynamic  employee—vlan    ge-0/0/2.0
```

Meaning When the interface on which the DHCP server connects to the switch has been set to trusted, the output (see preceding sample) shows, for each MAC address, the assigned IP address and lease time—that is, the time, in seconds, remaining before the lease expires.

If the DHCP server had been configured as untrusted, no entries would be added to the DHCP snooping database and nothing would be shown in the output of the **show dhcp snooping binding** command.

Verifying That Three-Color Policers Are Operational

Purpose Verify that three-color policers in firewall filter configurations are working properly.

Action Use the following operational mode commands to verify that a three-color policer is working properly:

- **show class-of-service forwarding-table classifiers**
- **show interfaces *interface-name* extensive**

- **show interfaces queue *interface-name***

Related Documentation

- Overview of Policers on page 4441
- Configuring Two-Color and Three-Color Policers to Control Traffic Rates on page 4538

Verifying That Two-Color Policers Are Operational

Purpose Verify that two-color policers in firewall filter configurations are working properly.

Action Use the **show firewall policer** operational mode command to verify that the policers are working properly:

```
user@switch> show firewall policer
Filter: egress-vlan-watch-employee
Filter: ingress-port-filter
Filter: ingress-port-limit-tcp-icmp
Policers:
Name                                              Packets
icmp-connection-policer                                10
tcp-connection-policer                                539
Filter: ingress-vlan-rogue-block
Filter: ingress-vlan-limit-guest
```

Meaning The **show firewall policer** command displays the names of all firewall filters and policers that are configured. For each policer that is specified in a filter configuration, the output field shows the current packet count for all packets that exceed the specified rate limits.

clear arp inspection statistics

Syntax clear arp inspection statistics
<interface *interface*>

Release Information Command introduced in Junos OS Release 9.0 for EX Series switches.
Command introduced in Junos OS Release 12.1 for the QFX Series.

Description Clear ARP inspection statistics.

Options **none**—Clears ARP statistics on all interfaces.

interface *interface-names*—(Optional) Clear ARP statistics on one or more interfaces.

Required Privilege Level clear

Related Documentation

- **show arp inspection statistics on page 4688**
- Example: Configuring Basic Port Security Features on page 4488

List of Sample Output **clear arp inspection statistics on page 4684**

Output Fields This command produces no output.

Sample Output

clear arp inspection statistics

```
user@switch> clear arp inspection statistics
```

clear dhcp snooping binding

Syntax

clear dhcp snooping binding
<mac (all | *mac-address*)>
<vlan (all | *vlan-name*)>
<vlan (all | *vlan-name*) mac (all | *mac-address*)>

Release Information

Command introduced in Junos OS Release 12.1 for the QFX Series.

Description

Clear the DHCP snooping database information.

Options

mac (all | *mac-address*)—(Optional) Clear DHCP snooping information for the specified MAC address or all MAC addresses.

vlan (all | *vlan-name*)—(Optional) Clear DHCP snooping information for the specified VLAN or all VLANs.

Required Privilege Level

clear

clear firewall

Syntax clear firewall (all | counter *counter-name* | filter *filter-name*)

Release Information Command introduced in Junos OS Release 11.1 for the QFX Series.

Description Clear statistics provided by firewall filters.

When you clear the counters of a filter, this not only impacts the counters shown by the CLI, but also the ones tracked by SNMP 2.

Options **all**—Clear the packet and byte counts for all firewall filter counters and clear the packet counts for all policer counters.

counter *counter-name*—Clear the packet and byte counts for the specified firewall filter counter.

filter *filter-name*—Clear the packet and byte counts for the specified firewall filter.

Required Privilege Level clear

Output Fields

Table 361 on page 4689 lists the output fields for the **show dhcp snooping binding** command. Output fields are listed in the approximate order in which they appear.

Table 361: show dhcp snooping binding Output Fields

Field Name	Field Description	Level of Output
MAC Address	MAC address of the network device; bound to the IP address.	All levels
IP Address	IP address of the network device; bound to the MAC address.	All levels
Lease	Lease granted to the IP address.	All levels
Type	How the MAC address was acquired.	All levels
VLAN	VLAN name of the network device whose MAC address is shown.	All levels
Interface	Interface address (port).	All levels

Sample Output

show dhcp snooping binding

```
user@switch> show dhcp snooping binding
```

```
DHCP Snooping Information:
MAC Address             IP Address Lease   Type     VLAN    Interface
-----------------       ---------- -----   -------  ----    ---------
00:00:01:00:00:03       192.0.2.0  640     dynamic  guest    ge-0/0/12.0
00:00:01:00:00:04       192.0.2.1  720     dynamic  guest    ge-0/0/12.0
00:00:01:00:00:05       192.0.2.5  800     dynamic  guest    ge-0/0/13.0
```

show firewall

Syntax

show firewall
<counter *counter-name*>
<filter *filter-name*>
<log <detail | interface *interface-name*>>
<terse>

Release Information Command introduced in Junos OS Release 11.1 for the QFX Series.

Description Display statistics about configured firewall filters.

Options

counter *counter-name*—(Optional) Display statistics about a particular firewall filter counter.

filter *filter-name*—(Optional) Display statistics about a particular firewall filter.

log—(Optional) Display log entries for all firewall filter activity.

terse—(Optional) Display firewall filter names only.

show firewall log detail on page 4693

Output Fields Table 362 on page 4691 lists the output fields for the **show firewall** command. Output fields are listed in the approximate order in which they appear.

Table 362: show firewall Output Fields

Field Name	Field Description	Level of Output
Filter	Name of the filter that is configured at the **[edit firewall family *family-name* filter]** hierarchy level.	All levels

Table 362: show firewall Output Fields *(continued)*

Field Name	Field Description	Level of Output
Counters	Display filter counter information: • Name—Name of a filter counter that has been configured with the **count** firewall filter action modifier. • Bytes—Number of bytes that match the filter term where the **count** action modifier was specified. • Packets—Number of packets that matched the filter term where the **count** action modifier was specified.	All levels
Policers	Display policer information: • Name—Name of the policer that is configured at the **[edit firewall policer]** hierarchy level. • Packets—Number of packets that matched the filter term where the **policer** action modifier was specified. This is the number of packets that exceeded the rate limits that the policer specifies.	All levels
Action	Filter action: • **A**—Accept • **D**—Discard	All levels
Interface	Interface on which the firewall filter is applied.	All levels
Protocol	Name of the packet protocol.	All levels
Packet Length	Length of the packet.	All levels
Src Addr	Source address of the packet.	All levels
Dest Addr	Destination address of the packet.	All levels

Sample Output

show firewall

```
user@switch> show firewall
Filter: egress-vlan-watch-employee
Counters:
Name                                                Bytes              Packets
counter-employee-web                                    0                    0
Filter: ingress-port-limit-tcp-icmp
Counters:
Name                                                Bytes              Packets
icmp-counter                                          560                   10
Policers:
Name                                              Packets
icmp-connection-policer                                10
tcp-connection-policer                                  0
Filter: ingress-vlan-rogue-block
Filter: ingress-vlan-limit-guest
```

show firewall filter filter-name

```
user@switch> show firewall filter ingress-port-limit-tcp-icmp
Filter: ingress-port-limit-tcp-icmp
Counters:
Name                                                Bytes              Packets
icmp-counter                                          560                   10
Policers:

CHAPTER 53

Troubleshooting

Troubleshooting Procedures

Troubleshooting Firewall Filter Configuration

Use the following information to troubleshoot your firewall filter configuration.

Firewall Filter Configuration Returns a No Space Available in TCAM Message

Problem When a firewall filter configuration exceeds the amount of available Ternary Content Addressable Memory (TCAM) space, the system returns the following **syslogd** message:

```
No space available in tcam.
Rules for filter filter-name will not be installed.
```

A switch returns this message during the commit operation if the firewall filter that has been applied to a port, VLAN, or Layer 3 interface exceeds the amount of space available in the TCAM table. The filter is not applied, but the commit operation for the firewall filter configuration is completed in the CLI module.

Solution When a firewall filter configuration exceeds the amount of available TCAM table space, you must configure a new firewall filter with fewer filter terms so that the space requirements for the filter do not exceed the available space in the TCAM table.

You can perform either of the following procedures to correct the problem:

To delete the filter and its binding and apply the new smaller firewall filter to the same binding:

1. Delete the filter and its binding to ports, VLANs, or Layer 3 interfaces. For example:

```
[edit]
user@switch# delete firewall family ethernet-switching filter ingress-vlan-rogue-block
user@switch# delete vlans employee-vlan description "filter to block rogue devices on employee-vlan"
user@switch# delete vlans employee-vlan filter input ingress-vlan-rogue-block
```
2. Commit the changes:

```
[edit]
user@switch# commit
```
3. Configure a smaller filter with fewer terms that does not exceed the amount of available TCAM space. For example:

```
[edit]
user@switch# set firewall family ethernet-switching filter new-ingress-vlan-rogue-block ...
```
4. Apply (bind) the new firewall filter to a port, VLAN , or Layer 3 interface. For example:

```
[edit]
user@switch# set vlans employee-vlan description "filter to block rogue devices on employee-vlan"
user@switch# set vlans employee-vlan filter input new-ingress-vlan-rogue-block
```
5. Commit the changes:

```
[edit]
user@switch# commit
```

To apply a new firewall filter and overwrite the existing binding but not delete the original filter:

1. Configure a firewall filter with fewer terms than the original filter:

```
[edit]
user@switch# set firewall family ethernet-switching filter new-ingress-vlan-rogue-block...
```
2. Apply the firewall filter to the port, VLAN, or Layer 3 interfaces to overwrite the binding of the original filter—for example:

```
[edit]
user@switch# set vlans employee-vlan description "smaller filter to block rogue devices on employee-vlan"
user@switch# set vlans employee-vlan filter input new-ingress-vlan-rogue-block
```
   Because you can apply no more than one firewall filter per VLAN per direction, the binding of the original firewall filter to the VLAN is overwritten with the new firewall filter **new-ingress-vlan-rogue-block**.

3. Commit the changes:

```
[edit]
user@switch# commit
```

NOTE: The original filter is not deleted and is still available in the configuration.

Filter Counts Previously Dropped Packet

Problem If you configure two or more filters in the same direction for a physical interface and one of the filters includes a counter, the counter will be incorrect if the following circumstances apply:

- You configure the filter that is applied to packets first to discard certain packets. For example, imagine that you have a VLAN filter that accepts packets sent to 10.10.1.0/24 addresses and implicitly discards packets sent to any other addresses. You apply the filter to the **admin** VLAN in the output direction, and interface xe-0/0/1 is a member of that VLAN.
- You configure a subsequent filter to accept and count packets that are dropped by the first filter. In this example, you have a port filter that accepts and counts packets sent to 192.168.1.0/24 addresses that is also applied to xe-0/0/1 in the output direction.

The egress VLAN filter is applied first and correctly discards packets sent to 192.168.1.0/24 addresses. The egress port filter is applied next and counts the discarded packets as matched packets. The packets are not forwarded, but the counter displayed by the egress port filter is incorrect.

Remember that the order in which filters are applied depends on the direction in which they are applied, as indicated here:

Ingress filters:

1. Port (Layer 2) filter
2. VLAN filter
3. Router (Layer 3) filter

Egress filters:

1. Router (Layer 3) filter
2. VLAN filter
3. Port (Layer 2) filter

Solution This is expected behavior.

Matching Packets Not Counted

Problem If you configure two egress filters with counters for a physical interface and a packet matches both of the filters, only one of the counters includes that packet.

For example:

- You configure an egress port filter with a counter for interface xe-0/0/1.
- You configure an egress VLAN filter with a counter for the **admin**VLAN, and interface xe-0/0/1 is a member of that VLAN.
- A packet matches both filters.

In this case, the packet is counted by only one of the counters even though it matched both filters.

Solution This is expected behavior.

Counter Reset When Editing Filter

Problem If you edit a firewall filter term, the value of any counter associated with any term in the same filter is set to 0, including the implicit counter for any policer referenced by the filter. Consider the following examples:

- Assume that your filter has **term1**, **term2**, and **term3**, and each term has a counter that has already counted matching packets. If you edit any of the terms in any way, the counters for all the terms are reset to 0.
- Assume that your filter has **term1** and **term2**. Also assume that **term2** has a **policer** action modifier and the implicit counter of the policer has already counted 1000 matching packets. If you edit **term1** or **term2** in any way, the counter for the policer referenced by **term2** is reset to 0.

Solution This is expected behavior.

Cannot Include loss-priority and policer Actions in Same Term

Problem You cannot include both of the following actions in the same firewall filter term in a QFX Series switch:

- **loss-priority**
- **policer**

If you do so, you see the following error message when you attempt to commit the configuration: “cannot support policer action if loss-priority is configured.”

Solution This is expected behavior.

Cannot Egress Filter Certain Traffic Originating on QFX Switch

Problem On a QFX Series switch, you cannot filter certain traffic with a firewall filter applied in the output direction if the traffic originates on the QFX switch. This limitation applies to control traffic for protocols such as ICMP (ping), STP, LACP, and so on.

Solution This is expected behavior.

Firewall Filter Match Condition Not Working with Q-in-Q Tunneling

Problem If you create a firewall filter that includes a match condition of **dot1q-tag** or **dot1q-user-priority** and apply the filter on input to a trunk port that participates in a service VLAN, the match condition does not work if the Q-in-Q EtherType is not 0x8100. (When Q-in-Q tunneling is enabled, trunk interfaces are assumed to be part of the service provider or data center network and therefore participate in service VLANs.)

Solution This is expected behavior. To set the Q-in-Q EtherType to 0x8100, enter the **set dot1q-tunneling ethertype 0x8100** statemen at the **[edit ethernet-switching-options]** hierarchy level. You must also configure the other end of the link to use the same Ethertype.

Egress Firewall Filters with Private VLANs

Problem If you apply a firewall filter in the output direction to a primary VLAN, the filter also applies to the secondary VLANs that are members of the primary VLAN when the traffic egresses with the primary VLAN tag or isolated VLAN tag, as listed below:

- Traffic forwarded from a secondary VLAN trunk port to a promiscuous port (trunk or access)
- Traffic forwarded from a secondary VLAN trunk port that carries an isolated VLAN to a PVLAN trunk port.
- Traffic forwarded from a promiscuous port (trunk or access) to a secondary VLAN trunk port
- Traffic forwarded from a PVLAN trunk port. to a secondary VLAN trunk port
- Traffic forwarded from a community port to a promiscuous port (trunk or access)

If you apply a firewall filter in the output direction to a primary VLAN, the filter does *not* apply to traffic that egresses with a community VLAN tag, as listed below:

- Traffic forwarded from a community trunk port to a PVLAN trunk port
- Traffic forwarded from a secondary VLAN trunk port that carries a community VLAN to a PVLAN trunk port
- Traffic forwarded from a promiscuous port (trunk or access) to a community trunk port
- Traffic forwarded from a PVLAN trunk port. to a community trunk port

If you apply a firewall filter in the output direction to a community VLAN, the following behaviors apply:

- The filter is applied to traffic forwarded from a promiscuous port (trunk or access) to a community trunk port (because the traffic egresses with the community VLAN tag).
- The filter is applied to traffic forwarded from a community port to a PVLAN trunk port (because the traffic egresses with the community VLAN tag).

- The filter is *not* applied to traffic forwarded from a community port to a promiscuous port (because the traffic egresses with the primary VLAN tag or untagged).

Solution These are expected behaviors. They occur only if you apply a firewall filter to a private VLAN in the output direction and do not occur if you apply a firewall filter to a private VLAN in the input direction.

Egress Filtering of L2PT Traffic Not Supported

Problem Egress filtering of L2PT traffic is not supported on the QFX3500 switch. That is, if you configure L2PT to tunnel a protocol on an interface, you cannot also use a firewall filter to filter traffic for that protocol on that interface in the output direction. If you commit a configuration for this purpose, the firewall filter is not applied to the L2PT-tunneled traffic.

Solution This is expected behavior.

Cannot Drop BGP Packets in Certain Circumstances

Problem BGP packets with a time-to-live (TTL) value greater than 1 cannot be discarded using a firewall filter applied to a loopback interface or applied on input to a Layer 3 interface. BGP packets with TTL value of 1 or 0 can be discarded using a firewall filter applied to a loopback interface or applied on input to a Layer 3 interface.

Solution This is expected behavior.

Invalid Statistics for Policer

Problem If you apply a single-rate two-color policer in more than 128 terms in a firewall filter, the output of the **show firewall** command displays incorrect data for the policer.

Solution This is expected behavior.

Policers can Limit Egress Filters

Problem The number of egress policers that you configure can affect the total number of allowed egress firewall filters. Every policer has two implicit counters that consume two entries in a 1024-entry TCAM that is used for counters, including counters that are configured as action modifiers in firewall filter terms. (Policers consume two entries because one is used for green packets and one is used for nongreen packets regardless of policer type.) If the TCAM becomes full, you cannot commit any more egress firewall filters that have terms with counters. For example, if you configure and commit 512 egress policers (two-color, three-color, or a combination of both policer types), all of the memory entries for counters are used up. If later in your configuration file you insert additional egress firewall filters with terms that also include counters, *none* of the terms in those filters are committed because there is no available memory space for the counters.

Here are some additional examples:

- Assume that you configure egress filters that include a total of 512 policers and no counters. Later in your configuration file you include another egress filter with 10 terms, 1 of which has a counter action modifier. None of the terms in this filter are committed because there is not enough TCAM space for the counter.
- Assume that you configure egress filters that include a total of 500 policers, so 1000 TCAM entries are occupied. Later in your configuration file you include the following two egress filters:
  - Filter A with 20 terms and 20 counters. All the terms in this filter are committed because there is enough TCAM space for all the counters.
  - Filter B comes after Filter A and has five terms and five counters. *None* of the terms in this filter are committed because there is not enough memory space for *all* the counters. (Five TCAM entries are required but only four are available.)

Solution You can prevent this problem by ensuring that egress firewall filter terms with counter actions are placed earlier in your configuration file than terms that include policers. In this circumstance, Junos OS commits policers even if there is not enough TCAM space for the implicit counters. For example, assume the following:

- You have 1024 egress firewall filter terms with counter actions.
- Later in your configuration file you have an egress filter with 10 terms. None of the terms have counters but one has a policer action modifier.

You can successfully commit the filter with 10 terms even though there is not enough TCAM space for the implicit counters of the policer. The policer is committed without the counters.

Troubleshooting Policer Configuration

Incomplete Count of Packet Drops

Problem Under certain circumstances, Junos OS might display a misleading number of packets dropped by an ingress policer.

If packets are dropped because of ingress admission control, policer statistics might not show the number of packet drops you would expect by calculating the difference between ingress and egress packet counts. This might happen if you apply an ingress policer to multiple interfaces, and the aggregate ingress rate of those interfaces exceeds the line rate of a common egress interface. In this case, packets might be dropped from the ingress buffer. These drops are not included in the count of packets dropped by the policer, which causes policer statistics to underreport the total number of drops.

Solution This is expected behavior.

Counter Reset When Editing Filter

Problem If you edit a firewall filter term, the value of any counter associated with any term in the same filter is set to 0, including the implicit counter for any policer referenced by the filter. Consider the following examples:

- Assume that your filter has **term1**, **term2**, and **term3**, and each term has a counter that has already counted matching packets. If you edit any of the terms in any way, the counters for all the terms are reset to 0.
- Assume that your filter has **term1** and **term2**. Also assume that **term2** has a **policer** action modifier and the implicit counter of the policer has already counted 1000 matching packets. If you edit **term1** or **term2** in any way, the counter for the policer referenced by **term2** is reset to 0.

Solution This is expected behavior.

Invalid Statistics for Policer

Problem If you apply a single-rate two-color policer in more than 128 terms in a firewall filter, the output of the **show firewall** command displays incorrect data for the policer.

Solution This is expected behavior.

Egress Policers on QFX3500 Devices Might Allow More Throughput Than Is Configured

Problem If you configure a policer to rate-limit throughput and apply it on egress to multiple interfaces on a QFX3500 switch or Node, the measured aggregate policed rate might be twice the configured rate, depending on which interfaces you apply the policer to. The doubling of the policed rate occurs if you apply a policer to multiple interfaces and *both* of the following are true:

- There is at least one policed interface in the range xe-0/0/0 to xe-0/0/23 or the range xe-0/1/1 to xe-0/1/7.
- There is at least one policed interface in the range xe-0/0/24 to xe-0/0/47 or the range xe-0/1/8 to xe-0/1/15.

For example, if you configure a policer to rate-limit traffic at 1 Gbps and apply the policer (by using a firewall filter) to xe-0/0/0 and xe-0/0/24 in the output direction, each interface is rate-limited at 1 Gbps, for a total allowed throughput of 2 Gbps. The same behavior occurs if you apply the policer to xe-0/1/1 and xe-0/0/24—each interface is rate-limited at 1 Gbps.

If you apply the same policer on egress to multiple interfaces in these groups, each *group* is rate-limited at 1 Gbps. For example, if you apply the policer to xe-0/0/0 through xe-0/0/4 (five interfaces) and xe-0/0/24 through xe-0/0/33 (ten interfaces), each group is rate-limited at 1 Gbps, for a total allowed throughput of 2 Gbps.

Here is another example: If you apply the policer to xe-0/0/0 through xe-0/0/4 and xe-0/1/1 through xe-0/1/5 (a total of ten interfaces), that group is rate-limited at 1 Gbps in aggregate. If you also apply the policer to xe-0/0/24, that one interface is rate-limited at 1 Gbps while the other ten are still rate-limited at 1 Gbps in aggregate.

Interfaces xe-0/1/1 through xe-0/1/15 are physically located on the QSFP+ uplink ports, according to the following scheme:

- xe-0/1/1 through xe-0/1/3 are on Q0.
- xe-0/1/4 through xe-0/1/7 are on Q1.
- xe-0/1/8 through xe-0/1/11 are on Q2.
- xe-0/1/2 through xe-0/1/15 are on Q3.

The doubling of the policed rate occurs only if the policer is applied in the output direction. If you configure a policer as described above but apply it in the input direction, the total allowed throughput for all interfaces is 1 Gbps.

Solution This is expected behavior.

Filter-Specific Egress Policers on QFX3500 Devices Might Allow More Throughput Than Is Configured

Problem You can configure policers to be filter-specific, which means that Junos OS creates only one policer instance regardless of how many times the policer is referenced. When you do this, rate limiting is applied in aggregate, so if you configure a policer to discard traffic that exceeds 1 Gbps and reference that policer in three different terms, the total bandwidth allowed by the filter is 1 Gbps. However, the behavior of a filter-specific policer is affected by how the firewall filter terms that reference the policer are stored in ternary content addressable memory (TCAM). If you create a filter-specific policer and reference it in multiple firewall filter terms, the policer allows more traffic than expected if the terms are stored in different TCAM slices. For example, if you configure a policer to discard traffic that exceeds 1 Gbps and reference that policer in three different terms that are stored in three separate memory slices, the total bandwidth allowed by the filter is 3 Gbps, not 1 Gbps.

Solution To prevent this unexpected behavior, use the information about TCAM slices presented in “Planning the Number of Firewall Filters to Create” on page 4435 to organize your configuration file so that all the firewall filter terms that reference a given filter-specific policer are stored in the same TCAM slice.

Policers Can Limit Egress Filters

Problem The number of egress policers that you configure can affect the total number of allowed egress firewall filters. Every policer has two implicit counters that consume two entries in a 1024-entry TCAM that is used for counters, including counters that are configured as action modifiers in firewall filter terms. (Policers consume two entries because one is used for green packets and one is used for nongreen packets regardless of policer type.) If the TCAM becomes full, you cannot commit any more egress firewall filters that have terms with counters. For example, if you configure and commit 512 egress policers (two-color, three-color, or a combination of both policer types), all of the memory entries for counters are used up. If later in your configuration file you insert additional egress firewall filters with terms that also include counters, *none* of the terms in those filters are committed because there is no available memory space for the counters.

Here are some additional examples:

- Assume that you configure egress filters that include a total of 512 policers and no counters. Later in your configuration file you include another egress filter with 10 terms, 1 of which has a counter action modifier. None of the terms in this filter are committed because there is not enough TCAM space for the counter.
- Assume that you configure egress filters that include a total of 500 policers, so 1000 TCAM entries are occupied. Later in your configuration file you include the following two egress filters:
  - Filter A with 20 terms and 20 counters. All the terms in this filter are committed because there is enough TCAM space for all the counters.
  - Filter B comes after Filter A and has five terms and five counters. *None* of the terms in this filter are committed because there is not enough memory space for *all* the counters. (Five TCAM entries are required but only four are available.)

Solution You can prevent this problem by ensuring that egress firewall filter terms with counter actions are placed earlier in your configuration file than terms that include policers. In this circumstance, Junos OS commits policers even if there is not enough TCAM space for the implicit counters. For example, assume the following:

- You have 1024 egress firewall filter terms with counter actions.
- Later in your configuration file you have an egress filter with 10 terms. None of the terms have counters but one has a policer action modifier.

You can successfully commit the filter with 10 terms even though there is not enough TCAM space for the implicit counters of the policer. The policer is committed without the counters.

CHAPTER 54

Overview

Port Mirroring

Understanding Port Mirroring

Port Mirroring Overview

Port mirroring copies packets entering or exiting a port or entering a VLAN and sends the copies to a local interface for local monitoring or to a VLAN for remote monitoring. Use port mirroring to send traffic to applications that analyze traffic for purposes such as monitoring compliance, enforcing policies, detecting intrusions, monitoring and predicting traffic patterns, correlating events, and so on.

Port mirroring is needed for traffic analysis on a switch because a switch normally sends packets only to the port to which the destination device is connected. You configure port mirroring on the switch to send copies of unicast traffic to a local interface or a VLAN and run an analyzer application on a device connected to the interface or VLAN. You configure port mirroring by using the **analyzer** statement.

Keep performance in mind when configuring port mirroring. For example, If you mirror traffic from multiple ports, the mirrored traffic may exceed the capacity of the output interface. We recommend that you limit the amount of copied traffic by selecting specific interfaces instead of using the **all** keyword. You can also limit the amount of mirrored traffic by using a firewall filter. Mirroring only the necessary packets reduces the possibility of a performance impact.

You can use port mirroring to copy any of the following:

- All packets entering or exiting an interface (in any combination)—For example, you can send copies of the packets entering some interfaces and the packets exiting other interfaces to the same local interface or VLAN. If you configure port mirroring to copy packets exiting an interface, traffic that originates on that switch or Node device (in a QFabric system) is not copied when it egresses. Only switched traffic is copied on egress. (See the limitation on egress mirroring below.)
- All packets entering a VLAN—You cannot use port mirroring to copy packets exiting a VLAN.
- Firewall-filtered sample—Sample of packets entering a port or VLAN. Configure a firewall filter to select certain packets for mirroring.

NOTE: **Firewall filters are not supported on egress ports; therefore, you cannot specify policy-based sampling of packets exiting an interface.**

Port-Mirroring Terminology

Table 365 on page 4714 lists the terms used in the documentation about port mirroring and provides definitions.

Table 365: Port Mirroring Terms and Definitions

Term	Description
Analyzer	Port-mirroring configuration. The analyzer includes a name, source interfaces or source VLAN, and a destination for mirrored packets (either a local access interface or a VLAN).
Output interface (also known as monitor interface)	Access interface to which packet copies are sent and to which a device running an analyzer application is connected. The following limitations apply to an output interface: • Cannot also be a source port. • Cannot be used for switching. • Cannot be an aggregated Ethernet interface (LAG). • Does not participate in Layer 2 protocols, such as Spanning Tree Protocol (STP). • Loses any existing VLAN associations when you configure it as an analyzer output interface. If the capacity of the output interface is insufficient to handle the traffic from the source ports, overflow packets are dropped.

Table 365: Port Mirroring Terms and Definitions *(continued)*

Output IP address	IP address of the device running an analyzer application. The device can be on a remote network. When you use this feature, the mirrored packets are GRE-encapsulated. The analyzer device must be able to de-encapsulate GRE-encapsulated packets, or the GRE-encapsulated packets must be de-encapsulated before reaching the analyzer device. (You can use a network sniffer to de-encapsulate the packets.) • An output IP address cannot be in the same subnetwork as any of the switch's management interfaces. • If you create virtual routing instances and also create an analyzer configuration that includes an output IP address, the output address belongs to the default virtual routing instance (inet.0 routing table).
Output VLAN (also known as monitor or analyzer VLAN)	VLAN to which copies are sent and to which a device running an analyzer application is connected. The analyzer VLAN can span multiple switches. The following limitations apply to an output VLAN: • Cannot be a private VLAN or VLAN range. • Cannot be shared by multiple **analyzer** statements. • An output VLAN interface cannot be a member of any other VLAN. • An output VLAN interface cannot be an aggregated Ethernet interface (LAG). • On the source (monitored) switch, only one interface can be a member of the analyzer VLAN.
Input interface (also known as mirrored or monitored interface)	Interface that provides traffic to be mirrored. This traffic can be entering or exiting the interface. (Ingress or egress traffic can be mirrored.) An input interface cannot also be an output interface for an analyzer.
Monitoring station	Computer running an analyzer application.
Local port mirroring	Port-mirroring configuration in which the mirrored packets are sent to an interface on the same switch.
Remote port mirroring	Flooding mirrored packets to an analyzer VLAN that you create to receive mirror traffic or sending the mirrored packets to a remote IP address. (You cannot send mirrored packets to a remote IP address on a QFabric system.)
Policy-based mirroring	Mirroring of packets that match the match a firewall filter term. The action **analyzer *analyzer-name*** is used in the firewall filter to send the packets to the analyzer.

Port Mirroring Constraints and Limitations

- Local and Remote Port Mirroring on page 4715
- Remote Port Mirroring Only on page 4717

Local and Remote Port Mirroring

The following constraints and limitations apply to local and remote port mirroring with the QFX Series:

- You can create a total of four port-mirroring configurations on a QFX Series standalone switch.

- You can create a total of four port-mirroring configurations on each Node group in a QFabric system, subject to the following constraints:
  - As many as four of the configurations can be for local port mirroring.
  - As many as three of the configurations can be for remote port mirroring.
- Regardless of whether you are configuring a standalone switch or a Node group, the following limits apply:
  - There can be no more than two configurations that mirror ingress traffic. (If you configure a firewall filter to send traffic to a port mirror—that is, you use the **analyzer** action modifier in a filter term—this counts as an ingress mirroring configuration for switch or Node group on which the filter is applied.)
  - There can be no more than two configurations that mirror egress traffic.

NOTE: **On QFabric systems, there is no system-wide limit on the total number of mirror sessions.**

- You can configure no more than one type of output in one port-mirroring configuration. That is, you can use no more than one of the following to complete a **set analyzer *name* output** statement:
  - **interface**
  - **ip-address**
  - **vlan**
- If you configure Junos OS to mirror egress packets, do not configure more than 2000 VLANs on a QFX3500 device or QFabric system. If you do so, some VLAN packets might contain incorrect VLAN IDs. This applies to any VLAN packets—not only the mirrored copies.
- The **ratio** and **loss-priority** options are not supported.
- Packets with physical layer errors are filtered out and are not sent to the output port or VLAN.
- If you use sFlow monitoring to sample traffic, it does not sample the mirror copies when they exit from the output interface.
- You cannot mirror packets exiting or entering the following ports:
  - Dedicated Virtual Chassis interfaces
  - Management interfaces (me0 or vme0)
  - Fibre Channel interfaces
  - Routed VLAN interfaces
- An aggregated Ethernet interface cannot be an output interface.

- Do not include an 802.1Q subinterface that has a unit number other than 0 in a port mirroring configuration. Port mirroring does not work with subinterfaces if their unit number is not 0. (You configure 802.1Q subinterfaces using the **vlan-tagging** statement.)
- When packet copies are sent out the output interface, they are not modified for any changes that are normally applied on egress, such as CoS rewriting.
- An interface can be the input interface for only one mirroring configuration. Do not use the same interface as the input interface for multiple mirroring configurations.
- CPU-generated packets (such as ARP, ICMP, BPDU, and LACP packets) cannot be mirrored on egress.
- VLAN-based mirroring is not supported for STP traffic.
- (QFabric systems only) If you configure a QFabric analyzer to mirror egress traffic and the input and output interfaces are on different Node devices, the mirrored copies have incorrect VLAN IDs. This limitation does not apply if you configure a QFabric analyzer to mirror egress traffic and the input and output interfaces are on the *same* Node device. In this case the mirrored copies have the correct VLAN IDs (as long as you do not configure more than 2000 VLANs on the QFabric system).

Remote Port Mirroring Only

The following constraints and limitations apply to remote port mirroring with the QFX Series:

- If you configure an output IP address, the address cannot be in the same subnetwork as any of the switch's management interfaces.
- If you create virtual routing instances and also create an analyzer configuration that includes an output IP address, the output address belongs to the default virtual routing instance (inet.0 routing table).
- An output VLAN cannot be a private VLAN or VLAN range.
- An output VLAN cannot be shared by multiple **analyzer** statements.
- An output VLAN interface cannot be a member of any other VLAN.
- An output VLAN interface cannot be an aggregated Ethernet interface.
- On the source (monitored) switch, only one interface can be a member of the analyzer VLAN.

Understanding Layer 3 Logical Interfaces

A Layer 3 logical interface is a logical division of a physical interface that operates at the network level and therefore can receive and forward 802.1Q VLAN tags. You can use Layer 3 logical interfaces to route traffic among multiple VLANs along a single trunk line that connects a Juniper Networks QFX3500 Switch to a Layer 2 switch. Only one physical connection is required between the switches.

To create Layer 3 logical interfaces on a switch, enable VLAN tagging, partition the physical interface into logical partitions, and bind the VLAN ID to the logical interface.

We recommend that you use the VLAN ID as the logical interface number when you configure the logical interface. QFX Series systems support a maximum of 4089 VLANs, which includes the default VLAN. You can, however, assign a VLAN ID in the range of 1 to 4094, but five of these VLAN IDs are reserved for internal use.

VLAN tagging places the VLAN ID in the frame header, allowing each physical interface to handle multiple VLANs. Double-tagging, which is assigning more than one VLAN ID in the frame header, is not supported. When you configure multiple VLANs on an interface, you must also enable tagging on that interface. Junos OS on switches supports a subset of the 802.1Q standard for receiving and forwarding routed or bridged Ethernet frames with single VLAN tags and running Virtual Router Redundancy Protocol (VRRP) over 802.1Q-tagged interfaces.

DHCP Relay

DHCP and BOOTP Relay Overview

You can configure a Juniper Networks switch to act as a Dynamic Host Configuration Protocol (DHCP) or Bootstrap Protocol (BOOTP) relay agent. This means that if the switch receives a broadcast DHCP or BOOTP request from a locally attached host (client), it relays the message to a specified DHCP or BOOTP server. You should configure the switch to be a DHCP/BOOTP relay agent if you have locally attached hosts and a distant DHCP or BOOTP server.

NOTE: Because DHCP and BOOTP messages are broadcast and are not directed to a specific server, switch, or router, Juniper switches cannot function as both a DHCP server and a DHCP/BOOTP relay agent at the same time. The Junos operating system (Junos OS) generates a commit error if both options are configured at the same time, and the commit operation does not succeed until one of the options is removed.

CHAPTER 55

Configuration

Configuration Examples

Example: Configuring Port Mirroring for Local Analysis

Use port mirroring to send traffic to applications that analyze traffic for purposes such as monitoring compliance, enforcing policies, detecting intrusions, monitoring and predicting traffic patterns, correlating events, and so on. Port mirroring copies packets entering or exiting an interface or entering a VLAN and sends the copies to a local interface for local monitoring.

This example describes how to configure port mirroring to copy traffic sent by employee computers to a switch to an access interface on the same switch.

Requirements

This example uses the following hardware and software components:

- Junos OS Release 11.1
- A switch

Overview and Topology

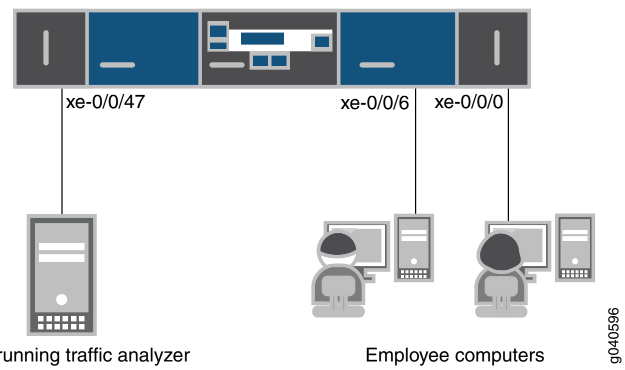
This topic includes two related examples that describe how to mirror traffic entering interfaces on the switch to an access interface on the same switch. The first example shows how to mirror all traffic sent by employee computers to the switch. The second example includes a filter to mirror only the employee traffic going to the Web.

In this example, **xe-0/0/0** and **xe-0/0/6** serve as connections for employee computers. Interface **xe-0/0/47** is connected to a device running an analyzer application.

NOTE: **Multiple ports mirrored to one interface can cause buffer overflow and dropped packets.**

Figure 169 on page 4722 shows the network topology for this example.

Figure 169: Network Topology for Local Port Mirroring Example



Mirroring All Employee Traffic for Local Analysis

To configure port mirroring for all traffic sent by employee computers for local analysis, perform the tasks explained in this section.

CLI Quick Configuration

To quickly configure local port mirroring for ingress traffic to the two ports connected to employee computers, copy the following commands and paste them into a switch terminal window:

```
[edit]
set interfaces xe-0/0/0 unit 0 family ethernet-switching
set interfaces xe-0/0/6 unit 0 family ethernet-switching
set interfaces xe-0/0/47 unit 0 family ethernet-switching
set ethernet-switching options analyzer employee-monitor input ingress interface xe-0/0/0.0
set ethernet-switching options analyzer employee-monitor input ingress interface xe-0/0/6.0
set ethernet-switching options analyzer employee-monitor output interface xe-0/0/47.0
```

Step-by-Step Procedure

To configure an analyzer called **employee-monitor** and specify the input (source) interfaces and the output interface:

1. Configure the interfaces connected to employee computers as input interfaces for the port-mirror analyzer **employee-monitor**:

```
[edit ethernet-switching-options]
user@switch# set analyzer employee-monitor input ingress interface xe–0/0/0.0
user@switch# set analyzer employee-monitor input ingress interface xe–0/0/6.0
```

2. Configure the output analyzer interface for the **employee-monitor** analyzer. This will be the destination interface for the mirrored packets:

```
[edit ethernet-switching-options]
user@switch# set analyzer employee-monitor output interface xe-0/0/47.0
```

Results Check the results of the configuration:

```
[edit]
user@switch# show ethernet-switching-options
  analyzer employee-monitor {
    input {
      ingress {
        interface xe-0/0/0.0;
        interface xe-0/0/6.0;
      }
    }
    output {
      interface {
        xe-0/0/47.0;
      }
    }
  }
}
```

Mirroring Employee-to-Web Traffic for Local Analysis

To mirror only traffic sent by employees to the Web for local analysis, perform the tasks explained in this section.

CLI Quick Configuration To quickly configure local port mirroring of traffic from employee computers that is destined for the Web, copy the following commands and paste them into a switch terminal window:

```
[edit]
set ethernet-switching-options analyzer employee–web–monitor output interface xe-0/0/47.0
set firewall family ethernet-switching filter watch-employee term employee-to-corp from destination-address 192.0.2.16/28
set firewall family ethernet-switching filter watch-employee term employee-to-corp from source-address 192.0.2.16/28
set firewall family ethernet-switching filter watch-employee term employee-to-corp then accept
set firewall family ethernet-switching filter watch-employee term employee-to-web from destination-port 80
set firewall family ethernet-switching filter watch-employee term employee-to-web then analyzer employee-web-monitor
set interfaces xe-0/0/0 unit 0 family ethernet-switching filter input watch-employee
set interfaces xe-0/0/6 unit 0 family ethernet-switching filter input watch-employee
```

Step-by-Step Procedure

To configure local port mirroring of employee-to-web traffic from the two ports connected to employee computers:

1. Configure the output interface:

```
[edit interfaces]
user@switch# set xe-0/0/47 unit 0 family ethernet-switching
```

2. Configure the **employee-web-monitor** analyzer output. (Configure only the output—the input comes from the filter.)

```
[edit ethernet-switching-options]
user@switch# set analyzer employee-web-monitor output interface xe-0/0/47.0
```

3. Configure a firewall filter called **watch-employee** that includes a term to match traffic sent to the Web and send it to the analyzer **employee-web-monitor**. Traffic to and from the corporate subnet (destination or source address of **192.0.2.16/28**) does not need to be copied, so create another term to accept that traffic before it reaches the term that sends Web traffic to the analyzer:

```
[edit firewall family ethernet-switching]
user@switch# set filter watch-employee term employee-to-corp from destination-address
192.0.2.16/28
user@switch# set filter watch-employee term employee-to-corp from source-address
192.0.2.16/28
user@switch# set filter watch-employee term employee-to-corp then accept
user@switch# set filter watch-employee term employee-to-web from destination-port 80
user@switch# set filter watch-employee term employee-to-web then analyzer
employee-web-monitor
```

4. Apply the firewall filter to the appropriate interfaces as an ingress filter (egress filters do not allow analyzers):

```
[edit interfaces]
user@switch# set xe-0/0/0 unit 0 family ethernet-switching filter input watch-employee
user@switch# set xe-0/0/6 unit 0 family ethernet-switching filter input watch-employee
```

Results

Check the results of the configuration:

```
[edit]
user@switch# show ethernet-switching-options
  analyzer employee-web-monitor {
    output {
      interface xe-0/0/47.0;
      }
    }
}
...
firewall family ethernet-switching {
  filter watch-employee {
    term employee-to-web {
      from {
        destination-port 80;
      }
      then analyzer employee-web-monitor;
    }
  }
}
...
interfaces {
```

```
    xe-0/0/0 {
      unit 0 {
        family ethernet-switching {
          filter {
            input watch-employee;
          }
        }
      }
    }
    xe-0/0/6 {
      family ethernet-switching {
        filter {
          input watch-employee;
        }
      }
    }
  }
```

Verification

Verifying That the Analyzer Has Been Correctly Created

Purpose Verify that the analyzer named **employee-monitor** or **employee-web-monitor** has been created on the switch with the appropriate input interfaces and appropriate output interface.

Action You can verify that the port mirror analyzer has been configured as expected using the **show analyzer** command.

```
user@switch> show analyzer
  Analyzer name                : employee-monitor
  Output interface             : xe-0/0/47.0
  Mirror ratio                 : 1
  Loss priority                : Low
  Ingress monitored interfaces : xe-0/0/0.0
  Ingress monitored interfaces : xe-0/0/6.0
  Egress monitored interfaces  : None
```

Meaning This output shows that the **employee-monitor** analyzer:

- Has a ratio of 1 (mirroring every packet, the default setting)
- Has a loss priority of low (set this option to high only when the analyzer output is to a VLAN)
- Is mirroring the traffic entering the **xe-0/0/0** and **xe-0/0/6** interfaces
- Is sending the mirrored traffic to the **xe-0/0/47** interface

Related Documentation

- Configuring Port Mirroring on page 4730

Example: Configuring Port Mirroring for Remote Analysis

Use port mirroring to send traffic to applications that analyze traffic for purposes such as monitoring compliance, enforcing policies, detecting intrusions, monitoring and predicting traffic patterns, correlating events, and so on. Port mirroring copies packets entering or exiting an interface or entering a VLAN and sends the copies either to a local interface for local monitoring or to a VLAN for remote monitoring. This example describes how to configure port mirroring for remote analysis.

Requirements

This example uses the following hardware and software components:

- Junos OS Release 12.1 for the QFX Series
- A switch

Overview and Topology

This topic includes two related examples that describe how to mirror traffic entering ports on the switch to an analyzer VLAN so that you can perform analysis using a remote device. The first example shows how to mirror all traffic sent by employee computers to the switch. The second example includes a filter to mirror only the employee traffic going to the Web.

In this example:

- Interfaces **ge-0/0/0** and **ge-0/0/1** are Layer 2 interfaces that connect to employee computers.
- Interface **ge-0/0/10** is a Layer 2 interface that connects to another switch.
- VLAN **remote-analyzer** is configured on all switches in the topology to carry the mirrored traffic.

NOTE: In addition to performing the configuration steps described here, you must also configure the analyzer VLAN (**remote-analyzer** in this example) on the other switches that are used to connect the source switch (the one in this configuration) to the one that the monitoring station is connected to.

Mirroring All Employee Traffic for Remote Analysis

CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **edit** hierarchy level:

```
[edit]
set vlans remote-analyzer vlan-id 999
set interfaces ge-0/0/10 unit 0 family ethernet-switching port-mode trunk
set interfaces ge-0/0/10 unit 0 family ethernet-switching vlan members 999
set ethernet-switching-options analyzer employee-monitor input ingress interface ge-0/0/0.0
set ethernet-switching-options analyzer employee-monitor input ingress interface ge-0/0/1.0
set ethernet-switching-options analyzer employee-monitor output vlan remote-analyzer
```

Step-by-Step Procedure

To configure basic remote port mirroring:

1. Configure the analyzer VLAN (called **remote-analyzer** in this example):

   ```
   [edit vlans]
   user@switch# set vlans remote-analyzer vlan-id 999
   ```

2. Configure the interface connected to another switch for trunk mode and associate it with the **remote-analyzer** VLAN:

   ```
   [edit interfaces]
   user@switch# set ge-0/0/10 unit 0 family ethernet-switching port-mode trunk
   user@switch# set ge-0/0/10 unit 0 family ethernet-switching vlan members 999
   ```

3. Configure the **employee-monitor** analyzer:

   ```
   [edit ethernet-switching-options]
   user@switch# set analyzer employee–monitor
   user@switch# set analyzer employee-monitor input ingress interface ge-0/0/0.0
   user@switch# set analyzer employee-monitor input ingress interface ge-0/0/1.0
   user@switch# set analyzer employee-monitor output vlan remote-analyzer
   ```

4. Configure the **remote-analyzer** VLAN on the switches that connect this switch to the monitoring workstation.

Results

Check the results of the configuration:

```
[edit]
user@switch# show
ethernet-switching-options {
  analyzer employee-monitor {
    input {
      ingress {
        interface ge-0/0/0.0;
        interface ge-0/0/1.0;
      }
    }
    output {
      vlan {
        remote-analyzer;
      }
    }
  }
}
```

Mirroring Employee-to-Web Traffic for Remote Analysis

CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **edit** hierarchy level:

```
[edit]
set vlans remote-analyzer vlan-id 999
set interfaces ge-0/0/10 unit 0 family ethernet-switching port mode trunk
set interfaces ge-0/0/10 unit 0 family ethernet-switching vlan members 999set
ethernet-switching-options analyzer employee-web-monitor loss-priority high output vlan 999
set firewall family ethernet-switching filter watch-employee term employee-to-web from
destination-port 80
set firewall family ethernet-switching filter watch-employee term employee-to-web then analyzer
employee-web-monitor
set ge-0/0/0 unit 0 family ethernet-switching filter input watch-employee
set interfaces ge-0/0/1 unit 0 family ethernet-switching filter input watch-employee
```

Step-by-Step Procedure

1. Configure the analyzer VLAN (called **remote-analyzer** in this example):

```
[edit vlans]
user@switch# set remote-analyzer vlan-id 999
```

2. Configure an interface to associate it with the **remote-analyzer** VLAN:

```
[edit interfaces]
user@switch# set interfaces ge-0/0/10 unit 0 family ethernet-switching port mode trunk
user@switch# set ge-0/0/10 unit 0 family ethernet-switching vlan members 999
```

3. Configure the **employee-web-monitor** analyzer. (Configure only the output—the input comes from the filter.)

```
[edit ethernet-switching-options]
user@switch# set ethernet-switching-optionsanalyzer employee-web-monitor output
vlan 999
```

4. Configure a firewall filter called **watch-employee** to match traffic sent to the Web and send it to the analyzer **employee-web-monitor**:

```
[edit firewall family ethernet-switching]
user@switch# set filter watch-employee term employee-to-web from destination-port 80
user@switch# set filter watch-employee term employee-to-web then analyzer
employee-web-monitor
```

5. Apply the firewall filter to the appropriate interfaces as an ingress filter:

```
[edit interfaces]
user@switch# set ge-0/0/0 unit 0 family ethernet-switching filterinput watch-employee
user@switch# set ge-0/0/1 unit 0 family ethernet-switching filter input watch-employee
```

6. Configure the **remote-analyzer** VLAN on the switches that connect this switch to the monitoring workstation.

Results

Check the results of the configuration:

```
[edit]
user@switch# show
interfaces {
  ...
  ge-0/0/10 {
    unit 0 {
      family ethernet-switching {
```

```
                port-mode trunk;
                vlan {
                    members remote-analyzer;
                }
            }
        }
    }
    ge-0/0/0 {
        unit 0 {
            family ethernet-switching {
                filter {
                    input watch-employee;
                }
            }
        }
    }
    ge-0/0/1 {
        unit 0 {
            family ethernet-switching {
                filter {
                    input watch-employee;
                }
            }
        }
    }
}
...
firewall {
    family ethernet-switching {
        ...
        filter watch-employee {
            term employee-to-web {
                from {
                    destination-port 80;
                }
                then analyzer employee-web-monitor;
            }
        }
    }
}
ethernet-switching-options {
    analyzer employee-web-monitor {
        output {
            vlan {
                999;
            }
        }
    }
vlans {
    remote-analyzer {
        vlan-id 999;
    }
}
```

Verification

Verifying That the Analyzer Has Been Correctly Created

Purpose Verify that the analyzer named **employee-monitor** or **employee-web-monitor** has been created on the switch with the appropriate input interfaces and appropriate output interface.

Action You can verify the port mirror analyzer is configured as expected using the **show analyzer** command.

```
user@switch> show analyzer
 Analyzer name                : employee-monitor
 Output VLAN                  : remote-analyzer
 Ingress monitored interfaces : ge-0/0/0.0
 Ingress monitored interfaces : ge-0/0/1.0
```

Meaning This output shows that the **employee-monitor** analyzer is mirroring the traffic entering **ge-0/0/0** and **ge-0/0/1** and is sending the mirror traffic to the analyzer **remote-analyzer**.

Configuration Tasks

Configuring Port Mirroring

You use port mirroring to copy packets and send the copies to a device running an application such as a network analyzer or intrusion detection application so that you can analyze traffic without delaying it. You can mirror traffic entering or exiting a port or entering a VLAN, and you can send the copies to a local access interface or to a VLAN through a trunk interface.

We recommend that you disable port mirroring when you are not using it. To avoid creating a performance issue If you do enable port mirroring, we recommend that you select specific input interfaces instead of using the **all** keyword. You can also limit the amount of mirrored traffic by using a firewall filter.

NOTE: If you want to create additional analyzers without deleting an existing analyzer, first disable the existing analyzer using the **disable analyzer *analyzer-name*** command.

NOTE: You must configure port mirroring output interfaces as **family ethernet-switching**.

- Configuring Port Mirroring for Local Analysis on page 4731
- Configuring Port Mirroring for Remote Analysis on page 4731
- Filtering the Traffic Entering an Analyzer on page 4732

Configuring Port Mirroring for Local Analysis

To mirror interface traffic to a local interface on the switch:

1. If you want to mirror traffic that is ingressing or egressing specific interfaces, choose a name for the port-mirroring configuration and configure what traffic should be mirrored by specifying the interfaces and direction of traffic:

   `[edit ethernet-switching-options]`
   `user@switch#` **set analyzer *analyzer-name* input (ingress | egress) interface *interface-name***

   NOTE: If you configure Junos OS to mirror egress packets, do not configure more than 2000 VLANs. If you do so, some VLAN packets might contain incorrect VLAN IDs.

   NOTE: If you configure mirroring for packets that egress an access interface, the original packets lose any VLAN tags when they exit the access interface, but the mirrored (copied) packets retain the VLAN tags when they are sent to the analyzer system.

2. If you want to specify that all traffic entering a VLAN should be mirrored, choose a name for the port-mirroring configuration and specify the VLAN:

   `[edit ethernet-switching-options]`
   `user@switch#` **set analyzer *analyzer-name* input ingress vlan *vlan-name***

   NOTE: You cannot configure port mirroring to copy traffic that egresses a VLAN.

3. Configure the destination interface for the mirrored packets:

   `[edit ethernet-switching-options]`
   `user@switch#` **set analyzer *analyzer-name* output interface *interface-name***

Configuring Port Mirroring for Remote Analysis

To mirror traffic to a VLAN for analysis at a remote location:

1. Configure a VLAN to carry the mirrored traffic:

   `[edit]`

`user@switch#` **set vlans *vlan-name* vlan-id *number***

2. Configure the interface that connects to another switch (the uplink interface) to trunk mode and associate it with the appropriate VLAN:

   `[edit]`
   `user@switch#` **set interfaces *interface-name* unit 0 family ethernet-switching port-mode trunk vlan members (*vlan-name* | *vlan-id*)**

3. Configure the analyzer:

   a. Choose a name for the analyzer:

      `[edit ethernet-switching-options]`
      `user@switch#` **set analyzer *analyzer-name***

   b. Specify the interface to be mirrored and whether the traffic should be mirrored on ingress or egress:

      `[edit ethernet-switching-options]`
      `user@switch#` **set analyzer *analyzer-name* input (ingress | egress) interface *interface-name***

   c. Specify the appropriate IP address or VLAN as the output (a VLAN is specified in this example:

      `[edit ethernet-switching-options]`
      `user@switch#` **set analyzer *analyzer-name* output vlan (*vlan-name* | *vlan-id*)**

      If you specify an IP address as the output, note the following constraints:

      - The address cannot be in the same subnetwork as any of the switch's management interfaces.
      - If you create virtual routing instances and also create an analyzer configuration that includes an output IP address, the output address belongs to the default virtual routing instance (**inet.0** routing table).
      - The analyzer device must be able to de-encapsulate GRE-encapsulated packets, or the GRE-encapsulated packets must be de-encapsulated before reaching the analyzer device. (You can use a network sniffer to de-encapsulate the packets.)

Filtering the Traffic Entering an Analyzer

In addition to specifying which traffic to mirror by configuring an analyzer, you can also use a firewall filter to exercise more control over which packets are copied. For example, you might use a filter to specify that only traffic from certain applications be mirrored. The filter can use any of the available match conditions and must have an action of **analyzer *analyzer-name***. If you use the same analyzer in multiple filters or terms, the output packets are copied only once.

NOTE: **You can include the action analyzer in ingress firewall filters only. You can apply ingress filters with this action to ports (Layer 2 interfaces), Layer 3 interfaces, and VLANs.**

When you use a firewall filter as the input to an analyzer, you output the copied traffic to a local interface or a VLAN just as you do when a firewall is not involved.

To configure port mirroring with filters:

1. Configure an analyzer for local or remote analysis. Configure only the output. For example, for local analysis enter:

   [edit ethernet-switching-options]
   user@switch# **set analyzer *analyzer-name* output interface *interface-name***

   NOTE: Do not configure input to this analyzer.

2. Create a firewall filter using any of the available match conditions and specify the action as **analyzer *analyzer-name***.

3. Apply the firewall filter to the interfaces or VLAN that should provide the input to the analyzer:

   [edit]
   user@switch# **set interfaces *interface-name* unit 0 family ethernet-switching filter input *filter-name***
   [edit]
   user@switch# **set vlan (*vlan-name* | *vlan-id*) filter input *filter-name***

Configuring DHCP and BOOTP Relay

You can configure the QFX Series to act as a Dynamic Host Configuration Protocol (DHCP) and Bootstrap Protocol (BOOTP) relay agent. This means that if a locally attached host can issue a DHCP or BOOTP request as a broadcast message and the switch relays the message to a specified DHCP or BOOTP server. You should configure a switch to be a DHCP and BOOTP relay agent if you have locally attached hosts and a remote DHCP or BOOTP server.

If you configure a switch to be a DHCP relay agent, you can also enable smart DHCP relay, which allows you to configure alternative gateway addresses for a DHCP server so that if the server fails to reply to the requests sent using the primary gateway address, the switch can resend the requests via the alternative gateway addresses. To use this feature, you must configure a routed VLAN interface or Layer 3 logical interface with multiple IP addresses and configure that interface to be a relay agent.

- Configuring a DHCP and BOOTP Relay Agent on page 4733
- Configuring DHCP Smart Relay on page 4735

Configuring a DHCP and BOOTP Relay Agent

To configure a switch to act as a DHCP and BOOTP relay agent, include the **bootp** statement at the **[edit forwarding-options helpers]** hierarchy level:

```
[edit forwarding-options helpers]
bootp {
  apply-secondary-as-giaddr text-description;
  client-response-ttl number;
  description text-description;
  interface (interface-name | interface-group) {
    client-response-ttl number;
    description text-description;
    maximum-hop-count number;
    minimum-wait-time seconds;
    no-listen;
    server address
    apply-secondary-as-giaddr
  }
  maximum-hop-count number;
  minimum-wait-time seconds;
  relay-agent-option;
  server server-identifier
}
```

To include a description of the BOOTP service, DHCP service, or interface, use the **description** statement.

To configure a logical interface or a group of logical interfaces with a specific DHCP relay or BOOTP configuration, include the **interface** statement.

To stop packets from being forwarded, include the **no-listen** statement.

To set the maximum allowed number in the hops field of the BOOTP message, include the **maximum-hop-count** statement. BOOTP messages that have a larger number in the hops field than the maximum allowed are not forwarded. If you omit the **maximum-hop-count** statement, the default maximum number of hops is four.

To set the minimum allowed number of seconds in the **secs** field of the BOOTP message, include the **minimum-wait-time** statement. This setting configures a minimum number of seconds since the client sent its first BOOTP request. BOOTP messages that have a smaller number in the **secs** field than the allowed minimum are not forwarded. The default value for the minimum wait time is zero (0).

To set the IP address that specify the DHCP or BOOTP server for the router, switch, or interface, include the **server** statement. You can include multiple **server** statements.

To set an IP time-to-live (TTL) value for DHCP response packets sent to a DHCP client, include the **client-response-ttl** statement.

The following example demonstrates a BOOTP relay agent configuration.

```
user@host# show forwarding-options
helpers {
  bootp {
    description "dhcp relay agent global parameters";
    server 192.168.55.44;
    server 172.16.0.3 routing-instance c3;
    maximum-hop-count 10;
    minimum-wait-time 8;
```

```
        interface {
          xe-0/0/1 {
            description "use this info for this interface";
            server 10.10.10.10;
            server 192.168.14.14;
            maximum-hop-count 11;
            minimum-wait-time 3;
          }
          xe-0/0/2 {
            no-listen; ###ignore DHCPDISCOVER messages on this interface
          }
          all {
            description "globals apply to all other interfaces";
          }
        }
      }
    }
```

Configuring DHCP Smart Relay

You can use DHCP smart relay to provide redundancy and resiliency to your DHCP relay configuration. Smart relay provides additional relay functionality and requires all of the configuration settings required by DHCP relay. To use DHCP smart relay, you also need an interface with multiple IP addresses assigned to it. You can achieve this by doing either of the following tasks:

- Create a routed VLAN interface and assign at least two IP addresses to it. See "Configuring Routed VLAN Interfaces" on page 1532 and "Example: Configuring Routing Between VLANs on One Switch" on page 1428 for information about this approach.
- Create a Layer 3 logical interface (by using VLAN tagging) and assign at least two IP addresses to it. See "Understanding Layer 3 Logical Interfaces" on page 1851 and "Configuring a Layer 3 Logical Interface" on page 2019 for information about this approach.

Once you have created an interface with multiple IP addresses, complete the smart relay configuration by entering one of the following statements:

- **set forwarding-options helpers bootp smart-relay-global**: Use this statement to enable smart relay on all the interfaces that are configured as relay agents.
- **set forwarding-options helpers bootp interface *interface-name* smart-relay-agent**: Use this statement to enable smart relay on a specific interface.

When smart relay is configured for an interface, the switch initially sends DHCP request (discover) messages out of that interface using the primary address of the interface as the gateway IP address (in the giaddr field) for the DHCP message. If no DHCP offer message is received from a server in reply, the switch allows the client to send as many as three more discover messages using the same gateway IP address. If no DHCP offer message is received after three retries, the switch resends the discover message using the alternate IP address as the gateway IP address. If you configure more than two IP addresses on the relay agent interface, the switch repeats this process until a DHCP offer message is received or all of the IP addresses have been used without success.

Configuration Statements for Port Mirroring

analyzer

Syntax

```
analyzer {
  name {
    input {
      egress {
        interface (all | interface-name);
      }
      ingress {
        interface (all | interface-name);
        vlan (vlan-id | vlan-name);
      }
    output {
      interface interface-name;
      ip-address ip-address;
      vlan (vlan-id | vlan-name);
    }
  }
}
```

Hierarchy Level

[edit ethernet-switching-options]

For platforms with ELS:

[edit forwarding-options]

Release Information

Statement introduced in Junos OS Release 11.1 for the QFX Series.
Option **output vlan** added in Junos OS Release 12.1 for the QFX Series.
Option **output ip-address** added in Junos OS Release 12.3 for the QFX Series.

Description

Configure port mirroring. You can create a total of four port-mirroring configurations on the QFX Series, subject to the following limits:

- There can be no more than two configurations that mirror ingress traffic.
- There can be no more than two configurations that mirror egress traffic.

Default

Port mirroring is disabled, and Junos OS creates no default analyzers.

Options

all—Mirror all the access interfaces. Using this option does not cause the QSFP+ or management interfaces to be mirrored.

CAUTION: Configuring the **all** option in a QFabric system causes all the access interfaces on all the nodes to be mirrored. Be cautious about using this option on a QFabric system.

name—Name of the analyzer. The name can include as many as 125 characters; must begin with a letter; and can include uppercase letters, lowercase letters, numbers, dashes, and underscores. No other special characters are allowed.

The remaining statements are explained separately.

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

egress

Syntax

```
egress {
  interface (all | interface-name);
}
```

Hierarchy Level
For platforms without ELS:

[edit ethernet-switching-options analyzer *name* input]

For platforms with ELS:

[edit forwarding-options analyzer *name* input]

Release Information
Statement introduced in Junos OS Release 11.2 for the QFX Series.

Description
Specify interfaces for which egressing traffic is mirrored.

The statement is explained separately.

NOTE: If you configure Junos OS to mirror egress packets, do not configure more than 2000 VLANs. If you do so, some of the mirrored packets might contain incorrect VLAN IDs.

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

ip-address (Port Mirroring)

Syntax ip-address *ip-address*;

Hierarchy Level [edit ethernet-switching-options analyzer *name* output]

Release Information Statement introduced in Junos OS Release 12.3 for the QFX Series.

Description Specify the IP address to which traffic should be mirrored (the IP address of the analyzer system). The device can be on a remote network. The analyzer device must be able to de-encapsulate GRE-encapsulated packets, or the GRE-encapsulated packets must be de-encapsulated before reaching the analyzer device. (You can use a network sniffer to de-encapsulate the packets.) This statement is not supported on QFabric systems.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Understanding Port Mirroring on page 4713
- Configuring Port Mirroring on page 4730
- Example: Configuring Port Mirroring for Local Analysis on page 4721

output

Syntax

```
output {
  interface interface-name;
  ip-address ip-address;
  vlan (vlan-id | vlan-name);
}
```

Hierarchy Level

For platforms without ELS:

[edit ethernet-switching-options analyzer *name*]

For platforms with ELS:

[edit forwarding-options analyzer *name*]

Release Information

Statement introduced in Junos OS Release 11.1 for the QFX Series.
Option **output vlan** added in Junos OS Release 12.1 for the QFX Series.

Description

Configure the destination for mirrored traffic, either an interface on the switch (for local monitoring) or a VLAN (for remote monitoring).

The statements are explained separately.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Configuring Port Mirroring on page 4730
- Example: Configuring Port Mirroring for Local Analysis on page 4721

vlan (Port Mirroring)

Syntax

vlan (*vlan-id* | *vlan-name*);

Hierarchy Level

For platforms without ELS:

[edit ethernet-switching-options analyzer *name* input ingress],
[edit ethernet-switching-options analyzer *name* output]

For platforms with ELS:

[edit forwarding-options analyzer *name* input (egress | ingress)]
[edit forwarding-options analyzer *name* output]

Release Information

Statement introduced in Junos OS Release 11.1 for the QFX Series.
Option**output vlan** added in Junos OS Release 12.1 for the QFX Series.

Description

Specify that traffic entering into a VLAN should be mirrored. Configure mirrored traffic to be sent to a VLAN for remote monitoring (output).

Options

vlan-id—Numeric VLAN identifer.

vlan-name—Name of the VLAN.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

Configuration Statements for Encryption

authentication-key-chains

Syntax

```
authentication-key-chains {
  key-chain key-chain-name {
    description text-string;
    key key {
      algorithm (md5 | hmac-sha-1);
      options (basic | isis-enhanced);
      secret secret-data;
      start-time yyyy-mm-dd.hh:mm:ss;
    }
    tolerance seconds;
  }
}
```

Hierarchy Level [edit security]

Release Information

Statement introduced in Junos OS Release 7.6.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Support for the BFD protocol introduced in Junos OS Release 9.6.
Support for the BFD protocol introduced in Junos OS Release 9.6 for EX Series switches.
Support for IS-IS introduced in JUNOS OS Release 11.2.
Statement introduced in Junos OS Release 11.3 for the QFX Series.

Description

Configure authentication key updates for the Border Gateway Protocol (BGP), the Label Distribution Protocol (LDP) routing protocols, the Bidirectional Forwarding Detection (BFD) protocol, and the Intermediate System-to-Intermediate System (IS-IS) protocol. When the **authentication-key-chains** statement is configured at the **[edit security]** hierarchy level, and is associated with the BGP, LDP, or IS-IS protocols at the **[edit protocols]** hierarchy level or with the BFD protocol using the **bfd-liveness-detection** statement, authentication key updates can occur without interrupting routing and signaling protocols such as Open Shortest Path First (OSPF) and Resource Reservation Setup Protocol (RSVP).

The remaining statements are explained separately.

Required Privilege Level

admin—To view this statement in the configuration.
admin-control—To add this statement to the configuration.

Related Documentation

- *Configuring the Authentication Key Update Mechanism for BGP and LDP Routing Protocols*
- Example: Configuring BFD Authentication for Static Routes on page 2332

cache-size

Syntax cache-size *bytes*;

Hierarchy Level [edit security certificates]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description (Encryption interface on M Series and T Series routers and EX Series switches only) Configure the cache size for digital certificates.

Options ***bytes***—Cache size for digital certificates.

Range: 64 through 4,294,967,295

Default: 2 megabytes (MB)

NOTE: **We recommend that you limit your cache size to 4 MB.**

Required Privilege Level admin—To view this statement in the configuration.
admin-control—To add this statement to the configuration

Related Documentation

- *Configuring Digital Certificates for an ES PIC*

cache-timeout-negative

Syntax cache-timeout-negative *seconds*;

Hierarchy Level [edit security certificates]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description (Encryption interface on M Series and T Series routers and EX Series switches only) Configure a negative cache for digital certificates.

Options ***seconds***—Negative time to cache digital certificates, in seconds.

Range: 10 through 4,294,967,295

Default: 20

CAUTION: **Configuring a large negative cache value can lead to a denial-of-service attack.**

Required Privilege Level admin—To view this statement in the configuration.
admin-control—To add this statement to the configuration

Related Documentation
- *Configuring Digital Certificates for an ES PIC*

ca-name

Syntax ca-name *ca-identity*;

Hierarchy Level [edit security certificates certification-authority]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description (Encryption interface on M Series and T Series routers and EX Series switches only) Specify the certificate authority (CA) identity to use in the certificate request.

Options ***ca-identity***—CA identity to use in the certificate request.

Required Privilege Level admin—To view this statement in the configuration.
admin-control—To add this statement to the configuration.

Related Documentation
- *Configuring Digital Certificates for an ES PIC*

certificates

Syntax

```
certificates {
  cache-size bytes;
  cache-timeout-negative seconds;
  certification-authority ca-profile-name {
    ca-name ca-identity;
    crl file-name;
    encoding (binary | pem);
    enrollment-url url-name;
    file certificate-filename;
    ldap-url url-name;
  }
  enrollment-retry attempts;
  local certificate-name {
    certificate-key-string;
    load-key-file URL filename;
  }
  maximum-certificates number;
  path-length certificate-path-length;
}
```

Hierarchy Level [edit security]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description (Encryption interface on M Series and T Series routers and EX Series switches only) Configure the digital certificates for IPsec.

The remaining statements are explained separately.

Required Privilege Level admin—To view this statement in the configuration.
admin-control—To add this statement to the configuration.

Related Documentation

- *Configuring Digital Certificates for an ES PIC*

certification-authority

Syntax

```
certification-authority ca-profile-name {
  ca-name ca-identity;
  crl file-name;
  encoding (binary | pem);
  enrollment-url url-name;
  file certificate-filename;
  ldap-url url-name;
}
```

Hierarchy Level [edit security certificates]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description (Encryption interface on M Series and T Series routers and EX Series switches only) Configure a certificate authority profile name.

The remaining statements are explained separately.

Required Privilege Level admin—To view this statement in the configuration.
admin-control—To add this statement to the configuration

Related Documentation

- *Configuring Digital Certificates for an ES PIC*

crl (Encryption Interface)

Syntax crl *file-name*;

Hierarchy Level [edit security certificates]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description (Encryption interface on M Series and T Series routers and EX Series switches only) Configure the certificate revocation list (CRL). A CRL is a time-stamped list identifying revoked certificates, which is signed by a CA and made available to the participating IPsec peers on a regular periodic basis.

Options ***file-name***—Specify the file from which to read the CRL.

Required Privilege Level admin—To view this statement in the configuration.
admin-control—To add this statement to the configuration

Related Documentation

- *Configuring Digital Certificates for an ES PIC*

encoding

Syntax encoding (binary | pem);

Hierarchy Level [edit security ike policy *ike-peer-address*],
[edit security certificates certification-authority *ca-profile-name*]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description (Encryption interface on M Series and T Series routers and EX Series switches only) Specify the file format used for the **local-certificate** and **local-key-pair** statements.

Options **binary**—Binary file format.

pem—Privacy-enhanced mail (PEM), an ASCII base 64 encoded format.

Default: **binary**

Required Privilege Level admin—To view this statement in the configuration.
admin-control—To add this statement to the configuration.

Related Documentation

- *Configuring Digital Certificates for an ES PIC*
- *Configuring an IKE Policy for Digital Certificates for an ES PIC*

enrollment-retry

Syntax enrollment-retry *attempts*;

Hierarchy Level [edit security certificates]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.

Description (Encryption interface on M Series and T Series routers and EX Series switches only) Specify how many times a router or switch can resend a digital certificate request.

Options ***attempts***—Number of enrollment retries.

Range: 0 through 100

Default: 0

Required Privilege Level admin—To view this statement in the configuration.
admin-control—To add this statement to the configuration.

Related Documentation

- *Configuring Digital Certificates for an ES PIC*

enrollment-url

Syntax enrollment-url *url-name*;

Hierarchy Level [edit security certificates certification-authority *ca-profile-name*]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description (Encryption interface on M Series and T Series routers and EX Series switches only) Specify where your router or switch sends Simple Certificate Enrollment Protocol-based (SCEP-based) certificate enrollment requests (certificate authority URL).

Options *url-name*—Certificate authority URL.

Required Privilege Level admin—To view this statement in the configuration.
admin-control—To add this statement to the configuration.

Related Documentation

- *Configuring Digital Certificates for an ES PIC*

file

Syntax file *certificate-filename*;

Hierarchy Level [edit security certificates certification-authority *ca-profile-name*]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description (Encryption interface on M Series and T Series routers and EX Series switches only) Specify the file from which to read the digital certificate.

Options *certificate-filename*—File from which to read the digital certificate.

Required Privilege Level admin—To view this statement in the configuration.
admin-control—To add this statement to the configuration.

Related Documentation

key (Authentication Keychain)

Syntax

```
key key {
  algorithm (md5 | hmac-sha-1);
  options (basic | isis-enhanced);
  secret secret-data;
  start-time yyyy-mm-dd.hh:mm:ss;
}
```

Hierarchy Level [edit security authentication-key-chains key-chain *key-chain-name*]

Release Information Statement introduced in Junos OS Release 7.6.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Support for the BFD protocol introduced in Junos OS Release 9.6.
Support for the BFD protocol introduced in Junos OS Release 9.6 for EX Series switches.
Support for IS-IS introduced in JUNOS OS Release 11.2.
Statement introduced in Junos OS Release 11.3 for QFX Series switches.

Description Configure the authentication element.

Options ***key***—Each key within a keychain is identified by a unique integer value.

Range: 0 through 63

The remaining statements are explained separately.

Required Privilege Level admin—To view this statement in the configuration.
admin-control—To add this statement to the configuration.

Related Documentation

key-chain (Security)

Syntax

```
keychain key-chain-name {
  description text-string;
  key key {
    algorithm (md5 | hmac-sha-1);
    options (basic | isis-enhanced);
    secret secret-data;
    start-time yyyy-mm-dd.hh:mm:ss;
  }
  tolerance seconds;
}
```

Hierarchy Level

[edit security authentication-key-chains]

Release Information

Statement introduced in Junos OS Release 7.6.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Support for the BFD protocol introduced in Junos OS Release 9.6.
Support for the BFD protocol introduced in Junos OS Release 9.6 for EX Series switches.
Support for IS-IS introduced in Junos OS Release 11.2.
Statement introduced in Junos OS Release 11.3 for the QFX Series.

Description

Create the key-chain configuration for the Border Gateway Protocol (BGP), the Label Distribution Protocol (LDP) routing protocols, the Bidirectional Forwarding Detection (BFD) protocol, and the Intermediate System-to-Intermediate System (IS-IS) protocol.

Options

key-chain-name—Authentication keychain name. It can be up to 126 characters. Characters can include any ASCII strings. If you include spaces, enclose all characters in quotation marks (“ ”).

Required Privilege Level

admin—To view this statement in the configuration.
admin-control—To add this statement to the configuration.

Related Documentation

- Example: Configuring Hitless Authentication Key Rollover for IS-IS on page 3211

ldap-url

Syntax <ldap-url *url-name*>;

Hierarchy Level [edit security certificates certification-authority *ca-profile-name*]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description (Encryption interface on M Series and T Series routers and EX Series switches only) (Optional) Specify the Lightweight Directory Access Protocol (LDAP) URL for digital certificates.

Options ***url-name***—Name of the LDAP URL.

Required Privilege Level system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

Related Documentation
- *Configuring Digital Certificates for an ES PIC*

local

Syntax

```
local certificate-name {
  certificate-key-string;
  load-key-file URL filename;
}
```

Hierarchy Level [edit security certificates]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Import a paired X.509 private key and authentication certificate, to enable Junos XML protocol client applications to establish Secure Sockets Layer (SSL) connections to the router or switch.

Options ***certificate-namecertificate-key-string***—String of alphanumeric characters that constitute the private key and certificate.

certificate-name—Name that uniquely identifies the certificate.

load-key-file *URL filename*—File that contains the private key and certificate. It can be one of two types of values:

- Pathname of a file on the local disk (assuming you have already used another method to copy the certificate file to the router's or switch's local disk)
- URL to the certificate file location (for instance, on the computer where the Junos XML protocol client application runs)

Required Privilege Level system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

Related Documentation

maximum-certificates

Syntax maximum-certificates *number*;

Hierarchy Level [edit security certificates]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description (Encryption interface on M Series and T Series routers and EX Series switches only) Configure the maximum number of peer digital certificates to be cached.

Options ***number***—Maximum number of peer digital certificates to be cached.

Range: 64 through 4,294,967,295 peer certificates

Default: 1024 peer certificates

Required Privilege Level system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

Related Documentation

- *Configuring Digital Certificates for an ES PIC*

path-length

Syntax path-length *certificate-path-length*;

Hierarchy Level [edit security certificates]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description (Encryption interface on M Series and T Series routers and EX Series switches only) Configure the digital certificate path length.

Options ***certificate-path-length***—Digital certificate path length.

Range: 2 through 15 certificates

Default: 15 certificates

Required Privilege Level admin—To view this statement in the configuration.
admin-control—To add this statement to the configuration.

Related Documentation

- *Configuring Digital Certificates for an ES PIC*

secret

Syntax secret *secret-data*;

Hierarchy Level [edit security authentication-key-chains key-chain *key-chain-name* key *key*]

Release Information Statement introduced in Junos OS Release 7.6.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Support for the BFD protocol introduced in Junos OS Release 9.6.
Support for the BFD protocol introduced in Junos OS Release 9.6 for EX Series switches.
Support for IS-IS introduced in JUNOS OS Release 11.2.
Statement introduced in Junos OS Release 11.3 for QFX Series switches.

Description Specify a password in encrypted text or plain text format. The secret password always appears in encrypted format.

Options ***secret-data***—Password to use; it can include spaces if the character string is enclosed in quotation marks.

Required Privilege Level admin—To view this statement in the configuration.
admin-control—To add this statement to the configuration.

Related Documentation

security

Syntax

```
security {
  authentication-key-chains {
    key-chain key-chain-name {
      key key {
        secret secret-data;
        start-time yyyy-mm-dd.hh:mm:ss;
      }
    }
  certificates {
    cache-size bytes;
    cache-timeout-negative seconds;
    certification-authority ca-profile-name {
      ca-name ca-identity;
      crl file-name;
      encoding (binary | pem);
      enrollment-url url-name;
      file certificate-filename;
      ldap-url url-name;
    }
    enrollment-retry attempts;
    local certificate-filename {
      certificate-key-string;
      load-key-file key-file-name;
    }
    maximum-certificates number;
    path-length certificate-path-length;
  }
  ssh-known-hosts {
    host {
      fetch-from-server host-name;
      load-key-file file-name;
    }
  }
  traceoptions {
    file filename <files number> <size size>;
    flag flag;
    level level;
    no-remote-trace
  }
}
```

Hierarchy Level [edit]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Configure security services. Most of the configuration statements do not have default values. If you do not specify an identifier for a statement that does not have a default value, you cannot commit the configuration.

Required Privilege Level

Related Documentation

ssh-known-hosts

Syntax

```
ssh-known-hosts {
  host host-name {
    fetch-from-server host-name;
    load-key-file file-name;
  }
}
```

Hierarchy Level [edit security ssh-known-hosts]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Configure SSH support for known hosts and for administering SSH host key updates.

Options **host *host-name***—Hostname of the SSH known host entry. This option has the following suboptions:

- **fetch-from-server *host-name***—Retrieve SSH public host key information from a specified server.
- **load-key-file *filename***—Import SSH host key information from the **/var/tmp/ssh-known-hosts** file.

Required Privilege Level admin—To view this statement in the configuration.
admin-control—To add this statement to the configuration.

Related Documentation

start-time (Authentication Key Transmission)

Syntax start-time (now | *yyyy-mm-dd.hh:mm:ss*);

Hierarchy Level [edit security authentication-key-chains key-chain *key-chain-name* key *key*]

Release Information Statement introduced in Junos OS Release 7.6.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Support for the BFD protocol introduced in Junos OS Release 9.6.
Support for the BFD protocol introduced in Junos OS Release 9.6 for EX Series switches.
Support for IS-IS introduced in JUNOS OS Release 11.2.
Statement introduced in Junos OS Release 11.3 for QFX Series switches.

Description Specify a start time for key transmission. You do not need to specify an end time for the key. If a new key is present with a new start time, the keychain rolls over to the new one. The start time must be unique within the keychain.

Options **now**—Start time as the current year, month, day, hour, minute, and second.

***day*days**—Start time as the specified number of days after the current day. For example, if the current day is the 12th and you configure **start-time 2day**, the start time will be on the 14th, exactly two days after the configuration is entered.

***hour*hours**—Start time as the specified number of hours after the current hour. For example, if the current hour is 9:00 and you configure **start-time 3hour**, the start time will be in 12:00, exactly three hours after the configuration is entered.

***minute*minutes**—Start time as the specified number of minutes after the current minute. For example, if the current minute is 27 minutes after the hour and you configure **start-time 5min**, the start time will be in 32 minutes after the hour, exactly five minutes after the configuration is entered.

***month*months**—Start time as the specified number of months after the current month. For example, if the current month is March and you configure **start-time 4month**, the start time will be in July, exactly four months after the configuration is entered.

***second*seconds**—Start time as the specified number of seconds after the current second. For example, if the current second is 10:20:40 and you configure **start-time 10seconds**, the start time will be 10:20:50, exactly 10 seconds after the configuration is entered.

***year*years**—Start time as the specified number of years after the current year. For example, if the current year is 2011 and you configure **start-time 1year**, the start time will be in 2012, exactly one year after the configuration is entered.

yyyy–mm-dd.hh:mm:ss—Start time in UTC (Coordinated Universal Time). The start time must be unique within the keychain.

Required Privilege Level admin—To view this statement in the configuration.
admin-control—To add this statement to the configuration.

Related Documentation

traceoptions

Syntax

traceoptions {
  file *filename* <files *number*> <size *size*>;
  flag all;
  flag certificates;
  flag database;
  flag general;
  flag ike;
  flag parse;
  flag policy-manager;
  flag routing-socket;
  flag timer;
  level
  no-remote-trace
}

Hierarchy Level

[edit security],
[edit services ipsec-vpn]

Trace options can be configured at either the **[edit security]** or the **[edit services ipsec-vpn]** hierarchy level, but not at both levels.

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description

Configure security trace options.

To specify more than one trace option, include multiple **flag** statements. Trace option output is recorded in the **/var/log/kmd** file.

NOTE: **The traceoptionsstatement is not supported on QFabric systems.**

Options

files ***number***—(Optional) Maximum number of trace files. When a trace file (for example, **kmd**) reaches its maximum size, it is renamed **kmd.0**, then **kmd.1**, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum number of files, you must also specify a maximum file size with the **size** option.

Range: 2 through 1000 files

Default: 0 files

size ***size***—(Optional) Maximum size of each trace file, in kilobytes (KB). When a trace file (for example, **kmd**) reaches this size, it is renamed, **kmd.0**, then **kmd.1** and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

Default: 1024 KB

flag ***flag***—Trace operation to perform. To specify more than one trace operation, include multiple **flag** statements.

- **all**—Trace all security events.
- **certificates**—Trace certificate events.
- **database**—Trace database events.
- **general**—Trace general events.
- **ike**—Trace IKE module processing.
- **parse**—Trace configuration processing.
- **policy-manager**—Trace policy manager processing.
- **routing-socket**—Trace routing socket messages.
- **timer**—Trace internal timer events.

level ***level***—(Optional) Set traceoptions level.

- **all**—match all levels.
- **error**—Match error conditions.
- **info**—Match informational messages.
- **notice**—Match conditions that should be handled specially.
- **verbose**—Match verbose messages.
- **warning**—Match warning messages.

no-remote-trace—(Optional) Disable remote tracing

Required Privilege Level

admin—To view the configuration.
admin-control—To add this statement to the configuration.

Administration

Monitoring Commands for Port Mirroring

- show analyzer

show analyzer

Syntax show analyzer <*analyzer-name*>

Release Information Command introduced in Junos OS Release 11.1 for the QFX Series.

Description Display information about port mirroring.

Options *analyzer-name*—(Optional) Displays the status of a specific analyzer (port-mirroring configuration).

Required Privilege Level view

Related Documentation

- *Layer 2 Port Mirroring Overview*
- Port Mirroring Constraints and Limitations on page 4715
- Example: Configuring Port Mirroring for Local Analysis on page 4721

List of Sample Output show analyzer on page 4776

Output Fields Table 366 on page 4776 describes the output fields for the **show analyzer** command. Output fields are listed in the approximate order in which they appear.

Table 366: show analyzer Output Fields

Field Name	Field Description
Analyzer name	Name of the analyzer.
Output interface	Local interface to which mirror packets are sent. If you configure an output interface, you cannot also configure an output VLAN.
Output VLAN	VLAN to which mirror packets are sent. If you configure an output VLAN, you cannot also configure an output interface.
Egress monitored interfaces	Interfaces for which egress traffic is mirrored.
Ingress monitored interfaces	Interfaces for which ingress traffic is mirrored.
Ingress monitored VLANs	VLANs for which ingress traffic is mirrored.

Sample Output

show analyzer

```
user@switch> show analyzer
Analyzer name                : employee-monitor
  Output interface           : ge-0/0/10.0
  Output VLAN                : remote-analyzer
```

```
Egress monitored interfaces  : ge-0/0/7.0
Ingress monitored interfaces : ge-0/0/8.0
Ingress monitored interfaces : ge-0/0/9.0
```

CHAPTER 57

Troubleshooting

Troubleshooting Procedures

Troubleshooting Port Mirroring

Port Mirroring Constraints and Limitations

Local and Remote Port Mirroring

The following constraints and limitations apply to local and remote port mirroring with the QFX Series:

- You can create a total of four port-mirroring configurations on a QFX Series standalone switch.
- You can create a total of four port-mirroring configurations on each Node group in a QFabric system, subject to the following constraints:
  - As many as four of the configurations can be for local port mirroring.
  - As many as three of the configurations can be for remote port mirroring.
- Regardless of whether you are configuring a standalone switch or a Node group, the following limits apply:
  - There can be no more than two configurations that mirror ingress traffic. (If you configure a firewall filter to send traffic to a port mirror—that is, you use the **analyzer** action modifier in a filter term—this counts as an ingress mirroring configuration for switch or Node group on which the filter is applied.)
  - There can be no more than two configurations that mirror egress traffic.

NOTE: On QFabric systems, there is no system-wide limit on the total number of mirror sessions.

- You can configure no more than one type of output in one port-mirroring configuration. That is, you can use no more than one of the following to complete a **set analyzer *name* output** statement:
  - **interface**
  - **ip-address**
  - **vlan**
- If you configure Junos OS to mirror egress packets, do not configure more than 2000 VLANs on a QFX3500 device or QFabric system. If you do so, some VLAN packets might contain incorrect VLAN IDs. This applies to any VLAN packets—not only the mirrored copies.
- The **ratio** and **loss-priority** options are not supported.
- Packets with physical layer errors are filtered out and are not sent to the output port or VLAN.
- If you use sFlow monitoring to sample traffic, it does not sample the mirror copies when they exit from the output interface.
- You cannot mirror packets exiting or entering the following ports:
  - Dedicated Virtual Chassis interfaces
  - Management interfaces (me0 or vme0)
  - Fibre Channel interfaces
  - Routed VLAN interfaces
- An aggregated Ethernet interface cannot be an output interface.
- Do not include an 802.1Q subinterface that has a unit number other than 0 in a port mirroring configuration. Port mirroring does not work with subinterfaces if their unit number is not 0. (You configure 802.1Q subinterfaces using the **vlan-tagging** statement.)
- When packet copies are sent out the output interface, they are not modified for any changes that are normally applied on egress, such as CoS rewriting.
- An interface can be the input interface for only one mirroring configuration. Do not use the same interface as the input interface for multiple mirroring configurations.
- CPU-generated packets (such as ARP, ICMP, BPDU, and LACP packets) cannot be mirrored on egress.
- VLAN-based mirroring is not supported for STP traffic.
- (QFabric systems only) If you configure a QFabric analyzer to mirror egress traffic and the input and output interfaces are on different Node devices, the mirrored copies have incorrect VLAN IDs. This limitation does not apply if you configure a QFabric analyzer

to mirror egress traffic and the input and output interfaces are on the *same* Node device. In this case the mirrored copies have the correct VLAN IDs (as long as you do not configure more than 2000 VLANs on the QFabric system).

Remote Port Mirroring Only

The following constraints and limitations apply to remote port mirroring with the QFX Series:

- If you configure an output IP address, the address cannot be in the same subnetwork as any of the switch's management interfaces.
- If you create virtual routing instances and also create an analyzer configuration that includes an output IP address, the output address belongs to the default virtual routing instance (inet.0 routing table).
- An output VLAN cannot be a private VLAN or VLAN range.
- An output VLAN cannot be shared by multiple **analyzer** statements.
- An output VLAN interface cannot be a member of any other VLAN.
- An output VLAN interface cannot be an aggregated Ethernet interface.
- On the source (monitored) switch, only one interface can be a member of the analyzer VLAN.

Egress Port Mirroring with VLAN Translation

Problem If you create a port-mirroring configuration that mirrors customer VLAN (CVLAN) traffic on egress and the traffic undergoes VLAN translation before being mirrored, the VLAN translation does not apply to the mirrored packets. That is, the mirrored packets retain the service VLAN (SVLAN) tag that should be replaced by the CVLAN tag on egress. The original packets are unaffected—on these packets VLAN translation works properly, and the SVLAN tag is replaced with the CVLAN tag on egress.

Solution This is expected behavior.

Egress Port Mirroring with Private VLANs

Problem If you create a port-mirroring configuration that mirrors private VLAN (PVLAN) traffic on egress, the mirrored traffic (the traffic that is sent to the analyzer system) has the VLAN tag of the ingress VLAN instead of the egress VLAN. For example, assume the following PVLAN configuration:

- Promiscuous trunk port that carries primary VLANs pvlan100 and pvlan400.
- Isolated access port that carries secondary VLAN isolated200. This VLAN is a member of primary VLAN pvlan100.
- Community port that carries secondary VLAN comm300. This VLAN is also a member of primary VLAN pvlan100.
- Output interface (monitor interface) that connects to the analyzer system. This interface forwards the mirrored traffic to the analyzer.

If a packet for pvlan100 enters on the promiscuous trunk port and exits on the isolated access port, the original packet is untagged on egress because it is exiting on an access port. However, the mirror copy retains the tag for pvlan100 when it is sent to the analyzer.

Here is another example: If a packet for comm300 ingresses on the community port and egresses on the promiscuous trunk port, the original packet carries the tag for pvlan100 on egress, as expected. However, the mirrored copy retains the tag for comm300 when it is sent to the analyzer.

Solution This is expected behavior.

PART 18

Storage

CHAPTER 58

Overview

Software Features Overview

Overview of Fibre Channel on the QFX Series

Fibre Channel (FC) is a high-speed network technology that interconnects network elements and allows them to communicate with one another. The International Committee for Information Technology Standards (INCITS) T11 Technical Committee sets FC standards.

FC networks provide high-performance characteristics such as lossless transport combined with flexible network topology. FC is primarily used in storage area networks (SANs) because it provides reliable, lossless, in-order frame transport between initiators and targets. FC components include initiators, targets, and FC-capable switches that interconnect FC devices and may also interconnect FC devices with Fibre Channel over Ethernet (FCoE) devices. Initiators originate I/O commands. Targets receive I/O commands. For example, a server can initiate an I/O request to a storage device target.

Juniper Networks QFX Series can function as an FCoE-FC gateway or as an FCoE transit switch.

FCoE transports native FC frames over an Ethernet network by encapsulating the unmodified frames in Ethernet. It also provides protocol extensions to discover FCoE devices through the Ethernet network. FCoE requires that the Ethernet network support data center bridging (DCB) extensions that ensure lossless transport and allow the Layer 2 Ethernet domain to meet the requirements of FC transport.

The FCoE-FC gateway functionality is a licensed feature on the QFX Series. As an FCoE-FC gateway, the switch connects FCoE devices on an Ethernet network to a SAN FC switch.

You do not need a license to use the switch as an FCoE transit switch. As an FCoE transit switch, the switch:

- Is a Layer 2 data center bridging (DCB) switch that can transport FCoE frames.
- Implements FCoE Initialization Protocol (FIP) snooping.
- Connects multiple FCoE endpoints to the FC network.

NOTE: **The QFX3600 switch does not support FC because it does not support native FC port configuration. The QFX3600 switch supports FCoE.**

QFX3500 and QFX3600 Virtual Chassis switches do not support FC or FCoE

.

This topic describes:

- Fibre Channel Transport Protocol on page 4787
- How FC Works on the QFX Series on page 4787
- Supported FC Features and Functions on page 4789
- Lossless Transport Support on page 4789

Fibre Channel Transport Protocol

The Fibre Channel Protocol is a transport protocol that consists of five layers as shown in Table 367 on page 4787:

Table 367: Fibre Channel Protocol Layers

FC Protocol Layer	Description
FC-0	Physical (cabling, connectors, and so on)
FC-1	Data link layer
FC-2	Network layer (defines the main protocols)
FC-3	Common services
FC-4	Protocol mapping

The FC protocol layers are generally split into three groups:

- FC-0 and FC-1 are the physical layers.
- FC-2 is the protocol layer, similar to OSI Layer 3.
- FC-3 and FC-4 are the services layers.

The FCoE-FC gateway operates the physical layers and the protocol layer, and provides FIP and service redirection at the services layer.

How FC Works on the QFX Series

The switch connects devices that support FC and Ethernet (such as FCoE servers on an Ethernet network) to an FC SAN, thus converging the Ethernet and FC networks on a single physical network infrastructure. The switch provides the class-of-service (CoS) features needed to handle the different types of traffic appropriately.

To converge FC and Ethernet networks, you can configure the switch as an:

- FCoE-FC Gateway on page 4787
- FCoE Transit Switch on page 4788
- FCoE VLANs on page 4788

FCoE-FC Gateway

When the switch functions as an FCoE-FC gateway, the switch aggregates FCoE traffic and performs the encapsulation and de-encapsulation of native FC frames in Ethernet as it transports the frames between FCoE devices in the Ethernet network and the FC switch. In effect, the switch translates Ethernet to FC and FC to Ethernet.

The gateway receives FC frames encapsulated in Ethernet from FCoE devices through an FCoE VLAN interface composed of one or more 10-Gigabit Ethernet interfaces. The gateway removes the Ethernet encapsulation from the FC frames, and then sends the native FC frames to the FC switch through a native FC interface.

The gateway receives native FC frames from the FC switch on the gateway's native FC interfaces. The gateway encapsulates the native FC frames in Ethernet, and then sends the encapsulated frames to the appropriate FCoE device through the FCoE VLAN interface.

To FCoE devices, the gateway behaves like an FC switch and can present multiple virtual F_Ports (VF_Ports) on a single interface. To an FC switch, the gateway behaves like an FC node that is doing N_Port ID virtualization (NPIV).

FCoE Transit Switch

When the switch functions as an FCoE transit switch, it forwards traffic (including FCoE traffic) based on Layer 2 media access control (MAC) forwarding and is a normal DCB-enabled Layer 2 switch that also performs FIP snooping. The switch aggregates FCoE traffic and passes it through to an FCF. The switch does not remove the Ethernet encapsulation from the FC frames, but it does preserve the class of service (CoS) required to transport FC frames.

The switch inspects (snoops) FIP information in order to create filters that permit only valid FCoE traffic to flow through the switch between FCoE devices and the FCF. The switch does not use native FC ports because the FC frames are encapsulated in Ethernet when they flow between the FCoE devices and the FCF. Virtual point-to-point links between each FCoE device and the FCF pass transparently through the switch, so the switch is not seen as a terminating point or an intermediate point by FCoE devices or by the FCF.

FCoE VLANs

On the QFX Series, all FCoE traffic must travel in a VLAN dedicated to transporting only FCoE traffic. Only FCoE interfaces should be members of an FCoE VLAN. Ethernet traffic that is not FCoE or FIP traffic must travel in a different VLAN.

NOTE: On a QFX3500 or QFabric system Node device, the same VLAN cannot be used in both transit switch mode and FCoE-FC gateway mode.

NOTE: FCoE VLANs (any VLAN that carries FCoE traffic) support only Spanning Tree Protocol (STP) and link aggregation group (LAG) Layer 2 features. IGMP snooping is enabled by default on all VLANs; be sure to disable IGMP snooping on FCoE VLANs.

You can configure more than one FCoE VLAN, but any given virtual link must be in only one FCoE VLAN.

NOTE: All 10-Gigabit Ethernet interfaces that connect to FCoE devices must have a native VLAN configured in order to transport FIP traffic, because FIP VLAN discovery and notification frames are exchanged as untagged packets.

BEST PRACTICE: Only FCoE traffic is permitted on the FCoE VLAN. A native VLAN might need to carry untagged traffic of different types and protocols. Therefore, it is a good practice to keep the native VLAN separate from FCoE VLANs.

Supported FC Features and Functions

QFX Series supports the following features and functionality:

- As an FCoE-FC gateway:
  - DCB, including Data Center Bridging Capability Exchange protocol (DCBX), priority-based flow control (PFC), enhanced transmission service (ETS), and 10-Gigabit Ethernet interfaces
  - FCoE Initialization Protocol (FIP)
  - Proxy for FCoE devices when communicating with FC switches and acts as a proxy for FC switches when communicating with FCoE devices
  - Up to 12 native FC interfaces per QFX3500 switch (each interface can be configured as a 2-Gigabit, 4-Gigabit, or 8-Gigabit Ethernet interface)
- As an FCoE transit switch:
  - DCB functions
  - FIP snooping
  - Transparent Layer 2 MAC forwarding of FCoE frames

Lossless Transport Support

The QFX Series supports up to six lossless forwarding classes. For lossless transport, you must enable PFC on the IEEE 802.1p code point of lossless forwarding classes. The following limitations apply to support lossless transport:

- The external cable length from the QFX3500 or QFabric system Node device to other devices cannot exceed 300 meters.
- The internal cable length from the QFabric system Node device to the QFabric system Interconnect device cannot exceed 150 meters.
- For FCoE traffic, the interface maximum transmission unit (MTU) must be at least 2180 bytes to accommodate the packet payload, headers, and checks.

Overview of FIP

Fibre Channel over Ethernet (FCoE) Initialization Protocol (FIP) is a Layer 2 protocol that establishes and maintains Fibre Channel (FC) virtual links between pairs of FCoE devices such as server FCoE Nodes (ENodes) and FC switches. FIP can also establish and maintain virtual links between FCoE devices and an FCoE-FC gateway such as the QFX Series, where the gateway acts on behalf of the FC switch.

FIP enables FCoE devices to discover one another and to initialize and maintain virtual links over a physical Ethernet network. This allows FCoE devices in the Ethernet network to access storage devices in the FC storage area network (SAN).

FIP solves the problem presented by the FC requirement for point-to-point connections (FC does not permit point-to-multipoint connections) by creating a unique virtual link for each connection between an ENode VN_Port and an FC switch VF_Port. Multiple virtual links can use a single physical link and virtual links can traverse Ethernet transit (passthrough) switches while appearing to be direct point-to-point connections to the FC switch.

FIP has its own EtherType (0x8914) to distinguish its traffic from payload-carrying FCoE traffic and other Ethernet traffic. FIP operations occur on a per-VLAN basis.

For more details about FIP, see the Technical Committee T11 organization document *Fibre Channel Backbone - 5 (FC-BB-5) Rev 2.00* available at http://www.t11.org/ftp/t11/pub/fc/bb-5/09-056v5.pdf.

Fibre Channel, FCoE, FIP, and FIP Snooping

Understanding Fibre Channel

Fibre Channel (FC) is a serial I/O interconnect network technology capable of supporting multiple protocols. It is used primarily for storage area networks (SANs). The committee standardizing FC is the International Committee for Information Technology Standards (INCITS).

When configured as a Fibre Channel over Ethernet (FCoE)-FC gateway, the QFX Series supports the transport of native FC traffic between FC switches and the gateway's native FC interfaces.

NOTE: **The QFX3600 switch does not support FC because it does not support native FC port configuration. In addition, QFX3500 and QFX3600 Virtual Chassis switches do not support FC.**

FC concepts include:

FC Fabrics

An FC fabric is a switched network topology that interconnects FC devices using FC switches, usually to create a SAN. An FC switch is a Layer 3 network switch that is compatible with the FC protocol, forwards FC traffic, and provides FC services to the components of the FC fabric. FC devices are usually servers or storage devices such as disk arrays.

Switches called FCoE forwarders (FCFs) perform a subset of FC switch functions. An FCF is a Layer 3 network switch that is compatible with the FC protocol and forwards FC traffic, but does not provide network services.

When configured as an FCoE-FC gateway, the QFX Series acts a proxy for the FCF functionality of an FC switch. The gateway provides FCoE devices on the Ethernet network access to the FC network without requiring the FC switches in the SAN to support Ethernet interfaces. The gateway is not an FCF and does not provide FC services.

FC network design often uses two fabrics (dual-rail topology) for redundancy. The two fabrics connect to edge devices but are otherwise unconnected, so that if one fabric goes down, the other fabric can continue to provide connectivity.

FC Port Types

The QFX Series supports the following FC port types:

- N_Port—An N_Port is a port on the node of an FC device such as a server or a storage device and is also known as a node port.
- F_Port—An F_Port is a port on an FC switch that connects to an FC device N_Port in a point-to-point connection. F_Ports are also known as fabric ports.

These port types are a subset of the existing FC port types that can be supported in an FC fabric.

FC Switches

FC switches provide FC services to the FC network. FC switches forward Layer 3 traffic. They may transport a combination of native FC traffic and other traffic, such as Internet Small Computer Systems Interface (iSCSI) or FCoE, or they may transport only native FC traffic. When an FC switch supports FCoE, it combines FCoE termination functions with the FC stack on an FC switching element. This is also known as a dual-stack switch.

When FC switches support FCoE, they present virtual FC interfaces in the form of virtual F_Ports (VF_Ports) to the FCoE nodes (ENodes) on FCoE devices. A VF_Port is an endpoint in a virtual point-to-point connection with an ENode virtual N_Port (VN_Port). A VF_Port emulates a native FC F_Port and performs similar functions. A VF_Port is an intermediate port in a connection between an FCoE device such as a server in the Ethernet network and a storage device in the FC SAN.

FC switches that support FCoE contain at least one lossless Ethernet media access controller (MAC) paired with an FCoE controller. The lossless Ethernet MAC implements Ethernet extensions to avoid frame loss due to congestion. The FCoE controller instantiates and terminates virtual port instances as they are needed. Each VF_Port instance has one unique virtual link to an ENode VN_Port.

FCoE support also requires one FCoE Link End Point (LEP) for each VF_Port connection. An FCoE LEP is a virtual FC interface mapped onto the physical Ethernet interface. It transmits and receives FCoE frames on the virtual link, and handles FC frame encapsulation for traffic going from the FC switch to the FCoE device and frame de-encapsulation of traffic received from the FCoE device.

When you configure the QFX Series as an FCoE-FC gateway, the gateway performs these FC-to-Ethernet and Ethernet-to-FC conversion functions so that the FC switch does not need Ethernet (FCoE) ports.

Adapters

FC host bus adapters (HBAs) in FC switches and devices perform functions similar to those of Ethernet adapters in Ethernet switches and devices. Switches that perform FCoE functions and FCoE devices have converged network adapters (CNAs) that support both native FC and Ethernet functionality.

N_Port ID Virtualization (NPIV)

FC requires a unique point-to-point link between the FC switch (F_Port) and each host N_Port. In order to avoid using one physical link for each F_Port to N_Port connection, the port connections must be virtualized so that they can share a physical link while maintaining logical separation.

FC accomplishes this by enabling you to create an independent virtual link for each FC session by mapping each session to a virtualized N_Port. This process is called N_Port ID virtualization (NPIV).

NPIV makes each virtual link look like a dedicated point-to-point link. In this way, multiple FC devices and multiple applications or virtual machines (VMs) on a single FC device can connect to an FC switch using one physical port instead of using a physical port for each connection. The virtual link creates a secure boundary between traffic from different sources on a single physical connection.

NPIV works by creating a unique virtual port identifier for each logical connection on a physical port. Conceptually, this is similar to splitting a single physical interface into multiple logical interfaces or subinterfaces. A virtual port identifier consists of the port's unique worldwide name (WWN) combined with a Fibre Channel ID (FCID) that the FC switch assigns to the virtual connection. This creates a virtual host bus adapter (HBA) for each virtual link that uniquely identifies the link to the FC switch.

FC Services

When you configure the QFX Series as an FCoE-FC gateway, the gateway connects FCoE devices in the Ethernet network to the FC fabric. The gateway does not provide FC services directly. The gateway logs in to the FC fabric and obtains FC services from the FC fabric, including:

- Management servers
  - Zone server—Defines which devices can connect to each other in the FC fabric.
  - Fabric configuration server—Discovers FC fabric topology and attributes.
  - Policy server—Distributes the rules for administering, managing, and controlling access to FC fabric resources.
  - HBA management server—Registers HBA information with the FC fabric.
- Domain manager—Allocates domain IDs to virtual switches.
- Fabric login server—Provides login services to the gateway so that the native FC ports on the gateway can perform initial fabric login (FLOGI) to the FC fabric and subsequent fabric discovery (FDISC) logins for the physical and virtual ports on the FCoE devices in the Ethernet network. This includes allocating Fibre Channel IDs (FCIDs) to ports.
- Name server—Discovers, registers, and unregisters N_Port attributes, including the attributes of the native FC ports on the gateway that connect to the FC fabric.
- Event server—Validates incoming events to ensure transaction integrity.
- Time server—Maintains a common time for devices in the FC fabric.
- Fabric controller
  - Fabric Shortest Path First (FSPF)—The FC fabric provides link-state path selection to the gateway.

- State change notification (SCN) / registered state change notification server (RSCN)—Notifies the appropriate nodes when new devices come online, when other nodes fail, or when changes on an online node affect system operation.

Understanding DCB Features and Requirements

Data center bridging (DCB) is a set of enhancements to the IEEE 802.1 bridge specifications. DCB modifies and extends Ethernet behavior to support I/O convergence in the data center. I/O convergence includes but is not limited to the transport of Ethernet LAN traffic and Fibre Channel (FC) storage area network (SAN) traffic on the same physical Ethernet network infrastructure.

A converged architecture saves cost by reducing the number of networks and switches required to support both types of traffic, reducing the number of interfaces required, reducing cable complexity, and reducing administration activities.

The Juniper Networks QFX Series supports the DCB features required to transport converged Ethernet and FC traffic while providing the class-of-service (CoS) and other characteristics FC requires for transmitting storage traffic. To accommodate FC traffic, DCB specifications provide:

- A flow control mechanism called priority-based flow control (PFC, described in IEEE 802.1Qbb) to help provide lossless transport.
- A discovery and exchange protocol for conveying configuration and capabilities among neighbors to ensure consistent configuration across the network, called Data Center Bridging Capability Exchange protocol (DCBX), which is an extension of Link Layer Data Protocol (LLDP, described in IEEE 802.1AB).
- A bandwidth management mechanism called enhanced transmission selection (ETS, described in IEEE 802.1Qaz).
- A congestion management mechanism called quantized congestion notification (QCN, described in IEEE 802.1Qau).

The switch supports the PFC, DCBX, and ETS standards but does not support QCN. The switch also provides the high-bandwidth interfaces (10-Gbps minimum) required to support DCB and converged traffic.

This topic describes the DCB standards and requirements the switch supports:

- Lossless Transport on page 4796
- ETS on page 4797
- DCBX on page 4797

Lossless Transport

FC traffic requires lossless transport (defined as no frames dropped because of congestion). Standard Ethernet does not support lossless transport, but the DCB extensions to Ethernet along with proper buffer management enable an Ethernet network to provide the level of class of service (CoS) necessary to transport FC frames encapsulated in Ethernet over an Ethernet network.

This section describes these factors in creating lossless transport over Ethernet:

PFC

PFC is a link-level flow control mechanism similar to Ethernet PAUSE (described in IEEE 802.3x). Ethernet PAUSE stops all traffic on a link for a period of time. PFC enables you to divide traffic on a link into eight priorities and stop the traffic of a selected priority without stopping the traffic assigned to other priorities on the link.

Pausing the traffic of a selected priority enables you to provide lossless transport for traffic assigned that priority and at the same time use standard lossy Ethernet transport for the rest of the link traffic.

Buffer Management

Buffer management is critical to the proper functioning of PFC, because if buffers are allowed to overflow, frames are dropped and transport is not lossless.

For each lossless flow priority, the switch requires sufficient buffer space to:

- Store frames sent during the time it takes to send the PFC pause frame across the cable between devices.
- Store the frames that are already on the wire when the sender receives the PFC pause frame.

The propagation delay due to cable length and speed, as well as processing speed, determines the amount of buffer space needed to prevent frame loss due to congestion.

The switch automatically sets the threshold for sending PFC pause frames to accommodate delay from cables as long as 150 meters (492 feet) and to accommodate large frames that might be on the wire when the switch sends the pause frame. This ensures that the switch sends pause frames early enough to allow the sender to stop transmitting before the receive buffers on the switch overflow.

Physical Interfaces

The switch supports 10-Gbps, full-duplex interfaces. The switch enables DCB capability only on 10-Gbps (or faster) Ethernet interfaces.

ETS

PFC divides traffic into up to eight separate streams (priorities, configured on the switch as forwarding classes) on a physical link. ETS enables you to manage the link bandwidth by:

- Grouping the priorities into priority groups (configured on the switch as forwarding class sets).
- Specifying the bandwidth available to each of the priority groups as a percentage of the total available link bandwidth.
- Allocating the bandwidth to the individual priorities in the priority group.

The available link bandwidth is the bandwidth remaining after servicing strict priority flows.

Managing link bandwidth with ETS provides several advantages:

- There is uniform management of all types of traffic on the link, both congestion-managed traffic and standard Ethernet traffic.
- When a priority group does not use all of its allocated bandwidth, other priority groups on the link can use that bandwidth as needed.

  When a priority in a priority group does not use all of its allocated bandwidth, other priorities in the group can use that bandwidth.

  The result is better bandwidth utilization, because priorities that consist of bursty traffic can share bandwidth during periods of low traffic transmission instead of consuming their entire bandwidth allocation when traffic loads are light.
- You can assign traffic types with different service needs to different priorities so that each traffic type receives appropriate treatment.
- Strict priority traffic retains its allocated bandwidth.

DCBX

DCB devices use DCBX to exchange configuration information with directly connected peers (switches and endpoints such as servers). DCBX is an extension of LLDP. If you disable LLDP on an interface, that interface cannot run DCBX. If you attempt to enable DCBX on an interface on which LLDP is disabled, the configuration commit fails.

DCBX can:

- Discover the DCB capabilities of peers.
- Detect DCB feature misconfiguration or mismatches between peers.
- Configure DCB features on peers.

You can configure DCBX operation for PFC, ETS, and for Layer 2 and Layer 4 applications such as FCoE and iSCSI. DCBX is enabled or disabled on a per-interface basis.

Understanding FCoE

Fibre Channel over Ethernet (FCoE) is a method of supporting converged Fibre Channel (FC) and Ethernet traffic on a data center bridging (DCB) network. FCoE encapsulates unmodified FC frames in Ethernet to transport the FC frames over a physical Ethernet network. The T11 Technical Committee, which is the International Committee for Information Technology Standards (INCITS) committee responsible for FC interfaces, developed the FCoE standard to provide a method for transporting FC frames over a DCB network. The T11 document *Fibre Channel Backbone - 5 (FC-BB-5) Rev 2.00* at http://www.t11.org/ftp/t11/pub/fc/bb-5/09-056v5.pdf provides details about the FCoE version 1 standard.

NOTE: The switch does not support T11 Annex F *FCoE Pre-FIP Virtual Link Instantiation Protocol*.

To the Ethernet network, an FCoE frame is the same as any other Ethernet frame because the Ethernet encapsulation provides the header information needed to forward the frames. However, to achieve the lossless behavior that FC transport requires, the Ethernet network must conform to DCB standards.

DCB standards create an environment over which FCoE can transport native FC traffic encapsulated in Ethernet while preserving the mandatory class of service (CoS) and other characteristics that FC traffic requires.

Supporting FCoE in a DCB network requires that the FCoE devices in the Ethernet network and the FC switches at the edge of the SAN network handle both Ethernet and native FC traffic. To handle Ethernet traffic, an FC switch does one of two things:

- Incorporates FCoE interfaces.
- Uses an FCoE-FC gateway such as a QFX Series to de-encapsulate FCoE traffic from FCoE devices into native FC and to encapsulate native FC traffic from the FC switch into FCoE and forward it to FCoE devices through the Ethernet network.

NOTE: QFX3500 and QFX3600 Virtual Chassis switches do not support FCoE .

FCoE concepts include:

- FCoE Frames on page 4801
- Virtual Links on page 4802
- FCoE VLANs on page 4802

FCoE Devices

Each FCoE device has a converged network adapter (CNA) that combines the functions of an FC host bus adapter (HBA) and a lossless Ethernet network interface card (NIC) with 10-Gbps Ethernet ports. The portion of the CNA that handles FCoE traffic is called an FCoE Node (ENode). An ENode combines FCoE termination functions and the client part of the FC stack on the CNA.

ENodes present virtual FC interfaces to FC switches in the form of virtual N_Ports (VN_Ports). A VN_Port is an endpoint in a virtual point-to-point connection called a virtual link. The other endpoint of the virtual link is an FC switch (or FCF) port. A VN_Port emulates a native FC N_Port and performs similar functions: handling the creation, detection, and flow of messages to and from the FC switch. A single ENode can host multiple VN_Ports. Each VN_Port has a separate, unique virtual link with a FC switch.

ENodes contain at least one lossless Ethernet media access controller (MAC). Each Ethernet MAC is paired with an FCoE controller. The lossless Ethernet MAC is a full-duplex Ethernet MAC that implements Ethernet extensions to avoid frame loss due to congestion and supports frames of at least 2500 bytes. The FCoE controller instantiates and terminates VN_Port instances dynamically as they are needed for FCoE sessions. Each VN_Port instance has a unique virtual link to an FC switch.

NOTE: **A *session* is a fabric login (FLOGI) or fabric discovery (FDISC) login to the FC SAN fabric. Session does not refer to end-to-end server-to-storage sessions.**

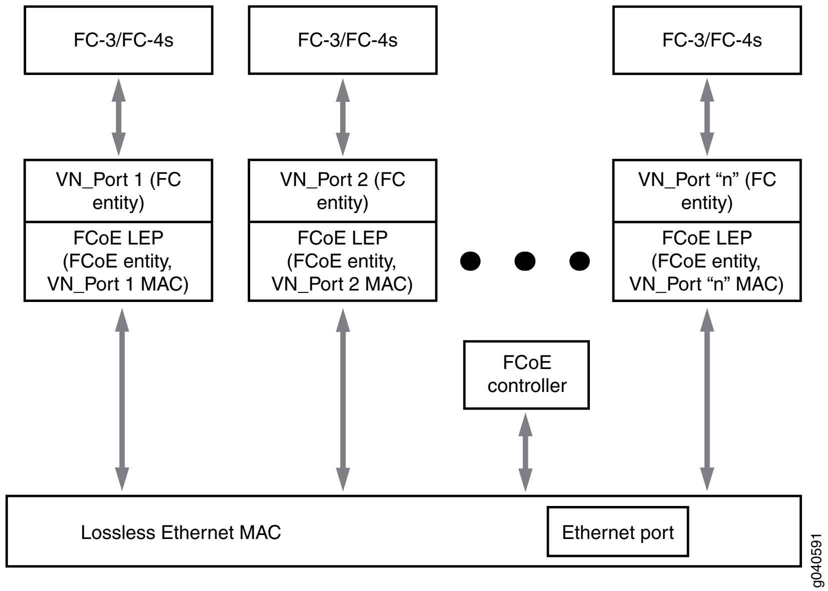
ENodes also contain one FCoE link end point (LEP) for each VN_Port connection. An FCoE LEP is a virtual FC interface mapped onto the physical Ethernet interface.

An FCoE LEP:

- Transmits and receives FCoE frames on the virtual link.
- Handles FC frame encapsulation for traffic going from the server to the FC switch.
- Performs frame de-encapsulation of traffic received from the FC switch.

Figure 170 on page 4801 shows a block diagram of the major ENode components.

Figure 170: ENode Components



FCoE Frames

The FCoE protocol specification replaces the FC0 and FC1 layers of the FC stack with Ethernet, but retains the FC frame header. Retaining the FC frame header enables the FC frame to pass directly to a native FC SAN after de-encapsulation. The FCoE header carries the FC start of file (SOF) bits and end of file (EOF) bits in an encoded format. FCoE supports two frame types, control frames and data frames. FCoE Initialization Protocol (FIP) carries all of the discovery and fabric login frames.

FIP control frames handle FCoE device discovery, initializing communication, and maintaining communication. They do not carry a data payload. FIP has its own EtherType (0x8914) to distinguish FIP traffic from FCoE traffic and other Ethernet traffic. To establish communication, the ENode uses the globally unique MAC address assigned to it by the CNA manufacturer.

After FIP establishes a connection between FCoE devices, the FCoE data frames handle the transport of the FC frames encapsulated in Ethernet. FCoE also has its own EtherType (0x8906) to distinguish FCoE frames from other Ethernet traffic and ensure the in-order frame handling that FC requires. FCoE frames include:

- 2112 bytes FC payload
- 24 bytes FC header
- 14 bytes standard Ethernet header
- 14 bytes FCoE header
- 8 bytes cyclic redundancy check (CRC) plus EOF
- 4 bytes VLAN header
- 4 bytes frame check sequence (FCS)

The payload, headers, and checks add up to 2180 bytes. Therefore, interfaces that carry FCoE traffic should have a configured maximum transmission unit (MTU) of 2180 or larger. An MTU size of 2180 bytes is the minimum size; some network administrators prefer an MTU of 2240 or 2500 bytes.

Virtual Links

Native FC uses point-to-point physical links between FC devices. In FCoE, virtual links replace the physical links. A virtual link emulates a point-to-point link between two FCoE device endpoints, such as a server VN_Port and an FC switch (or FCF) VF_Port.

Each FCoE interface can support multiple virtual links. The MAC addresses of the FCoE endpoints (the VN_Port and the VF_Port) uniquely identify each virtual link and allow traffic for multiple virtual links to share the same physical link while maintaining data separation and security.

A virtual link exists in one FCoE VLAN and cannot belong to more than one VLAN. Although the FC switch and the FCoE device detect a virtual link as a point-to-point connection, virtual links do not need to be direct connections between a VF_Port and a VN_Port. A virtual link can traverse one or more transit switches, also known as passthrough switches. A transit switch can transparently aggregate virtual links while still appearing and functioning as a point-to-point connection to the FCoE devices. However, a virtual link must remain within a single Layer 2 domain.

FCoE VLANs

On the QFX Series, all FCoE traffic must travel in a VLAN dedicated to transporting only FCoE traffic. Only FCoE interfaces should be members of an FCoE VLAN. Ethernet traffic that is not FCoE or FIP traffic must travel in a different VLAN.

NOTE: **On a QFX3500 or QFabric system Node device, the same VLAN cannot be used in both transit switch mode and FCoE-FC gateway mode.**

NOTE: **FCoE VLANs (any VLAN that carries FCoE traffic) support only Spanning Tree Protocol (STP) and link aggregation group (LAG) Layer 2 features. IGMP snooping is enabled by default on all VLANs; be sure to disable IGMP snooping on FCoE VLANs.**

You can configure more than one FCoE VLAN, but any given virtual link must be in only one FCoE VLAN.

NOTE: All 10-Gigabit Ethernet interfaces that connect to FCoE devices must have a native VLAN configured in order to transport FIP traffic, because FIP VLAN discovery and notification frames are exchanged as untagged packets.

On QFX5100 switches that use the Enhanced Layer 2 Software (ELS) CLI, it is not sufficient only to configure the native VLAN on the interface, the interface must also be configured as a member of the native VLAN. (This is because the ELS CLI does not support tagged-access interface mode, so interfaces that are members of FCoE VLANs must use trunk mode, and trunk port interfaces must be explicitly included as members of a native VLAN.)

In addition, the VLAN ID must match the native VLAN ID that you configure on the physical interface. For example, to configure a native VLAN with an ID of 20 on interface xe-0/0/15 that is a member of an FCoE VLAN, you must include both of the following statements in the configuration:

1. Configure the native VLAN on the interface:

   `user@switch#` **set interfaces xe-0/0/15 native-vlan-id 20**

   (The equivalent configuration statement on a non-ELS device such as a QFX3500 or QFX3600 switch would be **set interfaces xe-0/0/15 unit 0 family ethernet-switching native-vlan-id 20**.)

2. Configure the port as a member of the native VLAN (this step is not required on QFX3500 and QFX3600 switches):

   `user@switch#` **set interfaces xe-0/0/15 unit 0 family ethernet-switching vlan members 20**

BEST PRACTICE: Only FCoE traffic is permitted on the FCoE VLAN. A native VLAN might need to carry untagged traffic of different types and protocols. Therefore, it is a good practice to keep the native VLAN separate from FCoE VLANs.

Understanding FCoE Transit Switch Functionality

You can use the QFX Series as a Fibre Channel over Ethernet (FCoE) transit switch. An FCoE transit switch is a Layer 2 data center bridging (DCB) switch that can transport FCoE frames and implements FCoE Initialization Protocol (FIP) snooping. A DCB switch transports both FCoE and Ethernet LAN traffic over the same network infrastructure while preserving the class of service (CoS) that Fibre Channel (FC) traffic requires.

An FCoE transit switch does not encapsulate or de-encapsulate FC frames in Ethernet. It is an access switch that transports FC frames that have already been encapsulated in Ethernet between FCoE initiators such as servers and a storage area network (SAN) FC switch that supports both Ethernet and native FC traffic on its interfaces. The transit switch acts as a passthrough switch and is transparent to the FC switch, which detects each connection to an FCoE device as a direct point-to-point link.

When a QFX Series acts as a transit switch, the VLANs you configure for FCoE traffic can use any of the switch ports on the QFX Series or QFabric system Node device because the traffic in both directions is standard Ethernet traffic, not native FC traffic.

NOTE: The Ethernet interfaces that connect to FCoE devices must include a native VLAN to transport FIP traffic, because FIP VLAN discovery and notification frames are exchanged as untagged packets. It is a good practice to keep the native VLAN separate from the VLANs that carry FCoE traffic. FCoE VLANs should carry only FCoE traffic, but other types of untagged traffic might use the native VLAN.

QFX3500 and QFX3600 switches and QFabric system Node devices only require that you configure the native VLAN on the FCoE interfaces that belong to the FCoE VLAN by including the [**set interfaces** ***interface-name*** **unit** ***unit*** **family ethernet-switching native-vlan-id** ***native-vlan-id***] statement in the configuration.

QFX5100 switches require that you include two statements in the configuration to configure a native VLAN on FCoE interfaces. Include the [**set interfaces** ***interface-name*** **native-vlan-id** ***vlan-id***] statement in the configuration to configure the native VLAN on the interface, and also include the [**set interfaces** ***interface-name*** **unit** ***unit*** **family ethernet-switching native-vlan-id** ***vlan-id***] statement in the configuration to configure the port as a member of the native VLAN.

FCoE traffic should use a VLAN dedicated only to FCoE traffic. Do not mix FCoE traffic with standard Ethernet traffic on a VLAN on the switch.

NOTE: FCoE VLANs (any VLAN that carries FCoE traffic) support only Spanning Tree Protocol (STP) and link aggregation group (LAG) Layer 2 features. IGMP snooping is enabled by default on all VLANs; be sure to disable IGMP snooping on FCoE VLANs.

NOTE: **On a QFX3500 switch or on a QFabric system Node device, the same VLAN cannot be used in both transit switch mode and FCoE-FC gateway mode. If you configure both a transit switch and an FCoE-FC gateway on the same QFX3500 switch or QFabric system Node device, configure different FCoE VLANs for the transit switch and the FCoE-FC gateway.**

Transit switch architecture differs from FCoE-FC gateway architecture. As an FCoE-FC gateway, the system transports traffic to the FC SAN as native FC frames, and the VLAN must use an FCoE VLAN interface and native FC interfaces to transport that traffic. As a transit switch, the system forwards Ethernet traffic, and requires DCB configuration for lossless transport of that traffic and FIP snooping at FCoE device access ports, but not the FCoE-FC gateway features necessary for transporting FC traffic.

The QFX Series complies with DCB standards for ensuring lossless transport and low latency, and provides 10-Gbps ports for FCoE traffic. For lossless transport to function correctly, you must use priority-based flow control (PFC, described in IEEE 802.1Qbb) to create bandwidth reservations and ensure proper CoS for FCoE traffic.

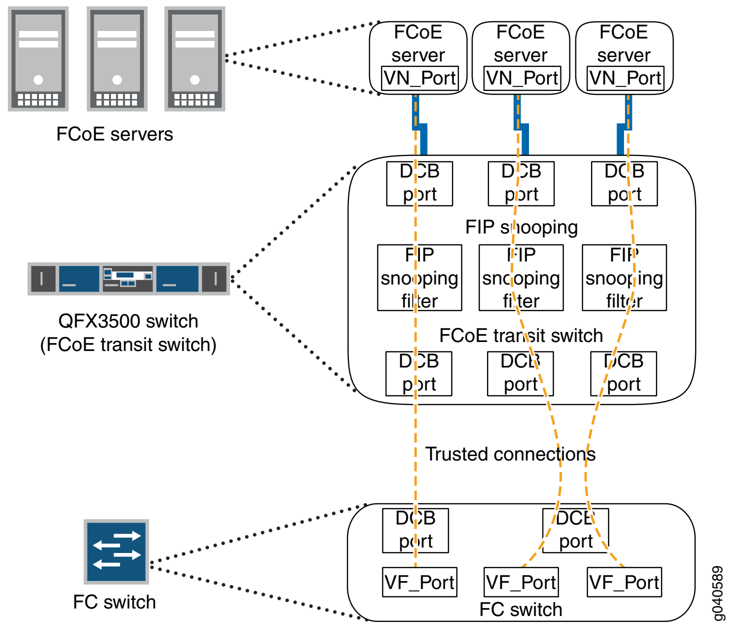
FIP snooping adds security by filtering access so that only traffic from servers that have successfully logged in to the FC network passes through the transit switch and reaches the FC network. The Technical Committee T11 organization specifications describe two types of FIP snooping:

- The FC-BB-5 specification describes VN_Port to VF_Port (VN2VF_Port) FIP snooping, which provides security for communication between FCoE device VN_Ports on the Ethernet network and FCF or FC switch VF_Ports.
- The FC-BB-6 specification describes VN_Port to VN_Port (VN2VN_Port) FIP snooping, which provides security for communication between FCoE device VN_Ports on the Ethernet network.

To accommodate the larger size of Ethernet-encapsulated frames, FCoE interfaces should be configured with a maximum transmission unit (MTU) size of at least 2180 bytes.

The transit switch transparently connects FCoE-capable devices such as servers in an Ethernet LAN to an FC switch or to a gateway switch (hereafter referred to as the FC switch), as shown in Figure 171 on page 4806. The transit switch acts as a transparent DCB access layer between FCoE servers and the FC switch.

Figure 171: FCoE Transit Switch Connecting FCoE Devices to an FC Switch



The transit switch performs FIP snooping at the ports connected to the FCoE devices. For VN2VF_Port FIP snooping, at the SAN edge, the FC switch must be able to convert the FCoE traffic to native FC traffic. (VN2VN_Port FIP snooping switches traffic between VN_Ports directly through the transit switch, without going through the FC switch, so no conversion of FCoE traffic to native FC traffic is needed.)

Encapsulated FCoE traffic flows through the transit switch to the FCoE ports on the FC switch. The FC switch removes the Ethernet encapsulation from the FCoE frames to restore the native FC frames. Native FC traffic travels out native FC ports to storage devices in the FC SAN.

Native FC traffic from storage devices flows to the FC switch FC ports, and the FC switch encapsulates that traffic in Ethernet as FCoE traffic. The FCoE traffic flows through the transit switch to the appropriate FCoE device.

NOTE: The FC switch and FC fabric apply appropriate zoning checks on traffic to and from each ENode and provide FC services (for example, name server, fabric login server, or event server).

NOTE: The QFX3500 switch supports VN_Port to VN_Port FIP snooping to allow FCoE initiators and targets to communicate directly through the switch without going through an FCoE forwarder (FCF) or an FC switch. An FCoE VLAN can support either VN2VF_Port FIP snooping (FC-BB-5) or VN2VN_Port FIP snooping (FC-BB-6), but not both. The same QFX3500 switch can have multiple FCoE VLANs configured, some FCoE VLANs for VN2VF FIP snooping traffic and others for VN2VN FIP snooping traffic.

For load balancing, increasing available bandwidth, and port failover protection, you can configure the 10-Gigabit Ethernet interfaces that belong to an FCoE VLAN as a link aggregation group (LAG). In addition, creating a LAG prevents spanning tree algorithms from blocking physical links and wasting bandwidth.

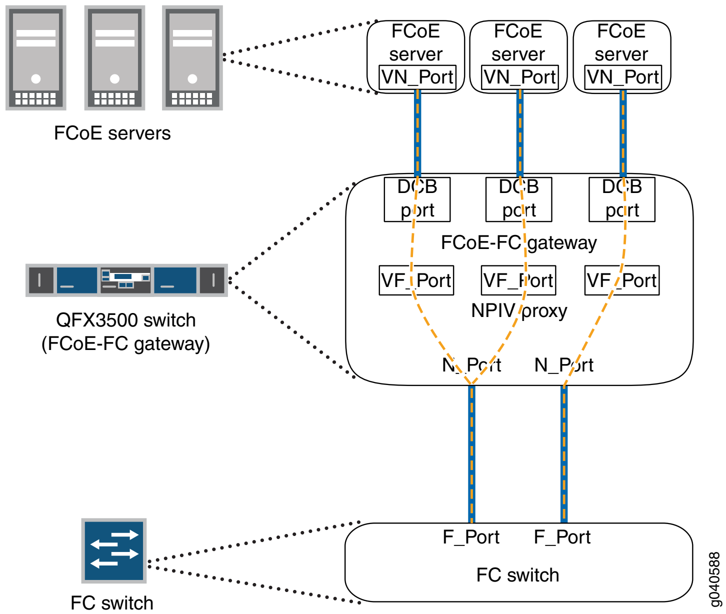
Understanding an FCoE-FC Gateway

A Fibre Channel over Ethernet (FCoE)-Fibre Channel (FC) gateway connects FCoE devices on an Ethernet network to an FC switch in an FC storage area network (SAN) as shown in Figure 172 on page 4808. To FCoE devices such as servers, the FCoE-FC gateway presents virtual fabric ports (VF_Ports) and appears to be an FCoE forwarder (FCF). To the FC switch, the FCoE-FC gateway presents a proxy node port (NP_Port) and appears to be an FC device.

Figure 172: FCoE-FC Gateway Topology



The FCoE-FC gateway handles FCoE Initialization Protocol (FIP) and FCoE traffic on the interfaces connected to FCoE devices. The gateway forwards native FC traffic on the interfaces to the FC switch. The gateway does not provide FC services (such as fabric login server or name server). It is a proxy for an FCF, not an FCF or an FC switch. The gateway transparently substitutes for the FC switch when communicating with FCoE devices and transparently substitutes for FCoE devices when communicating with the FC switch.

The gateway does not use an FC domain ID, so it extends the SAN fabric while saving domain resources. Using the gateway also means that the FC switch does not have to handle FCoE traffic (and therefore requires no FCoE blades or ports). The gateway converges Ethernet and FC backbones to leverage existing resources.

- Gateway FC Fabric on page 4809
- Fabric Services on page 4810
- FCoE-FC Gateway Traffic Switching on page 4810

Gateway FC Fabric

A gateway FC fabric is a QFX Series configuration construct. It is not the same thing as an FC fabric in the SAN; the gateway FC fabric is local to the switch. It creates associations that connect FCoE devices with converged network adapters (CNAs) on the Ethernet network to an FC switch on the Fibre Channel network. A gateway FC fabric consists of:

- A unique fabric name.
- A unique fabric ID.
- At least one dedicated VLAN for FCoE traffic. VLANs that carry FCoE traffic should not carry any other type of traffic.

  NOTE: **On a QFX3500 or QFabric system Node device, the same VLAN cannot be used in both transit switch mode and FCoE-FC gateway mode.**

- At least one FCoE VLAN interface (Layer 3 VLAN interface) that includes one or more 10-Gigabit Ethernet interfaces connected to FCoE devices. The FCoE VLANs transport traffic between the FCoE servers and the FCoE-FC gateway. Each FCoE VLAN must carry only FCoE traffic. You cannot mix FCoE traffic and standard Ethernet traffic on the same VLAN.

  The 10-Gigabit Ethernet interfaces that connect to FCoE devices must include a native VLAN to transport FIP traffic because FIP VLAN discovery and notification frames are exchanged as untagged packets.

  Each FCoE VLAN interface can present multiple VF_Port interfaces to the FCoE network.

  NOTE: **Storm control must be disabled on all Ethernet interfaces that belong to the FCoE VLAN to prevent FCoE traffic from being dropped.**

- One or more native FC interfaces. The native FC interfaces transport traffic between the gateway and the FC switch.

  TIP: **If the network does not use a dual-rail architecture for redundancy, configure more than one native FC interface for each FC fabric to create redundant connections between the FCoE devices and the FC switch. If one physical link goes down, any sessions it carried can log in again and connect to the FC switch on a different interface. Even in dual-rail architecture networks, creating redundant connections between the QFabric system and the FC switch is the best practice.**

You can also configure FIP parameters for the fabric or accept the default FIP parameters. VN_Port to VF_Port (VN2VF_Port) FIP snooping is automatically enabled on all server-facing ports because all ports are untrusted by default. You can disable VN2VF_Port FIP snooping on a port-by-port basis by marking a port as an FCoE trusted interface. You can disable VN2VF_Port FIP snooping on all Ethernet ports in an FC fabric by configuring the fabric as FCoE trusted.

Because the switch has 12 native FC ports and each FC fabric requires a minimum of one native FC port, the switch supports a maximum of 12 FC fabrics. However, as a best practice for redundancy, we recommend that you assign at least two native FC interfaces to each FC fabric.

On a QFabric system, all of the FC and FCoE traffic that belongs to a particular gateway FC fabric must ingress and egress the same gateway Node device. Gateway FC fabrics do not span across Node devices. All of the native FC interfaces and the Ethernet interfaces that belong to the FCoE VLAN must reside on the same gateway Node device to be included in an FC fabric on that Node device.

Traffic from FC and FCoE devices that are not in the same FC fabric remain separate and cannot communicate with each other through the gateway.

Fabric Services

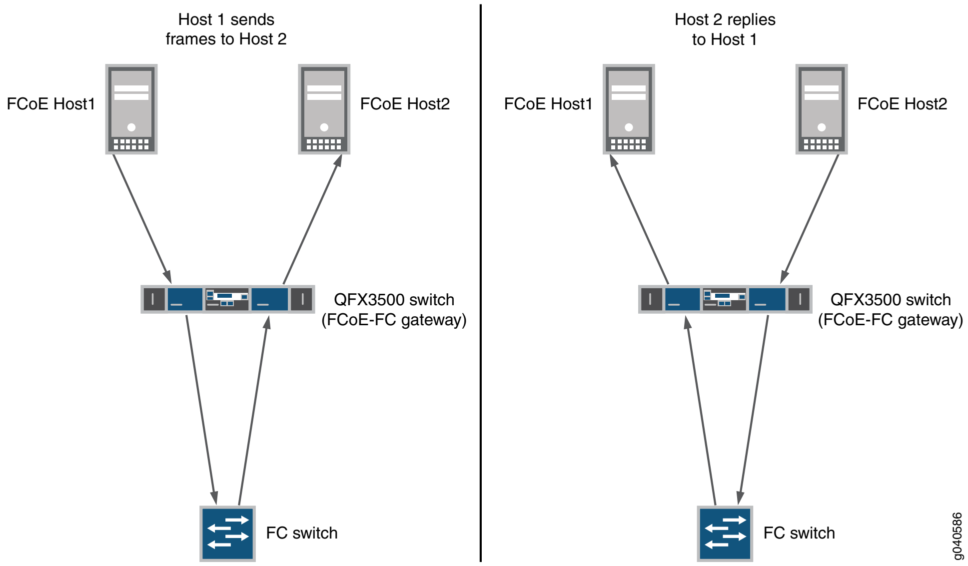
The FC switch provides all FC services (domain manager, name server, fabric login server, and so on) except FIP to the FCoE devices. The FC switch assigns all FCIDs (through N_Port ID virtualization) and fabric attributes to FCoE device VN_Ports.

The FCoE-FC gateway does not provide FC services (except FIP). The gateway relays communication between the FC switch and the FCoE devices, encapsulates and de-encapsulates native FC frames, converges Ethernet and FC backbones, and aggregates FCoE device VN_Port sessions.

FCoE-FC Gateway Traffic Switching

All traffic that flows through the gateway FC fabric is switched through the FC switch. Even if two hosts on the Ethernet FCoE network connect directly to the gateway, FCoE communication between them goes through the FC switch, as shown in Figure 173 on page 4811.

Figure 173: Traffic Switching Between FCoE Hosts Connected to the FC Network by an FCoE-FC Gateway



For example, FCoE host server *Host1* sends frames destined for FCoE host server *Host2*. Both *Host1* and *Host2* are directly connected to the gateway. The communication path looks like this:

1. *Host1* sends FCoE frames destined for *Host2* to the gateway .
2. The gateway de-encapsulates the FCoE frames from *Host1* into native FC frames and switches them to the FC switch.
3. The FC switch processes the native FC frames and sends them back to the gateway destined for *Host2*.
4. The gateway encapsulates the FC frames in Ethernet and sends the resulting FCoE frames to *Host2*.
5. When *Host2* replies, the FCoE reply goes to the gateway. The gateway de-encapsulates the reply and switches it to the FC switch for processing. The FC switch then sends it back to the gateway, which encapsulates the FC frames and sends them to *Host1*.

Understanding FCoE-FC Gateway Functions

When it functions as a Fibre Channel over Ethernet (FCoE)-Fibre Channel (FC) gateway, the QFX Series provides the following functions:

Login and Logout

Each of the native FC interfaces on the gateway performs a fabric login (FLOGI) to the FC switch when each interface initializes. This establishes the link between each gateway FC interface and the FC switch.

When FCoE devices on the Ethernet network send an FCoE Initialization Protocol (FIP) login (FIP FLOGI) or FIP discovery (FIP FDISC) request to the gateway, the gateway acts on behalf of those devices and converts their FIP FLOGI and FIP FDISC requests to FC FDISC requests. The gateway then sends the FC FDISC requests to the FC switch. When the FC switch responds to an FDISC request, the gateway converts the FC response into a FIP response and sends it to the appropriate FCoE device.

The gateway also converts FIP logout (LOGO) requests from FCoE devices into FC LOGO requests to the FC switch, and converts the FC switch response into a FIP response for the FCoE device.

FCoE and FC Frame Handling

When it receives FCoE frames from FCoE devices, the gateway strips away the Ethernet encapsulation from the FC frame before sending the native FC frame to the FC switch.

When it receives native FC frames from the FC switch, the gateway encapsulates the native FC frames in Ethernet before sending the resulting FCoE frames to the appropriate VN_Port.

Data Center Bridging

The Ethernet ports connected to the FCoE devices are 10-Gbps Ethernet ports and support data center bridging (DCB) specifications:

- Priority-based flow control (PFC, described in IEEE 802.1Qbb)
- Data Center Bridging Capability Exchange protocol (DCBX), which is an extension of Link Layer Data Protocol (LLDP, described in IEEE 802.1AB)
- Enhanced transmission selection (ETS, described in IEEE 802.1Qaz)
- 10-Gigabit Ethernet ports

Disabling the Fabric WWN Verification Check

The gateway connects to a SAN fabric using the gateway NP_Ports (native FC ports). When the NP_Ports initialize, each port sends a FLOGI to the FC switch to which it is connected in the SAN fabric. The FC switch sends a FLOGI accept (FLOGI-ACC) message back to each NP_Port. The FLOGI-ACC message includes the SAN fabric worldwide name (WWN). The gateway uses the SAN fabric WWN in the multicast discovery advertisement (MDA) that the gateway sends to the ENodes in the FCoE network.

Some FC switches substitute their own WWN (often the FC switch's virtual WWN) for the SAN fabric WWN in the FLOGI-ACC message. When the FC switch substitutes its own WWN for the fabric WWN, gateway NP_Ports that log in to the same SAN fabric might receive different fabric WWNs in the FLOGI-ACC messages if the NP_Ports are connected to different FC switches in that SAN fabric. This creates a problem, because different fabric WWNs indicate different SAN fabrics. But in this scenario, the different fabric WWNs come from different FC switches in the same SAN fabric.

If the gateway receives different fabric WWNs on NP_Ports that are connected to the same SAN fabric, the gateway uses the first fabric WWN it receives in the MDA it sends to the ENodes. The gateway isolates the NP_Ports connected to that fabric that receive a different fabric WWN in the FLOGI-ACC message. No ENode sessions are assigned to the isolated NP_Ports. FC traffic is assigned only to NP_Ports that receive a fabric WWN that matches the fabric WWN received by the first NP_Port to log in to the FC fabric. (If an NP_Port receives a fabric WWN that does not match the fabric WWN received by the first NP_Port to log in to the FC fabric, it does not carry traffic to the SAN fabric.)

In summary, the scenario is:

1. The gateway has multiple NP_Ports connected to more than one FC switch in a SAN fabric.
2. When the NP_Ports initialize, each NP_Port sends a FLOGI to the FC switch to which it is connected.
3. The FC switches substitute their own WWNs for the fabric WWN in the FLOGI-ACC message, so different NP_Ports receive different fabric WWNs.
4. In the MDA the gateway sends to FCoE devices, the gateway uses the fabric WWN that the first NP_Port to log in to the fabric receives in the FLOGI-ACC message. If other NP_Ports receive a different fabric WWN from other FC switches in the SAN fabric, that fabric WWN is not advertised.
5. NP_Ports that receive a fabric WWN that does not match the first received fabric WWN are isolated, and the ENode sessions cannot use those ports.

To prevent this from happening, you can disable the gateway fabric WWN verification check so that all NP_Ports connected to a SAN fabric are used to carry traffic between the gateway and the FC switch, regardless of the fabric WWN the NP_Port receives in the FLOGI-ACC message.

NOTE: Disabling or enabling the fabric WWN verification check logs out all FCoE sessions.

Load Balancing

The switch performs automatic link load balancing for the connections between the gateway and the FC SAN and can also perform load balancing for the connections between the gateway and the FCoE devices in the Ethernet network. On the native FC links (NP_Ports) between the gateway and the FC SAN, the gateway can use one of the following three load-balancing algorithms:

- Simple load balancing—The switch assigns each ENode FLOGI session and VN_Port FDISC session to the least-loaded link. The switch can place FDISC sessions on a different link than the parent FLOGI session (an ENode FLOGI session and its subsequent FDISC sessions can be placed on different links). Simple load balancing is the default load-balancing algorithm. Rebalancing the link load disrupts only selected sessions to minimize the impact (the switch uses an algorithm to log out only the sessions that need to be moved to other links to balance the load when those sessions log in again).
- ENode-based load balancing—When an ENode logs in to the fabric, the switch places all subsequent VN_Port FDISC sessions associated with that ENode on the same link as the ENode FLOGI session, regardless of the link load. New ENode FLOGIs are placed on the least-loaded link. The switch calculates the link load based on the combined total of FLOGIs and FDISCs on each NP_Port link. Rebalancing the link load disrupts all sessions (all sessions log out and then log in again).
- FLOGI-based load balancing—Similar to ENode-based load balancing; when an ENode logs in to the fabric, the switch places all subsequent VN_Port FDISC sessions associated with that ENode on the same link as the ENode FLOGI session, regardless of the link load. New ENode FLOGIs are placed on the least-loaded link.

NOTE: Changing the load-balancing algorithm when FCoE sessions are running forces the FCoE sessions to log out, then log in again.

You can balance the load on the Ethernet ports facing the FCoE devices by configuring those ports as a link aggregation group (LAG).

Understanding FCoE and FIP Session High Availability

The QFX Series provides high availability features to maintain storage network sessions when a system process is terminated and during certain types of upgrades:

High Availability for Fibre Channel Process Termination (FCoE-FC Gateway Mode)

In FCoE-FC gateway mode, the QFX3500 switch provides high availability to restore the FCoE sessions running on the switch in case the Fibre Channel (FC) process is terminated. A session is a fabric login (FLOGI) or fabric discovery (FDISC) login to the FC SAN fabric, not an end-to-end server-to-storage session.

The switch stores FCoE session data in a persistent storage module. If the FC process terminates, the switch restores the existing FCoE sessions on the same interfaces that they were on before the FC process terminated. Data traffic for existing sessions is not affected during session restoration.

For a brief time, the system does not process control traffic because of the FC process restart and session restoration. During this brief time, no new FCoE sessions can be established, and no existing sessions can log out.

NOTE: During the restoration process, if the FC process does not receive an *interface up* notification from a particular interface within a certain time, the switch times out the restore operation and discards the data on that interface. The previously existing FCoE sessions on that interface are not restored, and the ENodes must log in again.

NOTE: An FC process restart and session restoration resets the Fibre Channel statistics.

If the FC process terminates repeatedly, the operating system disables the process until you manually restart it. To restart the FC process manually, issue the **restart fibre-channel** command.

High Availability for FIP Snooping

You can configure the system to perform FIP snooping on Ethernet interfaces that are connected to FCoE devices that have ENodes. The QFX Series provides high availability to restore running FIP snooping sessions in case the Ethernet switching process is terminated.

The Ethernet switching process stores the FIP snooping state in a persistent storage module. If the Ethernet switching process terminates, the QFX Series restores the existing FIP snooping sessions on the same interfaces that they were on before the Ethernet switching process terminated. The high availability features preserve:

- Logged in ENodes
- Discovered FCFs
- Existing sessions
- Existing FIP snooping filters

The complete restoration process, including reconciling all valid states, takes a maximum of 8 seconds. During the restoration process, the switch can learn a new FCF or a new FC switch, and new ENodes can log in to the FC network. However, FDISC messages from an ENode that is already logged in to the network might be dropped if the ENode has not yet been restored.

When the Ethernet switching process terminates ungracefully, the FIP keepalive timer is reset to the normal initial value, not the value at the time of the Ethernet switching process termination.

In the event of an Ethernet switching process termination, ENodes remain logged in, and existing sessions are not interrupted.

NOTE: An Ethernet switching process restart and session restoration resets the FIP snooping statistics.

Nonstop Software Upgrade (QFabric Systems)

On QFabric system Node groups that have more than one Node device, nonstop software upgrade (NSSU) enables you to upgrade the Node devices with minimal packet loss and maximum uptime. NSSU automates software upgrades on the QFabric system components in an orderly and consistent manner to maximize system uptime.

The system upgrades components with redundant architectures, such as redundant server Node groups and network Node groups that have two or more members, in stages. While the system upgrades one component, the redundant component continues to function.

For example, while one member of a redundant server Node group is upgraded, the other member continues to forward traffic. When the first Node group member completes the upgrade, it comes online while the system upgrades the second member.

NSSU provides high availability for the lossless traffic forwarding required to support storage networks. If your system design includes redundancy (redundant Node devices in Node groups, LAGs, and so on) so that an alternate traffic path is available, when you upgrade a Node device, traffic is not impacted.

In fully redundant topologies, NSSU preserves FIP session, FIP snooping filter, VN2VF_Port session, and VN2VN_Port session information and prevents traffic loss in most cases. An exception is that Node devices that are directly connected to ENodes experience momentary traffic loss when the Node device reboots.

Understanding FIP Functions

Fibre Channel over Ethernet (FCoE) Initialization Protocol (FIP) performs four major functions:

- FIP VLAN discovery: FCoE device FCoE nodes (ENodes) discover the FCoE VLANs on which to transmit and receive FIP and FCoE traffic.
- FIP discovery: FCoE devices discover Fibre Channel (FC) switches to which they can connect.
- Initialization: FCoE devices perform fabric login (FLOGI) and fabric discovery (FDISC) to create a virtual link with an FC switch.
- Maintenance: The QFX Series ensures that the virtual link between the FCoE device and the FC switch remains valid, and also that the link termination logout (LOGO) functions properly.

When you configure the switch as an FCoE-FC gateway, it converts FIP requests and information from FCoE devices into FC requests and information and relays them to the FC switch. To FCoE devices, the gateway appears to be an FCoE forwarder (FCF) and presents virtual fabric port (VF_Port) interfaces to the server ENode. To FC switches, the gateway appears to be an FC device that supports N_Port ID virtualization (NPIV) and presents an N_Port interface to the FC switch F_Port interface. When you configure the QFX Series as an FCoE transit switch, you do not configure FIP parameters on the switch.

FIP FLOGI, FDISC, and LOGO are similar to the same processes in the native FC protocol.

This topic describes:

FIP VLAN Discovery

The gateway supports FIP VLAN discovery. Host ENodes use FIP VLAN discovery to discover the FCoE VLANs on which they will send and receive FIP and FCoE traffic and on which they will establish a virtual link with the FC switch. This means FCoE devices do not need manually configured FCoE VLANs.

FIP VLAN discovery and notification takes place on the native VLAN that the FCoE device uses for Ethernet traffic:

1. The ENode sends a FIP VLAN discovery request to a multicast address called *ALL-FCF-MACs* to which all FC switches and FCFs on the VLAN listen.
2. The FC switches and FCFs respond on the native VLAN with a list of the FCoE VLANs that are available for login.
3. The ENode selects an FCoE VLAN and continues the FIP process on that VLAN.

Except for FIP VLAN discovery, all other FIP and FCoE traffic runs on an FCoE VLAN.

BEST PRACTICE: **Only FCoE traffic is permitted on the FCoE VLAN. A native VLAN might need to carry untagged traffic of different types and protocols. Therefore, it is a good practice to keep the native VLAN separate from FCoE VLANs.**

FIP Discovery

The FIP discovery process allows an FCoE device ENode MAC to locate (discover) the FC switches in the FCoE VLAN to which it belongs. The ENode selects an FC switch to log in to from the available FC switches. Either the ENode MAC or the FC switch can initiate the FIP discovery process.

Server ENode MACs initiate FIP discovery:

1. When an ENode MAC comes online, it sends a multicast discovery solicitation message on its FCoE VLAN to a multicast address called *ALL-FCF-MACs* to which all FCFs (including the FCF functionality of FC switches) on the VLAN listen. The discovery solicitation message includes the ENode's addressing mode and the maximum protocol data unit (PDU) size the ENode MAC uses for FCoE traffic.

   The ENode uses the globally unique ENode MAC address assigned to it by the converged network adapter (CNA) manufacturer as an identifier in the FIP frame header.
2. The FCFs on the VLAN that have a similar supported addressing mode, match the maximum FCoE size, and can accept a login from the ENode reply to the discovery solicitation message by sending a solicited unicast discovery advertisement message to the soliciting ENode MAC.
3. The ENode MAC compiles a list of FCFs that are available for login, selects an FCF (the FCF with the highest priority setting), and is then ready to log in to the FCF.

The FIP discovery process is similar when the FC switch or FCF initiates discovery:

1. FCF MACs periodically send unsolicited multicast discovery advertisements on the FCoE VLAN to the *ALL-ENode-MACs* multicast address, to which all ENode MACs on the VLAN listen. The FIP keepalive advertisement period timer (FKA_ADV_PERIOD) controls the interval between multicast discovery advertisements. The multicast discovery advertisements inform ENodes on the VLAN that FCF VF_Ports are available for establishing virtual links with ENode VN_Ports.
2. ENodes on the FCoE VLAN create an entry for the FCF-MAC in their FCF-MAC lists.
3. An ENode can respond to the unsolicited multicast discovery advertisement with a unicast discovery solicitation message to the FCF.
4. Upon receiving the ENode's unicast discovery solicitation, the FCF replies with a unicast discovery advertisement sent to the ENode MAC.

After the ENode MAC selects an FCF to log in to, FIP initialization begins. To proceed from discovery to initialization, the server ENode addressing mode must match the FCF addressing mode and maximum FCoE size. In addition, the FCF must be configured to allow FIP FLOGI from that ENode.

FIP FLOGI

FIP initialization is the server ENode login process to the FCF after the ENode discovers the FCFs (including FC switches) on the FCoE VLAN:

1. The ENode sends a fabric login (FLOGI) request message to the FCF.
2. The FCF replies to confirm the ENode login and provides the ENode a locally unique MAC address to use for FCoE frame transactions. The locally unique MAC address identifies the VN_Port interface of the ENode for the session the login establishes. (The ENode continues to use the globally unique ENode MAC address for FIP frame transactions.)

The locally unique ENode MAC address for FCoE operations depends on whether the ENode address mode is configured as a fabric-provided MAC address (FPMA) or as a server-provided MAC address (SPMA; the gateway does not support ENodes in SPMA mode and rejects login attempts from ENodes in SPMA mode):

- For FPMA mode, the FCF provides a MAC address to the ENode during the FIP FLOGI exchange. The FPMA MAC address is a 48-bit value that is unique to the local fabric and consists of a 24-bit FCoE mapped address prefix (FC-MAP) and a 24-bit FC identifier (FCID). You can configure the FC-MAP value on the FCF or use the default value of 0EFC00h. The FCoE device must use the same FC-MAP value as the FCF, or else discovery and login fail.
- For SPMA mode, the server provides its MAC address to the FCF. The FCF compares the server MAC address to a list of addresses approved for FCoE access. The gateway does not support ENodes in SPMA mode.

Successful login instantiates a secure virtual link between the ENode and the FCF and terminates the FIP virtual link instantiation phase. The initiating server behind the ENode can exchange FC payloads with storage devices in the FC SAN by sending FCoE frames over the virtual link.

FIP FDISC

After an ENode successfully logs in to an FCF and establishes a virtual link, the ENode can request more virtual links (sessions) over the same physical link by sending a FIP fabric discovery (FDISC) request. FDISC allows the creation of multiple separate secure VN_Port virtual links on one physical link. Each virtual link receives a locally unique identifier from the FCF to enable security and separation between the VN_Port virtual links sharing a physical ENode port. This is called N_Port ID virtualization (NPIV).

FDISC is similar to FLOGI in that it requests a login and a unique ID from the FCF. The difference is that FLOGI obtains the initial login and ID for the physical link, whereas FDISC obtains additional logins and IDs so that multiple virtual links can share one physical link securely.

After a VN_Port FDISC is complete, the application using that VN_Port can send FCoE frames over the virtual link.

FIP Maintenance (Keepalive Messages)

Although FCoE protocol handles the payload communication between the initiating ENode and the target FC device, FIP continues to run in the background. FIP constantly updates ENode FCF lists by listening to the periodic FCF multicast discovery advertisements, and it verifies the ability to reach the FCF by transmitting periodic FIP keepalive advertisements.

The ENode sends periodic ENode FIP keepalive advertisements to the FCF with the ENode MAC address as the identifier. The ENode also sends periodic VN_Port FIP keepalive advertisements on behalf of each VN_Port on the ENode, using the VN_Port MAC address as the source MAC. The VN_Port FIP keepalive advertisements occur every 90 seconds. The keepalive advertisements reset the session timer for the virtual link connection to the FCF. If the FCF does not receive a keepalive advertisement for a logged-in ENode or VN_Port before the session timer expires, the virtual link is terminated.

The periodic unsolicited multicast discovery advertisements the FCF sends to the *ALL-ENode-MACs* address continuously verify that the FCF is still reachable. The ENode and the FCF periodic unsolicited multicast discovery advertisements occur at the configured FIP keepalive advertisement period interval (FKA_ADV_PERIOD) plus or minus a random offset to prevent a flood of simultaneous keepalive advertisements.

If the FCF does not receive the ENode keepalive advertisements before the FCF's FIP keepalive timer expires, the FCF considers the virtual link to the ENode as "down" and terminates the virtual link to the ENode. The keepalive timer expires in 2.5 times the configured timer value. This also terminates any VN_Port virtual links instantiated by that ENode.

If the FCF does not receive a VN_Port keepalive advertisement before the FCF's FIP keepalive timer expires, the FCF considers the virtual link to the VN_Port as "down" and terminates the virtual link to that VN_Port. The VN_Port keepalive timer expires in 2.5 times the configured timer value.

If the ENode does not receive the FCF unsolicited multicast discovery advertisement before the ENode's FIP keepalive timer expires, the ENode considers the virtual link to the FCF as "down" and all of the VN_Port virtual links to that FCF on the ENode are terminated.

FIP LOGO

FIP handles ENode and VN_Port logout when a session is finished.

Understanding FIP Implementation

In a network that converges Fibre Channel (FC) and Ethernet traffic, when you configure the QFX Series as a Fibre Channel over Ethernet (FCoE)-FC gateway, it translates FCoE Initialization Protocol (FIP) frames from FCoE nodes (ENodes) into native FC frames for FC switches and translates native FC frames from FC switches into FIP frames for ENodes. To an FCoE device, the gateway appears to be an FCoE forwarder (FCF) and presents a fabric port (F_Port) interface to the FCoE device ENode. To an FC switch, the gateway appears to be an FC host capable of N_Port ID virtualization (NPIV) and presents a node port (N_Port) interface to the FC switch F_Port interface.

NOTE: The N_Ports that the gateway presents to the FC switch are called proxy N_Ports (NP_Ports). To the FC switch, the gateway NP_Ports appear to be native FC N_Ports that are capable of performing NPIV. The NP_Ports are proxies for the FCoE devices in the Ethernet network. The NP_Ports convert FCoE traffic from the FCoE devices into native FC traffic for the FC switch. The NP_Ports also convert native FC traffic from the FC switch into FCoE traffic for the FCoE devices on the Ethernet network.

FIP Basics

FIP is enabled by default on all VLAN interfaces that belong to each FC fabric configured on the gateway. You can configure FIP parameters at a global level or on an individual interface. When you configure a parameter on an interface, it overrides the global configuration only for that interface. If you do not explicitly configure a FIP parameter, the gateway uses the default value.

In order for the gateway to connect FCoE devices with FCFs, the FIP parameters you configure on the gateway must be compatible with the parameters configured on the FC switch (for example, the FC-MAP values of the FC switch and of the FC fabric FIP configuration on the gateway must match, or the FC switch drops the frames).

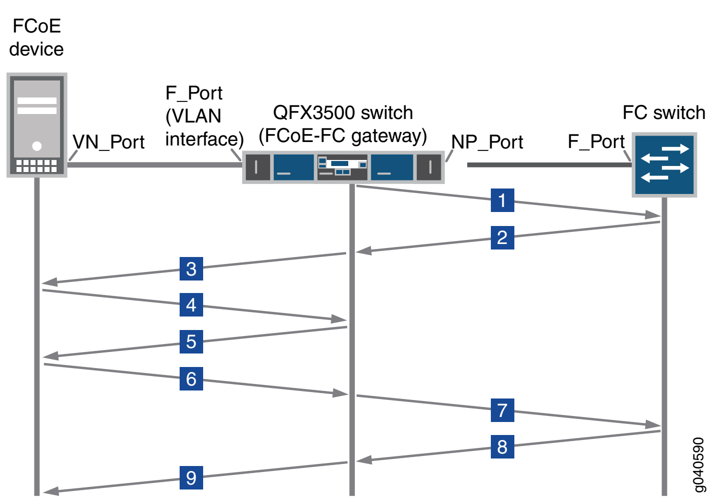
When the NP_Ports on the gateway come up, they perform an FC FLOGI to the connected FC switch. Successful login establishes communication between the gateway and the FC switch, and gateway NP_Ports are marked for sending FDISC messages. Successful login also creates a next-hop entry in the gateway for the FC switch. If the FC switch rejects the FLOGI request, no link is established. The gateway maintains a list of valid FCF-MACs with which ENodes can connect.

After establishing communication with an FC switch, the gateway can connect FCoE devices in the Ethernet network to the FC switch. All of the subsequent connections the gateway makes with FC switches as a proxy for ENodes (on behalf of ENodes) are virtualized (NPIV) connections.

Fabric Login and FIP Login Overview

Figure 174 on page 4822 provides a brief overview of the FCoE-FC gateway fabric login to the FC switch and the FCoE device FIP login to the gateway.

Figure 174: FCoE-FC Gateway Fabric Login and FIP Login



The numbers in the following list correspond to the numbers in Figure 174 on page 4822 and briefly describe each step of the login process:

1. The FCoE-FC gateway NP_Port sends an FC fabric login (FLOGI) request to the FC switch F_Port.
2. The FC switch accepts the gateway FLOGI.
3. The gateway sends FIP multicast discovery advertisements on the FCoE VLAN (the gateway F_Port interface) to all connected FCoE device ENodes.

4. The FCoE device ENode sends a discovery solicitation message to the gateway.
5. The gateway responds with a unicast discovery advertisement to the ENode.

NOTE: The gateway limits the number of discovery solicitations it accepts from FCoE devices to a maximum of 100 outstanding requests at any given time. If the gateway has 100 discovery solicitations outstanding, the gateway does not respond to new discovery solicitations. Instead, the gateway drops new discovery solicitations and reports the number of dropped discovery solicitations in the **Dropped** field of the **show fibre-channel fip statistics** command output. When there are fewer than 100 outstanding discovery solicitations, the system responds to new requests as usual with a discovery advertisement.

6. The FCoE device sends a FIP FLOGI or FIP FDISC message to the gateway.
7. The gateway converts the FIP FLOGI or FIP FDISC to an FC FDISC and forwards it to the FC switch to obtain a login for the FCoE device.
8. The FC switch responds to the FC FDISC by sending a new ID for the NPIV session to the gateway.
9. The gateway converts the FC FDISC response from the FC switch to a FIP FDISC response and forwards it to the FCoE device.

The following sections describe some of these steps in greater detail.

Proxy FIP Discovery

After the gateway establishes a connection with an FC switch:

1. The gateway sends periodic FIP multicast discovery advertisements on the FCoE VLAN so that ENodes can add the gateway to their FCF lists.
2. The ENode initializes and sends a multicast discovery solicitation message on the FCoE VLAN. If the ENode has already initialized and has a list of FCFs, it can send a unicast discovery solicitation message to a particular FCF such as the gateway.

   NOTE: The gateway limits the number of discovery solicitations it accepts from FCoE devices to a maximum of 100 outstanding requests at any given time. If the gateway has 100 discovery solicitations outstanding, the gateway does not accept new discovery solicitations until there are fewer than 100 discovery solicitations outstanding.

3. When the gateway receives a multicast discovery solicitation from an ENode, it responds by sending a unicast discovery advertisement to that ENode.

   When the gateway receives a unicast discovery solicitation from an ENode, it also responds with a unicast discovery advertisement to the ENode.

   To the ENode, the gateway appears to be an FCF.

The FIP discovery process adds the ENode to the gateway ENode database.

Proxy FIP Initialization

1. If the ENode chooses to log in to the gateway, it responds to the gateway's unicast discovery advertisement by sending a login request in the form of a FIP FLOGI if it is the initial connection to the gateway. If the ENode already has an established session with the gateway and another application or virtual machine wants to connect to the gateway, the ENode sends a FIP FDISC to the gateway.
2. The gateway receives the FIP FLOGI or FIP FDISC from the ENode, converts it into an FC FDISC, and sends it through the least-loaded NP_Port to the FC switch on behalf of the ENode. The FC FDISC message requests an FCID for the new virtual link.

   NOTE: **The gateway converts both ENode FIP FLOGI and FIP FDISC messages into FC FDISC messages, because the gateway has already performed FC FLOGI with the FC switch, so all subsequent connection requests on the gateway NP_Port are FDISC requests for virtual (NPIV) connections. FDISC messages request a virtual N_Port connection over an existing physical N_Port connection.**

3. The FC switch processes the request, accepts it, assigns a unique FCID for the connection, and then sends the response to the gateway. If the FC switch rejects the FDISC request, no virtual link is established.
4. The gateway maps the FC switch response to the ENode VN_Port, converts the FC acceptance message to a FIP FLOGI or FIP FDISC response, and sends it to the ENode VN_Port.
5. The ENode VN_Port accepts the FCID, and the virtual link is established.

If an ENode sends an FDISC, the proxy gateway switch checks whether the ENode has already performed a FLOGI to create the initial connection. If the ENode has not performed a FLOGI, the FDISC request is dropped.

The FC protocol does not recognize multipoint-to-point connections. Although the gateway can aggregate traffic from multiple FCoE servers on one NP_Port, each virtual link appears to be an individual point-to-point link between an FCoE ENode VN_Port and the FC switch, not as an aggregated multipoint-to-point link. The gateway is essentially invisible to the FC protocol, so the virtual link looks and acts like a point-to-point link from the FCoE device to the FC switch.

Proxy FIP Maintenance

The gateway sends and receives periodic FIP keepalive messages to and from ENode VN_Ports to maintain the connection between the gateway and the ENodes.

Proxy FIP Logout

As with FIP discovery and FIP FLOGI, the gateway represents the FCoE device in transactions with the FC switch and represents the FC switch in transactions with the FCoE device:

1. An ENode VN_Port sends a FIP LOGO message to log off and terminate the virtual link connection.
2. The gateway converts the FIP LOGO to an FC LOGO and relays it to the FC switch.
3. The FC switch responds to the LOGO request.
4. The gateway converts the FC LOGO response to a FIP LOGO response and relays it to the VN_Port, completing the logout and terminating the virtual link.

Understanding FIP Parameters on an FCoE-FC Gateway

By default, FIP is enabled, and the default FIP settings are valid on all FCoE interfaces that are part of the gateway FC fabric. You can configure some FIP parameters at a global level or on a specific interface. Some FIP parameters can be configured only at the global level or only at the individual interface level. When you configure a parameter at the interface level, the configuration overrides the global setting for that interface only.

FIP Keepalive Advertisement Period

The FIP keepalive advertisement period (fka-adv-period) is the time interval between messages that verify the connection is still valid and the device at the other end of the virtual link is still reachable. The ENode sends an ENode FIP keepalive advertisement to the gateway with the ENode MAC address as the source address to verify its reachability. The ENode also sends VN_Port FIP keepalive messages for every VN_Port on the ENode that is logged in to the gateway, with the VN_Port MAC address as the source address.

The FIP keepalive advertisement period also determines the time interval between unsolicited multicast discovery advertisements from the gateway to the *ALL-ENode-MACs* multicast address. Unsolicited multicast discovery advertisements serve as keepalive messages from the gateway to the ENodes and also advertise the gateway's presence on the network.

The gateway sends the periodic unsolicited multicast discovery advertisements to the ENodes. On the gateway, you can configure a global FIP keepalive advertisement period for an FC fabric and you can configure a FIP keepalive advertisement period for individual interfaces to override the global setting.

Addressing Mode

For FIP transactions, the ENode identifies itself using the globally unique MAC address assigned to the CNA by the manufacturer. After FIP has established a virtual link between an ENode VN_Port and the gateway, for FCoE transactions, the VN_Port identifies itself using a locally unique MAC address. The format of the locally unique MAC address depends on the addressing mode the fabric supports and the addressing mode the ENode is programmed to use.

The addressing mode is not a configurable parameter on the gateway. FC fabrics on the gateway support only the fabric provided MAC address (FPMA) addressing mode for FCoE transactions. The gateway does not support the server provided MAC address (SPMA) addressing mode. ENodes that use SPMA cannot log in to the gateway.

The FC switch assigns a locally unique FPMA to an ENode MAC through the FLOGI or FDISC process:

1. During the FIP discovery process, the ENode compiles a list of compatible FCFs (including the gateway) in the fabric. A compatible addressing mode is one of the criteria an FCF must meet to be added to an ENode's compatible FCFs list.
2. The ENode MAC transmits a FLOGI or FDISC to the FCF that includes the addressing modes the ENode supports.
3. If the FCF supports an addressing mode the ENode uses, the FCF accepts the FLOGI or FDISC and assigns the FPMA in the accept message (FIP FLOGI LS_ACC or FIP NPIV FDISC LS_ACC). If the ENode uses an addressing mode that is incompatible with the FCF, the FLOGI or FDISC is rejected.

The FPMA uniquely identifies a single VN_Port at that ENode MAC in FCoE transactions with the FCF. Each VN_Port connection receives its own unique FPMA to identify its virtual link connection. When an ENode uses NPIV to create multiple VN_Ports, each VN_Port virtual link receives its own unique FPMA to identify its traffic.

An FPMA consists of two concatenated 24-bit values:

1. The upper 24 bits are the FCF's FC-MAP value, which is a MAC address prefix that is unique to the fabric.
2. The lower 24 bits are the locally unique FCID that the FCF (FC switch) assigns to the VN_Port.

The combination of these values guarantees that each FPMA is unique within a fabric.

FC-MAP

The FCoE mapped address prefix (FC-MAP) value is a MAC address prefix used by the FCF that is unique within a given fabric. The FCF uses the FC-MAP for FCoE traffic within that fabric. The FCF rejects FCoE traffic that uses an FC-MAP value that does not match the FCF's FC-MAP value. In most cases, the FCF uses the default FC-MAP value (0EFC00), but a pool of 256 values is available (0EFC00 through 0EFCFF).

The gateway learns FC switches in the fabric that match the gateway fabric's FC-MAP value. To learn and communicate with an FC switch, the FC-MAP value for a fabric (or for the fabric's FCoE VLAN) on the gateway must match the FC switch's FC-MAP value. If the FC-MAP values do not match, no connection is established.

NOTE: Changing the FC-MAP value causes all logins to drop and forces the ENodes to log in again.

FCoE Trusted Fabric

By default, all interfaces are untrusted interfaces. You can globally configure all of the ports in a specified gateway FC fabric to be FCoE trusted. This reduces system overhead by eliminating the need for filters. The total number of FCoE sessions (ENode to FCF sessions) the system can support is 2500 sessions. Sessions are defined as the combined number of VN_Port to VF_Port sessions and VN_Port to VN_Port sessions. (Although VN2VF and VN2VN sessions run in different FCoE VLANs, the session limit is a system limit, not a per-VLAN limit.)

NOTE: A session is a FLOGI or FDISC login to the FC SAN fabric. Session does not refer to end-to-end server-to-storage sessions. There is no limit to the number of end-to-end server-to-storage sessions.

NOTE: Changing the fabric ports from untrusted to trusted removes any existing FIP snooping filters from the ports and terminates the existing sessions. Changing the fabric ports from trusted to untrusted forces all of the FCoE sessions on those ports to log out so that when the ENodes and VN_Ports log in again, the switch can build the appropriate FIP snooping filters.

Maximum Number of FCoE Sessions Per ENode

You can configure the maximum number of FCoE session logins from each ENode that are permitted on the gateway FC fabric. The number of sessions is the ENode FLOGI session plus the VN_Port FDISC sessions on that ENode. Regardless of whether the fabric is trusted or untrusted, the maximum number of FCoE sessions per ENode is

2500 sessions. The total number of sessions cannot exceed the gateway fabric's maximum limit of 2500 sessions.

The maximum number of FCoE sessions per ENode is a global configuration for all members of the gateway FC fabric and cannot be configured on a per-interface basis.

NOTE: Session does not refer to end-to-end server-to-storage sessions. There is no limit to the number of end-to-end server-to-storage sessions.

Priority

When the FIP discovery process offers an ENode the choice of more than one FCF-MAC on a given FCF to use for login, the ENode chooses the FCF-MAC to which to send a login request based on the FCF-MAC priority. The lower the priority number, the higher the FCF-MAC's priority. The ENode selects the highest-priority (lowest priority number) FCF-MAC for the login request.

An ENode can receive multiple FCF-MAC advertisements from the same FCF in two ways:

- During the FIP discovery process, an FCF can receive an ENode MAC's multicast discovery solicitation on multiple FCF-MACs. Each FCF-MAC replies with a unicast discovery advertisement to the ENode. The ENode determines that the advertisements are from the same FCF, because the value in the Name_Identifier descriptor is the same in each advertisement.
- During the FIP discovery process, an ENode MAC can receive unsolicited multicast discovery advertisements from multiple FCF-MACs on the same FCF. The ENode determines that the advertisements are from the same FCF, because the value in the Name_Identifier descriptor is the same in each advertisement.

On the gateway, you can configure the priority value for an entire fabric or for an individual interface. The default value for both the fabric and the individual interfaces is 128 (the highest priority is 0; the lowest priority is 255).

Understanding Fibre Channel Virtual Links

A virtual link emulates a secure point-to-point connection between the virtual node port (VN_Port) of a Fibre Channel over Ethernet (FCoE) node (ENode) and the virtual fabric port (VF_Port) of an FCoE forwarder (FCF). The combination of the FCF media access control (MAC) address and the VN_Port MAC address uniquely identifies each virtual link. Uniquely identifying each virtual link enables the logical separation of traffic that belongs to each virtual link. A single physical link between an ENode and an FCF can carry multiple virtual links and maintain secure, separate transport of traffic on the different virtual links.

Virtual links are necessary because Fibre Channel protocol does not recognize multipoint-to-point connections. Even when multiple connections are aggregated on one physical port, FCoE Initialization Protocol (FIP) presents each virtual link as an individual point-to-point link between an ENode VN_Port and an FCF VF_Port.

Understanding Interfaces on an FCoE-FC Gateway

When the QFX Series functions as an FCoE-FC gateway to connect FCoE devices on an Ethernet network to a Fibre Channel (FC) switch in a storage area network (SAN), it handles FCoE traffic from hosts and native FC traffic from the FC switch. To support this architecture, each local FC fabric configured on the gateway (in the **fc-fabrics** configuration hierarchy) must have:

- An Ethernet-network-facing F_Port interface for the FCoE VLAN to connect to FCoE device VN_Ports in the form of an FCoE VLAN interface. Multiple VF_Ports are initiated on the F_Port interface, one VF_Port for each ENode that logs in to the FC network.
- One or two blocks of six proxy N_Port (NP_Port) interfaces to connect to FC switch fabric ports (F_Ports).

Each FC fabric is local to the gateway on which you configure it. This means that both the FC switch and the FCoE devices must be connected to the same gateway (QFX3500 switch or QFabric system Node device), and that all of the interfaces configured for the local fabric also must be on that gateway. FC fabric traffic does not flow between different Node devices in a QFabric system.

This topic describes:

Native FC Interfaces to the FC Switch

You must configure either 6 or 12 of the physical interfaces on the gateway as native FC NP_Port interfaces to connect to FC switch F_Port interfaces. By default, all of the gateway interfaces are Ethernet interfaces, so you must explicitly configure the interfaces that you want to use as FC interfaces.

You can configure the FC-capable ports xe-0/0/0 through xe-0/0/5 as fc-0/0/0 through fc-0/0/5, and ports xe-0/0/42 through xe-0/0/47 as fc-0/0/42 through fc-0/0/47 to create blocks of native FC interfaces. You cannot individually configure a single port as a native FC interface. Within these port blocks, you cannot mix FC interfaces with Ethernet interfaces. All of the ports in a block must be either native FC interfaces or Ethernet interfaces.

You cannot configure ports xe-0/0/6 through xe-0/0/41 and ports xe-0/1/1 through xe-0/1/15 as native FC ports; they can only be Ethernet ports. Native FC ports do not handle Ethernet traffic (including FCoE traffic); they handle only native FC traffic and must connect to native FC ports.

You can configure:

- Six native FC interfaces by configuring either ports xe-0/0/0 through xe-0/0/5 as fc-0/0/0 through fc-0/0/5 *or* ports xe-0/0/42 through xe-0/0/47 as fc-0/0/42 through fc-0/0/47.
- Twelve native FC interfaces by configuring ports xe-0/0/0 through xe-0/0/5 as fc-0/0/0 through fc-0/0/5 *and* ports xe-0/0/42 through xe-0/0/47 as fc-0/0/42 through fc-0/0/47.
- No native FC interfaces by leaving ports xe-0/0/0 through xe-0/0/5 and ports xe-0/0/42 through xe-0/0/47 in their default state as Ethernet interfaces.

Each native FC interface can belong to only one local FC fabric configured on the gateway. You can configure up to 12 FC fabrics on a gateway, but each FC fabric must use different native FC interfaces to connect to an FCF. (Although the native FC ports are configured in blocks, each individual port can belong to a different FC fabric.) Native FC interfaces can be configured as loopback interfaces.

Port Mode

The gateway presents a proxy N_Port (NP_Port) interface to the FC switch. An NP_Port connects to a single FC switch F_Port using a point-to-point link (in other architectures an N_Port can also connect in a point-to-point link to another N_Port, but that is not a valid configuration on the gateway).

You must explicitly configure each native FC interface connected to an FC switch as an NP_Port. The gateway NP_Ports act as a proxy for the FCoE device virtual N_Ports (VN_Ports) when the VN_Ports attempt to connect to the FC switch.

When the FC switch is a trusted switch, configure the fabric as **fcoe-trusted** to reduce overhead caused by the VN_Port to VF_Port (VN2VF_Port) FIP snooping filters that are automatically installed on untrusted ports.

NPIV

FC requires a unique point-to-point link between the FC switch and each host N_Port. The gateway creates an independent virtual link for each FCoE device session by mapping each FCoE device to a virtualized N_Port through the gateway's proxy function. This process is called N_Port ID virtualization (NPIV).

NPIV makes each virtual link look like a dedicated point-to-point link to the FC switch. In this way, multiple FCoE devices, multiple applications, and multiple virtual machines on an FCoE device can connect to an FC switch using one physical port instead of using a physical port for each host connection. The virtual link creates a secure boundary between traffic from different sources that are on a single physical port.

FCoE-FC gateway mode implements NPIV as follows:

1. An NP_Port on the gateway comes up and logs in to the attached F_Port on the FC switch. The FC switch sees the gateway port as a physical FC device N_Port and assigns it a unique FCID. This establishes the physical point-to-point link between the gateway and the FC switch.
2. The gateway receives a FIP discovery message from an FCoE device that seeks to log in to the FC network. To the FCoE device, the gateway presents a virtual F_Port (VF_Port) interface and appears to be an FCF.
3. The gateway converts the FCoE device's message into an FC fabric discovery (FDISC) message and sends it through the least-loaded physical NP_Port to the FC switch. The FDISC message requests an FCID for the new virtual link.
4. The FC switch processes the request, accepts it, assigns a unique FCID for the connection, and sends the response.
5. The gateway maps the FC switch response to the host FCoE device's VN_Port and sends a FIP acceptance advertisement to the FCoE device.
6. The FCoE device accepts the FCID.

If the FC switch rejects the FDISC, the gateway relays the rejection to the FCoE device VN_Port.

Port Speed

The gateway supports configuring FC port speeds of 2 Gbps, 4 Gbps, or 8 Gbps. FC ports can also autonegotiate the port speed to 2, 4, or 8 Gbps.

FIP Login Session Limits

A FIP login session is a fabric login (FLOGI) or fabric discovery (FDISC) login to the FC SAN fabric. (A session here does not refer to an end-to-end server-to-storage session; there is no limit to the number of end-to-end server-to-storage sessions.) You can limit the maximum number of FIP login sessions on each gateway Node device (QFX3500 switch or QFabric system Node device configured in FCoE-FC gateway mode), on each local gateway FC fabric, and on each individual NP_Port interface in a local FC fabric:

- Gateway Node devices and Node groups—The total number of FIP login sessions on the gateway Node or Node group (the sum of the sessions on all of the NP_Port interfaces in all of the local FC fabrics on the gateway Node or Nodes) cannot exceed the limit. When a gateway reaches the maximum session limit, the gateway sends subsequent multicast discovery advertisements (MDAs) with the availability bit set to 0 (zero) to prevent additional ENode login attempts. If the maximum number of sessions is running on the gateway, ENodes cannot use the gateway to log in new sessions to the FC switch. When the number of sessions falls below the maximum, the gateway sets the availability bit in MDAs to 1 so that ENodes can again log in new sessions. When a session slot becomes available, the system accepts the first session request to fill the slot.
- FC fabric—The total number of FIP login sessions on an FC fabric (the sum of the sessions on all of the NP_Port interfaces that belong to the fabric) cannot exceed the limit. When a fabric reaches the maximum session limit, the gateway sends MDAs associated with that fabric with the availability bit set to 0 to prevent additional ENode login attempts.

  NOTE: **Other FC fabrics on the same gateway can still accept ENode logins as long as the maximum session limit for those fabrics and the maximum session limit for the gateway (the Node device) have not been met.**

- NP_Port interfaces—The total number of FIP login sessions cannot exceed the interface's limit. When an interface reaches the maximum session limit, the gateway removes it from the load-balancing list for that FC fabric to prevent the gateway from attempting to assign new sessions to the interface. Other interfaces in the FC fabric can still accept logins until the FC fabric or gateway reaches its maximum session limit. However, the interface that reached the maximum session limit cannot be assigned new sessions until the number of sessions on the interface falls below the limit.

  BEST PRACTICE: **Configure a maximum session limit for each NP_Port interface that is less than or equal to the number of FIP sessions the directly connected FC switch port is configured to support. This prevents the gateway from attempting to assign new login sessions to an interface when the connected FC switch port reaches its maximum number of sessions.**

FCoE Trusted and Untrusted Interface Session Limits

The maximum number of VN2VF_Port FCoE login sessions that each gateway can support is 2500 sessions, regardless of whether interfaces are trusted or untrusted. (In software releases earlier than Junos OS Release 12.3, the session limit on untrusted interfaces and untrusted fabrics was 376 sessions.)

Configuring Consistent Session Limits

The system does not perform commit checks to enforce consistent session limit configuration. For example, the system does not prevent you from configuring a higher limit for ENode sessions than the total session limit for the gateway Node device, or from configuring a higher limit on an interface than on the fabric to which the interface belongs.

To prevent unexpected FIP login rejections, you should configure consistent Node device, fabric, and interface session limits. For example:

- The session limit of an interface should not exceed the session limit of the fabric to which it belongs.
- For interfaces that belong to the same fabric, the sum of the interface session limits should not exceed the fabric session limit.
- The fabric session limit should not exceed the session limit of the gateway Node device.
- For fabrics that belong to the same gateway Node device, the sum of the fabric session limits should not exceed the Node device session limit.

Session limit configuration considerations include:

- The fabric session limit restricts how many sessions can run on the NP_Port interfaces that belong to that fabric. If the combined session limits of the interfaces exceed the fabric session limit, the total number of sessions on the interfaces is the fabric limit.

  For example, if a fabric has three NP_Port interfaces, and each NP_Port interface has a limit of 500 sessions (total of 1500 sessions for the three interfaces), but the fabric has a limit of 1000 sessions, the combined number of sessions on the three interfaces is limited to 1000 sessions.
- The gateway Node device session limit restricts how many sessions can run on the fabrics that belong to that gateway. If the combined session limits of the fabrics exceed the gateway Node device session limit, the total number of sessions on the fabrics is the gateway Node device limit.

  For example, if a gateway has two fabrics, and each fabric has a limit of 1000 sessions (total of 2000 sessions for the two fabrics), but the gateway has a limit of 1500 sessions, the combined number of sessions on the two fabrics is limited to 1500 sessions.

Hierarchically, the gateway Node device session limit is the maximum limit for all sessions on the gateway, regardless of fabric and interface session limits. In the same way, the fabric session limit supersedes the interface session limit.

When session limits are exceeded, no new logins are accepted until a session slot becomes free.

Decreasing Session Limits

If you decrease the session limit, the currently logged in sessions are terminated as follows:

- Gateway Node devices and Node groups—Decreasing the session limit terminates all of the sessions on the Node device (all sessions on all interfaces on all fabrics). If the gateway Node device is part of a Node group, all sessions on all members of the Node group are terminated.
- Fabric—Decreasing the session limit terminates all of the sessions on all of the interfaces that belong to the fabric.
- NP_Port interfaces—Decreasing the session limit terminates all of the sessions on the interface and also terminates all of the sessions on any other interfaces that belong to the same fabric.

After you decrease a session limit, the sessions are terminated even if the new session limit is greater than the number of currently active sessions. For example:

- An interface has 300 active sessions.
- The current session limit is 1000 sessions.
- You decrease the session limit to 500 sessions and commit the new configuration.
- All 300 sessions are logged out, even though the new session limit is greater than the number of sessions running.

After the session limit change takes effect, the ENodes log in again and establish new sessions, up to the new session limits.

Increasing Session Limits

Increasing the session limits does not disrupt logged in sessions.

Effect of Deactivating and Then Reactivating the Configuration on Session Limits

If you decrease session limits, all ENodes are logged out. Deactivating and then reactivating the configuration can have the same effect as decreasing the session limit, which results in the ENodes being logged out.

The ENode logouts occur because when you deactivate the configuration, the system reverts to the default session limit of 2500 sessions (the maximum number of sessions). When you reactivate the configuration, the system uses the configured session limit. Unless the configured session limit is equal to the maximum session limit, reactivating the configuration decreases the session limit, which causes the ENodes to be logged out.

For example, if you:

1. Configure and commit a limit of 400 sessions.
2. Allow ENodes to log in and start sessions.
3. Deactivate the configuration.

4. Reactivate the configuration.
5. The ENode sessions are logged out because deactivating the session increased the session limit from 400 to 2500.

Because an increase in the session limit does not affect existing sessions, the running ENode sessions are not affected. However, reactivating the configuration decreased the session limit from 2500 back to 400. The session limit decrease causes the ENode sessions to be logged out.

Trusted and Untrusted Interfaces

By default, gateway fabric interfaces are untrusted interfaces. If you do not configure a gateway fabric as an FCoE trusted fabric to set all of the gateway fabric interfaces as trusted interfaces, the gateway installs VN2VF_Port FIP snooping filters on the fabric ports.

If you configure a gateway fabric as an FCoE trusted fabric, the gateway does not install VN2VF_Port FIP snooping filters on the fabric interfaces. This is usually done when the gateway is connected to an FCoE transit switch that has VN2VF_Port FIP snooping enabled.

Regardless of whether an interface is trusted or untrusted, the maximum session limit is 2500 sessions.

NOTE: **The session limit for a Node group is the same as the session limit for an individual Node device, 2500 sessions. Even if more than one Node device in a Node group is acting as an FCoE-FC gateway, the total maximum number of sessions on all Node devices in the Node group is 2500 sessions.**

The default maximum login session value for Node devices (on QFabric systems, the maximum applies to each Node device), trusted fabrics, and interfaces in trusted fabrics is 2500 sessions.

Buffer-to-Buffer Credit Recovery

Buffer-to-buffer credits represent the number of receive buffers an interface can use to store FC frames. Buffer-to-buffer credit determines buffer-to-buffer flow control. When an interface transmits a frame, it decrements its buffer-to-buffer credit count by one. When the destination interface forwards the frame and frees a buffer, it sends a receiver ready (R_RDY) primitive to the transmitting interface. Each R_RDY primitive the transmitting interface receives increments its buffer-to-buffer credit count by one.

Both interfaces on an FC link track buffer-to-buffer credits. As long as buffer-to-buffer credits are available, the transmitter continues to send frames. If the number of buffer-to-buffer credits reaches zero (0), transmission stops until buffer-to-buffer credits are available, as indicated by the reception of an R_RDY primitive. Buffer-to-buffer credits can compensate for long cable distances to limit throughput and prevent buffer overflow.

However, if frame corruption or errors transmitting R_RDY primitives occur, the buffer-to-buffer credit counters on the sending and receiving interfaces do not have the same values. This causes the permanent loss of buffer-to-buffer credits. When credits are lost, the buffer credit count can decrement to zero and indicate that there is no available buffer space even if buffer space is actually available. This can result in unnecessary link idle time.

To recover lost buffer-to-buffer credits, you can configure a buffer-to-buffer credit state change number (BB_SC_N). BB_SC_N must be configured on both ends of the connection. If only one end of the connection is configured for BB_SC_N, the feature is disabled. The two directly connected FC interfaces communicate the BB_SC_N value during fabric login (FLOGI).

When you enable BB_SC_N on the interfaces on both ends of an FC link, the interfaces exchange buffer-to-buffer state change send (BB_SCs) and buffer-to-buffer state change receive (BB_SCr) primitives to track the number of frames sent and the number of R_RDY primitives received. The state change number determines the number of frames and R_RDY primitives the interfaces exchange between consecutive BB_SCn primitives and between consecutive BB_SCr primitives. The state change primitives inform each interface of the other interface's frame count and R_RDY count states.

The state counters should match so that each interface knows and agrees with the other interface's state. If the interface at either end of the link detects a discrepancy, it knows that a frame or an R_RDY primitive was corrupted or dropped.

For example, if a receiving interface has sent two R_RDY primitives but the BB_SCr that the interface receives from the sending interface only counts one R_RDY primitive received, it reveals that one R_RDY primitive was not delivered successfully and that one buffer-to-buffer credit was lost. When one of the interfaces on the link detects a discrepancy, the interfaces can take corrective action and recover the lost buffer-to-buffer credits.

Enabling the buffer-to-buffer credit recovery feature does not impact buffer resources and has an insignificant impact on processing resources.

If buffer-to-buffer credit recovery is not used, then when there is no buffer credit on a port, a timeout and recovery mechanism prevents buffer overflow.

FCoE VLAN Interface to FCoE Devices

Each FC fabric configured on the gateway includes at least one FCoE VLAN interface to connect the FCoE devices on the FCoE VLAN to the FC switch. (Including the FCoE VLAN interface and the native FC interfaces in the FC fabric configuration connects them.) FCoE VLANs can include any Ethernet interface on the switch that is in tagged-access or trunk mode. The best practice is to configure Ethernet interfaces that belong to FCoE VLANs in **tagged-access** port mode.

NOTE: The Ethernet interfaces that connect to FCoE devices must include a native VLAN to transport FIP traffic, because FIP VLAN discovery and notification frames are exchanged as untagged packets.

FCoE VLANs should carry only FCoE traffic. You should not mix FCoE traffic and standard Ethernet traffic on the same VLAN.

NOTE: FCoE VLANs (any VLAN that carries FCoE traffic) support only Spanning Tree Protocol (STP) and link aggregation group (LAG) Layer 2 features.

Each FCoE VLAN interface can belong to only one FC fabric configured on the gateway. A gateway FC fabric can have more than one FCoE VLAN, but each FCoE VLAN in the FC fabric must belong only to that FC fabric. You can configure more than one FC fabric on a gateway; each FC fabric must use different FCoE VLAN interfaces to connect to FCoE devices.

NOTE: Storm control must be disabled on all Ethernet interfaces that belong to the FCoE VLAN to prevent FCoE traffic from being dropped.

Port Mode

You must explicitly configure the FCoE VLAN interface in F_Port mode. All members of the FCoE VLAN use the FCoE VLAN interface as the connection to the gateway NP_Port interfaces and ultimately to the FC switch.

All of the 10-Gigabit Ethernet interfaces that are members of an FCoE VLAN should be configured as **tagged-access** port mode interfaces. However, the system also supports configuring these interfaces in **trunk** port mode.

BEST PRACTICE: Use **tagged-access** port mode for Ethernet interfaces that are connected to converged network adapters (CNAs) in FCoE access devices.

Use **trunk** port mode when an Ethernet interface is an interswitch link (ISL)—that is, when the port is connected to another switch. For example, if a port is connected to a transit switch that is performing VN2VF_Port FIP snooping, configure the port in **trunk** mode and as an FCoE trusted port.

The **tagged-access** port mode was not available in Junos OS Release 11.3 and earlier releases. In Release 11.3 and earlier, only **trunk** port mode was used for Ethernet interfaces that belong to an FCoE VLAN. Because **tagged-access** mode is now available, using **trunk** mode for interfaces connected to FCoE CNAs is not recommended.

If an existing configuration uses **trunk** mode for ports connected to FCoE CNAs, you can change the port mode to **tagged-access** without disrupting traffic. Although we recommend changing the port mode of these ports from **trunk** mode to **tagged-access** mode as a best practice, it is not mandatory. New configurations should use **tagged-access** mode for interfaces that connect to FCoE devices.

There are several advantages of configuring Ethernet ports connected to FCoE devices in **tagged-access** mode instead of in **trunk** mode:

- It is standard practice to configure ISL ports as trunk ports.
- It is standard practice not to configure ports that connect to servers as trunk ports.
- When an interface goes down, if that interface is in **trunk** mode, then the FCoE sessions on that interface are terminated only after the gateway stops receiving FIP keepalive messages from the ENode and exceeds 2.5 times the FIP keepalive timeout advertisement value. If the interface is in **tagged-access** mode and the interface goes down, the gateway sends a FIP message to terminate the sessions on the interface.
- Similarly, if an ENode session moves from one interface to another interface, if the original interface is in **trunk** mode, the session is not removed from the interface until the gateway stops receiving FIP keepalive messages and exceeds 2.5 times the FIP keepalive advertisement timeout value. But if the interface is in **tagged-access** mode, the gateway detects that the session is no longer on the interface, does not refresh the FIP keepalive timer, and thus ages out the session.

NOTE: FIP is enabled on the FCoE VLAN, which is a Layer 3 interface. As with other Layer 3 interfaces under Junos OS, when the last member (10-Gigabit Ethernet interface) of the FCoE VLAN is deleted, the FCoE VLAN interface is internally marked as “down.” When the Layer 3 FCoE VLAN interface is marked as “down”, FIP stops running on it. When the last member interface is deleted from an FCoE VLAN and FIP stops running, the result could be an immediate timeout for the VN_Ports that were connected on that interface, regardless of whether the port mode is **tagged-access** or **trunk**.

Disabling Storm Control on FCoE Interfaces

Storm control is not supported on the FCoE interfaces of an FCoE-FC gateway VLAN. Enabling storm control on an FCoE-FC gateway VLAN interface may cause FCoE packet loss. Storm control is disabled by default on all interfaces. However, if you enabled storm control globally on all switch interfaces or on any interfaces that are part of the FCoE VLAN interface, you must disable storm control on the Ethernet interfaces of the FCoE VLAN.

If storm control is enabled on only a few interfaces of the FCoE VLAN, you can disable storm control on individual interfaces by including the **delete ethernet-switching-options**

storm-control interface ***interface-name*** statement in the configuration, where ***interface-name*** is the name of the interface on which you want to disable storm control.

If storm control is enabled globally on the switch when the switch is acting as an FCoE-FC gateway, it is often easiest to disable storm control on all interfaces, then enable storm control only on Ethernet interfaces that are not part of the FCoE VLAN interface.

If storm control is enabled globally, you can disable storm control in either of two ways:

- Disable storm control on all interfaces, then enable storm control on the interfaces you want to use storm control. (From the default configuration, you cannot disable storm control on individual interfaces because the default configuration enables storm control on **all** interfaces, not on individual interfaces.)

  For example, if you want interfaces xe-0/0/20, xe-0/0/21, and xe-0/0/22 to use storm control, disable storm control on all interfaces, then enable storm control on those three interfaces:

  1. Disable storm control on all interfaces:

     `user@switch#` **delete ethernet-switching-options storm-control interface all**

  2. Enable storm control on interfaces xe-0/0/20, xe-0/0/21, and xe-0/0/22:

     `user@switch#` **set ethernet-switching-options storm-control interface xe-0/0/20**
     `user@switch#` **set ethernet-switching-options storm-control interface xe-0/0/21**
     `user@switch#` **set ethernet-switching-options storm-control interface xe-0/0/22**

- Disable storm control for all unknown unicast traffic on all interfaces by including the following statement in your configuration:

  `user@switch#` **set ethernet-switching-options storm-control interface all no-unknown-unicast**

NPIV Support

The gateway supports FCoE device NPIV. For example, a single physical FCoE device can have multiple virtual machines running on it. Each virtual machine can instantiate a separate virtual connection to the gateway, which results in its own virtual link to the FC switch. In this way, an FCoE device can have multiple separate connections to the FC SAN on a single physical port.

This is similar to the NPIV function the gateway performs with the FC switch to support multiple virtual FCoE device connections on one physical NP_Port.

The gateway presents multiple VF_Port interfaces on each FCoE VLAN interface to support the requirement for unique, secure virtual links.

VN2VF_Port FIP Snooping

The FCoE-facing ports that belong to an FCoE VLAN on a gateway are enabled for VN2VF_Port FIP snooping automatically. You can disable VN2VF_Port FIP snooping on any individual interface by configuring it as a trusted interface.

Assigning Interfaces to a Fibre Channel Fabric

You assign at least one FCoE VLAN interface and at least one native FC interface to each FC fabric you configure on the gateway. All of the interfaces that belong to an FC fabric must reside on the same gateway device. Interfaces on different gateways cannot belong to the same FC fabric, because an FC fabric is local to a single gateway device.

Deleting a Fibre Channel Interface

To delete an FC interface or an FCoE VLAN interface, you must delete the interface from the fabric first and then delete the interface from the switch.

Understanding Load Balancing in an FCoE-FC Gateway Proxy Fabric

You can balance or rebalance the load on the ports in an FCoE-FC gateway proxy fabric in order to avoid overutilizing or underutilizing the links. Load balancing is distributing sessions across the available native Fibre Channel (FC) interfaces (NP_Ports) that belong to a local gateway FC fabric to create a relatively equal load on all the fabric links. Load rebalancing is redistributing the existing sessions across the available NP_Port links on a local gateway FC fabric.

NOTE: **A session is a fabric login (FLOGI) or fabric discovery (FDISC) login to the FC SAN fabric. Session does not refer to end-to-end server-to-storage sessions.**

The fabric-facing NP_Port links of an FCoE-FC gateway use different load-balancing methods than the FCoE-network-facing Ethernet links. You can balance the load on the FCoE-network facing Ethernet port members of the FCoE-FC gateway by configuring the ports in a link aggregation group (LAG). This topic focuses on NP_Port load balancing.

Balancing the load on FCoE-FC gateway NP_Port links consists of two steps:

1. Choosing the algorithm used to balance and rebalance the link load
2. Choosing whether to rebalance link loads automatically or only when you explicitly request a rebalance (load-rebalancing method)

You can configure a different load-balancing algorithm and use a different rebalancing method for each local FC fabric on the FCoE-FC gateway. The load-balancing algorithm and automated rebalancing, if configured, apply to all NP_Port interfaces in the local FC fabric.

This topic describes:

Load-Balancing Algorithms

You can choose one of three load-balancing algorithms to configure the way the switch balances the link loads. The switch uses the configured algorithm to balance the link loads when NP_Ports are initialized and whenever link loads are rebalanced. Regardless of whether you configure automated load rebalancing or use on-demand load rebalancing, the switch uses the configured algorithm to balance the link load:

- Simple load balancing—The switch assigns each ENode FLOGI session and VN_Port FDISC session to the least-loaded link. The switch can place FDISC sessions on a different link than the parent FLOGI session (an ENode FLOGI session and its subsequent FDISC sessions can be placed on different links). Simple load balancing is the default load-balancing algorithm. Rebalancing the link load disrupts only selected sessions to minimize the impact (the switch uses an algorithm to log out only the sessions that need to be moved to other links to balance the load when those sessions log in again).
- ENode-based load balancing—When an ENode logs in to the fabric, the switch places all subsequent VN_Port FDISC sessions associated with that ENode on the same link as the ENode FLOGI session, regardless of the link load. New ENode FLOGIs are placed on the least-loaded link. The switch calculates the link load based on the combined total of FLOGIs and FDISCs on each NP_Port link. Rebalancing the link load disrupts all sessions (all sessions log out and then log in again).
- FLOGI-based load balancing—Similar to ENode-based load balancing; when an ENode logs in to the fabric, the switch places all subsequent VN_Port FDISC sessions associated with that ENode on the same link as the ENode FLOGI session, regardless of the link load. New ENode FLOGIs are placed on the least-loaded link.

  One difference between ENode-based load balancing and FLOGI-based load balancing is that the switch calculates the link load based only on the number of FLOGIs on each NP_Port link. The algorithm does not count FDISCs. Another difference is that instead of disrupting all sessions on a link load rebalance, the system disrupts only selected sessions to minimize the impact (the switch uses an algorithm to log out only the sessions that need to be moved to other links to balance the load when those sessions log in again).

NOTE: **Changing the load-balancing algorithm when FCoE sessions are running forces the FCoE sessions to log out and then log in again.**

If you do not explicitly configure the load-balancing algorithm, the switch uses simple load balancing by default on the all NP_Port interfaces that belong to a given local FC fabric.

The following sections describe how each algorithm works, its advantages and disadvantages, and what happens when NP_Port links come up for the first time, when an NP_Port link is added to existing links, and when you rebalance the link load:

Simple Load Balancing

Simple load balancing provides the most equal load balancing across links because each VN_Port FDISC session can be assigned to the least-loaded link, regardless of whether the parent ENode FLOGI session is on that link. (The parent ENode is the ENode that originates the logins to the fabric. After the parent ENode logs in, the VN_Ports on that ENode can log in to the fabric using FDISC.)

The FCoE-FC gateway performs simple load balancing by default on the NP_Ports that connect the gateway to the FC SAN. When an ENode sends a FLOGI request to the gateway, the gateway checks the NP_Ports that connect it to the FC SAN and assigns the new session to the least-loaded link.

Every time an ENode sends a FLOGI or an FDISC request, the gateway assigns the new session to the least-loaded NP_Port link. After the gateway assigns an ENode FLOGI session to an NP_Port, subsequent FDISC requests by the same ENode can result in sessions being assigned to different NP_Ports, because the gateway always assigns the new session to the least-loaded interface.

NOTE: **Because VN_Port sessions might be placed on a different link than their parent ENode, if the link that contains the ENode goes down, only the ENode session and any of its VN_Port sessions that are on that link go down. VN_Port sessions on other links remain active as long as the link is up and the VN_Port is not logged out.**

When a new link comes up, the switch logs out enough sessions so that when the sessions log in again, they are placed on the new link and the link loads are balanced. The switch uses an algorithm to log out sessions in the least disruptive manner by first logging out FDISCs whose FLOGI is not on the same link, then the least-loaded FLOGIs (loaded in terms of related FDISC logins).

Similarly, when you rebalance an existing link load, the switch logs out only enough sessions so that when the sessions log in again, they balance the load on the existing links. In this case (rebalance without a new link up), the switch takes into account the dependencies between FLOGIs and FDISCs when selecting sessions to log out.

The simple load-balancing algorithm uses the sum of the FLOGI and FDISC sessions to determine the session load on each link for both initial load balancing and load rebalancing.

ENode-Based Load Balancing

ENode-based load balancing can result in a less balanced load across the NP_Port links because the VN_Port FDISC sessions are assigned to the same link as the parent ENode FLOGI session, regardless of how many FDISC sessions are associated with the ENode. However, ENode-based load balancing has the advantage of keeping all of the sessions associated with a particular ENode on one link, which provides better control and predictability.

When you use the ENode-based load-balancing algorithm, the gateway assigns the ENode to an NP_Port link when the ENode sends its FLOGI message to the gateway. The gateway places the ENode session on the least-loaded link at that time. The VN_Port FDISC sessions associated with an ENode are placed on the same link as the ENode FLOGI session, regardless of the link load. Essentially, the ENode sessions are load-balanced, but the VN_Port sessions are not.

ENode-based load balancing ensures that each ENode and its associated VN_Port sessions are assigned to the same NP_Port link. ENode-based load balancing provides more control and predictability and ensures that if the link carrying an ENode goes down, all of the ENodes associated VN_Port sessions also go down.

The disadvantage of ENode-based load balancing is that if one ENode has a large number of sessions and the other ENodes do not, the link that carries the ENode with the large number of sessions might have a much larger load than the other NP_Port links in the gateway proxy fabric.

For example, if a gateway fabric has two NP_Ports connected to the FC fabric, and two ENodes log in to the fabric, one ENode session is placed on each link. If two VN_Port sessions are initiated on one of the ENodes, those sessions are placed on the same link as the parent ENode. If 1000 VN_Port sessions are initiated on the other ENode, all of the 1000 VN_Port sessions are placed on the same link as that ENode. In this case, one link has 3 sessions (1 ENode FLOGI session and 2 VN_Port FDISC sessions) and the other link has 1001 sessions (1 ENode FLOGI session and 1000 VN_Port FDISC sessions).

When a new link comes up or when you rebalance an existing load, the switch logs out all sessions (FLOGIs and FDISCs) in the fabric. As the sessions log in again, the switch assigns them to NP_Ports in a balanced manner, with all FDISCs assigned to the same link as the parent FLOGI. A new link coming up or a rebalance disrupts all of the existing sessions.

The ENode-based load-balancing algorithm uses the sum of the FLOGI and FDISC sessions to determine the session load on each link for both initial load balancing and load rebalancing.

FLOGI-Based Load Balancing

FLOGI-based load balancing is similar to ENode-based load balancing in most ways:

- It can result in a less balanced load across the NP_Port links because the VN_Port FDISC sessions are assigned to the same link as the parent ENode FLOGI session, regardless of how many FDISC sessions are associated with the ENode.
- When an ENode logs in with a FLOGI, the gateway places the session on the least-loaded link, and the FDISC logins associated with the FLOGI are placed on the same link, regardless of link load.
- Provides control and predictability because each ENode and its associated VN_Port (FDISC) sessions are assigned to the same link, so if the link an ENode is on goes down, all of its associated sessions also go down.
- If one ENode has a large number of sessions and the other ENodes do not, the link that carries the ENode with the large number of sessions might have a much larger load than the other NP_Port links in the gateway proxy fabric.

FLOGI-based load balancing differs from ENode-based load balancing in two important ways:

1. The switch uses the sum of the FLOGI sessions on a link to determine the link load. The switch does not use FDISC sessions when calculating the number of sessions on a link. (ENode-based load balancing uses the sum of the FLOGI and FDISC sessions to calculate the number of sessions on a link.)
2. When a new link comes up or when you rebalance an existing load, the switch logs out enough FLOGI (and FDISC) sessions so that when the FLOGI sessions log in again, the load is balanced. The switch balances the load based only on the number of FLOGI sessions, not the sum of FLOGI and FDISC sessions. However, the FDISC sessions associated with a FLOGI follow the FLOGI to the new link if the FLOGI session is part of the rebalancing.

The FLOGI-based load-balancing algorithm uses only the FLOGI sessions to determine the session load on each link for both initial load balancing and load rebalancing.

Load-Balancing Algorithm Comparison

Table 368 on page 4845 compares the three load-balancing algorithms and summarizes their differences, advantages, and disadvantages.

Table 368: Load-Balancing Algorithm Comparison

Load-Balancing Algorithm	Session Assignment	Session Disruption on Rebalance	Session Count Method	Advantages	Disadvantages
Simple (default algorithm)	FDISC sessions can be placed on different links than the parent FLOGI session	Minimum number of selected sessions logged out (FDISC sessions can be logged out independent of the parent FLOGI session)	Sum of FLOGI and FDISC sessions	• Most equal session distribution across links • Minimum number of sessions logged out when rebalancing • Least disruptive algorithm	• Less session control and predictability

Table 368: Load-Balancing Algorithm Comparison *(continued)*

Load-Balancing Algorithm	Session Assignment	Session Disruption on Rebalance	Session Count Method	Advantages	Disadvantages
ENode-based	FDISC sessions are always placed on the same link as the parent FLOGI session	All sessions are logged out	Sum of FLOGI and FDISC sessions	• Better session control and predictability (on link down, all sessions associated with an ENode go down)	• Most disruptive algorithm; all sessions logged out on rebalance • Might result in less balanced link load because FDISCs are placed on the same link as parent FLOGI
FLOGI-based	FDISC sessions are always placed on the same link as the parent FLOGI session	Minimum number of selected sessions logged out (but FDISC sessions logged out when parent FLOGI session is logged out)	FLOGI sessions only (FDISC sessions not included in the session count)	• Better session control and predictability (on link down, all sessions associated with an ENode go down) • Minimum number of sessions logged out when rebalancing	• Might result in less balanced link load because FDISCs are placed on the same link as parent FLOGI

Load-Rebalancing Methods

The load-rebalancing method determines the way the system redistributes sessions to balance the load on the NP_Ports that belong to a local FC fabric on an FCoE-FC gateway.

You can rebalance the existing load on existing NP_Port links using either of two methods:

- Automated load rebalancing—When a load rebalancing trigger occurs, the switch automatically rebalances the link loads by redistributing the sessions across the active NP_Port links. There are three possible load rebalancing triggers:

  1. When you enable automated load rebalancing, the switch checks the load balance on the existing NP_Port links. If the links are already balanced, the switch does not rebalance the link load. If the links are not balanced, the switch rebalances the link loads using the configured load-balancing algorithm.

     Enabling automated load rebalancing causes sessions to be logged out in accordance with the configured load-balancing algorithm if the link load is unbalanced. If the link load is already balanced when you enable automated load rebalancing, the links are not rebalanced. (Disabling automated load rebalancing is not disruptive because the link load is already balanced.)

  2. When a new NP_Port link comes up on a local FCoE-FC gateway fabric, the switch rebalances the link load using the configured load-balancing algorithm if automated load balancing is enabled.

  3. When the port speed is changed (unless the port speed change does not change the actual port speed, for example, changing the port speed from auto to 8 Gbps).

Use automated load rebalancing if you want link loads to be rebalanced automatically when a load-balancing trigger occurs, instead of at times of your choosing. Keep in mind that load rebalancing is a disruptive event (sessions are logged out).

- On-demand load rebalancing—You choose when to rebalance the NP_Port links by explicitly requesting a load rebalance using an operational command. The system rebalances the link load only when you issue the rebalancing command.

  Use on-demand load rebalancing if you only want to rebalance the link load once or if you want to rebalance the link loads at controlled times instead of automatically.

  You can also request a load rebalancing *dry run*. A dry run simulates rebalancing and lists the sessions that might be affected if you choose to perform an actual load-rebalancing operation. The link loads are not rebalanced when you request a dry run.

NP_Port Interface FIP Session Limit Effect on Load Balancing

The maximum number of FIP login sessions configured for each NP_Port interface affects load balancing. When an interface reaches its maximum number of FIP login sessions, that interface is removed from the list of interfaces used for load balancing. The other interfaces in the gateway fabric continue to accept ENode login sessions until they reach their configured maximum session limit. Only interfaces that have not reached their maximum session limit are included in the load-balancing calculations.

NOTE: **If all NP_Port interfaces in a gateway fabric reach their FIP login session limits, the fabric sends subsequent multicast discovery advertisements (MDAs) with the availability bit set to 0 (zero) to prevent additional ENode login attempts. While the maximum number of sessions is running on the gateway fabric, ENodes cannot use that fabric to log in to the FC switch. When the number of sessions falls below the maximum, the gateway sets the availability bit in MDAs to 1 so that ENodes can log in to the fabric again.**

Load-Balancing Triggers and Timing

Several events trigger load balancing. Some of the events trigger load balancing only when automated load balancing is enabled. Other events trigger load rebalancing whether or not automated rebalancing is enabled.

This section describes the load-balancing triggers, what happens when the trigger action occurs, and how the switch determines if and when to balance the link load:

- Load-Balancing Triggers on page 4847
- Load-Balancing Timer on page 4848

Load-Balancing Triggers

Table 369 on page 4848 describes the four different events can trigger load balancing or load rebalancing. In every case, link load rebalancing uses the configured load-balancing algorithm to determine the placement of sessions on links.

Table 369: Load-Balancing Triggers and Actions

Trigger Event	Action
New link comes up	Triggers a load-rebalancing operation regardless of whether or not automated load rebalancing is enabled. (The new link has no sessions, so the sessions on other links must be redistributed to balance the load.) The link load is not rebalanced if there are no sessions on the existing links or if there are so few sessions on the existing links that they cannot be redistributed.
On-demand load rebalancing request issued from CLI	The switch checks the NP_Port link load. If the load is not balanced across the links, the switch rebalances the link load. If the load is already balanced, nothing happens. NOTE: Requesting a dry run displays sessions that might be disrupted if you rebalance the link load, but does not rebalance the link load.
Automated load balancing configured for the first time	The switch checks the NP_Port link load. If the load is not balanced across the links, the switch rebalances the link load. If the load is already balanced, nothing happens.
NP_Port speed change	If automated rebalancing is enabled, changing the port speed brings the port up and down (flaps the port) and causes the switch to rebalance the link loads. If the port speed change does not change the actual port speed (for example, changing the port speed from *auto* to 8 Gbps), the link loads are not rebalanced. If automated rebalancing is not enabled, port speed changes do not cause link load rebalancing.

NOTE: When an NP_Port link goes down, it does not trigger load rebalancing. The loads on the remaining active links are already balanced, and as the sessions logged out from the down link log in again, they are they assigned to links in a balanced manner determined by the configured load-balancing algorithm.

Load-Balancing Timer

When you trigger load balancing from the CLI, the load-balancing action occurs immediately after you execute the command. However, when a load-balancing trigger occurs that is not a CLI command, the switch does not balance the link loads immediately. Instead, the switch follows an intelligent timer process:

1. The switch checks the current load balance on the NP_Port links in the local gateway FC fabric. If the load is already balanced, the switch does nothing, and there is no session disruption.
2. If the check shows that the link load is not balanced, the switch starts a 10-second timer. If no other load-balancing triggers occur during the 10-second interval, the switch rebalances the load.

If another load-balancing trigger occurs during the 10-second interval, the timer resets to 10 seconds. The 10-second timer prevents the switch from performing multiple disruptive load-rebalancing actions in a short period of time.

NOTE: The switch processes new sessions that log in after the timer starts in the normal manner. The new sessions are considered in the load-balancing evaluation and operation.

3. At a maximum of 30 seconds after the first load-balancing trigger occurs, the switch checks the link load balance again. If the links are already balanced, the switch cancels the load-rebalancing operation. If the links are not balanced, the switch rebalances the link loads.

NOTE: If the trigger event that started the load-rebalancing timer is no longer valid when the timer elapses, the switch cancels the rebalancing operation. For example, if a new NP_Port link comes up and triggers the timer, then goes down before the timer expires, the original link up event is no longer valid, and the switch cancels the rebalancing operation (unless another valid rebalancing trigger occurs in that time frame).

When a link load rebalancing operation is in progress, the switch defers any load-rebalancing triggers that occur until the load-rebalancing operation is complete. The new rebalancing operation begins after the current rebalancing operation finishes if a check shows that rebalancing is required.

If you explicitly request load rebalancing from the CLI using the **request fibre-channel proxy load-rebalance** operational command, the switch rejects the command and displays an error message stating that rebalancing is already in progress.

Load Rebalancing Behavior When a Link Goes Down

If an NP_Port link goes down, the ENode and VN_Port sessions on that link are logged out. The ENodes and VN_Port sessions log in again and are assigned to NP_Port links based on the link load and the load-balancing algorithm. If a link goes down, the switch does not rebalance the remaining load on the remaining links to avoid disrupting the existing ENode and VN_Port sessions. (Also, it is not necessary to rebalance the links in that manner because after a link goes down, the sessions on the remaining links are already balanced. As the logged out sessions log back in, the switch places them on the remaining active links in a balanced manner, according to the configured load-balancing algorithm.)

NOTE: When you use the simple load-balancing algorithm, an ENode and its associated VN_Port sessions might be on different links. In that case, if the NP_Port with the ENode goes down, only the VN_Ports on the same link are logged out. VN_Ports on other links remain up and running.

Interface Load Calculation Algorithm

A weighted round-robin (WRR) algorithm determines the interface load based on:

- The current number of sessions on the interface

NOTE: The configured load-balancing algorithm determines how the switch counts the number of sessions. For simple and ENode-based load balancing, the number of sessions is the sum of the FLOGI and FDISC sessions on each link. For FLOGI-based load balancing, the number of sessions is the sum of the FLOGI sessions on each link.

- The interface weight, which is the speed of the Fibre Channel link (2 Gbps, 4 Gbps, or 8 Gbps)

The interface load algorithm is:

(number-of-sessions * max-weight) / weight

where *max-weight* is an internal constant.

If the load on the FC interfaces is equal, the session is assigned to the interface with the highest link speed (the greatest weight).

For example, if the three FC interfaces have the characteristics shown in Table 370 on page 4850, the loads of the interfaces are not equal:

Table 370: FC Interface Session-Based Load-Balancing Characteristics for Unequal Loads

Interface	Number of Sessions	Weight (Speed)
fc-0/0/0	4	4 Gbps
fc-0/0/1	1	2 Gbps
fc-0/0/2	8	8 Gbps

In this example, interfaces fc-0/0/0 and fc-0/0/2 have a greater load than fc-0/0/1. For simple load balancing, the gateway assigns the next new FLOGI or FDISC to fc-0/0/1 because it is the least-loaded interface. For both ENode-based and FLOGI-based load balancing, the gateway assigns the next new FLOGI to fc-0/0/1 because it is the least-loaded interface. Then all VN_Port FDISCs from that ENode follow the ENode FLOGI and are also assigned to fc-0/0/1 regardless of the link load.

For another example, if the three FC interfaces have the characteristics shown in Table 371 on page 4851, the loads of the interfaces are equal:

Table 371: FC Interface Session-Based Load-Balancing Characteristics for Equal Loads

Interface	Number of Sessions	Weight (Speed)
fc-0/0/0	4	4 Gbps
fc-0/0/1	2	2 Gbps
fc-0/0/2	8	8 Gbps

In this case, all interfaces have the same relative load. For simple load balancing, the gateway assigns the next new FLOGI or FDISC to fc-0/0/2 because although the loads of the three interfaces are equal, fc-0/0/2 has the greatest weight. For both ENode-based and FLOGI-based load balancing, the gateway assigns the next new FLOGI to fc-0/0/2, and all VN_Port FDISCs from that ENode follow the ENode FLOGI and are also assigned to fc-0/0/2 regardless of the link load.

After the gateway establishes a session between an ENode or a VN_Port and an FC switch on an NP_Port, the session remains on that NP_Port until the ENode or VN_Port performs a LOGO.

If the physical FC interface link goes down, the FLOGI and FDISC sessions on the down link are logged out. The ENodes and VN_Ports log in again to start new sessions on other NP_Ports in the local gateway FC fabric in accordance with the configured load-balancing algorithm (assuming there is more than one NP_Port connected to the FC fabric).

Load-Balancing Scenarios

The configured load-balancing algorithm, the sequence in which ENodes log in to the FC network, the current session count (number of sessions per interface) and the interface speed determine the way the session load is balanced across the native FC interfaces (NP_Ports) in a gateway FC fabric. Whether you are balancing the link load for the first time or rebalancing an existing link load, the way the load is distributed across the active links is the same.

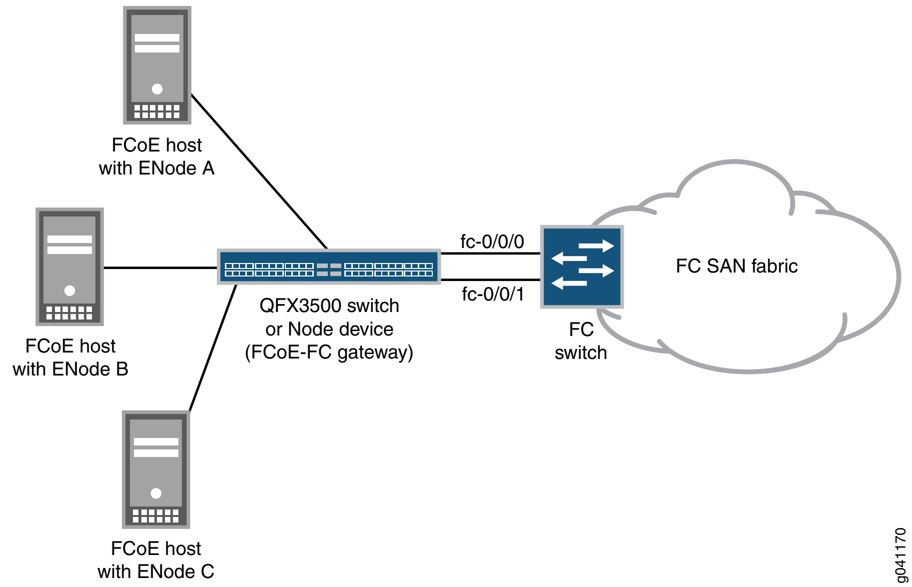
NOTE: **The way the switch counts the number of sessions on a port depends on the load-balancing algorithm. For simple and ENode-based load balancing, the sum of the FLOGI and FDISC sessions equals the session count. For FLOGI-based load balancing, only the FLOGI sessions are counted in the total session count.**

The following scenarios demonstrate how sessions are assigned to links for each load-balancing algorithm:

- Simple Load-Balancing Algorithm Scenario on page 4852
- ENode-Based Load-Balancing Algorithm Scenarios on page 4853
- FLOGI-Based Load-Balancing Algorithm Scenarios on page 4854

All of the scenarios use the topology shown in Figure 175 on page 4852.

Figure 175: Sample Load-Balancing Topology



Simple Load-Balancing Algorithm Scenario

Simple load balancing results in the most equal load distribution among the NP_Ports connected to an FC SAN fabric because VN_Port FDISC sessions do not need to "follow" the parent ENode FLOGI session on the same link between the gateway and the FC fabric. When a new FLOGI or FDISC session is initiated, it is assigned to the least-loaded link.

The simple load-balancing algorithm example uses the topology shown in Figure 175 on page 4852 and has the following characteristics:

- QFX Series configured as an FCoE-FC gateway
- Two gateway NP_Ports, **fc-0/0/0** and **fc-0/0/1**, connected to an FC SAN fabric switch at a speed of 8 Gbps
- Three ENodes, ENode_A, ENode_B, and ENode_C connected to the gateway
- NP_Ports **fc-0/0/0** and **fc-0/0/1**, and ENode_A, ENode_B, and ENode_C, belong to the same local FC fabric on the gateway

When the NP_Ports initialize, they send FLOGI messages to the FC switch and log in to the FC SAN fabric. The gateway then advertises the fabric to the ENodes on the Ethernet side of the network. At this point, the load on both of the NP_Ports is equal. Now the ENodes and VN_Ports start to log in to the fabric:

1. ENode_A sends a FLOGI to log in to the fabric. Because the loads on the two NP_Ports are equal, the session for ENode_A is randomly placed on one of the links. In this example, the ENode_A FLOGI session is placed on port **fc-0/0/0**.
2. Enode_B logs in. Because the load is less on port **fc-0/0/1**, the Enode_B FLOGI session is placed on port **fc-0/0/1**.

3. ENode_C logs in. Because the link loads are equal, the ENode_C login session is randomly placed on one of the links. In this example, the ENode_C login session is placed on port **fc-0/0/0**.
4. A VN_Port on ENode_A sends an FDISC to log in to the fabric. Because port **fc-0/0/1** currently is the least-loaded link, the VN_Port session is placed on port **fc-0/0/1**, even though its parent ENode session is on port **fc-0/0/0**.
5. As each new VN_Port session comes up, it is placed on the least-loaded link, regardless of the link on which its parent ENode session is placed.

ENode-Based Load-Balancing Algorithm Scenarios

ENode-based load balancing ensures that VN_Port FDISC sessions are placed on the same link as their parent ENode FLOGI sessions, regardless of the link load. ENode-based load balancing can result in a less-balanced load among the NP_Port links, but it provides the control and predictability of keeping ENodes and their VN_Port sessions on the same link.

The examples in this section use the topology shown in Figure 175 on page 4852.

- QFX Series configured as an FCoE-FC gateway
- Two gateway NP_Ports, **fc-0/0/0** and **fc-0/0/1**, connected to an FC SAN fabric switch at a speed of 8 Gbps
- Three ENodes connected to the gateway:
  - ENode_A, which has 2 VN_Port FDISC sessions
  - ENode_B, which has 20 VN_Port FDISC sessions
  - ENode_C, which has 100 VN_Port FDISC sessions
- NP_Ports **fc-0/0/0** and **fc-0/0/1**, and ENode_A, ENode_B, and ENode_C, belong to the same local FC fabric on the gateway

When the NP_Ports initialize, they send FLOGI messages to the FC switch and log in to the FC SAN fabric. The gateway then advertises the fabric to the ENodes on the Ethernet side of the network. At this point, the load on both of the NP_Ports is equal. Now the ENodes and VN_Ports start to log in to the fabric. As the following two scenarios show, how these sessions are placed on the links depends on the sequence in which they log in to the fabric.

Scenario 1:

1. ENode_A sends a FLOGI to log in to the fabric. Because the loads on the two NP_Ports are equal, the session for ENode_A is randomly placed on one of the links. In this example, the ENode_A FLOGI session is placed on port **fc-0/0/0**.
2. ENode_B logs in. Because the load is less on port **fc-0/0/1**, the ENode_B FLOGI session is placed on port **fc-0/0/1**.
3. The two VN_Ports on ENode_A log in to the fabric. Their sessions are placed on port **fc-0/0/0**, following ENode_A on the link. Now port **fc-0/0/0** has a greater load (one FLOGI session plus two FDISC sessions) than port **fc-0/0/1** (one FLOGI session).

4. The 20 VN_Ports on ENode_B log in to the fabric. Their sessions are placed on port **fc-0/0/1**, following ENode_B on the link. Now port **fc-0/0/0** has a lesser load (one FLOGI, two FDISC) than port **fc-0/0/1**.
5. ENode_C logs in. Because the load is less on port **fc-0/0/0**, the ENode_C FLOGI session is placed on port **fc-0/0/0**.
6. The 100 VN_Ports on ENode_C log in to the fabric. Their sessions follow the ENode_C session onto port **fc-0/0/0**.
7. If more VN_Ports come up, their FDISC sessions are placed on the same link as the corresponding parent ENode session.

Scenario 2:

1. ENode_A sends a FLOGI to log in to the fabric. Because the loads on the two NP_Ports are equal, the session for ENode_A is randomly placed on one of the links. In this example, the ENode_A FLOGI session is placed on port **fc-0/0/0**.
2. ENode_B logs in. Because the load is less on port **fc-0/0/1**, the ENode_B FLOGI session is placed on port **fc-0/0/1**.
3. The two VN_Ports on ENode_A log in to the fabric. Their sessions are placed on port **fc-0/0/0**, following ENode_A on the link. Now port **fc-0/0/0** has a greater load (one FLOGI session plus two FDISC sessions) than port **fc-0/0/1** (one FLOGI session).
4. In this step, the login sequence in Scenario 2 differs from the login sequence in Scenario 1, resulting in a different placement of sessions on the links, and therefore a different load on the links. ENode_C logs in before the ENode_B VN_Ports log in, which changes the session count on the links compared to the first scenario. Because the load in this scenario is less on port **fc-0/0/1**, the ENode_C FLOGI session is placed on port **fc-0/0/1** (instead of port **fc-0/0/0** as in the first scenario).
5. The 20 VN_Ports on ENode_B log in to the fabric. Their sessions are placed on port **fc-0/0/1**, following ENode_B on the link. Now port **fc-0/0/0** carries one FLOGI and two FDISC sessions, and port **fc-0/0/1** carries two FLOGI and 20 FDISC sessions.
6. The 100 VN_Ports on ENode_C log in to the fabric. Their sessions follow the ENode_C session onto port **fc-0/0/1**. Now port **fc-0/0/1** carries 2 FLOGI and 120 FDISC sessions, whereas port **fc-0/0/0** carries one FLOGI and two FDISC sessions.
7. If more VN_Ports come up, their FDISC sessions are placed on the same link as the corresponding parent ENode session.

Because of the sequence of ENode logins in Scenario 2, port **fc-0/0/1** carries a greater load than port **fc-0/0/0**. If the simple load-balancing algorithm had been used, the FLOGI and FDISC sessions would be allocated to the two links evenly. However, because the FDISC sessions are placed on the same link as their parent FLOGI sessions, this example demonstrates how using the ENode-based load-balancing algorithm can lead to scenarios in which the link loads are not equal.

FLOGI-Based Load-Balancing Algorithm Scenarios

FLOGI-based load balancing is similar in many ways to ENode-based load balancing. An important difference that affects how the switch places sessions on links is that for

FLOGI-based load balancing, only the FLOGI sessions are counted when the link load is calculated. FDISC sessions are not counted to determine the link load. Because ENode-based load balancing uses the sum of the FLOGI and FDISC sessions to determine the link load, an interface with exactly the same combination of FLOGI and FDISC sessions can have a different session count depending on the algorithm used. A different session count can change the interface to which the switch assigns the next session.

As with ENode-based load balancing, FLOGI-based load balancing ensures that VN_Port FDISC sessions are placed on the same link as their parent ENode FLOGI sessions, regardless of the link load. FLOGI-based load balancing can result in a less-balanced load among the NP_Port links, but it provides the control and predictability of keeping ENodes and their VN_Port sessions on the same link.

The examples in this section use the topology shown in Figure 175 on page 4852.

- QFX Series configured as an FCoE-FC gateway
- Two gateway NP_Ports, **fc-0/0/0** and **fc-0/0/1**, connected to an FC SAN fabric switch at a speed of 8 Gbps
- Three ENodes connected to the gateway:
  - ENode_A, which has 2 VN_Port FDISC sessions
  - ENode_B, which has 20 VN_Port FDISC sessions
  - ENode_C, which has 100 VN_Port FDISC sessions
- NP_Ports **fc-0/0/0** and **fc-0/0/1**, and ENode_A, ENode_B, and ENode_C, belong to the same local FC fabric on the gateway

When the NP_Ports initialize, they send FLOGI messages to the FC switch and log in to the FC SAN fabric. The gateway then advertises the fabric to the ENodes on the Ethernet side of the network. At this point, the load on both of the NP_Ports is equal. Now the ENodes and VN_Ports start to log in to the fabric.

Because FLOGI-based load balancing does not count FDISC sessions when calculating the link load, how the sessions are placed on the link depends only on the number of FLOGI sessions per interface, not on the number of FLOGI sessions plus FDISC sessions. This means that an ENode with a FLOGI session and many FDISC sessions is counted as having the same load as an ENode with a FLOGI session and no FDISC sessions.

Scenario 1:

1. ENode_A sends a FLOGI to log in to the fabric. Because the loads on the two NP_Ports are equal, the session for ENode_A is randomly placed on one of the links. In this example, the ENode_A FLOGI session is placed on port **fc-0/0/0**.
2. ENode_B logs in. Because the load is less on port **fc-0/0/1**, the ENode_B FLOGI session is placed on port **fc-0/0/1**.
3. The two VN_Ports on ENode_A log in to the fabric. Their sessions are placed on port **fc-0/0/0**, following ENode_A on the link. However, unlike simple load balancing or ENode-based load balancing, the session count of the two ports is still equal (one session each) because the FDISC sessions are not used in the session count.

4. The 20 VN_Ports on ENode_B log in to the fabric. Their sessions are placed on port **fc-0/0/1**, following ENode_B on the link. Again, unlike simple load balancing or ENode-based load balancing, the session count of the two ports is still equal (one session each) because the FDISC sessions are not used in the session count.
5. ENode_C logs in. Because the link loads are counted as equal, the ENode_C login session is randomly placed on one of the links. In this example, the ENode_C login session is placed on port **fc-0/0/0**.
6. The 100 VN_Ports on ENode_C log in to the fabric. Their sessions follow the ENode_C session onto port **fc-0/0/0**.
7. If more VN_Ports come up, their FDISC sessions are placed on the same link as the corresponding parent ENode session.

If a fourth ENode, ENode_D, sends a FLOGI to log in to the fabric, it is placed on port **fc-0/0/1** because port **fc-0/0/0** has a session count of two (two FLOGIs from ENode_A and ENode_C, FDISCs not counted) and port **fc-0/0/1** has a session count of one (one FLOGI from ENode_B, FDISCs not counted), so port **fc-0/0/1** is the least-loaded port.

With FLOGI-based load balancing, it is possible for ENodes with many FDISC sessions to be placed on the same link, whereas ENodes with few FDISC sessions are placed on different links because only FLOGIs are used in the session count.

Load Balancing on the FCoE Interfaces (Ethernet Links)

You can achieve load balancing on the 10-Gigabit Ethernet interfaces that belong to an FCoE VLAN by configuring them in one or more link aggregation groups (LAGs). In addition to load balancing, LAGs offer the advantages of protecting against port failover, increasing available link bandwidth, and preventing spanning-tree algorithms from blocking physical links and wasting bandwidth.

Understanding OxID Hash Control for FCoE Traffic Load Balancing

The originator exchange identifier (OxID) field is one of several fields that the switch can use in its hash function computation for FCoE traffic load balancing over multiple outgoing links in an Ethernet link aggregation group (LAG). The originator of an exchange between a pair of Fibre Channel (FC) endpoints (such as an FCoE host and an FC storage device) uses the OxID field as an identifier for that exchange. The originator also uses the OxID field to track the progress of the series of sequences that comprise the exchange.

When FCoE traffic traverses a LAG, it can take multiple different links between the source and destination endpoints. The idea is to distribute the FCoE traffic across the LAG links, thus balancing the link load. The switch creates a hash value from some of the packet header fields, and uses the hash value to assign each packet to one of the LAG links. The switch always uses five packet header fields to compute the hash value:

- Source ID (SID)
- Destination ID (DID)
- Fabric ID (FID)
- Source Port ID (SPID)
- Source Module ID (SMID)

In addition, the OxID field is included by default in the FCoE load-balancing hash computation. However, if you do not want to use the OxID field in the FCoE load-balancing hash computation, you can remove it from the computation by using the **set forwarding-options hash-key family fcoe oxid disable** command.

Including the OxID field in the load-balancing hash computation allows different exchanges between a pair of Fibre Channel (FC) endpoints (such as an FCoE host and an FC storage device) to take different paths across the network, thus improving the aggregate network throughput.

However, if the paths between different sets of FC endpoints have common links, congestion on one set of FC endpoints can affect the other set of endpoints. Such congestion can happen if the FCoE traffic on the two sets of endpoints uses the same priority (IEEE 802.1p code point). It is common for networks to use priority 3 (IEEE 802.1p code point 011) for FCoE traffic. However, on the QFX3500 switch, you can assign different IEEE priorities to different lossless FCoE flows as described in “Understanding CoS IEEE 802.1p Priorities for Lossless Traffic Flows” on page 5427 to further separate the traffic flows.

Understanding VN_Port to VF_Port FIP Snooping on an FCoE Transit Switch

Fibre Channel over Ethernet (FCoE) Initialization Protocol (FIP) snooping is a security mechanism that is designed to prevent unauthorized access and data transmission to a Fibre Channel (FC) network. It works by filtering traffic to permit only servers that have logged in to an FC network to access that network.

You explicitly enable VN_Port to VF_Port (VN2VF_Port) FIP snooping (FC-BB-5) on FCoE VLANs when the QFX Series is an FCoE transit switch at the access edge that connects FCoE devices on the Ethernet network to FC switches or gateways at the FC storage area network (SAN) edge. The transit switch applies FIP snooping filters at the ports associated with the FCoE VLANs on which you enable VN2VF_Port FIP snooping. An FCoE transit switch is a data center bridging (DCB) switch with FIP snooping capability.

An FCoE device that has a converged network adapter (CNA) uses the FIP process to log in to the FC network as an FCoE Node (ENode). The login process establishes a dedicated virtual link between a virtual N_Port (VN_Port) on the ENode and a virtual F_Port (VF_Port) on the FC switch. This dedicated virtual link emulates a point-to-point connection. The emulated connection is called a virtual link.

Virtual links pass transparently through the switch. The ENode VN_Port and the FC switch VF_Port do not detect the transit switch, and virtual links appear to be direct point-to-point links.

The QFX Series applies VN2VF_Port FIP snooping firewall filters at the directly attached edge ports associated with the FCoE VLANs on which you enable VN2VF_Port FIP snooping. FIP snooping provides security for virtual links by creating firewall filters based on information gathered (snooped) about FC devices during FIP transactions.

The QFX Series also supports VN_Port to VN_Port (VN2VN_Port) FIP snooping (FC-BB-6) to allow FCoE initiators and targets to communicate directly through the switch without going through an FCoE forwarder (FCF) or an FC switch, as described in "Understanding VN_Port to VN_Port FIP Snooping on an FCoE Transit Switch" on page 4865.

NOTE: An FCoE VLAN can support either VN2VF_Port FIP snooping (FC-BB-5) or VN2VN_Port FIP snooping (FC-BB-6), but not both. The same QFX Series switch can have multiple FCoE VLANs configured, some for VN2VF_Port FIP snooping traffic and others for VN2VN_Port FIP snooping traffic. On FCoE VLANs that are configured as VN2VN_Port snooping VLANs, VN2VF_Port FIP snooping traffic is dropped.

When you enable VN2VF_Port FIP snooping, the system snoops VN_Port to VF_Port packets and enforces security only on VN2VF_Port virtual links. When you enable VN2VN_Port FIP snooping, the system snoops VN_Port to VN_Port packets and enforces security only on VN2VN_Port virtual links.

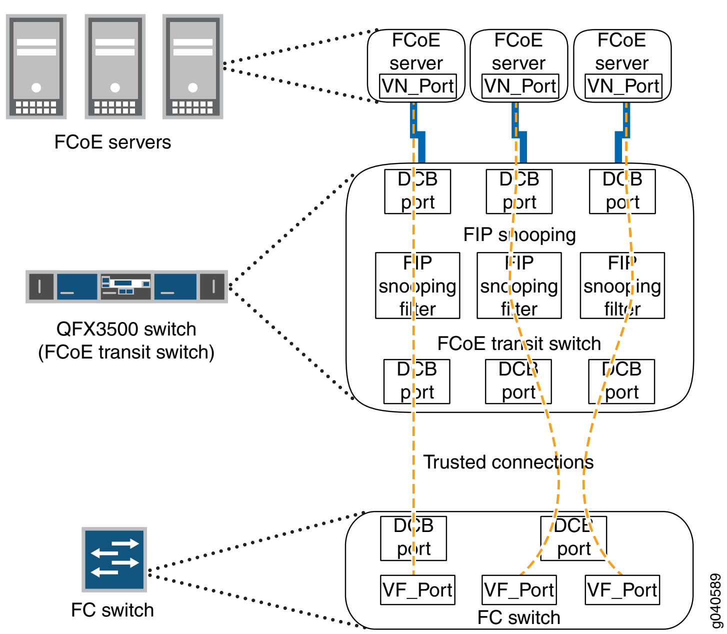
This topic describes:

FC Network Security

In traditional FC networks, the FC switch is usually a trusted entity, and server ENodes connect directly to its VF_Ports. After an ENode gains access to the network through the fabric login (FLOGI) process, the FC switch enforces zoning configurations, ensures that the ENode uses valid addresses, monitors the connection, and performs other security functions to prevent unauthorized access.

However, FCoE exposes FC frames to Ethernet networks, which do not have the same level of security as native FC networks. VN2VF_Port FIP snooping firewall filters emulate the native FC network security functions by preventing unauthorized access to the FC switch through the transit switch and by ensuring the security of the virtual link between each ENode and the FC switch, as shown in Figure 176 on page 4859. VN2VF_Port FIP snooping also prevents man-in-the-middle attacks.

Figure 176: FCoE Transit Switch Performs VN2VF_Port FIP Snooping



The transit switch performs VN2VF_Port FIP snooping at the ports connected to the FCoE devices. At the SAN edge, the FC switch must be able to convert the FCoE traffic to native FC traffic.

VN2VF_Port FIP Snooping Functions

When VN2VF_Port FIP snooping is enabled, the QFX3500 transit switch sets and applies filters to block all FCoE traffic by default. The transit switch monitors FIP logins, solicitations, and advertisements that pass through it and gathers information about the ENode address and the address of the port on the FC switch. The transit switch uses the information to construct firewall filters that permit access only to logged-in ENodes. All other traffic on the VLAN is denied.

For example, when an ENode on an FCoE VLAN performs a successful login to an FC switch port, the transit switch snoops the FIP information and constructs a firewall filter that provides access for the ENode to that port on the FC switch.

The firewall filters enable FCoE frames to pass through the transit switch only on a virtual link established between an FCoE device ENode VN_Port and the FC switch VF_Port to which it has logged in. The firewall filters ensure that ENodes can only connect to the FC switches they have successfully logged in to and that only valid FCoE traffic along valid paths is transmitted. VN2VF_Port FIP snooping maintains the filters by tracking FCoE sessions (ENode to FCF sessions).

FIP Snooping Firewall Filters

The effect of the firewall filters is to protect the FCoE ports. VN2VF_Port FIP snooping performs the following actions and checks to ensure that FCoE traffic is valid:

- Denies ENodes that use the FC switch media access control (MAC) address as the source address.
- Enables ENodes to transmit FIP and FCoE frames to the FC switch address.
- Ensures that the FCoE source address the FC switch assigns or accepts is only used for FCoE traffic.
- Ensures that FCoE frames are only addressed to the accepting FC switch.

Session Scalability

The system supports up to 2500 total FIP snooping sessions on an interface, a gateway FC fabric, a QFX Series switch, a QFabric Node device, or a QFabric Node group. For example, you can:

- Place all 2500 sessions on one FCoE interface.
- Split the 2500 sessions among multiple FCoE interfaces on one FCoE VLAN.
- Split the 2500 sessions among multiple FCoE interfaces on multiple FCoE VLANs.
- Split the 2500 sessions among the FCoE interfaces on multiple gateway FC fabrics on a switch.
- Split the 2500 sessions among the FCoE interfaces on multiple gateway FC fabrics on multiple Node devices in a QFabric Node group.

Regardless of how you allocate the sessions among interfaces and local FC fabrics on a QFX Series switch or on a QFabric system Node device or Node group, the combined FIP session limit is a maximum of 2500 sessions.

NOTE: **The total number of sessions the system can support is the combined number of VN2VF_Port sessions and VN2VN_Port sessions. If VN2VN_Port sessions are active, the total number of available VN2VF_Port sessions is reduced.**

VN2VF_Port FIP Snooping Implementation

You enable VN2VF_Port FIP snooping on a per-VLAN basis on VLANs that carry FCoE traffic. The switch snoops FIP frames at the ports associated with FCoE VLANs enabled for VN2VF_Port FIP snooping. The switch then installs the resulting firewall filters on the ports to ensure that all VN2VF_Port FIP snooping occurs on the switch network edge.

VN2VF_Port FIP snooping FCoE VLANs must meet the following criteria:

- An FCoE VLAN should be dedicated to FCoE traffic only.
- An FCoE VLAN cannot support both VN2VF_Port FIP snooping and VN2VN_Port FIP snooping simultaneously. You must configure separate FCoE VLANs for VN2VF_Port FIP snooping traffic and for VN2VN_Port FIP snooping traffic.

  NOTE: **Changing an FCoE VLAN from VN2VF_Port FIP snooping mode to VN2VN_Port snooping mode terminates the existing virtual links on the VLAN. The transit switch removes the existing FIP snooping filters, creates the new FIP snooping filters, and applies them to the FIP snooping ports. If you downgrade the software to Junos OS Release 12.1 or earlier, VLANs configured for VN2VN_Port FIP snooping revert to VN2VF_Port FIP snooping VLANs.**

- For QFX3500 switches, QFX3600 switches, and QFabric system Node devices, configure all access ports that belong to an FCoE VLAN (ports connected to a converged network adapter [CNA] in an FCoE device) in **tagged-access** port mode. Access ports associated with an FCoE VLAN should not be configured as access ports or trunk ports on these platforms, although trunk port configuration is supported.

  However, on QFX5100 switches that run the Enhanced Layer 2 Software (ELS) CLI, configure access ports that belong to an FCoE VLAN in **trunk** interface mode.
- All ports connected to an FC switch (or FCoE forwarder) must be configured in **trunk** port mode. Ports connected to an FC switch must be configured as trusted ports.
- FIP traffic uses the native VLAN (FIP VLAN discovery and notification frames are exchanged as untagged packets).
- All FCoE VLAN traffic must be tagged and cannot belong to the native VLAN.
- FCoE VLAN traffic cannot be untagged or priority-tagged.

When you enable VN2VF_Port FIP snooping, the switch inspects FIP frames.

The VN2VF_Port FIP snooping implementation includes these considerations:

- ENode-Facing Interfaces on page 4862
- Network-Facing Interfaces on page 4863
- FC-MAP on page 4863

ENode-Facing Interfaces

When the interfaces that belong to an FCoE VLAN connect directly to FCoE devices (there is no other transit switch between the FCoE devices and the QFX Series switch), we recommend that you enable VN2VF_Port FIP snooping on all FCoE VLANs that connect VN_Ports to VF_Ports. Enabling FIP snooping ensures secure connections between server ENodes and FC switches. (Enabling VN2VN_Port FIP snooping ensures secure connections on FCoE VLANs that connect VN_Ports to other VN_Ports). FIP snooping should always be enabled at the access edge.

Systems that run Enhanced Layer 2 Software (ELS) such as the QFX5100 switch support a slightly different configuration on ENode-facing interfaces than systems that do not run ELS. This section describes:

- Non-ELS Port Mode for FCoE Interfaces on page 4862
- ELS Interface Mode for FCoE Interfaces on page 4862
- Trusted and Untrusted FCoE Interfaces on page 4863

Non-ELS Port Mode for FCoE Interfaces

The interfaces that belong to FCoE VLANs (interfaces that connect to CNAs in FCoE devices) on systems that do not support ELS should be configured in **tagged-access** port mode. After you enable VN2VF_Port FIP snooping on an FCoE VLAN, the transit switch denies FCoE traffic from any ENode on that VLAN until the ENode performs a valid fabric login with an FC switch.

The **tagged-access** port mode was not available in Junos OS Release 11.3 and prior releases. In Release 11.3 and earlier, **trunk** port mode was used for Ethernet interfaces that connected to FCoE access devices. Because **tagged-access** mode is now available, using **trunk** mode for interfaces connected to FCoE CNAs is not recommended.

If an existing configuration uses **trunk** mode for ports connected to FCoE CNAs, you can change the port mode to **tagged-access** without disrupting traffic. Although we recommend changing the port mode of these ports from **trunk** to **tagged-access** as a best practice, it is not mandatory. New configurations should use **tagged-access** mode for interfaces that connect to FCoE devices.

ELS Interface Mode for FCoE Interfaces

The interfaces that belong to FCoE VLANs (interfaces that connect to CNAs in FCoE devices) on systems that support ELS should be configured in **trunk** interface mode. After you enable VN2VF_Port FIP snooping on an FCoE VLAN, the transit switch denies FCoE traffic from any ENode on that VLAN until the ENode performs a valid fabric login with an FC switch.

Trusted and Untrusted FCoE Interfaces

Do not configure ENode-facing interfaces as FCoE trusted interfaces when VN2VF_Port FIP snooping is enabled on those interfaces. If you enable VN2VF_Port FIP snooping on an FCoE VLAN and you configure ENode-facing interfaces that are members of the FIP snooping VLAN as **fcoe-trusted**, then FCoE devices might not be able to log in to the FC network.

Changing ports from untrusted to trusted removes any existing VN2VF_Port FIP snooping filters from the ports and terminates the existing sessions. Changing the fabric ports from trusted to untrusted forces all of the FCoE sessions on those ports to log out so that when the ENodes and VN_Ports log in again, the switch can build the appropriate VN2VF_Port FIP snooping filters.

Network-Facing Interfaces

When the switch acts an FCoE transit switch, you must configure any interface that is connected to a switch as an FCoE trusted interface in **trunk** port mode and as a 10-Gigabit Ethernet interface.

Switch-facing Ethernet interfaces have the following requirements and behaviors:

- You must explicitly configure switch-facing trunk ports on an FCoE transit switch as FCoE trusted interfaces.
- After you configure an FC switch-facing trunk port as a trusted interface, the FCoE transit switch always processes FC switch frames because they come from a source on a trusted interface.
- All ports in an FCoE VLAN must be configured as tagged access or trunk ports.

FC-MAP

When the switch acts as an FCoE transit switch and you enable VN2VF_Port FIP snooping on an FCoE VLAN, you can optionally specify a 24-bit FCoE mapped address prefix (FC-MAP) value. On a given VLAN, the transit switch learns only those FC switches that have a matching FC-MAP value. If the transit switch FCoE VLAN FC-MAP value does not match the FC switch FC-MAP value, the transit switch does not discover the FC switch on that VLAN, and the ENodes on that VLAN cannot access the FC switch. An FCoE VLAN can have one and only one FC-MAP value.

The FC-MAP value is a MAC address prefix unique to an FC switch in the FC SAN fabric that the FC switch uses to identify FCoE traffic for a given FC fabric (traffic on a particular FCoE VLAN). The FC switch combines the FC-MAP value with a unique 24-bit FCID value for the ENode VN_Port during the login process. This creates a 48-bit identifier that is unique to the fabric. The FC switch assigns this 48-bit value to the ENode VN_Port as its MAC address and unique identifier for the session. Each VN_Port session the ENode establishes with the FC switch receives a unique FCID from the FC switch, so an FCoE device can host multiple virtual links (one for each VN_Port) to an FC switch, each with a 48-bit MAC address that is unique to the fabric.

The VN2VF_Port FIP snooping filter compares the configured FC-MAP value with the FC-MAP value in the header of frames coming from the ENode VN_Port. If the values do not match, the transit switch denies access.

NOTE: Changing the FC-MAP value causes all logins to be dropped and forces ENodes to log in again.

NOTE: Do not configure static MAC addresses with the FC-MAP value as a prefix (the first 24 bits of the MAC address). If you configure a static MAC address that uses the FC-MAP value as a prefix, the system deletes the static MAC address automatically after you enable FIP snooping. The static MAC address configuration is not restored even if you disable FIP snooping later. (The system considers a static MAC address with the FC-MAP value as the prefix to be a misconfiguration.) Do not use a MAC address with the FC-MAP value as the prefix for any traffic other than the FIP snooping traffic when the QFX Series is acting as a transit switch.

T11 VN2VF_Port FIP Snooping Specification

For more details about VN2VF_Port FIP snooping, see http://www.t11.org/ftp/t11/pub/fc/bb-5/08-264v3.pdf for the Technical Committee T11 organization document *Increasing FCoE Robustness using FIP Snooping*.

Understanding VN_Port to VN_Port FIP Snooping on an FCoE Transit Switch

VN_Port to VN_Port (VN2VN_Port) Fibre Channel over Ethernet (FCoE) Initialization Protocol (FIP) snooping (FC-BB-6) on an FCoE transit switch is conceptually similar to VN_Port to VF_Port (VN2VF_Port) FIP snooping (FC-BB-5) on an FCoE transit switch. An FCoE transit switch is a data center bridging (DCB) switch with FIP snooping capability. VN2VN_Port FIP snooping provides security in the form of filters. The filters help prevent unauthorized access and data transmission on a bridge that connects ENodes on the Ethernet network.

The main difference between VN2VN_Port FIP snooping and VN2VF_Port FIP snooping is that you use VN2VN_Port FIP snooping when the FCoE devices reside on the Ethernet network, so there is no need to forward traffic between FCoE devices to the Fibre Channel (FC) network, and you use VN2VF_Port FIP snooping when FCoE devices on the Ethernet network need to access targets on the FC network, so FCoE traffic must be forwarded to the FC network. See "Understanding VN_Port to VF_Port FIP Snooping on an FCoE Transit Switch" on page 4858 for information about VN2VF_Port FIP snooping.

You enable VN2VN_Port FIP snooping on the FCoE VLAN that transports the VN2VN traffic. The transit switch applies VN2VN_Port FIP snooping filters at the ports associated with the FCoE VLANs on which you enable VN2VN FIP snooping.

A key benefit of VN2VN_Port FIP snooping is that it enables FCoE initiators and targets to communicate directly through the switch without going through an FCoE forwarder (FCF) or an FC switch. The transit switch does not differentiate between initiators and targets because the transit switch sees both VN_Ports as FIP virtual link end points. Direct VN2VN_Port communication requires secure access (FIP snooping filters) because ENodes are not trusted entities.

This topic describes:

VN2VN_Port FIP Snooping and FIP Snooping Virtual Links

FIP snooping under the T11 FC-BB-5 specification requires that an FC switch or an FCF be in the path between two VN_Ports when they communicate. Introduced in the T11 FC-BB-6 specification (see http://www.t11.org/ftp/t11/pub/fc/bb-6/10-019v3.pdf), VN2VN_Port FIP snooping allows the FCoE transit switch to connect two VN_Ports to each other directly, without going through an FC switch or an FCF, provided that the ENodes have logged in to the FC network.

In VN2VF_Port FIP snooping, when an ENode logs in to the FC network, the FCoE transit switch snoops the FIP communication between the ENode and the FC switch. In VN2VN_Port FIP snooping mode, the transit switch creates filters on the switch access ports to control VN_Port access to other VN_Ports on the Ethernet network. The VN2VN_Port FIP snooping filters allow the switch to establish a dedicated virtual link that emulates a point-to-point connection between two VN_Ports, through the switch.

Virtual links pass transparently through the transit switch. The VN_Ports do not detect the transit switch, and virtual links appear to be direct point-to-point links.

You explicitly enable VN2VN_Port FIP snooping on FCoE VLANs when the QFX Series switch or QFabric system is an FCoE transit switch connecting FCoE devices on the Ethernet network to each other and to FC switches or gateways at the FC storage area network (SAN) edge.

NOTE: An FCoE VLAN can support either VN2VF_Port FIP snooping or VN2VN_Port FIP snooping, but not both. Configure separate FCoE VLANs for VN2VF_Port FIP snooping traffic and for VN2VN_Port FIP snooping traffic. On FCoE VLANs that are configured as VN2VN_Port FIP snooping VLANs, VN_Port to VF_Port traffic is dropped.

When you enable FIP snooping, the system snoops VN2VF_Port packets and enforces security only on VN_Port to VF_Port virtual links. When you enable VN2VN_Port FIP snooping, the system snoops VN_Port to VN_Port FIP packets and enforces security only on VN_Port to VN_Port virtual links.

The transit switch applies VN2VN_Port FIP snooping filters at the ports associated with the FCoE VLANs on which you enable VN2VN_Port FIP snooping. VN2VN_Port FIP snooping provides security for virtual links by creating filters based on information gathered (snooped) about FCoE devices during FIP transactions.

VN2VN_Port Communication Modes

The transit switch supports two VN2VN_Port communication modes:

- Point-to-point mode
- Multipoint mode

In point-to-point mode, two ENodes are connected to the network and form a single VN_Port to VN_Port virtual link. This is analogous to the point-to-point FC link between an FC initiator and an FC target.

In multipoint mode, multiple ENodes are connected to the network and form multiple virtual links. Each virtual link is created between one pair of VN_Ports. This is analogous to loop mode in traditional FC networks.

The VN2VN_Port communication mode is not configured; it is determined by the number of ENodes connected to the network.

Network Security

In traditional FC networks, the FC switch is usually a trusted entity and the server ENodes are untrusted entities. The ENodes connect directly to the FC switch VF_Ports. After an ENode gains access to the network through the fabric login (FLOGI) process, the FC switch enforces zoning configurations, ensures that the ENode uses valid addresses, monitors the connection, and performs other security functions to prevent unauthorized access.

However, FCoE exposes FC frames to Ethernet networks, which do not have the same level of security as native FC networks. VN2VN_Port FIP snooping filters emulate the native FC network security functions by preventing unauthorized access and by ensuring the security of the virtual link between ENode VN_Ports. The transit switch performs VN2VN_Port FIP snooping at the ports connected to the FCoE VN_Port devices.

VN2VN_Port FIP Snooping Functions

When you enable VN2VN_Port FIP snooping, the transit switch sets and applies filters to block all FCoE traffic on the VLAN by default. The transit switch monitors FIP logins, solicitations, and advertisements that pass through it and gathers information about the ENode address. The transit switch uses the information to construct filters that permit access only to logged-in ENodes. All other traffic on the VLAN is denied.

The filters enable FCoE frames to pass through the transit switch only on a virtual link established between two VN_Ports. The filters ensure that ENodes can only connect to other ENodes if they have successfully logged in to each other, and that only valid FCoE traffic along valid paths is transmitted. VN2VN_Port FIP snooping maintains the filters by tracking VN_Port to VN_Port sessions.

Scalability

Because ENodes are untrusted and the system needs to apply filters to untrusted FIP snooping interfaces, the total number of combined VN2VN_Port FIP snooping sessions per switch is 376 sessions (ENode to ENode sessions) on untrusted interfaces. On interfaces that are configured as trusted interfaces, no FIP snooping filters are applied.

NOTE: **The total number of sessions the system can support is the combined number of VN2VF_Port sessions and VN2VN_Port sessions. If VN2VF_Port sessions are active, the total number of available VN2VN_Port sessions is reduced.**

VN2VN_Port FIP Snooping Implementation

You enable VN2VN_Port FIP snooping on a per-VLAN basis on VLANs that carry FCoE traffic. The switch snoops FIP frames at the ports associated with FCoE VLANs enabled for VN2VN_Port FIP snooping. The switch then installs the resulting filters on the ENode-facing ports to ensure that all FIP snooping occurs on the switch network edge.

VN2VN_Port FIP snooping FCoE VLANs must meet the following criteria:

- An FCoE VLAN should be dedicated to FCoE traffic only.
- An FCoE VLAN cannot support both VN2VF_Port FIP snooping (FC-BB-5) and VN2VN_Port FIP snooping (FC-BB-6) simultaneously. You must configure separate FCoE VLANs for FIP snooping traffic and for VN2VN_Port FIP snooping traffic.

NOTE: **Changing an FCoE VLAN from VN2VF_Port FIP snooping mode to VN2VN_Port FIP snooping mode terminates the existing virtual links on the VLAN. The transit switch removes the existing FIP snooping filters, creates the new FIP snooping filters, and applies them to the FIP snooping ports. If you downgrade the software to Junos OS Release 12.1 or earlier, VLANs configured for VN2VN_Port FIP snooping revert to VN2VF_Port FIP snooping VLANs.**

- For QFX3500 switches, QFX3600 switches, and QFabric system Node devices, as a best practice, you should configure all access ports that belong to an FCoE VLAN (ports connected to a converged network adapter [CNA] in an FCoE device) in **tagged-access** port mode. However, access and trunk port modes are also supported. For QFX5100 switches, configure access ports that belong to an FCoE VLAN in **trunk** interface mode.
- Access ports should be configured as untrusted ports.
- All ports connected to another transit switch must be configured in **trunk** port mode.
- FIP traffic uses the native VLAN.
- You can enable VN2VN_Port FIP snooping on a native VLAN.

ENode-Facing Interfaces

When the interfaces that belong to an FCoE VLAN connect directly to FCoE devices (there is no other transit switch between the FCoE devices and the QFX Series switch), we recommend that you either enable VN2VN_Port FIP snooping on all FCoE VLANs to ensure secure connections between VN_Ports, or enable VN2VF_Port FIP snooping on FCoE VLANs that connect ENodes to an FC switch. FIP snooping should always be enabled at the access edge.

Systems that run Enhanced Layer 2 Software (ELS) such as the QFX5100 switch support a slightly different configuration on ENode-facing interfaces than systems that do not run ELS. This section describes:

Non-ELS Port Mode for FCoE Interfaces

The interfaces that belong to FCoE VLANs (interfaces that connect to CNAs in FCoE devices) should be configured in **tagged-access** port mode, unless your CNA does not support tagged VN2VN traffic. After you enable VN2VN_Port FIP snooping on an FCoE

VLAN, the transit switch denies FCoE traffic from any ENode on that VLAN until the ENode performs a valid fabric login (FIP FLOGI) with another ENode.

The **tagged-access** port mode was not available in Junos OS Release 11.3 and prior releases. In Release 11.3 and earlier, **trunk** port mode was used for Ethernet interfaces that connected to FCoE access devices. Because **tagged-access** mode is now available, using **trunk** mode for interfaces connected to FCoE CNAs is not recommended.

If an existing configuration uses **trunk** mode for ports connected to FCoE CNAs, you can change the port mode to **tagged-access** without disrupting traffic. Although we recommend changing the port mode of these ports from **trunk** to **tagged-access** as a best practice, it is not mandatory. New configurations should use **tagged-access** mode for interfaces that connect to FCoE devices.

ELS Interface Mode for FCoE Interfaces

The interfaces that belong to FCoE VLANs (interfaces that connect to CNAs in FCoE devices) on systems that support ELS should be configured in **trunk** interface mode. After you enable VN2VF_Port FIP snooping on an FCoE VLAN, the transit switch denies FCoE traffic from any ENode on that VLAN until the ENode performs a valid fabric login with an FC switch.

Trusted and Untrusted FCoE Interfaces

Do not configure ENode-facing interfaces as FCoE trusted interfaces when VN2VF_Port FIP snooping is enabled on those interfaces. If you enable VN2VF_Port FIP snooping on an FCoE VLAN and you configure ENode-facing interfaces that are members of the FIP snooping VLAN as **fcoe-trusted**, then FCoE devices might not be able to log in to the FC network.

Changing ports from untrusted to trusted removes any existing VN2VF_Port FIP snooping filters from the ports and terminates the existing sessions. Changing the fabric ports from trusted to untrusted forces all of the FCoE sessions on those ports to log out so that when the ENodes and VN_Ports log in again, the switch can build the appropriate VN2VF_Port FIP snooping filters.

Network-Facing Interfaces (Connecting to Another Transit Switch)

Configure any interface that is connected to another transit switch (not to an ENode) as an FCoE trusted interface, in **trunk** port mode, and as a 10-Gigabit Ethernet interface.

Network-facing Ethernet interfaces have the following requirements and behaviors:

- You must explicitly configure network-facing trunk ports on an FCoE transit switch as FCoE trusted interfaces.
- After you configure a network-facing trunk port as a trusted interface, the FCoE transit switch always processes frames from the connected switch because they come from a source on a trusted interface.
- As a best practice, configure ports in an FCoE VLAN as tagged access ports, but access and trunk port modes are also supported to accommodate whatever types of VN2VN traffic your CNA supports.

Beacon Period (VN2VN_Port FIP Snooping Link Maintenance)

The transit switch needs to maintain the virtual links between VN_Ports, and needs to know when sessions begin and end, and when to install and remove the FIP snooping filters. FIP snooping uses a FIP keepalive advertisement to accomplish this task. VN2VN_Port FIP snooping does not exchange FIP keepalive timer information. Instead, you configure a *beacon period*, which performs the same function as a keepalive timer.

The beacon period is the time interval between messages which verify that the connection is still valid and that the device at the other end of the virtual link is still reachable. You set the beacon period value for each FCoE VLAN that you configure to do VN2VN_Port FIP snooping.

NOTE: **Explicitly set the beacon period when you configure VN2VN_Port FIP snooping. VN_Ports do not automatically send beacons.**

ENodes transmit periodic multicast N_Port_ID beacons to the ALL-VN2VN-ENode-MACs address. The transmission period varies by a random delay of between 0 ms and 100 ms to avoid synchronized bursts of multicast traffic on the network.

If the transit switch does not receive a beacon message from an ENode within 2.5 times the configured beacon period, the transit switch considers the virtual link to be down and terminates the virtual link to that ENode.

QFabric System Differences in VN2VN_Port FIP Snooping Traffic Handling

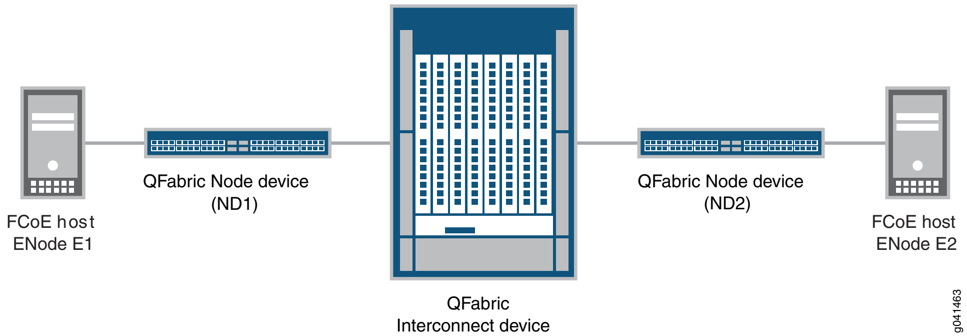
Configuring VN2VN_Port FIP snooping on a QFabric system is the same as configuring VN2VN_Port FIP snooping on the QFX Series. However, there are internal differences in the way a QFabric system handles VN2VN_Port FIP snooping traffic compared to the way a QFX Series switch handles VN2VN_Port FIP snooping traffic. The internal differences are transparent. Whether you configure VN2VN_Port FIP snooping on a QFabric system or on the QFX Series, the proper FIP snooping filters and forwarding information are installed on each device.

On the QFX Series, the VN2VN_Port FIP snooping traffic does not cross a fabric (Interconnect device). VN2VN_Port traffic enters and exits ports on a single switch, so the ingress port and the egress port have access to the same *local* forwarding and FIP snooping databases.

However, on a QFabric system, VN2VN_Port FIP snooping traffic might enter on the ingress port of one Node device, traverse the Interconnect device fabric, and exit on the egress port of a different Node device. In this case, the QFabric system must ensure that the FIP snooping database and forwarding information for the VN2VN_Port traffic is installed correctly on both of the Node devices so that traffic is correctly filtered and forwarded.

For example, Figure 177 on page 4871 shows that VN2VN_Port traffic from FCoE host ENode E1 enters the QFabric system at Node device ND1, traverses the Interconnect device fabric, and then exits from Node device ND2 before arriving at FCoE host ENode E2. Similarly, VN2VN_Port traffic from FCoE host ENode E2 enters the QFabric system at Node device ND2, traverses the Interconnect device fabric, and then exits from Node device ND1 before arriving at FCoE host ENode E1.

Figure 177: VN2VN_Port Traffic Across a QFabric Interconnect Device



When the QFabric system receives a FLOGI ACC from either ENode E1 or ENode E2, the QFabric system creates and installs the correct VN2VN_Port FIP snooping filters on both Node devices, and updates the forwarding tables accordingly.

In addition, the QFabric system must also ensure that the VN2VN_Port FIP snooping session statistics are correctly counted. Even though a session is running on each of the two Node devices, the QFabric system counts the complete VN2VN_Port connection as one session because the two Node devices belong to the same session. This ensures that VN2VN_Port sessions that traverse the Interconnect device fabric are counted as one unique session, not as two separate sessions.

Understanding FIP Snooping, FBF, and MVR Filter Scalability

The VLAN filter processor (VFP) ternary content addressable memory (TCAM) stores the VLAN filter configuration for three filter types:

- Fibre Channel over Ethernet (FCoE) Initialization Protocol (FIP) snooping—FIP snooping filters prevent an FCoE device from gaining unauthorized access to a Fibre Channel (FC) storage device or to another FCoE device. VN2VF_Port FIP snooping filters prevent an FCoE device from gaining unauthorized access to devices on an FC network. VN2VN_Port FIP snooping filters prevent an FCoE device from gaining unauthorized access to another FCoE device directly through the QFX Series or QFabric system, without traversing the FC network.

  The VFP TCAM stores the VN2VF_Port and VN2VN_Port FIP snooping filters that the switch automatically creates when you enable FIP snooping on a VLAN that carries FCoE traffic. See "Understanding VN_Port to VF_Port FIP Snooping on an FCoE Transit Switch" on page 4858 and "Understanding VN_Port to VN_Port FIP Snooping on an FCoE Transit Switch" on page 4865 for more information.

- Filter-based forwarding (FBF)—FBF enables you to use firewall filters to direct packets to virtual routing instances. The switch then forwards the matching packets based on the configuration of the routing instances. The VFP TCAM stores the terms you configure for FBF filters. See "Understanding Filter-Based Forwarding" on page 4412 for more information.

- Multicast VLAN registration (MVR)—MVR enables you to configure a multicast source VLAN (MVLAN) that is shared across a Layer 2 network. An MVLAN distributes IPTV multicast streams across different VLANs without having to create a separate multicast stream for each VLAN, and without compromising the security and separation of traffic in the different VLANs. The VFP TCAM stores the MVR rules you configure for MVLANs. See "Understanding Multicast VLAN Registration" on page 3974 for more information.

FIP snooping filters, FBF filters, and MVR rules share the VFP TCAM memory space. In most use cases, the VFP TCAM memory is sufficient to store filter terms and information for all three applications.

VFP TCAM Architecture and Allocation

When packets arrive at an ingress interface, the VFP TCAM is the first TCAM in the packet pipeline. The VFP TCAM stores a total of 1024 entries. The 1024 entries are partitioned into four equal *slices* of 256 entries.

The VFP TCAM allocates entries to three filter types (FIP snooping filters, FBF filter terms, and MVR rules) in 256-entry slices. The VFP TCAM dynamically allocates the minimum number of memory slices required to store the filters for a particular filter type, as needed.

The TCAM does not allocate partial slices to a filter type, and slices cannot be shared among filter types. At any given time, each slice contains entries for one and only one filter type.

For example, if you configure one MVR rule, the system allocates a whole slice to MVR rules, even if the MVR rule consumes only one TCAM entry. The remaining 256 entries in the slice allocated to MVR rules can store subsequently configured MVR rules, but not FIP snooping or FBF filters. Similarly, if FIP snooping filters consume 50 entries of a 256-entry slice, the remaining 206 entries in the FIP snooping slice are available only to store more FIP snooping filters, not to store FBF filter terms or MVR rules.

The VFP TCAM allocates slices to a filter type only if there is at least one configured filter or rule for that filter type. If no filters exist for a filter type, then the VFP TCAM does not allocate a slice to that filter type.

NOTE: **The VFP TCAM rejects partial filters. For example, if an FBF filter contains six terms, but there is only space in the TCAM for four of those terms, the whole filter is not committed.**

Each filter type can use from zero slices to all four slices of VFP TCAM space. However, if one filter type uses three slices, then only one slice remains, so only one other filter type can use the remaining slice. In that situation, if you configure filters for all three filter types, the last filter type that you configure receives no TCAM space for its filter entries. Filters that receive no TCAM entry space are not implemented.

VFP TCAM Entry Consumption

FIP snooping filters, FBF filters, and MVR rules consume VFP TCAM entry space in different ways:

- FIP Snooping Filter VFP TCAM Consumption on page 4873
- FBF Filter VFP TCAM Consumption on page 4874
- MVR Filter VFP TCAM Consumption on page 4875
- VFP TCAM Consumption Summary Table on page 4875

FIP Snooping Filter VFP TCAM Consumption

VN2VF_Port FIP snooping filters consume VFP TCAM entry space differently than VN2VN_Port FIP snooping filters:

- VN2VF_Port FIP Snooping Filter VFP TCAM Consumption on page 4874
- VN2VN_Port FIP Snooping Filter VFP TCAM Consumption on page 4874

NOTE: **One FCoE VLAN cannot support both VN2VF_Port traffic and VN2VN_Port traffic. Configure separate FCoE VLANs for VN2VF_Port traffic and for VN2VN_Port traffic.**

VN2VF_Port FIP Snooping Filter VFP TCAM Consumption

The switch uses an algorithm that allows one 256-entry slice of the VFP TCAM to store the maximum possible number of VN2VF_Port FIP snooping filters (2500 filters). VN2VF_Port FIP snooping filters never consume more than one slice of the VFP TCAM.

Regardless of whether there is one VN2VF_Port FIP snooping session or there are 2500 VN2VF_Port FIP snooping sessions, VN2VF_Port FIP snooping filters consume one slice of the VFP TCAM. (If there are no VN2VF_Port or VN2VN_Port FIP snooping sessions, the TCAM does not allocate a slice for FIP snooping filters.)

VN2VN_Port FIP Snooping Filter VFP TCAM Consumption

VN2VN_Port FIP snooping filters consume one VFP TCAM entry for each VN2VN_Port session. The maximum number of VN2VN_Port FIP snooping sessions is 376 sessions per switch. (If you configure an interface that carries VN2VN_Port FIP snooping traffic as a trusted interface, the switch does not apply filters on the trusted interface.)

Because the switch can have up to 376 VN2VN_Port sessions running simultaneously, with each session consuming one entry, VN2VN_Port FIP snooping filters consume VFP TCAM space as follows:

- 1–256 filters consume one slice
- 257–376 filters consume two slices

FBF Filter VFP TCAM Consumption

Each FBF filter term is double-wide, so each FBF filter term consumes two entries in the VFP TCAM. One 256-entry slice can contain up to 128 FBF filter terms. FBF filters consume VFP TCAM space as follows:

- 1–128 entries consume one slice
- 129–256 entries consume two slices
- 257–384 entries consume three slices
- 385–512 entries consume four slices

NOTE: In practice, FBF filters can consume only three slices of the VFP TCAM because FBF filters are also stored simultaneously in the ingress filter processor (IFP) TCAM, and the IFP TCAM can store only 384 FBF filter terms (768 entries, or 3 TCAM slices).

For example, if you configure FBF filters that contain 200 terms, then the FBF filters require 400 VFP TCAM entries and consume 2 slices.

FBF filter entries are simultaneously stored in the VFP TCAM and the IFP TCAM. The IFP TCAM can only contain up to 768 entries—256 fewer entries (1 slice) than the VFP TCAM. As with the VFP TCAM, FBF filters consume two IFP TCAM entries per filter term. In addition to FBF filter terms, the IFP TCAM stores filter entries for firewall filters.

CAUTION: There must be enough space in the VFP TCAM *and* the IFP TCAM for the FBF filter entries. If both TCAMs do not have enough space for the FBF filters, the switch rejects the portion of the configuration that it cannot store and sends a syslog message to notify you.

For example, if you configure FBF filters that have 400 terms, even though the VFP TCAM has enough space to store the resulting 800 entries, the switch rejects a portion of the configuration because the IFP TCAM can store a maximum of only 768 entries. If the IFP TCAM stores no other filter entries, the switch rejects 32 FBF filter entries.

In another example, if you configure firewall filters that have a total of 200 terms, which consume 200 entries in the IFP TCAM, and you then configure FBF filters that have a total of 300 terms, the switch rejects a portion of the configuration because the FBF filters require 600 entries. Combined with the 200 entries required for the firewall filters, the total number of 800 entries exceeds the maximum of 768 entries that the IFP TCAM can store. In this case, the switch accepts the first 768 entries and rejects the rest of the filter entries. The switch installs the filter entries in the order that they are committed; the rejected entries are the last entries the switch attempts to commit after the TCAM space is exhausted.

The IFP TCAM limit of 768 entries means that the true maximum number of FBF filter terms is 384 terms, even though the VFP TCAM can store up to 512 FBF terms.

MVR Filter VFP TCAM Consumption

Each MVR rule consumes one entry in the VFP TCAM, so MVR rules consume VFP TCAM space as follows:

- 1–256 rules consume one slice
- 257–512 rules consume two slices
- 513–758 rules consume three slices
- 759–1024 rules consume four slices

VFP TCAM Consumption Summary Table

Table 372 on page 4876 summarizes VFP TCAM consumption.

NOTE: FBF filters are simultaneously stored in the VFP TCAM and in the IFP TCAM. Due to the IFP TCAM limit of 768 entries (384 FBF filters), which is 256 entries fewer than the VFP TCAM, the effective VFP TCAM consumption limit for FBF filters is lower than the total amount of VFP TCAM entry space, even when no other filters consume VFP TCAM space.

Table 372: VFP TCAM Entry Consumption Summary

Filter Type	VPF TCAM Entry Consumption	Maximum VFP TCAM Slices Consumed	Other Limitations
VN2VF_Port FIP snooping filters	Never consumes more than one slice	One slice (regardless of number of sessions)	2500 session maximum
VN2VN_Port FIP snooping filters	One entry per session	Two	376 session maximum
FBF filters	Two entries per filter	Three (due to IFP TCAM limitation)	384 filters (due to IFP TCAM limitation)
MVR rules	One entry per rule	Four	1024 rule maximum

Rejected Filter Configurations (No Available VFP TCAM Space)

If there is not enough space available in the VFP TCAM to store the FIP snooping filters, the configured FBF filters, and the MVR rules, the switch rejects only the portion of the configuration that it cannot store. Any portion of the filter configuration that the TCAM can store, is stored. In most cases, even if the switch rejects part of the configuration, part of the configuration is also stored.

If the switch rejects any portion of a configuration, the switch sends a syslog message to notify you of the failure. The switch does not generate a commit error, and the rejected portion of the configuration remains on the switch, even though the rejected configuration does not function. (The accepted portions of the configuration function as expected.) The syslog message shows you the filter configuration that the switch rejected.

We strongly recommend that you always delete rejected filter configurations from the switch. It is important to delete rejected filter configurations because:

- Even though the rejected configuration remains on the switch, it does not function.
- After a reboot, there is no guarantee that the same filters will be rejected. The previously rejected filters might be accepted, and other filters that had previously been accepted might be rejected. Therefore, the functioning filter configuration could be changed inadvertently and unexpectedly.
- Even if a VFP TCAM slice becomes available, the switch does not automatically allocate the available slice to the rejected configuration. To use the available slice, you must delete and reconfigure the rejected configuration.

  For example, you configure FBF filters and MVR rules on a switch, and that switch also transports FCoE traffic with VN2VF_Port FIP snooping (never consumes more than one slice) enabled on FCoE access interfaces. After you commit the configuration, you check the syslog. You find that the VN2VF_Port FIP snooping and FBF filters consume all four slices of the VFP TCAM, and the MVR configuration was rejected. Instead of deleting the MVR configuration, you leave it on the switch. Subsequently, all VN2VF_Port FIP snooping sessions end, the FIP snooping filters time out and are removed from the VFP TCAM, so the slice that was allocated to VN2VF_Port FIP snooping filters becomes free. However, the MVR rules do *not* automatically receive the free slice.

To force the switch to allocate the free slice to the MVR rules, you should delete the MVR rules from the configuration and then reconfigure the MVR rules. When you commit the new configuration, check the syslog messages to ensure that the MVR rule configuration was accepted.

In this example, you could also choose to free a VFP TCAM slice for MVR rule storage by deleting some of the FBF filters. To do this, you delete both the unneeded FBF filters and the MVR rule configuration. Then you reconfigure the MVR rules, and check the syslog to ensure that the configuration was successful.

VFP TCAM Allocation and Consumption (Scaling) Examples

The following examples illustrate how FIP snooping entries, FBF filter entries, and MVR rule entries consume VFP TCAM slices:

- Example 1: Three Filter Types Consume Three Slices on page 4877
- Example 2: Three Filter Types Consume Four Slices on page 4877
- Example 3: Two Filter Types Consume Four Slices on page 4878
- Example 4: Three Filter Types Oversubscribe the VFP TCAM on page 4878

Example 1: Three Filter Types Consume Three Slices

Filters and rules are configured in the following sequence:

- 100 VN2VN_Port FIP snooping filters (1 slice)
- 2 MVR rules (1 slice, 2 entries)
- 60 FBF filter terms (1 slice, 120 entries)

One slice remains free. The slice allocated to VN2VN_Port FIP snooping filters can store 156 more filters before another slice is required. The slice allocated to MVR rules can store 254 more rules before another slice is required. The slice allocated to FBF filters can store 68 more filter terms (136 entries) before another slice is required. Providing that the IFP TCAM has space for the FBF filter terms, the switch accepts this configuration and rejects no filters.

Example 2: Three Filter Types Consume Four Slices

Filters and rules are configured in the following sequence:

- 2000 VN2VF_Port FIP snooping filters (always 1 slice)
- 18 MVR rules (1 slice, 18 entries)
- 150 FBF filter terms (2 slices, 300 entries)

All four slices are allocated to filter types. The slice allocated to MVR rules can store 238 more rules before it is full. The slice allocated to FBF filters can store 106 more filter terms (212 entries) before it is full. Providing that the IFP TCAM has space for the FBF filter terms, the switch accepts this configuration and rejects no filters.

NOTE: If you configure more MVR rules or FBF filters than entry space remaining in the slices, the switch rejects those rules and filters because no slice is available. The switch installs filters in the order that they were configured, so if filters are rejected, the filters configured last are rejected.

Example 3: Two Filter Types Consume Four Slices

Filters and rules are configured in the following sequence:

- 50 VN2VF_Port FIP snooping filters (always 1 slice)
- 300 FBF filter terms (3 slices, 600 entries)

All four slices are allocated to filter types. No slices are available for MVR rules. The third slice allocated to FBF filters can store 84 more filter terms (168 entries) before it consumes all of its entry space. Providing that the IFP TCAM has space for the FBF filter terms, the switch accepts this configuration and rejects no filters.

NOTE: If you configure MVR rules or if you configure more than 84 more FBF filters, the switch rejects those rules and filters because no slice is available for the MVR rules, and the FBF filter slice has entry space for only 84 more filter terms.

Example 4: Three Filter Types Oversubscribe the VFP TCAM

Filters and rules are configured in the following sequence:

- 1750 VN2VF_Port FIP snooping filters (always 1 slice)
- 10 MVR rules (1 slice, 10 entries)
- 275 FBF filter terms (2 slices, 512 accepted entries, 38 rejected entries)

All four slices are allocated to filter types. The slice allocated to MVR rules can store 246 more rules before it is full, but the number of FBF filter terms exceeds the amount of available VFP TCAM storage space. (The 275 FBF filter terms consume 550 VFP TCAM entries. However, there are only two available slices, for a total of 512 available entry spaces, so only 256 FBF filter terms can be stored, leaving 19 rejected FBF filter terms.)

The switch accepts the VN2VF_Port FIP snooping filters, the MVR rules, and 256 FBF filter terms. The switch retains the excess FBF filters in the configuration, but does not install those filters in the VFP TCAM. In this case, you delete the rejected FBF filter terms from the configuration. Alternatively, you could delete the MVR rules from the configuration to free a slice of the TCAM, and then delete and reconfigure the rejected FBF filters so that the system allocates the freed slice to the FBF filters.

NOTE: The sequence of configuration makes a difference; if there is not enough VFP TCAM space for a given filter type, the switch installs the filters that fit in the order they are configured. For example, if you configure the FBF filters before you configure the MVR rules, the VFP TCAM allocates one slice to FIP snooping filters, three slices to FBF filters (assuming the IFP TCAM has available space), and no slices to MVR rules, because all four slices are allocated before the switch attempts to install the MVR rules in the VFP TCAM.

Filter Configuration Recommendations

To utilize the VFP TCAM space most efficiently:

- Configure and Maintain the Fewest Number of Filters Needed on page 4879
- Always Delete Rejected Filter Configurations on page 4880

Configure and Maintain the Fewest Number of Filters Needed

To conserve VFP TCAM entry space, and because FBF filter storage also depends on the availability of IFP TCAM space, we recommend that you configure as few FBF filters and MVR rules as is practical to serve your network needs. The more filters you configure, the greater the possibility of exceeding TCAM storage capacity.

Several factors determine VFP TCAM consumption:

- Type of filters configured—Different filter types consume different amounts of VFP TCAM space. VN2VF_Port FIP snooping filters never consume more than one slice. MVR rules and VN2VN_Port FIP snooping filters consume entries in a slice at a rate of one entry per MVR rule or VN2VN_Port session. FBF filter terms consume entries in a slice at a rate of two entries per FBF filter term.
- Number of filters configured—Although the number of filters does not affect the number of slices allocated to the VN2VF_Port FIP snooping filter type (it is always one slice for one or more VN2VF_Port FIP snooping filters and no slice for no FIP snooping filters), the number of VN2VN_Port FIP snooping filters, MVR rules, and FBF filter terms that you configure determine how many VFP TCAM slices are required for each filter type.

  For example, if you configure 257 MVR rules, the MVR rule entries consume 2 slices. One slice stores 256 MVR rules (entries), and one slice stores 1 MVR rule (entry). In this case, if you can eliminate one MVR rule, you can free a slice to allocate to other filter types.
- Sequence of filter configuration—If you configure too many filters for the VFP TCAM to store, the last filters you configure are not stored in the TCAM.

  Always check the syslog after you configure FBF filters or MVR rules to ensure that the configuration was not rejected. If you enable FIP snooping on access ports, check the syslog to ensure that the configuration was not rejected due to lack of VFP TCAM space.

  If you check the syslog and a filter configuration has been rejected, delete the filters that were rejected from the configuration.

TIP: If you no longer need an FBF filter or an MVR rule, delete it from the configuration to conserve VFP TCAM space. Enable VN2VF_Port or VN2VN_Port FIP snooping on access ports only if the switch port is directly connected to FCoE devices. (FIP snooping should be performed at the access edge. FIP snooping should not be performed on traffic that has already been snooped and filtered at the access edge. If another switch between the QFX Series or QFabric system and the FCoE devices already performs FIP snooping, do not enable FIP snooping on the QFX Series or QFabric system.)

Always Delete Rejected Filter Configurations

The switch does not return a commit error if it rejects any portion of a configuration. Instead, the switch sends a syslog message to report the rejected portion of the configuration. The rejected portion of the configuration remains on the switch, but does not function.

After you configure FBF filters or MVR rules, or enable FIP snooping, check the syslog messages to ensure that the switch accepted the configuration. If the switch rejected any portion of the configuration, delete that portion of the configuration. (You do not need to delete the portion of the configuration that was accepted, unless you want to reconfigure those filters or rules.)

CAUTION: If you do not delete rejected filter configurations, and if you reboot the system, you cannot predict which filters the system installs after the reboot. For example, a switch with the following configuration has more configured filters than the VFP TCAM can support:

- VN2VF_Port FIP snooping sessions (always consumes one slice)
- 20 MVR rules (consume one slice)
- 300 FBF filters (attempt to consume three slices, but because only two slices are available, 256 filters consume two slices, and the remaining 44 filters are rejected)

If you do not delete the 44 rejected FBF filters, then if the switch reboots, the 44 FBF filters that were rejected might be accepted, and 44 different FBF filters might be rejected. This unpredictable behavior is the reason that you should check the syslog messages after you configure filters, and if any filters were rejected, you should always delete the rejected filters from the configuration.

Understanding MC-LAGs on an FCoE Transit Switch

Multichassis link aggregation groups (MC-LAGs) provide redundancy and load balancing between two QFX Series switches, multihoming support for client devices such as servers, and a loop-free Layer 2 network without running Spanning Tree Protocol (STP).

You can use an MC-LAG to provide a redundant aggregation layer for Fibre Channel over Ethernet (FCoE) traffic. To support lossless transport of FCoE traffic across an MC-LAG, you must configure the appropriate class of service (CoS) on both of the QFX Series switches with MC-LAG port members. The CoS configuration must be the same on both of the MC-LAG switches because MC-LAGs do not carry forwarding class and IEEE 802.1p priority information.

Ports that are part of an FCoE-FC gateway configuration (a virtual FCoE-FC gateway fabric) do not support MC-LAGs. Ports that are members of an MC-LAG act as passthrough transit switch ports.

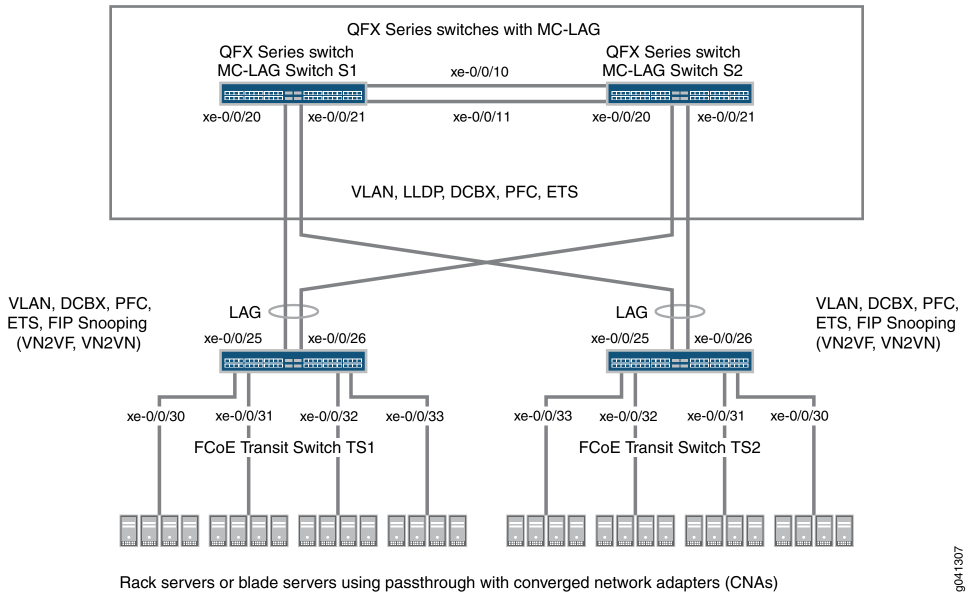
QFX Series switches support MC-LAGs. QFabric system Node devices do not support MC-LAGs, and QFX3500 and QFX3600 Virtual Chassis switches do not support FCoE.

This topic describes:

Supported Topology

QFX Series switches that are not directly connected to FCoE hosts and that act as passthrough transit switches support MC-LAGs for FCoE traffic in an *inverted-U* network topology. Figure 178 on page 4882 shows an inverted-U topology using QFX3500 switches.

Figure 178: Supported Topology for an MC-LAG on an FCoE Transit Switch



The following rules and guidelines apply to MC-LAGs when used for FCoE traffic. The rules and guidelines help ensure the proper handling and lossless transport characteristics required for FCoE traffic:

- The two QFX Series switches that form the MC-LAG (Switches S1 and S2) cannot use ports that are part of an FCoE-FC gateway fabric. The MC-LAG switch ports must be passthrough transit switch ports (used as part of an intermediate transit switch that is not directly connected to FCoE hosts).
- MC-LAG Switches S1 and S2 cannot be not directly connected to the FCoE hosts.
- The two QFX Series switches that serve as access devices for FCoE hosts (FCoE Transit Switches TS1 and TS2) use standard LAGs to connect to MC-LAG Switches S1 and S2. FCoE Transit Switches TS1 and TS2 can be standalone QFX Series switches or they can be Node devices in a QFabric system.
- Transit Switches TS1 and TS2 must use transit switch ports for the FCoE hosts and for the standard LAGs to MC-LAG Switches S1 and S2.
- Enable FIP snooping on the FCoE VLAN on Transit Switches TS1 and TS2. You can configure either VN_Port to VF_Port (VN2VF_Port) FIP snooping or VN_Port to VN_Port (VN2VN_Port) FIP snooping, depending on whether the FCoE hosts need to access targets in the FC SAN (VN2VF_Port FIP snooping) or targets in the Ethernet network (VN2VN_Port FIP snooping).

  FIP snooping should be performed at the access edge and is not supported on MC-LAG switches. Do not enable FIP snooping on MC-LAG Switches S1 and S2. (Do not enable FIP snooping on the MC-LAG ports that connect Switches S1 and S2 to Switches TS1 and TS2 or on the LAG ports that connect Switch S1 to S2.)
- The CoS configuration must be consistent on the MC-LAG switches. Because MC-LAGs carry no forwarding class or priority information, each MC-LAG switch needs to have

the same CoS configuration to support lossless transport. (On each MC-LAG switch, the name, egress queue, and CoS provisioning of each forwarding class must be the same, and the priority-based flow control (PFC) configuration must be the same.)

Transit Switches (Server Access)

The role of FCoE Transit Switches TS1 and TS2 is to connect FCoE hosts in a multihomed fashion to the MC-LAG switches. In essence, Transit Switches TS1 and TS2 act as access switches for the FCoE hosts. (FCoE hosts are directly connected to Transit Switches TS1 and TS2.)

The transit switch configuration depends on whether you want to do VN2VF_Port FIP snooping or VN2VN_Port FIP snooping, and whether the QFX Series transit switches also have ports configured as part of an FCoE-FC gateway virtual fabric. Ports that the QFX Series switch uses in an FCoE-FC gateway virtual fabric cannot be included in the transit switch LAG connection to the MC-LAG switches. (Ports cannot belong to both a transit switch and an FCoE-FC gateway; you must use different ports for each mode of operation.)

MC-LAG Switches (FCoE Aggregation)

The role of MC-LAG Switches S1 and S2 is to provide redundant, load-balanced connections between FCoE transit switches. In essence, MC-LAG Switches S1 and S2 act as aggregation switches. FCoE hosts are not directly connected to the MC-LAG switches.

The MC-LAG switch configuration is the same regardless of which type of FIP snooping that FCoE Transit Switches TS1 and TS2 perform.

FIP Snooping and FCoE Trusted Ports

To maintain secure access, enable VN2VF_Port FIP snooping or VN2VN_Port FIP snooping at the transit switch access ports connected directly to the FCoE hosts. FIP snooping should be performed at the access edge of the network to prevent unauthorized access. For example, in Figure 178 on page 4882, you enable FIP snooping on the FCoE VLANs on Transit Switches TS1 and TS2 that include the access ports connected to the FCoE hosts.

Do not enable FIP snooping on the switches used to create the MC-LAG. For example, in Figure 178 on page 4882, you would not enable FIP snooping on the FCoE VLANs on Switches S1 and S2.

Configure links between switches as FCoE trusted ports to reduce FIP snooping overhead and ensure that the system performs FIP snooping only at the access edge. In the sample topology, configure the Transit Switch TS1 and TS2 LAG ports connected to the MC-LAG switches as FCoE trusted ports, configure the Switch S1 and S2 MC-LAG ports connected to Switches TS1 and TS2 as FCoE trusted ports, and configure the ports in the LAG that connects Switches S1 to S2 as FCoE trusted ports.

CoS and Data Center Bridging (DCB)

The MC-LAG links do not carry forwarding class or priority information. The following CoS properties must have the same configuration on each MC-LAG switch or on each MC-LAG interface to support lossless transport:

- FCoE forwarding class name—For example, the forwarding class for FCoE traffic could use the default **fcoe** forwarding class on both MC-LAG switches.
- FCoE output queue—For example, the **fcoe** forwarding class could be mapped to queue 3 on both MC-LAG switches (queue 3 is the default mapping for the **fcoe** forwarding class).
- Classifier—The forwarding class for FCoE traffic must be mapped to the same IEEE 802.1p code point on each member interface of the MC-LAG on both MC-LAG switches. For example, the FCoE forwarding class **fcoe** could be mapped to IEEE 802.1p code point **011** (code point **011** is the default mapping for the **fcoe** forwarding class).
- Priority-based flow control (PFC)—PFC must be enabled on the FCoE code point on each MC-LAG switch and applied to each MC-LAG interface using a congestion notification profile.

You must also configure enhanced transmission selection (ETS) on the MC-LAG interfaces to provide sufficient scheduling resources (bandwidth, priority) for lossless transport. The ETS configuration can be different on each MC-LAG switch, as long as enough resources are scheduled to support lossless transport for the expected FCoE traffic.

LLDP and DCBX must be enabled on each MC-LAG member interface (LLDP and DCBX are enabled by default on all interfaces).

NOTE: As with all other FCoE configurations, FCoE traffic requires a dedicated VLAN that carries only FCoE traffic, and IGMP snooping must be disabled on the FCoE VLAN.

Understanding CoS Flow Control (Ethernet PAUSE and PFC)

Flow control supports lossless transmission by regulating traffic flows to avoid dropping frames during periods of congestion. Flow control stops and resumes the transmission of network traffic between two connected peer nodes on a full-duplex Ethernet physical link. Controlling the flow by pausing and restarting it prevents buffers on the nodes from overflowing and dropping frames. You configure flow control on a per-interface basis.

The QFX Series supports two methods of flow control:

- IEEE 802.3X Ethernet PAUSE
- IEEE 802.1Qbb priority-based flow control (PFC)

Ethernet PAUSE and PFC are link-level flow control mechanisms.

Ethernet PAUSE pauses transmission of all traffic on a physical Ethernet link.

PFC decouples the pause function from the physical Ethernet link and enables you to divide traffic on one link into eight priorities. You can think of the eight priorities as eight “lanes” of traffic that are mapped to forwarding classes and output queues. Each priority is mapped to a 3-bit IEEE 802.1p CoS code point flag in the VLAN header. You can enable PFC on one or more priorities (IEEE 802.1p code points) on a link. When PFC-enabled traffic is paused on a link, traffic that is not PFC-enabled continues to flow (or is dropped if congestion is severe enough).

Use Ethernet PAUSE when you want to prevent packet loss on all of the traffic on a link. Use PFC to prevent traffic loss only on specified types of traffic (for example, Fibre Channel over Ethernet traffic).

NOTE: **Depending on the amount of traffic on a link or assigned to a priority, pausing traffic can cause ingress port congestion and spread congestion through the network.**

Attempting to configure both Ethernet PAUSE and PFC on a link causes a commit error. Ethernet PAUSE and PFC are mutually exclusive configurations on an interface.

By default, all forms of flow control are disabled. You must explicitly enable flow control on interfaces to pause traffic.

Ethernet PAUSE

Ethernet PAUSE is a congestion relief feature that works by providing link-level flow control for all traffic on a full-duplex Ethernet link. Ethernet PAUSE works in both directions on the link. In one direction, an interface generates and sends Ethernet PAUSE messages to stop the connected peer from sending more traffic. In the other direction, the interface responds to Ethernet PAUSE messages it receives from the connected peer to stop sending traffic. Ethernet PAUSE also works on aggregated Ethernet interfaces. For example, if the connected peer interfaces are called Node A and Node B:

- When the receive buffers on interface Node A reach a certain level of fullness, the interface generates and sends an Ethernet PAUSE message to the connected peer (interface Node B) to tell the peer to stop sending frames. The Node B buffers store frames until the time period specified in the Ethernet PAUSE frame elapses; then Node B resumes sending frames to Node A.
- When interface Node A receives an Ethernet PAUSE message from interface Node B, interface Node A stops transmitting frames until the time period specified in the Ethernet PAUSE frame elapses; then Node A resumes transmission. (The Node A transmit buffers store frames until Node A resumes sending frames to Node B.)

  In this scenario, if Node B sends an Ethernet PAUSE frame with a time value of 0 to Node A, the 0 time value indicates to Node A that it can resume transmission. This happens when the Node B buffer empties to below a certain threshold and the buffer can once again accept traffic.

Symmetric flow control means an interface has the same Ethernet PAUSE configuration in both directions. The Ethernet PAUSE generation and Ethernet PAUSE response functions are both configured as enabled, or they are both disabled. You configure symmetric flow control by including the **flow-control** statement at the **[edit interfaces *interface-name* ether-options]** hierarchy level.

Asymmetric flow control allows you to configure the Ethernet PAUSE functionality in each direction independently on an interface. The configuration for generating Ethernet PAUSE messages and for responding to Ethernet PAUSE messages does not have to be the same. It can be enabled in both directions, disabled in both directions, or enabled in one direction and disabled in the other direction. You configure asymmetric flow control by including the **configured-flow-control** statement at the **[edit interfaces *interface-name* ether-options]** hierarchy level.

On any particular interface, symmetric and asymmetric flow control are mutually exclusive. Asymmetric flow control overrides and disables symmetric flow control. (If PFC is configured on an interface, the PFC configuration overrides Ethernet PAUSE flow control.) The QFX Series supports both symmetric and asymmetric flow control.

- Symmetric Flow Control on page 4886
- Asymmetric Flow Control on page 4887

Symmetric Flow Control

Symmetric flow control configures both the receive and transmit buffers in the same state. The interface can both send Ethernet PAUSE messages and respond to them (flow control is enabled), or the interface cannot send Ethernet PAUSE messages or respond to them (flow control is disabled).

When you enable symmetric flow control on an interface, the Ethernet PAUSE behavior depends on the configuration of the connected peer. With symmetric flow control enabled, the interface can perform any Ethernet PAUSE functions that the connected peer can perform. (When symmetric flow control is disabled, the interface does not send or respond to Ethernet PAUSE messages.)

Asymmetric Flow Control

Asymmetric flow control enables you to specify independently whether or not the interface receive buffer generates and sends Ethernet PAUSE messages to stop the connected peer from transmitting traffic, and whether or not the interface transmit buffer responds to Ethernet PAUSE messages it receives from the connected peer and stops transmitting traffic. The receive buffer configuration determines if the interface transmits Ethernet PAUSE messages, and the transmit buffer configuration determines if the interface receives and responds to Ethernet PAUSE messages:

- Receive buffers on—Enable Ethernet PAUSE transmission (generate and send Ethernet PAUSE frames)
- Transmit buffers on—Enable Ethernet PAUSE reception (respond to received Ethernet PAUSE frames)

You must explicitly set the flow control for both the receive buffer and the transmit buffer (**on** or **off**) to configure asymmetric Ethernet PAUSE. Table 373 on page 4887 describes the configured flow control state when you set the receive (Rx) and transmit (Tx) buffers on an interface:

Table 373: Asymmetric Ethernet PAUSE Flow Control Configuration

Receive (Rx) Buffer	Transmit (Tx) Buffer	Configured Flow Control State
On	Off	Interface generates and sends Ethernet PAUSE messages. Interface does not respond to Ethernet PAUSE messages (interface continues to transmit even if peer requests that the interface stop sending traffic).
Off	On	Interface responds to Ethernet PAUSE messages received from the connected peer, but does not generate or send Ethernet PAUSE messages. (The interface does not request that the connected peer stop sending traffic.)
On	On	Same functionality as symmetric Ethernet PAUSE. Interface generates and sends Ethernet PAUSE messages and responds to received Ethernet PAUSE messages.
Off	Off	Ethernet PAUSE flow control is disabled.

The configured flow control is the Ethernet PAUSE state configured on the interface.

On 1-Gigabit Ethernet interfaces, the QFX Series supports autonegotiation of Ethernet PAUSE with the connected peer. (The QFX Series does not support autonegotiation on 10-Gigabit Ethernet interfaces.) Autonegotiation enables the interface to exchange state advertisements with the connected peer so that the two devices can agree on the Ethernet PAUSE configuration. Each interface advertises its flow control state to the connected peer using a combination of the Ethernet PAUSE and ASM_DIR bits, as described in Table 374 on page 4888:

Table 374: Flow Control State Advertised to the Connected Peer (Autonegotiation)

Rx Buffer State	Tx Buffer State	PAUSE Bit	ASM_DIR Bit	Description
Off	Off	0	0	The interface advertises no Ethernet PAUSE capability. This is equivalent to disabling flow control on an interface.
On	On	1	0	The interface advertises symmetric flow control (both the transmission of Ethernet PAUSE messages and the ability to receive and respond to Ethernet PAUSE messages).
On	Off	0	1	The interface advertises asymmetric flow control (the transmission of Ethernet PAUSE messages, but not the ability to receive and respond to Ethernet PAUSE messages).
Off	On	1	1	The interface advertises both symmetric and asymmetric flow control. Although the interface does not generate and send Ethernet PAUSE requests to the peer, the interface supports both symmetric and asymmetric Ethernet PAUSE configuration on the peer because the peer is not affected if the peer does not receive Ethernet PAUSE requests. (If the interface responds to the peer's Ethernet PAUSE requests, that is sufficient to support either symmetric or asymmetric flow control on the peer.)

The flow control configuration on each switch interface interacts with the flow control configuration of the connected peer. Each peer advertises its state to the other peer. The interaction of the flow control configuration of the peers determines the flow control behavior (resolution) between them, as shown in Table 375 on page 4889. The first four columns show the Ethernet PAUSE configuration on the local QFX Series and on the connected peer (also known as the link partner). The last two columns show the Ethernet PAUSE resolution that results from the local and peer configurations on each interface. This illustrates how the Ethernet PAUSE configuration of each interface affects the Ethernet PAUSE behavior on the other interface.

NOTE: In the Resolution columns of the table, disabling Ethernet PAUSE transmit means that the interface receive buffers do not generate and send Ethernet PAUSE messages to the peer. Disabling Ethernet PAUSE receive means that the interface transmit buffers do not respond to Ethernet PAUSE messages received from the peer.

Table 375: Asymmetric Ethernet PAUSE Behavior on Local and Peer Interfaces

Local Interface (QFX Series)		Peer Interface			
PAUSE Bit	ASM_DIR Bit	PAUSE Bit	ASM_DIR Bit	Local Resolution	Peer Resolution
0	0	Don’t care	Don’t care	Disable Ethernet PAUSE transmit and receive	Disable Ethernet PAUSE transmit and receive
0	1	0	Don’t care	Disable Ethernet PAUSE transmit and receive	Disable Ethernet PAUSE transmit and receive
0	1	1	0	Disable Ethernet PAUSE transmit and receive	Disable Ethernet PAUSE transmit and receive
0	1	1	1	Enable Ethernet PAUSE transmit and disable Ethernet PAUSE receive	Disable Ethernet PAUSE transmit and enable Ethernet PAUSE receive
1	0	0	Don’t care	Disable Ethernet PAUSE transmit and receive	Disable Ethernet PAUSE transmit and receive
1	0	1	Don’t care	Enable Ethernet PAUSE transmit and receive	Enable Ethernet PAUSE transmit and receive
1	1	0	0	Disable Ethernet PAUSE transmit and receive	Disable Ethernet PAUSE transmit and receive
1	1	0	1	Enable Ethernet PAUSE receive and disable Ethernet PAUSE transmit	Enable Ethernet PAUSE transmit and disable Ethernet PAUSE receive
1	1	Don’t care	Don’t care	Enable Ethernet PAUSE transmit and receive	Enable Ethernet PAUSE transmit and receive

NOTE: For your convenience, Table 375 on page 4889 replicates Table 28B-3 of Section 2 of the IEEE 802.X specification.

PFC

PFC is a lossless transport and congestion relief feature that works by providing granular link-level flow control for each IEEE 802.1p code point (priority) on a full-duplex Ethernet link. When the receive buffer on a switch interface fills to a threshold, the switch transmits a pause frame to the sender (the connected peer) to temporarily stop the sender from transmitting more frames. The buffer threshold must be low enough so that the sender has time to stop transmitting frames and the receiver can accept the frames already on the wire before the buffer overflows. The switch automatically sets queue buffer thresholds to prevent frame loss.

When congestion forces one priority on a link to pause, all of the other priorities on the link continue to send frames. Only frames of the paused priority are not transmitted. When the receive buffer empties below another threshold, the switch sends a message that starts the flow again.

You configure PFC using a congestion notification profile (CNP). A CNP has two parts:

- Input—Specify the code point (or code points) on which to enable PFC, and optionally specify the maximum receive unit (MRU) and the cable length between the interface and the connected peer interface.
- Output—Specify the output queue or output queues that respond to pause messages from the connected peer.

You apply a PFC configuration by configuring a CNP on one or more interfaces. Each interface that uses a particular CNP is enabled to pause traffic with the priorities (code points) specified in that CNP. You can configure one CNP on an interface, and you can configure different CNPs on different interfaces. When you configure a CNP on an interface, ingress traffic that is mapped to a priority that the CNP enables for PFC is paused whenever the queue buffer fills to the pause threshold. (The pause threshold is not user-configurable.)

Configure PFC for a priority end to end along the entire data path to create a lossless lane of traffic on the network. You can selectively pause the traffic in any queue without pausing the traffic for other queues on the same link. You can create lossless lanes for traffic such as Fibre Channel over Ethernet (FCoE), LAN backup, or management, while using standard frame-drop congestion management for IP traffic on the same link.

Potential consequences of link-level flow control are:

- Ingress port congestion (configuring too many lossless flows can cause ingress port congestion)
- A paused priority that causes upstream devices to pause the same priority, thus spreading congestion back through the network

By definition, PFC supports symmetric pause only (as opposed to Ethernet PAUSE, which supports symmetric and asymmetric pause). With symmetric pause, a device can:

- Transmit pause frames to pause incoming traffic. (You configure this using the input stanza of a congestion notification profile.)
- Receive pause frames and stop sending traffic to a device whose buffer is too full to accept more frames. (You configure this using the output stanza of a congestion notification profile.)

Receiving a PFC frame from a connected peer pauses traffic on egress queues based on the IEEE 802.1p priorities that the PFC pause frame identifies. The priorities are 0 through 7. By default, the priorities map to queue numbers 0 through 7, respectively, and to specific forwarding classes, as shown in Table 376 on page 4891:

Table 376: Default PFC Priority to Queue and Forwarding Class Mapping

IEEE 802.1p Priority (Code Point)	Queue	Forwarding Class
0 (000)	0	best-effort
1 (001)	1	best-effort
2 (010)	2	best-effort
3 (011)	3	fcoe
4 (100)	4	no-loss
5 (101)	5	best-effort
6 (110)	6	network-control
7 (111)	7	network-control

For example, a received PFC pause frame that pauses priority 3 pauses output queue 3. If you do not want to use the default configuration, you can configure customized mapping of priorities to queues and forwarding classes.

NOTE: By convention, deployments with converged server access typically use IEEE 802.1p priority 3 for FCoE traffic. The default forwarding class configuration sets the **fcoe** forwarding class as a lossless forwarding class that is mapped to queue 3. The default classifier maps incoming priority 3 traffic to the **fcoe** forwarding class. *However, you must apply PFC to the entire FCoE data path to configure the end-to-end lossless behavior that FCoE traffic requires.*

If your network uses priority 3 for FCoE traffic, we recommend that you use the default configuration. If your network uses a priority other than 3 for FCoE traffic, you can configure lossless FCoE transport on any IEEE 80.21p priority as described in "Understanding CoS IEEE 802.1p Priorities for Lossless Traffic Flows" on page 5427 and "Understanding CoS IEEE 802.1p Priority Remapping on an FCoE-FC Gateway" on page 5446.

You enable PFC on a priority by:

1. Specifying the IEEE 802.1p code point to pause in the input stanza of a CNP
2. Applying the CNP to the ingress interfaces on which you want to pause the traffic

CAUTION: Any change to the PFC configuration on a port temporarily blocks the entire port (not just the priorities affected by the PFC change) so that the port can implement the change, then unblocks the port. Blocking the port stops ingress and egress traffic, and causes packet loss on all queues on the port until the port is unblocked.

A change to the PFC configuration means any change to a CNP, including changing the input portion of the CNP (enabling or disabling PFC on a priority, or changing the MRU or cable-length values) or changing the output portion the CNP that enables or disables output flow control on a queue. A PFC configuration change only affects ports that use the changed CNP.

The following actions change the PFC configuration:

- Deleting or disabling a PFC configuration (input or output) in a CNP that is in use on one or more interfaces. For example:
    1. An existing CNP with an input stanza that enables PFC on priorities 3, 5, and 6 is configured on interfaces xe-0/0/20 and xe-0/0/21.
    2. We disable the PFC configuration for priority 6 in the input CNP, and then commit the configuration.
    3. The PFC configuration change causes all traffic on interfaces xe-0/0/20 and xe-0/0/21 to stop until the PFC change has been implemented. When the PFC change has been implemented, traffic resumes.
- Configuring a CNP on an interface. (This changes the PFC state by enabling PFC on one or more priorities.)
- Deleting a CNP from an interface. (This changes the PFC state by disabling PFC on one or more priorities.)

When you associate the CNP with an interface, the interface uses PFC to send pause requests when the output queue buffer for the lossless traffic fills to the pause threshold.

Although unicast traffic and multidestination (multicast, broadcast, and destination lookup fail) traffic must use different classifiers, you can map a unicast queue (queue 0 through 7) and a multidestination queue (queue 8, 9, 10, or 11) to the same PFC priority so that both unicast and multicast traffic use that priority. Do not map multidestination traffic to lossless priorities. Starting with Junos OS Release 12.3, you can map one priority to multiple output queues.

NOTE: You can attach a maximum of one CNP to an interface, but you can create an unlimited number of CNPs that explicitly configure only the input stanza and use the default output stanza.

The output stanza of the CNP maps to a profile that interfaces use to respond to pause messages received from the connected peer. On standalone QFX3500 switches and QFX3600 switches, you can create two CNPs with an explicitly configured output stanza.

When a QFX3500 switch or a QFX3600 switch is a Node device in a QFabric system, you can create one CNP with an explicitly configured output stanza. (One fewer profile is available on QFabric systems because the system needs a default profile for fabric interfaces, which are not used as fabric interfaces when the switches are not part of a QFabric system. "Understanding CoS IEEE 802.1p Priorities for Lossless Traffic Flows" on page 5427 describes configuring output flow control.

Lossless Transport Support Summary

The QFX Series supports up to six lossless forwarding classes. For lossless transport, you must enable PFC on the IEEE 802.1p priorities (code points) mapped to lossless forwarding classes.

CAUTION: Any change to the PFC configuration on a port temporarily blocks the entire port (not just the priorities affected by the PFC change) so that the port can implement the change, then unblocks the port. Blocking the port stops ingress and egress traffic, and causes packet loss on all queues on the port until the port is unblocked.

The following limitation applies to support lossless transport on QFabric systems only:

- The internal fiber cable length from the QFabric system Node device to the QFabric system Interconnect device cannot exceed 150 meters.

The default CoS configuration provides two lossless forwarding classes, *fcoe* and *no-loss*. If you explicitly configure lossless forwarding classes, you must include the **no-loss** packet drop attribute to enable lossless behavior, or the traffic is not lossless. For both default and explicit lossless forwarding class configuration, you must configure CNP input stanzas to enable PFC on the priority of the lossless traffic and apply the CNPs to ingress interfaces.

NOTE: Junos OS Release 12.2 introduced changes to the way the QFX Series handles lossless forwarding classes (including the default **fcoe** and **no-loss** forwarding classes).

In Junos OS Release 12.1, either explicitly configuring the **fcoe** and **no-loss** forwarding classes or using the default configuration for these forwarding classes resulted in the same lossless behavior for traffic mapped to those forwarding classes.

However, in Junos OS Release 12.2, if you explicitly configure the **fcoe** or the **no-loss** forwarding class, that forwarding class is no longer treated as a lossless forwarding class. Traffic mapped to these forwarding classes is treated as lossy (best-effort) traffic. This is true even if the explicit configuration is exactly the same as the default configuration.

If your CoS configuration from Junos OS Release 12.1 or earlier includes the explicit configuration of the **fcoe** or the **no-loss** forwarding class, then when you upgrade to Junos OS Release 12.2, those forwarding classes are not lossless. To preserve the lossless treatment of these forwarding classes, delete the the explicit **fcoe** and **no-loss** forwarding class configuration before you upgrade to Junos OS Release 12.2.

See "Overview of CoS Changes Introduced in Junos OS Release 12.2" on page 5304 for detailed information about this change and how to delete an existing lossless configuration.

In Junos OS Release 12.3, the default behavior of the **fcoe** and **no-loss** forwarding classes is the same as in Junos OS Release 12.2. However, in Junos OS Release 12.3, you can configure up to six lossless forwarding classes. All explicitly configured lossless forwarding classes must include the new **no-loss** packet drop attribute or the forwarding class is lossy.

"Understanding CoS IEEE 802.1p Priorities for Lossless Traffic Flows" on page 5427 provides detailed information about the explicit configuration of lossless priorities and about the default configuration of lossless priorities, including the input and output stanzas of the CNP.

NOTE: PFC and Ethernet PAUSE are used only on Ethernet interfaces. Fabric (fte) ports on QFabric systems (Node device fabric ports and Interconnect device fabric ports) use link-layer flow control (LLFC) to ensure the appropriate treatment of lossless traffic.

Understanding Fibre Channel Terminology

To understand the Fibre Channel (FC) and Fibre Channel over Ethernet (FCoE) capabilities of the QFX Series, you should become familiar with the terms defined in Table 377 on page 4895.

Table 377: Fibre Channel Terms

Term	Definition
addressing mode	Format for the locally unique MAC address the FC switch assigns to FCoE devices for FCoE transactions after FIP establishes a connection between an FCoE device and the FC switch. The two addressing modes are *fabric-provided MAC address (FPMA)* and *server-provided MAC address (SPMA)*. The QFX Series supports only FPMA. During FLOGI or FDISC, the ENode advertises the addressing modes it supports. If the FC switch supports an addressing mode that the ENode uses, the virtual link can be established, and the devices can communicate. See also *fabric-provided MAC address (FPMA)* and *server-provided MAC address (SPMA)*.
ALL-ENode-MACs	Well-known multicast MAC address to which all FCoE ENodes listen. FCFs send multicast *FIP discovery advertisement* messages and *FIP keepalive* messages to the ALL-ENode-MACs address so that ENodes can discover and maintain connections to FCFs. The hexadecimal format of the address is **01:10:18:01:00:01**. See also *well-known address (WKA)*.
ALL-FCF-MACs	Well-known multicast MAC address to which all FCFs listen. ENodes send multicast *FIP discovery solicitation* messages to the ALL-FCF-MACs address to find out which FCFs can accept a login. The hexadecimal format of the address is **01:10:18:01:00:02**. See also *well-known address (WKA)*.
congestion notification	See *quantized congestion notification (QCN)*.
converged network adapter (CNA)	Physical adapter that combines the functions of a Fibre Channel *host bus adapter (HBA)* to process FCoE frames and a *lossless Ethernet network interface card (NIC)* to process non-FCoE Ethernet frames. CNAs have one or more Ethernet ports. CNAs encapsulate Fibre Channel frames in Ethernet for FCoE transport and de-encapsulate Fibre Channel frames from FCoE to native Fibre Channel. See also *host bus adapter (HBA)*.

Table 377: Fibre Channel Terms *(continued)*

Term	Definition
data center bridging (DCB)	Set of IEEE specifications that enhance Ethernet to allow it to support converged Ethernet (LAN) and Fibre Channel (SAN) traffic on one Ethernet network. DCB features include *priority-based flow control (PFC)*, *enhanced transmission selection (ETS)*, *Data Center Bridging Capability Exchange protocol (DCBX)*, *quantized congestion notification (QCN)*, and full-duplex 10-Gigabit Ethernet ports. See also *priority-based flow control (PFC)*, *Ethernet PAUSE*, *enhanced transmission selection (ETS)*, *Data Center Bridging Capability Exchange protocol (DCBX)*, and *quantized congestion notification (QCN)*.
expansion port (E_Port)	An expansion port in an FC switch/FCF that connects the FC switch/FCF to the E_Port of another FC switch/FCF to form an *Interswitch Link (ISL)* in a common FC fabric.
Data Center Bridging Capability Exchange protocol (DCBX)	Discovery and exchange protocol for conveying configuration and capabilities among neighbors to ensure consistent configuration across the network. It is an extension of the Link Layer Data Protocol (LLDP, described in IEEE 802.1AB) See also *data center bridging (DCB)*.
enhanced transmission selection (ETS)	Mechanism that provides finer granularity of bandwidth management within a link. See also *data center bridging (DCB)*.
ENode	See *FCoE Node (ENode)*
ENode MAC	*Lossless Ethernet MAC* paired with an *FCoE controller* in an ENode. See also *FCoE node (ENode)*.
ENode MAC address	Globally unique address assigned to the CNA by the manufacturer and used to identify the node for FIP transactions.
Ethernet PAUSE	As defined in IEEE 802.3X, a flow control mechanism that temporarily stops the transmission of Ethernet frames on a link for a specified period. A receiving element sends an Ethernet PAUSE frame when a sender transmits data faster than the receiver can accept it. Ethernet PAUSE affects the entire link, not just an individual flow. An Ethernet PAUSE frame temporarily stops all traffic transmission on the link and allows the receiver's input buffer to empty sufficiently to restart traffic on the link. Ethernet PAUSE messages are sent to the previous hop and do not automatically propagate to the source of the congestion. See also *priority-based flow control (PFC)*.
fabric	Interconnection of network nodes using one or more network switches that function as a network single logical entity.

Table 377: Fibre Channel Terms *(continued)*

Term	Definition
fabric discovery (FDISC)	Subsequent logins from the same ENode for different users, applications, or virtual machines after an ENode performs an initial FLOGI to log in to a switch. FC and FIP FDISC messages serve the same function in FC and FCoE networks, respectively. N_Ports send FC FDISC messages to the FC switch and VN_Ports send FIP FDISC messages to the FCF. After an N_Port acquires its initial N_Port ID through the FC FLOGI process, it can acquire additional N_Port IDs by sending an FC FDISC with a new worldwide port name and a source ID of 0x000000. The new port name and blank source ID tell the FC switch to assign a new N_Port ID to the N_Port. The different N_Port IDs allow multiple virtual machines or users on the N_Port to have separate, secure virtual links on the same physical N_Port. These additional ports are also referred to as VN_Ports. FIP FDISC works the same way, except the VN_Port logs in using a FIP FLOGI message. See also *fabric login (FLOGI)* and *N_Port ID*.
fabric login (FLOGI)	Creation of a logical connection to the FC switch and establishment of a node's operating environment. For FC devices, an N_Port logs in to the FC network by sending an FC FLOGI message to the F_Port of an FC switch. For FCoE devices, a VN_Port logs in to the FC network by sending a FIP FLOGI message to the VF_Port of an FC switch.
fabric port (F_Port)	FC port on an FC switch or an FCF that connects point-to-point to an FC node port (N_Port) on an FC host (server or storage device). An F_Port provides access to fabric services for FC devices. F_Ports are intermediate ports in a connection between FC device end-point N_Ports. For example, a connection between an FC host server and an FC storage device through an FC switch looks like this: FC server N_Port to FC switch ingress F_Port to FC switch egress F_Port to FC storage device N_Port. See also *node port (N_Port)*.
fabric-provided MAC address (FPMA)	MAC address that an FCF assigns to a single ENode MAC through the FLOGI or FDISC process that is unique to the local fabric. The FPMA uniquely identifies a single VN_Port at that ENode MAC in FCoE transactions with the FCF. Because an ENode can have more than one ENode MAC, an FCF can assign multiple FPMAs to an ENode, one FPMA per ENode MAC. An FPMA is a 48-bit value that consists of two 24-bit values, the N_Port ID and the FC-MAP value. The N_Port ID uniquely identifies the VN_Port and the FC-MAP value identifies the FCF. See also *FCoE node (ENode)*, *N_Port ID*, and *FCoE mapped address prefix (FC-MAP)*.
FCF-MAC	Lossless Ethernet MAC paired with an FCoE controller in an FCF. The FCF-MAC enables the FCF to handle FCoE traffic.

Table 377: Fibre Channel Terms *(continued)*

Term	Definition
FCoE controller	Instantiates and terminates VN_Port and VF_Port instances on an ENode. An ENode can have more than one FCoE controller. Each FCoE controller is paired with a lossless Ethernet MAC on the ENode. See also *lossless Ethernet MAC*.
FC forwarder (FCF)	Alternative term and acronym to refer to an FC switch that has all physical Fibre Channel ports and the necessary set of services as defined in the T11 Organization *Fibre Channel Switched Fabric* (FC-SW) standards.
FCoE forwarder (FCF)	Defined by the *Fibre Channel Backbone - 5 (FC-BB-5) Rev 2.00* specification available at http://www.t11.org/ftp/t11/pub/fc/bb-5/09-056v5.pdf as a device that has the necessary set of services as defined in FC-SW and the FCoE capabilities to act as an FCoE-based FC switch.
FCoE Initialization Protocol (FIP)	Layer 2 protocol for endpoint discovery, fabric login, and fabric association. FIP enables FCoE devices and FC switches to discover one another. Through FIP, FCoE nodes can log in to an FC switch, access the SAN FC fabric, and communicate with target FC devices. FIP messages also maintain the connection between the FCoE initiator and the FCF. FIP has its own EtherType (0x8914) to distinguish its traffic from payload-carrying FCoE traffic and other Ethernet traffic.
FCoE link endpoint (LEP)	Virtual FC interface mapped onto a physical Ethernet interface to handle FC frame encapsulation and de-encapsulation and transmission and reception of FC frames encapsulated in Ethernet through a single virtual link.
FCoE mapped address prefix (FC-MAP)	24-bit value that identifies the FC switch and is half of the 48-bit FPMA MAC address. The FC-MAP value can be configured on the FC switch and has a default value of 0EFC00h. The FC-MAP value was originally called the Fibre Channel Organizationally Unique Identifier (FC-OUI). See also *fabric-provided MAC address (FPMA)*.
FCoE node (ENode)	Fibre Channel node that has one or more lossless Ethernet MACs, each paired with an *FCoE Controller* in order to transmit FCoE frames. An ENode combines FCoE termination functions and the FC stack on a CNA. ENodes present virtual FC interfaces to FC switches or FCFs in the form of VN_Ports, which can establish FCoE virtual links with FC switch/FCF VF_Ports. ENodes perform FCoE related functions in a *converged network adapter (CNA)*. See also *converged network adapter (CNA)*.
FCoE-FC gateway	A form of N_Port virtualizer in which the node-facing ports are FCoE ports and the FC switch-facing ports are FC ports.
FCoE-FCoE gateway	A form of N_Port virtualizer in which the node-facing ports are FCoE ports and the FC switch-facing ports are FCoE ports.
FC-FC gateway	A form of N_Port virtualizer in which the node-facing ports are FC ports and the FC switch-facing ports are FC ports.

Table 377: Fibre Channel Terms *(continued)*

<table>
<tr><th>Term</th><th>Definition</th></tr>
<tr><td>FCoE transit switch (also known as a FIP snooping bridge)</td><td>Switch with a minimum set of features designed to support FCoE Layer 2 forwarding and FCoE security. The switch can also have optional additional features.

Minimum feature support is:

• Priority-based flow control (PFC)
• Enhanced transmission selection (ETS)
• Data Center Bridging Capability Exchange Protocol (DCBX), including the FCoE application TLV
• FIP snooping (minimum support is FIP automated filter programming at the ENode edge)

Additional FIP snooping capabilities can include learning the virtual FC connection paths (VN2VF, VN2VN, or VE2VE) and monitoring the FIP keepalive mechanisms. Other optional capabilities can also enhance FCoE within the standards. FIP snooping is typically configurable on a per-VLAN basis.

A transit switch has an FC stack even though it is not an FC switch or an FCF.</td></tr>
<tr><td>FCoE VLAN</td><td>VLAN dedicated to carrying only FCoE traffic. FCoE traffic must travel in a VLAN. Only FCoE interfaces should be members of an FCoE VLAN. Ethernet traffic that is not FCoE traffic must travel in a different VLAN.</td></tr>
<tr><td>Fibre Channel</td><td>High-speed network technology used for storage area networks (SANs).</td></tr>
<tr><td>Fibre Channel fabric</td><td>Network of Fibre Channel devices that allows communication among devices, device name lookup, security, and redundancy.

Also a local fabric on a QFX3500 switch with FCoE interfaces connected to FCoE devices on the Ethernet network and native FC interfaces connected to an FC switch in a SAN.</td></tr>
<tr><td>Fibre Channel ID (FCID)</td><td>24-bit value the FC switch assigns to the N_Port or VN_Port as a unique identifier within the local FC network. The FCID consists of an 8-bit domain value, an 8-bit area value, and an 8-bit port value. The FCID is sometimes called an N_Port ID.

See also N_Port ID.</td></tr>
<tr><td>Fibre Channel over Ethernet (FCoE)</td><td>Standard for transporting FC frames over Ethernet networks. FCoE encapsulates Fibre Channel frames in Ethernet so that the same high-speed Ethernet physical infrastructure can transport both data and storage traffic while preserving the lossless CoS that FC requires. FCoE has its own EtherType (0x8906) to differentiate it from other Ethernet traffic.

FCoE runs on a DCB network. FCoE servers connect to a switch that supports both FCoE and native FC protocols. This allows FCoE servers on the Ethernet network to access FC storage devices in the SAN fabric on one converged network.

See also data center bridging (DCB).</td></tr>
</table>

Table 377: Fibre Channel Terms *(continued)*

Term	Definition
Fibre Channel services	Functions required for establishing FC network connectivity among devices and for managing devices on the FC network, such as login servers, domain managers, name servers, and zone servers.
FC stack	FC or FCoE protocol capability implemented on a device to support the FC or FCoE functionality. Having an FC stack does not imply consuming a domain ID. Each FC or FCoE enabled server or storage device has an FC stack. Similarly, an FC or FCoE switch, an FCF, an FCoE-FC gateway, and an FCoE transit switch have FC stacks.
Fibre Channel switch	Network switch that implements the Fibre Channel protocol.
FIP discovery advertisement	Multicast or unicast message that the FC switch (or FCF) transmits to ENodes to advertise the switch's presence on the network so that ENodes can discover the switch and request to log in to the FC fabric. The FC switch periodically sends multicast FIP discovery advertisements to the ALL-ENode-MACs address, a well-known address to which all ENodes listen. The multicast messages advertise the FC switch to all ENodes on the VLAN and serve as keepalive messages to maintain connectivity between the FC switch and ENodes. When an ENode sends a FIP discovery solicitation message to the FC switch, the FC switch responds with a unicast FIP discovery advertisement to that ENode.
FIP discovery solicitation	Multicast or unicast message that an ENode transmits to FC switches (or FCFs) to find compatible switches in the network. When an ENode initializes, it sends a multicast FIP discovery solicitation to the ALL-FCF-MACs address, a well-known address to which all FC switches and FCFs listen. Compatible switches reply with a unicast FIP discovery advertisement. The ENode compiles a list of compatible switches, selects a switch, and logs in to that switch.
FIP keepalive	Periodic multicast FIP discovery advertisement sent from the FC switch or FCF to all ENodes to maintain connectivity.

Table 377: Fibre Channel Terms *(continued)*

Term	Definition
FIP snooping	For VN_Port to VF_Port (VN2VF) paths (Technical Committee T11 BB-FC-5 specification), FIP snooping is a security feature enabled for FCoE VLANs on an Ethernet switch that connects ENodes to FC switches or FCFs. FIP snooping inspects data in FIP frames and uses that data to create firewall filters. The filters permit only traffic from sources that perform a successful FLOGI to the FC switch. All other traffic on the VLAN is denied. FIP snooping filters are installed on the ports in the FCoE VLAN. For VN_Port to VN_Port (VN2VN) paths (Technical Committee T11 BB-FC-6 specification), the FIP snooping security feature filters access between VN_Ports in a similar manner to VN2VF_Port FIP snooping. FIP snooping can also apply similarly to VE_Port to VE_Port (VE2VE) paths. FIP snooping can also snoop to provide additional visibility of FCoE Layer 2 operation. See also *FCoE node (ENode)*.
FIP snooping bridge	See *FCoE transit switch* and *FIP snooping*.
host bus adapter (HBA)	Physical mechanism that connects a host system to other FC network and storage devices. HBAs have a unique worldwide node name (WWNN) for the HBA node, which all of the ports on the HBA share, and each port on an HBA has a unique worldwide port name (WWPN).
initiator	System component that originates an I/O command over an I/O bus or network. An FCoE server sending a request to an FC storage device is an example of an initiator.
iSCSI transit switch	Layer 2 Ethernet switch with a minimum set of best-practice Ethernet features to support iSCSI, along with optional enhancements. Minimum feature support is: • IEEE 802.3X asymmetric and symmetric flow control on ports not running in DCB mode • Priority-based flow control (PFC) • Enhanced transmission selection (ETS) • Data Center Bridging Capability Exchange Protocol (DCBX), including the iSCSI application TLV Other capabilities such as Internet storage name service (iSNS) are optional.
interswitch link (ISL)	Link between the *E_Ports* of two FC switches in a common FC fabric. When two FCoE-based FC switches are connected together, there is a virtual ISL through Layer 2.
logout (LOGO)	For FC devices, an N_Port logs out from the FC network by sending an FC LOGO message to the F_Port of an FC switch. The switch can also send a LOGO message to an N_Port to terminate its connection. For FCoE devices, a VN_Port logs out from the FC network by sending a FIP LOGO message to the VF_Port of an FC switch. The switch can also send a LOGO message to a VN_Port to terminate its connection.

Table 377: Fibre Channel Terms *(continued)*

Term	Definition
lossless Ethernet MAC	Full-duplex Ethernet MAC that implements Ethernet extensions to avoid Ethernet frame loss due to congestion and supports at least 2.5-KB jumbo frames. Each lossless Ethernet MAC combines with an FCoE Controller to perform FCoE termination functions on an ENode. See also *priority-based flow control (PFC)*, *quantized congestion notification (QCN)*, *FCoE controller*, and *FCoE node (ENode)*.
lossless Ethernet network	Ethernet network composed of only full-duplex links and lossless Ethernet MACs and with CoS and flow control to prevent dropping of frames.
lossless transport	In DCB networks, the ability to switch FCoE frames over an Ethernet network without dropping any frames. Lossless transport uses mechanisms such as priority-based flow control and quantized congestion notification to control traffic flows and avoid congestion.
N_Port ID	See *Fibre Channel ID (FCID)*.
N_Port ID virtualizer	Presents itself as an FC or FCoE switch to external devices, but connects to an actual FC or FCoE switch in the other direction to provide the FC-SW services. An N_Port ID virtualizer logs in to the actual FC or FCoE switch in the same way as a normal node device and uses the NPIV mechanism to proxy incoming FLOGIs to FDISCs on the actual FC or FCoE switch. An N_Port ID virtualizes has an FC stack even though it is not an FC switch or an FCF. The acronym *NPV* is commonly used for N_Port ID virtualizer even though the acronym is not defined in the standards.
N_Port ID Virtualization (NPIV)	NPIV enables a physical N_Port to acquire multiple N_Port IDs. Each N_Port ID maps to a different application (such as a virtual machine) or to a different user. This allows you to associate one F_Port with many N_Port IDs and create multiple discrete, secure virtual links over one physical point-to-point connection. NPIV increases resource and bandwidth utilization and allows the implementation of access control, zoning, and port security on a per-application or per-user basis. After an N_Port performs a FLOGI and receives its first N_Port ID, it can request more N_Port IDs by sending FDISC messages. See also *fabric login (FLOGI)*, *fabric discovery (FDISC)*, and *virtual link*.

Table 377: Fibre Channel Terms *(continued)*

Term	Definition
node port (N_Port)	N_Ports can be in two modes: • Fabric N_Port—Node port that is an FC host or storage device end port in a point-to-point link between the device and the F_Port of an FC switch. The point-to-point link can be virtual or physical. • Point-to-point N_Port—Node port that connects to another N_Port. The QFX3500 switch does not support this configuration. N_Ports handle creation, detection, and flow of messages to and from the connected devices.
node worldwide name (NWWN)	WWN that is unique worldwide and is assigned to an FC node. An NWWN is valid for multiple ports that are on that node (this identifies the ports as network interfaces of a particular node).
port mode	Role that the port plays in the FC fabric (endpoint device, FC switch connection to endpoint devices, interswitch link). See also *node port (N_Port)*, *virtual node port (VN_Port)*, *proxy node port (NP_Port)*, *fabric port (F_Port)*, and *virtual fabric port (VF_Port)*.
port worldwide name (PWWN)	WWN that is unique worldwide and is assigned to an FC port.
priority-based flow control (PFC)	Link-level flow control mechanism defined by IEEE 802.1Qbb that allows independent flow control for each class of service (as defined in the 3-bit CoS field of the Ethernet header by IEEE 802.1Q tags) to ensure that no frame loss from congestion occurs in DCB networks. PFC is an enhancement of the Ethernet PAUSE mechanism, but PFC controls classes of flows, whereas Ethernet PAUSE indiscriminately pauses all of the traffic on a link. With PFC, a receiving device can signal a transmitting device to pause transmission based on traffic class. PFC provides application-specific bandwidth reservations so you can ensure that time-critical protocols and applications such as FCoE receive the priority necessary to prevent frame loss. PFC allows the same physical link to carry FCoE traffic and provide lossless service while also carrying loss-tolerant Ethernet traffic. See also *Ethernet PAUSE*.
proxy gateway mode	Connects FCoE initiators to FC switches in a converged Ethernet and Fibre Channel network and acts as an intermediary for these devices. The FCoE-FC gateway represents and acts for the FCoE initiators in transactions from the FCoE initiators destined for an FC switch, including converting FIP and FCoE frames to FC frames. The gateway represents and acts for an FC switch in transactions from the FC switch destined for an FCoE initiator, including converting FC frames to FIP frames and encapsulating FC frames in Ethernet.
proxy node port (NP_Port)	N_Port on the QFX Series that performs proxy functions when it is configured as an FCoE-FC gateway. The NP_Port acts as a proxy for the FCoE device VN_Ports in transactions with the FC switch.

Table 377: Fibre Channel Terms *(continued)*

Term	Definition
quantized congestion notification (QCN)	Mechanism defined by IEEE 802.1Qau that manages network congestion within a Layer 2 domain. When a queue reaches a configured threshold, QCN throttles traffic at the source of the congestion by transmitting messages that propagate back to the source and temporarily stop the source from transmitting. When the queue crosses the threshold that indicates the congestion has dissipated, QCN sends a message to allow the source to resume transmitting frames.
session	Fabric login (FLOGI) or fabric discovery (FDISC) login to the FC SAN fabric. Session does not refer to end-to-end server-to-storage sessions.
server-provided MAC address (SPMA)	MAC address that an ENode assigns to one of its ENode MACs and is not assigned to any other ENode MAC in the same FCoE VLAN. An SPMA can be associated with more than one VN_Port at that ENode MAC. The QFX Series does not support SPMA. See also *ENode MAC* and *fabric-provided MAC address (FPMA)*.
storage area network (SAN)	Network whose primary purpose is the transfer of data between computer systems and storage devices. This term is most commonly used in the context of any network that supports block storage, usually iSCSI, FC, and FCoE networks.
target	System component that receives an I/O command. An FC storage device that receives a request from a server is an example of a target.
VE_Port	Virtual ports created to form a connection (an *interswitch link*) between two FCoE-based FC switches as part of a common FC fabric.
VE2VE (VE_Port to VE_Port)	The *Fibre Channel Backbone - 5 (FC-BB-5) Rev 2.00* specification capability of FCFs to connect to each other as a single FCoE FC SAN.
VN2VF (VN_Port to VF_Port)	The *Fibre Channel Backbone - 5 (FC-BB-5) Rev 2.00* specification capability of an ENode to connect to an FCF or to an FCoE-enabled FC SAN.
VN2VN (VN_Port to VN_Port)	The *Fibre Channel Backbone - 6 (FC-BB-6)* specification capability of an ENode to connect directly over Layer 2 to another ENode without the need of any FC-related services. This capability is most often used in small-scale FCoE SANs.
virtual fabric port (VF_Port)	Data-forwarding component that emulates an F_Port. A VF_Port is dynamically instantiated on successful completion of a FIP FLOGI exchange and connects to one or more VN_Ports. The term *virtual* indicates the use of a non-FC link such as an FCoE link. See also *fabric port (F_Port)*.
virtual link	Logical link connecting two FCoE Link End Points (LEPs) over a lossless Ethernet network, for example, the link between a VF_Port and a VN_Port. The MAC addresses of the two LEPs identifies a virtual link. See also *FCoE link end point (LEP)* and *lossless Ethernet network*.

Table 377: Fibre Channel Terms *(continued)*

Term	Definition
virtual node port (VN_Port)	Data-forwarding component that emulates an N_Port. With FCoE, a VN_Port is dynamically instantiated on successful completion of a FIP FLOGI exchange and connects to one or more VF_Ports. The term *virtual* indicates the use of a non-FC link such as an FCoE link. VN_Port is also used for the virtual N_Ports created in both FC and FCoE when additional NPIV-based logins occur over a previously created N_Port-to-VN_Port or N_Port-to-VF_Port connection. See also *node port (N_Port)*.
well-known address (WKA)	Address identifier used to access a service provided by an FC fabric. The service can be distributed in many elements throughout a fabric, or it can be centralized in one element. A WKA is always accessible, regardless of zoning. An example of a WKA is the *ALL-FCF-MACs* address to which all FCFs listen.
worldwide name (WWN)	64-bit identifier that is similar to a MAC address except that it is not used for forwarding. It uniquely identifies an FC device. The WWN is derived from the IEEE organizationally unique identifier (OUI) and vendor-supplied information. A WWN is unique worldwide.
worldwide node name (WWNN)	See *node worldwide name (NWWN)*.
worldwide port name (WWPN)	See *port worldwide name (PWWN)*.

DCBX

Understanding DCBX

Data Center Bridging Capability Exchange protocol (DCBX) is an extension of Link Layer Data Protocol (LLDP). If you disable LLDP on an interface, that interface cannot run DCBX. If you attempt to enable DCBX on an interface on which LLDP is disabled, the configuration commit operation fails. Data center bridging (DCB) devices use DCBX to exchange configuration information with directly connected peers.

This topic describes:

- DCBX and PFC on page 4912
- DCBX and ETS on page 4912

DCBX Basics

DCBX can:

- Discover the DCB capabilities of peers.
- Detect DCB feature misconfiguration or mismatches between peers.
- Configure DCB features on peers.

You can configure DCBX operation for priority-based flow control (PFC), Layer 2 and Layer 4 applications such as FCoE and iSCSI, and ETS. DCBX is enabled or disabled on a per-interface basis.

By default, for PFC and ETS, DCBX automatically negotiates administrative state and configuration with each interface's connected peer. To enable DCBX negotiation for applications, you must configure the applications, map them to IEEE 802.1p code points in an application map, and apply the application map to interfaces.

The FCoE application only needs to be included in an application map when you want an interface to exchange type, length, and values (TLVs) for other applications in addition to FCoE. If FCoE is the only application you want an interface to advertise, then you do not need to use an application map. For ETS, DCBX pushes the switch configuration to peers if they are set to learn the configuration from the switch (unless you disable sending the ETS recommendation TLV on interfaces in IEEE DCBX mode).

You can override the default behavior for PFC, for ETS, or for all applications mapped to an interface by turning off autonegotiation to force an interface to enable or disable that feature. You can also disable DCBX autonegotiation for applications on an interface by excluding those applications from the application map you apply to that interface or by deleting the application map from the interface.

The default autonegotiation behavior for applications that are mapped to an interface is:

- DCBX is enabled on the interface if the connected peer device also supports DCBX.
- DCBX is disabled on the interface if the connected peer device does not support DCBX.

During negotiation of capabilities, the switch can push the PFC configuration to an attached peer if the peer is configured as “willing” to learn the PFC configuration from other peers. The Juniper Networks switch does not support self autoprovisioning and does not change its configuration during autonegotiation to match the peer configuration. (The Juniper switch is not “willing” to learn the PFC configuration from peers.)

NOTE: When a port with DCBX enabled begins to exchange type, length, and value (TLV) entries, optional LLDP TLVs on that port are not advertised to neighbors, so that the switch can interoperate with a wider variety of converged network adapters (CNAs) and Layer 2 switches that support DCBX.

DCBX Modes and Support

This section describes DCBX support on the QFX Series:

- DCBX Modes (Versions) on page 4907
- Autonegotiation on page 4909
- CNA Support for DCBX Modes on page 4909
- Interface Support for DCBX on page 4909

DCBX Modes (Versions)

The QFX Series supports the two most common DCBX modes:

- IEEE DCBX—The newest DCBX version. Different TLVs have different subtypes (for example, the subtype for the ETS configuration TLV is 9); the IEEE DCBX Organizationally Unique Identifier (OUI) is 0x0080c2.
- DCBX version 1.01—The Converged Enhanced Ethernet (CEE) version of DCBX. It has a subtype of 2 and an OUI of 0x001b21.

IEEE DCBX and DCBX version 1.01 differ mainly in frame format. DCBX version 1.01 uses one TLV that includes all DCBX attribute information, which is sent as sub-TLVs. IEEE DCBX uses a unique TLV for each DCB attribute.

NOTE: **The QFX Series does not support pre-CEE (pre-DCB) DCBX versions. Unsupported older versions of DCBX have a subtype of 1 and an OUI of 0x001b21. The QFX Series drops LLDP frames that contain pre-CEE DCBX TLVs.**

Table 378 on page 4907 summarizes the differences between IEEE DCBX and DCBX version 1.01, including show command output:

Table 378: Summary of Differences Between IEEE DCBX and DCBX Version 1.01

Characteristic	IEEE DCBX	DCBX Version 1.01
OUI	0x0080c2	0x001b21
Frame Format	Sends a separate, unique TLV for each DCBX attribute. For example, IEEE DCBX uses separate TLVs for ETS, PFC, and each application. Configuration and Recommendation information is sent in different TLVs	Sends one TLV that includes all DCBX attribute information organized in sub-TLVs. The “willing” bit determines whether or not an interface can change its configuration to match the connected peer.
Symmetric/asymmetric configuration with peer	Asymmetric or symmetric	Symmetric only

Table 378: Summary of Differences Between IEEE DCBX and DCBX Version 1.01 *(continued)*

Characteristic	IEEE DCBX	DCBX Version 1.01
Differences in the **show dcbx interface** ***interface-name*** operational command	• Synchronization information is not shown because symmetric configuration is not required. • Operational state information is not shown because the operational states do not have to be symmetric. • TLV type is shown because unique TLVs are sent for each DCBX attribute. • ETS peer Configuration TLV and Recommendation TLV information is shown separately because they are different TLVs.	• Synchronization information is shown because symmetric configuration is required. • Operational state information is shown because the operational states do have to be symmetric. • TLV type is not shown because one TLV is used for all attribute information. • Recommendation TLV is not sent (DCBX Version 1.01 uses the “willing” bit to determine whether or not an interface uses the peer interface configuration).

For more information about how each DCBX mode exchanges TLVs, see the following specifications:

- For DCBX version 1.01—http://www.ieee802.org/1/files/public/docs2008/az-wadekar-dcbx-capability-exchange-discovery-protocol-1108-v1.01.pdf
- For IEEE DCBX—http://www.ieee802.org/1/files/private/az-drafts/d2/802-1az-d2-4.pdf

NOTE: **As of Junos OS Release 12.2, this document is located in a private area of the IEEE website, and access requires a password from the IEEE organization. If you are not an IEEE member, you might not be able to access this document until it moves to the public area of the IEEE website.**

You can configure interfaces to use the following DCBX modes:

- IEEE DCBX—The interface uses IEEE DCBX regardless of the configuration on the connected peer.
- DCBX version 1.01—The interface uses DCBX version 1.01 regardless of the configuration on the connected peer.
- Autonegotiation—The interface automatically negotiates with the connected peer to determine the DCBX version the peers use. Autonegotiation is the default DCBX mode.

If you configure a DCBX mode on an interface, the interface ignores DCBX protocol data units (PDUs) it receives from the connected peer if the PDUs do not match the DCBX version configured on the interface. For example, if you configure an interface to use IEEE DCBX and the connected peer sends DCBX version 1.01 LLDP PDUs, the interface ignores the version 1.01 PDUs. If you configure an interface to use DCBX version 1.01 and the peer sends IEEE DCBX LLDP PDUs, the interface ignores the IEEE DCBX PDUs.

NOTE: On interfaces that use the IEEE DCBX mode, the **show dcbx neighbors interface** *interface-name* operational command does not include application, PFC, or ETS operational state in the output.

Autonegotiation

Autonegotiation is the default DCBX mode. Each interface automatically negotiates with its connected peer to determine the DCBX version that both interfaces use to exchange DCBX information.

When an interface connects to its peer interface, the interface advertises IEEE DCBX TLVs to the peer. If the interface receives one IEEE DCBX PDU from the peer, the interface sets the DCBX mode as IEEE DCBX. If the interface receives three DCBX version 1.01 TLVs from the peer, the interface sets DCBX version 1.01 as the DCBX mode.

Autonegotiation works slightly differently on QFX3500 switches and QFabric systems:

- QFX3500 switch—When an interface connects to its peer interface, the interface advertises IEEE DCBX TLVs to the peer. If the interface receives an IEEE DCBX TLV from the peer, the interface sets IEEE DCBX as the DCBX mode. If the interface receives three consecutive DCBX version 1.01 TLVs from the peer, the interface sets DCBX version 1.01 as the DCBX mode.
- QFabric system—When an interface connects to its peer interface, the interface advertises DCBX version 1.01 TLVs to the peer. If the interface receives an IEEE DCBX TLVs from the peer, the interface sets IEEE DCBX as the DCBX mode. If the interface receives three consecutive DCBX version 1.01 TLVs from the peer, the interface retains DCBX version 1.01 as the DCBX mode.

NOTE: If the link flaps or the LLDP process restarts, the interface starts the autonegotiation process again. The interface does not use the last received DCBX communication mode.

CNA Support for DCBX Modes

Different CNA vendors support different versions and capabilities of DCBX. The DCBX configuration you use on QFX Series interfaces depends on the DCBX features that the CNAs in your network support.

Interface Support for DCBX

You can configure DCBX on 10-Gigabit Ethernet interfaces and on link aggregation group (LAG) interfaces whose member interfaces are all 10-Gigabit Ethernet interfaces.

DCBX Attribute Types

DCBX has three attribute types:

- Informational—These attributes are exchanged using LLDP, but do not affect DCBX state or operation; they only communicate information to the peer. For example, application priority TLVs are informational TLVs.
- Asymmetric—The values for these types of attributes do not have to be the same on the connected peer interfaces. Peers exchange asymmetric attributes when the attribute values can differ on each peer interface. The peer interface configurations might match or they might differ. For example, ETS Configuration and Recommendation TLVs are asymmetric TLVs.
- Symmetric—The intention is that the values for these types of attributes should be the same on both of the connected peer interfaces. Peer interfaces exchange symmetric attributes to ensure symmetric DCBX configuration for those attributes. For example, PFC Configuration TLVs are symmetric TLVs.

The following sections describe asymmetric and symmetric DCBX attributes:

Asymmetric Attributes

DCBX passes asymmetric attributes between connected peer interfaces to communicate parameter information about those attributes (features). The resulting configuration for an attribute might be different on each peer, so the parameters configured on one interface might not match the parameters on the connected peer interface.

There are two types of asymmetric attribute TLVs:

- Configuration TLV—Configuration TLVs communicate the current operational state and the state of the “willing” bit. The “willing” bit communicates whether or not the interface is willing to accept and use the configuration from the peer interface. If an interface is “willing,” the interface uses the configuration it receives from the peer interface. (The peer interface configuration can override the configuration on the “willing” interface.) If an interface is “not willing”, the configuration on the interface cannot be overridden by the peer interface configuration.
- Recommendation TLV—Recommendation TLVs communicate the parameters the interface recommends that the connected peer interface should use. When an interface sends a Recommendation TLV, if the connected peer is “willing,” the connected peer changes its configuration to match the parameters in the Recommendation TLV.

Symmetric Attributes

DCBX passes symmetric attributes between connected peer interfaces to communicate parameter information about those attributes (features), with the objective that both interfaces should use the same configuration. The intent is that the parameters configured on one interface should match the parameters on the connected peer interface.

There is one type of symmetric attribute TLV, the Configuration TLV. As with asymmetric attributes, symmetric attribute Configuration TLVs communicate the current operational state and the state of the “willing” bit. “Willing” interfaces use the peer interface parameter values for the attribute. (The attribute configuration of the peer overrides the configuration on the “willing” interface.)

DCBX Application Protocol TLV Exchange

DCBX advertises the switch’s capabilities for Layer 2 applications such as FCoE and Layer 4 applications such as iSCSI:

Application Protocol TLV Exchange

For all applications, DCBX advertises the application’s state and IEEE 802.1p code points on the interfaces to which the application is mapped. If an application is not mapped to an interface, that interface does not advertise the application’s TLVs. There is an exception for FCoE application protocol TLV exchange when FCoE is the only application you want DCBX to advertise on an interface.

FCoE Application Protocol TLV Exchange

Protocol TLV exchange for the FCoE application depends on whether FCoE is the only application you want the interface to advertise or whether you want the interface to exchange other application TLVs in addition to FCoE TLVs.

If FCoE is the only application you want DCBX to advertise on an interface, DCBX exchanges FCoE application protocol TLVs by default if the interface:

- Carries FCoE traffic (traffic mapped by CoS configuration to the FCoE forwarding class)
- Has a congestion notification profile with PFC enabled on the FCoE priority (IEEE 802.1p code point)
- Does *not* have an application map

NOTE: **If no CoS configuration for FCoE is mapped to an interface, that interface does not exchange FCoE application protocol TLVs.**

If you want DCBX to advertise FCoE and other applications on an interface, you must specify all of the applications, including FCoE, in an application map, and apply the application map to the desired interfaces.

NOTE: **If an application map is applied to an interface, the FCoE application must be explicitly configured in the application map, or the interface does not exchange FCoE TLVs.**

When DCBX advertises the FCoE application, it advertises the FCoE state and IEEE 802.1p code points. If a peer device connected to a switch interface does not support FCoE, DCBX uses autonegotiation to mark the interface as "FCoE down," and FCoE is disabled on that interface.

Disabling Application Protocol TLV Exchange

To disable DCBX application protocol exchange for all applications on an interface, issue the **set protocols dcbx interface** ***interface-name*** **applications no-auto-negotiation** command.

You can also disable DCBX application protocol exchange for applications on an interface by deleting the application map from the interface, or by deleting a particular application from the application map. However, when you delete an application from an application map, the application protocol is no longer exchanged on any interface which uses that application map.

DCBX and PFC

After you enable PFC on a switch interface, DCBX uses autonegotiation to control the operational state of the PFC functionality.

If the peer device connected to the interface supports PFC and is provisioned compatibly with the switch, DCBX sets the PFC operational state to enabled. If the peer device connected to the interface does not support PFC or is not provisioned compatibly with the switch, DCBX sets the operational state to disabled. (PFC must be symmetrical.)

If the peer advertises that it is "willing" to learn its PFC configuration from the switch, DCBX pushes the switch's PFC configuration to the peer and does not check the peer's administrative state.

You can manually override DCBX control of the PFC operational state on a per-interface basis by disabling autonegotiation. If you disable autonegotiation on an interface on which you have configured PFC, then PFC is enabled on that interface regardless of the peer configuration. To disable PFC on an interface, do not configure PFC on that interface.

DCBX and ETS

This section describes:

Default DCBX ETS Advertisement

If you do not configure ETS on an interface, the switch automatically creates a default priority group that contains all of the priorities (forwarding classes, which represent output queues) and assigns 100 percent of the port output bandwidth to that priority group. The default priority group is transparent. It does not appear in the configuration and is used for DCBX advertisement. DCBX advertises the default priority group, its priorities, and the assigned bandwidth.

If you configure ETS on an interface, DCBX advertises:

- Each priority group on the interface

- The priorities in each priority group
- The bandwidth properties of each priority group and priority

Any priority on that interface that is not part of an explicitly configured priority group (forwarding class set) is assigned to the automatically generated default priority group and receives no bandwidth. If you configure ETS on an interface, every forwarding class (priority) on that interface for which you want to forward traffic must belong to a forwarding class set (priority group).

ETS Advertisement and Peer Configuration

DCBX does not control the switch's ETS (hierarchical scheduling) operational state. If the connected peer is configured as "willing," DCBX pushes the switch's ETS configuration to the switch's peers if the ETS Recommendation TLV is enabled (it is enabled by default). If the peer does not support ETS or is not consistently provisioned with the switch, DCBX does not change the ETS operational state on the switch. The ETS operational state remains enabled or disabled based only on the switch hierarchical scheduling configuration and is enabled by default.

When ETS is configured, DCBX advertises the priority groups, the priorities in the priority groups, and the bandwidth configuration for the priority groups and priorities. Any priority (essentially a forwarding class or queue) that is not part of a priority group has no scheduling properties and receives no bandwidth.

You can manually override whether DCBX advertises the ETS state to the peer on a per-interface basis by disabling autonegotiation. This does not affect the ETS state on the switch or on the peer , but it does prevent the switch from sending the Recommendation TLV or the Configuration TLV to the connected peer. To disable ETS on an interface, do not configure priority groups (forwarding class sets) on the interface.

ETS Recommendation TLV

The ETS Recommendation TLV communicates the ETS settings that the switch wants the connected peer interface to use. If the peer interface is "willing," it changes its configuration to match the configuration in the ETS Recommendation TLV. By default, the switch interfaces send the ETS Recommendation TLV to the peer. The settings communicated are the egress ETS settings defined by configuring hierarchical scheduling on the interface.

We recommend that you use the same ETS settings on the connected peer that you use on the switch interface and that you leave the ETS Recommendation TLV enabled. However, on interfaces that use IEEE DCBX as the DCBX mode, if you want an asymmetric configuration between the switch interface and the connected peer, you can disable the ETS Recommendation TLV by including the **no-recommendation-tlv** statement at the **[edit protocols dcbx interface *interface-name* enhanced-transmission-selection]** hierarchy level.

NOTE: You can disable the ETS Recommendation TLV only when the DCBX mode on the interface is IEEE DCBX. Disabling the ETS Recommendation TLV has no effect if the DCBX mode on the interface is DCBX version 1.01. (IEEE DCBX uses separate application attribute TLVs, but DCBX version 1.01 sends all application attributes in the same TLV and uses sub-TLVs to separate the information.)

If you disable the ETS Recommendation TLV, the switch still sends the ETS Configuration TLV to the connected peer. The result is that the connected peer is informed about the switch DCBX ETS configuration, but even if the peer is “willing,” the peer does not change its configuration to match the switch configuration. This is asymmetric configuration—the two interfaces can have different parameter values for the ETS attribute.

For example, if you want a CNA connected to a switch interface to have different bandwidth allocations than the switch ETS configuration, you can disable the ETS Recommendation TLV and configure the CNA for the desired bandwidth. The switch interface and the CNA exchange configuration parameters, but the CNA does not change its configuration to match the switch interface configuration.

Understanding DCBX Application Protocol TLV Exchange

Data Center Bridging Capability Exchange protocol (DCBX) discovers the data center bridging (DCB) capabilities of connected peers. DCBX also advertises the capabilities of applications on interfaces by exchanging application protocol information through application type, length, and value (TLV) elements. DCBX is an extension of Link Layer Discovery Protocol (LLDP). LLDP must remain enabled on every interface on which you want to use DCBX.

NOTE: **LLDP and DCBX are enabled by default on all interfaces.**

Setting up application protocol exchange consists of:

- Defining applications
- Mapping the applications to IEEE 802.1p code points in an *application map*
- Configuring classifiers to prioritize incoming traffic and map the incoming traffic to the application by the traffic code points
- Applying the application maps and classifiers to interfaces

You need to explicitly define the applications that you want an interface to advertise. The FCoE application is a special case (see "Applications" on page 4915) and only needs to be defined on an interface if you want DCBX to exchange application protocol TLVs for other applications in addition to FCoE on that interface.

You also need to explicitly map all defined applications that you want an interface to advertise to IEEE 802.1p code points in an application map. The FCoE application is a special case (see "Application Maps" on page 4916) and only requires inclusion in an application map when you want an interface to use DCBX for other applications in addition to FCoE, as described later in this topic.

This topic describes:

Applications

Before an interface can exchange application protocol information, you need to define the applications that you want to advertise, except FCoE if FCoE is the only application that you want the interface to advertise.

NOTE: If FCoE is the only application that you want DCBX to advertise on an interface, DCBX exchanges FCoE application protocol TLVs by default if the interface:

- Carries FCoE traffic (traffic mapped by CoS configuration to the FCoE forwarding class and applied to the interface)
- Has a congestion notification profile with PFC enabled on the FCoE priority (IEEE 802.1p code point)
- Does *not* have an application map

If you apply an application map to an interface, then all applications that you want DCBX to advertise must be defined and configured in the application map, including the FCoE application.

If no CoS configuration for FCoE is mapped to an interface, that interface does not exchange FCoE application protocol TLVs.

You can define:

- Layer 2 applications by EtherType
- Layer 4 applications by a combination of protocol (TCP or UDP) and destination port number

The EtherType is a two-octet field in the Ethernet frame that denotes the protocol encapsulated in the frame. For a list of common EtherTypes, see http://standards.ieee.org/develop/regauth/ethertype/eth.txt on the IEEE standards organization website. For a list of port numbers and protocols, see the *Service Name and Transport Protocol Port Number Registry* at http://www.iana.org/assignments/service-names-port-numbers/service-names-port-numbers.xml on the Internet Assigned Numbers Authority (IANA) website.

You must explicitly define each application that you want to advertise, except FCoE. The FCoE application is defined by default (EtherType 0x8906).

Application Maps

An application map maps defined applications to one or more IEEE 802.1p code points. Each application map contains one or more applications. DCBX includes the configured application code points in the protocol TLVs exchanged with the connected peer.

To exchange protocol TLVs for an application, you must include the application in an application map. The FCoE application is a special case:

- If you want DCBX to exchange application protocol TLVs for more than one application on a particular interface, you must configure the applications, define an application map to map the applications to code points, and apply the application map to the interface. In this case, you must also define the FCoE application and add it to the application map.

This is the same process and treatment required for all other applications. In addition, for DCBX to exchange FCoE application TLVs, you must enable priority-based flow control (PFC) on the FCoE priority (the FCoE IEEE 802.1p code point) on the interface.

- If FCoE is the only application that you want DCBX to advertise on an interface, then you do not need to configure an application map and apply it to the interface. By default, when an interface has no application map, and the interface carries traffic mapped to the FCoE forwarding class, and PFC is enabled on the FCoE priority, the interface advertises FCoE TLVs (autonegotiation mode). DCBX exchanges FCoE application protocol TLVs by default until you apply an application map to the interface, remove the FCoE traffic from the interface (you can do this by removing the or editing the classifier for FCoE traffic), or disable PFC on the FCoE priority.

  If you apply an application map to an interface that did not have an application map and was exchanging FCoE application TLVs, and you do not include the FCoE application in the application map, the interface stops exchanging FCoE TLVs. Every interface that has an application map must have FCoE included in the application map (and PFC enabled on the FCoE priority) in order for DCBX to exchange FCoE TLVs.

Mapping an application to code points does two things:

- Maps incoming traffic with the same code points to that application
- Allows you to configure classifiers that map incoming application traffic, by code point, to a forwarding class and a loss priority, in order to apply class of service (CoS) to application traffic and prioritize application traffic

You apply an application map to an interface to enable DCBX application protocol exchange on that interface for each application specified in the application map. All of the applications that you want an interface to advertise must be configured in the application map that you apply to the interface, with the previously noted exception for the FCoE application when FCoE is the only application for which you want DCBX to exchange protocol TLVs on an interface.

Classifying and Prioritizing Application Traffic

When traffic arrives at an interface, the interface classifies the incoming traffic based on its code points. Classifiers map code points to loss priorities and forwarding classes. The loss priority prioritizes the traffic. The forwarding class determines the traffic output queue and CoS service level.

When you map an application to an IEEE 802.1p code point in an application map and apply the application map to an interface, incoming traffic on the interface that matches the application code points is mapped to the appropriate application. The application receives the loss priority and the CoS associated with the forwarding class for those code points, and is placed in the output queue associated with the forwarding class.

You can use the default classifier or you can configure a classifier to map the application code points defined in the application map to forwarding classes and loss priorities.

Enabling Interfaces to Exchange Application Protocol Information

Each interface with the **fcoe** forwarding class and PFC enabled on the FCoE code point is enabled for FCoE application protocol exchange by default until you apply an application map to the interface. If you apply an application map to an interface and you want that interface to exchange FCoE application protocol TLVs, you must include the FCoE application in the application map. (In all cases, to achieve lossless transport, you must also enable PFC on the FCoE code point or code points.)

Except when FCoE is the only protocol you want DCBX to advertise on an interface, interfaces on which you want to exchange application protocol TLVs must include the following two items:

- The application map that contains the application(s)
- A classifier

NOTE: You must also enable PFC on the code point of any traffic for which you want to achieve lossless transport.

Disabling DCBX Application Protocol Exchange

To disable DCBX application protocol exchange for all applications on an interface, issue the **set protocols dcbx interface** ***interface-name*** **applications no-auto-negotiation** command.

You can also disable DCBX application protocol exchange for applications on an interface by deleting the application map from the interface, or by deleting a particular application from the application map. However, when you delete an application from an application map, the application protocol is no longer exchanged on any interface which uses that application map.

On interfaces that use IEEE DCBX mode to exchange DCBX parameters, you can disable sending the enhanced transmission selection (ETS) Recommendation TLV to the peer if you want an asymmetric ETS configuration between the peers.

CHAPTER 59

Configuration

Configuration Examples

Example: Configuring CoS PFC for FCoE Traffic

Priority-based flow control (PFC, described in IEEE 802.1Qbb) is a link-level flow control mechanism that you apply at ingress interfaces. PFC enables you to divide traffic on one physical link into eight priorities. You can think of the eight priorities as eight “lanes” of traffic that correspond to queues (forwarding classes). Each priority is mapped to a 3-bit IEEE 802.1p CoS flag in the VLAN header.

You can selectively apply PFC to the traffic in any queue without pausing the traffic in other queues on the same link. You must apply PFC to FCoE traffic to ensure lossless transport.

To configure PFC on FCoE traffic, use the default FCoE forwarding-class-to-queue mapping and:

- Configure a classifier that associates the FCoE forwarding class with FCoE traffic.
- Configure a congestion notification profile to apply PFC to the FCoE traffic.
- Apply the classifier and the PFC configuration to ingress interfaces.
- Configure the bandwidth scheduling for the FCoE forwarding class output queue.

- Create a forwarding class set (priority group) that includes the FCoE forwarding class; this is required to configure enhanced transmission selection (ETS) and support data center bridging (DCB).
- Configure the bandwidth scheduling for the FCoE priority group.
- Apply the scheduling to the egress interfaces.

NOTE: If you are using Junos OS Release 12.2 or later, use the default forwarding classes for the lossless **fcoe** forwarding class. If you explicitly configure default lossless forwarding classes, the traffic mapped to those forwarding classes is treated as lossy (**best-effort**) traffic and does *not* receive lossless treatment.

In Junos OS Release 12.3 and later, you can include the *no-loss* packet drop attribute in explicit forwarding class configurations to configure a lossless forwarding class.

This example describes how to configure PFC for FCoE traffic:

Requirements

This example uses the following hardware and software components:

- A Juniper Networks QFX3500 Switch
- Junos OS Release 11.1 or later for the QFX Series

Overview

FCoE traffic requires PFC to ensure lossless packet transport. This example shows you how to:

- Assign FCoE traffic to the FCoE priority at the ingress.
- Create and apply CoS for the FCoE traffic using ETS (hierarchical port scheduling).
- Apply PFC to the FCoE traffic.
- Apply the configuration to ingress and egress interfaces.

NOTE: Configuring or changing PFC on an interface blocks the entire port until the PFC change is completed. After a PFC change is completed, the port is unblocked and traffic resumes. Blocking the port stops ingress and egress traffic, and causes packet loss on all queues on the port until the port is unblocked.

Each interface in this example is configured as both an ingress interface and an egress interface, so the classifier, congestion notification profile, and port scheduling are applied to all of the interfaces.

Topology

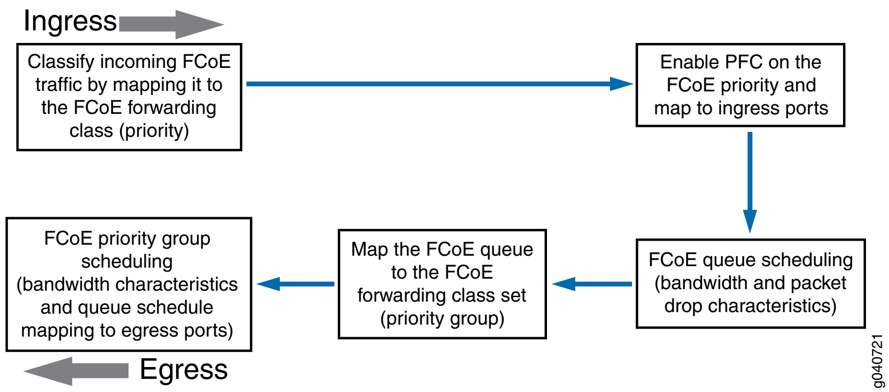
Table 379 on page 4923 shows the configuration components for this example.

Table 379: Components of the PFC for FCoE Traffic Configuration Topology

Component	Settings
Hardware	QFX3500 switch
Behavior aggregate classifier (maps the FCoE forwarding class to incoming packets by IEEE 802.1 code point)	Code point **011** to forwarding class **fcoe** and loss priority **low** Ingress interfaces: **xe-0/0/31**, **xe-0/0/32**, **xe-0/0/33**, **xe-0/0/34**
PFC congestion notification profile	**fcoe-cnp**: Code point **011** Ingress interfaces: **xe-0/0/31**, **xe-0/0/32**, **xe-0/0/33**, **xe-0/0/34**
FCoE queue scheduler	**fcoe-sched**: Minimum bandwidth **3g** Maximum bandwidth **100%** Priority **low**
Forwarding class-to-scheduler mapping	Scheduler map **fcoe-map**: Forwarding class **fcoe** Scheduler **fcoe-sched**
Forwarding class set (FCoE priority group)	**fcoe-pg**: Forwarding class **fcoe** Egress interfaces: **xe-0/0/31**, **xe-0/0/32**, **xe-0/0/33**, **xe-0/0/34**
Traffic control profile	**fcoe-tcp**: Scheduler map **fcoe-map** Minimum bandwidth **3g** Maximum bandwidth **100%**

Figure 179 on page 4924 shows a block diagram of the configuration components and the configuration flow of the CLI statements used in the example.

Figure 179: PFC for FCoE Traffic Configuration Components Block Diagram



Configuration

CLI Quick Configuration

To quickly configure PFC for FCoE traffic, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level:

```
[edit class-of-service]
set classifiers ieee-802.1 fcoe-classifier forwarding-class fcoe loss-priority low code-points 011
set congestion-notification-profile fcoe-cnp input ieee-802.1 code-point 011 pfc
set interfaces xe-0/0/31 unit 0 classifiers ieee-802.1 fcoe-classifier
set interfaces xe-0/0/32 unit 0 classifiers ieee-802.1 fcoe-classifier
set interfaces xe-0/0/33 unit 0 classifiers ieee-802.1 fcoe-classifier
set interfaces xe-0/0/34 unit 0 classifiers ieee-802.1 fcoe-classifier
set interfaces xe-0/0/31 congestion-notification-profile fcoe-cnp
set interfaces xe-0/0/32 congestion-notification-profile fcoe-cnp
set interfaces xe-0/0/33 congestion-notification-profile fcoe-cnp
set interfaces xe-0/0/34 congestion-notification-profile fcoe-cnp
set schedulers fcoe-sched priority low transmit-rate 3g
set schedulers fcoe-sched shaping-rate percent 100
set scheduler-maps fcoe-map forwarding-class fcoe scheduler fcoe-sched
set forwarding-class-sets fcoe-pg class fcoe
set traffic-control-profiles fcoe-tcp scheduler-map fcoe-map guaranteed-rate 3g
set traffic-control-profiles fcoe-tcp shaping-rate percent 100
set interfaces xe-0/0/31 forwarding-class-set fcoe-pg output-traffic-control-profile fcoe-tcp
set interfaces xe-0/0/32 forwarding-class-set fcoe-pg output-traffic-control-profile fcoe-tcp
set interfaces xe-0/0/33 forwarding-class-set fcoe-pg output-traffic-control-profile fcoe-tcp
set interfaces xe-0/0/34 forwarding-class-set fcoe-pg output-traffic-control-profile fcoe-tcp
```

Step-by-Step Procedure

To configure the FCoE forwarding class (priority), ingress classifier, output queue scheduling, forwarding class set (priority group) and its output port scheduling, PFC application, and interfaces to set up PFC for FCoE traffic:

1. Configure a classifier to set the loss priority and IEEE 802.1 code point assigned to the FCoE forwarding class at the ingress:

   ```
   [edit class-of-service]
   user@switch# set classifiers ieee-802.1 fcoe-classifier forwarding-class fcoe loss-priority low code-points 011
   ```

2. Configure PFC on the FCoE queue by applying FCoE to the IEEE 802.1 code point **011**:

```
[edit class-of-service]
user@switch# set congestion-notification-profile fcoe-cnp input ieee-802.1 code-point
011 pfc
```

3. Apply the PFC configuration to the ingress interfaces:

```
[edit class-of-service]
user@switch# set interfaces xe-0/0/31 congestion-notification-profile fcoe-cnp
user@switch# set interfaces xe-0/0/32 congestion-notification-profile fcoe-cnp
user@switch# set interfaces xe-0/0/33 congestion-notification-profile fcoe-cnp
user@switch# set interfaces xe-0/0/34 congestion-notification-profile fcoe-cnp
```

4. Assign the classifier to the ingress interfaces:

```
[edit class-of-service]
user@switch# set interfaces xe-0/0/31 unit 0 classifiers ieee-802.1 fcoe-classifier
user@switch# set interfaces xe-0/0/32 unit 0 classifiers ieee-802.1 fcoe-classifier
user@switch# set interfaces xe-0/0/33 unit 0 classifiers ieee-802.1 fcoe-classifier
user@switch# set interfaces xe-0/0/34 unit 0 classifiers ieee-802.1 fcoe-classifier
```

5. Configure output scheduling for the FCoE queue:

```
[edit class-of-service]
user@switch# set schedulers fcoe-sched priority low transmit-rate 3g
user@switch# set schedulers fcoe-sched shaping-rate percent 100
```

6. Map the FCoE forwarding class to the FCoE scheduler:

```
[edit class-of-service]
user@switch# set scheduler-maps fcoe-map forwarding-class fcoe scheduler fcoe-sched
```

7. Configure the forwarding class set for the FCoE traffic:

```
[edit class-of-service]
user@switch# set forwarding-class-sets fcoe-pg class fcoe
```

8. Define the traffic control profile for the FCoE forwarding class set:

```
[edit class-of-service]
user@switch# set traffic-control-profiles fcoe-tcp scheduler-map fcoe-map
guaranteed-rate 3g
user@switch# set traffic-control-profiles fcoe-tcp shaping-rate percent 100
```

9. Apply the FCoE forwarding class set and traffic control profile to the egress ports:

```
[edit class-of-service]
user@switch# set interfaces xe-0/0/31 forwarding-class-set fcoe-pg
output-traffic-control-profile fcoe-tcp
user@switch# set interfaces xe-0/0/32 forwarding-class-set fcoe-pg
output-traffic-control-profile fcoe-tcp
user@switch# set interfaces xe-0/0/33 forwarding-class-set fcoe-pg
output-traffic-control-profile fcoe-tcp
user@switch# set interfaces xe-0/0/34 forwarding-class-set fcoe-pg
output-traffic-control-profile fcoe-tcp
```

Results

Display the results of the configuration (the system shows only the explicitly configured parameters; it does not show default parameters such as the **fcoe** lossless forwarding class):

```
user@switch> show configuration class-of-service
classifiers {
```

```
ieee-802.1 fcoe-classifier {
   forwarding-class fcoe {
      loss-priority low code-points 011;
   }
}
traffic-control-profiles {
   fcoe-tcp {
      scheduler-map fcoe-map;
      shaping-rate percent 100;
      guaranteed-rate 3000000000;
   }
}
forwarding-class-sets {
   fcoe-pg {
      class fcoe;
   }
}
congestion-notification-profile {
   fcoe-cnp {
      input {
         ieee-802.1 {
            code-point 011 {
               pfc;
            }
         }
      }
   }
}
interfaces {
   xe-0/0/31 {
      congestion-notification-profile fcoe-cnp;
      forwarding-class-set {
         fcoe-pg {
            output-traffic-control-profile fcoe-tcp;
         }
      }
      unit 0 {
         classifiers {
            ieee-802.1 fcoe-classifier;
         }
      }
   }
   xe-0/0/32 {
      congestion-notification-profile fcoe-cnp;
      forwarding-class-set {
         fcoe-pg {
            output-traffic-control-profile fcoe-tcp;
         }
      }
      unit 0 {
         classifiers {
            ieee-802.1 fcoe-classifier;
         }
      }
   }
   xe-0/0/33 {
```

```
        congestion-notification-profile fcoe-cnp;
        forwarding-class-set {
          fcoe-pg {
            output-traffic-control-profile fcoe-tcp;
          }
        }
        unit 0 {
          classifiers {
            ieee-802.1 fcoe-classifier;
          }
        }
      }
      xe-0/0/34 {
        congestion-notification-profile fcoe-cnp;
        forwarding-class-set {
          fcoe-pg {
            output-traffic-control-profile fcoe-tcp;
          }
        }
        unit 0 {
          classifiers {
            ieee-802.1 fcoe-classifier;
          }
        }
      }
    }
    scheduler-maps {
      fcoe-map {
        forwarding-class fcoe scheduler fcoe-sched;
      }
    }
    schedulers {
      fcoe-sched {
        transmit-rate 3000000000;
        shaping-rate percent 100;
        priority low;
      }
    }
```

TIP: To quickly configure the interfaces, issue the **load merge terminal** command and then copy the hierarchy and paste it into the switch terminal window.

Verification

To verify that the PFC configuration for FCoE traffic components has been created and is operating properly, perform these tasks:

- Verifying That Priority-Based Flow Control Has Been Enabled on page 4928
- Verifying the Ingress Interface PFC Configuration on page 4928

Verifying That Priority-Based Flow Control Has Been Enabled

Purpose Verify that PFC is enabled on the FCoE queue to enable lossless transport.

Action List the congestion notification profiles using the operational mode command **show class-of-service congestion-notification**:

```
user@switch> show class-of-service congestion-notification
Type: Input, Name: fcoe-cnp, Index: 51697
Cable Length: 100 m
  Priority     PFC         MRU
  000          Disabled
  001          Disabled
  010          Disabled
  011          Enabled      2500
  100          Disabled
  101          Disabled
  110          Disabled
  111          Disabled
Type: Output
  Priority     Flow-Control-Queues
  000
               0
  001
               1
  010
               2
  011
               3
  100
               4
  101
               5
  110
               6
  111
               7
```

Meaning The **show class-of-service congestion-notification** operational command lists all of the congestion notification profiles and which IEEE 802.1p code points have PFC enabled. The command output shows that PFC is enabled on code point **011** for the **fcoe-cnp** congestion notification profile.

The command also shows the default cable length (100 meters), the default maximum receive unit (2500 bytes), and the default mapping of priorities to output queues because this example does not include configuring these options.

Verifying the Ingress Interface PFC Configuration

Purpose Verify that the classifier **fcoe-classifier** and the congestion notification profile **fcoe-cnp** are configured on ingress interfaces **xe-0/0/31**, **xe-0/0/32**, **xe-0/0/33**, and **xe-0/0/34**.

Action List the ingress interfaces using the operational mode command **show configuration class-of-service interfaces**:

```
user@switch> show configuration class-of-service interfaces xe-0/0/31
```

```
congestion-notification-profile fcoe-cnp;
unit 0 {
    classifiers {
        ieee-802.1 fcoe-classifier;
    }
}
```

```
user@switch> show configuration class-of-service interfaces xe-0/0/32
congestion-notification-profile fcoe-cnp;
unit 0 {
    classifiers {
        ieee-802.1 fcoe-classifier;
    }
}
```

```
user@switch> show configuration class-of-service interfaces xe-0/0/33
congestion-notification-profile fcoe-cnp;
unit 0 {
    classifiers {
        ieee-802.1 fcoe-classifier;
    }
}
```

```
user@switch> show configuration class-of-service interfaces xe-0/0/34
congestion-notification-profile fcoe-cnp;
unit 0 {
    classifiers {
        ieee-802.1 fcoe-classifier;
    }
}
```

Meaning The **show configuration class-of-service interfaces** commands list the congestion notification profile that is mapped to the interface (**fcoe-cnp**) and the IEEE 802.1p classifier associated with the interface (**fcoe-classifier**).

Example: Configuring DCBX Application Protocol TLV Exchange

Data Center Bridging Capability Exchange protocol (DCBX) discovers the data center bridging (DCB) capabilities of connected peers by exchanging application configuration information. DCBX detects feature misconfiguration and mismatches and can configure DCB on peers. DCBX is an extension of the Link Layer Discovery Protocol (LLDP). LLDP must remain enabled on every interface on which you want to use DCBX.

NOTE: LLDP and DCBX are enabled by default on all interfaces.

The switch supports DCBX application protocol exchange for Layer 2 and Layer 4 applications such as the Internet Small Computer System Interface (iSCSI). You specify applications by EtherType (for Layer 2 applications) or by the destination port and protocol (for Layer 4 applications; the protocol can be either TCP or UDP).

The QFX Series handles Fibre Channel over Ethernet (FCoE) application protocol exchange differently than other protocols in some cases:

- If FCoE is the only application for which you want to enable DCBX application protocol TLV exchange on an interface, you do not have to explicitly configure the FCoE application or an application map. By default, the QFX Series exchanges FCoE application protocol TLVs on all interfaces that carry FCoE traffic (traffic mapped to the **fcoe** forwarding class) and have priority-based flow control (PFC) enabled on the FCoE priority (the FCoE IEEE 802.1p code point). The default priority mapping for the FCoE application is IEEE 802.1p code point 011 (the default **fcoe** forwarding class code point).
- If you want an interface to use DCBX to exchange application protocol TLVs for any other applications in addition to FCoE, you must configure the applications (including FCoE), define an application map (including FCoE), and apply the application map to the interface. If you apply an application map to an interface, you must explicitly configure the FCoE application, or the interface does not exchange FCoE application protocol TLVs.

This example shows how to configure interfaces to exchange both Layer 2 and Layer 4 applications by configuring one interface to exchange iSCSI and FCoE application protocol information and configuring another interface to exchange iSCSI and Precision Time Protocol (PTP) application protocol information.

- Verification on page 4936

Requirements

This example uses the following hardware and software components:

- Juniper Networks QFX Series device
- Junos OS Release 12.1 or later for the QFX Series

Overview

The switch supports DCBX application protocol exchange for:

- Layer 2 applications, defined by EtherType
- Layer 4 applications, defined by destination port and protocol

NOTE: DCBX also advertises PFC and enhanced transmission selection (ETS) information. See "Configuring DCBX Autonegotiation" on page 5076 for how DCBX negotiates and advertises configuration information for these features and for the applications.

DCBX is configured on a per-interface basis for each supported feature or application. For applications that you want to enable for DCBX application protocol exchange, you must:

- Define the application name and configure the EtherType or the destination port and protocol (TCP or UDP) of the application. Use the EtherType for Layer 2 applications, and use the destination port and protocol for Layer 4 protocols.
- Map the application to an IEEE 802.1p code point in an application map.
- Add the application map to DCBX interface.

In addition, for all applications (including FCoE, even when you do not use an application map), you either must create an IEEE 802.1p classifier and apply it to the appropriate ingress interfaces or use the default classifier. A classifier maps the code points of incoming traffic to a forwarding class and a loss priority so that ingress traffic is assigned to the correct class of service (CoS). The forwarding class determines the output queue on the egress interface.

If you do not create classifiers, trunk and tagged-access ports use the unicast IEEE 802.1 default trusted classifier. Table 380 on page 4931 shows the default mapping of IEEE 802.1 code-point values to unicast forwarding classes and loss priorities for ports in trunk mode or tagged-access mode. Table 381 on page 4932 shows the default untrusted classifier IEEE 802.1 code-point values to unicast forwarding class mapping for ports in access mode.

Table 380: Default IEEE 802.1 Classifiers for Trunk Ports and Tagged-Access Ports (Default Trusted Classifier)

Code Point	Forwarding Class	Loss Priority
be (000)	best-effort	low
be1 (001)	best-effort	low
ef (010)	best-effort	low
ef1 (011)	fcoe	low
af11 (100)	no-loss	low
af12 (101)	best-effort	low
nc1 (110)	network-control	low

Table 380: Default IEEE 802.1 Classifiers for Trunk Ports and Tagged-Access Ports (Default Trusted Classifier) *(continued)*

Code Point	Forwarding Class	Loss Priority
nc2 (111)	network-control	low

Table 381: Default IEEE 802.1 Unicast Classifiers for Access Ports (Default Untrusted Classifier)

Code Point	Forwarding Class	Loss Priority
000	best-effort	low
001	best-effort	low
010	best-effort	low
011	best-effort	low
100	best-effort	low
101	best-effort	low
110	best-effort	low
111	best-effort	low

Topology

This example shows how to configure DCBX application protocol exchange for three protocols (iSCSI, PTP, and FCoE) on two interfaces. One interface exchanges iSCSI and FCoE application protocol information, and the other interface exchanges iSCSI and PTP application protocol information.

NOTE: You must map FCoE traffic to the interfaces on which you want to forward FCoE traffic. You must also enable PFC on the FCoE interfaces and create an ingress classifier for FCoE traffic, or else use the default classifier.

Table 382 on page 4932 shows the configuration components for this example.

Table 382: Components of DCBX Application Protocol Exchange Configuration Topology

Component	Settings
Hardware	QFX Series device
LLDP	Enabled by default on Ethernet interfaces

Table 382: Components of DCBX Application Protocol Exchange Configuration Topology *(continued)*

Component	Settings
DCBX	Enabled by default on Ethernet interfaces
iSCSI application (Layer 4)	Application name—**iscsi** protocol—**TCP** destination-port—**3260** code-points—**111**
PTP application (Layer 2)	Application name—**ptp** ether-type—**0x88F7** code-points—**001**, **101**
FCoE application (Layer 2)	Application name—**fcoe** ether-type—**0x8906** code-points—**011** NOTE: You explicitly configure the FCoE application because you are applying an application map to the interface. When you apply an application map to an interface, all applications must be explicitly configured and included in the application map.
Application maps	**dcbx-iscsi-fcoe-app-map**—Maps the iSCSI and FCoE applications to IEEE 802.1p code points **dcbx-iscsi-ptp-app-map**—Maps iSCSI and PTP applications to IEEE 802.1p code points
Interfaces	**xe-0/0/10**—Configured to exchange FCoE and iSCSI application TLVs (uses application map **dcbx-iscsi-fcoe-app-map**, carries FCoE traffic, and has PFC enabled on the FCoE priority) **xe-0/0/11**—Configured to exchange iSCSI and PTP application TLVs (uses application map **dcbx-iscsi-ptp-app-map**)
PFC congestion notification profile for FCoE application exchange	**fcoe-cnp**: • Code point—**011** • Interface—**xe-0/0/10**

Table 382: Components of DCBX Application Protocol Exchange Configuration Topology *(continued)*

Component	Settings
Behavior aggregate classifiers (map forwarding classes to incoming packets by the packet's IEEE 802.1 code point)	**fcoe-iscsi-cl1**: • Maps the **fcoe** forwarding class to the IEEE 802.1p code point used for the FCoE application (**011**) and a loss priority of **high** • Maps the **network-control** forwarding class to the IEEE 802.1p code point used for the iSCSI application (**111**) and a loss priority of **high** • Applied to interface **xe-0/0/10** **iscsi-ptp-cl2**: • Maps the **network-control** forwarding class to the IEEE 802.1p code point used for the iSCSI application (**111**) and a loss priority of **low** • Maps the **best-effort** forwarding class to the IEEE 802.1p code points used for the PTP application (**001** and **101**) and a loss priority of **low** • Applied to interface **xe-0/0/11**

NOTE: This example does not include scheduling (bandwidth allocation) configuration or lossless configuration for the iSCSI forwarding class.

Configuration

CLI Quick Configuration

To quickly configure DCBX application protocol exchange, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
set applications application iSCSI protocol tcp destination-port 3260
set applications application FCoE ether-type 0x8906
set applications application PTP ether-type 0x88F7
set policy-options application-maps dcbx-iscsi-fcoe-app-map application iSCSI code-points 111
set policy-options application-maps dcbx-iscsi-fcoe-app-map application FCoE code-points 011
set policy-options application-maps dcbx-iscsi-ptp-app-map application iSCSI code-points 111
set policy-options application-maps dcbx-iscsi-ptp-app-map application PTP code-points [001
101]
set protocols dcbx interface xe-0/0/10 application-map dcbx-iscsi-fcoe-app-map
set protocols dcbx interface xe-0/0/11 application-map dcbx-iscsi-ptp-app-map
set class-of-service congestion-notification-profile fcoe-cnp input ieee-802.1 code-point 011 pfc
set class-of-service interfaces xe-0/0/10 congestion-notification-profile fcoe-cnp
set class-of-service classifiers ieee-802.1 fcoe-iscsi-cl1 import default forwarding-class fcoe
loss-priority high code-points 011
set class-of-service classifiers ieee-802.1 fcoe-iscsi-cl1 import default forwarding-class
network-control loss-priority high code-points 111
set class-of-service classifiers ieee-802.1 iscsi-ptp-cl2 import default forwarding-class
network-control loss-priority low code-points 111
set class-of-service classifiers ieee-802.1 iscsi-ptp-cl2 import default forwarding-class best-effort
loss-priority low code-points [001 101]
set class-of-service interfaces xe-0/0/10 unit 0 classifiers ieee-802.1 fcoe-iscsi-cl1
```

set class-of-service interfaces xe-0/0/11 unit 0 classifiers ieee-802.1 iscsi-ptp-cl2

Configuring DCBX Application Protocol TLV Exchange

Step-by-Step Procedure

To define the applications, map the applications to IEEE 802.1p code points, apply the applications to interfaces, and create classifiers for DCBX application protocol exchange:

1. Define the iSCSI application by specifying its protocol and destination port, and define the FCoE and PTP applications by specifying their EtherTypes.

   ```
   [edit applications]
   user@switch# set application iSCSI protocol tcp destination-port 3260
   user@switch# set application FCoE ether-type 0x8906
   user@switch# set application PTP ether-type 0x88F7
   ```

2. Define an application map that maps the iSCSI and FCoE applications to IEEE 802.1p code points.

   ```
   [edit policy-options]
   user@switch# set application-maps dcbx-iscsi-fcoe-app-map application iSCSI code-points 111
   user@switch# set application-maps dcbx-iscsi-fcoe-app-map application FCoE code-points 011
   ```

3. Define the application map that maps the iSCSI and PTP applications to IEEE 802.1p code points.

   ```
   [edit policy-options]
   user@switch# set application-maps dcbx-iscsi-ptp-app-map application iSCSI code-points 111
   user@switch# set application-maps dcbx-iscsi-ptp-app-map application PTP code-points [001 101]
   ```

4. Apply the iSCSI and FCoE application map to interface **xe-0/0/10**, and apply the iSCSI and PTP application map to interface **xe-0/0/11**.

   ```
   [edit protocols dcbx]
   user@switch# set interface xe-0/0/10 application-map dcbx-iscsi-fcoe-app-map
   user@switch# set interface xe-0/0/11 application-map dcbx-iscsi-ptp-app-map
   ```

5. Create the congestion notification profile to enable PFC on the FCoE code point (**011**), and apply the congestion notification profile to interface **xe-0/0/10**.

   ```
   [edit class-of-service]
   user@switch# set congestion-notification-profile fcoe-cnp input ieee-802.1 code-point 011 pfc
   user@switch# set interfaces xe-0/0/10 congestion-notification-profile fcoe-cnp
   ```

6. Configure the classifier to apply to the interface that exchanges iSCSI and FCoE application information.

   ```
   [edit class-of-service classifiers]
   user@switch# set ieee-802.1 fcoe-iscsi-cl1 import default forwarding-class fcoe loss-priority high code-points 011
   user@switch# set ieee-802.1 fcoe-iscsi-cl1 import default forwarding-class network-control loss-priority high code-points 111
   ```

7. Configure the classifier to apply to the interface that exchanges iSCSI and PTP application information.

   ```
   [edit class-of-service classifiers]
   ```

```
user@switch# set ieee-802.1 iscsi-ptp-cl2 import default forwarding-class network-control loss-priority low code-points 111
user@switch# set ieee-802.1 iscsi-ptp-cl2 import default forwarding-class best-effort loss-priority low code-points [001 101]
```

8. Apply the classifiers to the appropriate interfaces.

```
[edit class-of-service]
user@switch# set interfaces xe-0/0/10 unit 0 classifiers ieee-802.1 fcoe-iscsi-cl1
user@switch# set interfaces xe-0/0/11 unit 0 classifiers ieee-802.1 iscsi-ptp-cl2
```

Verification

To verify that DCBX application protocol exchange configuration has been created and is operating properly, perform these tasks:

Verifying the Application Configuration

Purpose Verify that DCBX applications have been configured.

Action List the applications by using the configuration mode command **show applications**:

```
user@switch# show applications
application iSCSI {
   protocol tcp;
   destination-port 3260;
}

application fcoe {
   ether-type 0x8906;
}

application ptp {
   ether-type 0x88F7;
}
```

Meaning The **show applications** configuration mode command lists all of the configured applications and either their protocol and destination port (Layer 4 applications) or their EtherType (Layer 2 applications). The command output shows that the iSCSI application is configured with the **tcp** protocol and destination port **3260**, the FCoE application is configured with the EtherType **0x8906**, and that the PTP application is configured with the EtherType **0x88F7**.

Verifying the Application Map Configuration

Purpose Verify that the application maps have been configured.

Action List the application maps by using the configuration mode command **show policy-options application-maps**:

```
user@switch# show policy-options application-maps
dcbx-iscsi-fcoe-app-map {
   application iSCSI code-points 111;
   application FCoE code-points 011;
}

dcbx-iscsi-ptp-app-map {
   application iSCSI code-points 111;
   application PTP code-points [001 101];
}
```

Meaning The **show policy-options application-maps** configuration mode command lists all of the configured application maps and the applications that belong to each application map. The command output shows that there are two application maps, **dcbx-iscsi-fcoe-app-map** and **dcbx-iscsi-ptp-app-map**.

The application map **dcbx-iscsi-fcoe-app-map** consists of the iSCSI application, which is mapped to IEEE 802.1p code point **111**, and the FCoE application, which is mapped to IEEE 802.1p code point **011**.

The application map **dcbx-iscsi-ptp-app-map** consists of the iSCSI application, which is mapped to IEEE 802.1p code point **111**, and the PTP application, which is mapped to IEEE 802.1p code points **001** and **101**.

Verifying DCBX Application Protocol Exchange Interface Configuration

Purpose Verify that the application maps have been applied to the correct interfaces.

Action List the application maps by using the configuration mode command **show protocols dcbx**:

```
user@switch# show protocols dcbx
interface xe-0/0/10.0 {
   application-map dcbx-iscsi-fcoe-app-map;
}

interface xe-0/0/11.0 {
   application-map dcbx-iscsi-ptp-app-map;
}
```

Meaning The **show protocols dcbx** configuration mode command lists whether the interfaces are enabled for DCBX and lists the application map applied to each interface. The command output shows that interfaces **xe-0/0/10.0** and **xe-0/0/11.0** are enabled for DCBX, and that interface **xe-0/0/10.0** uses application map **dcbx-iscsi-fcoe-app-map**, and interface **xe-0/0/11.0** uses application map **dcbx-iscsi-ptp-app-map**.

Verifying the PFC Configuration

Purpose Verify that PFC has been enabled on the FCoE code point and applied to the correct interface.

Action Display the PFC configuration to verify that PFC is enabled on the FCoE code point (**011**) in the congestion notification profile **fcoe-cnp** by using the configuration mode command **show class-of-service congestion-notification-profile**:

```
user@switch# show class-of-service congestion-notification-profile
fcoe-cnp {
    input {
        ieee-802.1 {
            code-point 011 {
                pfc;
            }
        }
    }
}
```

Display the class-of-service (CoS) interface information to verify that the correct interface has PFC enabled for the FCoE application by using the configuration mode command **show class-of-service interfaces**:

```
user@switch# show class-of-service interfaces
xe-0/0/10 {
    congestion-notification-profile fcoe-cnp;
}
```

NOTE: The sample output does not include all of the information this command can show. The output is abbreviated to focus on verifying the PFC configuration.

Meaning The **show class-of-service congestion-notification-profile** configuration mode command lists the configured congestion notification profiles. The command output shows that the congestion notification profile **fcoe-cnp** has been configured and has enabled PFC on the IEEE 802.1p code point **011** (the default FCoE code point).

The **show class-of-service interfaces** configuration mode command shows the interface CoS configuration. The command output shows that the congestion notification profile **fcoe-cnp**, which enables PFC on the FCoE code point, is applied to interface **xe-0/0/10**.

Verifying the Classifier Configuration

Purpose Verify that the classifiers have been configured and applied to the correct interfaces.

Action Display the classifier configuration by using the configuration mode command **show class-of-service**:

```
user@switch# show class-of-service
classifiers {
    ieee-802.1 fcoe-iscsi-cl1 {
        import default;
        forwarding-class network-control {
            loss-priority high code-points 111;
        }
        forwarding-class fcoe {
            loss-priority high code-points 011;
```

```
            }
        }
        ieee-802.1 iscsi-ptp-cl2 {
            import default;
            forwarding-class network-control {
                loss-priority low code-points 111;
            }
            forwarding-class best-effort {
                loss-priority low code-points [ 001 101 ];
            }
        }
    }
    interfaces {
        xe-0/0/10 {
            congestion-notification-profile fcoe-cnp;
            unit 0 {
                classifiers {
                    ieee-802.1 fcoe-iscsi-cl1;
                }
            }
        }
        xe-0/0/11 {
            unit 0 {
                classifiers {
                    ieee-802.1 iscsi-ptp-cl2;
                }
            }
        }
    }
```

NOTE: The sample output does not include all of the information this command can show. The output is abbreviated to focus on verifying the classifier configuration.

Meaning The **show class-of-service** configuration mode command lists the classifier and CoS interface configuration, as well as other information not shown in this example. The command output shows that there are two classifiers configured, **fcoe-iscsi-cl1** and **iscsi-ptp-cl2**.

Classifier **fcoe-iscsi-cl1** uses the **default** classifier as a template and edits the template as follows:

- The forwarding class **network-control** is set to a loss priority of **high** and is mapped to code point **111** (the code point mapped to the iSCSI application).
- The forwarding class **fcoe** is set to a loss priority of **high** and is mapped to code point **011** (the code point mapped by default to the FCoE application).

Classifier **iscsi-ptp-cl2** uses the **default** classifier as a template and edits the template as follows:

- The forwarding class **network-control** is set to a loss priority of **low** and is mapped to IEEE 802.1p code point **111** (the code point mapped to the iSCSI application).

- The forwarding class **best-effort** is set to a loss priority of **low** and is mapped to IEEE 802.1p code points **001** and **101** (the code points mapped by default to the PTP application).

The command output also shows that classifier **fcoe-iscsi-cl1** is mapped to interface **xe-0/0/10.0** and that classifier **iscsi-ptp-cl2** is mapped to interface **xe-0/0/11.0**.

Configuration Examples (Original CLI Only)

Example: Configuring CoS for FCoE Transit Switch Traffic Across an MC-LAG

Multichassis link aggregation groups (MC-LAGs) provide redundancy and load balancing between two QFX Series switches, multihoming support for client devices such as servers, and a loop-free Layer 2 network without running Spanning Tree Protocol (STP).

NOTE: This example uses Junos OS without support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that supports ELS, see “Example: Configuring CoS for FCoE Transit Switch Traffic Across an MC-LAG” on page 5002.

You can use an MC-LAG to provide a redundant aggregation layer for Fiber Channel over Ethernet (FCoE) traffic in an *inverted-U* topology. To support lossless transport of FCoE traffic across an MC-LAG, you must configure the appropriate class of service (CoS) on both of the QFX Series switches with MC-LAG port members. The CoS configuration must be the same on both of the MC-LAG switches because an MC-LAG does not carry forwarding class and IEEE 802.1p priority information.

NOTE: This example describes how to configure CoS to provide lossless transport for FCoE traffic across an MC-LAG that connects two QFX Series switches. It also describes how to configure CoS on the FCoE transit switches that connect FCoE hosts to the QFX Series switches that form the MC-LAG.

This example does *not* describe how to configure the MC-LAG itself. For a detailed example of MC-LAG configuration, see "Example: Configuring Multichassis Link Aggregation" on page 1904. However, this example includes a subset of MC-LAG configuration that only shows how to configure interface membership in the MC-LAG.

Ports that are part of an FCoE-FC gateway configuration (a virtual FCoE-FC gateway fabric) do not support MC-LAGs. Ports that are members of an MC-LAG act as FCoE passthrough transit switch ports.

QFX Series switches support MC-LAGs. QFabric system Node devices do not support MC-LAGs, and QFX3500 and QFX3600 Virtual Chassis switches do not support FCoE.

This topic describes:

Requirements

This example uses the following hardware and software components:

- Two Juniper Networks QFX3500 Switches that form an MC-LAG for FCoE traffic.
- Two Juniper Networks QFX3500 Switches that provide FCoE server access in transit switch mode and that connect to the MC-LAG switches. These switches can be standalone QFX3500 switches or they can be Node devices in a QFabric system.
- FCoE servers (or other FCoE hosts) connected to the transit switches.
- Junos OS Release 12.2 or later for the QFX Series.

Overview

FCoE traffic requires lossless transport. This example shows you how to:

- Configure CoS for FCoE traffic on the two QFX3500 switches that form the MC-LAG, including priority-based flow control (PFC) and enhanced transmission selection (ETS; hierarchical scheduling of resources for the FCoE forwarding class priority and for the forwarding class set priority group).

  NOTE: **Configuring or changing PFC on an interface blocks the entire port until the PFC change is completed. After a PFC change is completed, the port is unblocked and traffic resumes. Blocking the port stops ingress and egress traffic, and causes packet loss on all queues on the port until the port is unblocked.**

- Configure CoS for FCoE on the two FCoE transit switches that connect FCoE hosts to the MC-LAG switches and enable FIP snooping on the FCoE VLAN at the FCoE transit switch access ports.
- Disable IGMP snooping on the FCoE VLAN.
- Configure the appropriate port mode, MTU, and FCoE trusted or untrusted state for each interface to support lossless FCoE transport.

Topology

QFX3500 switches that act as transit switches support MC-LAGs for FCoE traffic in an inverted-U network topology, as shown in Figure 180 on page 4942.

Figure 180: Supported Topology for an MC-LAG on an FCoE Transit Switch

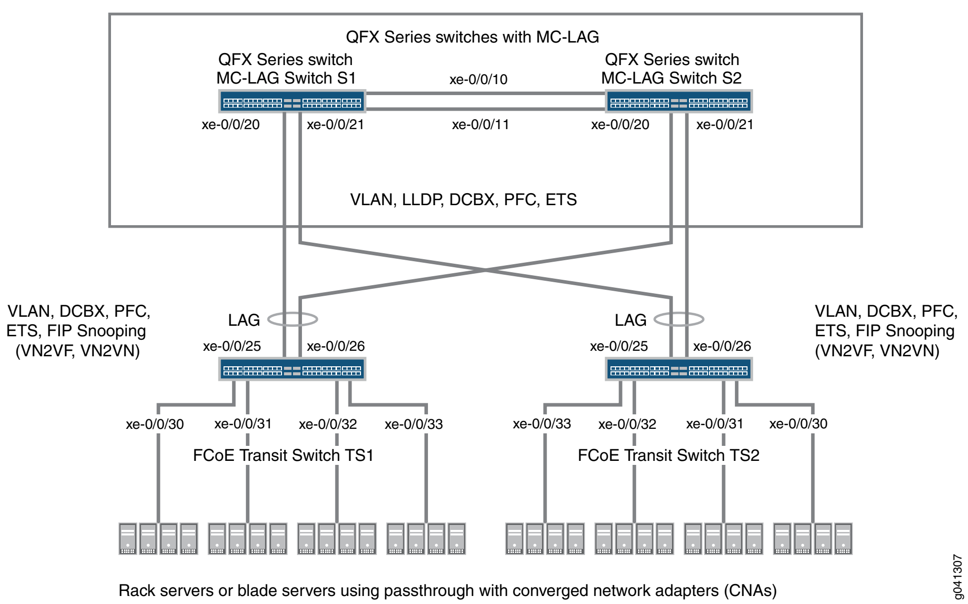

Table 383 on page 4943 shows the configuration components for this example.

Table 383: Components of the CoS for FCoE Traffic Across an MC-LAG Configuration Topology

Component	Settings
Hardware	Four QFX3500 switches (two to form the MC-LAG as passthrough transit switches and two transit switches for FCoE access).
Forwarding class (all switches)	Default **fcoe** forwarding class.
Classifier (forwarding class mapping of incoming traffic to IEEE priority)	Default IEEE 802.1p trusted classifier on all FCoE interfaces.
LAGs and MC-LAG	S1—Ports xe-0/0/10 and x-0/0/11 are members of LAG **ae0**, which connects Switch S1 to Switch S2. Ports xe-0/0/20 and xe-0/0/21 are members of MC-LAG **ae1**. All ports are configured in **trunk** port mode, as **fcoe-trusted**, and with an MTU of **2180**. S2—Ports xe-0/0/10 and x-0/0/11 are members of LAG **ae0**, which connects Switch S2 to Switch S1. Ports xe-0/0/20 and xe-0/0/21 are members of MC-LAG **ae1**. All ports are configured in **trunk** port mode, as **fcoe-trusted**, and with an MTU of **2180**. NOTE: Ports xe-0/0/20 and xe-0/0/21 on Switches S1 and S2 are the members of the MC-LAG. TS1—Ports xe-0/0/25 and x-0/0/26 are members of LAG **ae1**, configured in **trunk** port mode, as **fcoe-trusted**, and with an MTU of **2180**. Ports xe-0/0/30, xe-0/0/31, xe-0/0/32, and xe-0/0/33 are configured in **tagged-access** port mode, with an MTU of **2180**. TS2—Ports xe-0/0/25 and x-0/0/26 are members of LAG **ae1**, configured in **trunk** port mode, as **fcoe-trusted**, and with an MTU of **2180**. Ports xe-0/0/30, xe-0/0/31, xe-0/0/32, and xe-0/0/33 are configured in **tagged-access** port mode, with an MTU of **2180**.
FCoE queue scheduler (all switches)	**fcoe-sched**: Minimum bandwidth **3g** Maximum bandwidth **100%** Priority **low**
Forwarding class-to-scheduler mapping (all switches)	Scheduler map **fcoe-map**: Forwarding class **fcoe** Scheduler **fcoe-sched**

Table 383: Components of the CoS for FCoE Traffic Across an MC-LAG Configuration Topology *(continued)*

Component	Settings
Forwarding class set (FCoE priority group, all switches)	**fcoe-pg**: Forwarding class **fcoe** Egress interfaces: • S1—LAG **ae0** and MC-LAG **ae1** • S2—LAG **ae0** and MC-LAG **ae1** • TS1—LAG **ae1**, interfaces **xe-0/0/30**, **xe-0/0/31**, **xe-0/0/32**, and **xe-0/0/33** • TS2—LAG **ae1**, interfaces **xe-0/0/30**, **xe-0/0/31**, **xe-0/0/32**, and **xe-0/0/33**
Traffic control profile (all switches)	**fcoe-tcp**: Scheduler map **fcoe-map** Minimum bandwidth **3g** Maximum bandwidth **100%**
PFC congestion notification profile (all switches)	**fcoe-cnp**: Code point **011** Ingress interfaces: • S1—LAG **ae0** and MC-LAG **ae1** • S2—LAG **ae0** and MC-LAG **ae1** • TS1—LAG **ae1**, interfaces **xe-0/0/30**, **xe-0/0/31**, **xe-0/0/32**, and **xe-0/0/33** • TS2—LAG **ae1**, interfaces **xe-0/0/30**, **xe-0/0/31**, **xe-0/0/32**, and **xe-0/0/33**
FCoE VLAN name and tag ID	Name—**fcoe_vlan** ID—**100** Include the FCoE VLAN on the interfaces that carry FCoE traffic on all four switches. Disable IGMP snooping on the interfaces that belong to the FCoE VLAN on all four switches.
FIP snooping	Enable FIP snooping on Transit Switches TS1 and TS2 on the FCoE VLAN. Configure the LAG interfaces that connect to the MC-LAG switches as FCoE trusted interfaces so that they do not perform FIP snooping. This example enables VN2VN_Port FIP snooping on the FCoE transit switch interfaces connected to the FCoE servers. The example is equally valid with VN2VF_Port FIP snooping enabled on the transit switch access ports. The method of FIP snooping you enable depends on your network configuration.

NOTE: This example uses the default IEEE 802.1p trusted BA classifier, which is automatically applied to trunk mode and tagged access mode ports if you do not apply an explicitly configured classifier.

To configure CoS for FCoE traffic across an MC-LAG:

- Use the default FCoE forwarding class and forwarding-class-to-queue mapping (do not explicitly configure the FCoE forwarding class or output queue). The default FCoE forwarding class is **fcoe**, and the default output queue is queue **3**.

  NOTE: In Junos OS Release 12.2, traffic mapped to explicitly configured forwarding classes, even lossless forwarding classes such as **fcoe**, is treated as lossy (**best-effort**) traffic and does *not* receive lossless treatment. To receive lossless treatment in Release 12.2, traffic must use one of the default lossless forwarding classes (**fcoe** or **no-loss**).

  In Junos OS Release 12.3 and later, you can include the *no-loss* packet drop attribute in the explicit forwarding class configuration to configure a lossless forwarding class.

- Use the default trusted BA classifier, which maps incoming packets to forwarding classes by the IEEE 802.1p code point (CoS priority) of the packet. The trusted classifier is the default classifier for interfaces in trunk and tagged-access port modes. The default trusted classifier maps incoming packets with the IEEE 802.1p code point 3 (**011**) to the FCoE forwarding class. If you choose to configure the BA classifier instead of using the default classifier, you must ensure that FCoE traffic is classified into forwarding classes in exactly the same way on both MC-LAG switches. Using the default classifier ensures consistent classifier configuration on the MC-LAG ports.
- Configure a congestion notification profile that enables PFC on the FCoE code point (code point **011** in this example). The congestion notification profile configuration must be the same on both MC-LAG switches.
- Apply the congestion notification profile to the interfaces.
- Configure enhanced transmission selection (ETS, also known as hierarchical scheduling) on the interfaces to provide the bandwidth required for lossless FCoE transport. Configuring ETS includes configuring bandwidth scheduling for the FCoE forwarding class, a forwarding class set (priority group) that includes the FCoE forwarding class, and a traffic control profile to assign bandwidth to the forwarding class set that includes FCoE traffic.
- Apply the ETS scheduling to the interfaces.
- Configure the port mode, MTU, and FCoE trusted or untrusted state for each interface to support lossless FCoE transport.

In addition, this example describes how to enable FIP snooping on the Transit Switch TS1 and TS2 ports that are connected to the FCoE servers and how to disable IGMP snooping on the FCoE VLAN. To provide secure access, FIP snooping must be enabled on the FCoE access ports.

This example focuses on the CoS configuration to support lossless FCoE transport across an MC-LAG. This example does not describe how to configure the properties of MC-LAGs and LAGs, although it does show you how to configure the port characteristics required to support lossless transport and how to assign interfaces to the MC-LAG and to the LAGs.

Before you configure CoS, configure:

- The MC-LAGs that connect Switches S1 and S2 to Switches TS1 and TS2. ("Example: Configuring Multichassis Link Aggregation" on page 1904 describes how to configure MC-LAGs.)
- The LAGs that connect the Transit Switches TS1 and TS2 to MC-LAG Switches S1 and S2. ("Configuring Link Aggregation" on page 2019 describes how to configure LAGs.)
- The LAG that connects Switch S1 to Switch S2.

Configuration

To configure CoS for lossless FCoE transport across an MC-LAG, perform these tasks:

- Configuring MC-LAG Switches S1 and S2 on page 4948
- Configuring FCoE Transit Switches TS1 and TS2 on page 4949
- Results on page 4952

CLI Quick Configuration

To quickly configure CoS for lossless FCoE transport across an MC-LAG, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI for MC-LAG Switch S1 and MC-LAG Switch S2 at the **[edit]** hierarchy level. The configurations on Switches S1 and S2 are identical because the CoS configuration must be identical, and because this example uses the same ports on both switches.

Switch S1 and Switch S2

```
set class-of-service schedulers fcoe-sched priority low transmit-rate 3g
set class-of-service schedulers fcoe-sched shaping-rate percent 100
set class-of-service scheduler-maps fcoe-map forwarding-class fcoe scheduler fcoe-sched
set class-of-service forwarding-class-sets fcoe-pg class fcoe
set class-of-service traffic-control-profiles fcoe-tcp scheduler-map fcoe-map guaranteed-rate
3g
set class-of-service traffic-control-profiles fcoe-tcp shaping-rate percent 100

Configuring MC-LAG Switches S1 and S2

Step-by-Step Procedure

To configure CoS resource scheduling (ETS), PFC, the FCoE VLAN, and the LAG and MC-LAG interface membership and characteristics to support lossless FCoE transport across an MC-LAG (this example uses the default **fcoe** forwarding class and the default classifier to map incoming FCoE traffic to the FCoE IEEE 802.1p code point **011**, so you do not configure them):

1. Configure output scheduling for the FCoE queue:

   ```
   [edit class-of-service]
   user@switch# set schedulers fcoe-sched priority low transmit-rate 3g
   user@switch# set schedulers fcoe-sched shaping-rate percent 100
   ```

2. Map the FCoE forwarding class to the FCoE scheduler (**fcoe-sched**):

   ```
   [edit class-of-service]
   user@switch# set scheduler-maps fcoe-map forwarding-class fcoe scheduler fcoe-sched
   ```

3. Configure the forwarding class set (**fcoe-pg**) for the FCoE traffic:

   ```
   [edit class-of-service]
   user@switch# set forwarding-class-sets fcoe-pg class fcoe
   ```

4. Define the traffic control profile (**fcoe-tcp**) to use on the FCoE forwarding class set:

   ```
   [edit class-of-service]
   user@switch# set traffic-control-profiles fcoe-tcp scheduler-map fcoe-map
   guaranteed-rate 3g
   user@switch# set traffic-control-profiles fcoe-tcp shaping-rate percent 100
   ```

5. Apply the FCoE forwarding class set and traffic control profile to the LAG and MC-LAG interfaces:

   ```
   [edit class-of-service]
   user@switch# set interfaces ae0 forwarding-class-set fcoe-pg output-traffic-control-profile
   fcoe-tcp
   user@switch# set interfaces ae1 forwarding-class-set fcoe-pg output-traffic-control-profile
   fcoe-tcp
   ```

6. Enable PFC on the FCoE priority by creating a congestion notification profile (**fcoe-cnp**) that applies FCoE to the IEEE 802.1 code point **011**:

   ```
   [edit class-of-service]
   user@switch# set congestion-notification-profile fcoe-cnp input ieee-802.1 code-point
   011 pfc
   ```

7. Apply the PFC configuration to the LAG and MC-LAG interfaces:

   ```
   [edit class-of-service]
   user@switch# set interfaces ae0 congestion-notification-profile fcoe-cnp
   user@switch# set interfaces ae1 congestion-notification-profile fcoe-cnp
   ```

8. Configure the VLAN for FCoE traffic (**fcoe_vlan**):

   ```
   [edit vlans]
   user@switch# set fcoe_vlan vlan-id 100
   ```

9. Disable IGMP snooping on the FCoE VLAN:

   [edit protocols]
   user@switch# **set igmp-snooping vlan fcoe_vlan disable**

10. Add the member interfaces to the LAG between the two MC-LAG switches:

    [edit interfaces]
    user@switch# **set xe-0/0/10 ether-options 802.3ad ae0**
    user@switch# **set xe-0/0/11 ether-options 802.3ad ae0**

11. Add the member interfaces to the MC-LAG:

    [edit interfaces]
    user@switch# **set xe-0/0/20 ether-options 802.3ad ae1**
    user@switch# **set xe-0/0/21 ether-options 802.3ad ae1**

12. Configure the port mode as **trunk** and membership in the FCoE VLAN (**fcoe_vlan**)for the LAG (**ae0**) and for the MC-LAG (**ae1**):

    [edit interfaces]
    user@switch# **set interfaces ae0 unit 0 family ethernet-switching port-mode trunk vlan members fcoe_vlan**
    user@switch# **set interfaces ae1 unit 0 family ethernet-switching port-mode trunk vlan members fcoe_vlan**

13. Set the MTU to **2180** for the LAG and MC-LAG interfaces. 2180 bytes is the minimum size required to handle FCoE packets because of the payload and header sizes; you can configure the MTU to a higher number of bytes if desired, but not less than 2180 bytes:

    [edit interfaces]
    user@switch# **set ae0 mtu 2180**
    user@switch# **set ae1 mtu 2180**

14. Set the LAG and MC-LAG interfaces as FCoE trusted ports. Ports that connect to other switches should be trusted and should not perform FIP snooping:

    [edit]
    user@switch# **set ethernet-switching-options secure-access-port interface ae0 fcoe-trusted**
    user@switch# **set ethernet-switching-options secure-access-port interface ae1 fcoe-trusted**

Configuring FCoE Transit Switches TS1 and TS2

Step-by-Step Procedure

The CoS configuration on FCoE Transit Switches TS1 and TS2 is similar to the CoS configuration on MC-LAG Switches S1 and S2. However, the port configurations differ, and you must enable FIP snooping on the Switch TS1 and Switch TS2 FCoE access ports.

To configure resource scheduling (ETS), PFC, the FCoE VLAN, and the LAG interface membership and characteristics to support lossless FCoE transport across the MC-LAG (this example uses the default **fcoe** forwarding class and the default classifier to map incoming FCoE traffic to the FCoE IEEE 802.1p code point **011**, so you do not configure them):

1. Configure output scheduling for the FCoE queue:

   [edit class-of-service]
   user@switch# **set schedulers fcoe-sched priority low transmit-rate 3g**
   user@switch# **set schedulers fcoe-sched shaping-rate percent 100**

2. Map the FCoE forwarding class to the FCoE scheduler (**fcoe-sched**):

```
[edit class-of-service]
user@switch# set scheduler-maps fcoe-map forwarding-class fcoe scheduler fcoe-sched
```

3. Configure the forwarding class set (**fcoe-pg**) for the FCoE traffic:

```
[edit class-of-service]
user@switch# set forwarding-class-sets fcoe-pg class fcoe
```

4. Define the traffic control profile (**fcoe-tcp**) to use on the FCoE forwarding class set:

```
[edit class-of-service]
user@switch# set traffic-control-profiles fcoe-tcp scheduler-map fcoe-map
guaranteed-rate 3g
user@switch# set traffic-control-profiles fcoe-tcp shaping-rate percent 100
```

5. Apply the FCoE forwarding class set and traffic control profile to the LAG interface and to the FCoE access interfaces:

```
[edit class-of-service]
user@switch# set interfaces ae1 forwarding-class-set fcoe-pg output-traffic-control-profile
fcoe-tcp
user@switch# set class-of-service interfaces xe-0/0/30 forwarding-class-set fcoe-pg
output-traffic-control-profile fcoe-tcp
user@switch# set class-of-service interfaces xe-0/0/31 forwarding-class-set fcoe-pg
output-traffic-control-profile fcoe-tcp
user@switch# set class-of-service interfaces xe-0/0/32 forwarding-class-set fcoe-pg
output-traffic-control-profile fcoe-tcp
user@switch# set class-of-service interfaces xe-0/0/33 forwarding-class-set fcoe-pg
output-traffic-control-profile fcoe-tcp
```

6. Enable PFC on the FCoE priority by creating a congestion notification profile (**fcoe-cnp**) that applies FCoE to the IEEE 802.1 code point **011**:

```
[edit class-of-service]
user@switch# set congestion-notification-profile fcoe-cnp input ieee-802.1 code-point
011 pfc
```

7. Apply the PFC configuration to the LAG interface and to the FCoE access interfaces:

```
[edit class-of-service]
user@switch# set interfaces ae1 congestion-notification-profile fcoe-cnp
user@switch# set class-of-service interfaces xe-0/0/30 congestion-notification-profile
fcoe-cnp
user@switch# set class-of-service interfaces xe-0/0/31 congestion-notification-profile
fcoe-cnp
user@switch# set class-of-service interfaces xe-0/0/32 congestion-notification-profile
fcoe-cnp
user@switch# set class-of-service interfaces xe-0/0/33 congestion-notification-profile
fcoe-cnp
```

8. Configure the VLAN for FCoE traffic (**fcoe_vlan**):

```
[edit vlans]
user@switch# set fcoe_vlan vlan-id 100
```

9. Disable IGMP snooping on the FCoE VLAN:

```
[edit protocols]
user@switch# set igmp-snooping vlan fcoe_vlan disable
```

10. Add the member interfaces to the LAG:

```
[edit interfaces]
user@switch# set xe-0/0/25 ether-options 802.3ad ae1
```

user@switch# **set xe-0/0/26 ether-options 802.3ad ae1**

11. On the LAG (**ae1**), configure the port mode as **trunk** and membership in the FCoE VLAN (**fcoe_vlan**):

    [edit interfaces]
    user@switch# **set interfaces ae1 unit 0 family ethernet-switching port-mode trunk vlan members fcoe_vlan**

12. On the FCoE access interfaces (**xe-0/0/30**, **xe-0/0/31**, **xe-0/0/32**, **xe-0/0/33**), configure the port mode as **tagged-access** and membership in the FCoE VLAN (**fcoe_vlan**):

    [edit interfaces]
    user@switch# **set interfaces xe-0/0/30 unit 0 family ethernet-switching port-mode tagged-access vlan members fcoe_vlan**
    user@switch# **set interfaces xe-0/0/31 unit 0 family ethernet-switching port-mode tagged-access vlan members fcoe_vlan**
    user@switch# **set interfaces xe-0/0/32 unit 0 family ethernet-switching port-mode tagged-access vlan members fcoe_vlan**
    user@switch# **set interfaces xe-0/0/33 unit 0 family ethernet-switching port-mode tagged-access vlan members fcoe_vlan**

13. Set the MTU to **2180** for the LAG and FCoE access interfaces. 2180 bytes is the minimum size required to handle FCoE packets because of the payload and header sizes; you can configure the MTU to a higher number of bytes if desired, but not less than 2180 bytes:

    [edit interfaces]
    user@switch# **set ae1 mtu 2180**
    user@switch# **set xe-0/0/30 mtu 2180**
    user@switch# **set xe-0/0/31 mtu 2180**
    user@switch# **set xe-0/0/32 mtu 2180**
    user@switch# **set xe-0/0/33 mtu 2180**

14. Set the LAG interface as an FCoE trusted port. Ports that connect to other switches should be trusted and should not perform FIP snooping:

    [edit]
    user@switch# **set ethernet-switching-options secure-access-port interface ae1 fcoe-trusted**

    NOTE: Access ports xe-0/0/30, xe-0/0/31, xe-0/0/32, and xe-0/0/33 are not configured as FCoE trusted ports. The access ports remain in the default state as untrusted ports because they connect directly to FCoE devices and must perform FIP snooping to ensure network security.

15. Enable FIP snooping on the FCoE VLAN to prevent unauthorized FCoE network access (this example uses VN2VN_Port FIP snooping; the example is equally valid if you use VN2VF_Port FIP snooping):

    [edit]
    user@switch# **set ethernet-switching-options secure-access-port vlan fcoe_vlan examine-fip examine-vn2vn beacon-period 90000**

Results

Display the results of the CoS configuration on MC-LAG Switch S1 and on MC-LAG Switch S2 (the results on both switches are the same):

```
user@switch> show configuration class-of-service
traffic-control-profiles {
   fcoe-tcp {
      scheduler-map fcoe-map;
      shaping-rate percent 100;
      guaranteed-rate 3000000000;
   }
}
forwarding-class-sets {
   fcoe-pg {
      class fcoe;
   }
}
congestion-notification-profile {
   fcoe-cnp {
      input {
         ieee-802.1 {
            code-point 011 {
               pfc;
            }
         }
      }
   }
}
interfaces {
   ae0 {
      forwarding-class-set {
         fcoe-pg {
            output-traffic-control-profile fcoe-tcp;
         }
      }
      congestion-notification-profile fcoe-cnp;
   }
   ae1 {
      forwarding-class-set {
         fcoe-pg {
            output-traffic-control-profile fcoe-tcp;
         }
      }
      congestion-notification-profile fcoe-cnp;
   }
}
scheduler-maps {
   fcoe-map {
      forwarding-class fcoe scheduler fcoe-sched;
   }
}
schedulers {
   fcoe-sched {
      transmit-rate 3000000000;
```

```
        shaping-rate percent 100;
        priority low;
    }
}
```

NOTE: The forwarding class and classifier configurations are not shown because the show command does not display default portions of the configuration.

For MC-LAG verification commands, see "Example: Configuring Multichassis Link Aggregation" on page 1904.

Display the results of the CoS configuration on FCoE Transit Switch TS1 and on FCoE Transit Switch TS2 (the results on both transit switches are the same):

```
user@switch> show configuration class-of-service
traffic-control-profiles {
    fcoe-tcp {
        scheduler-map fcoe-map;
        shaping-rate percent 100;
        guaranteed-rate 3000000000;
    }
}
forwarding-class-sets {
    fcoe-pg {
        class fcoe;
    }
}
congestion-notification-profile {
    fcoe-cnp {
        input {
            ieee-802.1 {
                code-point 011 {
                    pfc;
                }
            }
        }
    }
}
interfaces {
    xe-0/0/30 {
        forwarding-class-set {
            fcoe-pg {
                output-traffic-control-profile fcoe-tcp;
            }
        }
        congestion-notification-profile fcoe-cnp;
    }
    xe-0/0/31 {
        forwarding-class-set {
            fcoe-pg {
                output-traffic-control-profile fcoe-tcp;
            }
```

```
        }
        congestion-notification-profile fcoe-cnp;
    }
    xe-0/0/32 {
        forwarding-class-set {
            fcoe-pg {
                output-traffic-control-profile fcoe-tcp;
            }
        }
        congestion-notification-profile fcoe-cnp;
    }
    xe-0/0/33 {
        forwarding-class-set {
            fcoe-pg {
                output-traffic-control-profile fcoe-tcp;
            }
        }
        congestion-notification-profile fcoe-cnp;
    }
    ae1 {
        forwarding-class-set {
            fcoe-pg {
                output-traffic-control-profile fcoe-tcp;
            }
        }
        congestion-notification-profile fcoe-cnp;
    }
}
scheduler-maps {
    fcoe-map {
        forwarding-class fcoe scheduler fcoe-sched;
    }
}
schedulers {
    fcoe-sched {
        transmit-rate 3000000000;
        shaping-rate percent 100;
        priority low;
    }
}
```

NOTE: The forwarding class and classifier configurations are not shown because the **show** command does not display default portions of the configuration.

Verification

To verify that the CoS components and FIP snooping have been configured and are operating properly, perform these tasks. Because this example uses the default **fcoe** forwarding class and the default IEEE 802.1p trusted classifier, the verification of those configurations is not shown:

Verifying That the Output Queue Schedulers Have Been Created

Purpose Verify that the output queue scheduler for FCoE traffic has the correct bandwidth parameters and priorities, and is mapped to the correct forwarding class (output queue). Queue scheduler verification is the same on each of the four switches.

Action List the scheduler map using the operational mode command **show class-of-service scheduler-map fcoe-map**:

```
user@switch> show class-of-service scheduler-map fcoe-map
Scheduler map: fcoe-map, Index: 9023

  Scheduler: fcoe-sched, Forwarding class: fcoe, Index: 37289
    Transmit rate: 3000000000 bps, Rate Limit: none, Buffer size: remainder,
    Buffer Limit: none, Priority: low
    Excess Priority: unspecified
    Shaping rate: 100 percent,
    drop-profile-map-set-type: mark
    Drop profiles:
      Loss priority   Protocol    Index    Name
      Low             any             1    <default-drop-profile>
      Medium high     any             1    <default-drop-profile>
      High            any             1    <default-drop-profile>
```

Meaning The **show class-of-service scheduler-map fcoe-map** command lists the properties of the scheduler map **fcoe-map**. The command output includes:

- The name of the scheduler map (**fcoe-map**)
- The name of the scheduler (**fcoe-sched**)
- The forwarding classes mapped to the scheduler (**fcoe**)
- The minimum guaranteed queue bandwidth (transmit rate **3000000000 bps**)
- The scheduling priority (**low**)

- The maximum bandwidth in the priority group the queue can consume (shaping rate **100 percent**)
- The drop profile loss priority for each drop profile name. This example does not include drop profiles because you do not apply drop profiles to FCoE traffic.

Verifying That the Priority Group Output Scheduler (Traffic Control Profile) Has Been Created

Purpose Verify that the traffic control profile **fcoe-tcp** has been created with the correct bandwidth parameters and scheduler mapping. Priority group scheduler verification is the same on each of the four switches.

Action List the FCoE traffic control profile properties using the operational mode command **show class-of-service traffic-control-profile fcoe-tcp**:

```
user@switch> show class-of-service traffic-control-profile fcoe-tcp
Traffic control profile: fcoe-tcp, Index: 18303
  Shaping rate: 100 percent
  Scheduler map: fcoe-map
  Guaranteed rate: 3000000000
```

Meaning The **show class-of-service traffic-control-profile fcoe-tcp** command lists all of the configured traffic control profiles. For each traffic control profile, the command output includes:

- The name of the traffic control profile (**fcoe-tcp**)
- The maximum port bandwidth the priority group can consume (shaping rate **100 percent**)
- The scheduler map associated with the traffic control profile (**fcoe-map**)
- The minimum guaranteed priority group port bandwidth (guaranteed rate **3000000000** in bps)

Verifying That the Forwarding Class Set (Priority Group) Has Been Created

Purpose Verify that the FCoE priority group has been created and that the **fcoe** priority (forwarding class) belongs to the FCoE priority group. Forwarding class set verification is the same on each of the four switches.

Action List the forwarding class sets using the operational mode command **show class-of-service forwarding-class-set fcoe-pg**:

```
user@switch> show class-of-service forwarding-class-set fcoe-pg
Forwarding class set: fcoe-pg, Type: normal-type, Forwarding class set index:
31420
  Forwarding class                       Index
  fcoe                                     1
```

Meaning The **show class-of-service forwarding-class-set fcoe-pg** command lists all of the forwarding classes (priorities) that belong to the **fcoe-pg** priority group, and the internal index number of the priority group. The command output shows that the forwarding class set **fcoe-pg** includes the forwarding class **fcoe**.

Verifying That Priority-Based Flow Control Has Been Enabled

Purpose Verify that PFC is enabled on the FCoE code point. PFC verification is the same on each of the four switches.

Action List the FCoE congestion notification profile using the operational mode command **show class-of-service congestion-notification fcoe-cnp**:

```
user@switch> show class-of-service congestion-notification fcoe-cnp
Type: Input, Name: fcoe-cnp, Index: 6879
Cable Length: 100 m
  Priority     PFC         MRU
  000          Disabled
  001          Disabled
  010          Disabled
  011          Enabled     2500
  100          Disabled
  101          Disabled
  110          Disabled
  111          Disabled
Type: Output
  Priority     Flow-Control-Queues
  000
               0
  001
               1
  010
               2
  011
               3
  100
               4
  101
               5
  110
               6
  111
               7
```

Meaning The **show class-of-service congestion-notification fcoe-cnp** command lists all of the IEEE 802.1p code points in the congestion notification profile that have PFC enabled. The command output shows that PFC is enabled on code point **011** (**fcoe** queue) for the **fcoe-cnp** congestion notification profile.

The command also shows the default cable length (100 meters), the default maximum receive unit (2500 bytes), and the default mapping of priorities to output queues because this example does not include configuring these options.

Verifying That the Interface Class of Service Configuration Has Been Created

Purpose Verify that the CoS properties of the interfaces are correct. The verification output on MC-LAG Switches S1 and S2 differs from the output on FCoE Transit Switches TS1 and TS2.

Action List the interface CoS configuration on MC-LAG Switches S1 and S2 using the operational mode command **show configuration class-of-service interfaces**:

```
user@switch> show configuration class-of-service interfaces
ae0 {
    forwarding-class-set {
        fcoe-pg {
            output-traffic-control-profile fcoe-tcp;
        }
    }
    congestion-notification-profile fcoe-cnp;
}

ae1 {
    forwarding-class-set {
        fcoe-pg {
            output-traffic-control-profile fcoe-tcp;
        }
    }
    congestion-notification-profile fcoe-cnp;
}
```

List the interface CoS configuration on FCoE Transit Switches TS1 and TS2 using the operational mode command **show configuration class-of-service interfaces**:

```
user@switch> show configuration class-of-service interfaces
xe-0/0/30 {
    forwarding-class-set {
        fcoe-pg {
            output-traffic-control-profile fcoe-tcp;
        }
    }
    congestion-notification-profile fcoe-cnp;
}
xe-0/0/31 {
    forwarding-class-set {
        fcoe-pg {
            output-traffic-control-profile fcoe-tcp;
        }
    }
    congestion-notification-profile fcoe-cnp;
}
xe-0/0/32 {
    forwarding-class-set {
        fcoe-pg {
            output-traffic-control-profile fcoe-tcp;
        }
    }
    congestion-notification-profile fcoe-cnp;
}
xe-0/0/33 {
    forwarding-class-set {
        fcoe-pg {
            output-traffic-control-profile fcoe-tcp;
        }
    }
    congestion-notification-profile fcoe-cnp;
}
ae1 {
    forwarding-class-set {
```

```
        fcoe-pg {
            output-traffic-control-profile fcoe-tcp;
        }
    }
    congestion-notification-profile fcoe-cnp;
}
```

Meaning The **show configuration class-of-service interfaces** command lists the class of service configuration for all interfaces. For each interface, the command output includes:

- The name of the interface (for example, **ae0** or **xe-0/0/30**)
- The name of the forwarding class set associated with the interface (**fcoe-pg**)
- The name of the traffic control profile associated with the interface (output traffic control profile, **fcoe-tcp**)
- The name of the congestion notification profile associated with the interface (**fcoe-cnp**)

NOTE: Interfaces that are members of a LAG are not shown individually. The LAG or MC-LAG CoS configuration is applied to all interfaces that are members of the LAG or MC-LAG. For example, the interface CoS configuration output on MC-LAG Switches S1 and S2 shows the LAG CoS configuration but does not show the CoS configuration of the member interfaces separately. The interface CoS configuration output on FCoE Transit Switches TS1 and TS2 shows the LAG CoS configuration but also shows the configuration for interfaces xe-0/0/30, xe-0/0/31, xe-0/0/32, and xe-0/0/33, which are not members of a LAG.

Verifying That the Interfaces Are Correctly Configured

Purpose Verify that the LAG membership, MTU, VLAN membership, and port mode of the interfaces are correct. The verification output on MC-LAG Switches S1 and S2 differs from the output on FCoE Transit Switches T1 and T2.

Action List the interface configuration on MC-LAG Switches S1 and S2 using the operational mode command **show configuration interfaces**:

```
user@switch> show configuration interfaces
xe-0/0/10 {
    ether-options {
        802.3ad ae0;
    }
}
xe-0/0/11 {
    ether-options {
        802.3ad ae0;
    }
}
xe-0/0/20 {
    ether-options {
        802.3ad ae1;
```

```
    }
}
xe-0/0/21 {
    ether-options {
        802.3ad ae1;
    }
}
ae0 {
    mtu 2180;
    unit 0 {
        family ethernet-switching {
            port-mode trunk;
            vlan {
                members fcoe_vlan;
            }
        }
    }
}
ae1 {
    mtu 2180;
    unit 0 {
        family ethernet-switching {
            port-mode trunk;
            vlan {
                members fcoe_vlan;
            }
        }
    }
}
```

List the interface configuration on FCoE Transit Switches TS1 and TS2 using the operational mode command **show configuration interfaces**:

```
user@switch> show configuration interfaces
xe-0/0/25 {
    ether-options {
        802.3ad ae1;
    }
}
xe-0/0/26 {
    ether-options {
        802.3ad ae1;
    }
}
xe-0/0/30 {
    mtu 2180;
    unit 0 {
        family ethernet-switching {
            port-mode tagged-access;
            vlan {
                members fcoe_vlan;
            }
        }
    }
}
xe-0/0/31 {
    mtu 2180;
    unit 0 {
        family ethernet-switching {
            port-mode tagged-access;
```

```
                vlan {
                    members fcoe_vlan;
                }
            }
        }
    }
    xe-0/0/32 {
        mtu 2180;
        unit 0 {
            family ethernet-switching {
                port-mode tagged-access;
                vlan {
                    members fcoe_vlan;
                }
            }
        }
    }
    xe-0/0/33 {
        mtu 2180;
        unit 0 {
            family ethernet-switching {
                port-mode tagged-access;
                vlan {
                    members fcoe_vlan;
                }
            }
        }
    }

    ae1 {
        mtu 2180;
        unit 0 {
            family ethernet-switching {
                port-mode trunk;
                vlan {
                    members fcoe_vlan;
                }
            }
        }
    }
```

Meaning The **show configuration interfaces** command lists the configuration of each interface by interface name.

For each interface that is a member of a LAG, the command lists only the name of the LAG to which the interface belongs.

For each LAG interface and for each interface that is not a member of a LAG, the command output includes:

- The MTU (**2180**)
- The unit number of the interface (**0**)
- The port mode (**trunk** mode for interfaces that connect two switches, **tagged-access** mode for interfaces that connect to FCoE hosts)
- The name of the VLAN in which the interface is a member (**fcoe_vlan**)

Verifying That FIP Snooping Is Enabled on the FCoE VLAN on FCoE Transit Switches TS1 and TS2 Access Interfaces

Purpose Verify that FIP snooping is enabled on the FCoE VLAN access interfaces. FIP snooping is enabled only on the FCoE access interfaces, so it is enabled only on FCoE Transit Switches TS1 and TS2. FIP snooping is not enabled on MC-LAG Switches S1 and S2 because FIP snooping is done at the Transit Switch TS1 and TS2 FCoE access ports.

Action List the port security configuration on FCoE Transit Switches TS1 and TS2 using the operational mode command **show configuration ethernet-switching-options secure-access-port**:

```
user@switch> show configuration ethernet-switching-options secure-access-port
interface ae1.0 {
    fcoe-trusted;
}
vlan fcoe_vlan {
    examine-fip {
        examine-vn2vn {
            beacon-period 90000;
        }
    }
}
```

Meaning The **show configuration ethernet-switching-options secure-access-port** command lists port security information, including whether a port is trusted. The command output shows that:

- LAG port **ae1.0**, which connects the FCoE transit switch to the MC-LAG switches, is configured as an FCoE trusted interface. FIP snooping is not performed on the member interfaces of the LAG (**xe-0/0/25** and **xe-0/0/26**).
- FIP snooping is enabled (**examine-fip**) on the FCoE VLAN (**fcoe_vlan**), the type of FIP snooping is VN2VN_Port FIP snooping (**examine-vn2vn**) and the beacon period is set to 90000 milliseconds. On Transit Switches TS1 and TS2, all interface members of the FCoE VLAN perform FIP snooping unless the interface is configured as FCoE trusted. On Transit Switches TS1 and TS2, interfaces **xe-0/0/30**, **xe-0/0/31**, **xe-0/0/32**, and **xe-0/0/33** perform FIP snooping because they are not configured as FCoE trusted. The interface members of LAG **ae1** (**xe-0/0/25** and **xe-0/0/26**) do not perform FIP snooping because the LAG is configured as FCoE trusted.

Verifying That the FIP Snooping Mode Is Correct on FCoE Transit Switches TS1 and TS2

Purpose Verify that the FIP snooping mode is correct on the FCoE VLAN. FIP snooping is enabled only on the FCoE access interfaces, so it is enabled only on FCoE Transit Switches TS1 and TS2. FIP snooping is not enabled on MC-LAG Switches S1 and S2 because FIP snooping is done at the Transit Switch TS1 and TS2 FCoE access ports.

Action List the FIP snooping configuration on FCoE Transit Switches TS1 and TS2 using the operational mode command **show fip snooping brief**:

```
user@switch> show fip snooping brief
```

```
VLAN: fcoe_vlan,    Mode: VN2VN Snooping
  FC-MAP: 0e:fd:00
…
```

NOTE: The output has been truncated to show only the relevant information.

Meaning The **show fip snooping brief** command lists FIP snooping information, including the FIP snooping VLAN and the FIP snooping mode. The command output shows that:

- The VLAN on which FIP snooping is enabled is **fcoe_vlan**
- The FIP snooping mode is VN2VN_Port FIP snooping (**VN2VN Snooping**)

Verifying That IGMP Snooping Is Disabled on the FCoE VLAN

Purpose Verify that IGMP snooping is disabled on the FCoE VLAN on all four switches.

Action List the IGMP snooping protocol information on each of the four switches using the **show configuration protocols igmp-snooping** command:

```
user@switch> show configuration protocols igmp-snooping
vlan fcoe_vlan {
    disable;
}
```

Meaning The **show configuration protocols igmp-snooping** command lists the IGMP snooping configuration for the VLANs configured on the switch. The command output shows that IGMP snooping is disabled on the FCoE VLAN (**fcoe_vlan**).

Example: Setting Up Fibre Channel and FCoE VLAN Interfaces in an FCoE-FC Gateway Fabric

To transmit Fibre Channel (FC) traffic between FCoE devices and a storage area network (SAN) FC switch, you configure a local FC fabric on the gateway. The gateway FC fabric includes FCoE and native FC interfaces, and a VLAN to carry FCoE traffic from FCoE-capable devices. The gateway FC fabric creates the path between the FCoE devices and the SAN.

This example describes how to configure the interfaces, VLAN, and FC fabric to connect FCoE devices to the FC switch and route traffic between the VLAN and FC interfaces:

Requirements

This example uses the following hardware and software components:

- A configured and provisioned Juniper Networks QFX3500 Switch to act as an FCoE-FC gateway
- FCoE-capable devices in an Ethernet network equipped with converged network adapters (CNAs)
- An FC switch to transmit and receive native FC traffic
- FC storage devices in the SAN
- Junos OS Release 11.1 or later for the QFX Series

Overview

No interfaces are configured for FC network connectivity by default. You need to configure the FC fabric and its interfaces explicitly. Each FC fabric consists of a combination of at least one FCoE VLAN interface between the FCoE-FC gateway and the FCoE devices, and one or more native FC interfaces between the FCoE-FC gateway and the FC switch.

An FCoE VLAN interface connects the FCoE-FC gateway to FCoE devices. FCoE traffic between the devices and the FCoE-FC gateway requires a dedicated VLAN used only for FCoE traffic. You cannot mix standard Ethernet traffic and FCoE traffic on the FCoE VLAN.

NOTE: **IGMP snooping is not supported on FCoE VLANs. Disable IGMP snooping on FCoE VLANs.**

Storm control is not supported on Ethernet interfaces that belong to the FCoE VLAN. Ensure that storm control is disabled on all Ethernet interfaces that belong to the FCoE VLAN to prevent FCoE traffic from being dropped.

When FCoE frames enter the FCoE-FC gateway, the gateway:

1. Strips the Ethernet encapsulation from the FCoE frames.
2. Sends the resulting native FC frames to the FC switch through the gateway's native FC interfaces.

Each FC interface and FCoE VLAN interface can belong to only one FC fabric. Different FC fabrics must use different native FC interfaces and different FCoE VLAN interfaces.

Multiple FC fabrics on the FCoE-FC gateway can connect to the same FC switch, but they must use different FC interfaces and different FCoE VLAN interfaces.

The Ethernet interfaces that belong to the FCoE VLAN should be configured in tagged-access port mode and must include the native VLAN because FIP VLAN discovery and notification frames are exchanged as untagged packets. These Ethernet interfaces require a maximum transmission unit (MTU) size of at least 2180 bytes to accommodate the FC payload and FCoE encapsulation. (Sometimes the MTU is rounded up to 2500 bytes. If larger frames are expected on the interface, set the MTU size accordingly.)

This example shows a simple configuration to illustrate the basic steps for creating:

- The FCoE-device-facing VLAN and its 10-Gigabit Ethernet interfaces
- The VLAN interface
- The FC-switch-facing native FC interfaces
- One FC fabric on the FCoE-FC gateway

Configuring these elements results in traffic being routed between the VLAN and FC interfaces, thus connecting the FCoE devices to the FC switch through the FCoE-FC gateway.

A VLAN called **blue** transports FCoE traffic between FCoE devices and the FCoE-FC gateway using an FCoE VLAN interface called **vlan.100**. The FCoE-FC gateway's **vlan.100** interface presents an F_Port interface to the FCoE devices on the VLAN. For each FCoE device ENode that logs in to the FCoE-FC gateway, the gateway instantiates a virtual F_Port (VF_Port) interface. This creates a virtual link between the ENode VN_Port and the FCoE-FC gateway. The FCoE-FC gateway's native FC interfaces transport FC traffic between the gateway and the FC switch.

Configuring both the FCoE VLAN interface and the native FC interfaces as part of a gateway fabric associates them in the switch and makes the connection between the FCoE servers and the FC switch.

Topology

The topology for this example consists of one QFX3500 switch with FC-capable ports to connect to the FC switch and with Ethernet ports in tagged-access mode to connect to the FCoE devices. Table 384 on page 4965 and Figure 181 on page 4966 show the configuration components of this example.

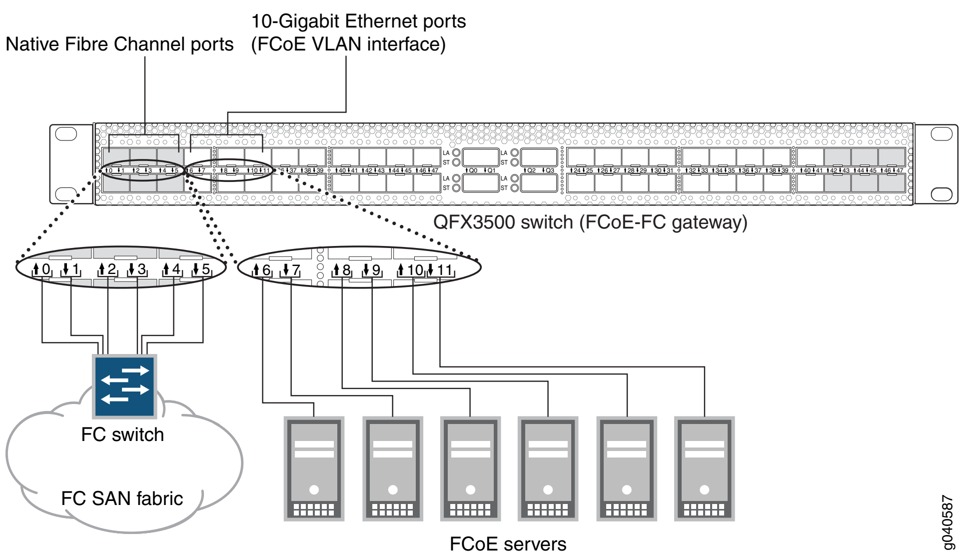
Table 384: Components of the Fibre Channel Interface Configuration Topology

Property	Settings
Switch hardware	QFX3500 switch in gateway mode
FCoE VLAN name and tag ID	**blue**, tag **100** IGMP snooping disabled on the FCoE VLAN.

Table 384: Components of the Fibre Channel Interface Configuration Topology *(continued)*

Property	Settings
Interfaces in VLAN **blue**	Interfaces: **xe-0/0/6**, **xe-0/0/7**, **xe-0/0/8**, **xe-0/0/9**, **xe-0/0/10**, **xe-0/0/11** Port mode: **tagged-access** MTU: **2180** Native VLAN: **1** NOTE: You can bundle two or more of the VLAN interfaces in a link aggregation group (LAG) if you wish. NOTE: FCoE VLANs (any VLAN that carries FCoE traffic) support only Spanning Tree Protocol (STP) and link aggregation group (LAG) Layer 2 features.
FCoE VLAN interface	**vlan.100** Port mode: **f-port**
Native Fibre Channel interfaces	Interfaces: **fc-0/0/0**, **fc-0/0/1**, **fc-0/0/2**, **fc-0/0/3**, **fc-0/0/4**, **fc-0/0/5** Port mode: **np-port** Speed: **4 Gbps**
Fibre Channel fabric **fcproxy1**	Fabric type: **proxy** Fabric ID: **1** FC interfaces: **fc-0/0/0**, **fc-0/0/1**, **fc-0/0/2**, **fc-0/0/3**, **fc-0/0/4**, **fc-0/0/5**

Figure 181: Fibre Channel Interface Configuration Topology



This configuration example creates a VLAN for FCoE traffic and routes its traffic to an FCoE VLAN interface that is part of the FC fabric. It also creates the FC interfaces needed to connect to the FC switch.

To set up FC interfaces and FCoE VLAN interfaces:

- Configure a VLAN to use as a dedicated FCoE VLAN:
  - Configure the interfaces the FCoE VLAN uses as Ethernet switching interfaces in tagged-access port mode.
  - If storm control is enabled, disable it on the interfaces.
  - Configure the interfaces the FCoE VLAN uses with the native VLAN.
  - Configure the FCoE VLAN to use the desired Ethernet interfaces.
  - Disable IGMP snooping on the FCoE VLAN. (IGMP snooping is enabled by default on all VLANs, but is not supported on FCoE VLANs).
- Configure the FCoE VLAN interface.
- Define the interface for the FCoE VLAN (associate the VLAN with the FCoE VLAN interface).
- Configure the physical FC interfaces (either one or two 6-port blocks) that connect to the FC switch.
- Configure the logical FC interfaces that connect to the FC switch.
- Configure the FCoE-FC gateway fabric:
  - Configure the fabric ID.
  - Configure the fabric as a proxy fabric.
  - Add the FCoE VLAN interface and the native FC interfaces to the fabric.

To keep the example simple, the configuration steps show six Ethernet interfaces in the FCoE VLAN and six native FC interfaces in the FC fabric. Use the same configuration procedure to add more interfaces to the FCoE VLAN or to the FC fabric.

Configuration

CLI Quick Configuration

To quickly configure FCoE and native FC interfaces on an FCoE-FC gateway and route traffic between the FCoE VLAN and FC interfaces, copy the following commands and paste them into the switch terminal window:

```
[edit]
set vlans blue vlan-id 100
set vlans native vlan-id 1
set interfaces xe-0/0/6 unit 0 family ethernet-switching port-mode tagged-access vlan members blue
set interfaces xe-0/0/7 unit 0 family ethernet-switching port-mode tagged-access vlan members blue
set interfaces xe-0/0/8 unit 0 family ethernet-switching port-mode tagged-access vlan members blue
set interfaces xe-0/0/9 unit 0 family ethernet-switching port-mode tagged-access vlan members blue
set interfaces xe-0/0/10 unit 0 family ethernet-switching port-mode tagged-access vlan members blue

set fc-fabrics fcproxy1 interface vlan.100
set fc-fabrics fcproxy1 interface fc-0/0/0.0
set fc-fabrics fcproxy1 interface fc-0/0/1.0
set fc-fabrics fcproxy1 interface fc-0/0/2.0
set fc-fabrics fcproxy1 interface fc-0/0/3.0
set fc-fabrics fcproxy1 interface fc-0/0/4.0
set fc-fabrics fcproxy1 interface fc-0/0/5.0
```

Step-by-Step Procedure

Configure FCoE and FC interfaces in an FCoE-FC gateway FC fabric and set up traffic routing between the FCoE VLAN and FC interfaces:

1. Configure the VLAN for FCoE traffic:

   ```
   [edit vlans]
   user@switch# set blue vlan-id 100
   ```

2. Configure the native VLAN:

   ```
   [edit vlans]
   user@switch# set native vlan-id 1
   ```

3. Configure the Ethernet interfaces for the FCoE VLAN in tagged-access mode and as members of the FCoE VLAN (VLAN **blue**):

   ```
   [edit interfaces]
   user@switch# set xe-0/0/6 unit 0 family ethernet-switching port-mode tagged-access
   vlan members blue
   ```

user@switch# **set xe-0/0/7 unit 0 family ethernet-switching port-mode tagged-access vlan members blue**
user@switch# **set xe-0/0/8 unit 0 family ethernet-switching port-mode tagged-access vlan members blue**
user@switch# **set xe-0/0/9 unit 0 family ethernet-switching port-mode tagged-access vlan members blue**
user@switch# **set xe-0/0/10 unit 0 family ethernet-switching port-mode tagged-access vlan members blue**
user@switch# **set xe-0/0/11 unit 0 family ethernet-switching port-mode tagged-access vlan members blue**

4. Configure the native VLAN on the Ethernet interfaces in the FCoE VLAN:

```
[edit interfaces]
user@switch# set xe-0/0/6 unit 0 family ethernet-switching native-vlan-id 1
user@switch# set xe-0/0/7 unit 0 family ethernet-switching native-vlan-id 1
user@switch# set xe-0/0/8 unit 0 family ethernet-switching native-vlan-id 1
user@switch# set xe-0/0/9 unit 0 family ethernet-switching native-vlan-id 1
user@switch# set xe-0/0/10 unit 0 family ethernet-switching native-vlan-id 1
user@switch# set xe-0/0/11 unit 0 family ethernet-switching native-vlan-id 1
```

5. Set the MTU to 2180 for each Ethernet interface:

```
[edit interfaces]
user@switch# set xe-0/0/6 mtu 2180
user@switch# set xe-0/0/7 mtu 2180
user@switch# set xe-0/0/8 mtu 2180
user@switch# set xe-0/0/9 mtu 2180
user@switch# set xe-0/0/10 mtu 2180
user@switch# set xe-0/0/11 mtu 2180
```

6. Assign the Ethernet interfaces to the FCoE VLAN:

```
[edit vlans blue interface]
user@switch# set xe-0/0/6.0
user@switch# set xe-0/0/7.0
user@switch# set xe-0/0/8.0
user@switch# set xe-0/0/9.0
user@switch# set xe-0/0/10.0
user@switch# set xe-0/0/11.0
```

7. Disable IGMP snooping on the FCoE VLAN:

```
[edit protocols]
user@switch# set igmp-snooping vlan blue disable
```

8. Configure the FCoE VLAN interface and port mode for the FCoE traffic:

```
[edit interfaces]
user@switch# set vlan unit 100 family fibre-channel port-mode f-port
```

9. Define the FCoE VLAN interface as the interface for the FCoE VLAN:

```
[edit vlans]
user@switch# set blue l3-interface vlan.100
```

10. Configure the physical FC interfaces the fabric uses to connect to the FC switch:

```
[edit chassis fpc 0 pic 0]
user@switch# set fibre-channel port-range 0 5
```

NOTE: When you configure ports as FC ports, the port designation changes from **xe-n/n/n.n** format to **fc-n/n/n.n** format to indicate that the interface is an FC interface. FC interfaces do not support 10-Gbps interface speed but instead conform to FC interface speeds of 2 Gbps, 4 Gbps, or 8 Gbps.

11. Configure the native FC interfaces and port mode:

```
[edit interfaces]
user@switch# set fc-0/0/0 unit 0 family fibre-channel port-mode np-port
user@switch# set fc-0/0/1 unit 0 family fibre-channel port-mode np-port
user@switch# set fc-0/0/2 unit 0 family fibre-channel port-mode np-port
user@switch# set fc-0/0/3 unit 0 family fibre-channel port-mode np-port
user@switch# set fc-0/0/4 unit 0 family fibre-channel port-mode np-port
user@switch# set fc-0/0/5 unit 0 family fibre-channel port-mode np-port
```

12. Configure the native FC interface port speed:

```
[edit interfaces]
user@switch# set fc-0/0/0 fibrechannel-options speed 4g
user@switch# set fc-0/0/1 fibrechannel-options speed 4g
user@switch# set fc-0/0/2 fibrechannel-options speed 4g
user@switch# set fc-0/0/3 fibrechannel-options speed 4g
user@switch# set fc-0/0/4 fibrechannel-options speed 4g
user@switch# set fc-0/0/5 fibrechannel-options speed 4g
```

13. Configure the FC fabric name and unique ID:

```
[edit fc-fabrics]
user@switch# set fcproxy1 fabric-id 1
```

14. Define the FC fabric as an FCoE-FC gateway:

```
[edit fc-fabrics]
user@switch# set fcproxy1 fabric-type proxy
```

15. Assign the FCoE VLAN interface to the fabric:

```
[edit fc-fabrics]
user@switch# set fcproxy1 interface vlan.100
```

16. Assign the native FC interfaces to the fabric:

```
[edit fc-fabrics]
user@switch# set fcproxy1 interface fc-0/0/0.0
user@switch# set fcproxy1 interface fc-0/0/1.0
user@switch# set fcproxy1 interface fc-0/0/2.0
user@switch# set fcproxy1 interface fc-0/0/3.0
user@switch# set fcproxy1 interface fc-0/0/4.0
user@switch# set fcproxy1 interface fc-0/0/5.0
```

Results Display the results of the configuration:

```
user@switch> show configuration
fc-0/0/0 {
  fibrechannel-options {
    speed 4g;
  }
```

```

        interface {
          xe-0/0/6.0;
          xe-0/0/7.0;
          xe-0/0/8.0;
          xe-0/0/9.0;
          xe-0/0/10.0;
          xe-0/0/11.0;
        }
```

```
        l3-interface vlan.100
    }
    native {
        vlan-id 1;
    }
}
```

TIP: To quickly configure the interfaces, issue the **load merge terminal** command and then copy the hierarchy and paste it into the switch terminal window.

Verification

To verify that the native FC interfaces and FCoE VLAN interface have been created, added to the FC fabric, and are operating properly, perform these tasks:

Verifying That the Native FC Interfaces and the FCoE VLAN Interface Have Been Created

Purpose Verify that the six native FC interfaces and the FCoE VLAN interface have been created on the switch and are configured in the correct mode.

Action List all of the FC interfaces configured on the switch using the **show fibre-channel interfaces** command:

```
user@switch> show fibre-channel interfaces
                          Native            Config   Oper
Interface     Idx   Type  Fabric-id    NPIV Mode     Mode     State
fc-0/0/0.0    70    FC    1            YES  NP       NP       up
fc-0/0/1.0    71    FC    1            YES  NP       NP       up
fc-0/0/2.0    72    FC    1            YES  NP       NP       up
fc-0/0/3.0    73    FC    1            YES  NP       NP       up
fc-0/0/4.0    74    FC    1            YES  NP       NP       up
fc-0/0/5.0    75    FC    1            YES  NP       NP       up
vlan.100      67    FCOE  1            YES  F        F        up
```

Meaning The **show fibre-channel interfaces** command lists all native FC interfaces and FCoE VLAN interfaces configured on the switch. The command output shows that the FC interfaces **fc-0/0/0.0**, **fc-0/0/1.0**, **fc-0/0/2.0**, **fc-0/0/3.0**, **fc-0/0/4.0**, and **fc-0/0/5.0** have been created and that those six interfaces:

- Are native Fibre Channel interfaces (type **FC**).
- Belong to the FC fabric with a configured fabric ID of **1**.

- Are capable of N_Port ID virtualization (NPIV).
- Have a configured mode and an operational mode of proxy N_Port (**NP**), which means that they should be connected to an FCF or an FC switch, not to an FCoE device, and that they carry native FC traffic.
- Show an operational state of **up**.

The command output also shows that the FCoE VLAN interface **vlan.100** has been created and that interface:

- Is an FCoE VLAN interface (type **FCOE)**.
- Belongs to the FC fabric with a configured fabric ID of **1**.
- Is capable of N_Port ID virtualization (NPIV).
- Has a configured mode and an operational mode of F_Port (**F**), which means that its interfaces connect to FCoE devices and carry FCoE traffic.
- Shows an operational state of **up**.

Verifying That the FCoE VLAN Includes the Correct Ethernet Interfaces

Purpose Verify that the FCoE VLAN **blue** has been created with the correct VLAN tag (**100**) and with the correct Ethernet interfaces.

Action List all of the interfaces configured on the switch in VLAN **blue** using the **show vlans** command:

```
user@switch> show vlans blue
Name           Tag     Interfaces
blue           100
                     xe-0/0/6.0, xe-0/0/7.0, xe-0/0/8.0, xe-0/0/9.0, xe-0/0/10.0

                       xe-0/0/11.0
```

Meaning The **show vlans blue** command lists the interfaces that are members of the FCoE VLAN **blue**. The command output shows that the **blue** VLAN has a tag ID of 100 and includes the interfaces **xe-0/0/6.0**, **xe-0/0/7.0**, **xe-0/0/8.0**, **xe-0/0/9.0**, **xe-0/0/10.0**, and **xe-0/0/11.0**.

Verifying That the FC Fabric Includes the Correct Interfaces

Purpose Verify that the FC fabric configuration is configured on the switch with the correct native FC and FCoE VLAN interfaces.

Action List all of the interfaces configured on FC fabrics on the switch using the **show fibre-channel fabric** command:

```
user@switch> show fibre-channel fabric
Name           Fabric-id     Type     Interfaces
fcproxy1       1             PROXY
                                      fc-0/0/0.0
                                      fc-0/0/1.0
                                      fc-0/0/2.0
```

```
fc-0/0/3.0
fc-0/0/4.0
fc-0/0/5.0
vlan.100
```

Meaning The **show fibre-channel fabric** command lists the interfaces that are members of each FC fabric. The command output shows that the only fabric configured on the switch is named **fcproxy1**, has a fabric-id of **1**, and is a **proxy** fabric in an FCoE-FC gateway. The command output also shows that the native FC interfaces **fc-0/0/0.0**, **fc-0/0/1.0**, **fc-0/0/2.0**, **fc-0/0/3.0**, **fc-0/0/4.0**, and **fc-0/0/5.0**, and the FCoE VLAN interface **vlan.100** belong to **fcproxy1**.

Verifying Native FC Interface Operation

Purpose Verify that the native FC interfaces are online and display the number of FC sessions on each interface.

Action List all of the native FC NP_Port interface states and sessions by FC fabric using the **show fibre-channel proxy np-port** command:

```
user@switch> show fibre-channel proxy np-port
Fabric: fcproxy1, Fabric-id: 1
NP-Port     State              Sessions      LB state   LB weight
fc-0/0/0.0  online             3             ON         4
fc-0/0/1.0  online             3             ON         4
fc-0/0/2.0  online             2             ON         4
fc-0/0/3.0  online             2             ON         4
fc-0/0/4.0  online             2             ON         4
fc-0/0/5.0  online             2             ON         4
```

Meaning The **show fibre-channel proxy np-port** command lists the interfaces that are configured as native FC proxy N_Port interfaces. The command output shows:

- The fabric name is **fcproxy1** and its fabric ID is **1**.
- The interfaces are **online**.
- The number of FC sessions (virtual links) running on each interface.
- The load-balancing (LB) state is **ON** for all of the interfaces.
- The LB weight reflects the port speed of each interface, which is **4** Gbps.

Verifying That IGMP Snooping Has Been Disabled on the FCoE VLAN

Purpose Verify that IGMP snooping is disabled on the FCoE VLAN.

Action List the IGMP snooping protocol information for the FCoE VLAN using the **show configuration protocols igmp-snooping vlan blue** command:

```
user@switch> show configuration protocols igmp-snooping vlan blue
    disable;
```

Meaning The **show configuration protocols igmp-snooping vlan blue** command lists the IGMP snooping configuration for the FCoE VLAN. The command output shows that IGMP snooping is disabled on the FCoE VLAN.

Example: Configuring VN2VN_Port FIP Snooping (FCoE Hosts Directly Connected to the Same FCoE Transit Switch)

This example shows how to configure VN_Port to VN_Port (VN2VN_Port) FIP snooping when the hosts are directly connected to the same FCoE transit switch.

NOTE: **This example uses Junos OS without support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that supports ELS, see** “Example: Configuring VN2VN_Port FIP Snooping (FCoE Hosts Directly Connected to the Same FCoE Transit Switch)” on page 5025.

VN2VN_Port FIP snooping on an FCoE transit switch provides security to help prevent unauthorized access and data transmission on a bridge that connects ENodes in the Ethernet network. VN2VN_Port FIP snooping provides security for virtual links by creating filters based on information gathered (snooped) about FCoE devices during FIP transactions.

VN2VN_Port FIP snooping is conceptually similar to VN2VN_Port FIP snooping between VN_Ports and VF_Ports, but VN2VN_Port FIP snooping does not require traffic between VN_Ports to traverse the Fibre Channel (FC) switch or FCoE forwarder (FCF). Instead, a VN_Port communicates transparently through the transit switch on a virtual link that emulates a direct connection to the VN_Port at the other end of the virtual link.

To configure VN2VN_Port FIP snooping when the hosts are directly connected to the same FCoE transit switch, you must follow these configuration rules:

- VN2VN_Port traffic must use a dedicated FCoE VLAN, and all ENodes that communicate using VN2VN_Port FIP snooping must use that FCoE VLAN. You cannot mix VN2VN_Port FIP snooping traffic with VN2VF_Port FIP snooping traffic in the same FCoE VLAN.

  NOTE: An FCoE VLAN can support either VN2VF_Port FIP snooping or VN2VN_Port FIP snooping, but not both. Configure separate FCoE VLANs for VN2VF_Port FIP snooping traffic and for VN2VN_Port FIP snooping traffic. On FCoE VLANs that are configured as VN2VN_Port FIP snooping VLANs, VN_Port to VF_Port (FIP snooping) traffic is dropped.

- ENode-facing ports must be set in **tagged-access** port mode.
- ENode-facing ports must be untrusted ports.
- Network-facing (switch-facing) ports must be set in **trunk** port mode.
- Network-facing ports must be FCoE trusted ports.
- Explicitly configure the beacon period. The beacon period is essentially a keepalive timer for virtual link maintenance.

When you enable VN2VF_Port FIP snooping, the system snoops VN_Port to VF_Port packets and enforces security only on VN_Port to VF_Port virtual links. When you enable VN2VN_Port FIP snooping, the system snoops VN_Port to VN_Port packets and enforces security only on VN_Port to VN_Port virtual links.

The transit switch applies VN2VN_Port FIP snooping filters at the ports associated with the FCoE VLANs on which you enable VN2VN FIP snooping.

This example describes how to configure VN2VN_Port FIP snooping when the FCoE hosts are directly connected to the same transit switch:

Requirements

This example uses the following hardware and software components:

- One Juniper Networks QFX3500 Switch used as a transit switch
- Junos OS Release 12.2 or later for the QFX Series
- Two FCoE hosts that have ENodes

Overview

This example shows you how to:

- Set the correct interface port modes on the transit switch.
- Configure the interfaces to use the dedicated FCoE VLAN for VN2VN_Port FIP snooping.
- Configure the dedicated FCoE VLAN for VN2VN_Port FIP snooping traffic.
- Enable VN2VN_Port FIP snooping on the FCoE VLAN and configure the beacon period.

Topology

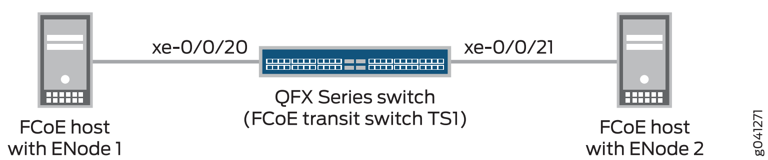
Table 385 on page 4979 shows the configuration components for this example.

Table 385: Components of the VN2VN_Port FIP Snooping Configuration Topology (FCoE Hosts Directly Connected to the Same FCoE Transit Switch)

Component	Settings
Hardware	QFX3500 switch (FCoE transit switch TS1) Two FCoE hosts that have ENodes (ENode1 and ENode2, respectively)
Interfaces and port modes	• Interface **xe-0/0/20**, port mode **tagged-access**, connects directly to the FCoE host with ENode1. • Interface **xe-0/0/21**, port mode **tagged-access**, connects directly to the FCoE host with ENode2.
Interface VLAN membership	Both interfaces use VLAN **vlan200**.
VN2VN_Port FIP snooping VLAN	VLAN name—**vlan200** VLAN ID—200
FIP snooping mode and beacon period	Set **examine-vn2vn** (VN2VN_Port FIP snooping) Beacon period—90000 ms

Figure 182 on page 4979 shows the network topology for this example.

Figure 182: VN2VN_Port FIP Snooping (FCoE Hosts Connected to Same Transit Switch) Topology



Configuration

CLI Quick Configuration

To quickly configure VN2VN_Port FIP snooping for FCoE hosts connected directly to the same transit switch, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level:

set interfaces xe-0/0/20 unit 0 family ethernet-switching port-mode tagged-access
set interfaces xe-0/0/21 unit 0 family ethernet-switching port-mode tagged-access
set interfaces xe-0/0/20 unit 0 family ethernet-switching vlan members vlan200
set interfaces xe-0/0/21 unit 0 family ethernet-switching vlan members vlan200
set vlans vlan200 vlan-id 200
set ethernet-switching-options secure-access-port vlan vlan200 examine-fip examine-vn2v2 beacon-period 90000

Configuring VN2VN_Port FIP Snooping (FCoE Hosts Directly Connected to the Same FCoE Transit Switch)

Step-by-Step Procedure

To configure interface port modes, configure interface VLAN membership in the FCoE VLAN dedicated to VN2VN_Port traffic, configure the VLAN, set the beacon period, and enable VN2VN_Port FIP snooping:

1. Configure the port modes of the interfaces that connect directly to the FCoE host ENodes:

   `user@switch#` **set interfaces xe-0/0/20 unit 0 family ethernet-switching port-mode tagged-access**
   set interfaces xe-0/0/21 unit 0 family ethernet-switching port-mode tagged-access

2. Configure the interface VLAN membership so that the interfaces connected to theENodes are members of the dedicated VN2VN_Port VLAN (**vlan200**):

   `user@switch#` **set interfaces xe-0/0/20 unit 0 family ethernet-switching vlan members vlan200**
   set interfaces xe-0/0/21 unit 0 family ethernet-switching vlan members vlan200

3. Configure the FCoE VLAN dedicated to VN2VN_Port FIP snooping:

   `user@switch#` **set vlans vlan200 vlan-id 200**

4. Enable VN2VN_Port FIP snooping on the VLAN and configure the beacon period:

   `user@switch#` **set ethernet-switching-options secure-access-port vlan vlan200 examine-fip examine-vn2v2 beacon-period 90000**

Verification

To verify that the VN2VN_Port FIP snooping configuration has been created and is operating properly, perform these tasks:

- Verifying That VN2VN_Port FIP Snooping is Enabled on the FCoE VLAN on page 4980
- Verifying the Interface Port Mode on page 4981

Verifying That VN2VN_Port FIP Snooping is Enabled on the FCoE VLAN

Purpose

Verify that VN2VN_Port FIP snooping is enabled on the correct VLAN (**vlan200**), the beacon period is set to **90000** milliseconds, and the correct interfaces (**xe-0/0/20** and **xe-0/0/21**) are members of the VLAN.

Action List the FIP snooping information using the operational mode command **show fip snooping detail**.

```
user@switch> show fip snooping detail
VLAN: vlan200,  Mode: VN2VN Snooping
  FC-MAP: 0e:fd:00
  Beacon_Period:  90000
  VN2VN Mode: Point-to-Point
    Enode Information
    Enode-MAC: 10:10:94:01:00:02,       Interface: xe-0/0/20
      Active VN_Ports : 1
      VN_Port Information
      VN-Port MAC: 0e:fd:00:00:0a:01
         Active Sessions    : 1
         Session Information
     Vlink far-end VN-Port-MAC: 0e:fd:00:00:0b:01
    Enode-MAC: 10:10:94:01:00:02,       Interface: xe-0/0/21
      Active VN_Ports : 1
      VN_Port Information
      VN-Port MAC: 0e:fd:00:00:0b:01
         Active Sessions    : 1
         Session Information
     Vlink far-end VN-Port-MAC: 0e:fd:00:00:0a:01
```

Meaning The **show fip snooping detail** command lists all of the transit switch information about VN2VN_Port FIP snooping and VN2VF_Port FIP snooping. The command shows that:

- The VLAN is **vlan200**.
- The mode is FIP snooping mode **VN2VN**, for VN2VN_Port FIP snooping. (If the Mode field shows **VN2VF**, then the FIP snooping mode is VN2VF_Port FIP snooping.)
- The beacon period is **90000**.
- The interfaces for the ENodes are **xe-0/0/20** and **xe-0/0/21**.

In addition, this useful command shows information about the ENodes and the VN2VN_Port sessions.

Verifying the Interface Port Mode

Purpose Verify that the interface port modes are **tagged-access**.

Action List the Ethernet switching interfaces to confirm the port mode using the **show ethernet-switching interfaces detail** operational command.

Use the operational mode commands **show ethernet-switching interfaces xe-0/0/20.0 detail** and **show ethernet-switching interfaces xe-0/0/21.0 detail** to list the Ethernet switching interface information. The output is truncated to show only the relevant portions:

```
user@switch> show ethernet-switching interfaces xe-0/0/20.0 detail
Interface: xe-0/0/20.0, Index: 75, State: up, Port mode: Tagged-Access
.
.
.
```

```
user@switch> show ethernet-switching interfaces xe-0/0/21.0 detail
Interface: xe-0/0/21.0, Index: 83, State: up, Port mode: Tagged-Access
.
.
.
```

Meaning The **show ethernet-switching interfaces detail** command lists the port mode as **tagged-access** for both interfaces.

Example: Configuring VN2VN_Port FIP Snooping (FCoE Hosts Directly Connected to Different FCoE Transit Switches)

This example shows how to configure VN_Port to VN_Port (VN2VN_Port) FIP snooping when the hosts are directly connected to different FCoE transit switches, and the transit switches are directly connected to each other.

NOTE: **This example uses Junos OS without support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that supports ELS, see** “Example: Configuring VN2VN_Port FIP Snooping (FCoE Hosts Directly Connected to Different FCoE Transit Switches)” on page 5030.

VN2VN_Port FIP snooping on an FCoE transit switch provides security to help prevent unauthorized access and data transmission on a bridge that connects ENodes in the Ethernet network. VN2VN_Port FIP snooping provides security for virtual links by creating filters based on information gathered (snooped) about FCoE devices during FIP transactions.

VN2VN_Port FIP snooping is conceptually similar to VN2VF_Port FIP snooping between VN_Ports and VF_Ports, but VN2VN_Port FIP snooping does not require traffic between VN_Ports to traverse the Fibre Channel (FC) switch or FCoE forwarder (FCF). Instead, a VN_Port communicates transparently through one or more transit switches on a virtual link that emulates a direct connection to the VN_Port at the other end of the virtual link.

To configure VN2VN_Port FIP snooping when the hosts are directly connected to different FCoE transit switches, and the transit switches are directly connected to each other, you must follow these configuration rules:

- VN2VN_Port traffic must use a dedicated FCoE VLAN, and all ENodes that communicate using VN2VN_Port FIP snooping must use that FCoE VLAN. The FCoE VLAN must be configured on each transit switch. You cannot mix VN2VN_Port FIP snooping traffic with VN2VF_Port FIP snooping traffic in the same FCoE VLAN.

NOTE: **An FCoE VLAN can support either VN2VF_Port FIP snooping or VN2VN_Port FIP snooping, but not both. Configure separate FCoE VLANs for VN2VF_Port FIP snooping traffic and for VN2VN_Port FIP snooping traffic. On FCoE VLANs that are configured as VN2VN_Port FIP snooping VLANs, VN2VF_Port traffic is dropped.**

- ENode-facing ports must be set in **tagged-access** port mode.
- ENode-facing ports must be untrusted ports.
- Network-facing (switch-facing) ports must be set in **trunk** port mode.
- Network-facing ports must be FCoE trusted ports.
- Explicitly configure the beacon period. The beacon period is essentially a keepalive timer for virtual link maintenance.

When you enable VN2VF_Port FIP snooping, the system snoops VN_Port to VF_Port packets and enforces security only on VN_Port to VF_Port virtual links. When you enable VN2VN_Port FIP snooping, the system snoops VN_Port to VN_Port packets and enforces security only on VN_Port to VN_Port virtual links.

The transit switch applies VN2VN_Port FIP snooping filters at the ports associated with the FCoE VLANs on which you enable VN2VN FIP snooping.

This example describes how to configure VN2VN_Port FIP snooping when the FCoE hosts are directly connected to different transit switches, and the transit switches are directly connected to each other:

- Requirements on page 4983
- Overview on page 4984
- Configuration on page 4985
- Verification on page 4986

Requirements

This example uses the following hardware and software components:

- Two Juniper Networks QFX3500 Switches used as transit switches
- Junos OS Release 12.2 or later for the QFX Series
- Two FCoE hosts that have ENodes

Overview

This example shows you how to:

- Set the correct interface port modes on the transit switch.
- Configure the interfaces to use the dedicated FCoE VLAN for VN2VN_Port FIP snooping.
- Configure the network-facing interfaces as FCoE trusted interfaces.
- Configure the dedicated FCoE VLAN for VN2VN_Port FIP snooping traffic.
- Enable VN2VN_Port FIP snooping on the FCoE VLAN and configure the beacon period.

Topology

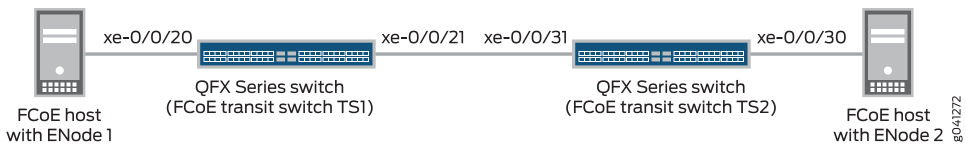
Table 386 on page 4984 shows the configuration components for this example.

Table 386: Components of the VN2VN_Port FIP Snooping Configuration Topology (FCoE Hosts Directly Connected to Different FCoE Transit Switches)

Component	Settings
Hardware	Two QFX3500 switches (FCoE transit switch TS1 and FCoE transit switch TS2) Two FCoE hosts that have ENodes (ENode1 and ENode2, respectively)
Interfaces and port modes	• Interface **xe-0/0/20**, port mode **tagged-access**, connects directly from transit switch TS1 to the FCoE host with ENode1. • Interface **xe-0/0/21**, port mode **trunk**, connects directly from transit switch TS1 to transit switch TS2. • Interface **xe-0/0/31**, port mode **trunk**, connects directly from transit switch TS2 to transit switch TS1. • Interface **xe-0/0/30**, port mode **tagged-access**, connects directly from transit switch TS2 to the FCoE host with ENode2.
Interface VLAN membership	The interfaces on both transit switches use VLAN **vlan200**.
VN2VN_Port FIP snooping VLAN	VLAN name (both transit switches)—**vlan200** VLAN ID—200
FIP snooping mode and beacon period	Set **examine-vn2vn** (VN2VN_Port FIP snooping) Beacon period—90000 ms

Figure 183 on page 4984 shows the network topology for this example.

Figure 183: VN2VN_Port FIP Snooping (FCoE Hosts Connected to Different Transit Switches) Topology



Configuration

To configure VN2VN_Port FIP snooping for VN_Ports that are directly connected to different transit switches (and the transit switches are directly connected to each other), perform these tasks:

- Configuring VN2VN_Port FIP Snooping on FCoE Transit Switch TS1 on page 4985
- Configuring VN2VN_Port FIP Snooping on FCoE Transit Switch TS2 on page 4986

CLI Quick Configuration

The configuration for each FCoE transit switch is shown separately.

To quickly configure VN2VN_Port FIP snooping for FCoE hosts connected directly to different transit switches, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level. To configure FCoE transit switch TS1:

```
set interfaces xe-0/0/20 unit 0 family ethernet-switching port-mode tagged-access
set interfaces xe-0/0/21 unit 0 family ethernet-switching port-mode trunk
set interfaces xe-0/0/20 unit 0 family ethernet-switching vlan members vlan200
set interfaces xe-0/0/21 unit 0 family ethernet-switching vlan members vlan200
set ethernet-switching-options secure-access-port interface xe-0/0/21 fcoe-trusted
set vlans vlan200 vlan-id 200
set ethernet-switching-options secure-access-port vlan vlan200 examine-fip examine-vn2v2
beacon-period 90000
```

To quickly configure VN2VN_Port FIP snooping for FCoE hosts connected directly to different transit switches, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level. To configure FCoE transit switch TS2:

```
set interfaces xe-0/0/30 unit 0 family ethernet-switching port-mode tagged-access
set interfaces xe-0/0/31 unit 0 family ethernet-switching port-mode trunk
set interfaces xe-0/0/30 unit 0 family ethernet-switching vlan members vlan200
set interfaces xe-0/0/31 unit 0 family ethernet-switching vlan members vlan200
set vlans vlan200 vlan-id 200
set ethernet-switching-options secure-access-port interface xe-0/0/31 fcoe-trusted
set ethernet-switching-options secure-access-port vlan vlan200 examine-fip examine-vn2v2
beacon-period 90000
```

Configuring VN2VN_Port FIP Snooping on FCoE Transit Switch TS1

Step-by-Step Procedure

To configure interface port modes, configure interface VLAN membership in the FCoE VLAN dedicated to VN2VN_Port traffic, set the network-facing port as FCoE trusted, configure the VLAN, set the beacon period, and enable VN2VN_Port FIP snooping:

1. Configure the port modes of the interfaces that connect directly to the FCoE host with ENode1 (**xe-0/0/20**) and to FCoE transit switch TS2 (**xe-0/0/21**):

   ```
   user@switch# set interfaces xe-0/0/20 unit 0 family ethernet-switching port-mode
   tagged-access
   set interfaces xe-0/0/21 unit 0 family ethernet-switching port-mode trunk
   ```

2. Configure the interface VLAN membership so that the interfaces are members of the dedicated VN2VN_Port VLAN (**vlan200**):

user@switch# **set interfaces xe-0/0/20 unit 0 family ethernet-switching vlan members vlan200**
set interfaces xe-0/0/21 unit 0 family ethernet-switching vlan members vlan200

3. Configure the network-facing port (**xe-0/0/21**) as an FCoE trusted port:

   user@switch# **set ethernet-switching-options secure-access-port interface xe-0/0/21 fcoe-trusted**

4. Configure the FCoE VLAN dedicated to VN2VN_Port FIP snooping:

   user@switch# **set vlans vlan200 vlan-id 200**

5. Enable VN2VN_Port FIP snooping on the VLAN and configure the beacon period:

   user@switch# **set ethernet-switching-options secure-access-port vlan vlan200 examine-fip examine-vn2v2 beacon-period 90000**

Configuring VN2VN_Port FIP Snooping on FCoE Transit Switch TS2

Step-by-Step Procedure

To configure interface port modes, configure interface VLAN membership in the FCoE VLAN dedicated to VN2VN_Port traffic, set the network-facing port as FCoE trusted, configure the VLAN, set the beacon period, and enable VN2VN_Port FIP snooping:

1. Configure the port modes of the interfaces that connect directly to the FCoE host with ENode2 (**xe-0/0/30**) and to FCoE transit switch TS1 (**xe-0/0/31**):

   user@switch# **set interfaces xe-0/0/30 unit 0 family ethernet-switching port-mode tagged-access**
   set interfaces xe-0/0/31 unit 0 family ethernet-switching port-mode trunk

2. Configure the interface VLAN membership so that the interfaces are members of the dedicated VN2VN_Port VLAN (**vlan200**):

   user@switch# **set interfaces xe-0/0/30 unit 0 family ethernet-switching vlan members vlan200**
   set interfaces xe-0/0/31 unit 0 family ethernet-switching vlan members vlan200

3. Configure the network-facing port (**xe-0/0/31**) as an FCoE trusted port:

   user@switch# **set ethernet-switching-options secure-access-port interface xe-0/0/31 fcoe-trusted**

4. Configure the FCoE VLAN dedicated to VN2VN_Port FIP snooping:

   user@switch# **set vlans vlan200 vlan-id 200**

5. Enable VN2VN_Port FIP snooping on the VLAN and configure the beacon period:

   user@switch# **set ethernet-switching-options secure-access-port vlan vlan200 examine-fip examine-vn2v2 beacon-period 90000**

Verification

To verify that the VN2VN_Port FIP snooping configuration has been created and is operating properly on both switches, perform these tasks:

- Verifying That VN2VN_Port FIP Snooping is Enabled on the FCoE VLAN (Transit Switches TS1 and TS2) on page 4987
- Verifying the Interface Port Mode on page 4989

Verifying That VN2VN_Port FIP Snooping is Enabled on the FCoE VLAN (Transit Switches TS1 and TS2)

Purpose Verify that VN2VN_Port FIP snooping is enabled on the correct VLAN (**vlan200**), the beacon period is set to **90000** milliseconds, and that the correct interfaces (**xe-0/0/20** and **xe-0/0/21** on TS1, and **xe-0/0/30**and **xe-0/0/31** on TS2) are members of the VLAN.

Action List the FIP snooping information on transit switch TS1 using the operational mode command **show fip snooping detail**

```
user@switch> show fip snooping detail
VLAN: vlan200,  Mode: VN2VN Snooping
  FC-MAP: 0e:fd:00
  Beacon_Period:  90000
  VN2VN Mode: Point-to-Point
    Enode Information
    Enode-MAC: 10:10:94:01:00:02,       Interface: xe-0/0/20
      Active VN_Ports : 1
      VN_Port Information
      VN-Port MAC: 0e:fd:00:00:0a:01
         Active Sessions    : 1
         Session Information
     Vlink far-end VN-Port-MAC: 0e:fd:00:00:0b:01
    Enode-MAC: 10:10:94:01:00:02,       Interface: xe-0/0/21
      Active VN_Ports : 1
      VN_Port Information
      VN-Port MAC: 0e:fd:00:00:0b:01
         Active Sessions    : 1
         Session Information
     Vlink far-end VN-Port-MAC: 0e:fd:00:00:0a:01
```

List the FIP snooping information on transit switch TS2 using the operational mode command **show fip snooping detail**

```
user@switch> show fip snooping detail
VLAN: vlan200,  Mode: VN2VN Snooping
  FC-MAP: 0e:fd:00
  Beacon_Period:  90000
  VN2VN Mode: Point-to-Point
    Enode Information
    Enode-MAC: 10:10:94:01:00:02,       Interface: xe-0/0/30
      Active VN_Ports : 1
      VN_Port Information
      VN-Port MAC: 0e:fd:00:00:0b:01
         Active Sessions    : 1
         Session Information
     Vlink far-end VN-Port-MAC: 0e:fd:00:00:0a:01
    Enode-MAC: 10:10:94:01:00:02,       Interface: xe-0/0/31
      Active VN_Ports : 1
      VN_Port Information
      VN-Port MAC: 0e:fd:00:00:0a:01
         Active Sessions    : 1
         Session Information
     Vlink far-end VN-Port-MAC: 0e:fd:00:00:0b:01
```

Meaning The **show fip snooping detail** command lists all of the transit switch information about VN2VN_Port FIP snooping and VN2VF_Port FIP snooping on each transit switch. The command shows that:

- The VLAN is **vlan200**.
- The mode is FIP snooping mode **VN2VN**, for VN2VN_Port FIP snooping. (If the Mode field shows **VN2VF**, then the FIP snooping mode is VN2VF_Port FIP snooping.)

- The beacon period is **90000**.
- The interfaces connected to the ENodes are **xe-0/0/20** and **xe-0/0/21** on transit switch TS1, and **xe-0/0/30** and **xe-0/0/31** on transit switch TS2. Because the transit switches are transparent passthrough switches, the network-facing trunk ports "see" the FCoE host ENodes at the far end of the VN2VN_Port virtual link.

In addition, this useful command shows information about the ENodes and the VN2VN_Port sessions.

Verifying the Interface Port Mode

Purpose Verify that the interface port modes are **tagged-access** for ENode-facing ports and **trunk** for network-facing ports on each transit switch.

Action List the Ethernet switching interfaces to confirm the port mode using the **show ethernet-switching interfaces detail** operational command.

Use the operational mode commands **show ethernet-switching interfaces xe-0/0/20.0 detail** and **show ethernet-switching interfaces xe-0/0/21.0 detail** to list the Ethernet switching interface information on FCoE transit switch TS1. The output is truncated to show only the relevant portions:

```
user@switch> show ethernet-switching interfaces xe-0/0/20.0 detail
Interface: xe-0/0/20.0, Index: 75, State: up, Port mode: Tagged-Access
.
.
.

user@switch> show ethernet-switching interfaces xe-0/0/21.0 detail
Interface: xe-0/0/21.0, Index: 83, State: up, Port mode: Trunk
.
.
.
```

List the Ethernet switching interface information on FCoE transit switch TS2 using the operational mode commands **show ethernet-switching interfaces xe-0/0/30.0 detail** and **show ethernet-switching interfaces xe-0/0/31.0 detail**:

```
user@switch> show ethernet-switching interfaces xe-0/0/30.0 detail
Interface: xe-0/0/30.0, Index: 56, State: up, Port mode: Tagged-Access
.
.
.

user@switch> show ethernet-switching interfaces xe-0/0/31.0 detail
Interface: xe-0/0/31.0, Index: 59, State: up, Port mode: Trunk
.
.
.
```

Example: Configuring VN2VN_Port FIP Snooping (FCoE Hosts Indirectly Connected Through an Aggregation Layer FCoE Transit Switch)

This example shows how to configure VN_Port to VN_Port (VN2VN_Port) FIP snooping when the hosts are indirectly connected through an aggregation layer FCoE transit switch. Each FCoE host ENode is directly connected to an FCoE transit switch, but the FCoE transit switches are not directly connected to each other. The FCoE transit switches are both connected to a third FCoE transit switch that acts as an aggregation layer switch.

NOTE: This example uses Junos OS without support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that supports ELS, see "Example: Configuring VN2VN_Port FIP Snooping (FCoE Hosts Indirectly Connected Through an Aggregation Layer FCoE Transit Switch)" on page 5036.

VN2VN_Port FIP snooping on an FCoE transit switch provides security to help prevent unauthorized access and data transmission on a bridge that connects ENodes in the Ethernet network. VN2VN_Port FIP snooping provides security for virtual links by creating filters based on information gathered (snooped) about FCoE devices during FIP transactions.

VN2VN_Port FIP snooping is conceptually similar to VN2VN_Port FIP snooping between VN_Ports and VF_Ports, but VN2VN_Port FIP snooping does not require traffic between VN_Ports to traverse the Fibre Channel (FC) switch or FCoE forwarder (FCF). Instead, a VN_Port communicates transparently through one or more transit switches on a virtual link that emulates a direct connection to the VN_Port at the other end of the virtual link.

To configure VN2VN_Port FIP snooping when the hosts are indirectly connected, you must follow these configuration rules:

- VN2VN_Port traffic must use a dedicated FCoE VLAN, and all ENodes that communicate using VN2VN_Port FIP snooping must use that FCoE VLAN. The FCoE VLAN must be configured on each transit switch. You cannot mix VN2VN_Port FIP snooping traffic with VN2VF_Port FIP snooping traffic in the same FCoE VLAN.

  NOTE: An FCoE VLAN can support either VN2VF_Port FIP snooping or VN2VN_Port FIP snooping, but not both. Configure separate FCoE VLANs for VN2VF_Port FIP snooping traffic and for VN2VN_Port FIP snooping traffic. On FCoE VLANs that are configured as VN2VN_Port FIP snooping VLANs, VN_Port to VF_Port traffic is dropped.

- ENode-facing ports must be set in **tagged-access** port mode.

- ENode-facing ports must be untrusted ports.
- Network-facing (switch-facing) ports must be set in **trunk** port mode.
- Network-facing ports must be FCoE trusted ports.
- Explicitly configure the beacon period. The beacon period is essentially a keepalive timer for virtual link maintenance.

When you enable FIP snooping, the system snoops VN_Port to VF_Port packets and enforces security only on VN_Port to VF_Port virtual links. When you enable VN2VN_Port FIP snooping, the system snoops VN_Port to VN_Port packets and enforces security only on VN_Port to VN_Port virtual links.

The transit switch applies VN2VN_Port FIP snooping filters at the ports associated with the FCoE VLANs on which you enable VN2VN FIP snooping.

This example describes how to configure VN2VN_Port FIP snooping when the FCoE hosts are indirectly connected across an aggregation layer FCoE transit switch:

- Requirements on page 4991
- Overview on page 4991
- Configuration on page 4993
- Verification on page 4995

Requirements

This example uses the following hardware and software components:

- Three Juniper Networks QFX3500 Switches used as transit switches
- Junos OS Release 12.2 or later for the QFX Series
- Two FCoE hosts that have ENodes

Overview

This example shows you how to:

- Set the correct interface port modes on the transit switch.
- Configure the interfaces to use the dedicated FCoE VLAN for VN2VN_Port FIP snooping.
- Configure the network-facing interfaces as FCoE trusted interfaces.
- Configure the dedicated FCoE VLAN for VN2VN_Port FIP snooping traffic.
- Enable VN2VN_Port FIP snooping on the FCoE VLAN and configure the beacon period.

Topology

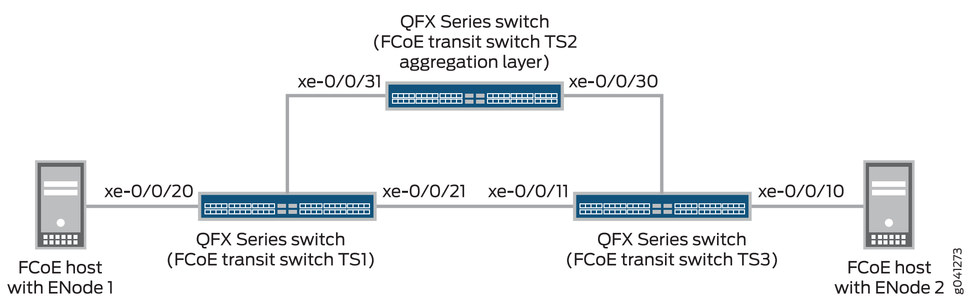
Table 387 on page 4992 shows the configuration components for this example.

Table 387: Components of the VN2VN_Port FIP Snooping Configuration Topology (FCoE Hosts Indirectly Connected Across an Aggregation Layer FCoE Transit Switch)

Component	Settings
Hardware	Three QFX3500 switches, two of which are FCoE transit switches that are directly attached to the FCoE hosts (transit switches TS1 and TS2) and one of which is an aggregation layer FCoE transit switch (TS3) Two FCoE hosts that have ENodes (ENode1 and ENode2, respectively)
Interfaces and port modes	• Interface **xe-0/0/20**, port mode **tagged-access**, connects directly from transit switch TS1 to the FCoE host with ENode1. • Interface **xe-0/0/21**, port mode **trunk**, connects directly from transit switch TS1 to aggregation layer transit switch TS2. • Interface **xe-0/0/31**, port mode **trunk**, connects directly from aggregation layer transit switch TS2 to transit switch TS1. • Interface **xe-0/0/30**, port mode **trunk**, connects directly from aggregation layer transit switch TS2 to transit switch TS3. • Interface **xe-0/0/11**, port mode **trunk**, connects directly from transit switch TS3 to aggregation layer transit switch TS2. • Interface **xe-0/0/10**, port mode **tagged-access**, connects directly from transit switch TS3 to the FCoE host with ENode2.
Interface VLAN membership	The interfaces on all three switches use VLAN **vlan200**.
VN2VN_Port FIP snooping VLAN	VLAN name (all three switches)—**vlan200** VLAN ID—200
FIP snooping mode and beacon period	Set **examine-vn2vn** (VN2VN_Port FIP snooping) Beacon period—90000 ms

Figure 184 on page 4992 shows the network topology for this example.

Figure 184: VN2VN_Port FIP Snooping (FCoE Hosts Indirectly Connected) Topology



Configuration

To configure VN2VN_Port FIP snooping for VN_Ports that are indirectly connected across an aggregation layer FCoE transit switch, perform these tasks:

- Configuring VN2VN_Port FIP Snooping on FCoE Transit Switch TS1 on page 4994
- Configuring VN2VN_Port FIP Snooping on Aggregation Layer FCoE Transit Switch TS2 on page 4994
- Configuring VN2VN_Port FIP Snooping on FCoE Transit Switch TS3 on page 4995

CLI Quick Configuration

The configuration for each FCoE transit switch is shown separately.

To quickly configure VN2VN_Port FIP snooping for FCoE hosts that are indirectly connected across an aggregation layer FCoE transit switch, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level. To configure FCoE transit switch TS1:

```
set interfaces xe-0/0/20 unit 0 family ethernet-switching port-mode tagged-access
set interfaces xe-0/0/21 unit 0 family ethernet-switching port-mode trunk
set interfaces xe-0/0/20 unit 0 family ethernet-switching vlan members vlan200
set interfaces xe-0/0/21 unit 0 family ethernet-switching vlan members vlan200
set ethernet-switching-options secure-access-port interface xe-0/0/21 fcoe-trusted
set vlans vlan200 vlan-id 200
set ethernet-switching-options secure-access-port vlan vlan200 examine-fip examine-vn2v2
beacon-period 90000
```

To quickly configure VN2VN_Port FIP snooping for FCoE hosts that are indirectly connected across an aggregation layer FCoE transit switch, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level. To configure FCoE transit switch TS2:

```
set interfaces xe-0/0/30 unit 0 family ethernet-switching port-mode trunk
set interfaces xe-0/0/31 unit 0 family ethernet-switching port-mode trunk
set interfaces xe-0/0/30 unit 0 family ethernet-switching vlan members vlan200
set interfaces xe-0/0/31 unit 0 family ethernet-switching vlan members vlan200
set vlans vlan200 vlan-id 200
set ethernet-switching-options secure-access-port interface xe-0/0/30 fcoe-trusted
set ethernet-switching-options secure-access-port interface xe-0/0/31 fcoe-trusted
set ethernet-switching-options secure-access-port vlan vlan200 examine-fip examine-vn2v2
beacon-period 90000
```

To quickly configure VN2VN_Port FIP snooping for FCoE hosts that are indirectly connected across an aggregation layer FCoE transit switch, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level. To configure FCoE transit switch TS3:

```
set interfaces xe-0/0/10 unit 0 family ethernet-switching port-mode tagged-access
set interfaces xe-0/0/11 unit 0 family ethernet-switching port-mode trunk
set interfaces xe-0/0/10 unit 0 family ethernet-switching vlan members vlan200
set interfaces xe-0/0/11 unit 0 family ethernet-switching vlan members vlan200
set vlans vlan200 vlan-id 200
set ethernet-switching-options secure-access-port interface xe-0/0/11 fcoe-trusted
set ethernet-switching-options secure-access-port vlan vlan200 examine-fip examine-vn2v2
beacon-period 90000
```

Configuring VN2VN_Port FIP Snooping on FCoE Transit Switch TS1

Step-by-Step Procedure

To configure interface port modes, configure interface VLAN membership in the FCoE VLAN dedicated to VN2VN_Port traffic, set the network-facing port as FCoE trusted, configure the VLAN, set the beacon period, and enable VN2VN_Port FIP snooping:

1. Configure the port modes of the interfaces that connect directly to the FCoE host with ENode1 (**xe-0/0/20**) and to aggregation layer FCoE transit switch TS2 (**xe-0/0/21**):

   `user@switch#` **set interfaces xe-0/0/20 unit 0 family ethernet-switching port-mode tagged-access**
   set interfaces xe-0/0/21 unit 0 family ethernet-switching port-mode trunk

2. Configure the interface VLAN membership so that the interfaces are members of the dedicated VN2VN_Port VLAN (**vlan200**):

   `user@switch#` **set interfaces xe-0/0/20 unit 0 family ethernet-switching vlan members vlan200**
   set interfaces xe-0/0/21 unit 0 family ethernet-switching vlan members vlan200

3. Configure the network-facing port (**xe-0/0/21**) as an FCoE trusted port:

   `user@switch#` **set ethernet-switching-options secure-access-port interface xe-0/0/21 fcoe-trusted**

4. Configure the FCoE VLAN dedicated to VN2VN_Port FIP snooping:

   `user@switch#` **set vlans vlan200 vlan-id 200**

5. Enable VN2VN_Port FIP snooping on the VLAN and configure the beacon period:

   `user@switch#` **set ethernet-switching-options secure-access-port vlan vlan200 examine-fip examine-vn2v2 beacon-period 90000**

Configuring VN2VN_Port FIP Snooping on Aggregation Layer FCoE Transit Switch TS2

Step-by-Step Procedure

To configure interface port modes, configure interface VLAN membership in the FCoE VLAN dedicated to VN2VN_Port traffic, set the network-facing ports as FCoE trusted, configure the VLAN, set the beacon period, and enable VN2VN_Port FIP snooping:

1. Configure the port modes of the interfaces that connect directly to FCoE transit switches TS1 (**xe-0/0/31**) and TS3 (**xe-0/0/30**). Both interfaces are network-facing and must be configured as trunk interfaces:

   `user@switch#` **set interfaces xe-0/0/30 unit 0 family ethernet-switching port-mode trunk**
   set interfaces xe-0/0/31 unit 0 family ethernet-switching port-mode trunk

2. Configure the interface VLAN membership so that the interfaces are members of the dedicated VN2VN_Port VLAN (**vlan200**):

   `user@switch#` **set interfaces xe-0/0/30 unit 0 family ethernet-switching vlan members vlan200**
   set interfaces xe-0/0/31 unit 0 family ethernet-switching vlan members vlan200

3. Configure the network-facing ports (**xe-0/0/30** and **xe-0/0/31**) as FCoE trusted ports:

   `user@switch#` **set ethernet-switching-options secure-access-port interface xe-0/0/30 fcoe-trusted** user@switch# **set ethernet-switching-options secure-access-port interface xe-0/0/31 fcoe-trusted**

4. Configure the FCoE VLAN dedicated to VN2VN_Port FIP snooping:

   user@switch# **set vlans vlan200 vlan-id 200**

5. Enable VN2VN_Port FIP snooping on the VLAN and configure the beacon period:

   user@switch# **set ethernet-switching-options secure-access-port vlan vlan200 examine-fip examine-vn2v2 beacon-period 90000**

Configuring VN2VN_Port FIP Snooping on FCoE Transit Switch TS3

Step-by-Step Procedure

To configure interface port modes, configure interface VLAN membership in the FCoE VLAN dedicated to VN2VN_Port traffic, set the network-facing port as FCoE trusted, configure the VLAN, set the beacon period, and enable VN2VN_Port FIP snooping:

1. Configure the port modes of the interfaces that connect directly to the FCoE host with ENode2 (**xe-0/0/10**) and to aggregation layer FCoE transit switch TS2 (**xe-0/0/11**):

   user@switch# **set interfaces xe-0/0/10 unit 0 family ethernet-switching port-mode tagged-access**
   set interfaces xe-0/0/11 unit 0 family ethernet-switching port-mode trunk

2. Configure the interface VLAN membership so that the interfaces are members of the dedicated VN2VN_Port VLAN (**vlan200**):

   user@switch# **set interfaces xe-0/0/10 unit 0 family ethernet-switching vlan members vlan200**
   set interfaces xe-0/0/11 unit 0 family ethernet-switching vlan members vlan200

3. Configure the network-facing port (**xe-0/0/11**) as an FCoE trusted port:

   user@switch# **set ethernet-switching-options secure-access-port interface xe-0/0/11 fcoe-trusted**

4. Configure the FCoE VLAN dedicated to VN2VN_Port FIP snooping:

   user@switch# **set vlans vlan200 vlan-id 200**

5. Enable VN2VN_Port FIP snooping on the VLAN and configure the beacon period:

   user@switch# **set ethernet-switching-options secure-access-port vlan vlan200 examine-fip examine-vn2v2 beacon-period 90000**

Verification

To verify that the VN2VN_Port FIP snooping configuration has been created and is operating properly on all three switches, perform these tasks:

- Verifying That VN2VN_Port FIP Snooping Is Enabled on the FCoE VLAN (All Three Transit Switches) on page 4995
- Verifying the Interface Port Mode on page 4998

Verifying That VN2VN_Port FIP Snooping Is Enabled on the FCoE VLAN (All Three Transit Switches)

Purpose

Verify that VN2VN_Port FIP snooping is enabled on the correct VLAN (**vlan200**), the beacon period is set to **90000** milliseconds, and that the correct interfaces (**xe-0/0/20** and **xe-0/0/21** on TS1, **xe-0/0/30** and **xe-0/0/31** aggregation layer TS2, and **xe-0/0/10** and **xe-0/0/11** on TS3) are members of the VLAN.

Action List the FIP snooping information on transit switch TS1 using the operational mode command **show fip snooping detail**

```
user@switch> show fip snooping detail
VLAN: vlan200,  Mode: VN2VN Snooping
  FC-MAP: 0e:fd:00
  Beacon_Period:  90000
  VN2VN Mode: Point-to-Point
    Enode Information
    Enode-MAC: 10:10:94:01:00:02,       Interface: xe-0/0/20
      Active VN_Ports : 1
      VN_Port Information

```

Meaning The **show fip snooping detail** command lists all of the transit switch information about VN2VN_Port FIP snooping and VN2VF_Port FIP snooping on each transit switch. The command shows that:

- The VLAN is **vlan200**.
- The mode is FIP snooping mode **VN2VN**, for VN2VN_Port FIP snooping. (If the Mode field shows **VN2VF**, then the FIP snooping mode is VN2VF_Port FIP snooping.)
- The beacon period is **90000**.
- The interfaces connected to the ENodes are **xe-0/0/20** and **xe-0/0/21** on transit switch TS1, **xe-0/0/30** and **xe-0/0/31** on aggregation layer transit switch TS2, and **xe-0/0/10** and **xe-0/0/11** on transit switch TS3. Because the transit switches are transparent passthrough switches, the network-facing trunk ports “see” the FCoE host ENodes at the far end of the VN2VN_Port virtual link.

In addition, this useful command shows information about the ENodes and the VN2VN_Port sessions.

Verifying the Interface Port Mode

Purpose Verify that the interface port modes are **tagged-access** for ENode-facing ports and **trunk** for network-facing ports on each transit switch.

Action List the Ethernet switching interfaces to confirm the port mode using the **show ethernet-switching interfaces detail** operational command for each interface. The output is truncated to show only the relevant portions.

List the Ethernet switching interface information on FCoE transit switch TS1 using the operational mode commands **show ethernet-switching interfaces xe-0/0/20.0 detail** and **show ethernet-switching interfaces xe-0/0/21.0 detail**:

```
user@switch> show ethernet-switching interfaces xe-0/0/20.0 detail
Interface: xe-0/0/20.0, Index: 75, State: up, Port mode: Tagged-Access
.
.
.

user@switch> show ethernet-switching interfaces xe-0/0/21.0 detail
```

```
Interface: xe-0/0/21.0, Index: 83, State: up, Port mode: Trunk
.
.
.
```

List the Ethernet switching interface information on aggregation layer FCoE transit switch TS2 using the operational mode commands **show ethernet-switching interfaces xe-0/0/30.0 detail** and **show ethernet-switching interfaces xe-0/0/31.0 detail**:

```
user@switch> show ethernet-switching interfaces xe-0/0/30.0 detail
Interface: xe-0/0/30.0, Index: 71, State: up, Port mode: Trunk
.
.
.

user@switch> show ethernet-switching interfaces xe-0/0/31.0 detail
Interface: xe-0/0/31.0, Index: 73, State: up, Port mode: Trunk
.
.
.
```

List the Ethernet switching interface information on FCoE transit switch TS3 using the operational mode commands **show ethernet-switching interfaces xe-0/0/10.0 detail** and **show ethernet-switching interfaces xe-0/0/11.0 detail**:

```
user@switch> show ethernet-switching interfaces xe-0/0/10.0 detail
Interface: xe-0/0/10.0, Index: 56, State: up, Port mode: Tagged-Access
.
.
.

user@switch> show ethernet-switching interfaces xe-0/0/11.0 detail
Interface: xe-0/0/11.0, Index: 59, State: up, Port mode: Trunk
.
.
.
```

Example: Configuring Automated Fibre Channel Interface Load Rebalancing

Automated Fibre Channel (FC) interface (NP_Port) load rebalancing configures the switch to rebalance the session loads on the native FC interfaces automatically on a load-rebalancing trigger event. (Alternatively, you can rebalance the link load on the FC interfaces on demand so that you control when the link load is rebalanced.) Rebalancing the FC link load is a disruptive action that causes some or all of the current sessions to log out, then log in again to be placed on the active FC links in a balanced manner.

This example shows you how to configure and verify automated FC link load rebalancing on an FCoE-FC gateway local FC fabric.

Requirements

This example uses the following hardware and software components:

- Juniper Networks QFX3500 Switch
- Junos OS Release 12.3 or later for the QFX Series

Overview

When a load rebalancing trigger occurs, the switch automatically rebalances the link loads by redistributing the sessions across the active NP_Port links.

There are three possible load-rebalancing triggers:

1. When you enable automated load rebalancing, the switch checks the load balance on the existing NP_Port links. If the links are already balanced, the switch does not rebalance the link load. If the links are not balanced, the switch rebalances the link loads using the configured load-balancing algorithm.
2. When a new NP_Port link comes up on a local FCoE-FC gateway fabric, the switch rebalances the link load using the configured load-balancing algorithm if automated load balancing is enabled.
3. When the port speed is changed (unless the port speed change does not change the actual port speed, for example, changing the port speed from auto to 8 Gbps).

Automated load rebalancing logs out sessions in accordance with the configured load-balancing algorithm. Disabling automated load rebalancing is not disruptive because the link load is already balanced.

Use automated load rebalancing if you want link loads to be rebalanced automatically instead of at times of your choosing. Keep in mind that load rebalancing is a disruptive event (sessions are logged out).

Topology

This example configures automated load rebalancing on a local FC fabric on an FCoE-FC gateway. This example does not show you how to configure the load-balancing algorithm or any other load-balancing characteristics. The load-balancing configuration for this example is:

- FC fabric name—fc_fabric_100
- FC fabric ID—100

- FC fabric type—Proxy
- FC fabric interfaces—fc-0/0/0, fc-0/0/1, fc-0/0/42, fc-0/0/43, vlan.100, vlan.20
- Load-balancing algorithm—Simple
- No fabric WWN verify—Configured
- Traceoptions—Configured to log in file fc_fabric_100_proxy.log

Configuration

To configure automated load balancing on a local FC fabric, perform this task:

- [xref target has no title]
- Results on page 5001

CLI Quick Configuration

To quickly configure automated load balancing, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level:

```
[edit]
set fc-fabrics fc_fabric_100 proxy auto-load-rebalance
```

Step-by-Step Procedure

- Configure automated load balancing on FC fabric fc_fabric_100:

  ```
  user@switch# set fc-fabrics fc_fabric_100 proxy auto-load-rebalance
  ```

Results

Display the results of the configuration:

```
user@switch> show configuration fc-fabrics
fc_fabric_100 {
    fabric-id 100;
    fabric-type proxy;
    interface {
        fc-0/0/0.0;
        fc-0/0/1.0;
        vlan.100;
        vlan.20;
        fc-0/0/42.0;
        fc-0/0/43.0;
    }
    proxy {
        traceoptions {
            file fc_fabric_100_proxy.log size 20m;
            flag all;
        }
        load-balance-algorithm simple;
        auto-load-rebalance;
        no-fabric-wwn-verify;
    }
}
```

Verification

Verifying That Automated Load Rebalancing Is Enabled

Purpose Verify that automated load rebalancing is configured on local FC fabric **fc_fabric_100**.

Action Verify the results of the automated load-rebalancing configuration using the operational mode command **show fibre-channel proxy fabric-state fabric fc_fabric_100**:

```
user@switch> show fibre-channel proxy fabric-state fabric fc_fabric_100
Fabric: fc_fabric_100, Fabric-id: 100
Proxy load balance algorithm: Simple, Fabric WWN verification: No
Auto load rebalance enabled  : Yes
Last rebalance start-time    : Never
Last rebalance end-time      : Never
Last rebalance trigger       : None
Last rebalance trigger-time  : Mon Sep 10 21:42:30 2012 usec: 814602
Last rebalance trigger-result: None
```

Meaning The **show fibre-channel proxy fabric-state fabric fc_fabric_100** operational command displays information about the specified local FC fabric. The output shows that the **Auto load rebalance enabled** field value is **Yes**, which indicates that automated load rebalancing is enabled on fabric fc_fabric_100.

- Example: Configuring VN2VN_Port FIP Snooping (FCoE Hosts Indirectly Connected Through an Aggregation Layer FCoE Transit Switch) on page 5036

Example: Configuring CoS for FCoE Transit Switch Traffic Across an MC-LAG

Multichassis link aggregation groups (MC-LAGs) provide redundancy and load balancing between two QFX Series switches, multihoming support for client devices such as servers, and a loop-free Layer 2 network without running Spanning Tree Protocol (STP).

NOTE: This example uses the Junos OS Enhanced Layer 2 Software (ELS) configuration style for QFX Series switches. If your switch runs software that does not support ELS, see "Example: Configuring CoS for FCoE Transit Switch Traffic Across an MC-LAG" on page 4940. For ELS details, see "Getting Started with Enhanced Layer 2 Software" on page 58.

You can use an MC-LAG to provide a redundant aggregation layer for Fiber Channel over Ethernet (FCoE) traffic in an *inverted-U* topology. To support lossless transport of FCoE traffic across an MC-LAG, you must configure the appropriate class of service (CoS) on both of the QFX Series switches with MC-LAG port members. The CoS configuration must be the same on both of the MC-LAG switches because an MC-LAG does not carry forwarding class and IEEE 802.1p priority information.

Ports that are members of an MC-LAG act as FCoE passthrough transit switch ports.

NOTE: This example describes how to configure CoS to provide lossless transport for FCoE traffic across an MC-LAG that connects two QFX Series switches. It also describes how to configure CoS on the FCoE transit switches that connect FCoE hosts to the QFX Series switches that form the MC-LAG.

This example does *not* describe how to configure the MC-LAG itself. For a detailed example of MC-LAG configuration, see "Example: Configuring Multichassis Link Aggregation" on page 1904. However, this example includes a subset of MC-LAG configuration that only shows how to configure interface membership in the MC-LAG.

QFX3500 and QFX3600 Virtual Chassis switches do not support FCoE.

This topic describes:

Requirements

This example uses the following hardware and software components:

- Two Juniper Networks QFX5100 Switches running the ELS CLI that form an MC-LAG for FCoE traffic.
- Two Juniper Networks QFX5100 Switches running the ELS CLI that provide FCoE server access in transit switch mode and that connect to the MC-LAG switches.
- FCoE servers (or other FCoE hosts) connected to the transit switches.
- Junos OS Release 13.2 or later for the QFX Series.

Overview

FCoE traffic requires lossless transport. This example shows you how to:

- Configure CoS for FCoE traffic on the two QFX5100 switches that form the MC-LAG, including priority-based flow control (PFC) and enhanced transmission selection (ETS; hierarchical scheduling of resources for the FCoE forwarding class priority and for the forwarding class set priority group).

NOTE: Configuring or changing PFC on an interface blocks the entire port until the PFC change is completed. After a PFC change is completed, the port is unblocked and traffic resumes. Blocking the port stops ingress and egress traffic, and causes packet loss on all queues on the port until the port is unblocked.

- Configure CoS for FCoE on the two FCoE transit switches that connect FCoE hosts to the MC-LAG switches and enable FIP snooping on the FCoE VLAN at the FCoE transit switch access ports.
- Configure the appropriate port mode, MTU, and FCoE trusted or untrusted state for each interface to support lossless FCoE transport.

NOTE: Do not enabled IGMP snooping on the FCoE VLAN. (IGMP snooping is enabled on the default VLAN by default, but is disabled by default on all other VLANs.)

Topology

QFX5100 switches that act as transit switches support MC-LAGs for FCoE traffic in an inverted-U network topology, as shown in Figure 180 on page 4942.

Figure 185: Supported Topology for an MC-LAG on an FCoE Transit Switch

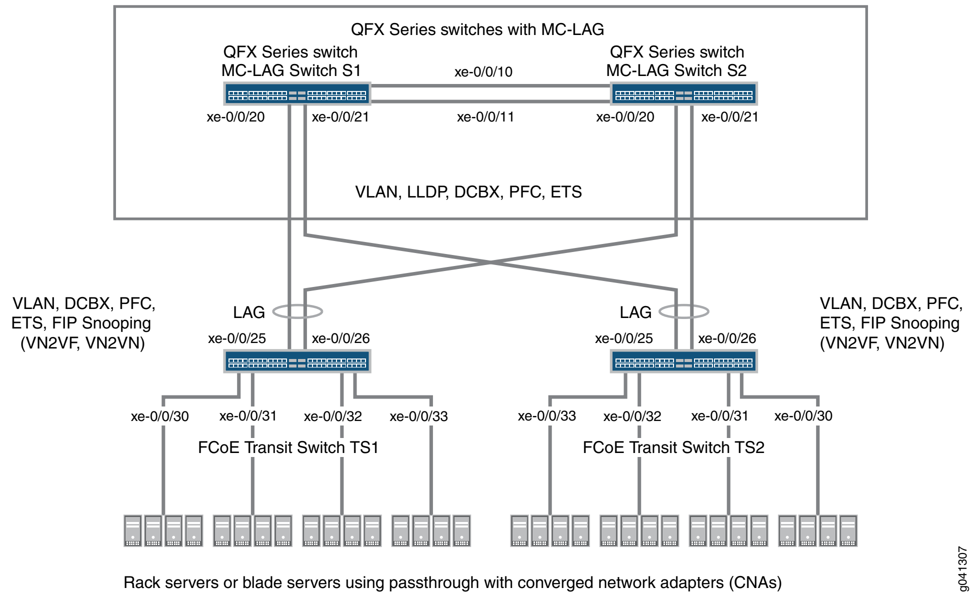

Table 383 on page 4943 shows the configuration components for this example.

Table 388: Components of the CoS for FCoE Traffic Across an MC-LAG Configuration Topology

Component	Settings
Hardware	Four QFX5100 switches running the ELS CLI (two to form the MC-LAG as passthrough transit switches and two transit switches for FCoE access).
Forwarding class (all switches)	Default **fcoe** forwarding class.
Classifier (forwarding class mapping of incoming traffic to IEEE priority)	Default IEEE 802.1p trusted classifier on all FCoE interfaces.

Table 388: Components of the CoS for FCoE Traffic Across an MC-LAG Configuration Topology *(continued)*

Component	Settings
LAGs and MC-LAG	S1—Ports xe-0/0/10 and x-0/0/11 are members of LAG **ae0**, which connects Switch S1 to Switch S2. Ports xe-0/0/20 and xe-0/0/21 are members of MC-LAG **ae1**. All ports are configured in **trunk** interface mode, as **fcoe-trusted**, and with an MTU of **2180**. S2—Ports xe-0/0/10 and x-0/0/11 are members of LAG **ae0**, which connects Switch S2 to Switch S1. Ports xe-0/0/20 and xe-0/0/21 are members of MC-LAG **ae1**. All ports are configured in **trunk** interface mode, as **fcoe-trusted**, and with an MTU of **2180**. NOTE: Ports xe-0/0/20 and xe-0/0/21 on Switches S1 and S2 are the members of the MC-LAG. TS1—Ports xe-0/0/25 and x-0/0/26 are members of LAG **ae1**, configured in **trunk** interface mode, as **fcoe-trusted**, and with an MTU of **2180**. Ports xe-0/0/30, xe-0/0/31, xe-0/0/32, and xe-0/0/33 are configured in **trunk** interface mode, with an MTU of **2180**. TS2—Ports xe-0/0/25 and x-0/0/26 are members of LAG **ae1**, configured in **trunk** interface mode, as **fcoe-trusted**, and with an MTU of **2180**. Ports xe-0/0/30, xe-0/0/31, xe-0/0/32, and xe-0/0/33 are configured in **trunk** interface mode, with an MTU of **2180**.
FCoE queue scheduler (all switches)	**fcoe-sched**: Minimum bandwidth **3g** Maximum bandwidth **100%** Priority **low**
Forwarding class-to-scheduler mapping (all switches)	Scheduler map **fcoe-map**: Forwarding class **fcoe** Scheduler **fcoe-sched**
Forwarding class set (FCoE priority group, all switches)	**fcoe-pg**: Forwarding class **fcoe** Egress interfaces: • S1—LAG **ae0** and MC-LAG **ae1** • S2—LAG **ae0** and MC-LAG **ae1** • TS1—LAG **ae1**, interfaces **xe-0/0/30**, **xe-0/0/31**, **xe-0/0/32**, and **xe-0/0/33** • TS2—LAG **ae1**, interfaces **xe-0/0/30**, **xe-0/0/31**, **xe-0/0/32**, and **xe-0/0/33**
Traffic control profile (all switches)	**fcoe-tcp**: Scheduler map **fcoe-map** Minimum bandwidth **3g** Maximum bandwidth **100%**

Table 388: Components of the CoS for FCoE Traffic Across an MC-LAG Configuration Topology *(continued)*

Component	Settings
PFC congestion notification profile (all switches)	**fcoe-cnp**: Code point **011** Ingress interfaces: • S1—LAG **ae0** and MC-LAG **ae1** • S2—LAG **ae0** and MC-LAG **ae1** • TS1—LAG **ae1**, interfaces **xe-0/0/30**, **xe-0/0/31**, **xe-0/0/32**, and **xe-0/0/33** • TS2—LAG **ae1**, interfaces **xe-0/0/30**, **xe-0/0/31**, **xe-0/0/32**, and **xe-0/0/33**
FCoE VLAN name and tag ID	Name—**fcoe_vlan** ID—**100** Include the FCoE VLAN on the interfaces that carry FCoE traffic on all four switches.
FIP snooping	Enable FIP snooping on Transit Switches TS1 and TS2 on the FCoE VLAN. Configure the LAG interfaces that connect to the MC-LAG switches as FCoE trusted interfaces so that they do not perform FIP snooping. This example enables VN2VN_Port FIP snooping on the FCoE transit switch interfaces connected to the FCoE servers. The example is equally valid with VN2VF_Port FIP snooping enabled on the transit switch access ports. The method of FIP snooping you enable depends on your network configuration.

NOTE: This example uses the default IEEE 802.1p trusted BA classifier, which is automatically applied to trunk mode interfaces if you do not apply an explicitly configured classifier.

To configure CoS for FCoE traffic across an MC-LAG:

- Use the default FCoE forwarding class and forwarding-class-to-queue mapping (do not explicitly configure the FCoE forwarding class or output queue). The default FCoE forwarding class is **fcoe**, and the default output queue is queue **3**.
- Use the default trusted BA classifier, which maps incoming packets to forwarding classes by the IEEE 802.1p code point (CoS priority) of the packet. The trusted classifier is the default classifier for interfaces in trunk interface mode. The default trusted classifier maps incoming packets with the IEEE 802.1p code point 3 (**011**) to the FCoE forwarding class. If you choose to configure the BA classifier instead of using the default classifier, you must ensure that FCoE traffic is classified into forwarding classes in exactly the same way on both MC-LAG switches. Using the default classifier ensures consistent classifier configuration on the MC-LAG ports.

- Configure a congestion notification profile that enables PFC on the FCoE code point (code point **011** in this example). The congestion notification profile configuration must be the same on both MC-LAG switches.
- Apply the congestion notification profile to the interfaces.
- Configure enhanced transmission selection (ETS, also known as hierarchical scheduling) on the interfaces to provide the bandwidth required for lossless FCoE transport. Configuring ETS includes configuring bandwidth scheduling for the FCoE forwarding class, a forwarding class set (priority group) that includes the FCoE forwarding class, and a traffic control profile to assign bandwidth to the forwarding class set that includes FCoE traffic.
- Apply the ETS scheduling to the interfaces.
- Configure the interface mode, MTU, and FCoE trusted or untrusted state for each interface to support lossless FCoE transport.

In addition, this example describes how to enable FIP snooping on the Transit Switch TS1 and TS2 ports that are connected to the FCoE servers. To provide secure access, FIP snooping must be enabled on the FCoE access ports.

This example focuses on the CoS configuration to support lossless FCoE transport across an MC-LAG. This example does not describe how to configure the properties of MC-LAGs and LAGs, although it does show you how to configure the port characteristics required to support lossless transport and how to assign interfaces to the MC-LAG and to the LAGs.

Before you configure CoS, configure:

- The MC-LAGs that connect Switches S1 and S2 to Switches TS1 and TS2. ("Example: Configuring Multichassis Link Aggregation" on page 1904 describes how to configure MC-LAGs.)
- The LAGs that connect the Transit Switches TS1 and TS2 to MC-LAG Switches S1 and S2. ("Configuring Link Aggregation" on page 2019 describes how to configure LAGs.)
- The LAG that connects Switch S1 to Switch S2.

Configuration

To configure CoS for lossless FCoE transport across an MC-LAG, perform these tasks:

CLI Quick Configuration

To quickly configure CoS for lossless FCoE transport across an MC-LAG, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI for MC-LAG Switch S1 and MC-LAG Switch S2 at the **[edit]** hierarchy level. The configurations on Switches S1 and S2 are identical because the CoS configuration must be identical, and because this example uses the same ports on both switches.

Switch S1 and Switch S2

```
set class-of-service schedulers fcoe-sched priority low transmit-rate 3g

Configuring MC-LAG Switches S1 and S2

Step-by-Step Procedure

To configure CoS resource scheduling (ETS), PFC, the FCoE VLAN, and the LAG and MC-LAG interface membership and characteristics to support lossless FCoE transport across an MC-LAG (this example uses the default **fcoe** forwarding class and the default classifier to map incoming FCoE traffic to the FCoE IEEE 802.1p code point **011**, so you do not configure them):

1. Configure output scheduling for the FCoE queue:

   ```
   [edit class-of-service]
   user@switch# set schedulers fcoe-sched priority low transmit-rate 3g
   user@switch# set schedulers fcoe-sched shaping-rate percent 100
   ```

2. Map the FCoE forwarding class to the FCoE scheduler (**fcoe-sched**):

   ```
   [edit class-of-service]
   user@switch# set scheduler-maps fcoe-map forwarding-class fcoe scheduler fcoe-sched
   ```

3. Configure the forwarding class set (**fcoe-pg**) for the FCoE traffic:

   ```
   [edit class-of-service]
   user@switch# set forwarding-class-sets fcoe-pg class fcoe
   ```

4. Define the traffic control profile (**fcoe-tcp**) to use on the FCoE forwarding class set:

   ```
   [edit class-of-service]
   user@switch# set traffic-control-profiles fcoe-tcp scheduler-map fcoe-map
   guaranteed-rate 3g
   user@switch# set traffic-control-profiles fcoe-tcp shaping-rate percent 100
   ```

5. Apply the FCoE forwarding class set and traffic control profile to the LAG and MC-LAG interfaces:

   ```
   [edit class-of-service]
   user@switch# set interfaces ae0 forwarding-class-set fcoe-pg output-traffic-control-profile
   fcoe-tcp
   user@switch# set interfaces ae1 forwarding-class-set fcoe-pg output-traffic-control-profile
   fcoe-tcp
   ```

6. Enable PFC on the FCoE priority by creating a congestion notification profile (**fcoe-cnp**) that applies FCoE to the IEEE 802.1 code point **011**:

```
[edit class-of-service]
user@switch# set congestion-notification-profile fcoe-cnp input ieee-802.1 code-point 011 pfc
```

7. Apply the PFC configuration to the LAG and MC-LAG interfaces:

```
[edit class-of-service]
user@switch# set interfaces ae0 congestion-notification-profile fcoe-cnp
user@switch# set interfaces ae1 congestion-notification-profile fcoe-cnp
```

8. Configure the VLAN for FCoE traffic (**fcoe_vlan**):

```
[edit vlans]
user@switch# set fcoe_vlan vlan-id 100
```

9. Add the member interfaces to the LAG between the two MC-LAG switches:

```
[edit interfaces]
user@switch# set xe-0/0/10 ether-options 802.3ad ae0
user@switch# set xe-0/0/11 ether-options 802.3ad ae0
```

10. Add the member interfaces to the MC-LAG:

```
[edit interfaces]
user@switch# set xe-0/0/20 ether-options 802.3ad ae1
user@switch# set xe-0/0/21 ether-options 802.3ad ae1
```

11. Configure the interface mode as **trunk** and membership in the FCoE VLAN (**fcoe_vlan**)for the LAG (**ae0**) and for the MC-LAG (**ae1**):

```
[edit interfaces]
user@switch# set interfaces ae0 unit 0 family ethernet-switching interface-mode trunk vlan members fcoe_vlan
user@switch# set interfaces ae1 unit 0 family ethernet-switching interface-mode trunk vlan members fcoe_vlan
```

12. Set the MTU to **2180** for the LAG and MC-LAG interfaces. 2180 bytes is the minimum size required to handle FCoE packets because of the payload and header sizes; you can configure the MTU to a higher number of bytes if desired, but not less than 2180 bytes:

```
[edit interfaces]
user@switch# set ae0 mtu 2180
user@switch# set ae1 mtu 2180
```

13. Set the LAG and MC-LAG interfaces as FCoE trusted ports. Ports that connect to other switches should be trusted and should not perform FIP snooping:

```
[edit]
user@switch# set vlans fcoe_vlan forwarding-options fip-security interface ae0 fcoe-trusted
user@switch# set vlans fcoe_vlan forwarding-options fip-security interface ae1fcoe-trusted
```

Configuring FCoE Transit Switches TS1 and TS2

Step-by-Step Procedure

The CoS configuration on FCoE Transit Switches TS1 and TS2 is similar to the CoS configuration on MC-LAG Switches S1 and S2. However, the port configurations differ, and you must enable FIP snooping on the Switch TS1 and Switch TS2 FCoE access ports.

To configure resource scheduling (ETS), PFC, the FCoE VLAN, and the LAG interface membership and characteristics to support lossless FCoE transport across the MC-LAG (this example uses the default **fcoe** forwarding class and the default classifier to map incoming FCoE traffic to the FCoE IEEE 802.1p code point **011**, so you do not configure them):

1. Configure output scheduling for the FCoE queue:

   ```
   [edit class-of-service]
   user@switch# set schedulers fcoe-sched priority low transmit-rate 3g
   user@switch# set schedulers fcoe-sched shaping-rate percent 100
   ```

2. Map the FCoE forwarding class to the FCoE scheduler (**fcoe-sched**):

   ```
   [edit class-of-service]
   user@switch# set scheduler-maps fcoe-map forwarding-class fcoe scheduler fcoe-sched
   ```

3. Configure the forwarding class set (**fcoe-pg**) for the FCoE traffic:

   ```
   [edit class-of-service]
   user@switch# set forwarding-class-sets fcoe-pg class fcoe
   ```

4. Define the traffic control profile (**fcoe-tcp**) to use on the FCoE forwarding class set:

   ```
   [edit class-of-service]
   user@switch# set traffic-control-profiles fcoe-tcp scheduler-map fcoe-map
   guaranteed-rate 3g
   user@switch# set traffic-control-profiles fcoe-tcp shaping-rate percent 100
   ```

5. Apply the FCoE forwarding class set and traffic control profile to the LAG interface and to the FCoE access interfaces:

   ```
   [edit class-of-service]
   user@switch# set interfaces ae1 forwarding-class-set fcoe-pg output-traffic-control-profile
   fcoe-tcp
   user@switch# set class-of-service interfaces xe-0/0/30 forwarding-class-set fcoe-pg
   output-traffic-control-profile fcoe-tcp
   user@switch# set class-of-service interfaces xe-0/0/31 forwarding-class-set fcoe-pg
   output-traffic-control-profile fcoe-tcp
   user@switch# set class-of-service interfaces xe-0/0/32 forwarding-class-set fcoe-pg
   output-traffic-control-profile fcoe-tcp
   user@switch# set class-of-service interfaces xe-0/0/33 forwarding-class-set fcoe-pg
   output-traffic-control-profile fcoe-tcp
   ```

6. Enable PFC on the FCoE priority by creating a congestion notification profile (**fcoe-cnp**) that applies FCoE to the IEEE 802.1 code point **011**:

   ```
   [edit class-of-service]
   user@switch# set congestion-notification-profile fcoe-cnp input ieee-802.1 code-point
   011 pfc
   ```

7. Apply the PFC configuration to the LAG interface and to the FCoE access interfaces:

   ```
   [edit class-of-service]
   user@switch# set interfaces ae1 congestion-notification-profile fcoe-cnp
   ```

```
user@switch# set class-of-service interfaces xe-0/0/30 congestion-notification-profile fcoe-cnp
user@switch# set class-of-service interfaces xe-0/0/31 congestion-notification-profile fcoe-cnp
user@switch# set class-of-service interfaces xe-0/0/32 congestion-notification-profile fcoe-cnp
user@switch# set class-of-service interfaces xe-0/0/33 congestion-notification-profile fcoe-cnp
```

8. Configure the VLAN for FCoE traffic (**fcoe_vlan**):

```
[edit vlans]
user@switch# set fcoe_vlan vlan-id 100
```

9. Add the member interfaces to the LAG:

```
[edit interfaces]
user@switch# set xe-0/0/25 ether-options 802.3ad ae1
user@switch# set xe-0/0/26 ether-options 802.3ad ae1
```

10. On the LAG (**ae1**), configure the interface mode as **trunk** and membership in the FCoE VLAN (**fcoe_vlan**):

```
[edit interfaces]
user@switch# set interfaces ae1 unit 0 family ethernet-switching interface-mode trunk vlan members fcoe_vlan
```

11. On the FCoE access interfaces (**xe-0/0/30**, **xe-0/0/31**, **xe-0/0/32**, **xe-0/0/33**), configure the interface mode as **trunk** and membership in the FCoE VLAN (**fcoe_vlan**):

```
[edit interfaces]
user@switch# set interfaces xe-0/0/30 unit 0 family ethernet-switching interface-mode trunk vlan members fcoe_vlan
user@switch# set interfaces xe-0/0/31 unit 0 family ethernet-switching interface-mode trunk vlan members fcoe_vlan
user@switch# set interfaces xe-0/0/32 unit 0 family ethernet-switching interface-mode trunk vlan members fcoe_vlan
user@switch# set interfaces xe-0/0/33 unit 0 family ethernet-switching interface-mode trunk vlan members fcoe_vlan
```

12. Set the MTU to **2180** for the LAG and FCoE access interfaces. 2180 bytes is the minimum size required to handle FCoE packets because of the payload and header sizes; you can configure the MTU to a higher number of bytes if desired, but not less than 2180 bytes:

```
[edit interfaces]
user@switch# set ae1 mtu 2180
user@switch# set xe-0/0/30 mtu 2180
user@switch# set xe-0/0/31 mtu 2180
user@switch# set xe-0/0/32 mtu 2180
user@switch# set xe-0/0/33 mtu 2180
```

13. Set the LAG interface as an FCoE trusted port. Ports that connect to other switches should be trusted and should not perform FIP snooping:

```
[edit]
user@switch# set vlans fcoe_vlan forwarding-options fip-security interface ae1 fcoe-trusted
```

NOTE: Access ports xe-0/0/30, xe-0/0/31, xe-0/0/32, and xe-0/0/33 are not configured as FCoE trusted ports. The access ports remain in the default state as untrusted ports because they connect directly to FCoE devices and must perform FIP snooping to ensure network security.

14. Enable FIP snooping on the FCoE VLAN to prevent unauthorized FCoE network access (this example uses VN2VN_Port FIP snooping; the example is equally valid if you use VN2VF_Port FIP snooping):

    ```
    [edit]
    user@switch# set vlans fcoe_vlan forwarding-options fip-security examine-vn2vn beacon-period 90000
    ```

Results

Display the results of the CoS configuration on MC-LAG Switch S1 and on MC-LAG Switch S2 (the results on both switches are the same):

```
user@switch> show configuration class-of-service
traffic-control-profiles {
  fcoe-tcp {
    scheduler-map fcoe-map;
    shaping-rate percent 100;
    guaranteed-rate 3000000000;
  }
}
forwarding-class-sets {
  fcoe-pg {
    class fcoe;
  }
}
congestion-notification-profile {
  fcoe-cnp {
    input {
      ieee-802.1 {
        code-point 011 {
          pfc;
        }
      }
    }
  }
}
interfaces {
  ae0 {
    forwarding-class-set {
      fcoe-pg {
        output-traffic-control-profile fcoe-tcp;
      }
    }
    congestion-notification-profile fcoe-cnp;
  }
  ae1 {
```

```
    forwarding-class-set {
      fcoe-pg {
        output-traffic-control-profile fcoe-tcp;
      }
    }
    congestion-notification-profile fcoe-cnp;
  }
}
scheduler-maps {
  fcoe-map {
    forwarding-class fcoe scheduler fcoe-sched;
  }
}
schedulers {
  fcoe-sched {
    transmit-rate 3000000000;
    shaping-rate percent 100;
    priority low;
  }
}
```

NOTE: The forwarding class and classifier configurations are not shown because the show command does not display default portions of the configuration.

For MC-LAG verification commands, see "Example: Configuring Multichassis Link Aggregation" on page 1904.

Display the results of the CoS configuration on FCoE Transit Switch TS1 and on FCoE Transit Switch TS2 (the results on both transit switches are the same):

```
user@switch> show configuration class-of-service
traffic-control-profiles {
  fcoe-tcp {
    scheduler-map fcoe-map;
    shaping-rate percent 100;
    guaranteed-rate 3000000000;
  }
}
forwarding-class-sets {
  fcoe-pg {
    class fcoe;
  }
}
congestion-notification-profile {
  fcoe-cnp {
    input {
      ieee-802.1 {
        code-point 011 {
          pfc;
        }
      }
    }
```

```
    }
}
interfaces {
    xe-0/0/30 {
        forwarding-class-set {
            fcoe-pg {
                output-traffic-control-profile fcoe-tcp;
            }
        }
        congestion-notification-profile fcoe-cnp;
    }
    xe-0/0/31 {
        forwarding-class-set {
            fcoe-pg {
                output-traffic-control-profile fcoe-tcp;
            }
        }
        congestion-notification-profile fcoe-cnp;
    }
    xe-0/0/32 {
        forwarding-class-set {
            fcoe-pg {
                output-traffic-control-profile fcoe-tcp;
            }
        }
        congestion-notification-profile fcoe-cnp;
    }
    xe-0/0/33 {
        forwarding-class-set {
            fcoe-pg {
                output-traffic-control-profile fcoe-tcp;
            }
        }
        congestion-notification-profile fcoe-cnp;
    }
    ae1 {
        forwarding-class-set {
            fcoe-pg {
                output-traffic-control-profile fcoe-tcp;
            }
        }
        congestion-notification-profile fcoe-cnp;
    }
}
scheduler-maps {
    fcoe-map {
        forwarding-class fcoe scheduler fcoe-sched;
    }
}
schedulers {
    fcoe-sched {
        transmit-rate 3000000000;
        shaping-rate percent 100;
        priority low;
    }
}
```

NOTE: The forwarding class and classifier configurations are not shown because the show command does not display default portions of the configuration.

Verification

To verify that the CoS components and FIP snooping have been configured and are operating properly, perform these tasks. Because this example uses the default **fcoe** forwarding class and the default IEEE 802.1p trusted classifier, the verification of those configurations is not shown:

Verifying That the Output Queue Schedulers Have Been Created

Purpose Verify that the output queue scheduler for FCoE traffic has the correct bandwidth parameters and priorities, and is mapped to the correct forwarding class (output queue). Queue scheduler verification is the same on each of the four switches.

Action List the scheduler map using the operational mode command **show class-of-service scheduler-map fcoe-map**:

```
user@switch> show class-of-service scheduler-map fcoe-map
Scheduler map: fcoe-map, Index: 9023

  Scheduler: fcoe-sched, Forwarding class: fcoe, Index: 37289
    Transmit rate: 3000000000 bps, Rate Limit: none, Buffer size: remainder,
    Buffer Limit: none, Priority: low
    Excess Priority: unspecified
    Shaping rate: 100 percent,
    drop-profile-map-set-type: mark
    Drop profiles:
      Loss priority   Protocol    Index    Name
      Low             any             1    <default-drop-profile>
      Medium high     any             1    <default-drop-profile>
      High            any             1    <default-drop-profile>
```

Meaning The **show class-of-service scheduler-map fcoe-map** command lists the properties of the scheduler map **fcoe-map**. The command output includes:

- The name of the scheduler map (**fcoe-map**)
- The name of the scheduler (**fcoe-sched**)
- The forwarding classes mapped to the scheduler (**fcoe**)
- The minimum guaranteed queue bandwidth (transmit rate **3000000000 bps**)
- The scheduling priority (**low**)
- The maximum bandwidth in the priority group the queue can consume (shaping rate **100 percent**)
- The drop profile loss priority for each drop profile name. This example does not include drop profiles because you do not apply drop profiles to FCoE traffic.

Verifying That the Priority Group Output Scheduler (Traffic Control Profile) Has Been Created

Purpose Verify that the traffic control profile **fcoe-tcp** has been created with the correct bandwidth parameters and scheduler mapping. Priority group scheduler verification is the same on each of the four switches.

Action List the FCoE traffic control profile properties using the operational mode command **show class-of-service traffic-control-profile fcoe-tcp**:

```
user@switch> show class-of-service traffic-control-profile fcoe-tcp
Traffic control profile: fcoe-tcp, Index: 18303
  Shaping rate: 100 percent
  Scheduler map: fcoe-map
  Guaranteed rate: 3000000000
```

Meaning The **show class-of-service traffic-control-profile fcoe-tcp** command lists all of the configured traffic control profiles. For each traffic control profile, the command output includes:

- The name of the traffic control profile (**fcoe-tcp**)
- The maximum port bandwidth the priority group can consume (shaping rate **100 percent**)
- The scheduler map associated with the traffic control profile (**fcoe-map**)
- The minimum guaranteed priority group port bandwidth (guaranteed rate **3000000000** in bps)

Verifying That the Forwarding Class Set (Priority Group) Has Been Created

Purpose Verify that the FCoE priority group has been created and that the **fcoe** priority (forwarding class) belongs to the FCoE priority group. Forwarding class set verification is the same on each of the four switches.

Action List the forwarding class sets using the operational mode command **show class-of-service forwarding-class-set fcoe-pg**:

```
user@switch> show class-of-service forwarding-class-set fcoe-pg
Forwarding class set: fcoe-pg, Type: normal-type, Forwarding class set index:
31420
  Forwarding class                       Index
  fcoe                                     1
```

Meaning The **show class-of-service forwarding-class-set fcoe-pg** command lists all of the forwarding classes (priorities) that belong to the **fcoe-pg** priority group, and the internal index number of the priority group. The command output shows that the forwarding class set **fcoe-pg** includes the forwarding class **fcoe**.

Verifying That Priority-Based Flow Control Has Been Enabled

Purpose Verify that PFC is enabled on the FCoE code point. PFC verification is the same on each of the four switches.

Action List the FCoE congestion notification profile using the operational mode command **show class-of-service congestion-notification fcoe-cnp**:

```
user@switch> show class-of-service congestion-notification fcoe-cnp
Type: Input, Name: fcoe-cnp, Index: 6879
Cable Length: 100 m
  Priority     PFC         MRU
  000          Disabled
  001          Disabled
  010          Disabled
  011          Enabled     2500
  100          Disabled
  101          Disabled
  110          Disabled
  111          Disabled
Type: Output
  Priority     Flow-Control-Queues
  000
               0
  001
               1
  010
               2
  011
               3
  100
               4
  101
               5
  110
               6
  111
               7
```

Meaning The **show class-of-service congestion-notification fcoe-cnp** command lists all of the IEEE 802.1p code points in the congestion notification profile that have PFC enabled. The command output shows that PFC is enabled on code point **011** (**fcoe** queue) for the **fcoe-cnp** congestion notification profile.

The command also shows the default cable length (100 meters), the default maximum receive unit (2500 bytes), and the default mapping of priorities to output queues because this example does not include configuring these options.

Verifying That the Interface Class of Service Configuration Has Been Created

Purpose Verify that the CoS properties of the interfaces are correct. The verification output on MC-LAG Switches S1 and S2 differs from the output on FCoE Transit Switches TS1 and TS2.

Action List the interface CoS configuration on MC-LAG Switches S1 and S2 using the operational mode command **show configuration class-of-service interfaces**:

```
user@switch> show configuration class-of-service interfaces
ae0 {
    forwarding-class-set {
        fcoe-pg {
            output-traffic-control-profile fcoe-tcp;
        }
    }
    congestion-notification-profile fcoe-cnp;
}

ae1 {
    forwarding-class-set {
        fcoe-pg {
            output-traffic-control-profile fcoe-tcp;
        }
    }
    congestion-notification-profile fcoe-cnp;
}
```

List the interface CoS configuration on FCoE Transit Switches TS1 and TS2 using the operational mode command **show configuration class-of-service interfaces**:

```
user@switch> show configuration class-of-service interfaces
xe-0/0/30 {
    forwarding-class-set {
        fcoe-pg {
            output-traffic-control-profile fcoe-tcp;
        }
    }
    congestion-notification-profile fcoe-cnp;
}
xe-0/0/31 {
    forwarding-class-set {
        fcoe-pg {
            output-traffic-control-profile fcoe-tcp;
        }
    }
    congestion-notification-profile fcoe-cnp;
}
xe-0/0/32 {
    forwarding-class-set {
        fcoe-pg {
            output-traffic-control-profile fcoe-tcp;
        }
    }
```

```
        congestion-notification-profile fcoe-cnp;
    }
    xe-0/0/33 {
        forwarding-class-set {
            fcoe-pg {
                output-traffic-control-profile fcoe-tcp;
            }
        }
        congestion-notification-profile fcoe-cnp;
    }
    ae1 {
        forwarding-class-set {
            fcoe-pg {
                output-traffic-control-profile fcoe-tcp;
            }
        }
        congestion-notification-profile fcoe-cnp;
    }
```

Meaning The **show configuration class-of-service interfaces** command lists the class of service configuration for all interfaces. For each interface, the command output includes:

- The name of the interface (for example, **ae0** or **xe-0/0/30**)
- The name of the forwarding class set associated with the interface (**fcoe-pg**)
- The name of the traffic control profile associated with the interface (output traffic control profile, **fcoe-tcp**)
- The name of the congestion notification profile associated with the interface (**fcoe-cnp**)

NOTE: Interfaces that are members of a LAG are not shown individually. The LAG or MC-LAG CoS configuration is applied to all interfaces that are members of the LAG or MC-LAG. For example, the interface CoS configuration output on MC-LAG Switches S1 and S2 shows the LAG CoS configuration but does not show the CoS configuration of the member interfaces separately. The interface CoS configuration output on FCoE Transit Switches TS1 and TS2 shows the LAG CoS configuration but also shows the configuration for interfaces **xe-0/0/30**, **xe-0/0/31**, **xe-0/0/32**, and **xe-0/0/33**, which are not members of a LAG.

Verifying That the Interfaces Are Correctly Configured

Purpose Verify that the LAG membership, MTU, VLAN membership, and port mode of the interfaces are correct. The verification output on MC-LAG Switches S1 and S2 differs from the output on FCoE Transit Switches T1 and T2.

Action List the interface configuration on MC-LAG Switches S1 and S2 using the operational mode command **show configuration interfaces**:

`user@switch>` **show configuration interfaces**

```
xe-0/0/10 {
    ether-options {
        802.3ad ae0;
    }
}
xe-0/0/11 {
    ether-options {
        802.3ad ae0;
    }
}
xe-0/0/20 {
    ether-options {
        802.3ad ae1;
    }
}
xe-0/0/21 {
    ether-options {
        802.3ad ae1;
    }
}
ae0 {
    mtu 2180;
    unit 0 {
        family ethernet-switching {
            interface-mode trunk;
            vlan {
                members fcoe_vlan;
            }
        }
    }
}
ae1 {
    mtu 2180;
    unit 0 {
        family ethernet-switching {
            interface-mode trunk;
            vlan {
                members fcoe_vlan;
            }
        }
    }
}
```

List the interface configuration on FCoE Transit Switches TS1 and TS2 using the operational mode command **show configuration interfaces**:

```
user@switch> show configuration interfaces
xe-0/0/25 {
    ether-options {
        802.3ad ae1;
    }
}
xe-0/0/26 {
    ether-options {
        802.3ad ae1;
    }
}
xe-0/0/30 {
    mtu 2180;
    unit 0 {
```

```
            family ethernet-switching {
                interface-mode trunk;
                vlan {
                    members fcoe_vlan;
                }
            }
        }
    }
    xe-0/0/31 {
        mtu 2180;
        unit 0 {
            family ethernet-switching {
                interface-mode trunk;
                vlan {
                    members fcoe_vlan;
                }
            }
        }
    }
    xe-0/0/32 {
        mtu 2180;
        unit 0 {
            family ethernet-switching {
                interface-mode trunk;
                vlan {
                    members fcoe_vlan;
                }
            }
        }
    }
    xe-0/0/33 {
        mtu 2180;
        unit 0 {
            family ethernet-switching {
                interface-mode trunk;
                vlan {
                    members fcoe_vlan;
                }
            }
        }
    }

    ae1 {
        mtu 2180;
        unit 0 {
            family ethernet-switching {
                interface-mode trunk;
                vlan {
                    members fcoe_vlan;
                }
            }
        }
    }
```

Meaning The **show configuration interfaces** command lists the configuration of each interface by interface name.

For each interface that is a member of a LAG, the command lists only the name of the LAG to which the interface belongs.

For each LAG interface and for each interface that is not a member of a LAG, the command output includes:

- The MTU (**2180**)
- The unit number of the interface (**0**)
- The interface mode (**trunk** mode both for interfaces that connect two switches and for interfaces that connect to FCoE hosts)
- The name of the VLAN in which the interface is a member (**fcoe_vlan**)

Verifying That FIP Snooping Is Enabled on the FCoE VLAN on FCoE Transit Switches TS1 and TS2 Access Interfaces

Purpose Verify that FIP snooping is enabled on the FCoE VLAN access interfaces. FIP snooping is enabled only on the FCoE access interfaces, so it is enabled only on FCoE Transit Switches TS1 and TS2. FIP snooping is not enabled on MC-LAG Switches S1 and S2 because FIP snooping is done at the Transit Switch TS1 and TS2 FCoE access ports.

Action List the port security configuration on FCoE Transit Switches TS1 and TS2 using the operational mode command **show configuration vlans fcoe_vlan forwarding-options fip-security**:

```
user@switch> show configuration vlans fcoe_vlan forwarding-options fip-security
interface ae1.0 {
    fcoe-trusted;
}
examine-vn2vn {
    beacon-period 90000;
}
```

Meaning The **show configuration vlans fcoe_vlan forwarding-options fip-security** command lists VLAN FIP security information, including whether a port member of the VLAN is trusted. The command output shows that:

- LAG port **ae1.0**, which connects the FCoE transit switch to the MC-LAG switches, is configured as an FCoE trusted interface. FIP snooping is not performed on the member interfaces of the LAG (**xe-0/0/25** and **xe-0/0/26**).
- VN2VN_Port FIP snooping is enabled (**examine-vn2vn**) on the FCoE VLAN and the beacon period is set to 90000 milliseconds. On Transit Switches TS1 and TS2, all interface members of the FCoE VLAN perform FIP snooping unless the interface is configured as FCoE trusted. On Transit Switches TS1 and TS2, interfaces **xe-0/0/30**, **xe-0/0/31**, **xe-0/0/32**, and **xe-0/0/33** perform FIP snooping because they are not configured as FCoE trusted. The interface members of LAG **ae1** (**xe-0/0/25** and **xe-0/0/26**) do not perform FIP snooping because the LAG is configured as FCoE trusted.

Verifying That the FIP Snooping Mode Is Correct on FCoE Transit Switches TS1 and TS2

Purpose Verify that the FIP snooping mode is correct on the FCoE VLAN. FIP snooping is enabled only on the FCoE access interfaces, so it is enabled only on FCoE Transit Switches TS1 and TS2. FIP snooping is not enabled on MC-LAG Switches S1 and S2 because FIP snooping is done at the Transit Switch TS1 and TS2 FCoE access ports.

Action List the FIP snooping configuration on FCoE Transit Switches TS1 and TS2 using the operational mode command **show fip snooping brief**:

```
user@switch> show fip snooping brief
VLAN: fcoe_vlan,    Mode: VN2VN Snooping
  FC-MAP: 0e:fc:00
…
```

NOTE: The output has been truncated to show only the relevant information.

Meaning The **show fip snooping brief** command lists FIP snooping information, including the FIP snooping VLAN and the FIP snooping mode. The command output shows that:

- The VLAN on which FIP snooping is enabled is **fcoe_vlan**
- The FIP snooping mode is VN2VN_Port FIP snooping (**VN2VN Snooping**)

Example: Configuring VN2VN_Port FIP Snooping (FCoE Hosts Directly Connected to the Same FCoE Transit Switch)

This example shows how to configure VN_Port to VN_Port (VN2VN_Port) FIP snooping when the hosts are directly connected to the same FCoE transit switch.

NOTE: This example uses the Junos OS Enhanced Layer 2 Software (ELS) configuration style for QFX Series switches. If your switch runs software that does not support ELS, see "Example: Configuring VN2VN_Port FIP Snooping (FCoE Hosts Directly Connected to the Same FCoE Transit Switch)" on page 4977. For ELS details, see "Getting Started with Enhanced Layer 2 Software" on page 58.

VN2VN_Port FIP snooping on an FCoE transit switch provides security to help prevent unauthorized access and data transmission on a bridge that connects ENodes in the Ethernet network. VN2VN_Port FIP snooping provides security for virtual links by creating filters based on information gathered (snooped) about FCoE devices during FIP transactions.

VN2VN_Port FIP snooping is conceptually similar to VN2VN_Port FIP snooping between VN_Ports and VF_Ports, but VN2VN_Port FIP snooping does not require traffic between VN_Ports to traverse the Fibre Channel (FC) switch or FCoE forwarder (FCF). Instead, a VN_Port communicates transparently through the transit switch on a virtual link that emulates a direct connection to the VN_Port at the other end of the virtual link.

To configure VN2VN_Port FIP snooping when the hosts are directly connected to the same FCoE transit switch, you must follow these configuration rules:

- VN2VN_Port traffic must use a dedicated FCoE VLAN, and all ENodes that communicate using VN2VN_Port FIP snooping must use that FCoE VLAN. You cannot mix VN2VN_Port FIP snooping traffic with VN2VF_Port FIP snooping traffic in the same FCoE VLAN.

NOTE: **An FCoE VLAN can support either VN2VF_Port FIP snooping or VN2VN_Port FIP snooping, but not both. Configure separate FCoE VLANs for VN2VF_Port FIP snooping traffic and for VN2VN_Port FIP snooping traffic. On FCoE VLANs that are configured as VN2VN_Port FIP snooping VLANs, VN_Port to VF_Port (FIP snooping) traffic is dropped.**

- ENode-facing ports must be set in **trunk** interface mode.
- ENode-facing ports must be untrusted ports.
- Network-facing (switch-facing) ports must be set in **trunk** interface mode.
- Network-facing ports must be FCoE trusted ports.
- Explicitly configure the beacon period. The beacon period is essentially a keepalive timer for virtual link maintenance.

When you enable VN2VF_Port FIP snooping, the system snoops VN_Port to VF_Port packets and enforces security only on VN_Port to VF_Port virtual links. When you enable VN2VN_Port FIP snooping, the system snoops VN_Port to VN_Port packets and enforces security only on VN_Port to VN_Port virtual links.

The transit switch applies VN2VN_Port FIP snooping filters at the ports associated with the FCoE VLANs on which you enable VN2VN FIP snooping.

This example describes how to configure VN2VN_Port FIP snooping when the FCoE hosts are directly connected to the same transit switch:

Requirements

This example uses the following hardware and software components:

- One Juniper Networks QFX5100 Switch running the ELS CLI and used as a transit switch

- Junos OS Release 13.2 or later for the QFX Series
- Two FCoE hosts that have ENodes

Overview

This example shows you how to:

- Set the correct interface mode on the transit switch.
- Configure the interfaces to use the dedicated FCoE VLAN for VN2VN_Port FIP snooping.
- Configure the dedicated FCoE VLAN for VN2VN_Port FIP snooping traffic.
- Enable VN2VN_Port FIP snooping on the FCoE VLAN and configure the beacon period.

Topology

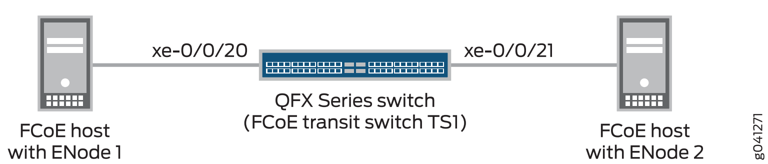
Table 385 on page 4979 shows the configuration components for this example.

Table 389: Components of the VN2VN_Port FIP Snooping Configuration Topology (FCoE Hosts Directly Connected to the Same FCoE Transit Switch)

Component	Settings
Hardware	QFX5100 switch running the ELS CLI (FCoE transit switch TS1) Two FCoE hosts that have ENodes (ENode1 and ENode2, respectively)
Interfaces and interface mode	• Interface **xe-0/0/20**, interface mode **trunk**, connects directly to the FCoE host with ENode1. • Interface **xe-0/0/21**, interface mode **trunk**, connects directly to the FCoE host with ENode2.
Interface VLAN membership	Both interfaces use VLAN **vlan200**.
VN2VN_Port FIP snooping VLAN	VLAN name—**vlan200** VLAN ID—200
FIP snooping mode and beacon period	Set **examine-vn2vn** (VN2VN_Port FIP snooping) Beacon period—90000 ms

Figure 182 on page 4979 shows the network topology for this example.

Figure 186: VN2VN_Port FIP Snooping (FCoE Hosts Connected to Same Transit Switch) Topology



Configuration

CLI Quick Configuration

To quickly configure VN2VN_Port FIP snooping for FCoE hosts connected directly to the same transit switch, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level:

set interfaces xe-0/0/20 unit 0 family ethernet-switching interface-mode trunk
set interfaces xe-0/0/21 unit 0 family ethernet-switching interface-mode trunk
set interfaces xe-0/0/20 unit 0 family ethernet-switching vlan members vlan200
set interfaces xe-0/0/21 unit 0 family ethernet-switching vlan members vlan200
set vlans vlan200 vlan-id 200
set vlans vlan200 forwarding-options fip-security examine-vn2vn beacon-period 90000

Configuring VN2VN_Port FIP Snooping (FCoE Hosts Directly Connected to the Same FCoE Transit Switch)

Step-by-Step Procedure

To configure interface mode, configure interface VLAN membership in the FCoE VLAN dedicated to VN2VN_Port traffic, configure the VLAN, set the beacon period, and enable VN2VN_Port FIP snooping:

1. Configure the modes of the interfaces that connect directly to the FCoE host ENodes:

   `user@switch#` **set interfaces xe-0/0/20 unit 0 family ethernet-switching interface-mode trunk**
   set interfaces xe-0/0/21 unit 0 family ethernet-switching interface-mode trunk

2. Configure the interface VLAN membership so that the interfaces connected to theENodes are members of the dedicated VN2VN_Port VLAN (**vlan200**):

   `user@switch#` **set interfaces xe-0/0/20 unit 0 family ethernet-switching vlan members vlan200**
   set interfaces xe-0/0/21 unit 0 family ethernet-switching vlan members vlan200

3. Configure the FCoE VLAN dedicated to VN2VN_Port FIP snooping:

   `user@switch#` **set vlans vlan200 vlan-id 200**

4. Enable VN2VN_Port FIP snooping on the VLAN and configure the beacon period:

   `user@switch#` **set vlans vlan200 forwarding-options fip-security examine-vn2vn beacon-period 90000**

Verification

To verify that the VN2VN_Port FIP snooping configuration has been created and is operating properly, perform these tasks:

- Verifying That VN2VN_Port FIP Snooping is Enabled on the FCoE VLAN on page 5028

Verifying That VN2VN_Port FIP Snooping is Enabled on the FCoE VLAN

Purpose

Verify that VN2VN_Port FIP snooping is enabled on the correct VLAN (**vlan200**), the beacon period is set to **90000** milliseconds, and the correct interfaces (**xe-0/0/20** and **xe-0/0/21**) are members of the VLAN.

Action List the FIP snooping information using the operational mode command **show fip snooping detail**.

```
user@switch> show fip snooping detail
VLAN: vlan200,  Mode: VN2VN Snooping
  FC-MAP: 0e:fd:00
  Beacon_Period:  90000
  VN2VN Mode: Point-to-Point
    Enode Information
    Enode-MAC: 10:10:94:01:00:02,       Interface: xe-0/0/20
      Active VN_Ports : 1
      VN_Port Information
      VN-Port MAC: 0e:fd:00:00:0a:01
         Active Sessions    : 1
         Session Information
     Vlink far-end VN-Port-MAC: 0e:fd:00:00:0b:01
    Enode-MAC: 10:10:94:01:00:02,       Interface: xe-0/0/21
      Active VN_Ports : 1
      VN_Port Information
      VN-Port MAC: 0e:fd:00:00:0b:01
         Active Sessions    : 1
         Session Information
     Vlink far-end VN-Port-MAC: 0e:fd:00:0o:0a:01
```

Meaning The **show fip snooping detail** command lists all of the transit switch information about VN2VN_Port FIP snooping and VN2VF_Port FIP snooping. The command shows that:

- The VLAN is **vlan200**.
- The mode is FIP snooping mode **VN2VN**, for VN2VN_Port FIP snooping. (If the Mode field shows **VN2VF**, then the FIP snooping mode is VN2VF_Port FIP snooping.)
- The beacon period is **90000**.
- The interfaces for the ENodes are **xe-0/0/20** and **xe-0/0/21**.

In addition, this useful command shows information about the ENodes and the VN2VN_Port sessions.

Example: Configuring VN2VN_Port FIP Snooping (FCoE Hosts Directly Connected to Different FCoE Transit Switches)

This example shows how to configure VN_Port to VN_Port (VN2VN_Port) FIP snooping when the hosts are directly connected to different FCoE transit switches, and the transit switches are directly connected to each other.

> NOTE: This example uses the Junos OS Enhanced Layer 2 Software (ELS) configuration style for QFX Series switches. If your switch runs software that does not support ELS, see "Example: Configuring VN2VN_Port FIP Snooping (FCoE Hosts Directly Connected to Different FCoE Transit Switches)" on page 4982. For ELS details, see "Getting Started with Enhanced Layer 2 Software" on page 58.

VN2VN_Port FIP snooping on an FCoE transit switch provides security to help prevent unauthorized access and data transmission on a bridge that connects ENodes in the Ethernet network. VN2VN_Port FIP snooping provides security for virtual links by creating filters based on information gathered (snooped) about FCoE devices during FIP transactions.

VN2VN_Port FIP snooping is conceptually similar to VN2VF_Port FIP snooping between VN_Ports and VF_Ports, but VN2VN_Port FIP snooping does not require traffic between VN_Ports to traverse the Fibre Channel (FC) switch or FCoE forwarder (FCF). Instead, a VN_Port communicates transparently through one or more transit switches on a virtual link that emulates a direct connection to the VN_Port at the other end of the virtual link.

To configure VN2VN_Port FIP snooping when the hosts are directly connected to different FCoE transit switches, and the transit switches are directly connected to each other, you must follow these configuration rules:

- VN2VN_Port traffic must use a dedicated FCoE VLAN, and all ENodes that communicate using VN2VN_Port FIP snooping must use that FCoE VLAN. The FCoE VLAN must be configured on each transit switch. You cannot mix VN2VN_Port FIP snooping traffic with VN2VF_Port FIP snooping traffic in the same FCoE VLAN.

  > NOTE: An FCoE VLAN can support either VN2VF_Port FIP snooping or VN2VN_Port FIP snooping, but not both. Configure separate FCoE VLANs for VN2VF_Port FIP snooping traffic and for VN2VN_Port FIP snooping traffic. On FCoE VLANs that are configured as VN2VN_Port FIP snooping VLANs, VN2VF_Port traffic is dropped.

- ENode-facing ports must be set in **trunk** interface mode.
- ENode-facing ports must be untrusted ports.
- Network-facing (switch-facing) ports must be set in **trunk** interface mode.

- Network-facing ports must be FCoE trusted ports.
- Explicitly configure the beacon period. The beacon period is essentially a keepalive timer for virtual link maintenance.

When you enable VN2VF_Port FIP snooping, the system snoops VN_Port to VF_Port packets and enforces security only on VN_Port to VF_Port virtual links. When you enable VN2VN_Port FIP snooping, the system snoops VN_Port to VN_Port packets and enforces security only on VN_Port to VN_Port virtual links.

The transit switch applies VN2VN_Port FIP snooping filters at the ports associated with the FCoE VLANs on which you enable VN2VN FIP snooping.

This example describes how to configure VN2VN_Port FIP snooping when the FCoE hosts are directly connected to different transit switches, and the transit switches are directly connected to each other:

Requirements

This example uses the following hardware and software components:

- Two Juniper Networks QFX5100 Switches running the ELS CLI and used as transit switches
- Junos OS Release 13.2 or later for the QFX Series
- Two FCoE hosts that have ENodes

Overview

This example shows you how to:

- Set the correct interface mode on the transit switch.
- Configure the interfaces to use the dedicated FCoE VLAN for VN2VN_Port FIP snooping.
- Configure the network-facing interfaces as FCoE trusted interfaces.
- Configure the dedicated FCoE VLAN for VN2VN_Port FIP snooping traffic.
- Enable VN2VN_Port FIP snooping on the FCoE VLAN and configure the beacon period.

Topology

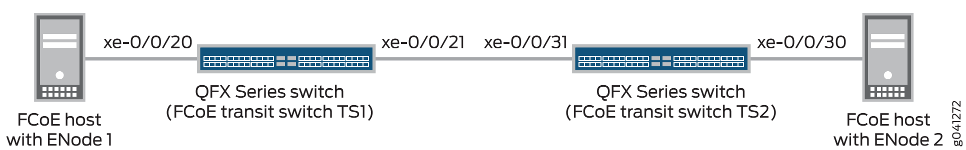
Table 386 on page 4984 shows the configuration components for this example.

Table 390: Components of the VN2VN_Port FIP Snooping Configuration Topology (FCoE Hosts Directly Connected to Different FCoE Transit Switches)

Component	Settings
Hardware	Two QFX5100 switches running the ELS CLI (FCoE transit switch TS1 and FCoE transit switch TS2) Two FCoE hosts that have ENodes (ENode1 and ENode2, respectively)
Interfaces and interface mode	• Interface **xe-0/0/20**, interface mode **trunk**, connects directly from transit switch TS1 to the FCoE host with ENode1. • Interface **xe-0/0/21**, interface mode **trunk**, connects directly from transit switch TS1 to transit switch TS2. • Interface **xe-0/0/31**, interface mode **trunk**, connects directly from transit switch TS2 to transit switch TS1. • Interface **xe-0/0/30**, interface mode **trunk**, connects directly from transit switch TS2 to the FCoE host with ENode2.
Interface VLAN membership	The interfaces on both transit switches use VLAN **vlan200**.
VN2VN_Port FIP snooping VLAN	VLAN name (both transit switches)—**vlan200** VLAN ID—200
FIP snooping mode and beacon period	Set **examine-vn2vn** (VN2VN_Port FIP snooping) Beacon period—90000 ms

Figure 183 on page 4984 shows the network topology for this example.

Figure 187: VN2VN_Port FIP Snooping (FCoE Hosts Connected to Different Transit Switches) Topology



Configuration

To configure VN2VN_Port FIP snooping for VN_Ports that are directly connected to different transit switches (and the transit switches are directly connected to each other), perform these tasks:

- Configuring VN2VN_Port FIP Snooping on FCoE Transit Switch TS1 on page 5033
- Configuring VN2VN_Port FIP Snooping on FCoE Transit Switch TS2 on page 5034

CLI Quick Configuration

The configuration for each FCoE transit switch is shown separately.

To quickly configure VN2VN_Port FIP snooping for FCoE hosts connected directly to different transit switches, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level. To configure FCoE transit switch TS1:

FCoE Transit Switch TS1

set interfaces xe-0/0/20 unit 0 family ethernet-switching interface-mode trunk
set interfaces xe-0/0/21 unit 0 family ethernet-switching interface-mode trunk
set interfaces xe-0/0/20 unit 0 family ethernet-switching vlan members vlan200
set interfaces xe-0/0/21 unit 0 family ethernet-switching vlan members vlan200
set vlans vlan200 vlan-id 200
set vlans vlan200 forwarding-options fip-security interface xe-0/0/21 fcoe-trusted
set vlans vlan200 forwarding-options fip-security examine-vn2vn beacon-period 90000

To quickly configure VN2VN_Port FIP snooping for FCoE hosts connected directly to different transit switches, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level. To configure FCoE transit switch TS2:

FCoE Transit Switch TS2

set interfaces xe-0/0/30 unit 0 family ethernet-switching interface-mode trunk
set interfaces xe-0/0/31 unit 0 family ethernet-switching interface-mode trunk
set interfaces xe-0/0/30 unit 0 family ethernet-switching vlan members vlan200
set interfaces xe-0/0/31 unit 0 family ethernet-switching vlan members vlan200
set vlans vlan200 vlan-id 200
set vlans vlan200 forwarding-options fip-security interface xe-0/0/31 fcoe-trusted
set vlans vlan200 forwarding-options fip-security examine-vn2vn beacon-period 90000

Configuring VN2VN_Port FIP Snooping on FCoE Transit Switch TS1

Step-by-Step Procedure

To configure interface mode, configure interface VLAN membership in the FCoE VLAN dedicated to VN2VN_Port traffic, set the network-facing port as FCoE trusted, configure the VLAN, set the beacon period, and enable VN2VN_Port FIP snooping:

1. Configure the modes of the interfaces that connect directly to the FCoE host with ENode1 (**xe-0/0/20**) and to FCoE transit switch TS2 (**xe-0/0/21**):

   `user@switch#` **set interfaces xe-0/0/20 unit 0 family ethernet-switching interface-mode trunk**
   set interfaces xe-0/0/21 unit 0 family ethernet-switching interface-mode trunk

2. Configure the interface VLAN membership so that the interfaces are members of the dedicated VN2VN_Port VLAN (**vlan200**):

   `user@switch#` **set interfaces xe-0/0/20 unit 0 family ethernet-switching vlan members vlan200**
   set interfaces xe-0/0/21 unit 0 family ethernet-switching vlan members vlan200

3. Configure the FCoE VLAN dedicated to VN2VN_Port FIP snooping:

   `user@switch#` **set vlans vlan200 vlan-id 200**

4. Configure the network-facing port (**xe-0/0/21**) as an FCoE trusted port:

   `user@switch#` **set vlans vlan200 forwarding-options fip-security interface xe-0/0/21 fcoe-trusted**

5. Enable VN2VN_Port FIP snooping on the VLAN and configure the beacon period:

   `user@switch#` **set vlans vlan200 forwarding-options fip-security examine-vn2vn beacon-period 90000**

Configuring VN2VN_Port FIP Snooping on FCoE Transit Switch TS2

Step-by-Step Procedure

To configure interface mode, configure interface VLAN membership in the FCoE VLAN dedicated to VN2VN_Port traffic, set the network-facing port as FCoE trusted, configure the VLAN, set the beacon period, and enable VN2VN_Port FIP snooping:

1. Configure the modes of the interfaces that connect directly to the FCoE host with ENode2 (**xe-0/0/30**) and to FCoE transit switch TS1 (**xe-0/0/31**):

   `user@switch#` **set interfaces xe-0/0/30 unit 0 family ethernet-switching interface-mode trunk**
   set interfaces xe-0/0/31 unit 0 family ethernet-switching interface-mode trunk

2. Configure the interface VLAN membership so that the interfaces are members of the dedicated VN2VN_Port VLAN (**vlan200**):

   `user@switch#` **set interfaces xe-0/0/30 unit 0 family ethernet-switching vlan members vlan200**
   set interfaces xe-0/0/31 unit 0 family ethernet-switching vlan members vlan200

3. Configure the FCoE VLAN dedicated to VN2VN_Port FIP snooping:

   `user@switch#` **set vlans vlan200 vlan-id 200**

4. Configure the network-facing port (**xe-0/0/31**) as an FCoE trusted port:

   `user@switch#` **set vlans vlan200 forwarding-options fip-security interface xe-0/0/31 fcoe-trusted**

5. Enable VN2VN_Port FIP snooping on the VLAN and configure the beacon period:

   `user@switch#` **set vlans vlan200 forwarding-options fip-security examine-vn2vn beacon-period 90000**

Verification

To verify that the VN2VN_Port FIP snooping configuration has been created and is operating properly on both switches, perform these tasks:

- Verifying That VN2VN_Port FIP Snooping is Enabled on the FCoE VLAN (Transit Switches TS1 and TS2) on page 5034

Verifying That VN2VN_Port FIP Snooping is Enabled on the FCoE VLAN (Transit Switches TS1 and TS2)

Purpose

Verify that VN2VN_Port FIP snooping is enabled on the correct VLAN (**vlan200**), the beacon period is set to **90000** milliseconds, and that the correct interfaces (**xe-0/0/20** and **xe-0/0/21** on TS1, and **xe-0/0/30**and **xe-0/0/31** on TS2) are members of the VLAN.

Action List the FIP snooping information on transit switch TS1 using the operational mode command **show fip snooping detail**

```
user@switch> show fip snooping detail
VLAN: vlan200,  Mode: VN2VN Snooping
  FC-MAP: 0e:fc:00
  Beacon_Period:  90000
  VN2VN Mode: Point-to-Point
    Enode Information
    Enode-MAC: 10:10:94:01:00:02,       Interface: xe-0/0/20
      Active VN_Ports : 1
      VN_Port Information
      VN-Port MAC: 0e:fc:00:01:0a:01
         Active Sessions    : 1
         Session Information
     Vlink far-end VN-Port-MAC: 0e:fc:00:01:0b:01
    Enode-MAC: 10:10:94:01:00:02,       Interface: xe-0/0/21
      Active VN_Ports : 1
      VN_Port Information
      VN-Port MAC: 0e:fc:00:01:0b:01
         Active Sessions    : 1
         Session Information
     Vlink far-end VN-Port-MAC: 0e:fc:00:01:0a:01
```

List the FIP snooping information on transit switch TS2 using the operational mode command **show fip snooping detail**

```
user@switch> show fip snooping detail
VLAN: vlan200,  Mode: VN2VN Snooping
  FC-MAP: 0e:fd:00
  Beacon_Period:  90000
  VN2VN Mode: Point-to-Point
    Enode Information
    Enode-MAC: 10:10:94:01:00:02,       Interface: xe-0/0/30
      Active VN_Ports : 1
      VN_Port Information
      VN-Port MAC: 0e:fd:00:00:0b:01
         Active Sessions    : 1
         Session Information
     Vlink far-end VN-Port-MAC: 0e:fd:00:00:0a:01
    Enode-MAC: 10:10:94:01:00:02,       Interface: xe-0/0/31
      Active VN_Ports : 1
      VN_Port Information
      VN-Port MAC: 0e:fd:00:00:0a:01
         Active Sessions    : 1
         Session Information
     Vlink far-end VN-Port-MAC: 0e:fd:00:00:0b:01
```

Meaning The **show fip snooping detail** command lists all of the transit switch information about VN2VN_Port FIP snooping and VN2VF_Port FIP snooping on each transit switch. The command shows that:

- The VLAN is **vlan200**.
- The mode is FIP snooping mode **VN2VN**, for VN2VN_Port FIP snooping. (If the Mode field shows **VN2VF**, then the FIP snooping mode is VN2VF_Port FIP snooping.)

- The beacon period is **90000**.
- The interfaces connected to the ENodes are **xe-0/0/20** and **xe-0/0/21** on transit switch TS1, and **xe-0/0/30** and **xe-0/0/31** on transit switch TS2. Because the transit switches are transparent passthrough switches, the network-facing trunk ports “see” the FCoE host ENodes at the far end of the VN2VN_Port virtual link.

In addition, this useful command shows information about the ENodes and the VN2VN_Port sessions.

Example: Configuring VN2VN_Port FIP Snooping (FCoE Hosts Indirectly Connected Through an Aggregation Layer FCoE Transit Switch)

This example shows how to configure VN_Port to VN_Port (VN2VN_Port) FIP snooping when the hosts are indirectly connected through an aggregation layer FCoE transit switch. Each FCoE host ENode is directly connected to an FCoE transit switch, but the FCoE transit switches are not directly connected to each other. The FCoE transit switches are both connected to a third FCoE transit switch that acts as an aggregation layer switch.

NOTE: **This example uses the Junos OS Enhanced Layer 2 Software (ELS) configuration style for QFX Series switches. If your switch runs software that does not support ELS, see** “Example: Configuring VN2VN_Port FIP Snooping (FCoE Hosts Indirectly Connected Through an Aggregation Layer FCoE Transit Switch)” on page 4990**. For ELS details, see** “Getting Started with Enhanced Layer 2 Software” on page 58.

VN2VN_Port FIP snooping on an FCoE transit switch provides security to help prevent unauthorized access and data transmission on a bridge that connects ENodes in the Ethernet network. VN2VN_Port FIP snooping provides security for virtual links by creating filters based on information gathered (snooped) about FCoE devices during FIP transactions.

VN2VN_Port FIP snooping is conceptually similar to VN2VN_Port FIP snooping between VN_Ports and VF_Ports, but VN2VN_Port FIP snooping does not require traffic between VN_Ports to traverse the Fibre Channel (FC) switch or FCoE forwarder (FCF). Instead, a VN_Port communicates transparently through one or more transit switches on a virtual link that emulates a direct connection to the VN_Port at the other end of the virtual link.

To configure VN2VN_Port FIP snooping when the hosts are indirectly connected, you must follow these configuration rules:

- VN2VN_Port traffic must use a dedicated FCoE VLAN, and all ENodes that communicate using VN2VN_Port FIP snooping must use that FCoE VLAN. The FCoE VLAN must be configured on each transit switch. You cannot mix VN2VN_Port FIP snooping traffic with VN2VF_Port FIP snooping traffic in the same FCoE VLAN.

  NOTE: **An FCoE VLAN can support either VN2VF_Port FIP snooping or VN2VN_Port FIP snooping, but not both. Configure separate FCoE VLANs for VN2VF_Port FIP snooping traffic and for VN2VN_Port FIP snooping traffic. On FCoE VLANs that are configured as VN2VN_Port FIP snooping VLANs, VN_Port to VF_Port traffic is dropped.**

- ENode-facing ports must be set in **trunk** interface mode.
- ENode-facing ports must be untrusted ports.
- Network-facing (switch-facing) ports must be set in **trunk** interface mode.
- Network-facing ports must be FCoE trusted ports.
- Explicitly configure the beacon period. The beacon period is essentially a keepalive timer for virtual link maintenance.

When you enable FIP snooping, the system snoops VN_Port to VF_Port packets and enforces security only on VN_Port to VF_Port virtual links. When you enable VN2VN_Port FIP snooping, the system snoops VN_Port to VN_Port packets and enforces security only on VN_Port to VN_Port virtual links.

The transit switch applies VN2VN_Port FIP snooping filters at the ports associated with the FCoE VLANs on which you enable VN2VN FIP snooping.

This example describes how to configure VN2VN_Port FIP snooping when the FCoE hosts are indirectly connected across an aggregation layer FCoE transit switch:

Requirements

This example uses the following hardware and software components:

- Three Juniper Networks QFX5100 Switches running the ELS CLI and used as transit switches
- Junos OS Release 13.2 or later for the QFX Series
- Two FCoE hosts that have ENodes

Overview

This example shows you how to:

- Set the correct interface mode on the transit switch.
- Configure the interfaces to use the dedicated FCoE VLAN for VN2VN_Port FIP snooping.
- Configure the network-facing interfaces as FCoE trusted interfaces.
- Configure the dedicated FCoE VLAN for VN2VN_Port FIP snooping traffic.
- Enable VN2VN_Port FIP snooping on the FCoE VLAN and configure the beacon period.

Topology

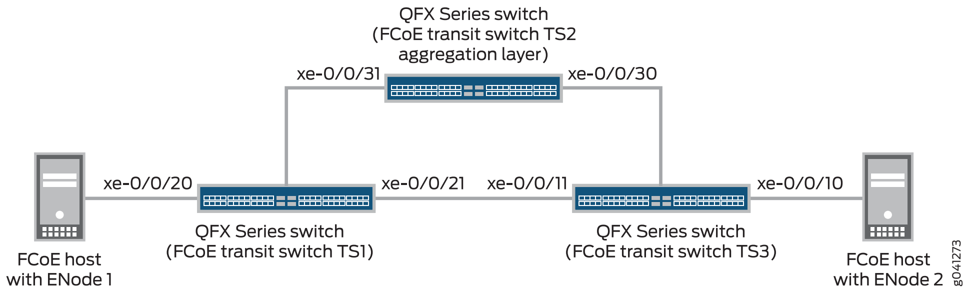
Table 387 on page 4992 shows the configuration components for this example.

Table 391: Components of the VN2VN_Port FIP Snooping Configuration Topology (FCoE Hosts Indirectly Connected Across an Aggregation Layer FCoE Transit Switch)

Component	Settings
Hardware	Three QFX5100 switches running the ELS CLI, two of which are FCoE transit switches that are directly attached to the FCoE hosts (transit switches TS1 and TS2) and one of which is an aggregation layer FCoE transit switch (TS3) Two FCoE hosts that have ENodes (ENode1 and ENode2, respectively)
Interfaces and interface mode	• Interface **xe-0/0/20**, interface mode **trunk**, connects directly from transit switch TS1 to the FCoE host with ENode1. • Interface **xe-0/0/21**, interface mode **trunk**, connects directly from transit switch TS1 to aggregation layer transit switch TS2. • Interface **xe-0/0/31**, interface mode **trunk**, connects directly from aggregation layer transit switch TS2 to transit switch TS1. • Interface **xe-0/0/30**, interface mode **trunk**, connects directly from aggregation layer transit switch TS2 to transit switch TS3. • Interface **xe-0/0/11**, interface mode **trunk**, connects directly from transit switch TS3 to aggregation layer transit switch TS2. • Interface **xe-0/0/10**, interface mode **trunk**, connects directly from transit switch TS3 to the FCoE host with ENode2.
Interface VLAN membership	The interfaces on all three switches use VLAN **vlan200**.
VN2VN_Port FIP snooping VLAN	VLAN name (all three switches)—**vlan200** VLAN ID—200
FIP snooping mode and beacon period	Set **examine-vn2vn** (VN2VN_Port FIP snooping) Beacon period—90000 ms

Figure 184 on page 4992 shows the network topology for this example.

Figure 188: VN2VN_Port FIP Snooping (FCoE Hosts Indirectly Connected) Topology



Configuration

To configure VN2VN_Port FIP snooping for VN_Ports that are indirectly connected across an aggregation layer FCoE transit switch, perform these tasks:

- Configuring VN2VN_Port FIP Snooping on FCoE Transit Switch TS1 on page 5040
- Configuring VN2VN_Port FIP Snooping on Aggregation Layer FCoE Transit Switch TS2 on page 5041
- Configuring VN2VN_Port FIP Snooping on FCoE Transit Switch TS3 on page 5041

CLI Quick Configuration

The configuration for each FCoE transit switch is shown separately.

To quickly configure VN2VN_Port FIP snooping for FCoE hosts that are indirectly connected across an aggregation layer FCoE transit switch, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level. To configure FCoE transit switch TS1:

FCoE Transit Switch TS1

```
set interfaces xe-0/0/20 unit 0 family ethernet-switching interface-mode trunk
set interfaces xe-0/0/21 unit 0 family ethernet-switching interface-mode trunk
set interfaces xe-0/0/20 unit 0 family ethernet-switching vlan members vlan200
set interfaces xe-0/0/21 unit 0 family ethernet-switching vlan members vlan200
set vlans vlan200 vlan-id 200
set vlans vlan200 forwarding-options fip-security interface xe-0/0/21 fcoe-trusted
set vlans vlan200 forwarding-options fip-security examine-vn2vn beacon-period 90000
```

To quickly configure VN2VN_Port FIP snooping for FCoE hosts that are indirectly connected across an aggregation layer FCoE transit switch, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level. To configure FCoE transit switch TS2:

FCoE Transit Switch TS2

```
set interfaces xe-0/0/30 unit 0 family ethernet-switching interface-mode trunk
set interfaces xe-0/0/31 unit 0 family ethernet-switching interface-mode trunk
set interfaces xe-0/0/30 unit 0 family ethernet-switching vlan members vlan200
set interfaces xe-0/0/31 unit 0 family ethernet-switching vlan members vlan200
set vlans vlan200 vlan-id 200
```

```
set vlans vlan200 forwarding-options fip-security interface xe-0/0/30 fcoe-trusted
set vlans vlan200 forwarding-options fip-security interface xe-0/0/31 fcoe-trusted
set vlans vlan200 forwarding-options fip-security examine-vn2vn beacon-period 90000
```

To quickly configure VN2VN_Port FIP snooping for FCoE hosts that are indirectly connected across an aggregation layer FCoE transit switch, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level. To configure FCoE transit switch TS3:

FCoE Transit Switch TS3

```
set interfaces xe-0/0/10 unit 0 family ethernet-switching interface-mode trunk
set interfaces xe-0/0/11 unit 0 family ethernet-switching interface-mode trunk
set interfaces xe-0/0/10 unit 0 family ethernet-switching vlan members vlan200
set interfaces xe-0/0/11 unit 0 family ethernet-switching vlan members vlan200
set vlans vlan200 vlan-id 200
set vlans vlan200 forwarding-options fip-security interface xe-0/0/11 fcoe-trusted
set vlans vlan200 forwarding-options fip-security examine-vn2vn beacon-period 90000
```

Configuring VN2VN_Port FIP Snooping on FCoE Transit Switch TS1

Step-by-Step Procedure

To configure interface mode, configure interface VLAN membership in the FCoE VLAN dedicated to VN2VN_Port traffic, set the network-facing port as FCoE trusted, configure the VLAN, set the beacon period, and enable VN2VN_Port FIP snooping:

1. Configure the modes of the interfaces that connect directly to the FCoE host with ENode1 (**xe-0/0/20**) and to aggregation layer FCoE transit switch TS2 (**xe-0/0/21**):

   ```
   user@switch# set interfaces xe-0/0/20 unit 0 family ethernet-switching interface-mode trunk
   set interfaces xe-0/0/21 unit 0 family ethernet-switching interface-mode trunk
   ```

2. Configure the interface VLAN membership so that the interfaces are members of the dedicated VN2VN_Port VLAN (**vlan200**):

   ```
   user@switch# set interfaces xe-0/0/20 unit 0 family ethernet-switching vlan members vlan200
   set interfaces xe-0/0/21 unit 0 family ethernet-switching vlan members vlan200
   ```

3. Configure the FCoE VLAN dedicated to VN2VN_Port FIP snooping:

   ```
   user@switch# set vlans vlan200 vlan-id 200
   ```

4. Configure the network-facing port (**xe-0/0/21**) as an FCoE trusted port:

   ```
   user@switch# set vlans vlan200 forwarding-options fip-security interface xe-0/0/21 fcoe-trusted
   ```

5. Enable VN2VN_Port FIP snooping on the VLAN and configure the beacon period:

   ```
   user@switch# set vlans vlan200 forwarding-options fip-security examine-vn2vn beacon-period 90000
   ```

Configuring VN2VN_Port FIP Snooping on Aggregation Layer FCoE Transit Switch TS2

Step-by-Step Procedure

To configure interface mode, configure interface VLAN membership in the FCoE VLAN dedicated to VN2VN_Port traffic, set the network-facing ports as FCoE trusted, configure the VLAN, set the beacon period, and enable VN2VN_Port FIP snooping:

1. Configure the mode of the interfaces that connect directly to FCoE transit switches TS1 (**xe-0/0/31**) and TS3 (**xe-0/0/30**). Both interfaces are network-facing and must be configured as trunk interfaces:

   `user@switch#` **set interfaces xe-0/0/30 unit 0 family ethernet-switching interface-mode trunk**
   set interfaces xe-0/0/31 unit 0 family ethernet-switching interface-mode trunk

2. Configure the interface VLAN membership so that the interfaces are members of the dedicated VN2VN_Port VLAN (**vlan200**):

   `user@switch#` **set interfaces xe-0/0/30 unit 0 family ethernet-switching vlan members vlan200**
   set interfaces xe-0/0/31 unit 0 family ethernet-switching vlan members vlan200

3. Configure the FCoE VLAN dedicated to VN2VN_Port FIP snooping:

   `user@switch#` **set vlans vlan200 vlan-id 200**

4. Configure the network-facing ports (**xe-0/0/30** and **xe-0/0/31**) as FCoE trusted ports:

   `user@switch#` **set vlans vlan200 forwarding-options fip-security interface xe-0/0/30 fcoe-trusted**
   `user@switch#` **set vlans vlan200 forwarding-options fip-security interface xe-0/0/31 fcoe-trusted**

5. Enable VN2VN_Port FIP snooping on the VLAN and configure the beacon period:

   `user@switch#` **set vlans vlan200 forwarding-options fip-security examine-vn2vn beacon-period 90000**

Configuring VN2VN_Port FIP Snooping on FCoE Transit Switch TS3

Step-by-Step Procedure

To configure interface mode, configure interface VLAN membership in the FCoE VLAN dedicated to VN2VN_Port traffic, set the network-facing port as FCoE trusted, configure the VLAN, set the beacon period, and enable VN2VN_Port FIP snooping:

1. Configure the mode of the interfaces that connect directly to the FCoE host with ENode2 (**xe-0/0/10**) and to aggregation layer FCoE transit switch TS2 (**xe-0/0/11**):

   `user@switch#` **set interfaces xe-0/0/10 unit 0 family ethernet-switching interface-mode trunk**
   set interfaces xe-0/0/11 unit 0 family ethernet-switching interface-mode trunk

2. Configure the interface VLAN membership so that the interfaces are members of the dedicated VN2VN_Port VLAN (**vlan200**):

   `user@switch#` **set interfaces xe-0/0/10 unit 0 family ethernet-switching vlan members vlan200**
   set interfaces xe-0/0/11 unit 0 family ethernet-switching vlan members vlan200

3. Configure the FCoE VLAN dedicated to VN2VN_Port FIP snooping:

   `user@switch#` **set vlans vlan200 vlan-id 200**

4. Configure the network-facing port (**xe-0/0/11**) as an FCoE trusted port:

   `user@switch#` **set vlans vlan200 forwarding-options fip-security interface xe-0/0/11 fcoe-trusted**

5. Enable VN2VN_Port FIP snooping on the VLAN and configure the beacon period:

   `user@switch#` **set vlans vlan200 forwarding-options fip-security examine-vn2vn beacon-period 90000**

Verification

To verify that the VN2VN_Port FIP snooping configuration has been created and is operating properly on all three switches, perform these tasks:

- Verifying That VN2VN_Port FIP Snooping Is Enabled on the FCoE VLAN (All Three Transit Switches) on page 5042

Verifying That VN2VN_Port FIP Snooping Is Enabled on the FCoE VLAN (All Three Transit Switches)

Purpose Verify that VN2VN_Port FIP snooping is enabled on the correct VLAN (**vlan200**), the beacon period is set to **90000** milliseconds, and that the correct interfaces (**xe-0/0/20** and **xe-0/0/21** on TS1, **xe-0/0/30** and **xe-0/0/31** aggregation layer TS2, and **xe-0/0/10** and **xe-0/0/11** on TS3) are members of the VLAN.

Action List the FIP snooping information on transit switch TS1 using the operational mode command **show fip snooping detail**

```
user@switch> show fip snooping detail
VLAN: vlan200,  Mode: VN2VN Snooping
  FC-MAP: 0e:fc:00
  Beacon_Period:  90000
  VN2VN Mode: Point-to-Point
    Enode Information
    Enode-MAC: 10:10:94:01:00:02,       Interface: xe-0/0/20
      Active VN_Ports : 1
      VN_Port Information
      VN-Port MAC: 0e:fc:00:01:0a:01
         Active Sessions    : 1
         Session Information
     Vlink far-end VN-Port-MAC: 0e:fc:00:01:0b:01
    Enode-MAC: 10:10:94:01:00:02,       Interface: xe-0/0/21
      Active VN_Ports : 1
      VN_Port Information
      VN-Port MAC: 0e:fc:00:01:0b:01
         Active Sessions    : 1
         Session Information
     Vlink far-end VN-Port-MAC: 0e:fc:00:01:0a:01
```

List the FIP snooping information on aggregation layer transit switch TS2 using the operational mode command **show fip snooping detail**

```
user@switch> show fip snooping detail
VLAN: vlan200,  Mode: VN2VN Snooping
  FC-MAP: 0e:fc:00
  Beacon_Period:  90000
  VN2VN Mode: Point-to-Point
    Enode Information
    Enode-MAC: 10:10:94:01:00:02,       Interface: xe-0/0/30
      Active VN_Ports : 1
      VN_Port Information
      VN-Port MAC: 0e:fc:00:01:0b:01
         Active Sessions    : 1
         Session Information
     Vlink far-end VN-Port-MAC: 0e:fc:00:01:0a:01
    Enode-MAC: 10:10:94:01:00:02,       Interface: xe-0/0/31
      Active VN_Ports : 1
      VN_Port Information
      VN-Port MAC: 0e:fc:00:01:0a:01
         Active Sessions    : 1
         Session Information
     Vlink far-end VN-Port-MAC: 0e:fc:00:01:0b:01
```

List the FIP snooping information on transit switch TS3 using the operational mode command **show fip snooping detail**

```
user@switch> show fip snooping detail
VLAN: vlan200,  Mode: VN2VN Snooping
  FC-MAP: 0e:fd:00
  Beacon_Period:  90000
  VN2VN Mode: Point-to-Point
    Enode Information
```

```
Enode-MAC: 10:10:94:01:00:02,       Interface: xe-0/0/10
  Active VN_Ports : 1
  VN_Port Information
  VN-Port MAC: 0e:fd:00:00:0b:01
     Active Sessions    : 1
     Session Information
 Vlink far-end VN-Port-MAC: 0e:fd:00:00:0a:01
Enode-MAC: 10:10:94:01:00:02,       Interface: xe-0/0/11
  Active VN_Ports : 1
  VN_Port Information
  VN-Port MAC: 0e:fd:00:00:0a:01
     Active Sessions    : 1
     Session Information
 Vlink far-end VN-Port-MAC: 0e:fd:00:00:0b:01
```

Meaning The **show fip snooping detail** command lists all of the transit switch information about VN2VN_Port FIP snooping and VN2VF_Port FIP snooping on each transit switch. The command shows that:

- The VLAN is **vlan200**.
- The mode is FIP snooping mode **VN2VN**, for VN2VN_Port FIP snooping. (If the Mode field shows **VN2VF**, then the FIP snooping mode is VN2VF_Port FIP snooping.)
- The beacon period is **90000**.
- The interfaces connected to the ENodes are **xe-0/0/20** and **xe-0/0/21** on transit switch TS1, **xe-0/0/30** and **xe-0/0/31** on aggregation layer transit switch TS2, and **xe-0/0/10** and **xe-0/0/11** on transit switch TS3. Because the transit switches are transparent passthrough switches, the network-facing trunk ports “see” the FCoE host ENodes at the far end of the VN2VN_Port virtual link.

In addition, this useful command shows information about the ENodes and the VN2VN_Port sessions.

Configuration Tasks (Fibre Channel, FCoE, FIP, and FIP Snooping)

Configuring an FCoE-FC Gateway Fibre Channel Fabric

Fibre Channel (FC) fabric configuration consists of creating a unique name and identifier for each FC fabric you want to create and configuring it as an FCoE-FC gateway.

You can create a maximum of 12 FC fabrics on a QFX3500 switch. After you create a fabric, you can create and assign interfaces to the fabric, configure FIP parameters for the fabric, and set proxy traceoptions.

To configure an FC fabric using the CLI, specify a unique name and identification number for the fabric:

1. Configure the fabric name and fabric ID:

   ```
   [edit]
   user@switch# set fc-fabrics fabric-name fabric-id fabric-id
   ```

   NOTE: Changing the fabric name or the fabric ID causes all logins to drop and forces the ENodes to log in again.

   For example, to configure an FC fabric with the name **fab_ulous** and the fabric ID **10** (the range of **fabric-id** values is 1 through 4095):

   ```
   [edit]
   user@switch# set fc-fabrics fab_ulous fabric-id 10
   ```
2. Configure the fabric as a gateway fabric:

```
[edit fc-fabrics fabric-name]
user@switch# set fabric-type proxy
```

For example, to configure the FC fabric with the name **fab_ulous** as a gateway fabric:

```
[edit fc-fabrics fab_ulous]
user@switch# set fabric-type proxy
```

Disabling the Fabric WWN Verification Check

When a QFX Series NP_Port sends a fabric login (FLOGI) request to a Fibre Channel (FC) switch, the FLOGI accept (FLOGI-ACC) reply from the FC switch contains the SAN fabric worldwide name (WWN). The QFX Series uses the SAN fabric WWN in the multicast discovery advertisement (MDA) that the QFX Series sends to the ENodes in the FCoE network.

However, some FC switches substitute their own WWN (often the FC switch's virtual WWN) for the SAN fabric WWN in the FLOGI-ACC message. In this case, different NP_Ports that log in to the same FC fabric might receive different fabric WWNs in the FLOGI-ACC messages if the NP_Ports are connected to different FC switches in the SAN fabric.

If the QFX Series receives different fabric WWNs on NP_Ports that are connected to the same SAN fabric, the QFX Series uses the first fabric WWN it receives in the MDA it sends to the ENodes. The QFX Series isolates the NP_Ports that receive a different fabric WWN from other FC switches in that SAN fabric. No ENode sessions are assigned to the isolated NP_Ports. FC traffic is assigned only to NP_Ports that receive a fabric WWN in the FLOGI-ACC message that matches the fabric WWN received by the first NP_Port to log in to the FC fabric. (If an NP_Port receives a fabric WWN that does not match the fabric WWN received by the first NP_Port to log in to the FC fabric, it does not carry traffic to the SAN fabric.)

To prevent ENodes from being isolated due to a mismatched fabric WWN, you can disable the gateway fabric WWN verification check. Disabling the fabric WWN verification check enables all NP_Ports connected to a SAN fabric are used to carry traffic between the gateway and the FC switch, regardless of the fabric WWN the NP_Port receives in the FLOGI-ACC message.

NOTE: **Disabling or enabling the fabric WWN verification check logs out all FCoE sessions.**

To disable the fabric WWN verification check:

- `[edit fc-fabrics` *`fabric-name`* `proxy]`
  `user@switch#` **set no-fabric-wwn-verify**

Configuring a Physical Fibre Channel Interface

When you configure the switch as an FCoE-FC gateway, you must configure either 6 or 12 of the physical interfaces as native FC interfaces. Native FC interfaces connect to the storage area network (SAN) FC switch.

You can configure ports xe-0/0/0 through xe-0/0/5 as fc-0/0/0 through fc-0/0/5, and ports xe-0/0/42 through xe-0/0/47 as fc-0/0/42 through fc-0/0/47 to create blocks of native FC interfaces. You cannot individually configure a single port as a native FC interface. Within these port blocks, you cannot mix FC interfaces with Ethernet interfaces. All of the ports in a block must be either native FC interfaces or Ethernet interfaces.

You can configure:

- Six native FC interfaces by configuring either ports xe-0/0/0 through xe-0/0/5 as fc-0/0/0 through fc-0/0/5, or ports xe-0/0/42 through xe-0/0/47 as fc-0/0/42 through fc-0/0/47.
- Twelve native FC interfaces by configuring ports xe-0/0/0 through xe-0/0/5 as fc-0/0/0 through fc-0/0/5 and ports xe-0/0/42 through xe-0/0/47 as fc-0/0/42 through fc-0/0/47.
- No native FC interfaces by leaving ports xe-0/0/0 through xe-0/0/5 and ports xe-0/0/42 through xe-0/0/47 in their default state as Ethernet interfaces.

- To configure physical FC interfaces using the CLI, specify the physical port block you want to configure on the switch as native FC interfaces:

  ```
  [edit chassis]
  user@switch# set fpc fpc pic pic fibre-channel port-range port-range-low port-range-high
  ```

  For example, to configure six native FC interfaces, you can configure ports 0 through 5 as physical FC interfaces:

  ```
  [edit chassis]
  user@switch# set fpc 0 pic 0 fibre-channel port-range 0 5
  ```

  To configure 12 native FC interfaces requires two separate statements:

  ```
  [edit chassis]
  user@switch# set fpc 0 pic 0 fibre-channel port-range 0 5
  user@switch# set fpc 0 pic 0 fibre-channel port-range 42 47
  ```

Configuring a Fibre Channel Interface

When a QFX3500 acts as an FCoE-FC gateway, native Fibre Channel (FC) traffic flows between the switch and the storage area network (SAN) FC switch. When you configure a port as an FC interface, it transports only FC traffic. It does not transport Ethernet traffic.

You can configure ports xe-0/0/0 through xe-0/0/5 as fc-0/0/0 through fc-0/0/5 and ports xe-0/0/42 through xe-0/0/47 as fc-0/0/42 through fc-0/0/47 to create blocks of native FC interfaces.

Each of these blocks of ports must be configured either as all Ethernet ports or as all native FC ports. Within each block of ports, you cannot mix FC and Ethernet interfaces. This means that you can configure 0, 6, or 12 ports as native FC ports. "Configuring a Physical Fibre Channel Interface" on page 5048 describes how to configure the port blocks as physical FC interfaces.

NOTE: **Do not configure ports that you want to use for native FC traffic as part of an Ethernet VLAN or as Ethernet ports.**

Configure a port as an FC interface when the port connects to the F_Port of an FC switch.

FC interface configuration includes:

- Explicitly specifying one or more ports as an FC family interface in NP_Port mode (mandatory).
- Configuring the FC interface options port speed and buffer-to-buffer credit state change number (BB_SC_N) (optional).
- Configuring the interface as a loopback interface (optional).

The buffer-to-buffer state change number feature prevents the loss of buffer-to-buffer credits between the two interfaces on either end of an FC link. The state change number determines the number of frames and receiver ready (R_RDY) primitives the interfaces exchange between the state change send (BB_SCs) and the state change receive (BB_SCr) primitives used to track these transactions.

Enabling BB_SC_N by configuring BB_SC_N on both of the FC link interfaces:

- Requests that $2^{BB\_SC\_N}$ number of frames be sent between two consecutive BB_SCs primitives, and
- Requests that $2^{BB\_SC\_N}$ number of R_RDY primitives be sent between two consecutive BB_SCr primitives.

When the number of R_RDY primitives received equals $2^{BB\_SC\_N}$, the R_RDY counter resets to zero. When the number of frames received equals $2^{BB\_SC\_N}$, the frame counter resets to zero. The interfaces calculate the number of buffer-to-buffer credits lost based on counter discrepancies and take corrective action to recover the lost credits.

If you enable BB_SC_N, the recommended BB_SC_N setting is eight. Setting the BB_SC_N number to zero (0) disables the feature. If either of the two connected FC interfaces is configured with zero as the BB_SC_N value, then both interfaces disable the feature. If the two connected FC interfaces have different nonzero BB_SC_N numbers configured, both interfaces use the higher number.

For the port to transport FC traffic, you must also set the physical port as an FC port using the **port-range** command.

To configure an FC interface using the CLI:

1. Specify the interface as family FC and set the port mode to NP_Port (setting the port mode to NP_Port is a mandatory configuration):

   ```
   [edit]
   user@switch# set interfaces interface-name unit unit family fibre-channel port-mode np-port
   ```

   For example, to configure the interface **fc-0/0/3** as an FC interface and set the port mode to **np-port**:

   ```
   [edit]
   user@switch# set interfaces fc-0/0/3 unit 0 family fibre-channel port-mode np-port
   ```
2. Configure the FC interface speed option:

   ```
   [edit]
   user@switch: set interfaces interface-name fibrechannel-options speed (auto-negotiation | 2g | 4g | 8g)
   ```

   For example, to set the FC interface speed option to **8g** for the interface **fc-0/0/3**:

   ```
   [edit]
   user@switch: set interfaces fc-0/0/3 fibrechannel-options speed 8g
   ```

   The default port mode is **auto-negotiation**, which sets the port speed to match the speed of the attached FC F_Port interface (2 Gbps, 4 Gbps, or 8 Gbps).

3. Configure the optional buffer-to-buffer credit state change number:

   ```
   [edit]
   user@switch: set interfaces interface-name fibrechannel-options bb-sc-n 0..15
   ```

   For example, to set the FC interface buffer-to-buffer credit state change number to **8** for the interface **fc-0/0/3**:

   ```
   [edit]
   user@switch: set interfaces fc-0/0/3 fibrechannel-options bb-sc-n 8
   ```

After you configure one or more FC interfaces, assign them and an FCoE VLAN to an FC fabric.

Configuring an FCoE VLAN Interface on an FCoE-FC Gateway

When you configure the switch as an FCoE-FC gateway, a Layer 3 FCoE VLAN interface transmits and receives Fibre Channel over Ethernet (FCoE) traffic between the gateway and FCoE-capable servers on the Ethernet network. Configuring a Layer 3 FCoE VLAN interface on the switch creates virtual fabric port (VF_Port) interfaces facing the FCoE server virtual node ports (VN_Ports).

The FCoE VLAN interface is the interface for the dedicated VLAN the FCoE servers use for FCoE traffic. Each FC fabric requires at least one dedicated FCoE VLAN and at least one Layer 3 FCoE VLAN interface to transport FCoE traffic. On QFabric systems, the FCoE VLAN interface, the FCoE VLAN, and the interfaces that are members of the FCoE VLAN must be on the same Node device.

NOTE: FCoE VLANs (any VLANs that carries FCoE traffic) support only Spanning Tree Protocol (STP) and link aggregation group (LAG) Layer 2 features.

NOTE: To configure an FCoE VLAN on a device that you are using as transit switch, you do not an FCoE VLAN interface. Instead, use the procedure described in "Configuring VLAN Interfaces for FCoE Traffic on an FCoE Transit Switch" on page 5066.

Before you configure an FCoE VLAN interface, create the FCoE VLAN and assign 10-Gigabit Ethernet interfaces configured in tagged-access port mode to the VLAN. These 10-Gigabit Ethernet interfaces are the physical interfaces that transport the FCoE traffic to and from the FCoE devices in the Ethernet network.

Each Ethernet interface that connects to FCoE devices must also include the native VLAN to transport FIP traffic, because FIP VLAN discovery and notification frames are exchanged as untagged packets. The FCoE VLAN must carry only FCoE traffic. A VLAN cannot transport a mix of FCoE and standard Ethernet traffic.

FCoE VLAN interface configuration includes:

- Configuring a VLAN to use as a dedicated FCoE VLAN.
- Configuring a native VLAN for FIP traffic.
- Configuring member interfaces for the FCoE VLAN.
- Configuring the FCoE VLAN as a Fibre Channel (family) VLAN and setting the port mode value to **f-port**. Explicitly configuring the FCoE VLAN interface in F_Port mode is

mandatory. The switch interface with which the FCoE server VN_Ports communicate must present a VF_Port to the servers.

- Configuring the FCoE VLAN interface as the Layer 3 interface for FCoE traffic.

To configure an FCoE VLAN interface:

1. Configure a dedicated FCoE VLAN:

   ```
   [edit vlans]
   user@switch# set vlan-name vlan-id vlan-id
   ```

   For example, to configure a VLAN named **fcoe_vlan** with a VLAN ID of **100** as the FCoE VLAN:

   ```
   [edit vlans]
   user@switch# set fcoe_vlan vlan-id 100
   ```

2. Configure a native VLAN for FIP traffic:

   ```
   [edit vlans]
   user@switch# set native vlan-id vlan-id
   ```

   For example, to configure the native VLAN with a VLAN ID of **1**:

   ```
   [edit vlans]
   user@switch# set native vlan-id 1
   ```

3. Configure member interfaces for the FCoE VLAN (use **ethernet-switching** as the family and **tagged-access** as the port mode):

   ```
   [edit interfaces]
   user@switch# set interface-name unit unit family family port-mode mode vlan members
   vlan-name
   ```

   For example, to configure the interface **xe-0/0/10** as a member of the FCoE VLAN **fcoe_vlan**:

   ```
   [edit interfaces]
   user@switch# set xe-0/0/10 unit 0 family ethernet-switching port-mode tagged-access vlan
   members fcoe_vlan
   ```

4. Configure the native VLAN on the FCoE VLAN member interfaces:

   ```
   [edit interfaces]
   user@switch# set interface-name unit unit family family native-vlan-id vlan-id
   ```

   For example, to configure the interface **xe-0/0/10** as a member of the native VLAN with the native VLAN ID **1**:

   ```
   [edit interfaces]
   user@switch# set xe-0/0/10 unit 0 family ethernet-switching native-vlan-id 1
   ```

5. Assign the Ethernet interfaces to the FCoE VLAN:

   ```
   [edit vlans]
   user@switch# set vlan-name interface interface-name
   ```

   For example, to assign the interface **xe-0/0/10.0** to the FCoE VLAN named **fcoe_vlan**:

   ```
   [edit vlans]
   user@switch# set fcoe_vlan interface xe-0/0/10.0
   ```

6. Define an interface as an FCoE VLAN interface in F_Port mode (to present a VF_Port to the FCoE servers):

```
[edit interfaces]
user@switch# set vlan unit unit family fibre-channel port-mode f-port
```

   For example, to configure VLAN unit **100** as an FCoE VLAN interface and set the port mode to **f-port**:

```
[edit interfaces]
user@switch# set vlan unit 100 family fibre-channel port-mode f-port
```

7. Define the Layer 3 FCoE VLAN interface:

```
[edit vlans]
user@switch# set vlan-name l3-interface vlan-interface-name
```

   For example, to configure VLAN interface unit **100** (the FCoE VLAN interface defined earlier in this example) as the Layer 3 FCoE VLAN interface for FCoE VLAN **fcoe_vlan**:

```
[edit vlans]
user@switch# set fcoe_vlan l3-interface vlan.100
```

Assigning Interfaces to a Fibre Channel Fabric

When you configure the switch as an FCoE-FC gateway, you assign one or more (up to 12) native Fibre Channel (FC) interfaces and at least one FCoE VLAN interface to each FC fabric. FC interfaces transport native FC traffic between the proxy gateway and the storage area network (SAN) FC switch. FCoE VLAN interfaces transport FCoE traffic between FCoE-capable servers and the gateway.

Each FC fabric needs both types of interfaces to transport traffic between FCoE servers on the Ethernet network and FC storage devices in the core FC network behind the FC switch. FCoE traffic between the FCoE servers and the gateway must travel in a dedicated FCoE VLAN. Native FC traffic passes between the gateway and the FC switch on the native FC interfaces.

You must configure the FC interfaces and the FCoE VLAN interfaces that you assign to a particular fabric on the same Juniper Networks QFX3500 Switch. Traffic between an FCoE device and the FC switch must ingress and egress the same gateway.

To assign core-facing native FC interfaces and a server-facing FCoE VLAN interface to an FC fabric, configure a fabric and then specify the interfaces:

1. Assign the native FC interfaces to the FC fabric:

```
[edit fc-fabrics fabric-name]
user@switch: set interface interface-name
user@switch: set interface interface-name
user@switch: set interface interface-name
...
```

2. Assign an FCoE VLAN interface to the FC fabric:

```
[edit fc-fabrics fabric-name]
user@switch: set interface vlan-name
```

For example, to assign the native FC interfaces **fc-0/0/0.0**, **fc-0/0/1.0**, and **fc-0/0/2.0** and the FCoE VLAN interface **vlan.100** to an FC fabric named **san_tana**:

```
user@switch: set fc-fabrics san_tana interface fc-0/0/0.0
user@switch: set fc-fabrics san_tana interface fc-0/0/1.0
user@switch: set fc-fabrics san_tana interface fc-0/0/2.0
user@switch: set fc-fabrics san_tana interface vlan.100
```

Deleting a Fibre Channel Interface

Before you delete a Fibre Channel (FC) interface, you must first delete the interface from the FC fabric configuration. This prevents configuration errors that would result if you deleted an FC interface from the **[edit interfaces]** hierarchy level but did not delete the interface from the FC fabric.

When you configure the switch as an FCoE-FC gateway, FC interfaces transmit and receive native FC traffic between the gateway and the FC switch. You can configure ports xe-0/0/0 through xe-0/0/5 as fc-0/0/0 through fc-0/0/5 and ports xe-0/0/42 through xe-0/0/47 as fc-0/0/42 through fc-0/0/47 to create one or two blocks of six native FC interfaces.

To delete an FC interface using the CLI:

1. Delete the FC interface from the FC fabric to which it belongs:

   ```
   [edit]
   user@switch# delete fc-fabrics fabric-name interface interface-name
   ```

   For example, to delete the FC interface **fc-0/0/3.0** from an FC fabric named **sanfab1**:

   ```
   [edit]
   user@switch# delete fc-fabrics sanfab1 interface fc-0/0/3.0
   ```
2. Delete the FC interface from the switch **[edit interfaces]** hierarchy:

   ```
   [edit]
   user@switch: delete interfaces interface-name
   ```

   For example, to delete the interface **fc-0/0/3.0** from the switch:

   ```
   [edit]
   user@switch: delete interfaces fc-0/0/3.0
   ```

The FC interface has been deleted from the FC fabric and from the switch.

Disabling Storm Control on FCoE Interfaces on an FCoE-FC Gateway

Storm control is not supported on the FCoE interfaces of an FCoE-FC gateway VLAN. Enabling storm control on an FCoE-FC gateway VLAN interface may cause FCoE packet loss. Storm control is disabled by default on all interfaces. However, if you enabled storm control globally on all switch interfaces or on any interfaces that are part of the FCoE VLAN interface, you must disable storm control on the Ethernet interfaces of the FCoE VLAN.

If storm control is enabled on only a few interfaces of the FCoE VLAN, you can disable storm control on individual interfaces by including the **delete ethernet-switching-options storm-control interface *interface-name*** statement in the configuration, where ***interface-name*** is the name of the interface on which you want to disable storm control.

If storm control is enabled globally on the switch when the switch is acting as an FCoE-FC gateway, it is often easiest to disable storm control on all interfaces, then enable storm control only on Ethernet interfaces that are not part of the FCoE VLAN interface.

If storm control is enabled globally, you can disable storm control in either of two ways:

- Disable storm control on all interfaces, then enable storm control on the interfaces you want to use storm control. (From the default configuration, you cannot disable storm control on individual interfaces because the default configuration enables storm control on **all** interfaces, not on individual interfaces.)

  For example, if you want interfaces xe-0/0/20, xe-0/0/21, and xe-0/0/22 to use storm control, disable storm control on all interfaces, then enable storm control on those three interfaces:

  1. Disable storm control on all interfaces:

     ```
     user@switch# delete ethernet-switching-options storm-control interface all
     ```

  2. Enable storm control on interfaces xe-0/0/20, xe-0/0/21, and xe-0/0/22:

     ```
     user@switch# set ethernet-switching-options storm-control interface xe-0/0/20
     user@switch# set ethernet-switching-options storm-control interface xe-0/0/21
     user@switch# set ethernet-switching-options storm-control interface xe-0/0/22
     ```

- Disable storm control for all unknown unicast traffic on all interfaces by including the following statement in your configuration:

  ```
  user@switch# set ethernet-switching-options storm-control interface all no-unknown-unicast
  ```

Defining the Proxy Load-Balancing Algorithm

When the QFX Series is configured as an FCoE-FC gateway, it balances the FCoE session load assigned to each NP_Port link between the gateway and the FC switch in the FC

SAN to avoid overloading or underutilizing each link. The QFX Series supports three types of load-balancing mechanisms:

- Simple load balancing—Load balancing is based on the weighted utilization (session load) of the NP_Ports connected to an FC fabric. The session load is the sum of the FLOGI and FDISC sessions on each link. Each new ENode fabric login (FLOGI) or VN_Port fabric discovery (FDISC) session is assigned to the least-loaded link, so an FDISC session initiated by the VN_Port on an ENode might not be assigned to the same link as the parent ENode's FLOGI session. Simple load balancing is the default algorithm. Simple load balancing is the default load-balancing algorithm. Rebalancing the link load disrupts only selected sessions to minimize the impact (the switch uses an algorithm to log out only the sessions that need to be moved to other links to balance the load when those sessions log in again).
- ENode-based load balancing—Load balancing is based on the weighted utilization (session load) of the NP_Ports connected to an FC fabric. The session load is the sum of the FLOGI and FDISC sessions on each link. However, when an ENode logs in to the fabric, the switch places all subsequent VN_Port FDISC sessions associated with that ENode on the same link as the ENode FLOGI session, regardless of the link load. New ENode FLOGIs are placed on the least-loaded link. The switch calculates the link load based on the combined total of FLOGIs and FDISCs on each NP_Port link. Rebalancing the link load disrupts all sessions (all sessions log out and then log in again).
- FLOGI-based load balancing—Load balancing is based on the weighted utilization (session load) of the NP_Ports connected to an FC fabric. The session load is the sum of the FLOGI sessions on each link. FDISC sessions are not counted. When an ENode logs in to the fabric, the switch places all subsequent VN_Port FDISC sessions associated with that ENode on the same link as the ENode FLOGI session, regardless of the link load. New ENode FLOGIs are placed on the least-loaded link. Rebalancing the link load disrupts only selected sessions to minimize the impact (the switch uses an algorithm to log out only the sessions that need to be moved to other links to balance the load when those sessions log in again).

To define the proxy load-balancing algorithm for a proxy fabric on the FCoE-FC gateway, set the algorithm as **enode-based**, **simple**, or **flogi-based**:

- `[edit fc-fabrics` *`fabric-name`* `proxy]`
  `user@switch#` **set load-balance-algorithm (enode-based | simple | flogi-based)**

  For example, to configure a gateway fabric named **san_fab1** to use **enode-based** load balancing:

  `user@switch#` **set fc-fabrics san_fab1 proxy load-balance-algorithm enode-based**

Simulating On-Demand Fibre Channel Link Load Rebalancing (Dry Run Test)

On-demand Fibre Channel (FC) link load rebalancing is a disruptive action that causes sessions to log out of the network, then log back in to be placed on FC links (NP_Ports) in a balanced manner. The number of sessions logged out to rebalance the links depends on the load-balancing algorithm used (simple, ENode-based, or FLOGI-based) and whether or not the load is already balanced. (If the link load is already balanced, the switch does not rebalance the loads when you request on-demand load rebalancing.)

You can use the **dry-run** option to list the sessions that might be affected (logged out to be redistributed among the active FC interface links) by on-demand load rebalancing *before* you actually rebalance the link load. (Because new sessions might log in between the time you perform a dry run and the time you request on-demand load rebalancing, the affected sessions may change. Therefore, the sooner that you perform an on-demand load rebalance after you perform a dry run, the more accurate the dry run results are likely to be.)

To request a link load rebalancing dry run:

```
user@switch> request fibre-channel proxy load-rebalance dry-run fabric fabric-name
```

For example, to request a dry run on an FC fabric named *fc_fabric_100* to display a list of sessions that might be disrupted if you request an actual link load rebalance:

```
user@switch> request fibre-channel proxy load-rebalance dry-run fabric fc_fabric_100
Fabric: fc_fabric_100, Fabric-id: 100
F-Port                        FCID     Port-WWN                NP-Port
vlan.100                      0x8a013a 02:01:00:64:00:00:00:2a fc-0/0/1.0
vlan.100                      0x8a013c 02:01:00:64:00:00:00:2b fc-0/0/1.0
vlan.100                      0x8a0146 02:01:00:64:00:00:00:2e fc-0/0/1.0
vlan.100                      0x8a014c 02:01:00:64:00:00:00:2f fc-0/0/1.0
```

Enabling and Disabling CoS OxID Hash Control

The originator exchange identifier (OxID) field is one of several fields that the switch can use in its hash function computation for FCoE traffic load balancing over multiple outgoing links. You can configure whether or not the switch uses the OxID in the hash computation.

Including the OxID field in the load-balancing hash computation allows different exchanges between a pair of Fibre Channel (FC) endpoints (such as an FCoE host and an FC storage device) to take different paths across the network, thus improving the aggregate network throughput.

However, if the paths between different sets of FC endpoints have common links, congestion on one set of FC endpoints can affect the other set of endpoints. Such congestion can happen if the FCoE traffic on the two sets of endpoints uses the same priority (IEEE 802.1p code point). It is common for networks to use priority 3 (IEEE 802.1p code point 011) for FCoE traffic. However, on the QFX3500, you can assign different IEEE priorities to different lossless FCoE flows as described in "Understanding CoS IEEE 802.1p Priorities for Lossless Traffic Flows" on page 5427 to further separate the traffic flows.

OxID hash control is enabled by default.

- To enable OxID hash control field for FCoE traffic load balancing:

```
[edit forwarding-options hash-key]
user@switch# set family fcoe oxid enable
```

- To disable OxID hash control field for FCoE traffic load balancing:

```
[edit forwarding-options hash-key]
user@switch# set family fcoe oxid disable
```

Configuring FIP on an FCoE-FC Gateway

Fibre Channel over Ethernet (FCoE) Initialization Protocol (FIP) establishes and maintains Fibre Channel (FC) virtual links between pairs of FCoE devices. A virtual link emulates the physical point-to-point link that FC requires between two FC devices.

FIP is enabled by default and uses the default FIP settings on all FCoE interfaces that are part of the gateway FC fabric. You can use the default FIP parameter values, or you can configure FIP parameters globally or on a per-interface basis. Configuring FIP on an individual interface overrides the global FIP configuration.

You can configure the following parameters globally for the fabric and per interface:

- FIP keepalive message transmission interval—This interval is the time period between sending FIP keepalive messages.

- Priority—If an FCoE node (ENode) connects to more than one switch, the priority value determines the switch to which the ENode connects. The switch with the lowest priority number has the highest priority.

You can only configure the following parameters globally on an FC fabric:

- FC-MAP—The 24-bit FCoE mapped address prefix that identifies the attached FC switch in the SAN fabric. The FC-MAP value is used in the fabric provided MAC address (FPMA) created for each ENode that logs in. This value must be the same for the FC switch and the QFX Series.

  NOTE: **Changing the FC-MAP value causes all logins to drop and forces the ENodes to log in again.**

- FCoE trusted—You can globally configure all of the Ethernet ports in a specified FC fabric to be FCoE trusted. You might want to configure interfaces as FCoE trusted if the interfaces are connected to a transit switch that is performing FIP snooping. For interfaces that are directly connected to FCoE hosts, FIP snooping should be enabled, and you should not configure the fabric as FCoE trusted.

  NOTE: **Do not configure interfaces with FIP snooping enabled as FCoE trusted.**

  Configuring interfaces as FCoE trusted reduces system overhead by eliminating the need for filters. The total number of sessions the system can support is 2500 sessions. Sessions are defined as the combined number of VN_Port to VF_Port sessions and VN_Port to VN_Port sessions. (Although VN2VF and VN2VN sessions run in different FCoE VLANs, the session limit is a system limit, not a per-VLAN limit.)

  NOTE: **A session is a FLOGI or FDISC login to the FC SAN fabric. Session does not refer to end-to-end storage sessions. There is no limit to the number of end-to-end storage sessions.**

  NOTE: **Changing the fabric ports from untrusted to trusted removes any existing FIP snooping filters from the ports. Changing the fabric ports from trusted to untrusted forces all of the FCoE sessions on those ports to log out so that when the ENodes and VN_Ports log in again, the switch can build the appropriate FIP snooping filters.**

- Maximum number of FCoE sessions per ENode—You can globally configure the maximum number of FCoE sessions (FLOGI plus FDISC) permitted from an ENode. The maximum number of sessions per ENode is 2000 sessions. The total number of sessions (VN2VF_Port sessions and VN2VN_Port sessions combined) cannot exceed the gateway fabric's maximum limit of 2500 sessions.

To configure FIP options globally using the CLI:

1. Specify the fabric on which you want to configure FIP:

```
[edit]
user@switch# set fc-fabrics fabric-name protocols fip
```

2. Configure the FIP keepalive message transmission interval in milliseconds to specify the amount of time between periodic FIP discovery advertisements for the fabric interfaces (the default is 8000 ms; the range is 250 through 90000 ms):

```
[edit fc-fabrics fabric-name protocols fip]
user@switch# set fka-adv-period milliseconds
```

3. Configure the priority value the switch advertises to ENodes in the range from 0 through 255; the default value is 128:

```
[edit fc-fabrics fabric-name protocols fip]
user@switch# set priority priority
```

4. Configure the FC-MAP value to match the FC-MAP value of the attached FC switch in the FC SAN fabric; the range of possible values is 0EFC00 through 0EFCFF, and the default value is 0EFC00:

```
[edit fc-fabrics fabric-name protocols fip]
user@switch# set fc-map fc-map
```

5. Configure the interfaces in the FC fabric as FCoE trusted (in this example, we assume that the interfaces have not been enabled for FIP snooping):

```
[edit fc-fabrics fabric-name protocols fip]
user@switch# set fcoe-trusted
```

6. Configure the maximum number of FCoE sessions for each ENode in the fabric:

```
[edit fc-fabrics fabric-name protocols fip]
user@switch# set max-sessions-per-enode
```

For example, to configure all FCoE interfaces associated with an FC fabric called **movieco_san** with a FIP keepalive interval value of **25000** milliseconds, a priority of **70**, an FC-MAP value of **0EFC01**, as FCoE trusted, and with a maximum number of FCoE sessions per ENode of 200 sessions:

```
[edit fc-fabrics movieco_san protocols fip]
user@switch# set fka-adv-period 25000
user@switch# set priority 70
user@switch# set fc-map 0EFC01
user@switch# set fcoe-trusted
user@switch# set max-sessions-per-enode 200
```

To override the global FC fabric FIP configuration for a specific FCoE interface using the CLI:

1. Specify the fabric and interface on which you want to configure FIP:

```
[edit fc-fabrics fabric-name protocols fip interface interface-name]
```

2. Configure the FIP keepalive message transmission interval and priority:

```
[edit fc-fabrics fabric-name protocols fip interface interface-name]
user@switch# set fka-adv-period milliseconds
user@switch# set priority priority
```

Setting the Maximum Number of FIP Login Sessions per ENode

When the switch acts as an FCoE-FC gateway, FCoE node (ENode) devices in the Ethernet network use the gateway to connect to the Fibre Channel (FC) storage area network (SAN). You can limit the maximum number of FIP login sessions permitted on each ENode. Limiting the number of login sessions can prevent login session rejections caused when the connected FC switch port configuration limits the number of FIP login sessions.

The maximum number of FIP sessions per ENode is 2000 sessions (FLOGI plus FDISC sessions). The limit you set applies to every ENode in the specified gateway fabric. Each ENode in the fabric can have up to the maximum number of sessions, but the total number of active sessions cannot exceed the session limits you apply to the fabric or the Node device.

There are also configurable FIP login session limits that you can apply to the gateway FC fabric, to the QFX3500 switch or QFabric system Node device, and to the interfaces in each FC fabric.

- To set a maximum number of FIP login sessions per ENode using the CLI:

  ```
  [edit fc-fabrics fc-fabric-name protocols fip]
  user@switch# set max-sessions-per-enode max-login-sessions
  ```

  For example, to configure the ENodes on an FC fabric named **sanfab1** with a maximum FIP login session limit of **250** sessions:

  ```
  [edit fc-fabrics sanfab1]
  user@switch# set protocols fip max-sessions-per-enode 250
  ```

Setting the Maximum Number of FIP Login Sessions per FC Interface

When the switch acts as an FCoE-FC gateway, NP_Ports are the native FC interfaces the gateway uses to connect to the FC switch. You can limit the maximum number of FIP login sessions permitted on an NP_Port interface. Limiting the number of login sessions on an interface can prevent login session rejections caused when the connected FC switch port configuration limits the number of FIP login sessions.

TIP: **A good practice is to configure a maximum number of login sessions on each NP_Port that is less than or equal to the maximum number of login sessions permitted on the connected FC switch port.**

The maximum number of FIP sessions is 2500 sessions. (This is the combined total of all VN2VF_Port and VN2VN_Port sessions on the system.)

There are also configurable FIP login session limits that you can apply to the gateway FC fabric, to the QFX3500 switch or QFabric system Node device, and to the ENodes in each FC fabric. To prevent unexpected FIP login rejections, the sum of the maximum FIP login sessions on all of the NP_Port interfaces that belong to an FC fabric should not exceed the maximum number of sessions the FC fabric supports or the device supports.

- To set a maximum number of FIP login sessions on an NP_Port using the CLI:

  ```
  [edit fc-fabrics fc-fabric-name interface interface-name]
  user@switch# set max-login-sessions max-login-sessions
  ```

  For example, to configure NP_Port interface **fc-0/0/5** with a maximum FIP login session limit of **500** sessions on an FC fabric named **sanfab1**:

  ```
  [edit fc-fabrics sanfab1]
  user@switch# set interface fc-0/0/5 max-login-sessions 500
  ```

- Understanding Interfaces on an FCoE-FC Gateway on page 4829

Setting the Maximum Number of FIP Login Sessions per FC Fabric

When the QFX Series acts an FCoE-FC gateway, you configure at least one local FC fabric on the gateway. A gateway FC fabric creates associations that connect FCoE devices on an Ethernet network to an FC switch on a Fibre Channel network. Each FC fabric on a gateway includes native FC interfaces (NP_Ports) that connect the gateway to the FC switch. When FCoE devices want to log in to the FC switch, the gateway sends the FIP login requests to the FC switch on the NP_Port links.

You can limit the maximum number of FIP login sessions permitted on a gateway FC fabric. If a QFX3500 switch or QFabric system Node device has more than one FC fabric, limiting the number of login sessions on an FC fabric can prevent one FC fabric from using all of the login sessions available on the device.

The maximum number of FIP sessions is 2500 sessions. (This is the combined total of all VN2VF_Port and VN2VN_Port sessions on the system.)

There are also configurable FIP login session limits that you can apply to the FC fabric NP_Port interfaces, to the QFX3500 switch or QFabric system Node device, and to the ENodes in each FC fabric. To prevent unexpected FIP login rejections:

- The sum of the maximum FIP login sessions on all of the NP_Port interfaces that belong to an FC fabric should not exceed the maximum number of sessions the FC fabric supports or the device supports.
- The sum of the maximum FIP login sessions on all of the FC fabrics on a device should not exceed the maximum number of sessions per device.

- To set a maximum number of FIP login sessions on an FC fabric using the CLI:

  ```
  [edit fc-fabrics fc-fabric-name]
  user@switch# set max-login-sessions max-login-sessions
  ```

  For example, to configure an FC fabric named **sanfab1** with a maximum FIP login session limit of **2000** sessions:

  ```
  [edit fc-fabrics sanfab1]
  user@switch# set fc-fabrics sanfab1 max-login-sessions 2000
  ```

Related Documentation

- Understanding Interfaces on an FCoE-FC Gateway on page 4829

Setting the Maximum Number of FIP Login Sessions per Node Device

When a QFX3500 switch or QFabric system Node device acts an FCoE-FC gateway, it connects FCoE devices on an Ethernet network to an FC switch in a Fibre Channel network. You can limit the maximum number of FIP login sessions for the FCoE devices on each Node device.

For QFX3500 switches, the maximum limit means that the sum of the FIP login sessions on all of the local FC fabrics on that QFX3500 switch cannot exceed the device maximum.

For the QFabric system, the limit applies to each Node device in the QFabric system. For example, if you configure a maximum FIP login session value of 2000 sessions, each Node device in the QFabric system can have a total of up to 2000 FIP login sessions running on its FC fabrics.

The maximum number of FIP sessions a device can support is 2500 sessions. (This is the combined total of all VN2VF_Port and VN2VN_Port sessions on the system.)

There are also configurable FIP login session limits that you can apply to the FC fabrics on the devices, to the NP_Port interfaces in each FC fabric, and to the ENodes in each FC fabric. To prevent unexpected FIP login rejections:

- The sum of the maximum FIP login sessions for all of the FC fabrics on a device should not exceed the maximum number of sessions per device.
- The sum of the maximum FIP login sessions on all of the NP_Port interfaces that belong to an FC fabric should not exceed the maximum number of sessions the FC fabric supports or the device supports.

- To set a maximum number of FIP login sessions for Node devices using the CLI:

  ```
  [edit fc-options]
  user@switch# set max-login-sessions-per-node max-login-sessions-per-node
  ```

  For example, to configure a maximum FIP login limit of **2000** sessions on a QFX3500 switch or on all Node devices in a QFabric system:

  ```
  [edit fc-options]
  user@switch# set max-login-sessions-per-node 2000
  ```

Configuring VLAN Interfaces for FCoE Traffic on an FCoE Transit Switch

When you configure a QFX Series as a Fibre Channel over Ethernet (FCoE) transit switch, you must configure a VLAN that transports only FCoE traffic. FCoE traffic requires a dedicated VLAN and cannot share a VLAN with any other type of traffic. Because FCoE traffic is tagged traffic, the port (or interface) mode cannot be access mode, it must be either tagged-access port-mode (for switches that run the original CLI, such as QFX3500 and QFX3600 standalone switches and QFabric system Node devices) or trunk interface-mode (for switches that run the Enhanced Layer 2 Software (ELS) CLI, such as the QFX5100 switch).

However, each interface that belongs to an FCoE VLAN must not only transport the tagged FCoE traffic, it must also transport the untagged FCoE Initialization Protocol (FIP) traffic. FIP communicates with the storage area network (SAN) Fibre Channel (FC) switch to set up the FCoE session for the FCoE client.

To transport untagged traffic on a tagged-access or trunk mode interface, the interface must have a native VLAN configured on it. Therefore, each interface that belongs to an FCoE VLAN must also have a native VLAN on it.

There are slight differences in the way you configure a native VLAN on an interface, depending on whether the switch uses the ELS CLI or the original CLI. This topic describes both methods.

NOTE: FCoE VLANs (any VLANs that carries FCoE traffic) support only Spanning Tree Protocol (STP) and link aggregation group (LAG) Layer 2 features.

NOTE: To configure an FCoE VLAN on a QFX3500 switch or a QFabric system Node device that you are using as an FCoE-FC gateway, you must also configure an FCoE VLAN interface as described in “Configuring an FCoE VLAN Interface on an FCoE-FC Gateway” on page 5051. (QFX3600, QFX5100, and Virtual Chassis switches do not support FCoE-FC gateway configuration.)

FCoE VLAN configuration includes:

- Configuring a VLAN to use as a dedicated FCoE VLAN
- Configuring the interface members of the FCoE VLAN.
- Configuring a native VLAN for FIP traffic.

This topic includes two configuration procedures, one for switches that run the original CLI, and one for switches that run the ELS CLI.

Original CLI Configuration

To configure an FCoE VLAN on a non-ELS switch (QFX3500, QFX3600, QFabric system Node devices):

1. Configure a dedicated FCoE VLAN:

   ```
   [edit vlans]
   user@switch# set vlan-name vlan-id vlan-id
   ```

   For example, to configure a VLAN named **fcoe_vlan** with a VLAN ID of **100** as the FCoE VLAN:

   ```
   [edit vlans]
   user@switch# set fcoe_vlan vlan-id 100
   ```

2. Configure the FCoE VLAN on the interface (use **ethernet-switching** as the family and **tagged-access** as the port mode):

   ```
   [edit interfaces]
   user@switch# set interface-name unit unit family family port-mode mode vlan members
   vlan-name
   ```

   For example, to configure the interface **xe-0/0/10** as a member of the FCoE VLAN **fcoe_vlan**:

   ```
   [edit interfaces]
   user@switch# set xe-0/0/10 unit 0 family ethernet-switching port-mode tagged-access vlan
   members fcoe_vlan
   ```

3. Configure the Ethernet interface membership in the FCoE VLAN:

   ```
   [edit vlans]
   user@switch# set vlan-name interface interface-name
   ```

   For example, to assign the interface **xe-0/0/10.0** to the FCoE VLAN named **fcoe_vlan**:

   ```
   [edit vlans]
   user@switch# set fcoe_vlan interface xe-0/0/10.0
   ```

4. Configure a native VLAN for the untagged FIP traffic:

   ```
   [edit vlans]
   user@switch# set native vlan-id vlan-id
   ```

   For example, to configure the native VLAN with a VLAN ID of **1**:

   ```
   [edit vlans]
   user@switch# set native vlan-id 1
   ```

5. Assign member interfaces to the native VLAN:

   ```
   [edit interfaces]
   user@switch# set interface-name unit unit family family native-vlan-id vlan-id
   ```

   For example, to configure the interface **xe-0/0/10** as a member of the native VLAN with the native VLAN ID **1**:

   ```
   [edit interfaces]
   user@switch# set xe-0/0/10 unit 0 family ethernet-switching native-vlan-id 1
   ```

ELS CLI Configuration

To configure an FCoE VLAN on a QFX5100 switch running ELS:

1. Configure a dedicated FCoE VLAN:

   ```
   [edit vlans]
   user@switch# set vlan-name vlan-id vlan-id
   ```

   For example, to configure a VLAN named **fcoe_vlan** with a VLAN ID of **100** as the FCoE VLAN:

   ```
   [edit vlans]
   user@switch# set fcoe_vlan vlan-id 100
   ```

2. Configure the FCoE VLAN on the interface (use **ethernet-switching** as the family and **trunk** as the interface mode):

   ```
   [edit interfaces]
   user@switch# set interface-name unit unit family family interface-mode mode vlan members vlan-name
   ```

   For example, to configure the interface **xe-0/0/10** as a member of the FCoE VLAN **fcoe_vlan**:

   ```
   [edit interfaces]
   user@switch# set xe-0/0/10 unit 0 family ethernet-switching interface-mode trunk vlan members fcoe_vlan
   ```

3. Configure the Ethernet interface membership in the FCoE VLAN:

   ```
   [edit vlans]
   user@switch# set vlan-name interface interface-name
   ```

   For example, to assign the interface **xe-0/0/10.0** to the FCoE VLAN named **fcoe_vlan**:

   ```
   [edit vlans]
   user@switch# set fcoe_vlan interface xe-0/0/10.0
   ```

4. Configure a native VLAN on the physical Ethernet interface for the untagged FIP traffic:

   ```
   [edit interfaces]
   user@switch# set interface-name native-vlan-id vlan-id
   ```

   For example, to configure the native VLAN on interface **xe-0/0/10** with a VLAN ID of **1**:

   ```
   [edit interfaces]
   user@switch# set xe-0/0/10 native-vlan-id 1
   ```

5. Configure the Ethernet interface as a member of the native VLAN:

   ```
   [edit interfaces]
   user@switch# set interface-name unit unit family family vlan members native-vlan-id
   ```

   NOTE: The *native-vlan-id* number must be the same as the native VLAN ID number that you configured on the physical Ethernet interface (see step 4).

   For example, to configure the interface **xe-0/0/10** as a member of the native VLAN with the native VLAN ID **1**:

   ```
   [edit interfaces]
   ```

`user@switch#` **set xe-0/0/10 unit 0 family ethernet-switching vlan members 1**

Configuring VN2VF_Port FIP Snooping and FCoE Trusted Interfaces on an FCoE Transit Switch

VN_Port to VF_Port (VN2VF_Port) Fibre Channel over Ethernet (FCoE) Initialization Protocol (FIP) snooping uses information gathered during FIP discovery and login to create firewall filters that provide security against unauthorized access to the FC switch or FCoE forwarder (FCF) through the EX4500 or QFX Series when the switch is acting as an FCoE transit switch. The firewall filters allow only FCoE devices that succeed at logging in to the FC fabric to access the FCF through the transit switch. VN2VF_Port FIP snooping provides security for the point-to-point virtual links that connect host FCoE Nodes (ENodes) and FCFs in the FCoE VLAN by denying access to any device that does not successfully log in to the FCF.

VN2VF_Port FIP snooping is disabled by default. You enable VN2VF_Port FIP snooping on a per-VLAN basis for VLANs that carry FCoE traffic. Ensure that a VLAN that carries FCoE traffic carries only FCoE traffic, because enabling VN2VF_Port FIP snooping denies access for all other Ethernet traffic.

NOTE: All of the transit switch ports are untrusted by default. If an ENode on an FCoE device logs in to an FCF before you enable VN2VF_Port FIP snooping on the VLAN and you then enable VN2VF_Port FIP snooping, the transit switch denies traffic from the ENode because the transit switch has not snooped (learned) the ENode state. The following process automatically logs the ENode back in to the FCF to reestablish the connection:

1. VN2VF_Port FIP snooping is enabled on an FCoE VLAN on the switch.
2. The switch denies existing connections between servers and the FCF on the FCoE VLAN by filtering the FCoE traffic and FIP traffic, so no keepalive messages from the ENodes reach the FCF.
3. The FCF port timer for each ENode and for each VN_Port on each ENode expires.
4. The FCF sends each ENode whose port timer has expired a Clear Virtual LInks (CVL) message.
5. The CVL message causes the ENode to log in again.

Because the FCF is a trusted source, you configure interfaces that connect to the FCF as FCoE trusted interfaces. FCoE trusted interfaces do not filter traffic (FIP snooping filtering should occur only at the FCoE access edge), but VN2VF_Port FIP snooping continues to run on trusted interfaces so that the switch learns the FCF state.

NOTE: Do not configure ENode-facing interfaces both with FIP snooping enabled and as trusted interfaces. FCoE VLANs with interfaces that are directly connected to FCoE hosts should be configured with FIP snooping enabled and the interfaces should *not* be trusted interfaces. Ethernet interfaces that are connected to an FCF should be configured as trusted interfaces and should not have FIP snooping enabled. Interfaces that are connected to a transit switch that is performing FIP snooping can be configured as trusted interfaces if the FCoE VLAN is not enabled for FIP snooping.

Optionally, you can specify an FC-MAP value for each FCoE VLAN. On a given FCoE VLAN, the switch learns only FCFs that have a matching FC-MAP value. The default FC-MAP value is 0EFC00h for all FC devices. (Enter hexadecimal values for FC-MAP preceded by the hexadecimal indicator “0x”—for example, 0x0EFC00.) If you change the FC-MAP value of an FCF, change the FC-MAP value for the FCoE VLAN it belongs to on the switch and on the servers you want to communicate with the FCF. An FCoE VLAN can have one and only one FC-MAP value.

There are differences in the way you configure FIP snooping and FCoE trusted interfaces on a switch that depend on whether the switch uses the original QFX/QFabric CLI (for example, a standalone QFX3500 or QFX3600 switch or a QFabric system Node device) or the Enhanced Layer 2 Software (ELS) CLI (for example, a standalone QFX5100 switch). This topic includes two configuration procedures, one for switches that run the original CLI, and one for switches that run the ELS CLI.

Original CLI Configuration

To enable VN2VF_Port FIP snooping:

- To enable VN2VF_Port FIP snooping on a single VLAN and specify the optional FC-MAP value:

  ```
  [edit ethernet-switching-options secure-access-port]
  user@switch# set vlan vlan-name examine-fip fc-map fc-map-value
  ```

  For example, to enable VN2VF_Port FIP snooping on a VLAN named **san1_vlan** and change the FC-MAP value to **0x0EFC03**:

  ```
  [edit ethernet-switching-options secure-access-port]
  user@switch# set vlan san1_vlan examine-fip fc-map 0x0EFC03
  ```

  NOTE: Changing the FC-MAP value causes all logins to drop and forces ENodes to log in again.

- To enable VN2VF_Port FIP snooping on all VLANs and use the default FC-MAP value:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan all examine-fip
```

- To configure an interface as an FCoE trusted interface:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface interface-name fcoe-trusted
```

For example, to configure interface **xe-0/0/30** as an FCoE trusted interface:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface xe-0/0/30 fcoe-trusted
```

ELS CLI Configuration

To enable VN2VF_Port FIP snooping:

- To enable VN2VF_Port FIP snooping on a VLAN and specify the optional FC-MAP value:

```
[edit]
user@switch# set vlans vlan-name forwarding-options fip-security fc-map fc-map-value
examine-vn2vf
```

For example, to enable VN2VF_Port FIP snooping on a VLAN named **san1_vlan** and change the FC-MAP value to **0x0EFC03**:

```
[edit]
user@switch# set vlans san1_vlan forwarding-options fip-security fc-map 0x0EFC03
examine-vn2vf
```

NOTE: Changing the FC-MAP value causes all logins to drop and forces ENodes to log in again.

- To configure an interface as an FCoE trusted interface:

```
[edit]
user@switch# set vlans vlan-name forwarding-options fip-security interface interface-name
fcoe-trusted
```

For example, to configure interface **xe-0/0/30** on VLAN named **san1_vlan** as an FCoE trusted interface:

```
[edit]
user@switch# set vlans san1_vlan forwarding-options fip-security interface xe-0/0/30
fcoe-trusted
```

Disabling VN2VF_Port FIP Snooping on an FCoE-FC Gateway Switch Interface

When the switch acts an FCoE-FC gateway, the FCoE-network-facing Ethernet interfaces in the FCoE VLAN are automatically enabled for VN_Port to VF_Port (VN2VF_Port) FIP snooping. You can disable VN2VF_Port FIP snooping on an individual Ethernet interface or you can disable VN2VF_Port FIP snooping globally for all Ethernet interfaces in a gateway Fibre Channel (FC) fabric.

Disable VN2VF_Port FIP snooping on an Ethernet interface by configuring it as an FCoE trusted interface. Disable VN2VF_Port FIP snooping on all Ethernet interfaces in an FC fabric by configuring the FC fabric as FCoE trusted.

Do not disable VN2VF_Port FIP snooping on an interface unless you are certain that the interface is connected to a trusted device. Do not disable VN2VF_Port FIP snooping on an FC fabric unless all of the FCoE-network-facing interfaces in the fabric are either connected to a transit switch that is performing VN2VF_Port FIP snooping on the FCoE devices as they log in to the FC network or all of the interfaces are connected to trusted devices.

VN2VF_Port FIP snooping installs firewall filters that block FIP and FCoE frames from sources that have not logged in to the switch and prevents unauthorized access to the network. Disabling VN2VF_Port FIP snooping disables these firewall filters and permits access to all FIP and FCoE frames transported on that interface.

- To disable VN2VF_Port FIP snooping on an FCoE-device-facing Ethernet interface in an FCoE VLAN, configure that interface as a trusted interface:

  ```
  [edit ethernet-switching-options secure-access-port]
  user@switch# set interface interface-name fcoe-trusted
  ```

  For example, to configure interface **xe-0/0/7** as a trusted FC interface:

  ```
  [edit ethernet-switching-options secure-access-port]
  user@switch# set interface xe-0/0/7 fcoe-trusted
  ```

- To disable VN2VF_Port FIP snooping on all FCoE-device-facing interfaces in a gateway FC fabric, configure that fabric as a trusted fabric:

  ```
  [edit]
  user@switch# set fc-fabrics fabric-name protocols fip fcoe-trusted
  ```

  For example, to configure an FC fabric named *santastic* as an FCoE trusted fabric:

  ```
  [edit]
  user@switch# set fc-fabrics santastic protocols fip fcoe-trusted
  ```

Enabling VN2VN_Port FIP Snooping and Configuring the Beacon Period on an FCoE Transit Switch

VN_Port to VN_Port (VN2VN_Port) FIP snooping on an FCoE transit switch provides security to help prevent unauthorized access and data transmission on a bridge that connects ENodes in the Ethernet network. VN2VN_Port FIP snooping provides security for virtual links by creating filters based on information gathered (snooped) about FCoE devices during FIP transactions.

VN2VN_Port FIP snooping is conceptually similar to VN2VF_Port FIP snooping between VN_Ports and VF_Ports, but VN2VN_Port FIP snooping does not require traffic between VN_Ports to traverse the Fibre Channel (FC) switch or FCoE forwarder (FCF). Instead, a VN_Port communicates transparently through the transit switch on a virtual link that emulates a direct connection to the VN_Port at the other end of the virtual link.

VN2VN_Port FIP snooping is disabled by default. You enable VN2VN_Port FIP snooping on a per-VLAN basis on VLANs that carry VN2VN_Port FCoE traffic. Ensure that the VLAN carries only FCoE traffic between VN_Ports, because enabling VN2VN_Port FIP snooping denies access for all other traffic, including VN2VF_Port FIP snooping traffic.

All ENodes that you want to communicate using VN2VN_Port FIP snooping must use an FCoE VLAN dedicated to VN2VN_Port traffic. You cannot mix VN2VN_Port FIP snooping traffic with VN2VF_Port FIP snooping traffic in the same FCoE VLAN.

NOTE: **An FCoE VLAN can support either VN2VF_Port FIP snooping or VN2VN_Port FIP snooping, but not both. Configure separate FCoE VLANs for VN2VF_Port FIP snooping traffic and for VN2VN_Port FIP snooping traffic. On FCoE VLANs that are configured as VN2VN_Port FIP snooping VLANs, VN2VF_Port traffic is dropped.**

The *beacon period* is conceptually similar to the FIP keepalive period (timer) for VN2VF_Port FIP snooping virtual link maintenance. The beacon period performs virtual link maintenance for VN2VN_Port FIP snooping. It is the time interval between messages that verify the connection is still valid and the device at the other end of the virtual link is still reachable. You set the beacon period value for each FCoE VLAN that you configure to do VN2VN_Port FIP snooping.

NOTE: **In addition to enabling VN2VN_Port FIP snooping and configuring the beacon period, you must also configure a dedicated FCoE VLAN for the VN2VN_Port traffic, and set the FCoE transit switch ports in the proper port mode and trusted or untrusted state (interfaces are untrusted by default). See the VN2VN_Port FIP snooping configuration example topics for complete configurations of several common network topologies.**

There are differences in the way you configure a native VLAN on an interface that depend on whether the switch uses the original QFX/QFabric CLI (for example, a standalone QFX3500 or QFX3600 switch or a QFabric system Node device) or the Enhanced Layer

2 Software (ELS) CLI (for example, a standalone QFX5100 switch). This topic includes two configuration procedures, one for switches that run the original CLI, and one for switches that run the ELS CLI.

Original CLI Configuration

To enable VN2VN_Port FIP snooping and set the beacon period on an FCoE VLAN that is dedicated to VN2VN_Port traffic:

- `[edit ethernet-switching-options secure-access-port]`
  `user@switch#` **set vlan *vlan-name* examine-fip examine-vn2vn beacon-period *milliseconds***

  For example, to enable VN2VN_Port FIP snooping on a VLAN named **vlan200** and set the beacon period to **90000** milliseconds:

  `[edit ethernet-switching-options secure-access-port]`
  `user@switch#` **set vlan vlan200 examine-fip examine-vn2vn beacon-period 90000**

ELS CLI Configuration

To enable VN2VN_Port FIP snooping and set the beacon period on an FCoE VLAN that is dedicated to VN2VN_Port traffic:

- `[edit]`
  `user@switch#` **set vlans *vlan-name* forwarding-options fip-security examine-vn2vn beacon-period *milliseconds***

  For example, to enable VN2VN_Port FIP snooping on a VLAN named **vlan200** and set the beacon period to **90000** milliseconds:

  `[edit]`
  `user@switch#` **set vlans vlan200 forwarding-options fip-security examine-vn2vn beacon-period 90000**

Configuration Tasks (DCBX)

- Configuring an Application Map for DCBX Application Protocol TLV Exchange on page 5081
- Applying an Application Map to an Interface for DCBX Application Protocol TLV Exchange on page 5082

Configuring the DCBX Mode

You can configure the DCBX mode that an interface uses to communicate with the connected peer. QFX Systems support three DCBX modes:

- Autonegotiation—The interface negotiates with the connected peer to determine the DCBX mode. This is the default DCBX mode.
- IEEE DCBX—The interface uses IEEE DCBX type, length, and value (TLV) to exchange DCBX information with the connected peer. QFX3500 Node devices come up with IEEE DCBX enabled by default and then autonegotiate with the connected peer to determine the final DCBX mode.
- DCBX Version 1.01—The interface uses Converged Enhanced Ethernet (CEE) DCBX version 1.01 TLVs to exchange DCBX information with the connected peer. QFabric Node devices come up with DCBX version 1.01 enabled by default and then autonegotiate with the connected peer to determine the final DCBX mode.

NOTE: QFX Systems do not support pre-CEE (pre-DCB) versions of DCBX such as DCBX version 1.00. If a QFX Series interface receives an LLDP frame with pre-CEE DCBX TLVs, the system drops the frame.

Configure the DCBX mode by specifying the mode for one interface or for all interfaces.

- To configure the DCBX mode, specify the interface and the mode:

  ```
  [edit protocols dcbx]
  user@switch# set interface interface-name mode (auto-negotiate | ieee-dcbx | dcbx-version-1.01)
  ```

  For example, to configure DCBX version 1.01 on interface **xe-0/0/21**:

  ```
  user@switch# set protocols dcbx interface xe-0/0/21 mode dcbx-version-1.01
  ```

  To configure IEEE DCBX on all interfaces:

  ```
  user@switch# set protocols dcbx interface all mode ieee-dcbx
  ```

Configuring DCBX Autonegotiation

Data Center Bridging Capability Exchange protocol (DCBX) discovers the data center bridging (DCB) capabilities of peers by exchanging feature configuration information. DCBX also detects feature misconfiguration and mismatches, and can configure DCB on peers. DCBX is an extension of the Link Layer Discovery Protocol (LLDP), and LLDP must remain enabled on every interface for which you want to use DCBX. If you attempt to enable DCBX on an interface on which LLDP is disabled, the configuration commit operation fails.

NOTE: LLDP and DCBX are enabled by default on all interfaces.

The switch supports DCBX autonegotiation for:

- Priority-based flow control (PFC) configuration
- Layer 2 and Layer 4 applications such as Fibre Channel over Ethernet (FCoE) and Internet Small Computer System Interface (iSCSI)
- Enhanced transmission selection (ETS) advertisement

DCBX autonegotiation is configured on a per-interface basis for each supported feature or application. The PFC and application DCBX exchanges use autonegotiation by default. The default autonegotiation behavior is:

- DCBX is enabled on the interface if the connected peer device also supports DCBX.
- DCBX is disabled on the interface if the connected peer device does not support DCBX.

You can override the default behavior for each feature by turning off autonegotiation to force an interface to enable or disable the feature.

Autonegotiation of ETS means that when ETS is enabled on an interface (priority groups are configured), the interface advertises its ETS configuration to the peer device. In this case, priorities (forwarding classes) that are not part of a priority group (forwarding class set) receive no bandwidth and are advertised in an automatically generated default forwarding class. If ETS is not enabled on an interface (no priority groups are configured), all of the priorities are advertised in one automatically generated default priority group that receives 100 percent of the port bandwidth.

Disabling ETS autonegotiation prevents the interface from sending the Recommendation TLV or the Configuration TLV to the connected peer.

On interfaces that use IEEE DCBX mode to exchange DCBX parameters, you can disable autonegotiation of the enhanced transmission selection (ETS) Recommendation TLV to the peer if you want an asymmetric ETS configuration between the peers. DCBX still exchanges the ETS Configuration TLV if you disable the ETS Recommendation TLV.

Autonegotiation of PFC means that when PFC is enabled on an interface, if the peer device connected to the interface supports PFC and is provisioned compatibly with the switch, DCBX sets the PFC operational state to enabled. If the peer device connected to the interface does not support PFC or is not provisioned compatibly with the switch, DCBX sets the operational state to disabled.

In addition, if the peer advertises that it is “willing” to learn its PFC configuration from the switch, DCBX pushes the switch’s PFC configuration to the peer and does not check the peer’s administrative state. The switch does not learn PFC configuration from peers (the switch does not advertise its state as “willing”).

Disabling PFC autonegotiation prevents the interface from exchanging PFC configuration information with the peer. It forces the interface to enable PFC if PFC is configured on the interface or to disable PFC if PFC is not configured on the interface. If you disable PFC autonegotiation, the assumption is that the peer is also configured manually.

Autonegotiation of applications depends on whether or not you apply an application map to an interface. If you apply an application map to an interface, the interface autonegotiates DCBX for each application in the application map. PFC must be enabled on the FCoE priority (the FCoE IEEE 802.1p code point) for the interface to advertise the FCoE application. The interface only advertises applications that are included in the application map.

For example, if you apply an application map to an interface and the application map does not include the FCoE application, then that interface does not perform DCBX advertisement of FCoE.

If you do not apply an application map to an interface, DCBX does not advertise applications on that interface, with the exception of FCoE, which is handled differently than other applications.

NOTE: **If you do not apply an application map to an interface, the interface performs autonegotiation of FCoE if the interface carries traffic in the FCoE forwarding class and also has PFC enabled on the FCoE priority. On such interfaces, if DCBX detects that the peer device connected to the interface supports FCoE, the switch advertises its FCoE capability and IEEE 802.1p code point on that interface. If DCBX detects that the peer device connected to the interface does not support FCoE, DCBX marks that interface as “FCoE down” and disables FCoE on the interface.**

When DCBX marks an interface as “FCoE down,” the behavior of the switch depends on how you use it in the network:

- When the switch acts as an FCoE-FC gateway, it does not send or receive FCoE Initialization Protocol (FIP) packets.
- When the switch acts as an FCoE transit switch, the interface drops all of the FIP packets it receives. In addition, FIP packets received from an FCoE forwarder (FCF) are not forwarded to interfaces marked as “FCoE down.”

Disabling autonegotiation prevents the interface from exchanging application information with the peer. In this case, the assumption is that the peer is also configured manually.

To disable DCBX autonegotiation of PFC, applications (including FCoE), and ETS using the CLI:

1. Turn off autonegotiation for PFC.

   ```
   [edit]
   user@switch# set protocols dcbx interface interface-name priority-flow-control no-auto-negotiation
   ```

2. Turn off autonegotiation for applications.

   ```
   [edit]
   user@switch# set protocols dcbx interface interface-name applications no-auto-negotiation
   ```

3. Turn off autonegotiation for ETS.

   ```
   [edit]
   user@switch# set protocols dcbx interface interface-name enhanced-transmission-selection no-auto-negotiation
   ```

To disable autonegotiation of the ETS Recommendation TLV so that DCBX exchanges only the ETS Configuration TLV:

- ```
  [edit protocols dcbx interface interface-name]
  user@switch# set enhanced-transmission-selection no-recommendation-tlv
  ```

  ```

## Disabling the ETS Recommendation TLV

The enhanced transmission selection (ETS) Recommendation TLV communicates the ETS settings that the switch wants the connected peer interface to use. If the peer interface is “willing,” the peer interface changes its configuration to match the configuration in the ETS Recommendation TLV. By default, the switch interfaces send the ETS Recommendation TLV to the peer. The settings communicated are the egress ETS settings defined by configuring hierarchical scheduling on the interface.

We recommend that you use the same ETS settings on the connected peer that you use on the switch interface and that you leave the ETS Recommendation TLV enabled. However, on interfaces that use IEEE DCBX as the DCBX mode, if you want an asymmetric configuration between the switch interface and the connected peer, you can disable the ETS Recommendation TLV.

NOTE: **Disabling the ETS Recommendation TLV on interfaces that use DCBX version 1.01 as the DCBX mode has no effect and does not change DCBX behavior.**

If you disable the ETS Recommendation TLV, the switch still sends the ETS Configuration TLV to the connected peer. The result is that the connected peer is informed about the switch DCBX ETS configuration, but even if the peer is “willing,” the peer does not change its configuration to match the switch configuration. This is asymmetric configuration—the two interfaces can have different parameter values for the ETS attribute.

To disable the ETS Recommendation TLV:

- `[edit protocols dcbx interface` *`interface-name`*`]`
  `user@switch#` **set enhanced-transmission-selection no-recommendation-tlv**

## Defining an Application for DCBX Application Protocol TLV Exchange

Define each application for which you want DCBX to exchange application protocol information. You can define Layer 2 and Layer 4 applications. After you define applications, you map them to IEEE 802.1p code points, and then apply the application map to the interfaces on which you want DCBX to exchange application protocol information with connected peers. (See *Related Documentation* for how to configure application maps and apply them to interfaces, and for an example of the entire procedure that also includes classifier configuration.)

NOTE: In Junos OS Release 12.1, the FCoE application was configured by default, so you did not need to configure it in an application map. In Junos OS Release 12.2, if you want DCBX to advertise the FCoE application on an interface and you apply an application map to that interface, you must explicitly configure FCoE in the application map. You also must enable priority-based flow control (PFC) on the FCoE code point on all interfaces that you want to advertise FCoE. If you apply an application map to an interface, the interface sends DCBX TLVs only for the applications configured in the application map.

Define Layer 2 applications by mapping an application name to an EtherType. Define Layer 4 applications by mapping an application name to a protocol (TCP or UDP) and a destination port.

- To define a Layer 2 application, specify the name of the application and its EtherType:

  `[edit applications]`
  `user@switch#` **set application *application-name* ether-type *ether-type***

  For example, to configure an application named **PTP** (for Precision Time Protocol) that uses the EtherType **0x88F7**:

  `user@switch#` **set applications application ptp ether-type 0x88F7**

- To define a Layer 4 application, specify the name of the application, its protocol (TCP or UDP), and its destination port:

  `[edit]`
  `user@switch#` **set applications application *application-name* protocol (tcp | udp) destination-port** *`port-value`*

  For example, to configure an application named **iscsi** (for Internet Small Computer System Interface) that uses the protocol **TCP** and the destination port **3260**:

  `user@switch#` **set applications application iscsi protocol tcp destination-port 3260**

## Configuring an Application Map for DCBX Application Protocol TLV Exchange

After you define applications for which you want to exchange DCBX application protocol information, map the applications to IEEE 802.1p code points. The IEEE 802.1p code points identify incoming traffic and allow you to map that traffic to the desired application. You then apply the application map to the interfaces on which you want DCBX to exchange application protocol information with connected peers. (See *Related Documentation* for how to define applications and apply the application map to interfaces, and for an example of the entire procedure that also includes classifier configuration.)

NOTE: **In Junos OS Release 12.1, the FCoE application was configured by default, so you did not need to configure it in an application map. In Junos OS Release 12.2, if you want DCBX to advertise the FCoE application on an interface and you apply an application map to that interface, you must explicitly configure FCoE in the application map. You also must enable priority-based flow control (PFC) on the FCoE code point on all interfaces that you want to advertise FCoE. If you apply an application map to an interface, the interface sends DCBX TLVs only for the applications configured in the application map.**

Configure an application map by creating an application map name and mapping an application to one or more IEEE 802.1p code points.

- To define an application map, specify the name of the application map, the name of the application, and the IEEE 802.1p code points of the incoming traffic that you want to associate with the application in the application map:

  `[edit policy-options]`
  `user@switch#` **set application-maps *application-map-name* application *application-name* code-points [ *aliases* ] [ *bit-patterns* ]**

  For example, to configure an application map named **ptp-app-map** that includes an application named **PTP** (for Precision Time Protocol) and map the application to IEEE 802.1p code points **001** and **101**:

  `user@switch#` **set policy-options application-maps ptp-app-map application ptp code points [ 001 101 ]**

**Related Documentation**

## Applying an Application Map to an Interface for DCBX Application Protocol TLV Exchange

After you define applications and map them to IEEE 802.1p code points in an application map, apply the application map to the interfaces on which you want DCBX to exchange the application protocol information with connected peers. (See *Related Documentation* for how to define applications and configure application maps to interfaces, and for an example of the entire procedure that also includes classifier configuration.)

NOTE: In Junos OS Release 12.1, the FCoE application was configured by default, so you did not need to configure it in an application map. In Junos OS Release 12.2, if you want DCBX to advertise the FCoE application on an interface and you apply an application map to that interface, you must explicitly configure FCoE in the application map. You also must enable priority-based flow control (PFC) on the FCoE code point on all interfaces that you want to advertise FCoE. If you apply an application map to an interface, the interface sends DCBX TLVs only for the applications configured in the application map.

- To apply an application map to a DCBX interface, specify the DCBX interface and the application map name:

  ```
  [edit protocols]
  user@switch# set dcbx interface interface-name application-map application-map-name
  ```

  For example, to apply an application map named **ptp-app-map** on interface **xe-0/0/11**:

  ```
  user@switch# set protocols dcbx interface xe-0/0/11 application-map ptp-app-map
  ```

- *Understanding DCBX Application Protocol TLV Exchange on EX Series Switches*

applications (DCBX)

Syntax

```
applications {
  no-auto-negotiation;
}
```

Hierarchy Level [edit protocols dcbx interface *interface-name*]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.
Statement introduced in Junos OS Release 12.1 for the EX Series

Description Configure Data Center Bridging Capability Exchange protocol (DCBX) applications on an interface.

Options The remaining statements are explained separately.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

-

beacon-period

Syntax beacon-period *milliseconds*;

Hierarchy Level Original CLI

[edit ethernet-switching options secure-access-port vlan (all | *vlan-name*) examine-fip examine-vn2vn]

ELS CLI for Platforms that Support FCoE

[edit vlans *vlan-name* forwarding-options fip-security]

NOTE: **The beacon-period configuration statement is in a different hierarchy on the original CLI than on the Enhanced Layer 2 Software (ELS) CLI.**

Release Information Statement introduced in Junos OS Release 12.2 for the QFX Series.
Statement introduced for the ELS CLI in Junos OS Release 13.2 for the QFX Series.

Description Set the interval between periodic beacons. Beacons perform virtual link maintenance for VN_Ports in a way that is similar to FIP keepalive advertisements.

The ENode sends periodic beacons every 90 seconds on behalf of the VN_Port. Each received beacon resets the session timer for the virtual link connection to the other VN_Port. If the FCF does not receive a beacon before the beacon timer expires, the VN_Port is considered as “down” and the virtual link is terminated. The beacon timer expires in 2.5 times the configured beacon timer value.

Options *milliseconds*—Time in milliseconds between beacons.

Range: 250 through 90000 milliseconds

Default: 8000 milliseconds

Required Privilege Level storage—To view this statement in the configuration.
storage-control—To add this statement to the configuration.

- Example: Configuring VN2VN_Port FIP Snooping (FCoE Hosts Indirectly Connected Through an Aggregation Layer FCoE Transit Switch) on page 5036

code-points (Application Maps)

Syntax code-points [*aliases*] [*bit-patterns*];

Hierarchy Level [edit policy-options application-maps *application-map-name* application *application-name*]

Release Information Statement introduced in Junos OS Release 12.1 for EX Series switches.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Define one or more code-point aliases or bit sets for an application.

Options ***aliases***—Name of the alias or aliases.

bit-patterns—Value of the code-point bits, in decimal form.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

dcbx

Syntax

```
dcbx {
  disable;
  interface (interface-name | all) {
    disable;
    application-map application-map-name;
    applications {
      no-auto-negotiation;
    }
    enhanced-transmission-selection {
      no-auto-negotiation;
      no-recommendation-tlv;
      recommendation-tlv {
        no-auto-negotiation;
      }
    }
    dcbx-version (auto-negotiate | ieee-dcbx | dcbx-version-1.01);
    priority-flow-control {
      no-auto-negotiation;
    }
  }
}
```

Hierarchy Level [edit protocols]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.
Statement introduced in Junos OS Release 11.3 for EX Series switches.
mode and **recommendation-tlv** statements introduced in Junos OS Release 12.2 for the QFX Series.

Description Configure DCBX properties.

Options The statements are explained separately.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- **show dcbx neighbors on page 5177**

- *Understanding DCB Features and Requirements on EX Series Switches*
- *Disabling DCBX to Disable PFC Autonegotiation on EX Series Switches (CLI Procedure)*

dcbx-version

Syntax dcbx-version (auto-negotiate | ieee-dcbx | dcbx-version-1.01);

Hierarchy Level [edit protocols dcbx interface (all | *interface-name*)]

Release Information Statement introduced in Junos OS Release 12.2 for the QFX Series.

Description Set the DCBX version for the specified interface or interfaces.

QFX3500 switches come up in IEEE DCBX mode and then autonegotiate with the connected peer to set the DCBX version.

QFabric system Node devices come up using DCBX version 1.01, and then autonegotiate with the connected peer to set the DCBX mode.

Default The default DCBX mode is autonegotation.

Options **auto-negotiate**—Automatically negotiate the DCBX version with the connected peer.

ieee-dcbx—Force the interface to use IEEE DCBX mode, regardless of the peer configuration.

dcbx-version-1.01—Force the interface to use version 1.01 DCBX mode, regardless of the peer configuration.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- **show dcbx neighbors on page 5177**
- Configuring DCBX Autonegotiation on page 5076
- Understanding DCBX on page 4905

destination-port (Applications)

Syntax destination-port *port-value*;

Hierarchy Level [edit applications application *application-name*]

Release Information Statement introduced in Junos OS Release 12.1 for EX Series switches.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Transmission Control Protocol (TCP) or User Datagram Protocol (UDP) destination port number, which combines with **protocol** to identify an application type. The Internet Assigned Numbers Authority (IANA) assigns port numbers. See the IANA *Service Name and Transport Protocol Port Number Registry* at http://www.iana.org/assignments/service-names-port-numbers/service-names-port-numbers.xml for a list of assigned port numbers.

NOTE: To create an application for iSCSI, use the protocol **tcp** with the destination port number **3260**.

Options *port-value*—Identifier for the port.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

disable (DCBX)

Syntax disable

Hierarchy Level [edit protocols dcbx]

[edit protocols dcbx interface *interface-name*]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.
Statement introduced in Junos OS Release 11.3 for EX Series switches.

Description Disable Data Center Bridging Capability Exchange protocol (DCBX) on one or more 10-Gigabit Ethernet interfaces.

Default DCBX is enabled by default on all 10-Gigabit or higher Ethernet interfaces.

DCBX is enabled by default on all 10-Gigabit Ethernet interfaces on EX4500 CEE-enabled switches.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Configuring DCBX Autonegotiation on page 5076
- *Disabling DCBX to Disable PFC Autonegotiation on EX Series Switches (CLI Procedure)*

enhanced-transmission-selection

Syntax

```
enhanced-transmission-selection {
  no-auto-negotiation;
  no-recommendation-tlv;
  recommendation-tlv {
    no-auto-negotiation;
  }
}
```

Hierarchy Level [edit protocols dcbx interface *interface-name*]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Disable advertising the enhanced transmission selection (ETS) state of the interface to the peer. To disable ETS on the interface, do not enable ETS on the interface in the class-of-service (CoS) configuration.

Disabling ETS autonegotiation stops the QFX Series from advertising the ETS Configuration TLV and the ETS Recommendation TLV.

Disabling the ETS recommendation TLV stops the QFX Series from advertising the ETS Recommendation TLV, but the ETS Configuration TLV is still advertised.

Options **no-auto-negotiation**—Disable automatic negotiation of ETS (Configuration TLV and Recommendation TLV)

no-recommendation-tlv—Disable automatic negotiation of the ETS Recommendation TLV

recommendation-tlv—Enable automatic negotiation of ETS Recommendation TLV

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

ether-type

Syntax ether-type *ether-type*;

Hierarchy Level [edit applications application *application-name*]

Release Information Statement introduced in Junos OS Release 12.1 for EX Series switches.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Two-octet field in an Ethernet frame that defines the protocol encapsulated in the frame payload. See http://standards.ieee.org/develop/regauth/ethertype/eth.txt for a list of Institute of Electrical and Electronics Engineers (IEEE) EtherTypes.

NOTE: To create a FIP application, use the EtherType 0x8914.

Options ***type***—Identifier for the EtherType.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

examine-vn2vn

Syntax

```
examine-vn2vn {
  beacon-period milliseconds;
}
```

Hierarchy Level

Original CLI

[edit ethernet-switching options secure-access-port vlan (all | *vlan-name*) examine-fip]

ELS CLI for Platforms that Support FCoE

[edit vlans *vlan-name* forwarding-options fip-security]

NOTE: The examine-vn2vn configuration statement is in a different hierarchy on the original CLI than on the Enhanced Layer 2 Software (ELS) CLI.

Release Information

Statement introduced in Junos OS Release 12.2 for the QFX Series.
Statement introduced for the ELS CLI in Junos OS Release 13.2 for the QFX Series.

Description

Enable VN_Port to VN_Port (VN2VN) FIP snooping on a specified VLAN. The VLAN must be a dedicated FCoE VLAN that transports only FCoE traffic. A VLAN cannot support VN2VN FIP snooping and VN_Port to VF_Port FIP snooping (VN2VF) simultaneously. Configure separate VLANs for VN2VN FIP snooping and VN2VF FIP snooping.

When you enable VN2VN FIP snooping on a VLAN, the VN2VF session filters are removed and the all existing VN2VF sessions are terminated.

The remaining statement is explained separately.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Example: Configuring VN2VN_Port FIP Snooping (FCoE Hosts Directly Connected to the Same FCoE Transit Switch) on page 4977
- Example: Configuring VN2VN_Port FIP Snooping (FCoE Hosts Directly Connected to Different FCoE Transit Switches) on page 4982

- Example: Configuring VN2VN_Port FIP Snooping (FCoE Hosts Indirectly Connected Through an Aggregation Layer FCoE Transit Switch) on page 5036

fc-map

Syntax fc-map *fc-map-value*;

Hierarchy Level Original CLI

[edit ethernet-switching options secure-access-port vlan (all | *vlan-name*) examine-fip]

ELS CLI for Platforms that Support FCoE

[edit vlans *vlan-name* forwarding-options fip-security]

NOTE: The fc-map configuration statement is in a different hierarchy on the original CLI than on the Enhanced Layer 2 Software (ELS) CLI.

QFX Series that Support FCoE-FC Gateway Configuration

[edit fc-fabrics *fc-fabric-name* protocols fip]

Release Information Statement introduced in Junos OS Release 10.4 for EX Series switches.
Statement introduced in Junos OS Release 11.1 for the QFX Series.
Statement introduced for the ELS CLI in Junos OS Release 13.2 for the QFX Series.

Description Set the FCoE mapped address prefix (FC-MAP) value for the FCoE VLAN to match the FC switch (or FCoE forwarder) FC-MAP value for the FC fabric. The FC-MAP value is a unique MAC address prefix an FC switch uses to identify FCoE traffic for a given FC fabric (traffic on a particular FCoE VLAN).

You can configure the FC-MAP value or use the default value. The default FC-MAP value is different for VN_Port to VF_Port (VN2VF_Port) FIP snooping (0x0EFC00) than for VN_Port to VN_Port (VN2VN_Port) FIP snooping.

The FC switch provides the FC-MAP value to FCoE nodes (ENodes) in the FIP discovery advertisement message. If the EX Series switch or the QFX Series FCoE VLAN FC-MAP value does not match the FC switch FC-MAP value, neither device discovers the FC switch on that VLAN, and the ENodes on that VLAN cannot access the FC switch. The FC switch accepts only FCoE traffic that uses the correct FC-MAP value as part of the VN_Port MAC address.

When the QFX Series acts as an FCoE-FC gateway, the FC-MAP value for the gateway and the FCoE devices must match the FC switch FC-MAP value in order to communicate with the FC switch.

NOTE: Changing the FC-MAP value causes all logins to drop and forces the ENodes to log in again.

Options ***fc-map-value***—FC-MAP value, hexadecimal value preceded by “0x”.

Range: 0x0EFC00 through 0x0EFCFF

Default: 0x0EFC00 for VN2VF_Port FIP snooping0x0EFD00 for VN2VN_Port FIP snooping

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

fcoe-trusted

Syntax fcoe-trusted;

Hierarchy Level Original CLI

[edit ethernet-switching-options secure-access-port interface *interface-name*]

ELS CLI for Platforms that Support FCoE

[edit vlans *vlan-name* forwarding-options fip-security interface *interface-name*]

NOTE: **The fcoe-trusted configuration statement is in a different hierarchy on the original CLI than on the Enhanced Layer 2 Software (ELS) CLI.**

QFX Series that Support FCoE-FC Gateway Configuration

[edit fc-fabrics *fc-fabric-name* protocols fip]

Release Information Statement introduced in Junos OS Release 10.4 for EX Series switches.
Statement introduced in Junos OS Release 11.1 for the QFX Series.
Statement introduced for the FC fabric in Junos OS Release 11.3 for the QFX Series.
Statement introduced for the ELS CLI in Junos OS Release 13.2 for the QFX Series.

Description Configure the specified 10-Gigabit Ethernet interface to trust Fibre Channel over Ethernet (FCoE) traffic. If an interface is connected to another switch such as an FCoE forwarder (FCF) or a transit switch, you can configure the interface as trusted so that the interface forwards FCoE traffic from the switch to the FCoE devices without installing FIP snooping filters.

(QFX Series FCoE-FC gateway) Configure the specified local Fibre Channel fabric to trust FCoE traffic on all ports in the fabric. Changing the fabric ports from untrusted to trusted removes any existing FIP snooping filters from the ports. Changing the fabric ports from trusted to untrusted by removing the **fcoe-trusted** configuration from the fabric forces all of the FCoE sessions on those ports to log out so that when the ENodes and VN_Ports log in again, the switch can build the appropriate FIP snooping filters.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- **show fip snooping on page 5254**

interface (DCBX)

Syntax

```
interface (interface-name | all) {
  disable;
  application-map application-map-name;
  applications {
    no-auto-negotiation;
  }
  enhanced-transmission-selection {
    no-auto-negotiation;
    no-recommendation-tlv;
    recommendation-tlv {
      no-auto-negotiation;
    }
  }
  dcbx-version (auto-negotiate | ieee-dcbx | dcbx-version-1.01);
  priority-flow-control {
    no-auto-negotiation;
  }
}
```

Hierarchy Level [edit protocols dcbx]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.
Statement introduced in Junos OS Release 11.3 for the EX Series switches.
Mode and **recommendation-tlv** statements introduced in Junos OS Release 12.2 for the QFX Series.

Description Configure DCBX properties on an interface.

Options *interface-name*—Name of the interface.

The remaining statements are explained separately.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- **show dcbx neighbors on page 5177**

no-fcoe-trusted

Syntax no-fcoe-trusted;

Hierarchy Level Original CLI

[edit ethernet-switching-options secure-access-port interface *interface-name*]

ELS CLI for Platforms that Support FCoE

[edit vlans *vlan-name* forwarding-options fip-security interface *interface-name*]

NOTE: The **no-fcoe-trusted** configuration statement is in a different hierarchy on the original CLI than on the Enhanced Layer 2 Software (ELS) CLI.

Release Information Statement introduced in Junos OS Release 10.4 for EX Series switches.
Statement introduced in Junos OS Release 11.1 for the QFX Series.
Statement introduced for the ELS CLI in Junos OS Release 13.2 for the QFX Series.

Description Configure the specified 10-Gigabit Ethernet interface not to trust Fibre Channel over Ethernet (FCoE) traffic. If an interface is directly connected to an FCoE device, the interface should not be configured as an FCoE trusted interface. If an interface that you want to connect to an FCoE device has been configured as an FCoE trusted interface, use the **no-fcoe-trusted** statement to convert the interface to an untrusted interface. Untrusted interfaces can perform FIP snooping to provide access security for FCoE traffic.

However, if an interface is connected to another switch such as an FCoE forwarder (FCF) or a transit switch, you can configure the interface as trusted so that the interface forwards FCoE traffic from the switch to the FCoE devices without installing FIP snooping filters.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

policy-options

Syntax

```
policy-options
  application-maps application-map-name {
    application application-name {
      code-points [ aliases ] [ bit-patterns ];
    }
  }
  policy-statement policy-name {
    term term-name {
      from {
        family family-name;
        match-conditions;
        policy subroutine-policy-name;
        prefix-list prefix-list-name;
        prefix-list-filter prefix-list-name match-type <actions>;
        route-filter destination-prefix match-type <actions>;
        source-address-filter source-prefix match-type <actions>;
      }
      to {
        match-conditions;
        policy subroutine-policy-name;
      }
      then actions;
    }
  }
```

Hierarchy Level [edit]

Release Information Statement introduced in Junos OS Release 12.1 for the QFX Series.
Statement introduced in Junos OS Release 12.1 for the EX Series.

Description Configure options such as application maps for DCBX application protocol exchange and policy statements.

Required Privilege Level storage—To view this statement in the configuration.
storage-control—To add this statement to the configuration.

Related Documentation

priority-flow-control

Syntax

```
priority-flow-control {
  no-auto-negotiation;
}
```

Hierarchy Level [edit protocols dcbx interface (all | *interface-name*)]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.
Statement introduced in Junos OS Release 11.3 for EX Series switches.

Description Disable autonegotiation of priority-based flow control (PFC) on one or more Ethernet interfaces. Autonegotiation enables PFC on an interface only if the switch and the peer device connected to the switch both support PFC and have the same PFC configuration. Disabling autonegotiation on an interface forces the interface to use the PFC state (enabled or disabled) that is configured on the switch by the configuration and assignment of the congestion notification profile.

Options **no-auto-negotiation**—Disable automatic negotiation of PFC.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Understanding DCB Features and Requirements on page 4795

protocol (Applications)

Syntax protocol (tcp | udp);

Hierarchy Level [edit applications application *application-name*]

Release Information Statement introduced in Junos OS Release 12.1 for EX Series switches.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Networking protocol type, which combines with **destination-port** to identify an application type.

NOTE: To create an application for iSCSI, use the protocol **tcp** with the destination port number **3260**.

Options **tcp**—Transmission Control Protocol

udp—User Datagram Protocol

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

recommendation-tlv

Syntax

```
recommendation-tlv {
  no-auto-negotiation;
}
```

Hierarchy Level [edit protocols dcbx interface *interface-name* enhanced-transmission-selection]

Release Information Statement introduced in Junos OS Release 12.2 for the QFX Series.

Description Disable or enable DCBX to send the ETS Recommendation TLV (also known as the Information TLV) on egress. This feature is valid only if the interface DCBX mode is IEEE DCBX. If the interface DCBX mode is DCBX version 1.01, this statement has no effect. (DCBX version 1.01 does not advertise separate TLVs for individual attributes.)

Default DCBX-enabled interfaces send the ETS recommendation TLV unless it is disabled.

Options **no-auto-negotiation**—Disable sending of the ETS recommendation TLV.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- **show dcbx neighbors on page 5177**
- Configuring DCBX Autonegotiation on page 5076

Configuration Statements (Original CLI Only)

auto-load-rebalance

Syntax auto-load-rebalance;

Hierarchy Level [edit fc-fabrics *fabric-name* proxy]

Release Information Command introduced in Junos OS Release 12.3 for the QFX Series.

Description Configure the system to rebalance NP_Port link loads automatically on an FCoE-FC gateway proxy fabric if the link loads become unbalanced. Load rebalancing is a disruptive action that forces some or all sessions (depending on the configured load-balancing algorithm) to log out and then log in again. When sessions log in again, they are placed on NP_Port interfaces so that the link loads are balanced.

Required Privilege Level storage—To view this statement in the configuration.
storage-control—To add this statement to the configuration.

Related Documentation

- Monitoring Fibre Channel Interface Load Balancing on page 5147

bb-sc-n

Syntax bb-sc-n *bb-sc-n*;

Hierarchy Level [edit interfaces *interface-name* fibrechannel-options]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Configure the buffer-to-buffer credit state change number to prevent the permanent loss of Fibre Channel credits over time (buffer-to-buffer credit recovery).

Options *bb-sc-n*—Number of buffer-to-buffer state change credits.

Range: 0 through 15

Default: 0 (disabled)

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Understanding Interfaces on an FCoE-FC Gateway on page 4829

description (Fibre Channel Fabrics)

Syntax description *description*

Hierarchy Level [edit fc-fabrics *fabric-name*]

Description Text string that describes the Fibre Channel fabric. The text string has no effect on the operation of the fabric.

Options *description*—Text that describes the fabric. Text can include letters, numbers, and hyphens (-) and can be up to 255 characters in length. If the text includes spaces, enclose the entire text string in quotation marks.

Required Privilege Level storage—To view this statement in the configuration.
storage-control—To add this statement to the configuration.

Related Documentation

examine-fip

Syntax

```
examine-fip {
  examine-vn2vn {
    beacon-period milliseconds;
  }
  fc-map fc-map-value;
}
```

Hierarchy Level [edit ethernet-switching-options secure-access-port vlan (all | *vlan-name*)]

Release Information Statement introduced in Junos OS Release 10.4 for EX Series switches.
Statement introduced in Junos OS Release 11.1 for the QFX Series.
Statement **examine-vn2vn** introduced in Junos OS Release 12.2 for the QFX Series.

Description

NOTE: This statement supports the original CLI. If your switch runs the Enhanced Layer 2 Software (ELS) CLI, see examine-vn2vf for VN_Port to VF_Port (VN2VF_Port) FIP snooping, and see examine-vn2vn for VN_Port to VN_Port (VN2VN_Port) FIP snooping. For ELS details, see “Getting Started with Enhanced Layer 2 Software” on page 58.

Enable FIP snooping on a specified VLAN. Ensure that the VLAN is a dedicated FCoE VLAN that transports only FCoE traffic.

(QFX Series only) Enable VN2VN_Port FIP snooping on the specified VLAN. The VLAN must be a dedicated FCoE VLAN that transports only VN2VN_Port traffic. One FCoE VLAN cannot support both VN2VF_Port FIP snooping and VN2VN_Port FIP snooping. Configure separate, dedicated FCoE VLANs for VN2VN_Port FIP snooping and VN2VN_Port FIP snooping.

The remaining statements are explained separately.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

fabric-id

Syntax fabric-id *fc-fabric-id*;

Hierarchy Level [edit fc-fabrics *fc-fabric-name*]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Configure a unique identifier for the FC fabric.

NOTE: **Changing the ID of an FC fabric causes all logins to drop and forces the ENodes to log in again.**

Options *fc-fabric-id* —Unique identifier of the FC fabric.

Required Privilege Level storage—To view this statement in the configuration.
storage-control—To add this statement to the configuration.

fibrechannel-options

Syntax

```
fibrechannel-options {
  bb-sc-n
  (loopback | no-loopback);
  speed (auto-negotiation | 2g | 4g | 8g);
}
```

Hierarchy Level [edit interfaces *interface-name*]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Configure FC interface properties such as speed and loopback mode.

Options The statements are explained separately.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- show fibre-channel interfaces on page 5234

fip

Syntax

```
fip {
  fcoe-trusted;
  fc-map fc-map-value;
  fka-adv-period milliseconds;
  interface {
    interface-name {
      fka-adv-period milliseconds;
      priority priority;
    }
  }
  max-sessions-per-enode max-sessions-per-enode;
  priority priority;
  traceoptions {
    file filename <replace> <size size> <files number> <no-stamp>;
    <world-readable | no-world-readable>;
    flag flag <flag-modifier> <disable>;
  }
}
```

Hierarchy Level [edit fc-fabrics *fc-fabric-name* protocols]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Configure global or interface-specific FIP options. Individual interface settings override global settings.

Options The statements are explained separately.

Required Privilege Level storage—To view this statement in the configuration.
storage-control—To add this statement to the configuration.

Related Documentation

- **show fibre-channel fip on page 5205**
- Configuring FIP on an FCoE-FC Gateway on page 5059

fka-adv-period

Syntax fka-adv-period *milliseconds*;

Hierarchy Level [edit fc-fabrics *fc-fabric-name* protocols fip],
[edit fc-fabrics *fc-fabric-name* protocols fip interface *interface-name*]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Set the global or interface-specific interval between periodic FIP keepalive advertisements. An interval set at the interface level overrides the global setting.

Options *milliseconds*—Time in milliseconds between FIP keepalive advertisements.

Range: 250 through 90000 milliseconds

Default: 8000 milliseconds

Required Privilege Level storage—To view this statement in the configuration.
storage-control—To add this statement to the configuration.

Related Documentation

interface (Fibre Channel Fabric)

Syntax

```
interface {
  interface-name {
    max-login-sessions max-login-sessions;
  }
  interface-name {
    max-login-sessions max-login-sessions;
  }
  <...> {
    max-login-sessions max-login-sessions;
  }
  vlan.interface-name;
}
```

Hierarchy Level [edit fc-fabrics *fc-fabric-name*]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Associate one or more native Fibre Channel (FC) interfaces with an FC fabric and one VLAN interface for FCoE traffic. An FC interface can be associated with only one FC fabric.

Options ***interface-name***—Name of the native FC interface. You can assign one or more FC interfaces to an FC fabric.

vlan.*vlan-interface-name*—Name of the VLAN interface for FCoE traffic. You can assign one VLAN interface to an FC fabric.

The remaining statement is explained separately.

Required Privilege Level storage—To view this statement in the configuration.
storage-control—To add this statement to the configuration.

interface (FIP)

Syntax

```
interface {
  interface-name {
    fka-adv-period milliseconds;
    priority priority;
  }
}
```

Hierarchy Level [edit fc-fabrics *fc-fabric-name* protocols fip]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Configure FIP options on a per-interface basis. (Override global FIP configuration for a specified interface.)

Options *interface-name*—Name of the interface.

The statements are explained separately.

Required Privilege Level storage—To view this statement in the configuration.
storage-control—To add this statement to the configuration.

Related Documentation

- Configuring FIP on an FCoE-FC Gateway on page 5059
- Overview of FIP on page 4790

load-balance-algorithm

Syntax load-balance-algorithm (simple | enode-based | flogi-based);

Hierarchy Level [edit fc-fabrics *fabric-name* proxy]

Release Information Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Set the load-balancing algorithm that the QFX Series uses to distribute FCoE sessions (FLOGI and FDISC sessions from the FCoE devices in the Ethernet network) among the NP_Port links to the FC switch.

NOTE: **Changing the load-balancing algorithm when FCoE sessions are running forces the FCoE sessions to log out, then log in again.**

Options **simple**—Load balancing is based on the weighted utilization (load) of the NP_Ports connected to an FC fabric. Each new FLOGI or FDISC is assigned to the least-loaded link. When a link load rebalance occurs, the system minimizes disruption by using an algorithm to log out only the sessions that need to be moved to other links to balance the link load. To further minimize disruption, the algorithm logs out the sessions with the fewest dependencies (for example, FDISC sessions are logged out before FLOGI sessions). When the sessions log in again, they are placed on NP_Port interfaces in a manner that balances the link loads. This is the default load-balancing algorithm.

enode-based—Load balancing is based on the ENode FLOGI. When an ENode logs in to the fabric, all subsequent FDISC sessions (VN_Port sessions) associated with that ENode are placed on the same link as the ENode FLOGI session, regardless of the link load. New ENode FLOGIs are placed on the least-loaded link. When a link load rebalance occurs, the system logs off all sessions. The sessions log in again and are placed on NP_Port interfaces in a balanced manner.

flogi-based—FLOGI-based load balancing is similar to ENode-based load balancing, but the behavior when the loads are rebalanced is different. Load balancing is based on the ENode FLOGI. When an ENode logs in to the fabric, all subsequent FDISC sessions associated with that ENode are placed on the same link as the ENode FLOGI session, regardless of the link load. New ENode FLOGIs are placed on the least-loaded link. When a link load rebalance occurs, the system minimizes disruption by using an algorithm to log out only the sessions that need to be moved to other links to balance the link load. When the logged out sessions log back in, they are placed on NP_Port interfaces in a manner that balances the link loads.

Required Privilege Level storage—To view this statement in the configuration.
storage-control—To add this statement to the configuration.

loopback (Fibre Channel Interface)

Syntax (loopback | no-loopback);

Hierarchy Level [edit **interfaces** *interface-name* **fibrechannel-options**]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Enable or disable loopback mode for FC interfaces.

Default By default, loopback mode is disabled on FC interfaces.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- **show fibre-channel interfaces on page 5234**
- Configuring a Fibre Channel Interface on page 5049

max-login-sessions

Syntax max-login-sessions *max-login-sessions*;

Hierarchy Level [edit fc-fabrics *fc-fabric-name*];
[edit fc-fabrics *fc-fabric-name* interface *interface-name*];

Release Information Statement introduced in Junos OS Release 12.2 for the QFX Series.

Description Set the maximum number of FCoE initialization protocol (FIP) session logins permitted for an individual NP_Port interface in an FCoE-FC gateway fabric (FC fabric) or for the entire FCoE-FC gateway fabric. You can set a maximum FIP session limit for each NP_Port interface connected to an FC switch. You can also set a maximum FIP session limit for the entire FC fabric. The sum of the maximum login sessions permitted on the NP_Port interfaces in an FC fabric should not exceed the maximum login sessions configured for that FC fabric.

The maximum number of FIP sessions (the combined total of all VN2VF_Port and VN2VN_Port sessions on the system) is 2500 sessions.

Options *max-login-sessions*—Maximum number of FIP login sessions.

Range: 128 through 2500

Default: 2500

Required Privilege Level storage—To view this statement in the configuration.
storage-control—To add this statement to the configuration.

Related Documentation

- max-login-sessions-per-node on page 5125
- Setting the Maximum Number of FIP Login Sessions per FC Interface on page 5063
- Setting the Maximum Number of FIP Login Sessions per FC Fabric on page 5064
- Understanding Interfaces on an FCoE-FC Gateway on page 4829

max-login-sessions-per-node

Syntax max-login-sessions-per-node *max-login-sessions-per-node*;

Hierarchy Level [edit fc-options]

Release Information Statement introduced in Junos OS Release 12.2 for the QFX Series.

Description Set the maximum number of FCoE initialization protocol (FIP) session logins permitted on a Node device. (This is the combined total of all VN2VF_Port and VN2VN_Port sessions on the Node device.)

On a QFX3500 switch, the **max-login-sessions-per-node** command sets the maximum FIP session login limit for all of the FC fabrics configured on the device. The combined number of FIP sessions on all FC fabrics on the device should not exceed this limit.

On a QFabric system, the **max-login-sessions-per-node** command globally sets the maximum FIP session login limit for each QFabric system Node device in the QFabric system. For example, if you set the Node limit to 2000 login sessions, then each QFabric Node device supports up to 2000 FIP login sessions. The total configured maximum number of login sessions of all of the FC fabrics on a Node device should not exceed the Node session limit.

NOTE: FIP login session limits configured at the FC fabric level or at the FC fabric interface level might limit a Node device to fewer total sessions than the configured Node limit.

Options *max-login-sessions-per-node*—Maximum number of FIP login sessions.

Range: 128 through 2500

Default: 2500

Required Privilege Level storage—To view this statement in the configuration.
storage-control—To add this statement to the configuration.

Related Documentation

- max-login-sessions on page 5124
- Setting the Maximum Number of FIP Login Sessions per Node Device on page 5065
- Understanding Interfaces on an FCoE-FC Gateway on page 4829

max-sessions-per-enode

Syntax max-sessions-per-enode *max-sessions-per-enode*;

Hierarchy Level [edit fc-fabrics *fc-fabric-name* protocols fip]

Release Information Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Set the maximum number of FCoE login sessions (FLOGI plus FDISC) from a single ENode allowed on the gateway FC fabric (the fabric configured on the QFabric system). The maximum number of logins per ENode is 2000 sessions.

NOTE: A session is a FLOGI or FDISC login to the FC SAN fabric. Session does not refer to end-to-end storage sessions. There is no limit to the number of end-to-end storage sessions.

Options *max-sessions-per-enode*—Maximum number of FCoE sessions a single ENode can establish on the switch.

Range: 32 through 2000

Default: 32

Required Privilege Level storage—To view this statement in the configuration.
storage-control—To add this statement to the configuration.

no-fabric-wwn-verify

Syntax no-fabric-wwn-verfiy;

Hierarchy Level [edit fc-fabrics *fabric-name* proxy]

Release Information Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Disable the fabric worldwide name (WWN) verification check in the fabric login accept message (FLOGI-ACC) for implicit FLOGIs. If you enable this option, when a QFX Series NP_Port performs a FLOGI to the FC fabric, the QFX Series does not verify the fabric WWN in the FLOGI-ACC against the current fabric WWN.

NOTE: **Disabling or enabling the fabric WWN verification check logs out all FCoE sessions.**

Default Disabled. By default, all implicit FLOGIs from the QFX Series NP_Ports to the FC fabric are verified against the current fabric WWN.

Required Privilege Level storage—To view this statement in the configuration.
storage-control—To add this statement to the configuration.

Related Documentation

oxid

Syntax oxid (enable | disable)

Hierarchy Level [edit forwarding-options hash-key family fcoe]

Release Information Statement introduced in Junos OS Release 12.3 for the QFX Series.

Description Enable or disable whether the switch uses the originator exchange identifier (OxID) field for hash control for FCoE traffic load balancing.

Default OxID hash control is enabled by default.

Options **oxid (enable | disable)**—Enable or disable whether the switch uses the OxID hash control field for FCoE traffic load balancing.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

- Enabling and Disabling CoS OxID Hash Control on page 5059
- Understanding OxID Hash Control for FCoE Traffic Load Balancing on page 4857

port-mode (Fibre Channel Interfaces)

Syntax port-mode (f-port | np-port);

Hierarchy Level [edit interfaces vlan unit *unit* family fibre-channel],
[edit interfaces *interface-name* unit *logical-unit-number* family fibre-channel]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Configure the FCoE VLAN interface port mode to F_Port to connect the switch to FCoE initiators, or configure the native FC interface port mode to proxy N_Port (NP_Port) to connect the switch to an FC switch fabric port (F_Port).

Options **f-port**—Configure an FCoE VLAN interface to connect to FCoE initiator Virtual N_Ports (VN_Ports).

np-port—Configure a native FC port to connect to an FC switch F_Port.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

port-range

Syntax port-range *port-range-low port-range-high*;

Hierarchy Level [edit chassis fpc *fpc-id* pic *pic-id* fibre-channel]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Configure a contiguous block of ports as FC ports. You can configure the FC-capable ports xe-0/0/0 through xe-0/0/5 as fc-0/0/0 through fc-0/0/5, and ports xe-0/0/42 through xe-0/0/47 as fc-0/0/42 through fc-0/0/47 to create blocks of native FC interfaces. You cannot individually configure a single port as a native FC interface. Within these port blocks, you cannot mix FC interfaces with Ethernet interfaces. All of the ports in a block must be either native FC interfaces or Ethernet interfaces.

You can configure:

- Six native FC interfaces by configuring either ports xe-0/0/0 through xe-0/0/5 as fc-0/0/0 through fc-0/0/5, or ports xe-0/0/42 through xe-0/0/47 as fc-0/0/42 through fc-0/0/47.
- Twelve native FC interfaces by configuring ports xe-0/0/0 through xe-0/0/5 as fc-0/0/0 through fc-0/0/5 and ports xe-0/0/42 through xe-0/0/47 as fc-0/0/42 through fc-0/0/47.
- No native FC interfaces by leaving ports xe-0/0/0 through xe-0/0/5 and ports xe-0/0/42 through xe-0/0/47 in their default state as Ethernet interfaces.

Options ***port-range-low***—Lowest-numbered port in the block of native FC interfaces, either **0** or **42**.

port-range-high—Highest-numbered port in the block of native FC interfaces. The value is **5** if the ***port-range-low*** value is **0**. The value is **47** if the ***port-range-low*** value is **42**.

NOTE: **Only a complete block of ports, xe-0/0/0 through xe-0/0/5, xe-0/0/42 through xe0/0/47, or both, can be configured as FC ports.**

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

priority (FIP)

Syntax priority *priority*;

Hierarchy Level [edit fc-fabrics *fc-fabric-name* protocols fip],
[edit fc-fabrics *fc-fabric-name* protocols fip interface *interface-name*]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Sets the global or interface-specific priority value associated with the switch FCF-MAC. CNAs use the priority value to determine the switch with which they will perform FIP FLOGI. The lower the value, the higher the priority. The switch advertises this value to the server ENodes on the FCoE network. A priority value set at the interface level overrides the global setting.

Options *priority* —Value that determines the FCF an ENode selects to perform FIP FLOGI. The lower the priority number, the higher the priority of the FCF.

Range: 0 through 255

Default: 128

Required Privilege Level storage—To view this statement in the configuration.
storage-control—To add this statement to the configuration.

protocols (FIP)

Syntax

```
protocols {
  fip {
    fcoe-trusted;
    fc-map fc-map-value;
    fka-adv-period milliseconds;
    interface {
      interface-name {
        fka-adv-period milliseconds;
        priority priority;
      }
    }
    max-sessions-per-enode max-sessions-per-enode;
    priority priority;
    traceoptions {
      file filename <replace> <size size> <files number> <no-stamp>;
      <world-readable | no-world-readable>;
      flag flag <flag-modifier> <disable>;
    }
  }
}
```

Hierarchy Level [edit fc-fabrics *fc-fabric-name*]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Configure global or interface-specific FC protocol options. Individual interface settings override global settings.

Options The statements are explained separately.

Required Privilege Level storage—To view this statement in the configuration.
storage-control—To add this statement to the configuration.

Related Documentation

- show fibre-channel fip on page 5205

proxy (Fibre Channel)

Syntax

```
proxy {
  auto-load-rebalance
  load-balance-algorithm (simple | enode-based | flog-based);
  no-fabric-wwn-verify;
  traceoptions {
    file filename <replace> <size size> <files number> <no-stamp>
    <world-readable | no-world-readable>;
    flag flag <flag-modifier> <disable>;
  }
}
```

Hierarchy Level [edit fc-fabrics *fabric-name*]

Description Configure proxy fabric operations.

Options The statement is explained separately.

Required Privilege Level storage—To view this statement in the configuration.
storage-control—To add this statement to the configuration.

Related Documentation
- Understanding FCoE-FC Gateway Functions on page 4812

speed (Fibre Channel Interfaces)

Syntax speed (auto-negotiation | 2g | 4g | 8g);

Hierarchy Level [edit interfaces *interface-name* fibrechannel-options]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Configure FC interface speed.

Options **auto-negotiation**—Automatically negotiate interface speed to match the speed of the attached link (2 Gbps, 4 Gbps, 8 Gbps).

2g—2 Gbps link speed

4g—4 Gbps link speed

8g—8 Gbps link speed

Default: auto-negotiation

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

traceoptions (FC-2 Fibre Channel)

Syntax

```
traceoptions {
  file filename <replace> <size size> <files number> <no-stamp>;
  <world-readable | no-world-readable>;
  flag flag <flag-modifier>;
}
```

Hierarchy Level [edit fc-fabrics *fabric-name* fc2]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Set FC-2 protocol tracing options.

NOTE: **The traceoptions statement is not supported on the QFabric system.**

Default Traceoptions is disabled.

Options

file ***name***—Name of the file to receive the tracing operation output. Enclose the name in quotation marks. Traceoption output files are located in the **/var/log/** directory.

files ***number***—(Optional) Maximum number of trace files. When a trace file named ***trace-file*** reaches its maximum size, it is renamed ***trace-file*.0**. The traceoption output continues in a second trace file named ***trace-file*.1**. When ***trace-file*.1** reaches its maximum size, output continues in a third file named ***trace-file*.2**, and so on. When the maximum number of trace files is reached, the oldest trace file is overwritten.

If you specify a maximum number of files, you must also specify a maximum file size with the **size** option.

Range: 2 through 1000 files

Default: 1 trace file

flag—Tracing operation to perform. To specify more than one tracing operation, include multiple **flag** statements:

- **all** —Trace all operations.
- **error**—Trace all error events
- **normal**—Trace all normal events.

Default: If you do not specify the **normal** option, only unusual or abnormal operations are traced.

- **parse**—Trace configuration parsing.
- **rx-frame**—(Optional) Trace received frames.
- **rx-frame-header**—(Optional) Trace received frame headers.

- **tx-frame**—(Optional) Trace transmitted frames.
- **tx-frame-header**—(Optional) Trace transmitted frame headers.

no-stamp—(Optional) Do not place timestamp information at the beginning of each line in the trace file.

Default: If you omit this option, timestamp information is placed at the beginning of each line of the tracing output.

no-world-readable—(Optional) Prevent any user from reading the log file.

replace—(Optional) Replace an existing trace file if there is one.

Default: If you do not include this option, tracing output is appended to an existing trace file.

size ***size***—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named ***trace-file*** reaches its maximum size, it is renamed ***trace-file*** **.0**. Incoming tracefile data is logged in the now empty ***trace-file***. When ***trace-file*** again reaches its maximum size, ***trace-file*.0** is renamed ***trace-file*.1** and ***trace-file*** is renamed ***trace-file*.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you must also specify a maximum number of trace files with the **files** option.

Syntax: ***x*k** to specify KB, ***x*m** to specify MB, or ***x*g** to specify GB

Range: 10 KB through the maximum file size of 4 GB (the maximum is lower if 4 GB is not supported on your system)

Default: 1 MB

world-readable—(Optional) Allow any user to read the log file.

Required Privilege Level

storage—To view this statement in the configuration.
storage-control—To add this statement to the configuration.

traceoptions (Fibre Channel)

Syntax

```
traceoptions {
  file filename <replace> <size size> <files number> <no-stamp>
  <world-readable | no-world-readable>;
  flag flag <flag-modifier>;
}
```

Hierarchy Level [edit fc-options]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Set FC protocol tracing options.

NOTE: **The traceoptions statement is not supported on the QFabric system.**

Default Traceoptions is disabled.

Options **file** ***name***—Name of the file to receive the tracing operation output. Enclose the name in quotation marks. Traceoption output files are located in the **/var/log/** directory.

files ***number***—(Optional) Maximum number of trace files. When a trace file named ***trace-file*** reaches its maximum size, it is renamed ***trace-file*.0**. The traceoption output continues in a second trace file named ***trace-file*.1**. When ***trace-file*.1** reaches its maximum size, output continues in a third file named ***trace-file*.2**, and so on. When the maximum number of trace files is reached, the oldest trace file is overwritten.

If you specify a maximum number of files, you must also specify a maximum file size with the **size** option.

Range: 2 through 1000 files

Default: 1 trace file

flag—Tracing operation to perform. To specify more than one tracing operation, include multiple **flag** statements:

- **all**—Trace all operations.
- **fabric**—Trace virtual fabric events.
- **fc2**—Trace the FC2 (network layer protocols) events.
- **fip**—Trace the Fibre Channel over Ethernet (FCoE) Initialization Protocol events.
- **flogi** —Trace the fabric login server events.
- **forwarding-database**—Trace the forwarding database and next-hop events.
- **interface**—Trace the interface events.

- **krt**—Trace the communication over the routing socket.
- **lib**—Trace library calls.
- **lif**—Trace Fibre Channel logical interface (fc-lif) events.
- **vswitch**—Trace virtual switch events.

The following are the global tracing options:

- **all**—All trace operations.
- **config-internal**—Trace configuration internals.
- **general**—Trace general events.
- **normal**—All normal events.

Default: If you do not specify this option, only unusual or abnormal operations are traced.

- **parse**—Trace configuration parsing.
- **state**—Trace state transitions.
- **task**—Trace protocol task processing.
- **timer**—Trace protocol task timer processing.

no-stamp—(Optional) Do not place timestamp information at the beginning of each line in the trace file.

Default: If you omit this option, timestamp information is placed at the beginning of each line of the tracing output.

no-world-readable—(Optional) Prevent any user from reading the log file.

replace—(Optional) Replace an existing trace file if there is one.

Default: If you do not include this option, tracing output is appended to an existing trace file.

size *size*—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named ***trace-file*** reaches its maximum size, it is renamed ***trace-file* .0.** Incoming tracefile data is logged in the now empty ***trace-file***. When ***trace-file*** again reaches its maximum size, ***trace-file*.0** is renamed ***trace-file*.1** and ***trace-file*** is renamed ***trace-file*.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you must also specify a maximum number of trace files with the **files** option.

Syntax: ***x*k** to specify KB, ***x*m** to specify MB, or ***x*g** to specify GB

Range: 10 KB through the maximum file size of 4 GB (maximum is lower if 4 GB is not supported on your system)

Default: 1 MB

world-readable—(Optional) Allow any user to read the log file.

Required Privilege Level

storage—To view this statement in the configuration.
storage-control—To add this statement to the configuration.

traceoptions (FIP Protocol Fibre Channel)

Syntax

```
traceoptions {
  file filename <replace> <size size> <files number> <no-stamp>
  <world-readable | no-world-readable>;
  flag flag <flag-modifier>
}
```

Hierarchy Level [edit fc-fabrics *fabric-name* protocols fip]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Set proxy FC protocol tracing options.

NOTE: **The traceoptions statement is not supported on the QFabric system.**

Default Traceoptions is disabled.

Options

file ***name***—Name of the file to receive the tracing operation output. Enclose the name in quotation marks. Traceoption output files are located in the **/var/log/** directory.

files ***number*** —(Optional) Maximum number of trace files. When a trace file named ***trace-file*** reaches its maximum size, it is renamed ***trace-file*.0**. The traceoption output continues in a second trace file named ***trace-file*.1**. When ***trace-file*.1** reaches its maximum size, output continues in a third file named ***trace-file*.2**, and so on. When the maximum number of trace files is reached, the oldest trace file is overwritten.

If you specify a maximum number of files, you must also specify a maximum file size with the size option.

Range: 2 through 1000 files

Default: 1 trace file

flag—Tracing operation to perform. To specify more than one tracing operation, include multiple **flag** statements:

- **all**—Trace all operations.
- **error**—Trace all error events
- **normal**—Trace all normal events.

Default: If you do not specify this option, only unusual or abnormal operations are traced.

- **packet**—Trace packet decoding operations
- **parse**—Trace configuration parsing.
- **state**—Trace state transitions.

no-stamp—(Optional) Do not place timestamp information at the beginning of each line in the trace file.

Default: If you omit this option, timestamp information is placed at the beginning of each line of the tracing output.

no-world-readable—(Optional) Prevent any user from reading the log file.

replace—(Optional) Replace an existing trace file if there is one.

Default: If you do not include this option, tracing output is appended to an existing trace file.

size ***size***—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named ***trace-file*** reaches its maximum size, it is renamed ***trace-file*****.0.** Incoming tracefile data is logged in the now empty ***trace-file***. When ***trace-file*** again reaches its maximum size, ***trace-file*****.0** is renamed ***trace-file*****.1** and ***trace-file*** is renamed ***trace-file*****.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you must also specify a maximum number of trace files with the **files** option.

Syntax: ***x*****k** to specify KB, ***x*****m** to specify MB, or ***x*****g** to specify GB

Range: 10 KB through the maximum file size of 4 GB (maximum is lower if 4 GB is not supported on your system)

Default: 1 MB

world-readable—(Optional) Allow any user to read the log file.

Required Privilege Level

storage—To view this statement in the configuration.
storage-control—To add this statement to the configuration.

traceoptions (Proxy Fibre Channel)

Syntax

```
traceoptions {
  file filename <replace> <size size> <files number> <no-stamp>
  <world-readable | no-world-readable>;
  flag flag <flag-modifier>
}
```

Hierarchy Level [edit fc-fabrics *fabric-name* proxy]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Set proxy FC protocol tracing options.

NOTE: **The traceoptions statement is not supported on the QFabric system.**

Default Traceoptions is disabled.

Options **file** ***name***—Name of the file to receive the tracing operation output. Enclose the name in quotation marks. Traceoption output files are located in the **/var/log/** directory.

files ***number***—(Optional) Maximum number of trace files. When a trace file named ***trace-file*** reaches its maximum size, it is renamed ***trace-file*.0**. The traceoption output continues in a second trace file named ***trace-file*.1**. When ***trace-file*.1** reaches its maximum size, output continues in a third file named ***trace-file*.2**, and so on. When the maximum number of trace files is reached, the oldest trace file is overwritten.

If you specify a maximum number of files, you must also specify a maximum file size with the **size** option.

Range: 2 through 1000 files

Default: 1 trace file

flag—Tracing operation to perform. To specify more than one tracing operation, include multiple **flag** statements:

- **all**—Trace all operations.
- **error**—Trace all error events.
- **interface**—Trace the interface events.
- **normal**—Trace all normal events.

Default: If you do not specify this option, only unusual or abnormal operations are traced.

- **packet**—Trace packet decoding operations
- **parse**—Trace configuration parsing.

- **state**—Trace state transitions.

no-stamp—(Optional) Do not place timestamp information at the beginning of each line in the trace file.

Default: If you omit this option, timestamp information is placed at the beginning of each line of the tracing output.

no-world-readable—(Optional) Prevent any user from reading the log file.

replace—(Optional) Replace an existing trace file if there is one.

Default: If you do not include this option, tracing output is appended to an existing trace file.

size *size*—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named ***trace-file*** reaches its maximum size, it is renamed ***trace-file*.0**. Incoming tracefile data is logged in the now empty ***trace-file***. When ***trace-file*** again reaches its maximum size, ***trace-file*.0** is renamed ***trace-file*.1** and ***trace-file*** is renamed ***trace-file*.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you must also specify a maximum number of trace files with the **files** option.

Syntax: ***x*k** to specify KB, ***x*m** to specify MB, or ***x*g** to specify GB

Range: 10 KB through the maximum file size of 4 GB (maximum is lower if 4 GB is not supported on your system)

Default: 1 MB

world-readable—(Optional) Allow any user to read the log file.

Required Privilege Level

storage—To view this statement in the configuration.
storage-control—To add this statement to the configuration.

Configuration Statements (ELS CLI for Platforms that Support FCoE Only)

examine-vn2vf

Syntax examine-vn2vf

Hierarchy Level [edit vlans *vlan-name* forwarding-options fip-security]

Release Information Statement introduced for the ELS CLI in Junos OS Release 13.2 for the QFX Series.

Description

NOTE: This statement supports the Enhanced Layer 2 Software (ELS) CLI. If your switch runs the original (non-ELS) software, see examine-fip. For ELS details, see "Getting Started with Enhanced Layer 2 Software" on page 58.

Enable VN_Port to VF_Port (VN2VF_Port) FIP snooping on the specified VLAN. Ensure that the VLAN is a dedicated FCoE VLAN that transports only FCoE traffic.

If the switch also performs VN_Port to VN_Port (VN2VN_Port) FIP snooping, ensure that the VN2VN_Port traffic is on a different VLAN than the VN2VF_Port traffic. You cannot mix VN2VF_Port and VN2VN_Port traffic in the same VLAN, so you must use separate VLANs for VN2VF_Port and VN2VN_Port traffic.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- examine-vn2vn on page 5098

- Understanding FCoE Transit Switch Functionality on page 4804
- Configuring VN2VF_Port FIP Snooping and FCoE Trusted Interfaces on an FCoE Transit Switch on page 5069

interface (FIP Snooping)

Syntax
```
interface interface-name {
  (fcoe-trusted| no-fcoe-trusted);
}
```

Hierarchy Level [edit vlans *vlan-name* forwarding-options fip-security]

Release Information Statement introduced for the ELS CLI in Junos OS Release 13.2 for the QFX Series.

Description

NOTE: This statement supports the Enhanced Layer 2 Software (ELS) CLI. If your switch runs the original (non-ELS) software, see interface (Secure Access Port) for how to specify an interface to configure as FCoE trusted or FCoE untrusted. For ELS details, see "Getting Started with Enhanced Layer 2 Software" on page 58.

Specify an interface to set as FCoE trusted or as FCoE untrusted. Configure interfaces that connect to other switches as trusted interfaces. Configure interfaces that connect directly to FCoE devices as untrusted interfaces and enabled FIP snooping on the untrusted interfaces to prevent unauthorized access to the storage network.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Configuring VN2VF_Port FIP Snooping and FCoE Trusted Interfaces on an FCoE Transit Switch on page 5069
- Understanding FCoE Transit Switch Functionality on page 4804

fip-security

Syntax

```
fip-security {
  examine-vn2vf;
  examine-vn2vn {
    beacon-period milliseconds;
  }
  fc-map fc-map-value;
  interface interface-name {
    (fcoe-trusted | no-fcoe-trusted;)
  }
}
```

Hierarchy Level [edit vlans *vlan-name* forwarding-options]

Release Information Statement introduced for the ELS CLI in Junos OS Release 13.2 for the QFX Series.

Description

NOTE: This statement supports the Enhanced Layer 2 Software (ELS) CLI. If your switch runs the original (non-ELS) software, see examine-fip. For ELS details, see "Getting Started with Enhanced Layer 2 Software" on page 58.

Configure FIP snooping and FCoE interface properties.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

CHAPTER 60

Administration

Routine Monitoring

Monitoring Fibre Channel Interface Load Balancing

You can use operational mode commands to monitor load balancing when the switch is in FCoE-FC gateway mode:

Monitoring the Interface Load-Balancing State

Purpose Monitor the number of sessions, whether load balancing is enabled or disabled, and the load-balancing weight for each native Fibre Channel (FC) interface.

NOTE: A session is a FLOGI or FDISC login to the FC SAN fabric. Session does not refer to end-to-end storage sessions.

Action To monitor the load-balancing state of the native FC interfaces in the CLI, enter the following CLI command:

user@switch> **show fibre-channel proxy np-port**

For example:

```
user@switch> show fibre-channel proxy np-port
Fabric: sanfab1, Fabric-id: 10
NP-Port      State              Sessions       LB state   LB weight
fc-0/0/0.0   online             5              ON         4
fc-0/0/1.0   online             5              ON         4
fc-0/0/2.0   online             10             ON         8

Fabric: fc_fab2, Fabric-id: 200
```

```
NP-Port      State             Sessions      LB state    LB weight
fc-0/0/44.0 isolated           0             OFF         0

Fabric: fc_fabric_100, Fabric-id: 100
NP-Port      State             Sessions      LB state    LB weight
fc-0/0/46.0 online             1             ON          8
```

Meaning Table 392 on page 5148 summarizes key output fields for the FC interface load-balancing state.

Table 392: Summary of Key FC Interface Load-Balancing Output Fields

Field	Values
Fabric	Name of the fabric.
Fabric-id	Fabric ID number.
NP-Port	NP_Port interface connected to the FCoE forwarder (FCF) or the FC switch.
State	FCID state of the NP_Port interface: • **online**—The port is online and connected to the FC switch. FCoE devices can log in to the FC switch using this port. • **isolated**—The port is isolated and is not part of the load-balancing function. FCoE devices cannot log in to the FC switch using this port. • **offline**—The port is offline.
Sessions	Number of active sessions on the NP_Port interface.
LB state	Load-balancing state: • **On**—Load balancing is on • **Off**—Load balancing is off.
LB weight	Load-balancing weight, which reflects the port speed: • **2**—Port speed is 2 Gbps. • **4**—Port speed is 4 Gbps. • **8**—Port speed is 8 Gbps.

The gateway determines the least-loaded interface using the following weighted round-robin (WRR) algorithm:

(number-of-sessions * max-weight) / weight

where *max-weight* is an internal constant. If the load on the FC interfaces is equal, the session is assigned to the interface with the highest link speed (the greatest weight).

Monitoring the Fabric Load-Balancing Algorithm

Purpose Monitor the type of load-balancing algorithm (simple, ENode-based, or FLOGI-based) used on the native FC interfaces, whether or not automated load rebalancing is enabled, and the load rebalancing state of the fabric.

Action To monitor the load-balancing algorithm used on the native FC interfaces and the load rebalancing state in the CLI, enter the following CLI command:

user@switch> **show fibre-channel proxy fabric-state**

For example:

```
user@switch> show fibre-channel proxy fabric-state
Fabric: sanfab1, Fabric-id: 10
Proxy load balance algorithm: Simple, Fabric WWN verification: Yes
Auto load rebalance enabled  : No
Last rebalance start-time    : Never
Last rebalance end-time      : Never
Last rebalance trigger       : Link-up
Last rebalance trigger-time  : Mon Sep 10 21:42:30 2012 usec: 814602
Last rebalance trigger-result: Not-configured

Fabric: fc_fab2, Fabric-id: 200
Proxy load balance algorithm: ENode based, Fabric WWN verification: Yes
Auto load rebalance enabled  : No
Last rebalance start-time    : Never
Last rebalance end-time      : Never
Last rebalance trigger       : Link-up
Last rebalance trigger-time  : Mon Sep 17 17:23:35 2012 usec: 619684
Last rebalance trigger-result: Not-configured

Fabric: fc_fabric_100, Fabric-id: 100
Proxy load balance algorithm: FLOGI based, Fabric WWN verification: No
Auto load rebalance enabled  : Yes
Last rebalance start-time    : Never
Last rebalance end-time      : Never
Last rebalance trigger       : Config-CLI
Last rebalance trigger-time  : Fri Nov  2 08:56:16 2012 usec: 004487
Last rebalance trigger-result: Not-required
```

Meaning You can configure each local FC fabric on an FCoE-FC gateway to use one of three types of load-balancing algorithms, *simple*, *ENode-based*, or *FLOGI-based*. All of the native FC interfaces (NP_Ports) in a particular gateway FC fabric use the same load-balancing algorithm (the load-balancing algorithm is applied on a per-fabric basis).

Table 393 on page 5149 summarizes key output fields for the FC interface load-balancing algorithm and state.

Table 393: show fibre-channel proxy fabric-state Output Fields

Field Name	Field Description
Fabric	Name of the fabric.
Fabric-id	Fabric ID number.

Table 393: show fibre-channel proxy fabric-state Output Fields *(continued)*

Field Name	Field Description
Proxy load balance algorithm	Load-balancing algorithm used on the FCoE-FC gateway FC fabric: • Simple—Load balancing is based on the weighted utilization (load) of the NP_Ports connected to an FC fabric. Each new FLOGI or FDISC is assigned to the least-loaded link. On a link load rebalance, only the sessions that need to be moved to another link are logged out. When those sessions log in again, they are placed on active NP_Port interfaces in a balanced manner. • ENode-based—Load balancing is based on the ENode FLOGI. When an ENode logs in to the fabric, all subsequent FDISC sessions (VN_Port sessions) associated with that ENode are placed on the same link as the ENode FLOGI session, regardless of the link load. New ENode FLOGIs are placed on the least-loaded link. On a link load rebalance, all sessions are logged out. When the sessions log in again, they are placed on active NP_Port interfaces in a balanced manner. • FLOGI-based—Load balancing is based on the ENode FLOGI. When an ENode logs in to the fabric, all subsequent FDISC sessions (VN_Port sessions) associated with that ENode are placed on the same link as the ENode FLOGI session, regardless of the link load. New ENode FLOGIs are placed on the least-loaded link. On a link load rebalance, only the sessions that need to be moved to another link are logged out. When those sessions log in again, they are placed on active NP_Port interfaces in a balanced manner.
Fabric WWN verification	Fabric worldwide name (WWN) verification check state on the FCoE-FC gateway fabric: • Yes—Fabric WWN verification check is enabled. • No—Fabric WWN verification check is disabled.
Auto load rebalance enabled	Automated link load rebalancing configuration for the FCoE-FC gateway fabric: • No—Automated load balancing is disabled (default state). • Yes—Automated load balancing is enabled.
Last rebalance start-time	Time that the last link load rebalance began on the FCoE-FC gateway fabric: • Never—The link load has never been rebalanced. • Timestamp value—Time the last link load rebalancing started.
Last rebalance end-time	Time that the last link load rebalance ended on the FCoE-FC gateway fabric: • Never—The link load has never been rebalanced. • Timestamp value—Time the last link load rebalancing ended.

Table 393: show fibre-channel proxy fabric-state Output Fields *(continued)*

Field Name	Field Description
Last rebalance trigger	Event that triggered the last link load rebalance on the FCoE-FC gateway fabric: • None—The link load has never been rebalanced. • Config-CLI—Configure (enable) automated load balancing. • Request-CLI—Rebalance requested from the CLI using the **request fibre-channel proxy load-rebalance fabric *fabric-name*** operational command. • Preview-CLI—Rebalancing *dry run* requested from the CLI using the **request fibre-channel proxy load-rebalance dry-run fabric *fabric-name*** operational command. Indicates that the switch completed the dry run. A dry run simulates a link load rebalance and displays a list of sessions that might be affected if you request an actual rebalance. • Link-up—New FC link (NP_Port) up on the FCoE-FC gateway fabric, which causes a rebalance to distribute sessions to the new link. • Restore-complete—If the FC process on the switch restarts, the switch attempts to restore the session state that existed before the restart. When automated rebalance is enabled, restore-complete indicates that the sessions have been restored and rebalanced.
Last rebalance trigger-time	Time that the last link load rebalance was triggered on the FCoE-FC gateway fabric: • Never—Link load rebalancing has never been triggered. • Timestamp value—Time the last link load rebalancing was triggered.
Last rebalance trigger-result	Result of the last trigger event on the FCoE-FC gateway fabric: • Never—Link load rebalancing has never been triggered. • Not-configured—Automated rebalancing is not configured on the FCoE-FC gateway fabric. • Not-required—Last rebalance trigger did not require rebalancing the link load (the link load was already balanced across the active NP_Port links). • In-progress—Link load rebalancing is in progress and has not finished yet. • Restore-in-progress—The switch is recovering from an FC process restart and is in the process of restoring the sessions to the active NP_Port links. • Success—Link load rebalancing was successful. • Logged-out-all—All sessions have been logged out. • Preview-complete—The switch has finished simulating a dry run rebalancing request from the CLI (**request fibre-channel proxy load-rebalance dry-run fabric *fabric-name*** operational command) and reported the sessions that might be affected if you request an actual link load rebalance. • Fabric-deletion-in-progress—FCoE-FC gateway fabric is in the process of being deleted. NOTE: A trigger event does not necessarily result in a rebalance action. Link load rebalancing only occurs if the NP_Port interface session load is not balanced at the time of the trigger event.

clear fibre-channel fc2 statistics

Syntax

clear fibre-channel fc2 statistics
<fabric *fabric-name*>

Release Information

Command introduced in Junos OS Release 11.1 for the QFX Series.

Description

Clear FC-2 (network layer) Fibre Channel statistics globally or on a specified Fibre Channel fabric.

Options

fabric *fabric-name*—(Optional) Clear FC-2 statistics only on the specified fabric.

Required Privilege Level

view

Related Documentation

Sample Output

clear fibre-channel fc2 statistics

```
user@switch> clear fibre-channel fc2 statistics
```

clear fibre-channel fip enode

Syntax **clear fibre-channel fip enode** ***enode-mac***

Release Information Command introduced in Junos OS Release 11.1 for the QFX Series.

Description Clear Fibre Channel over Ethernet (FCoE) node (ENode) information for a specified ENode. This operation deletes the ENode state from the switch database and from the FIP snooping firewall filters, which causes the ENode to lose the connection to the Fibre Channel (FC) fabric and to log in to the fabric again. If you clear an ENode, all VN_Ports associated with that ENode are also cleared and lose their connection to the FC fabric and must log in to the fabric again.

Options *enode-mac*—MAC address of the ENode.

clear fibre-channel fip vn-port

Syntax **clear fibre-channel fip vn-port** ***vn-port--mac***

Release Information Command introduced in Junos OS Release 11.1 for the QFX Series.

Description Clear virtual N_Port (VN_Port) information for a specified VN_Port. This operation deletes the VN_Port state from the switch database and from the FIP snooping firewall filters, which causes the VN_Port to lose its connection to the Fibre Channel fabric and to log in to the fabric again. When you clear a VN_Port, other VN_Ports associated with the same Fibre Channel over Ethernet (FCoE) Node (ENode) are not affected and are not cleared.

Options ***vn-port-mac***—MAC address of the VN_Port.

clear fip snooping vlan

Syntax **clear fip snooping vlan** ***vlan-name***

Release Information Command introduced in Junos OS Release 10.4 for EX Series switches.
Command introduced in Junos OS Release 11.1 for the QFX Series.

Description Clear FIP snooping information for the specified VLAN. This operation deletes all ENode and FCF information for the VLAN from the switch database and causes the ENodes to lose their connections to the FCFs. After clearing a VLAN, the switch relearns all of the FCFs and ENodes on the VLAN, and the ENodes must log in to the FCF again.

Options ***vlan-name***—Name of the VLAN.

request fibre-channel proxy load-rebalance

Syntax

request fibre-channel proxy load-rebalance
<dry-run>
fabric <*fabric-name*>
<brief | detail>

Release Information

Command introduced in Junos OS Release 12.3 for the QFX Series.

Description

Rebalance the link load on one or more FCoE-FC gateway proxy fabrics (local Fibre Channel fabrics on the gateway) on demand. Load rebalancing is a disruptive action that forces some or all sessions (depending on the configured load-balancing algorithm) to log out and then log in again. When sessions log in again, they are placed on NP_Port interfaces so that the link loads are balanced.

Link load rebalancing occurs 10 seconds after you run the rebalancing command, unless another rebalancing trigger occurs before the 10 seconds elapse. If another rebalancing event occurs before the 10-second timer elapses, the timer is extended. Rebalancing occurs a maximum of 30 seconds after you run the rebalancing command, regardless of whether more rebalancing events occur.

You can also perform a *dry run* to see a list of sessions that might be affected (logged out) if you request a load rebalance. A dry run does not rebalance the link loads; it only lists the sessions that might be affected if you rebalance.

Options

dry-run—(Optional) Simulates performing link load rebalancing and displays a list of sessions that might be affected if you rebalance the link loads.

fabric *fabric-name*—Name of the fabric on which you want to rebalance the link loads. If you do not specify a fabric name with the fabric keyword, all fabrics on the FCoE-FC gateway rebalance their link loads.

brief | detail—(Optional) Display the specified level of output.

Additional Information

Requesting link load rebalancing is a one-time, on-demand operation. You must explicitly request load rebalancing every time you want to rebalance the link loads. Alternatively, you can configure automated load rebalancing if you want the NP_Port links to be rebalanced automatically whenever a load-rebalancing trigger occurs.

Output Fields Table 394 on page 5165 lists the output fields for the **request fibre-channel proxy load-rebalance dry-run** command. Output fields are listed in the approximate order in which they appear.

Table 394: request fibre-channel proxy load-rebalance dry-run Output Fields

Field Name	Field Description
Fabric	Name of the fabric.
Fabric-id	Fabric ID number.
F-Port	FCoE VLAN interface (VF_Port interface to the FCoE network).
FCID	VN_Port Fibre Channel identifier provided by the Fibre Channel over Ethernet Forwarder (FCoE forwarder) or the Fibre Channel switch.
Port-WWN	Unique worldwide name (WWN) of the VN_Port.
NP-Port	Name of the native Fibre Channel interface.

Sample Output

request fibre-channel proxy load-rebalance dry-run fabric fc_fabric_100

```
user@host> request fibre-channel proxy load-rebalance dry-run fabric fc_fabric_100
Fabric: fc_fabric_100, Fabric-id: 100

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
Command introduced in Junos OS Release 11.1 for the QFX Series.
Command introduced in Junos OS Release 12.2 for ACX Series routers.
Options added:

- **dynamic-flow-capture** in Junos OS Release 7.4.
- **dlsw** in Junos OS Release 7.5.
- **event-processing** in Junos OS Release 7.5.
- **ppp** in Junos OS Release 7.5.
- **l2ald** in Junos OS Release 8.0.
- **link-management** in Release 8.0.
- **pgcp-service** in Junos OS Release 8.4.
- **sbc-configuration-process** in Junos OS Release 9.5.
- **services pgcp gateway** in Junos OS Release 9.6.
- **sfc** and **all-sfc** for the TX Matrix Router in Junos OS Release 9.6.

Description

Restart a Junos OS process.

CAUTION: Never restart a software process unless instructed to do so by a customer support engineer. A restart might cause the router or switch to drop calls and interrupt transmission, resulting in possible loss of data.

Options

none—Same as **gracefully**.

adaptive-services—(Optional) Restart the configuration management process that manages the configuration for stateful firewall, Network Address Translation (NAT), intrusion detection services (IDS), and IP Security (IPsec) services on the Adaptive Services PIC.

all-chassis—(TX Matrix and TX Matrix Plus routers only) (Optional) Restart the software process on all chassis.

all-lcc—(TX Matrix and TX Matrix Plus routers only) (Optional) For a TX Matrix router, restart the software process on all T640 routers connected to the TX Matrix router. For a TX Matrix Plus router, restart the software process on all T1600 routers connected to the TX Matrix Plus router.

all-members—(MX Series routers only) (Optional) Restart the software process for all members of the Virtual Chassis configuration.

all-sfc—(TX Matrix Plus routers only) (Optional) For a TX Matrix Plus router, restart the software processes for the TX Matrix Plus router (or switch-fabric chassis).

ancpd-service—(Optional) Restart the Access Node Control Protocol (ANCP) process, which works with a special Internet Group Management Protocol (IGMP) session to collect outgoing interface mapping events in a scalable manner.

application-identification—(Optional) Restart the process that identifies an application using intrusion detection and prevention (IDP) to allow or deny traffic based on applications running on standard or nonstandard ports.

audit-process—(Optional) Restart the RADIUS accounting process that gathers statistical data that can be used for general network monitoring, analyzing, and tracking usage patterns, for billing a user based on the amount of time or type of services accessed.

auto-configuration—(Optional) Restart the Interface Auto-Configuration process.

autoinstallation—(EX Series switches only) (Optional) Restart the autoinstallation process.

captive-portal-content-delivery—(Optional) Restart the HTTP redirect service by specifying the location to which a subscriber's initial Web browser session is redirected, enabling initial provisioning and service selection for the subscriber.

ce-l2tp-service—(M10, M10i, M7i, and MX Series routers only) (Optional) Restart the Universal Edge Layer 2 Tunneling Protocol (L2TP) process, which establishes L2TP tunnels and Point-to-Point Protocol (PPP) sessions through L2TP tunnels.

chassis-control—(Optional) Restart the chassis management process.

class-of-service—(Optional) Restart the class-of-service (CoS) process, which controls the router's or switch’s CoS configuration.

clksyncd-service—(Optional) Restart the external clock synchronization process, which uses synchronous Ethernet (SyncE).

database-replication—(EX Series switches and MX Series routers only) (Optional) Restart the database replication process.

datapath-trace-service—(Optional) Restart the packet path tracing process.

dhcp—(J Series routers and EX Series switches only) (Optional) Restart the software process for a Dynamic Host Configuration Protocol (DHCP) server. A DHCP server allocates network IP addresses and delivers configuration settings to client hosts without user intervention.

dhcp-service—(Optional) Restart the Dynamic Host Configuration Protocol process.

dialer-services—(J Series routers and EX Series switches only) (Optional) Restart the ISDN dial-out process.

diameter-service—(Optional) Restart the diameter process.

disk-monitoring—(Optional) Restart disk monitoring, which checks the health of the hard disk drive on the Routing Engine.

dlsw—(J Series routers and QFX Series only) (Optional) Restart the data link switching (DLSw) service.

dot1x-protocol—(EX Series switches only) (Optional) Restart the port-based network access control process.

dynamic-flow-capture—(Optional) Restart the dynamic flow capture (DFC) process, which controls DFC configurations on Monitoring Services III PICs.

ecc-error-logging—(Optional) Restart the error checking and correction (ECC) process, which logs ECC parity errors in memory on the Routing Engine.

ethernet-connectivity-fault-management—(Optional) Restart the process that provides IEEE 802.1ag Operation, Administration, and Management (OAM) connectivity fault management (CFM) database information for CFM maintenance association end points (MEPs) in a CFM session.

ethernet-link-fault-management—(EX Series switches and MX Series routers only) (Optional) Restart the process that provides the OAM link fault management (LFM) information for Ethernet interfaces.

ethernet-switching—(EX Series switches only) (Optional) Restart the Ethernet switching process.

event-processing—(Optional) Restart the event process (eventd).

fibre-channel—(QFX Series only) (Optional) Restart the Fibre Channel process.

firewall—(Optional) Restart the firewall management process, which manages the firewall configuration and enables accepting or rejecting packets that are transiting an interface on a router or switch.

general-authentication-service—(EX Series switches and MX Series routers only) (Optional) Restart the general authentication process.

gracefully—(Optional) Restart the software process.

iccp-service—(Optional) Restart the Inter-Chassis Communication Protocol (ICCP) process.

idp-policy—(Optional) Restart the intrusion detection and prevention (IDP) protocol process.

immediately—(Optional) Immediately restart the software process.

interface-control—(Optional) Restart the interface process, which controls the router's or switch's physical interface devices and logical interfaces.

ipsec-key-management—(Optional) Restart the IPsec key management process.

isdn-signaling—(J Series routers and QFX Series only) (Optional) Restart the ISDN signaling process, which initiates ISDN connections.

kernel-replication—(Optional) Restart the kernel replication process, which replicates the state of the backup Routing Engine when graceful Routing Engine switchover (GRES) is configured.

l2-learning—(Optional) Restart the Layer 2 address flooding and learning process.

l2cpd-service—(Optional) Restart the Layer 2 Control Protocol process, which enables features such as Layer 2 protocol tunneling and nonstop bridging.

l2tp-service— (M10, M10i, M7i, and MX Series routers only) (Optional) Restart the Layer 2 Tunneling Protocol (L2TP) process, which sets up client services for establishing Point-to-Point Protocol (PPP) tunnels across a network and negotiating Multilink PPP if it is implemented.

l2tp-universal-edge—(MX Series routers only) (Optional) Restart the L2TP process, which establishes L2TP tunnels and PPP sessions through L2TP tunnels.

lacp—(Optional) Restart the Link Aggregation Control Protocol (LACP) process. LACP provides a standardized means for exchanging information between partner systems on a link to allow their link aggregation control instances to reach agreement on the identity of the LAG to which the link belongs, and then to move the link to that LAG, and to enable the transmission and reception processes for the link to function in an orderly manner.

lcc *number*—(TX Matrix and TX Matrix Plus routers only) (Optional) For a TX Matrix router, restart the software process for a specific T640 router that is connected to the TX Matrix router. For a TX Matrix Plus router, restart the software process for a specific router that is connected to the TX Matrix Plus router.

Replace *number* with the following values depending on the LCC configuration:

- 0 through 3, when T640 routers are connected to a TX Matrix router in a routing matrix.
- 0 through 3, when T1600 routers are connected to a TX Matrix Plus router in a routing matrix.
- 0 through 7, when T1600 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix.
- 0, 2, 4, or 6, when T4000 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix.

license-service—(EX Series switches only) (Optional) Restart the feature license management process.

link-management— (TX Matrix and TX Matrix Plus routers and EX Series switches only) (Optional) Restart the Link Management Protocol (LMP) process, which establishes and maintains LMP control channels.

lldpd-service—(EX Series switches only) (Optional) Restart the Link Layer Discovery Protocol (LLDP) process.

local—(MX Series routers only) (Optional) Restart the software process for the local Virtual Chassis member.

local-policy-decision-function— (Optional) Restart the process for the Local Policy Decision Function, which regulates collection of statistics related to applications and application groups and tracking of information about dynamic subscribers and static interfaces.

mac-validation— (Optional) Restart the Media Access Control (MAC) validation process, which configures MAC address validation for subscriber interfaces created on demux interfaces in dynamic profiles on MX Series routers.

member *member-id*—(MX Series routers only) (Optional) Restart the software process for a specific member of the Virtual Chassis configuration. Replace ***member-id*** with a value of **0** or **1**.

mib-process—(Optional) Restart the Management Information Base (MIB) version II process, which provides the router's MIB II agent.

mobile-ip—(Optional) Restart the Mobile IP process, which configures Junos OS Mobile IP features.

mountd-service—(EX Series switches and MX Series routers only) (Optional) Restart the service for NFS mount requests.

mpls-traceroute—(Optional) Restart the MPLS Periodic Traceroute process.

mspd—(Optional) Restart the Multiservice process.

multicast-snooping—(EX Series switches and MX Series routers only) (Optional) Restart the multicast snooping process, which makes Layer 2 devices, such as VLAN switches, aware of Layer 3 information, such as the media access control (MAC) addresses of members of a multicast group.

named-service—(Optional) Restart the DNS Server process, which is used by a router or a switch to resolve hostnames into addresses.

network-access-service—(J Series routers and QFX Series only) (Optional) Restart the network access process, which provides the router's Challenge Handshake Authentication Protocol (CHAP) authentication service.

nfsd-service—(Optional) Restart the Remote NFS Server process, which provides remote file access for applications that need NFS-based transport.

packet-triggered-subscribers—(Optional) Restart the packet-triggered subscribers and policy control (PTSP) process, which allows the application of policies to dynamic subscribers that are controlled by a subscriber termination device.

peer-selection-service—(Optional) Restart the Peer Selection Service process.

pgcp-service—(Optional) Restart the pgcpd service process running on the Routing Engine. This option does not restart pgcpd processes running on mobile station PICs. To restart pgcpd processes running on mobile station PICs, use the **services pgcp gateway** option.

pgm—(Optional) Restart the process that implements the Pragmatic General Multicast (PGM) protocol for assisting in the reliable delivery of multicast packets.

pic-services-logging—(Optional) Restart the logging process for some PICs. With this process, also known as fsad (the file system access daemon), PICs send special logging information to the Routing Engine for archiving on the hard disk.

pki-service—(Optional) Restart the PKI Service process.

ppp—(Optional) Restart the Point-to-Point Protocol (PPP) process, which is the encapsulation protocol process for transporting IP traffic across point-to-point links.

ppp-service—(Optional) Restart the Universal Edge PPP process, which is the encapsulation protocol process for transporting IP traffic across Universal Edge routers.

pppoe—(Optional) Restart the Point-to-Point Protocol over Ethernet (PPPoE) process, which combines PPP that typically runs over broadband connections with the Ethernet link-layer protocol that allows users to connect to a network of hosts over a bridge or access concentrator.

protected-system-domain-service—(Optional) Restart the Protected System Domain (PSD) process.

redundancy-interface-process—(Optional) Restart the ASP redundancy process.

remote-operations—(Optional) Restart the remote operations process, which provides the ping and traceroute MIBs.

root-system-domain-service—(Optional) Restart the Root System Domain (RSD) service.

routing—(ACX Series routers, QFX Series, EX Series switches, and MX Series routers only) (Optional) Restart the routing protocol process.

routing <logical-system *logical-system-name*>—(Optional) Restart the routing protocol process, which controls the routing protocols that run on the router or switch and maintains the routing tables. Optionally, restart the routing protocol process for the specified logical system only.

sampling—(Optional) Restart the sampling process, which performs packet sampling based on particular input interfaces and various fields in the packet header.

sbc-configuration-process—(Optional) Restart the session border controller (SBC) process of the border signaling gateway (BSG).

scc—(TX Matrix routers only) (Optional) Restart the software process on the TX Matrix router (or switch-card chassis).

sdk-service—(Optional) Restart the SDK Service process, which runs on the Routing Engine and is responsible for communications between the SDK application and Junos OS. Although the SDK Service process is present on the router, it is turned off by default.

secure-neighbor-discovery—(QFX Series, EX Series switches, and MX Series routers only) (Optional) Restart the secure Neighbor Discovery Protocol (NDP) process, which provides support for protecting NDP messages.

sfc *number*—(TX Matrix Plus routers only) (Optional) Restart the software process on the TX Matrix Plus router (or switch-fabric chassis). Replace ***number*** with **0**.

service-deployment—(Optional) Restart the service deployment process, which enables Junos OS to work with the Session and Resource Control (SRC) software.

services—(Optional) Restart a service.

services pgcp gateway *gateway-name*—(Optional) Restart the pgcpd process for a specific border gateway function (BGF) running on an MS-PIC. This option does not restart the pgcpd process running on the Routing Engine. To restart the pgcpd process on the Routing Engine, use the **pgcp-service** option.

sflow-service—(EX Series switches only) (Optional) Restart the flow sampling (sFlow technology) process.

snmp—(Optional) Restart the SNMP process, which enables the monitoring of network devices from a central location and provides the router's or switch's SNMP master agent.

soft—(Optional) Reread and reactivate the configuration without completely restarting the software processes. For example, BGP peers stay up and the routing table stays constant. Omitting this option results in a graceful restart of the software process.

static-subscribers—(Optional) Restart the static subscribers process, which associates subscribers with statically configured interfaces and provides dynamic service activation and activation for these subscribers.

statistics-service—(Optional) Restart the process that manages the Packet Forwarding Engine statistics.

subscriber-management—(Optional) Restart the Subscriber Management process.

subscriber-management-helper—(Optional) Restart the Subscriber Management Helper process.

tunnel-oamd—(Optional) Restart the Tunnel OAM process, which enables the Operations, Administration, and Maintenance of Layer 2 tunneled networks. Layer 2 protocol tunneling (L2PT) allows service providers to send Layer 2 PDUs across the provider's cloud and deliver them to Juniper Networks EX Series Ethernet Switches that are not part of the local broadcast domain.

usb-control—(J Series routers and MX Series routers only) (Optional) Restart the USB control process.

vrrp—(ACX Series routers, EX Series switches, and MX Series routers only) (Optional) Restart the Virtual Router Redundancy Protocol (VRRP) process, which enables hosts on a LAN to make use of redundant routing platforms on that LAN without requiring more than the static configuration of a single default route on the hosts.

web-management—(J Series routers, QFX Series, EX Series switches, and MX Series routers only) (Optional) Restart the Web management process.

List of Sample Output restart interfaces on page 5175

Output Fields When you enter this command, you are provided feedback on the status of your request.

Sample Output

restart interfaces

```
user@host> restart interfaces
interfaces process terminated
interfaces process restarted
```

show dcbx

Syntax show dcbx

Release Information Command introduced in Junos OS Release 11.3 for the QFX Series.

Description List DCBX status (enabled or disabled) and the interfaces on which DCBX is enabled.

Required Privilege Level view

Related Documentation

- show dcbx neighbors on page 5177
- Configuring DCBX Autonegotiation on page 5076

Output Fields Table 395 on page 5176 lists the output fields for the **show dcbx** command. Output fields are listed in the approximate order in which they appear.

Table 395: show dcbx output fields

Field Name	Field Description
DCBX	Status of DCBX on the switch or for the specified interface: • Enabled—DCBX is enabled on the switch or on the specified interface • Disabled—DCBX is disabled on the switch or on the specified interface
Interface	Name of the interface

Sample Output

show dcbx

```
user@switch> show dcbx
DCBX                         : Enabled
Interface        DCBX
xe-0/0/9.0       enabled
xe-0/0/32.0      enabled
xe-0/0/36.0      enabled
```

show dcbx neighbors

Syntax

show dcbx neighbors
<interface ***interface-name*****>**
<terse>

Release Information

Command introduced in Junos OS Release 11.1 for the QFX Series.
Command introduced in Junos OS Release 11.3 for EX Series switches.

Description

Display information about Data Center Bridging Capability Exchange protocol (DCBX) neighbor interfaces.

Options

none—Display information about all DCBX neighbor interfaces.

interface-name—(Optional) Display information for the specified interface.

terse—Display the specified level of output.

Required Privilege Level

Output Fields

Table 396 on page 5177 lists the output fields for the **show dcbx neighbors** command. Output fields are listed in the approximate order in which they appear.

Table 396: show dcbx neighbors Output Fields

Field Name	Field Description
Interface	Name of the interface.

Table 396: show dcbx neighbors Output Fields *(continued)*

Field Name		Field Description
Parent Interface		Name of the link aggregation group (LAG) interface to which the DCBX interface belongs.
Active-application-map		Name of the application map applied to the interface.
Protocol-Mode		(QFX Series) DCBX protocol mode the interface uses: • IEEE DCBX Version—The interface uses IEEE DCBX mode. • DCBX Version 1.01—The interface uses DCBX version 1.01. NOTE: On interfaces that use the IEEE DCBX mode, the **show dcbx neighbors interface** ***interface-name*** operational command does not include application, PFC, or ETS operational state in the output.
Protocol-State		(DCBX Version 1.01 only) DCBX protocol state synchronization status: • **in-sync**—The local interface received an acknowledge message from the peer to indicate that the peer received a state change message sent by the local interface. • **ack-pending**—The local interface has not yet received an acknowledge message from the peer to indicate that the peer received a state change message sent by the local interface.
Local-Advertisement		(DCBX Version 1.01 only) Status of advertisements that the local interface sends to the peer.
	Operational version	Version of the DCBX standard used.
	sequence-number	Number of state change messages sent to the peer. If the interface **Protocol-State** value is **in-sync**, this number should match the **acknowledge-id** number in the **Peer-Advertisement** section. If the interface **Protocol-State** value is **ack-pending**, this number does not match the **acknowledge-id** number in the **Peer-Advertisement** section.
	acknowledge-id	Number of acknowledge messages received from the peer. If the **Protocol-State** value is **in-sync**, this number should match the **sequence-number** value in the **Peer-Advertisement** section. If the **Protocol-State** value is **ack-pending**, this number does not match the **sequence-number** value in the **Peer-Advertisement** section.

Table 396: show dcbx neighbors Output Fields *(continued)*

Field Name		Field Description
Peer-Advertisement		(DCBX Version 1.01 only) Status of advertisements that the peer sends to the local interface.
	Operational version	Version of the DCBX standard used.
	sequence-number	Number of state change messages the peer sent to the local interface. If this number matches the **acknowledge-id** number in the **Local-Advertisement** field, this indicates that the local interface has acknowledged all of the peer's state change messages and is synchronized. If this number does not match the **acknowledge-id** number in the **Local-Advertisement** field, this indicates that the peer has not yet received an acknowledgment for a state change message from the local interface.
	acknowledge-id	Number of acknowledge messages the peer has received from the local interface. If this number matches the **sequence-number** value in the **Local-Advertisement** field, this indicates that the peer has acknowledged all of the local interface's state change messages and is in synchronization. If this number does not match the **sequence-number** value in the **Local-Advertisement** field, this indicates that the peer has not yet sent an acknowledgment for a state change message from the local interface.

Table 396: show dcbx neighbors Output Fields *(continued)*

Field Name			Field Description
Feature: PFC			Priority-based flow control (PFC) feature DCBX state information.
	Protocol-State		(DCBX Version 1.01 only) DCBX protocol state synchronization status: • **ack-pending**—The local interface has not yet received an acknowledge message from the peer to indicate that the peer received a PFC state change message sent by the local interface. • **in-sync**—The local interface received an acknowledge message from the peer to indicate that the peer received a PFC state change message sent by the local interface. • **not-applicable**—PFC autonegotiation is disabled.
	Operational State		(DCBX Version 1.01 only) Operational state of the feature: **enabled** or **disabled**.
	Local-Advertisement		Status of advertisements that the local interface sends to the peer.
		Enable	(DCBX Version 1.01 only) State that the local interface advertises to the peer: • **Yes**—The feature is enabled. • **No**—The feature is disabled.
		Willing	Willingness of the local interface to learn the PFC configuration from the peer using DCBX: • **Yes**—The local interface is willing to learn the PFC configuration from the peer. • **No**—The local interface is not willing to learn the PFC configuration from the peer.
		Mac auth Bypass Capability	(IEEE DCBX only) (QFX Series) Media access controller (MAC) authentication bypass provides access to devices based on MAC address authentication. This is not supported, so the only value seen in the local advertisement field is **no**.
		Error	(DCBX Version 1.01 only) Configuration compatibility error status: • **No**—No error detected. Local and peer configuration are compatible. • **Yes**—Error detected. Local and peer configuration are not compatible.

Table 396: show dcbx neighbors Output Fields *(continued)*

Field Name		Field Description
	Operational State	PFC operational state on the interface: • Enabled—PFC is enabled on the interface • Disabled—PFC is disabled on the interface
	Maximum Traffic Classes capable to support PFC	Largest number of traffic classes the local interface supports for PFC: • **6** (EX Series switches) • **8** (QFX Series)
	Code Point	PFC code point, which is specified in the 3-bit class-of-service field in the VLAN header.
	Admin Mode	PFC administrative state for each code point on the local interface: • **Enabled**—PFC is enabled for the code point. • **Disabled**—PFC is disabled for the code point.
	Operational Mode	(QFX Series) PFC operational mode for each code point: • Enable—PFC is enabled on the code point. • Disable—PFC is disabled on the code point.
Peer-Advertisement		Status of advertisements that the peer sends to the local interface.
	Enable	(DCBX Version 1.01 only) State that the peer advertises to the local interface: • **Yes**—The feature is enabled. • **No**—The feature is disabled.
	Willing	Willingness of the peer to learn the PFC configuration from the local interface using DCBX: • **Yes**—The peer is willing to learn the PFC configuration from the local interface. • **No**—The peer is not willing to learn the PFC configuration from the local interface.
	Error	(DCBX Version 1.01 only) Configuration compatibility error status: • **No**—No error detected. Local and peer configuration are compatible. • **Yes**—Error detected. Local and peer configuration are not compatible.

Table 396: show dcbx neighbors Output Fields *(continued)*

Field Name		Field Description
	Operational State	PFC operational state on the interface: • Enabled—PFC is enabled on the interface • Disabled—PFC is disabled on the interface
	Mac auth Bypass Capability	(IEEE DCBX only) (QFX Series) Media access controller (MAC) authentication bypass provides access to devices based on MAC address authentication. Although the QFX Series does not support this feature, the connected peer might support it. This field reports the peer state: • **Yes**—The connected peer supports MAC authentication bypass. • **No**—The connected peer does not support MAC authentication bypass.
	Maximum Traffic Classes capable to support PFC	Largest number of traffic classes the peer supports for PFC: • **6** (EX Series switches) • **8** (QFX Series)
	Code Point	PFC code point, which is specified in the 3-bit class-of-service field in the VLAN header.
	Admin Mode	PFC administrative state for each code point on the peer: • **Enabled**—PFC is enabled for the code point. • **Disabled**—PFC is disabled for the code point.

Table 396: show dcbx neighbors Output Fields *(continued)*

Field Name			Field Description
Feature: Application			State information for the DCBX application.
	Protocol-State		(DCBX Version 1.01 only) DCBX protocol state synchronization status: • **in-sync**—The local interface received an acknowledge message from the peer to indicate that the peer received an FCoE state change message sent by the local interface. • **ack-pending**—The local interface has not yet received an acknowledge message from the peer to indicate that the peer received an FCoE state change message sent by the local interface. • **not-applicable**—The local interface is set to **no-auto-negotiation** (autonegotiation is disabled). If the interface is associated with an FCoE forwarding class, the interface advertises FCoE capability even if the connected peer does not advertise FCoE capability.
	Local-Advertisement		Status of advertisements that the local interface sends to the peer. If the local interface is set to **no-auto-negotiation** (autonegotiation is disabled), the local advertisement portion of the output is not shown.
		Enable	(DCBX Version 1.01 only) State that the local interface advertises to the peer: • **Yes**—The feature is enabled. • **No**—The feature is disabled.
		Willing	(DCBX Version 1.01 only) Willingness of the local interface to learn the FCoE interface state from the peer using DCBX: • **Yes**—The local interface is willing to learn the FCoE interface state from the peer. • **No**—The local interface is not willing to learn the FCoE interface state from the peer.
		Error	(DCBX Version 1.01 only) Configuration compatibility error status: • **No**—No error detected. The local and peer configuration are compatible. • **Yes**—Error detected. The local and peer configuration are not compatible.
		Appl-Name	Name of the application:

Table 396: show dcbx neighbors Output Fields *(continued)*

Field Name			Field Description
		Ethernet-Type	(DCBX Version 1.01 only) Ethernet type (EtherType) of the application. For example, **0x8906** indicates the EtherType for the FCoE application. Either the EtherType (for Layer 2 applications) or the Socket Number (for Layer 4 applications) of the application is displayed in the output.
		Socket-Number	Destination port socket number of the application, if applicable. Either the EtherType (for Layer 2 applications) or the Socket Number (for Layer 4 applications) of the application is displayed in the output.
		Priority-Field or **Priority-Map**	Priority assigned to the application. For EX Series switches, the priority of the FCoE application is determined by the PFC congestion notification profile that has been configured and associated with the FCoE interface. For other applications, the priority is based on the application map.
		Status	(DCBX Version 1.01 only) Local status when autonegotiation is enabled: • **Enabled**—The application feature is enabled on both the local interface and the peer interface. (The local configuration and the peer configuration match.) • **Disabled**—The local configuration and the peer configuration do not match. NOTE: If there is a configuration mismatch in one application between the switch and the peer, all the other applications including FCoE are disabled.
	Peer-Advertisement		Status of advertisements that the peer sends to the local interface.
		Enable	(DCBX Version 1.01 only) State that the peer advertises to the local interface: • **Yes**—The feature is enabled. • **No**—The feature is disabled.
		Willing	(DCBX Version 1.01 only) Willingness of the peer to learn the FCoE interface state from the local interface using DCBX: • **Yes**—The peer is willing to learn the FCoE interface state from the local interface. • **No**—The peer is not willing to learn the FCoE interface state from the local interface.

Table 396: show dcbx neighbors Output Fields *(continued)*

Field Name		Field Description
	Error	(DCBX Version 1.01 only) Configuration compatibility error status: • **No**—No error detected. Local and peer configuration are compatible. • **Yes**—Error detected. Local and peer configuration are not compatible.
	Appl-Name	Name of the application: • **FCoE**—Fibre Channel over Ethernet
	Ethernet-Type	Ethernet type (EtherType) of the application. For example, **0x8906** indicates the EtherType for the FCoE application. Either the EtherType (for Layer 2 applications) or the Socket-Number (for Layer 4 applications) of the application is displayed in the output.
	Socket-Number	Destination port socket number of the application, if applicable. Either the EtherType (for Layer 2 applications) or the Socket Number (for Layer 4 applications) of the application is displayed in the output.
	Priority-Field or **Priority-Map**	Priority assigned to the application.
	Status	(DCBX Version 1.01 only) Peer interface status: • **Enabled**—The application feature is enabled on both the local interface and the peer interface. (The local configuration and the peer configuration match.) • **Disabled**—The local configuration and the peer configuration do not match.

Table 396: show dcbx neighbors Output Fields *(continued)*

Field Name			Field Description
Feature: ETS			Enhanced Transmission Selection (ETS) DCBX state information.
	Protocol-State		(DCBX Version 1.01 only) ETS protocol state synchronization status: • **in-sync**—The local interface received an acknowledge message from the peer to indicate that the peer received an ETS state change message sent by the local interface. • **ack-pending**—The local interface has not yet received an acknowledge message from the peer to indicate that the peer received an ETS state change message sent by the local interface.
	Operational State		(DCBX Version 1.01 only) Operational state of the feature, **enabled** or **disabled**.
	Local-Advertisement		Status of advertisements that the local interface sends to the peer.
		Enable	(DCBX Version 1.01 only) State that the local interface advertises to the peer: • **Yes**—The feature is enabled. • **No**—The feature is disabled.
		TLV Type	(IEEE DCBX only) Type of ETS TLV: • Configuration—Advertises the Configuration TLV, which communicates the local ETS configuration to the peer but does not ask the peer to use the configuration. • Recommendation—Advertises the Recommendation TLV, which communicates the local ETS configuration to the peer, and if the peer is “willing,” configures the peer interface to match the local ETS configuration. • Recommendation-or-Configuration—Advertises both TLVs.
		Willing	Willingness of the local interface to learn the ETS state from the peer using DCBX (EX Series switches always advertise **No** for this field): • **Yes**—Local interface is willing to learn the ETS state from the peer. • **No**—Local interface is not willing to learn the ETS state from the peer.
		Credit Based Shaper	

Table 396: show dcbx neighbors Output Fields *(continued)*

Field Name		Field Description
		(IEEE DCBX only) Alternative method of flow control to buffer-to-buffer credit. The QFX Series does not support a credit-based shaper, so the value of this field is always **No**.
	Error	(DCBX Version 1.01 only) Configuration error status: • **No**—No error. This should always be the switch ETS error state. • **Yes**—Error detected.
	Maximum Traffic Classes capable to support PFC	(DCBX Version 1.01 only) Largest number of traffic classes the local interface supports for PFC.
	Maximum Traffic Classes supported	(IEEE DCBX only) Largest number of traffic classes the local interface supports for ETS. (EX Series switches support only one traffic class for ETS. However, a different value might be shown for this field.)
	Code Point	PFC code point, which is specified in the 3-bit class-of-service field in the VLAN header.
	Priority-Group	Class-of-service (CoS) priority group (forwarding class set) identification number.
	Percentage B/W	Configured minimum percentage of link bandwidth allocated to the priority group. Only explicitly configured values appear in this output column. If the link bandwidth is the default percentage, it is not shown. (EX Series switches allocate 100% of link bandwidth to the default priority group, group 7.)
	Transmission Selection Algorithm	(IEEE DCBX only) The transmission selection algorithm used by the interface. The QFX Series supports ETS but does not support using the credit-based shaper algorithm, so the only value shown in this field is **ETS**.
Peer-Advertisement		Status of advertisements that the peer sends to the local interface.
	Enable	

Table 396: show dcbx neighbors Output Fields *(continued)*

Field Name		Field Description
		(DCBX Version 1.01 only) State that the peer advertises to the local interface: • **Yes**—The feature is enabled. • **No**—The feature is disabled.
	TLV Type	(IEEE DCBX only) Type of ETS TLV: • Configuration—Advertises the Configuration TLV, which communicates the local ETS configuration to the peer but does not ask the peer to use the configuration. • Recommendation—Advertises the Recommendation TLV, which communicates the local ETS configuration to the peer, and if the peer is “willing,” configures the peer interface to match the local ETS configuration. • Configuration/Recommendation—Advertises both TLVs.
	Willing	Willingness of the peer to learn the ETS state from the local interface using DCBX: • **Yes**—Peer is willing to learn the ETS state from the local interface. • **No**—Peer is not willing to learn the ETS state from the local interface.
	Credit Based Shaper	(IEEE DCBX only) Alternative method of flow control to buffer-to-buffer credit. The QFX Series does not support a credit-based shaper, so the value of this field is always **No**.
	Error	(DCBX Version 1.01 only) Configuration error status of the peer: • **No**—No error in peer ETS TLV. • **Yes**—Error in peer ETS TLV.
	Maximum Traffic Classes capable to support PFC	(DCBX Version 1.01 only) Largest number of traffic classes the local interface supports for PFC.
	Maximum Traffic Classes supported	(IEEE DCBX only) Largest number of traffic classes the local interface supports for ETS. (EX Series switches support only one traffic class for ETS. However, a different value might be shown for this field.)
	Code Point	

Table 396: show dcbx neighbors Output Fields *(continued)*

Field Name		Field Description
		PFC code point, which is specified in the 3-bit class-of-service field in the VLAN header.
	Priority-Group	CoS priority group (forwarding class set) identification number.
	Percentage B/W	Configured minimum percentage of link bandwidth allocated to the priority group. (EX Series switches allocate 100% of link bandwidth to the default priority group, group 7.)
	Transmission Selection Algorithm	(IEEE DCBX only) Transmission selection algorithm used by the interface. The QFX Series supports ETS but does not support using the credit-based shaper algorithm, so the only value shown in this field is **ETS**.
PFC		(QFX Series, **terse** option only) DCBX TLV advertisement state for PFC: • Disabled—PFC configuration matches the configuration on the connected peer and PFC is disabled • Enabled—PFC configuration matches the configuration on the connected peer and PFC is enabled • Not Advt—Interface does not advertise PFC to the connected peer
ETS		(**terse** option only) Local DCBX TLV advertisement state for ETS: • Advt—Interface advertises ETS TLVs • Disabled—ETS is disabled on the interface (interface does not advertise ETS)
ETS Rec		(**terse** option only) DCBX TLV peer advertisement state for ETS (state received from the connected DCBX peer): • Advt—Peer interface advertises ETS TLVs • Not Advt—Peer interface does not advertise ETS NOTE: When the DCBX mode is DCBX version 1.01, no peer information is displayed.

Table 396: show dcbx neighbors Output Fields *(continued)*

Field Name	Field Description
Version	(**terse** option only) The DCBX version used on the interface and whether the DCBX version was autonegotiated or explicitly configured: • **IEEE**—The interface uses IEEE DCBX. • **1.01**—The interface uses DCBX version 1.01. When the DCBX version used is the result of autonegotiation, the term **(Auto)** appears next to the version. For example, **IEEE (Auto)** indicates that the interface autonegotiated with the connected peer to use IEEE DCBX. Autonegotiation is enabled by default.

show fibre-channel fabric

Syntax
show fibre-channel fabric
<extensive | summary>
<*fabric-name*>
<sort-by (name | fabric-id)>

Release Information Command introduced in Junos OS Release 11.1 for the QFX Series.

Description Display Fibre Channel fabric information.

Options *fabric-name*—(Optional) Display output only for the specified fabric.

extensive | summary—(Optional) Display the specified level of output.

sort-by (name | fabric-id)—(Optional) Sort output by fabric name or fabric ID.

Required Privilege Level view

Output Fields Table 399 on page 5203 lists the output fields for the **show fibre-channel fc2 statistics** command. Output fields are listed in the approximate order in which they appear.

Table 399: show fibre-channel fc2 statistics Output Fields

Field Name	Field Description
Global statistics	Statistics for all fabrics.
Frame buffers allocated	Number of frame buffers currently allocated to all fabrics.
Frame buffers freed	Number of frame buffers freed.
Frames dropped	Number of dropped frames.
Fabric statistics	Fabric-specific statistics.
Fabric	Name of the fabric.
Fabric-id	Identification number of the fabric.
Tx-FRJTs	Number of fabric frame rejects (F_RJTs).
Tx-PRJTs	Number of port frame rejects (P_RJTs).
Tx-LSRJTs	Number of link service rejections.
Tx-ABTS	Number of abort sequence frames sent.
Rx-Drops	Number of received frames dropped.

Table 399: show fibre-channel fc2 statistics Output Fields *(continued)*

Field Name	Field Description
Rx-ABTS	Number of abort sequence frames received.

Sample Output

show fibre-channel fc2 statistics

```
user@switch> show fibre-channel fc2 statistics
Global statistics:

Frame buffers allocated: 60
Frame buffers freed:     60
Frames dropped:          0

Fabric statistics:

Fabric : fip-proxy, Fabric-id: 1
Tx-FRJTs:     0
Tx-PRJTs:     0
Tx-LSRJTs:    0
Tx-ABTS:      0
Rx-Drops:     0
Rx-ABTS:      0
```

show fibre-channel fip

Output Fields

Table 400 on page 5205 lists the output fields for the **show fibre-channel fip** command. Output fields are listed in the approximate order in which they appear. A session is a FLOGI or FDISC login to the FC SAN fabric. Session does not refer to end-to-end storage sessions.

Table 400: show fibre-channel fip Output Fields

Field Name	Field Description	Level of Output
Configured max FIP sessions per Node Device	Configured maximum number of FIP sessions permitted on the Node device. For QFabric systems, this is the maximum number of FIP sessions permitted on each Node device in the fabric. For QFX3500 devices, this is the maximum number of FIP sessions permitted on the device.	**detail**
Node Device	Node device identifier.	**detail**
Total FIP sessions	Total number of FIP sessions on the FCoE-FC gateway switch.	**detail**

Table 400: show fibre-channel fip Output Fields *(continued)*

Field Name		Field Description	Level of Output
Total FCoE filters		Total number of FIP filters on the FCoE-FC gateway switch.	**detail**
Fabric Name		Name of the fabric and in parentheses the fabric ID.	All
FC-MAP		FCoE mapped address prefix of the FCoE forwarder for the fabric.	**detail**
FKA-ADV-PERIOD		Period of time in milliseconds between FIP keepalive advertisements configured for the FC fabric.	**detail**
MAX-SESSIONS-PER-ENODE		Maximum number of concurrent sessions (FLOGI and FDISC combined) that each ENode can instantiate.	**detail**
FCoE trusted		Whether ports on the FC fabric are trusted or untrusted: • **Yes**—Ports on the FC fabric are trusted; FIP snooping is turned off. • **No**—Ports on the FC fabric are not trusted; FIP snooping is turned on.	**detail**
Member		Information about an FCF that is a member of the fabric.	All
	• **FCF-MAC**	MAC address used in discovery advertisements.	All
	• **FKA-ADV-PERIOD**	Period of time in milliseconds between FIP keepalive advertisements configured for the FC interface.	**detail**
	• **FKA-ADV-D-BIT**	Disable FIP keepalive advertisement monitoring bit. The state is always **off**.	**detail**
	• **Type**	Type of interface: • **VF_Port Capable**—Interface can act as a VF_Port interface.	**detail**
	• **Priority**	Priority value associated with the switch FCF-MAC. Converged network adapters (CNAs) use the priority value to determine the switch with which they will perform FIP FLOGI. The lower the value, the higher the priority. Value range: 0 through 255.	**detail**
	• **State**	FIP state on the fabric: • **Enable**—FIP is enabled on the fabric. • **Disable**—FIP is disabled on the fabric.	**detail**

Table 400: show fibre-channel fip Output Fields *(continued)*

Field Name	Field Description	Level of Output
ENode	Information about a connected FCoE node (ENode).	All
• **ENode-MAC**	MAC address of the connected ENode.	All
• **Enode State**	Login state internal to Junos OS.	All
• **Configured ENode timer**	User-configured FIP keepalive advertisement interval in milliseconds.	**detail**
• **Running ENode timer**	Runtime interval in milliseconds of the last FIP keepalive advertisement received. This value changes every time an FKA_ADV is received.	**detail**
• **Active FIP Sessions**	Number of active FIP sessions on the ENode.	**detail**
• **VN-Port-MAC**	MAC address of a VN_Port on the ENode.	All
• **Session State**	Session state internal to Junos OS.	**detail**
• **Configured FKA-ADV**	User-configured FIP keepalive advertisement interval in milliseconds.	**detail**
• **Running FKA-ADV**	Runtime interval in milliseconds of the last FIP keepalive advertisement received. This value changes every time an FKA_ADV is received.	**detail**
• **Configured VN-Port Timer**	Configured state of the VN_Port keepalive timer in milliseconds. This value is always 90 and is not user-configurable.	**detail**
• **Running VN-Port Timer**	Running state of the VN_Port keepalive timer in milliseconds.	**detail**
• **FCID**	Fibre Channel ID of the VN_Port.	**detail**
• **WWN**	Unique worldwide name of the VN_Port.	**detail**

show fibre-channel fip enode

Syntax

show fibre-channel fip enode ***enode-mac***
<brief | detail>
<vn-port-mac ***vn-port-mac*****>**

Release Information

Command introduced in Junos OS Release 11.1 for the QFX Series.

Description

Display Fibre Channel over Ethernet (FCoE) Initialization Protocol (FIP) information for a specified ENode or a specified VN_Port on an ENode.

Options

brief | detail—(Optional) Display the specified level of output.

enode-mac—Display information for the ENode specified by the MAC address.

vn-port-mac ***vn-port-mac***—(Optional) Display information only for the specified VN_Port.

Output Fields

Table 401 on page 5210 lists the output fields for the **show fibre-channel fip enode** command. Output fields are listed in the approximate order in which they appear. A session is a FLOGI or FDISC login to the FC SAN fabric. Session does not refer to end-to-end storage sessions.

Table 401: show fibre-channel fip enode Output Fields

Field Name	Field Description	Level of Output
Fabric Name	Name of the fabric and in parentheses the fabric ID.	All
FC-MAP	FCoE mapped address prefix of the FCoE forwarder for the fabric.	**detail**
FKA-ADV-PERIOD	Period of time in milliseconds between FIP keepalive advertisements configured for the FC fabric.	**detail**

Table 401: show fibre-channel fip enode Output Fields *(continued)*

Field Name		Field Description	Level of Output
MAX-SESSIONS-PER-ENODE		Maximum number of concurrent sessions (FLOGI and FDISC combined) that each ENode can instantiate.	**detail**
FCoE trusted		Whether ports on the FC fabric are trusted or untrusted: • **Yes**—Ports on the FC fabric are trusted; FIP snooping is turned off. • **No**—Ports on the FC fabric are not trusted; FIP snooping is turned on.	**detail**
Member		Information about an FCF that is a member of the fabric.	All
	• FCF-MAC	MAC address used in discovery advertisements.	All
	• FKA-ADV-PERIOD	Period of time in milliseconds between FIP keepalive advertisements configured for the FC interface.	**detail**
	• FKA-ADV-D-BIT	Disable FIP keepalive advertisement monitoring bit. The state is always **off**.	**detail**
	• Type	Type of interface: • **VF_Port Capable**—Interface can act as a VF_Port interface.	**detail**
	• Priority	Priority value associated with the switch FCF-MAC. Converged network adapters (CNAs) use the priority value to determine the switch with which they will perform FIP FLOGI. The lower the value, the higher the priority. Value range: 0 through 255.	**detail**
	• State	FIP state on the fabric: • **Enable**—FIP is enabled on the fabric. • **Disable**—FIP is disabled on the fabric.	**detail**

Table 401: show fibre-channel fip enode Output Fields *(continued)*

Field Name	Field Description	Level of Output
ENode	Information about a connected FCoE node (ENode).	All
• **ENode-MAC**	MAC address of the connected ENode.	All
• **ENode State**	Login state internal to Junos OS.	All
• **Configured ENode timer**	User-configured FIP keepalive advertisement interval in milliseconds.	**detail**
• **Running ENode timer**	Runtime interval in milliseconds of the last FIP keepalive advertisement received. This value changes every time an FKA_ADV is received.	**detail**
• **Active FIP Sessions**	Number of active FIP sessions on the ENode.	**detail**
• **VN-Port-MAC**	MAC address of a VN_Port on the ENode.	**detail**
• **Session State**	Session state internal to Junos OS.	**detail**
• **Configured FKA-ADV**	User-configured FIP keepalive advertisement interval in milliseconds.	**detail**
• **Running FKA-ADV**	Runtime interval in seconds of the last FIP keepalive advertisement received. This value changes every time an FKA_ADV is received.	**detail**
• **Configured VN-Port Timer**	Configured state of the VN_Port keepalive timer in seconds. This value is always 90 and is not user-configurable.	**detail**
• **Running VN-Port Timer**	Running state of the VN_Port keepalive timer in seconds.	**detail**
• **FCID**	Fibre Channel ID of the VN_Port.	**detail**
• **WWN**	Unique worldwide name of the VN_Port.	**detail**

Sample Output

show fibre-channel fip enode

```

show fibre-channel fip statistics on page 5225

Output Fields

Table 405 on page 5223 lists the output fields for the **show fibre-channel fip statistics** command. Output fields are listed in the approximate order in which they appear.

Table 405: show fibre-channel fip statistics Output Fields

Field Name	Field Description
Fabric name	Name of the fabric.
Interface name	Name of the FCoE VLAN interface.

Table 405: show fibre-channel fip statistics Output Fields *(continued)*

Field Name		Field Description
FIP Message Type		Type of FIP message for the displayed row of statistics..
	• **MDS**	Number of multicast discovery solicitations.
	• **UDS**	Number of unicast discovery solicitations.
	• **FLOGI**	Number of fabric login (FLOGI) messages.
	• **FDISC**	Number of fabric discovery (FDISC) messages.
	• **LOGO**	Number of fabric logout (LOGO) messages.
	• **ENODE KA**	Number of ENode keepalive messages.
	• **VN_Port KA**	Number of VN_Port keepalive messages.
	• **MDA**	Number of multicast discovery advertisements.
	• **UDA**	Number of unicast discovery advertisements.
	• **FLOGI ACC**	Number of fabric login requests accepted.
	• **FLOGI RJT**	Number of fabric login requests rejected.
	• **FDISC ACC**	Number of fabric discovery requests accepted.
	• **FDISC RJT**	Number of fabric discovery requests rejected.
	• **LOGO ACC**	Number of logout requests accepted.
	• **LOGO RJT**	Number of logout requests rejected.
	• **CVL**	Number of clear virtual links (CVL) messages.
	• **CVL ALL**	Number of CVL all messages.
Received		Number of messages received.
Sent		Number of messages sent.
Rx errors		Number of receive errors.

Table 405: show fibre-channel fip statistics Output Fields *(continued)*

Field Name		Field Description
Dropped		Number of dropped messages. NOTE: One cause of dropped messages is that the system limits the number of discovery solicitations (MDS and UDS) it accepts to a maximum of 100 outstanding requests at any given time. If the system has 100 discovery solicitations outstanding, the system does not respond to new discovery solicitations. Instead, the system drops new discovery solicitations and reports the number of dropped discovery solicitations in this field. When there are fewer than 100 outstanding discovery solicitations, the system responds to new requests as usual with a discovery advertisement.
General Statistics	**Number of frames recvd with invalid src-mac**	Number of frames received that have an invalid source media access control (MAC) address.
	Number of frames recvd with invalid version	Number of FIP frames received with an Invalid FIP version.
	Number of frames recvd with invalid opcode	Number of FIP validation descriptors with an invalid opcode received.
	Number of frames recvd with invalid subcode	Number of FIP validation descriptors with an invalid subcode received.
	Number of frames recvd on inactive FCF	Number of frames received on a logical interface if FIP is not active on that logical interface (for example, if a WWN is not allocated to that logical interface).

Sample Output

show fibre-channel fip statistics

```
user@switch> show fibre-channel fip statistics
Fabric name: proxy2

Interface name: vlan.100
FIP Message type      Received     Sent      Rx errors    Dropped
MDS                   22236        0         0            17089
UDS                   0            0         0            0
FLOGI                 1257         0         8            0
FDISC                 0            0         0            0
LOGO                  0            0         0            0
ENODE KA              455          0         6            0
VN_Port KA            22           0         0            0
MDA                   0            243       0            0
UDA                   0            5147      0            0
FLOGI ACC             0            376       0            0
FLOGI RJT             0            881       0            0
FDISC ACC             0            0         0            0
FDISC RJT             0            0         0            0
LOGO ACC              0            0         0            0
LOGO RJT              0            0         0            0
```

```
CVL                    0            374      0            0
CVL ALL                0            380      0            0

General Statistics:

Number of frame recvd with invalid src-mac:          0
Number of frame recvd with invalid version:          0
Number of frame recvd with invalid opcode:           0
Number of frame recvd with invalid subcode:          0
Number of frame recvd on inactive FCF:               0
```

show fibre-channel flogi fport

Syntax

show fibre-channel flogi fport
<fabric *fabric-name*>

Release Information Command introduced in Junos OS Release 11.1 for the QFX Series.

Description Display Fibre Channel fabric login (FLOGI) F_Port information.

Options **fabric *fabric-name***—(Optional) Display output only for the specified fabric.

Required Privilege Level view

Output Fields Table 406 on page 5227 lists the output fields for the **show fibre-channel flogi fport** command. Output fields are listed in the approximate order in which they appear.

Table 406: show fibre-channel flogi fport Output Fields

Field Name	Field Description
Fabric	Name of the fabric.
Interface	Name of the switch VF_Port interface.
Mac-Address	Media access control (MAC) address of the ENode.
State	Interface physical state: **up** or **down**.
Logins	Number of logins to the VF_Port.
NPIV	N_Port ID virtualization (NPIV) state: **Yes** or **No**.
FLOGI-Port-WWN	Unique worldwide name (WWN) of the VN_Port performing fabric login (FLOGI) to the switch VF_Port.

Sample Output

show fibre-channel flogi fport

```
user@switch> show fibre-channel flogi fport
Fabric: proxy2
Interface       Mac-Address         State  Logins   NPIV  FLOGI-Port-WWN
vlan.100       00:10:94:00:00:02   Up     2        Yes   20:00:10:94:00:01:00:01
vlan.100       00:10:94:00:00:03   Up     2        Yes   20:00:10:94:00:02:00:01
```

show fibre-channel flogi nport

Syntax

show fibre-channel flogi nport

Output Fields Table 408 on page 5231 lists the output fields for the **show fibre-channel flogi statistics** command. Output fields are listed in the approximate order in which they appear.

Table 408: show fibre-channel flogi statistics Output Fields

Field Name	Field Description
Fabric	Name of the fabric.
FLOGI-Server Message type	Type of message: • **FLOGI**—Fabric login (FLOGI) messages. • **FDISC**—Fabric discovery (FDISC) messages. • **FLOGO**—Fabric logout messages. • **FLOGO-LS-ACC**—Fabric logout link service accept messages. • **LS-Accept**—Link service accept messages. • **LS-Reject**—Link service reject messages. • **invalid**—Invalid messages.
Received	Number of messages received for a given message type.
Sent	Number of messages sent for a given message type.
Fabric	Name of the fabric.
Rx errors	Number of receive errors for a given type of message.

Table 408: show fibre-channel flogi statistics Output Fields *(continued)*

Field Name		Field Description
General Statistics	• Number of FC2 Header Parse Errors	Number of errors parsing the FC-2 header.
	• Number of FLOGI Parse Errors	Number of errors parsing fabric login requests.
	• Number of FDISC Parse Errors	Number of errors parsing fabric discovery requests.
	• Number of FLOGO Parse Errors	Number of errors parsing fabric logout requests.
	• Number of Logins Discarded as Domain-ID not available	Number of discarded logins due to unavailability of a domain ID.
	• Number of Logins Discarded as FCID not available	Number of discarded logins due to the unavailability of a Fibre Channel ID.
	• Number of FCID requests deferred	Number of deferred FCID requests.
	• Number of deferred FCID requests failed	Number of deferred FCID requests that failed.

Sample Output

show fibre-channel flogi statistics

```
user@switch> show fibre-channel flogi statistics
Fabric: proxy2

FLOGI-Server Message type    Received       Sent   Rx errors
FLOGI                        2              0      0
FDISC                        2              0      0

show fibre-channel interfaces detail on page 5236

Output Fields Table 409 on page 5234 lists the output fields for the **show fibre-channel interfaces** command. Output fields are listed in the approximate order in which they appear.

Table 409: show fibre-channel interfaces Output Fields

Field Name	Field Description	Level of Output
Interface	Name of the FC interface.	All
Idx or **Index**	Interface index internal to Junos OS.	All
Type	Type of interface: • **FC**—Native FC interface • **FCOE**—Fibre Channel over Ethernet interface	All
Native Fabric-id	Identification number of the QFX Series fabric.	All
NPIV	N_Port ID virtualization (NPIV) state: **Yes** or **No**.	All

Table 409: show fibre-channel interfaces Output Fields *(continued)*

Field Name	Field Description	Level of Output
Config-Mode	User-configured port mode: • **F**—The port is configured as a VF_Port, an FCoE port connected to FCoE devices. • **NP**—The port is configured as a proxy N_Port (NP_Port), a native FC port connected to an FC switch.	All
Oper-Mode	Operational port mode: • **F**—The port is operating as a VF_Port, an FCoE port connected to FCoE devices. • **NP**—The port is operating as an NP_Port, a native FC port connected to an FC switch or an FCoE forwarder (FCF).	All
State	Interface state: **up** or **down**.	All
WWN	Unique worldwide name (WWN) of the port.	**detail**
FSM-State	Finite state machine state, internal to Junos OS.	**detail**
Class ID	Fibre Channel interface class ID, internal to Junos OS.	**detail**
BB_SC_N	Buffer-to-buffer state change number.	**detail**
Tx B2B credits	Number of buffer-to-buffer credits advertised by the neighbor switch that is connected to the FC interface.	**detail**
Fabric	Name of the fabric.	**detail**
Remote-MAC	Media access control (MAC) address of the remotely connected FCoE device VN_Port interface.	**detail**
Tagging	Not used. Value is shown as **untagged**.	**detail**
Mode	Logical interface (LIF) mode of operation.	**detail**
H/W token	Unique identifier for the FCoE VLAN interface, internal to Junos OS.	**detail**

Output Fields

Table 412 on page 5241 lists the output fields for the **show fibre-channel proxy fabric-state** command. Output fields are listed in the approximate order in which they appear.

Table 412: show fibre-channel proxy fabric-state Output Fields

Field Name	Field Description
Fabric	Name of the fabric.
Fabric-id	Fabric ID number.
Proxy load balance algorithm	Load-balancing algorithm used on the FCoE-FC gateway FC fabric: • Simple—Load balancing is based on the weighted utilization (load) of the NP_Ports connected to an FC fabric. Each new FLOGI or FDISC is assigned to the least-loaded link. On a link load rebalance, only the sessions that need to be moved to another link are logged out. When those sessions log in again, they are placed on active NP_Port interfaces in a balanced manner. • ENode-based—Load balancing is based on the ENode FLOGI. When an ENode logs in to the fabric, all subsequent FDISC sessions associated with that ENode are placed on the same link as the ENode FLOGI session, regardless of the link load. New ENode FLOGIs are placed on the least-loaded link. On a link load rebalance, all sessions are logged out. When the sessions log in again, they are placed on active NP_Port interfaces in a balanced manner. • FLOGI-based—Load balancing is based on the ENode FLOGI. When an ENode logs in to the fabric, all subsequent FDISC sessions associated with that ENode are placed on the same link as the ENode FLOGI session, regardless of the link load. New ENode FLOGIs are placed on the least-loaded link. On a link load rebalance, only the sessions that need to be moved to another link are logged out. When those sessions log in again, they are placed on active NP_Port interfaces in a balanced manner.

Table 412: show fibre-channel proxy fabric-state Output Fields *(continued)*

Field Name	Field Description
Fabric WWN verification	Fabric worldwide name (WWN) verification check state on the FCoE-FC gateway fabric: • Yes—Fabric WWN verification check is enabled. • No—Fabric WWN verification check is disabled.
Auto load rebalance enabled	Automated link load rebalancing configuration for the FCoE-FC gateway fabric: • No—Automated load balancing is disabled (default state). • Yes—Automated load balancing is enabled.
Last rebalance start-time	Time that the last link load rebalance began on the FCoE-FC gateway fabric: • Never—The link load has never been rebalanced. • Timestamp value—Time the last link load rebalancing started.
Last rebalance end-time	Time that the last link load rebalance ended on the FCoE-FC gateway fabric: • Never—The link load has never been rebalanced. • Timestamp value—Time the last link load rebalancing ended.
Last rebalance trigger	Event that triggered the last link load rebalance on the FCoE-FC gateway fabric: • None—The link load has never been rebalanced. • Config-CLI—Configure (enable) automated load balancing. • Request-CLI—Rebalance requested from the CLI using the **request fibre-channel proxy load-rebalance fabric *fabric-name*** operational command. • Preview-CLI—Rebalancing *dry run* requested from the CLI using the **request fibre-channel proxy load-rebalance dry-run fabric *fabric-name*** operational command. Indicates that the switch completed the dry run. A dry run simulates a link load rebalance and displays a list of sessions that might be affected if you request an actual rebalance. • Link-up—New FC link (NP_Port) up on the FCoE-FC gateway fabric, which causes a rebalance to distribute sessions to the new link. • Restore-complete—If the FC process on the switch restarts, the switch attempts to restore the session state that existed before the restart. When automated rebalance is enabled, restore-complete indicates that the sessions have been restored and rebalanced.
Last rebalance trigger-time	Time that the last link load rebalance was triggered on the FCoE-FC gateway fabric: • Never—Link load rebalancing has never been triggered. • Timestamp value—Time the last link load rebalancing was triggered.

Table 412: show fibre-channel proxy fabric-state Output Fields *(continued)*

Field Name	Field Description
Last rebalance trigger-result	Result of the last trigger event on the FCoE-FC gateway fabric: • Never—Link load rebalancing has never been triggered. • Not-configured—Automated rebalancing is not configured on the FCoE-FC gateway fabric. • Not-required—Last rebalance trigger did not require rebalancing the link load (the link load was already balanced across the active NP_Port links). • In-progress—Link load rebalancing is in progress and has not finished yet. • Restore-in-progress—The switch is recovering from an FC process restart and is in the process of restoring the sessions to the active NP_Port links. • Success—Link load rebalancing was successful. • Logged-out-all—All sessions have been logged out. • Preview-complete—The switch has finished simulating a dry run rebalancing request from the CLI (**request fibre-channel proxy load-rebalance dry-run fabric** ***fabric-name*** operational command) and reported the sessions that might be affected if you request an actual link load rebalance. • Fabric-deletion-in-progress—FCoE-FC gateway fabric is in the process of being deleted. NOTE: A trigger event does not necessarily result in a rebalance action. Link load rebalancing only occurs if the NP_Port interface session load is not balanced at the time of the trigger event.

Sample Output

show fibre-channel proxy fabric-state

```
user@switch> show fibre-channel proxy fabric-state
Fabric: san_fab1, Fabric-id: 10
Proxy load balance algorithm: Simple, Fabric WWN verification: Yes
Auto load rebalance enabled  : No
Last rebalance start-time    : Never
Last rebalance end-time      : Never
Last rebalance trigger       : Link-up
Last rebalance trigger-time  : Mon Sep 10 21:42:30 2012 usec: 814602
Last rebalance trigger-result: Not-configured

Fabric: san_fab2, Fabric-id: 20
Proxy load balance algorithm: ENode based, Fabric WWN verification: Yes
Auto load rebalance enabled  : No

Output Fields Table 413 on page 5245 lists the output fields for the **show fibre-channel proxy login-table** command. Output fields are listed in the approximate order in which they appear.

Table 413: show fibre-channel proxy login-table Output Fields

Field Name	Field Description	Level of Output
Fabric	Name of the fabric.	All
Fabric-id	Fabric ID number.	All
F-Port	One of the following two values: • VF_Port interface connected to the Fibre Channel over Ethernet (FCoE) host, shown as the FCoE VLAN interface. • QFX Series FC port that is logged in to the FC switch, shown by a hyphen (-) to indicate that it is not the FCoE device VN_Port.	All
FCID	VN_Port Fibre Channel identifier provided by the Fibre Channel over Ethernet (FCoE) forwarder (FCF) or the Fibre Channel switch.	All

Table 413: show fibre-channel proxy login-table Output Fields *(continued)*

Field Name	Field Description	Level of Output
Port-WWN	Unique worldwide name (WWN) of the VN_Port.	All
Node-WWN	Unique WWN of the node hosting the VN_Ports.	**detail**
NP-Port	NP_Port interface connected to the FCoE forwarder (FCF) or the Fibre Channel switch.	All
Class	FLOGI service class.	**detail**
Fabric port WWN	Unique WWN of the fabric port (VF_Port).	**detail**
Fabric WWN	Unique WWN of the fabric generated by the FCF.	**detail**

Sample Output

show fibre-channel proxy login-table

```
user@switch> show fibre-channel proxy login-table

List of Sample Output

show fibre-channel proxy np-port on page 5249
show fibre-channel proxy np-port detail on page 5249

Output Fields

Table 414 on page 5248 lists the output fields for the **show fibre-channel proxy np-port** command. Output fields are listed in the approximate order in which they appear.

Table 414: show fibre-channel proxy np-port Output Fields

Field Name	Field Description	Level of Output
Fabric	Name of the fabric.	All
Fabric-id	Fabric ID number.	All
NP-Port	NP_Port interface connected to the FCoE forwarder (FCF) or the Fibre Channel switch.	All
State	FCID state of the NP_Port interface.	All
Sessions	Number of active sessions on the NP_Port interface. A session is a FLOGI or FDISC login to the FC SAN fabric. Session does not refer to end-to-end storage sessions.	All

Table 414: show fibre-channel proxy np-port Output Fields *(continued)*

Field Name	Field Description	Level of Output
Configured max login sessions	Configured maximum number of FIP login sessions permitted on the interface.	**detail**
Enodes	Number of ENodes with sessions on the NP_Port.	**detail**
LB state	Load-balancing state: • **On**—Load balancing is on • **Off**—Load balancing is off.	All
LB weight	Load balance weight, which reflects the port speed: • **2**—Port speed is 2 Gbps. • **4**—Port speed is 4 Gbps. • **8**—Port speed is 8 Gbps.	All
Ref-count	Reference count internal to Junos OS.	**detail**
Flags	Flags internal to Junos OS. NOTE: When an NP_Port interface reaches its configured maximum number of FIP sessions, the **Flags** field displays the flag **MAX-LOGINS-REACHED**.	**detail**

Sample Output

Field Name	Field Description	Level of Output
VLAN	Name of the VLAN.	All
Mode	(QFX Series only) Snooping mode enabled on the FCoE VLAN: • VN2VF Snooping—The FCoE VLAN is configured for FIP snooping between an ENode VN_Port and a switch VF_Port. • VN2VN Snooping—The FCoE VLAN is configured for VN_Port to VN_Port FIP snooping between ENode VN_Ports.	All

Table 416: show fip snooping Output Fields *(continued)*

Field Name	Field Description	Level of Output
FC-MAP	FCoE mapped address prefix of the FCoE forwarder for the VLAN.	All
FCF or **FCF-MAC**	MAC address of the FCF.	All
Session Count or **Active Sessions**	Current number of virtual link sessions with VN_Ports.	All
VN_Port Count	(QFX Series only) Number of VN_Ports active on an ENode.	**brief**
Configured FKA-ADV	FIP keepalive interval in seconds configured on the FCF multiplied by three. For example, if the FKA_ADV period configured on the FCF is 86 seconds, the value of this field is 258. For the QFX Series only, the output of this field is always 0 (zero) if the VLAN is an FCoE-FC gateway VLAN. If the VLAN is a FIP snooping VLAN (a transit switch VLAN), then the output is accurate. This is because for an FCoE-FC gateway VLAN, FIP snooping is performed internally and the keepalive advertisements are not tracked by the switch's Ethernet module.	**detail**
Running FKA-ADV	Runtime interval in seconds of the last FIP keepalive advertisement the FCF received. This value changes every time the FCF receives an FKA_ADV. For the QFX Series only, the output of this field is always 0 (zero) if the VLAN is an FCoE-FC gateway VLAN. If the VLAN is a FIP snooping VLAN (a transit switch VLAN), then the output is accurate. This is because for an FCoE-FC gateway VLAN, FIP snooping is performed internally and the keepalive advertisements are not tracked by the switch's Ethernet module.	**detail**
Beacon Period	(QFX Series only) Beacon period interval in milliseconds.	**detail**
VN2VN Mode	(QFX Series only) Mode of VN2VN_Port snooping: • Multi-Point—Multiple ENodes are connected to the network and form multiple virtual links. Each virtual link is created between one pair of VN_Ports. This is analogous to the loop mode in traditional FC networks. • Point-to-Point—Two ENodes are connected to the network and form a single VN_Port to VN_Port virtual link. This is analogous to the point-to-point FC link between an FC initiator and an FC target.	**detail**
ENode-MAC	MAC address of the connected FCoE node (ENode).	All
Interface	Interface connected to the ENode.	**detail**
VN-Port MAC	MAC address of a VN_Port on the ENode.	All

Table 416: show fip snooping Output Fields *(continued)*

Field Name	Field Description	Level of Output
FKA-ADV	Runtime interval in seconds of the last FIP keepalive advertisement the ENode sent to the FCF on behalf of the VN_Port (VN_Port FKA_ADV). This value changes every time the ENode sends a VN_Port FKA_ADV to the FCF.	**detail**
Active VN_Ports	(QFX Series only) Number of VN_Ports active on an ENode.	**detail**
Vlink far-end VN-Port-MAC	(QFX Series only) Media access control (MAC) address of the VN_Port at the other end of the virtual link.	**detail**

Sample Output

show fip snooping enode

Syntax

show fip snooping enode *enode-mac*
<brief | detail>
<vlan *vlan-name*>

Release Information

Command introduced in Junos OS Release 10.4 for EX Series switches.
Command introduced in Junos OS Release 11.1 for the QFX Series.

Description

Display FIP snooping FCoE node (ENode) information.

Options

brief | detail—(Optional) Display the specified level of output.

enode-mac—Display information for the ENode specified by the MAC address.

vlan *vlan-name*—(Optional) Display FIP snooping information for the ENode on only the specified VLAN.

Required Privilege Level

Output Fields

Table 417 on page 5258 lists the output fields for the **show fip snooping enode** command. Output fields are listed in the approximate order in which they appear.

Table 417: show fip snooping enode Output Fields

Field Name	Field Description	Level of Output
ENode and **ENode MAC**	MAC address of the ENode.	All
VLAN	Name of the VLAN.	All
Interface	Interface connected to the ENode.	All

Table 417: show fip snooping enode Output Fields *(continued)*

Field Name	Field Description	Level of Output
Mode	(QFX Series only) Snooping mode enabled on the FCoE VLAN: • VN2VF Snooping—The FCoE VLAN is configured for FIP snooping between an ENode VN_Port and a switch VF_Port. • VN2VN Snooping—The FCoE VLAN is configured for VN_Port to VN_Port FIP snooping between ENode VN_Ports.	All
VN_Port Count	(QFX Series only) Number of VN_Ports active on an ENode.	**brief**
Session Count	Current number of virtual link sessions with VN_Ports.	All
Configured FKA-ADV	FIP keepalive interval in seconds configured on the FCoE forwarder (FCF) multiplied by three. For example, if the FKA_ADV period configured on the FCF is 86 seconds, the value of this field is 258. This value remains constant. For the QFX Series only, the output of this field is always 0 (zero) if the VLAN is an FCoE-FC gateway VLAN. If the VLAN is a FIP snooping VLAN (a transit switch VLAN), then the output is accurate. This is because for an FCoE-FC gateway VLAN, FIP snooping is performed internally and the keepalive advertisements are not tracked by the switch's Ethernet module.	**detail**
Running FKA-ADV	Runtime interval in seconds of the last FIP keepalive advertisement the ENode sent to the FCF. This value changes every time the ENode sends an FKA_ADV to the FCF. For the QFX Series only, the output of this field is always 0 (zero) if the VLAN is an FCoE-FC gateway VLAN. If the VLAN is a FIP snooping VLAN (a transit switch VLAN), then the output is accurate. This is because for an FCoE-FC gateway VLAN, FIP snooping is performed internally and the keepalive advertisements are not tracked by the switch's Ethernet module.	**detail**
VN-Port or **VN-Port-MAC**	MAC address of a VN_Port on the ENode.	All
FKA-ADV	Runtime interval in seconds of the last FIP keepalive advertisement the ENode sent to the FCF on behalf of the VN_Port (VN_Port FKA_ADV). This value changes every time the ENode sends a VN_Port FKA_ADV to the FCF.	**detail**
FCF or **FCF-MAC**	MAC address of the FCF to which the VN_Port is connected.	All
Beacon Period	(QFX Series only) Beacon period interval in milliseconds.	**detail**

show fip snooping fcf

Syntax

show fip snooping fcf *fcf-mac*
<**brief | detail**>
<**vlan** *vlan-name*>

Release Information

Command introduced in Junos OS Release 10.4 for EX Series switches.
Command introduced in Junos OS Release 11.1 for the QFX Series.

Description

Display FIP snooping FCoE forwarder (FCF) information.

Options

brief | detail—(Optional) Display the specified level of output.

fcf-mac—Display information for the FCF specified by the MAC address.

vlan-name—(Optional) Display FIP snooping information for the FCF on only the specified VLAN.

Required Privilege Level

Output Fields

Table 420 on page 5268 lists the output fields for the **show fip snooping statistics** command. Output fields are listed in the approximate order in which they appear.

Table 420: show fip snooping statistics Output Fields

Field Name	Field Description
VLAN	Name of the VLAN for which a set of statistics is displayed.
Mode	(QFX Series only) Snooping mode enabled on the FCoE VLAN: • VN2VF Snooping—The FCoE VLAN is configured for FIP snooping between an ENode VN_Port and a switch VF_Port. • VN2VN Snooping—The FCoE VLAN is configured for VN_Port to VN_Port FIP snooping between ENode VN_Ports.
Number of MDS	Number of multicast discovery solicitation messages sent on the VLAN.

Table 420: show fip snooping statistics Output Fields *(continued)*

Field Name	Field Description
Number of UDS	Number of unicast discovery solicitation messages sent on the VLAN.
Number of FLOGI	Number of fabric logins on the VLAN.
Number of FDISC	Number of fabric discovery logins on the VLAN.
Number of LOGO	Number of fabric logouts on the VLAN.
Number of ENode-keep-alive	Number of ENode keepalive messages sent on the VLAN.
Number of VNPort-keep-alive	Number of VN_Port keepalive messages sent on the VLAN.
Number of MDA	Number of multicast discovery advertisement messages sent on the VLAN.
Number of UDA	Number of unicast discovery advertisement messages sent on the VLAN.
Number of FLOGI_ACC	Number of fabric logins accepted on the VLAN.
Number of FLOGI_RJT	Number of fabric logins rejected on the VLAN.
Number of FDISC_ACC	Number of fabric discoveries accepted on the VLAN.
Number of FDISC_RJT	Number of fabric discoveries rejected on the VLAN.
Number of LOGO_ACC	Number of fabric logouts accepted on the VLAN.
Number of LOGO_RJT	Number of fabric logouts rejected on the VLAN.
Number of CVL	Number of clear virtual links (CVL) actions on the VLAN.
Number of VN_Port Probes Req	(QFX Series only) Number of multicast N_Port_ID probes sent to the ALL-VN2VN-ENode-MACs multicast address on the VLAN.
Number of VN_Port Claim Notif	(QFX Series only) Number of multicast N_Port_ID claim notifications sent on the VLAN.
Number of VN_Port Beacons	(QFX Series only) Number of multicast beacons sent on the VLAN.
Number of VN_Port Probes Reply	(QFX Series only) Number of replies to N_Port_ID probes sent on the VLAN. Replies are unicast to the ENode MAC address of the probe requester.

Table 420: show fip snooping statistics Output Fields *(continued)*

Field Name	Field Description
Number of VN_Port Claim Reply	(QFX Series only) Number of replies to N_Port_ID claim notifications sent on the VLAN. Replies are unicast to the ENode MAC address of the claim notifier.

Sample Output

show fip snooping statistics (FIP Snooping)

```
user@switch> show fip snooping statistics
VLAN: fcoevlan1      Mode: VN2VF Snooping

    Number of MDS:              2
    Number of UDS:              2
    Number of FLOGI:            2
    Number of FDISC:            2
    Number of LOGO:             0
    Number of Enode-keep-alive:  200
    Number of VNPort-keep-alive: 200

    Number of MDA:              25
    Number of UDA:              2
    Number of FLOGI_ACC:        2
    Number of FLOGI_RJT:        0
    Number of FDISC_ACC:        2
    Number of FDISC_RJT:        0
    Number of LOGO_ACC:         0
    Number of LOGO_RJT:         0
    Number of CVL:              0
```

show fip snooping statistics (VN2VN_Port Snooping)

```
user@switch> show fip snooping statistics
VLAN: vlan101   Mode: VN2VN Snooping

Number of VN_Port Probes Req:        3
Number of VN_Port Claim Notif:       3
Number of VN_Port Beacons:           0

Number of VN_Port Probes Reply:      3
Number of VN_Port Claim Reply:       3
Number of FLOGI:                     0
Number of FLOGI_ACC:                 0
Number of FLOGI_RJT:                 0
Number of FDISC:                     0
Number of FDISC_ACC:                 0
Number of FDISC_RJT:                 0

Number of LOGO_RJT:                  0
```

show fip snooping vlan

Syntax

show fip snooping vlan ***vlan-name***
<brief | detail>

Release Information

Command introduced in Junos OS Release 10.4 for EX Series switches.
Command introduced in Junos OS Release 11.1 for the QFX Series.

Description

Display FIP snooping VLAN information.

Options

brief | detail—(Optional) Display the specified level of output.

vlan-name—Display information for the specified VLAN.

Required Privilege Level

view

Output Fields

Table 421 on page 5271 lists the output fields for the **show fip snooping vlan** command. Output fields are listed in the approximate order in which they appear.

Table 421: show fip snooping vlan Output Fields

Field Name	Field Description	Level of Output
VLAN	Name of the VLAN.	All

Table 421: show fip snooping vlan Output Fields *(continued)*

Field Name	Field Description	Level of Output
Mode	(QFX Series only) Snooping mode enabled on the FCoE VLAN: • VN2VF Snooping—The FCoE VLAN is configured for FIP snooping between an ENode VN_Port and a switch VF_Port. • VN2VN Snooping—The FCoE VLAN is configured for VN_Port to VN_Port FIP snooping between ENode VN_Ports.	All
VN_Port count	(QFX Series only) Number of VN_Ports active on an ENode when the mode is VN2VN_Port FIP snooping.	
FC-MAP	FCoE mapped address prefix of the FCoE forwarder for the VLAN.	All
Beacon_Period	(QFX Series only) Beacon period interval in milliseconds.	**detail**
VN2VN Mode	(QFX Series only) Mode of VN2VN_Port snooping: • Multi-Point—Multiple ENodes are connected to the network and form multiple virtual links. Each virtual link is created between one pair of VN_Ports. This is analogous to the loop mode in traditional FC networks. • Point-to-Point—Two ENodes are connected to the network and form a single VN_Port to VN_Port virtual link. This is analogous to the point-to-point FC link between an FC initiator and an FC target.	**detail**
FCF or **FCF-MAC**	MAC address of the FCF.	All
Session Count or **Active Sessions**	Current number of virtual link sessions with VN_Ports.	All
Configured FKA-ADV	FIP keepalive interval in seconds configured on the FCF multiplied by three. For example, if the FKA_ADV period configured on the FCF is 86 seconds, the value of this field is 258.	**detail**
Running FKA-ADV	Runtime interval in seconds of the last FIP keepalive advertisement the FCF received. This value changes every time the FCF receives an FKA_ADV.	**detail**

Table 421: show fip snooping vlan Output Fields *(continued)*

Field Name	Field Description	Level of Output
ENode-MAC	MAC address of the connected ENode.	All
• **Interface**	Interface connected to the ENode.	**detail**
• **Configured FKA-ADV**	FIP keepalive interval in seconds configured on the FCF multiplied by three. For example, if the FKA_ADV period configured on the FCF is 86 seconds, the value of this field is 258. This value remains constant.	**detail**
• **Running FKA-ADV**	Runtime interval in seconds of the last FIP keepalive advertisement the ENode sent to the FCF. This value changes every time the ENode sends an FKA_ADV to the FCF.	**detail**
• **VN-Port MAC**	MAC address of a VN_Port on the ENode.	All
• **FKA-ADV**	Runtime interval in seconds of the last FIP keepalive advertisement the ENode sent to the FCF on behalf of the VN_Port (VN_Port FKA_ADV). This value changes every time the ENode sends a VN_Port FKA_ADV to the FCF.	**detail**
• **Active VN_Ports**	(QFX Series only) Number of VN_Ports active on an ENode.	**detail**
• **Vlink far-end VN-Port-MAC**	(QFX Series only) Media access control (MAC) address of the VN_Port at the other end of the virtual link.	**detail**

Sample Output

```

show fip vlan-discovery

Syntax **show fip vlan-discovery (enodes | statistics)**

Release Information Command introduced in Junos OS Release 12.1 for the QFX Series.

Description Display FCoE VLAN information from the Fibre Channel switch or FCoE forwarder (FCF).

Options **enodes**—Display VLAN discovery information for each ENode.

statistics—Display VLAN discovery information statistics.

Required Privilege Level view

Output Fields Table 422 on page 5275 lists the output fields for the **show fip vlan-discovery** command. Output fields are listed in the approximate order in which they appear.

Table 422: show fip vlan-discovery Output Fields

Field Name	Field Description	Level of Output
Enode-MAC	Media access control (MAC) address of the ENode.	**enodes**
Interface	Name of the interface.	**enodes**
Unsolicited notification count	Number of unsolicited VLAN discovery notifications.	All
Solicited notification count	Number of solicited VLAN discovery notifications.	**statistics**
Node Group Name	Displays the name of the Node group on QFabric systems.	**statistics**
Request count	Number of VLAN discovery requests sent by the ENode. This number should match the **Solicited notification count** number.	**statistics**
VLAN tags	Tags of the FIP-enabled VLANs.	**enodes**

Sample Output

show fip vlan-discovery enodes

```
user@switch> show fip vlan-discovery enodes

Enode-MAC            Interface      Unsolicited     Vlan Tags
                                    Notification
                                    Count
00:10:94:00:00:02    xe-0/0/9.0        0            400
```

show fip vlan-discovery statistics (QFX3500)

```
user@switch> show fip vlan-discovery statistics
Request count: 0
Solicited notification count: 0
Unsolicited notification count: 1
```

show fip vlan-discovery statistics (QFabric Systems)

```
user@switch> show fip vlan-discovery statistics
NW-NG-0:
--------------------------------------------
Request count: 0
Solicited notification count: 0
Unsolicited notification count: 1

BBAK0399:
--------------------------------------------
Request count: 0
Solicited notification count: 0
Unsolicited notification count: 1

Request count: 0
Solicited notification count: 0
Unsolicited notification count: 1
```

show route forwarding-table family fibre-channel

Syntax

show route forwarding-table family fibre-channel
<brief | detail | extensive>
<all>
<destination *destination-prefix*>
<interface-name *interface-name*>
<label *label*>
<matching *ip-prefix*>
<multicast>
<summary>
<table *routing-table-name*>
<vlan *vlan-name*>
<vpn *vpn-instance-name*>

Release Information Command introduced in Junos OS Release 11.1 for the QFX Series.

Description Display Fibre Channel family forwarding table route information.

Options

brief | detail | extensive—(Optional) Display the specified level of output.

all—Display all routing forwarding tables.

destination *destination-prefix*—Destination prefix.

interface-name *interface-name*—Name of the interface.

label *label*—Display route entries for the specified label name.

matching *ip-prefix*—Display route entries for the specified IP prefix or length.

multicast—Display multicast routes.

summary—Display route count instead of details.

table *routing-table-name*—Name of the routing table.

vlan *vlan-name*—Name of the VLAN.

vpn *vpn-instance-name*—Name of the VPN instance.

Required Privilege Level view

List of Sample Output show route forwarding-table family fibre-channel on page 5278

Output Fields Table 423 on page 5278 lists the output fields for the **show route forwarding-table family fibre-channel** command. Output fields are listed in the approximate order in which they appear.

Table 423: show route forwarding-table family fibre-channel Output Fields

Field Name	Field Description
Routing table	Name of the routing table.
Destination	Route destination.
Type	Type of route internal to Junos OS.
RtRef	Route reference count internal to Junos OS.
Next hop Type	Type of next hop internal to Junos OS.
Index	Next-hop index identifier.
NhRef	Number of routes that refer to the next hop.
Netif	Interface used to reach the next hop.

Sample Output

show route forwarding-table family fibre-channel

```
user@switch> show route forwarding-table family fibre-channel
Routing table: default.fibre-channel
Fibre Channel:
Destination       Type RtRef Next hop          Type Index NhRef Netif
default           perm     0                   dscd   126     1
0x30000/24        user     0                   ucst   674     2 fc-0/0/0.0
0x30001/24        user     0                   ucst   675     2 vlan.100

```

CHAPTER 61

Troubleshooting

Troubleshooting Procedures

Troubleshooting Dropped FCoE Traffic

Problem Fibre Channel over Ethernet (FCoE) traffic for which you want guaranteed delivery is dropped.

Cause There are several possible causes of dropped FCoE traffic (the list numbers of the possible causes correspond to the list numbers of the solutions in the *Solution* section.):

1. Priority-based flow control (PFC) is not enabled on the FCoE priority (IEEE 802.1p code point) in both the input and output stanzas of the congestion notification profile.
2. The FCoE traffic is not classified correctly at the ingress interface. FCoE traffic should either use the default **fcoe** forwarding class and classifier configuration (maps the **fcoe** forwarding class to IEEE 802.1p code point 011) or be mapped to a lossless forwarding class and to the code point enabled for PFC on the input and output interfaces.
3. The congestion notification profile that enables PFC on the FCoE priority is not attached to the interface.
4. The forwarding class set (priority group) used for guaranteed delivery traffic does not include the forwarding class used for FCoE traffic.
5. Insufficient bandwidth has been allocated for the FCoE queue or for the forwarding class set to which the FCoE queue belongs.
6. If you are using Junos OS Release 12.2, the **fcoe** forwarding class has been explicitly configured instead of using the default **fcoe** forwarding class configuration (forwarding-class-to-queue mapping).

NOTE: If you are using Junos OS Release 12.2, use the default forwarding-class-to-queue mapping for the lossless **fcoe** and **no-loss** forwarding classes. If you explicitly configure the lossless forwarding classes, the traffic mapped to those forwarding classes is treated as lossy (best effort) traffic and does *not* receive lossless treatment.

7. If you are using Junos OS Release 12.3 or later and you are not using the default **fcoe** forwarding class configuration, the forwarding class used for FCoE is not configured with the **no-loss** packet drop attribute. In Junos OS 12.3 or later, explicit forwarding classes configurations must include the **no-loss** packet drop attribute to be treated as lossless forwarding classes.

Solution The list numbers of the possible solutions correspond to the list numbers of the causes in the *Cause* section.

1. Check the congestion notification profile (CNP) to see if PFC is enabled on the FCoE priority (the correct IEEE 802.1p code point) on both input and output interfaces. Use the **show class-of-service congestion-notification** operational command to show the code points that are enabled for PFC in each CNP.

   If you are using the default configuration, FCoE traffic is mapped to code point 011 (priority 3). In this case, the input stanza of the CNP should show that PFC is enabled on code point 011, and the output stanza should show that priority 011 is mapped to flow control queue 3.

   If you explicitly configured a forwarding class for FCoE traffic, ensure that:

   - You specified the **no-loss** packet drop attribute in the forwarding class configuration
   - The code point mapped to the FCoE forwarding class in the ingress classifier is the code point enabled for PFC in the CNP input stanza
   - The code point and output queue used for FCoE traffic are mapped to each other in the CNP output stanza (if you are not using the default priority and queue, you must explicitly configure each output queue that you want to respond to PFC messages)

   For example, if you explicitly configure a forwarding class for FCoE traffic that is mapped to output queue 5 and to code point 101 (priority 5), the output of the **show class-of-service congestion-notification** looks like:

```
Name: fcoe_p5_cnp, Index: 12183
Type: Input
Cable Length: 100 m
  Priority     PFC          MRU
  000          Disabled
  001          Disabled
  010          Disabled
  011          Disabled
  100          Disabled
  101          Enabled      2500
  110          Disabled
  111          Disabled
Type: Output
  Priority     Flow-Control-Queues
  101
               5
```

2. Use the **show class-of-service classifier type ieee-802.1p** operational command to check if the classifier maps the forwarding class used for FCoE traffic to the correct IEEE 802.1p code point.
3. Ensure that the congestion notification profile and classifier are attached to the correct ingress interface. Use the operational command **show configuration class-of-service interfaces *interface-name***.
4. Check that the forwarding class set includes the forwarding class used for FCoE traffic. Use the operational command **show configuration class-of-service forwarding-class-sets** to show the configured priority groups and their forwarding classes.

5. Verify the amount of bandwidth allocated to the queue mapped to the FCoE forwarding class and to the forwarding class set to which the FCoE traffic queue belongs. Use the **show configuration class-of-service schedulers *scheduler-name*** operational command (specify the scheduler for FCoE traffic as the ***scheduler-name***) to see the minimum guaranteed bandwidth (**transmit-rate**) and maximum bandwidth (**shaping-rate**) for the queue.

   Use the **show configuration class-of-service traffic-control-profiles *traffic-control-profile*** operational command (specify the traffic control profile used for FCoE traffic as the ***traffic-control-profile***) to see the minimum guaranteed bandwidth (**guaranteed-rate**) and maximum bandwidth (**shaping-rate**) for the forwarding class set.

6. Delete the explicit FCoE forwarding-class-to-queue mapping so that the system uses the default FCoE forwarding-class-to-queue mapping. Include the **delete forwarding-classes class fcoe queue-num 3** statement at the **[edit class-of-service]** hierarchy level to remove the explicit configuration. The system then uses the default configuration for the FCoE forwarding class and preserves the lossless treatment of FCoE traffic.

7. Use the **show class-of-service forwarding-class** operational command to display the configured forwarding classes. The *No-Loss* column shows whether lossless transport is enabled or disabled for each forwarding class. If the forwarding class used for FCoE traffic is not enabled for lossless transport, include the **no-loss** packet drop attribute in the forwarding class configuration (**set class-of-service forwarding-classes class *fcoe-forwarding-class-name* queue-num *queue-number* no-loss**).

See “Example: Configuring CoS PFC for FCoE Traffic” on page 4921 for step-by-step instructions on how to configure PFC for FCoE traffic, including classifier, interface, congestion notification profile, PFC, and bandwidth scheduling configuration.

Troubleshooting Fibre Channel Interface Deletion

Problem You deleted a Fibre Channel (FC) interface at the **[edit interfaces]** hierarchy level, but the commit check fails so the interface is not deleted.

Cause You must first delete the FC interface from the FC fabric on the QFX Series before you can delete the FC interface at the **[edit interfaces]** hierarchy level. You must perform both operations to delete a FC interface.

Solution First delete the interface from the FC fabric and then delete the interface from the QFX Series:

1. Delete the FC interface from the FC fabric to which it belongs:

   ```
   [edit]
   user@switch# delete fc-fabrics fabric-name interface interface-name
   ```

   For example, to delete the FC interface **fc-0/0/3.0** from an FC fabric named **sanfab1**:

   ```
   [edit]
   user@switch# delete fc-fabrics sanfab1 interface fc-0/0/3.0
   ```
2. Delete the FC interface at the **[edit interfaces]** hierarchy level:

   ```
   [edit]
   user@switch: delete interfaces interface-name
   ```

   For example, to delete the interface **fc-0/0/3.0** from the switch:

   ```
   [edit]
   user@switch: delete interfaces fc-0/0/3.0
   ```

Troubleshooting Dropped FIP Traffic

Problem Fibre Channel over Ethernet (FCoE) Initialization Protocol (FIP) traffic such as FIP VLAN discovery and notification frames is dropped on the QFX Series.

Cause The interface on which the FIP traffic is dropped does not have a native VLAN configured. FIP VLAN discovery and notification messages are exchanged as untagged packets on the native VLAN. (After the FCoE session with the Fibre Channel switch is established, FCoE traffic uses the FCoE VLAN.)

Solution Check to ensure that every 10-Gigabit Ethernet interface that connects to an FCoE device includes a native VLAN. Configure a native VLAN on all 10-Gigabit Ethernet interfaces that connect to FCoE devices.

NOTE: **Make sure that the native VLAN you are using on the QFX Series is the same native VLAN that the FCoE devices use for Ethernet traffic.**

The procedure for configuring a native VLAN on an interface is different on switches that use the original CLI than on switches that use the Enhanced Layer 2 Software (ELS) CLI. This topic provides the configuration procedure for each CLI.

Configuring a Native VLAN on Switches Using the Original CLI

To configure a native VLAN on an interface:

1. Set the interface port mode to **tagged-access** if you have not already done so:

   ```
   [edit]
   user@switch# set interfaces interface unit unit family ethernet-switching port-mode
   tagged-access
   ```

   For example, to set the port mode to **tagged-access** for interface **xe-0/0/6.0**:

   ```
   [edit]
   user@switch# set interfaces xe-0/0/6 unit 0 family ethernet-switching port-mode
   tagged-access
   ```

2. Configure the native VLAN if it does not already exist:

   ```
   [edit]
   user@switch# set vlans vlan-name vlan-id vlan-id
   ```

   For example, to name the native VLAN **native** and use the VLAN ID **1**:

   ```
   [edit]
   user@switch# set vlans native vlan-id 1
   ```

3. Configure the native VLAN on the interface:

   ```
   [edit]
   user@switch# set interfaces interface unit unit family ethernet-switching native-vlan-id
   vlan-id
   ```

   For example, to configure a native VLAN with the VLAN ID **1** on interface **xe-0/0/6.0**:

   ```
   [edit]
   user@switch# set interfaces xe-0/0/6 unit 0 family ethernet-switching native-vlan-id 1
   ```

Configuring a Native VLAN on Switches Using the ELS CLI

To configure a native VLAN on an interface:

1. Set the interface mode to **trunk** if you have not already done so:

   ```
   [edit]
   user@switch# set interfaces interface unit unit family ethernet-switching interface-mode
   trunk
   ```

   For example, to set the interface mode to **trunk** for interface **xe-0/0/6.0**:

   ```
   [edit]
   user@switch# set interfaces xe-0/0/6 unit 0 family ethernet-switching interface-mode trunk
   ```

2. Configure the native VLAN if it does not already exist:

   ```
   [edit]
   user@switch# set vlans vlan-name vlan-id vlan-id
   ```

   For example, to name the native VLAN **native** and use the VLAN ID **1**:

   ```
   [edit]
   user@switch# set vlans native vlan-id 1
   ```

3. Configure the native VLAN on the physical Ethernet interface:

```
[edit]
user@switch# set interfaces interface native-vlan-id vlan-id
```

For example, to configure a native VLAN with the VLAN ID **1** on interface **xe-0/0/6.0**:

```
[edit]
user@switch# set interfaces xe-0/0/6 native-vlan-id 1
```

4. Configure the Ethernet interface as a member of the native VLAN:

```
[edit]
user@switch# set interfaces interface unit unit family ethernet-switching vlan members
vlan-name
```

For example, to configure an Ethernet interface as a member of a native VLAN with the VLAN ID **1** on interface **xe-0/0/6.0**:

```
[edit]
user@switch# set interfaces xe-0/0/6 unit 0 family ethernet-switching vlan members native
```

CHAPTER 62

Overview

CoS Upgrade and Change Overview

Overview of CoS Upgrade Requirements (Junos OS Release 11.1 or 11.2 to a Later Release)

Before you upgrade to Junos OS Release 11.3, you must deactivate the CoS configuration if the CoS configuration includes any of the following features:

- **excess-rate** option
- **strict-high** or **high** priority queues
- Any of the Junos OS Release 11.1 or 11.2 default multidestination forwarding classes

CAUTION: If your CoS configuration contains any of the features listed above and you attempt to upgrade from Junos OS Release 11.1 or 11.2 to a later version without first editing the configuration, the Junos OS might not restart.

Junos OS Release 11.3 and later for QFX Series no longer supports the **excess-rate** statement, the **strict** priority option, or the default multidestination forwarding classes used in Junos OS Release 11.1 and 11.2. In addition, Junos OS Release 11.3 introduces new restrictions on how to configure and use **strict-high** priority queues.

This topic does not describe how to perform the software upgrade procedure. It describes how to deactivate your CoS configuration, edit your CoS configuration, and reactivate your CoS configuration at the appropriate times.

Use the following procedure to upgrade safely from Junos OS Release 11.1 or 11.2 to a later release:

1. Deactivate the CoS configuration *before* you upgrade the software:

   `user@switch#` **deactivate class-of-service**
2. Follow the upgrade procedure to Junos OS Release 11.3 or later software.
3. Make the following changes to the CoS configuration while the CoS configuration is still deactivated:
   - Remove the **excess-rate** statement from the CoS configuration if you have used it at the **[edit class-of-service schedulers]** or **[edit class-of-service traffic-control-profiles]** hierarchy level.
   - Remove the **strict-high** and **strict** priority queue configurations if you have used them at the **[edit class-of-service schedulers]** hierarchy level.
   - Remove the default multidestination forwarding classes (**mcast-be**, **mcast-af**, **mcast-ef**, and **mcast-nc**) if you have used them at the **[edit class-of-service schedulers]**, **[edit class-of-service rewrite-rules]**, **[edit class-of-service classifiers]**, **[edit class-of-service scheduler-maps]**, or **[edit class-of-service forwarding-class-sets]** hierarchy level. Alternatively, you can change the mapping of the multidestination traffic to use the new default multidestination forwarding class (**mcast**).
4. If desired, configure **strict-high** priority queues in accordance with the Junos OS Release 11.3 or later configuration rules, and map multidestination traffic to the default multidestination forwarding class (**mcast**).

5. Activate the CoS configuration:

   `user@switch#` **activate class-of-service**

6. Commit the CoS configuration:

   `user@switch#` **commit**

NOTE: If you configured the **transmit-rate** option for any queues under the **[edit class-of-service schedulers]** hierarchy level, if the rate is configured as an exact rate in Mbps, we recommend that you reconfigure the **transmit-rate** option as a percentage. This is because the scheduler converts exact rates to percentages, and when the exact rate is below 1 Gbps, some granularity may be lost in the conversion. You can avoid this potential issue by specifying the **transmit-rate** option as a percentage.

Overview of CoS Upgrade Requirements to Junos OS Release 12.2

Before you upgrade to Junos OS Release 12.2, you might need to edit the class-of-service (CoS) configuration, because the way the QFX Series handles lossless forwarding classes has changed in Junos OS Release 12.2.

By default, the **fcoe** and **no-loss** forwarding classes are mapped to output queue 3 and output queue 4, respectively. These are the only two forwarding classes (and the only two queues) that support lossless transport.

In Junos OS Release 12.1 and earlier, explicitly setting the lossless **fcoe** and **no-loss** forwarding classes resulted in the same CoS behavior as using the default configuration. However, in Junos OS Release 12.2, the behavior when you explicitly configure the lossless forwarding classes differs from the behavior when you use the default forwarding classes.

NOTE: The default behavior differs from the explicit configuration behavior even if the explicit configuration is exactly the same as the default configuration.

- If you use the default forwarding class configuration for the lossless queues (the configuration does not include explicit setting of the **fcoe** or the **no-loss** forwarding classes), then the **fcoe** and **no-loss** queues behave as lossless queues.

  If your CoS configuration does not explicitly configure the **fcoe** and **no-loss** forwarding classes, you can upgrade from Junos OS Release 12.1 to Junos OS Release 12.2, and the behavior of the two lossless queues remains the lossless.

- If your configuration includes statements that explicitly configure the **fcoe** or the **no-loss** forwarding class (using the **[set class-of-service forwarding-classes class *class-name* queue-num *queue-number*]** statement), after you upgrade to Junos OS Release 12.2, those queues do *not* receive lossless treatment and behave as lossy (**best-effort**) queues.

  If your CoS configuration explicitly configures the **fcoe** and **no-loss** forwarding classes, to retain the lossless behavior of those queues, you need to remove the explicit configuration for these two forwarding classes from the CoS configuration *before* you upgrade.

If you upgrade to Junos OS Release 12.2 and the **fcoe** and **no-loss** forwarding classes are explicitly configured, then those two queues continue to be used, but the traffic is treated as lossy traffic, not lossless traffic. To make the queues for these two forwarding classes lossless, you must delete the explicit forwarding class configuration.

CAUTION: **If you explicitly configured the fcoe or the no-loss forwarding class and you upgrade to Junos OS Release 12.2, the system does not return an upgrade error or a commit error, or a generate a syslog message, to notify you that these forwarding classes are no longer lossless. Traffic mapped to these forwarding classes is not treated as lossless traffic until you remove the explicit forwarding class configuration.**

Before you upgrade, delete the **fcoe** and **no-loss** forwarding classes from the explicit configuration to preserve the lossless behavior of traffic mapped to these forwarding classes.

- To delete the explicit **fcoe** forwarding class configuration:

  ```
  [edit]
  user@switch# delete class-of-service forwarding-class class fcoe queue-num 3
  user@switch# commit
  ```

- To delete the explicit **no-loss** forwarding class configuration:

  ```
  [edit]
  user@switch# delete class-of-service forwarding-class class no-loss queue-num 4
  user@switch# commit
  ```

NOTE: If you try to delete these forwarding classes and they have not been explicitly configured on the system, the system returns the message **warning: statement not found**. This simply means that there is no explicit configuration to delete and does not change the lossless behavior of the **fcoe** and **no-loss** forwarding classes.

After you delete the explicit configuration for the **fcoe** and **no-loss** forwarding classes, traffic mapped to those forwarding classes retains its lossless behavior after the upgrade to Junos OS Release 12.2.

Overview of CoS Upgrade Requirements to Junos OS Release 12.3 (QFX3500 and QFX3600 Switches) or to Junos OS Release 13.1 (QFabric Systems)

Before you upgrade to Junos OS Release 12.3 (QFX3500 and QFX3600 switches) or to Junos OS Release 13.1 (QFabric systems), you might need to edit the class-of-service (CoS) configuration, because the way the QFX Series handles lossless forwarding classes has changed from earlier Junos OS releases. (Throughout this document, changes introduced on standalone switches in Junos OS Release 12.3 are introduced on QFabric systems in Junos OS Release 13.1 unless otherwise noted.)

Support for Six Lossless Forwarding Classes

By default, the *fcoe* and *no-loss* forwarding classes are mapped to output queue 3 and output queue 4, respectively, and to IEEE 802.1p priority 3 (code point 011) and priority 4 (code point 100), respectively. These are the only two forwarding classes (and the only two queues) that support lossless transport in the default configuration.

If you use the default CoS configuration, you do not need to edit the CoS configuration after upgrading to Junos OS Release 12.3 (QFX3500 and QFX3600 switches) or to Junos OS Release 13.1 (QFabric system) because the default CoS configuration is backward-compatible.

Junos OS Release 12.3 increases the support for lossless forwarding classes (priorities) from two forwarding classes to six forwarding classes. To support configuring lossless forwarding classes, Junos OS Release 12.3 introduces a new option to forwarding class configuration: the *no-loss* packet drop attribute.

NOTE: The new *no-loss* packet drop attribute and the previously existing *no-loss* default forwarding class have the same name, but they are not the same. You can use the no-loss packet drop attribute on any unicast forwarding class.

If you explicitly configure any lossless forwarding class (including explicitly configuring the default fcoe and no-loss forwarding classes), you *must* specify the no-loss packet drop attribute to obtain lossless behavior. If you do not explicitly configure the fcoe and no-loss forwarding classes, those forwarding classes remain lossless.

The addition of the no-loss packet drop attribute to forwarding class configuration means that when you upgrade from an earlier release to Junos OS Release 12.3, the new software might not preserve the lossless forwarding class configuration of the fcoe and no-loss forwarding classes.

If you used the default forwarding class configuration for the fcoe and no-loss forwarding classes, the CoS configuration is backward-compatible. You do not have to do anything to preserve the lossless behavior of traffic that uses those forwarding classes when you upgrade to Junos OS Release 12.3. (This is because the default configuration of these two forwarding classes includes the no-loss packet drop attribute.)

However, if you explicitly configured the fcoe or the no-loss forwarding class by including the **set forwarding-classes class *forwarding-class-name* queue-num *queue-number*** at the **[edit class-of-service]** hierarchy level, then those forwarding classes are no longer lossless, they are lossy. In Junos OS Release 12.3 and later, you must include the *no-loss* packet drop attribute in any explicit forwarding class configuration to configure a lossless forwarding class.

For example, before Junos OS Release 12.3, the following explicit configuration resulted in a lossless forwarding class:

`user@switch#` **set class-of-service forwarding-classes class fcoe queue-num 3**

However, in Junos OS Release 12.3, this configuration is lossy because it does not include the no-loss packet drop attribute. To preserve lossless behavior, after upgrading to Junos OS Release 12.3, you need to add the no-loss drop attribute:

`user@switch#` **set class-of-service forwarding-classes class fcoe queue-num 3 no-loss**

Alternatively, you can delete the explicit configuration before you upgrade to Junos OS Release 12.3 so that the system uses the default forwarding class, which is lossless:

`user@switch#` **delete class-of-service forwarding-classes class fcoe queue-num 3**

NOTE: The explicit configuration of other forwarding classes does not affect the lossless (or lossy) state of the fcoe and no-loss forwarding classes, because only the fcoe and no-loss forwarding classes are lossless forwarding classes before Junos OS Release 12.3. For example, if you explicitly configured the best-effort forwarding class but you used the default fcoe and no-loss forwarding classes in Junos OS Release 12.2, then when you upgrade to Junos OS Release 12.3, the fcoe and no-loss forwarding classes are still lossless (and the best-effort forwarding class retains its explicit configuration).

NOTE: To achieve lossless behavior for the traffic belonging to any forwarding class, you must also enable PFC on the IEEE 802.1p priority mapped to the forwarding class and ensure that DCBX exchanges the protocol TLVs for the application with the connected peer.

Scheduling on QFabric System Node Device Fabric (fte) Ports

Junos OS Release 13.1 introduces the ability to configure scheduling on the fabric (fte) ports of QFabric system Node devices. In earlier Junos OS releases, Node device fabric port scheduling was done by default, with no user configuration.

In Junos OS Release 13.1, the default fabric port scheduler configuration is similar to the default scheduler configuration on access interfaces. Similar to the access port default configuration, the default fabric port scheduler supports the five default forwarding classes (best-effort, fcoe, no-loss, network-control, and mcast). If you configure any new forwarding classes, you must configure scheduling on the fabric ports to allocate bandwidth to those forwarding classes, just as you must configure scheduling on the access ports for user-defined forwarding classes.

Strict-High Priority Scheduling on QFabric System Node Device Fabric (fte) Ports

If a fabric interface handles strict-high priority traffic, you must define a separate fc-set (priority group) for strict-high priority traffic. Strict-high priority traffic cannot be mixed with traffic of other priorities in an fc-set. For example, you might choose to create different fc-sets for best effort, lossless, strict-high priority, and multidestination traffic.

Related Documentation

- Overview of CoS Upgrade Requirements (Junos OS Release 11.1 or 11.2 to a Later Release) on page 32

Overview of CoS Changes Introduced in Junos OS Release 11.3

Junos OS Release 11.3 introduces many changes to class-of-service (CoS) functionality and to the CoS default values. This overview summarizes the changes, which other documents describe in detail.

NOTE: Some of the CoS changes are not backward compatible with Junos OS Releases 11.1 and 11.2. "Overview of CoS Upgrade Requirements (Junos OS Release 11.1 or 11.2 to a Later Release)" on page 32 describes how to upgrade to Junos OS Release 11.3 if you have configured CoS on your QFX3500 switch.

This topic describes the following changes in CoS default values and behavior:

CoS Default Value Changes

The default values of the following CoS components have changed in Junos OS Release 11.3:

Default Forwarding Classes

In Junos OS Releases 11.1 and 11.2, there were eight default forwarding classes, four unicast default forwarding classes and four default multidestination (multicast, broadcast, and destination lookup fail) forwarding classes. Table 424 on page 5296 shows the old default forwarding classes and default queue mapping:

Table 424: Junos OS Release 11.1 and 11.2 Default Forwarding Classes and Queue Mapping

Default Forwarding Class	Description	Default Queue Mapping
best-effort (be)	Unicast best-effort traffic	0
no-loss	Unicast guaranteed delivery for TCP no-loss traffic	2

Table 424: Junos OS Release 11.1 and 11.2 Default Forwarding Classes and Queue Mapping *(continued)*

Default Forwarding Class	Description	Default Queue Mapping
fcoe	Unicast guaranteed delivery for FCoE traffic	3
network-control	Unicast network control traffic	7
multicast-best-effort (mcast-be)	Multidestination best-effort traffic	8
multicast-expedited-forwarding (mcast-ef)	Multidestination low-loss, low-latency traffic	9
multicast-assured-forwarding (mcast-af)	Multidestination assured forwarding traffic	10
multicast-network-control (mcast-nc)	Multidestination network control traffic	11

Junos OS Release 11.3 changes the default forwarding classes and queue mapping in the following ways:

- Instead of eight default forwarding classes, there are five default forwarding classes.
- The same four unicast default forwarding classes remain valid, but the default queue mapping of the no-loss forwarding class has changed from queue 2 to queue 4.
- There is now only one default multidestination forwarding class instead of four default multidestination forwarding classes. All multidestination traffic is assigned by default to the default multidestination forwarding class.

NOTE: The rest of the forwarding class characteristics remain the same as before. For example, the QFX Series still supports 12 forwarding classes and 12 output queues. You can still configure a total of eight unicast forwarding classes and four multidestination forwarding classes. The unicast queues are still queues 0 through 7 and the multidestination queues are still queues 8 through 11. Unicast traffic must be mapped to unicast queues, and multidestination traffic must be mapped to multidestination queues. The queue to which a forwarding class is mapped determines whether the forwarding class is unicast or multidestination.

Table 425 on page 5297 shows the default forwarding classes and queue mapping in Junos OS 11.3 and later:

Table 425: Junos OS Release 11.3 Default Forwarding Classes and Queue Mapping

Default Forwarding Class	Description	Default Queue Mapping
best-effort (be)	Best-effort traffic class	0
fcoe	Guaranteed delivery for FCoE traffic	3

Table 425: Junos OS Release 11.3 Default Forwarding Classes and Queue Mapping *(continued)*

Default Forwarding Class	Description	Default Queue Mapping
no-loss	Guaranteed delivery for TCP no-loss traffic	4
network-control (nc)	Network control traffic	7
mcast	Multicast traffic	8

Default IEEE 802.1p Unicast Classifiers

In Junos OS Release 11.1 and 11.2, there were default unicast classifiers only for best-effort and network-control traffic, as shown in Table 426 on page 5298:

Table 426: Junos OS Release 11.1 and 11.2 Default IEEE 802.1 Unicast Classifiers

Code Point	Forwarding Class	Loss Priority
be (000)	best-effort	low
be1 (001)	best-effort	low
ef (010)	best-effort	low
ef1 (011)	best-effort	low
af11 (100)	best-effort	low
af12 (101)	best-effort	low
nc1 (110)	network-control	low
nc2 (111)	network-control	low

Junos OS Release 11.3 introduces new default classifiers for FCoE and no-loss traffic, replacing the best-effort classifiers mapped to IEEE 802.1p code points 011 and 100, respectively, as shown in Table 427 on page 5298:

Table 427: Junos OS Release 11.3 Default IEEE 802.1 Unicast Classifiers

Code Point	Forwarding Class	Loss Priority
be (000)	best-effort	low
be1 (001)	best-effort	low
ef (010)	best-effort	low
ef1 (011)	fcoe	low
af11 (100)	no-loss	low

Table 427: Junos OS Release 11.3 Default IEEE 802.1 Unicast Classifiers *(continued)*

Code Point	Forwarding Class	Loss Priority
af12 (101)	best-effort	low
nc1 (110)	network-control	low
nc2 (111)	network-control	low

Default IEEE 802.1p Multidestination Classifiers

In Junos OS Release 11.1 and 11.2, there were default multidestination classifiers for best-effort and network-control traffic, as shown in Table 428 on page 5299:

Table 428: Junos OS Release 11.1 and 11.2 Default IEEE 802.1 Multidestination Classifiers

Code Point	Forwarding Class	Loss Priority
be (000)	mcast-be	low
be1 (001)	mcast-be	low
ef (010)	mcast-be	low
ef1 (011)	mcast-be	low
af11 (100)	mcast-be	low
af12 (101)	mcast-be	low
nc1 (110)	mcast-nc	low
nc2 (111)	mcast-nc	low

Junos OS Release 11.3 replaces the best-effort and network-control multidestination classifiers and maps all IEEE 802.1p code points to the new default multidestination forwarding class, as shown in Table 429 on page 5299:

Table 429: Junos OS Release 11.3 Default IEEE 802.1 Multidestination Classifiers

Code Point	Forwarding Class	Loss Priority
be (000)	mcast	low
be1 (001)	mcast	low
ef (010)	mcast	low
ef1 (011)	mcast	low
af11 (100)	mcast	low

Table 429: Junos OS Release 11.3 Default IEEE 802.1 Multidestination Classifiers *(continued)*

Code Point	Forwarding Class	Loss Priority
af12 (101)	mcast	low
nc1 (110)	mcast	low
nc2 (111)	mcast	low

Default Scheduler

In Junos OS Release 11.1 and 11.2, there were four default schedulers:

- Unicast best effort
- Unicast network control
- Multidestination best effort
- Multidestination network control

Table 430 on page 5300 shows the default scheduler configuration in Junos OS Release 11.1 and 11.2:

Table 430: Junos OS Release 11.1 and 11.2 Default Schedulers

Default Scheduler and Queue Number	Guaranteed Rate (Minimum Bandwidth)	Shaping Rate (Maximum Bandwidth)	Excess Rate (Extra Bandwidth Sharing)	Priority
Best-effort scheduler (queue 0)	75%	None	25%	Low
Network-control scheduler (queue 7)	5%	None	25%	Low
Best-effort multidestination scheduler (queue 8)	15%	None	25%	Low
Network-control multidestination scheduler (queue 11)	5%	None	25%	Low

Junos OS Release 11.3 replaces the four old classifiers with five new classifiers:

- Unicast best effort
- FCoE
- No loss
- Unicast network control
- Multidestination

There are now four different default unicast classifiers to provide default CoS for lossless queues (FCoE and no-loss traffic). Because there is only one default multidestination forwarding class in Junos OS Release 11.3, there is only one default multidestination classifier for all multidestination traffic. Also, the excess rate default value is removed from the scheduler because the **excess-rate** statement is no longer supported, as described elsewhere in this document. Table 431 on page 5301 shows the default scheduler configuration in Junos OS Releases 11.3:

Table 431: Default Schedulers

Default Scheduler and Queue Number	Guaranteed Rate (Minimum Bandwidth)	Shaping Rate (Maximum Bandwidth)	Excess Bandwidth Sharing	Priority
Best-effort scheduler (queue 0)	5%	None	5%	Low
FCoE scheduler (queue 3)	35%	None	35%	Low
No-loss scheduler (queue 4)	35%	None	35%	Low
Network-control scheduler (queue 7)	5%	None	5%	Low
Multidestination scheduler (queue 8)	20%	None	20%	Low

NOTE: **The minimum guaranteed bandwidth rate also determines the amount of excess (extra) bandwidth that the queue can share. Extra bandwidth is allocated to queues in proportion to the minimum guaranteed bandwidth rate of each queue.**

Queue Priority Configuration Changes

In Junos OS Release 11.1 and 11.2, you could configure strict-high priority queues with a guaranteed minimum bandwidth and configure forwarding class sets (priority groups) with a mix of low priority and strict-high priority queues. In Junos OS Release 11.3 and later, these configurations are invalid, and several other changes have also been implemented:

- Priority configuration in Junos OS Release 11.1 and 11.2 provided three priority levels: **strict-high**, **high**, and **low**. In Junos OS Release 11.3, the **high** priority option has been removed. Only the **strict-high** and **low** priority options are valid in Release 11.3.
- Minimum guaranteed bandwidth (transmit rate) is not allowed on strict-high priority queues. Minimum guaranteed bandwidth (guaranteed rate) is not allowed on forwarding class sets that contain strict-high priority queues.

- You cannot configure a multidestination queue as a strict-high priority queue. You cannot configure a queue as a strict-high priority queue if it belongs to the multidestination forwarding class set.
- Only one forwarding class set can contain strict-high priority queues. If you want to configure a strict-high priority queue, you must also configure a separate forwarding class set for the strict-high priority queue. A forwarding class set cannot contain a mixture of low priority and strict-high priority queues.

The rest of the queue priority characteristics remain the same as before. For example, you can configure only one queue as a strict-high priority queue.

NOTE: **If you have configured strict-high or high priority queues in Junos OS Release 11.1 or 11.2, the changes in Release 11.3 are not backward compatible. Please read** "Overview of CoS Upgrade Requirements (Junos OS Release 11.1 or 11.2 to a Later Release)" on page 32 **before you upgrade to Release 11.3.**

Minimum Guaranteed Bandwidth (Transmit Rate and Guaranteed Rate) Changes

The following restrictions have been placed on minimum guaranteed bandwidth configuration in Junos OS Release 11.3:

- You cannot configure a guaranteed minimum bandwidth (transmit rate) for strict-high priority queues.
- Queues (forwarding classes) with a configured transmit rate cannot be included in a forwarding class set that has strict-high priority queues.
- You cannot configure a guaranteed minimum bandwidth (guaranteed rate) for forwarding class sets that include strict-high priority queues.
- For transmit rates below 1 Gbps, we recommend that you configure the transmit rate as a percentage instead of as a fixed rate. This is because the system converts fixed rates into percentages and may round small fixed rates to a lower percentage. For example, a fixed rate of 350 Mbps is rounded down to 3 percent instead of 3.5 percent.

Excess Rate Statement Disabled

The **excess-rate** statement has been disabled in Junos OS Release 11.3. Excess rate was used to specify the way extra bandwidth was shared among queues.

The **excess-rate** statement was used at the **[edit class-of-service schedulers]** hierarchy level for queue scheduling configuration and at the **[edit class-of-service traffic-control-profiles]** hierarchy level for forwarding class set scheduling configuration.

In Junos OS Release 11.3, extra bandwidth sharing among queues is proportional to the minimum guaranteed bandwidth (transmit rate) of the queue. Extra bandwidth sharing among forwarding class sets (priority groups) is proportional to the minimum guaranteed bandwidth (guaranteed rate) of the forwarding class set.

NOTE: If you have configured the excess-rate option in Junos OS Release 11.1 or 11.2, the changes in Release 11.3 are not backward compatible. Please read "Overview of CoS Upgrade Requirements (Junos OS Release 11.1 or 11.2 to a Later Release)" on page 32 before you upgrade to Release 11.3.

Queue Scheduling (Low and Strict-High Priority Queues)

In Junos OS Release 11.1 and 11.2, if you configured a guaranteed minimum bandwidth (transmit rate) for low-priority queues, the low-priority queues received their guaranteed minimum bandwidth from the same bandwidth pool as the strict-high priority queue, using round-robin scheduling. Until the minimum bandwidth requirements of all queues were met, the strict-high priority queue and low-priority queues that had a guaranteed minimum bandwidth were treated equally. After the minimum bandwidth requirements of all queues were met, the strict-high priority queue received as much of the leftover bandwidth as it needed. This meant that the only way to ensure that a strict-high priority queue received all of the bandwidth it needed was not to configure a guaranteed minimum bandwidth for other queues.

In Junos OS Release 11.3 and later, queue scheduling has changed so that queues receive bandwidth in the following sequence:

1. The strict-high priority queue receives all of the bandwidth it needs before any other queue is served. The strict-high priority queue can take the full port bandwidth if necessary and can starve other queues on the port.
2. The guaranteed minimum bandwidth (transmit rate) of low-priority queues is served until the minimum is met or the queues are empty.
3. All other low-priority queues and needs that exceed the minimum bandwidth are served.

Multidestination Traffic Changes

The changes to the default forwarding classes and classifiers affects multidestination traffic handling in Junos OS Release 11.3:

- The number of default multidestination forwarding classes has been reduced from four default multidestination forwarding classes in Junos OS Release 11.1 and 11.2 to one default multidestination in Release 11.3 (see Table 425 on page 5297).
- The default classifier configuration for multidestination traffic has changed so that there is now one default classifier for all multidestination traffic (see Table 429 on page 5299).
- By default, all IEEE 802.1p code points map to the default multidestination forwarding class.

- The default scheduler for multidestination traffic has changed so that there is now one default scheduler for all multidestination traffic (see Table 431 on page 5301).
- You cannot configure multidestination queues as strict-high priority queues and you cannot include strict-high priority queues in a forwarding class set that contains multidestination queues.

Overview of CoS Changes Introduced in Junos OS Release 12.2

Junos OS Release 12.2 introduces some changes to class-of-service (CoS) functionality and to the CoS default values. This overview summarizes the changes, which other documents describe in detail.

This topic describes the following changes in CoS default values and behavior:

- Lossless Forwarding Classes (fcoe and no-loss) on page 5304
- Default MTU for Headroom Buffer Calculation for Lossless Forwarding Classes on page 5305
- CoS for Layer 3 Physical Interfaces on page 5305
- DSCP IPv6 Classifiers and Rewrite Rules on page 5305

Lossless Forwarding Classes (fcoe and no-loss)

The way the QFX Series handles lossless forwarding classes (the **fcoe** and **no-loss** forwarding classes) changes in Junos OS Release 12.2. In Junos OS Release 12.2 and in earlier releases, by default, the **fcoe** and **no-loss** forwarding classes are mapped to output queue 3 and output queue 4, respectively. These are the only two forwarding classes (and the only two queues) that support lossless transport.

In earlier releases, explicitly setting the lossless **fcoe** and **no-loss** forwarding classes resulted in the same CoS behavior as using the default configuration. However, in Junos OS Release 12.2, the behavior when you explicitly configure the lossless forwarding classes differs from the behavior when you use the default forwarding classes.

NOTE: **The default behavior differs from the explicit configuration behavior even if the explicit configuration is exactly the same as the default configuration.**

If you use the default forwarding class settings for the lossless queues (the configuration does not include explicit setting of the **fcoe** or the **no-loss** forwarding classes), then the **fcoe** and **no-loss** queues behave as lossless queues. When you upgrade to Junos OS Release 12.2, traffic assigned to the **fcoe** and **no-loss** queues continues to be treated as lossless traffic.

If your configuration explicitly sets the **fcoe** or the **no-loss** forwarding class (**set class-of-service forwarding-classes class *class-name* queue-num *queue-number***), after you upgrade to Junos OS Release 12.2, those queues do *not* receive lossless treatment and behave as lossy (**best-effort**) queues. To retain lossless treatment of the **fcoe** and **no-loss** queues, delete the explicit lossless forwarding class configuration before you upgrade to Junos OS Release 12.2.

CAUTION: If you explicitly configured the fcoe or the no-loss forwarding class, and you upgrade to Junos OS Release 12.2, the system does not return an upgrade error or a commit error, or a generate a syslog message, to notify you that these forwarding classes are no longer lossless. Traffic mapped to these forwarding classes is not treated as lossless traffic until you remove the explicit forwarding class configuration.

Default MTU for Headroom Buffer Calculation for Lossless Forwarding Classes

The default maximum transmission unit (MTU) the system uses for buffer headroom calculation is 2500 bytes for traffic classified into the **fcoe** forwarding class or the **no-loss** forwarding class.

In Junos OS Release 12.2, the default MTU used for buffer headroom calculation for the **fcoe** and **no-loss** forwarding classes remains 2500 bytes. However, if the buffer is filled, in Junos OS Release 12.2 you might experience commit failures.

CoS for Layer 3 Physical Interfaces

Before Junos OS Release 12.2, the QFX Series supported only Layer 2 CoS. Junos OS Release 12.2 introduces CoS support for Layer 3 traffic at the physical interface level.

If a physical Layer 3 interface has at least one logical interface configured on it, you can configure Layer 3 CoS for the physical interface. The CoS configured on the physical interface applies to all of the logical Layer 3 interfaces on that physical interface. The system does not support Layer 3 CoS configuration on individual Layer 3 logical interfaces.

DSCP IPv6 Classifiers and Rewrite Rules

Junos OS Release 12.2 introduces support for DSCP IPv6 classifiers and rewrite rules. The existing DSCP IP default classifier is now also the DSCP IPv6 default classifier.

You can configure and apply DSCP IPv6 classifiers and DSCP IPv6 rewrite rules to Layer 2 logical interfaces and to Layer 3 physical interfaces.

NOTE: DSCP IPv6 classifiers are not supported for multidestination (multicast, broadcast, and destination lookup fail) traffic.

CoS Overview

Overview of Junos OS CoS for the QFX Series

When a network experiences congestion and delay, some packets must be dropped. Junos OS class of service (CoS) enables you to divide traffic into classes and set various levels of throughput and packet loss when congestion occurs. You have greater control over packet loss because you can configure rules tailored to your needs.

You can configure CoS features to provide multiple classes of service for different applications. CoS also allows you to rewrite the Differentiated Services code point (DSCP) or IEEE 802.1p code-point bits of packets leaving an interface, thus allowing you to tailor packets for the network requirements of the remote peers.

CoS provides multiple classes of service for different applications. You can configure multiple forwarding classes for transmitting packets, define which packets are placed into each output queue, schedule the transmission service level for each queue, and manage congestion using a random early detection (RED) algorithm.

In designing CoS applications, you must carefully consider your service needs, and you must thoroughly plan and design your CoS configuration to ensure consistency and interoperability across all platforms in a CoS domain.

Because QFX Series implements CoS in hardware rather than in software, you can experiment with and deploy CoS features without affecting packet forwarding and switching performance.

NOTE: CoS policies can be enabled or disabled on each switch interface. Also, each physical and logical interface on the switch can have associated custom CoS rules.

When you change or when you deactivate and then reactivate the class-of-service configuration, the system experiences packet drops because the system momentarily blocks traffic to change the mapping of incoming traffic to input queues.

This topic describes:

CoS Standards

The following RFCs define the standards for the QFX Series CoS capabilities:

- RFC 2474, *Definition of the Differentiated Services Field in the IPv4 and IPv6 Headers*
- RFC 2597, *Assured Forwarding PHB Group*

- RFC 2598, *An Expedited Forwarding PHB*
- RFC 2698, *A Two Rate Three Color Marker*

QFX Series also supports the following data center bridging (DCB) standards to provide the CoS (and other characteristics) Fibre Channel requires for transmitting storage traffic over an Ethernet network:

- IEEE 802.1Qbb, priority-based flow control (PFC)
- IEEE 802.1Qaz, enhanced transmission selection (ETS)
- IEEE 802.1AB (LLDP) extension called Data Center Bridging Capability Exchange Protocol (DCBX)

How Junos CoS Works

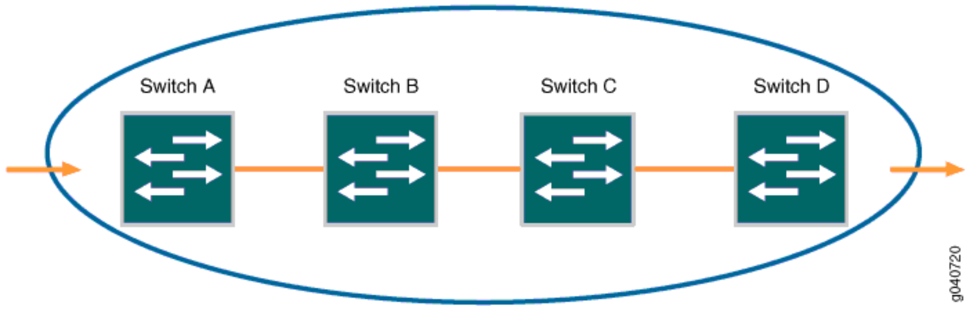
Junos CoS works by examining traffic entering at the edge of your network. The switch classifies traffic into defined service groups to provide the special treatment of traffic across the network. For example, you can send voice traffic across certain links and data traffic across other links. In addition, the data traffic streams can be serviced differently along the network path to ensure that higher-paying customers receive better service. As the traffic leaves the network at the far edge, you can reclassify the traffic to meet the policies of the targeted peer by rewriting the DSCP or IEEE 802.1 code-point bits.

To support CoS, you must configure each switch in the network. Generally, each switch examines the packets that enter it to determine their CoS settings. These settings dictate which packets are transmitted first to the next downstream switch. Switches at the edges of the network might be required to alter the CoS settings of the packets that enter the network to classify the packets into the appropriate service groups.

In Figure 189 on page 5309, Switch A is receiving traffic. As each packet enters, Switch A examines the packet's current CoS settings and classifies the traffic into one of the groupings defined on the switch. This definition allows Switch A to prioritize its resources for servicing the traffic streams it receives. Switch A might alter the CoS settings (forwarding class and loss priority) of the packets to better match the defined traffic groups.

When Switch B receives the packets, it examines the CoS settings, determines the appropriate traffic groups, and processes the packet according to those settings. It then transmits the packets to Switch C, which performs the same actions. Switch D also examines the packets and determines the appropriate groups. Because Switch D sits at the far end of the network, it can reclassify (rewrite) the CoS code-point bits of the packets before transmitting them.

Figure 189: Packet Flow Across the Network



Default CoS Behavior

If you do not configure CoS settings, the software performs some CoS functions to ensure that the system forwards traffic and protocol packets with minimum delay when the network is experiencing congestion. Some CoS settings, such as classifiers, are automatically applied to each logical interface that you configure. Other settings, such as rewrite rules, are applied only if you explicitly associate them with an interface.

Overview of Policers

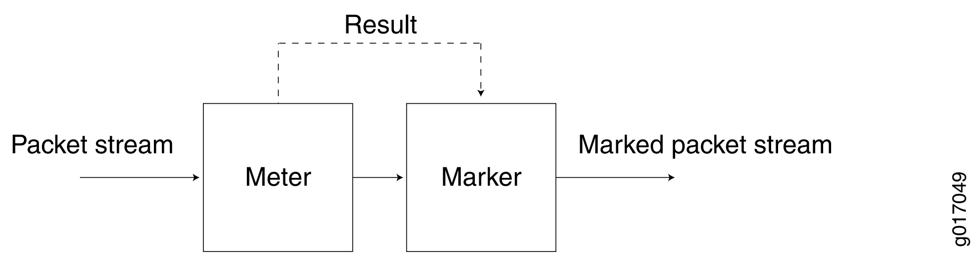
A switch polices traffic by limiting the input or output transmission rate of a class of traffic according to user-defined criteria. Policing (or rate-limiting) traffic allows you to control the maximum rate of traffic sent or received on an interface and to provide multiple priority levels or classes of service.

Policer Overview

You use policers to apply limits to traffic flow and set consequences for packets that exceed these limits—usually applying a higher loss priority—so that if packets encounter downstream congestion, they can be discarded first. Policers apply only to unicast packets.

Policers provide two functions: metering and marking. A policer meters (measures) each packet against traffic rates and burst sizes that you configure. It then passes the packet and the metering result to the marker, which assigns a packet loss priority that corresponds to the metering result. Figure 153 on page 4442 illustrates this process.

Figure 190: Flow of Tricolor Marking Policer Operation



After you name and configure a policer, you use it by specifying it as an action in one or more firewall filters.

Policer Types

A switch supports three types of policers:

- Single-rate two-color marker—A two-color policer (or "policer" when used without qualification) meters the traffic stream and classifies packets into two categories of packet loss priority (PLP) according to a configured bandwidth and burst-size limit. You can mark packets that exceed the bandwidth and burst-size limit with a specified PLP or simply discard them.

  You can specify this type of policer in an ingress or egress firewall.

  NOTE: **A two-color policer is most useful for metering traffic at the port (physical interface) level.**

- Single-rate three-color marker—This type of policer is defined in RFC 2697, *A Single Rate Three Color Marker*, as part of an assured forwarding (AF) per-hop-behavior (PHB) classification system for a Differentiated Services (DiffServ) environment. This type of policer meters traffic based on one rate—the configured committed information rate (CIR) as well as the committed burst size (CBS) and the excess burst size (EBS). The CIR specifies the average rate at which bits are admitted to the switch. The CBS specifies the usual burst size in bytes and the EBS specifies the maximum burst size in bytes. The EBS must be greater than or equal to the CBS, and neither can be 0.

  You can specify this type of policer in an ingress or egress firewall.

NOTE: A single-rate three-color marker (TCM) is most useful when a service is structured according to packet length and not peak arrival rate.

- Two-rate three-color marker—This type of policer is defined in RFC 2698, *A Two Rate Three Color Marker*, as part of an assured forwarding per-hop-behavior classification system for a Differentiated Services environment. This type of policer meters traffic based on two rates—the CIR and peak information rate (PIR) along with their associated burst sizes, the CBS and peak burst size (PBS). The PIR specifies the maximum rate at which bits are admitted to the network and must be greater than or equal to the CIR.

  You can specify this type of policer in an ingress or egress firewall.

NOTE: A two-rate three-color policer is most useful when a service is structured according to arrival rates and not necessarily packet length.

See Table 346 on page 4443 for information about how metering results are applied for each of these policer types.

Policer Actions

Policer actions are implicit or explicit and vary by policer type. *Implicit* means that Junos OS assigns the loss priority automatically. Table 346 on page 4443 describes the policer actions.

Table 432: Policer Actions

Policer	Marking	Implicit Action	Configurable Action
Single-rate two-color	Green (conforming)	Assign low loss priority	None
	Red (nonconforming)	None	Discard
Single-rate three-color	Green (conforming)	Assign low loss priority	None
	Yellow (above the CIR and CBS)	Assign medium-high loss priority	None
	Red (above the EBS)	Assign high loss priority	Discard

Table 432: Policer Actions *(continued)*

Policer	Marking	Implicit Action	Configurable Action
Two-rate three-color	Green (conforming)	Assign low loss priority	None
	Yellow (above the CIR and CBS)	Assign medium-high loss priority	None
	Red (above the PIR and PBS)	Assign high loss priority	Discard

NOTE: **If you specify a policer in an egress firewall filter, the only supported action is discard.**

Policer Colors

Single-rate and two-rate three-color policers can operate in two modes:

- Color-blind—In color-blind mode, the three-color policer assumes that all packets examined have not been previously marked or metered. In other words, the three-color policer is “blind” to any previous coloring a packet might have had.
- Color-aware—In color-aware mode, the three-color policer assumes that all packets examined have been previously marked or metered. In other words, the three-color policer is “aware” of the previous coloring a packet might have had. In color-aware mode, the three-color policer can increase the PLP of a packet but cannot decrease it. For example, if a color-aware three-color policer meters a packet with a medium PLP marking, it can raise the PLP level to high but cannot reduce the PLP level to low.

Filter-Specific Policers

You can configure policers to be filter-specific, which means that Junos OS creates only one policer instance regardless of how many times the policer is referenced. When you do this, rate limiting is applied in aggregate, so if you configure a policer to discard traffic that exceeds 1 Gbps and reference that policer in three different terms, the total bandwidth allowed by the filter is 1 Gbps. However, the behavior of a filter-specific policer is affected by how the firewall filter terms that reference the policer are stored in TCAM. If you create a filter-specific policer and reference it in multiple firewall filter terms, the policer allows more traffic than expected if the terms are stored in different TCAM slices. For example, if you configure a policer to discard traffic that exceeds 1 Gbps and reference that policer in three different terms that are stored in three separate memory slices, the total bandwidth allowed by the filter is 3 Gbps, not 1 Gbps.

To prevent this unexpected behavior from occurring, use the information about TCAM slices presented in “Planning the Number of Firewall Filters to Create” on page 4435 to organize your configuration file so that all the firewall filter terms that reference a given filter-specific policer are stored in the same TCAM slice.

Suggested Naming Convention for Policers

We recommend that you use the naming convention ***policertypeTCM#-color type*** when configuring three-color policers and ***policer#*** when configuring two-color policers. TCM stands for three-color marker. Because policers can be numerous and must be applied correctly to work, a simple naming convention makes it easier to apply the policers properly. For example, the first single-rate, color-aware three-color policer configured would be named **srTCM1-ca**. The second two-rate, color-blind three-color configured would be named **trTCM2-cb**. The elements of this naming convention are explained below:

- sr (single-rate)
- tr (two-rate)
- TCM (tricolor marking)
- 1 or 2 (number of marker)
- ca (color-aware)
- cb (color-blind)

Policer Counters

Each policer that you configure includes an implicit counter that counts the number of packets that exceed the rate limits that are specified for the policer. If you use the same policer in multiple terms—either within the same filter or in different filters—the implicit counter counts all the packets that are policed in all of these terms. If you want to obtain separate packet counts for each term, use these options:

- Configure a unique policer for each term.
- Configure only one policer, but use a unique, explicit counter in each term.

Policer Algorithms

Policing uses the *token-bucket algorithm*, which enforces a limit on average bandwidth while allowing bursts up to a specified maximum value. It offers more flexibility than the *leaky bucket algorithm* in allowing a certain amount of bursty traffic before it starts discarding packets.

How Many Policers are Supported?

You can configure and commit the following numbers of policers on QFX3500 and QFX3600 devices when they are operating as standalone switches:

- Two-color policers used in ingress firewall filters: 767
- Three-color policers used in ingress firewall filters: 767
- Two-color policers used in egress firewall filters: 1022
- Three-color policers used in egress firewall filters: 512

Policers can Limit Egress Firewall Filters

The number of egress policers that you configure can affect the total number of allowed egress firewall filters. Every policer has two implicit counters that consume two entries in a 1024-entry TCAM that is used for counters, including counters that are configured as action modifiers in firewall filter terms. (Policers consume two entries because one is used for green packets and one is used for nongreen packets regardless of policer type.) If the TCAM becomes full, you cannot commit any more egress firewall filters that have terms with counters. For example, if you configure and commit 512 egress policers (two-color, three-color, or a combination of both policer types), all of the memory entries for counters are used up. If later in your configuration file you insert additional egress firewall filters with terms that also include counters, *none* of the terms in those filters are committed because there is no available memory space for the counters.

Here are some additional examples:

- Assume that you configure egress filters that include a total of 512 policers and no counters. Later in your configuration file you include another egress filter with 10 terms, 1 of which has a counter action modifier. None of the terms in this filter are committed because there is not enough TCAM space for the counter.
- Assume that you configure egress filters that include a total of 500 policers, so 1000 TCAM entries are occupied. Later in your configuration file you include the following two egress filters:
  - Filter A with 20 terms and 20 counters. All the terms in this filter are committed because there is enough TCAM space for all the counters.
  - Filter B comes after Filter A and has five terms and five counters. *None* of the terms in this filter are committed because there is not enough memory space for *all* the counters. (Five TCAM entries are required but only four are available.)

You can prevent this problem by ensuring that egress firewall filter terms with counter actions are placed earlier in your configuration file than terms that include policers. In this circumstance, Junos OS commits policers even if there is not enough TCAM space for the implicit counters. For example, assume the following:

- You have 1024 egress firewall filter terms with counter actions.
- Later in your configuration file you have an egress filter with 10 terms. None of the terms have counters but one has a policer action modifier.

You can successfully commit the filter with 10 terms even though there is not enough TCAM space for the implicit counters of the policer. The policer is committed without the counters.

Understanding Junos CoS Components

This topic describes the Junos operating system (OS) class-of-service (CoS) components for the QFX Series:

Code-Point Aliases

A code-point alias assigns a name to a pattern of code-point bits. You can use this name instead of the bit pattern when you configure other CoS components such as classifiers and rewrite rules.

Policers

Policers limit traffic of a certain class to a specified bandwidth and burst size. Packets exceeding the policer limits can be discarded, or can be assigned to a different forwarding class, a different loss priority, or both. You define policers with filters that you can associate with input interfaces.

Classifiers

Packet classification associates incoming packets with a particular CoS servicing level. In Junos OS, *classifiers* associate packets with a forwarding class and loss priority and assign packets to output queues based on the associated forwarding class. Junos OS supports two general types of classifiers:

- Behavior aggregate (BA) or CoS value traffic classifiers—Examine the CoS value in the packet header. The value in this single field determines the CoS settings applied to the packet. BA classifiers allow you to set the forwarding class and loss priority of a packet based on the Differentiated Services code point (DSCP) value or IEEE 802.1p value.
- Multifield traffic classifiers—Examine multiple fields in the packet, such as source and destination addresses and source and destination port numbers of the packet. With multifield classifiers, you set the forwarding class and loss priority of a packet based on firewall filter rules.

You can create unicast classifiers for unicast traffic and multidestination classifiers for multicast, broadcast, and destination lookup fail traffic. You cannot assign unicast traffic and multidestination traffic to the same classifier.

You can apply unicast classifiers to one or more interfaces. Multidestination classifiers apply to all of the switch interfaces and cannot be applied to individual interfaces.

Forwarding Classes

Forwarding classes group packets for transmission and CoS. You assign each packet to an output queue based on the packet's forwarding class. Forwarding classes affect the forwarding, scheduling, and rewrite marking policies applied to packets as they transit the switch.

The switch provides five default forwarding classes:

- fcoe—Fibre Channel over Ethernet traffic
- no-loss—Lossless traffic
- be—Best-effort traffic
- nc—Network control traffic
- mcast—Multicast traffic

The switch supports a total of 12 forwarding classes (8 unicast forwarding classes and 4 multicast forwarding classes), which provide flexibility in classifying traffic.

Forwarding Class Sets

You can group forwarding classes (output queues) into *forwarding class sets* in order to apply CoS to groups of traffic that require similar treatment. Forwarding class sets map traffic into priority groups to support enhanced transmission selection (ETS, described in IEEE 802.1Qaz).

You can configure up to three unicast forwarding class sets and one multicast forwarding class set. For example, you can configure different forwarding class sets to apply CoS to unicast groups of local area network (LAN) traffic, storage area network (SAN) traffic, and high-performance computing (HPC) traffic, and configure another group for multicast traffic.

Within each forwarding class set, you can configure special CoS treatment for the traffic mapped to each individual queue. This provides the ability to configure CoS in a two-tier hierarchical manner. At the forwarding class set tier, you configure CoS for groups of traffic using a *traffic control profile*. At the queue tier, you configure CoS for individual output queues within a forwarding class set using a *scheduler* that you map to a queue (forwarding class) using a *scheduler map*.

Flow Control (Ethernet PAUSE and Priority-Based Flow Control)

Ethernet PAUSE (described in IEEE 802.3X) is a link-level flow control mechanism. During periods of network congestion, Ethernet PAUSE stops all traffic on a full-duplex Ethernet link for a period of time specified in the PAUSE message.

Priority-based flow control (PFC, described in IEEE 802.1Qbb) is part of the IEEE data center bridging (DCB) specifications for creating a lossless Ethernet environment to transport loss-sensitive flows such as Fibre Channel over Ethernet (FCoE) traffic.

PFC is a link-level flow control mechanism similar to Ethernet PAUSE. However, Ethernet PAUSE stops all traffic on a link for a period of time. PFC decouples the pause function from the physical link and divides the traffic on the link into eight priorities (3-bit IEEE 802.1p code points). You can think of the eight priorities as eight "lanes" of traffic. You can apply pause selectively to the traffic on any priority without pausing the traffic on other priorities on the same link.

The granularity that PFC provides allows you to configure different levels of CoS for different types of traffic on the link. You can create lossless lanes for traffic such as FCoE, LAN backup, or management, while using standard frame-drop methods of congestion management for IP traffic on the same link.

NOTE: **If you transport FCoE traffic, you must enable PFC on the priority assigned to FCoE traffic (usually code point 011 on interfaces that carry FCoE traffic).**

Tail-Drop Profiles

A tail-drop profile (drop profile) defines parameters that enable the network to drop packets during periods of congestion. A drop profile defines the conditions under which packets of different loss priorities drop, by determining the probability of dropping a packet for each loss priority when output queues become congested. Drop profiles essentially set a value for a level of queue fullness—when the queue fills to the level of the queue fullness value, packets drop.

You can associate different drop profiles with different loss priorities to set the probability of dropping packets. You can apply a drop profile for each loss priority to a forwarding class (output queue) by applying a drop profile to a scheduler, and then mapping the scheduler to a forwarding class using a scheduler map. When the queue mapped to the forwarding class experiences congestion, the drop profile determines the level of packet drop for traffic of each loss priority in that queue.

Loss priority affects the scheduling of a packet without affecting the packet's relative ordering. Typically you mark packets exceeding a particular service level with a high loss priority.

Schedulers

Each switch interface has multiple queues assigned to store packets. The switch determines which queue to service based on a particular method of scheduling. This process often involves determining the sequence in which different types of packets should be transmitted.

You can define the priority (**priority**), minimum bandwidth (**transmit-rate**), maximum bandwidth (**shaping-rate**), and tail-drop profiles to be applied to a particular queue for packet transmission. Extra bandwidth is shared among queues in proportion to the minimum guaranteed bandwidth of each queue.

A scheduler map associates a specified forwarding class with a scheduler configuration. You can associate up to four user-defined scheduler maps with the interfaces.

Rewrite Rules

A *rewrite rule* sets the appropriate CoS bits in the outgoing packet. This allows the next downstream device to classify the packet into the appropriate service group. Rewriting (marking) outbound packets is useful when the switch is at the border of a network and must change the CoS values to meet the policies of the targeted peer.

NOTE: Ingress firewall filters can also rewrite forwarding class and loss priority values.

Understanding CoS Packet Flow

When a packet traverses a QFX Series Node device, the Node device provides the appropriate level of service to the packet using either default class of service (CoS) settings or CoS settings that you configure. On ingress ports, the Node device classifies packets into appropriate forwarding classes and assigns a loss priority to the packets. On egress ports, the Node device applies packet scheduling and (if you have configured them) rewrite rules to re-mark packets.

On the QFX Series, you can configure CoS on Layer 2 logical interfaces, and you can configure CoS on Layer 3 physical interfaces if you have defined at least one logical interface on the Layer 3 physical interface. You cannot configure CoS on Layer 2 physical interfaces and Layer 3 logical interfaces.

For Layer 2 traffic, either use the default CoS settings or configure CoS on each logical interface. You can apply different CoS settings to different Layer 2 logical interfaces.

For Layer 3 traffic, either use the default CoS settings or configure CoS on the physical interface (not on the logical unit). The QFX Series uses the CoS applied on the physical Layer 3 interface for all logical Layer 3 interfaces configured on the physical Layer 3 interface.

The QFX Series applies to CoS to packets as they flow through the system:

- An interface has one or more classifiers of different types applied to it (configure this at the **[edit class-of-service interfaces]** hierarchy level). The classifier types are based on the portion of the incoming packet that the classifier examines (IEEE 802.1p code point bits or DSCP code point bits).
- When a packet enters an ingress port, the classifier assigns the packet to a forwarding class and a loss priority based on the code point bits of the packet (configure this at the **[edit class-of-service classifiers]** hierarchy level).
- The QFX Series assigns each forwarding class to an output queue (configure this at the **[edit class-of-service forwarding-classes]** hierarchy level).
- Input (and output) policers meter traffic and can change the forwarding class and loss priority if a traffic flow exceeds its service level.
- A scheduler map is applied to each interface. When a packet exits an egress port, the scheduler map controls how it is treated (configure this at the **[edit class-of-service interfaces]** hierarchy level). A scheduler map assigns schedulers to forwarding classes (configure this at the **[edit class-of-service scheduler-maps]** hierarchy level).
- A scheduler defines how traffic is treated at the egress interface output queue (configure this at the **[edit class-of-service schedulers]** hierarchy level). You control the transmit rate, shaping rate, priority, and drop profile of each forwarding class by mapping schedulers to forwarding classes in scheduler maps, then applying scheduler maps to interfaces.

- A drop-profile defines how aggressively to drop packets that are mapped to a particular scheduler (configure this at the **[edit class-of-service drop-profiles]** hierarchy level).
- A rewrite rule takes effect as the packet leaves an interface that has a rewrite rule configured (configure this at the **[edit class-of-service rewrite-rules]** hierarchy level). The rewrite rule writes information to the packet (for example, a rewrite rule can re-mark the code point bits of outgoing traffic) according to the forwarding class and loss priority of the packet.

Figure 191 on page 5320 is a high-level flow diagram of how packets from various sources enter QFX Series interfaces, are classified at the ingress, and then scheduled (provided bandwidth) at the egress queues.

Figure 191: CoS Classifier, Queues, and Scheduler

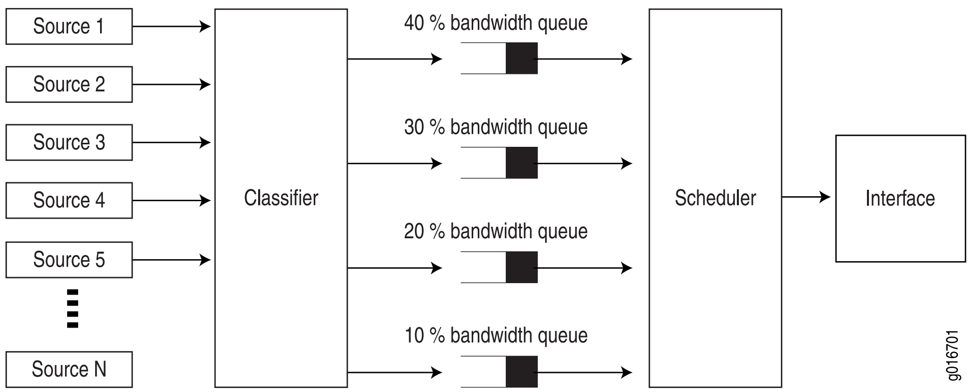

Figure 192 on page 5320 shows the packet flow through the CoS components that you can configure.

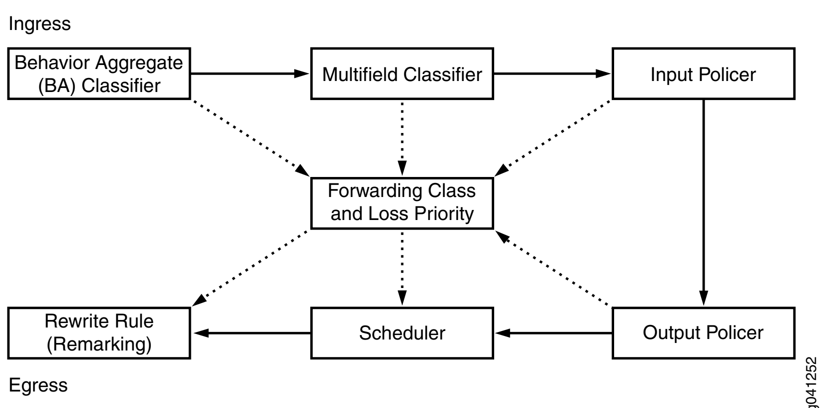
Figure 192: Packet Flow Through Configurable CoS Components



The middle box ("Forwarding Class and Loss Priority") represents two values that you can use on ingress and egress interfaces. The system uses these values for classifying traffic on ingress interfaces and for rewrite rule re-marking on egress interfaces. Each outer box represents a process component. The components in the top row apply to incoming packets. The components in the bottom row apply to outgoing packets.

The solid-line arrows show the direction of packet flow from ingress to egress. The dotted-line arrows show inputs and outputs or show settings and actions based on those settings.

For example, the BA classifier sets the forwarding class and loss priority of incoming packets, so the forwarding class and loss priority are outputs of the classifier and the arrow points away from the classifier. The scheduler receives the forwarding class and loss priority settings, and queues the outgoing packets based on those settings, so the arrow points toward the scheduler.

CoS Inputs and Outputs Overview

Some CoS components map one set of values to another set of values. Each mapping contains one or more inputs and one or more outputs. When you configure a mapping, you set the outputs for a given set of inputs, as shown in Table 433 on page 5321.

Table 433: CoS Mappings—Inputs and Outputs

CoS Mappings	Inputs	Outputs	Comments
classifiers	code-points	forwarding-class, loss-priority	The map sets the forwarding class and packet loss priority (PLP) for a specific set of code points.
drop-profile-map	*loss-priority*, protocol	drop-profile	The map sets the drop profile for a specific PLP and protocol type.
rewrite-rules	loss-priority, forwarding-class	code-points	The map sets the code points for a specific forwarding class and PLP.
rewrite-value (Fibre Channel Interfaces)	forwarding-class	code-point	The map sets the code point for the forwarding class specified in the fixed classifier attached to the native Fibre Channel (NP_Port) interface.

Understanding Default CoS Settings

If you do not configure CoS settings on the QFX Series, Junos OS performs some CoS functions to ensure that traffic and protocol packets are forwarded with minimum delay when the network experiences congestion. Some default mappings are automatically applied to each logical interface that you configure.

You can display default CoS settings by issuing the **show class-of-service** operational mode command.

This topic describes the default configurations for the following CoS components:

Default Forwarding Classes and Queue Mapping

Table 434 on page 5322 shows the default mapping of the default forwarding classes to queues and packet drop attribute.

Table 434: Default Forwarding Classes and Queue Mapping

Default Forwarding Class	Description	Default Queue Mapping	Packet Drop Attribute
best-effort (be)	Best-effort traffic class (priority 0, IEEE 802.1p code point 000)	0	drop
fcoe	Guaranteed delivery for FCoE traffic (priority 3, IEEE 802.1p code point 011)	3	no-loss
no-loss	Guaranteed delivery for TCP no-loss traffic (priority 4, IEEE 802.1p code point 100)	4	no-loss

Table 434: Default Forwarding Classes and Queue Mapping *(continued)*

Default Forwarding Class	Description	Default Queue Mapping	Packet Drop Attribute
network-control (nc)	Network control traffic (priority 7, IEEE 802.1p code point 111)	7	drop
mcast	Multidestination traffic	8	drop NOTE: You cannot configure multidestination forwarding classes as no-loss (lossless) traffic classes.

Default Forwarding Class Sets (Priority Groups)

If you do not explicitly configure forwarding class sets, the system automatically creates a default forwarding class set that contains all of the forwarding classes on the switch. The system assigns 100 percent of the port output bandwidth to the default forwarding class set.

Ingress traffic is classified based on the default classifier settings. The forwarding classes (queues) in the default forwarding class set receive bandwidth based on the default scheduler settings. Forwarding classes that are not part of the default scheduler receive no bandwidth.

The default forwarding class set is transparent. It does not appear in the configuration and is used for Data Center Bridging Capability Exchange (DCBX) protocol advertisement.

Default Code-Point Aliases

Table 435 on page 5323 shows the default mapping of code-point aliases to IEEE code points.

Default Classifiers

The QFX Series applies default unicast IEEE 802.1, unicast DSCP, and multidestination classifiers to each interface that does not have explicitly configured classifiers. If you explicitly configure one type of classifier but not other types of classifiers, the system uses only the configured classifier and does not use default classifiers for other types of traffic. There are two different default unicast IEEE 802.1 classifiers, a trusted classifier for ports that are in trunk mode or tagged-access mode, and an untrusted classifier for ports that are in access mode.

Table 437 on page 5325 shows the default mapping of IEEE 802.1 code-point values to unicast forwarding classes and loss priorities for ports in trunk mode or tagged-access mode.

Table 437: Default IEEE 802.1 Unicast Classifiers for Ports in Trunk Mode or Tagged Access Mode (Trusted Classifier)

Code Point	Forwarding Class	Loss Priority
be (000)	best-effort	low
be1 (001)	best-effort	low
ef (010)	best-effort	low
ef1 (011)	fcoe	low

cs5 (101000)	best-effort	low
nc1 (110000)	network-control	low
nc2 (111000)	network-control	low

NOTE: There are no default DSCP IP or IPv6 classifiers for multidestination traffic. DSCP IPv6 classifiers are not supported for multidestination traffic.

Default Rewrite Rules

There are no default rewrite rules. If you do not explicitly configure rewrite rules, the switch does not reclassify egress traffic.

Default Drop Profile

Table 441 on page 5328 shows the default drop profile configuration.

Table 441: Default Drop Profile

Fill Level	Drop Probability
100	100

Default Schedulers

Table 442 on page 5328 shows the default scheduler configuration.

Table 442: Default Schedulers

Default Scheduler and Queue Number	Guaranteed Rate (Minimum Bandwidth)	Shaping Rate (Maximum Bandwidth)	Excess Bandwidth Sharing	Priority	Buffer Size
Best-effort scheduler (queue 0)	5%	None	5%	low	5%
FCoE scheduler (queue 3)	35%	None	35%	low	35%
No-loss scheduler (queue 4)	35%	None	35%	low	35%
Network-control scheduler (queue 7)	5%	None	5%	low	5%
Multidestination scheduler (queue 8)	20%	None	20%	low	20%

NOTE: The minimum guaranteed bandwidth rate also determines the amount of excess (extra) bandwidth that the queue can share. Extra bandwidth is allocated to queues in proportion to the minimum guaranteed bandwidth rate of each queue.

Default Scheduler Maps

Table 443 on page 5328 shows the default mapping of forwarding classes to schedulers.

Table 443: Default Scheduler Maps

Forwarding Class	Scheduler
best-effort	Default BE scheduler

Table 443: Default Scheduler Maps *(continued)*

Forwarding Class	Scheduler
fcoe	Default FCoE scheduler
no-loss	No-loss scheduler
network-control	Default network-control scheduler
mcast-be	Default multidestination scheduler

Default Shared Buffer Configuration

Table Table 444 on page 5329 and Table 445 on page 5329 show the default shared buffer allocations:

Table 444: Default Ingress Shared Buffer Configuration

Total Shared Ingress Buffer	Lossless Buffer	Lossless-Headroom Buffer	Lossy Buffer
100%	9%	45%	46%

Table 445: Default Egress Shared Buffer Configuration

Total Shared Egress Buffer	Lossless Buffer	Lossy Buffer	Multicast Buffer
100%	50%	31%	19%

Understanding Host Inbound Traffic Classification

The destination address of traffic that enters the switch can be an external device such as another switch, a router, or a server, or the destination can be the host (the switch

Routing Engine or CPU). When the destination is an external device, the DSCP and IEEE 802.1p code-point bits of incoming traffic are preserved as the traffic travels through the switch to the egress port. At the egress port, the code-point bits are either preserved when the packets are sent to the next hop or they are rewritten according to the rewrite rule attached to the egress interface.

When the destination of incoming traffic is the host, DSCP bits are preserved. However, IEEE 802.1p bits are not preserved. The IEEE 802.1p bits of traffic destined for the host are set to zero (0). This does not affect system behavior because the switch prioritizes traffic destined for the host based on the protocol type. For example, the switch gives a higher priority to BPDU traffic than to ping traffic.

Understanding Host Routing Engine Outbound Traffic Queues and Defaults

The host Routing Engine and CPU generate outbound traffic that is transmitted using different protocols. You cannot configure a classifier to map different types of outbound traffic that the host generates to forwarding classes (queues). The traffic that the host generates is assigned to forwarding classes by default as shown in Table 446 on page 5331.

If you want to separate host outbound traffic from other traffic or if you want to assign that traffic to a particular queue, you can configure a single forwarding class for all traffic that the host generates. If you configure a forwarding class for outbound host traffic, that forwarding class is used globally for all traffic generated by the host. (That is, the host outbound traffic is mapped to the selected queue on all egress interfaces.) Configuring a forwarding class for host outbound traffic does not affect transit or incoming traffic.

Whether you use the default host outbound traffic forwarding class configuration or configure a forwarding class for all host outbound traffic, the configuration applies to all Layer 2 and Layer 3 protocols and to all application-level traffic such as FTP and ping operations.

If you configure a queue for host outbound traffic, the queue must be properly configured on all interfaces.

NOTE: **Fibre Channel over Ethernet (FCoE) Initialization Protocol (FIP) packets generated by the CPU are always transmitted on the fcoe queue (queue 3), even if you configure a queue for host outbound traffic. This helps to ensure lossless behavior for FCoE traffic. QFabric systems classify FIP control packets into the same traffic class (fcoe) across the Interconnect device (fabric) and the egress Node device.**

By default, traffic generated by the host is sent to the best effort queue (queue 0) or to the network control queue (queue 7). Table 446 on page 5331 lists the default host traffic to output queue mapping.

Table 446: Routing Engine Protocol Default Queue Mapping

Routing Engine Protocol	Default Queue Mapping
Address Resolution Protocol (ARP) reply	Queue 0
ARP request	Queue 0
Border Gateway Protocol (BGP)	Queue 0
BGP TCP Retransmission	Queue 7
Fibre Channel over Ethernet (FCoE) Initialization Protocol (FIP)	Queue 3
File Transfer Protocol (FTP)	Queue 0
Internet Control Message Protocol (ICMP) reply	Queue 0
ICMP request	Queue 0
Internet Group Management Protocol (IGMP) query	Queue 7
IGMP report	Queue 0

Understanding CoS Code-Point Aliases

A code-point alias assigns a name to a pattern of code-point bits. You can use this name instead of the bit pattern when you configure other CoS components such as classifiers, drop-profile maps, and rewrite rules.

Behavior aggregate classifiers use class-of-service (CoS) values such as Differentiated Services code points (DSCPs) and IEEE 802.1 bits to associate incoming packets with a particular CoS servicing level. You can assign a meaningful name or alias to the CoS values and use that alias instead of bits when configuring CoS components. These aliases are not part of the specifications but are well known through usage. For example, the alias for DSCP 101110 is widely accepted as ef (expedited forwarding).

When you configure classes and define classifiers, you can refer to the markers by alias names. You can configure alias names for user-defined classifiers. If the value of an alias changes, it alters the behavior of any classifier that references it.

You can configure code-point aliases for the following type of CoS markers:

- dscp or dscp-ipv6—Handles incoming IP and IPv6 packets.
- ieee-802.1—Handles Layer 2 CoS.

This topic covers:

- Default Code-Point Aliases on page 5332

Understanding CoS Classifiers

Packet classification associates incoming packets with a particular class-of-service (CoS) servicing level. Classifiers associate packets with a forwarding class and a loss priority, and assign packets to output queues based on the associated forwarding class. There are three general types of classifiers:

- Behavior aggregate (BA) classifiers—DSCP and DSCP IPv6 classify IP and IPv6 traffic, EXP classifies MPLS traffic, and IEEE 802.1p classifiers classify all other traffic. (Although this topic covers EXP classifiers, for more details about EXP classifiers, see "Understanding CoS MPLS EXP Classifiers and Rewrite Rules" on page 3744.)
- Fixed classifiers—Fixed classifiers classify all ingress traffic on a physical interface into one forwarding class, regardless of the CoS bits in the packet header.
- Multifield (MF) classifiers—MF classifiers classify traffic based on more than one field in the packet header and take precedence over BA and fixed classifiers.

Interfaces and Output Queues

On Gigabit Ethernet interfaces, 10-Gigabit Ethernet interfaces, and link aggregation (LAG) interfaces, you can apply classifiers to Layer 2 logical interfaces and to Layer 3 physical interfaces if the Layer 3 physical interface has at least one defined logical interface. Classifiers applied to Layer 3 physical interfaces are used on all logical interfaces on that physical interface. "Understanding Applying CoS Classifiers and Rewrite Rules to Interfaces" on page 5344 describes the interaction between classifiers and interfaces in greater detail.

You can configure both a BA classifier and an MF classifier on an interface. If you do this, the BA classification is performed first and then the MF classification is performed. If the two classification results conflict, the MF classification result overrides the BA classification result.

You cannot configure a fixed classifier and a BA classifier on the same interface.

You can configure both a DSCP or a DSCP IPv6 classifier and an IEEE 802.1p classifier on the same interface. IP traffic uses the DSCP or DSCP IPv6 classifier. All other traffic uses the IEEE classifier (except when you configure a global EXP classifier; in that case, MPLS traffic uses the EXP classifier). You can configure only one DSCP classifier on a physical interface (either one DSCP classifier or one DSCP IPv6 classifier, but not both).

Although you can configure as many EXP classifiers as you want, the switch uses only one MPLS EXP classifier as a global classifier on all interfaces. After you configure an MPLS EXP classifier, you can configure it as the global EXP classifier by including the EXP classifier in the **[edit class-of-service system-defaults classifiers exp]** hierarchy. All switch interfaces use the EXP classifier specified using this configuration statement to classify MPLS traffic.

You can create unicast BA classifiers for unicast traffic and multicast BA classifiers for multidestination traffic, which includes multicast, broadcast, and destination lookup fail (DLF) traffic. You cannot assign unicast traffic and multidestination traffic to the same BA classifier.

On each interface, the switch has separate output queues for unicast traffic and for multidestination traffic:

- The switch supports 12 output queues, with 8 queues dedicated to unicast traffic and 4 queues dedicated to multidestination traffic.
- Queues 0 through 7 are unicast traffic queues. You can apply only unicast BA classifiers to unicast queues. A unicast BA classifier should contain only forwarding classes that are mapped to unicast queues.
- Queues 8 through 11 are multidestination traffic queues. You can apply only multidestination BA classifiers to multidestination queues. A multidestination BA classifier should contain only forwarding classes that are mapped to multidestination queues.

You can apply unicast classifiers to one or more interfaces. Multidestination classifiers and EXP classifiers apply to all of the switch interfaces and cannot be applied to individual interfaces. Use the DSCP multidestination classifier for both IP and IPv6 multidestination traffic. The DSCP IPv6 classifier is not supported for multidestination traffic.

Behavior Aggregate Classifiers

The behavior aggregate classifier maps a class-of-service (CoS) value to a forwarding class and loss priority. The forwarding class determines the output queue. A scheduler uses the loss priority to control packet discard during periods of congestion by associating different drop profiles with different loss priorities.

The switch supports three types of BA classifiers:

- Differentiated Services Code Point (DSCP) for IP DiffServ (IP and IPv6)
- IEEE 802.1p CoS bits
- MPLS EXP

BA classifiers are based on fixed-length fields, which makes them computationally more efficient than MF classifiers. Therefore, core devices, which handle high traffic volumes, are normally configured to perform BA classification.

Unicast and multicast traffic cannot share the same classifier. You can map unicast traffic and multicast traffic to the same classifier CoS value, but the unicast traffic must belong to a unicast classifier and the multicast traffic must belong to a multidestination classifier.

Default Behavior Aggregate Classification

Juniper Networks Junos OS automatically assigns implicit default classifiers to all logical interfaces based on the type of interface. Table 449 on page 5336 lists different types of interfaces and the corresponding implicit default BA classifiers.

Table 449: Default BA Classification

Type of Interface	Default BA Classification
Layer 2 interface in trunk mode or in tagged-access mode	**ieee8021p-default**
Layer 3 interface	**dscp-default**
Layer 2 interface in access mode	**ieee8021p-untrusted**

NOTE: There are default BA classifiers for the **best-effort**, **fcoe**, **no-loss**, **network-control**, and **mcast** forwarding classes.

NOTE: There is no default MPLS EXP classifier. You must configure an EXP classifier and apply it globally to all interfaces by including it in the **[edit class-of-service system-defaults classifiers exp]** hierarchy.

If an EXP classifier is not configured, then if a fixed classifier is applied to the interface, the MPLS traffic uses the fixed classifier. If no EXP classifier and no fixed classifier is applied to the interface, MPLS traffic is treated as best-effort traffic. DSCP classifiers are not applied to MPLS traffic.

Because the EXP classifier is global, you cannot configure some ports to use a fixed IEEE 802.1p classifier for MPLS traffic on some interfaces and the global EXP classifier for MPLS traffic on other interfaces. When you configure a global EXP classifier, all MPLS traffic on all interfaces uses the EXP classifier, even interfaces that have a fixed classifier.

When you explicitly associate a unicast classifier with a logical interface, you override the default unicast classifier with the explicit unicast classifier.

NOTE: You can apply only one classifier of each type, DSCP and IEEE 802.1p, to a Layer 2 interface. If both types of classifiers are present, DSCP classifiers take precedence over IEEE 802.1p classifiers. (If you also configure a global EXP classifier, only MPLS traffic uses the EXP classifier, and other traffic uses the configured or default classifier for that traffic type.)

Importing a Classifier

You can use any existing classifier, including the default classifiers, as the basis for defining a new classifier. You accomplish this using the **import** statement.

The imported classifier is used as a template and is not modified. The modifications you make become part of a new classifier (and a new template) identified by the name of the new classifier. Whenever you commit a configuration that assigns a new class-name and loss-priority value to a code-point alias or set of bits, it replaces that entry in the new classifier template. As a result, you must explicitly specify every CoS value in every designation that requires modification.

Multidestination Classifiers

Multidestination classifiers are applied to all interfaces and cannot be applied to individual interfaces. You can configure both a DSCP multidestination classifier and an IEEE multidestination classifer. IP and IPv6 traffic use the DSCP classifier, and all other traffic uses the IEEE classifier.

DSCP IPv6 multidestination classifiers are not supported, so IPv6 traffic uses the DSCP multidestination classifier.

The default multidestination classifier is the IEEE 802.1p multidestination classifier.

PFC Priorities

The eight IEEE 802.1p code points correspond to the eight priorities that priority-based flow control (PFC) uses to differentiate traffic classes for lossless transport. When you map a forwarding class (which maps to an output queue) to an IEEE 802.1p CoS value, the IEEE 802.1p CoS value identifies the priority.

Although you can map a priority to any output queue (by mapping the priority to a forwarding class), we recommend that the priority and the unicast forwarding class match in a one-to-one correspondence in which priority 0 is assigned to queue 0, priority 1 is assigned to queue 1, and so on, as shown in Table 450 on page 5338. A one-to-one correspondence of queue and priority numbers makes it easier to configure and maintain the mapping of forwarding classes to priorities and queues.

Table 450: Default IEEE 802.1p Code Point to PFC Priority, Output Queue, and Forwarding Class Mapping

IEEE 802.1p Code Point	PFC Priority	Unicast Output Queue	Forwarding Class and Packet Drop Attribute
000	0	0	best-effort (drop)
001	1	1	best-effort (drop)
010	2	2	best-effort (drop)
011	3	3	fcoe (no-loss)
100	4	4	no-loss (no-loss)
101	5	5	best-effort (drop)
110	6	6	network-control (drop)
111	7	7	network-control (drop)

NOTE: By convention, deployments with converged server access typically use IEEE 802.1p priority 3 (011) for FCoE traffic. The default mapping of the fcoe forwarding class is to queue 3. Apply priority-based flow control (PFC) to the entire FCoE data path to configure the end-to-end lossless behavior that FCoE requires. We recommend that you use priority 3 for FCoE traffic unless your network architecture requires that you use a different priority.

Fixed Classifiers on Ethernet Interfaces

Fixed classifiers map all traffic on an interface to a forwarding class and a loss priority. (As opposed to BA classifiers, which map traffic into multiple different forwarding classes based on the CoS field value in the packet header.) The forwarding class determines the output queue. Incoming traffic of all IEEE 802.1p priorities is classified into the forwarding class specified in the fixed classifier. A scheduler uses the loss priority to control packet discard during periods of congestion by associating different drop profiles with different loss priorities.

You cannot configure a fixed classifier and a DSCP or IEEE 802.1p BA classifier on the same interface. If you configure a fixed classifier on an interface, you cannot configure a DSCP or an IEEE classifier on that interface. If you configure a DSCP classifier, an IEEE classifier, or both classifiers on an interface, you cannot configure a fixed classifier on that interface.

NOTE: Because EXP classifiers are global, you can configure both a global EXP classifier and also apply fixed classifiers on interfaces. When both the global EXP classifier and a fixed classifier are applied to an interface, MPLS traffic uses the EXP classifier and all other traffic uses the fixed classifier.

To switch from a fixed classifier to a BA classifier or to switch from a BA classifier to a fixed classifier, deactivate the existing classifier attachment on the interface, and then attach the new classifier to the interface.

NOTE: If you configure a fixed classifier that classifies all incoming traffic into the **fcoe** forwarding class (or any forwarding class designed to handle FCoE traffic), you must ensure that all traffic that enters the interface is FCoE traffic and is tagged with the FCoE IEEE 802.1p code point (priority).

Fixed Classifiers on Native Fibre Channel Interfaces (NP_Ports)

Applying a fixed classifier to a native Fibre Channel (FC) interface (NP_Port) is a special case. By default, native FC interfaces classify incoming traffic from the FC SAN into the **fcoe** forwarding class and map the traffic to IEEE 802.1p priority 3 (code point 011). When you apply a fixed classifier to an FC interface, you also configure a priority rewrite value for the interface. The FC interface uses the priority rewrite value as the IEEE 802.1p tag value for all incoming packets instead of the default value of 3.

For example, if you specify a priority rewrite value of 5 (code point 101) for an FC interface, the interface tags all incoming traffic from the FC SAN with priority 5 and classifies the traffic into the forwarding class specified in the fixed classifier.

NOTE: The forwarding class specified in the fixed classifier on FC interfaces must be a lossless forwarding class.

Multifield Classifiers

Multifield classifiers examine multiple fields in a packet such as source and destination addresses and source and destination port numbers of the packet. With MF classifiers, you set the forwarding class and loss priority of a packet based on firewall filter rules.

MF classification is normally performed at the network edge because of the general lack of DiffServ code point (DSCP) support in end-user applications. On a switch at the edge of a network, an MF classifier provides the filtering functionality that scans through a variety of packet fields to determine the forwarding class for a packet. Typically, a classifier performs matching operations on the selected fields against a configured value.

Packet Classification for Routed VLAN Interfaces (RVIs)

You cannot apply classifiers directly to routed VLAN interfaces (RVIs) because the members of RVIs are VLANs, not ports. However, you can apply classifiers to the VLAN port members of an RVI. You can also apply MF classifiers to RVIs.

Understanding CoS MPLS EXP Classifiers and Rewrite Rules

You can use class of service (CoS) within MPLS networks to prioritize certain types of traffic during periods of congestion by applying packet classifiers and rewrite rules to the MPLS traffic. (For information about DSCP and IEEE 802.1p classifiers and general information about classifiers, see "Understanding CoS Classifiers" on page 5334. For information about DSCP and IEEE 802.1p rewrite rules, see "Understanding CoS Rewrite Rules" on page 5414.)

When a packet enters a customer-edge interface on the ingress provider edge (PE) switch, the switch associates the packet with a particular CoS servicing level before placing the packet onto the label-switched path (LSP). The switches within the LSP utilize the CoS value set at the ingress PE switch. The CoS value that was embedded in the classifier is translated and encoded in the MPLS header by means of the experimental (EXP) bits.

EXP classifiers map incoming MPLS packets to a forwarding class and a loss priority, and assign MPLS packets to output queues based on the forwarding class mapping. EXP classifiers are behavior aggregate (BA) classifiers.

EXP rewrite rules change (rewrite) the CoS value of the EXP bits in outgoing packets on the egress queues of the switch so that the new (rewritten) value matches the policies of a targeted peer. Policy matching allows the downstream routing platform or switch in a neighboring network to classify each packet into the appropriate service group.

NOTE: There is no default EXP classifier. There is no default EXP rewrite rule. If you want to classify incoming MPLS packets using the EXP bits, you must configure a global EXP classifier. If you want to rewrite the EXP bit value at the egress interface, you must configure EXP rewrite rules and apply them to logical interfaces.

This topic includes:

EXP Classifiers

Unlike DSCP and IEEE 802.1p BA classifiers, EXP classifiers are global to the switch and apply to all switch interfaces. When you configure and apply an EXP classifier, MPLS traffic on all interfaces uses the EXP classifier, even on interfaces that also have a fixed classifier. If an interface has both an EXP classifier and a fixed classifier, the EXP classifier is applied to MPLS traffic and the fixed classifier is applied to all other traffic.

Also unlike DSCP and IEEE 802.1p BA classifiers, there is no default EXP classifier. If you want to classify MPLS traffic based on the EXP bits, you must explicitly configure an EXP classifier and apply it the switch interfaces. Each EXP classifier has eight entries that correspond to the eight EXP CoS values (0 through 7, which correspond to bits 000 through 111).

You can configure as many EXP classifiers as you want. However, the switch uses only one MPLS EXP classifier as a global classifier on all interfaces. After you configure an MPLS EXP classifier, you can configure it as the global EXP classifier by including the EXP classifier in the **[edit class-of-service system-defaults classifiers exp]** hierarchy. All switch interfaces use the global EXP classifier to classify MPLS traffic.

Only one EXP classifier can be configured as the global EXP classifier at any time. If you want to change the global EXP classifier, delete the global EXP classifier configuration (use the **user@switch# delete class-of-service system-defaults classifiers exp** configuration statement), then configure the new global EXP classifier.

If an EXP classifier is not configured, then if a fixed classifier is applied to the interface, the MPLS traffic uses the fixed classifier. If no EXP classifier and no fixed classifier is applied to the interface, MPLS traffic is treated as best-effort traffic. DSCP classifiers are not applied to MPLS traffic.

Because the EXP classifier is global, you cannot configure some ports to use a fixed IEEE 802.1p classifier for MPLS traffic on some interfaces and the global EXP classifier for MPLS traffic on other interfaces. When you configure a global EXP classifier, all MPLS traffic on all interfaces uses the EXP classifier.

NOTE: The switch uses only the outermost label of incoming EXP packets for classification.

NOTE: MPLS packets with 802.1Q tags are not supported.

EXP Rewrite Rules

As MPLS packets enter or exit a network, edge switches might be required to alter the class-of-service (CoS) settings of the packets. EXP rewrite rules set the value of the EXP CoS bits within the header of the outgoing MPLS packet. Each rewrite rule reads the current forwarding class and loss priority associated with the packet, locates the chosen CoS value from a table, and writes that CoS value into the packet header, replacing the old CoS value. EXP rewrite rules apply only to MPLS traffic.

EXP rewrite rules apply only to logical interfaces. You cannot apply EXP rewrite rules to physical interfaces.

There are no default EXP rewrite rules. If you want to rewrite the EXP value in MPLS packets, you must configure EXP rewrite rules and apply them to logical interfaces. If no rewrite rules are applied, all MPLS labels that are pushed have a value of zero (0). The EXP value remains unchanged on MPLS labels that are swapped.

You can configure as many EXP rewrite rules as you want, but you can only apply 16 EXP rewrite rules at any time on the switch. On a given logical interface, all pushed MPLS labels have the same EXP rewrite rule applied to them. You can apply different EXP rewrite rules to different logical interfaces on the same physical interface.

You can apply an EXP rewrite rule to an interface that has a DSCP, DSCP IPv6, or IEEE 802.1p rewrite rule. Only MPLS traffic uses the EXP rewrite rule. MPLS traffic does not use DSCP or DSCP IPv6 rewrite rules.

If the switch is performing penultimate hop popping (PHP), EXP rewrite rules do not take effect. If both an EXP classifier and an EXP rewrite rule are configured on the switch, then the EXP value from the last popped label is copied into the inner label. If either an EXP classifier or an EXP rewrite rule (but not both) is configured on the switch, then the inner label EXP value is sent unchanged.

NOTE: **On each physical interface, either all forwarding classes that are being used on the interface must have rewrite rules configured or no forwarding classes that are being used on the interface can have rewrite rules configured. On any physical port, do not mix forwarding classes with rewrite rules and forwarding classes without rewrite rules.**

Schedulers

The schedulers for using CoS with MPLS are the same as for the other CoS configurations on the QFX Series. Default schedulers are provided only for the best-effort, fcoe, no-loss, and network-control forwarding classes. If you configure a custom forwarding class for MPLS traffic, you need to configure a scheduler to support that forwarding class and provide bandwidth to that forwarding class. See “Understanding CoS Output Queue Schedulers” on page 5371 and “Example: Configuring Queue Schedulers” on page 5511 for more information.

Understanding Applying CoS Classifiers and Rewrite Rules to Interfaces

At ingress interfaces, classifiers group incoming traffic into classes based on the IEEE 802.1p, DSCP, or MPLS EXP class of service (CoS) code point bits in the packet header. At egress interfaces, you can use rewrite rules to change (re-mark) the code point bits before the interface forwards the packets. At ingress interfaces, classifiers group incoming traffic into classes based on the IEEE 802.1p, DSCP, or MPLS EXP CoS code point bits in the packet header. At egress interfaces, rewrite rules can change (re-mark) the code point bits before the interface forwards the packets.

You can apply classifiers and rewrite rules to interfaces to control the level of CoS applied to each packet as it traverses the system and the network. This topic describes:

Supported Classifier and Rewrite Rule Types

Table 451 on page 5344 shows the types of classifiers and rewrite rules that the QFX Series supports:

Table 451: Supported Classifiers and Rewrite Rules

Classifier or Rewrite Rule Type	Description
Fixed classifier	Classifies all ingress traffic on a physical interface into one fixed forwarding class, regardless of the CoS bits in the packet header.
DSCP and DSCP IPv6 unicast classifiers	Classifies IP and IPv6 traffic into forwarding classes and assigns loss priorities to the traffic.
IEEE 802.1p unicast classifier	Classifies Ethernet traffic into forwarding classes and assigns loss priorities to the traffic.
MPLS EXP classifier	Classifies MPLS traffic into forwarding classes and assigns loss priorities to the traffic. The system uses one global EXP classifier on all switch interfaces.
DSCP multidestination classifier (also used for IPv6 multidestination traffic)	Classifies IP and IPv6 multicast, broadcast, and destination lookup fail (DLF) traffic into multidestination forwarding classes. Multidestination classifiers are applied to all interfaces and cannot be applied to individual interfaces.

Table 451: Supported Classifiers and Rewrite Rules *(continued)*

Classifier or Rewrite Rule Type	Description
IEEE 802.1p multidestination classifier	Classifies Ethernet multicast, broadcast, and destination lookup fail (DLF) traffic into multidestination forwarding classes. Multidestination classifiers are applied to all interfaces and cannot be applied to individual interfaces.
DSCP and DSCP IPv6 rewrite rules	Re-marks the DSCP code points of IP and IPv6 packets before forwarding the packets.
IEEE 802.1p rewrite rule	Re-marks the IEEE 802.1p code points of Ethernet packets before forwarding the packets.
MPLS EXP rewrite rule	Re-marks the EXP code points of MPLS packets before forwarding the packets.

NOTE: On native Fibre Channel (FC) interfaces (NP_Ports) only, you can specify a rewrite value to set the IEEE 802.1p code point of incoming FC traffic when the NP_Port encapsulates the FC packet in Ethernet before forwarding it to the FCoE network (see "Understanding CoS IEEE 802.1p Priority Remapping on an FCoE-FC Gateway" on page 5446).

DSCP, IEEE 802.1p, and MPLS EXP classifiers are behavior aggregate (BA) classifiers. Unlike DSCP and IEEE 802.1p classifiers, EXP classifiers are global and apply to all interfaces. Also unlike DSCP and IEEE 802.1p classifiers, for MPLS traffic only, EXP classifiers overwrite fixed classifiers. (An interface that has a fixed classifier uses the EXP classifier for MPLS traffic, not the fixed classifier.)

Multidestination classifiers are global and apply to all interfaces; you cannot apply a multidestination classifier to individual interfaces.

Classifying packets into forwarding classes assigns packets to the output queues associated with the forwarding classes. Classifying traffic into a forwarding class associates the CoS scheduling for the forwarding class with that traffic.

NOTE: In addition to BA classifiers and fixed classifiers, which classify traffic based on the CoS field in the packet header, you can use firewall filters to configure multifield (MF) classifiers. MF classifiers classify traffic based on more than one field in the packet header and take precedence over BA and fixed classifiers.

Ethernet Interfaces Supported for Classifier and Rewrite Rule Configuration

To apply a classifier to incoming traffic or a rewrite rule to outgoing traffic, you need to apply the classifier or rewrite rule to one or more interfaces. When you apply a classifier or rewrite rule to an interface, the interface uses the classifier to group incoming traffic into forwarding classes and uses the rewrite rule to re-mark the CoS code point value of each packet before it leaves the system.

Not all interfaces types support all types of CoS configuration. This section describes:

Interface Types That Support Classifier and Rewrite Rule Configuration

You can apply classifiers to all Ethernet interfaces. For Layer 3 LAGs, configure BA or fixed classifiers on the LAG (ae) interface. The classifier configured on the LAG is valid on all of the LAG member interfaces.

You can apply fixed classifiers to native FC interfaces (NP_Ports). You cannot apply other types of classifiers or rewrite rules to native FC interfaces. You can rewrite the value of the IEEE 802.1p code point of incoming FC traffic when the interface encapsulates it in Ethernet before forwarding it to the FCoE network as described in "Understanding CoS IEEE 802.1p Priority Remapping on an FCoE-FC Gateway" on page 5446.

Classifier and Rewrite Rule Physical and Logical Ethernet Interface Support

The QFX Series Ethernet ports can function as:

- Layer 2 physical interfaces (family ethernet-switching)
- Layer 2 logical interfaces (family ethernet-switching)
- Layer 3 physical interfaces (family inet/inet6)
- Layer 3 logical interfaces (family inet/inet6)

You can apply CoS classifiers and rewrite rules only to the following interfaces:

- Layer 2 logical interfaces
- Layer 3 physical interfaces if at least one logical Layer 3 interface is configured on the physical interface

NOTE: **The CoS you configure on a Layer 3 physical interface is applied to all of the Layer 3 logical interfaces on that physical interface. This means that each Layer 3 interface uses the same classifiers and rewrite rules for all of the Layer 3 traffic on that interface.**

You cannot apply classifiers or rewrite rules to Layer 2 physical interfaces or to Layer 3 logical interfaces. Table 452 on page 5347 shows on which interfaces you can configure and apply classifiers and rewrite rules.

Table 452: Ethernet Interface Support for Classifier and Rewrite Rule Configuration

CoS Classifiers and Rewrite Rules	Layer 2 Physical Interfaces	Layer 2 Logical Interfaces	Layer 3 Physical Interfaces (If at Least One Logical Layer 3 Interface Is Defined)	Layer 3 Logical Interfaces
Fixed classifier	No	Yes	Yes	No
DSCP classifier	No	Yes	Yes	No
DSCP IPv6 classifier	No	Yes	Yes	No
IEEE 802.1p classifier	No	Yes	Yes	No
EXP classifier	Global classifier, applies to all switch interfaces. Cannot be configured on individual interfaces.			
DSCP rewrite rule	No	Yes	Yes	No
DSCP IPv6 rewrite rule	No	Yes	Yes	No
IEEE 802.1p rewrite rule	No	Yes	Yes	No
EXP rewrite rule	No	Yes	Yes	No

NOTE: IEEE 802.1p mutidestination and DSCP multidestination classifiers are applied to all interfaces and cannot be applied to individual interfaces. No DSCP IPv6 multidestination classifier is supported. IPv6 multidestination traffic uses the DSCP multidestination classifier.

Routed VLAN Interfaces (RVIs) and Integrated Routing and Bridging (IRB) Interfaces

You cannot apply classifiers and rewrite rules directly to routed VLAN interfaces (RVIs) or integrated routing and bridging (IRB) interfaces because the members of RVIs and IRBs are VLANs, not ports. However, you can apply classifiers and rewrite rules to the VLAN port members of an RVI or an IRB. You can also apply MF classifiers to RVIs and IRBs.

Default Classifiers

If you do not explicitly configure classifiers on an Ethernet interface, the QFX Series applies default classifiers (see “Understanding Default CoS Settings” on page 5322) so that the traffic receives basic CoS treatment. The factors that determine the default classifier applied to the interface include the interface type (Layer 2 or Layer 3), the port mode (trunk, tagged-access, or access), and whether logical interfaces have been configured. The system applies a default classifier using the following rules:

- If the physical interface has at least one Layer 3 logical interface configured, it uses the default DSCP classifier.
- If the physical interface has a Layer 2 logical interface in trunk mode or tagged-access mode, it uses the default trusted classifier.
- If the physical interface has a Layer 2 logical interface in access mode, it uses the default untrusted classifier.
- If the physical interface has no logical interface configured, no default classifier is applied.
- The default multidestination classifier is the IEEE 802.1p multidestination classifier.
- There is no default MPLS EXP classifier. If you want to classify traffic using EXP bits, you must configure an EXP classifier and configure it as the global system default EXP classifier.

Default Rewrite Rules

No default rewrite rules are applied to interfaces. If you want to re-mark packets at the egress interface, you must explicitly configure a rewrite rule.

Classifier Precedence

You can apply multiple unicast classifiers (MF, fixed, IEEE 802.1p, DSCP, or EXP) to a physical or logical Ethernet interface to handle different types of traffic. (EXP classifiers are global and apply to all MPLS traffic on all interfaces.) When you apply more than one classifier to an interface, the system uses an order of precedence to determine which classifier to use on physical and logical interfaces:

- Unicast Classifier Precedence on Physical Ethernet Interfaces on page 5348
- Unicast Classifier Precedence on Logical Ethernet Interfaces on page 5349

Unicast Classifier Precedence on Physical Ethernet Interfaces

The precedence of unicast classifiers on physical interfaces, from the highest-priority classifier to the lowest-priority classifier, is:

- MF classifier on a logical interface (no classifier has a higher priority than MF classifiers)
- Fixed classifier on the physical interface
- DSCP or DSCP IPv6 classifier on the physical interface
- IEEE 802.1p classifier on the physical interface

NOTE: If an EXP classifier is configured, MPLS traffic uses the EXP classifier, even if an MF or fixed classifier is applied to the interface. If an EXP classifier is not configured, then if a fixed classifier is applied to the interface, the MPLS traffic uses the fixed classifier. If no EXP classifier and no fixed classifier is applied to the interface, MPLS traffic is treated as best-effort traffic. DSCP classifiers are not applied to MPLS traffic.

You can apply a DSCP classifier, an IEEE 802.1p classifier, and an EXP classifier on a physical interface. When all three classifiers are on an interface, IP traffic uses the DSCP classifier, MPLS traffic uses the EXP classifier, and all other traffic uses the IEEE classifier.

NOTE: You cannot apply a fixed classifier and a DSCP or IEEE classifier to the same interface. If a DSCP classifier, an IEEE classifier, or both are on an interface, you cannot apply a fixed classifier to that interface unless you first delete the DSCP and IEEE classifiers. If a fixed classifier is on an interface, you cannot apply a DSCP classifier or an IEEE classifier unless you first delete the fixed classifier.

Unicast Classifier Precedence on Logical Ethernet Interfaces

The precedence of unicast classifiers on logical interfaces, from the highest priority classifier to the lowest priority classifier, is:

- MF classifier on a logical interface (no classifier has a higher priority than MF classifiers)
- Fixed classifier on the logical interface
- DSCP or DSCP IPv6 classifier on the physical interface
- IEEE 802.1p classifier on the physical interface

NOTE: If an EXP classifier is configured, MPLS traffic uses the EXP classifier, even if a fixed classifier is applied to the interface. If an EXP classifier is not configured, then if a fixed classifier is applied to the interface, the MPLS traffic uses the fixed classifier. If no EXP classifier and no fixed classifier is applied to the interface, MPLS traffic is treated as best-effort traffic.

You can apply both a DSCP classifier and an IEEE 802.1p classifier on a logical interface. When both a DSCP and an IEEE classifier are on an interface, IP traffic uses the DSCP classifier, and all other traffic uses the IEEE classifier. If an MPLS EXP classifier is also applied to the interface, only MPLS traffic uses the EXP classifier.

Classifier Behavior and Limitations

Consider the following behaviors and constraints when you apply classifiers to physical and logical Ethernet interfaces:

- You can configure only one DSCP classifier (IP or IPv6) on a physical interface. You cannot configure both types of DSCP classifier on one physical interface. Both IP and IPv6 traffic use whichever DSCP classifier is configured on the interface.
- When you configure a DSCP or a DSCP IPv6 classifier on a physical interface and the physical interface has at least one logical Layer 3 interface, all packets (IP, IPv6, and non-IP) use that classifier.

- An interface with both a DSCP classifier (IP or IPv6) and an IEEE 802.1p classifier uses the DSCP classifier for IP and IPv6 packets, and uses the IEEE classifier for all other packets.
- Fixed classifiers and BA classifiers (DSCP and IEEE classifiers) are not permitted simultaneously on an interface. If you configure a fixed classifier on an interface, you cannot configure a DSCP or an IEEE classifier on that interface. If you configure a DSCP classifier, an IEEE classifier, or both classifiers on an interface, you cannot configure a fixed classifier on that interface.
- When you configure an IEEE 802.1p classifier on a physical interface and a DSCP classifier is not explicitly configured on that interface, the interface uses the IEEE classifier for all types of packets. No default DSCP classifier is applied to the interface. (In this case, if you want a DSCP classifier on the interface, you must explicitly configure it.)
- The system does not apply a default classifier to a physical interface until you create a logical interface on that physical interface. If you configure a Layer 3 logical interface, the system uses the default DSCP classifier. If you configure a Layer 2 logical interface, the system uses the default IEEE 802.1p trusted classifier if the port is in trunk mode or tagged-access mode, or the default IEEE 802.1p untrusted classifier if the port is in access mode.
- MF classifiers configured on logical interfaces take precedence over BA and fixed classifiers, with the exception of the global EXP classifier, which is always used for MPLS traffic. (Use firewall filters to configure MF classifiers.) When BA or fixed classifiers are present on an interface, you can still configure an MF classifier on that interface.
- There is no default EXP classifier for MPLS traffic.
- You can configure as many EXP classifiers as you want, but the switch uses only one MPLS EXP classifier as a global classifier on all interfaces. After you configure an MPLS EXP classifier, you can configure it as the global EXP classifier by including the EXP classifier in the **[edit class-of-service system-defaults classifiers exp]** hierarchy. All switch interfaces use the EXP classifier specified using this configuration statement to classify MPLS traffic, even on interfaces that have a fixed classifier. No other traffic uses the EXP classifier.

Rewrite Rule Precedence and Behavior

The following rules apply on both physical and logical Ethernet interfaces for rewrite rules:

- If you configure both one DSCP (or DSCP IPv6) rewrite rule and one IEEE 802.1p rewrite rule on an interface, both rewrite rules take effect. Traffic with IP and IPv6 headers use the DSCP rewrite rule, and traffic with a VLAN tag uses the IEEE rewrite rule.
- If you do not explicitly configure a rewrite rule, there is no default rewrite rule, so the system does not apply any rewrite rule to the interface.
- You can apply a DSCP rewrite rule or a DSCP IPv6 rewrite rule to an interface, but you cannot apply both a DSCP and a DSCP IPv6 rewrite rule to the same interface. Both IP and IPv6 packets use the same DSCP rewrite rule, regardless if the configured rewrite rule is DSCP or DSCP IPv6.

- MPLS EXP rewrite rules apply only to logical interfaces. You cannot apply to an EXP rewrite rule to a physical interface. You can configure as many EXP rewrite rules as you want, but you can only use 16 EXP rewrite rules at any time on the switch.
- A logical interface can use both DSCP (or DSCP IPv6) and EXP rewrite rules.
- DSCP and DSCP IPv6 rewrite rules are not applied to MPLS traffic.
- If the switch is performing penultimate hop popping (PHP), EXP rewrite rules do not take effect. If both an EXP classifier and an EXP rewrite rule are configured on the switch, then the EXP value from the last popped label is copied into the inner label. If either an EXP classifier or an EXP rewrite rule (but not both) is configured on the switch, then the inner label EXP value is sent unchanged.

Classifier and Rewrite Rule Configuration Interaction with Ethernet Interface Configuration

You can apply classifiers and rewrite rules only on Layer 2 logical interfaces and Layer 3 physical interfaces (if the Layer 3 physical interface has at least one defined logical interface). This section focuses on BA classifiers, but the interaction between BA classifiers and interfaces described in this section also applies to fixed classifiers and rewrite rules.

NOTE: Multidestination classifiers and EXP classifiers are global and apply to all switch interfaces. See "Defining CoS Unicast BA Classifiers (DSCP, DSCP IPv6, IEEE 802.1p)" on page 5673 for how to configure multidestination classifiers and see "Defining CoS Unicast BA Classifiers (DSCP, DSCP IPv6, IEEE 802.1p)" on page 5673 for how to configure EXP classifiers.

There are two components to applying classifiers or rewrite rules to interfaces:

1. Setting the interface family (inet, inet6, or ethernet-switching; ethernet-switching is the default interface family) in the **[edit interfaces]** configuration hierarchy.
2. Applying a classifier or rewrite rule to the interface in the **[edit class-of-service]** hierarchy.

These are separate operations that can be set and committed at different times. Because the type of classifier or rewrite rule you can apply to an interface depends on the interface family configuration, the system performs checks to ensure that the configuration is valid. The method the system uses to notify you of an invalid configuration depends on the **set** operation that causes the invalid configuration.

When applying the classifier or rewrite rule to the interface in the **[edit class-of-service]** hierarchy causes an invalid configuration, the system rejects the configuration and returns a commit check error.

When setting the interface family in the **[edit interfaces]** configuration hierarchy causes an invalid configuration, the system creates a syslog error message. When you receive the error message, you need to remove the classifier or rewrite rule configuration from the logical interface and apply it to the physical interface, or remove the classifier or rewrite rule configuration from the physical interface and apply it to the logical interface.

For classifiers, if you do not take action to correct the error, the system programs the default classifier for the interface family on the interface. (There are no default rewrite rules. If the commit check fails, no rewrite rule is applied to the interface.)

Two scenarios illustrate these situations:

- Scenario 1: Applying a Classifier to an Ethernet Interface Causes a Commit Check Error on page 5352
- Scenario 2: Configuring the Ethernet Interface Family Causes a Syslog Error on page 5352

NOTE: **Both of these scenarios also apply to fixed classifiers and rewrite rules.**

Scenario 1: Applying a Classifier to an Ethernet Interface Causes a Commit Check Error

In Scenario 1, we set the interface family, and then specify an invalid classifier.

1. Set and commit the interface as a Layer 3 (family **inet**) interface:

   ```
   [edit interfaces]
   user@switch# set xe-0/0/20 unit 0 family inet
   user@switch# commit
   ```

   This commit operation succeeds.

2. Set and commit a DSCP classifier on the logical interface (this example uses a DSCP classifier named **dscp1**):

   ```
   [edit class-of-service]
   user@switch# set interfaces xe-0/0/20 unit 0 classifiers dscp dscp1
   user@switch# commit
   ```

   This configuration is not valid, because it attempts to apply a classifier to a Layer 3 logical interface. Because the failure is caused by the class-of-service configuration and not by the interface configuration, the system rejects the commit operation and issues a commit error, not a syslog message.

   Note that the commit operation succeeds if you apply the classifier to the physical Layer 3 interface as follows:

   ```
   [edit class-of-service]
   user@switch# set interfaces xe-0/0/20 classifiers dscp dscp1
   user@switch# commit
   ```

   Because the logical unit is not specified, the classifier is applied to the physical Layer 3 interface in a valid configuration, and the commit check succeeds.

Scenario 2: Configuring the Ethernet Interface Family Causes a Syslog Error

In Scenario 2, we set the classifier first, then set an invalid interface type.

1. Set and commit a DSCP classifier on a Layer 3 logical interface, assuming that the interface has no existing configuration:

   ```
   [edit class-of-service]
   user@switch# set interfaces xe-0/0/20 unit 0 classifiers dscp dscp1
   user@switch# commit
   ```

This commit succeeds. Because no explicit configuration existed on the interface, it is by default a Layer 2 (**family ethernet-switching**) interface. Layer 2 logical interfaces support BA classifiers, so applying the classifier is a valid configuration.

2. Set and commit the interface as a Layer 3 interface (family **inet**) interface:

```
[edit interfaces]
user@switch# set xe-0/0/20 unit 0 family inet
user@switch# commit
```

This configuration is not valid because it attempts to change an interface from Layer 2 (**family ethernet-switching**) to Layer 3 (**family inet**) when a classifier has already been applied to a logical interface. Layer 3 logical interfaces do not support classifiers. Because the failure is caused by the interface configuration and not by the class-of-service configuration, the system does not issue a commit error, but instead issues a syslog message.

When the system issues the syslog message, it programs the default classifier for the interface type on the interface. In this scenario, the interface has been configured as a Layer 3 interface, so the system applies the default DSCP profile to the physical Layer 3 interface.

In this scenario, to install a configured DSCP classifier, you remove the misconfigured classifier from the Layer 3 logical interface and apply it to the Layer 3 physical interface. For example:

```
[edit]
user@switch# delete class-of-service interfaces xe-0/0/20 unit 0 classifiers dscp dscp1
user@switch# commit
user@switch# set class-of-service interfaces xe-0/0/20 classifiers dscp dscp1
user@switch# commit
```

Understanding CoS Forwarding Classes

Forwarding classes group traffic and assign the traffic to output queues. Each forwarding class is mapped to an output queue. Classification identifies the output queue for each incoming packet by mapping the packet code point bits to forwarding classes. The forwarding class to queue mapping defines the output queue used for the packet.

A classifier must associate each packet with one of the following five default forwarding classes or with a user-configured forwarding class in order to assign an output queue to the packet:

- fcoe—Guaranteed delivery for Fibre Channel over Ethernet (FCoE) traffic.
- no-loss—Guaranteed delivery for TCP lossless traffic.
- best-effort—Provides best-effort delivery without a service profile. Loss priority is typically not carried in a class-of-service (CoS) value.
- network-control—Supports protocol control and is typically high priority.
- mcast—Provides no service profile for multidestination (multicast, broadcast, and destination lookup fail) packets.

The switch supports up to 12 forwarding classes, thus enabling flexible, differentiated, packet classification. For example, you can configure multiple classes of best-effort traffic such as **best-effort**, **best-effort1**, and **best-effort2**.

The switch supports up to 12 output queues: 8 output queues for unicast traffic (queues 0 through 7) and 4 output queues for multidestination traffic (queues 8 through 11). Forwarding classes mapped to unicast queues are associated with unicast traffic, and forwarding classes mapped to multidestination queues are associated with multidestination traffic. You cannot map unicast and multidestination traffic to the same queue. You cannot map a strict-high priority queue to a multidestination forwarding class (queues 8 through 11 do not support strict-high priority configuration).

Default Forwarding Classes

Table 453 on page 5355 shows the four default forwarding classes defined for unicast traffic, and Table 454 on page 5356 shows the four default forwarding classes defined for multicast traffic.

If desired, you can rename the forwarding classes associated with the queues supported on your switch. Assigning a new class name to an output queue does not alter the default classification or scheduling that is applicable to that queue. CoS configurations can be quite complicated, so unless it is required by your scenario, we recommend that you not alter the default class names or queue number associations.

Table 453: Default Forwarding Classes for Unicast Packets

Forwarding Class Name	Default Queue Mapping	Comments
best-effort (be)	0	The software does not apply any special CoS handling to packets with 000000 in the DiffServ field. This is a backward compatibility feature. These packets are usually dropped under congested network conditions. By default, this is a lossy forwarding class with a packet drop attribute of **drop**.
fcoe	3	The software delivers assured bandwidth, low loss, low delay, and low delay variation (jitter) end to end for packets in this service class. The software accepts excess traffic in this class, but in contrast to the assured forwarding class, the out-of-profile expedited-forwarding class packets can be forwarded out of sequence or dropped. NOTE: By convention, deployments with converged server access typically use IEEE 802.1p priority 3 (011) for FCoE traffic. The default mapping of the **fcoe** forwarding class is to queue 3. Apply priority-based flow control (PFC) to the entire FCoE data path to configure the end-to-end lossless behavior that FCoE requires. We recommend that you use priority 3 for FCoE traffic unless your network architecture requires that you use a different priority. By default, this is a lossless forwarding class with a packet drop attribute of **no-loss**.
no-loss	4	The software offers a high level of assurance that the packets are delivered as long as the packet flow from the customer stays within a certain service profile that you define. The software accepts excess traffic, but it applies a tail-drop profile to determine if the excess packets are dropped and not forwarded. Up to two drop probabilities (low and high) are defined for this service class. By default, this is a lossless forwarding class with a packet drop attribute of **no-loss**.
network-control (nc)	7	The software delivers packets in this service class with a high priority. (These packets are not delay-sensitive.) Typically, these packets represent routing protocol hello or keepalive messages. Because loss of these packets jeopardizes proper network operation, packet delay is preferable to packet discard. By default, this is a lossy forwarding class with a packet drop attribute of **drop**.

Table 454: Default Forwarding Classes for Multicast Packets

Forwarding Class Name	Default Queue Mapping	Comments
mcast	8	The software does not apply any special CoS handling to the multidestination packets. These packets are usually dropped under congested network conditions. By default, this is a lossy forwarding class with a packet drop attribute of **drop**.

NOTE: Mirrored traffic is always sent to the queue that corresponds to the multidestination forwarding class. The switched copy of the mirrored traffic is forwarded with the priority determined by the behavior aggregate classification process.

Forwarding Class Configuration Rules

Take the following rules into account when you configure forwarding classes:

- Queue Assignment Rules on page 5356
- Scheduling Rules on page 5356
- Rewrite Rules on page 5357

Queue Assignment Rules

The following rules govern queue assignment:

- CoS configurations that specify more queues than the switch can support are not accepted. The commit operation fails with a detailed message that states the total number of queues available.
- All default CoS configurations are based on queue number. The name of the forwarding class that appears in the default configuration is the forwarding class currently associated with that queue.
- Only unicast forwarding classes can be mapped to unicast queues (0 through 7), and only multidestination forwarding classes can be mapped to multidestination queues (8 through 11).
- Strict-high priority queues cannot be mapped to multidestination forwarding classes. (Strict-high priority traffic cannot be mapped to queues 8 through 11).
- If you map more than one forwarding class to a queue, all of the forwarding classes mapped to the same queue must have the same packet drop attribute (all of the forwarding classes must be lossy, or all of the forwarding classes mapped to a queue must be lossless).

Scheduling Rules

When you define a forwarding class that is used on the switch (the behavior aggregate classifier has a forwarding class and you expect traffic for the forwarding class), you must also define a scheduling policy for the forwarding class. Defining a scheduling policy means:

- Mapping a scheduler to the forwarding class in a scheduler map
- Including the forwarding class in a forwarding class set
- Associating the scheduler map with a traffic control profile
- Attaching the traffic control profile to a forwarding class set and an interface

Rewrite Rules

On each physical interface, either all forwarding classes that are being used on the interface must have rewrite rules configured, or no forwarding classes that are being used on the interface can have rewrite rules configured. On any physical port, do not mix forwarding classes with rewrite rules and forwarding classes without rewrite rules.

Lossless Transport Support

The QFX Series supports up to six lossless forwarding classes. For lossless transport, you must enable PFC on the IEEE 802.1p code point of lossless forwarding classes. The following limitations apply to support lossless transport:

- The external cable length from the QFX3500 or QFabric system Node device to other devices cannot exceed 300 meters.
- The internal cable length from the QFabric system Node device to the QFabric system Interconnect device cannot exceed 150 meters.
- For FCoE traffic, the interface maximum transmission unit (MTU) must be at least 2180 bytes to accommodate the packet payload, headers, and checks.
- Changing any portion of a PFC configuration on a port blocks the entire port until the change is completed. After a PFC change is completed, the port is unblocked and traffic resumes. Changing the PFC configuration means any change to a congestion notification profile that is configured on a port (enabling or disabling PFC on a code point, changing the MRU or cable-length value, or specifying an output flow control queue). Blocking the port stops ingress and egress traffic, and causes packet loss on all queues on the port until the port is unblocked.

NOTE: Junos OS Release 12.2 introduces changes to the way the QFX Series handles lossless forwarding classes (the **fcoe** and **no-loss** forwarding classes).

In Junos OS Release 12.1, both explicitly configuring the **fcoe** and **no-loss** forwarding classes, and using the default configuration for these forwarding classes, resulted in the same lossless behavior for traffic mapped to those forwarding classes.

However, in Junos OS Release 12.2, if you explicitly configure the **fcoe** or the **no-loss** forwarding class, that forwarding class is no longer treated as a lossless forwarding class. Traffic mapped to these forwarding classes is treated as lossy (**best-effort**) traffic. This is true even if the explicit configuration is exactly the same as the default configuration.

If your CoS configuration from Junos OS Release 12.1 or earlier includes the explicit configuration of the **fcoe** or the **no-loss** forwarding class, then when you upgrade to Junos OS Release 12.2, those forwarding classes are not lossless. To preserve the lossless treatment of these forwarding classes, delete the explicit **fcoe** and **no-loss** forwarding class configuration before you upgrade to Junos OS Release 12.2.

See "Overview of CoS Changes Introduced in Junos OS Release 12.2" on page 5304 for detailed information about this change and how to delete an existing lossless configuration.

In Junos OS Release 12.3, the default behavior of the **fcoe** and **no-loss** forwarding classes is the same as in Junos OS Release 12.2. However, in Junos OS Release 12.3, you can configure up to six lossless forwarding classes. All explicitly configured lossless forwarding classes must include the new **no-loss** packet drop attribute or the forwarding class is lossy.

Understanding CoS Forwarding Class Sets (Priority Groups)

A forwarding class set is the Junos OS configuration construct that equates to a priority group in enhanced transmission selection (ETS, described in IEEE 802.1Qaz). The switch implements ETS using a two-tier hierarchical scheduler.

A priority group is a group of queues (priorities). Mapping a forwarding class to a queue defines the traffic for that queue, so a priority equates to a queue (forwarding class). The queues in a priority group share the port bandwidth allocated to that priority group. The traffic for queues in one priority group usually share similar traffic-handling requirements.

You can configure up to three unicast forwarding class sets and one multicast forwarding class set. Only unicast forwarding classes can belong to unicast forwarding class sets. Only multicast forwarding classes can belong to the multicast forwarding class set.

If you configure a strict-high priority queue, you must observe the following rules when configuring forwarding class sets:

- You must create a separate forwarding class set for the strict-high priority queue.
- Only one forwarding class set can contain strict-high priority queues.
- Strict-high priority queues cannot belong to the same forwarding class set as queues that are not strict-high priority.
- A strict-high priority queue cannot belong to a multidestination forwarding class set.
- You cannot configure a guaranteed minimum bandwidth (guaranteed rate) for a forwarding class set that includes a strict-high priority queue. (You also cannot configure a guaranteed minimum bandwidth for a strict-high queue.)

You must use hierarchical scheduling to define CoS for output queues. The two-tier hierarchical scheduler defines bandwidth resources for the priority group, and then allocates those resources among the priorities that belong to the priority group.

If you do not explicitly configure forwarding class sets, the system automatically creates a default forwarding class set that contains all of the forwarding classes on the switch. The system assigns 100 percent of the port output bandwidth to the default forwarding class set. Ingress traffic is classified based on the default classifier settings. The forwarding classes (queues) in the default forwarding class set receive bandwidth based on the default scheduler settings. Forwarding classes that are not part of the default scheduler receive no bandwidth. The default priority group is transparent. It does not appear in the configuration and is used for Data Center Bridging Capability Exchange Protocol (DCBX) advertisement.

When you explicitly configure forwarding class sets and map them to an interface, any forwarding class that you do not map to a forwarding class set receives no guaranteed bandwidth on that interface. Forwarding classes that belong to the default forwarding class set might receive bandwidth if the other forwarding class sets are not using all of the port bandwidth. However, the amount of bandwidth forwarding classes that are not in explicitly configured forwarding class sets receive is not guaranteed. The bandwidth for the default forwarding class depends on whether extra port bandwidth is available and therefore is not deterministic.

To guarantee bandwidth for forwarding classes in a predictable manner, be sure to map all forwarding classes that you expect to carry traffic on an interface to a forwarding class set and map the forwarding class set to the interface.

Understanding Default CoS Scheduling and Classification

If you do not configure hierarchical scheduling on an interface, the switch uses the default classifiers for ingress traffic and the default schedulers for egress traffic. Default scheduling and classification handle all traffic types (best-effort, FCoE, no-loss, network-control, and multidestination traffic).

Hierarchical scheduling groups egress queues (priorities, configured as forwarding classes) into priority groups (forwarding class sets). If you use only the default traffic scheduling and classification, the switch automatically creates a default priority group that contains all of the priorities (forwarding classes, which represent output queues) and assigns 100 percent of the port output bandwidth to that priority group. The forwarding classes (queues) in the default forwarding class set receive bandwidth based on the default classifier settings. The default priority group is transparent. It does not appear in the configuration and is used for Data Center Bridging Capability Exchange (DCBX) protocol advertisement.

NOTE: If you explicitly configure one or more priority groups on an interface, any forwarding class that is not assigned to a priority group on that interface receives *no bandwidth*. This means that if you configure hierarchical scheduling on an interface, every forwarding class (priority) that you want to forward traffic on that interface must belong to a forwarding class set (priority group).

The following sections describe:

- Default Classification on page 5360
- Default Scheduling on page 5363
- Default DCBX Advertisement on page 5364
- Default Scheduling and Classification Summary on page 5364

Default Classification

The default classifiers assign unicast and multicast best-effort and network-control ingress traffic to forwarding classes and loss priorities. The QFX Series applies default unicast IEEE 802.1, unicast DSCP, and multidestination classifiers to each interface that does not have explicitly configured classifiers. If you explicitly configure one type of classifier but not other types of classifiers, the system uses only the configured classifier and does not use default classifiers for other types of traffic. There are two different default unicast IEEE 802.1 classifiers, a trusted classifier for ports that are in trunk mode or tagged-access mode, and an untrusted classifier for ports that are in access mode.

Table 455 on page 5361 shows the default mapping of IEEE 802.1 code-point values to unicast forwarding classes and loss priorities for ports in trunk mode or tagged-access mode.

Table 455: Default IEEE 802.1 Unicast Classifiers for Ports in Trunk Mode or Tagged-Access Mode (Trusted Classifier)

Code Point	Forwarding Class	Loss Priority
be (000)	best-effort	low
be1 (001)	best-effort	low
ef (010)	best-effort	low
ef1 (011)	fcoe	low
af11 (100)	no-loss	low
af12 (101)	best-effort	low
nc1 (110)	network-control	low
nc2 (111)	network-control	low

Table 456 on page 5361 shows the default mapping of IEEE 802.1p code-point values to unicast forwarding classes and loss priorities for ports in access mode (all incoming traffic is mapped to best-effort forwarding classes).

Table 456: Default IEEE 802.1 Unicast Classifiers for Ports in Access Mode (Untrusted Classifier)

Code Point	Forwarding Class	Loss Priority
000	best-effort	low
001	best-effort	low
010	best-effort	low
011	best-effort	low
100	best-effort	low
101	best-effort	low

Table 456: Default IEEE 802.1 Unicast Classifiers for Ports in Access Mode (Untrusted Classifier) *(continued)*

Code Point	Forwarding Class	Loss Priority
110	best-effort	low
111	best-effort	low

Table 457 on page 5362 shows the default mapping of IEEE 802.1 code-point values to multidestination (multicast, broadcast, and destination lookup fail traffic) forwarding classes and loss priorities.

Table 457: Default IEEE 802.1 Multidestination Classifiers

Code Point	Forwarding Class	Loss Priority
be (000)	mcast	low
be1 (001)	mcast	low
ef (010)	mcast	low
ef1 (011)	mcast	low
af11 (100)	mcast	low
af12 (101)	mcast	low
nc1 (110)	mcast	low
nc2 (111)	mcast	low

Table 458 on page 5362 shows the default mapping of DSCP code-point values to unicast forwarding classes and loss priorities for DSCP IP and DCSP IPv6.

Table 458: Default DSCP IP and IPv6 Unicast Classifiers

Code Point	Forwarding Class	Loss Priority
ef (101110)	best-effort	low
af11 (001010)	best-effort	low
af12 (001100)	best-effort	low
af13 (001110)	best-effort	low
af21 (010010)	best-effort	low
af22 (010100)	best-effort	low

Table 458: Default DSCP IP and IPv6 Unicast Classifiers *(continued)*

Code Point	Forwarding Class	Loss Priority
af23 (010110)	best-effort	low
af31 (011010)	best-effort	low
af32 (011100)	best-effort	low
af33 (011110)	best-effort	low
af41 (100010)	best-effort	low
af42 (100100)	best-effort	low
af43 (100110)	best-effort	low
be (000000)	best-effort	low
cs1 (001000)	best-effort	low
cs2 (010000)	best-effort	low
cs3 (011000)	best-effort	low
cs4 (100000)	best-effort	low
cs5 (101000)	best-effort	low
nc1 (110000)	network-control	low
nc2 (111000)	network-control	low

NOTE: There are no default DSCP IP or IPv6 multidestination classifiers for multidestination traffic. DSCP IPv6 multidestination classifiers are not supported for multidestination traffic.

Default Scheduling

The default schedulers allocate egress bandwidth resources to unicast and multicast best-effort and network-control egress traffic as shown in Table 459 on page 5363:

Table 459: Default Scheduler Configuration

Default Scheduler and Queue Number	Guaranteed Rate (Minimum Bandwidth)	Shaping Rate (Maximum Bandwidth)	Excess Bandwidth Sharing	Priority	Buffer Size
Best-effort scheduler (queue 0)	5%	None	5%	low	5%

Table 459: Default Scheduler Configuration *(continued)*

Default Scheduler and Queue Number	Guaranteed Rate (Minimum Bandwidth)	Shaping Rate (Maximum Bandwidth)	Excess Bandwidth Sharing	Priority	Buffer Size
FCoE scheduler (queue 3)	35%	None	35%	low	35%
No-loss scheduler (queue 4)	35%	None	35%	low	35%
Network-control scheduler (queue 7)	5%	None	5%	low	5%
Multidestination scheduler (queue 8)	20%	None	20%	low	20%

NOTE: The minimum guaranteed bandwidth rate also determines the amount of excess (extra) bandwidth that the queue can share. Extra bandwidth is allocated to queues in proportion to the minimum guaranteed bandwidth rate of each queue.

Default DCBX Advertisement

When you configure hierarchical scheduling on an interface, DCBX advertises each priority group, the priorities in each priority group, and the bandwidth properties of each priority and priority group.

If you do not configure hierarchical scheduling on an interface, DCBX advertises the automatically created default priority group and its priorities. DCBX also advertises the default bandwidth allocation of the priority group, which is 100 percent of the port bandwidth.

Default Scheduling and Classification Summary

If you do not configure hierarchical scheduling on an interface:

- Default classifiers classify ingress traffic.
- Default schedulers schedule egress traffic.
- DCBX advertises a single default priority group with 100 percent of the port bandwidth allocated to that priority group. All priorities (forwarding classes) are assigned to the default priority group and receive bandwidth based on their default schedulers. The default priority group is generated automatically and is not user-configurable.

Understanding CoS Hierarchical Port Scheduling (ETS)

Scheduling defines the class-of-service (CoS) properties of output queues. These properties include the amount of interface bandwidth assigned to the queue, the queue priority, and the drop profiles associated with the queue.

Hierarchical port scheduling is a two-tier process that provides better port bandwidth utilization and greater flexibility to allocate resources to queues and to groups of queues. Hierarchical scheduling includes the Junos OS implementation of enhanced transmission selection (ETS, described in IEEE 802.1Qaz).

The two tiers used in hierarchical scheduling are priorities and priority groups, as shown in Table 460 on page 5366.

Table 460: Hierarchical Scheduling Tiers

Junos OS Configuration Construct	Equivalent ETS Construct	Description
Forwarding class	Priority	Think about priorities (forwarding classes) as output queues. You map forwarding classes to queues, so each forwarding class is in essence an output queue. When you use a classifier to map a forwarding class to an IEEE 802.1p code point, the code point identifies that traffic's priority for priority-based flow control (PFC). Thus the forwarding class, the queue mapped to the forwarding class, and the priority mapped to the forwarding class all identify the same traffic.
Forwarding class set	Priority group	Priority groups (forwarding class sets) are groups of priorities. Forwarding class membership in a forwarding class set defines the priority group to which each priority belongs. You can configure up to three unicast priority groups and one multicast forwarding class set.

NOTE: If you explicitly configure one or more priority groups on an interface, any priority that is not assigned to a priority group on that interface is assigned to an automatically generated default priority group and receives *no bandwidth*. This means that if you configure hierarchical scheduling on an interface, every forwarding class that you want to forward traffic on that interface must belong to a forwarding class set.

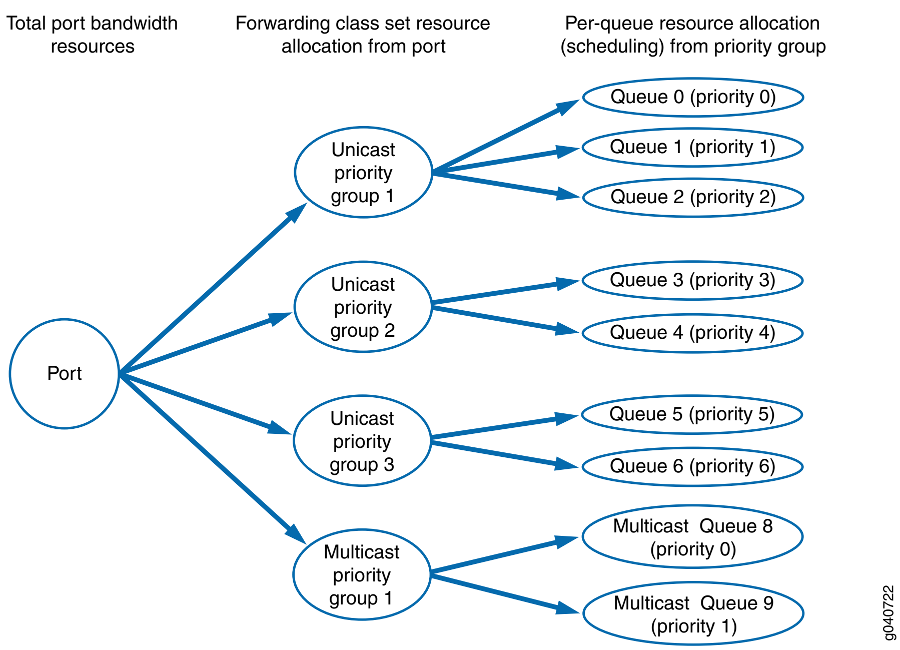
This topic describes:

Hierarchical Scheduling and ETS

Two-tier hierarchical scheduling enables you to manage bandwidth efficiently by enabling you to define the CoS properties for each priority group and for each priority. One tier of the hierarchical scheduler allocates port bandwidth to a priority group. The other tier of the hierarchical scheduler determines the portion of the priority group bandwidth that a queue can use.

The CoS properties you configure for a priority group define the port bandwidth resources available to the queues in that priority group. The CoS properties you configure for each queue specify the portion or percentage of the total bandwidth configured for the priority group that is available to the queue. Figure 193 on page 5367 shows the relationship of port resource allocation to priority groups and priority group resource allocation to queues (priorities).

Figure 193: Hierarchical Scheduling Tiers



If a queue is not using its allocated bandwidth, ETS shares the unused bandwidth among the other queues in the priority group. If link bandwidth is available or if a priority group on a link is not using its allocated bandwidth, ETS shares the unused bandwidth with other priority groups on the link. In this way ETS improves link bandwidth utilization and provides each queue with the maximum bandwidth. Priorities that consist of bursty traffic can share bandwidth during periods of low traffic transmission instead of consuming their entire bandwidth allocation when traffic loads are light.

NOTE: The available link bandwidth is the bandwidth remaining after servicing strict-high priority flows.

ETS Advertisement in DCBX

When you configure hierarchical scheduling on a port, Data Center Bridging Capability Exchange Protocol (DCBX) advertises:

- Each priority group
- The priorities in each priority group
- The bandwidth properties of each priority group and priority

When you configure hierarchical scheduling on a port, any priority that is not part of an explicitly configured priority group is assigned to the automatically generated default priority group and receives no bandwidth. The default priority group is transparent. It does not appear in the configuration.

Hierarchical Scheduling Process

Hierarchical scheduling consists of multiple configuration steps that create the priorities and the priority groups, schedule their resources, and assign them to interfaces. The steps below correspond to the six blocks in the packet flow diagram shown in Figure 194 on page 5369:

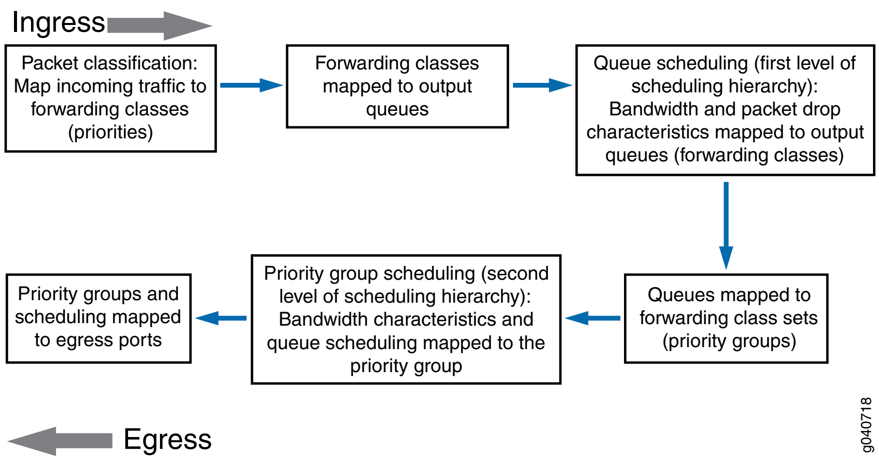
1. Packet classification:
   - Classify incoming traffic into priorities. This consists of either using the default classifiers or configuring classifiers to map IEEE 802.1p code points and loss priorities to the forwarding classes.
   - Apply the classifiers to ingress interfaces. This groups incoming traffic into forwarding classes (priorities) by mapping code points to forwarding classes and loss priorities on the specified interface.
2. Configure the output queues for the forwarding classes (priorities). This consists of either using the default forwarding classes and forwarding-class-to-queue mapping or creating your own forwarding classes and mapping them to queues.
3. Allocate resources to the forwarding classes:
   - Define resources for the priorities. This consists of configuring schedulers to set minimum guaranteed bandwidth, maximum bandwidth, drop profiles for Weighted Random Early Detection (WRED), and bandwidth priority to apply to a forwarding class. Extra bandwidth is shared among queues in proportion to the minimum guaranteed bandwidth of each queue.
   - Map resources to priorities. This consists of mapping forwarding classes to schedulers by using a scheduler map.
4. Configure priority groups. This consists of mapping forwarding classes (priorities) to forwarding class sets (priority groups) to define the priorities that belong to each priority group.
5. Define resources for the priority groups. This consists of configuring traffic control profiles to set minimum guaranteed bandwidth and maximum bandwidth for a priority group. Traffic control profiles also specify a scheduler map, which defines the resources

(schedulers) for the priorities in the priority group. Extra port bandwidth is shared among priority groups in proportion to the minimum guaranteed bandwidth of each priority group.

The traffic control profile bandwidth settings determine the port resources available to the priority group, and the schedulers specified in the scheduler map determine the amount of the priority group resources that each priority receives.

6. Apply the hierarchical scheduling to a port. This consists of attaching one or more priority groups to a port interface. For each priority group, you also attach a traffic control profile. Different priority groups on the same port can use different traffic control profiles.

Figure 194: Hierarchical Scheduling Packet Flow



Strict-High Priority Queues and Hierarchical Scheduling

If you configure a strict-high priority queue, you must observe the following rules:

- You must create a separate forwarding class set (priority group) for the strict-high priority queue.
- Only one forwarding class set can contain strict-high priority queues.
- Strict-high priority queues cannot belong to the same forwarding class set as queues that are not strict-high priority.
- A strict-high priority queue cannot belong to a multidestination forwarding class set.

NOTE: On a QFabric system, if a fabric (fte) interface handles strict-high priority traffic, you must define a separate fc-set (priority group) for strict-high priority traffic. Strict-high priority traffic cannot be mixed with traffic of other priorities in an fc-set. For example, you might choose to create different fc-sets for best effort, lossless, strict-high priority, and multidestination traffic.

Default Hierarchical Scheduling

If you do not explicitly configure hierarchical scheduling, the switch uses the default settings:

- The switch automatically creates a default forwarding class set that contains all of the forwarding classes on the switch. The switch assigns 100 percent of the port output bandwidth to the default forwarding class set. The default forwarding class set is transparent. It does not appear in the configuration and is used for Data Center Bridging Capability Exchange Protocol (DCBX) advertisement.
- Ingress traffic is classified based on the default classifier settings.
- The forwarding classes (queues) in the default forwarding class set receive bandwidth based on the default scheduler settings.

Understanding CoS Output Queue Schedulers

Output queue scheduling defines the class-of-service (CoS) properties of output queues (priorities). Queue scheduling works with priority group scheduling to create a two-tier hierarchical scheduler. The hierarchical scheduler allocates bandwidth to a group of queues (priority group), and queue scheduling determines the portion of the priority group's bandwidth that a particular queue can use.

Scheduler maps associate queue schedulers with forwarding classes (output queues). You can associate each scheduler map with a traffic control profile, and then associate each traffic control profile with a forwarding class set (priority group) and a port interface. In conjunction with the priority group scheduling configured in the traffic control profile, queue scheduling configures the output queues, packet schedulers, and tail-drop processes that operate according to this mapping.

NOTE: When you configure bandwidth for a queue or a priority group, the switch considers only the data as the configured bandwidth. The switch does not account for the bandwidth consumed by the preamble and the interframe gap (IFG). Therefore, when you calculate and configure the bandwidth requirements for a queue or for a priority group, consider the preamble and the IFG as well as the data in the calculations.

Output Queue Scheduling Components

Table 461 on page 5371 provides a quick reference to the scheduler components you can configure to determine the bandwidth properties of output queues, and Table 462 on page 5372 provides a quick reference to some related scheduling configuration components.

Table 461: Output Queue Scheduler Components

Output Queue Scheduler Component	Description
Priority	Sets the scheduling priority applied to the queue.
Shaping rate	Sets the maximum bandwidth the queue can consume.

Table 461: Output Queue Scheduler Components *(continued)*

Output Queue Scheduler Component	Description
Transmit rate	Sets the minimum guaranteed bandwidth for the queue. Extra bandwidth is shared among queues in proportion to the minimum guaranteed bandwidth of each queue.
Drop profile	Sets the probability of dropping packets as the queue fills up.
Loss priority	Sets the traffic loss priority to which a drop profile applies.
Drop profile map	Maps a drop profile to a loss priority.
Buffer size	Sets the size of the queue buffer.

Table 462: Other Scheduling Components

Other Scheduling Components	Description
Scheduler map	Maps schedulers to queues (forwarding classes, also called priorities).
Forwarding class	Maps traffic to a queue (priority).
Traffic control profile	Sets scheduling for the forwarding class set (priority group) and associates a scheduler map with the forwarding class set to apply queue scheduling to the forwarding classes in the forwarding class set. Extra port bandwidth is shared among forwarding class sets in proportion to the minimum guaranteed bandwidth of each forwarding class set.
Forwarding class set	Name of a priority group. You map forwarding classes to priority groups. A forwarding class set consists of one or more forwarding classes.

Default Schedulers

Each forwarding class requires an associated scheduler. The default configuration uses only four forwarding classes, unicast best-effort (queue 0), unicast network-control (queue 3), multicast best-effort (queue 8), and multicast network control (queue 11). You can use the default schedulers or you can define new schedulers for these four forwarding classes. For any other forwarding class, you must explicitly configure a scheduler.

Table 463 on page 5372 shows the default schedulers.

Table 463: Default Schedulers

Default Scheduler and Queue Number	Guaranteed Rate (Minimum Bandwidth)	Shaping Rate (Maximum Bandwidth)	Excess Bandwidth Sharing	Priority	Buffer Size
Best-effort scheduler (queue 0)	5%	None	5%	Low	5%

Table 463: Default Schedulers *(continued)*

Default Scheduler and Queue Number	Guaranteed Rate (Minimum Bandwidth)	Shaping Rate (Maximum Bandwidth)	Excess Bandwidth Sharing	Priority	Buffer Size
FCoE scheduler (queue 3)	35%	None	35%	Low	35%
No-loss scheduler (queue 4)	35%	None	35%	Low	35%
Network-control scheduler (queue 7)	5%	None	5%	Low	5%
Multidestination scheduler (queue 8)	20%	None	20%	Low	20%

NOTE: **The minimum guaranteed bandwidth rate also determines the amount of excess (extra) bandwidth that the queue can share. Extra bandwidth is allocated to queues in proportion to the minimum guaranteed bandwidth rate of each queue.**

There are no resources assigned by default to queues 1, 2, 5, 6, 9, 10, and 11. You can define new unicast forwarding classes to assign to queues 1, 2, 5, and 6, and new multidestination forwarding classes to assign to queues 9, 10, and 11, which do not have default mappings to a forwarding class. You can assign resources to these queues manually using schedulers. In addition, you can change the default forwarding-class-to-queue mappings and the default schedulers.

By default, each queue can exceed the assigned bandwidth if additional bandwidth is available from other queues in the forwarding class set. When a forwarding class does not fully use the allocated minimum transmission bandwidth (transmit rate), other forwarding classes in the forwarding class set can use the remaining bandwidth if those forwarding classes receive more traffic than their allocated bandwidth.

Transmit Rate (Minimum Guaranteed Bandwidth)

The transmit rate determines the minimum guaranteed bandwidth for each forwarding class. It also determines how much excess (extra) bandwidth each low-priority queue can share; each queue shares extra bandwidth in proportion to its transmit rate. You specify the rate in bits per second as a fixed value such as 1 Mbps or as a percentage of the total forwarding class set minimum guaranteed bandwidth (the guaranteed rate set in the traffic control profile). Either the default scheduler or a scheduler you configure allocates a portion of the outgoing interface bandwidth to each forwarding class.

NOTE: For transmit rates below 1 Gbps, we recommend that you configure the transmit rate as a percentage instead of as a fixed rate. This is because the system converts fixed rates into percentages and may round small fixed rates to a lower percentage. For example, a fixed rate of 350 Mbps is rounded down to 3 percent instead of 3.5 percent.

You cannot configure a transmit rate for strict-high priority queues. Queues (forwarding classes) with a configured transmit rate cannot be included in a forwarding class set that has strict-high priority queues.

The allocated bandwidth can exceed the configured minimum rate if additional bandwidth is available from other queues in the forwarding class set. In case of congestion, the configured transmit rate is guaranteed for the queue. This property enables you to ensure that each queue receives the amount of bandwidth appropriate to its level of service.

NOTE: Configuring the minimum guaranteed bandwidth (transmit rate) for a forwarding class does not work unless you also configure the minimum guaranteed bandwidth (guaranteed rate) for the forwarding class set in the traffic control profile.

Additionally, the sum of the transmit rates of the queues in a forwarding class set should not exceed the guaranteed rate for the forwarding class set. (You cannot guarantee a minimum bandwidth for the queues that is greater than the minimum bandwidth guaranteed for the entire set of queues.)

Sharing Extra Bandwidth

Extra bandwidth is available to low-priority queues when the minimum guaranteed bandwidth of the queues does not use the full amount of forwarding class set bandwidth. This extra bandwidth is shared among the forwarding classes in the set based on the minimum guaranteed bandwidth of each queue.

For example, in a forwarding class set, Queue A has a transmit rate of 1 Gbps, Queue B has a transmit rate of 1 Gbps, and Queue C has a transmit rate of 2 Gbps. After servicing the minimum guaranteed bandwidth of these queues, the forwarding class set has an extra 2 Gbps of bandwidth available, and all three queues still have packets to forward. The queues receive the extra bandwidth in proportion to their transmit rates, so Queue A receives an extra 500 Mbps, Queue B receives an extra 500 Mbps, and Queue C receives an extra 1 Gbps.

Shaping Rate (Maximum Bandwidth)

The shaping rate determines the maximum bandwidth each forwarding class can consume. You specify the rate in bits per second as a fixed value such as 3 Mbps or as a percentage of the total forwarding class set maximum bandwidth (the shaping rate set in the traffic control profile).

The maximum bandwidth for a queue depends on the total bandwidth available to the forwarding class set to which the queue belongs and how much bandwidth the other queues in the forwarding class set consume.

NOTE: **In QFabric systems, if any queue that contains outgoing packets does not transmit packets for 12 consecutive seconds, the port automatically resets. A strict-high priority queue (or several queues with higher priorities than the starved queue) can consume all of the port bandwidth and prevent another queue from transmitting packets. To prevent a queue from being starved for bandwidth, you can configure a shaping rate on the queue or queues to prevent them from consuming all of the port bandwidth.**

Scheduling Priority

Scheduling priority determines the order in which an output interface transmits traffic from the queues, thus ensuring that queues containing important traffic receive better access to the outgoing interface. The priority setting in the scheduler determines the priority for the queue.

Two levels of scheduling priority are supported:

- Low—Low-priority queues transmit traffic based on the weighted round robin (WRR) algorithm. The scheduler first determines if an individual queue is within its defined bandwidth profile. The scheduler then regularly reevaluates whether each individual queue is within its defined bandwidth profile and compares the amount of data the queue transmits to the amount of bandwidth the scheduler allocates to the queue. When the transmitted amount is less than the allocated amount, the queue is considered to be in profile. A queue is out of profile when its transmitted amount is larger than its allocated amount. Out of profile queue data is transmitted only if bandwidth is available. Otherwise, it is buffered if buffer space is available. If no buffer space is available, the traffic may be dropped.
- Strict-high—You can configure only one queue as **strict-high** priority. The other 11 queues are **low** priority.

  The **strict-high** priority queue receives preferential treatment over the low-priority queues. The **strict-high** priority queue receives all of its configured bandwidth before low-priority queues are serviced. Low-priority queues do not transmit traffic until the strict-high priority queue is empty. Carefully consider how much bandwidth you want to allocate to the **strict-high** priority queue to avoid starving the low-priority queues.

  If you configure a strict-high priority queue, you must observe the following rules:

  - You must create a separate forwarding class set (priority group) for the strict-high priority queue.
  - Only one forwarding class set can contain strict-high priority queues.
  - Strict-high priority queues cannot belong to the same forwarding class set as queues that are not strict-high priority.

- A strict-high priority queue cannot belong to a multidestination forwarding class set.
- You cannot configure a minimum guaranteed bandwidth for a strict-high priority queue. (You cannot configure a transmit rate for a strict-high priority queue scheduler, and you cannot configure a guaranteed rate for a forwarding class set that has a strict-high priority queue.)

Junos OS performs priority queueing using the following steps:

1. Services the strict-high priority queue before any other queues are served
2. Services the minimum bandwidth (transmit rate) of low-priority queues until the minimum is met or the queues are empty
3. Services all other low-priority queues and needs that exceed the minimum bandwidth

Scheduler Drop-Profile Maps

Drop-profile maps associate drop profiles with a scheduler. A drop-profile map sets the drop profile for a specific packet loss priority (PLP) and protocol type:

- PLP—Low, medium-high, high. You configure the PLP during classifier configuration. When you use a scheduler map to associate a forwarding class with a scheduler, you can use a drop-profile map to map different drop profiles to the forwarding class for different PLPs.
- Protocol type—Drop profiles match all protocol types.

Buffer Size

Most of the total system buffer space is divided into two buffer pools, shared buffers and dedicated buffers. Shared buffers are a global pool that the ports share dynamically as needed. Dedicated buffers are a reserved portion of the buffer pool that is distributed evenly to all of the ports. Each port receives an equal allocation of dedicated buffer space. The dedicated buffer allocation to ports is not configurable because it is reserved for the ports.

The queue buffers are allocated from the dedicated buffer pool assigned to the port. By default, ports divide their allocation of dedicated buffers among the egress queues in the same proportion as the default scheduler sets the minimum guaranteed transmission rates (**transmit-rate**) for traffic. Only the queues included in the default scheduler receive dedicated buffers.

If you do not use the default configuration, you can explicitly configure the queue buffer size in either of two ways:

- As a percentage—The queue receives the specified percentage of dedicated port buffers when the queue is mapped to the scheduler and the scheduler is mapped to a port.
- As a remainder—After the port services the queues that have an explicit percentage buffer size configuration, the remaining port dedicated buffer space is divided equally among the other queues to which a scheduler is attached. (No default or explicit

scheduler means no dedicated buffer allocation for the queue.) If you configure a scheduler and you do not specify a buffer size as a percentage, *remainder* is the default setting.

NOTE: **The total of all of the explicitly configured buffer size percentages for all of the queues on a port cannot exceed 100 percent.**

For a complete discussion about queue buffer configuration in the context of ingress and egress port buffer configuration, see "Understanding CoS Buffer Configuration" on page 5391.

Scheduler Maps

A scheduler map associates a specified forwarding class with a scheduler configuration. After configuring a scheduler, you must include it in a scheduler map, associate the scheduler map with a traffic control profile, and then associate the traffic control profile with an interface and a forwarding class set.

You can associate up to four user-defined scheduler maps with traffic control profiles.

Understanding CoS Priority Group Scheduling

Priority group scheduling defines the class-of-service (CoS) properties of a group of output queues (priorities). Priority group scheduling works with output queue scheduling to create a two-tier hierarchical scheduler. The hierarchical scheduler allocates bandwidth to a group of queues (a priority group, called a forwarding class set in Junos OS configuration). Queue scheduling determines the portion of the priority group bandwidth that the particular queue can use.

You configure priority group scheduling in a traffic control profile and then associate the traffic control profile with a forwarding class set and an interface. You attach a scheduler map to the traffic control profile to specify the queue scheduling characteristics.

NOTE: When you configure bandwidth for a queue or a priority group, the switch considers only the data as the configured bandwidth. The switch does not account for the bandwidth consumed by the preamble and the interframe gap (IFG). Therefore, when you calculate and configure the bandwidth requirements for a queue or for a priority group, consider the preamble and the IFG as well as the data in the calculations.

Priority Group Scheduling Components

Table 464 on page 5378 provides a quick reference to the traffic control profile components you can configure to determine the bandwidth properties of priority groups, and Table 465 on page 5379 provides a quick reference to some related scheduling configuration components.

Table 464: Priority Group Scheduler Components

Traffic Control Profile Component	Description
Guaranteed rate	Sets the minimum guaranteed port bandwidth for the priority group. Extra port bandwidth is shared among priority groups in proportion to the guaranteed rate of each priority group on the port.
Shaping rate	Sets the maximum port bandwidth the priority group can consume.
Scheduler map	Maps schedulers to queues (forwarding classes, also called priorities). This determines the portion of the priority group bandwidth that a queue receives.

Table 465: Other Scheduling Components

Other Scheduling Components	Description
Forwarding class	Maps traffic to a queue (priority).
Forwarding class set	Name of a priority group. You map forwarding classes to priority groups. A forwarding class set consists of one or more forwarding classes.
Scheduler	Sets the bandwidth and scheduling priority of individual queues (forwarding classes).

Default Traffic Control Profile

There is no default traffic control profile.

Guaranteed Rate (Minimum Guaranteed Bandwidth)

The guaranteed rate determines the minimum guaranteed bandwidth for each priority group. It also determines how much excess (extra) port bandwidth the priority group can share; each priority group shares extra port bandwidth in proportion to its guaranteed rate. You specify the rate in bits per second as a fixed value such as 3 Mbps or as a percentage of the total port bandwidth.

The minimum transmission bandwidth can exceed the configured rate if additional bandwidth is available from other priority groups on the port. In case of congestion, the configured guaranteed rate is guaranteed for the priority group. This property enables you to ensure that each priority group receives the amount of bandwidth appropriate to its level of service.

NOTE: Configuring the minimum guaranteed bandwidth (transmit rate) for a forwarding class does not work unless you also configure the minimum guaranteed bandwidth (guaranteed rate) for the forwarding class set in the traffic control profile.

Additionally, the sum of the transmit rates of the queues in a forwarding class set should not exceed the guaranteed rate for the forwarding class set. (You cannot guarantee a minimum bandwidth for the queues that is greater than the minimum bandwidth guaranteed for the entire set of queues.)

You cannot configure a guaranteed rate for forwarding class sets that include strict-high priority queues.

Sharing Extra Bandwidth

Extra bandwidth is available to priority groups when the priority groups do not use the full amount of available port bandwidth. This extra port bandwidth is shared among the priority groups based on the minimum guaranteed bandwidth of each priority group.

For example, Port A has three priority groups: fc-set-1, fc-set-2, and fc-set-3. Fc-set-1 has a guaranteed rate of 2 Gbps, fc-set-2 has a guaranteed rate of 2 Gbps, and fc-set-3 has a guaranteed rate of 4 Gbps. After servicing the minimum guaranteed bandwidth of these priority groups, the port has an extra 2 Gbps of available bandwidth, and all three priority groups have still have packets to forward. The priority groups receive the extra bandwidth in proportion to their guaranteed rates, so fc-set-1 receives an extra 500 Mbps, fc-set-2 receives an extra 500 Mbps, and fc-set-3 receives an extra 1 Gbps.

Shaping Rate (Maximum Bandwidth)

The shaping rate determines the maximum bandwidth the priority group can consume. You specify the rate in bits per second as a fixed value such as 5 Mbps or as a percentage of the total port bandwidth.

The maximum bandwidth for a priority group depends on the total bandwidth available on the port and how much bandwidth the other priority groups on the port consume.

Scheduler Maps

A scheduler map maps schedulers to queues. When you associate a scheduler map with a traffic control profile, then associate the traffic control profile with an interface and a forwarding class set, the scheduling defined by the scheduler map determines the portion of the priority group resources that each individual queue can use.

You can associate up to four user-defined scheduler maps with traffic control profiles.

Understanding CoS Traffic Control Profiles

A traffic control profile defines the output bandwidth and scheduling characteristics of forwarding class sets (priority groups). The forwarding classes (queues) mapped to a forwarding class set share the bandwidth that you assign to the forwarding class set in the traffic control profile.

This two-tier hierarchical scheduling architecture provides flexibility in allocating resources among queues and:

- Assigns a portion of port bandwidth to a priority group. You define the port resources for the priority group in a traffic control profile.
- Allocates priority group bandwidth among the queues that belong to the priority group. A scheduler map attached to the traffic control profile defines the amount of the priority group's resources that each queue can use.

Attaching a priority group and traffic control profile to a port defines the hierarchical scheduling properties of the group and the queues that belong to the group.

The ability to create priority groups supports enhanced transmission selection (ETS, described in IEEE 802.1Qaz). When a priority group does not use its allocated port bandwidth, ETS shares the excess port bandwidth among other priority groups on the port in proportion to their guaranteed minimum bandwidth (guaranteed rate). This utilizes the port bandwidth better than scheduling schemes that require setting strict priorities that reserve bandwidth for all groups whether it is needed or not. ETS allows traffic groups that need extra bandwidth to use it if the bandwidth is available, while preserving the ability to specify the minimum guaranteed bandwidth for traffic groups.

Traffic control profiles define the following CoS properties for priority groups:

- Minimum guaranteed bandwidth—Also known as the committed information rate (CIR). This is the minimum amount of port bandwidth the priority group receives. Priorities in the priority group receive their minimum guaranteed bandwidth as a portion of the priority group's minimum guaranteed bandwidth. The **guaranteed-rate** statement defines the minimum guaranteed bandwidth.

  NOTE: **You cannot apply a traffic control profile with a minimum guaranteed bandwidth to a priority group that includes strict-high priority queues.**

- Shared excess (extra) bandwidth—When the priority groups on a port do not consume the full amount of bandwidth allocated to them or there is unallocated link bandwidth available, priority groups can contend for that extra bandwidth if they need it. Priorities in the priority group contend for extra bandwidth as a portion of the priority group's extra bandwidth. The amount of extra bandwidth for which a priority group can contend is proportional to the priority group's guaranteed minimum bandwidth (guaranteed rate).

- Maximum bandwidth—Also known as peak information rate (PIR). This is the maximum amount of port bandwidth the priority group receives. Priorities in the priority group receive their maximum bandwidth as a portion of the priority group's maximum bandwidth. The **shaping-rate** statement defines the maximum bandwidth.
- Queue scheduling—Each traffic control profile includes a scheduler map. The scheduler map maps priorities (forwarding classes) to schedulers to define the scheduling characteristics of the individual priorities in the priority group. The resources scheduled for each priority represent portions of the resources that the traffic control profile schedules for the entire priority group, not portions of the total link bandwidth. The **scheduler-maps** statement defines the mapping of forwarding classes to schedulers.

Understanding CoS Priority Group and Queue Guaranteed Rates (Minimum Bandwidth)

You can set a guaranteed minimum bandwidth for individual forwarding classes (queues) and for groups of forwarding classes called forwarding class sets (priority groups). Setting a minimum guaranteed bandwidth ensures that priority groups and queues receive the bandwidth required to support the expected traffic.

This topic covers:

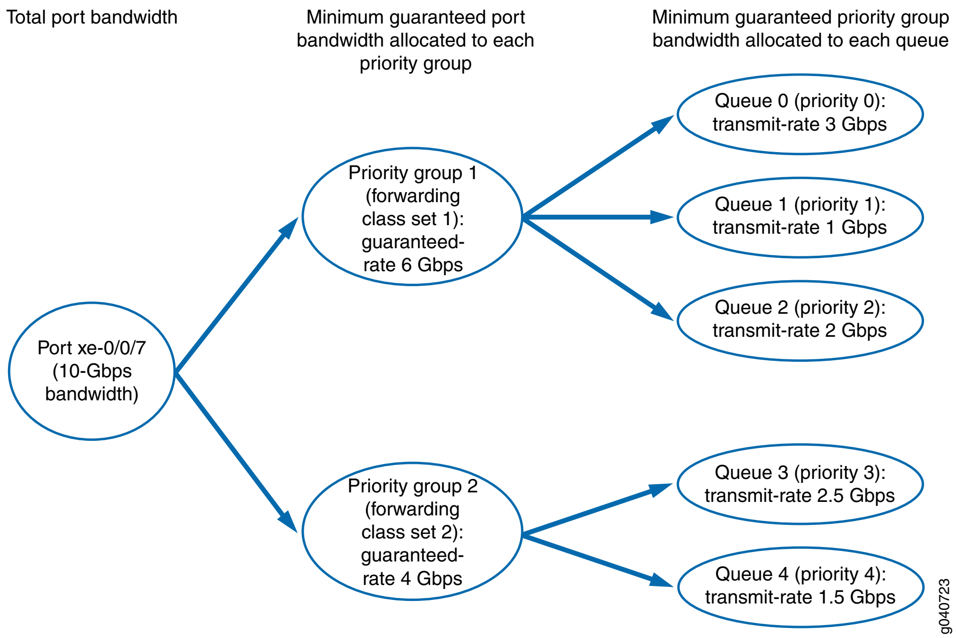
Guaranteeing Bandwidth Using Hierarchical Scheduling

The **guaranteed-rate** value for the priority group defines the minimum amount of bandwidth allocated to a forwarding class set on a port, whereas the **transmit-rate** value of the queue defines the minimum amount of bandwidth allocated to a particular queue in a priority group. The queue bandwidth is a portion of the priority group bandwidth.

NOTE: You cannot configure a minimum guaranteed bandwidth (transmit rate) for a forwarding class that is mapped to a strict-high priority queue, and you cannot configure a minimum guaranteed bandwidth (guaranteed rate) for a priority group that includes strict-high priority queues.

Figure 195 on page 5383 shows how the total port bandwidth is allocated to priority groups (forwarding class sets) based on the guaranteed rate of each priority group. It also shows how the guaranteed bandwidth of each priority group is allocated to the queues in the priority group based on the transmit rate of each queue.

Figure 195: Allocating Guaranteed Bandwidth Using Hierarchical Scheduling



The sum of the priority group guaranteed rates cannot exceed the total port bandwidth. If you configure guaranteed rates whose sum exceeds the port bandwidth, the system sends a syslog message to notify you that the configuration is not valid. However, the system does not perform a commit check. If you commit a configuration in which the sum of the guaranteed rates exceeds the port bandwidth, the hierarchical scheduler behaves unpredictably.

The sum of the queue transmit rates cannot exceed the total guaranteed rate of the priority group to which the queues belong. If you configure transmit rates whose sum exceeds the priority group guaranteed rate, the commit check fails and the system rejects the configuration.

NOTE: You must set both the priority group **guaranteed-rate** value and the queue **transmit-rate** value in order to configure the minimum bandwidth for individual queues. If you set the **transmit-rate** value but do not set the **guaranteed-rate** value, the configuration fails.

You can set the **guaranteed-rate** value for a priority group without setting the **transmit-rate** value for individual queues in the priority group. However, queues that do not have a configured **transmit-rate** value can become starved for bandwidth if other higher-priority queues need the priority group's bandwidth. To avoid starving a queue, it is a good practice to configure a **transmit-rate** value for most queues.

If you configure the guaranteed rate of a priority group as a percentage, configure all of the transmit rates associated with that priority group as percentages. In this case, if any of the transmit rates are configured as absolute values instead of percentages, the configuration is not valid and the system sends a syslog message.

Priority Group Guaranteed Rate (Minimum Bandwidth)

Setting a priority group **guaranteed-rate** enables you to reserve a portion of the port bandwidth for the forwarding classes (queues) in that forwarding class set. The minimum bandwidth (**guaranteed-rate**) that you configure for a priority group sets the minimum bandwidth available to all of the forwarding classes in the forwarding class set.

The combined **guaranteed-rate** value of all of the forwarding class sets associated with an interface cannot exceed the amount of bandwidth available on that interface.

You configure the priority group **guaranteed-rate** in the traffic control profile. You cannot apply a traffic control profile that has a guaranteed rate to a priority group that includes strict-high priority queues.

Queue Transmit Rate (Minimum Bandwidth)

Setting a queue **transmit-rate** enables you to reserve a portion of the priority group bandwidth for the individual queue. For example, a queue that handles Fibre Channel over Ethernet (FCoE) traffic might require a minimum rate of 4 Gbps to ensure the class of service that storage area network (SAN) traffic requires.

The priority group **guaranteed-rate** sets the aggregate minimum amount of bandwidth available to the queues that belong to the priority group. The cumulative total minimum bandwidth the queues consume cannot exceed the minimum bandwidth allocated to the priority group to which they belong. (The combined transmit rates of the queues in a priority group cannot exceed the priority group's guaranteed rate.)

You must configure the **guaranteed-rate** value of the priority group in order to set a **transmit-rate** value for individual queues that belong to the priority group. The reason is that if there is no guaranteed bandwidth for a priority group, there is no way to guarantee bandwidth for queues in that priority group.

You configure the queue **transmit-rate** in the scheduler configuration. You cannot configure a transmit rate for strict-high priority queues.

Understanding CoS Priority Group Shaping and Queue Shaping (Maximum Bandwidth)

If the amount of traffic on an interface exceeds the maximum bandwidth of the interface, it leads to congestion. You can use priority group (forwarding class set) shaping and queue shaping to manage the excess traffic and avoid congestion.

The maximum bandwidth sets the most bandwidth a priority group or a queue can use after all of the priority group and queue minimum bandwidth requirements are met, even if more bandwidth is available.

This topic covers:

- Priority Group Shaping on page 5385
- Queue Shaping on page 5385
- Shaping Maximum Bandwidth Using Hierarchical Scheduling on page 5386

Priority Group Shaping

Priority group shaping enables you to shape the aggregate traffic of a forwarding class set on a port to a maximum rate that is less than the line or port rate. The maximum bandwidth (**shaping-rate**) that you configure for a priority group sets the maximum bandwidth available to all of the forwarding classes (queues) in the forwarding class set.

If a port has more than one priority group and the combined **shaping-rate** value of the priority groups is greater than the amount of port bandwidth available, the bandwidth is shared proportionally among the priority groups.

You configure the priority group **shaping-rate** in the traffic control profile.

Queue Shaping

Queue shaping throttles the rate at which queues transmit packets. For example, using queue shaping, you can rate-limit a strict-high priority queue so that the strict-priority queue does not lock out (or starve) low-priority queues. Similarly, for any queue, you can configure queue shaping (**shaping-rate**) to set the maximum bandwidth for a particular queue.

The **shaping-rate** value of the priority group sets the aggregate maximum amount of bandwidth available to the queues that belong to the priority group. The cumulative total bandwidth the queues consume cannot exceed the maximum bandwidth of the priority group to which they belong on a port.

If a priority group has more than queue and the combined **shaping-rate** value of the queues is greater than the amount of bandwidth available to the priority group, the bandwidth is shared proportionally among the queues.

You configure the queue **shaping-rate** in the scheduler configuration.

Shaping Maximum Bandwidth Using Hierarchical Scheduling

Priority group shaping defines the maximum bandwidth allocated to a forwarding class set on a port, whereas queue shaping defines a limit on maximum bandwidth usage per queue. The queue bandwidth is a portion of the priority group bandwidth.

Figure 196 on page 5386 shows how the port bandwidth is allocated to priority groups (forwarding class sets) based on the shaping rate of each priority group, and how the bandwidth of each priority group is allocated to the queues in the priority group based on the shaping rate of each queue.

Figure 196: Setting Maximum Bandwidth Using Hierarchical Scheduling

- Defining CoS Traffic Control Profiles (Priority Group Scheduling) on page 5684

Understanding CoS Scheduling Behavior and Configuration Considerations

Many factors affect scheduling configuration and bandwidth requirements, including:

- When you configure bandwidth for a queue or a priority group, the switch considers only the data as the configured bandwidth. The switch does not account for the bandwidth consumed by the preamble and the interframe gap (IFG). Therefore, when you calculate and configure the bandwidth requirements for a queue or for a priority group, consider the preamble and the IFG as well as the data in the calculations.
- When you define a forwarding class that will be used on the switch (the behavior aggregate classifier has a forwarding class and you expect traffic for the forwarding class), you must also define a scheduling policy for the forwarding class. Defining a scheduling policy means:
  - Mapping a scheduler to the forwarding class in a scheduler map
  - Including the forwarding class in a forwarding class set
  - Associating the scheduler map with a traffic control profile
  - Attaching the traffic control profile to a forwarding class set and an interface
- On each physical interface, either all forwarding classes that are being used on the interface must have rewrite rules configured, or no forwarding classes that are being used on the interface can have rewrite rules configured. On any physical port, do not mix forwarding classes with rewrite rules and forwarding classes without rewrite rules.
- For packets that carry both an inner VLAN tag and an outer VLAN tag, the rewrite rule rewrites only the outer VLAN tag.
- Configuring the minimum guaranteed bandwidth (**transmit-rate**) for a queue (forwarding class) does not work unless you also configure the minimum guaranteed bandwidth (**guaranteed-rate**) for the priority group (forwarding class set) in the traffic control profile.

  Additionally, the sum of the transmit rates of the queues in a forwarding class set should not exceed the guaranteed rate for the forwarding class set. (You cannot guarantee a minimum bandwidth for the queues that is greater than the minimum bandwidth guaranteed for the entire set of queues.) If you configure transmit rates whose sum exceeds the guaranteed rate of the forwarding class set, the commit check fails and the system rejects the configuration.
- The sum of the priority group guaranteed rates cannot exceed the total port bandwidth. If you configure guaranteed rates whose sum exceeds the port bandwidth, the system sends a syslog message to notify you that the configuration is not valid. However, the system does not perform a commit check. If you commit a configuration in which the sum of the guaranteed rates exceeds the port bandwidth, the hierarchical scheduler behaves unpredictably.

- If you configure the **guaranteed-rate** of a priority group as a percentage, configure all of the transmit rates associated with that priority group as percentages. In this case, if any of the transmit rates are configured as absolute values instead of percentages, the configuration is not valid and the system sends a syslog message.
- There are several factors to consider if you want to configure strict-high priority queues:
  - You cannot configure a minimum guaranteed bandwidth (**transmit-rate**) for a strict-high priority queue. You cannot configure a minimum guaranteed bandwidth (**guaranteed-rate**) for a forwarding class set that includes a strict-high priority queue.
  - You must create a separate forwarding class set for the strict-high priority queue.
  - Only one forwarding class set can contain strict-high priority queues.
  - Strict-high priority queues cannot belong to the same forwarding class set as queues that are not strict-high priority.
  - A strict-high priority queue cannot belong to a multidestination forwarding class set.
- In QFabric systems, if any queue that contains outgoing packets does not transmit packets for 12 consecutive seconds, the port automatically resets. Failure of a queue to transmit packets for 12 consecutive seconds may be due to:
  - A strict-high priority queue consuming all of the port bandwidth
  - Several queues consuming all of the port bandwidth
  - Any queue or port receiving continuous priority-based flow control (PFC) or 802.3x Ethernet PAUSE messages (received PFC and PAUSE messages prevent a queue or a port, respectively, from transmitting packets because of network congestion)
  - Other conditions that prevent a queue from obtaining port bandwidth for 12 consecutive seconds

  If the cause is a strict-high priority queue consuming all of the port bandwidth, you can use rate shaping to configure a maximum rate for the strict-high priority queue and prevent it from using all of the port bandwidth. To configure rate shaping, include the **shaping-rate (*rate* | percent *percentage*)** statement at the **[edit class-of-service schedulers *scheduler-name*]** hierarchy level and apply the shaping rate to the strict-high priority scheduler.

  If several queues consume all of the port bandwidth, you can use a scheduler to rate shape those queues and prevent them from using all of the port bandwidth.
- For transmit rates below 1 Gbps, we recommend that you configure the transmit rate as a percentage instead of as a fixed rate. This is because the system converts fixed rates into percentages and may round small fixed rates to a lower percentage. For example, a fixed rate of 350 Mbps is rounded down to 3 percent instead of 3.5 percent.
- When you set the maximum bandwidth for a queue or for a priority group (**shaping-rate**) at 100 Kbps or lower, the traffic shaping behavior is accurate only within +/– 20 percent of the configured **shaping-rate**.
- Ingress port congestion can occur during periods of egress port congestion if an ingress port forwards traffic to more than one egress port, and at least one of those egress ports experiences congestion. If this occurs, the congested egress port can cause the

ingress port to exceed its fair allocation of ingress buffer resources. When the ingress port exceeds its buffer resource allocation, frames are dropped at the ingress. Ingress port frame drop affects not only the congested egress ports, but also all of the egress ports to which the congested ingress port forwards traffic.

If a congested ingress port drops traffic that is destined for one or more uncongested egress ports, configure a weighted random early detection (WRED) drop profile and apply it to the egress queue that is causing the congestion. The drop profile prevents the congested egress queue from affecting egress queues on other ports by dropping frames at the egress instead of causing congestion at the ingress port.

NOTE: **Do not configure drop profiles for the fcoe and no-loss forwarding classes. FCoE and other lossless traffic queues require lossless behavior. Use priority-based flow control (PFC) to prevent frame drop on lossless priorities.**

- On an ingress port, do not configure classifiers that map the same IEEE 802.1p code point to both a multidestination traffic flow and a lossless unicast traffic flow (such as the default lossless **fcoe** or **no-loss** forwarding classes). Any code point used for multidestination traffic on a port should not be used to classify unicast traffic into a lossless forwarding class on the same port.

  If a multidestination traffic flow and a lossless unicast traffic flow use the same code point on a port, the multidestination traffic is treated the same way as the lossless traffic. For example, if priority-based flow control (PFC) is applied to the lossless traffic, the multidestination traffic of the same code point is also paused. During periods of congestion, treating multidestination traffic the same as lossless unicast traffic can create ingress port congestion for the multidestination traffic and affect the multidestination traffic on all of the egress ports the multidestination traffic uses.

  For example, the following configuration can cause ingress port congestion for the multidestination flow:

  1. For unicast traffic, IEEE 802.1p code point 011 is classified into the **fcoe** forwarding class:

     `user@switch#` **set class-of-service classifiers ieee-802.1 ucast_cl forwarding-class fcoe loss-priority low code-points 011**

  2. For multidestination traffic, IEEE 802.1p code point **011** is classified into the **mcast** forwarding class:

     `user@switch#` **set class-of-service classifiers ieee-802.1 mcast-cl forwarding-class mcast loss-priority low code-points 011**
