Configuring the Static PIM RP Address on the Non-RP Routing Device

Consider statically defining an RP if the network does not have many different RPs defined or if the RP assignment does not change very often. The Junos IPv6 PIM implementation supports only static RP configuration. Automatic RP announcement and bootstrap routers are not available with IPv6.

You configure a static RP address on the non-RP routing device. This enables the non-RP routing device to recognize the local statically defined RP. For example, if R0 is a non-RP router and R1 is the local RP router, you configure R0 with the static RP address of R1. The static IP address is the routable address assigned to the loopback interface on R1. In the following example, the loopback address of the RP is 2001:db8:85a3::8a2e:370:7334.

You can configure a static RP address globally or for a routing instance. This example shows how to configure a static RP address in a routing instance for IPv6.

To configure the static RP address:

1. On a non-RP routing device, configure the routing instance to point to the routable address assigned to the loopback interface of the RP.

```
[routing-instances VPN-A protocols pim rp]
user@host# set static address 2001:db8:85a3::8a2e:370:7334
```

NOTE: Logical systems are also supported. You can configure a static RP address in a logical system only if the logical system is not directly connected to a source.

2. (Optional) Set the PIM sparse mode version.

For each static RP address, you can optionally specify the PIM version. The default PIM version is version 1.

```
[edit routing-instances VPN-A protocols pim rp]
user@host# set static address 2001:db8:85a3::8a2e:370:7334 version 2
```

NOTE: The default PIM version can be version 1 or version 2, depending on the mode you are configuring. PIM version 1 is the default for RP mode ([edit pim rp static address *address*]). PIM version 2 is the default for interface mode ([edit pim interface *interface-name*]). Explicitly configured versions override the defaults.

3. (Optional) Set the group address range.

By default, a routing device running PIM is eligible to be the RP for all IPv4 or IPv6 groups (224.0.0.0/4 or FF70::/12 to FFF0::/12). The following example limits the groups for which the 2001:db8:85a3::8a2e:370:7334 address can be the RP.

```
[edit routing-instances VPN-A protocols pim rp]
user@host# set static address 2001:db8:85a3::8a2e:370:7334 group-ranges fec0::/10
```

The RP that you select for a particular group must be consistent across all routers in a multicast domain.

4. (Optional) Override dynamic RP for the specified group address range.

If you configure both static RP mapping and dynamic RP mapping (such as auto-RP) in a single routing instance, allow the static mapping to take precedence for the given static RP group range, and allow dynamic RP mapping for all other groups.

If you exclude this statement from the configuration and you use both static and dynamic RP mechanisms for different group ranges within the same routing instance, the dynamic RP mapping takes precedence over the static RP mapping, even if static RP is defined for a specific group range.

```
[edit routing-instances VPN-A protocols pim rp static address
  2001:db8:85a3::8a2e:370:7334]
user@host# set override
```

5. Monitor the operation of PIM by running the **show pim** commands. Run **show pim ?** to display the supported commands.

Anycast RP

- [Example: Configuring PIM Anycast With or Without MSDP on page 3999](#)
- [Configuring a PIM Anycast RP Router with MSDP on page 4002](#)
- [Configuring a PIM Anycast RP Router Using Only PIM on page 4003](#)
- [Configuring All PIM Anycast Non-RP Routers on page 4004](#)
- [Example: Configuring Multiple RPs in a Domain with Anycast RP on page 4005](#)

Example: Configuring PIM Anycast With or Without MSDP

When you configure anycast RP, you bypass the restriction of having one active rendezvous point (RP) per multicast group, and instead deploy multiple RPs for the same group range. The RP routers share one unicast IP address. Sources from one RP are known to other RPs that use the Multicast Source Discovery Protocol (MSDP). Sources and receivers use the closest RP, as determined by the interior gateway protocol (IGP).

You can use anycast RP within a domain to provide redundancy and RP load sharing. When an RP stops operating, sources and receivers are taken to a new RP by means of unicast routing.

You can configure anycast RP to use PIM and MSDP for IPv4, or PIM alone for both IPv4 and IPv6 scenarios. Both are discussed in this section.

We recommend a static RP mapping with anycast RP over a bootstrap router and auto-RP configuration because it provides all the benefits of a bootstrap router and auto-RP without the complexity of the BSR and auto-RP mechanisms.

All systems on a subnet must run the same version of PIM.

The default PIM version can be version 1 or version 2, depending on the mode you are configuring. PIMv1 is the default RP mode (at the **[edit protocols pim rp static address address]** hierarchy level). However, PIMv2 is the default for interface mode (at the **[edit protocols pim interface interface-name]** hierarchy level). Explicitly configured versions override the defaults. This example explicitly configures PIMv2 on the interfaces.

The following example shows an anycast RP configuration for the RP routers, first with MSDP and then using PIM alone, and for non-RP routers.

1. For a network using an RP with MSDP, configure the RP using the **lo0** loopback interface, which is always up. Include the **address** statement and specify the unique and routable router ID and the RP address at the **[edit interfaces lo0 unit 0 family inet]** hierarchy level. In this example, the router ID is **198.58.3.254** and the shared RP address is **198.58.3.253**. Include the **primary** statement for the first address. Including the **primary** statement selects the router's primary address from all the preferred addresses on all interfaces.

```
interfaces {
  lo0 {
    description "PIM RP";
    unit 0 {
      family inet {
        address 198.58.3.254/32;
        primary;
        address 198.58.3.253/32;
      }
    }
  }
}
```

2. Specify the RP address. Include the **address** statement at the **[edit protocols pim rp local]** hierarchy level (the same address as the secondary **lo0** interface).

For all interfaces, include the **mode** statement to set the mode to **sparse** and the **version** statement to specify PIM version 2 at the **[edit protocols pim rp local interface all]** hierarchy level. When configuring all interfaces, exclude the **fxp0.0** management interface by including the **disable** statement for that interface.

```
protocols {
  pim {
    rp {
      local {
        family inet;
        address 198.58.3.253;
      }
      interface all {
        mode sparse;
        version 2;
      }
      interface fxp0.0 {
        disable;
      }
    }
  }
}
```

3. Configure MSDP peering. Include the **peer** statement to configure the address of the MSDP peer at the **[edit protocols msdp]** hierarchy level. For MSDP peering, use the unique, primary addresses instead of the anycast address. To specify the local address for MSDP peering, include the **local-address** statement at the **[edit protocols msdp peer]** hierarchy level.

```
protocols {
  msdp {
    peer 198.58.3.250 {
      local-address address 198.58.3.254;
    }
  }
}
```

NOTE: If you need to configure a PIM RP for both IPv4 and IPv6 scenarios, perform Step 4 and Step 5. Otherwise, go to Step 6.

4. Configure an RP using the **lo0** loopback interface, which is always up. Include the **address** statement to specify the unique and routable router address and the RP address at the **[edit interfaces lo0 unit 0 family inet]** hierarchy level. In this example, the router ID is **198.58.3.254** and the shared RP address is **198.58.3.253**. Include the **primary** statement on the first address. Including the **primary** statement selects the router's primary address from all the preferred addresses on all interfaces.

```
interfaces {
  lo0 {
    description "PIM RP";
    unit 0 {
      family inet {
        address 198.58.3.254/32 {
```

```

        primary;
    }
    address 198.58.3.253/32;
}
}
}
}

```

5. Include the **address** statement at the **[edit protocols pim rp local]** hierarchy level to specify the RP address (the same address as the secondary **lo0** interface).

For all interfaces, include the **mode** statement to set the mode to **sparse**, and the **version** statement to specify PIM version 2 at the **[edit protocols pim rp local interface all]** hierarchy level. When configuring all interfaces, exclude the **fxp0.0** management interface by including the **disable** statement for that interface.

Include the **anycast-pim** statement to configure anycast RP without MSDP (for example, if IPv6 is used for multicasting). The other RP routers that share the same IP address are configured using the **rp-set** statement. There is one entry for each RP, and the maximum that can be configured is 15. For each RP, specify the routable IP address of the router and whether MSDP source active (SA) messages are forwarded to the RP.

MSDP configuration is not necessary for this type of IPv4 anycast RP configuration.

```

protocols {
  pim {
    rp {
      local {
        family inet {
          address 198.58.3.253;
          anycast-pim {
            rp-set {
              address 198.58.3.240;
              address 198.58.3.241 forward-msdp-sa;
            }
            local-address 198.58.3.254; #If not configured, use lo0 primary
          }
        }
      }
    }
  }
  interface all {
    mode sparse;
    version 2;
  }
  interface fxp0.0 {
    disable;
  }
}
}

```

6. Configure the non-RP routers. The anycast RP configuration for a non-RP router is the same whether MSDP is used or not. Specify a static RP by adding the address at the **[edit protocols pim rp static]** hierarchy level. Include the **version** statement at the **[edit protocols pim rp static address]** hierarchy level to specify PIM version 2.

```
protocols {
  pim {
    rp {
      static {
        address 198.58.3.253 {
          version 2;
        }
      }
    }
  }
}
```

7. Include the **mode** statement at the **[edit protocols pim interface all]** hierarchy level to specify sparse mode on all interfaces. Then include the **version** statement at the **[edit protocols pim rp interface all mode]** to configure all interfaces for PIM version 2. When configuring all interfaces, exclude the **fxp0.0** management interface by including the **disable** statement for that interface.

```
protocols {
  pim {
    interface all {
      mode sparse;
      version 2;
    }
    interface fxp0.0 {
      disable;
    }
  }
}
```

Configuring a PIM Anycast RP Router with MSDP

Add the **address** statement at the **[edit protocols pim rp local]** hierarchy level to specify the RP address (the same address as the secondary **lo0** interface).

For all interfaces, use the **mode** statement to set the mode to **sparse** and the **version** statement to specify PIM version 2 at the **[edit protocols pim rp local interface all]** hierarchy level. When configuring all interfaces, exclude the **fxp0.0** management interface by adding the **disable** statement for that interface.

```
protocols {
  pim {
    rp {
      local {
        family inet;
        address 198.58.3.253;
      }
      interface all {
        mode sparse;
        version 2;
      }
      interface fxp0.0 {
        disable;
      }
    }
  }
}
```

```

    }
  }

```

To configure MSDP peering, add the **peer** statement to configure the address of the MSDP peer at the **[edit protocols msdp]** hierarchy level. For MSDP peering, use the unique, primary addresses instead of the anycast address. To specify the local address for MSDP peering, add the **local-address** statement at the **[edit protocols msdp peer]** hierarchy level.

```

protocols {
  msdp {
    peer 198.58.3.250 {
      local-address 198.58.3.254;
    }
  }
}

```

Configuring a PIM Anycast RP Router Using Only PIM

In this example, configure an RP using the **lo0** loopback interface, which is always up. Use the **address** statement to specify the unique and routable router address and the RP address at the **[edit interfaces lo0 unit 0 family inet]** hierarchy level. In this case, the router ID is 198.58.3.254/32 and the shared RP address is 198.58.3.253/32. Add the flag statement **primary** to the first address. Using this flag selects the router's primary address from all the preferred addresses on all interfaces.

```

interfaces {
  lo0 {
    description "PIM RP";
    unit 0 {
      family inet {
        address 198.58.3.254/32 {
          primary;
        }
        address 198.58.3.253/32;
      }
    }
  }
}

```

Add the **address** statement at the **[edit protocols pim rp local]** hierarchy level to specify the RP address (the same address as the secondary **lo0** interface).

For all interfaces, use the **mode** statement to set the mode to **sparse**, and include the **version** statement to specify PIM version 2 at the **[edit protocols pim rp local interface all]** hierarchy level. When configuring all interfaces, exclude the **fxp0.0** management interface by adding the **disable** statement for that interface.

Use the **anycast-pim** statement to configure anycast RP without MSDP (for example, if IPv6 is used for multicasting). The other RP routers that share the same IP address are configured using the **rp-set** statement. There is one entry for each RP, and the maximum that can be configured is 15. For each RP, specify the routable IP address of the router and whether MSDP source active (SA) messages are forwarded to the RP.

```
protocols {
  pim {
    rp {
      local {
        family inet {
          address 198.58.3.253;
          anycast-pim {
            rp-set {
              address 198.58.3.240;
              address 198.58.3.241 forward-msdp-sa;
            }
            local-address 198.58.3.254; #If not configured, use lo0 primary
          }
        }
      }
    }
  }
  interface all {
    mode sparse;
    version 2;
  }
  interface fxp0.0 {
    disable;
  }
}
```

MSDP configuration is not necessary for this type of IPv4 anycast RP configuration.

Configuring All PIM Anycast Non-RP Routers

Use the **mode** statement at the **[edit protocols pim rp interface all]** hierarchy level to specify sparse mode on all interfaces. Then add the **version** statement at the **[edit protocols pim rp interface all mode]** to configure all interfaces for PIM version 2. When configuring all interfaces, exclude the **fxp0.0** management interface by adding the **disable** statement for that interface.

```
protocols {
  pim {
    interface all {
      mode sparse;
      version 2;
    }
    interface fxp0.0 {
      disable;
    }
  }
}
```

Example: Configuring Multiple RPs in a Domain with Anycast RP

This example shows how to configure anycast RP on each RP router in the PIM-SM domain. With this configuration you can deploy more than one RP for a single group range. This enables load balancing and redundancy.

- [Requirements on page 4005](#)
- [Overview on page 4005](#)
- [Configuration on page 4005](#)
- [Verification on page 4007](#)

Requirements

Before you begin:

- Configure the router interfaces. See the *Junos OS Network Interfaces Library for Routing Devices*.
- Configure an interior gateway protocol or static routing. See the *Junos OS Routing Protocols Library for Routing Devices*.
- Configure PIM Sparse Mode on the interfaces. See “[Enabling PIM Sparse Mode](#)” on [page 3986](#).

Overview

When you configure anycast RP, the RP routers in the PIM-SM domain use a shared address. In this example, the shared address is 10.1.1.2/32. Anycast RP uses Multicast Source Discovery Protocol (MSDP) to discover and maintain a consistent view of the active sources. Anycast RP also requires an RP selection method, such as static, auto-RP, or bootstrap RP. This example uses static RP and shows only one RP router configuration.

Configuration

| | |
|--------------------------------|---|
| CLI Quick Configuration | To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level. |
| RP Routers | <pre> set interfaces lo0 unit 0 family inet address 192.168.132.1/32 primary set interfaces lo0 unit 0 family inet address 10.1.1.2/32 set protocols msdp local-address 192.168.132.1 set protocols msdp peer 192.168.12.1 set protocols pim rp local address 10.1.1.2 set routing-options router-id 192.168.132.1 </pre> |
| Non-RP Routers | <pre> set protocols pim rp static address 10.1.1.2 </pre> |

Step-by-Step Procedure The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure anycast RP:

1. On each RP router in the domain, configure the shared anycast address on the router's loopback address.

```
[edit interfaces]
user@host# set lo0 unit 0 family inet address 10.1.1.2/32
```

2. On each RP router in the domain, make sure that the router's regular loopback address is the primary address for the interface, and set the router ID.

```
[edit interfaces]
user@host# set lo0 unit 0 family inet address 192.168.132.1/32 primary
```

```
[edit routing-options]
user@host# set router-id 192.168.132.1
```

3. On each RP router in the domain, configure the local RP address, using the shared address.

```
[edit protocols pim]
user@host# set rp local address 10.1.1.2
```

4. On each RP router in the domain, create MSDP sessions to the other RPs in the domain.

```
[edit protocols msdp]
user@host# set local-address 192.168.132.1
user@host# set peer 192.168.12.1
```

5. On each non-RP router in the domain, configure a static RP address using the shared address.

```
[edit protocols pim]
user@host# set rp static address 10.1.1.2
```

6. If you are done configuring the devices, commit the configuration.

```
user@host# commit
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@host# show interfaces
lo0 {
  unit 0 {
    family inet {
      address 192.168.132.1/32 {
        primary;
      }
      address 10.1.1.2/32;
    }
  }
}
```

```

    }
  }
}

```

On the RP routers:

```

user@host# show protocols
msdp {
  local-address 192.168.132.1;
  peer 192.168.12.1;
}
pim {
  rp {
    local {
      address 10.1.1.2;
    }
  }
}
}

```

On the non-RP routers:

```

user@host# show protocols
pim {
  rp {
    static {
      address 10.1.1.2;
    }
  }
}

user@host# show routing-options
router-id 192.168.132.1;

```

Verification

To verify the configuration, run the `show pim rps extensive inet` command.

PIM Bootstrap Router

- [Configuring PIM Bootstrap Properties for IPv4 or IPv6 on page 4007](#)
- [Example: Rejecting PIM Bootstrap Messages at the Boundary of a PIM Domain on page 4009](#)
- [Example: Configuring PIM BSR Filters on page 4009](#)

Configuring PIM Bootstrap Properties for IPv4 or IPv6

For correct operation, every multicast router within a PIM domain must be able to map a particular multicast group address to the same rendezvous point (RP). The bootstrap

router mechanism is one way that a multicast router can learn the set of group-to-RP mappings. Bootstrap routers are supported in IPv4 and IPv6.

To determine which routing device is the RP, all routing devices within a PIM domain collect bootstrap messages. A PIM domain is a contiguous set of routing devices that implement PIM. All devices are configured to operate within a common boundary. The domain's bootstrap router initiates bootstrap messages, which are sent hop by hop within the domain. The routing devices use bootstrap messages to distribute RP information dynamically and to elect a bootstrap router when necessary.

You can configure bootstrap properties globally or for a routing instance. This example shows the global configuration.

To configure the bootstrap router properties:

1. Configure the bootstrap priority.

By default, each routing device has a bootstrap priority of 0, which means the routing device can never be the bootstrap router. The routing device with the highest priority value is elected to be the bootstrap router. In the case of a tie, the routing device with the highest IP address is elected to be the bootstrap router. A simple bootstrap configuration assigns a bootstrap priority value to a routing device.

NOTE: In the IPv4-only configuration, specifying a bootstrap priority of 0 disables the bootstrap function and does not cause the routing device to send BSR packets with a 0 in the priority field. In the combined IPv4 and IPv6 configuration, specifying a bootstrap priority of 0 does not disable the function, but causes the routing device to send BSR packets with a 0 in the priority field. To disable the bootstrap function in the IPv4 and IPv6 configuration, delete the `bootstrap` statement.

```
user@host# edit protocols pim rp
user@host# set bootstrap family inet priority 3
```

2. (Optional) Create import and export policies to control the flow of bootstrap messages to and from the RP, and apply the policies to PIM. Import and export policies are useful when some of the routers in your PIM domain have interfaces that connect to other PIM domains. Configuring a policy prevents bootstrap messages from crossing domain boundaries. The **import** statement prevents messages from being imported into the RP. The **export** statement prevents messages from being exported from the RP.

```
[edit protocols pim rp]
user@host# set bootstrap family inet import pim-bootstrap-import
user@host# set bootstrap family inet export pim-bootstrap-export
user@host# exit
```

3. Configure the policies.

```
user@host# edit policy-options policy-statement pim-bootstrap-import
[edit policy-options policy-statement pim-bootstrap-import]
user@host# set from interface se-0/0/0
user@host# set then reject
user@host# exit
```

```

user@host# edit policy-options policy-statement pim-bootstrap-export
user@host# set from interface se-0/0/0
user@host# set then reject
user@host# exit

```

4. Monitor the operation of PIM bootstrap routers by running the `show pim bootstrap` command.

Related Documentation

- [Understanding PIM Sparse Mode on page 3941](#)
- [Example: Rejecting PIM Bootstrap Messages at the Boundary of a PIM Domain on page 4009](#)
- [show pim bootstrap on page 4356](#) in the CLI Explorer

Example: Rejecting PIM Bootstrap Messages at the Boundary of a PIM Domain

In this example, the `from interface so-0-1/0 then reject` policy statement rejects bootstrap messages from the specified interface (the example is configured for both IPv4 and IPv6 operation):

```

protocols {
  pim {
    rp {
      bootstrap {
        family inet {
          priority 1;
          import pim-import;
          export pim-export;
        }
        family inet6 {
          priority 1;
          import pim-import;
          export pim-export;
        }
      }
    }
  }
}
policy-options {
  policy-statement pim-import {
    from interface so-0/1/0;
    then reject;
  }
  policy-statement pim-export {
    to interface so-0/1/0;
    then reject;
  }
}

```

Example: Configuring PIM BSR Filters

Configure a filter to prevent BSR messages from entering or leaving your network. Add this configuration to all routers:

```
protocols {
  pim {
    rp {
      bootstrap-import no-bsr;
      bootstrap-export no-bsr;
    }
  }
}
policy-options {
  policy-statement no-bsr {
    then reject;
  }
}
```

PIM Filtering

- [Configuring Interface-Level PIM Neighbor Policies on page 4010](#)
- [Filtering Outgoing PIM Join Messages on page 4011](#)
- [Filtering Incoming PIM Join Messages on page 4012](#)
- [Configuring Register Message Filters on a PIM RP and DR on page 4013](#)

Configuring Interface-Level PIM Neighbor Policies

You can configure a policy to filter unwanted PIM neighbors. In the following example, the PIM interface compares neighbor IP addresses with the IP address in the policy statement before any hello processing takes place. If any of the neighbor IP addresses (primary or secondary) match the IP address specified in the prefix list, PIM drops the hello packet and rejects the neighbor.

If you configure a PIM neighbor policy after PIM has already established a neighbor adjacency to an unwanted PIM neighbor, the adjacency remains intact until the neighbor hold time expires. When the unwanted neighbor sends another hello message to update its adjacency, the router recognizes the unwanted address and rejects the neighbor.

To configure a policy to filter unwanted PIM neighbors:

1. Configure the policy. The neighbor policy must be a properly structured policy statement that uses a prefix list (or a route filter) containing the neighbor primary address (or any secondary IP addresses) in a prefix list, and the **reject** option to reject the unwanted address.

```
[edit policy-options]
user@host# set prefix-list nbrGroup 1 20.20.20.1/32
user@host# set policy-statement nbr-policy from prefix-list nbrGroup1
user@host# set policy-statement nbr-policy then reject
```

2. Configure the interface globally or in the routing instance. This example shows the configuration for the routing instance.

```
[edit routing-instances PIM.master protocols pim]
user@host# set neighbor-policy nbr-policy
```

3. Verify the configuration by checking the **Hello dropped on neighbor policy** field in the output of the **show pim statistics** command.

Filtering Outgoing PIM Join Messages

When the core of your network is using MPLS, PIM join and prune messages stop at the customer edge (CE) routers and are not forwarded toward the core, because these routers do not have PIM neighbors on the core-facing interfaces. When the core of your network is using IP, PIM join and prune messages are forwarded to the upstream PIM neighbors in the core of the network.

When the core of your network is using a mix of IP and MPLS, you might want to filter certain PIM join and prune messages at the upstream egress interface of the CE routers.

You can filter PIM sparse mode (PIM-SM) join and prune messages at the egress interfaces for IPv4 and IPv6 in the upstream direction. The messages can be filtered based on the group address, source address, outgoing interface, PIM neighbor, or a combination of these values. If the filter is removed, the join is sent after the PIM periodic join timer expires.

To filter PIM sparse mode join and prune messages at the egress interfaces, create a policy rejecting the group address, source address, outgoing interface, or PIM neighbor, and then apply the policy.

The following example filters PIM join and prune messages for group addresses 224.0.1.2 and 225.1.1.1.

1. In configuration mode, create the policy.

```
user@host# set policy-options policy-statement block-groups term t1 from route-filter
224.0.1.2/32 exact
user@host# set policy-options policy-statement block-groups term t1 from route-filter
225.1.1.1/32 exact
user@host# set policy-options policy-statement block-groups term t1 then reject
user@host# set policy-options policy-statement block-groups term last then accept
```

2. Verify the policy configuration by running the **show policy-options** command.

```
user@host# show policy-options
policy-statement block-groups {
  term t1 {
    from {
      route-filter 224.0.1.2/32 exact;
      route-filter 225.1.1.1/32 exact;
      then reject;
    }
    term last {
      then accept;
    }
  }
}
```

3. Apply the PIM join and prune message filter.

```
user@host> set protocols pim export block-groups
```

4. After the configuration is committed, use the **show pim statistics** command to verify that outgoing PIM join and prune messages are being filtered.

```
user@host> show pim statistics | grep filtered
RP Filtered Source                0
Rx Joins/Prunes filtered          0
Tx Joins/Prunes filtered          254
```

The egress filter count is shown on the **Tx Joins/Prunes filtered** line.

Filtering Incoming PIM Join Messages

Multicast scoping controls the propagation of multicast messages. Whereas multicast scoping prevents the actual multicast data packets from flowing in or out of an interface, PIM join filters prevent a state from being created in a router. A state—the (*,G) or (S,G) entries—is the information used for forwarding unicast or multicast packets. Using PIM join filters prevents the transport of multicast traffic across a network and the dropping of packets at a scope at the edge of the network. Also, PIM join filters reduce the potential for denial-of-service (DoS) attacks and PIM state explosion—large numbers of PIM join messages forwarded to each router on the rendezvous-point tree (RPT), resulting in memory consumption.

To use PIM join filters to efficiently restrict multicast traffic from certain source addresses, create and apply the routing policy across all routers in the network.

See [Table 301 on page 4012](#) for a list of match conditions.

Table 301: PIM Join Filter Match Conditions

| Match Condition | Matches On |
|------------------------------|--|
| interface | Router interface or interfaces specified by name or IP address |
| neighbor | Neighbor address (the source address in the IP header of the join and prune message) |
| route-filter | Multicast group address embedded in the join and prune message |
| source-address-filter | Multicast source address embedded in the join and prune message |

The following example shows how to create a PIM join filter. The filter is composed of a route filter and a source address filter—**bad-groups** and **bad-sources**, respectively. the **bad-groups** filter prevents (*,G) or (S,G) join messages from being received for all groups listed. The **bad-sources** filter prevents (S,G) join messages from being received for all sources listed. The **bad-groups** filter and **bad-sources** filter are in two different terms. If route filters and source address filters are in the same term, they are logically ANDed.

To filter incoming PIM join messages:

1. Configure the policy.

```
[edit policy-statement pim-join-filter term bad-groups]
user@host# set from route-filter 224.0.1.2/32 exact
user@host# set from route-filter 239.0.0.0/8 orlonger
user@host# set then reject

[edit policy-statement pim-join-filter term bad-sources]
user@host# set from source-address-filter 10.0.0.0/8 orlonger
user@host# set from source-address-filter 127.0.0.0/8 orlonger
user@host# set then reject

[edit policy-statement pim-join-filter term last]
user@host# set then accept
```

2. Apply one or more policies to routes being imported into the routing table from PIM.

```
[edit protocols pim]
user@host# set import pim-join-filter
```

3. Verify the configuration by checking the output of the **show pim join** and **show policy** commands.

Configuring Register Message Filters on a PIM RP and DR

PIM register messages are sent to the rendezvous point (RP) by a designated router (DR). When a source for a group starts transmitting, the DR sends unicast PIM register packets to the RP.

Register messages have the following purposes:

- Notify the RP that a source is sending to a group.
- Deliver the initial multicast packets sent by the source to the RP for delivery down the shortest-path tree (SPT).

The PIM RP keeps track of all active sources in a single PIM sparse mode domain. In some cases, you want more control over which sources an RP discovers, or which sources a DR notifies other RPs about. A high degree of control over PIM register messages is provided by RP or DR register message filtering. Message filtering prevents unauthorized groups and sources from registering with an RP router.

You configure RP or DR register message filtering to control the number and location of multicast sources that an RP discovers. You can apply register message filters on a DR to control outgoing register messages, or apply them on an RP to control incoming register messages.

When anycast RP is configured, all RPs in the anycast RP set need to be configured with the same register message filtering policy.

You can configure message filtering globally or for a routing instance. These examples show the global configuration.

To configure an RP filter to drop the register packets for multicast group range 224.1.1.0/24 from source address 10.10.94.2:

1. On the RP, configure the policy.

```
[edit policy-options policy-statement incoming-policy-for-rp from]
user@host# set route-filter 224.1.1.0/24 orlonger
user@host# set source-address-filter 10.10.94.2/32 exact
user@host# set then reject
user@host# exit
```

2. Apply the policy to the RP.

```
[edit protocols pim rp]
user@host# set rp-register-policy incoming-policy-for-rp
user@host# set local address 10.10.10.5
user@host# exit
```

To configure a DR filter to prevent sending register packets for group range 224.1.1.0/24 and source address 10.10.10.1/32:

1. On the DR, configure the policy.

```
[edit policy-options policy-statement outgoing-policy-for-rp]
user@host# set from route-filter 224.1.1.0/24 orlonger
user@host# set from source-address-filter 10.10.10.1/32 exact
user@host# set then reject
user@host# exit
```

2. Apply the policy to the DR.

The static address is the address of the RP to which you do not want the DR to send the filtered register messages.

```
[edit protocols pim rp]
user@host# set dr-register-policy outgoing-policy-for-dr
user@host# set static 10.10.10.3
user@host# exit
```

To configure a policy expression to accept register messages for multicast group 224.1.1.5 but reject those for 224.1.1.1:

1. On the RP, configure the policies.

```
[edit policy-options policy-statement reject_224_1_1_1]
user@host# set from route-filter 224.1.1.0/24 orlonger
user@host# set from source-address-filter 10.10.94.2/32 exact
user@host# set then reject
user@host# exit
```

```
[edit policy-options policy-statement accept_224_1_1_5]
user@host# set term one from route-filter 224.1.1.5/32 exact
```

```

user@host# set term one from source-address-filter 10.10.94.2/32 exact
user@host# set term one then accept
user@host# set term two then reject
user@host# exit

```

2. Apply the policies to the RP.

```

[edit protocols pim rp]
user@host# set rp-register-policy [ reject_224_1_1_1 | accept_224_1_1_5 ]
user@host# set local address 10.10.10.5

```

To monitor the operation of the filters, run the **show pim statistics** command. The command output contains the following fields related to filtering:

- RP Filtered Source
- Rx Joins/Prunes filtered
- Tx Joins/Prunes filtered
- Rx Register msgs filtering drop
- Tx Register msgs filtering drop

Example: Configuring the PIM Assert Timeout

This example shows how to configure the timeout period for a PIM assert forwarder.

- [Requirements on page 4015](#)
- [Overview on page 4016](#)
- [Configuration on page 4017](#)

Requirements

Before you begin:

- Configure the router interfaces. See the *Junos OS Network Interfaces Library for Routing Devices*.
- Configure an interior gateway protocol or static routing. See the *Junos OS Routing Protocols Library for Routing Devices*.
- Configure PIM Sparse Mode on the interfaces. See [“Enabling PIM Sparse Mode” on page 3986](#).

Overview

The role of PIM assert messages is to determine the forwarder on a network with multiple routers. The forwarder is the router that forwards multicast packets to a network with multicast group members. The forwarder is generally the same as the PIM DR.

A router sends an assert message when it receives a multicast packet on an interface that is listed in the outgoing interface list of the matching routing entry. Receiving a message on an outgoing interface is an indication that more than one router forwards the same multicast packets to a network.

In [Figure 136 on page 4017](#), both routing devices R1 and R2 forward multicast packets for the same (S,G) entry on a network. Both devices detect this situation and both devices send assert messages on the Ethernet network. An assert message contains, in addition to a source address and group address, a unicast cost metric for sending packets to the source, and a preference metric for the unicast cost. The preference metric expresses a preference between unicast routing protocols. The routing device with the smallest preference metric becomes the forwarder (also called the assert winner). If the preference metrics are equal, the device that sent the lowest unicast cost metric becomes the forwarder. If the unicast metrics are also equal, the routing device with the highest IP address becomes the forwarder. After the transmission of assert messages, only the forwarder continues to forward messages on the network.

When an assert message is received and the RPF neighbor is changed to the assert winner, the assert timer is set to an assert timeout period. The assert timeout period is restarted every time a subsequent assert message for the route entry is received on the incoming interface. When the assert timer expires, the routing device resets its RPF neighbor according to its unicast routing table. Then, if multiple forwarders still exist, the forwarders reenter the assert message cycle. In effect, the assert timeout period determines how often multicast routing devices enter a PIM assert message cycle.

The range is from 5 through 210 seconds. The default is 180 seconds.

Assert messages are useful for LANs that connect multiple routing devices and no hosts.

[Figure 136 on page 4017](#) shows the topology for this example.

Figure 136: PIM Assert Topology

Configuration

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure an assert timeout:

1. Configure the timeout period, in seconds.

```
[edit protocols pim]
user@host# set assert-timeout 60
```
2. (Optional) Trace assert messages.

```
[edit protocols pim]
user@host# set traceoptions file PIM.log
user@host# set traceoptions flag assert detail
```
3. If you are done configuring the device, commit the configuration.

```
user@host# commit
```
4. To verify the configuration, run the following commands:
 - `show pim join`
 - `show pim statistics`

Related Documentation

Example: Configuring the PIM SPT Threshold Policy

This example shows how to apply a policy that suppresses the transition from the rendezvous-point tree (RPT) rooted at the RP to the shortest-path tree (SPT) rooted at the source.

- [Requirements on page 4018](#)
- [Overview on page 4018](#)
- [Configuration on page 4019](#)
- [Verification on page 4021](#)

Requirements

Before you begin:

- Configure the router interfaces. See the *Junos OS Network Interfaces Library for Routing Devices*.
- Configure an interior gateway protocol or static routing. See the *Junos OS Routing Protocols Library for Routing Devices*.
- Configure PIM Sparse Mode on the interfaces. See [“Enabling PIM Sparse Mode” on page 3986](#).

Overview

Multicast routing devices running PIM sparse mode can forward the same stream of multicast packets onto the same LAN through an RPT rooted at the RP or through an SPT rooted at the source. In some cases, the last-hop routing device needs to stay on the shared RPT to the RP and not transition to a direct SPT to the source. Receiving the multicast data traffic on SPT is optimal but introduces more state in the network, which might not be desirable in some multicast deployments. Ideally, low-bandwidth multicast streams can be forwarded on the SPT, and high-bandwidth streams can use the SPT. This example shows how to configure such a policy.

This example includes the following settings:

- **spt-threshold**—Enables you to configure an SPT threshold policy on the last-hop routing device to control the transition to a direct SPT. When you include this statement in the main PIM instance, the PE router stays on the RPT for control traffic.
- **infinity**—Applies an SPT cutover threshold of infinity to a source-group address pair, so that the last-hop routing device never transitions to a direct SPT. For all other source-group address pairs, the last-hop routing device transitions immediately to a direct SPT rooted at the source DR. This statement must reference a properly configured policy to set the SPT cutover threshold for a particular source-group pair to infinity. The use of values other than infinity for the SPT threshold is not supported. You can configure more than one policy.
- **policy-statement**—Configures the policy. The simplest type of SPT threshold policy uses a route filter and source address filter to specify the multicast group and source

addresses and to set the SPT threshold for that pair of addresses to infinity. The policy is applied to the main PIM instance.

This example sets the SPT transition value for the source-group pair 10.10.10.1 and 224.1.1.1 to infinity. When the policy is applied to the last-hop router, multicast traffic from this source-group pair never transitions to a direct SPT to the source. Traffic will continue to arrive through the RP. However, traffic for any other source-group address combination at this router transitions to a direct SPT to the source.

Note these points when configuring the SPT threshold policy:

- Configuration changes to the SPT threshold policy affect how the routing device handles the SPT transition.

Note these points when configuring the SPT threshold policy:

- Configuration changes to the SPT threshold policy affect how the routing device handles the SPT transition.

Note these points when configuring the SPT threshold policy:

- Configuration changes to the SPT threshold policy affect how the routing device handles the SPT transition.
- When the policy is configured for the first time, the routing device continues to transition to the direct SPT for the source-group address pair until the PIM-join state is cleared with the **clear pim join** command.
- If you do not clear the PIM-join state when you apply the infinity policy configuration for the first time, you must apply it before the PE router is brought up.
- When the policy is deleted for a source-group address pair for the first time, the routing device does not transition to the direct SPT for that source-group address pair until the PIM-join state is cleared with the **clear pim join** command.
- When the policy is changed for a source-group address pair for the first time, the routing device does not use the new policy until the PIM-join state is cleared with the **clear pim join** command.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
[edit]
set policy-options policy-statement spt-infinity-policy term one from route-filter
  224.1.1.1/32 exact
set policy-options policy-statement spt-infinity-policy term one from source-address-filter
  10.10.10.1/32 exact
set policy-options policy-statement spt-infinity-policy term one then accept
set policy-options policy-statement spt-infinity-policy term two then reject
set protocols pim spt-threshold infinity spt-infinity-policy
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure an SPT threshold policy:

1. Apply the policy.

```
[edit]
user@host# edit protocols pim
[edit protocols pim]
user@host# set spt-threshold infinity spt-infinity-policy
[edit protocols pim]
user@host# exit
```

2. Configure the policy.

```
[edit]
user@host# edit policy-options policy-statement spt-infinity-policy
[edit policy-options policy-statement spt-infinity-policy]
user@host# set term one from route-filter 224.1.1.1/32 exact
[edit policy-options policy-statement spt-infinity-policy]
user@host# set term one from source-address-filter 10.10.10.1/32 exact
[edit policy-options policy-statement spt-infinity-policy]
user@host# set term one then accept
[edit policy-options policy-statement spt-infinity-policy]
user@host# set term two then reject
[edit policy-options policy-statement spt-infinity-policy]
user@host# exit
policy-statement {
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

4. Clear the PIM join cache to force the configuration to take effect.

```
[edit]
user@host# run clear pim join
```

Results

Confirm your configuration by entering the **show policy-options** command and the **show protocols** command from configuration mode. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@host# show policy-options
policy-statement spt-infinity-policy {
  term one {
    from {
      route-filter 224.1.1.1/32 exact;
      source-address-filter 10.10.10.1/32 exact;
    }
    then accept;
  }
  term two {
    then reject;
  }
}
```

```

    }
  }
  user@host# show protocols
  pim {
    spt-threshold {
      infinity spt-infinity-policy;
    }
  }
}

```

Verification

To verify the configuration, run the `show pim join` command.

PIM and the BFD Protocol

- [Configuring BFD for PIM on page 4021](#)
- [Configuring BFD Authentication for PIM on page 4023](#)

Configuring BFD for PIM

The Bidirectional Forwarding Detection (BFD) Protocol is a simple hello mechanism that detects failures in a network. BFD works with a wide variety of network environments and topologies. A pair of routing devices exchanges BFD packets. Hello packets are sent at a specified, regular interval. A neighbor failure is detected when the routing device stops receiving a reply after a specified interval. The BFD failure detection timers have shorter time limits than the Protocol Independent Multicast (PIM) hello hold time, so they provide faster detection.

The BFD failure detection timers are adaptive and can be adjusted to be faster or slower. The lower the BFD failure detection timer value, the faster the failure detection and vice versa. For example, the timers can adapt to a higher value if the adjacency fails (that is, the timer detects failures more slowly). Or a neighbor can negotiate a higher value for a timer than the configured value. The timers adapt to a higher value when a BFD session flap occurs more than three times in a span of 15 seconds. A back-off algorithm increases the receive (Rx) interval by two if the local BFD instance is the reason for the session flap. The transmission (Tx) interval is increased by two if the remote BFD instance is the reason for the session flap. You can use the **clear bfd adaptation** command to return BFD interval timers to their configured values. The **clear bfd adaptation** command is hitless, meaning that the command does not affect traffic flow on the routing device.

You must specify the minimum transmit and minimum receive intervals to enable BFD on PIM.

To enable failure detection:

1. Configure the interface globally or in a routing instance.

This example shows the global configuration.

```
[edit protocols pim]
user@host# edit interface fe-1/0/0.0 family inet bfd-liveness-detection
```

2. Configure the minimum transmit interval.

This is the minimum interval after which the routing device transmits hello packets to a neighbor with which it has established a BFD session. Specifying an interval smaller than 300 ms can cause undesired BFD flapping.

```
[edit protocols pim interface fe-1/0/0.0 family inet bfd-liveness-detection]
user@host# set transmit-interval 350
```

3. Configure the minimum interval after which the routing device expects to receive a reply from a neighbor with which it has established a BFD session.

Specifying an interval smaller than 300 ms can cause undesired BFD flapping.

```
[edit protocols pim interface fe-1/0/0.0 family inet bfd-liveness-detection]
user@host# set minimum-receive-interval 350
```

4. (Optional) Configure other BFD settings.

As an alternative to setting the receive and transmit intervals separately, configure one interval for both.

```
[edit protocols pim interface fe-1/0/0.0 family inet bfd-liveness-detection]
user@host# set minimum-interval 350
```

5. Configure the threshold for the adaptation of the BFD session detection time.

When the detection time adapts to a value equal to or greater than the threshold, a single trap and a single system log message are sent.

```
[edit protocols pim interface fe-1/0/0.0 family inet bfd-liveness-detection]
user@host# set detection-time threshold 800
```

6. Configure the number of hello packets not received by a neighbor that causes the originating interface to be declared down.

```
[edit protocols pim interface fe-1/0/0.0 family inet bfd-liveness-detection]
user@host# set multiplier 50
```

7. Configure the BFD version.

```
[edit protocols pim interface fe-1/0/0.0 family inet bfd-liveness-detection]
user@host# set version 1
```

8. Specify that BFD sessions should not adapt to changing network conditions.

We recommend that you not disable BFD adaptation unless it is preferable not to have BFD adaptation enabled in your network.

```
[edit protocols pim interface fe-1/0/0.0 family inet bfd-liveness-detection]
user@host# set no-adaptation
```

9. Verify the configuration by checking the output of the **show bfd session** command.

Related Documentation

- *show bfd session* in the [CLI Explorer](#)

Configuring BFD Authentication for PIM

Beginning with Junos OS Release 9.6, you can configure authentication for Bidirectional Forwarding Detection (BFD) sessions running over Protocol Independent Multicast (PIM). Routing instances are also supported. The following steps are needed to configure authentication on a BFD session:

1. Specify the BFD authentication algorithm for the PIM protocol.
2. Associate the authentication keychain with the PIM protocol.
3. Configure the related security authentication keychain.

The following sections provide instructions for configuring and viewing BFD authentication on PIM:

- [Configuring BFD Authentication Parameters on page 4023](#)
- [Viewing Authentication Information for BFD Sessions on page 4024](#)

Configuring BFD Authentication Parameters

BFD authentication is only supported in the Canada and United States version of the Junos OS image and is not available in the export version.

To configure BFD authentication:

1. Specify the algorithm (**keyed-md5**, **keyed-sha-1**, **meticulous-keyed-md5**, **meticulous-keyed-sha-1**, or **simple-password**) to use for BFD authentication on a PIM route or routing instance.

```
[edit protocols pim]
```

```
user@host# set interface ge-0/1/5 family inet bfd-liveness-detection authentication  
algorithm keyed-sha-1
```

NOTE: Nonstop active routing (NSR) is not supported with the **meticulous-keyed-md5** and **meticulous-keyed-sha-1** authentication algorithms. BFD sessions using these algorithms might go down after a switchover.

2. Specify the keychain to be used to associate BFD sessions on the specified PIM route or routing instance with the unique security authentication keychain attributes.

The keychain you specify must match the keychain name configured at the **[edit security authentication key-chains]** hierarchy level.

```
[edit protocols pim]
```

```
user@host# set interface ge-0/1/5 family inet bfd-liveness-detection authentication  
keychain bfd-pim
```

NOTE: The algorithm and keychain must be configured on both ends of the BFD session, and they must match. Any mismatch in configuration prevents the BFD session from being created.

3. Specify the unique security authentication information for BFD sessions:

- The matching keychain name as specified in Step 2.
- At least one key, a unique integer between 0 and 63. Creating multiple keys allows multiple clients to use the BFD session.
- The secret data used to allow access to the session.
- The time at which the authentication key becomes active, in the format *yyyy-mm-dd.hh:mm:ss*.

[edit security]

```
user@host# set authentication-key-chains key-chain bfd-pim key 53 secret
$9$ggaJDmPQ6/tJgF/AtREVsyPsnCtUHM start-time 2009-06-14.10:00:00
```

4. (Optional) Specify loose authentication checking if you are transitioning from nonauthenticated sessions to authenticated sessions.

[edit protocols pim]

```
user@host# set interface ge-0/1/5 family inet bfd-liveness-detection authentication
loose-check
```

5. (Optional) View your configuration by using the **show bfd session detail** or **show bfd session extensive** command.

6. Repeat these steps to configure the other end of the BFD session.

Viewing Authentication Information for BFD Sessions

You can view the existing BFD authentication configuration by using the **show bfd session detail** and **show bfd session extensive** commands.

The following example shows BFD authentication configured for the **ge-0/1/5** interface. It specifies the keyed SHA-1 authentication algorithm and a keychain name of **bfd-pim**. The authentication keychain is configured with two keys. Key 1 contains the secret data "**\$9\$ggaJDmPQ6/tJgF/AtREVsyPsnCtUHM**" and a start time of June 1, 2009, at 9:46:02 AM PST. Key 2 contains the secret data "**\$9\$a5jiKW9L.reP38ny.TszF2/9**" and a start time of June 1, 2009, at 3:29:20 PM PST.

[edit protocols pim]

```
interface ge-0/1/5 {
  family inet {
    bfd-liveness-detection {
      authentication {
        key-chain bfd-pim;
        algorithm keyed-sha-1;
      }
    }
  }
}
```

```

}
[edit security]
authentication key-chains {
  key-chain bfd-pim {
    key 1 {
      secret "$9$ggaJDmPQ6/tJgF/AtREVsyPsnCtUHm";
      start-time "2009-6-1.09:46:02 -0700";
    }
    key 2 {
      secret "$9$a5jiKW9l.reP38ny.TszF2/9";
      start-time "2009-6-1.15:29:20 -0700";
    }
  }
}
}

```

If you commit these updates to your configuration, you see output similar to the following example. In the output for the **show bfd session detail** command, **Authenticate** is displayed to indicate that BFD authentication is configured. For more information about the configuration, use the **show bfd session extensive** command. The output for this command provides the keychain name, the authentication algorithm and mode for each client in the session, and the overall BFD authentication configuration status, keychain name, and authentication algorithm and mode.

show bfd session detail

```
user@host# show bfd session detail
```

| Address | State | Interface | Detect Time | Transmit Interval | Multiplier |
|----------|-------|------------|-------------|-------------------|------------|
| 50.0.0.2 | Up | ge-0/1/5.0 | 0.900 | 0.300 | 3 |

Client PIM, TX interval 0.300, RX interval 0.300, **Authenticate**

Configuring IGMP

Before you begin:

1. Determine whether the router is directly attached to any multicast sources. Receivers must be able to locate these sources.
2. Determine whether the router is directly attached to any multicast group receivers. If receivers are present, IGMP is needed.
3. Determine whether to configure multicast to use sparse, dense, or sparse-dense mode. Each mode has different configuration considerations.
4. Determine the address of the RP if sparse or sparse-dense mode is used.
5. Determine whether to locate the RP with the static configuration, BSR, or auto-RP method.

6. Determine whether to configure multicast to use its own RPF routing table when configuring PIM in sparse, dense, or sparse-dense mode.
7. Configure the SAP and SDP protocols to listen for multicast session announcements. See *Configuring the Session Announcement Protocol*.

To configure the Internet Group Management Protocol (IGMP), include the **igmp** statement:

```
igmp {
  accounting;
  interface interface-name {
    disable;
    (accounting | no-accounting);
    group-policy [ policy-names ];
    immediate-leave;
    oif-map map-name;
    promiscuous-mode;
    ssm-map ssm-map-name;
    static {
      group multicast-group-address {
        exclude;
        group-count number;
        group-increment increment;
        source ip-address {
          source-count number;
          source-increment increment;
        }
      }
    }
  }
  version version;
}
query-interval seconds;
query-last-member-interval seconds;
query-response-interval seconds;
robust-count number;
traceoptions {
  file filename <files number> <size size> <world-readable | no-world-readable>;
  flag flag <flag-modifier> <disable>;
}
```

You can include this statement at the following hierarchy levels:

- [edit protocols]
- [edit logical-systems *logical-system-name* protocols]

By default, IGMP is enabled on all interfaces on which you configure Protocol Independent Multicast (PIM), and on all broadcast interfaces on which you configure the Distance Vector Multicast Routing Protocol (DVMRP).

NOTE: You can configure IGMP on an interface without configuring PIM. PIM is generally not needed on IGMP downstream interfaces. Therefore, only one “pseudo PIM interface” is created to represent all IGMP downstream (IGMP-only) interfaces on the router. This reduces the amount of router resources, such as memory, that are consumed. You must configure PIM on upstream IGMP interfaces to enable multicast routing, perform reverse-path forwarding for multicast data packets, populate the multicast forwarding table for upstream interfaces, and in the case of bidirectional PIM and PIM sparse mode, to distribute IGMP group memberships into the multicast routing domain.

Enabling IGMP

The Internet Group Management Protocol (IGMP) manages multicast groups by establishing, maintaining, and removing groups on a subnet. Multicast routing devices use IGMP to learn which groups have members on each of their attached physical networks. IGMP must be enabled for the router to receive IPv4 multicast packets. IGMP is only needed for IPv4 networks, because multicast is handled differently in IPv6 networks. IGMP is automatically enabled on all IPv4 interfaces on which you configure PIM and on all IPv4 broadcast interfaces when you configure DVMRP.

If IGMP is not running on an interface—either because PIM and DVMRP are not configured on the interface or because IGMP is explicitly disabled on the interface—you can explicitly enable IGMP.

To explicitly enable IGMP:

1. If PIM and DVMRP are not running on the interface, explicitly enable IGMP by including the interface name.

```
[edit protocols igmp]
user@host# set interface fe-0/0/0.0
```

2. See if IGMP is disabled on any interfaces. In the following example, IGMP is disabled on a Gigabit Ethernet interface.

```
[edit protocols igmp]
user@host# show
interface fe-0/0/0.0;
interface ge-1/0/0.0 {
  disable;
}
```

3. Enable IGMP on the interface by deleting the **disable** statement.

```
[edit protocols igmp]
delete interface ge-1/0/0.0 disable
```

4. Verify the configuration.

```
[edit protocols igmp]
user@host# show
interface fe-0/0/0.0;
```

```
interface ge-1/0/0.0;
```

5. Verify the operation of IGMP on the interfaces by checking the output of the **show igmp interface** command.

Changing the IGMP Version

By default, the routing device runs IGMPv2. Routing devices running different versions of IGMP determine the lowest common version of IGMP that is supported by hosts on their subnet and operate in that version.

To enable source-specific multicast (SSM) functionality, you must configure version 3 on the host and the host's directly connected routing device. If a source address is specified in a multicast group that is statically configured, the version must be set to IGMPv3.

If a static multicast group is configured with the source address defined, and the IGMP version is configured to be version 2, the source is ignored and only the group is added. In this case, the join is treated as an IGMPv2 group join.

If you configure the IGMP version setting at the individual interface hierarchy level, it overrides the **interface all** statement.

If you have already configured the routing device to use IGMP version 1 (IGMPv1) and then configure it to use IGMPv2, the routing device continues to use IGMPv1 for up to 6 minutes and then uses IGMPv2.

To change to IGMPv3 for SSM functionality:

1. Configure the IGMP interface.

```
[edit protocols igmp]
user@host# set interface ge-0/0/0 version 3
```

2. Verify the configuration by checking the version field in the output of the **show igmp interfaces** command. The **show igmp statistics** command has version-specific output fields, such as V1 Membership Report, V2 Membership Report, and V3 Membership Report.

Modifying the IGMP Host-Query Message Interval

The objective of IGMP is to keep routers up to date with group membership of the entire subnet. Routers need not know who all the members are, only that members exist. Each host keeps track of which multicast groups are subscribed to. On each link, one router is elected the querier. The IGMP querier router periodically sends general host-query messages on each attached network to solicit membership information. The messages are sent to the all-systems multicast group address, 224.0.0.1.

The query interval, the response interval, and the robustness variable are related in that they are all variables that are used to calculate the group membership timeout. The group membership timeout is the number of seconds that must pass before a multicast router determines that no more members of a host group exist on a subnet. The group membership timeout is calculated as the (robustness variable x query-interval) + (query-response-interval). If no reports are received for a particular group before the group membership timeout has expired, the routing device stops forwarding remotely-originated multicast packets for that group onto the attached network.

By default, host-query messages are sent every 125 seconds. You can change this interval to change the number of IGMP messages sent on the subnet.

To modify the query interval:

1. Configure the interval.

```
[edit protocols igmp]  
user@host# set query-interval 200
```

The value can be from 1 through 1024 seconds.

2. Verify the configuration by checking the IGMP Query Interval field in the output of the **show igmp interface** command.
3. Verify the operation of the query interval by checking the Membership Query field in the output of the **show igmp statistics** command.

Modifying the IGMP Last-Member Query Interval

The last-member query interval is the maximum amount of time between group-specific query messages, including those sent in response to leave-group messages. You can configure this interval to change the amount of time it takes a routing device to detect the loss of the last member of a group.

When the routing device that is serving as the querier receives a leave-group message from a host, the routing device sends multiple group-specific queries to the group being left. The querier sends a specific number of these queries at a specific interval. The number of queries sent is called the last-member query count. The interval at which the queries are sent is called the last-member query interval. Because both settings are configurable, you can adjust the leave latency. The IGMP leave latency is the time between a request to leave a multicast group and the receipt of the last byte of data for the multicast group.

The last-member query count x (times) the last-member query interval = (equals) the amount of time it takes a routing device to determine that the last member of a group has left the group and to stop forwarding group traffic.

The default last-member query interval is 1 second. You can configure a subsecond interval up to one digit to the right of the decimal point. The configurable range is 0.1 through 0.9, then in 1-second intervals 1 through 999,999.

To modify this interval:

1. Configure the time (in seconds) that the routing device waits for a report in response to a group-specific query.

```
[edit protocols igmp]
user@host# set query-last-member-interval 0.1
```

2. Verify the configuration by checking the IGMP Last Member Query Interval field in the output of the **show igmp interfaces** command.

NOTE: You can configure the last-member query count by configuring the robustness variable. The two are always equal.

Specifying Immediate-Leave Host Removal for IGMP

The immediate leave setting is useful for minimizing the leave latency of IGMP memberships. When this setting is enabled, the routing device leaves the multicast group immediately after the last host leaves the multicast group.

The immediate-leave setting enables host tracking, meaning that the device keeps track of the hosts that send join messages. This allows IGMP to determine when the last host sends a leave message for the multicast group.

When the immediate leave setting is enabled, the device removes an interface from the forwarding-table entry without first sending IGMP group-specific queries to the interface. The interface is pruned from the multicast tree for the multicast group specified in the IGMP leave message. The immediate leave setting ensures optimal bandwidth management for hosts on a switched network, even when multiple multicast groups are being used simultaneously.

When immediate leave is disabled and one host sends a leave group message, the routing device first sends a group query to determine if another receiver responds. If no receiver responds, the routing device removes all hosts on the interface from the multicast group. Immediate leave is disabled by default for both IGMP version 2 and IGMP version 3.

NOTE: Although host tracking is enabled for IGMPv2 and MLDv1 when you enable immediate leave, use immediate leave with these versions only when there is one host on the interface. The reason is that IGMPv2 and MLDv1 use a report suppression mechanism whereby only one host on an interface sends a group join report in response to a membership query. The other interested hosts suppress their reports. The purpose of this mechanism is to avoid a flood of reports for the same group. But it also interferes with host tracking, because the router only knows about the one interested host and does not know about the others.

To enable immediate leave on an interface:

1. Configure immediate leave on the IGMP interface.

```
[edit protocols IGMP]
user@host# set interface ge-0/0/0.1 immediate-leave
```

2. Verify the configuration by checking the Immediate Leave field in the output of the `show igmp interface` command.

Filtering Unwanted IGMP Reports at the IGMP Interface Level

Suppose you need to limit the subnets that can join a certain multicast group. The **group-policy** statement enables you to filter unwanted IGMP reports at the interface level. When this statement is enabled on a router running IGMP version 2 (IGMPv2) or version 3 (IGMPv3), after the router receives an IGMP report, the router compares the group against the specified group policy and performs the action configured in that policy (for example, rejects the report if the policy matches the defined address or network).

You define the policy to match only IGMP group addresses (for IGMPv2) by using the policy's **route-filter** statement to match the group address. You define the policy to match IGMP (source, group) addresses (for IGMPv3) by using the policy's **route-filter** statement to match the group address and the policy's **source-address-filter** statement to match the source address.

To filter unwanted IGMP reports:

1. Configure an IGMPv2 policy.

```
[edit policy-statement reject_policy_v2]
user@host# set from route-filter 224.1.1.1/32 exact
user@host# set from route-filter 239.0.0.0/8 orlonger
```

```
user@host# set then reject
```

2. Configure an IGMPv3 policy.

```
[edit policy-statement reject_policy_v3]
user@host# set from route-filter 224.1.1.1/32 exact
user@host# set from route-filter 239.0.0.0/8 orlonger
user@host# set from source-address-filter 10.0.0.0/8 orlonger
user@host# set from source-address-filter 127.0.0.0/8 orlonger
user@host# set then reject
```

3. Apply the policies to the IGMP interfaces on which you prefer not to receive specific group or (source, group) reports. In this example, **ge-0/0/0.1** is running IGMPv2, and **ge-0/1/1.0** is running IGMPv3.

```
[edit protocols igmp]
user@host# set interface ge-0/0/0.1 group-policy reject_policy_v2
user@host# set interface ge-0/1/1.0 group-policy reject_policy_v3
```

4. Verify the operation of the filter by checking the Rejected Report field in the output of the **show igmp statistics** command.

Accepting IGMP Messages from Remote Subnetworks

By default, IGMP interfaces accept IGMP messages only from the same subnet. Including the **promiscuous-mode** statement enables the routing device to accept IGMP messages from indirectly connected subnets.

NOTE: When you enable IGMP on an unnumbered Ethernet interface that uses a /32 loopback address as a donor address, you must configure IGMP promiscuous mode to accept the IGMP packets received on this interface.

NOTE: When enabling promiscuous-mode, all routers on the ethernet segment must be configured with the promiscuous mode statement. Otherwise, only the interface configured with lowest IPv4 address acts as the querier for IGMP for this Ethernet segment.

To enable IGMP promiscuous mode on an interface:

1. Configure the IGMP interface.

```
[edit protocols igmp]
user@host# set interface ge-0/1/1.0 promiscuous-mode
```

2. Verify the configuration by checking the Promiscuous Mode field in the output of the **show igmp interface** command.

3. Verify the operation of the filter by checking the Rx non-local field in the output of the **show igmp statistics** command.

Modifying the IGMP Query Response Interval

The query response interval is the maximum amount of time that can elapse between when the querier router sends a host-query message and when it receives a response from a host. Configuring this interval allows you to adjust the burst peaks of IGMP messages on the subnet. Set a larger interval to make the traffic less bursty. Bursty traffic refers to an uneven pattern of data transmission: sometimes a very high data transmission rate, whereas at other times a very low data transmission rate.

The query response interval, the host-query interval, and the robustness variable are related in that they are all variables that are used to calculate the group membership timeout. The group membership timeout is the number of seconds that must pass before a multicast router determines that no more members of a host group exist on a subnet. The group membership timeout is calculated as the (robustness variable x query-interval) + (query-response-interval). If no reports are received for a particular group before the group membership timeout has expired, the routing device stops forwarding remotely originated multicast packets for that group onto the attached network.

The default query response interval is 10 seconds. You can configure a subsecond interval up to one digit to the right of the decimal point. The configurable range is 0.1 through 0.9, then in 1-second intervals 1 through 999,999.

To modify the query response interval:

1. Configure the interval.

```
[edit protocols igmp]  
user@host# set query-response-interval 0.4
```

2. Verify the configuration by checking the IGMP Query Response Interval field in the output of the **show igmp interface** command.
3. Verify the operation of the query interval by checking the Membership Query field in the output of the **show igmp statistics** command.

**Related
Documentation**

- [Understanding IGMP on page 3959](#)

- [show igmp statistics on page 4302](#)

Modifying the IGMP Robustness Variable

Fine-tune the IGMP robustness variable to allow for expected packet loss on a subnet. The robust count automatically changes certain IGMP message intervals for IGMPv2 and IGMPv3. Increasing the robust count allows for more packet loss but increases the leave latency of the subnetwork.

When the query router receives an IGMP leave message on a shared network running IGMPv2, the query router must send an IGMP group query message a specified number of times. The number of IGMP group query messages sent is determined by the robust count.

The value of the robustness variable is also used in calculating the following IGMP message intervals:

- Group member interval—Amount of time that must pass before a multicast router determines that there are no more members of a group on a network. This interval is calculated as follows: (robustness variable x query-interval) + (1 x query-response-interval).
- Other querier present interval—The robust count is used to calculate the amount of time that must pass before a multicast router determines that there is no longer another multicast router that is the querier. This interval is calculated as follows: (robustness variable x query-interval) + (0.5 x query-response-interval).
- Last-member query count—Number of group-specific queries sent before the router assumes there are no local members of a group. The number of queries is equal to the value of the robustness variable.

In IGMPv3, a change of interface state causes the system to immediately transmit a state-change report from that interface. In case the state-change report is missed by one or more multicast routers, it is retransmitted. The number of times it is retransmitted is the robust count minus one. In IGMPv3, the robust count is also a factor in determining the group membership interval, the older version querier interval, and the other querier present interval.

By default, the robustness variable is set to 2. You might want to increase this value if you expect a subnet to lose packets.

The number can be from 2 through 10.

To change the value of the robustness variable:

1. Configure the robust count.

When you set the robust count, you are in effect configuring the number of times the querier retries queries on the connected subnets.

```
[edit protocols igmp]
user@host# set robust-count 5
```

2. Verify the configuration by checking the IGMP Robustness Count field in the output of the **show igmp interfaces** command.

Limiting the Maximum IGMP Message Rate

This section describes how to change the limit for the maximum number of IGMP packets transmitted in 1 second by the router.

Increasing the maximum number of IGMP packets transmitted per second might be useful on a router with a large number of interfaces participating in IGMP.

To change the limit for the maximum number of IGMP packets the router can transmit in 1 second, include the **maximum-transmit-rate** statement and specify the maximum number of packets per second to be transmitted.

Related Documentation

- [maximum-transmit-rate \(Protocols IGMP\) on page 4192](#)

Enabling IGMP Static Group Membership

You can create IGMP static group membership to test multicast forwarding without a receiver host. When you enable IGMP static group membership, data is forwarded to an interface without that interface receiving membership reports from downstream hosts. The router on which you enable static IGMP group membership must be the designated router (DR) for the subnet. Otherwise, traffic does not flow downstream.

When enabling IGMP static group membership, you cannot configure multiple groups using the **group-count**, **group-increment**, **source-count**, and **source-increment** statements if the **all** option is specified as the IGMP interface.

Class-of-service (CoS) adjustment is not supported with IGMP static group membership.

In this example, you create static group 225.1.1.1.

1. On the DR, configure the static groups to be created by including the **static** statement and **group** statement and specifying which IP multicast address of the group to be created. When creating groups individually, you must specify a unique address for each group.

```
[edit protocols igmp]  
user@host# set interface fe-0/1/2 static group 225.1.1.1
```

2. After you commit the configuration, use the **show configuration protocol igmp** command to verify the IGMP protocol configuration.

```
user@host> show configuration protocol igmp

interface fe-0/1/2.0 {
  static {
    group 225.1.1.1;
  }
}
```

3. After you have committed the configuration and the source is sending traffic, use the **show igmp group** command to verify that static group 225.1.1.1 has been created.

```
user@host> show igmp group
Interface: fe-0/1/2
Group: 225.1.1.1
Source: 10.0.0.2
Last reported by: Local
Timeout: 0 Type: Static
```

NOTE: When you configure static IGMP group entries on point-to-point links that connect routing devices to a rendezvous point (RP), the static IGMP group entries do not generate join messages toward the RP.

When you create IGMP static group membership to test multicast forwarding on an interface on which you want to receive multicast traffic, you can specify that a number of static groups be automatically created. This is useful when you want to test forwarding to multiple receivers without having to configure each receiver separately.

In this example, you create three groups.

1. On the DR, configure the number of static groups to be created by including the **group-count** statement and specifying the number of groups to be created.

```
[edit protocols igmp]
user@host# set interface fe-0/1/2 static group 225.1.1.1 group-count 3
```

2. After you commit the configuration, use the **show configuration protocol igmp** command to verify the IGMP protocol configuration.

```
user@host> show configuration protocol igmp

interface fe-0/1/2.0 {
  static {
    group 225.1.1.1 {
      group-count 3;
    }
  }
}
```

3. After you have committed the configuration and after the source is sending traffic, use the **show igmp group** command to verify that static groups 225.1.1.1, 225.1.1.2, and 225.1.1.3 have been created.

```
user@host> show igmp group
```

```
Interface: fe-0/1/2
  Group: 225.1.1.1
    Source: 10.0.0.2
    Last reported by: Local
    Timeout: 0 Type: Static
  Group: 225.1.1.2
    Source: 10.0.0.2
    Last reported by: Local
    Timeout: 0 Type: Static
  Group: 225.1.1.3
    Source: 10.0.0.2
    Last reported by: Local
    Timeout: 0 Type: Static
```

When you create IGMP static group membership to test multicast forwarding on an interface on which you want to receive multicast traffic, you can also configure the group address to be automatically incremented for each group created. This is useful when you want to test forwarding to multiple receivers without having to configure each receiver separately and when you do not want the group addresses to be sequential.

In this example, you create three groups and increase the group address by an increment of two for each group.

1. On the DR, configure the group address increment by including the **group-increment** statement and specifying the number by which the address should be incremented for each group. The increment is specified in dotted decimal notation similar to an IPv4 address.

```
[edit protocols igmp]
```

```
user@host# set interface fe-0/1/2 static group 225.1.1.1 group-count 3 group-increment 0.0.0.2
```

2. After you commit the configuration, use the **show configuration protocol igmp** command to verify the IGMP protocol configuration.

```
user@host> show configuration protocol igmp
```

```
interface fe-0/1/2.0 {
  version 3;
  static {
    group 225.1.1.1 {
      group-increment 0.0.0.2;
      group-count 3;
    }
  }
}
```

3. After you have committed the configuration and after the source is sending traffic, use the **show igmp group** command to verify that static groups 225.1.1.1, 225.1.1.3, and 225.1.1.5 have been created.

```
user@host> show igmp group
Interface: fe-0/1/2
  Group: 225.1.1.1
    Source: 10.0.0.2
    Last reported by: Local
    Timeout: 0 Type: Static
  Group: 225.1.1.3
```

```

Source: 10.0.0.2
Last reported by: Local
Timeout: 0 Type: Static
Group: 225.1.1.5
Source: 10.0.0.2
Last reported by: Local
Timeout: 0 Type: Static

```

When you create IGMP static group membership to test multicast forwarding on an interface on which you want to receive multicast traffic, and your network is operating in source-specific multicast (SSM) mode, you can also specify that the multicast source address be accepted. This is useful when you want to test forwarding to multicast receivers from a specific multicast source.

If you specify a group address in the SSM range, you must also specify a source.

If a source address is specified in a multicast group that is statically configured, the IGMP version on the interface must be set to IGMPv3. IGMPv2 is the default value.

In this example, you create group 225.1.1.1 and accept IP address 10.0.0.2 as the only source.

1. On the DR, configure the source address by including the **source** statement and specifying the IPv4 address of the source host.

```

[edit protocols igmp]
user@host# set interface fe-0/1/2 static group 225.1.1.1 source 10.0.0.2

```

2. After you commit the configuration, use the **show configuration protocol igmp** command to verify the IGMP protocol configuration.

```

user@host> show configuration protocol igmp

interface fe-0/1/2.0 {
  version 3;
  static {
    group 225.1.1.1 {
      source 10.0.0.2;
    }
  }
}

```

3. After you have committed the configuration and the source is sending traffic, use the **show igmp group** command to verify that static group 225.1.1.1 has been created and that source 10.0.0.2 has been accepted.

```

user@host> show igmp group
Interface: fe-0/1/2
Group: 225.1.1.1
Source: 10.0.0.2
Last reported by: Local
Timeout: 0 Type: Static

```

When you create IGMP static group membership to test multicast forwarding on an interface on which you want to receive multicast traffic, you can specify that a number of multicast sources be automatically accepted. This is useful when you want to test forwarding to multicast receivers from more than one specified multicast source.

In this example, you create group 225.1.1.1 and accept addresses 10.0.0.2, 10.0.0.3, and 10.0.0.4 as the sources.

1. On the DR, configure the number of multicast source addresses to be accepted by including the **source-count** statement and specifying the number of sources to be accepted.

```
[edit protocols igmp]
```

```
user@host# set interface fe-0/1/2 static group 225.1.1.1 source 10.0.0.2 source-count 3
```

2. After you commit the configuration, use the **show configuration protocol igmp** command to verify the IGMP protocol configuration.

```
user@host> show configuration protocol igmp
```

```
interface fe-0/1/2.0 {  
  version 3;  
  static {  
    group 225.1.1.1 {  
      source 10.0.0.2 {  
        source-count 3;  
      }  
    }  
  }  
}
```

3. After you have committed the configuration and the source is sending traffic, use the **show igmp group** command to verify that static group 225.1.1.1 has been created and that sources 10.0.0.2, 10.0.0.3, and 10.0.0.4 have been accepted.

```
user@host> show igmp group
```

```
Interface: fe-0/1/2  
  Group: 225.1.1.1  
    Source: 10.0.0.2  
    Last reported by: Local  
    Timeout: 0 Type: Static  
  Group: 225.1.1.1  
    Source: 10.0.0.3  
    Last reported by: Local  
    Timeout: 0 Type: Static  
  Group: 225.1.1.1  
    Source: 10.0.0.4  
    Last reported by: Local  
    Timeout: 0 Type: Static
```

When you configure static groups on an interface on which you want to receive multicast traffic, and specify that a number of multicast sources be automatically accepted, you can also specify the number by which the address should be incremented for each source accepted. This is useful when you want to test forwarding to multiple receivers without having to configure each receiver separately and you do not want the source addresses to be sequential.

In this example, you create group 225.1.1.1 and accept addresses 10.0.0.2, 10.0.0.4, and 10.0.0.6 as the sources.

1. Configure the multicast source address increment by including the **source-increment** statement and specifying the number by which the address should be incremented for each source. The increment is specified in dotted decimal notation similar to an IPv4 address.

```
[edit protocols igmp]
```

```
user@host# set interface fe-0/1/2 static group 225.1.1.1 source 10.0.0.2 source-count 3 source-increment 0.0.0.2
```

2. After you commit the configuration, use the **show configuration protocol igmp** command to verify the IGMP protocol configuration.

```
user@host> show configuration protocol igmp
```

```
interface fe-0/1/2.0 {
  version 3;
  static {
    group 225.1.1.1 {
      source 10.0.0.2 {
        source-count 3;
        source-increment 0.0.0.2;
      }
    }
  }
}
```

3. After you have committed the configuration and after the source is sending traffic, use the **show igmp group** command to verify that static group 225.1.1.1 has been created and that sources 10.0.0.2, 10.0.0.4, and 10.0.0.6 have been accepted.

```
user@host> show igmp group
```

```
Interface: fe-0/1/2
  Group: 225.1.1.1
    Source: 10.0.0.2
    Last reported by: Local
    Timeout: 0 Type: Static
  Group: 225.1.1.1
    Source: 10.0.0.4
    Last reported by: Local
    Timeout: 0 Type: Static
  Group: 225.1.1.1
    Source: 10.0.0.6
    Last reported by: Local
    Timeout: 0 Type: Static
```

When you configure static groups on an interface on which you want to receive multicast traffic and your network is operating in source-specific multicast (SSM) mode, you can specify that certain multicast source addresses be excluded.

By default the multicast source address configured in a static group operates in include mode. In include mode the multicast traffic for the group is accepted from the source address configured. You can also configure the static group to operate in exclude mode. In exclude mode the multicast traffic for the group is accepted from any address other than the source address configured.

If a source address is specified in a multicast group that is statically configured, the IGMP version on the interface must be set to IGMPv3. IGMPv2 is the default value.

In this example, you exclude address 10.0.0.2 as a source for group 225.1.1.1.

1. On the DR, configure a multicast static group to operate in exclude mode by including the **exclude** statement and specifying which IPv4 source address to exclude.

```
[edit protocols igmp]
```

```
user@host# set interface fe-0/1/2 static group 225.1.1.1 exclude source 10.0.0.2
```

2. After you commit the configuration, use the **show configuration protocol igmp** command to verify the IGMP protocol configuration.

```
user@host> show configuration protocol igmp
```

```
interface fe-0/1/2.0 {  
  version 3;  
  static {  
    group 225.1.1.1 {  
      exclude;  
      source 10.0.0.2;  
    }  
  }  
}
```

3. After you have committed the configuration and the source is sending traffic, use the **show igmp group detail** command to verify that static group 225.1.1.1 has been created and that the static group is operating in exclude mode.

```
user@host> show igmp group detail
```

```
Interface: fe-0/1/2  
  Group: 225.1.1.1  
    Group mode: Exclude  
    Source: 10.0.0.2  
    Last reported by: Local  
    Timeout: 0 Type: Static
```

Recording IGMP Join and Leave Events

To determine whether IGMP tuning is needed in a network, you can configure the routing device to record IGMP join and leave events. You can record events globally for the routing device or for individual interfaces.

[Table 302 on page 4043](#) describes the recordable IGMP events.

Table 302: IGMP Event Messages

| ERRMSG Tag | Definition |
|-----------------------------|--|
| RPD_IGMP_JOIN | Records IGMP join events. |
| RPD_IGMP_LEAVE | Records IGMP leave events. |
| RPD_IGMP_ACCOUNTING_ON | Records when IGMP accounting is enabled on an IGMP interface. |
| RPD_IGMP_ACCOUNTING_OFF | Records when IGMP accounting is disabled on an IGMP interface. |
| RPD_IGMP_MEMBERSHIP_TIMEOUT | Records IGMP membership timeout events. |

To enable IGMP accounting:

1. Enable accounting globally or on an IGMP interface. This example shows both options.

```
[edit protocols igmp]
user@host# set accounting
user@host# set interface fe-0/1/0.2 accounting
```

2. Configure the events to be recorded and filter the events to a system log file with a descriptive filename, such as **igmp-events**.

```
[edit system syslog file igmp-events]
user@host# set any info
user@host# set match ".*RPD_IGMP_JOIN.* | .*RPD_IGMP_LEAVE.* |
.*RPD_IGMP_ACCOUNTING.* | .*RPD_IGMP_MEMBERSHIP_TIMEOUT.*"
```

3. Periodically archive the log file.

This example rotates the file size when it reaches 100 KB and keeps three files.

```
[edit system syslog file igmp-events]
user@host# set archive size 100000
user@host# set archive files 3
user@host# set archive archive-sites "ftp://user@host1//var/tmp" password
"anonymous"
user@host# set archive archive-sites "ftp://user@host2//var/tmp" password "test"
user@host# set archive transfer-interval 24
user@host# set archive start-time 2011-01-07:12:30
```

4. You can monitor the system log file as entries are added to the file by running the **monitor start** and **monitor stop** commands.

```
user@host> monitor start igmp-events
```

```
*** igmp-events ***
```

```
Apr 16 13:08:23 host mgd[16416]: UI_CMDLINE_READ_LINE: User 'user', command  
'run monitor start igmp-events '  
monitor
```

Limiting the Number of IGMP Multicast Group Joins on Logical Interfaces

The **group-limit** statement enables you to limit the number of IGMP multicast group joins for logical interfaces. When this statement is enabled on a router running IGMP version 2 (IGMPv2) or version 3 (IGMPv3), the limit is applied upon receipt of the group report. Once the group limit is reached, subsequent join requests are rejected.

When configuring limits for IGMP multicast groups, keep the following in mind:

- Each any-source group (*G) counts as one group toward the limit.
- Each source-specific group (S,G) counts as one group toward the limit.
- Groups in IGMPv3 exclude mode are counted toward the limit.
- Multiple source-specific groups count individually toward the group limit, even if they are for the same group. For example, (S1, G1) and (S2, G1) would count as two groups toward the configured limit.
- Combinations of any-source groups and source-specific groups count individually toward the group limit, even if they are for the same group. For example, (*, G1) and (S, G1) would count as two groups toward the configured limit.
- Configuring and committing a group limit on a network that is lower than what already exists on the network results in the removal of all groups from the configuration. The groups must then request to rejoin the network (up to the newly configured group limit).
- You can dynamically limit multicast groups on IGMP logical interfaces using dynamic profiles.

Beginning with Junos OS 12.2, you can optionally configure a system log warning threshold for IGMP multicast group joins received on the logical interface. It is helpful to review the system log messages for troubleshooting purposes and to detect if an excessive amount of IGMP multicast group joins have been received on the interface. These log messages convey when the configured group limit has been exceeded, when the configured threshold has been exceeded, and when the number of groups drop below the configured threshold.

The **group-threshold** statement enables you to configure the threshold at which a warning message is logged. The range is 1 through 100 percent. The warning threshold is a percentage of the group limit, so you must configure the **group-limit** statement to configure

a warning threshold. For instance, when the number of groups exceed the configured warning threshold, but remain below the configured group limit, multicast groups continue to be accepted, and the device logs the warning message. In addition, the device logs a warning message after the number of groups drop below the configured warning threshold. You can further specify the amount of time (in seconds) between the log messages by configuring the **log-interval** statement. The range is 6 through 32,767 seconds.

You might consider throttling log messages because every entry added after the configured threshold and every entry rejected after the configured limit causes a warning message to be logged. By configuring a log interval, you can throttle the amount of system log warning messages generated for IGMP multicast group joins.

To limit multicast group joins on an IGMP logical interface:

1. Access the logical interface at the IGMP protocol hierarchy level.

```
[edit]
user@host# edit protocols igmp interface interface-name
```

2. Specify the group limit for the interface.

```
[edit protocols igmp interface interface-name]
user@host# set group-limit limit
```

3. (Optional) Configure the threshold at which a warning message is logged.

```
[edit protocols igmp interface interface-name]
user@host# set group-threshold value
```

4. (Optional) Configure the amount of time between log messages.

```
[edit protocols igmp interface interface-name]
user@host# set log-interval seconds
```

To confirm your configuration, use the **show protocols igmp** command. To verify the operation of IGMP on the interface, including the configured group limit and the optional warning threshold and interval between log messages, use the **show igmp interface** command.

Tracing IGMP Protocol Traffic

Tracing operations record detailed messages about the operation of routing protocols, such as the various types of routing protocol packets sent and received, and routing policy actions. You can specify which trace operations are logged by including specific tracing flags. The following table describes the flags that you can include.

| Flag | Description |
|---------------------|-----------------------|
| all | Trace all operations. |
| client-notification | Trace notifications. |

| Flag | Description |
|--------------------------|---|
| general | Trace general flow. |
| group | Trace group operations. |
| host-notification | Trace host notifications. |
| leave | Trace leave group messages (IGMPv2 only). |
| mtrace | Trace mtrace packets. Use the mtrace command to troubleshoot the software. |
| normal | Trace normal events. |
| packets | Trace all IGMP packets. |
| policy | Trace policy processing. |
| query | Trace IGMP membership query messages, including general and group-specific queries. |
| report | Trace membership report messages. |
| route | Trace routing information. |
| state | Trace state transitions. |
| task | Trace task processing. |
| timer | Trace timer processing. |

In the following example, tracing is enabled for all routing protocol packets. Then tracing is narrowed to focus only on IGMP packets of a particular type. To configure tracing operations for IGMP:

1. (Optional) Configure tracing at the routing options level to trace all protocol packets.

```
[edit routing-options traceoptions]
user@host# set file all-packets-trace
user@host# set flag all
```

2. Configure the filename for the IGMP trace file.

```
[edit protocols igmp traceoptions]
user@host# set file igmp-trace
```

3. (Optional) Configure the maximum number of trace files.

```
[edit protocols igmp traceoptions]
user@host# set file files 5
```

4. (Optional) Configure the maximum size of each trace file.

```
[edit protocols igmp traceoptions]
user@host# set file size 1m
```

5. (Optional) Enable unrestricted file access.

```
[edit protocols igmp traceoptions]
user@host# set file world-readable
```

6. Configure tracing flags. Suppose you are troubleshooting issues with a particular multicast group. The following example shows how to flag all events for packets associated with the group IP address.

```
[edit protocols igmp traceoptions]
user@host# set flag group | match 232.1.1.2
```

7. View the trace file.

```
user@host> file list /var/log
user@host> file show /var/log/igmp-trace
```

Disabling IGMP

To disable IGMP on an interface, include the **disable** statement:

```
disable;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols igmp interface *interface-name*]**
- **[edit logical-systems *logical-system-name* protocols igmp interface *interface-name*]**

IGMP Snooping

- [Configuring IGMP Snooping on page 4048](#)
- [Example: Configuring IGMP Snooping on page 4049](#)
- [Using a Switch as an IGMP Querier on page 4051](#)

Configuring IGMP Snooping

With IGMP snooping enabled, a switch monitors the IGMP (Internet Group Management Protocol) traffic between hosts and multicast routers and uses what it learns to forward multicast traffic to only the downstream interfaces that are connected to interested receivers. This conserves bandwidth by allowing the switch to send multicast traffic to only those interfaces that are connected to devices that want to receive the traffic (instead of flooding the traffic to all the downstream VLAN interfaces).

NOTE: You cannot configure IGMP snooping on a secondary VLAN.

To enable IGMP snooping and configure individual options as needed for your network by using the CLI:

1. Enable IGMP snooping on a VLAN:

```
[edit protocols]
user@switch# set igmp-snooping vlan employee-vlan
```

2. Configure the switch to immediately remove group membership from interfaces on a VLAN when it receives a leave message through that VLAN, and have it not forward any membership queries for the multicast group to the VLAN (IGMPv2 only):

```
[edit protocols]
user@switch# set igmp-snooping vlan vlan-name immediate-leave
```

3. Configure an interface to belong to a multicast group:

```
[edit protocols]
user@switch# set igmp-snooping vlan vlan-name interface interface-name static group
group-address
```

4. Configure an interface to forward IGMP queries received from multicast routers.

```
[edit protocols]
user@switch# set igmp-snooping vlan vlan-name interface interface-name
multicast-router-interface
```

5. Configure the switch to wait for four timeout intervals before timing out a multicast group on a VLAN:

```
[edit protocols]
user@switch# set igmp-snooping vlan vlan-name robust-count 4
```

6. If you want the switch to act as an IGMP querier, enter the following:

```
[edit protocols]
user@switch# set igmp-snooping vlan vlan-name igmp-querier source-address source address
```

The switch uses the address that you configure as the source address in the IGMP queries that it sends. If there are any multicast routers on the same local network, make sure the source address for the IGMP querier is greater (a higher number) than the IP addresses for those routers on the network. This ensures that switch is always the IGMP querier on the network.

NOTE: The `igmp-querier` statement is not supported on QFabric systems.

Example: Configuring IGMP Snooping

With IGMP snooping enabled, a switch monitors the IGMP (Internet Group Management Protocol) traffic between hosts and multicast routers and uses what it learns to forward multicast traffic to only the downstream interfaces that are connected to interested receivers. This conserves bandwidth by allowing the switch to send multicast traffic to only those interfaces that are connected to devices that want to receive the traffic (instead of flooding the traffic to all the downstream VLAN interfaces).

This example describes how to configure IGMP snooping:

- [Requirements on page 4049](#)
- [Overview and Topology on page 4049](#)
- [Configuration on page 4050](#)

Requirements

This example requires Junos OS Release 11.1 or later on a QFX Series product.

Before you configure IGMP snooping, be sure you have:

- Configured the **employee-vlan** VLAN
- Assigned interfaces **ge-0/0/1**, **ge-0/0/2**, and **ge-0/0/3** to **employee-vlan**

Overview and Topology

In this example you configure an interface to receive multicast traffic from a source and configure some multicast-related behavior for downstream interfaces. The example assumes that IGMP snooping was previously disabled for the VLAN.

[Table 303 on page 4049](#) shows the components of the topology for this example.

Table 303: Components of the IGMP Snooping Topology

| Components | Settings |
|---|---|
| VLAN name | employee-vlan , tag 20 |
| Interfaces in employee-vlan | ge-0/0/1 , ge-0/0/2 , ge-0/0/3 |
| Multicast IP address for employee-vlan | 225.100.100.100 |

Configuration

To configure basic IGMP snooping on a switch:

CLI Quick Configuration

To quickly configure IGMP snooping, copy the following commands and paste them into a terminal window:

```
[edit protocols]
set igmp-snooping vlan employee-vlan
set igmp-snooping vlan employee-vlan interface ge-0/0/3 static group 225.100.100.100
set igmp-snooping vlan employee-vlan interface ge-0/0/2 multicast-router-interface
set igmp-snooping vlan employee-vlan robust-count 4
```

Step-by-Step Procedure

Configure IGMP snooping:

1. Enable and configure IGMP snooping on the VLAN **employee-vlan**:

```
[edit protocols]
user@switch# set igmp-snooping vlan employee-vlan
```

2. Configure a interface to belong to a multicast group:

```
[edit protocols]
user@switch# set igmp-snooping vlan employee-vlan interface ge-0/0/3 static group
225.100.100.100
```

3. Configure an interface to forward IGMP queries received from multicast routers.

```
[edit protocols]
user@switch# set igmp-snooping vlan employee-vlan interface ge-0/0/2
multicast-router-interface
```

4. Configure the switch to wait for four timeout intervals before timing out a multicast group on a VLAN:

```
[edit protocols]
user@switch# set igmp-snooping vlan employee-vlan robust-count 4
```

Results Check the results of the configuration:

```
user@switch# show protocols igmp-snooping
vlan employee-vlan {
  robust-count 4;
}
interface ge-0/0/2 {
  multicast-router-interface;
}
interface ge-0/0/3 {
  static {
    group 225.100.100.100;
  }
}
```

Using a Switch as an IGMP Querier

If IGMP snooping is enabled on a pure Layer 2 local network (that is, Layer 3 is not enabled on the network), and there is not multicast router in the network, multicast traffic might not be properly forwarded through the network. This problem occurs if the local network is configured such that multicast traffic must be forwarded between switches in order to reach a multicast receiver. In this case, an upstream switch does not forward multicast traffic to a downstream switch (and therefore to the multicast receivers attached to the downstream switch) because the downstream switch does not forward IGMP reports to the upstream switch. You can solve this problem by configuring one of the switches to be an IGMP querier. This switch sends periodic general query packets to all the switches in the network, which ensures that the snooping membership tables are updated and prevents any multicast traffic loss.

If you configure multiple switches to be IGMP queriers, the switch with the highest (greatest) IGMP querier source address takes precedence and acts as the querier. Switches with lower IGMP querier source addresses stop sending IGMP queries unless they do not receive IGMP queries for 255 seconds. If a switch with a lower IGMP querier source address does not receive any IGMP queries during that period, it starts sending queries again.

To configure a switch to act as an IGMP querier, enter the following:

```
[edit protocols]
user@switch# set igmp-snooping vlan vlan-name igmp-querier source-address source address
```

NOTE: The `igmp-querier` statement is not supported on QFabric systems.

Changing the IGMP Snooping Group Timeout Value

The IGMP snooping group timeout value determines how long a switch waits to receive an IGMP query from a multicast router before removing a multicast group from its

multicast cache table. A switch calculates the timeout value by using the **query-interval** and **query-response-interval** values.

When you enable IGMP snooping, the **query-interval** and **query-response-interval** values are applied to all VLANs on the switch. The values are:

- **query-interval**—125 seconds
- **query-response-interval**—10 seconds

The switch automatically calculates the group timeout value for an IGMP snooping-enabled switch by multiplying the **query-interval** value by 2 (the default **robust-count** value) and then adding the **query-response-interval** value. By default, the switch waits 260 seconds to receive an IGMP query before removing a multicast group from its multicast cache table: $(125 \times 2) + 10 = 260$.

You can modify the group timeout value by changing the **robust-count** value. For example, if you want the system to wait 510 seconds before timing groups out— $(125 \times 4) + 10 = 510$ —enter this command:

```
[edit protocols]
user@switch# set igmp-snooping vlan employee-vlan robust-count (IGMP Snooping) 4
```

Configuring Multicast VLAN Registration (CLI Procedure)

Multicast VLAN registration (MVR) enables hosts that are not part of a multicast source VLAN (MVLAN) to still receive multicast streams from the MVLAN, allowing an MVLAN to be shared across a Layer 2 network. Hosts remain in their own VLANs for bandwidth and security reasons but are able to receive multicast streams from the MVLAN.

You can configure one or more VLANs on a switch to be MVLANs or MVR receiver VLANs. By default, MVR is not configured on EX Series switches and the QFX Series.

NOTE: MVR is supported on VLANs running IGMP version 2 (IGMPv2) only.

NOTE: When you configure MVR, the following restrictions apply:

- You cannot enable multicast protocols on VLAN interfaces that are members of MVLANs.
- If you configure an MVLAN in proxy mode, IGMP snooping proxy mode is automatically enabled on all MVR receiver VLANs of this MVLAN. If a VLAN is an MVR receiver VLAN for multiple MVLANs, all of the MVLANs must have proxy mode enabled or all must have proxy mode disabled. You can enable proxy mode only on VLANs that are configured as MVR source VLANs and that are not configured for Q-in-Q tunneling.
- After you configure a VLAN as an MVLAN, that VLAN is no longer available for other uses.

To configure MVR:

1. Configure the VLAN named mv0 to be an MVLAN:

```
[edit protocols]
user@switch# set igmp-snooping vlan mv0 data-forwarding source groups
225.10.0.0/16
```

2. Configure the MVLAN mv0 to be a proxy VLAN:

```
[edit protocols]
user@switch# set igmp-snooping vlan mv0 proxy source-address 10.0.0.1
```

3. Configure the VLAN named v2 to be an MVR receiver VLAN with mv0 as its source:

```
[edit protocols]
user@switch# set igmp-snooping vlan v2 data-forwarding receiver source-vlans mv0
```

4. Install forwarding entries in the MVR receiver VLAN:

```
[edit protocols]
user@switch# set igmp-snooping vlan mv0 data-forwarding receiver install
```

Example: Configuring Multicast VLAN Registration

Multicast VLAN registration (MVR) enables hosts that are not part of a multicast VLAN (MVLAN) to receive multicast streams from the MVLAN, which enable the MVLAN to be shared across the Layer 2 network and eliminate the need to send duplicate multicast streams to each requesting VLAN in the network. Hosts remain in their own VLANs for bandwidth and security reasons.

This example describes how to configure MVR on EX Series switches and the QFX Series.

- [Requirements on page 4054](#)
- [Overview and Topology on page 4054](#)
- [Configuration on page 4057](#)

Requirements

This example uses the following hardware and software components:

- One EX Series switch or the QFX Series
- Junos OS Release 9.6 or later for EX Series switches or Junos OS Release 12.3 or later for the QFX Series

Before you configure MVR, be sure you have:

- Configured two or more VLANs on the switch. See the task for your platform:
 - [Example: Setting Up Bridging with Multiple VLANs for EX Series Switches](#)
 - [“Example: Setting Up Bridging with Multiple VLANs” on page 1451](#) for the QFX Series
- Connected the switch to a network that can transmit IPTV multicast streams from a video server.
- Connected a host that is capable of receiving IPTV multicast streams to an interface in one of the VLANs.

Overview and Topology

In a standard Layer 2 network, a multicast stream received on one VLAN is never distributed to interfaces outside that VLAN. If hosts in multiple VLANs request the same multicast stream, a separate copy of that multicast stream is distributed to the requesting VLANs.

MVR introduces the concept of a *multicast source VLAN* (MVLAN), which is created by MVR and becomes the only VLAN over which multicast traffic flows throughout the Layer 2 network. Multicast traffic can then be selectively forwarded from interfaces on the MVLAN (source ports) to hosts that are connected to interfaces (multicast receiver ports) that are not part of the multicast source VLAN. When you configure an MVLAN, you assign a range of multicast group addresses to it. You then configure other VLANs

to be MVR receiver VLANs, which receive multicast streams from the MVLAN. The MVR receiver ports comprise all the interfaces that exist on any of the MVR receiver VLANs.

You can configure MVR to operate in one of two modes: transparent mode (the default mode) or proxy mode. Both modes enable MVR to forward only one copy of a multicast stream to the Layer 2 network.

In transparent mode, the switch receives one copy of each IPTV multicast stream and then replicates the stream only to those hosts that want to receive it, while forwarding all other types of multicast traffic without modification. [Figure 137 on page 4056](#) shows how MVR operates in transparent mode.

In proxy mode, the switch acts as a proxy for the IGMP multicast router in the MVLAN for MVR group memberships established in the MVR receiver VLANs and generates and sends IGMP packets into the MVLAN as needed. [Figure 138 on page 4057](#) shows how MVR operates in proxy mode.

This example shows how to configure MVR in both transparent mode and proxy mode on an EX Series switch or the QFX Series. The topology includes a video server that is connected to a multicast router, which in turn forwards the IPTV multicast traffic in the MVLAN to the Layer 2 network.

[Figure 137 on page 4056](#) shows the MVR topology in transparent mode. Interfaces P1 and P2 on Switch C belong to service VLAN s0 and MVLAN mv0. Interface P4 of Switch C also belongs to service VLAN s0. In the upstream direction of the network, only non-IPTV traffic is being carried in individual customer VLANs of service VLAN s0. VLAN c0 is an example of this type of customer VLAN. IPTV traffic is being carried on MVLAN mv0. If any host on any customer VLAN connected to port P4 requests an MVR stream, Switch C takes the stream from VLAN mv0 and replicates that stream onto port P4 with tag mv0. IPTV traffic, along with other network traffic, flows from port P4 out to the Digital Subscriber Line Access Multiplexer (DSLAM) D1.

Figure 137: MVR Topology in Transparent Mode

Figure 138 on page 4057 shows the MVR topology in proxy mode. Interfaces P1 and P2 on Switch C belong to MVLAN mv0 and customer VLAN c0. Interface P4 on Switch C is an access port of customer VLAN c0. In the upstream direction of the network, only non-IPTV traffic is being carried on customer VLAN c0. Any IPTV traffic requested by hosts on VLAN c0 is replicated untagged to port P4 based on streams received in MVLAN mv0. IPTV traffic flows from port P4 out to an IPTV-enabled device in Host H1. Other traffic, such as data and voice traffic, also flows from port P4 to other network devices in Host H1.

Figure 138: MVR Topology in Proxy Mode

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit protocols igmp-snooping]** hierarchy level.

```
set vlan mv0 data-forwarding source groups 225.10.0.0/16
set vlan v2 data-forwarding receiver source-vlans mv0
set vlan v2 data-forwarding receiver install
set vlan mv0 proxy source-address 10.1.1.1
```

Step-by-Step Procedure The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure MVR:

1. Configure VLAN mv0 to be an MVLAN:

```
[edit protocols igmp-snooping]  
user@switch# set vlan mv0 data-forwarding source groups 225.10.0.0/16
```
2. Configure VLAN v2 to be a multicast receiver VLAN with mv0 as its source:

```
[edit protocols igmp-snooping]  
user@switch# set vlan v2 data-forwarding receiver source-vlans mv0
```
3. (Optional) Install forwarding entries in the multicast receiver VLAN v2:

```
[edit protocols igmp-snooping]  
user@switch# set vlan v2 data-forwarding receiver install
```
4. (Optional) Configure MVR in proxy mode:

```
[edit protocols igmp-snooping]  
user@switch# set vlan mv0 proxy source-address 10.1.1.1
```

Results From configuration mode, confirm your configuration by entering the **show** command at the **[edit protocols igmp-snooping]** hierarchy level. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit protocols igmp-snooping]  
user@switch# show  
vlan mv0 {  
  proxy {  
    source-address 10.1.1.1;  
  }  
  data-forwarding {  
    source {  
      groups 225.10.0.0/16;  
    }  
  }  
}  
vlan v2 {  
  data-forwarding {  
    receiver {  
      source-vlans mv0;  
      install;  
    }  
  }  
}
```

Configuring VLAN-Specific IGMP Snooping Parameters

All of the IGMP snooping statements configured with the **igmp-snooping** statement, with the exception of the **traceoptions** statement, can be qualified with the same statement at the VLAN level. To configure IGMP snooping parameters at the VLAN level, include the **vlan** statement:

```
vlan vlan-id;
  immediate-leave;
  interface interface-name {
    group-limit limit;
    host-only-interface;
    multicast-router-interface;
    static {
      group ip-address {
        source ip-address;
      }
    }
  }
  proxy {
    source-address ip-address;
  }
  query-interval seconds;
  query-last-member-interval seconds;
  query-response-interval seconds;
  robust-count number;
}
```

You can include this statement at the following hierarchy levels:

- [edit bridge-domains *bridge-domain-name* protocols igmp-snooping]
- [edit routing-instances *routing-instance-name* bridge-domains *bridge-domain-name* protocols igmp-snooping]

Understanding MLD

The Multicast Listener Discovery (MLD) Protocol manages the membership of hosts and routers in multicast groups. IP version 6 (IPv6) multicast routers use MLD to learn, for each of their attached physical networks, which groups have interested listeners. Each routing device maintains a list of host multicast addresses that have listeners for each subnetwork, as well as a timer for each address. However, the routing device does not need to know the address of each listener—just the address of each host. The routing device provides addresses to the multicast routing protocol it uses, which ensures that multicast packets are delivered to all subnetworks where there are interested listeners. In this way, MLD is used as the transport for the Protocol Independent Multicast (PIM) Protocol.

MLD is an integral part of IPv6 and must be enabled on all IPv6 routing devices and hosts that need to receive IP multicast traffic. The Junos OS supports MLD versions 1 and 2. Version 2 is supported for source-specific multicast (SSM) include and exclude modes.

In include mode, the receiver specifies the source or sources it is interested in receiving the multicast group traffic from. Exclude mode works the opposite of include mode. It allows the receiver to specify the source or sources it is not interested in receiving the multicast group traffic from.

For each attached network, a multicast routing device can be either a querier or a nonquerier. A querier routing device, usually one per subnet, solicits group membership information by transmitting MLD queries. When a host reports to the querier routing device that it has interested listeners, the querier routing device forwards the membership information to the rendezvous point (RP) routing device by means of the receiver's (host's) designated router (DR). This builds the rendezvous-point tree (RPT) connecting the host with interested listeners to the RP routing device. The RPT is the initial path used by the sender to transmit information to the interested listeners. Nonquerier routing devices do not transmit MLD queries on a subnet but can do so if the querier routing device fails.

All MLD-configured routing devices start as querier routing devices on each attached subnet (see [Figure 126 on page 3966](#)). The querier routing device on the right is the receiver's DR.

Figure 139: Routing Devices Start Up on a Subnet

To elect the querier routing device, the routing devices exchange query messages containing their IPv6 source addresses. If a routing device hears a query message whose IPv6 source address is numerically lower than its own selected address, it becomes a nonquerier. In [Figure 127 on page 3967](#), the routing device on the left has a source address numerically lower than the one on the right and therefore becomes the querier routing device.

NOTE: In the practical application of MLD, several routing devices on a subnet are nonqueriers. If the elected querier routing device fails, query messages are exchanged among the remaining routing devices. The routing device with the lowest IPv6 source address becomes the new querier routing device. The IPv6 Neighbor Discovery Protocol (NDP) implementation drops incoming Neighbor Announcement (NA) messages that have a broadcast or multicast address in the target link-layer address option. This behavior is recommended by RFC 2461.

Figure 140: Querier Routing Device Is Determined

The querier routing device sends general MLD queries on the **link-scope all-nodes** multicast address FF02::1 at short intervals to all attached subnets to solicit group membership information (see [Figure 128 on page 3967](#)). Within the query message is the *maximum response delay* value, specifying the maximum allowed delay for the host to respond with a report message.

Figure 141: General Query Message Is Issued

If interested listeners are attached to the host receiving the query, the host sends a report containing the host's IPv6 address to the routing device (see [Figure 129 on page 3967](#)). If the reported address is not yet in the routing device's list of multicast addresses with interested listeners, the address is added to the list and a timer is set for the address. If the address is already on the list, the timer is reset. The host's address is transmitted to the RP in the PIM domain.

Figure 142: Reports Are Received by the Querier Routing Device

If the host has no interested multicast listeners, it sends a done message to the querier routing device. On receipt, the querier routing device issues a multicast address-specific query containing the last **listener query interval** value to the multicast address of the host. If the routing device does not receive a report from the multicast address, it removes the multicast address from the list and notifies the RP in the PIM domain of its removal (see [Figure 130 on page 3968](#)).

Figure 143: Host Has No Interested Receivers and Sends a Done Message to Routing Device

If a done message is not received by the querier routing device, the querier routing device continues to send multicast address-specific queries. If the timer set for the address on receipt of the last report expires, the querier routing device assumes there are no longer interested listeners on that subnet, removes the multicast address from the list, and notifies the RP in the PIM domain of its removal (see [Figure 131 on page 3968](#)).

Figure 144: Host Address Timer Expires and Address Is Removed from Multicast Address List

Configuring MLD

To configure the Multicast Listener Discovery (MLD) Protocol, include the **mld** statement:

```
mld {
  accounting;
  interface interface-name {
    disable;
    (accounting | no-accounting);
    group-policy [ policy-names ];
    immediate-leave;
    oif-map [ map-names ];
    passive;
    ssm-map ssm-map-name;
    static {
      group mcast-group-address {
        exclude;
        group-count number;
        group-increment increment;
        source ip-address {
          source-count number;
          source-increment increment;
        }
      }
    }
  }
  version version;
}
maximum-transmit-rate packets-per-second;
query-interval seconds;
query-last-member-interval seconds;
query-response-interval seconds;
robust-count number;
traceoptions {
  file filename <files number> <size size> <world-readable | no-world-readable>;
  flag flag <flag-modifier> <disable>;
}
}
```

You can include this statement at the following hierarchy levels:

- [edit protocols]
- [edit logical-systems *logical-system-name* protocols]

By default, MLD is enabled on all broadcast interfaces when you configure Protocol Independent Multicast (PIM) or the Distance Vector Multicast Routing Protocol (DVMRP).

Enabling MLD

The Multicast Listener Discovery (MLD) Protocol manages multicast groups by establishing, maintaining, and removing groups on a subnet. Multicast routing devices use MLD to learn which groups have members on each of their attached physical networks. MLD must be enabled for the router to receive IPv6 multicast packets. MLD is only needed for IPv6 networks, because multicast is handled differently in IPv4 networks. MLD is enabled on all IPv6 interfaces on which you configure PIM and on all IPv6 broadcast interfaces when you configure DVMRP.

MLD specifies different behaviors for multicast listeners and for routers. When a router is also a listener, the router responds to its own messages. If a router has more than one interface to the same link, it needs to perform the router behavior over only one of those interfaces. Listeners, on the other hand, must perform the listener behavior on all interfaces connected to potential receivers of multicast traffic.

If MLD is not running on an interface—either because PIM and DVMRP are not configured on the interface or because MLD is explicitly disabled on the interface—you can explicitly enable MLD.

To explicitly enable MLD:

1. If PIM and DVMRP are not running on the interface, explicitly enable MLD by including the interface name.

```
[edit protocols mld]
user@host# set interface fe-0/0/0.0
```

2. Check to see if MLD is disabled on any interfaces. In the following example, MLD is disabled on a Gigabit Ethernet interface.

```
[edit protocols mld]
user@host# show

interface fe-0/0/0.0;
interface ge-0/0/0.0 {
    disable;
}
```

3. Enable MLD on the interface by deleting the **disable** statement.

```
[edit protocols mld]
delete interface ge-0/0/0.0 disable
```

4. Verify the configuration.

```
[edit protocols mld]
user@host# show

interface fe-0/0/0.0;
interface ge-0/0/0.0;
```

5. Verify the operation of MLD by checking the output of the **show mld interface** command.

Modifying the MLD Version

By default, the router supports MLD version 1 (MLDv1). To enable the router to use MLD version 2 (MLDv2) for source-specific multicast (SSM) only, include the **version 2** statement.

If you configure the MLD version setting at the individual interface hierarchy level, it overrides configuring the IGMP version using the **interface all** statement.

If a source address is specified in a multicast group that is statically configured, the version must be set to MLDv2.

To change an MLD interface to version 2:

1. Configure the MLD interface.

```
[edit protocols mld]
user@host# set interface fe-0/0/0.0 version 2
```

2. Verify the configuration by checking the **version** field in the output of the **show mld interface** command. The **show mld statistics** command has version-specific output fields, such as the counters in the **MLD Message type** field.

Modifying the MLD Host-Query Message Interval

The objective of MLD is to keep routers up to date with IPv6 group membership of the entire subnet. Routers need not know who all the members are, only that members exist. Each host keeps track of which multicast groups are subscribed to. On each link, one router is elected the querier. The MLD querier router periodically sends general host-query messages on each attached network to solicit membership information. These messages solicit group membership information and are sent to the **link-scope all-nodes** address **FF02::1**. A general host-query message has a maximum response time that you can set by configuring the query response interval.

The query response timeout, the query interval, and the robustness variable are related in that they are all variables that are used to calculate the multicast listener interval. The multicast listener interval is the number of seconds that must pass before a multicast router determines that no more members of a host group exist on a subnet. The multicast listener interval is calculated as the (robustness variable x query-interval) + (1 x query-response-interval). If no reports are received for a particular group before the multicast listener interval has expired, the routing device stops forwarding remotely-originated multicast packets for that group onto the attached network.

By default, host-query messages are sent every 125 seconds. You can change this interval to change the number of MLD messages sent on the subnet.

To modify the query interval:

1. Configure the interval.

```
[edit protocols mld]
user@host# set query-interval 200
```

The value can be from 1 through 1024 seconds.

2. Verify the configuration by checking the **MLD Query Interval** field in the output of the **show mld interface** command.
3. Verify the operation of the query interval by checking the **Listener Query** field in the output of the **show mld statistics** command.

Modifying the MLD Query Response Interval

The query response interval is the maximum amount of time that can elapse between when the querier router sends a host-query message and when it receives a response from a host. You can change this interval to adjust the burst peaks of MLD messages on the subnet. Set a larger interval to make the traffic less bursty.

The query response timeout, the query interval, and the robustness variable are related in that they are all variables that are used to calculate the multicast listener interval. The multicast listener interval is the number of seconds that must pass before a multicast router determines that no more members of a host group exist on a subnet. The multicast listener interval is calculated as the (robustness variable x query-interval) + (1 x query-response-interval). If no reports are received for a particular group before the multicast listener interval has expired, the routing device stops forwarding remotely-originated multicast packets for that group onto the attached network.

The default query response interval is 10 seconds. You can configure a subsecond interval up to one digit to the right of the decimal point. The configurable range is 0.1 through 0.9, then in 1-second intervals 1 through 999,999.

To modify the query response interval:

1. Configure the interval.

```
[edit protocols mld]  
user@host# set query-response-interval 0.5
```

2. Verify the configuration by checking the **MLD Query Response Interval** field in the output of the **show mld interface** command.
3. Verify the operation of the query interval by checking the **Listener Query** field in the output of the **show mld statistics** command.

Modifying the MLD Last-Member Query Interval

The last-member query interval (also called the last-listener query interval) is the maximum amount of time between group-specific query messages, including those sent in response to done messages sent on the **link-scope-all-routers** address FF02::2. You can lower this interval to reduce the amount of time it takes a router to detect the loss of the last member of a group.

When the routing device that is serving as the querier receives a leave-group (done) message from a host, the routing device sends multiple group-specific queries to the group. The querier sends a specific number of these queries, and it sends them at a specific interval. The number of queries sent is called the last-listener query count. The interval at which the queries are sent is called the last-listener query interval. Both settings are configurable, thus allowing you to adjust the leave latency. The IGMP leave latency

is the time between a request to leave a multicast group and the receipt of the last byte of data for the multicast group.

The last-listener query count x (times) the last-listener query interval = (equals) the amount of time it takes a routing device to determine that the last member of a group has left the group and to stop forwarding group traffic.

The default last-listener query interval is 1 second. You can configure a subsecond interval up to one digit to the right of the decimal point. The configurable range is 0.1 through 0.9, then in 1-second intervals 1 through 999,999.

To modify this interval:

1. Configure the time (in seconds) that the routing device waits for a report in response to a group-specific query.

```
[edit protocols mld]
```

```
user@host# set query-last-member-interval 0.1
```

2. Verify the configuration by checking the **MLD Last Member Query Interval** field in the output of the **show igmp interfaces** command.

NOTE: You can configure the last-member query count by configuring the robustness variable. The two are always equal.

Specifying Immediate-Leave Host Removal for MLD

The immediate leave setting is useful for minimizing the leave latency of MLD memberships. When this setting is enabled, the routing device leaves the multicast group immediately after the last host leaves the multicast group.

The immediate-leave setting enables host tracking, meaning that the device keeps track of the hosts that send join messages. This allows MLD to determine when the last host sends a leave message for the multicast group.

When the immediate leave setting is enabled, the device removes an interface from the forwarding-table entry without first sending MLD group-specific queries to the interface. The interface is pruned from the multicast tree for the multicast group specified in the MLD leave message. The immediate leave setting ensures optimal bandwidth management for hosts on a switched network, even when multiple multicast groups are being used simultaneously.

When immediate leave is disabled and one host sends a leave group message, the routing device first sends a group query to determine if another receiver responds. If no receiver responds, the routing device removes all hosts on the interface from the multicast group. Immediate leave is disabled by default for both MLD version 1 and MLD version 2.

NOTE: Although host tracking is enabled for IGMPv2 and MLDv1 when you enable immediate leave, use immediate leave with these versions only when there is one host on the interface. The reason is that IGMPv2 and MLDv1 use a report suppression mechanism whereby only one host on an interface sends a group join report in response to a membership query. The other interested hosts suppress their reports. The purpose of this mechanism is to avoid a flood of reports for the same group. But it also interferes with host tracking, because the router only knows about the one interested host and does not know about the others.

To enable immediate leave:

1. Configure immediate leave on the MLD interface.

```
[edit protocols mld]
user@host# set interface ge-0/0/0.1 immediate-leave
```

2. Verify the configuration by checking the **Immediate Leave** field in the output of the **show mld interface** command.

Filtering Unwanted MLD Reports at the MLD Interface Level

Suppose you need to limit the subnets that can join a certain multicast group. The **group-policy** statement enables you to filter unwanted MLD reports at the interface level.

When the **group-policy** statement is enabled on a router, after the router receives an MLD report, the router compares the group against the specified group policy and performs the action configured in that policy (for example, rejects the report if the policy matches the defined address or network).

You define the policy to match only MLD group addresses (for MLDv1) by using the policy's **route-filter** statement to match the group address. You define the policy to match MLD (source, group) addresses (for MLDv2) by using the policy's **route-filter** statement to match the group address and the policy's **source-address-filter** statement to match the source address.

To filter unwanted MLD reports:

1. Configure an MLDv1 policy.

```
[edit policy-statement reject_policy_v1]
user@host# set from route-filter fec0:1:1:4::/64 exact
user@host# set then reject
```

2. Configure an MLDv2 policy.

```
[edit policy-statement reject_policy_v2]
user@host# set from route-filter fec0:1:1:4::/64 exact
user@host# set from source-address-filter fe80::2e0:81ff:fe05:1a8d/32 orlonger
user@host# set then reject
```

3. Apply the policies to the MLD interfaces where you prefer not to receive specific group or (source, group) reports. In this example, **ge-0/0/0.1** is running MLDv1 and **ge-0/1/1.0** is running MLDv2.

```
[edit protocols mld]
user@host# set interface ge-0/0/0.1 group-policy reject_policy_v1
user@host# set interface ge-0/1/1.0 group-policy reject_policy_v2
```

4. Verify the operation of the filter by checking the **Rejected Report** field in the output of the **show mld statistics** command.

Example: Modifying the MLD Robustness Variable

This example shows how to configure and verify the MLD robustness variable in a multicast domain.

- [Requirements on page 4069](#)
- [Overview on page 4069](#)
- [Configuration on page 4070](#)
- [Verification on page 4070](#)

Requirements

Before you begin:

- Configure the router interfaces. See the *Junos OS Network Interfaces Library for Routing Devices*.
- Configure an interior gateway protocol or static routing. See the *Junos OS Routing Protocols Library for Routing Devices*.
- Enable IPv6 unicast routing. See the *Junos OS Routing Protocols Library for Routing Devices*.
- Enable PIM. See [“PIM Overview” on page 3937](#).

Overview

The MLD robustness variable can be fine-tuned to allow for expected packet loss on a subnet. Increasing the robust count allows for more packet loss but increases the leave latency of the subnetwork.

The value of the robustness variable is used in calculating the following MLD message intervals:

- Group member interval—Amount of time that must pass before a multicast router determines that there are no more members of a group on a network. This interval is calculated as follows: (robustness variable x query-interval) + (1 x query-response-interval).
- Other querier present interval—Amount of time that must pass before a multicast router determines that there is no longer another multicast router that is the querier. This interval is calculated as follows: (robustness variable x query-interval) + (0.5 x query-response-interval).

- Last-member query count—Number of group-specific queries sent before the router assumes there are no local members of a group. The default number is the value of the robustness variable.

By default, the robustness variable is set to 2. The number can be from 2 through 10. You might want to increase this value if you expect a subnet to lose packets.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
set protocols mld robust-count 5
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To change the value of the robustness variable:

1. Configure the robust count.

```
[edit protocols mld]  
user@host# set robust-count 5
```

2. If you are done configuring the device, commit the configuration.

```
[edit protocols mld]  
user@host# commit
```

Verification

To verify the configuration is working properly, check the **MLD Robustness Count** field in the output of the **show mld interfaces** command.

Limiting the Maximum MLD Message Rate

You can change the limit for the maximum number of MLD packets transmitted in 1 second by the router.

Increasing the maximum number of MLD packets transmitted per second might be useful on a router with a large number of interfaces participating in MLD.

To change the limit for the maximum number of MLD packets the router can transmit in 1 second, include the **maximum-transmit-rate** statement and specify the maximum number of packets per second to be transmitted.

Enabling MLD Static Group Membership

You can create MLD static group membership to test multicast forwarding without a receiver host. When you enable MLD static group membership, data is forwarded to an interface without that interface receiving membership reports from downstream hosts.

Class-of-service (CoS) adjustment is not supported with MLD static group membership.

When you configure static groups on an interface on which you want to receive multicast traffic, you can specify the number of static groups to be automatically created.

In this example, you create static group ff0e::1:ff05:1a8d.

1. Configure the static groups to be created by including the **static** statement and **group** statement and specifying which IPv6 multicast address of the group to be created.

```
[edit protocols mld]
```

```
user@host# set interface fe-0/1/2 static group ff0e::1:ff05:1a8d
```

2. After you commit the configuration, use the **show configuration protocol mld** command to verify the MLD protocol configuration.

```
user@host> show configuration protocol mld
```

```
interface fe-0/1/2.0 {
  static {
    group ff0e::1:ff05:1a8d;
  }
}
```

3. After you have committed the configuration and after the source is sending traffic, use the **show mld group** command to verify that static group ff0e::1:ff05:1a8d has been created.

```
user@host> show mld group
Interface: fe-0/1/2
Group: ff0e::1:ff05:1a8d
Group mode: Include
Source: fe80::2e0:81ff:fe05:1a8d
Last reported by: Local
Timeout: 0 Type: Static
```

NOTE: You must specify a unique address for each group.

Automatically create static groups

When you create MLD static group membership to test multicast forwarding on an interface on which you want to receive multicast traffic, you can specify that a number of static groups be automatically created. This is useful when you want to test forwarding to multiple receivers without having to configure each receiver separately.

In this example, you create three groups.

1. Configure the number of static groups to be created by including the **group-count** statement and specifying the number of groups to be created.

```
[edit protocols mld]
```

```
user@host# set interface fe-0/1/2 static group ff0e::1:ff05:1a8d group-count 3
```

2. After you commit the configuration, use the **show configuration protocol mld** command to verify the MLD protocol configuration.

```
user@host> show configuration protocol mld
```

```
interface fe-0/1/2.0 {
  static {
    group ff0e::1:ff05:1a8d {
      group-count 3;
    }
  }
}
```

3. After you have committed the configuration and the source is sending traffic, use the **show mld group** command to verify that static groups ff0e::1:ff05:1a8d, ff0e::1:ff05:1a8e, and ff0e::1:ff05:1a8f have been created.

```
user@host> show mld group
```

```
Interface: fe-0/1/2
  Group: ff0e::1:ff05:1a8d
    Source: fe80::2e0:81ff:fe05:1a8d
    Last reported by: Local
    Timeout: 0 Type: Static
Interface: fe-0/1/2
  Group: ff0e::1:ff05:1a8e
    Source: fe80::2e0:81ff:fe05:1a8d
    Last reported by: Local
    Timeout: 0 Type: Static
Interface: fe-0/1/2
  Group: ff0e::1:ff05:1a8f
    Source: fe80::2e0:81ff:fe05:1a8d
    Last reported by: Local
    Timeout: 0 Type: Static
```

Automatically increment group addresses

When you configure static groups on an interface on which you want to receive multicast traffic and you specify the number of static groups to be automatically created, you can also configure the group address to be automatically incremented by some number of addresses.

In this example, you create three groups and increase the group address by an increment of two for each group.

1. Configure the group address increment by including the **group-increment** statement and specifying the number by which the address should be incremented for each group. The increment is specified in a format similar to an IPv6 address.

```
[edit protocols mld]
```

```
user@host# set interface fe-0/1/2 static group ff0e::1:ff05:1a8d group-count 3
group-increment ::2
```

2. After you commit the configuration, use the **show configuration protocol mld** command to verify the MLD protocol configuration.

```
user@host> show configuration protocol mld
```

```
interface fe-0/1/2.0 {
  static {
```

```

        group ff0e::1:ff05:1a8d {
            group-increment ::2;
            group-count 3;
        }
    }
}

```

3. After you have committed the configuration and the source is sending traffic, use the **show mld group** command to verify that static groups ff0e::1:ff05:1a8d, ff0e::1:ff05:1a8f, and ff0e::1:ff05:1a91 have been created.

```
user@host> show mld group
```

```

Interface: fe-0/1/2
  Group: ff0e::1:ff05:1a8d
    Source: fe80::2e0:81ff:fe05:1a8d
    Last reported by: Local
    Timeout: 0 Type: Static

```

Specify multicast source address (in SSM mode)

When you configure static groups on an interface on which you want to receive multicast traffic and your network is operating in source-specific multicast (SSM) mode, you can specify the multicast source address to be accepted.

If you specify a group address in the SSM range, you must also specify a source.

If a source address is specified in a multicast group that is statically configured, the MLD version must be set to MLDv2 on the interface. MLDv1 is the default value.

In this example, you create group ff0e::1:ff05:1a8d and accept IPv6 address fe80::2e0:81ff:fe05:1a8d as the only source.

1. Configure the source address by including the **source** statement and specifying the IPv6 address of the source host.

```

[edit protocols mld]
user@host# set interface fe-0/1/2 static group ff0e::1:ff05:1a8d source
fe80::2e0:81ff:fe05:1a8d

```

2. After you commit the configuration, use the **show configuration protocol mld** command to verify the MLD protocol configuration.

```

user@host> show configuration protocol mld

interface fe-0/1/2.0 {
    static {

```

```
group ff0e::1:ff05:1a8d {
  source fe80::2e0:81ff:fe05:1a8d;
}
}
```

3. After you have committed the configuration and the source is sending traffic, use the **show mld group** command to verify that static group ff0e::1:ff05:1a8d has been created and that source fe80::2e0:81ff:fe05:1a8d has been accepted.

```
user@host> show mld group
```

```
Interface: fe-0/1/2
Group: ff0e::1:ff05:1a8d
Source: fe80::2e0:81ff:fe05:1a8d
Last reported by: Local
Timeout: 0 Type: Static
```

Automatically specify multicast sources

When you configure static groups on an interface on which you want to receive multicast traffic, you can specify a number of multicast sources to be automatically accepted.

In this example, you create static group ff0e::1:ff05:1a8d and accept fe80::2e0:81ff:fe05:1a8d, fe80::2e0:81ff:fe05:1a8e, and fe80::2e0:81ff:fe05:1a8f as the source addresses.

1. Configure the number of multicast source addresses to be accepted by including the **source-count** statement and specifying the number of sources to be accepted.

```
[edit protocols mld]
```

```
user@host# set interface fe-0/1/2 static group ff0e::1:ff05:1a8d source
fe80::2e0:81ff:fe05:1a8d source-count 3
```

2. After you commit the configuration, use the **show configuration protocol mld** command to verify the MLD protocol configuration.

```
user@host> show configuration protocol mld
```

```
interface fe-0/1/2.0 {
  static {
    group ff0e::1:ff05:1a8d {
      source fe80::2e0:81ff:fe05:1a8d {
        source-count 3;
      }
    }
  }
}
```

3. After you have committed the configuration and the source is sending traffic, use the **show mld group** command to verify that static group ff0e::1:ff05:1a8d has been created and that sources fe80::2e0:81ff:fe05:1a8d, fe80::2e0:81ff:fe05:1a8e, and fe80::2e0:81ff:fe05:1a8f have been accepted.

```
user@host> show mld group
```

```
Interface: fe-0/1/2
Group: ff0e::1:ff05:1a8d
```

```

        Source: fe80::2e0:81ff:fe05:1a8d
        Last reported by: Local
        Timeout: 0 Type: Static

    Source: fe80::2e0:81ff:fe05:1a8f
    Last reported by: Local
    Timeout: 0 Type: Static

```

Automatically increment source addresses

When you configure static groups on an interface on which you want to receive multicast traffic, and specify a number of multicast sources to be automatically accepted, you can also specify the number by which the address should be incremented for each source accepted.

In this example, you create static group ff0e::1:ff05:1a8d and accept fe80::2e0:81ff:fe05:1a8d, fe80::2e0:81ff:fe05:1a8f, and fe80::2e0:81ff:fe05:1a91 as the sources.

1. Configure the number of multicast source addresses to be accepted by including the **source-increment** statement and specifying the number of sources to be accepted.

```
[edit protocols mld]
```

```
user@host# set interface fe-0/1/2 static group ff0e::1:ff05:1a8d source
fe80::2e0:81ff:fe05:1a8d source-count 3 source-increment ::2
```

2. After you commit the configuration, use the **show configuration protocol mld** command to verify the MLD protocol configuration.

```
user@host> show configuration protocol mld
```

```

interface fe-0/1/2.0 {
  static {
    group ff0e::1:ff05:1a8d {
      source fe80::2e0:81ff:fe05:1a8d {
        source-count 3;
        source-increment ::2;
      }
    }
  }
}

```

3. After you have committed the configuration and the source is sending traffic, use the **show mld group** command to verify that static group ff0e::1:ff05:1a8d has been created and that sources fe80::2e0:81ff:fe05:1a8d, fe80::2e0:81ff:fe05:1a8f, and fe80::2e0:81ff:fe05:1a91 have been accepted.

```
user@host> show mld group
```

```
Interface: fe-0/1/2
```

```
Group: ff0e::1:ff05:1a8d

Exclude multicast source addresses (in SSM mode)

When you configure static groups on an interface on which you want to receive multicast traffic and your network is operating in source-specific multicast (SSM) mode, you can specify that certain multicast source addresses be excluded.

By default the multicast source address configured in a static group operates in include mode. In include mode the multicast traffic for the group is accepted from the configured source address. You can also configure the static group to operate in exclude mode. In exclude mode the multicast traffic for the group is accepted from any address other than the configured source address.

If a source address is specified in a multicast group that is statically configured, the MLD version must be set to MLDv2 on the interface. MLDv1 is the default value.

In this example, you exclude address fe80::2e0:81ff:fe05:1a8d as a source for group ff0e::1:ff05:1a8d.

1. Configure a multicast static group to operate in exclude mode by including the **exclude** statement and specifying which IPv6 source address to be excluded.

```
[edit protocols mld]
user@host# set interface fe-0/1/2 static group ff0e::1:ff05:1a8d exclude source
fe80::2e0:81ff:fe05:1a8d
```

2. After you commit the configuration, use the **show configuration protocol mld** command to verify the MLD protocol configuration.

```
user@host> show configuration protocol mld

interface fe-0/1/2.0 {
  static {
    group ff0e::1:ff05:1a8d {
      exclude;
      source fe80::2e0:81ff:fe05:1a8d;
    }
  }
}
```

3. After you have committed the configuration and the source is sending traffic, use the **show mld group detail** command to verify that static group ff0e::1:ff05:1a8d has been created and that the static group is operating in exclude mode.

```
user@host> show mld group detail
Interface: fe-0/1/2
  Group: ff0e::1:ff05:1a8d
    Group mode: Exclude
    Source: fe80::2e0:81ff:fe05:1a8d
    Last reported by: Local
    Timeout: 0 Type: Static
```

Similar configuration is available for IPv4 multicast traffic using the IGMP protocol.

Example: Recording MLD Join and Leave Events

This example shows how to determine whether MLD tuning is needed in a network by configuring the routing device to record MLD join and leave events.

- [Requirements on page 4077](#)
- [Overview on page 4077](#)
- [Configuration on page 4078](#)
- [Verification on page 4079](#)

Requirements

Before you begin:

- Configure the router interfaces. See the *Junos OS Network Interfaces Library for Routing Devices*.
- Configure an interior gateway protocol or static routing. See the *Junos OS Routing Protocols Library for Routing Devices*.
- Enable IPv6 unicast routing. See the *Junos OS Routing Protocols Library for Routing Devices*.
- Enable PIM. See “[PIM Overview](#)” on page 3937.

Overview

[Table 304 on page 4078](#) describes the recordable MLD join and leave events.

Table 304: MLD Event Messages

| ERRMSG Tag | Definition |
|----------------------------|--|
| RPD_MLD_JOIN | Records MLD join events. |
| RPD_MLD_LEAVE | Records MLD leave events. |
| RPD_MLD_ACCOUNTING_ON | Records when MLD accounting is enabled on an MLD interface. |
| RPD_MLD_ACCOUNTING_OFF | Records when MLD accounting is disabled on an MLD interface. |
| RPD_MLD_MEMBERSHIP_TIMEOUT | Records MLD membership timeout events. |

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
set protocols mld interface fe-0/1/0.2 accounting
set system syslog file mld-events any info
set system syslog file mld-events match ".*RPD_MLD_JOIN.* | .*.RPD_MLD_LEAVE.* |
.*RPD_MLD_ACCOUNTING.* | .*.RPD_MLD_MEMBERSHIP_TIMEOUT.*"
set system syslog file mld-events archive size 100000
set system syslog file mld-events archive files 3
set system syslog file mld-events archive transfer-interval 1440
set system syslog file mld-events archive archive-sites "ftp://user@host1//var/tmp"
password "anonymous"
set system syslog file mld-events archive archive-sites "ftp://user@host2//var/tmp"
password "test"
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure recording of MLD join and leave events:

1. Enable accounting globally or on an MLD interface. This example shows the interface configuration.

```
[edit protocols mld]
user@host# set interface fe-0/1/0.2 accounting
```

2. Configure the events to be recorded, and filter the events to a system log file with a descriptive filename, such as **mld-events**.

```
[edit system syslog file mld-events]
user@host# set any info
[edit system syslog file mld-events]
user@host# set match ".*RPD_MLD_JOIN.* | .*.RPD_MLD_LEAVE.* |
.*RPD_MLD_ACCOUNTING.* | .*.RPD_MLD_MEMBERSHIP_TIMEOUT.*"
```

3. Periodically archive the log file.

This example rotates the file every 24 hours (1440 minutes) when it reaches 100 KB and keeps three files.

```
[edit system syslog file mld-events]
user@host# set archive size 100000
[edit system syslog file mld-events]
user@host# set archive files 3
[edit system syslog file mld-events]
user@host# set archive archive-sites "ftp://user@host1//var/tmp" password
"anonymous"
[edit system syslog file mld-events]
user@host# set archive archive-sites "ftp://user@host2//var/tmp" password "test"
[edit system syslog file mld-events]
user@host# set archive transfer-interval 1440
[edit system syslog file mld-events]
user@host# set archive start-time 2011-01-07:12:30
```

4. If you are done configuring the device, commit the configuration.

```
[edit system syslog file mld-events]]
user@host# commit
```

Verification

You can view the system log file by running the `file show` command.

```
user@host> file show mld-events
```

You can monitor the system log file as entries are added to the file by running the ***monitor start*** and ***monitor stop*** commands.

```
user@host> monitor start mld-events
```

```
*** mld-events ***
Apr 16 13:08:23 host mgd[16416]: UI_CMDLINE_READ_LINE: User 'user', command 'run
monitor start mld-events '
monitor
```

Configuring the Number of MLD Multicast Group Joins on Logical Interfaces

The **group-limit** statement enables you to limit the number of MLD multicast group joins for logical interfaces. When this statement is enabled on a router running MLD version 2, the limit is applied upon receipt of the group report. Once the group limit is reached, subsequent join requests are rejected.

When configuring limits for MLD multicast groups, keep the following in mind:

- Each any-source group (*G) counts as one group toward the limit.
- Each source-specific group (S,G) counts as one group toward the limit.
- Groups in MLDv2 exclude mode are counted toward the limit.
- Multiple source-specific groups count individually toward the group limit, even if they are for the same group. For example, (S1, G1) and (S2, G1) would count as two groups toward the configured limit.

- Combinations of any-source groups and source-specific groups count individually toward the group limit, even if they are for the same group. For example, (*, G1) and (S, G1) would count as two groups toward the configured limit.
- Configuring and committing a group limit on a network that is lower than what already exists on the network results in the removal of all groups from the configuration. The groups must then request to rejoin the network (up to the newly configured group limit).
- You can dynamically limit multicast groups on MLD logical interfaces by using dynamic profiles. For detailed information about creating dynamic profiles, see the *Junos OS Subscriber Management and Services Library*.

Beginning with Junos OS 12.2, you can optionally configure a system log warning threshold for MLD multicast group joins received on the logical interface. It is helpful to review the system log messages for troubleshooting purposes and to detect if an excessive amount of MLD multicast group joins have been received on the interface. These log messages convey when the configured group limit has been exceeded, when the configured threshold has been exceeded, and when the number of groups drop below the configured threshold.

The **group-threshold** statement enables you to configure the threshold at which a warning message is logged. The range is 1 through 100 percent. The warning threshold is a percentage of the group limit, so you must configure the **group-limit** statement to configure a warning threshold. For instance, when the number of groups exceed the configured warning threshold, but remain below the configured group limit, multicast groups continue to be accepted, and the device logs a warning message. In addition, the device logs a warning message after the number of groups drop below the configured warning threshold. You can further specify the amount of time (in seconds) between the log messages by configuring the **log-interval** statement. The range is 6 through 32,767 seconds.

You might consider throttling log messages because every entry added after the configured threshold and every entry rejected after the configured limit causes a warning message to be logged. By configuring a log interval, you can throttle the amount of system log warning messages generated for MLD multicast group joins.

To limit multicast group joins on an MLD logical interface:

1. Access the logical interface at the MLD protocol hierarchy level.

```
[edit]
user@host# edit protocols mld interface interface-name
```

2. Specify the group limit for the interface.

```
[edit protocols mld interface interface-name]
user@host# set group-limit limit
```

3. (Optional) Configure the threshold at which a warning message is logged.

```
[edit protocols mld interface interface-name]
user@host# set group-threshold value
```

4. (Optional) Configure the amount of time between log messages.

```
[edit protocols mld interface interface-name]
user@host# set log-interval seconds
```

To confirm your configuration, use the **show protocols mld** command. To verify the operation of MLD on the interface, including the configured group limit and the optional warning threshold and interval between log messages, use the **show mld interface** command.

Tracing MLD Protocol Traffic

Tracing operations record detailed messages about the operation of routing protocols, such as the various types of routing protocol packets sent and received, and routing policy actions. You can specify which trace operations are logged by including specific tracing flags. The following table describes the flags that you can include.

| Flag | Description |
|----------------------------|--|
| all | Trace all operations. |
| client-notification | Trace notifications. |
| general | Trace general flow. |
| group | Trace group operations. |
| host-notification | Trace host notifications. |
| leave | Trace leave group messages. |
| mtrace | Trace mtrace packets. Use the mtrace command to troubleshoot the software. |
| normal | Trace normal events. |
| packets | Trace all MLD packets. |
| policy | Trace policy processing. |
| query | Trace MLD membership query messages, including general and group-specific queries. |
| report | Trace membership report messages. |
| route | Trace routing information. |
| state | Trace state transitions. |
| task | Trace task processing. |
| timer | Trace timer processing. |

In the following example, tracing is enabled for all routing protocol packets. Then tracing is narrowed to focus only on MLD packets of a particular type. To configure tracing operations for MLD:

1. (Optional) Configure tracing at the routing options level to trace all protocol packets.

```
[edit routing-options traceoptions]
user@host# set file all-packets-trace
user@host# set flag all
```

2. Configure the filename for the MLD trace file.

```
[edit protocols mld traceoptions]
user@host# set file mld-trace
```

3. (Optional) Configure the maximum number of trace files.

```
[edit protocols mld traceoptions]
user@host# set file files 5
```

4. (Optional) Configure the maximum size of each trace file.

```
[edit protocols mld traceoptions]
user@host# set file size 1m
```

5. (Optional) Enable unrestricted file access.

```
[edit protocols mld traceoptions]
user@host# set file world-readable
```

6. Configure tracing flags. Suppose you are troubleshooting issues with a particular interface. The following example shows how to flag all events for packets associated with the interface name.

```
[edit protocols mld traceoptions]
user@host# set flag all | match fe-1/0/1.0
```

7. View the trace file.

```
user@host> file list /var/log
user@host> file show /var/log/mld-trace
```

Disabling MLD

To disable MLD on an interface, include the **disable** statement:

```
interface interface-name {
  disable;
}
```

You can include this statement at the following hierarchy levels:

- [edit protocols mld]
- [edit logical-systems *logical-system-name* protocols mld]

Configuring MSDP

To configure the Multicast Source Discovery Protocol (MSDP), include the **msdp** statement:

```
msdp {
  disable;
  active-source-limit {
    maximum number;
    threshold number;
  }
  data-encapsulation (disable | enable);
  export [ policy-names ];
  group group-name {
    ... group-configuration ...
  }
  hold-time seconds;
  import [ policy-names ];
  local-address address;
  keep-alive seconds;
  peer address {
    ... peer-configuration ...
  }
  rib-group group-name;
  source ip-prefix </prefix-length> {
    active-source-limit {
      maximum number;
      threshold number;
    }
  }
  sa-hold-time seconds;
  traceoptions {
    file filename <files number> <size size> <world-readable | no-world-readable>;
    flag flag <flag-modifier> <disable>;
  }
  group group-name {
    disable;
    export [ policy-names ];
    import [ policy-names ];
    local-address address;
    mode (mesh-group | standard);
  }
}
```

```

peer address {
  ... same statements as at the [edit protocols msdp peer address] hierarchy level shown
  just following ...
}
traceoptions {
  file filename <files number> <size size> <world-readable | no-world-readable>;
  flag flag <flag-modifier> <disable>;
}
}
peer address {
  disable;
  active-source-limit {
    maximum number;
    threshold number;
  }
  authentication-key peer-key;
  default-peer;
  export [ policy-names ];
  import [ policy-names ];
  local-address address;
  traceoptions {
    file filename <files number> <size size> <world-readable | no-world-readable>;
    flag flag <flag-modifier> <disable>;
  }
}
}

```

You can include this statement at the following hierarchy levels:

- [edit protocols]
- [edit routing-instances *routing-instance-name* protocols]
- [edit logical-systems *logical-system-name* protocols]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols]

By default, MSDP is disabled.

Tracing MSDP Protocol Traffic

Tracing operations record detailed messages about the operation of routing protocols, such as the various types of routing protocol packets sent and received, and routing policy actions. You can specify which trace operations are logged by including specific tracing flags. The following table describes the flags that you can include.

| Flag | Description |
|------|-----------------------|
| all | Trace all operations. |

| Flag | Description |
|-------------------------------|--|
| general | Trace general events. |
| keepalive | Trace keepalive messages. |
| normal | Trace normal events. |
| packets | Trace all MSDP packets. |
| policy | Trace policy processing. |
| route | Trace MSDP changes to the routing table. |
| source-active | Trace source-active packets. |
| source-active-request | Trace source-active request packets. |
| source-active-response | Trace source-active response packets. |
| state | Trace state transitions. |
| task | Trace task processing. |
| timer | Trace timer processing. |

You can configure MSDP tracing for all peers, for all peers in a particular group, or for a particular peer.

In the following example, tracing is enabled for all routing protocol packets. Then tracing is narrowed to focus only on MSDP peers in a particular group. To configure tracing operations for MSDP:

1. (Optional) Configure tracing by including the **traceoptions** statement at the **[edit routing-options]** hierarchy level and set the **all-packets-trace** and **all** flags to trace all protocol packets.

```
[edit routing-options traceoptions]
user@host# set file all-packets-trace
user@host# set flag all
```

2. Configure the filename for the MSDP trace file.

```
[edit protocols msdp group groupa traceoptions]
user@host# set file msdp-trace
```

3. (Optional) Configure the maximum number of trace files.

```
[edit protocols msdp group groupa traceoptions]
user@host# set file files 5
```

4. (Optional) Configure the maximum size of each trace file.

```
[edit protocols msdp group groupa traceoptions]
```

```
user@host# set file size 1m
```

5. (Optional) Enable unrestricted file access.

```
[edit protocols msdp group groupa traceoptions]  
user@host# set file world-readable
```

6. Configure tracing flags. Suppose you are troubleshooting issues with the source-active cache for **groupa**. The following example shows how to trace messages associated with the group address.

```
[edit protocols msdp group groupa traceoptions]  
user@host# set flag source-active | match 230.0.0.3
```

7. View the trace file.

```
user@host> file list /var/log  
user@host> file show /var/log/msdp-trace
```

Configuring the Interface to Accept Traffic from a Remote Source

You can configure an incoming interface to accept traffic from a remote source. A remote source is a source that is not on the same subnet as the incoming interface. This enables the remote source to be learned and advertised by MSDP so that receivers in other MSDP areas can join the source. You do not need to disable RPF checking, but you do need to ensure that the best path to reach the remote source is through the incoming interface.

In this sample configuration, the incoming interface (**ge-1/3/0**) is on a provider edge (PE) router on the receiver side of a multicast VPN.

To accept traffic from a remote source:

1. Edit the incoming interface.

```
[edit protocols pim interface ge-1/3/0.0]  
user@host# set accept-remote-source
```

2. If the incoming interface is not the only way to reach the remote source, ensure that the best path to reach the remote source is through the incoming interface. One way to do this is to use AS path prepending on the other possible routes.

```
[edit policy-options policy-statement as-path-prepend term prepend]  
user@host# set from route-filter 192.168.0.0/16 orlonger  
user@host# set from route-filter 172.16.0.0/16 orlonger  
user@host# set then as-path-prepend "1111"
```

Another way to do this might be to configure a static route on the receiver side PE router to the source.

4. After the configuration is committed, use the **show pim statistics** and **show msdp source** commands to verify that the interface is accepting traffic from the remote source.

Example: Configuring MSDP

Configure a router to act as a PIM sparse-mode rendezvous point and an MSDP peer:

```
[edit]
routing-options {
  interface-routes {
    rib-group ifrg;
  }
  rib-groups {
    ifrg {
      import-rib [inet.0 inet.2];
    }
    mcrg {
      export-rib inet.2;
      import-rib inet.2;
    }
  }
}
protocols {
  bgp {
    group lab {
      type internal;
      family any;
      neighbor 192.168.6.18 {
        local-address 192.168.6.17;
      }
    }
  }
  pim {
    dense-groups {
      224.0.1.39/32;
      224.0.1.40/32;
    }
    rib-group mcrg;
    rp {
      local {
        address 192.168.1.1;
      }
    }
    interface all {
      mode sparse-dense;
      version 1;
    }
  }
  msdp {
```

```
rib-group mcrg;  
group lab {  
    peer 192.168.6.18 {  
        local-address 192.168.6.17;  
    }  
}  
}
```

Example: Configuring MSDP with Active Source Limits and Mesh Groups

This example shows how to configure MSDP to filter source-active messages and limit the flooding of source-active messages.

- [Requirements on page 4088](#)
- [Overview on page 4088](#)
- [Configuration on page 4092](#)
- [Verification on page 4094](#)

Requirements

Before you begin:

- Configure the router interfaces. See the *Junos OS Network Interfaces Library for Routing Devices*.
- Configure an interior gateway protocol or static routing. See the *Junos OS Routing Protocols Library for Routing Devices*.
- Enable PIM sparse mode. See “[PIM Overview](#)” on page 3937.
- Configure the router as a PIM sparse-mode RP. See “[Configuring Local PIM RPs](#)” on page 3995.

Overview

A router interested in MSDP messages, such as an RP, might have to process a large number of MSDP messages, especially source-active messages, arriving from other routers. Because of the potential need for a router to examine, process, and create state tables for many MSDP packets, there is a possibility of an MSDP-based denial-of-service (DoS) attack on a router running MSDP. To minimize this possibility, you can configure the router to limit the number of source active messages the router accepts. Also, you can configure a threshold for applying random early discard (RED) to drop some but not all MSDP active source messages. Beginning with Junos OS 12.2, you can optionally configure a warning threshold so the device can log warning messages in the system log when a certain number of source-active messages have been received. It is helpful to review the system log messages for troubleshooting purposes and to detect if an excessive amount of source-active messages have been received. These log messages convey when the configured message limit has been exceeded, when the configured warning threshold has been exceeded, and when the number of messages drop below the configured warning threshold.

By default, the router accepts 25,000 source active messages before ignoring the rest. The limit can be from 1 through 1,000,000. The limit is applied to both the number of messages and the number of MSDP peers.

By default, the router accepts 24,000 source-active messages before applying the RED profile to prevent a possible DoS attack. This number can also range from 1 through 1,000,000. The next 1000 messages are screened by the RED profile and the accepted messages processed. If you configure no drop profiles (as this example does not), RED is still in effect and functions as the primary mechanism for managing congestion. In the default RED drop profile, when the packet queue fill-level is 0 percent, the drop probability is 0 percent. When the fill-level is 100 percent, the drop probability is 100 percent.

NOTE: The router ignores source-active messages with encapsulated TCP packets. Multicast does not use TCP; segments inside source-active messages are most likely the result of worm activity.

The number configured for the threshold must be less than the number configured for the maximum number of active MSDP sources.

The warning threshold is a percentage of maximum number of MSDP source-active messages received, so you must configure the source-active message limit to configure a warning threshold. The range for the warning threshold is 1 through 100 percent. You can further specify the amount of time (in seconds) between the log messages. The range is 6 through 32,767 seconds.

You can configure an active source limit globally, for a group, or for a peer. If active source limits are configured at multiple levels of the hierarchy (as shown in this example), all are applied.

You can configure an active source limit for an address range as well as for a specific peer. A per-source active source limit uses an IP prefix and prefix length instead of a specific address. You can configure more than one per-source active source limit. The longest match determines the limit.

Per-source active source limits can be combined with active source limits at the peer, group, and global (instance) hierarchy level. Per-source limits are applied before any other type of active source limit. Limits are tested in the following order:

- Per-source
- Per-peer or group
- Per-instance

An active source message must “pass” all limits established before being accepted. For example, if a source is configured with an active source limit of 10,000 active multicast groups and the instance is configured with a limit of 5000 (and there are no other sources or limits configured), only 5000 active source messages are accepted from this source.

MSDP mesh groups are groups of peers configured in a full-mesh topology that limits the flooding of source-active messages to neighboring peers. Every mesh group member

must have a peer connection with every other mesh group member. When a source-active message is received from a mesh group member, the source-active message is always accepted but is not flooded to other members of the same mesh group. However, the source-active message is flooded to non-mesh group peers or members of other mesh groups. By default, standard flooding rules apply if **mesh-group** is not specified.

CAUTION: When configuring MSDP mesh groups, you must configure all members the same way. If you do not configure a full mesh, excessive flooding of source-active messages can occur.

A common application for MSDP mesh groups is peer-reverse-path-forwarding (peer-RPF) check bypass. For example, if there are two MSDP peers inside an autonomous system (AS), and only one of them has an external MSDP session to another AS, the internal MSDP peer often rejects incoming source-active messages relayed by the peer with the external link. Rejection occurs because the external MSDP peer must be reachable by the internal MSDP peer through the next hop toward the source in another AS, and this next-hop condition is not certain. To prevent rejections, configure an MSDP mesh group on the internal MSDP peer so it always accepts source-active messages.

NOTE: An alternative way to bypass the peer-RPF check is to configure a default peer. In networks with only one MSDP peer, especially stub networks, the source-active message always needs to be accepted. An MSDP default peer is an MSDP peer from which all source-active messages are accepted without performing the peer-RPF check. You can establish a default peer at the peer or group level by including the **default-peer** statement.

Table 305 on page 4090 explains how flooding is handled by peers in this example. Figure 145 on page 4091 illustrates source-active message flooding between different mesh groups and peers within the same mesh group.

Table 305: Source-Active Message Flooding Explanation

| Source-Active Message Received From | Source-Active Message Flooded To | Source-Active Message Not Flooded To |
|-------------------------------------|--|--------------------------------------|
| Peer 21 | Peer 11, Peer 12, Peer 13, Peer 31, Peer 32 | Peer 22 |
| Peer 11 | Peer 21, Peer 22, Peer 31, Peer 32 | Peer 12, Peer 13 |
| Peer 31 | Peer 21, Peer 22, Peer 11, Peer 12, Peer 13, Peer 32 | — |

Figure 145: Source-Active Message Flooding

This example includes the following settings:

- **active-source-limit maximum 10000**—Applies a limit of 10,000 active sources to all other peers.
- **active-source-limit log-warning 80**—(Optional) Applies a warning threshold of 80 percent. In this example, the active source maximum is 10,000, so the device will start logging warning messages once it receives 8,000 active source messages.
- **active-source-limit log-interval 20**—(Optional) Applies a 20 second waiting period between system log messages.
- **data-encapsulation disable**—On an RP router using MSDP, disables the default encapsulation of multicast data received in MSDP register messages inside MSDP source-active messages.

MSDP data encapsulation mainly concerns bursty sources of multicast traffic. Sources that send only one packet every few minutes have trouble with the timeout of state relationships between sources and their multicast groups (S,G). Routers lose data while they attempt to reestablish (S,G) state tables. As a result, multicast register messages contain data, and this data encapsulation in MSDP source-active messages can be turned on or off through configuration.

By default, MSDP data encapsulation is enabled. An RP running MSDP takes the data packets arriving in the source's register message and encapsulates the data inside an MSDP source-active message.

However, data encapsulation creates both a multicast forwarding cache entry in the **inet.1** table (this is also the forwarding table) and a routing table entry in the **inet.4** table. Without data encapsulation, MSDP creates only a routing table entry in the **inet.4** table. In some circumstances, such as the presence of Internet worms or other forms of DoS attack, the router's forwarding table might fill up with these entries. To prevent the forwarding table from filling up with MSDP entries, you can configure the router not to use MSDP data encapsulation. However, if you disable data encapsulation, the router ignores and discards the encapsulated data. Without data encapsulation,

multicast applications with bursty sources having transmit intervals greater than about 3 minutes might not work well.

- **group MSDP-group local-address 10.1.2.3**—Specifies the address of the local router (this router).
- **group MSDP-group mode mesh-group**—Specifies that all peers belonging to the MSDP-group group are mesh group members.
- **group MSDP-group peer 10.10.10.10**—Prevents the sending of source-active messages to neighboring peer 10.10.10.10.
- **group MSDP-group peer 10.10.10.10 active-source-limit maximum 7500**—Applies a limit of 7500 active sources to MSDP peer 10.10.10.10 in group MSDP-group.
- **peer 10.0.0.1 active-source-limit maximum 5000 threshold 4000**—Applies a threshold of 4000 active sources and a limit of 5000 active sources to MSDP peer 10.0.0.1.
- **source 10.1.0.0/16 active-source-limit maximum 500**—Applies a limit of 500 active sources to any source on the 10.1.0.0/16 network.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
set protocols msdp data-encapsulation disable
set protocols msdp active-source-limit maximum 10000
set protocols msdp active-source-limit log-warning 80
set protocols msdp active-source-limit log-interval 20
set protocols msdp peer 10.0.0.1 active-source-limit maximum 5000
set protocols msdp peer 10.0.0.1 active-source-limit threshold 4000
set protocols msdp source 10.1.0.0/16 active-source-limit maximum 500
set protocols msdp group MSDP-group mode mesh-group
set protocols msdp group MSDP-group local-address 10.1.2.3
set protocols msdp group MSDP-group peer 10.10.10.10 active-source-limit maximum
7500
```

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure MSDP source active routes and mesh groups:

1. (Optional) Disable data encapsulation.

```
[edit protocols msdp]
user@host# set data-encapsulation disable
```

2. Configure the active source limits.

```
[edit protocols msdp]
user@host# set peer 10.0.0.1 active-source-limit maximum 5000 threshold 4000
```

```

user@host# set group MSDP-group peer 10.10.10.10 active-source-limit maximum
7500
user@host# set active-source-limit maximum 10000
user@host# set source 10.1.0.0/16 active-source-limit maximum 500

```

3. (Optional) Configure the threshold at which warning messages are logged and the amount of time between log messages.

```

[edit protocols msdp]
user@host# set active-source-limit log-warning 80
user@host# set active-source-limit log-interval 20

```

4. Configure the mesh group.

```

[edit protocols msdp]
user@host# set group MSDP-group mode mesh-group
user@host# set group MSDP-group peer 10.10.10.10
user@host# set group MSDP-group local-address 10.1.2.3

```

5. If you are done configuring the device, commit the configuration.

```

[edit routing-instances]
user@host# commit

```

Results

Confirm your configuration by entering the **show protocols** command.

```

user@host# show protocols
msdp {
  data-encapsulation disable;
  active-source-limit {
    maximum 10000;
    log-warning 80;
    log-interval 20;
  }
  peer 10.0.0.1 {
    active-source-limit {
      maximum 5000;
      threshold 4000;
    }
  }
  source 10.1.0.0/16 {
    active-source-limit {
      maximum 500;
    }
  }
  group MSDP-group {
    mode mesh-group;
    local-address 10.1.2.3;
    peer 10.10.10.10 {
      active-source-limit {
        maximum 7500;
      }
    }
  }
}

```

Verification

To verify the configuration, run the following commands:

- `show msdp source-active`
- `show msdp statistics`

Related Documentation

- *Example: Configuring MSDP in a Routing Instance*
- [Filtering MSDP SA Messages on page 3969](#)
- *Configuring RED Drop Profiles in the Junos OS Class of Service Library for Routing Devices*
- [Configuring Local PIM RPs on page 3995](#)

Example: Configuring PIM Anycast With or Without MSDP

When you configure anycast RP, you bypass the restriction of having one active rendezvous point (RP) per multicast group, and instead deploy multiple RPs for the same group range. The RP routers share one unicast IP address. Sources from one RP are known to other RPs that use the Multicast Source Discovery Protocol (MSDP). Sources and receivers use the closest RP, as determined by the interior gateway protocol (IGP).

You can use anycast RP within a domain to provide redundancy and RP load sharing. When an RP stops operating, sources and receivers are taken to a new RP by means of unicast routing.

You can configure anycast RP to use PIM and MSDP for IPv4, or PIM alone for both IPv4 and IPv6 scenarios. Both are discussed in this section.

We recommend a static RP mapping with anycast RP over a bootstrap router and auto-RP configuration because it provides all the benefits of a bootstrap router and auto-RP without the complexity of the BSR and auto-RP mechanisms.

All systems on a subnet must run the same version of PIM.

The default PIM version can be version 1 or version 2, depending on the mode you are configuring. PIMv1 is the default RP mode (at the **[edit protocols pim rp static address address]** hierarchy level). However, PIMv2 is the default for interface mode (at the **[edit protocols pim interface interface-name]** hierarchy level). Explicitly configured versions override the defaults. This example explicitly configures PIMv2 on the interfaces.

The following example shows an anycast RP configuration for the RP routers, first with MSDP and then using PIM alone, and for non-RP routers.

1. For a network using an RP with MSDP, configure the RP using the **lo0** loopback interface, which is always up. Include the **address** statement and specify the unique and routable router ID and the RP address at the **[edit interfaces lo0 unit 0 family inet]** hierarchy level. In this example, the router ID is **198.58.3.254** and the shared RP address is **198.58.3.253**. Include the **primary** statement for the first address. Including the

primary statement selects the router's primary address from all the preferred addresses on all interfaces.

```

interfaces {
  lo0 {
    description "PIM RP";
    unit 0 {
      family inet {
        address 198.58.3.254/32;
        primary;
        address 198.58.3.253/32;
      }
    }
  }
}

```

2. Specify the RP address. Include the **address** statement at the **[edit protocols pim rp local]** hierarchy level (the same address as the secondary **lo0** interface).

For all interfaces, include the **mode** statement to set the mode to **sparse** and the **version** statement to specify PIM version 2 at the **[edit protocols pim rp local interface all]** hierarchy level. When configuring all interfaces, exclude the **fxp0.0** management interface by including the **disable** statement for that interface.

```

protocols {
  pim {
    rp {
      local {
        family inet;
        address 198.58.3.253;
      }
      interface all {
        mode sparse;
        version 2;
      }
      interface fxp0.0 {
        disable;
      }
    }
  }
}

```

3. Configure MSDP peering. Include the **peer** statement to configure the address of the MSDP peer at the **[edit protocols msdp]** hierarchy level. For MSDP peering, use the unique, primary addresses instead of the anycast address. To specify the local address for MSDP peering, include the **local-address** statement at the **[edit protocols msdp peer]** hierarchy level.

```

protocols {
  msdp {
    peer 198.58.3.250 {
      local-address address 198.58.3.254;
    }
  }
}

```

NOTE: If you need to configure a PIM RP for both IPv4 and IPv6 scenarios, perform Step 4 and Step 5. Otherwise, go to Step 6.

4. Configure an RP using the **lo0** loopback interface, which is always up. Include the **address** statement to specify the unique and routable router address and the RP address at the **[edit interfaces lo0 unit 0 family inet]** hierarchy level. In this example, the router ID is **198.58.3.254** and the shared RP address is **198.58.3.253**. Include the **primary** statement on the first address. Including the **primary** statement selects the router's primary address from all the preferred addresses on all interfaces.

```
interfaces {
  lo0 {
    description "PIM RP";
    unit 0 {
      family inet {
        address 198.58.3.254/32 {
          primary;
        }
        address 198.58.3.253/32;
      }
    }
  }
}
```

5. Include the **address** statement at the **[edit protocols pim rp local]** hierarchy level to specify the RP address (the same address as the secondary **lo0** interface).

For all interfaces, include the **mode** statement to set the mode to **sparse**, and the **version** statement to specify PIM version 2 at the **[edit protocols pim rp local interface all]** hierarchy level. When configuring all interfaces, exclude the **fxp0.0** management interface by including the **disable** statement for that interface.

Include the **anycast-pim** statement to configure anycast RP without MSDP (for example, if IPv6 is used for multicasting). The other RP routers that share the same IP address are configured using the **rp-set** statement. There is one entry for each RP, and the maximum that can be configured is 15. For each RP, specify the routable IP address of the router and whether MSDP source active (SA) messages are forwarded to the RP.

MSDP configuration is not necessary for this type of IPv4 anycast RP configuration.

```
protocols {
  pim {
    rp {
      local {
        family inet {
          address 198.58.3.253;
          anycast-pim {
            rp-set {
              address 198.58.3.240;
              address 198.58.3.241 forward-msdp-sa;
            }
            local-address 198.58.3.254; #If not configured, use lo0 primary
          }
        }
      }
    }
  }
}
```

```

    }
  }
}
interface all {
  mode sparse;
  version 2;
}
interface fxp0.0 {
  disable;
}
}
}

```

6. Configure the non-RP routers. The anycast RP configuration for a non-RP router is the same whether MSDP is used or not. Specify a static RP by adding the address at the **[edit protocols pim rp static]** hierarchy level. Include the **version** statement at the **[edit protocols pim rp static address]** hierarchy level to specify PIM version 2.

```

protocols {
  pim {
    rp {
      static {
        address 198.58.3.253 {
          version 2;
        }
      }
    }
  }
}

```

7. Include the **mode** statement at the **[edit protocols pim interface all]** hierarchy level to specify sparse mode on all interfaces. Then include the **version** statement at the **[edit protocols pim rp interface all mode]** to configure all interfaces for PIM version 2. When configuring all interfaces, exclude the **fxp0.0** management interface by including the **disable** statement for that interface.

```

protocols {
  pim {
    interface all {
      mode sparse;
      version 2;
    }
    interface fxp0.0 {
      disable;
    }
  }
}

```

Configuring a PIM Anycast RP Router with MSDP

Add the **address** statement at the **[edit protocols pim rp local]** hierarchy level to specify the RP address (the same address as the secondary **lo0** interface).

For all interfaces, use the **mode** statement to set the mode to **sparse** and the **version** statement to specify PIM version 2 at the **[edit protocols pim rp local interface all]** hierarchy level. When configuring all interfaces, exclude the **fxp0.0** management interface by adding the **disable** statement for that interface.

```
protocols {
  pim {
    rp {
      local {
        family inet;
        address 198.58.3.253;
      }
      interface all {
        mode sparse;
        version 2;
      }
      interface fxp0.0 {
        disable;
      }
    }
  }
}
```

To configure MSDP peering, add the **peer** statement to configure the address of the MSDP peer at the **[edit protocols msdp]** hierarchy level. For MSDP peering, use the unique, primary addresses instead of the anycast address. To specify the local address for MSDP peering, add the **local-address** statement at the **[edit protocols msdp peer]** hierarchy level.

```
protocols {
  msdp {
    peer 198.58.3.250 {
      local-address 198.58.3.254;
    }
  }
}
```

Source-Specific Multicast

- [Example: Configuring PIM SSM on a Network on page 4098](#)
- [Example: Configuring an SSM-Only Domain on page 4100](#)
- [Example: Configuring SSM Mapping on page 4100](#)
- [Example: Configuring Source-Specific Multicast Groups with Any-Source Override on page 4103](#)
- [Example: Configuring SSM Maps for Different Groups to Different Sources on page 4106](#)

Example: Configuring PIM SSM on a Network

The following example shows how PIM SSM is configured between a receiver and a source in the network illustrated in [Figure 146 on page 4099](#).

Figure 146: Network on Which to Configure PIM SSM

This example shows how to configure the IGMP version to IGMPv3 on all receiving host interfaces.

1. Enable IGMPv3 on all host-facing interfaces, and disable IGMP on the **fxp0.0** interface on Router 1.

```

user@router1# set protocols igmp interface all version 3
user@router1# set protocols igmp interface fxp0.0 disable

```

NOTE: When you configure IGMPv3 on a router, hosts on interfaces configured with IGMPv2 cannot join the source tree.

2. After the configuration is committed, use the **show configuration protocol igmp** command to verify the IGMP protocol configuration.

```

user@router1> show configuration protocol igmp

[edit protocols igmp]
interface all {
    version 3;
}
interface fxp0.0 {
    disable;
}

```

3. Use the **show igmp interface** command to verify that IGMP interfaces are configured.

```

user@router1> show igmp interface
Interface      State    Querier      Timeout  Version  Groups
fe-0/0/0.0     Up       198.58.3.245  213      3         0
fe-0/0/1.0     Up       198.58.3.241  220      3         0
fe-0/0/2.0     Up       198.58.3.237  218      3         0
Configured Parameters:
IGMP Query Interval (1/10 secs): 1250
IGMP Query Response Interval (1/10 secs): 100
IGMP Last Member Query Interval (1/10 secs): 10
IGMP Robustness Count: 2
Derived Parameters:
IGMP Membership Timeout (1/10 secs): 2600
IGMP Other Querier Present Timeout (1/10 secs): 2550

```

4. Use the **show pim join extensive** command to verify the PIM join state on Router 2 and Router 3 (the upstream routers).

```

user@router2> show pim join extensive
232.1.1.1      10.4.1.2      sparse
Upstream interface: fe-1/1/3.0

```

```
Upstream State: Local Source
Keepalive timeout: 209
Downstream Neighbors:
  Interface: so-1/0/2.0
    10.10.71.1      State: Join   Flags: S   Timeout: 209
```

5. Use the **show pim join extensive** command to verify the PIM join state on Router 1 (the router connected to the receiver).

```
user@router1> show pim join extensive
232.1.1.1      10.4.1.2      sparse
Upstream interface: so-1/0/2.0
Upstream State: Join to Source
Keepalive timeout: 209
Downstream Neighbors:
  Interface: fe-0/2/3.0
    10.3.1.1      State: Join   Flags: S   Timeout: Infinity
```

Example: Configuring an SSM-Only Domain

Deploying an SSM-only domain is much simpler than deploying an ASM domain because it only requires a few configuration steps. Enable PIM sparse mode on all interfaces by adding the **mode** statement at the **[edit protocols pim interface all]** hierarchy level. When configuring all interfaces, exclude the **fxp0.0** management interface by adding the **disable** statement for that interface. Then configure IGMPv3 on all host-facing interfaces by adding the **version** statement at the **[edit protocols igmp interface *interface-name*]** hierarchy level.

In the following example, the host-facing interface is **fe-0/1/2**:

```
[edit]
protocols {
  pim {
    interface all {
      mode sparse;
      version 2;
    }
    interface fxp0.0 {
      disable;
    }
  }
  igmp {
    interface fe-0/1/2 {
      version 3;
    }
  }
}
```

Example: Configuring SSM Mapping

SSM mapping does not require that all hosts support IGMPv3. SSM mapping translates IGMPv1 or IGMPv2 membership reports to an IGMPv3 report. This enables hosts running IGMPv1 or IGMPv2 to participate in SSM until the hosts transition to IGMPv3.

SSM mapping applies to all group addresses that match the policy, not just those that conform to SSM addressing conventions (232/8 for IPv4, ff30::/32 through ff3F::/32 for IPv6).

We recommend separate SSM maps for IPv4 and IPv6 if both address families require SSM support. If you apply an SSM map containing both IPv4 and IPv6 addresses to an interface in an IPv4 context (using IGMP), only the IPv4 addresses in the list are used. If there are no such addresses, no action is taken. Similarly, if you apply an SSM map containing both IPv4 and IPv6 addresses to an interface in an IPv6 context (using MLD), only the IPv6 addresses in the list are used. If there are no such addresses, no action is taken.

In this example, you create a policy to match the group addresses that you want to translate to IGMPv3. Then you define the SSM map that associates the policy with the source addresses where these group addresses are found. Finally, you apply the SSM map to one or more IGMP (for IPv4) or MLD (for IPv6) interfaces.

1. Create an SSM policy named **ssm-policy-example**. The policy terms match the IPv4 SSM group address 232.1.1.1/32 and the IPv6 SSM group address ff35::1/128. All other addresses are rejected.

```
user@router1# set policy-options policy-statement ssm-policy-example term A from
route-filter 232.1.1.1/32 exact
user@router1# set policy-options policy-statement ssm-policy-example term A then
accept
user@router1# set policy-options policy-statement ssm-policy-example term B from
route-filter ff35::1/128 exact
user@router1# set policy-options policy-statement ssm-policy-example term B then
accept
```

2. After the configuration is committed, use the **show configuration policy-options** command to verify the policy configuration.

```
user@host> show configuration policy-options

[edit policy-options]
policy-statement ssm-policy-example {
  term A {
    from {
      route-filter 232.1.1.1/32 exact;
    }
    then accept;
  }
  term B {
    from {
      route-filter ff35::1/128 exact;
    }
    then accept;
  }
  then reject;
}
```

The group addresses must match the configured policy for SSM mapping to occur.

3. Define two SSM maps, one called **ssm-map-ipv6-example** and one called **ssm-map-ipv4-example**, by applying the policy and configuring the source addresses as a multicast routing option.

```
user@host# set routing-options multicast ssm-map ssm-map-ipv6-example policy
ssm-policy-example
user@host# set routing-options multicast ssm-map ssm-map-ipv6-example source
fec0::1 fec0::12
user@host# set routing-options multicast ssm-map ssm-map-ipv4-example policy
ssm-policy-example
user@host# set routing-options multicast ssm-map ssm-map-ipv4-example source
10.10.10.4
user@host# set routing-options multicast ssm-map ssm-map-ipv4-example source
192.168.43.66
```

4. After the configuration is committed, use the **show configuration routing-options** command to verify the policy configuration.

```
user@host> show configuration routing-options

[edit routing-options]
multicast {
  ssm-map ssm-map-ipv6-example {
    policy ssm-policy-example;
    source [ fec0::1 fec0::12 ];
  }
  ssm-map ssm-map-ipv4-example {
    policy ssm-policy-example;
    source [ 10.10.10.4 192.168.43.66 ];
  }
}
```

We recommend separate SSM maps for IPv4 and IPv6.

5. Apply SSM maps for IPv4-to-IGMP interfaces and SSM maps for IPv6-to-MLD interfaces:

```
user@host# set protocols igmp interface fe-0/1/0.0 ssm-map ssm-map-ipv4-example
user@host# set protocols mld interface fe-0/1/1.0 ssm-map ssm-map-ipv6-example
```

6. After the configuration is committed, use the **show configuration protocol** command to verify the IGMP and MLD protocol configuration.

```
user@router1> show configuration protocol

[edit protocols]
igmp {
  interface fe-0/1/0.0 {
    ssm-map ssm-map-ipv4-example;
  }
}
mld {
  interface fe-0/1/1.0 {
    ssm-map ssm-map-ipv6-example;
  }
}
```

7. Use the **show igmp interface** and the **show mld interface** commands to verify that the SSM maps are applied to the interfaces.

```

user@host> show igmp interface fe-0/1/0.0
Interface: fe-0/1/0.0
  Querier: 192.168.224.28
  State:      Up Timeout:      None Version:  2 Groups:  2
  SSM Map: ssm-map-ipv4-example

user@host> show mld interface fe-0/1/1.0
Interface: fe-0/1/1.0
  Querier: fec0:0:0:0:1::12
  State:      Up Timeout:      None Version:  2 Groups:  2
  SSM Map: ssm-map-ipv6-example

```

Example: Configuring Source-Specific Multicast Groups with Any-Source Override

This example shows how to extend source-specific multicast (SSM) group operations beyond the default IP address range of 232.0.0.0 through 232.255.255.255. This example also shows how to accept any-source multicast (ASM) join messages (*G) for group addresses that are within the default or configured range of SSM groups. This allows you to support a mix of any-source and source-specific multicast groups simultaneously.

- [Requirements on page 4103](#)
- [Overview on page 4103](#)
- [Configuration on page 4105](#)
- [Verification on page 4106](#)

Requirements

Before you begin, configure the router interfaces. See the *Junos OS Network Interfaces Library for Routing Devices*.

Overview

To deploy SSM, configure PIM sparse mode on all routing device interfaces and issue the necessary SSM commands, including specifying IGMPv3 or MLDv2 on the receiver's LAN. If PIM sparse mode is not explicitly configured on both the source and group members interfaces, multicast packets are not forwarded. Source lists, supported in IGMPv3 and MLDv2, are used in PIM SSM. Only sources that are specified send traffic to the SSM group.

In a PIM SSM-configured network, a host subscribes to an SSM channel (by means of IGMPv3 or MLDv2) to join group G and source S (see [Figure 147 on page 4104](#)). The directly connected PIM sparse-mode router, the receiver's designated router (DR), sends an (S,G) join message to its reverse-path forwarding (RPF) neighbor for the source. Notice in [Figure 147 on page 4104](#) that the RP is not contacted in this process by the receiver, as would be the case in normal PIM sparse-mode operations.

Figure 147: Receiver Sends Messages to Join Group G and Source S

The (S,G) join message initiates the source tree and then builds it out hop by hop until it reaches the source. In [Figure 148 on page 4104](#), the source tree is built across the network to Router 3, the last-hop router connected to the source.

Figure 148: Router 3 (Last-Hop Router) Joins the Source Tree

Using the source tree, multicast traffic is delivered to the subscribing host (see [Figure 149 on page 4104](#)).

Figure 149: (S,G) State Is Built Between the Source and the Receiver

SSM can operate in include mode or in exclude mode. In exclude mode the receiver specifies a list of sources that it does not want to receive the multicast group traffic from. The routing device forwards traffic to the receiver from any source except the sources specified in the exclusion list. The receiver accepts traffic from any sources except the sources specified in the exclusion list.

This example works with the simple RPF topology shown in [Figure 150 on page 4104](#).

Figure 150: Simple RPF Topology

Configuration

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
set protocols ospf area 0.0.0.0 interface fxp0.0 disable
set protocols ospf area 0.0.0.0 interface all
set protocols pim rp local address 10.255.72.46
set protocols pim rp local group-ranges 239.0.0.0/24
set protocols pim interface fe-1/0/0.0 mode sparse
set protocols pim interface lo0.0 mode sparse
set routing-options multicast ssm-groups 232.0.0.0/8
set routing-options multicast ssm-groups 239.0.0.0/8
set routing-options multicast asm-override-ssm
```

Step-by-Step Procedure The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure an RPF policy:

1. Configure OSPF.

```
[edit protocols ospf]
user@host# set area 0.0.0.0 interface fxp0.0 disable
user@host# set area 0.0.0.0 interface all
```

2. Configure PIM sparse mode.

```
[edit protocols pim]
user@host# set rp local address 10.255.72.46
user@host# set rp local group-ranges 239.0.0.0/24
user@host# set interface fe-1/0/0.0 mode sparse
user@host# set interface lo0.0 mode sparse
```

3. Configure additional SSM groups.

```
[edit routing-options]
user@host# set ssm-groups [ 232.0.0.0/8 239.0.0.0/8 ]
```

4. Configure the RP to accept ASM join messages for groups within the SSM address range.

```
[edit routing-options]
user@host# set multicast asm-override-ssm
```

5. If you are done configuring the device, commit the configuration.

```
user@host# commit
```

Results

Confirm your configuration by entering the **show protocols** and **show routing-options** commands.

```
user@host# show protocols
ospf {
  area 0.0.0.0 {
    interface fxp0.0 {
      disable;
    }
    interface all;
  }
}
pim {
  rp {
    local {
      address 10.255.72.46;
      group-ranges {
        239.0.0.0/24;
      }
    }
  }
  interface fe-1/0/0.0 {
    mode sparse;
  }
  interface lo0.0 {
    mode sparse;
  }
}

user@host# show routing-options
multicast {
  ssm-groups [ 232.0.0.0/8 239.0.0.0/8 ];
  asm-override-ssm;
}
```

Verification

To verify the configuration, run the following commands:

- [show igmp group](#)
- [show igmp statistics](#)
- [show pim join](#)

Related Documentation

- [Source-Specific Multicast Groups Overview on page 3970](#)

Example: Configuring SSM Maps for Different Groups to Different Sources

- [Multiple SSM Maps and Groups for Interfaces on page 4106](#)
- [Example: Configuring Multiple SSM Maps Per Interface on page 4107](#)

Multiple SSM Maps and Groups for Interfaces

You can configure multiple source-specific multicast (SSM) maps so that different groups map to different sources, which enables a single multicast group to map to different sources for different interfaces.

Example: Configuring Multiple SSM Maps Per Interface

This example shows how to assign more than one SSM map to an IGMP interface.

- [Requirements on page 4107](#)
- [Overview on page 4107](#)
- [Configuration on page 4107](#)
- [Verification on page 4109](#)

Requirements

This example requires Junos OS Release 11.4 or later.

Overview

In this example, you configure a routing policy, POLICY-ipv4-example1, that maps multicast group join messages over an IGMP logical interface to IPv4 multicast source addresses based on destination IP address as follows:

| Routing Policy Name | Multicast Group Join Messages for a Route Filter at This Destination Address | Multicast Source Addresses |
|-----------------------------|--|------------------------------|
| POLICY-ipv4-example1 term 1 | 232.1.1.1 | 10.10.10.4,
192.168.43.66 |
| POLICY-ipv4-example1 term 2 | 232.1.1.2 | 10.10.10.5,
192.168.43.67 |

You apply routing policy POLICY-ipv4-example1 to IGMP logical interface fe-0/1/0.0.

Configuration

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure this example, perform the following task:

CLI Quick Configuration

To quickly configure this example, copy the following configuration commands into a text file, remove any line breaks, and then paste the commands into the CLI at the [edit] hierarchy level.

```

set policy-options policy-statement POLICY-ipv4-example1 term 1 from route-filter
  232.1.1.1/32 exact
set policy-options policy-statement POLICY-ipv4-example1 term 1 then ssm-source
  10.10.10.4
set policy-options policy-statement POLICY-ipv4-example1 term 1 then ssm-source
  192.168.43.66
set policy-options policy-statement POLICY-ipv4-example1 term 1 then accept
set policy-options policy-statement POLICY-ipv4-example1 term 2 from route-filter
  232.1.1.2/32 exact
set policy-options policy-statement POLICY-ipv4-example1 term 2 then ssm-source
  10.10.10.5

```

```

set policy-options policy-statement POLICY-ipv4-example1 term 2 then ssm-source
192.168.43.67
set policy-options policy-statement POLICY-ipv4-example1 term 2 then accept
set protocols igmp interface fe-0/1/0.0 ssm-map-policy POLICY-ipv4-example1

```

Step-by-Step Procedure

To configure multiple SSM maps per interface:

1. Configure protocol-independent routing options for route filter 232.1.1.1, and specify the multicast source addresses to which matching multicast groups are to be mapped.

```

[edit policy-options policy-statement POLICY-ipv4-example1 term 1]
user@host# set from route-filter 232.1.1.1/32 exact
user@host# set then ssm-source 10.10.10.4
user@host# set then ssm-source 192.168.43.66
user@host# set then accept

```

2. Configure protocol-independent routing options for route filter 232.1.1.2, and specify the multicast source addresses to which matching multicast groups are to be mapped.

```

[edit policy-options policy-statement POLICY-ipv4-example1 term 2]
user@host# set from route-filter 232.1.1.2/32 exact
user@host# set then ssm-source 10.10.10.5
user@host# set then ssm-source 192.168.43.67
user@host# set then accept

```

3. Apply the policy map POLICY-ipv4-example1 to IGMP logical interface fe-0/1/1/0.

```

[edit protocols igmp interface fe-0/1/0.0]
user@host# set ssm-map-policy POLICY-ipv4-example1

```

Results

After the configuration is committed, confirm the configuration by entering the **show policy-options** and **show protocols** configuration mode commands. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```

user@host#> show policy-options
policy-statement POLICY-ipv4-example1 {
  term 1 {
    from {
      route-filter 232.1.1.1/32 exact;
    }
    then {
      ssm-source [ 10.10.10.4 192.168.43.66 ];
      accept;
    }
  }
  term 2 {
    from {
      route-filter 232.1.1.2/32 exact;
    }
    then {
      ssm-source [ 10.10.10.5 192.168.43.67 ];
      accept;
    }
  }
}

```

```

}

user@host# show protocols
igmp {
  interface fe-0/1/0.0 {
    ssm-map-policy POLICY-ipv4-example1;
  }
}

```

Verification

Confirm that the configuration is working properly.

- [Displaying Information About IGMP-Enabled Interfaces on page 4109](#)
- [Displaying the PIM Groups on page 4109](#)
- [Displaying the Entries in the IP Multicast Forwarding Table on page 4109](#)

Displaying Information About IGMP-Enabled Interfaces

Purpose Verify that the SSM map policy POLICY-ipv4-example1 is applied to logical interface fe-0/1/0.0.

Action Use the [show igmp interface](#) operational mode command for the IGMP logical interface to which you applied the SSM map policy.

```

user@host> show igmp interface
Interface: fe-0/1/0.0
  Querier: 10.111.30.1
  State:          Up Timeout:      None Version:  2 Groups:      2
  SSM Map Policy: POLICY-ipv4-example1;

```

```

Configured Parameters:
IGMP Query Interval: 125.0
IGMP Query Response Interval: 10.0
IGMP Last Member Query Interval: 1.0
IGMP Robustness Count: 2

```

```

Derived Parameters:
IGMP Membership Timeout: 260.0
IGMP Other Querier Present Timeout: 255.0

```

The command output displays the name of IGMP logical interface (fe-0/1/0.0), the address of the routing device that has been elected to send membership queries and group information.

Displaying the PIM Groups

Purpose Verify the Protocol Independent Multicast (PIM) source and group pair (S,G) entries.

Action Use the [show pim join extensive 232.1.1.1](#) operational mode command to display the PIM source and group pair (S,G) entries for the 232.1.1.1 group.

Displaying the Entries in the IP Multicast Forwarding Table

Purpose Verify that the IP multicast forwarding table displays the mroute state.

Action Use the [show multicast route extensive](#) operational mode command to display the entries in the IP multicast forwarding table to verify that the **Route state** is active and that the **Forwarding state** is forwarding.

address (Anycast RPs)

| | |
|---------------------------------|--|
| Syntax | <code>address <i>address</i> <forward-msdp-sa>;</code> |
| Hierarchy Level | <code>[edit logical-systems <i>logical-system-name</i> protocols pim rp local (inet inet6) anycast-pim rp-set],</code>
<code>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols</code>
<code>pim rp local (inet inet6) anycast-pim rp-set],</code>
<code>[edit protocols pim rp local (inet inet6) anycast-pim rp-set],</code>
<code>[edit routing-instances <i>routing-instance-name</i> protocols pim rp local (inet inet6) anycast-pim</code>
<code>rp-set]</code> |
| Release Information | Statement introduced in Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series. |
| Description | Configure the anycast rendezvous point (RP) addresses in the RP set. Multiple addresses can be configured in an RP set. If the RP has peer Multicast Source Discovery Protocol (MSDP) connections, then the RP must forward MSDP source active (SA) messages. |
| Options | <i>address</i> —RP address in an RP set.

<i>forward-msdp-sa</i> —(Optional) Forward MSDP SAs to this address. |
| Required Privilege Level | routing —To view this statement in the configuration.
routing-control —To add this statement to the configuration. |

address (Local RPs)

detection-time (BFD for PIM)

| | |
|--------------------------|--|
| Syntax | <pre>detection-time {
 threshold milliseconds;
}</pre> |
| Hierarchy Level | [edit protocols pim interface <i>interface-name</i> bfd-liveness-detection],
[edit routing-instances <i>routing-instance-name</i> protocols pim interface <i>interface-name</i> bfd-liveness-detection] |
| Release Information | Statement introduced in Junos OS Release 8.2.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Support for BFD authentication introduced in Junos OS Release 9.6.
Statement introduced in Junos OS Release 12.1 for the QFX Series. |
| Description | <p>Enable BFD failure detection. The BFD failure detection timers are adaptive and can be adjusted to be faster or slower. The lower the BFD failure detection timer value, the faster the failure detection and vice versa. For example, the timers can adapt to a higher value if the adjacency fails (that is, the timer detects failures more slowly). Or a neighbor can negotiate a higher value for a timer than the configured value. The timers adapt to a higher value when a BFD session flap occurs more than three times in a span of 15 seconds. A back-off algorithm increases the receive (Rx) interval by two if the local BFD instance is the reason for the session flap. The transmission (Tx) interval is increased by two if the remote BFD instance is the reason for the session flap. You can use the clear bfd adaptation command to return BFD interval timers to their configured values. The clear bfd adaptation command is hitless, meaning that the command does not affect traffic flow on the routing device.</p> <p>The remaining statement is explained separately.</p> |
| Required Privilege Level | routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration. |

| Syntax | <code>minimum-receive-interval <i>milliseconds</i>;</code> |
| Hierarchy Level | [<code>edit protocols pim interface <i>interface-name</i> bfd-liveness-detection</code>],
[<code>edit routing-instances <i>routing-instance-name</i> protocols pim interface <i>interface-name</i> bfd-liveness-detection</code>] |
| Release Information | Statement introduced in Junos OS Release 8.1.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 12.1 for the QFX Series. |
| Description | Configure the minimum interval after which the local routing device must receive a reply from a neighbor with which it has established a BFD session. Optionally, instead of using this statement, you can configure the minimum receive interval using the minimum-interval statement at the [<code>edit protocols pim interface <i>interface-name</i> bfd-liveness-detection</code>] hierarchy level. |
| Options | <i>milliseconds</i> —Minimum receive interval.
Range: 1 through 255,000 milliseconds |
| Required Privilege Level | routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration. |
| Related Documentation | <ul style="list-style-type: none"> • Configuring BFD for PIM on page 4021 |

mode (Protocols PIM)

| | |
|----------------------------|--|
| Syntax | mode (dense sparse sparse-dense); |
| Hierarchy Level | [edit protocols pim interface <i>interface-name</i>],
[edit routing-instances <i>routing-instance-name</i> protocols pim interface <i>interface-name</i>] |
| Release Information | Statement introduced in Junos OS Release 11.3 for the QFX Series. |
| Description | Configure PIM to operate in sparse, dense, or sparse-dense mode. |

NOTE: The QFX Series does not support dense or sparse-dense mode.

| | |
|---------------------------------|--|
| Options | dense —Operate in dense mode.
sparse —Operate in sparse mode.
sparse-dense —Operate in sparse-dense mode.
Default: sparse |
| Required Privilege Level | routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration. |

multiplier

| | |
|---------------------------------|--|
| Syntax | multiplier <i>number</i> ; |
| Hierarchy Level | [edit protocols pim interface <i>interface-name</i> bfd-liveness-detection],
[edit routing-instances <i>routing-instance-name</i> protocols pim interface <i>interface-name</i> bfd-liveness-detection] |
| Release Information | Statement introduced in Junos OS Release 8.1.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 12.1 for the QFX Series. |
| Description | Configure the number of hello packets not received by a neighbor that causes the originating interface to be declared down. |
| Options | number —Number of hello packets.
Range: 1 through 255
Default: 3 |
| Required Privilege Level | routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration. |
| Related Documentation | <ul style="list-style-type: none">• Configuring BFD for PIM on page 4021 |

neighbor-policy

| | |
|---------------------------------|---|

<code>[edit routing-instances <i>instance-name</i> protocols pim rp bidirectional address <i>address</i>],</code>
<code>[edit routing-instances <i>routing-instance-name</i> protocols pim rp local family (inet inet6)]</code> |
| Release Information | Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.
Support for bidirectional RP addresses introduced in Junos OS Release 12.1. |
| Description | For PIM-SM, configure this routing device's priority for becoming an RP.

For bidirectional PIM, configure this RP address' priority for becoming an RP.

The bootstrap router uses this field when selecting the list of candidate rendezvous points to send in the bootstrap message. A smaller number increases the likelihood that the routing device or RP address becomes the RP. A priority value of 0 means that bootstrap router can override the group range being advertised by the candidate RP. |
| Options | <i>number</i> —Priority for becoming an RP. A lower value corresponds to a higher priority.
Range: 0 through 255
Default: 1 |
| Required Privilege Level | routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration. |

reset-tracking-bit

| | |
|---------------------------------|--|
| Syntax | reset-tracking-bit; |
| Hierarchy Level | [edit protocols pim],
[edit protocols pim interface <i>interface-name</i>],
[edit routing-instances <i>routing-instance-name</i> protocols pim],
[edit routing-instances <i>routing-instance-name</i> protocols pim interface <i>interface-name</i>],
[edit logical-systems <i>logical-system-name</i> protocols pim],
[edit logical-systems <i>logical-system-name</i> protocols pim interface <i>interface-name</i>],
[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols
pim interface <i>interface-name</i>] |
| Release Information | Statement introduced in Junos OS Release 10.1.
Statement introduced in Junos OS Release 11.3 for the QFX Series. |
| Description | Change the value of a tracking bit (T-bit) field in the LAN prune delay hello option from the default of 1 to 0, which enables join suppression for a multicast interface. When the network starts receiving multiple identical join messages, join suppression triggers a random timer with a value of 66 through 84 milliseconds ($1.1 \times$ periodic through $1.4 \times$ periodic, where periodic is 60 seconds). This creates an interval during which no identical join messages are sent. Eventually, only one of the identical messages is sent. Join suppression is triggered each time identical messages are sent for the same join. |
| Required Privilege Level | routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration. |
| Related Documentation | <ul style="list-style-type: none">• Example: Enabling Join Suppression on page 3991• override-interval on page 4153• propagation-delay on page 4161 |

rpf-selection

| | |
|---------------------------------|--|
| Syntax | <pre>rpf-selection {
 group group-address {
 source source-address {
 next-hop next-hop-address;
 }
 wildcard-source {
 next-hop next-hop-address;
 }
 }
 prefix-list prefix-list-addresses {
 source source-address {
 next-hop next-hop-address;
 }
 wildcard-source {
 next-hop next-hop-address;
 }
 }
}</pre> |
| Hierarchy Level | [edit routing-instances <i>routing-instance-name</i> protocols pim] |
| Release Information | Statement introduced in JUNOS Release 10.4.
Statement introduced in Junos OS Release 11.3 for the QFX Series. |
| Description | Configure the PIM RPF next-hop neighbor for a specific group and source for a VRF routing instance.

The remaining statements are explained separately. |
| Default | If you omit the rpf-selection statement, PIM RPF checks typically choose the best path determined by the unicast protocol for all multicast flows. |
| Options | source-address —Specific source address for the PIM group. |
| Required Privilege Level | view-level—To view this statement in the configuration.
control-level—To add this statement to the configuration. |
| Related Documentation | <ul style="list-style-type: none">• <i>Example: Configuring PIM RPF Selection</i> |

source (PIM RPF Selection)

| | |
|---------------------------------|--|

threshold (PIM BFD Detection Time)

| | |
|----------------------------|--|
| Syntax | <code>threshold <i>milliseconds</i>;</code> |
| Hierarchy Level | [edit protocols pim interface <i>interface-name</i> bfd-liveness-detection detection-time],
[edit routing-instances <i>routing-instance-name</i> protocols pim interface <i>interface-name</i> bfd-liveness-detection detection-time] |
| Release Information | Statement introduced in Junos OS Release 8.2.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Support for BFD authentication introduced in Junos OS Release 9.6.
Statement introduced in Junos OS Release 12.1 for the QFX Series. |
| Description | Specify the threshold for the adaptation of the BFD session detection time. When the detection time adapts to a value equal to or greater than the threshold, a single trap and a single system log message are sent. |

NOTE: The threshold value must be equal to or greater than the transmit interval.

The threshold time must be equal to or greater than the value specified in the [minimum-interval](#) or the [minimum-receive-interval](#) statement.

| | |
|---------------------------------|--|
| Options | <i>milliseconds</i> —Value for the detection time adaptation threshold.
Range: 1 through 255,000 |
| Required Privilege Level | routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration. |
| Related Documentation | <ul style="list-style-type: none">• Configuring BFD for PIM on page 4021• bfd-liveness-detection on page 4119• detection-time on page 4124• minimum-interval on page 4147• minimum-receive-interval on page 4149 |

threshold (PIM BFD Transmit Interval)

| | |
|----------------------------|--|
| Syntax | <code>threshold <i>milliseconds</i>;</code> |
| Hierarchy Level | [edit protocols pim interface <i>interface-name</i> bfd-liveness-detection transmit-interval],
[edit routing-instances <i>routing-instance-name</i> protocols pim interface <i>interface-name</i> bfd-liveness-detection transmit-interval] |
| Release Information | Statement introduced in Junos OS Release 8.2.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 12.1 for the QFX Series. |
| Description | Specify the threshold for the adaptation of the BFD session transmit interval. When the transmit interval adapts to a value greater than the threshold, a single trap and a single system message are sent. |
| Options | <i>milliseconds</i> —Value for the transmit interval adaptation threshold.
Range: 0 through 4,294,967,295 ($2^{32} - 1$) |

NOTE: The threshold value specified in the `threshold` statement must be greater than the value specified in the `minimum-interval` statement for the `transmit-interval` statement.

| | |
|---------------------------------|---|
| Required Privilege Level | routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration. |
| Related Documentation | <ul style="list-style-type: none"> • Configuring BFD for PIM on page 4021 • bfd-liveness-detection on page 4119 |

transmit-interval (PIM BFD Liveness Detection)

| | |
|--------------------------|--|
| Syntax | <pre>transmit-interval {
 <i>minimum-interval</i> <i>milliseconds</i>;
 <i>threshold</i> <i>milliseconds</i>;
}</pre> |
| Hierarchy Level | [edit protocols pim interface <i>interface-name</i> bfd-liveness-detection],
[edit routing-instances <i>routing-instance-name</i> protocols pim interface <i>interface-name</i> bfd-liveness-detection] |
| Release Information | Statement introduced in Junos OS Release 8.2.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Support for BFD authentication introduced in Junos OS Release 9.6.
Statement introduced in Junos OS Release 12.1 for the QFX Series. |
| Description | <p>Specify the transmit interval for the bfd-liveness-detection statement. The negotiated transmit interval for a peer is the interval between the sending of BFD packets to peers. The receive interval for a peer is the minimum interval between receiving packets sent from its peer; the receive interval is not negotiated between peers. To determine the transmit interval, each peer compares its configured minimum transmit interval with its peer's minimum receive interval. The larger of the two numbers is accepted as the transmit interval for that peer.</p> <p>The remaining statements are explained separately.</p> |
| Required Privilege Level | routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration. |
| Related Documentation | <ul style="list-style-type: none">• Configuring BFD for PIM on page 4021• bfd-liveness-detection on page 4119• threshold on page 4173• minimum-interval on page 4148• minimum-receive-interval on page 4149 |

traceoptions (Protocols PIM)

| | |
|----------------------------|--|
| Syntax | <pre>traceoptions { file <i>filename</i> <files <i>number</i>> <size <i>size</i>> <world-readable no-world-readable>; flag <i>flag</i> <flag-modifier> <disable>; }</pre> |
| Hierarchy Level | <p>[edit logical-systems <i>logical-system-name</i> protocols pim],
 [edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols pim],
 [edit protocols pim],
 [edit routing-instances <i>routing-instance-name</i> protocols pim]</p> |
| Release Information | <p>Statement introduced before Junos OS Release 7.4.
 Statement introduced in Junos OS Release 9.0 for EX Series switches.
 Statement introduced in Junos OS Release 11.3 for the QFX Series.</p> |
| Description | <p>Configure PIM tracing options.</p> <p>To specify more than one tracing operation, include multiple flag statements.</p> |
| Default | The default PIM trace options are those inherited from the routing protocol's traceoptions statement included at the [edit routing-options] hierarchy level. |
| Options | <p>disable—(Optional) Disable the tracing operation. You can use this option to disable a single operation when you have defined a broad group of tracing operations, such as all.</p> <p>file <i>filename</i>—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory /var/log. We recommend that you place tracing output in the pim-log file.</p> <p>files <i>number</i>—(Optional) Maximum number of trace files. When a trace file named trace-file reaches its maximum size, it is renamed trace-file.0, then trace-file.1, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.</p> <p>If you specify a maximum number of files, you must also include the size statement to specify the maximum file size.</p> <p>Range: 2 through 1000 files
 Default: 2 files</p> <p>flag <i>flag</i>—Tracing operation to perform. To specify more than one tracing operation, include multiple flag statements.</p> <p>PIM Tracing Flags</p> <ul style="list-style-type: none"> • assert—Assert messages • bidirectional-df-election—Bidirectional PIM designated-forwarder (DF) election events |

- **bootstrap**—Bootstrap messages
- **cache**—Packets in the PIM sparse mode routing cache
- **graft**—Graft and graft acknowledgment messages
- **hello**—Hello packets
- **join**—Join messages
- **mt**—Multicast tunnel messages
- **nsr-synchronization**—Nonstop active routing (NSR) synchronization messages
- **packets**—All PIM packets
- **prune**—Prune messages
- **register**—Register and register stop messages
- **rp**—Candidate RP advertisements
- **all**—All tracing operations
- **general**—A combination of the **normal** and **route** trace operations
- **normal**—All normal operations

Default: If you do not specify this option, only unusual or abnormal operations are traced.

- **policy**—Policy operations and actions
- **route**—Routing table changes
- **state**—State transitions
- **task**—Interface transactions and processing
- **timer**—Timer usage

flag-modifier—(Optional) Modifier for the tracing flag. You can specify one or more of these modifiers:

- **detail**—Detailed trace information
- **receive**—Packets being received
- **send**—Packets being transmitted

no-stamp—(Optional) Do not place timestamp information at the beginning of each line in the trace file.

Default: If you omit this option, timestamp information is placed at the beginning of each line of the tracing output.

no-world-readable—(Optional) Do not allow users to read the log file.

replace—(Optional) Replace an existing trace file if there is one.

Default: If you do not include this option, tracing output is appended to an existing trace file.

size *size*—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named **trace-file** reaches this size, it is renamed **trace-file.0**. When **trace-file** again reaches this size, **trace-file.0** is renamed **trace-file.1** and **trace-file** is renamed **trace-file.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you must also include the **files** statement to specify the maximum number of trace files.

Syntax: **xk** to specify KB, **xm** to specify MB, or **xg** to specify GB

Range: 0 KB through the maximum file size supported on your system

Default: 1 MB

world-readable—(Optional) Allow any user to read the log file.

Release Information Statement introduced before Junos OS Release 7.4.
 Statement introduced in Junos OS Release 12.1 for the QFX Series.
 Statement introduced in Junos OS Release 12.3R2 for EX Series switches.

Description Enable IGMP on the router or switch. IGMP must be enabled for the router or switch to receive multicast packets.

The remaining statements are explained separately.

| | |
|------------------------------|--|
| Default | IGMP is disabled on the router or switch. IGMP is automatically enabled on all broadcast interfaces when you configure Protocol Independent Multicast (PIM) or Distance Vector Multicast Routing Protocol (DVMRP). |
| Required Privilege | routing—To view this statement in the configuration. |
| Level | routing-control—To add this statement to the configuration. |
| Related Documentation | <ul style="list-style-type: none">• Enabling IGMP on page 4028 |

immediate-leave (Protocols IGMP)

| | |
|---------------------------------|--|
| Syntax | immediate-leave; |
| Hierarchy Level | [edit logical-systems <i>logical-system-name</i> protocols igmp interface <i>interface-name</i>],
[edit protocols igmp interface <i>interface-name</i>] |
| Release Information | Statement introduced in Junos OS Release 8.3.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 12.1 for the QFX Series. |
| Description | <p>The immediate leave setting is useful for minimizing the leave latency of IGMP memberships. When this setting is enabled, the routing device leaves the multicast group immediately after the last host leaves the multicast group.</p> <p>Starting in Junos OS Release 9.3, both IGMP version 2 and IGMP version 3 do host tracking when the immediate-leave statement is configured. This means that the multicast group leaves only when the last host leaves. The routing device keeps track of the hosts that send join messages. This allows IGMP to determine when the last host sends a leave message for the multicast group.</p> <p>When the immediate leave setting is enabled, the device removes an interface from the forwarding-table entry without first sending IGMP group-specific queries to the interface. The interface is pruned from the multicast tree for the multicast group specified in the IGMP leave message. The immediate leave setting ensures optimal bandwidth management for hosts on a switched network, even when multiple multicast groups are being used simultaneously.</p> <p>When immediate leave is disabled and one host sends a leave group message, the routing device first sends a group query to determine if another receiver responds. If no receiver responds, the routing device removes all hosts on the interface from the multicast group. Immediate leave is disabled by default for both IGMP version 2 and IGMP version 3.</p> |
| | <div> NOTE: Although host tracking is enabled for IGMPv2 and MLDv1 when you enable immediate leave, use immediate leave with these versions only when there is one host on the interface. The reason is that IGMPv2 and MLDv1 use a report suppression mechanism whereby only one host on an interface sends a group join report in response to a membership query. The other interested hosts suppress their reports. The purpose of this mechanism is to avoid a flood of reports for the same group. But it also interferes with host tracking, because the routing device only knows about the one interested host and does not know about the others.</div> |
| Required Privilege Level | routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration. |

 [edit protocols **igmp** interface *interface-name*]

Release Information Statement introduced before Junos OS Release 7.4.
 Statement introduced in Junos OS Release 9.0 for EX Series switches.
 Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Test multicast forwarding on an interface without a receiver host.

The **static** statement simulates IGMP joins on a routing device statically on an interface without any IGMP hosts. It is supported for both IGMPv2 and IGMPv3 joins. This statement is especially useful for testing multicast forwarding on an interface without a receiver host.

NOTE: To prevent joining too many groups accidentally, the **static** statement is not supported with the **interface all** statement.

The remaining statements are explained separately.

Required Privilege Level routing and trace—To view this statement in the configuration.
 routing-control and trace-control—To add this statement to the configuration.

| Release Information | <p>Statement introduced before Junos OS Release 7.4.</p> <p>Statement introduced in Junos OS Release 9.0 for EX Series switches.</p> <p>Statement introduced in Junos OS Release 12.1 for the QFX Series.</p> |
| Description | <p>Configure IGMP tracing options.</p> <p>To specify more than one tracing operation, include multiple flag statements.</p> <p>To trace the paths of multicast packets, use the mtrace command.</p> |
| Default | The default IGMP trace options are those inherited from the routing protocols traceoptions statement included at the [edit routing-options] hierarchy level. |
| Options | <p>disable—(Optional) Disable the tracing operation. You can use this option to disable a single operation when you have defined a broad group of tracing operations, such as all.</p> <p>file <i>filename</i>—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory /var/log. We recommend that you place tracing output in the file igmp-log.</p> <p>files <i>number</i>—(Optional) Maximum number of trace files. When a trace file named trace-file reaches its maximum size, it is renamed trace-file.0, then trace-file.1, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.</p> <p>If you specify a maximum number of files, you must also include the size statement to specify the maximum file size.</p> <p>Range: 2 through 1000 files</p> <p>Default: 2 files</p> <p>flag—Tracing operation to perform. To specify more than one tracing operation, include multiple flag statements.</p> <p>IGMP Tracing Flags</p> <ul style="list-style-type: none"> leave—Leave group messages (for IGMP version 2 only). mtrace—Mtrace packets. Use the mtrace command to troubleshoot the software. packets—All IGMP packets. |

- **query**—IGMP membership query messages, including general and group-specific queries.
- **report**—Membership report messages.

Global Tracing Flags

- **all**—All tracing operations
- **general**—A combination of the **normal** and **route** trace operations
- **normal**—All normal operations

Default: If you do not specify this option, only unusual or abnormal operations are traced.

- **policy**—Policy operations and actions
- **route**—Routing table changes
- **state**—State transitions
- **task**—Interface transactions and processing
- **timer**—Timer usage

flag-modifier—(Optional) Modifier for the tracing flag. You can specify one or more of these modifiers:

- **detail**—Detailed trace information
- **receive**—Packets being received
- **send**—Packets being transmitted

no-stamp—(Optional) Do not place timestamp information at the beginning of each line in the trace file.

Default: If you omit this option, timestamp information is placed at the beginning of each line of the tracing output.

no-world-readable—(Optional) Do not allow users to read the log file.

replace—(Optional) Replace an existing trace file if there is one.

Default: If you do not include this option, tracing output is appended to an existing trace file.

size size—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named **trace-file** reaches this size, it is renamed **trace-file.0**. When **trace-file** again reaches this size, **trace-file.0** is renamed **trace-file.1** and **trace-file** is renamed **trace-file.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you must also include the **files** statement to specify the maximum number of trace files.

Syntax: *xk* to specify KB, *xm* to specify MB, or *xg* to specify GB

Range: 10 KB through the maximum file size supported on your system

Default: 1 MB

world-readable—(Optional) Allow any user to read the log file.

Required Privilege Level routing and trace—To view this statement in the configuration.
routing-control and trace-control—To add this statement to the configuration.

| Syntax | <code>disable;</code> |
| Hierarchy Level | [edit protocols igmp-snooping vlan <i>vlan-name</i>] |
| Release Information | Statement introduced in Junos OS Release 11.1 for the QFX Series. |
| Description | Disable IGMP snooping on all interfaces in a VLAN. |
| Required Privilege Level | routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration. |
| Related Documentation | <ul style="list-style-type: none"> • Example: Configuring IGMP Snooping on page 4049 • Configuring IGMP Snooping on page 4048 |

group (IGMP Snooping)

| | |
|---------------------------------|--|
| Syntax | <code>group ip-address;</code> |
| Hierarchy Level | [edit protocols igmp-snooping vlan <i>vlan-name</i> interface <i>interface-name</i> static] |
| Release Information | Statement introduced in Junos OS Release 11.1 for the QFX Series. |
| Description | Configure a static multicast group using a valid IP multicast address. |
| Default | None. |
| Options | <i>ip-address</i> —IP address of the multicast group receiving data on an interface. |
| Required Privilege Level | routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration. |
| Related Documentation | <ul style="list-style-type: none"> • show igmp-snooping vlans on page 4312 • Example: Configuring IGMP Snooping on page 4049 • Configuring IGMP Snooping on page 4048 |

groups (Multicast VLAN Registration)

| | |
|---------------------------------|--|
| Syntax | <code>groups group-prefix;</code> |
| Hierarchy Level | [edit protocols igmp-snooping vlan (all <i>vlan-name</i>) data-forwarding source] |
| Release Information | Statement introduced in Junos OS Release 9.6 for EX Series switches.
Statement introduced in Junos OS Release 12.3 for the QFX Series. |
| Description | Specify the IP address range of the multicast VLAN (MVLAN) source interfaces. |
| Default | Disabled |
| Options | <i>group-prefix</i> —IP address range of the source group. Each MVLAN must have exactly one groups statement. If there are multiple MVLANs on the switch, their group ranges must be unique. |
| Required Privilege Level | routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration. |
| Related Documentation | <ul style="list-style-type: none">• Example: Configuring Multicast VLAN Registration on page 4054• Configuring Multicast VLAN Registration (CLI Procedure) on page 4053 |

igmp-querier

| | |
|---------------------------------|---|
| Syntax | <code>igmp-querier source-addresssource address;</code> |
| Hierarchy Level | [edit protocols igmp-snooping vlan <i>vlan-name</i>] |
| Release Information | Statement introduced in Junos OS Release 12.3 for the QFX Series. |
| Description | Configure the switch to be an IGMP querier. If there are any multicast routers on the same local network, make sure the source address for the IGMP querier is greater (a higher number) than the IP addresses for those routers on the network. This ensures that switch is always the IGMP querier on the network. |
| Required Privilege Level | routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration. |
| Related Documentation | <ul style="list-style-type: none">• Example: Configuring IGMP Snooping on page 4049• Configuring IGMP Snooping on page 4048• show igmp-snooping vlans on page 4312• show configuration protocols igmp on page 4292 |

igmp-snooping

```
Syntax  igmp-snooping {
        traceoptions {
            file filename <files number> <size size> <world-readable | no-world-readable> <match
              regex>;
            flag flag (detail | disable | receive | send);
        }
        vlan vlan-name {
            data-forwarding {
                source {

source-vlans

| | |
|---------------------------------|--|
| Syntax | <code>source-vlans <i>vlan-list</i>;</code> |
| Hierarchy Level | [edit protocols igmp-snooping vlan (all <i>vlan-name</i>) data-forwarding receiver] |
| Release Information | Statement introduced in Junos OS Release 9.6 for EX Series switches.
Statement introduced in Junos OS Release 12.3 for the QFX Series. |
| Description | Specify a list of multicast VLANs (MVLANS) from which this multicast receiver VLAN receives multicast traffic. Either all of these MVLANS must be in proxy mode or none of them can be in proxy mode. |
| Default | Disabled |
| Options | <i>vlan-list</i> —Names of the MVLANS. |
| Required Privilege Level | routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration. |
| Related Documentation | <ul style="list-style-type: none">• Example: Configuring Multicast VLAN Registration on page 4054• Configuring Multicast VLAN Registration (CLI Procedure) on page 4053 |

static (IGMP Snooping)

| | |
|---------------------------------|--|
| Syntax | <pre>static {
 group <i>ip-address</i>;
}</pre> |
| Hierarchy Level | [edit protocols igmp-snooping vlan <i>vlan-name</i> interface <i>interface-name</i>] |
| Release Information | Statement introduced in Junos OS Release 11.1 for the QFX Series. |
| Description | Statically define multicast groups on an interface.

The remaining statement is explained separately. |
| Default | No multicast groups are statically defined. |
| Required Privilege Level | routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration. |
| Related Documentation | <ul style="list-style-type: none">• Example: Configuring IGMP Snooping on page 4049• Configuring IGMP Snooping on page 4048• show igmp-snooping vlans on page 4312 |

traceoptions (IGMP Snooping)

| | |
|----------------------------|---|
| Syntax | <pre> traceoptions { file <i>filename</i> <files <i>number</i>> <no-stamp> <size <i>size</i>> <replace> <world-readable no-world-readable>; flag <i>flag</i> (detail disable receive send); } </pre> |
| Hierarchy Level | <p>For platforms without ELS:</p> <p>[edit protocols igmp-snooping]</p> <p>For platforms with ELS:</p> <p>[edit protocols igmp-snooping vlan]</p> |
| Release Information | Statement introduced in Junos OS Release 11.1 for the QFX Series. |
| Description | Define tracing operations for IGMP snooping. |
| Default | The traceoptions feature is disabled by default. |
| Options | <p>file <i>filename</i>—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory /var/log.</p> <p>files <i>number</i>—(Optional) Maximum number of trace files. When a trace file named trace-file reaches its maximum size, it is renamed trace-file.0, then trace-file.1, and so on, until the maximum number of trace files is reached (xk to specify KB, xm to specify MB, or xg to specify gigabytes), at which point the oldest trace file is overwritten. If you specify a maximum number of files, you also must specify a maximum file size with the size option.</p> <p>Range: 2 through 1000</p> <p>Default: 3 files</p> <p>flag <i>flag</i> —Tracing operation to perform. To specify more than one tracing operation, include multiple flag statements. You can include the following flags:</p> <ul style="list-style-type: none"> • all—All tracing operations. • general—Trace general IGMP snooping protocol events. • krt—Trace communication over routing sockets. • nexthop— Trace next-hop related events. • normal—Trace normal IGMP snooping protocol events. • packets—Trace all IGMP packets. • policy—Trace policy processing. • query—Trace IGMP membership query messages. • report—Trace membership report messages. |

- **route**—Trace routing information.
- **state**—Trace IGMP state transitions.
- **task**—Trace routing protocol task processing.
- **timer**—Trace routing protocol timer processing.
- **vlan**—Trace VLAN related events.

no-stamp—(Optional) Do not time stamp trace file.

no-world-readable—(Optional) Restrict file access to the user who created the file.

size size —(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named **trace-file** reaches its maximum size, it is renamed **trace-file.0**, then **trace-file.1**, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten. If you specify a maximum number of files, you also must specify a maximum file size with the **files** option. Use **xk** to specify KB, **xm** to specify MB, or **xg** to specify gigabytes.

Range: 10 KB through 1 gigabytes

Default: 128 KB

world-readable—(Optional) Enable unrestricted file access.

| | |
|---------------------------------|---|
| Required Privilege Level | routing—To view this statement in the configuration. |
| | routing-control—To add this statement to the configuration. |

version (IGMP Snooping)

| | |
|----------------------------|--|
| Syntax | <code>version number;</code> |
| Hierarchy Level | [edit protocols igmp-snooping vlan (all <i>vlan-name</i>)] |
| Release Information | Statement introduced in Junos OS Release 11.1 for EX Series switches.
Statement introduced in Junos OS Release 12.1 for the QFX Series. |
| Description | Specify the IGMP version for the IGMP general query that the switch sends to hosts when an interface comes up. The configured IGMP version affects only the version of the general queries sent by a switch. It does not affect the version of IGMP messages that the switch can snoop. For example, If the switch is configured for IGMP version 1 (IGMPv1), it can snoop IGMPv2 and IGMPv3 messages. |
| Default | If you do not configure the version statement, the default is IGMPv2. |
| Options | version —IGMP version number.
Range: 1 and 2. |

NOTE: IGMP v3 snooping is not supported.

| | |
|---------------------------------|---|
| Required Privilege Level | routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration. |

immediate-leave (IGMP Snooping)

| | |
|---|--|
| Syntax | immediate-leave; |
| Hierarchy Level | [edit protocols igmp-snooping vlan <i>vlan-name</i>] |
| Release Information | Statement introduced in Junos OS Release 11.1 for the QFX Series. |
| Description | After the switch receives a leave group membership message from a host, immediately remove the group membership from the interface and suppress the sending of any group-specific queries for the multicast group. |
| <div> NOTE: When configuring this statement, ensure that the IGMP interface has only one IGMPv2 host connected. If more than one IGMPv2 host is connected to the switch through the same interface and one of the hosts sends a leave message, the switch removes all hosts on the interface from the multicast group. The switch loses contact with the hosts in the multicast group that did not send a leave message until they send join requests in response to the next general multicast listener query from the router.</div> | |
| Default | The immediate-leave feature is disabled. |
| Required Privilege Level | routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration. |
| Related Documentation | <ul style="list-style-type: none">• Example: Configuring IGMP Snooping on page 4049• Configuring IGMP Snooping on page 4048• show igmp-snooping vlans on page 4312 |

vlan (IGMP Snooping)

| | |
|----------------------------|--|
| Syntax | <pre> vlan <i>vlan-name</i> { <i>immediate-leave</i>; interface <i>interface-name</i> { <i>multicast-router-interface</i>; static { <i>group ip-address</i>; } } <i>version number</i>; } </pre> |

    }  
}
```

Hierarchy Level [edit protocols]

Release Information Statement introduced in Junos OS Release 13.2 for the QFX Series.

Description Enable IGMP snooping on the router or switch.

Default IGMP snooping is disabled on the router or switch.

Options The statements are explained separately.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

immediate-leave (Bridge Domains)

| | |
|----------------------------|--|
| Syntax | <code>immediate-leave;</code> |
| Hierarchy Level | <pre>[edit bridge-domains <i>bridge-domain-name</i> protocols igmp-snooping], [edit bridge-domains <i>bridge-domain-name</i> protocols igmp-snooping <i>interface</i> <i>interface-name</i>], [edit bridge-domains <i>bridge-domain-name</i> protocols igmp-snooping vlan <i>vlan-id</i> <i>interface</i> <i>interface-name</i>], [edit routing-instances <i>routing-instance-name</i> bridge-domains <i>bridge-domain-name</i> protocols igmp-snooping], [edit routing-instances <i>routing-instance-name</i> bridge-domains <i>bridge-domain-name</i> protocols igmp-snooping <i>interface</i> <i>interface-name</i>], [edit routing-instances <i>routing-instance-name</i> bridge-domains <i>bridge-domain-name</i> protocols vlan <i>vlan-id</i> igmp-snooping <i>interface</i> <i>interface-name</i>] [edit protocols igmp-snooping vlan <i>interface</i>]</pre> |
| Release Information | <p>Statement introduced in Junos OS Release 8.5.</p> <p>Statement introduced in Junos OS Release 13.2 for the QFX series.</p> |
| Description | <p>The immediate leave setting is useful for minimizing the leave latency of IGMP memberships. When this setting is enabled, the routing device leaves the multicast group immediately after the last host leaves the multicast group.</p> <p>The immediate-leave setting enables host tracking, meaning that the device keeps track of the hosts that send join messages. This allows IGMP to determine when the last host sends a leave message for the multicast group.</p> <p>When the immediate leave setting is enabled, the device removes an interface from the forwarding-table entry without first sending IGMP group-specific queries to the interface. The interface is pruned from the multicast tree for the multicast group specified in the IGMP leave message. The immediate leave setting ensures optimal bandwidth management for hosts on a switched network, even when multiple multicast groups are being used simultaneously.</p> <p>When immediate leave is disabled and one host sends a leave group message, the routing device first sends a group query to determine if another receiver responds. If no receiver responds, the routing device removes all hosts on the interface from the multicast group. Immediate leave is disabled by default for both IGMP version 2 and IGMP version 3.</p> |

NOTE: Although host tracking is enabled for IGMPv2 and MLDv1 when you enable immediate leave, use immediate leave with these versions only when there is one host on the interface. The reason is that IGMPv2 and MLDv1 use a report suppression mechanism whereby only one host on an interface sends a group join report in response to a membership query. The other interested hosts suppress their reports. The purpose of this mechanism is to avoid a flood of reports for the same group. But it also interferes with host tracking, because the routing device only knows about the one interested host and does not know about the others.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

 [edit protocols [msdp](#)],
 [edit routing-instances *routing-instance-name* protocols [msdp](#)]

Release Information Statement introduced before Junos OS Release 7.4.
 Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Define an MSDP peer group. MSDP peers within groups share common tracing options, if present and not overridden for an individual peer with the [peer](#) statement. To configure multiple MSDP groups, include multiple **group** statements.

By default, the group's options are identical to the global MSDP options. To override the global options, include group-specific options within the **group** statement.

The group must contain at least one peer.

Options *group-name*—Name of the MSDP group.

The remaining statements are explained separately.

Required Privilege routing—To view this statement in the configuration.
Level routing-control—To add this statement to the configuration.

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Apply one or more policies to routes being imported into the routing table from MSDP.

Options *policy-names*—Name of one or more policies.

Required Privilege routing—To view this statement in the configuration.
Level routing-control—To add this statement to the configuration.

| Release Information | <p>Statement introduced before Junos OS Release 7.4.</p> <p>Statement introduced in Junos OS Release 12.1 for the QFX Series.</p> |
| Description | <p>Configure MSDP tracing options.</p> <p>To specify more than one tracing operation, include multiple flag statements.</p> |
| Default | <p>The default MSDP trace options are those inherited from the routing protocol's traceoptions statement included at the [edit routing-options] hierarchy level.</p> |
| Options | <p>disable—(Optional) Disable the tracing operation. You can use this option to disable a single operation when you have defined a broad group of tracing operations, such as all.</p> <p>file <i>filename</i>—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory /var/log. We recommend that you place tracing output in the msdp-log file.</p> <p>files <i>number</i>—(Optional) Maximum number of trace files. When a trace file named trace-file reaches its maximum size, it is renamed trace-file.0, then trace-file.1, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.</p> |

If you specify a maximum number of files, you must also include the **size** statement to specify the maximum file size.

Range: 2 through 1000 files

Default: 2 files

flag *flag*—Tracing operation to perform. To specify more than one tracing operation, include multiple **flag** statements.

MSDP Tracing Flags

- **keepalive**—Keepalive messages
- **packets**—All MSDP packets
- **route**—MSDP changes to the routing table
- **source-active**—Source-active packets
- **source-active-request**—Source-active request packets
- **source-active-response**—Source-active response packets

Global Tracing Flags

- **all**—All tracing operations
- **general**—A combination of the **normal** and **route** trace operations
- **normal**—All normal operations

Default: If you do not specify this option, only unusual or abnormal operations are traced.

- **policy**—Policy operations and actions
- **route**—Routing table changes
- **state**—State transitions
- **task**—Interface transactions and processing
- **timer**—Timer usage

flag-modifier—(Optional) Modifier for the tracing flag. You can specify one or more of these modifiers:

- **detail**—Detailed trace information
- **receive**—Packets being received
- **send**—Packets being transmitted

no-stamp—(Optional) Do not place timestamp information at the beginning of each line in the trace file.

Default: If you omit this option, timestamp information is placed at the beginning of each line of the tracing output.

no-world-readable—(Optional) Do not allow any user to read the log file.

replace—(Optional) Replace an existing trace file if there is one.

Default: If you do not include this option, tracing output is appended to an existing trace file.

size size—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named **trace-file** reaches this size, it is renamed **trace-file.0**. When **trace-file** again reaches this size, **trace-file.0** is renamed **trace-file.1** and **trace-file** is renamed **trace-file.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you must also include the **files** statement to specify the maximum number of trace files.

Syntax: **xk** to specify KB, **xm** to specify MB, or **xg** to specify GB

Range: 10 KB through the maximum file size supported on your system

Default: 1 MB

world-readable—(Optional) Allow any user to read the log file.

Administration

- [Routine Monitoring on page 4257](#)
- [Monitoring Commands for Multicast Protocols on page 4258](#)

Routine Monitoring

- [Monitoring IGMP Snooping on page 4257](#)
- [Verifying the IGMP Snooping Group Timeout Value on page 4258](#)

Monitoring IGMP Snooping

- Purpose** Use the monitoring feature to view status and information about the IGMP snooping configuration.
- Action** To display IGMP snooping details in the CLI, enter the following commands:
 - `show igmp-snooping vlans`
 - `show igmp-snooping statistics`
 - `show igmp-snooping route`
 - `show igmp-snooping membership`
- Meaning** [Table 306 on page 4257](#) summarizes the IGMP snooping details displayed.

Table 306: Summary of IGMP Snooping Output Fields

| Field | Values |
|-----------------------|---|
| IGMP Snooping Monitor | |
| VLAN | VLAN for which IGMP snooping is enabled. |
| Interfaces | Interface connected to a multicast router. |
| Groups | Number of the multicast groups learned by the VLAN. |
| MRouters | Multicast router. |
| Receivers | Multicast receiver. |

Table 306: Summary of IGMP Snooping Output Fields (*continued*)

| Field | Values |
|------------------------|--|
| IGMP Route Information | |
| VLAN | VLAN for which IGMP snooping is enabled. |
| Next-Hop | Next hop assigned by the switch after performing the route lookup. |
| Group | Multicast groups learned by the VLAN. |

- Related Documentation**
- [IGMP Snooping Overview on page 3962](#)
 - [Example: Configuring IGMP Snooping on page 4049](#)
 - [Configuring IGMP Snooping on page 4048](#)
 - [Changing the IGMP Snooping Group Timeout Value on page 4051](#)

Verifying the IGMP Snooping Group Timeout Value

Purpose Verify that the IGMP snooping group timeout value has been changed correctly from its default value.

Action Display the IGMP snooping membership information, which contains the group timeout value that was derived from the IGMP configuration:

```
user@switch> show igmp-snooping membership detail
VLAN: v43 Tag: 43 (Index: 4)
Group: 225.0.0.1
Receiver count: 1, Flags: <v2-hosts>
ge-0/0/15.0 Uptime: 00:00:05 timeout: 510
```

Meaning The IGMP snooping group timeout value determines how long a switch waits to receive an IGMP query from a multicast router before removing a multicast group from its multicast cache table. When you enable IGMP snooping, the default IGMP snooping group timeout value of 260 seconds is applied to all VLANs, which means that the switch waits 260 seconds to receive an IGMP query before removing a multicast group from its multicast cache table. You can change the timeout value by using the **robust-count** option.

<interface <i>interface-name</i> >
<logical-system (all <i>logical-system-name</i>)> |
| Syntax (EX Series Switch and the QFX Series) | clear multicast statistics
<inet inet6>
<instance <i>instance-name</i> >
<interface <i>interface-name</i> > |
| Release Information | Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
inet6 and instance options introduced in Junos OS Release 10.0 for EX Series switches.
Command introduced in Junos OS Release 11.3 for the QFX Series. |
| Description | Clear IP multicast statistics. |
| Options | none —Clear multicast statistics for all supported address families on all interfaces.

inet —(Optional) Clear multicast statistics for IPv4 family addresses.

inet6 —(Optional) Clear multicast statistics for IPv6 family addresses.

instance <i>instance-name</i> —(Optional) Clear multicast statistics for the specified instance.

interface <i>interface-name</i> —(Optional) Clear multicast statistics on a specific interface.

logical-system (all <i>logical-system-name</i>) —(Optional) Perform this operation on all logical systems or on a particular logical system. |
| Required Privilege Level | clear |
| Related Documentation | <ul style="list-style-type: none">• <i>show multicast statistics</i> |

mtrace

| | |
|---------------------------------|--|
| Syntax | <code>mtrace source</code>
<logical-system <i>logical-system-name</i> >
<routing-instance <i>routing-instance-name</i> > |
| Release Information | Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
Command introduced in Junos OS Release 9.5 for SRX1400, SRX3400, SRX3600, SRX5600, and SRX5800 devices.
Command introduced in Junos OS Release 11.3 for the QFX Series.
Command introduced in Junos OS Release 12.3 for the PTX Series. |
| Description | Display trace information about an IP multicast path. |
| Options | <i>source</i> —Source hostname or address.

<i>logical-system (logical-system-name)</i> —(Optional) Perform this operation on a logical system.

<i>routing-instance routing-instance-name</i> —(Optional) Trace a particular routing instance. |
| Additional Information | The mtrace command for multicast traffic is similar to the traceroute command used for unicast traffic. Unlike traceroute , mtrace traces traffic backwards, from the receiver to the source. |
| Required Privilege Level | view |
| List of Sample Output | mtrace source on page 4283 |
| Output Fields | Table 307 on page 4281 describes the output fields for the mtrace command. Output fields are listed in the approximate order in which they appear. |

Table 307: mtrace Output Fields

| Field Name | Field Description |
|-----------------------------------|---|
| Mtrace from | IP address of the receiver. |
| to | IP address of the source. |
| via group | IP address of the multicast group (if any). |
| Querying full reverse path | Indicates the full reverse path query has begun. |
| <i>number-of-hops</i> | Number of hops from the source to the named router or switch. |
| <i>router-name</i> | Name of the router or switch for this hop. |
| <i>address</i> | Address of the router or switch for this hop. |

Table 307: mtrace Output Fields (*continued*)

| Field Name | Field Description |
|-----------------|--|
| <i>protocol</i> | Protocol used (for example, PIM). |
| Round trip time | Average round-trip time, in milliseconds (ms). |
| total ttl of | Time-to-live (TTL) threshold. |

Sample Output

mtrace source

```
user@host> mtrace 192.1.4.2
Mtrace from 192.1.4.2 to 192.1.1.2 via group 0.0.0.0
Querying full reverse path... * *
 0 routerA.lab.mycompany.net (192.1.1.2)
-1 routerB.lab.mycompany.net (192.1.2.2) PIM thresh^ 1
-2 routerC.lab.mycompany.net (192.1.3.2) PIM thresh^ 1
-3 hostA.lab.mycompany.net (192.1.4.2)
Round trip time 2 ms; total ttl of 2 required.
```

mtrace from-source

Syntax `mtrace from-source source source`
`<brief | detail>`
`<extra-hops extra-hops>`
`<group group>`
`<interval interval>`
`<loop>`
`<max-hops max-hops>`
`<max-queries max-queries>`
`<multicast-response | unicast-response>`
`<no-resolve>`
`<no-router-alert>`
`<response response>`
`<routing-instance routing-instance-name>`
`<ttl ttl>`
`<wait-time wait-time>`

Release Information Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
Command introduced in Junos OS Release 11.3 for the QFX Series.

Description Display trace information about an IP multicast path from a source to this router or switch. If you specify a group address with this command, Junos OS returns additional information, such as packet rates and losses.

Options **brief | detail**—(Optional) Display the specified level of output.

extra-hops *extra-hops*—(Optional) Number of hops to take after reaching a nonresponsive router. You can specify a number between **0** and **255**.

group *group*—(Optional) Group address for which to trace the path. The default group address is **0.0.0.0**.

interval *interval*—(Optional) Number of seconds to wait before gathering statistics again. The default value is **10** seconds.

loop—(Optional) Loop indefinitely, displaying rate and loss statistics.

max-hops *max-hops*—(Optional) Maximum hops to trace toward the source. The range of values is **0** through **255**. The default value is **32** hops.

max-queries *max-queries*—(Optional) Maximum number of query attempts for any hop. The range of values is 1 through **32**. The default is **3**.

multicast-response—(Optional) Always request the response using multicast.

no-resolve—(Optional) Do not attempt to display addresses symbolically.

no-router-alert—(Optional) Do not use the router-alert IP option.

response *response*—(Optional) Send trace response to a host or multicast address.

routing-instance *routing-instance-name*—(Optional) Trace a particular routing instance.

source *source*—Source hostname or address.

ttl *tll*—(Optional) IP time-to-live (TTL) value. You can specify a number between 0 and 255. Local queries to the multicast group use a value of 1. Otherwise, the default value is 127.

unicast-response—(Optional) Always request the response using unicast.

wait-time *wait-time*—(Optional) Number of seconds to wait for a response. The default value is 3.

List of Sample Output [mtrace from-source on page 4286](#)

Output Fields [Table 308 on page 4285](#) describes the output fields for the **mtrace from-source** command. Output fields are listed in the approximate order in which they appear.

Table 308: mtrace from-source Output Fields

| Field Name | Field Description |
|-----------------------------------|---|
| Mtrace from | IP address of the receiver. |
| to | IP address of the source. |
| via group | IP address of the multicast group (if any). |
| Querying full reverse path | Indicates the full reverse path query has begun. |
| number-of-hops | Number of hops from the source to the named router or switch. |
| router-name | Name of the router or switch for this hop. |
| address | Address of the router or switch for this hop. |
| protocol | Protocol used (for example, PIM). |
| Round trip time | Average round-trip time, in milliseconds (ms). |
| total ttl of | Time-to-live (TTL) threshold. |
| source | Source address. |
| Response Dest | Response destination address. |
| Overall | Average packet rate for all traffic at each hop. |

Table 308: mtrace from-source Output Fields (*continued*)

| Field Name | Field Description |
|---|--|
| Packet Statistics for Traffic From | Number of packets lost, number of packets sent, percentage of packets lost, and average packet rate at each hop. |
| Receiver | IP address receiving the multicast. |
| Query source | IP address sending the mtrace query. |

Sample Output

mtrace from-source

```

user@host> mtrace from-source source 192.1.4.2 group 225.1.1.1
Mtrace from 192.1.4.2 to 192.1.1.2 via group 225.1.1.1
Querying full reverse path... * *

packet from 192.1.3.2 to 224.0.0.2
from 192.1.3.2 to 192.1.3.38 via group 224.1.1.1 (mxhop=60)

Mtrace query at Oct 22 13:36:30 by 192.1.3.2, resp to same, qid 7c88ad
packet from 192.1.3.2 to 224.0.0.2
from 192.1.3.2 to 192.1.3.38 via group 224.1.1.1 (mxhop=60)
```

mtrace to-gateway

| | |
|----------------------------|--|
| Syntax | <pre> mtrace to-gateway gateway gateway <brief detail> <extra-hops extra-hops> <group group> <interface interface-name> <interval interval> <loop> <max-hops max-hops> <max-queries max-queries> <multicast-response unicast-response> <no-resolve> <no-router-alert> <response response> <routing-instance routing-instance-name> <tll ttl> <unicast-response> <wait-time wait-time> </pre> |
| Release Information | <p>Command introduced before Junos OS Release 7.4.</p> <p>Command introduced in Junos OS Release 9.0 for EX Series switches.</p> <p>Command introduced in Junos OS Release 11.3 for the QFX Series.</p> |
| Description | Display trace information about a multicast path from this router or switch to a gateway router or switch. |
| Options | <p>gateway gateway—Send the trace query to a gateway multicast address.</p> <p>brief detail—(Optional) Display the specified level of output.</p> <p>extra-hops extra-hops—(Optional) Number of hops to take after reaching a nonresponsive router or switch. You can specify a number between 0 and 255.</p> <p>group group—(Optional) Group address for which to trace the path. The default group address is 0.0.0.0.</p> <p>interface interface-name—(Optional) Source address for sending the trace query.</p> <p>interval interval—(Optional) Number of seconds to wait before gathering statistics again. The default value is 10.</p> <p>loop—(Optional) Loop indefinitely, displaying rate and loss statistics.</p> <p>max-hops max-hops—(Optional) Maximum hops to trace toward the source. You can specify a number between 0 and 255. The default value is 32.</p> <p>max-queries max-queries—(Optional) Maximum number of query attempts for any hop. You can specify a number between 0 and 255. The default value is 3.</p> <p>multicast-response—(Optional) Always request the response using multicast.</p> <p>no-resolve—(Optional) Do not attempt to display addresses symbolically.</p> |

no-router-alert—(Optional) Do not use the router-alert IP option.

response *response*—(Optional) Send trace response to a host or multicast address.

routing-instance *routing-instance-name*—(Optional) Trace a particular routing instance.

ttl *tll*—(Optional) IP time-to-live value. You can specify a number between 0 and 225. Local queries to the multicast group use TTL 1. Otherwise, the default value is 127.

unicast-response—(Optional) Always request the response using unicast.

wait-time *wait-time*—(Optional) Number of seconds to wait for a response. The default value is 3.

show configuration protocols igmp

| | |
|---------------------------------|---|
| Syntax | show configuration protocols igmp |
| Release Information | Command introduced in Junos OS Release 11.3 for the QFX Series. |
| Description | Display Internet Group Management Protocol (IGMP) information. |
| Required Privilege Level | view |
| Related Documentation | <ul style="list-style-type: none"> • IGMP Snooping Overview on page 3962 • Configuring IGMP Snooping on page 4048 |
| List of Sample Output | show configuration protocols igmp on page 4292 |
| Output Fields | Table 311 on page 4292 describes the output fields for the show configuration protocols igmp command that relate to IGMP querying. |

Table 311: show igmp group Output Fields

| Field Name | Field Description | Level of Output |
|-------------------------|--|-----------------|
| accounting | Enables notification for join and leave events. | All levels |
| igmp-querier | Configured source address for the IGMP querier. | All levels |
| interface | Name of the interface that receives IGMP membership reports. | All levels |
| query-interval | Interval at which the IGMP querier sends general host-query messages to solicit membership information. | All levels |
| query-response-interval | How long the IGMP querier waits to receive a response from a query message before sending another query. | All levels |
| src-address | Source address of IGMP queries. | |
| version | IGMP version. | All levels |

Sample Output

show configuration protocols igmp

```

user@switch> show configuration protocols igmp
query-interval 150;
query-response-interval 50;
accounting;
interface vlan.43 {
  version 2;
}
igmp-querier {

```

```
src-address 10.0.0.2;  
}
```

show igmp group

| | |
|---|---|
| Syntax | show igmp group
<brief detail>
<group-name>
<logical-system (all <i>logical-system-name</i>)> |
| Syntax (EX Series Switch and the QFX Series) | show igmp group
<brief detail>
<group-name> |
| Release Information | Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
Command introduced in Junos OS Release 11.3 for the QFX Series. |
| Description | Display Internet Group Management Protocol (IGMP) group membership information. |
| Options | none —Display standard information about membership for all IGMP groups.

brief detail —(Optional) Display the specified level of output.

group-name —(Optional) Display group membership for the specified IP address only.

logical-system (all <i>logical-system-name</i>) —(Optional) Perform this operation on all logical systems or on a particular logical system. |
| Required Privilege Level | view |
| Related Documentation | <ul style="list-style-type: none"> clear igmp membership on page 4261 |
| List of Sample Output | show igmp group (Include Mode) on page 4295
show igmp group (Exclude Mode) on page 4296
show igmp group brief on page 4296
show igmp group detail on page 4296 |
| Output Fields | Table 311 on page 4292 describes the output fields for the show igmp group command. Output fields are listed in the approximate order in which they appear. |

Table 312: show igmp group Output Fields

| Field Name | Field Description | Level of Output |
|-------------------|---|-----------------|
| Interface | Name of the interface that received the IGMP membership report. A name of local indicates that the local routing device joined the group itself. | All levels |
| Group | Group address. | All levels |
| Group Mode | Mode the SSM group is operating in: Include or Exclude . | All levels |
| Source | Source address. | All levels |

Table 312: show igmp group Output Fields (*continued*)

| Field Name | Field Description | Level of Output |
|------------------|---|-----------------|
| Source timeout | Time remaining until the group traffic is no longer forwarded. The timer is refreshed when a listener in include mode sends a report. A group in exclude mode or configured as a static group displays a zero timer. | detail |
| Last reported by | Address of the host that last reported membership in this group. | All levels |
| Timeout | Time remaining until the group membership is removed. | brief none |
| Group timeout | Time remaining until a group in exclude mode moves to include mode. The timer is refreshed when a listener in exclude mode sends a report. A group in include mode or configured as a static group displays a zero timer. | detail |
| Type | Type of group membership: <ul style="list-style-type: none"> • Dynamic—Host reported the membership. • Static—Membership is configured. | All levels |

Sample Output

show igmp group (Include Mode)

```

user@host> show igmp group
Interface: t1-0/1/0.0
  Group: 232.1.1.1
    Group mode: Include
    Source: 10.0.0.2

```

show igmp interface

| | |
|---|--|
| Syntax | show igmp interface
<brief detail>
<interface-name>
<logical-system (all <i>logical-system-name</i>)> |
| Syntax (EX Series Switches and the QFX Series) | show igmp interface
<brief detail>
<interface-name> |
| Release Information | Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
Command introduced in Junos OS Release 11.3 for the QFX Series. |
| Description | Display information about Internet Group Management Protocol (IGMP)-enabled interfaces. |
| Options | <p>none—Display standard information about all IGMP-enabled interfaces.</p> <p>brief detail—(Optional) Display the specified level of output.</p> <p>interface-name—(Optional) Display information about the specified IGMP-enabled interface only.</p> <p>logical-system (all <i>logical-system-name</i>)—(Optional) Perform this operation on all logical systems or on a particular logical system.</p> |
| Required Privilege Level | view |
| Related Documentation | <ul style="list-style-type: none"> clear igmp membership on page 4261 |
| List of Sample Output | show igmp interface on page 4300
show igmp interface brief on page 4300
show igmp interface detail on page 4301
show igmp interface <interface-name> on page 4301 |
| Output Fields | <p>Table 313 on page 4298 describes the output fields for the show igmp interface command. Output fields are listed in the approximate order in which they appear.</p> |

Table 313: show igmp interface Output Fields

| Field Name | Field Description | Level of Output |
|------------|---|-----------------|
| Interface | Name of the interface. | All levels |
| Querier | Address of the routing device that has been elected to send membership queries. | All levels |
| State | State of the interface: Up or Down . | All levels |

Table 313: show igmp interface Output Fields (*continued*)

| Field Name | Field Description | Level of Output |
|---------------------------|---|-----------------|
| SSM Map Policy | Name of the source-specific multicast (SSM) map policy that has been applied to the IGMP interface. | All levels |
| Timeout | How long until the IGMP querier is declared to be unreachable, in seconds. | All levels |
| Version | IGMP version being used on the interface: 1, 2, or 3. | All levels |
| Groups | Number of groups on the interface. | All levels |
| Group limit | Maximum number of groups allowed on the interface. Any joins requested after the limit is reached are rejected. | All levels |
| Group threshold | Configured threshold at which a warning message is generated.

This threshold is based on a percentage of groups received on the interface. If the number of groups received reaches the configured threshold, the device generates a warning message. | All levels |
| Group log-interval | Time (in seconds) between consecutive log messages. | All levels |
| Immediate Leave | State of the immediate leave option: <ul style="list-style-type: none"> • On—Indicates that the router removes a host from the multicast group as soon as the router receives a leave group message from a host associated with the interface. • Off—Indicates that after receiving a leave group message, instead of removing a host from the multicast group immediately, the router sends a group query to determine if another receiver responds. | All levels |
| Promiscuous Mode | State of the promiscuous mode option: <ul style="list-style-type: none"> • On—Indicates that the router can accept IGMP reports from subnetworks that are not associated with its interfaces. • Off—Indicates that the router can accept IGMP reports only from subnetworks that are associated with its interfaces. | All levels |
| Passive | State of the passive mode option: <ul style="list-style-type: none"> • On—Indicates that the router can run IGMP on the interface but not send or receive control traffic such as IGMP reports, queries, and leaves. • Off—Indicates that the router can run IGMP on the interface and send or receive control traffic such as IGMP reports, queries, and leaves. <p>The passive statement enables you to selectively activate up to two out of a possible three available query or control traffic options. When enabled, the following options appear after the on state declaration:</p> <ul style="list-style-type: none"> • send-general-query—The interface sends general queries. • send-group-query—The interface sends group-specific and group-source-specific queries. • allow-receive—The interface receives control traffic. | All levels |
| OIF map | Name of the OIF map (if configured) associated with the interface. | All levels |

Table 313: show igmp interface Output Fields (*continued*)

| Field Name | Field Description | Level of Output |
|-----------------------|--|-----------------|
| SSM map | Name of the source-specific multicast (SSM) map (if configured) used on the interface. | All levels |
| Configured Parameters | Information configured by the user: <ul style="list-style-type: none"> IGMP Query Interval—Interval (in seconds) at which this router sends membership queries when it is the querier. IGMP Query Response Interval—Time (in seconds) that the router waits for a report in response to a general query. IGMP Last Member Query Interval—Time (in seconds) that the router waits for a report in response to a group-specific query. IGMP Robustness Count—Number of times the router retries a query. | All levels |
| Derived Parameters | Derived information: <ul style="list-style-type: none"> IGMP Membership Timeout—Timeout period (in seconds) for group membership. If no report is received for these groups before the timeout expires, the group membership is removed. IGMP Other Querier Present Timeout—Time (in seconds) that the router waits for the IGMP querier to send a query. | All levels |

Sample Output

show igmp interface

```

user@host> show igmp interface
Interface: at-0/3/1.0
  Querier: 10.111.30.1
  State:      Up Timeout:   None Version:  2 Groups:    4
  SSM Map Policy: ssm-policy-A
Interface: so-1/0/0.0
  Querier: 10.111.10.1
  State:      Up Timeout:   None Version:  2 Groups:    2
  SSM Map Policy: ssm-policy-B
Interface: so-1/0/1.0
  Querier: 10.111.20.1
  State:      Up Timeout:   None Version:  2 Groups:    4
  SSM Map Policy: ssm-policy-C
Immediate Leave: On
Promiscuous Mode: Off

Configured Parameters:
IGMP Query Interval: 125.0
IGMP Query Response Interval: 10.0
IGMP Last Member Query Interval: 1.0
IGMP Robustness Count: 2

Derived Parameters:
IGMP Membership Timeout: 260.0
IGMP Other Querier Present Timeout: 255.0

```

show igmp interface brief

The output for the **show igmp interface brief** command is identical to that for the **show igmp interface** command. For sample output, see [show igmp interface on page 4300](#).

show igmp interface detail

The output for the **show igmp interface detail** command is identical to that for the **show igmp interface** command. For sample output, see [show igmp interface on page 4300](#).

show igmp interface <interface-name>

```
user@host# show igmp interface ge-3/2/0.0
Interface: ge-3/2/0.0
Querier: 20.1.1.1
State: Up Timeout:   None Version:  3 Groups:    1
Group limit: 8
Group threshold: 60
Group log-interval: 10
Immediate leave: Off
Promiscuous mode: Off
```

Table 316: show igmp-snooping route Output Fields

| Field Name | Field Description |
|------------|--|
| Table | (For internal use only. Value is always 0.) |
| VLAN | Name of the VLAN. |
| Group | Multicast group address. |
| Interfaces | Interfaces on which IGMP packets were snooped. |
| Next-hop | ID associated with the next-hop device. |

Sample Output

show igmp-snooping route

```

user@switch> show igmp-snooping route
VLAN          Group          Next-hop
V11           224.1.1.1, *      533
               Interfaces: ge-0/0/13.0, ge-0/0/1.0
VLAN          Group          Next-hop
v12           224.1.1.3, *      534
               Interfaces: ge-0/0/13.0, ge-0/0/0.0

```

show igmp-snooping route vlan v1

```

user@switch> show igmp-snooping route vlan v1
Table: 0
VLAN          Group          Next-hop
v1           224.1.1.1, *      1266
               Interfaces: ge-0/0/0.0
v1           224.1.1.3, *      1266
               Interfaces: ge-0/0/0.0
v1           224.1.1.5, *      1266
               Interfaces: ge-0/0/0.0
v1           224.1.1.7, *      1266
               Interfaces: ge-0/0/0.0
v1           224.1.1.9, *      1266
               Interfaces: ge-0/0/0.0
v1           224.1.1.11, *     1266
               Interfaces: ge-0/0/0.0

```

show igmp-snooping statistics

| | |
|---------------------------------|---|
| Syntax | show igmp-snooping statistics |
| Release Information | Command introduced in Junos OS Release 11.1 for the QFX Series. |
| Description | Display IGMP snooping statistics. |
| Required Privilege Level | view |
| Related Documentation | <ul style="list-style-type: none"> • Monitoring IGMP Snooping on page 4257 • Configuring IGMP Snooping on page 4048 • show igmp-snooping route on page 4308 • show igmp-snooping vlans on page 4312 |
| List of Sample Output | show igmp-snooping statistics on page 4311 |
| Output Fields | Table 317 on page 4310 lists the output fields for the show igmp-snooping statistics command. Output fields are listed in the approximate order in which they appear. |

Table 317: show igmp-snooping statistics Output Fields

| Field Name | Field Description |
|-------------------|---|
| Bad length | IGMP packet has illegal or bad length. |
| Bad checksum | IGMP or IP checksum is incorrect. |
| Invalid interface | Packet was received through an invalid interface. |
| Not local | Number of packets received from senders that are not local. |
| Receive unknown | Unknown IGMP type. |
| Timed out | Number of timeouts for all multicast groups. |
| IGMP Type | Type of IGMP message (Queries , Reports , Leaves , or Other). |
| Received | Number of IGMP packets received. |
| Transmitted | Number of IGMP packets transmitted. |
| Recv Errors | Number of general receive errors. |

Sample Output

show igmp-snooping statistics

```
user@switch> show igmp-snooping statistics
```

```
Bad length: 0 Bad checksum: 0 Invalid interface: 0
```

```
Not local: 0 Receive unknown: 0 Timed out: 58
```

| IGMP Type | Received | Transmitted | Recv Errors |
|-----------|----------|-------------|-------------|
| Queries: | 74295 | 0 | 0 |
| Reports: | 18148423 | 0 | 16333523 |
| Leaves: | 0 | 0 | 0 |
| Other: | 0 | 0 | 0 |

show igmp-snooping vlans

| | |
|---------------------------------|--|
| Syntax | show igmp-snooping vlans
<brief detail>
<vlan <i>vlan-id</i> <i>vlan-name</i> > |
| Release Information | Command introduced in Junos OS Release 11.1 for the QFX Series. |
| Description | Display IGMP snooping VLAN information. |
| Options | <p>none—Display general parameters.</p> <p>brief detail—(Optional) Display the specified level of output.</p> <p>vlan <i>vlan-id</i> vlan <i>vlan-number</i>—(Optional) Display VLAN information for the specified VLAN.</p> |
| Required Privilege Level | view |
| Related Documentation | <ul style="list-style-type: none"> • Monitoring IGMP Snooping on page 4257 • Configuring IGMP Snooping on page 4048 • show igmp-snooping route on page 4308 • show igmp-snooping statistics on page 4310 |
| List of Sample Output | show igmp-snooping vlans on page 4313
show igmp-snooping vlans vlan on page 4313
show igmp-snooping vlans vlan detail on page 4313 |
| Output Fields | Table 318 on page 4312 lists the output fields for the show igmp-snooping vlans command. Output fields are listed in the approximate order in which they appear. |

Table 318: show igmp-snooping vlans Output Fields

| Field Name | Field Description | Level of Output |
|------------------------|---|-----------------|
| VLAN | Name of the VLAN. | All levels |
| IGMP-L2-Querier | Source address for IGMP snooping queries (if switch is an IGMP querier) | All levels |
| Interfaces | Number of interfaces in the VLAN. | All levels |
| Groups | Number of groups in the VLAN. | All levels |
| MRouters | Number of multicast routers associated with the VLAN. | All levels |
| Receivers | Number of host receivers in the VLAN. | All levels |

Table 318: show igmp-snooping vlans Output Fields (*continued*)

| Field Name | Field Description | Level of Output |
|--------------------|--|-----------------|
| Tag | Numerical identifier of the VLAN. | detail |
| tagged untagged | Interface participates in a tagged (802.1Q) or untagged (native) VLAN. | detail |
| vlan-interface | Internal VLAN interface identifier. | detail |
| Membership timeout | Membership timeout value. | detail |
| Querier timeout | Timeout value for interfaces dynamically marked as router or switch interfaces (interfaces that receive queries). When the querier timeout is reached, the switch marks the interface as a host interface. | detail |
| Interface | Name of the interface. | detail |
| Reporters | Number of dynamic groups on an interface. | detail |

Sample Output

show igmp-snooping vlans

```

user@switch> show igmp-snooping vlans
VLAN      Interfaces Groups MRouters Receivers
default   0          0      0        0
v1        11         50      0        0
v10       1          0      0        0
v11       1          0      0        0
v180      3          0      1        0
v181      3          0      0        0
v182      3          0      0        0

```

show igmp-snooping vlans vlan

```

user@switch> show igmp-snooping vlans vlan v10
user@switch> show igmp-snooping vlans vlan v10
VLAN      Interfaces Groups MRouters Receivers
v10       1          0      0        0

```

show igmp-snooping vlans vlan detail

```

user@switch> show igmp-snooping vlans vlan v10 detail
VLAN: v10, Tag: 10, vlan-interface: vlan.10
      Interface: ge-0/0/10.0, tagged, Groups: 0
IGMP-L2-Querier: Stopped, SourceAddress: 10.10.1.2

```

show msdp

| | |
|---------------------------------|---|
| Syntax | <pre>show msdp <brief detail> <instance <i>instance-name</i>> <logical-system (all <i>logical-system-name</i>)> <peer <i>peer-address</i>></pre> |
| Release Information | <p>Command introduced before Junos OS Release 7.4.</p> <p>Command introduced in Junos OS Release 12.1 for the QFX Series.</p> |
| Description | Display Multicast Source Discovery Protocol (MSDP) information. |
| Options | <p>none—Display standard MSDP information for all routing instances.</p> <p>brief detail—(Optional) Display the specified level of output.</p> <p>instance <i>instance-name</i>—(Optional) Display information for the specified instance only.</p> <p>logical-system (all <i>logical-system-name</i>)—(Optional) Perform this operation on all logical systems or on a particular logical system.</p> <p>peer <i>peer-address</i>—(Optional) Display information about the specified peer only.</p> |

| Related Documentation | <ul style="list-style-type: none"> • show msdp source on page 4316 • show msdp source-active on page 4318 • show msdp statistics on page 4321 |
| List of Sample Output | <p>show msdp on page 4315</p> <p>show msdp brief on page 4315</p> <p>show msdp detail on page 4315</p> |
| Output Fields | Table 319 on page 4314 describes the output fields for the show msdp command. Output fields are listed in the approximate order in which they appear. |

Table 319: show msdp Output Fields

| Field Name | Field Description | Level of Output |
|---------------|--|-----------------|
| Peer address | IP address of the peer. | All levels |
| Local address | Local address of the peer. | All levels |
| State | Status of the MSDP connection: Listen , Established , or Inactive . | All levels |
| Last up/down | Time at which the most recent peer-state change occurred. | All levels |

Table 319: show msdp Output Fields (*continued*)

| Field Name | Field Description | Level of Output |
|----------------------|---|-----------------|
| Peer-Group | Peer group name. | All levels |
| SA Count | Number of source-active cache entries advertised by each peer that were accepted, compared to the number that were received, in the format <i>number-accepted/number-received</i> . | All levels |
| Peer Connect Retries | Number of peer connection retries. | detail |
| State timer expires | Number of seconds before another message is sent to a peer. | detail |
| Peer Times out | Number of seconds to wait for a response from the peer before the peer is declared unavailable. | detail |
| SA accepted | Number of entries in the source-active cache accepted from the peer. | detail |
| SA received | Number of entries in the source-active cache received by the peer. | detail |

Sample Output

show msdp

```

user@host> show msdp
Peer address    Local address  State      Last up/down Peer-Group SA Count
198.32.8.193    198.32.8.195  Established 5d 19:25:44 North23    120/150

198.32.8.198    198.32.8.195  Established 3d 19:33:04 North23   2305/3000

```

show msdp brief

The output for the **show msdp brief** command is identical to that for the **show msdp** command. For sample output, see [show msdp on page 4315](#).

show msdp detail

```

user@host> show msdp detail
Peer: 10.255.70.15
Local address: 10.255.70.19
State: Established
Peer Connect Retries: 0
State timer expires: 22
Peer Times out: 49
SA accepted: 0
SA received: 0

```

show msdp source

| | |
|---------------------------------|---|
| Syntax | <code>show msdp source</code>
<code><instance <i>instance-name</i>></code>
<code><logical-system (all <i>logical-system-name</i>)></code>
<code><source-address></code> |
| Release Information | Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 12.1 for the QFX Series. |
| Description | Display multicast sources learned from Multicast Source Discovery Protocol (MSDP). |
| Options | none —Display standard MSDP source information for all routing instances.

instance <i>instance-name</i> —(Optional) Display information for the specified instance only.

logical-system (all <i>logical-system-name</i>) —(Optional) Perform this operation on all logical systems or on a particular logical system.

source-address —(Optional) IP address and optional prefix length. Display information for the specified source address only. |
| Required Privilege Level | view |
| Related Documentation | <ul style="list-style-type: none">• show msdp on page 4314• show msdp source-active on page 4318• show msdp statistics on page 4321 |
| List of Sample Output | show msdp source on page 4317 |

Output Fields Table 320 on page 4317 describes the output fields for the **show msdp source** command. Output fields are listed in the approximate order in which they appear.

Table 320: show msdp source Output Fields

| Field Name | Field Description |
|----------------|---|
| Source address | IP address of the source. |
| /Len | Length of the prefix for this IP address. |
| Type | Discovery method for this multicast source: <ul style="list-style-type: none"> • Configured—Source-active limit explicitly configured for this source. • Dynamic—Source-active limit established when this source was discovered. |
| Maximum | Source-active limit applied to this source. |
| Threshold | Source-active threshold applied to this source. |
| Exceeded | Number of source-active messages received from this source exceeding the established maximum. |

Sample Output

show msdp source

```

user@host> show msdp source
Source address /Len  Type      Maximum  Threshold  Exceeded
0.0.0.0       /0    Configured    5         none        0
10.1.0.0      /16   Configured    500        none        0
10.1.1.1      /32   Configured    10000      none        0
10.1.1.2      /32   Dynamic       6936       none        0
10.1.5.5      /32   Dynamic       500        none       123
10.2.1.1      /32   Dynamic        2         none        0

```

show msdp source-active

| | |
|---------------------------------|---|
| Syntax | <code>show msdp source-active</code>
<code><brief detail></code>
<code><group <i>group</i>></code>
<code><instance <i>instance-name</i>></code>
<code><local></code>
<code><logical-system (all <i>logical-system-name</i>)></code>
<code><originator <i>originator</i>></code>
<code><peer <i>peer-address</i>></code>
<code><source <i>source-address</i>></code> |
| Release Information | Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 12.1 for the QFX Series. |
| Description | Display the Multicast Source Discovery Protocol (MSDP) source-active cache. |
| Options | none —Display standard MSDP source-active cache information for all routing instances.

brief detail —(Optional) Display the specified level of output.

group <i>group</i> —(Optional) Display source-active cache information for the specified group.

instance <i>instance-name</i> —(Optional) Display information for the specified instance.

local —(Optional) Display all source-active caches originated by this router.

logical-system (all <i>logical-system-name</i>) —(Optional) Perform this operation on all logical systems or on a particular logical system.

originator <i>originator</i> —(Optional) Display information about the peer that originated the source-active cache entries.

peer <i>peer-address</i> —(Optional) Display the source-active cache of the specified peer.

source <i>source-address</i> —(Optional) Display the source-active cache of the specified source. |
| Required Privilege Level | view |

show msdp source-active source on page 4320 |
| Output Fields | Table 321 on page 4319 describes the output fields for the show msdp source-active command. Output fields are listed in the approximate order in which they appear. |

Table 321: show msdp source-active Output Fields

| Field Name | Field Description |
|---|--|
| Global active source limit exceeded | Number of times all peers have exceeded configured active source limits. |
| Global active source limit maximum | Configured number of active source messages accepted by the device. |
| Global active source limit threshold | Configured threshold for applying random early discard (RED) to drop some but not all MSDP active source messages. |
| Global active source limit log-warning | Threshold at which a warning message is logged (percentage of the number of active source messages accepted by the device). |
| Global active source limit log interval | Time (in seconds) between consecutive log messages. |
| Group address | Multicast address of the group. |
| Source address | IP address of the source. |
| Peer address | IP address of the peer. |
| Originator | Router ID configured on the source of the rendezvous point (RP) that originated the message, or the loopback address when the router ID is not configured. |
| Flags | Flags: Accept, Reject, or Filtered. |

Sample Output

show msdp source-active

```

user@host> show msdp source-active
Group address  Source address  Peer address  Originator  Flags
230.0.0.0      192.168.195.46  local        10.255.14.30  Accept
230.0.0.1      192.168.195.46  local        10.255.14.30  Accept

Table 322: show msdp statistics Output Fields

| Field Name | Field Description |
|---|---|
| Global active source limit exceeded | Number of times all peers have exceeded configured active source limits. |
| Global active source limit maximum | Configured number of active source messages accepted by the device. |
| Global active source limit threshold | Configured threshold for applying random early discard (RED) to drop some but not all MSDP active source messages. |
| Global active source limit log-warning | Threshold at which a warning message is logged (percentage of the number of active source messages accepted by the device). |
| Global active source limit log interval | Time (in seconds) between consecutive log messages. |
| Peer | Address of peer. |

Table 322: show msdp statistics Output Fields (*continued*)

| Field Name | Field Description |
|-------------------------------------|---|
| Last State Change | How long ago the peer state changed. |
| Last message received from the peer | How long ago the last message was received from the peer. |
| RPF Failures | Number of reverse path forwarding (RPF) failures. |
| Remote Closes | Number of times the remote peer closed. |
| Peer Timeouts | Number of peer timeouts. |
| SA messages sent | Number of source-active messages sent. |
| SA messages received | Number of source-active messages received. |
| SA request messages sent | Number of source-active request messages sent. |
| SA request messages received | Number of source-active request messages received. |
| SA response messages sent | Number of source-active response messages sent. |
| SA response messages received | Number of source-active response messages received. |
| Active source exceeded | Number of times this peer has exceeded configured source-active limits. |
| Active source Maximum | Configured number of active source messages accepted by this peer. |
| Active source threshold | Configured threshold on this peer for applying random early discard (RED) to drop some but not all MSDP active source messages. |
| Active source log-warning | Configured threshold on this peer at which a warning message is logged (percentage of the number of active source messages accepted by the device). |
| Active source log-interval | Time (in seconds) between consecutive log messages on this peer. |
| Keepalive messages sent | Number of keepalive messages sent. |
| Keepalive messages received | Number of keepalive messages received. |
| Unknown messages received | Number of unknown messages received. |

Table 322: show msdp statistics Output Fields (*continued*)

| Field Name | Field Description |
|-------------------------|------------------------------------|
| Error messages received | Number of error messages received. |

Sample Output

show msdp statistics

```

user@host> show msdp statistics
Global active source limit exceeded: 0

show multicast flow-map

| | |
|---|--|
| Syntax | show multicast flow-map
<brief detail>
<logical-system (all <i>logical-system-name</i>)> |
| Syntax (EX Series Switch and the QFX Series) | show multicast flow-map
<brief detail> |
| Release Information | Command introduced in Junos OS Release 8.2.
Command introduced in Junos OS Release 9.0 for EX Series switches.
Command introduced in Junos OS Release 11.3 for the QFX Series. |
| Description | Display configuration information about IP multicast flow maps. |
| Options | none —Display configuration information about IP multicast flow maps on all systems.

brief detail —(Optional) Display the specified level of output.

logical-system (all <i>logical-system-name</i>) —(Optional) Perform this operation on all logical systems or on a particular logical system. |
| Required Privilege Level | view |
| List of Sample Output | show multicast flow-map on page 4326
show multicast flow-map detail on page 4326 |
| Output Fields | Table 323 on page 4325 describes the output fields for the show multicast flow-map command. Output fields are listed in the approximate order in which they appear. |

Table 323: show multicast flow-map Output Fields

| Field Name | Field Description | Levels of Output |
|---------------------------|---|------------------|
| Name | Name of the flow map. | All levels |
| Policy | Name of the policy associated with the flow map. | All levels |
| Cache-timeout | Cache timeout value assigned to the flow map. | All levels |
| Bandwidth | Bandwidth setting associated with the flow map. | All levels |
| Adaptive | Whether or not adaptive mode is enabled for the flow map. | none |
| Flow-map | Name of the flow map. | detail |
| Adaptive Bandwidth | Whether or not adaptive mode is enabled for the flow map. | detail |
| Redundant Sources | Redundant sources defined for the same destination group. | detail |

Sample Output

show multicast flow-map

```
user@host> show multicast flow-map
Instance: master
Name      Policy      Cache timeout      Bandwidth Adaptive
map2      policy2      never              2000000 no
map1      policy1      60 seconds        2000000 no
```

Sample Output

show multicast flow-map detail

```
user@host> show multicast flow-map detail
Instance: master
Flow-map: map1
  Policy:      policy1
  Cache Timeout: 600 seconds
  Bandwidth:   2000000
  Adaptive Bandwidth: yes
  Redundant Sources: 11.11.11.11
  Redundant Sources: 11.11.11.12
  Redundant Sources: 11.11.11.13
```

show multicast interface

| | |
|---|--|
| Syntax | show multicast interface
<logical-system (all <i>logical-system-name</i>)> |
| Syntax (EX Series Switch and the QFX Series) | show multicast interface |
| Release Information | Command introduced in Junos OS Release 8.3.
Command introduced in Junos OS Release 9.0 for EX Series switches.
Command introduced in Junos OS Release 11.3 for the QFX Series. |
| Description | Display bandwidth information about IP multicast interfaces. |
| Options | none —Display all interfaces that have multicast configured.

logical-system (all <i>logical-system-name</i>) —(Optional) Perform this operation on all logical systems or on a particular logical system. |
| Required Privilege Level | view |
| List of Sample Output | show multicast interface on page 4328 |
| Output Fields | Table 324 on page 4327 describes the output fields for the show multicast interface command. Output fields are listed in the approximate order in which they appear. |

Table 324: show multicast interface Output Fields

| Field Name | Field Description |
|---|--|
| Interface | Name of the multicast interface. |
| Maximum bandwidth (bps) | Maximum bandwidth setting, in bits per second, for this interface. |
| Remaining bandwidth (bps) | Amount of bandwidth, in bits per second, remaining on the interface. |
| Mapped bandwidth deduction (bps) | <p>Amount of bandwidth, in bits per second, used by any flows that are mapped to the interface.</p> <p>NOTE: Adding the mapped bandwidth deduction value to the local bandwidth deduction value results in the total deduction value for the interface.</p> <p>This field does not appear in the output when the no QoS adjustment feature is disabled.</p> |

Table 324: show multicast interface Output Fields (*continued*)

| Field Name | Field Description |
|--|--|
| Local bandwidth deduction (bps) | <p>Amount of bandwidth, in bits per second, used by any mapped flows that are traversing the interface.</p> <p>NOTE: Adding the mapped bandwidth deduction value to the local bandwidth deduction value results in the total deduction value for the interface.</p> <p>This field does not appear in the output when the no QoS adjustment feature is disabled.</p> |
| Reverse OIF mapping | <p>State of the reverse OIF mapping feature (on or off).</p> <p>NOTE: This field does not appear in the output when the no QoS adjustment feature is disabled.</p> |
| Reverse OIF mapping no QoS adjustment | <p>State of the no QoS adjustment feature (on or off) for interfaces that are using reverse OIF mapping.</p> <p>NOTE: This field does not appear in the output when the no QoS adjustment feature is disabled.</p> |
| Leave timer | <p>Amount of time a mapped interface remains active after the last mapping ends.</p> <p>NOTE: This field does not appear in the output when the no QoS adjustment feature is disabled.</p> |
| No QoS adjustment | <p>State (on) of the no QoS adjustment feature when this feature is enabled.</p> <p>NOTE: This field does not appear in the output when the no QoS adjustment feature is disabled.</p> |

Sample Output

show multicast interface

```

user@host> show multicast interface
Interface           Maximum bandwidth (bps) Remaining bandwidth (bps)
fe-0/0/3            10000000                0
fe-0/0/3.210        10000000                -2000000
fe-0/0/3.220        100000000               100000000
fe-0/0/3.230        20000000                18000000
fe-0/0/2.200        100000000               100000000

```

show multicast minfo

| | |
|---------------------------------|---|
| Syntax | <code>show multicast minfo</code>
<code><host></code> |
| Release Information | Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
Command introduced in Junos OS Release 11.3 for the QFX Series. |
| Description | Display configuration information about IP multicast networks, including neighboring multicast router addresses. |
| Options | none —Display configuration information about all multicast networks.

host —(Optional) Display configuration information about a particular host. Replace <i>host</i> with a hostname or IP address. |
| Required Privilege Level | view |
| List of Sample Output | show multicast minfo on page 4330 |
| Output Fields | Table 325 on page 4329 describes the output fields for the show multicast minfo command. Output fields are listed in the approximate order in which they appear. |

Table 325: show multicast minfo Output Fields

| Field Name | Field Description |
|--------------------------------------|--|
| <i>source-address</i> | Query address, hostname (DNS name or IP address of the source address), and multicast protocol version or the software version of another vendor. |
| <i>ip-address-1—>ip-address-2</i> | Queried router interface address and directly attached neighbor interface address, respectively. |
| <i>(name or ip-address)</i> | Name or IP address of neighbor. |
| <i>[metric/threshold/type/flags]</i> | Neighbor's multicast profile: <ul style="list-style-type: none"> metric—Always has a value of 1, because minfo queries the directly connected interfaces of a device. threshold—Multicast threshold time-to-live (TTL). The range of values is 0 through 255. type—Multicast connection type: pim or tunnel. flags—Flags for this route: <ul style="list-style-type: none"> querier—Queried router is the designated router for the neighboring session. leaf—Link is a leaf in the multicast network. down—Link status indicator. |

Sample Output

show multicast mrinfo

```
user@host> show multicast mrinfo 10.35.4.1
10.35.4.1 (10.35.4.1) [version 12.0]:
  192.168.195.166 -> 0.0.0.0 (local) [1/0/pim/querier/leaf]
  10.38.20.1 -> 0.0.0.0 (local) [1/0/pim/querier/leaf]
  10.47.1.1 -> 10.47.1.2 (10.47.1.2) [1/5/pim]
  0.0.0.0 -> 0.0.0.0 (local) [1/0/pim/down]
```

show multicast next-hops

| | |
|---|---|
| Syntax | <pre>show multicast next-hops <brief detail> <identifier-number> <inet inet6> <logical-system (all <i>logical-system-name</i>)></pre> |
| Syntax (EX Series Switch and the QFX Series) | <pre>show multicast next-hops <brief detail> <identifier-number> <inet inet6></pre> |
| Release Information | <p>Command introduced before Junos OS Release 7.4.</p> <p>Command introduced in Junos OS Release 9.0 for EX Series switches.</p> <p>inet6 option introduced in Junos OS Release 10.0 for EX Series switches.</p> <p>detail option display of next-hop ID number introduced in Junos OS Release 11.1 for M Series and T Series routers and EX Series switches.</p> <p>Command introduced in Junos OS Release 11.3 for the QFX Series.</p> <p>Support for bidirectional PIM added in Junos OS Release 12.1.</p> |
| Description | Display the entries in the IP multicast next-hop table. |
| Options | <p>none—Display standard information about all entries in the multicast next-hop table for all supported address families.</p> <p>brief detail—(Optional) Display the specified level of output.</p> <p>When you include the detail option on M Series and T Series routers and EX Series switches, the downstream interface name includes the next-hop ID number in parentheses, in the form fe-0/1/2.0-(1048574) where 1048574 is the next-hop ID number.</p> <p>identifier-number—(Optional) Show a particular next hop by ID number. The range of values is 1 through 65,535.</p> <p>inet inet6—(Optional) Display entries for IPv4 or IPv6 family addresses, respectively.</p> <p>logical-system (all <i>logical-system-name</i>)—(Optional) Perform this operation on all logical systems or on a particular logical system.</p> |
| Required Privilege Level | view |
| List of Sample Output | <p>show multicast next-hops on page 4332</p> <p>show multicast next-hops (Bidirectional PIM on page 4332</p> <p>show multicast next-hops brief on page 4333</p> <p>show multicast next-hops detail on page 4333</p> |
| Output Fields | <p>Table 326 on page 4332 describes the output fields for the show multicast next-hops command. Output fields are listed in the approximate order in which they appear.</p> |

Table 326: show multicast next-hops Output Fields

| Field Name | Field Description |
|--------------------------------|--|
| Family | Protocol family (such as INET). |
| ID | Next-hop identifier of the prefix. The identifier is returned by the routing device's Packet Forwarding Engine. |
| Refcount | Number of cache entries that are using this next hop. |
| KRefcount | Kernel reference count for the next hop. |
| Downstream interface | Interface names associated with each multicast next-hop ID. |
| Incoming interface list | List of interfaces that accept incoming traffic. Only shown for routes that do not use strict RPF-based forwarding, for example for bidirectional PIM. |

Sample Output

show multicast next-hops

```

user@host> show multicast next-hops
Family: INET
ID      Refcount  KRefcount  Downstream interface
262142      4           2  so-1/0/0.0
262143      2           1  mt-1/1/0.49152
262148      2           1  mt-1/1/0.32769

```

show multicast next-hops (Bidirectional PIM)

```

user@host> show multicast next-hops
Family: INET

Output Fields [Table 329 on page 4339](#) describes the output fields for the **show multicast route** command. Output fields are listed in the approximate order in which they appear.

Table 329: show multicast route Output Fields

| Field Name | Field Description | Level of Output |
|--------------------------------------|---|-------------------------|
| family | IPv4 address family (INET) or IPv6 address family (INET6). | All levels |
| Group | Group address.

For any-source multicast routes, for example for bidirectional PIM, the group address includes the prefix length. | All levels |
| Source | Prefix and length of the source as it is in the multicast forwarding table. | All levels |
| Incoming interface list | List of interfaces that accept incoming traffic. Only shown for routes that do not use strict RPF-based forwarding, for example for bidirectional PIM. | All levels |
| Upstream interface | Name of the interface on which the packet with this source prefix is expected to arrive. | All levels |
| Downstream interface list | List of interface names to which the packet with this source prefix is forwarded. | All levels |
| Number of outgoing interfaces | Total number of outgoing interfaces for each (S,G) entry. | extensive |
| Session description | Name of the multicast session. | detail extensive |
| Statistics | Rate at which packets are being forwarded for this source and group entry (in Kbps and pps), and number of packets that have been forwarded to this prefix. If one or more of the kilobits per second packet forwarding statistic queries fails or times out, the statistics field displays Forwarding statistics are not available .

NOTE: On QFX Series switches, this field does not report valid statistics. | detail extensive |
| Next-hop ID | Next-hop identifier of the prefix. The identifier is returned by the routing device's Packet Forwarding Engine and is also displayed in the output of the show multicast nexthops command. | detail extensive |

Table 329: show multicast route Output Fields (*continued*)

| Field Name | Field Description | Level of Output |
|---|---|--------------------------|
| Incoming interface list ID | For bidirectional PIM, incoming interface list identifier.

Identifiers for interfaces that accept incoming traffic. Only shown for routes that do not use strict RPF-based forwarding, for example for bidirectional PIM. | detail extensive |
| Upstream protocol | The protocol that maintains the active multicast forwarding route for this group or source.

When the show multicast route extensive command is used with the display-origin-protocol option, the field name is only Protocol and not Upstream Protocol . However, this field also displays the protocol that installed the active route. | detail extensive |
| Route type | Type of multicast route. Values can be (S,G) or (*,G). | summary |
| Route state | Whether the group is Active or Inactive . | summary extensive |
| Route count | Number of multicast routes. | summary |
| Forwarding state | Whether the prefix is pruned or forwarding. | extensive |
| Cache lifetime/timeout | Number of seconds until the prefix is removed from the multicast forwarding table. A value of never indicates a permanent forwarding entry. A value of forever indicates routes that do not have keepalive times. | extensive |
| Wrong incoming interface notifications | Number of times that the upstream interface was not available. | extensive |
| Uptime | Time since the creation of a multicast route. | extensive |

show multicast rpf

| | |
|---|--|
| Syntax | <code>show multicast rpf</code>
<code><inet inet6></code>
<code><instance <i>instance-name</i>></code>
<code><logical-system (all <i>logical-system-name</i>)></code>
<code><prefix></code>
<code><summary></code> |
| Syntax (EX Series Switch and the QFX Series) | <code>show multicast rpf</code>
<code><inet inet6></code>
<code><instance <i>instance-name</i>></code>
<code><prefix></code>
<code><summary></code> |
| Release Information | Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
inet6 and instance options introduced in Junos OS Release 10.0 for EX Series switches.
Command introduced in Junos OS Release 11.3 for the QFX Series. |
| Description | Display information about multicast reverse-path-forwarding (RPF) calculations. |
| Options | none —Display RPF calculation information for all supported address families.

inet inet6 —(Optional) Display the RPF calculation information for IPv4 or IPv6 family addresses, respectively.

instance <i>instance-name</i> —(Optional) Display information about multicast RPF calculations for a specific multicast instance.

logical-system (all <i>logical-system-name</i>) —(Optional) Perform this operation on all logical systems or on a particular logical system.

prefix —(Optional) Display the RPF calculation information for the specified prefix.

summary —(Optional) Display a summary of all multicast RPF information. |
| Required Privilege Level | view |
| List of Sample Output | show multicast rpf on page 4345
show multicast rpf inet6 on page 4346
show multicast rpf prefix on page 4347
show multicast rpf summary on page 4347 |

Output Fields Table 330 on page 4345 describes the output fields for the **show multicast rpf** command. Output fields are listed in the approximate order in which they appear.

Table 330: show multicast rpf Output Fields

| Field Name | Field Description |
|---------------|---|
| Instance | Name of the routing instance. (Displayed when multicast is configured within a routing instance.) |
| Source prefix | Prefix and length of the source as it exists in the multicast forwarding table. |
| Protocol | How the route was learned. |
| Interface | Upstream RPF interface.

NOTE: The displayed interface information does not apply to bidirectional PIM RP addresses. This is because the show multicast rpf command does not take into account equal-cost paths or the designated forwarder. For accurate upstream RPF interface information, always use the show pim join extensive command when bidirectional PIM is configured. |
| Neighbor | Upstream RPF neighbor.

NOTE: The displayed neighbor information does not apply to bidirectional PIM. This is because the show multicast rpf command does not take into account equal-cost paths or the designated forwarder. For accurate upstream RPF neighbor information, always use the show pim join extensive command when bidirectional PIM is configured. |

Sample Output

show multicast rpf

```

Command introduced in Junos OS Release 11.3 for the QFX Series.
Support for bidirectional PIM added in Junos OS Release 12.1.
Support for the instance all option added in Junos OS Release 12.1. |
| Description | Display information about the interfaces on which Protocol Independent Multicast (PIM) is configured. |
| Options | <p>none—Display interface information for all family addresses for the main instance.</p> <p>inet inet6—(Optional) Display interface information for IPv4 or IPv6 family addresses, respectively.</p> <p>instance (<i>instance-name</i> all)—(Optional) Display information about interfaces for a specific PIM-enabled routing instance or for all routing instances.</p> <p>logical-system (all <i>logical-system-name</i>)—(Optional) Perform this operation on all logical systems or on a particular logical system.</p> |
| Required Privilege Level | view |
| List of Sample Output | show pim interfaces on page 4359 |
| Output Fields | Table 335 on page 4358 describes the output fields for the show pim interfaces command. Output fields are listed in the approximate order in which they appear. |

Table 335: show pim interfaces Output Fields

| Field Name | Field Description |
|-----------------|--|
| Instance | Name of the routing instance. |
| Name | Interface name. |
| State | State of the interface. The state also is displayed in the show interfaces command. |

Table 335: show pim interfaces Output Fields (*continued*)

| Field Name | Field Description |
|---------------------|--|
| Mode | <p>PIM mode running on the interface:</p> <ul style="list-style-type: none"> • B—In bidirectional mode, multicast groups are carried across the network over bidirectional shared trees. This type of tree minimizes PIM routing state, which is especially important in networks with numerous and dispersed senders and receivers. • S—In sparse mode, routing devices must join and leave multicast groups explicitly. Upstream routing devices do not forward multicast traffic to this routing device unless this device has sent an explicit request (using a join message) to receive multicast traffic. • Dense—Unlike sparse mode, where data is forwarded only to routing devices sending an explicit request, dense mode implements a flood-and-prune mechanism, similar to DVMRP (the first multicast protocol used to support the multicast backbone). (Not supported on QFX Series.) • Sparse-Dense—Sparse-dense mode allows the interface to operate on a per-group basis in either sparse or dense mode. A group specified as dense is not mapped to a rendezvous point (RP). Instead, data packets destined for that group are forwarded using PIM-Dense Mode (PIM-DM) rules. A group specified as sparse is mapped to an RP, and data packets are forwarded using PIM-Sparse Mode (PIM-SM) rules. (Not supported on QFX Series.) <p>When sparse-dense mode is configured, the output includes both S and D. When bidirectional-sparse mode is configured, the output includes S and B. When bidirectional-sparse-dense mode is configured, the output includes B, S, and D.</p> |
| IP | Version number of the address family on the interface: 4 (IPv4) or 6 (IPv6). |
| V | PIM version running on the interface: 1 or 2. |
| State | <p>State of PIM on the interface:</p> <ul style="list-style-type: none"> • Active—Bidirectional mode is enabled on the interface and on all PIM neighbors. • DR—Designated router. • NotCap—Bidirectional mode is not enabled on the interface. This can happen when bidirectional PIM is not configured locally, when one of the neighbors is not configured for bidirectional PIM, or when one of the neighbors has not implemented the bidirectional PIM protocol. • NotDR—Not the designated router. • P2P—Point to point. |
| NbrCnt | Number of neighbors that have been seen on the interface. |
| JoinCnt(sg) | Number of (s,g) join messages that have been seen on the interface. |
| JointCnt(*g) | Number of (*g) join messages that have been seen on the interface. |
| DR address | Address of the designated router. |

Sample Output

show pim interfaces

```
user@host> show pim interfaces
Stat = Status, V = Version, NbrCnt = Neighbor Count,
S = Sparse, D = Dense, B = Bidirectional,
DR = Designated Router, P2P = Point-to-point link,
```

Active = Bidirectional is active, NotCap = Not Bidirectional Capable

| Name | Stat | Mode | IP | V | State | NbrCnt | JoinCnt(sg/*g) | DR address |
|----------------|------|------|----|---|--------------|--------|----------------|------------|
| ge-0/3/0.0 | Up | S | 4 | 2 | NotDR,NotCap | 1 | 0/0 | 40.0.0.3 |
| ge-0/3/3.50 | Up | S | 4 | 2 | DR,NotCap | 1 | 9901/100 | 50.0.0.2 |
| ge-0/3/3.51 | Up | S | 4 | 2 | DR,NotCap | 1 | 0/0 | 51.0.0.2 |
| pe-1/2/0.32769 | Up | S | 4 | 2 | P2P,NotCap | 0 | 0/0 | |

show pim join

| | |
|---|--|
| Syntax | <pre>show pim join <brief detail extensive summary> <bidirectional dense sparse> <exact> <inet inet6> <instance <i>instance-name</i>> <logical-system (all <i>logical-system-name</i>)> <range> <rp <i>ip-address/prefix</i> source <i>ip-address/prefix</i>> <sg star-g></pre> |
| Syntax (EX Series Switch and the QFX Series) | <pre>show pim join <brief detail extensive summary> <dense sparse> <exact> <inet inet6> <instance <i>instance-name</i>> <range> <rp <i>ip-address/prefix</i> source <i>ip-address/prefix</i>> <sg star-g></pre> |
| Release Information | <p>Command introduced before Junos OS Release 7.4.</p> <p>Command introduced in Junos OS Release 9.0 for EX Series switches.</p> <p>summary option introduced in Junos OS Release 9.6.</p> <p>inet6 and instance options introduced in Junos OS Release 10.0 for EX Series switches.</p> <p>Support for bidirectional PIM added in Junos OS Release 12.1.</p> <p>Command introduced in Junos OS Release 11.3 for the QFX Series.</p> <p>Multiple new filter options introduced in Junos OS Release 13.2.</p> |
| Description | <p>Display information about Protocol Independent Multicast (PIM) groups for all PIM modes.</p> <p>For bidirectional PIM, display information about PIM group ranges (*G-range) for each active bidirectional RP group range, in addition to each of the joined (*G) routes.</p> |
| Options | <p>none—Display the standard information about PIM groups for all supported family addresses for all routing instances.</p> <p>brief detail extensive summary—(Optional) Display the specified level of output.</p> <p>bidirectional dense sparse—(Optional) Display information about PIM bidirectional mode, dense mode, or sparse and source-specific multicast (SSM) mode entries.</p> <p>exact—(Optional) Display information about only the group that exactly matches the specified group address.</p> <p>inet inet6—(Optional) Display PIM group information for IPv4 or IPv6 family addresses, respectively.</p> |

instance *instance-name*—(Optional) Display information about groups for the specified PIM-enabled routing instance only.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

range—(Optional) Address range of the group, specified as *prefix/prefix-length*.

rp *ip-address/prefix* | source *ip-address/prefix*—(Optional) Display information about the PIM entries with a specified rendezvous point (RP) address and prefix or with a specified source address and prefix. You can omit the prefix.

sg | star-g—(Optional) Display information about PIM (S,G) or (*G) entries.

Output Fields [Table 336 on page 4362](#) describes the output fields for the **show pim join** command. Output fields are listed in the approximate order in which they appear.

Table 336: show pim join Output Fields

| Field Name | Field Description | Level of Output |
|-------------|--|-------------------------------------|
| Instance | Name of the routing instance. | brief detail extensive summary none |
| Family | Name of the address family: inet (IPv4) or inet6 (IPv6). | brief detail extensive summary none |
| Route type | Type of multicast route: (S,G) or (*G). | summary |
| Route count | Number of (S,G) routes and number of (*G) routes. | summary |

Table 336: show pim join Output Fields (*continued*)

| Field Name | Field Description | Level of Output |
|-----------------------------------|---|-----------------------------|
| R | Rendezvous Point Tree. | brief detail extensive none |
| S | Sparse. | brief detail extensive none |
| W | Wildcard. | brief detail extensive none |
| Group | Group address. | brief detail extensive none |
| Bidirectional group prefix length | For bidirectional PIM, length of the IP prefix for RP group ranges. | All levels |
| Source | Multicast source: <ul style="list-style-type: none"> • * (wildcard value) • <i>ipv4-address</i> • <i>ipv6-address</i> | brief detail extensive none |
| RP | Rendezvous point for the PIM group. | brief detail extensive none |
| Flags | PIM flags: <ul style="list-style-type: none"> • bidirectional—Bidirectional mode entry. • dense—Dense mode entry. • rptree—Entry is on the rendezvous point tree. • sparse—Sparse mode entry. • spt—Entry is on the shortest-path tree for the source. • wildcard—Entry is on the shared tree. | brief detail extensive none |
| Upstream interface | RPF interface toward the source address for the source-specific state (S,G) or toward the rendezvous point (RP) address for the non-source-specific state (*G).

For bidirectional PIM, RP Link means that the interface is directly connected to a subnet that contains a phantom RP address.

A pseudo multipoint LDP (M-LDP) interface appears on egress nodes in M-LDP point-to-multipoint LSPs with inband signaling. | brief detail extensive none |

Table 336: show pim join Output Fields (*continued*)

| Field Name | Field Description | Level of Output |
|--------------------------|---|------------------|
| Upstream neighbor | <p>Information about the upstream neighbor: Direct, Local, Unknown, or a specific IP address.</p> <p>For bidirectional PIM, Direct means that the interface is directly connected to a subnet that contains a phantom RP address.</p> <p>The multipoint LDP (M-LDP) root appears on egress nodes in M-LDP point-to-multipoint LSPs with inband signaling.</p> | extensive |
| Upstream state | <p>Information about the upstream interface:</p> <ul style="list-style-type: none"> • Join to RP—Sending a join to the rendezvous point. • Join to Source—Sending a join to the source. • Local RP—Sending neither join messages nor prune messages toward the RP, because this routing device is the rendezvous point. • Local Source—Sending neither join messages nor prune messages toward the source, because the source is locally attached to this routing device. • Prune to RP—Sending a prune to the rendezvous point. • Prune to Source—Sending a prune to the source. <p>NOTE: RP group range entries have None in the Upstream state field because RP group ranges do not trigger actual PIM join messages between routing devices.</p> | extensive |

Table 336: show pim join Output Fields (*continued*)

| Field Name | Field Description | Level of Output |
|---|---|------------------|
| Downstream neighbors | <p>Information about downstream interfaces:</p> <ul style="list-style-type: none"> • Interface—Interface name for the downstream neighbor.
A pseudo PIM-SM interface appears for all IGMP-only interfaces.
A pseudo multipoint LDP (M-LDP) interface appears on ingress root nodes in M-LDP point-to-multipoint LSPs with inband signaling. • Interface address—Address of the downstream neighbor. • State—Information about the downstream neighbor: join or prune. • Flags—PIM join flags: R (RPtree), S (Sparse), W (Wildcard), or zero. • Uptime—Time since the downstream interface joined the group. • Time since last Join—Time since the last join message was received from the downstream interface. • Time since last Prune—Time since the last prune message was received from the downstream interface. | extensive |
| Number of downstream interfaces | Total number of outgoing interfaces for each (S,G) entry. | extensive |
| Assert Timeout | Length of time between assert cycles on the downstream interface. Not displayed if the assert timer is null. | extensive |
| Keepalive timeout | Time remaining until the downstream join state is updated (in seconds). If the downstream join state is not updated before this keepalive timer reaches zero, the entry is deleted. If there is a directly connected host, Keepalive timeout is Infinity . | extensive |
| Uptime | Time since the creation of (S,G) or (*,G) state. The uptime is not refreshed every time a PIM join message is received for an existing (S,G) or (*,G) state. | extensive |
| Bidirectional accepting interfaces | <p>Interfaces on the routing device that forward bidirectional PIM traffic.</p> <p>The reasons for forwarding bidirectional PIM traffic are that the interface is the winner of the designated forwarder election (DF Winner), or the interface is the reverse path forwarding (RPF) interface toward the RP (RPF).</p> | extensive |

Table 337: show pim neighbors Output Fields

| Field Name | Field Description | Level of Output |
|--|--|-------------------|
| Instance | Name of the routing instance. | All levels |
| Interface | Interface through which the neighbor is reachable. | All levels |
| Neighbor addr | Address of the neighboring PIM routing device. | All levels |
| IP | IP version: 4 or 6. | All levels |
| V | PIM version running on the neighbor: 1 or 2. | All levels |
| Mode | PIM mode of the neighbor: Sparse , Dense , SparseDense , or Unknown . When the neighbor is running PIM version 2, this mode is always Unknown . | All levels |
| Option | Can be one or more of the following: <ul style="list-style-type: none"> • B—Bidirectional Capable. • H—Hello Option Holdtime. • G—Generation Identifier. • P—Hello Option DR Priority. • L—Hello Option LAN Prune Delay. | brief none |
| Uptime | Time the neighbor has been operational since the PIM process was last initialized, in the format dd:hh:mm:ss ago for less than a week and nwnd:hh:mm:ss ago for more than a week. | All levels |
| Address | Address of the neighboring PIM routing device. | detail |
| BFD | Status and operational state of the Bidirectional Forwarding Detection (BFD) protocol on the interface: Enabled , Operational state is up , or Disabled . | detail |
| Hello Option Holdtime | Time for which the neighbor is available, in seconds. The range of values is 0 through 65,535. | detail |
| Hello Default Holdtime | Default holdtime and the time remaining if the holdtime option is not in the received hello message. | detail |
| Hello Option DR Priority | Designated router election priority. The range of values is 0 through 255. | detail |
| Hello Option Generation ID | 9-digit or 10-digit number used to tag hello messages. | detail |
| Hello Option Bi-Directional PIM supported | Neighbor can process bidirectional PIM messages. | detail |
| Hello Option LAN Prune Delay | Time to wait before the neighbor receives prune messages, in the format delay nnn ms override nnnn ms . | detail |

Table 337: show pim neighbors Output Fields (*continued*)

| Field Name | Field Description | Level of Output |
|----------------------------|---|-----------------|
| Join Suppression supported | Neighbor is capable of join suppression. | detail |
| Rx Join | Information about joins received from the neighbor. <ul style="list-style-type: none"> Group—Group addresses in the join message. Source—Address of the source in the join message. Timeout—Time for which the join is valid. | detail |

Output Fields [Table 338 on page 4380](#) describes the output fields for the **show pim rps** command. Output fields are listed in the approximate order in which they appear.

Table 338: show pim rps Output Fields

| Field Name | Field Description | Level of Output |
|---------------------------------|--|-------------------------|
| Instance | Name of the routing instance. | All levels |
| Family or Address family | Name of the address family: inet (IPv4) or inet6 (IPv6). | All levels |
| RP address | Address of the rendezvous point. | All levels |
| Type | Type of RP: <ul style="list-style-type: none"> auto-rp—Address of the RP known through the Auto-RP protocol. bootstrap—Address of the RP known through the bootstrap router protocol (BSR). embedded—Address of the RP known through an embedded RP (IPv6). static—Address of RP known through static configuration. | brief none |
| Holdtime | How long to keep the RP active, with time remaining, in seconds. | All levels |
| Timeout | How long until the local routing device determines the RP to be unreachable, in seconds. | All levels |
| Groups | Number of groups currently using this RP. | All levels |
| Group prefixes | Addresses of groups that this RP can span. | brief none |
| Learned via | Address and method by which the RP was learned. | detail extensive |
| Mode | The PIM mode of the RP: bidirectional or sparse.

If a sparse and bidirectional RPs are configured with the same RP address, they appear as separate entries in both formats. | All levels |
| Time Active | How long the RP has been active, in the format hh:mm:ss . | detail extensive |

Table 338: show pim rps Output Fields (*continued*)

| Field Name | Field Description | Level of Output |
|---------------------------------------|--|---|
| Device Index | Index value of the order in which Junos OS finds and initializes the interface.

For bidirectional RPs, the Device Index output field is omitted because bidirectional RPs do not require encapsulation and de-encapsulation interfaces. | detail extensive |
| Subunit | Logical unit number of the interface.

For bidirectional RPs, the Subunit output field is omitted because bidirectional RPs do not require encapsulation and de-encapsulation interfaces. | detail extensive |
| Interface | Either the encapsulation or the de-encapsulation logical interface, depending on whether this routing device is a designated router (DR) facing an RP router, or is the local RP, respectively.

For bidirectional RPs, the Interface output field is omitted because bidirectional RPs do not require encapsulation and de-encapsulation interfaces. | detail extensive |
| Group Ranges | Addresses of groups that this RP spans. | detail extensive

<i>group-address</i> |
| Active groups using RP | Number of groups currently using this RP. | detail extensive |
| total | Total number of active groups for this RP. | detail extensive |
| Register State for RP | Current register state for each group:
<ul style="list-style-type: none"> • Group—Multicast group address. • Source—Multicast source address for which the PIM register is sent or received, depending on whether this router is a designated router facing an RP router, or is the local RP, respectively: • First Hop—PIM-designated routing device that sent the Register message (the source address in the IP header). • RP Address—RP to which the Register message was sent (the destination address in the IP header). • State:
On the designated router: <ul style="list-style-type: none"> • Send—Sending Register messages. • Probe—Sent a null register. If a Register-Stop message does not arrive in 5 seconds, the designated router resumes sending Register messages. • Suppress—Received a Register-Stop message. The designated router is waiting for the timer to resume before changing to Probe state. • On the RP: <ul style="list-style-type: none"> • Receive—Receiving Register messages. | extensive |
| Anycast-PIM rpset | If anycast RP is configured, the addresses of the RPs in the set. | extensive |
| Anycast-PIM local address used | If anycast RP is configured, the local address used by the RP. | extensive |

Table 338: show pim rps Output Fields (*continued*)

| Field Name | Field Description | Level of Output |
|-----------------------------------|--|----------------------|
| Anycast-PIM Register State | <p>If anycast RP is configured, the current register state for each group:</p> <ul style="list-style-type: none"> • Group—Multicast group address. • Source—Multicast source address for which the PIM register is sent or received, depending on whether this routing device is a designated router facing an RP router, or is the local RP, respectively. • Origin—How the information was obtained: <ul style="list-style-type: none"> • DIRECT—From a local attachment • MSDP—From the Multicast Source Discovery Protocol (MSDP) • DR—From the designated router | extensive |
| RP selected | For sparse mode and bidirectional mode, the identity of the RP for the specified group address. | <i>group-address</i> |

<code><instance <i>instance-name</i>></code>
<code><source-prefix></code> |
| Release Information | Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
inet6 and instance options introduced in Junos OS Release 10.0 for EX Series switches.
Command introduced in Junos OS Release 11.3 for the QFX Series. |
| Description | Display information about the Protocol Independent Multicast (PIM) source reverse path forwarding (RPF) state. |
| Options | none —Display standard information about the PIM RPF state for all supported family addresses for all routing instances.

brief detail —(Optional) Display the specified level of output.

inet inet6 —(Optional) Display information for IPv4 or IPv6 family addresses, respectively.

instance <i>instance-name</i> —(Optional) Display information about the RPF state for a specific PIM-enabled routing instance.

logical-system (all <i>logical-system-name</i>) —(Optional) Perform this operation on all logical systems or on a particular logical system.

source-prefix —(Optional) Display the state for source RPF states in the given range. |
| Required Privilege Level | view |
| List of Sample Output | show pim source on page 4387
show pim source brief on page 4387
show pim source detail on page 4387
show pim source (Egress Node with Multipoint LDP Inband Signaling for Point-to-Multipoint LSPs) on page 4388 |
| Output Fields | Table 339 on page 4387 describes the output fields for the show pim source command. Output fields are listed in the approximate order in which they appear. |

Table 339: show pim source Output Fields

| Field Name | Field Description |
|---------------------------|---|
| Instance | Name of the routing instance. |
| Source | Address of the source or reverse path. |
| Prefix/length | Prefix and prefix length for the route used to reach the RPF address. |
| Upstream Protocol | |
| Upstream interface | RPF interface toward the source address.

A pseudo multipoint LDP (M-LDP) interface appears on egress nodes in M-LDP point-to-multipoint LSPs with inband signaling. |
| Upstream Neighbor | Address of the RPF neighbor used to reach the source address.

The multipoint LDP (M-LDP) root appears on egress nodes in M-LDP point-to-multipoint LSPs with inband signaling. |

Sample Output

show pim source

```

user@host> show pim source
Instance: PIM.master Family: INET

Source 10.255.14.144
  Prefix 10.255.14.144/32
  Upstream interface Local
  Upstream neighbor Local

Source 10.255.70.15
  Prefix 10.255.70.15/32
  Upstream interface so-1/0/0.0
  Upstream neighbor 10.111.10.2

Instance: PIM.master Family: INET6

```

show pim source brief

The output for the **show pim source brief** command is identical to that for the **show pim source** command. For sample output, see [show pim source on page 4387](#).

show pim source detail

```

user@host> show pim source detail
Instance: PIM.master Family: INET

Source 10.255.14.144
  Prefix 10.255.14.144/32
  Upstream interface Local
  Upstream neighbor Local
  Active groups:228.0.0.0
  239.1.1.1

```

239.1.1.1

Source 10.255.70.15
Prefix 10.255.70.15/32
Upstream interface so-1/0/0.0
Upstream neighbor 10.111.10.2
Active groups:239.1.1.1

Instance: PIM.master Family: INET6

show pim source (Egress Node with Multipoint LDP Inband Signaling for Point-to-Multipoint LSPs)

user@host> show pim source

Instance: PIM.master Family: INET

Source 1.1.1.1
Prefix 1.1.1.1/32
Upstream interface Local
Upstream neighbor Local

Source 1.2.7.7
Prefix 1.2.7.0/24
Upstream protocol MLDP
Upstream interface Pseudo MLDP
Upstream neighbor MLDP LSP root <1.1.1.2>

Source 192.168.219.11
Prefix 192.168.219.0/28
Upstream protocol MLDP
Upstream interface Pseudo MLDP
Upstream neighbor MLDP LSP root <1.1.1.2>

Instance: PIM.master Family: INET6

Source abcd::1:2:7:7
Prefix abcd::1:2:7:0/120
Upstream protocol MLDP
Upstream interface Pseudo MLDP
Upstream neighbor MLDP LSP root <1.1.1.2>

show pim statistics

| | |
|---|---|
| Syntax | <pre>show pim statistics <inet inet6> <instance <i>instance-name</i>> <interface <i>interface-name</i>> <logical-system (all <i>logical-system-name</i>)></pre> |
| Syntax (EX Series Switch and the QFX Series) | <pre>show pim statistics <inet inet6> <instance <i>instance-name</i>> <interface <i>interface-name</i>></pre> |

| Output Fields | <p>Table 340 on page 4390 describes the output fields for the show pim statistics command. Output fields are listed in the approximate order in which they appear.</p> |

Table 340: show pim statistics Output Fields

| Field Name | Field Description |
|-------------------------|---|
| Instance | <p>Name of the routing instance.</p> <p>This field only appears if you specify an interface, for example:</p> <ul style="list-style-type: none"> • inet interface <i>interface-name</i> • inet6 interface <i>interface-name</i> • interface <i>interface-name</i> |
| Family | <p>Output is for IPv4 or IPv6 PIM statistics. INET indicates IPv4 statistics, and INET6 indicates IPv6 statistics.</p> <p>This field only appears if you specify an interface, for example:</p> <ul style="list-style-type: none"> • inet interface <i>interface-name</i> • inet6 interface <i>interface-name</i> • interface <i>interface-name</i> |
| PIM statistics | PIM statistics for all interfaces or for the specified interface. |
| PIM message type | Message type for which statistics are displayed. |
| Received | Number of received statistics. |
| Sent | Number of messages sent of a certain type. |
| Rx errors | Number of received packets that contained errors. |
| V2 Hello | PIM version 2 hello packets. |
| V2 Register | PIM version 2 register packets. |
| V2 Register Stop | PIM version 2 register stop packets. |
| V2 Join Prune | PIM version 2 join and prune packets. |
| V2 Bootstrap | PIM version 2 bootstrap packets. |
| V2 Assert | PIM version 2 assert packets. |
| V2 Graft | PIM version 2 graft packets. |
| V2 Graft Ack | PIM version 2 graft acknowledgment packets. |
| V2 Candidate RP | PIM version 2 candidate RP packets. |

Table 340: show pim statistics Output Fields (*continued*)

| Field Name | Field Description |
|---|--|
| V2 State Refresh | PIM version 2 control messages related to PIM dense mode (PIM-DM) state refresh.

State refresh is an extension to PIM-DM. It not supported in Junos OS. |
| V2 DF Election | PIM version 2 send and receive messages associated with bidirectional PIM designated forwarder election. |
| V1 Query | PIM version 1 query packets. |
| V1 Register | PIM version 1 register packets. |
| V1 Register Stop | PIM version 1 register stop packets. |
| V1 Join Prune | PIM version 1 join and prune packets. |
| V1 RP Reachability | PIM version 1 RP reachability packets. |
| V1 Assert | PIM version 1 assert packets. |
| V1 Graft | PIM version 1 graft packets. |
| V1 Graft Ack | PIM version 1 graft acknowledgment packets. |
| AutoRP Announce | Auto-RP announce packets. |
| AutoRP Mapping | Auto-RP mapping packets. |
| AutoRP Unknown type | Auto-RP packets with an unknown type. |
| Anycast Register | Auto-RP announce packets. |
| Anycast Register Stop | Auto-RP announce packets. |
| Global Statistics | Summary of PIM statistics for all interfaces. |
| Hello dropped on neighbor policy | Number of hello packets dropped because of a configured neighbor policy. |
| Unknown type | Number of PIM control packets received with an unknown type. |
| V1 Unknown type | Number of PIM version 1 control packets received with an unknown type. |
| Unknown Version | Number of PIM control packets received with an unknown version. The version is not version 1 or version 2. |

Table 340: show pim statistics Output Fields (*continued*)

| Field Name | Field Description |
|--|---|
| Neighbor unknown | Number of PIM control packets received (excluding PIM hello) without first receiving the hello packet. |
| Bad Length | Number of PIM control packets received for which the packet size does not match the PIM length field in the packet. |
| Bad Checksum | Number of PIM control packets received for which the calculated checksum does not match the checksum field in the packet. |
| Bad Receive If | Number of PIM control packets received on an interface that does not have PIM configured. |
| Rx Bad Data | Number of PIM control packets received that contain data for TCP Bad register packets. |
| Rx Intf disabled | Number of PIM control packets received on an interface that has PIM disabled. |
| Rx V1 Require V2 | Number of PIM version 1 control packets received on an interface configured for PIM version 2. |
| Rx V2 Require V1 | Number of PIM version 2 control packets received on an interface configured for PIM version 1. |
| Rx Register not RP | Number of PIM register packets received when the routing device is not the RP for the group. |
| Rx Register no route | Number of PIM register packets received when the RP does not have a unicast route back to the source. |
| Rx Register no decap if | Number of PIM register packets received when the RP does not have a de-encapsulation interface. |
| Null Register Timeout | Number of NULL register timeout packets. |
| RP Filtered Source | Number of PIM packets received when the routing device has a source address filter configured for the RP. |
| Rx Unknown Reg Stop | Number of register stop messages received with an unknown type. |
| Rx Join/Prune no state | Number of join and prune messages received for which the routing device has no state. |
| Rx Join/Prune on upstream if | Number of join and prune messages received on the interface used to reach the upstream routing device, toward the RP. |
| Rx Join/Prune for invalid group | Number of join or prune messages received for invalid multicast group addresses. |

Table 340: show pim statistics Output Fields (*continued*)

| Field Name | Field Description |
|---------------------------------------|---|
| Rx Join/Prune messages dropped | Number of join and prune messages received and dropped. |
| Rx sparse join for dense group | Number of PIM sparse mode join messages received for a group that is configured for dense mode. |
| Rx Graft/Graft Ack no state | Number of graft and graft acknowledgment messages received for which the router or switch has no state. |
| Rx Graft on upstream if | Number of graft messages received on the interface used to reach the upstream routing device, toward the RP. |
| Rx CRP not BSR | Number of BSR messages received in which the PIM message type is Candidate-RP-Advertisement, not Bootstrap. |
| Rx BSR when BSR | Number of BSR messages received in which the PIM message type is Bootstrap. |
| Rx BSR not RPF if | Number of BSR messages received on an interface that is not the RPF interface. |
| Rx unknown hello opt | Number of PIM hello packets received with options that Junos OS does not support. |
| Rx data no state | Number of PIM control packets received for which the routing device has no state for the data type. |
| Rx RP no state | Number of PIM control packets received for which the routing device has no state for the RP. |
| Rx aggregate | Number of PIM aggregate MDT packets received. |
| Rx malformed packet | Number of PIM control packets received with a malformed IP unicast or multicast address family. |
| No RP | Number of PIM control packets received with no RP address. |
| No register encaps if | Number of PIM register packets received when the first-hop routing device does not have an encapsulation interface. |
| No route upstream | Number of PIM control packets received when the routing device does not have a unicast route to the the interface used to reach the upstream routing device, toward the RP. |
| Nexthop Unusable | Number of PIM control packets with an unusable nexthop. A path can be unusable if the route is hidden or the link is down. |
| RP mismatch | Number of PIM control packets received for which the routing device has an RP mismatch. |

Table 340: show pim statistics Output Fields (*continued*)

| Field Name | Field Description |
|--|--|
| RP mode mismatch | RP mode (sparse or bidirectional) mismatches encountered when processing join and prune messages. |
| RPF neighbor unknown | Number of PIM control packets received for which the routing device has an unknown RPF neighbor for the source. |
| Rx Joins/Prunes filtered | The number of join and prune messages filtered because of configured route filters and source address filters. |
| Tx Joins/Prunes filtered | The number of join and prune messages filtered because of configured route filters and source address filters. |
| Embedded-RP invalid addr | Number of packets received with an invalid embedded RP address in PIM join messages and other types of messages sent between routing domains. |
| Embedded-RP limit exceed | Number of times the limit configured with the maximum-rps statement is exceeded. The maximum-rps statement limits the number of embedded RPs created in a specific routing instance. The range is from 1 through 500. The default is 100. |
| Embedded-RP added | <p>Number of packets in which the embedded RP for IPv6 is added.</p> <p>The following receive events trigger extraction of an IPv6 embedded RP address on the routing device:</p> <ul style="list-style-type: none"> • Multicast Listener Discovery (MLD) report for an embedded RP multicast group address • PIM join message with an embedded RP multicast group address • Static embedded RP multicast group address associated with an interface • Packets sent to an embedded RP multicast group address received on the DR <p>An embedded RP node discovered through these receive events is added if it does not already exist on the routing platform.</p> |
| Embedded-RP removed | Number of packets in which the embedded RP for IPv6 is removed. The embedded RP is removed whenever all PIM join states using this RP are removed or the configuration changes to remove the embedded RP feature. |
| Rx Register msgs filtering drop | Number of received register messages dropped because of a filter configured for PIM register messages. |
| Tx Register msgs filtering drop | Number of register messages dropped because of a filter configured for PIM register messages. |
| Rx Bidir Join/Prune on non-Bidir if | Error counter for join and prune messages received on non-bidirectional PIM interfaces. |

Table 340: show pim statistics Output Fields (*continued*)

| Field Name | Field Description |
|---|---|
| Rx Bidir Join/Prune on non-DF if | Error counter for join and prune messages received on non-designated forwarder interfaces. |
| V4 (S,G) Maximum | Maximum number of (S,G) IPv4 multicast routes accepted for the VPN routing and forwarding (VRF) routing instance. If this number is met, additional (S,G) entries are not accepted. |
| V4 (S,G) Accepted | Number of accepted (S,G) IPv4 multicast routes. |
| V4 (S,G) Threshold | Threshold at which a warning message is logged (percentage of the maximum number of (S,G) IPv4 multicast routes accepted by the device). |
| V4 (S,G) Log Interval | Time (in seconds) between consecutive log messages. |
| V6 (S,G) Maximum | Maximum number of (S,G) IPv6 multicast routes accepted for the VPN routing and forwarding (VRF) routing instance. If this number is met, additional (S,G) entries are not accepted. |
| V6 (S,G) Accepted | Number of accepted (S,G) IPv6 multicast routes. |
| V6 (S,G) Threshold | Threshold at which a warning message is logged (percentage of the maximum number of (S,G) IPv6 multicast routes accepted by the device). |
| V6 (S,G) Log Interval | Time (in seconds) between consecutive log messages. |
| V4 (grp-prefix, RP) Maximum | Maximum number of group-to-rendezvous point (RP) IPv4 multicast mappings accepted for the VRF routing instance. If this number is met, additional mappings are not accepted. |
| V4 (grp-prefix, RP) Accepted | Number of accepted group-to-RP IPv4 multicast mappings. |
| V4 (grp-prefix, RP) Threshold | Threshold at which a warning message is logged (percentage of the maximum number of group-to-RP IPv4 multicast mappings accepted by the device). |
| V4 (grp-prefix, RP) Log Interval | Time (in seconds) between consecutive log messages. |
| V6 (grp-prefix, RP) Maximum | Maximum number of group-to RP IPv6 multicast mappings accepted for the VRF routing instance. If this number is met, additional mappings are not accepted. |
| V6 (grp-prefix, RP) Accepted | Number of accepted group-to-RP IPv6 multicast mappings. |

Table 340: show pim statistics Output Fields (*continued*)

| Field Name | Field Description |
|---|---|
| V6 (grp-prefix, RP) Threshold | Threshold at which a warning message is logged (percentage of the maximum number of group-to-RP IPv6 multicast mappings accepted by the device). |
| V6 (grp-prefix, RP) Log Interval | Time (in seconds) between consecutive log messages. |
| V4 Register Maximum | Maximum number of IPv4 PIM registers accepted for the VRF routing instance. If this number is met, additional PIM registers are not accepted.

You configure the register limits on the RP. |
| V4 Register Accepted | Number of accepted IPv4 PIM registers. |
| V4 Register Threshold | Threshold at which a warning message is logged (percentage of the maximum number of IPv4 PIM registers accepted by the device). |
| V4 Register Log Interval | Time (in seconds) between consecutive log messages. |
| V6 Register Maximum | Maximum number of IPv6 PIM registers accepted for the VRF routing instance. If this number is met, additional PIM registers are not accepted.

You configure the register limits on the RP. |
| V6 Register Accepted | Number of accepted IPv6 PIM registers. |
| V6 Register Threshold | Threshold at which a warning message is logged (percentage of the maximum number of IPv6 PIM registers accepted by the device). |
| V6 Register Log Interval | Time (in seconds) between consecutive log messages. |

Sample Output

show pim statistics

```

user@host> show pim statistics
PIM Message type    Received    Sent    Rx errors
V2 Hello            15          32         0

<all-chassis all-lcc lcc <i>number</i> sfc <i>number</i> > |
| Release Information | Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
sfc option introduced for the TX Matrix Plus router in Junos OS Release 9.6.
Command introduced in Junos OS Release 12.1 for the QFX Series. |
| Description | Display system-wide Internet Group Management Protocol (IGMP) statistics. |
| Options | <p>none—Display system statistics for IGMP.</p> <p>all-chassis—(TX Matrix routers and TX Matrix Plus routers only) (Optional) Display system statistics for IGMP for all the routers in the chassis.</p> <p>all-lcc—(TX Matrix routers and TX Matrix Plus routers only) (Optional) On a TX Matrix router, display system statistics for IGMP for all T640 routers (or line-card chassis) connected to the TX Matrix router. On a TX Matrix Plus router, display system statistics for IGMP for all connected T1600 or T4000 LCCs.</p> <p>all-members—(EX4200 switches only) (Optional) Display IGMP statistics for all members of the Virtual Chassis configuration.</p> <p>lcc <i>number</i>—(TX Matrix routers and TX Matrix Plus routers only) (Optional) On a TX Matrix router, display system statistics for IGMP for a specific T640 router that is connected to the TX Matrix router. On a TX Matrix Plus router, display system statistics for IGMP for a specific router that is connected to the TX Matrix Plus router. Replace <i>number</i> with the following values depending on the LCC configuration:</p> <ul style="list-style-type: none">• 0 through 3, when T640 routers are connected to a TX Matrix router in a routing matrix.• 0 through 3, when T1600 routers are connected to a TX Matrix Plus router in a routing matrix.• 0 through 7, when T1600 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix.• 0, 2, 4, or 6, when T4000 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix. |

local—(EX4200 switches only) (Optional) Display IGMP statistics for the local Virtual Chassis member.

member *member-id*—(EX4200 switches only) (Optional) Display IGMP statistics for the specified member of the Virtual Chassis configuration. Replace *member-id* with a value from 0 through 9.

scc—(TX Matrix routers only) (Optional) Display system statistics for IGMP for the TX Matrix router (or switch-card chassis).

sfc *number*—(TX Matrix Plus routers only) (Optional) Display system statistics for IGMP for the TX Matrix Plus router. Replace *number* with 0.

Additional Information By default, when you issue the **show system statistics igmp** command on the master Routing Engine of a TX Matrix router or a TX Matrix Plus router, the command is broadcast to all the master Routing Engines of the LCCs connected to it in the routing matrix. Likewise, if you issue the same command on the backup Routing Engine of a TX Matrix or a TX Matrix Plus router, the command is broadcast to all backup Routing Engines of the LCCs that are connected to it in the routing matrix.

Overview of Firewall Filters

Firewall filters provide rules that define whether to accept or discard packets that are transiting an interface on a QFX Series product. If a packet is accepted, you can configure additional actions to perform on the packet, such as class-of-service (CoS) marking (grouping similar types of traffic together and treating each type of traffic as a class with its own level of service priority) and traffic policing (controlling the maximum rate of traffic sent or received). You configure firewall filters to determine whether to accept or discard a packet before it enters or exits any of these:

- Port
- VLAN

- Layer 3 (routed) interface
- Routed VLAN interface (RVI)

An *ingress* firewall filter is applied to packets that are entering an interface or VLAN, and an *egress* firewall filter is applied to packets that are exiting an interface or VLAN.

NOTE: Firewall filters are sometimes called *access control lists (ACLs)*.

- [Firewall Filter Types on page 4410](#)
- [Firewall Filter Components on page 4411](#)
- [Firewall Filter Processing on page 4411](#)

Firewall Filter Types

The following firewall filter types are supported on the QFX Series:

- Port (Layer 2) firewall filter—Port firewall filters apply to Layer 2 traffic transiting system ports.
- VLAN firewall filter—VLAN firewall filters provide access control for packets that enter a VLAN, are bridged within a VLAN, or leave a VLAN.
- Router (Layer 3) firewall filter—You can apply a router firewall filter in both ingress and egress directions on IPv4 or IPv6 Layer 3 (routed) interfaces, routed VLAN interfaces (RVI) and a loopback interface, which filters traffic sent to the switch itself or generated by the switch. (You apply a filter to a loopback interface in the input direction to protect the switch from unwanted traffic. You might want to apply a filter to a loopback interface in the output direction so that you can set the forwarding class and DSCP bit value for packets that originate on the switch itself. This feature gives you very fine control over the classification of CPU generated packets. For example, you might want to assign different DSCP values and forwarding classes to traffic generated by different routing protocols so the traffic for those protocols can be treated in a differentiated manner by other devices.)

NOTE: You can apply a firewall filter to a management interface (for example, `me0`) on a QFX3500 device. You cannot apply a firewall filter to a management interface on a QFX3000-G or QFX3000-M system.

- MPLS filter—You can apply a firewall filter to an MPLS interface

To apply a firewall filter:

1. Configure the firewall filter.
2. Apply the firewall filter to a port, VLAN, or router interface.

NOTE: You can apply only one firewall filter to a port, VLAN, or interface for a given direction. For example, for interface ge-0/0/6.0, you can apply one filter for the ingress direction and one for the egress direction.

Firewall Filter Components

In a firewall filter, you first define the family address type (ethernet-switching, inet (for IPv4), inet6 (for IPv6), or mpls) and then define one or more terms that specify the filtering criteria and the action to take if a match occurs.

Each term consists of the following components:

- **Match conditions**—Specify values that a packet must contain to be considered a match. You can specify values for most fields in the IP, TCP, UDP, or ICMP headers. You can also match on interface names.
- **Action**—Specifies what to do if a packet matches the match conditions. A filter can accept, discard, or reject a matching packet and then perform additional actions, such as counting, classifying, and policing. If no action is specified for a term, the default is to accept the matching packet.

Firewall Filter Processing

If there are multiple terms in a filter, the order of the terms is important. If a packet matches the first term, the switch executes the action defined by that term, and no other terms are evaluated. If the switch does not find a match between the packet and the first term, it compares the packet to the next term. If no match occurs between the packet and the second term, the system continues to compare the packet to each successive term in the filter until a match is found. If the packet does not match any terms in the filter, the switch discards the packet by default.

Understanding Filter-Based Forwarding

You can use firewall filters in conjunction with virtual routing instances to specify different routes for packets to travel in their networks. To set up this feature—called filter-based forwarding—you specify a filter and match criteria and then specify the virtual routing instance to send packets to.

You might want to use filter-based forwarding to route specific types of traffic through a firewall or other security device before the traffic continues on its path. You can also use filter-based forwarding to give certain types of traffic preferential treatment. For example, you might want to ensure that the highest-priority traffic is forwarded over a 40-Gigabit Ethernet link. You might also use filter-based forwarding to obtain more control over load balancing than dynamic routing protocols provide.

NOTE: You can create as many as 128 filters or terms that direct packets to a given virtual routing instance.

Filters used for filter-based forwarding consume memory in two ternary content addressable memories (TCAMs), and this affects the number of supported filters. See [“Planning the Number of Firewall Filters to Create” on page 4435](#) and [“Understanding FIP Snooping, FBF, and MVR Filter Scalability” on page 4872](#) for more information. The section *FBF Filter VFP TCAM Consumption* in the latter topic specifically addresses the number of supported filters when using filter-based forwarding.

Understanding How Firewall Filters Are Evaluated

A firewall filter consists of one or more terms, and the order of the terms within a filter is important. Before you configure firewall filters, you should understand how the QFX Series products evaluate the terms within a filter and how packets are evaluated against the terms.

When a firewall filter consists of a single term, the filter is evaluated as follows:

- If the packet matches all the conditions, the action in the **then** statement is taken.
- If the packet matches all the conditions, and no action is specified in the **then** statement, the default action **accept** is taken.
- If the packet does not match all the conditions, the switch discards it.

When a firewall filter consists of more than one term, the filter is evaluated sequentially:

1. The packet is evaluated against the conditions in the **from** statement in the first term.
2. If the packet matches all the conditions in the term, the action in the **then** statement is taken and the evaluation ends. Subsequent terms in the filter are not evaluated.
3. If the packet does not match all the conditions in the term, the packet is evaluated against the conditions in the **from** statement in the second term.

This process continues until the packet matches all the conditions in the **from** statement in one of the subsequent terms or there are no more terms in the filter.

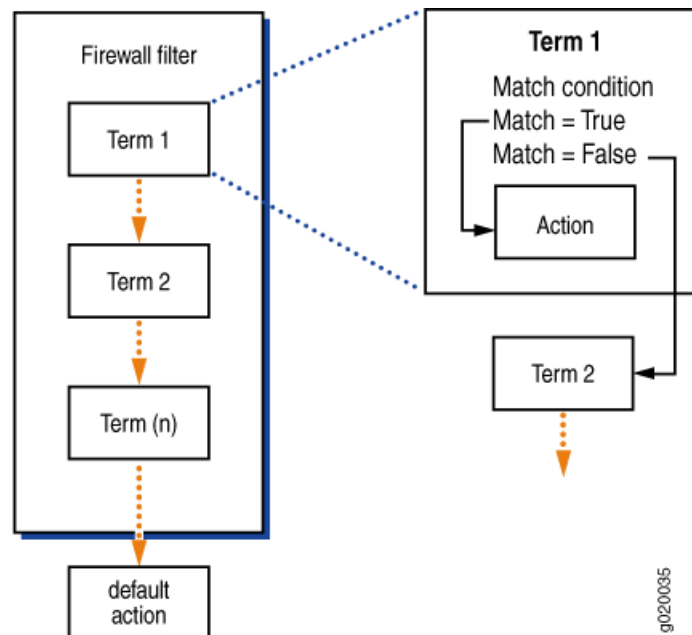

4. If a packet passes through all the terms in the filter without a match, the switch discards it.

NOTE: The order of conditions in a **from** statement is not important because a packet must match all the conditions to be considered a match.

Figure 151 on page 4413 shows how QFX Series products evaluate the terms within a firewall filter.

Figure 151: Evaluation of Terms Within a Firewall Filter

If you do not include a **from** statement in a term, all packets will match the term and be processed by the **then** statement. If a term does not contain a **then** statement or if an action has not been configured in the **then** statement, the term accepts any matching packets.

Every firewall filter contains an implicit **deny** statement at the end of the filter, which is equivalent to the following explicit filter term:

```
term implicit-rule {  
    then discard;  
}
```

Consequently, a packet that does not match any of the terms in a firewall filter is discarded. If you configure a filter that has no terms, all packets that pass through the filter are discarded.

NOTE: Firewall filtering is supported on packets that are at least 64 bytes long.

Understanding How Firewall Filters Control Packet Flows

A switch supports firewall filters that allow you to control flows of data packets and local packets. *Data packets* transit a switch as they are forwarded from a source to a destination. *Local packets* are destined for or sent by a Routing Engine (they do not transit a switch). Local packets usually contain routing protocol data, data for IP services such as Telnet or SSH, or data for administrative protocols such as the Internet Control Message Protocol (ICMP).

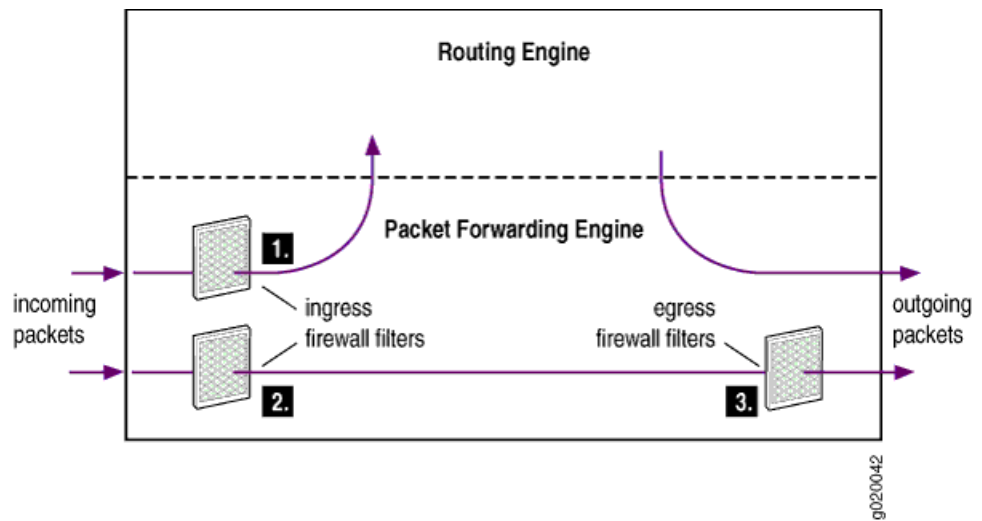

Firewall filters affect packet flows entering into or exiting from a switch as follows:

- Ingress firewall filters affect the flow of data packets that are received on switch interfaces. When a switch receives a data packet, the Packet Forwarding Engine in the system that contains the ingress interface determines where to forward the packet by looking in its Layer 2 or Layer 3 forwarding table for the best route to the destination. Data packets are forwarded to an egress interface. Locally destined packets are forwarded to the Routing Engine.
- Egress firewall filters affect data packets that are transiting a switch but do not affect packets sent by the Routing Engine. These filters are applied by the Packet Forwarding Engine in the system that contains the egress interface.

[Figure 152 on page 4415](#) illustrates the application of ingress and egress firewall filters to control the flow of packets through a switch:

1. Ingress firewall filter applied to locally destined packets that are received on switch interfaces and are destined for the Routing Engine.
2. Ingress firewall filter applied to data packets that are received on switch interfaces and will transit the switch.
3. Egress firewall filter applied to data packets that are transiting the switch.

Understanding Firewall Filter Match Conditions

Before you define terms for firewall filters, you must understand how the conditions in a term are handled and how to specify interface, numeric, address, and bit-field filter match conditions to achieve the desired filter results.

- [Filter Match Conditions on page 4415](#)
- [Numeric Filter Match Conditions on page 4416](#)
- [Interface Filter Match Conditions on page 4416](#)
- [IP Address Filter Match Conditions on page 4417](#)
- [MAC Address Filter Match Conditions on page 4417](#)
- [Bit-Field Filter Match Conditions on page 4418](#)

Filter Match Conditions

In the **from** statement of a firewall filter term, you specify the conditions that the packet must match for the action in the **then** statement to be taken. All conditions must match for the action to be implemented. The order in which you specify match conditions is not important, because a packet must match all the conditions in a term for a match to occur.

If you specify multiple values for the same condition, a match on any one of those values matches that condition. For example, if you specify multiple IP source addresses using the **source-address** statement, a packet that contains any one of those IP source addresses

matches the condition. In some cases you can specify multiple values for the same condition by enclosing the possible values in square brackets, as in:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set protocol (icmp | udp)
```

In other cases you must enter multiple statements, as in:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set source-address 10.1.1.1
user@switch# set source-address 10.1.1.2
```

If you specify no match conditions in a term, that term matches all packets.

NOTE: Unlike traditional Junos OS firewall filters, you cannot use `except` in a condition statement to negate the condition.

Numeric Filter Match Conditions

You can specify numeric filter match conditions that are identified by a numeric value, such as port and protocol numbers. For numeric filter match conditions, you specify the condition and a single value that a field in a packet must contain to be considered a match.

You can specify the numeric value in one of the following ways:

- Single number—A match occurs if the value of the field matches the number. For example, to match Telnet traffic:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set source-port 23
```

- Text synonym for a single number—A match occurs if the value of the field matches the number that corresponds to the synonym. For example, to match Telnet traffic:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set source-port telnet
```

- To specify multiple values for the same match condition in a filter term, enter each value in its own match statement. For example, a match occurs in the following term if the value of the source port in the packet is 22 or 23.

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set source-port 22
user@switch# set source-port 23
```

Interface Filter Match Conditions

You can specify an interface filter match condition to match an interface on which a packet is received or transmitted. For example, if you apply a filter to a VLAN you might want the filter to match on some interfaces that participate in the VLAN and not match on other interfaces in the VLAN. When you specify the name of the interface, you must include a logical unit.

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set interface ge-0/0/6.0
```

In this example, the final character (0) specifies the logical unit. You can include the wildcard (*) as part of the interface name. For example:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set interface ge-0/*/6.0
user@switch# set interface ge-0/1/*0
user@switch# set interface ge-0/0/6.*
```

Note that you must specify a value or a wildcard for the logical unit.

IP Address Filter Match Conditions

You can specify an address filter match condition to match an IP source or destination address or prefix in a packet. Specify the address or prefix type and the address or prefix itself. For example:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set destination-address 10.2.1.0/24;
```

If you omit the prefix length, it defaults to /32. For example:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set destination-address 10
[edit firewall family family-name filter filter-name term term-name from]
user@switch# show
destination-address {
  10.0.0.0/32;
}
```

To specify more than one IP address or prefix in a filter term, enter each address or prefix in its own match statement. For example, a match occurs in the following term if the source address of a packet matches either of the following prefixes:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set source-address 10.1.0.0/16
user@switch# set source-address 10.2.0.0/16
```

MAC Address Filter Match Conditions

You can specify a MAC address filter match condition to match a source or destination MAC address. You specify the address type and value that a packet must contain to be considered a match.

You can specify the MAC address as six hexadecimal bytes in any of the following formats:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set destination-mac-address 00:11:22:33:44:55
```

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set destination-mac-address 0011.2233.4455
```

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set destination-mac-address 001122334455
```

Regardless of the formats you use, the system resolves the address to the standard format, in this case 00:11:22:33:44:55.

To specify more than one MAC address in a filter term, enter each MAC address in its own match statement. For example, a match occurs in the following term if the value of the MAC source address matches either of the following addresses:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set source-mac-address 00:11:22:33:44:55
```

```
user@switch# set source-mac-address 00:11:22:33:20:15
```

Bit-Field Filter Match Conditions

You can specify bit-field filter match conditions to match particular bits within certain fields in Ethernet frames and IP, TCP, UDP, and ICMP headers. You usually specify the field and the bit within the field that must be set in a packet to be considered a match.

In most cases you can use a keyword to specify the bit you want to match on. For example, to match on a TCP SYN packet you can enter **syn**, as in:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set tcp-flags syn
```

You can also enter **0x02** because the SYN bit is the third least-significant bit of the 8-bit tcp-flags field:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set tcp-flags 0x02
```

To match multiple bit-field values, use the logical operators, which are described in [Table 341 on page 4418](#). The operators are listed in order from highest precedence to lowest precedence. Operations are evaluated from left to right.

Table 341: Actions for Firewall Filters

| Logical Operators | Description |
|-------------------|-------------|
| ! | Negation |
| & | Logical AND |
| | Logical OR |

If you use a logical operator, enclose the values in quotation marks and do not include any spaces. For example, the following statement matches the second packet of a TCP handshake:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set tcp-flags "syn&ack"
```

To negate a match, precede the value with an exclamation point. For example, the following statement matches only the initial packet of a TCP handshake:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set tcp-flags "syn&!ack"
```

You can use text synonyms to specify some common bit-field matches. For example, the following statement also matches the initial packet of a TCP handshake:

```
[edit firewall family family-name filter filter-name term term-name from]
user@switch# set tcp-initial
```

Firewall Filter Match Conditions and Actions

Each term in a firewall filter consists of *match conditions* and an *action*. Match conditions are the fields and values that a packet must contain to be considered a match. You can define single or multiple match conditions in *match statements*. You can also include no match statement, in which case the term matches all packets.

When a packet matches a filter, a switch takes the action specified in the term. In addition, you can specify action modifiers to count, mirror, rate-limit, and classify packets. If no match conditions are specified for the term, the switch accepts the packet by default.

This topic describes the various match conditions, actions, and action modifiers that you can define in a firewall filter.

- [Table 342 on page 4419](#) describes the match conditions you can specify when configuring a firewall filter. Some of the numeric range and bit-field match conditions allow you to specify a text synonym. To see a list of all the synonyms for a match condition, type `?` at the appropriate place in a statement.
- [Table 343 on page 4430](#) shows the actions that you can specify in a term.
- [Table 344 on page 4431](#) shows the action modifiers you can use to count, mirror, rate-limit, and classify packets.

Table 342: Supported Match Conditions for Firewall Filters

| Match Condition | Description | Direction and Interface |
|---|---|---|
| arp-type | ARP request packet or ARP reply packet. | Egress and ingress ports. |
| destination-address
<i>ip-address</i> | IP destination address field, which is the address of the final destination node. | Ingress ports, VLANs, IPv4 (inet) interfaces, and IPv6 (inet6) interfaces.

Egress IPv4 (inet) interfaces, and IPv6 (inet6) interfaces. |
| destination-mac-address <i>mac-address</i> | Destination media access control (MAC) address of the packet. | Ingress ports, VLANs and IPv4 (inet) interfaces.

Egress ports and VLANs. |

Table 342: Supported Match Conditions for Firewall Filters (*continued*)

| Match Condition | Description | Direction and Interface |
|-------------------------------|---|---|
| destination-port value | <p>TCP or UDP destination port field. Typically, you specify this match in conjunction with the protocol match statement. For the following well-known ports you can specify text synonyms (the port numbers are also listed):</p> <p>afs (1483), bgp (179), biff (512), bootpc (68), bootps (67),</p> <p>cmd (514), cvspserver (2401),</p> <p>dhcp (67), domain (53),</p> <p>eklogin (2105), ekshell (2106), exec (512),</p> <p>finger (79), ftp (21), ftp-data (20),</p> <p>http (80), https (443),</p> <p>ident (113), imap (143),</p> <p>kerberos-sec (88), klogin (543), kpasswd (761), krb-prop (754), krbupdate (760), kshell (544),</p> <p>ldap (389), login (513),</p> <p>mobileip-agent (434), mobileip-mn (435), msdp (639),</p> <p>netbios-dgm (138), netbios-ns (137), netbios-ssn (139), nfsd (2049), nntp (119), ntalk (518), ntp (123),</p> <p>pop3 (110), pptp (1723), printer (515),</p> <p>radacct (1813), radius (1812), rip (520), rkinit (2108),</p> <p>smtp (25), snmp (161), snmptrap (162), snpp (444), socks (1080), ssh (22), sunrpc (111), syslog (514),</p> <p>tacacs-ds (65), talk (517), telnet (23), tftp (69), timed (525),</p> <p>who (513),</p> <p>xdmcp (177),</p> <p>zephyr-clt (2103), zephyr-hm (2104)</p> | <p>Ingress ports, VLANs, IPv4 (inet) interfaces, and IPv6 (inet6) interfaces.</p> <p>Egress IPv4 (inet) interfaces.</p> |

Table 342: Supported Match Conditions for Firewall Filters (*continued*)

| Match Condition | Description | Direction and Interface |
|---|---|--|
| destination-port range-optimize <i>range</i> | Match a range of TCP or UDP port ranges while using the available memory more efficiently. Using this condition allows you to configure more firewall filters than if you configure individual destination ports. | Egress and ingress IPv4 (inet) interfaces. |
| destination-prefix-list <i>prefix-list</i> | IP destination prefix list field. You can define a list of IP address prefixes under a prefix-list alias for frequent use. Define this list at the [edit policy-options] hierarchy level. | Ingress ports, VLANs, IPv4 (inet) interfaces, and IPv6 (inet6) interfaces.

Egress IPv4 (inet) interfaces and IPv6 (inet6) interfaces. |
| dot1q-tag <i>number</i> | 802.1Q VLAN ID field in the Ethernet frame. The tag values can be 1–4094. | Ingress ports and VLANs.

Egress ports and VLANs (<i>Number</i> must be the VLAN ID of the VLAN you want to match). |
| dot1q-user-priority <i>number</i> | <p>802.1Q priority field in the Ethernet frame (used for class-of-service priorities). Values can be 0–7.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed):</p> <ul style="list-style-type: none"> • best-effort (0)—Best effort • background (1)—Background • standard (2)—Standard or spare • excellent-load (3)—Excellent load • controlled-load (4)—Controlled load • video (5)—Video • voice (6)—Voice • network-control (7)—Network control reserved traffic | Ingress ports and VLANs.

Egress ports and VLANs. |

Table 342: Supported Match Conditions for Firewall Filters (*continued*)

| Match Condition | Description | Direction and Interface |
|-------------------|--|--|
| dscp value | <p>Differentiated Services code point (DSCP). The DiffServ protocol uses the type-of-service (ToS) byte in the IP header. The most-significant 6 bits of this byte form the DSCP.</p> <p>You can specify DSCP in hexadecimal, binary, or decimal form.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed):</p> <ul style="list-style-type: none"> • be—best effort (default) • ef (46)—as defined in RFC 3246, <i>An Expedited Forwarding PHB</i>. • af11 (10), af12 (12), af13 (14); af21 (18), af22 (20), af23 (22); af31 (26), af32 (28), af33 (30); af41 (34), af42 (36), af43 (38)
These four classes, with three drop precedences in each class, for a total of 12 code points, are defined in RFC 2597, <i>Assured Forwarding PHB</i>. • cs0, cs1, cs2, cs3, cs4, cs5, cs6, cs7, cs5 | <p>Ingress ports, VLANs, and IPv4 (inet) interfaces.</p> <p>Egress IPv4 (inet) interfaces.</p> |

Table 342: Supported Match Conditions for Firewall Filters (*continued*)

| Match Condition | Description | Direction and Interface |
|-----------------------------|--|--|
| ether-type value | <p>Ethernet type field of a packet. The EtherType value specifies what protocol is being transported in the Ethernet frame. In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed):</p> <ul style="list-style-type: none"> • aarp (0x80F3)—EtherType value AARP • appletalk (0x809B)—EtherType value AppleTalk • arp (0x0806)—EtherType value ARP • fcoe (0x8906)—EtherType value FCoE • fip (0x8914)—EtherType value FIP • ipv4 (0x0800)—EtherType value IPv4 • ipv6 (0x08DD)—EtherType value IPv6 • mpls-multicast (0x8848)—EtherType value MPLS multicast • mpls-unicast (0x8847)—EtherType value MPLS unicast • oam (0x88A8)—EtherType value OAM • ppp (0x880B)—EtherType value PPP • pppoe-discovery (0x8863)—EtherType value PPPoE Discovery Stage • pppoe-session (0x8864)—EtherType value PPPoE Session Stage • sna (0x80D5)—EtherType value SNA | <p>Ingress ports and VLANs.</p> <p>Egress ports and VLANs.</p> |
| exp | Match on MPLS EXP bits. | <p>Ingress MPLS interfaces.</p> <p>Egress MPLS interfaces.</p> |
| fragment-flags value | <p>IP fragmentation flags. In place of the numeric value, you can specify one of the following text synonyms (the hexadecimal values are also listed):</p> <ul style="list-style-type: none"> • is-fragment • dont-fragment (0x4000) • more-fragments (0x2000) • reserved (0x8000) | Ingress ports and VLANs. |

Table 342: Supported Match Conditions for Firewall Filters (*continued*)

| Match Condition | Description | Direction and Interface |
|------------------------|--|---|
| icmp-code value | <p>ICMP code field. Because the meaning of the value depends upon the associated icmp-type, you must specify a value for icmp-type along with a value for icmp-code. In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed). The keywords are grouped by the ICMP type with which they are associated:</p> <ul style="list-style-type: none"> <i>IPv4</i>:
parameter-problem—ip-header-bad (0), required-option-missing (1) <i>IPv6</i>:
parameter-problem—ip6-header-bad (0), unrecognized-next-header (1), unrecognized-option (2) redirect—redirect-for-network (0), redirect-for-host (1), redirect-for-tos-and-net (2), redirect-for-tos-and-host (3) time-exceeded—ttl-eq-zero-during-reassembly (1), ttl-eq-zero-during-transit (0) <i>IPv4</i>:
unreachable—network-unreachable (0), host-unreachable (1), protocol-unreachable (2), port-unreachable (3), fragmentation-needed (4), source-route-failed (5), destination-network-unknown (6), destination-host-unknown (7), source-host-isolated (8), destination-network-prohibited (9), destination-host-prohibited (10), network-unreachable-for-TOS (11), host-unreachable-for-TOS (12), communication-prohibited-by-filtering (13), host-precedence-violation (14), precedence-cutoff-in-effect (15) <i>IPv6</i>:
unreachable—address-unreachable (3), administratively-prohibited (1), no-route-to-destination (0), port-unreachable (4) | <p>Ingress ports, VLANs, IPv4 (inet) interfaces, and IPv6 (inet6) interfaces.</p> <p>Egress IPv4 (inet) interfaces.</p> |

Table 342: Supported Match Conditions for Firewall Filters (*continued*)

| Match Condition | Description | Direction and Interface |
|--|---|---|
| icmp-type <i>value</i> | <p>ICMP message type field. Typically, you specify this match in conjunction with the protocol match statement to determine which protocol is being used on the port. In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed):</p> <p><i>IPv4:</i> echo-reply (0), destination unreachable (3), source-quench (4), redirect (5), echo-request (8), IPv4 (inet)-advertisement (9), IPv4 (inet)-solicit (10), time-exceeded (11), parameter-problem (12), timestamp (13), timestamp-reply (14), info-request (15), info-reply (16), mask-request (17), mask-reply (18)</p> <p><i>IPv6:</i> destination-unreachable (1), packet-too-big (2), time-exceeded (3), parameter-problem (4), echo-request (128), echo-reply (129), membership-query (130), membership-report (131), membership-termination (132), router-solicit (133), router-advertisement (134), neighbor-solicit (135), neighbor-advertisement (136), redirect (137), router-renumbering (138), node-information-request (139), node-information-reply (140)</p> <p>See also icmp-code <i>variable</i>.</p> | <p>Ingress ports, VLANs, IPv4 (inet) interfaces, and IPv6 (inet6) interfaces.</p> <p>Egress IPv4 (inet) interfaces.</p> |
| interface <i>interface-name</i> | <p>Interface on which the packet is received, including the logical unit. You can include the wildcard character (*) as part of an interface name or logical unit.</p> <p>NOTE: An interface from which a packet is sent cannot be used as a match condition.</p> | <p>Ingress ports, VLANs, IPv4 (inet) interfaces, and IPv6 (inet6) interfaces.</p> <p>Egress IPv4 (inet) interfaces and IPv6 (inet6) interfaces.</p> |
| ip-destination-address <i>address</i> | 32-bit address that is the final destination node address for the packet. | <p>Ingress ports, VLANs, and IPv4 (inet) interfaces.</p> <p>Egress IPv4 (inet) interfaces.</p> |
| ip-options | Specify any to create a match if anything is specified in the options field in the IP header. | <p>Ingress ports, VLANs, and IPv4 (inet) interfaces.</p> <p>Egress IPv4 (inet) interfaces.</p> |

Table 342: Supported Match Conditions for Firewall Filters (*continued*)

| Match Condition | Description | Direction and Interface |
|---|---|---|
| ip-precedence <i>ip-precedence-field</i> | IP precedence field. In place of the numeric field value, you can specify one of the following text synonyms (the field values are also listed): critical-ecp (0xa0), flash (0x60), flash-override (0x80), immediate (0x40), internet-control (0xc0), net-control (0xe0), priority (0x20), or routine (0x00). | Ingress ports, VLANs, and IPv4 (inet) interfaces.

Egress IPv4 (inet) interfaces. |
| ip-protocol <i>number</i> | IP protocol field. | Ingress ports, VLANs, and IPv4 (inet) interfaces.

Egress IPv4 (inet) interfaces. |
| ip-source-address <i>address</i> | IP address of the source node sending the packet. | Ingress ports, VLANs, and IPv4 (inet) interfaces.

Egress IPv4 (inet) interfaces. |
| ip-version <i>address</i> | IP version of the packet. | Ingress ports, VLANs, and IPv4 (inet) interfaces.

Egress IPv4 (inet) interfaces. |
| is-fragment | Using this condition causes a match if the More Fragments flag is enabled in the IP header or if the fragment offset is not zero. | Ingress ports, VLANs, and IPv4 (inet) interfaces.

Egress IPv4 (inet) interfaces. |
| l2-encap-type <i>llc-non-snap</i> | Match on logical link control (LLC) layer packets for non-Subnet Access Protocol (SNAP) Ethernet Encapsulation type. | Ingress ports and VLANs.

Egress ports and VLANs. |
| label | Match on MPLS label bits. | Ingress MPLS interfaces.

Egress MPLS interfaces. |
| learn-vlan-id <i>number</i> | VLAN identifier used for MAC learning. | Ingress ports and VLANs.

Egress ports and VLANs. |
| next-header | IPv4 or IPv6 protocol value. In place of the numeric value, you can specify one of the following text synonyms (the numeric values are also listed):

hop-by-hop (0), icmp (1), icmp6 (58), igmp (2), ipip (4), tcp (6), egp (8), udp (17), ipv6 (41), routing (43), fragment (44), rsvp (46), gre (47), esp (50), ah (51), icmp6 (58), no-next-header (59), dstopts (60), ospf (89), pim (103), vrrp (112), sctp (132) | Ingress ports, VLANs, and IPv6 (inet6) interfaces.

Egress IPv6 (inet6) interfaces. |

Table 342: Supported Match Conditions for Firewall Filters (*continued*)

| Match Condition | Description | Direction and Interface |
|------------------|--|---|
| packet-length | Packet length in bytes. You must enter a value between 0 and 65535. | Ingress ports, VLANs, IPv4 (inet), and IPv6 (inet6) interfaces.

Egress IPv4 (inet) interfaces. |
| payload-protocol | IPv4 or IPv6 protocol value. In place of the numeric value, you can specify one of the following text synonyms (the numeric values are also listed):

hop-by-hop (0), icmp (1), icmp6 (58), igmp (2), ipip (4), tcp (6), egp (8), udp (17), ipv6 (41), routing (43), fragment (44), rsvp (46), gre (47), esp (50), ah (51), icmp6 (58), no-next-header (59), dstopts (60), ospf (89), pim (103), vrrp (112), sctp (132) | Ingress ports, VLANs, and IPv6 (inet6) interfaces.

Egress IPv6 (inet6) interfaces. |
| precedence value | IP precedence bits in the type-of-service (ToS) byte in the IP header. (This byte can also be used for the DiffServ DSCP.) In place of the numeric value, you can specify one of the following text synonyms (the numeric values are also listed):

<ul style="list-style-type: none"> • routine (0) • priority (1) • immediate (2) • flash (3) • flash-override (4) • critical-ecp (5) • internet-control (6) • net-control (7) | Ingress ports, VLANs, and IPv4 (inet) interfaces.

Egress IPv4 (inet) interfaces. |
| protocol type | IPv4 or IPv6 protocol value. In place of the numeric value, you can specify one of the following text synonyms (the numeric values are also listed):

hop-by-hop (0), icmp (1), icmp6, igmp (2), ipip (4), tcp (6), egp (8), udp (17), ipv6 (41), routing (43), fragment (44), rsvp (46), gre (47), esp (50), ah (51), icmp6 (58), no-next-header (59), dstopts (60), ospf (89), pim (103), vrrp (112), sctp (132) | Ingress ports, VLANs and IPv4 (inet) interfaces.

Egress IPv4 (inet) interfaces. |

Table 342: Supported Match Conditions for Firewall Filters (*continued*)

| Match Condition | Description | Direction and Interface |
|--|--|---|
| rat-type
tech-type-value | <p>Match the radio-access technology (RAT) type specified in the 8-bit Tech-Type field of Proxy Mobile IPv4 (PMIPv4) access technology type extension. The technology type specifies the access technology through which the mobile device is connected to the access network. Specify a single value, a range of values, or a set of values. You can specify a technology type as a numeric value from 0 through 255 or as a system keyword.</p> <ul style="list-style-type: none"> Numeric value 1 matches IEEE 802.3. Numeric value 2 matches IEEE 802.11a/b/g. Numeric value 3 matches IEEE 802.16e Numeric value 4 matches IEEE 802.16m. Text string eutran matches 4G. Text string geran matches 2G. Text string utran matches 3G. | Egress and ingress IPv4 (inet) interfaces. |
| sample | Sample the packet traffic. Apply this option only if you have enabled traffic sampling. | Egress and ingress IPv4 (inet) interfaces. |
| source-address
ip-address | IP source address field, which is the address of the node that sent the packet. | <p>Ingress ports, VLANs, IPv4 (inet) interfaces, and IPv6 (inet6) interfaces.</p> <p>Egress IPv4 (inet) interfaces.</p> |
| source-mac-address <i>mac-address</i> | Source media access control (MAC) address of the packet. | <p>Ingress ports and VLANs.</p> <p>Egress ports and VLANs.</p> |
| source-port <i>value</i> | TCP or UDP source port. Typically, you specify this match in conjunction with the protocol match statement. In place of the numeric field, you can specify one of the text synonyms listed under destination-port . | <p>Ingress ports, VLANs, IPv4 (inet) interfaces, and IPv6 (inet6) interfaces.</p> <p>Egress IPv4 (inet) interfaces.</p> |
| source-port range-optimize <i>range</i> | Match a range of TCP or UDP port ranges while using the available memory more efficiently. Using this condition allows you to configure more firewall filters than if you configure individual source ports. | Egress and ingress IPv4 (inet) interfaces. |

Table 342: Supported Match Conditions for Firewall Filters (*continued*)

| Match Condition | Description | Direction and Interface |
|--|--|--|
| source-prefix-list <i>prefix-list</i> | IP source prefix list. You can define a list of IP address prefixes under a prefix-list alias for frequent use. Define this list at the [edit policy-options] hierarchy level. | Ingress ports, VLANs, IPv4 (inet) interfaces, and IPv6 (inet6) interfaces.

Egress IPv4 (inet) interfaces. |
| tcp-established | Match packets of an established TCP connection. This condition matches packets other than those used to set up a TCP connection—that is, three-way handshake packets are not matched.

When you specify tcp-established , a switch does not implicitly verify that the protocol is TCP. You must also specify the protocol tcp match condition. | Ingress ports, VLANs, IPv4 (inet) interfaces, and IPv6 (inet6) interfaces.

Egress IPv4 (inet) interfaces. |
| tcp-flags <i>value</i> | One or more TCP flags:
<ul style="list-style-type: none">• ack (0x10)• fin (0x01)• push (0x08)• rst (0x04)• syn (0x02)• urgent (0x20) | Ingress ports, VLANs, IPv4 (inet) interfaces, and IPv6 (inet6) interfaces.

Egress IPv4 (inet) interfaces. |
| tcp-initial | Match the first TCP packet of a connection. A match occurs when the TCP flag SYN is set and the TCP flag ACK is not set.

When you specify tcp-initial , a switch does not implicitly verify that the protocol is TCP. You must also specify the protocol tcp match condition. | Ingress ports, VLANs, IPv4 (inet) interfaces, and IPv6 (inet6) interfaces.

Egress IPv4 (inet) interfaces. |
| traffic-class | 8-bit field that specifies the class-of-service (CoS) priority of the packet. The traffic-class field is used to specify a DiffServ code point (DSCP) value. This field was previously used as the type-of-service (ToS) field in IPv4, and, the semantics of this field (for example, DSCP) are identical to those of IPv4.

You can specify one of the following text synonyms (the field values are also listed):

af11 (10), af12 (12), af13 (14), af21 (18), af22 (20), af23 (22), af31 (26), af32 (28), af33 (30), af41 (34), af42 (36), af43 (38), cs0 (0), cs1 (8), cs2 (16), cs3 (24), cs4 (32), cs5 (40), cs6 (48), cs7 (56), ef (46) | Ingress ports, VLANs, and IPv6 (inet6) interfaces.

Egress IPv6 (inet6) interfaces. |

Table 342: Supported Match Conditions for Firewall Filters (*continued*)

| Match Condition | Description | Direction and Interface |
|------------------------------------|---|---|
| ttl value | IP Time-to-live (TTL) field in decimal. The value can be 1-255. | Ingress IPv4 (inet) interfaces.
Egress IPv4 (inet) interfaces. |
| user-vlan-1p-priority value | Match on the IEEE 802.1p user priority bits in the customer VLAN tag (the inner tag in a dual-tag frame with 802.1Q VLAN tags). Specify a single value or multiple values from 0 through 7. | Ingress ports, VLANs, and IPv4 (inet) interfaces.
Egress IPv4 (inet) interfaces. |
| user-vlan-id number | Match the first VLAN identifier that is part of the payload. | Ingress ports, VLANs, and IPv4 (inet) interfaces.
Egress IPv4 (inet) interfaces. |
| vlan (vlan-name vlan-id) | VLAN names or ID. | Ingress ports and VLANs.
Egress ports and VLANs. |

Use **then** statements to define actions that should occur if a packet matches all conditions in a **from** statement. [Table 343 on page 4430](#) shows the actions that you can specify in a term. (If you do not include a **then** statement, the system accepts packets that match the filter.)

Table 343: Actions for Firewall Filters

| Action | Description |
|----------------------------|---|
| accept | Accept a packet. This is the default action for packets that match a term. |
| discard | Discard a packet silently without sending an Internet Control Message Protocol (ICMP) message. |
| reject message-type | <p>Discard a packet and send a “destination unreachable” ICMPv4 message (type 3). To log rejected packets, configure the syslog action modifier.</p> <p>You can specify one of the following message types: administratively-prohibited (default), bad-host-tos, bad-network-tos, host-prohibited, host-unknown, host-unreachable, network-prohibited, network-unknown, network-unreachable, port-unreachable, precedence-cutoff, precedence-violation, protocol-unreachable, source-host-isolated, source-route-failed, or tcp-reset.</p> <p>If you specify tcp-reset, the system sends a TCP reset if the packet is a TCP packet; otherwise nothing is sent.</p> <p>If you do not specify a message type, the ICMP notification “destination unreachable” is sent with the default message “communication administratively filtered.”</p> <p>NOTE: The reject action is supported on ingress interfaces only.</p> |

Table 343: Actions for Firewall Filters (*continued*)

| Action | Description |
|--|--|
| routing-instance <i>instance-name</i> | Forward matched packets to a virtual routing instance. |
| vlan <i>VLAN-name</i> | Forward matched packets to a specific VLAN. |
| NOTE: The vlan action is supported on ingress interfaces only. | |

You can also specify the action modifiers listed in [Table 344 on page 4431](#) to count, mirror, rate-limit, and classify packets.

Table 344: Action Modifiers for Firewall Filters

| Action Modifier | Description |
|--------------------------------------|--|
| analyzer <i>analyzer-name</i> | <p>Mirror traffic (copy packets) to an analyzer configured at the [edit ethernet-switching-options analyzer] hierarchy level.</p> <p>You can specify port mirroring for ingress port, VLAN, and IPv4 (inet) firewall filters only.</p> |
| count <i>counter-name</i> | Count the number of packets that match the term. |
| dscp <i>value</i> | <p>Differentiated Services code point (DSCP). The DiffServ protocol uses the type-of-service (ToS) byte in the IP header. The most-significant 6 bits of this byte form the DSCP.</p> <p>You can specify DSCP in hexadecimal, binary, or decimal form.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed):</p> <ul style="list-style-type: none"> be—best effort (default) ef (46)—as defined in RFC 3246, <i>An Expedited Forwarding PHB</i>. af11 (10), af12 (12), af13 (14);

Understanding How a Firewall Filter Tests a Protocol

When examining match conditions in a firewall filter, a switch tests only the fields that you specify. It does not implicitly test any fields that you do not explicitly configure. For example, if you specify a match condition of **source-port ssh**, there is no implied test to determine if the protocol is TCP. In this case, the switch considers any packet that has a value of **22** (decimal) in the 2-byte field that follows a *presumed* IP header to be a match. To ensure that the term matches on TCP packets, you also specify a **protocol tcp** match condition.

For the following match conditions, you should explicitly specify the protocol match condition in the same term:

- **destination-port**—Specify **protocol tcp** or **protocol udp**.
- **icmp-code**—Specify **protocol icmp** and **icmp-type**.
- **icmp-type**—Specify **protocol tcp** or **protocol udp**.
- **source-port**—Specify **protocol tcp** or **protocol udp**.
- **tcp-flags**—Specify **protocol tcp**.

Understanding Firewall Filter Planning

Before you create a firewall filter and apply it, determine what you want the filter to accomplish and how to use its match conditions and actions to achieve your goals. It is important that you understand how packets are matched, the default and configured actions of the firewall filter, and where to apply the firewall filter.

You can apply no more than one firewall filter per port, VLAN, or router interface per direction (input and output). For example, for a given port you can apply at most one filter in the input direction and one filter in the output direction. You should try to be conservative in the number of terms (rules) that you include in each firewall filter, because a large number of terms requires longer processing time during a commit operation and can make testing and troubleshooting more difficult.

Before you configure and apply firewall filters, answer the following questions for each of them:

1. What is the purpose of the filter?

For example, the system can drop packets based on header information, rate-limit traffic, classify packets into forwarding classes, log and count packets, or prevent denial-of-service attacks.

2. What are the appropriate match conditions? Determine the packet header fields that the packet must contain for a match. Possible fields include:

- Layer 2 header fields—Source and destination MAC addresses, 802.1Q tag, Ethernet type, or VLAN.
- Layer 3 header fields—Source and destination IP addresses, protocols, and IP options (IP precedence, IP fragmentation flags, or TTL type).
- TCP header fields—Source and destination ports and flags.
- ICMP header fields—Packet type and code.

3. What are the appropriate actions to take if a match occurs?

The system can accept, discard, or reject packets.

4. What additional action modifiers might be required?

For example, you can configure the system to mirror (copy) packets to a specified port, count matching packets, apply traffic management, or police packets.

5. On what port, router interface, or VLAN should the firewall filter be applied?

Start with the following basic guidelines:

- If packets entering or leaving a Layer 2 interface (port) need to be filtered, apply the filter at the **[edit family ethernet switching filter]** hierarchy level. This is a port filter.
- If packets entering or leaving any port in a specific VLAN need to be filtered, use a VLAN filter.

- If packets entering or leaving a Layer 3 (routed) interface or routed VLAN interface (RVI) need to be filtered, use a router firewall filter. Apply the filter to the interface at the **[edit family inet]** hierarchy level. You can also apply a router firewall filter on a loopback interface.

Before you choose the interface or VLAN on which to apply a firewall filter, understand how that placement can affect traffic flow to other interfaces. In general, apply a filter close to the source device if the filter matches on source or destination IP addresses, IP protocols, or protocol information—such as ICMP message types, and TCP or UDP port numbers. However, you should apply a filter close to the destination device if the filter matches *only* on a source IP address. When you apply a filter too close to the source device, the filter could prevent that source device from accessing other services that are available on the network.

NOTE: Egress firewall filters do not affect the flow of locally generated control packets from the Routing Engine.

6. In which direction should the firewall filter be applied?

You typically configure different actions for traffic entering an interface than you configure for traffic exiting an interface.

7. How many filters should I create?

See “[Planning the Number of Firewall Filters to Create](#)” on [page 4435](#) for information about how many firewall filters you can apply.

Understanding How Many Firewall Filters Are Supported

QFX3500, QFX3600, and QFX5100 switches and QFabric Node devices support the maximum numbers of firewall filter terms per type of attachment point shown in [Table 345 on page 4436](#).

Table 345: Supported Firewall Filter Numbers

| Filter Type | QFX3500, QFX3600 | QFX5100 |
|-------------|------------------|---------|
| Ingress | 768 | 1536 |
| Egress | 1024 | 1024 |

These totals are applied in aggregate. For example, on the QFX3500 and QFX3600 you can apply a total of 768 terms in all your port filters, Layer 3 filters, and VLAN filters that are applied in the input direction and 1024 terms in port filters, Layer 3 filters, and VLAN filters that are applied in the output direction.

NOTE: If you want to create more than 512 egress VLAN filters, your first VLAN ID should be 6 and the subsequent VLAN IDs should increase by 1. For example, to create 1024 egress VLAN filters, the first VLAN ID would be 6, the second ID would be 7, and the sequence would continue through VLAN ID 1029. Similarly, if you want to create fewer than 512 egress VLAN filters but want the total number of terms in those filters to exceed 512, you should number your VLAN IDs in the same manner. If you do not use this approach to create your VLAN IDs, the total number of allowed terms or filters will be less than 1024 and might be 512.

The ternary content addressable memory (TCAM) for firewall filters is divided into slices that accommodate 256 terms, and all the terms in a memory slice must be in filters of the same type and applied in the same direction. A memory slice is reserved as soon as you commit a filter. For example, if you create a port filter and apply it in the input direction, a memory slice is reserved that will only store ingress port filters. If you create and apply only one ingress port filter and that filter has only one term, the rest of this slice is unused and is unavailable for other filter types.

Continuing with the above example, assume that you create and apply 256 ingress port filters with one term each so that one memory slice is filled. This leaves two more memory slices available for ingress filters. (Remember that the maximum number of ingress terms is 768.) If you then create and apply an ingress Layer 3 filter with one term, another memory slice is reserved for ingress Layer 3 filters. As before, the rest of the slice is unused and is unavailable for different filter types. At this point there is one memory slice available for any ingress filter type.

Now assume that you create and apply a VLAN ingress filter. The final memory slice is reserved for VLAN ingress filters. Memory allocation for ingress filters (once again assuming one term per filter) is as follows:

- Slice 1: Filled with 256 ingress port filters. You cannot commit any more ingress port filters.
- Slice 2: Contains one ingress Layer 3 filter with one term. You can commit 255 more terms in ingress Layer 3 filters.
- Slice 3: Contains one ingress VLAN filter with one term. You can commit 255 more terms in ingress VLAN filters.

Here is another example. Assume that you create 257 ingress port filters with one term per filter—that is, you create one more term than a single memory slice can accommodate. When you apply the filters and commit the configuration, the filter memory allocation is:

- Slice 1: Filled with 256 ingress port filters. You cannot apply any more ingress port filters.
- Slice 2: Contains one ingress port filter. You can apply 255 more terms in ingress port filters.
- Slice 3: This slice is unassigned. You can create and apply 256 terms in ingress filters of any type (port, Layer 3, or VLAN), but all the filters must be of the same type.

Egress Filters

All of the preceding principles also apply to egress filters, but four memory slices are used because IPv4 Layer 3 filters and IPv6 Layer 3 filters are stored in separate slices. The memory slices for egress filters are the same size as those for ingress filters, so the maximum number of egress filter terms is therefore 1024.

Avoid Configuring too Many Filters

If you violate any of these restrictions and commit a configuration that is not in compliance, Junos OS rejects the excessive filters. For example, if you configure 300 ingress port filters and 300 ingress Layer 3 filters and try to commit the configuration, Junos OS does the following (again assuming one term per filter):

- Accepts the 300 ingress port filters (storing them in two memory slices).
- Accepts the first 256 ingress Layer 3 filters it processes (storing them in the third memory slice).
- Rejects the remaining 44 ingress Layer 3 filters.

NOTE: In this situation, be sure to delete excessive filters (for example, the remaining 44 ingress Layer 3 filters) from the configuration before you reboot the device. If you reboot a device that has a noncompliant configuration, you cannot predict which filters are installed after the reboot. Using the example above, the 44 ingress Layer 3 filters that were originally rejected might be installed, and 44 of the port filters that were originally accepted might be rejected.

Policers can Limit Egress Filters

The number of egress policers that you configure can affect the total number of allowed egress firewall filters. Every policer has two implicit counters that consume two entries in a 1024-entry TCAM that is used for counters, including counters that are configured as action modifiers in firewall filter terms. (Policers consume two entries because one is used for green packets and one is used for nongreen packets regardless of policer type.) If the TCAM becomes full, you cannot commit any more egress firewall filters that have terms with counters. For example, if you configure and commit 512 egress policers (two-color, three-color, or a combination of both policer types), all of the memory entries for counters are used up. If later in your configuration file you insert additional egress firewall filters with terms that also include counters, *none* of the terms in those filters are committed because there is no available memory space for the counters.

Here are some additional examples:

- Assume that you configure egress filters that include a total of 512 policers and no counters. Later in your configuration file you include another egress filter with 10 terms, 1 of which has a counter action modifier. None of the terms in this filter are committed because there is not enough TCAM space for the counter.
- Assume that you configure egress filters that include a total of 500 policers, so 1000 TCAM entries are occupied. Later in your configuration file you include the following two egress filters:
 - Filter A with 20 terms and 20 counters. All the terms in this filter are committed because there is enough TCAM space for all the counters.
 - Filter B comes after Filter A and has five terms and five counters. *None* of the terms in this filter are committed because there is not enough memory space for *all* the counters. (Five TCAM entries are required but only four are available.)

You can prevent this problem from occurring by ensuring that egress firewall filter terms with counter actions are placed earlier in your configuration file than terms that include policers. In this circumstance, Junos OS commits policers even if there is not enough TCAM space for the implicit counters. For example, assume the following:

- You have 1024 egress firewall filter terms with counter actions.
- Later in your configuration file you have an egress filter with 10 terms. None of the terms have counters but one has a policer action modifier.

You can successfully commit the filter with 10 terms even though there is not enough TCAM space for the implicit counters of the policer. The policer is committed without the counters.

Planning for Filter-Specific Policers

You can configure policers to be filter-specific, which means that Junos OS creates only one policer instance regardless of how many times the policer is referenced. When you do this, rate limiting is applied in aggregate, so if you configure a policer to discard traffic that exceeds 1 Gbps and reference that policer in three different terms, the total bandwidth

allowed by the filter is 1 Gbps. However, the behavior of a filter-specific policer is affected by how the firewall filter terms that reference the policer are stored in ternary content addressable memory (TCAM). If you create a filter-specific policer and reference it in multiple firewall filter terms, the policer allows more traffic than expected if the terms are stored in different TCAM slices. For example, if you configure a policer to discard traffic that exceeds 1 Gbps and reference that policer in three different terms that are stored in three separate memory slices, the total bandwidth allowed by the filter is 3 Gbps, not 1 Gbps.

To prevent this unexpected behavior from occurring, use the information about TCAM slices presented above to organize your configuration file so that all the firewall filter terms that reference a given filter-specific policer are stored in the same TCAM slice.

Planning for Filter-Based Forwarding

You can use firewall filters in conjunction with virtual routing instances to specify different routes for packets to travel in their networks. To set up this feature—called filter-based forwarding—you specify a filter and match criteria and then specify the virtual routing instance to send packets to. Filters used in this way also consume memory in an additional TCAM. See “[Understanding FIP Snooping, FBF, and MVR Filter Scalability](#)” on page 4872 for more information. The section *FBF Filter VFP TCAM Consumption* in this topic specifically addresses the number of supported filters when using filter-based forwarding.

Understanding Firewall Filter Processing Points for Bridged and Routed Packets

You apply firewall filters at multiple processing points in the forwarding path. At each processing point, the action to be taken on a packet is determined by the configuration of the filter and the results of the lookup in the forwarding or routing table.

For both bridged (Layer 2) unicast packets and routed (Layer 3) unicast packets, firewall filters are applied in the prescribed order shown below (assuming that each filter is present and a packet is accepted by each one).

Bridged packets:

1. Ingress port filter
2. Ingress VLAN filter
3. Egress VLAN filter
4. Egress port filter

Routed packets:

1. Ingress port firewall filter
2. Ingress VLAN firewall filter (Layer 2 CoS)
3. Ingress router firewall filter (Layer 3 CoS)
4. Egress router firewall filter
5. Egress VLAN firewall filter
6. Egress port filter

NOTE: MAC learning occurs before filters are applied, so QFX Series products learn the MAC addresses of packets that are dropped by ingress filters.

Applying Firewall Filters to Interfaces

For a firewall filter to work, you must apply it to at least one interface. To do this, include the **filter** statement when configuring a logical interface at the **[edit interfaces]** hierarchy level:

```
[edit interfaces]
user@switch# set interface-name unit logical-unit-number family family-name filter (input |
output) filter-name
```

In the **input** statement, specify a firewall filter to be evaluated when packets are received on the interface. Input filters applied to a loopback interface affect only traffic destined for the Routing Engine.

In the **output** statement, specify a filter to be evaluated when packets exit the interface.

NOTE: When you create a loopback interface, it is important to apply an ingress filter to it so the Routing Engine is protected. We recommend that when you apply a filter to the loopback interface lo0, you include the **apply-groups** statement. Doing so ensures that the filter is automatically inherited on every loopback interface, including lo0 and other loopback interfaces.

Overview of Policers

A switch polices traffic by limiting the input or output transmission rate of a class of traffic according to user-defined criteria. Policing (or rate-limiting) traffic allows you to control the maximum rate of traffic sent or received on an interface and to provide multiple priority levels or classes of service.

- [Policers can Limit Egress Firewall Filters on page 4445](#)

Policer Overview

You use policers to apply limits to traffic flow and set consequences for packets that exceed these limits—usually applying a higher loss priority—so that if packets encounter downstream congestion, they can be discarded first. Policers apply only to unicast packets.

Policers provide two functions: metering and marking. A policer meters (measures) each packet against traffic rates and burst sizes that you configure. It then passes the packet and the metering result to the marker, which assigns a packet loss priority that corresponds to the metering result. [Figure 153 on page 4442](#) illustrates this process.

Figure 153: Flow of Tricolor Marking Policer Operation

9017049

After you name and configure a policer, you use it by specifying it as an action in one or more firewall filters.

Policer Types

A switch supports three types of policers:

- Single-rate two-color marker—A two-color policer (or “policer” when used without qualification) meters the traffic stream and classifies packets into two categories of packet loss priority (PLP) according to a configured bandwidth and burst-size limit. You can mark packets that exceed the bandwidth and burst-size limit with a specified PLP or simply discard them.

You can specify this type of policer in an ingress or egress firewall.

NOTE: A two-color policer is most useful for metering traffic at the port (physical interface) level.

- Single-rate three-color marker—This type of policer is defined in RFC 2697, *A Single Rate Three Color Marker*, as part of an assured forwarding (AF) per-hop-behavior (PHB) classification system for a Differentiated Services (DiffServ) environment. This type of policer meters traffic based on one rate—the configured committed information rate (CIR) as well as the committed burst size (CBS) and the excess burst size (EBS). The CIR specifies the average rate at which bits are admitted to the switch. The CBS specifies the usual burst size in bytes and the EBS specifies the maximum burst size in bytes. The EBS must be greater than or equal to the CBS, and neither can be 0.

You can specify this type of policer in an ingress or egress firewall.

NOTE: A single-rate three-color marker (TCM) is most useful when a service is structured according to packet length and not peak arrival rate.

- Two-rate three-color marker—This type of policer is defined in RFC 2698, *A Two Rate Three Color Marker*, as part of an assured forwarding per-hop-behavior classification system for a Differentiated Services environment. This type of policer meters traffic based on two rates—the CIR and peak information rate (PIR) along with their associated burst sizes, the CBS and peak burst size (PBS). The PIR specifies the maximum rate at which bits are admitted to the network and must be greater than or equal to the CIR.

You can specify this type of policer in an ingress or egress firewall.

NOTE: A two-rate three-color policer is most useful when a service is structured according to arrival rates and not necessarily packet length.

See [Table 346 on page 4443](#) for information about how metering results are applied for each of these policer types.

Policer Actions

Policer actions are implicit or explicit and vary by policer type. *Implicit* means that Junos OS assigns the loss priority automatically. [Table 346 on page 4443](#) describes the policer actions.

Table 346: Policer Actions

| Policer | Marking | Implicit Action | Configurable Action |
|-------------------------|--------------------------------|----------------------------------|---------------------|
| Single-rate two-color | Green (conforming) | Assign low loss priority | None |
| | Red (nonconforming) | None | Discard |
| Single-rate three-color | Green (conforming) | Assign low loss priority | None |
| | Yellow (above the CIR and CBS) | Assign medium-high loss priority | None |
| | Red (above the EBS) | Assign high loss priority | Discard |
| Two-rate three-color | Green (conforming) | Assign low loss priority | None |
| | Yellow (above the CIR and CBS) | Assign medium-high loss priority | None |
| | Red (above the PIR and PBS) | Assign high loss priority | Discard |

NOTE: If you specify a policer in an egress firewall filter, the only supported action is discard.

Policer Colors

Single-rate and two-rate three-color policers can operate in two modes:

- **Color-blind**—In color-blind mode, the three-color policer assumes that all packets examined have not been previously marked or metered. In other words, the three-color policer is “blind” to any previous coloring a packet might have had.
- **Color-aware**—In color-aware mode, the three-color policer assumes that all packets examined have been previously marked or metered. In other words, the three-color policer is “aware” of the previous coloring a packet might have had. In color-aware mode, the three-color policer can increase the PLP of a packet but cannot decrease it. For example, if a color-aware three-color policer meters a packet with a medium PLP marking, it can raise the PLP level to high but cannot reduce the PLP level to low.

Filter-Specific Policers

You can configure policers to be filter-specific, which means that Junos OS creates only one policer instance regardless of how many times the policer is referenced. When you do this, rate limiting is applied in aggregate, so if you configure a policer to discard traffic that exceeds 1 Gbps and reference that policer in three different terms, the total bandwidth allowed by the filter is 1 Gbps. However, the behavior of a filter-specific policer is affected by how the firewall filter terms that reference the policer are stored in TCAM. If you create a filter-specific policer and reference it in multiple firewall filter terms, the policer allows more traffic than expected if the terms are stored in different TCAM slices. For example, if you configure a policer to discard traffic that exceeds 1 Gbps and reference that policer in three different terms that are stored in three separate memory slices, the total bandwidth allowed by the filter is 3 Gbps, not 1 Gbps.

To prevent this unexpected behavior from occurring, use the information about TCAM slices presented in [“Planning the Number of Firewall Filters to Create” on page 4435](#) to organize your configuration file so that all the firewall filter terms that reference a given filter-specific policer are stored in the same TCAM slice.

Suggested Naming Convention for Policers

We recommend that you use the naming convention ***policertypeTCM#-color type*** when configuring three-color policers and ***policer#*** when configuring two-color policers. TCM stands for three-color marker. Because policers can be numerous and must be applied correctly to work, a simple naming convention makes it easier to apply the policers properly. For example, the first single-rate, color-aware three-color policer configured would be named **srTCM1-ca**. The second two-rate, color-blind three-color configured would be named **trTCM2-cb**. The elements of this naming convention are explained below:

- sr (single-rate)
- tr (two-rate)
- TCM (tricolor marking)
- 1 or 2 (number of marker)
- ca (color-aware)
- cb (color-blind)

Policer Counters

Each policer that you configure includes an implicit counter that counts the number of packets that exceed the rate limits that are specified for the policer. If you use the same policer in multiple terms—either within the same filter or in different filters—the implicit counter counts all the packets that are policed in all of these terms. If you want to obtain separate packet counts for each term, use these options:

- Configure a unique policer for each term.
- Configure only one policer, but use a unique, explicit counter in each term.

Policer Algorithms

Policing uses the *token-bucket algorithm*, which enforces a limit on average bandwidth while allowing bursts up to a specified maximum value. It offers more flexibility than the *leaky bucket algorithm* in allowing a certain amount of bursty traffic before it starts discarding packets.

How Many Policers are Supported?

You can configure and commit the following numbers of policers on QFX3500 and QFX3600 devices when they are operating as standalone switches:

- Two-color policers used in ingress firewall filters: 767
- Three-color policers used in ingress firewall filters: 767
- Two-color policers used in egress firewall filters: 1022
- Three-color policers used in egress firewall filters: 512

Policers can Limit Egress Firewall Filters

The number of egress policers that you configure can affect the total number of allowed egress firewall filters. Every policer has two implicit counters that consume two entries in a 1024-entry TCAM that is used for counters, including counters that are configured as action modifiers in firewall filter terms. (Policers consume two entries because one is used for green packets and one is used for nongreen packets regardless of policer type.) If the TCAM becomes full, you cannot commit any more egress firewall filters that have terms with counters. For example, if you configure and commit 512 egress policers (two-color, three-color, or a combination of both policer types), all of the memory entries for counters are used up. If later in your configuration file you insert additional egress firewall filters with terms that also include counters, *none* of the terms in those filters are committed because there is no available memory space for the counters.

Here are some additional examples:

- Assume that you configure egress filters that include a total of 512 policers and no counters. Later in your configuration file you include another egress filter with 10 terms, 1 of which has a counter action modifier. None of the terms in this filter are committed because there is not enough TCAM space for the counter.

- Assume that you configure egress filters that include a total of 500 policers, so 1000 TCAM entries are occupied. Later in your configuration file you include the following two egress filters:
 - Filter A with 20 terms and 20 counters. All the terms in this filter are committed because there is enough TCAM space for all the counters.
 - Filter B comes after Filter A and has five terms and five counters. *None* of the terms in this filter are committed because there is not enough memory space for *all* the counters. (Five TCAM entries are required but only four are available.)

You can prevent this problem by ensuring that egress firewall filter terms with counter actions are placed earlier in your configuration file than terms that include policers. In this circumstance, Junos OS commits policers even if there is not enough TCAM space for the implicit counters. For example, assume the following:

- You have 1024 egress firewall filter terms with counter actions.
- Later in your configuration file you have an egress filter with 10 terms. None of the terms have counters but one has a policer action modifier.

You can successfully commit the filter with 10 terms even though there is not enough TCAM space for the implicit counters of the policer. The policer is committed without the counters.

Understanding Policers with Link Aggregation Groups

If you apply a policer to a link aggregation group (LAG) on a QFX3500 switch or node, the policer applies to all the interfaces in the LAG in aggregate. For example, if you configure a policer to rate-limit at 1 Gbps and apply the policer (by using a firewall filter) to a LAG that has two member interfaces on a single switch or node, the total allowed throughput for both members is 1 Gbps.

If you apply a policer to a LAG that has members on different nodes in a QFabric network Node group or redundant server Node group, the configured rate applies to the interface on each node. For example, if you configure a policer to rate-limit at 1 Gbps and apply the policer to a LAG that has one member on server node A and one member on server node B, the allowed throughput for each member is 1 Gbps, for a total allowed throughput of 2 Gbps.

Understanding Color-Aware Mode for Single-Rate Tricolor Marking

In color-aware mode, the treatment the packet receives depends on its classification. Marking can increase a preassigned PLP but cannot decrease it.

Summary of PLP Changes

[Table 348 on page 4447](#) shows how a packet's incoming priority can be modified with single-rate marking.

Table 348: Color-Aware Mode Single-Rate PLP Mapping

| Incoming PLP | Packet Metered Against | Possible Cases | Outgoing PLP |
|--------------|------------------------|---|--------------|
| low | CIR, CBS, and EBS | Conforming | low |
| | | Packet exceeds the CIR and CBS but does not exceed the EBS. | medium-high |
| | | Packet exceeds the EBS. | high |
| medium-low | EBS only | Packet does not exceed the EBS. | medium-low |
| | | Packet exceeds the EBS. | high |
| medium-high | EBS only | Packet does not exceed the EBS. | medium-high |
| | | Packet exceeds the EBS. | high |

Table 348: Color-Aware Mode Single-Rate PLP Mapping (*continued*)

| Incoming PLP | Packet Metered Against | Possible Cases | Outgoing PLP |
|--------------|-----------------------------|----------------|--------------|
| high | Not metered by the policer. | All cases. | high |

The following sections describe single-rate color-aware PLP mapping in more detail.

Effect on Green Packets (Low PLP)

Packets belonging to the green class have already been marked by a classifier with low PLP. The marking policer can leave the PLP unchanged or increase it to medium-high or high, so these packets are therefore metered against both the CBS and the EBS. For example, if a behavior aggregate or multifield classifier marks a packet with low PLP and the two-rate TCM policer is in color-aware mode, the output loss priority is as follows:

- If the rate of traffic flow is less than the CIR, packets remain marked as low PLP.
- If bursts exceed the CBS but not the EBS, some of the packets are marked as medium-high PLP, and some of the packets remain marked as low PLP.
- If bursts exceed the EBS, some of the packets are marked as high PLP, and some of the packets remain marked as low PLP.

Effect on Yellow Packets (Medium PLP)

Packets belonging to the yellow class have already been marked by a classifier with medium-low or medium-high PLP. The marking policer can leave the PLP unchanged or increase it to high, so these packets are therefore metered against the EBS only. For example, if a behavior aggregate or multifield classifier marks a packet with medium-low PLP and the two-rate TCM policer is in color-aware mode, the output loss priority is as follows:

- If the rate of traffic flow is less than the CBS, the packets remain marked as medium-low PLP.
- If the rate of traffic flow is greater than the CBS but less than the EBS, the packets remain marked as medium-low PLP.
- If the rate of traffic flow is greater than the EBS, some of the packets are marked as high PLP and some remain marked as medium-low PLP.

If a BA or multifield classifier marks a packet with medium-high PLP and the two-rate TCM policer is in color-aware mode, the policer assigns output loss priority as follows:

- If the rate of traffic flow is less than the CBS, the packets remain marked as medium-high PLP.
- If the rate of traffic flow is greater than the CBS but less than the EBS, the packets remain marked as medium-high PLP.
- If the rate of traffic flow is greater than the EBS, some of the packets are marked as high PLP and some remain marked as medium-high PLP.

Effect on Red Packets (High PLP)

Packets belonging to the red class have already been marked by a classifier with high PLP. Because the policer cannot decrease the PLP, it does not change it, and these packets are not metered against the CBS or the EBS.

Understanding Color-Blind Mode for Two-Rate Tricolor Marking

With the color-blind mode of two-rate tricolor marking, all packets are evaluated against the committed information rate (CIR). If a packet exceeds the CIR, it is evaluated against the peak information rate (PIR). Packets that exceed the CIR but are below the PIR are marked yellow (medium-high). Packets that exceed the PIR are marked red (high).

Table 349: Color-Blind Mode TCM Color-to-PLP Mapping

| Color | PLP | Meaning |
|--------|--------------------|---|
| Green | low | Packet does not exceed the CIR. |
| Yellow | medium-high | Packet exceeds the CIR but does not exceed the PIR. |
| Red | high | Packet exceeds the PIR. |

- Related Documentation**

Understanding Color-Aware Mode for Two-Rate Tricolor Marking

In color-aware mode, the treatment the packet receives depends on its classification. Marking can increase the preassigned PLP but cannot decrease it

Summary of PLP Changes

Table 350 on page 4449 shows how a packet's incoming priority can be modified with two-rate marking.

Table 350: Color-Aware Mode Two-Rate PLP Mapping

| Incoming PLP | Packet Metered Against | Possible Cases | Outgoing PLP |
|--------------|------------------------|---|--------------------|
| low | CIR and PIR | Packet does not exceed the CIR. | low |
| | | Packet exceeds the CIR but not the PIR. | medium-high |
| | | Packet exceeds the PIR. | high |

Table 350: Color-Aware Mode Two-Rate PLP Mapping (*continued*)

| Incoming PLP | Packet Metered Against | Possible Cases | Outgoing PLP |
|--------------|-----------------------------|---------------------------------|--------------|
| medium-low | PIR only | Packet does not exceed the PIR. | medium-low |
| | | Packet exceeds the PIR. | high |
| medium-high | PIR only | Packet does not exceed the PIR. | medium-high |
| | | Packet exceeds the PIR. | high |
| high | Not metered by the policer. | All cases. | high |

The following sections describe color-aware two-rate PLP mapping in more detail.

Effect on Green Packets (Low PLP)

Packets belonging to the green class have already been marked by a classifier with low PLP. The marking policer can leave the packet's PLP unchanged or increase the PLP to medium-high or high. These packets are therefore metered against both the CIR and the PIR. For example, if a behavior aggregate or multifield classifier marks a packet with low PLP and the two-rate TCM policer is in color-aware mode, the output loss priority is as follows:

- If the rate of traffic flow is less than the CIR, the packets remain marked as low PLP.
- If the rate of traffic flow is greater than the CIR but less than the PIR, some of the packets are marked as medium-high PLP and some of the packets remain marked as low PLP.
- If the rate of traffic flow is greater than the PIR, some of the packets are marked as high PLP and some of the packets remain marked as low PLP.

Effect on Yellow Packets (Medium PLP)

Packets belonging to the yellow class have already been marked by a classifier with medium-low or medium-high PLP. The marking policer can leave the PLP unchanged or increase it to high. These packets are therefore metered against the PIR only. For example, if a behavior aggregate (BA) or multifield classifier marks a packet with medium-low PLP and the two-rate TCM policer is in color-aware mode, the policer assigns output loss priority as follows:

- If the rate of traffic flow is less than the CIR, the packets remain marked as medium-low PLP.
- If the rate of traffic flow is greater than the CIR but less than the PIR, the packets remain marked as medium-low PLP.
- If the rate of traffic flow is greater than the PIR, some of the packets are marked as high PLP and some of the packets remain marked as medium-low PLP.

If a BA or multifield classifier marks a packet with medium-high PLP and the two-rate TCM policer is in color-aware mode, the policer assigns output loss priority as follows:

- If the rate of traffic flow is less than the CIR, the packets remain marked as medium-high PLP.
- If the rate of traffic flow is greater than the CIR but less than the PIR, the packets remain marked as medium-high PLP.
- If the rate of traffic flow is greater than the PIR, some of the packets are marked as high PLP and some of the packets remain marked as medium-high PLP.

Effect on Red Packets (High PLP)

Packets belonging to the red class have already been marked by a classifier with high PLP. Because the policer cannot decrease the PLP, it does not change it, and these packets are not metered against the CIR or the PIR.

Overview of Access Port Protection

Port security features can protect a switch against various types of attacks. Protection methods against some common attacks are:

- [Mitigation of Ethernet Switching Table Overflow Attacks on page 4452](#)
- [Mitigation of Rogue DHCP Server Attacks on page 4452](#)
- [Protection Against ARP Spoofing Attacks on page 4452](#)
- [Protection Against DHCP Snooping Database Alteration Attacks on page 4453](#)
- [Protection Against DHCP Starvation Attacks on page 4453](#)

Mitigation of Ethernet Switching Table Overflow Attacks

In an overflow attack on an Ethernet switching table, an intruder sends so many requests from new MAC addresses that the table cannot learn all the addresses. The attack forces the switch to send broadcast messages when it needs to send traffic to addresses for which it lacks MAC addresses. In addition to generating unnecessary traffic, the attacker might be able to sniff the broadcast packets.

To mitigate such attacks, you can configure a limit for learned MAC addresses or allow only specific MAC addresses. Use the MAC limit feature to control the total number of MAC addresses that can be added to the Ethernet switching table for the specified interface or interfaces. By setting the MAC addresses that are explicitly allowed, you ensure that the addresses of network devices whose network access is critical are guaranteed to be included in the Ethernet switching table.

Mitigation of Rogue DHCP Server Attacks

By default, all access ports are untrusted, and all trunk ports are trusted with regard to DHCP. Trusted ports allow DHCP servers to provide IP addresses and other information to requesting devices. If someone connects an unauthorized DHCP server to a trusted port, the unauthorized server can start issuing IP addresses and configuration information to the network's DHCP clients. The information provided to the clients by this server can disrupt their network access. The unauthorized server might also assign itself as the default gateway device for the network. An attacker can then sniff the network traffic and perpetrate a man-in-the-middle attack—that is, it misdirects traffic intended for a legitimate network device to a device of its choice.

To mitigate this problem, set the interface to which the unauthorized server is connected as untrusted. That action blocks all ingress DHCP server messages from that interface.

NOTE: The switch logs all DHCP server packets that are received on untrusted ports. For example:

```
5 untrusted DHCPOFFER received, interface xe-0/0/2.0[65], vlan v1[10] server
ip/mac 12.12.12.1/00:00:00:00:01:12 offer ip/client mac
12.12.12.253/00:AA:BB:CC:DD:01
```

You can use these messages to detect unauthorized DHCP servers on the network.

NOTE: If you attach a DHCP server to an access port, you must configure the port as trusted.

Protection Against ARP Spoofing Attacks

In ARP spoofing, an attacker sends faked ARP messages on the network. The attacker associates its own MAC address with the IP address of a network device connected to

the switch. Any traffic sent to that IP address is instead sent to the attacker. Now the attacker can create various types of problems, including sniffing the packets that were meant for another host and perpetrating man-in-the-middle attacks. (In a man-in-the-middle attack, the attacker intercepts messages between two hosts, reads them, and perhaps alters them, all without the original hosts knowing that their communications have been compromised.)

To protect against ARP spoofing on your switch, enable both DHCP snooping and dynamic ARP inspection (DAI). DHCP snooping builds and maintains the DHCP snooping table. That table contains the MAC addresses, IP addresses, lease times, binding types, VLAN information, and interface information for the untrusted interfaces on the switch. DAI uses the information in the DHCP snooping table to validate ARP packets. Invalid ARP packets are blocked, and when they are blocked, a system log message is recorded that includes the type of ARP packet and the sender's IP address and MAC address.

See [“Example: Configuring DHCP Snooping and DAI to Protect the Switch from ARP Spoofing Attacks” on page 4513](#).

Protection Against DHCP Snooping Database Alteration Attacks

In an attack designed to alter the DHCP snooping database, an intruder introduces a DHCP client on one of the switch's untrusted access interfaces that has a MAC address identical to that of a client on another untrusted port. The intruder acquires the DHCP lease, which results in changes to the entries in the DHCP snooping table. Subsequently, what would have been valid ARP requests from the legitimate client are blocked.

To protect against this type of alteration of the DHCP snooping database, configure MAC addresses that are explicitly allowed on the interface. See [“Example: Configuring Allowed MAC Addresses to Protect the Switch from DHCP Snooping Database Alteration Attacks” on page 4518](#).

Protection Against DHCP Starvation Attacks

In a DHCP starvation attack, an attacker floods an Ethernet LAN with DHCP requests from spoofed (counterfeit) MAC addresses so that trusted DHCP servers cannot keep up with requests from legitimate DHCP clients. The address space of those servers is completely used up, so they can no longer assign IP addresses and lease times to clients. DHCP requests from those clients are either dropped—that is, the result is a denial of service (DoS)—or directed to a rogue DHCP server set up by the attacker to imitate a legitimate DHCP server.

To protect the switch from DHCP starvation attacks, use the MAC limiting feature. Specify the maximum number of MAC addresses that the switch can learn on the access interfaces to which DHCP clients connect. The DHCP server or servers can then supply only the specified number of IP addresses over each of those interfaces. If a DHCP starvation attack occurs after the maximum number of IP addresses has been assigned, the attack fails.

Port Security Overview

Ethernet LANs are vulnerable to attacks such as address spoofing (forging) and Layer 2 denial of service (DoS) on network devices. Port security features help protect the access ports on your switch against the loss of information and productivity that can result from such attacks.

Juniper Networks Junos operating system (Junos OS) provides features to help secure ports on the switch. Ports can be categorized as either trusted or untrusted. You apply policies appropriate to each category to protect ports against various types of attacks.

Basic port security features are enabled in the switch's default configuration. You can configure additional features with minimal configuration steps.

Depending on the particular feature, you can configure the feature either on VLANs or interfaces.

Port security features supported on switches are:

- DHCP snooping—Filters and blocks ingress Dynamic Host Configuration Protocol (DHCP) server messages on untrusted ports; builds and maintains an IP address to MAC address binding (IP-MAC binding) database, which is called the DHCP snooping database.

NOTE: DHCP snooping is not enabled in the default switch configurations. DHCP snooping is enabled on a per-VLAN basis. The details of enabling DHCP snooping depend on the particular switch.

- DHCPv6 snooping—DHCP snooping for IPv6.
- DHCP option 82—Also known as the DHCP Relay Agent information option. This DHCPv4 feature helps protect the switch against attacks such as spoofing of IP addresses and media access control (MAC) addresses and DHCP IP address starvation. Option 82 provides information about the network location of a DHCP client, and the DHCP server uses this information to implement IP addresses or other parameters for the client.
- DHCPv6 option 37—Option 37 is the DHCP for IPv6 (DHCPv6) equivalent of option 82 and is enabled by default when DHCPv6 snooping is enabled on a VLAN.
- Dynamic ARP inspection (DAI)—Prevents Address Resolution Protocol (ARP) spoofing attacks. ARP requests and replies are compared against entries in the DHCP snooping database, and filtering decisions are made on the basis of the results of those comparisons. You enable DAI on a VLAN.

- IPv6 Neighbor Discovery (ND) inspection—Prevents IPv6 address spoofing attacks. Neighbor discovery requests and replies are compared against entries in the DHCPv6 snooping database, and filtering decisions are made on the basis of the results of those comparisons. You enable ND inspection on a VLAN.
- IP source guard—Mitigates the effects of IP address spoofing attacks on the Ethernet LAN. With IP source guard enabled, the source IP address in the packet sent from an untrusted access interface is validated against the source MAC address in the DHCP snooping database. The packet is forwarded if the source IP-MAC binding is valid; if the binding is not valid, the packet is discarded. You enable IP source guard on a VLAN. EX Series switches support IPv6 source guard also.

NOTE: IP source guard is not supported on the QFX Series.

- MAC limiting—Protects against flooding of the Ethernet switching table (also known as the MAC forwarding table or Layer 2 forwarding table). You can enable MAC limiting on an interface.
- MAC move limiting—(Not supported on EX9200) Tracks MAC movement and detects MAC spoofing on access ports. You enable this feature on a VLAN.
- Persistent MAC learning—Also known as sticky MAC. Persistent MAC learning enables interfaces to retain dynamically learned MAC addresses across switch reboots. You enable this feature on an interface.
- Trusted DHCP server—Configuring the DHCP server on a trusted port protects against rogue DHCP servers sending leases. You enable this feature on an interface (port). By default, access ports are untrusted, and trunk ports are trusted. (Access ports are the switch ports that connect to Ethernet endpoints such as user PCs and laptops, servers, and printers. Trunk ports are the switch ports that connect an Ethernet switch to other switches or to routers.)

Understanding DHCP Snooping for Port Security

DHCP snooping enables the switch to monitor and control DHCP messages received from untrusted devices connected to the switch. When DHCP snooping is enabled, the system snoops the DHCP messages to view DHCP lease information and build and maintain a database of valid IP address to MAC address (IP-MAC) bindings called the DHCP snooping database. Only clients with valid bindings are allowed access to the network.

- [DHCP Snooping Basics on page 4456](#)
- [DHCP Snooping Process on page 4457](#)
- [DHCP Server Access on page 4458](#)
- [DHCP Snooping Table on page 4461](#)

- [Snooping DHCP Packets That Have Invalid IP Addresses on page 4461](#)
- [Prioritizing Snooped Packets on page 4462](#)

DHCP Snooping Basics

Dynamic Host Configuration Protocol (DHCP) allocates IP addresses dynamically, *leasing* addresses to devices so that the addresses can be reused when no longer needed. Hosts and end devices that require IP addresses obtained through DHCP must communicate with a DHCP server across the LAN.

DHCP snooping acts as a guardian of network security by keeping track of valid IP addresses assigned to downstream network devices by a trusted DHCP server (the server is connected to a trusted network port).

By default, all trunk ports on the switch are trusted and all access ports are untrusted for DHCP snooping.

When DHCP snooping is enabled, the lease information from the switch is used to create the DHCP snooping database, a mapping of IP address to MAC-address pairs.

NOTE: DHCP snooping is disabled in the default switch configuration. You must explicitly enable DHCP snooping by setting `examine-dhcp` at the `[edit ethernet-switching-options secure-access-port]` hierarchy level.

Entries in the DHCP database are updated in these events:

- When a DHCP client releases an IP address (sends a DHCPRELEASE message), the associated mapping entry is deleted from the database.
- If you move a network device from one VLAN to another, typically the device needs to acquire a new IP address. Therefore, its entry in the database, including the VLAN ID, is updated.

- When the lease time (timeout value) assigned by the DHCP server expires, the associated entry is deleted from the database.

TIP: By default, the IP-MAC bindings are lost when the switch is rebooted and DHCP clients (the network devices, or hosts) must reacquire bindings. However, you can configure the bindings to persist by setting the `dhcp-snooping-file` statement to store the database file either locally or remotely.

You can configure the switch to snoop DHCP server responses only from particular VLANs. Doing this prevents spoofing of DHCP server messages.

You configure DHCP snooping per VLAN, not per interface (port). DHCP snooping is disabled by default.

DHCP Snooping Process

The basic process of DHCP snooping consists of the following steps:

NOTE: When DHCP snooping is enabled for a VLAN, all DHCP packets sent from that network devices in that VLAN are subjected to DHCP snooping. The final IP-MAC binding occurs when the DHCP server sends DHCPACK to the DHCP client.

1. The network device sends DHCPDISCOVER packet to request IP address.
2. The switch forwards the packet to the DHCP server.
3. The server sends a DHCPOFFER packet to offer an address. If the DHCPOFFER packet is from a trusted interface, the switch forwards the packet to the DHCP client.
4. The network device sends a DHCPREQUEST packet to accept the IP address. The switch adds an IP-MAC placeholder binding to the database. The entry is considered a placeholder until a DHCPACK packet is received from the server. Until then, the IP address could still be assigned to some other host.
5. The server sends a DHCPACK packet to assign the IP address or a DHCPNAK packet to deny the address request.
6. The switch updates the DHCP database in accordance with the type of packet received:
 - Upon receipt of a DHCPACK packet, the switch updates lease information for the IP-MAC binding in its database.
 - Upon receipt of a DHCPNACK packet, the switch deletes the placeholder.

NOTE: The DHCP database is updated only after the DHCPREQUEST packet has been sent.

For general information about the messages that the DHCP client and DHCP server exchange during the assignment of an IP address for the client, see the [Junos OS System Basics Configuration Guide](#).

DHCP Server Access

A switch's access to the DHCP server can be configured in three ways:

- [Switch, DHCP Clients, and DHCP Server Are All on the Same VLAN on page 4458](#)
- [Switch Acts as DHCP Server on page 4459](#)
- [Switch Acts as Relay Agent on page 4460](#)

Switch, DHCP Clients, and DHCP Server Are All on the Same VLAN

When the switch, DHCP clients, and DHCP server are *all members of the same VLAN*, the DHCP server can be connected to the switch in one of two ways:

- The server is directly connected to the same switch as the one connected to the DHCP clients (the hosts, or network devices, that are requesting IP addresses from the server). The VLAN is enabled for DHCP snooping to protect the untrusted access ports. The trunk port is configured by default as a trusted port. See [Figure 154 on page 4458](#).
- The server is connected to an intermediary switch (Switch 2) that is connected through a trunk port to the switch (Switch 1) that the DHCP clients are connected to. Switch 2 is being used as a transit switch. The VLAN is enabled for DHCP snooping to protect the untrusted access ports. The trunk port is configured by default as a trusted port. See [Figure 155 on page 4459](#)—in the figure, **ge-0/0/11** is a trusted trunk port.

Figure 154: DHCP Server Connected Directly to Switch

Figure 155: DHCP Server Connected Directly to Switch 2, with Switch 2 Connected to Switch 1 Through a Trusted Trunk Port

Switch Acts as DHCP Server

NOTE: The switch acting as a DHCP server is not supported on the QFX Series switch.

The switch itself is configured as a DHCP server; this is known as a “local” configuration. See [Figure 156 on page 4460](#).

Figure 156: Switch Is the DHCP Server

**Switch Acts as Relay Agent**

The switch functions as a relay agent when the DHCP clients or the DHCP server is connected to the switch through a Layer 3 interface. The Layer 3 interfaces on the switch are configured as routed VLAN interfaces (RVIs,) or integrated routing and bridging interfaces (IRBs). The trunk interfaces are trusted by default.

These two scenarios illustrate the switch acting as a relay agent:

- The DHCP server and clients are in different VLANs.
- The switch is connected to a router that is in turn connected to the DHCP server. See [Figure 157 on page 4461](#).

Figure 157: Switch Acting as Relay Agent Through Router to DHCP Server

DHCP Snooping Table

The software creates a DHCP snooping information table that displays the content of the DHCP snooping database. The table shows current IP-MAC bindings, as well as lease time, type of binding, names of associated VLANs, and associated interface.

To display the DHCP snooping database, issue the operational mode command `show dhcp snooping binding`.

Static IP Address Additions to the DHCP Snooping Database

You can add specific static IP addresses to the database as well as have the addresses dynamically assigned through DHCP snooping. To add static IP addresses, you supply the IP address, the MAC address of the device, the interface on which the device is connected, and the VLAN with which the interface is associated. No lease time is assigned to the entry. The statically configured entry never expires.

Snooping DHCP Packets That Have Invalid IP Addresses

If you enable DHCP snooping on a VLAN and then devices on that VLAN send DHCP packets that request invalid IP addresses, these invalid IP addresses will be stored in the DHCP snooping database until they are deleted when their default timeout is reached. To eliminate this unnecessary consumption of space in the DHCP snooping database, the switch drops the DHCP packets that request invalid IP addresses, preventing the snooping of these packets. The invalid IP addresses are:

- 0.0.0.0
- 128.0.x.x
- 191.255.x.x

- 192.0.0.x
- 223.255.255.x
- 224.x.x.x
- 240.x.x.x to 255.255.255.255

Prioritizing Snooped Packets

NOTE: Prioritizing snooped packets is not supported on the QFX Series.

You can use class-of-service (CoS) forwarding classes and queues to prioritize DHCP snooped packets for a specified VLAN. This type of configuration places the DHCP snooped packets for that VLAN in the desired egress queue, so that the security procedure does not interfere with the transmittal of high-priority traffic. For additional information, see *Example: Using CoS Forwarding Classes to Prioritize Snooped Packets in Heavy Network Traffic*.

Understanding DAI for Port Security

Dynamic ARP inspection (DAI) protects switches against ARP spoofing.

DAI inspects Address Resolution Protocol (ARP) packets on the LAN and uses the information in the DHCP snooping database on the switch to validate ARP packets and to protect against ARP spoofing (also known as ARP poisoning or ARP cache poisoning). ARP requests and replies are compared against entries in the DHCP snooping database, and filtering decisions are made based on the results of those comparisons. When an attacker tries to use a forged ARP packet to spoof an address, the switch compares the address with entries in the database. If the media access control (MAC) address or IP address in the ARP packet does not match a valid entry in the DHCP snooping database, the packet is dropped.

ARP packets are sent to the Routing Engine and are rate-limited to protect the switch from CPU overload.

- [Address Resolution Protocol on page 4463](#)
- [ARP Spoofing on page 4463](#)
- [Dynamic ARP Inspection on page 4464](#)
- [Prioritizing Inspected Packets on page 4464](#)

Address Resolution Protocol

Sending IP packets on a multi-access network requires mapping an IP address to an Ethernet MAC address.

Ethernet LANs use ARP to map MAC addresses to IP addresses.

The switch maintains this mapping in a cache that it consults when forwarding packets to network devices. If the ARP cache does not contain an entry for the destination device, the host (the DHCP client) broadcasts an ARP request for that device's address and stores the response in the cache.

ARP Spoofing

ARP spoofing is one way to initiate man-in-the-middle attacks. The attacker sends an ARP packet that spoofs the MAC address of another device on the LAN. Instead of the switch sending traffic to the proper network device, the switch sends the traffic to the device with the spoofed address that is impersonating the proper device. If the impersonating device is the attacker's machine, the attacker receives all the traffic from the switch that must have gone to another device. The result is that traffic from the switch is misdirected and cannot reach its proper destination.

One type of ARP spoofing is gratuitous ARP, which is when a network device sends an ARP request to resolve its own IP address. In normal LAN operation, gratuitous ARP messages indicate that two devices have the same MAC address. They are also broadcast when a network interface card (NIC) in a device is changed and the device is rebooted, so that other devices on the LAN update their ARP caches. In malicious situations, an attacker can poison the ARP cache of a network device by sending an ARP response to

the device that directs all packets destined for a certain IP address to go to a different MAC address instead.

To prevent MAC spoofing through gratuitous ARP and through other types of spoofing, the switches examine ARP responses through DAI.

Dynamic ARP Inspection

DAI examines ARP requests and responses on the LAN and validates ARP packets. The switch intercepts ARP packets from an access port and validates them against the DHCP snooping database. If no IP-MAC entry in the database corresponds to the information in the ARP packet, DAI drops the ARP packet and the local ARP cache is not updated with the information in that packet. DAI also drops ARP packets when the IP address in the packet is invalid. ARP probe packets are not subjected to dynamic ARP inspection. The switch always forwards such packets.

Junos OS for EX Series switches and the QFX Series uses DAI for ARP packets received on access ports because these ports are untrusted by default. Trunk ports are trusted by default, and therefore ARP packets bypass DAI on them.

You configure DAI for each VLAN, not for each interface (port). By default, DAI is disabled for all VLANs.

If you set an interface to be a DHCP trusted port, it is also trusted for ARP packets.

NOTE:

- If your switch uses Junos OS for EX Series switches with support for the Enhanced Layer 2 Software (ELS) configuration style, see *Enabling a Trusted DHCP Server (CLI Procedure)* for information about configuring an access interface to be a DHCP trusted port. .
- If your switch is not using Junos OS for EX Series switches with support for the Enhanced Layer 2 Software (ELS) configuration style, see “[Enabling a Trusted DHCP Server \(CLI Procedure\)](#)” on page 4555 for information about configuring an access interface to be a DHCP trusted port.

For packets directed to the switch to which a network device is connected, ARP queries are broadcast on the VLAN. The ARP responses to those queries are subjected to the DAI check.

For DAI, all ARP packets are trapped to the PFE. To prevent CPU overloading, ARP packets destined for the Routing Engine are rate-limited.

If the DHCP server goes down and the lease time for an IP-MAC entry for a previously valid ARP packet runs out, that packet is blocked.

Prioritizing Inspected Packets

NOTE: Prioritizing inspected packets is not supported on the QFX Series.

You can use class-of-service (CoS) forwarding classes and queues to prioritize DAI packets for a specified VLAN. This type of configuration places inspected packets for that VLAN in the egress queue, that you specify, ensuring that the security procedure does not interfere with the transmission of high-priority traffic.

Understanding MAC Limiting and MAC Move Limiting for Port Security

MAC limiting protects against flooding of the Ethernet switching table (also known as the MAC forwarding table or Layer 2 forwarding table). You enable this feature on Layer 2 interfaces (ports). MAC move limiting detects MAC movement and MAC spoofing on access interfaces. You enable this feature on VLANs.

- [MAC Limiting on page 4465](#)
- [MAC Move Limiting on page 4466](#)
- [Actions for MAC Limiting on page 4466](#)
- [MAC Addresses That Exceed the MAC Limit or MAC Move Limit on page 4466](#)

MAC Limiting

MAC limiting sets a limit on the number of MAC addresses that can be learned on a single Layer 2 access interface or on all the Layer 2 access interfaces on the switch. Junos OS provides two MAC limiting methods:

- **Maximum number of MAC addresses**—You configure the maximum number of dynamic MAC addresses allowed per interface. When the limit is exceeded, incoming packets with new MAC addresses can be ignored, dropped, or logged. You can also specify that the interface be shut down or temporarily disabled.
- **Allowed MAC addresses**—You configure specific “allowed” MAC addresses for the access interface. Any MAC address that is not in the list of configured addresses is not

learned, and the switch logs an appropriate message. Allowed MAC binds MAC addresses to a VLAN so that the address does not get registered outside the VLAN. If an allowed MAC setting conflicts with a dynamic MAC setting, the allowed MAC setting takes precedence.

NOTE: If you do not want the system to log messages about invalid MAC addresses received by an interface that has been configured for allowed MAC addresses, disable the logging by configuring the `no-allowed-mac-log` statement.

You configure MAC limiting per interface, not per VLAN. You can specify the maximum number of dynamic MAC addresses that can be learned on a single Layer 2 access interface (including tagged-access interfaces) or on all Layer 2 access interfaces.

MAC Move Limiting

MAC move limiting causes the switch to track the number of times a MAC address can move to a new interface (port). It can help to prevent MAC spoofing, and it can also detect and prevent loops.

If a MAC address moves more than the configured number of times within 1 second, the switch performs the configured action. You can configure MAC move limiting to apply to all VLANs or to a specific VLAN.

Actions for MAC Limiting

You can choose to have one of the following actions performed when the limit of MAC addresses or the limit of MAC moves is exceeded:

- **drop**—Drop the packet and generate a system log entry. This is the default.
- **log**—Do not drop the packet but generate a system log entry.
- **none**—Take no action.
- **shutdown**—Disable the interface and generate an alarm. If you configure the switch with the `port-error-disable` statement, the disabled interface recovers automatically upon expiration of the specified timeout. If this is not configured, you can bring up the disabled interfaces by running the `clear ethernet-switching port-error` command.

See descriptions of results of these various action settings in [“Verifying That MAC Limiting Is Working Correctly” on page 4674](#).

If you set a MAC limit to apply to all interfaces on the switch, you can override that setting for a particular interface by specifying action **none**. See [“Configuring the none Action to Override a MAC Limit Applied to All Interfaces \(CLI Procedure\)” on page 4549](#)

MAC Addresses That Exceed the MAC Limit or MAC Move Limit

If you have configured the `port-error-disable` statement, you can view which interfaces are temporarily disabled because the MAC limit or MAC move limit was exceeded. Use the `show ethernet-switching interfaces` command.

The log messages that indicate the MAC limit or MAC move limit has been exceeded include the offending MAC addresses.

Understanding Trusted and Untrusted Ports

By default, all access ports are untrusted and all trunk ports are trusted in regard to DHCP. Trusted ports allow DHCP servers to provide IP addresses and other information to requesting devices. Untrusted ports drop traffic from DHCP servers to prevent unauthorized servers from providing any configuration information to clients.

If you attach a DHCP server to an access port, you must configure the port as trusted. Before you do so, ensure that the server is physically secure—that is, that access to the server is monitored and controlled.

Understanding Trusted DHCP Servers for Port Security

Any interface on the switch that connects to a DHCP server can be configured as a trusted port. Configuring a DHCP server on a trusted port protects against rogue DHCP servers sending leases.

Ensure that the DHCP server interface is physically secure—that is, that access to the server is monitored and controlled at the site—before you configure the port as trusted.

Understanding DHCP Option 82 for Port Security

You can use DHCP option 82, also known as the DHCP relay agent information option, to help protect the switch against attacks such as spoofing (forging) of IP addresses and MAC addresses, and DHCP IP address starvation. Hosts on untrusted access interfaces on Ethernet LAN switches send requests for IP addresses in order to access the Internet. The switch forwards or relays these requests to DHCP servers, and the servers send offers for IP address leases in response. Attackers can use these messages to perpetrate address spoofing and starvation.

Option 82 provides information about the network location of a DHCP client, and the DHCP server uses this information to implement IP addresses or other parameters for the client. The Juniper Networks Junos operating system (Junos OS) implementation of DHCP option 82 supports RFC 3046, *DHCP Relay Agent Information Option*, at <http://tools.ietf.org/html/rfc3046>.

This topic covers:

- [DHCP Option 82 Processing on page 4468](#)
- [Suboption Components of Option 82 on page 4469](#)
- [Configurations That Support Option 82 on page 4469](#)

DHCP Option 82 Processing

If DHCP option 82 is enabled on the switch, then when a DHCP client that is connected to the switch on an untrusted interface sends a DHCP request, the switch inserts information about the client's network location into the packet header of that request. The switch then sends the request to the DHCP server. The DHCP server reads the option 82 information in the packet header and uses it to implement the IP address or another parameter for the client. See "[Suboption Components of Option 82](#)" on page 4469 for details about option 82 information.

You can enable DHCP option 82 on a single VLAN or on all VLANs on the switch. You can also configure it on Layer 3 interfaces (in routed VLAN interfaces, or RVIs) when the switch is functioning as a relay agent.

When option 82 is enabled on the switch, then this sequence of events occurs when a DHCP client sends a DHCP request:

1. The switch receives the request and inserts the option 82 information in the packet header.
2. The switch forwards or relays the request to the DHCP server.
3. The server uses the DHCP option 82 information to formulate its reply and sends a response back to the switch. It does not alter the option 82 information.

4. The switch strips the option 82 information from the response packet.
5. The switch forwards the response packet to the client.

NOTE: To use the DHCP option 82 feature, you must ensure that the DHCP server is configured to accept option 82. If it is not configured to accept option 82, then when it receives requests containing option 82 information, it does not use the information in setting parameters and it does not echo the information in its response message.

Suboption Components of Option 82

When configuring DHCP option 82, you can use the following suboptions:

- circuit ID—Identifies the circuit (interface and/or VLAN) on the switch on which the request was received. The circuit ID contains the interface name and/or VLAN name, with the two elements separated by a colon—for example, **xe-0/0/10:vlan1**. If the request packet is received on a Layer 3 interface, the circuit ID is just the interface name—for example, **xe-0/0/10**.

Use the **prefix** option to add an optional prefix to the circuit ID. If you enable the **prefix** option, the hostname for the switch is used as the prefix; for example, **switch1:xe-0/0/10:vlan1..**

You can also specify that the interface description be used rather than the interface name and that the VLAN ID be used rather than the VLAN name.

- remote ID—Identifies the host. By default, the remote ID is the MAC address of the switch. You can specify that the remote ID be the hostname of the switch, the interface description, or a character string of your choice. You can also add an optional prefix to the remote ID.
- vendor ID—Identifies the vendor of the host. If you specify the **vendor-id** option but do not enter a value, the default value **Juniper** is used. To specify a value, you type a character string.

Configurations That Support Option 82

You can use option 82 with the following configurations:

- The DHCP client and the DHCP server are on the same VLAN. In this case the switch forwards the requests from the clients on untrusted access interfaces to the server on a trusted interface. For this configuration, you set DHCP option 82 at the **[edit ethernet-switching-options secure-access-port vlan]** hierarchy level.
- The DHCP client or the DHCP server is connected to the switch through a Layer 3 interface and the switch is configured to relay DHCP requests. [Figure 158 on page 4470](#) illustrates a scenario for the switch-as-relay-agent; in this instance, the switch relays requests through a router to the server.

Figure 158: Switch Relays DHCP Requests to Server

For the configuration shown in [Figure 158 on page 4470](#), you set DHCP option 82 at the `[edit forwarding-options helpers bootp]` hierarchy level.

Understanding Static ARP Entries

You can create explicit mappings between IP addresses and MAC addresses, which are called static ARP table entries. Unlike dynamically learned ARP entries, static entries do not age out. You might want to create static ARP entries in a troubleshooting situation or if your device is unable to learn a MAC address dynamically for any reason.

- `arp`

Device Security

- [Understanding Storm Control on page 4471](#)
- [Understanding Unicast RPF on page 4473](#)
- [Understanding Unknown Unicast Forwarding on page 4477](#)

Understanding Storm Control

A traffic storm occurs when broadcast packets prompt receiving devices to broadcast packets in response. This prompts further responses, creating a snowball effect. The switch is flooded with packets, which creates unnecessary traffic that leads to poor performance or even a complete loss of service by some clients. Storm control causes a device to monitor traffic levels and take a specified action when a specified traffic level—called the *storm control level*—is exceeded, thus preventing packets from proliferating and degrading service. You can configure devices to drop broadcast and unknown unicast packets, shut down interfaces, or temporarily disable interfaces when the storm control level is exceeded.

Storm control is disabled by default. If you configure storm control and do not specify a storm control level, the default level is 80 percent of the available bandwidth for ingress traffic. You can change the storm control level by configuring it as a specific bandwidth value. (The **level** configuration statement, which allows you to configure the storm control level as a percentage of the combined broadcast and unknown unicast streams, is deprecated and might be removed from future releases. We recommend that you phase out its use and replace it with the **bandwidth** statement.)

.....

NOTE: There is no default rate limiting of BUM traffic to 80% on MX platforms. If the storm control profile is not attached to the IFL, BUM traffic can go up to the line rate.

.....

.....

NOTE: When you configure storm control bandwidth, the value you configure is rounded off internally to the closest multiple of 64 Kbps, and the rounded-off value represents the bandwidth that is actually enforced. For example, if you configure a bandwidth limit of 150 Kbps, storm control enforces a bandwidth limit of 128 Kbps.

.....

.....

NOTE: Storm control must be disabled on all Ethernet interfaces that belong to the FCoE VLAN to prevent FCoE traffic from being dropped. Configuring storm control on an Ethernet interface and including that interface in an FCoE-FC gateway may have undesirable effects, including FCoE packet loss. After disabling storm control on all interfaces, enable storm control on any interfaces that are not part of an FCoE-FC gateway on which you want to use storm control.

.....

CAUTION: The Junos OS allows you to configure a storm control value that exceeds the bandwidth of the interface. If you configure an interface this way, storm control does not drop broadcast or unknown unicast packets even if they consume all the available bandwidth.

Broadcast, multicast, and unicast packets are sent as part of normal operations, so to recognize a storm, you must be able to identify when traffic has reached an abnormal level. Suspect a storm when operations begin timing out and network response times slow down. Users might be unable to access expected services. Monitor the percentage of broadcast and unknown unicast traffic in the network when it is operating normally. This data can then be used as a benchmark to determine when traffic levels are too high. You can then configure storm control to set the level at which you want to drop broadcast and unknown unicast traffic.

Understanding Unicast RPF

Unicast reverse-path forwarding (RPF) helps protect the switch against denial-of-service (DoS) and distributed denial-of-service (DDoS) attacks by verifying the unicast source address of each packet that arrives on an ingress interface where unicast RPF is enabled. It also helps ensure that traffic arriving on ingress interfaces comes from a network source that the receiving interface can reach.

When you enable unicast RPF, the switch forwards a packet only if the receiving interface is the best return path to the packet's unicast source address. This is known as strict mode unicast RPF.

NOTE: On Juniper Networks EX3200, EX4200, and EX4300 Ethernet Switches, the switch applies unicast RPF *globally* to all interfaces when unicast RPF is configured on any interface. For additional information, see [“Limitations of the Unicast RPF Implementation on EX3200, EX4200, and EX4300 Switches”](#) on page 4476.

This topic covers:

- [Unicast RPF for Switches Overview](#) on page 4473

Unicast RPF for Switches Overview

Unicast RPF functions as an ingress filter that reduces the forwarding of IP packets that might be spoofing an address. By default, unicast RPF is disabled on the switch interfaces.

The type of unicast RPF provided on the switches—that is, strict mode unicast RPF is especially useful on untrusted interfaces. An untrusted interface is an interface where untrusted users or processes can place packets on the network segment.

The switch supports only the active paths method of determining the best return path back to a unicast source address. The active paths method looks up the best reverse path entry in the forwarding table. It does not consider alternate routes specified using routing-protocol-specific methods when determining the best return path.

If the forwarding table lists the receiving interface as the interface to use to forward the packet back to its unicast source, it is the best return path interface.

Use strict mode unicast RPF only on symmetrically routed interfaces. (For information about symmetrically routed interfaces, see [“When to Enable Unicast RPF”](#) on page 4474.)

For more information about strict unicast RPF, see RFC 3704, *Ingress Filtering for Multihomed Networks* at <http://www.ietf.org/rfc/rfc3704.txt>.

Unicast RPF Implementation

This section includes:

- [Unicast RPF Packet Filtering on page 4474](#)
- [Bootstrap Protocol \(BOOTP\) and DHCP Requests on page 4474](#)
- [Default Route Handling on page 4474](#)

Unicast RPF Packet Filtering

When you enable unicast RPF on the switch, the switch handles traffic in the following manner:

- If the switch receives a packet on the interface that is the best return path to the unicast source address of that packet, the switch forwards the packet.
- If the best return path from the switch to the packet's unicast source address is not the receiving interface, the switch discards the packet.
- If the switch receives a packet that has a source IP address that does not have a routing entry in the forwarding table, the switch discards the packet.

Bootstrap Protocol (BOOTP) and DHCP Requests

Bootstrap protocol (BOOTP) and DHCP request packets are sent with a broadcast MAC address and therefore the switch does not perform unicast RPF checks on them. The switch forwards all BOOTP packets and DHCP request packets without performing unicast RPF checks.

Default Route Handling

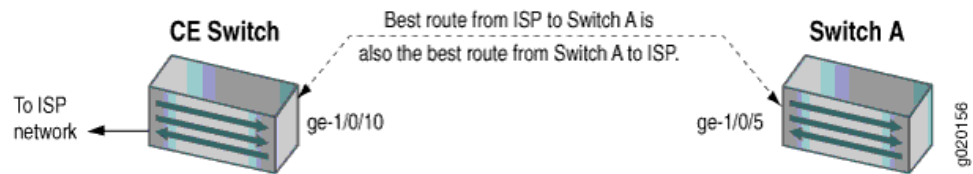

If the best return path to the source is the default route (**0.0.0.0**) and the default route points to **reject**, the switch discards the packets. If the default route points to a valid network interface, the switch performs a normal unicast RPF check on the packets.

When to Enable Unicast RPF

Enable unicast RPF when you want to ensure that traffic arriving on a network interface comes from a source that resides on a network that that interface can reach. You can enable unicast RPF on untrusted interfaces to filter spoofed packets. For example, a common application for unicast RPF is to help defend an enterprise network from DoS/DDoS attacks coming from the Internet.

Enable unicast RPF only on symmetrically routed interfaces. A symmetrically routed interface uses the same route in both directions between the source and the destination, as shown in [Figure 159 on page 4475](#). Symmetrical routing means that if an interface receives a packet, the switch uses the same interface to send a reply to the packet source (the receiving interface matches the forwarding-table entry for the best return path to the source).

Figure 159: Symmetrically Routed Interfaces

Enabling unicast RPF on asymmetrically routed interfaces (where different interfaces receive a packet and reply to its source) results in packets from legitimate sources being filtered (discarded) because the best return path is not the same interface that received the packet.

The following switch interfaces are most likely to be symmetrically routed and thus are candidates for unicast RPF enabling:

- The service provider edge to a customer
- The customer edge to a service provider
- A single access point out of the network (usually on the network perimeter)
- A terminal network that has only one link

NOTE: Because unicast RPF is enabled globally on EX3200, EX4200, and EX4300 switches, ensure that *all* interfaces are symmetrically routed before you enable unicast RPF on these switches. Enabling unicast RPF on asymmetrically routed interfaces results in packets from legitimate sources being filtered.

TIP: Enabling unicast RPF as close as possible to the traffic source stops spoofed traffic before it can proliferate or reach interfaces that do not have unicast RPF enabled.

When Not to Enable Unicast RPF

Typically, you will not enable unicast RPF if:

- Switch interfaces are multihomed.
- Switch interfaces are trusted interfaces.
- BGP is carrying prefixes and some of those prefixes are not advertised or are not accepted by the ISP under its policy. (The effect in this case is the same as filtering an interface by using an incomplete access list.)
- Switch interfaces face the network core. Core-facing interfaces are usually asymmetrically routed.

An asymmetrically routed interface uses different paths to send and receive packets between the source and the destination, as shown in [Figure 160 on page 4476](#). This means

that if an interface receives a packet, that interface does not match the forwarding table entry as the best return path back to the source. If the receiving interface is not the best return path to the source of a packet, unicast RPF causes the switch to discard the packet even though it comes from a valid source.

Figure 160: Asymmetrically Routed Interfaces

NOTE: Do not enable unicast RPF on EX3200, EX4200, and EX4300 switches if any switch interfaces are asymmetrically routed, because unicast RPF is enabled globally on all interfaces of these switches. All switch interfaces must be symmetrically routed for you to enable unicast RPF without the risk of the switch discarding traffic that you want to forward.

Limitations of the Unicast RPF Implementation on EX3200, EX4200, and EX4300 Switches

On EX3200, EX4200, and EX4300 switches, the switch implements unicast RPF on a global basis. You cannot enable unicast RPF on a per-interface basis. Unicast RPF is globally disabled by default.

- When you enable unicast RPF on any interface, it is automatically enabled on all switch interfaces, including link aggregation groups (LAGs), integrated routing and bridging (IRB) interfaces, and routed VLAN interfaces (RVIs).
- When you disable unicast RPF on the interface (or interfaces) on which you enabled unicast RPF, it is automatically disabled on all switch interfaces.

NOTE: You must explicitly disable unicast RPF on every interface on which it was explicitly enabled or unicast RPF remains enabled on all switch interfaces.

QFX switches and EX3200 and EX4200 switches do not perform unicast RPF filtering on equal-cost multipath (ECMP) traffic. The unicast RPF check examines only one best return path to the packet source, but ECMP traffic employs an address block consisting of multiple paths. Using unicast RPF to filter ECMP traffic on these switches can result in the switch discarding packets that you want to forward because the unicast RPF filter does not examine the entire ECMP address block.

Understanding Unknown Unicast Forwarding

Unknown unicast traffic consists of unicast packets with unknown destination MAC addresses. By default, the switch floods these unicast packets that are traveling in a VLAN to all interfaces that are members of the VLAN. Forwarding this type of traffic can create unnecessary traffic that leads to poor network performance or even a complete loss of network service. This is known as a traffic storm.

To prevent a storm, you can disable the flooding of unknown unicast packets to all VLAN interfaces by configuring one VLAN or all VLANs to forward all unknown unicast traffic to a specific interface. This channels the unknown unicast traffic to a single interface.

Firewall and Policer Configuration Examples

- [Example: Using Filter-Based Forwarding to Route Application Traffic to a Security Device on page 4479](#)
- [Example: Using Two-Color Policers and Prefix Lists on page 4483](#)
- [Example: Using Policers to Manage Oversubscription on page 4486](#)

Example: Using Filter-Based Forwarding to Route Application Traffic to a Security Device

You can configure filter-based forwarding by using a firewall filter to forward matched traffic to a specific virtual routing instance.

This example describes how to set up filter-based forwarding:

- [Requirements on page 4480](#)
- [Overview and Topology on page 4480](#)

- [Configuration on page 4480](#)
- [Verification on page 4482](#)

Requirements

This example requires Junos OS Release 12.2X50-D20 or later.

Overview and Topology

In this example, traffic from one application server that is destined for a different application server is matched by a firewall filter based on the IP address of the source application server. Any matching packets are routed to a virtual routing instance that sends the traffic to a security device. In this case, the security device must be able to forward the traffic to the destination application server. For this example, assume that the address of the destination application server is 192.168.0.1.

Configuration

To configure filter-based forwarding:

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste them into the CLI at the **[edit]** hierarchy level.

```
[edit]
set interfaces xe-0/0/0 unit 0 family inet address 10.1.0.1/24
set interfaces xe-0/0/3 unit 0 family inet address 10.1.3.1/24
set firewall family inet filter f1 term t1 from source-address 10.1.0.50/32
set firewall family inet filter f1 term t1 from protocol tcp
set interfaces xe-0/0/0 unit 0 family inet filter input f1
set routing-instances vrf01 instance-type virtual-router
set routing-instances vrf01 interface xe-0/0/3.0
set routing-instances vrf01 routing-options static route 192.168.0.1/24 next-hop 10.1.3.254
set firewall family inet filter f1 term t1 then routing-instance vrf01
```

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*. To configure filter-based forwarding:

1. Configure an interface to connect to the application server:

```
[edit interfaces]
user@switch# set xe-0/0/0 unit 0 family inet address 10.1.0.1/24
```

2. Configure an interface to connect to the security device:

```
[edit interfaces]
user@switch# set xe-0/0/3 unit 0 family inet address 10.1.3.1/24
```

3. Create a firewall filter that matches packets based on the address of the application server that the traffic will be sent from. Also configure the filter so that it matches only TCP packets:

```
[edit firewall]
user@switch# set family inet filter f1 term t1 from source-address 10.1.0.50/32
user@switch# set firewall family inet filter f1 term t1 from protocol tcp
```

4. Apply the filter to the interface that connects to the source application server and configure it to match incoming packets:

```
[edit interfaces]
```

- ```

user@switch# set xe-0/0/0 unit 0 family inet filter input f1

```
5. Create a virtual router:
 

```

[edit]
user@switch# set routing-instances vrf01 instance-type virtual-router

```
  6. Associate the virtual router with the interface that connects to the security device:
 

```

[edit routing-instances]
user@switch# set vrf01 interface xe-0/0/3.0

```
  7. Configure the routing information for the virtual routing instance:
 

```

[edit routing-instances]
user@switch# set vrf01 routing-options static route 192.168.0.1/24 next-hop 10.1.3.254

```
  8. Set the filter to forward packets to the virtual router:
 

```

[edit firewall]
user@switch# set family inet filter f1 term t1 then routing-instance vrf01

```

### Results

Check the results of the configuration:

```

user@switch> show configuration
interfaces {
 xe-0/0/0 {
 unit 0 {
 family inet {
 filter {
 input f1;
 }
 address 10.1.0.1/24;
 }
 }
 }
 xe-0/0/3 {
 unit 0 {
 family inet {
 address 10.1.3.1/24;
 }
 }
 }
}
firewall {
 family inet {
 filter f1 {
 term t1 {
 from {
 source-address {
 10.1.0.50/32;
 }
 protocol tcp;
 }
 then {
 routing-instance vrf01;
 }
 }
 }
 }
}

```

```

}
routing-instances {
 vrf01 {
 instance-type virtual-router;
 interface xe-0/0/1.0;
 routing-options {
 static {
 route 12.34.56.0/24 next-hop 10.1.3.254;
 }
 }
 }
}
}

```

## Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying That Filter-Based Forwarding Was Configured on page 4482](#)

### Verifying That Filter-Based Forwarding Was Configured

**Purpose** Verify that filter-based forwarding was properly enabled on the switch.

**Action** 1. Use the **show interfaces filters** command:

```

user@switch> show interfaces filters xe-0/0/0.0
Interface Admin Link Proto Input Filter Output Filter
xe-0/0/0.0 up down inet f1

```

2. Use the **show route forwarding-table** command:

```

user@switch> show route forwarding-table

```

Routing table: default.inet

Internet:

Destination	Type	RtRef	Next hop	Type	Index	NhRef	Netif

## Example: Using Two-Color Policers and Prefix Lists

If you provide specific amounts of bandwidth to internal or external customers, you can use policing to make sure that customers do not consume more bandwidth than they should receive. For example, you might connect many customers to one 10-Gbps interface and want to ensure that none of them congest the interface by using more bandwidth than they have been allotted.

You could accomplish this by creating a two-color policer similar to the following for each customer:

```

firewall {
 policer Limit-Customer-1 {
 if-exceeding {
 bandwidth-limit 100m;
 burst-size-limit 150m;
 }
 then discard;
 }
}

```

Creating a policer for each customer is clearly not a scalable solution, however. As an alternative, you can create prefix lists that group classes of customers and then create policers for each prefix list. For example, you could create prefix lists such as **Class-A-Customer-Prefixes**, **Class-B-Customer-Prefixes**, and **Class-C-Customer-Prefixes** (at the **[edit policy-options]** hierarchy level) and create the following corresponding policers:

```
firewall {
 policer Class-A {
 if-exceeding {
 bandwidth-limit 100m;
 burst-size-limit 150m;
 }
 then discard;
 }
 policer Class-B {
 if-exceeding {
 bandwidth-limit 75m;
 burst-size-limit 100m;
 }
 then discard;
 }
 policer Class-C {
 if-exceeding {
 bandwidth-limit 50m;
 burst-size-limit 75m;
 }
 then discard;
 }
}
```

You must create filter terms that specify the prefix lists in their **from** statements and the corresponding policers in their **then** statements similar to the following:

```
firewall
 family inet {
 filter Class-A-Customers {
 term term-1 {
 from {
 destination-prefix-list {
 Class-A-Customer-Prefixes;
 }
 }
 then policer Class-A;
 }
 }
 filter Class-B-Customers {
 term term-1 {
 from {
 destination-prefix-list {
 Class-B-Customer-Prefixes;
 }
 }
 then policer Class-B;
 }
 }
 filter Class-C-Customers {
 term term-1 {
 from {
 destination-prefix-list {
 Class-C-Customer-Prefixes;
 }
 }
 }
 }
 }
}
```

```

 then policer Class-C;
 }
}
}

```

Here are the steps to create this firewall configuration:

1. Create the first policer:

```

[edit firewall]
user@switch# set policer Class-A if-exceeding bandwidth-limit 100m burst-size-limit 150m
user@switch# set policer Class-A then discard

```

2. Create the second policer:

```

[edit firewall]
user@switch# set policer Class-B if-exceeding bandwidth-limit 75m burst-size-limit 100m
user@switch# set policer Class-B then discard

```

3. Create the third policer:

```

[edit firewall]
user@switch# set policer Class-C if-exceeding bandwidth-limit 50m burst-size-limit 75m
user@switch# set policer Class-C then discard

```

4. Create a filter for class A customers:

```

[edit firewall]
user@switch# edit family inet filter Class-A-Customers

```

5. Configure the filter to send packets matching the **Class-A-Customer-Prefixes** prefix list to the **Class-A** policer:

```

[edit firewall family inet filter Class-A-Customers]
user@switch# set term term-1 from source-prefix-list Class-A-Customers
user@switch# set term term-1 then policer Class-A

```

6. Create a filter for class B customers:

```

[edit firewall]
user@switch# edit family inet filter Class-B-Customers

```

7. Configure the filter to send packets matching the **Class-B-Customer-Prefixes** prefix list to the **Class-B** policer:

```

[edit firewall family inet filter Class-B-Customers]
user@switch# set term term-1 from source-prefix-list Class-B-Customers
user@switch# set term term-1 then policer Class-B

```

8. Create a filter for class C customers:

```

[edit firewall]
user@switch# edit family inet filter Class-C-Customers

```

9. Configure the filter to send packets matching the **Class-C-Customer-Prefixes** prefix list to the **Class-C** policer:

```

[edit firewall family inet filter Class-C-Customers]
user@switch# set term term-1 from source-prefix-list Class-C-Customers
user@switch# set term term-1 then policer Class-C

```

10. Apply the filters you created to the appropriate interfaces in the output direction.

**NOTE:** Note that the implicit deny statement in this filter will block traffic from any source that does not match one of the prefix lists. If you want the filter to allow this traffic, you must include an explicit term for this purpose.

- Related Documentation**
- [Overview of Policers on page 4441](#)
  - [Applying Firewall Filters to Interfaces on page 4440](#)
  - *prefix-list*

### Example: Using Policers to Manage Oversubscription

You might want to use a policer when an interface is oversubscribed and you want to control what will happen if congestion occurs. For example, you might have servers connected to a switch as listed in [Table 351 on page 4486](#).

**Table 351: Servers Connected to Switch**

Server Type	Connection	IP Address
Network application server	1-gigabit interface	10.0.0.1
Authentication server	1-gigabit interface	10.0.0.2
Database server	10-gigabit interface	10.0.0.3

In this example, users access services provided by the network application server, which requests information from the database server as appropriate. When it receives a request from a user, the network application server first contacts the authentication server to verify the user's credentials. When a user is authenticated and the network application server provides the requested service, all the packets sent from the database server to the application server must transit the 1-Gigabit Ethernet interface connected to the application server twice—once on ingress to the application server and again on egress to the user.

The sequence of events for a user session is as follows:

1. A user connects to the application server and requests a service.
2. The application server requests the user's credentials and relays them to the authentication server.
3. If the authentication server verifies the credentials, the application server initiates the requested service.
4. The application server requests the files necessary to meet the user's request from the database server.
5. The database server sends the requested files to the application server.
6. The application server includes the requested files in its response to the user.

Traffic from the database server to the application server might congest the 1-gigabit interface to which that the application server is connected. This congestion might prevent the server from responding to requests from users and creating new sessions for them. You can use policing to make sure that this does not occur.

To create this firewall configuration, perform the following steps on the database server:

1. Create a policer to drop traffic from the database server to the application server if it exceeds certain limits:

```
[edit firewall]
user@switch# set policer Database-Egress-Policer if-exceeding bandwidth-limit 400
burst-size-limit 500m
user@switch# set policer Database-Egress-Policer then discard
```

2. Create a filter to examine traffic from the database server to the application server:

```
[edit firewall]
user@switch# edit family inet filter Database-Egress-Filter
```

3. Configure the filter to apply the policer to traffic egressing the database server and destined for the application server:

```
[edit firewall family inet filter Database-Egress-Filter]
user@switch# set term term-1 from destination-address 10.0.0.1
user@switch# set term term-1 then policer Database-Egress-Policer
```

4. If required, configure a term to allow traffic from the database server to other destinations (otherwise the traffic will be dropped by the implicit deny statement):

```
[edit firewall family inet filter Database-Egress-Filter]
user@switch# set term term-2 then accept
```

Note that omitting a **from** statement causes the term to match all packets, which is the desired behavior.

5. Install the egress filter as an output filter on the database server interface that is connected the application server:

```
[edit interfaces]
user@switch# set xe-0/0/3 unit 0 family inet filter output Database-Egress-Filter
```

Here is how the final configuration would appear:

```
firewall {
 policer Database-Egress-Policer {
 if-exceeding {
 bandwidth-limit 400;
 burst-size-limit 500m;
 }
 then discard;
 }
 family inet {
 filter Database-Egress-Filter {
 term term-1 {
 from {
 destination-address {
 10.0.0.1/24;
 }
 }
 then policer Database-Egress-Policer;
 }
 term term-2 { # If required, include this term so that traffic from the database server
 # to other destinations is allowed.
 then accept;
 }
 }
 }
}
```

```
}
]
```

### Example: Configuring Basic Port Security Features

You can configure DHCP snooping, dynamic ARP inspection (DAI), MAC limiting, persistent MAC learning, and MAC move limiting on the access ports of switches to protect the switches and the Ethernet LAN against address spoofing and Layer 2 denial-of-service (DoS) attacks. You can also configure a trusted DHCP server and specific (allowed) MAC addresses for the switch interfaces.

This example describes how to configure basic port security features on a switch:

- [Requirements on page 4488](#)
- [Overview and Topology on page 4489](#)
- [Configuration on page 4491](#)
- [Verification on page 4492](#)

---

#### Requirements

---

This example uses the following hardware and software components:

- One EX Series switch or one QFX3500 switch
- Junos OS Release 11.4 or later for EX Series switches or Junos OS Release 12.1 or later for the QFX Series

- A DHCP server to provide IP addresses to network devices on the switch

Before you configure basic port security features, be sure you have:

- Connected the DHCP server to the switch.
- Configured a VLAN on the switch. See the task for your platform:
  - *Configuring VLANs for EX Series Switches (CLI Procedure)*
  - “Configuring VLANs” on page 1534 for the QFX Series

**NOTE:** In this example, the DHCP server and its clients are all members of a single VLAN on the switch.

### Overview and Topology

Ethernet LANs are vulnerable to address spoofing and DoS attacks on network devices. To protect the devices from such attacks, you can configure:

- DHCP snooping to validate DHCP server messages
- DAI to protect against MAC spoofing
- MAC limiting to constrain the number of MAC addresses the switch adds to its MAC address cache
- MAC move limiting to help prevent MAC spoofing
- Persistent MAC learning (sticky MAC) to constrain the MAC addresses that can be learned on an interface to the first ones learned, even after a reboot of the switch
- Trusted DHCP server configured on a trusted port to protect against rogue DHCP servers sending leases

This example shows how to configure these security features on a switch connected to a DHCP server.

The setup for this example includes the VLAN **employee-vlan** on the switch. [Figure 161 on page 4490](#) illustrates the topology for this example.

Figure 161: Network Topology for Basic Port Security

The components of the topology for this example are shown in [Table 352 on page 4490](#).

Table 352: Components of the Port Security Topology

Properties	Settings
Switch hardware	One EX Series switch or one QFX3500 switch
VLAN name and ID	<b>employee-vlan</b> , tag 20
VLAN subnets	192.0.2.16/28 192.0.2.17 through 192.0.2.30 192.0.2.31 is subnet's broadcast address
Interfaces in <b>employee-vlan</b>	<code>ge-0/0/1</code> , <code>ge-0/0/2</code> , <code>ge-0/0/3</code> , <code>ge-0/0/8</code>
Interface for DHCP server	<code>ge-0/0/8</code>

In this example, the switch is initially configured with the default port security setup. In the default switch configuration:

- Secure port access is activated on the switch.
- DHCP snooping and DAI are disabled on all VLANs.
- All access ports are untrusted, and all trunk ports are trusted for DHCP snooping.

In the configuration tasks for this example, you set the DHCP server as trusted; you enable DHCP snooping, DAI, and MAC move limiting on a VLAN; you set a value for a MAC limit on some interfaces; you configure some specific (allowed) MAC addresses on an interface; and you configure persistent MAC learning on an interface.

## Configuration

To configure basic port security on a switch whose DHCP server and client ports are in a single VLAN:

### CLI Quick Configuration

To quickly configure basic port security on the switch, copy the following commands and paste them into the switch terminal window:

```
[edit ethernet-switching-options secure-access-port]
set interface ge-0/0/1 mac-limit 4
set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:80
set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:81
set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:83
set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:85
set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:88
set interface ge-0/0/2 mac-limit 4
set interface ge-0/0/1 persistent-learning
set interface ge-0/0/8 dhcp-trusted
set vlan employee-vlan arp-inspection
set vlan employee-vlan examine-dhcp
set vlan employee-vlan mac-move-limit 5
```

### Step-by-Step Procedure

Configure basic port security on the switch:

1. Enable DHCP snooping on the VLAN:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee-vlan examine-dhcp
```

2. Specify the interface (port) from which DHCP responses are allowed:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface ge-0/0/8 dhcp-trusted
```

3. Enable dynamic ARP inspection (DAI) on the VLAN:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee-vlan arp-inspection
```

4. Configure a MAC limit of 4 and use the default action, **drop**. (Packets are dropped, and the MAC address is not added to the Ethernet switching table if the MAC limit is exceeded on the interfaces):

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface ge-0/0/1 mac-limit 4
user@switch# set interface ge-0/0/2 mac-limit 4
```

5. Allow learned MAC addresses for a particular interface to persist across restarts of the switch and interface-down events by enabling persistent MAC learning:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface ge-0/0/1 persistent-learning
```

6. Configure a MAC move limit of 5 and use the default action, **drop**. (Packets are dropped, and the MAC address is not added to the Ethernet switching table if a MAC address has exceeded the MAC move limit):

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee-vlan mac-move-limit 5
```

7. Configure allowed MAC addresses:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:80
user@switch# set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:81
user@switch# set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:83
```

```
user@switch# set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:85
user@switch# set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:88
```

### Results

Check the results of the configuration:

```
[edit ethernet-switching-options secure-access-port]
user@switch# show
interface ge-0/0/1.0 {
 mac-limit 4;
 persistent-learning;
}
interface ge-0/0/2.0 {
 allowed-mac [00:05:85:3a:82:80 00:05:85:3a:82:81 00:05:85:3a:82:83
 00:05:85:3a:82:85 00:05:85:3a:82:88];
 mac-limit 4;
}
interface ge-0/0/8.0 {
 dhcp-trusted;
}
vlan employee-vlan {
 arp-inspection
 examine-dhcp;
 mac-move-limit 5;
}
```

### Verification

---

To confirm that the configuration is working properly:

- [Verifying That DHCP Snooping Is Working Correctly on the Switch on page 4492](#)
- [Verifying That DAI Is Working Correctly on the Switch on page 4493](#)
- [Verifying That MAC Limiting, MAC Move Limiting, and Persistent MAC Learning Are Working Correctly on the Switch on page 4494](#)
- [Verifying That Allowed MAC Addresses Are Working Correctly on the Switch on page 4494](#)

#### ***Verifying That DHCP Snooping Is Working Correctly on the Switch***

**Purpose** Verify that DHCP snooping is working on the switch.

**Action** Send some DHCP requests from network devices (here they are DHCP clients) connected to the switch.

Display the DHCP snooping information when the interface on which the DHCP server connects to the switch is trusted. The following output results when requests are sent from the MAC addresses and the server has provided the IP addresses and leases:

```
user@switch> show dhcp snooping binding
```

DHCP Snooping Information:

MAC Address	IP Address	Lease	Type	VLAN	Interface
00:05:85:3A:82:77	192.0.2.17	600	dynamic	employee-vlan	ge-0/0/1.0
00:05:85:3A:82:79	192.0.2.18	653	dynamic	employee-vlan	ge-0/0/1.0
00:05:85:3A:82:80	192.0.2.19	720	dynamic	employee-vlan	ge-0/0/2.0
00:05:85:3A:82:81	192.0.2.20	932	dynamic	employee-vlan	ge-0/0/2.0
00:05:85:3A:82:83	192.0.2.21	1230	dynamic	employee-vlan	ge-0/0/2.0
00:05:85:27:32:88	192.0.2.22	3200	dynamic	employee-vlan	ge-0/0/2.0

**Meaning** When the interface on which the DHCP server connects to the switch has been set to trusted, the output (see preceding sample) shows, for each MAC address, the assigned IP address and lease time—that is, the time, in seconds, remaining before the lease expires.

If the DHCP server had been configured as untrusted, no entries would be added to the DHCP snooping database, and nothing would be shown in the output of the **show dhcp snooping binding** command.

#### *Verifying That DAI Is Working Correctly on the Switch*

**Purpose** Verify that DAI is working on the switch.

**Action** Send some ARP requests from network devices connected to the switch.

Display the DAI information:

```
user@switch> show arp inspection statistics
```

ARP inspection statistics:

Interface	Packets received	ARP inspection pass	ARP inspection failed
ge-0/0/1.0	7	5	2
ge-0/0/2.0	10	10	0
ge-0/0/3.0	12	12	0

**Meaning** The sample output shows the number of ARP packets received and inspected per interface, with a listing of how many packets passed and how many failed the inspection on each interface. The switch compares the ARP requests and replies against the entries in the DHCP snooping database. If a MAC address or IP address in the ARP packet does not match a valid entry in the database, the packet is dropped.

**Verifying That MAC Limiting, MAC Move Limiting, and Persistent MAC Learning Are Working Correctly on the Switch**

**Purpose** Verify that MAC limiting, MAC move limiting, and persistent MAC learning are working on the switch.

**Action** Suppose that two packets have been sent from hosts on **ge-0/0/1** and five packets from hosts on **ge-0/0/2**, with both interfaces set to a MAC limit of 4 with the default action **drop** and **ge-0/0/1** enabled for persistent MAC learning.

Display the MAC addresses learned:

```
user@switch> show ethernet-switching table
Ethernet-switching table: 7 entries, 4 learned, 2 persistent entries
```

VLAN	MAC address	Type	Age	Interfaces
employee-vlan	*	Flood	-	All-members
employee-vlan	00:05:85:3A:82:77	Persistent	0	ge-0/0/1.0
employee-vlan	00:05:85:3A:82:79	Persistent	0	ge-0/0/1.0
employee-vlan	00:05:85:3A:82:80	Learn	0	ge-0/0/2.0
employee-vlan	00:05:85:3A:82:81	Learn	0	ge-0/0/2.0
employee-vlan	00:05:85:3A:82:83	Learn	0	ge-0/0/2.0
employee-vlan	00:05:85:3A:82:85	Learn	0	ge-0/0/2.0

Now suppose packets have been sent from two of the hosts on **ge-0/0/2** after they have been moved to other interfaces more than five times in 1 second, with **employee-vlan** set to a MAC move limit of 5 with the default action **drop**.

Display the MAC addresses in the table:

```
user@switch> show ethernet-switching table
Ethernet-switching table: 7 entries, 2 learned, 2 persistent entries
```

VLAN	MAC address	Type	Age	Interfaces
employee-vlan	*	Flood	-	All-members
employee-vlan	00:05:85:3A:82:77	Persistent	0	ge-0/0/1.0
employee-vlan	00:05:85:3A:82:79	Persistent	0	ge-0/0/1.0
employee-vlan	00:05:85:3A:82:80	Learn	0	ge-0/0/2.0
employee-vlan	00:05:85:3A:82:81	Learn	0	ge-0/0/2.0
employee-vlan	*	Flood	-	ge-0/0/2.0
employee-vlan	*	Flood	-	ge-0/0/2.0

**Meaning** The first sample output shows that with a MAC limit of 4 for each interface, the fifth MAC address on **ge-0/0/2** was not learned because it exceeded the MAC limit. The second sample output shows that MAC addresses for three of the hosts on **ge-0/0/2** were not learned, because the hosts had been moved back more than five times in 1 second.

Interface **ge-0/0/1.0** was enabled for persistent MAC learning, so the MAC addresses associated with this interface are of the type **persistent**.

**Verifying That Allowed MAC Addresses Are Working Correctly on the Switch**

**Purpose** Verify that allowed MAC addresses are working on the switch.

**Action** Display the MAC cache information after five allowed MAC addresses have been configured on interface `ge-0/0/2`:

```
user@switch> show ethernet-switching table
Ethernet-switching table: 5 entries, 4 learned
```

VLAN	MAC address	Type	Age	Interfaces
employee-vlan	00:05:85:3A:82:80	Learn	0	ge-0/0/2.0
employee-vlan	00:05:85:3A:82:81	Learn	0	ge-0/0/2.0
employee-vlan	00:05:85:3A:82:83	Learn	0	ge-0/0/2.0
employee-vlan	00:05:85:3A:82:85	Learn	0	ge-0/0/2.0
employee-vlan	*	Flood	-	ge-0/0/2.0

**Meaning** Because the MAC limit value for this interface has been set to 4, only four of the five configured allowed addresses are learned.

  - [show ethernet-switching table on page 1700](#)

### Example: Configuring MAC Limiting to Protect the Switch from DHCP Starvation Attacks

In a DHCP starvation attack, an attacker floods an Ethernet LAN with DHCP requests from spoofed (counterfeit) MAC addresses. The switch's trusted DHCP server or servers cannot keep up with the requests and can no longer assign IP addresses and lease times to legitimate DHCP clients on the switch. Requests from those clients are either dropped or directed to a rogue DHCP server set up by the attacker.

This example describes how to configure MAC limiting, a port security feature, to protect the switch against DHCP starvation attacks:

- [Requirements on page 4496](#)
- [Overview and Topology on page 4496](#)
- [Configuration on page 4497](#)
- [Verification on page 4498](#)

### Requirements

---

This example uses the following hardware and software components:

- One QFX3500 switch
- Junos OS Release 12.1 or later for the QFX Series
- A DHCP server to provide IP addresses to network devices on the switch

Before you configure MAC limiting, a port security feature, to mitigate DHCP starvation attacks, be sure you have:

- Connected the DHCP server to the switch.
- Configured the VLAN **employee-vlan** on the switch. See [“Example: Setting Up Bridging with Multiple VLANs” on page 1451](#).

### Overview and Topology

---

Ethernet LANs are vulnerable to address spoofing and DoS attacks on network devices. This example describes how to protect the switch against one common type of attack, a DHCP starvation attack.

This example shows how to configure port security features on a switch that is connected to a DHCP server.

The setup for this example includes the VLAN **employee-vlan** on the switch. [Figure 162 on page 4497](#) illustrates the topology for this example.

Figure 162: Network Topology for Basic Port Security

The components of the topology for this example are shown in [Table 353 on page 4497](#).

Table 353: Components of the Port Security Topology

Properties	Settings
Switch hardware	One QFX3500 switch
VLAN name and ID	<b>employee-vlan</b>
Interfaces in <b>employee-vlan</b>	<code>ge-0/0/1</code> , <code>ge-0/0/2</code> , <code>ge-0/0/3</code> , <code>ge-0/0/8</code>
Interface for DHCP server	<code>ge-0/0/8</code>

In this example, the switch has already been configured as follows:

- Secure port access is activated on the switch.
- No MAC limit is set on any of the interfaces.
- DHCP snooping is disabled on the VLAN **employee-vlan**.
- All access interfaces are untrusted, which is the default setting.

### Configuration

To configure the MAC limiting port security feature to protect the switch against DHCP starvation attacks:

<b>CLI Quick Configuration</b>	<p>To quickly configure MAC limiting, copy the following commands and paste them into the switch terminal window:</p> <pre>[edit ethernet-switching-options secure-access-port] user@switch# set interface ge-0/0/1 mac-limit 3 action drop user@switch# set interface ge-0/0/2 mac-limit 3 action drop</pre>
<b>Step-by-Step Procedure</b>	<p>Configure MAC limiting:</p> <ol style="list-style-type: none"><li>1. Configure a MAC limit of <b>3</b> on <b>ge-0/0/1</b> and specify that packets with new addresses be dropped if the limit has been exceeded on the interface: <pre>[edit ethernet-switching-options secure-access-port] user@switch# set interface ge-0/0/1 mac-limit (Access Port Security) 3 action drop</pre></li><li>2. Configure a MAC limit of <b>3</b> on <b>ge-0/0/2</b> and specify that packets with new addresses be dropped if the limit has been exceeded on the interface: <pre>[edit ethernet-switching-options secure-access-port] user@switch# set interface ge-0/0/2 mac-limit 3 action drop</pre></li></ol>
<b>Results</b>	<p>Check the results of the configuration:</p> <pre>[edit ethernet-switching-options secure-access-port] user@switch# show interface ge-0/0/1.0 {     mac-limit 3 action drop; } interface ge-0/0/2.0 {     mac-limit 3 action drop; }</pre>

---

### Verification

Confirm that the configuration is working properly.

#### *Verifying That MAC Limiting Is Working Correctly on the Switch*

**Purpose** Verify that MAC limiting is working on the switch.

**Action** Send some DHCP requests from network devices (here they are DHCP clients) connected to the switch.

Display the MAC addresses learned when DHCP requests are sent from hosts on **ge-0/0/1** and from hosts on **ge-0/0/2**, with both interfaces set to a MAC limit of **3** with the action **drop**:

```
user@switch> show ethernet-switching table
Ethernet-switching table: 7 entries, 6 learned
```

VLAN	MAC address	Type	Age	Interfaces
default	*	Flood	-	ge-0/0/2.0
default	00:05:85:3A:82:77	Learn	0	ge-0/0/1.0
default	00:05:85:3A:82:79	Learn	0	ge-0/0/1.0
default	00:05:85:3A:82:80	Learn	0	ge-0/0/1.0
default	00:05:85:3A:82:81	Learn	0	ge-0/0/2.0
default	00:05:85:3A:82:83	Learn	0	ge-0/0/2.0
default	00:05:85:3A:82:85	Learn	0	ge-0/0/2.0

**Meaning** The sample output shows that with a MAC limit of **3** for each interface, the DHCP request for a fourth MAC address on **ge-0/0/2** was dropped because it exceeded the MAC limit.

Because only 3 MAC addresses can be learned on each of the two interfaces, attempted DHCP starvation attacks fail.

- Related Documentation**
- [Understanding MAC Limiting and MAC Move Limiting for Port Security on page 4465](#)
  - [Configuring MAC Limiting on page 4545](#)

## Example: Configuring MAC Limiting, Including Dynamic and Allowed MAC Addresses, to Protect the Switch from Ethernet Switching Table Overflow Attacks

In an Ethernet switching table overflow attack, an intruder sends so many requests from new MAC addresses that the Ethernet switching table fills up and then overflows, forcing the switch to broadcast all messages.

This example describes how to configure MAC limiting and allowed MAC addresses, two port security features, to protect the switch from Ethernet switching table attacks:

- [Requirements on page 4499](#)
- [Overview and Topology on page 4500](#)
- [Configuration on page 4501](#)
- [Verification on page 4502](#)

### Requirements

This example uses the following hardware and software components:

- One EX Series switch or QFX3500 switch

- Junos OS Release 9.0 or later for EX Series switches or Junos OS 12.1 or later for the QFX Series.
- A DHCP server to provide IP addresses to network devices on the switch

Before you configure specific port security features to mitigate common access-interface attacks, be sure you have:

- Connected the DHCP server to the switch.
- Configured a VLAN on the switch. See the task for your platform:

### Overview and Topology

Ethernet LANs are vulnerable to address spoofing and DoS attacks on network devices. This example describes how to protect the switch from an attack on the Ethernet switching table that causes the table to overflow and thus forces the switch to broadcast all messages.

This example shows how to configure port security features on a switch connected to a DHCP server.

The setup for this example includes the VLAN **employee-vlan** on the switch. The procedure for creating that VLAN is described in the topic *Example: Setting Up Bridging with Multiple VLANs for EX Series Switches* and “*Example: Setting Up Bridging with Multiple VLANs*” on page 1451 for the QFX Series. That procedure is not repeated here. Figure 163 on page 4500 illustrates the topology for this example.

Figure 163: Network Topology for Basic Port Security

The components of the topology for this example are shown in Table 354 on page 4501.

Table 354: Components of the Port Security Topology

Properties	Settings
Switch hardware	One EX Series switch or one QFX3500 switch
VLAN name and ID	<b>employee-vlan</b> , tag 20
VLAN subnets	192.0.2.16/28 192.0.2.17 through 192.0.2.30 192.0.2.31 is subnet's broadcast address
Interfaces in <b>employee-vlan</b>	ge-0/0/1, ge-0/0/2, ge-0/0/3, ge-0/0/8
Interface for DHCP server	ge-0/0/8

In this example, use the MAC limit feature to control the total number of MAC addresses that can be added to the Ethernet switching table for the specified interface. Use the allowed MAC addresses feature to ensure that the addresses of network devices whose network access is critical are guaranteed to be included in the Ethernet switching table.

In this example, the switch has already been configured as follows:

- Secure port access is activated on the switch.
- No MAC limit is set on any of the interfaces.
- All access interfaces are untrusted, which is the default setting.

### Configuration

To configure MAC limiting and some allowed MAC addresses to protect the switch against Ethernet switching table overflow attacks:

#### CLI Quick Configuration

To quickly configure MAC limiting, clear the MAC forwarding table, and configure some allowed MAC addresses, copy the following commands and paste them into the switch terminal window:

```
[edit ethernet-switching-options secure-access-port]
set interface ge-0/0/1 mac-limit 4 action drop
set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:80
set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:81
set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:83
set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:85
exit
exit
clear ethernet-switching-table interface ge-0/0/1
```

#### Step-by-Step Procedure

Configure MAC limiting and some allowed MAC addresses:

1. Configure a MAC limit of 4 on **ge-0/0/1** and specify that incoming packets with different addresses be dropped once the limit is exceeded on the interface:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface ge-0/0/1 mac-limit (Access Port Security) 4 action drop
```

2. Clear the current entries for interface ge-0/0/1 from the MAC address forwarding table :

```
user@switch# clear ethernet-switching-table interface ge-0/0/1
```

3. Configure the allowed MAC addresses on ge-0/0/2:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:80
user@switch# set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:81
user@switch# set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:83
user@switch# set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:85
```

**Results** Check the results of the configuration:

```
[edit ethernet-switching-options secure-access-port]
user@switch# show
interface ge-0/0/1.0 {
 mac-limit 4 action drop;
}
interface ge-0/0/2.0 {
 allowed-mac [00:05:85:3a:82:80 00:05:85:3a:82:81 00:05:85:3a:82:83 00:05:85:3a:82:85];
}
```

### Verification

To confirm that the configuration is working properly:

- [Verifying That MAC Limiting Is Working Correctly on the Switch on page 4502](#)

#### *Verifying That MAC Limiting Is Working Correctly on the Switch*

**Purpose** Verify that MAC limiting is working on the switch.

**Action** Display the MAC cache information after DHCP requests have been sent from hosts on **ge-0/0/1**, with the interface set to a MAC limit of 4 with the action **drop**, and after four allowed MAC addresses have been configured on interface **ge-0/0/2**:

```
user@switch> show ethernet-switching table
Ethernet-switching table: 5 entries, 4 learned
```

VLAN	MAC address	Type	Age	Interfaces
employee-vlan	00:05:85:3A:82:71	Learn	0	ge-0/0/1.0
employee-vlan	00:05:85:3A:82:74	Learn	0	ge-0/0/1.0
employee-vlan	00:05:85:3A:82:77	Learn	0	ge-0/0/1.0
employee-vlan	00:05:85:3A:82:79	Learn	0	ge-0/0/1.0
employee-vlan	*	Flood	0	ge-0/0/1.0
employee-vlan	00:05:85:3A:82:80	Learn	0	ge-0/0/2.0
employee-vlan	00:05:85:3A:82:81	Learn	0	ge-0/0/2.0
employee-vlan	00:05:85:3A:82:83	Learn	0	ge-0/0/2.0
employee-vlan	00:05:85:3A:82:85	Learn	0	ge-0/0/2.0
employee-vlan	*	Flood	-	ge-0/0/2.0

**Meaning** The sample output shows that with a MAC limit of 4 for the interface, the DHCP request for a fifth MAC address on **ge-0/0/1** was dropped because it exceeded the MAC limit and

that only the specified allowed MAC addresses have been learned on the **ge-0/0/2** interface.

## Example: Configuring a DHCP Server Interface as Untrusted to Protect the Switch from Rogue DHCP Server Attacks

In a rogue DHCP server attack, an attacker has introduced a rogue server into the network, allowing it to give IP address leases to the network's DHCP clients and to assign itself as the gateway device.

This example describes how to configure a DHCP server interface as untrusted to protect the switch from a rogue DHCP server:

- [Requirements on page 4503](#)
- [Overview and Topology on page 4504](#)
- [Configuration on page 4505](#)
- [Verification on page 4505](#)

### Requirements

This example uses the following hardware and software components:

- One EX Series switch or one QFX3500 switch
- Junos OS Release 9.0 or later for EX Series switches or Junos OS Release 12.1 or later for the QFX Series
- A DHCP server to provide IP addresses to network devices on the switch

Before you configure an untrusted DHCP server interface to mitigate rogue DHCP server attacks, be sure you have:

- Connected the DHCP server to the switch.
- Enabled DHCP snooping on the VLAN.
- Configured a VLAN on the switch. See the task for your platform:
  - [Example: Setting Up Bridging with Multiple VLANs for EX Series Switches](#)
  - [“Example: Setting Up Bridging with Multiple VLANs” on page 1451](#) for the QFX Series

## Overview and Topology

Ethernet LANs are vulnerable to address spoofing and DoS attacks on network devices. This example describes how to protect the switch from rogue DHCP server attacks.

This example shows how to explicitly configure an untrusted interface on an EX3200-24P switch and a QFX3500 switch. [Figure 164 on page 4504](#) illustrates the topology for this example.

**Figure 164: Network Topology for Basic Port Security**

The components of the topology for this example are shown in [Table 355 on page 4504](#).

**Table 355: Components of the Port Security Topology**

Properties	Settings
Switch hardware	One EX3200-24P, 24 ports (8 PoE ports) or one QFX3500 switch
VLAN name and ID	<b>employee-vlan</b> , tag 20
VLAN subnets	192.0.2.16/28 192.0.2.17 through 192.0.2.30 192.0.2.31 is the subnet's broadcast address
Interfaces in <b>employee-vlan</b>	ge-0/0/1, ge-0/0/2, ge-0/0/3, ge-0/0/8
Interface for DHCP server	ge-0/0/8

In this example, the switch has already been configured as follows:

- Secure port access is activated on the switch.

- DHCP snooping is enabled on the VLAN **employee-vlan**.
- The interface (port) where the rogue DHCP server has connected to the switch is currently trusted.

### Configuration

To configure the DHCP server interface as untrusted because the interface is being used by a rogue DHCP server:

**CLI Quick Configuration** To quickly set the rogue DHCP server interface as untrusted, copy the following command and paste it into the switch terminal window:

```
[edit ethernet-switching-options secure-access-port]
set interface ge-0/0/8 no-dhcp-trusted
```

**Step-by-Step Procedure** To set the DHCP server interface as untrusted:

- Specify the interface (port) from which DHCP responses are not allowed:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface ge-0/0/8 no-dhcp-trusted
```

**Results** Check the results of the configuration:

```
[edit ethernet-switching-options secure-access-port]
user@switch# show
interface ge-0/0/8.0 {
 no-dhcp-trusted;
}
```

### Verification

Confirm that the configuration is working properly.

#### *Verifying That the DHCP Server Interface Is Untrusted*

**Purpose** Verify that the DHCP server is untrusted.

- Action**
1. Send some DHCP requests from network devices (here they are DHCP clients) connected to the switch.
  2. Display the DHCP snooping information when the port on which the DHCP server connects to the switch is not trusted.

**Meaning** There is no output from the command because no entries are added to the DHCP snooping database.

- Related Documentation**
- [Example: Configuring Basic Port Security Features on page 4488](#)
  - [Enabling a Trusted DHCP Server \(CLI Procedure\) on page 4555](#)
  - [Enabling a Trusted DHCP Server \(J-Web Procedure\)](#)
  - [secure-access-port](#)

- [secure-access-port on page 4622](#)
- [show dhcp snooping binding on page 4689](#)

### Example: Configuring DHCP Snooping, DAI , and MAC Limiting on a Switch with Access to a DHCP Server Through a Second Switch

You can configure DHCP snooping, dynamic ARP inspection (DAI), and MAC limiting on the access interfaces of switches to protect the switch and the Ethernet LAN against address spoofing and Layer 2 denial-of-service (DoS) attacks. To obtain those basic settings, you can use the switch's default configuration for port security, configure the MAC limit, and enable DHCP snooping and DAI on a VLAN. You can configure those features when the DHCP server is connected to a different switch from the one to which the DHCP clients (network devices) are connected.

This example describes how to configure port security features on a switch whose hosts obtain IP addresses and lease times from a DHCP server connected to a second switch:

- [Requirements on page 4506](#)
- [Overview and Topology on page 4507](#)
- [Configuring a VLAN, Interfaces, and Port Security Features on Switch 1 on page 4508](#)
- [Configuring a VLAN and Interfaces on Switch 2 on page 4510](#)
- [Verification on page 4511](#)

---

#### Requirements

This example uses the following hardware and software components:

- One EX Series switch or QFX3500 switch—"Switch 1" in this example.
- An additional EX Series switch or QFX3500 switch—"Switch 2" in this example. You do not configure port security on this second switch.
- Junos OS Release 9.0 or later for EX Series switches or Junos OS Release 12.1 or later for the QFX Series.
- A DHCP server connected to Switch 2. You use the server to provide IP addresses to network devices connected to Switch 1.
- At least two network devices (hosts) that you connect to access interfaces on Switch 1. These devices are DHCP clients.

Before you configure DHCP snooping, DAI, and MAC limiting port security features, be sure you have:

- Connected the DHCP server to Switch 2.
- Configured a VLAN on the switch. See the task for your platform:
  - [Example: Setting Up Bridging with Multiple VLANs for EX Series Switches](#)
  - ["Example: Setting Up Bridging with Multiple VLANs" on page 1451](#) for the QFX Series

### Overview and Topology

Ethernet LANs are vulnerable to address spoofing and DoS attacks on network devices. To protect the devices from such attacks, you can configure:

- DHCP snooping to validate DHCP server messages
- DAI to protect against ARP spoofing
- MAC limiting to constrain the number of MAC addresses the switch adds to its MAC address cache

This example shows how to configure these port security features on Switch 1. Switch 1 is connected to another switch (Switch 2) that is not configured with port security features. That second switch is connected to a DHCP server. (See [Figure 165 on page 4507](#).) Network devices (hosts) that are connected to Switch 1 send requests for IP addresses (that is, the devices are DHCP clients). Those requests are transmitted from Switch 1 to Switch 2 and then to the DHCP server connected to Switch 2. Responses to the requests are transmitted along the reverse path of the one followed by the requests.

The setup for this example includes the VLAN **employee-vlan** on both switches.

[Figure 165 on page 4507](#) shows the network topology for the example.

**Figure 165: Network Topology for Port Security Setup with Two Switches on the Same VLAN**

The components of the topology for this example are shown in [Table 356 on page 4508](#).

**Table 356: Components of Port Security Setup on Switch 1 with a DHCP Server Connected to Switch 2**

Properties	Settings
Switch hardware	One EX Series switch or one QFX3500 switch (Switch 1), and an additional EX Series switch or QFX3500 switch (Switch 2)
VLAN name and ID	<b>employee-vlan</b> , tag 20
VLAN subnets	192.0.2.16/28 192.0.2.17 through 192.0.2.30 192.0.2.31 is subnet's broadcast address
Trunk interface on both switches	<b>ge-0/0/11</b>
Access interfaces on Switch 1	<b>ge-0/0/1</b> , <b>ge-0/0/2</b> , and <b>ge-0/0/3</b>
Access interface on Switch 2	<b>ge-0/0/1</b>
Interface for DHCP server	<b>ge-0/0/1</b> on Switch 2

Switch 1 is initially configured with the default port security setup. In the default configuration on the switch:

- Secure port access is activated on the switch.
- The switch does not drop any packets, which is the default setting.
- DHCP snooping and dynamic ARP inspection (DAI) are disabled on all VLANs.
- All access interfaces are untrusted and trunk interfaces are trusted; these are the default settings.

In the configuration tasks for this example, you configure a VLAN on both switches.

In addition to configuring the VLAN, you enable DHCP snooping on Switch 1. In this example, you also enable DAI and a MAC limit of 5 on Switch 1.

Because the interface that connects Switch 2 to Switch 1 is a trunk interface, you do not have to configure this interface to be trusted. As noted above, trunk interfaces are automatically trusted, so DHCP messages coming from the DHCP server to Switch 2 and then on to Switch 1 are trusted.

#### Configuring a VLAN, Interfaces, and Port Security Features on Switch 1

##### **CLI Quick Configuration**

To quickly configure a VLAN, interfaces, and port security features, copy the following commands and paste them into the switch terminal window:

```
[edit]
set ethernet-switching-options secure-access-port interface ge-0/0/1 mac-limit 5 action drop
clear ethernet-switching table interface ge-0/0/1
set ethernet-switching-options secure-access-port vlan employee-vlan arp-inspection
set ethernet-switching-options secure-access-port vlan employee-vlan examine-dhcp
set interfaces ge-0/0/1 unit 0 family ethernet-switching vlan members 20
set interfaces ge-0/0/2 unit 0 family ethernet-switching vlan members 20
```

```

set interfaces ge-0/0/3 unit 0 family ethernet-switching vlan members 20
set interfaces ge-0/0/11 unit 0 family ethernet-switching port-mode trunk
set interfaces ge-0/0/11 unit 0 family ethernet-switching vlan members 20
set vlans employee-vlan vlan-id 20

```

**Step-by-Step Procedure** To configure MAC limiting, a VLAN, and interfaces on Switch 1 and enable DAI and DHCP on the VLAN:

1. Configure the VLAN **employee-vlan** with VLAN ID **20**:  

```

[edit vlans]
user@switch1# set employee-vlan vlan-id 20

```
2. Configure an interface on Switch 1 as a trunk interface:  

```

[edit interfaces]
user@switch1# set ge-0/0/11 unit 0 family ethernet-switching port-mode trunk

```
3. Associate the VLAN with interfaces **ge-0/0/1**, **ge-0/0/2**, **ge-0/0/3**, and **ge-0/0/11**:  

```

[edit interfaces]
user@switch1# set ge-0/0/1 unit 0 family ethernet-switching vlan members 20
user@switch1# set ge-0/0/2 unit 0 family ethernet-switching vlan members 20
user@switch1# set ge-0/0/3 unit 0 family ethernet-switching vlan members 20
user@switch1# set ge-0/0/11 unit 0 family ethernet-switching vlan members 20

```
4. Enable DHCP snooping on the VLAN:  

```

[edit ethernet-switching-options secure-access-port]
user@switch1# set vlan employee-vlan examine-dhcp

```
5. Enable DAI on the VLAN:  

```

[edit ethernet-switching-options secure-access-port]
user@switch1# set vlan employee-vlan arp-inspection

```
6. Configure a MAC limit of **5** on **ge-0/0/1** and use the default action, drop (packets with new addresses are dropped if the limit has been exceeded):  

```

[edit ethernet-switching-options secure-access-port]
user@switch1# set interface ge-0/0/1 mac-limit 5 drop

```
7. Clear the existing MAC address table entries from interface **ge-0/0/1**:  

```

user@switch1# clear ethernet-switching table interface ge-0/0/1

```

**Results** Display the results of the configuration:

```

[edit]
user@switch1# show
ethernet-switching-options {
 secure-access-port {
 interface ge-0/0/1.0 {
 mac-limit 5 action drop;
 }
 vlan employee-vlan {
 arp-inspection;
 examine-dhcp;
 }
 }
}
interfaces {
 ge-0/0/1 {
 unit 0 {
 family ethernet-switching {
 vlan {

```

```
 members 20;
 }
}
}
ge-0/0/2 {
 unit 0 {
 family ethernet-switching {
 vlan {
 members 20;
 }
 }
 }
}
ge-0/0/3 {
 unit 0 {
 family ethernet-switching {
 vlan {
 members 20;
 }
 }
 }
}
ge-0/0/11 {
 unit 0 {
 family ethernet-switching {
 port-mode trunk;
 vlan {
 members 20;
 }
 }
 }
}
vllans {
 employee-vlan {
 vlan-id 20;
 }
}
```

---

### Configuring a VLAN and Interfaces on Switch 2

To configure the VLAN and interfaces on Switch 2:

#### CLI Quick Configuration

To quickly configure the VLAN and interfaces on Switch 2, copy the following commands and paste them into the switch terminal window:

```
[edit]
set interfaces ge-0/0/1 unit 0 family ethernet-switching port-mode trunk
set interfaces ge-0/0/11 unit 0 family ethernet-switching port-mode trunk
set vlans employee-vlan vlan-id 20
```

#### Step-by-Step Procedure

To configure the VLAN and interfaces on Switch 2:

1. Configure an interface on Switch 2 as a trunk interface:

```
[edit interfaces]
```

- ```

user@switch2# set ge-0/0/11 unit 0 ethernet-switching port-mode trunk
2. Associate the VLAN with interfaces ge-0/0/1 and ge-0/0/11:

[edit interfaces]
user@switch2# set ge-0/0/1 unit 0 family ethernet-switching vlan members 20
user@switch2# set ge-0/0/11 unit 0 family ethernet-switching vlan members 20

```

Results Display the results of the configuration:

```

[edit]
user@switch2# show
interfaces {
  ge-0/0/1 {
    unit 0 {
      family ethernet-switching {
        vlan {
          members 20;
        }
      }
    }
  }
  ge-0/0/11 {
    unit 0 {
      family ethernet-switching {
        port-mode trunk;
        vlan {
          members 20;
        }
      }
    }
  }
}
vlans {
  employee-vlan {
    vlan-id 20;
  }
}

```

Verification

To confirm that the configuration is working properly.

- [Verifying That DHCP Snooping Is Working Correctly on Switch 1 on page 4511](#)
- [Verifying That DAI Is Working Correctly on Switch 1 on page 4512](#)
- [Verifying That MAC Limiting Is Working Correctly on Switch 1 on page 4512](#)

Verifying That DHCP Snooping Is Working Correctly on Switch 1

Purpose Verify that DHCP snooping is working on Switch 1.

Action Send some DHCP requests from network devices (here they are DHCP clients) connected to the switch.

Display the DHCP snooping information when the interface through which Switch 2 sends the DHCP server replies to clients connected to Switch 1 is trusted. The server has provided the IP addresses and leases:

```
user@switch1> show dhcp snooping binding
```

DHCP Snooping Information:

| MAC Address | IP Address | Lease | Type | VLAN | Interface |
|-------------------|------------|-------|---------|---------------|------------|
| 00:05:85:3A:82:77 | 192.0.2.17 | 600 | dynamic | employee-vlan | ge-0/0/1.0 |
| 00:05:85:3A:82:79 | 192.0.2.18 | 653 | dynamic | employee-vlan | ge-0/0/1.0 |
| 00:05:85:3A:82:80 | 192.0.2.19 | 720 | dynamic | employee-vlan | ge-0/0/1.0 |
| 00:05:85:3A:82:81 | 192.0.2.20 | 932 | dynamic | employee-vlan | ge-0/0/1.0 |
| 00:05:85:3A:82:83 | 192.0.2.21 | 1230 | dynamic | employee-vlan | ge-0/0/1.0 |
| 00:05:85:3A:82:90 | 192.0.2.20 | 932 | dynamic | employee-vlan | ge-0/0/2.0 |
| 00:05:85:3A:82:91 | 192.0.2.21 | 1230 | dynamic | employee-vlan | ge-0/0/3.0 |

Meaning The output shows, for each MAC address, the assigned IP address and lease time—that is, the time, in seconds, remaining before the lease expires.

Verifying That DAI Is Working Correctly on Switch 1

Purpose Verify that DAI is working on Switch 1.

Action Send some ARP requests from network devices connected to the switch.

Display the DAI information:

```
user@switch1> show arp inspection statistics
```

ARP inspection statistics:

| Interface | Packets received | ARP inspection pass | ARP inspection failed |
|------------|------------------|---------------------|-----------------------|
| ge-0/0/1.0 | 7 | 5 | 2 |
| ge-0/0/2.0 | 10 | 10 | 0 |
| ge-0/0/3.0 | 18 | 15 | 3 |

Meaning The sample output shows the number of ARP packets received and inspected per interface, with a listing of how many packets passed and how many failed the inspection on each interface. The switch compares the ARP requests and replies against the entries in the DHCP snooping database. If a MAC address or IP address in the ARP packet does not match a valid entry in the database, the packet is dropped.

Verifying That MAC Limiting Is Working Correctly on Switch 1

Purpose Verify that MAC limiting is working on Switch 1.

Action Display the MAC addresses that are learned when DHCP requests are sent from hosts on **ge-0/0/1**:

```
user@switch1> show ethernet-switching table
```

Ethernet-switching table: 6 entries, 5 learned

| VLAN | MAC address | Type | Age | Interfaces |
|---------------|-------------------|-------|-----|------------|
| employee-vlan | 00:05:85:3A:82:77 | Learn | 0 | ge-0/0/1.0 |
| employee-vlan | 00:05:85:3A:82:79 | Learn | 0 | ge-0/0/1.0 |
| employee-vlan | 00:05:85:3A:82:80 | Learn | 0 | ge-0/0/1.0 |
| employee-vlan | 00:05:85:3A:82:81 | Learn | 0 | ge-0/0/1.0 |
| employee-vlan | 00:05:85:3A:82:83 | Learn | 0 | ge-0/0/1.0 |
| employee-vlan | * | Flood | - | ge-0/0/1.0 |

Meaning The sample output shows that five MAC addresses have been learned for interface **ge-0/0/1**, which corresponds to the MAC limit of **5** set in the configuration. The last line of the output shows that a sixth MAC address request was dropped, as indicated by the asterisk (*) in the **MAC address** column.

 - [show ethernet-switching table on page 1700](#)

Example: Configuring DHCP Snooping and DAI to Protect the Switch from ARP Spoofing Attacks

In an ARP spoofing attack, the attacker associates its own MAC address with the IP address of a network device connected to the switch. Traffic intended for that IP address is now sent to the attacker instead of being sent to the intended destination. The attacker can send faked, or “spoofed,” ARP messages on the LAN.

NOTE: When dynamic ARP inspection (DAI) is enabled, the switch logs the number of invalid ARP packets that it receives on each interface, along with the sender’s IP and MAC addresses. You can use these log messages to discover ARP spoofing on the network. ARP probe packets are not subjected to dynamic ARP inspection. The switch always forwards such packets.

This example describes how to configure DHCP snooping and dynamic ARP inspection (DAI), two port security features, to protect the switch against ARP spoofing attacks:

- [Requirements on page 4514](#)
- [Overview and Topology on page 4514](#)
- [Configuration on page 4515](#)
- [Verification on page 4516](#)

Requirements

This example uses the following hardware and software components:

- One EX Series switch or one QFX3500 switch
- Junos OS Release 11.4 or later for EX Series switches or Junos OS Release 12.1 or later for the QFX Series
- A DHCP server to provide IP addresses to network devices on the switch

Before you configure DHCP snooping and DAI (two port security features) to mitigate ARP spoofing attacks, be sure you have:

- Connected the DHCP server to the switch.
- Configured a VLAN on the switch. See the task for your platform:
 - *Example: Setting Up Bridging with Multiple VLANs for EX Series Switches*
 - [“Example: Setting Up Bridging with Multiple VLANs” on page 1451](#) for the QFX Series

Overview and Topology

Ethernet LANs are vulnerable to address spoofing and DoS attacks on network devices. This example describes how to protect the switch against one common type of attack, an ARP spoofing attack.

In an ARP spoofing attack, the attacker sends faked ARP messages, thus creating various types of problems on the LAN—for example, the attacker might launch a man-in-the-middle attack.

This example shows how to configure port security features on a switch that is connected to a DHCP server. The setup for this example includes the VLAN **employee-vlan** on the switch. The procedure for creating that VLAN is described in the topic *Example: Setting Up Bridging with Multiple VLANs for EX Series Switches* and [“Example: Setting Up Bridging with Multiple VLANs” on page 1451](#) for the QFX Series. That procedure is not repeated here. [Figure 166 on page 4515](#) illustrates the topology for this example.

Figure 166: Network Topology for Basic Port Security

The components of the topology for this example are shown in [Table 357 on page 4515](#).

Table 357: Components of the Port Security Topology

| Properties | Settings |
|------------------------------------|--|
| Switch hardware | One EX3200-24P, 24 ports (8 PoE ports) or one QFX3500 switch |
| VLAN name and ID | employee-vlan , tag 20 |
| VLAN subnets | 192.0.2.16/28
192.0.2.17 through 192.0.2.30
192.0.2.31 is the subnet's broadcast address |
| Interfaces in employee-vlan | ge-0/0/1, ge-0/0/2, ge-0/0/3, ge-0/0/8 |
| Interface for DHCP server | ge-0/0/8 |

In this example, the switch has already been configured as follows:

- Secure port access is activated on the switch.
- DHCP snooping is disabled on the VLAN **employee-vlan**.
- All access ports are untrusted, which is the default setting.

Configuration

To configure DHCP snooping and dynamic ARP inspection (DAI) to protect the switch against ARP attacks:

CLI Quick Configuration To quickly configure DHCP snooping and dynamic ARP inspection (DAI), copy the following commands and paste them into the switch terminal window:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface ge-0/0/8 dhcp-trusted
user@switch# set vlan employee-vlan examine-dhcp
user@switch# set vlan employee-vlan arp-inspection
```

Step-by-Step Procedure Configure DHCP snooping and dynamic ARP inspection (DAI) on the VLAN:

1. Set the **ge-0/0/8** interface as trusted:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface ge-0/0/8 dhcp-trusted
```
2. Enable DHCP snooping on the VLAN:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee-vlan examine-dhcp
```
3. Enable DAI on the VLAN:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee-vlan arp-inspection
```

Results Check the results of the configuration:

```
[edit ethernet-switching-options secure-access-port]
user@switch# show
interface ge-0/0/8.0 {
  dhcp-trusted;
}
vlan employee-vlan {
  arp-inspection;
  examine-dhcp;
}
```

Verification

Confirm that the configuration is working properly.

- [Verifying That DHCP Snooping Is Working Correctly on the Switch on page 4516](#)
- [Verifying That DAI Is Working Correctly on the Switch on page 4517](#)

Verifying That DHCP Snooping Is Working Correctly on the Switch

Purpose Verify that DHCP snooping is working on the switch.

Action Send some DHCP requests from network devices (here they are DHCP clients) connected to the switch.

Display the DHCP snooping information when the port on which the DHCP server connects to the switch is trusted. The following output results when requests are sent from the MAC addresses and the server has provided the IP addresses and leases:

```
user@switch> show dhcp-snooping binding
DHCP Snooping Information:
MAC Address      IP Address      Lease    Type    VLAN      Interface
-----
00:05:85:3A:82:77 192.0.2.17      600     dynamic employee-vlan ge-0/0/1.0
00:05:85:3A:82:79 192.0.2.18      653     dynamic employee-vlan ge-0/0/1.0
00:05:85:3A:82:80 192.0.2.19      720     dynamic employee-vlan ge-0/0/2.0
00:05:85:3A:82:81 192.0.2.20      932     dynamic employee-vlan ge-0/0/2.0
00:05:85:3A:82:83 192.0.2.21      1230    dynamic employee-vlan ge-0/0/2.0
00:05:85:27:32:88 192.0.2.22      3200    dynamic employee-vlan ge-0/0/3.0
```

Meaning When the interface on which the DHCP server connects to the switch has been set to trusted, the output (see preceding sample) shows, for each MAC address, the assigned IP address and lease time—that is, the time, in seconds, remaining before the lease expires.

Verifying That DAI Is Working Correctly on the Switch

Purpose Verify that DAI is working on the switch.

Action Send some ARP requests from network devices connected to the switch.

Display the DAI information:

```
user@switch> show arp inspection statistics
ARP inspection statistics:
Interface      Packets received  ARP inspection pass  ARP inspection failed
-----
ge-0/0/1.0      7                 5                    2
ge-0/0/2.0     10                10                   0
ge-0/0/3.0     12                12                   0
```

Meaning The sample output shows the number of ARP packets received and inspected per interface, with a listing of how many packets passed and how many failed the inspection on each interface. The switch compares the ARP requests and replies against the entries in the DHCP snooping database. If a MAC address or IP address in the ARP packet does not match a valid entry in the database, the packet is dropped.

Example: Configuring Allowed MAC Addresses to Protect the Switch from DHCP Snooping Database Alteration Attacks

In one type of attack on the DHCP snooping database, an intruder introduces a DHCP client on an untrusted access interface with a MAC address identical to that of a client on another untrusted interface. The intruder then acquires the DHCP lease of that other client, thus changing the entries in the DHCP snooping table. Subsequently, what would have been valid ARP requests from the legitimate client are blocked.

This example describes how to configure allowed MAC addresses, a port security feature, to protect the switch from DHCP snooping database alteration attacks:

- [Requirements on page 4518](#)
- [Overview and Topology on page 4518](#)
- [Configuration on page 4520](#)
- [Verification on page 4520](#)

Requirements

This example uses the following hardware and software components:

- One EX Series switch or one QFX3500 switch
- Junos OS Release 11.4 or later for EX Series switches or Junos OS Release 12.1 or later for the QFX Series
- A DHCP server to provide IP addresses to network devices on the switch

Before you configure specific port security features to mitigate common access-interface attacks, be sure you have:

- Connected the DHCP server to the switch.
- Configured a VLAN on the switch. See the task for your platform:
 - [Example: Setting Up Bridging with Multiple VLANs for EX Series Switches](#)
 - [“Example: Setting Up Bridging with Multiple VLANs” on page 1451](#) for the QFX Series

Overview and Topology

Ethernet LANs are vulnerable to address spoofing and DoS attacks on network devices. This example describes how to protect the switch from an attack on the DHCP snooping database that alters the MAC addresses assigned to some clients.

This example shows how to configure port security features on a switch that is connected to a DHCP server.

The setup for this example includes the VLAN **employee-vlan** on the switch. [Figure 167 on page 4519](#) illustrates the topology for this example.

Figure 167: Network Topology for Basic Port Security

The components of the topology for this example are shown in [Table 358 on page 4519](#).

Table 358: Components of the Port Security Topology

| Properties | Settings |
|------------------------------------|--|
| Switch hardware | One EX3200-24P, 24 ports (8 PoE ports) or one QFX3500 switch |
| VLAN name and ID | employee-vlan , tag 20 |
| VLAN subnets | 192.0.2.16/28
192.0.2.17 through 192.0.2.30
192.0.2.31 is the subnet's broadcast address |
| Interfaces in employee-vlan | ge-0/0/1, ge-0/0/2, ge-0/0/3, ge-0/0/8 |
| Interface for DHCP server | ge-0/0/8 |

In this example, the switch has already been configured as follows:

- Secure port access is activated on the switch.
- DHCP snooping is enabled on the VLAN **employee-vlan**.
- All access ports are untrusted, which is the default setting.

Configuration

To configure allowed MAC addresses to protect the switch against DHCP snooping database alteration attacks:

CLI Quick Configuration To quickly configure some allowed MAC addresses on an interface, copy the following commands and paste them into the switch terminal window:

```
[edit ethernet-switching-options secure-access-port]
set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:80
set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:81
set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:83
set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:85
set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:88
```

Step-by-Step Procedure To configure some allowed MAC addresses on an interface:
Configure the five allowed MAC addresses on an interface:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:80
user@switch# set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:81
user@switch# set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:83
user@switch# set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:85
user@switch# set interface ge-0/0/2 allowed-mac 00:05:85:3A:82:88
```

Results Check the results of the configuration:

```
[edit ethernet-switching-options secure-access-port]
user@switch# show
interface ge-0/0/2.0 {
    allowed-mac [ 00:05:85:3a:82:80 00:05:85:3a:82:81 00:05:85:3a:82:83 00:05:85:
:3a:82:85 00:05:85:3a:82:88 ];
}
```

Verification

Confirm that the configuration is working properly.

- [Verifying That Allowed MAC Addresses Are Working Correctly on the Switch on page 4520](#)

Verifying That Allowed MAC Addresses Are Working Correctly on the Switch

Purpose Verify that allowed MAC addresses are working on the switch.

Action Display the MAC cache information:

```
user@switch> show ethernet-switching table
Ethernet-switching table: 6 entries, 5 learned
```

| VLAN | MAC address | Type | Age | Interfaces |
|---------------|-------------------|-------|-----|------------|
| employee-vlan | 00:05:85:3A:82:80 | Learn | 0 | ge-0/0/2.0 |
| employee-vlan | 00:05:85:3A:82:81 | Learn | 0 | ge-0/0/2.0 |
| employee-vlan | 00:05:85:3A:82:83 | Learn | 0 | ge-0/0/2.0 |
| employee-vlan | 00:05:85:3A:82:85 | Learn | 0 | ge-0/0/2.0 |
| employee-vlan | 00:05:85:3A:82:88 | Learn | 0 | ge-0/0/2.0 |
| employee-vlan | * | Flood | - | ge-0/0/2.0 |

Meaning The output shows that the five MAC addresses configured as allowed MAC addresses have been learned and are displayed in the MAC cache. The last MAC address in the list, one that had not been configured as allowed, has not been added to the list of learned addresses.

Example: Setting Up DHCP Option 82 with a Switch with No Relay Agent Between Clients and a DHCP Server

You can use DHCP option 82, also known as the DHCP relay agent information option, to help protect the switch against attacks such as spoofing (forging) of IP addresses and MAC addresses, and DHCP IP address starvation. Option 82 provides information about the network location of a DHCP client, and the DHCP server uses this information to implement IP addresses or other parameters for the client.

This example describes how to configure DHCP option 82 on a switch with DHCP clients, DHCP server, and switch all on the same VLAN:

- [Requirements on page 4521](#)
- [Overview and Topology on page 4522](#)
- [Configuration on page 4523](#)

Requirements

This example uses the following hardware and software components:

- One EX Series switch or one QFX3500 switch

- Junos OS Release 9.3 or later for EX Series switches or Junos OS Release 12.1 or later for the QFX Series
- A DHCP server to provide IP addresses to network devices on the switch

Before you configure DHCP option 82 on the switch, be sure you have:

- Connected and configured the DHCP server.

NOTE: Your DHCP server must be configured to accept DHCP option 82. If it is not configured for DHCP option 82, it does not use the DHCP option 82 information in the requests sent to it when it formulates its reply messages.

- Configured the **employee** VLAN on the switch and associated the interfaces on which the clients and the server connect to the switch with that VLAN. See the task for your platform:
 - *Configuring VLANs for EX Series Switches (CLI Procedure)*
 - “Configuring VLANs” on page 1534 for the QFX Series

Overview and Topology

If DHCP option 82 is enabled on the switch, then when a network device—a DHCP client—that is connected to the switch on an untrusted interface sends a DHCP request, the switch inserts information about the client's network location into the packet header of that request. The switch then sends the request to the DHCP server. The DHCP server reads the option 82 information in the packet header and uses it to implement the IP address or other parameter for the client.

DHCP option 82 is enabled on an individual VLAN or on all VLANs on the switch.

When option 82 is enabled on the switch, then this sequence of events occurs when a DHCP client sends a DHCP request:

1. The switch receives the request and inserts the option 82 information in the packet header.
2. The switch forwards the request to the DHCP server.
3. The server uses the DHCP option 82 information to formulate its reply and sends a response back to the switch. It does not alter the option 82 information.
4. The switch strips the option 82 information from the response packet.
5. The switch forwards the response packet to the client.

Figure 168 on page 4523 illustrates the topology for this example.

Figure 168: Network Topology for Configuring DHCP Option 82 on a Switch That Is on the Same VLAN as the DHCP Clients and the DHCP Server

In this example, you configure DHCP option 82 on the switch. The switch connects to the DHCP server on interface `ge-0/0/8`. The DHCP clients connect to the switch on interfaces `ge-0/0/1`, `ge-0/0/2`, and `ge-0/0/3`. The switch, server, and clients are all members of the **employee** VLAN.

Configuration

CLI Quick Configuration

To quickly configure DHCP option 82, copy the following commands and paste them into the switch terminal window:

```
set ethernet-switching-options secure-access-port vlan employee dhcp-option82
set ethernet-switching-options secure-access-port vlan employee dhcp-option82 circuit-id prefix
hostname
set ethernet-switching-options secure-access-port vlan employee dhcp-option82 circuit-id
use-vlan-id
set ethernet-switching-options secure-access-port vlan employee dhcp-option82 remote-id
set ethernet-switching-options secure-access-port vlan employee dhcp-option82 remote-id
prefix mac
set ethernet-switching-options secure-access-port vlan employee dhcp-option82 remote-id
use-string employee-switch1
set ethernet-switching-options secure-access-port vlan employee dhcp-option82 vendor-id
```

Step-by-Step Procedure

To configure DHCP option 82:

1. Specify DHCP option 82 for the **employee** VLAN:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee dhcp-option82
```
2. Configure a prefix for the circuit ID suboption (the prefix is always the hostname of the switch):

```
[edit ethernet-switching-options secure-access-port]
```

- ```
user@switch# set vlan employee dhcp-option82 circuit-id prefix hostname
```
3. Specify that the circuit ID suboption value contains the VLAN ID rather than the VLAN name (the default):
- ```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee dhcp-option82 circuit-id use-vlan-id
```
4. Specify that the remote ID suboption be included in the DHCP option 82 information:
- ```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee dhcp-option82 remote-id
```
5. Configure a prefix for the remote ID suboption (here, the prefix is the MAC address of the switch):
- ```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee dhcp-option82 remote-id prefix mac
```
6. Specify that the remote ID suboption value contain a character string (here, the string is **employee-switch1**):
- ```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee dhcp-option82 remote-id use-string employee-switch1
```
7. Configure a vendor ID suboption value, and use the default value. To use the default value, do not type a character string after the **vendor-id** option keyword:
- ```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee dhcp-option82 vendor-id
```

Results Check the results of the configuration:

```
[edit ethernet-switching-options secure-access-port]
user@switch# show
vlan employee {
  dhcp-option82 {
    circuit-id {
      prefix hostname;
      use-vlan-id;
    }
    remote-id {
      prefix mac;
      use-string employee-switch1;
    }
    vendor-id;
  }
}
```

Example: Setting Up DHCP Option 82 with a Switch as a Relay Agent Between Clients and a DHCP Server

You can use DHCP option 82, also known as the DHCP relay agent information option, to help protect the switch against attacks such as spoofing (forging) of IP addresses and MAC addresses, and DHCP IP address starvation. Option 82 provides information about the network location of a DHCP client, and the DHCP server uses this information to implement IP addresses or other parameters for the client.

This example describes how to configure DHCP option 82 on a switch that is on the same VLAN with the DHCP clients but on a different VLAN from the DHCP server. In this example, the switch acts as a relay agent:

- [Requirements on page 4525](#)
- [Overview and Topology on page 4526](#)
- [Configuration on page 4526](#)

Requirements

This example uses the following hardware and software components:

- One EX4200-24P switch or one QFX3500 switch
- Junos OS Release 9.3 or later for EX Series switches or Junos OS Release 12.1 or later for the QFX Series
- A DHCP server to provide IP addresses to network devices on the switch

Before you configure DHCP option 82 on the switch, be sure you have:

- Connected and configured the DHCP server.

NOTE: Your DHCP server must be configured to accept DHCP option 82. If it is not configured for DHCP option 82, it does not use the DHCP option 82 information in the requests sent to it when it formulates its reply messages.

- Configured the **employee** VLAN on the switch and associated the interfaces on which the clients connect to the switch with that VLAN. See the task for your platform:
 - [Configuring VLANs for EX Series Switches \(CLI Procedure\)](#)
 - [“Configuring VLANs” on page 1534](#) for the QFX Series
- Configured the **corporate** VLAN for the DHCP server.
- Configured the switch as a BOOTP relay agent. See *DHCP/BOOTP Relay for Switches Overview*.
- Configured the routed VLAN interface (RVI) to allow the switch to relay packets to the server and receive packets from the server. See *Configuring Routed VLAN Interfaces (CLI Procedure)* or [“Configuring Routed VLAN Interfaces” on page 1532](#) for the QFX Series.

Overview and Topology

If DHCP option 82 is enabled on the switch, then when a network device—a DHCP client—that is connected to the switch on an untrusted interface sends a DHCP request, the switch inserts information about the client's network location into the packet header of that request. The switch then sends the request (in this setting, it relays the request) to the DHCP server. The DHCP server reads the option 82 information in the packet header and uses it to implement the IP address or other parameter for the client.

When option 82 is enabled on the switch, then this sequence of events occurs when a DHCP client sends a DHCP request:

1. The switch receives the request and inserts the option 82 information in the packet header.
2. The switch relays the request to the DHCP server.
3. The server uses the DHCP option 82 information to formulate its reply and sends a response back to the switch. It does not alter the option 82 information.
4. The switch strips the option 82 information from the response packet.
5. The switch forwards the response packet to the client.

In this example, you configure option 82 on the switch. The switch is configured as a BOOTP relay agent. The switch connects to the DHCP server through the routed VLAN interface (RVI) that you configured. The switch and clients are members of the **employee** VLAN. The DHCP server is a member of the **corporate** VLAN.

Configuration

To configure DHCP option 82:

CLI Quick Configuration

To quickly configure DHCP option 82, copy the following commands and paste them into the switch terminal window:

```
set forwarding-options helpers bootp dhcp-option82
set forwarding-options helpers bootp dhcp-option82 circuit-id prefix hostname
set forwarding-options helpers bootp dhcp-option82 circuit-id use-vlan-id
set forwarding-options helpers bootp dhcp-option82 remote-id
set forwarding-options helpers bootp dhcp-option82 remote-id prefix mac
set forwarding-options helpers bootp dhcp-option82 remote-id use-string employee-switch1
set forwarding-options helpers bootp dhcp-option82 vendor-id
```

Step-by-Step Procedure

To configure DHCP option 82:

1. Specify DHCP option 82 for the **employee** VLAN:

```
[edit forwarding-options helpers bootp]
user@switch# set dhcp-option82
```
2. Configure a prefix for the circuit ID suboption (the prefix is always the hostname of the switch):

```
[edit forwarding-options helpers bootp]
user@switch# set dhcp-option82 circuit-id prefix hostname
```
3. Specify that the circuit ID suboption value contains the VLAN ID rather than the VLAN name (the default):

- ```
[edit forwarding-options helpers bootp]
user@switch# set dhcp-option82 circuit-id use-vlan-id
```
4. Specify that the remote ID suboption be included in the DHCP option 82 information:
 

```
[edit forwarding-options helpers bootp]
user@switch# set dhcp-option82 remote-id
```
  5. Configure a prefix for the remote ID suboption (here, the prefix is the MAC address of the switch):
 

```
[edit forwarding-options helpers bootp]
user@switch# set dhcp-option82 remote-id prefix mac
```
  6. Specify that the remote ID suboption value contains a character string (here, the string is **employee-switch1**):
 

```
[edit forwarding-options helpers bootp]
user@switch# set dhcp-option82 remote-id use-string employee-switch1
```
  7. Configure a vendor ID suboption value, and use the default value. To use the default value, do not type a character string after the **vendor-id** option keyword:
 

```
[edit forwarding-options helpers bootp]
user@switch# set dhcp-option82 vendor-id
```

**Results** Check the results of the configuration:

```
[edit forwarding-options helpers bootp]
user@switch# show
dhcp-option82 {
 circuit-id {
 prefix hostname;
 use-vlan-id;
 }
 remote-id {
 prefix mac;
 use-string employee-switch1;
 }
 vendor-id;
}
```

## Device Security Configuration Example (Original CLI Only)

- [Example: Configuring Storm Control to Prevent Network Outages on page 4527](#)

### Example: Configuring Storm Control to Prevent Network Outages

Using storm control can prevent problems caused by broadcast storms. You can configure storm control to rate-limit broadcast traffic and unknown unicast traffic at a specified

level and to drop packets when the specified traffic level is exceeded, which prevents packets from proliferating and degrading service or causing a security issue. You can also configure the switch to shut down or temporarily disable an interface when the storm control limit is exceeded.

This example shows how to configure storm control:

**NOTE:** This example uses a Junos OS release that does not support the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that supports ELS, see [“Example: Configuring Storm Control to Prevent Network Outages” on page 4529](#).

- [Requirements on page 4528](#)
- [Overview and Topology on page 4528](#)
- [Configuration on page 4529](#)

---

### Requirements

This example uses the following hardware and software components:

- A switch
- Junos OS Release 11.1 or later

---

### Overview and Topology

A traffic storm occurs when broadcast packets prompt receiving devices to broadcast packets in response. This prompts further responses, creating a snowball effect. The switch is flooded with packets, and the resulting unnecessary traffic leads to poor performance or even a complete loss of service by some clients. Storm control causes a device to monitor traffic levels and take a specified action when a specified traffic level—called the *storm control level*—is exceeded, thus preventing packets from proliferating and degrading service.

Storm control monitors the incoming broadcast traffic and unknown unicast traffic and compares it with the level that you specify. If broadcast traffic and unknown unicast traffic exceed the specified level, the switch drops packets for the controlled traffic types. Storm control is enabled by default on all interfaces, and the default level is 80 percent of the available bandwidth.

This example shows how to configure the storm control level on interface **xe-0/0/0** by setting the level to a traffic rate of 5000000 Kbps, based on the total of the combined broadcast and unknown unicast streams. If broadcast traffic and unknown unicast traffic exceed these levels, the switch drops packets for the controlled traffic types.

## Configuration

<b>Step-by-Step Procedure</b>	<p>To configure storm control for a 10-Gigabit Ethernet interface to the equivalent of 50 percent of the available bandwidth:</p> <ul style="list-style-type: none"> <li>Specify the level of allowed broadcast traffic and unknown unicast traffic on a specific interface:</li> </ul> <pre>[edit ethernet-switching-options] user@switch# set storm-control interface xe-0/0/0 bandwidth 5000000</pre>
<b>Results</b>	<p>Display the results of the configuration:</p> <pre>[edit ethernet-switching-options] user@switch# show storm-control interface xe-0/0/0 {     bandwidth 5000000; }</pre>
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li><a href="#">Understanding Storm Control on page 4471</a></li> <li><a href="#">Configuring Autorecovery for MAC Limited or Storm Control Interfaces (CLI Procedure) on page 4549</a></li> <li><a href="#">action-shutdown on page 4650</a></li> <li><a href="#">interface (Storm Control) on page 4666</a></li> <li><a href="#">port-error-disable on page 4600</a></li> </ul>

## Device Security Configuration Example (ELS CLI Only)

- [Example: Configuring Storm Control to Prevent Network Outages on page 4529](#)

### Example: Configuring Storm Control to Prevent Network Outages

Storm control enables you to prevent network outages caused by broadcast storms on the LAN. You can configure storm control on to rate-limit broadcast traffic, multicast traffic, and unknown unicast traffic at a specified level and to have packets dropped when the specified traffic level is exceeded, thereby preventing packets from proliferating and degrading the LAN.

**NOTE:** This example uses a Junos OS release that supports the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that does not support ELS, see [“Example: Configuring Storm Control to Prevent Network Outages” on page 4527](#).

- [Requirements on page 4530](#)
- [Overview and Topology on page 4530](#)
- [Configuration on page 4530](#)

## Requirements

---

This example uses the following hardware and software components:

- One QFX Series switch running Junos OS with ELS
- Junos OS Release 13.2 or later

## Overview and Topology

---

A storm is generated when messages are broadcast on a network and each message prompts a receiving node to respond by broadcasting its own messages on the network. This, in turn, prompts further responses, creating a snowball effect and resulting in a broadcast storm that can cause network outages.

You can use storm control to prevent broadcast storms by specifying the amount, also known as the *storm control level*, of broadcast traffic, multicast traffic, and unknown unicast traffic to be allowed on an interface. You specify the storm control level as the traffic rate in kilobits per second (Kbps) of the combined applicable traffic streams or as the percentage of available bandwidth used by the combined applicable traffic streams. By default, storm control is enabled on all interfaces at a level of 80 percent of the available bandwidth.

Storm control monitors the level of applicable incoming traffic and compares it with the level that you specify. If the combined level of the applicable traffic exceeds the specified level, the switch drops packets for the controlled traffic types. As an alternative to having the switch drop packets, you can configure storm control to shut down interfaces or temporarily disable interfaces (see the **action-shutdown** statement or the **recovery-timeout** statement) when the storm control level is exceeded.

The topology used in this example consists of one switch connected to various network devices. This example shows how to configure the storm control level on interface xe-0/0/0 by setting the level to a traffic rate of 15,000 Kbps, based on the traffic rate of the combined applicable traffic streams. If the combined traffic exceeds this level, the switch drops packets for the controlled traffic types to prevent a network outage.

## Configuration

---

### CLI Quick Configuration

To quickly configure storm control based on the traffic rate in kilobits per second of the combined traffic streams, copy the following command and paste it into the switch terminal window:

```
[edit]
set forwarding-options storm-control-profiles sc-profile all bandwidth-level 15000
set interfaces xe-0/0/0 unit 0 family ethernet-switching storm-control sc-profile
```

### Step-by-Step Procedure

To configure storm control:

1. Configure a storm control profile, **sc-profile**, and specify the traffic rate in kilobits per second of the combined traffic streams:

```
[edit]
user@switch> set forwarding-options storm-control-profiles sc-profile all bandwidth-level 15000
```

2. Bind the storm control profile, **sc**, to a logical interface:

```
[edit]
user@switch> set interfaces xe-0/0/0 unit 0 family ethernet-switching storm-control
sc-profile
```

**Results** Display the results of the configuration:

```
[edit forwarding-options]
user@switch> show storm-control-profiles sc-profile
all {
 bandwidth 15000;
}

[edit]
user@switch> show interfaces xe-0/0/0
unit 0 {
 family ethernet-switching {
 vlan {
 members default;
 }
 storm-control sc-profile;
 }
}
```

- [Configuring MPLS Firewall Filters and Policers on page 4540](#)

### Configuring Firewall Filters

You can configure firewall filters in a switch to control traffic that enters switch ports or enters and exits VLANs and Layer 3 (routed) interfaces. To use a firewall filter, you must configure the filter and then apply it to a port, VLAN, or Layer 3 interface.

- [Configuring a Firewall Filter on page 4532](#)
- [Applying a Firewall Filter to a Port on page 4533](#)
- [Applying a Firewall Filter to a VLAN on page 4534](#)
- [Applying a Firewall Filter to a Layer 3 \(Routed\) Interface on page 4534](#)

## Configuring a Firewall Filter

---

To configure a firewall filter:

1. Configure the family address type, filter name, term name, and at least one match condition—for example, match on packets that contain a specific source address:

```
[edit]
user@switch# set firewall family ethernet-switching filter ingress-port-filter term term-one
from source-address 192.0.2.14
```

For a firewall filter that is applied to a port or VLAN, specify the family address type **ethernet-switching**. For a firewall filter that is applied to a Layer 3 (routed) interface, specify the family address type **inet**.

The filter and term names can contain letters, numbers, and hyphens (-) and can be up to 64 characters long. Each filter name must be unique. A filter can contain one or more terms, and each term name must be unique within a filter.

2. Configure additional match conditions. For example, match on packets that contain a specific source port:

```
[edit firewall family ethernet-switching filter ingress-port-filter term
term-one from]
user@switch# set source-port 80
```

You can specify one or more match conditions in a single **from** statement. For a match to occur, the packet must match all the conditions in the term. The **from** statement is optional, but if included in a term, it cannot be empty. If you omit the **from** statement, all packets are considered to match.

3. If you want to apply a firewall filter to multiple interfaces and be able to see counters specific to each interface, configure the **interface-specific** option:

```
[edit firewall family ethernet-switching filter ingress-port-filter]
user@switch# set interface-specific
```

4. In each firewall filter term, specify the actions to take if the packet matches all the conditions in that term. You can specify an action and action modifiers:

- To specify a filter action, for example, to discard packets that match the conditions of the filter term:

```
[edit firewall family ethernet-switching filter ingress-port-filter term
term-one then]
user@switch# set discard
```

You can specify no more than one action (**accept**, **discard**, **reject**, **routing-instance**, or **vlan**) per term.

- To specify action modifiers, for example, to count and classify packets to a forwarding class:

```
[edit firewall family ethernet-switching filter ingress-port-filter term
term-one then]
user@switch# set count counter-one
user@switch# set forwarding-class expedited-forwarding
user@switch# set loss-priority high
```

You can specify any of the following action modifiers in a **then** statement:

- **analyzer** *analyzer-name*—Mirror port traffic to a specified analyzer, which you must configure at the **[ethernet-switching-options]** level.
- **count** *counter-name*—Count the number of packets that pass this filter term.

**NOTE:** We recommend that you configure a counter for each term in a firewall filter, so that you can monitor the number of packets that match the conditions specified in each filter term.

**NOTE:** On the QFX Series, filters automatically count packets that have been dropped on ingress because of cyclic redundancy check (CRC) errors.

- **forwarding-class** *class*—Assign packets to a forwarding class.
- **log**—Log the packet header information in the Routing Engine.
- **loss-priority** *priority*—Set the priority of dropping a packet.
- **policer** *policer-name*—Apply rate-limiting to the traffic.
- **syslog**—Log an alert for this packet.

If you omit the **then** statement or do not specify an action, packets that match all the conditions in the **from** statement are accepted. However, you should always explicitly configure an action in the **then** statement. You can include no more than one action statement, but you can use any combination of action modifiers. For an action or action modifier to take effect, all conditions in the **from** statement must match.

**NOTE:** Implicit discard is also applicable to a firewall filter applied to the loopback interface, lo0.

### Applying a Firewall Filter to a Port

To apply a firewall filter to an ingress port:

1. Provide a meaningful description of the firewall filter in the configuration of the port to which the filter will be applied:

[edit]

```
user@switch# set interfaces ge-0/0/6 description "filter to limit tcp traffic at trunk port for employee-vlan"
```

2. Apply the filter to the interface, specifying the unit number, family address type, the direction of the filter (for packets entering the port), and the filter name:

[edit]

```
user@switch# set ge-0/0/6 unit 0 family ethernet-switching filter input ingress-port-filter
```

For firewall filters that are applied to ports, the family address type must be **ethernet-switching**.

**NOTE:** You can apply only one filter to a port for a given direction (ingress or egress).

---

### Applying a Firewall Filter to a VLAN

---

To apply a firewall filter to a VLAN:

1. Provide a meaningful description of the firewall filter in the configuration of the VLAN to which the filter will be applied:

```
[edit]
user@switch# set vlans employee-vlan vlan-id 20 description "filter to block rogue devices
on employee-vlan"
```

2. Apply firewall filters to filter packets that are entering or exiting the VLAN:

- To apply a filter to match packets that are entering the VLAN:

```
[edit]
user@switch# set vlans employee-vlan vlan-id 20 filter input ingress-vlan-rogue-block
```

- To apply a firewall filter to match packets that are exiting the VLAN:

```
[edit]
user@switch# set vlans employee-vlan vlan-id 20 filter output egress-vlan-filter
```

**NOTE:** You can apply only one filter to a VLAN for a given direction (ingress or egress).

---

### Applying a Firewall Filter to a Layer 3 (Routed) Interface

---

To apply a firewall filter to a Layer 3 routed interface:

1. Provide a meaningful description of the firewall filter in the configuration of the interface to which the filter will be applied:

```
[edit]
user@switch# set interfaces ge-0/1/6 description "filter to count and monitor traffic on layer
3 interface"
```

2. You can apply firewall filters to filter packets that enter or exit a Layer 3 routed interface:

- To apply a firewall filter to filter packets that enter a Layer 3 interface:

```
[edit]
user@switch# set interfaces ge-0/1/6 unit 0 family inet filter input ingress-router-filter
```

- To apply a firewall filter to filter packets that exit a Layer 3 interface:

```
[edit]
user@switch# set interfaces ge-0/1/6 unit 0 family inet filter output egress-router-filter
```

For firewall filters applied to Layer 3 routed interfaces, the family address type must be **inet**.

**NOTE:** You can apply only one filter to an interface for a given direction (ingress or egress).

## Applying Firewall Filters to Interfaces

For a firewall filter to work, you must apply it to at least one interface. To do this, include the **filter** statement when configuring a logical interface at the **[edit interfaces]** hierarchy level:

```
[edit interfaces]
user@switch# set interface-name unit logical-unit-number family family-name filter (input |
output) filter-name
```

In the **input** statement, specify a firewall filter to be evaluated when packets are received on the interface. Input filters applied to a loopback interface affect only traffic destined for the Routing Engine.

In the **output** statement, specify a filter to be evaluated when packets exit the interface.

**NOTE:** When you create a loopback interface, it is important to apply an ingress filter to it so the Routing Engine is protected. We recommend that when you apply a filter to the loopback interface **lo0**, you include the **apply-groups** statement. Doing so ensures that the filter is automatically inherited on every loopback interface, including **lo0** and other loopback interfaces.

#### Related Documentation

- [Configuring Firewall Filters on page 4531](#)

## Assigning Forwarding Classes and Loss Priority

You can configure firewall filters to assign packet loss priority (PLP) and forwarding classes so that if congestion occurs, the marked packets can be dropped according to the priority you set. The valid match conditions are one or more of the six packet header fields: destination address, source address, IP protocol, source port, destination port, and DSCP. In other words, you can set the forwarding class and the PLP for each packet entering or an interface with a specific destination address, source address, IP protocol, source port, destination port, or DSCP.

**NOTE:** Junos OS assigns forwarding classes and PLP on ingress only. Do not use a filter that assigns forwarding classes or PLP as an egress filter.

When tricolor marking is enabled, a switch supports four PLP designations: **low**, **medium-low**, **medium-high**, and **high**. You can also specify any of the forwarding classes listed in [Table 359 on page 4536](#)

**Table 359: Unicast Forwarding Classes**

Unicast Forwarding Class	For CoS Traffic Type
be	Best-effort traffic
no-loss	Guaranteed delivery for TCP traffic
fcoe	Guaranteed delivery for Fibre Channel over Ethernet (FCoE) traffic
nc	Network-control traffic

To assign forwarding classes in firewall filters:

1. Configure the family address type and filter name:
 

```
[edit]
user@switch# edit firewall family ethernet-switching filter ingress-filter
```
2. Configure the terms of the filter as appropriate, including the **forwarding-class** and **loss-priority** action modifiers. For example, each of the following terms in the filter examines various packet header fields and assigns the appropriate forwarding class and packet loss priority:
  - The term **corp-traffic** matches all IPv4 packets with a **10.1.1.0/24** source address and assigns the packets to forwarding class **no-loss** with a loss priority of **low**:
 

```
[edit firewall family ethernet-switching filter ingress-filter]
user@switch# set term corp-traffic from source-address 10.1.1.0/24;
user@switch# set term corp-traffic then forwarding-class no-loss
user@switch# set term corp-traffic then loss-priority low
```
  - The term **data-traffic** matches all IPv4 packets with a **10.1.2.0/24** source address and assigns the packets to forwarding class **be** (best effort) with a loss priority of **medium-high**:

```
[edit firewall family ethernet-switching filter ingress-filter]
user@switch# set term data-traffic from source-address 10.1.2.0/24;
user@switch# set term data-traffic then forwarding-class be
user@switch# set term data-traffic then loss-priority medium-high
```

- Because the loss of network-generated packets can jeopardize proper network operation, the delay of these packets is preferable to discarding these packets. The term **network-traffic** assigns the packets with an IP precedence of **net-control** to forwarding class **nc** (network control) with a loss priority of **low**:

```
[edit firewall family ethernet-switching filter ingress-filter]
user@switch# set term network-traffic from precedence net-control
user@switch# set term network-traffic then forwarding-class nc
user@switch# set term network-traffic then loss-priority low
```

- The last term **accept-traffic** matches any packets that did not match on any of the preceding terms and assigns the packets to forwarding class **be** with a loss priority of **high**:

```
[edit firewall family ethernet-switching filter ingress-filter]
user@switch# set term accept-traffic then forwarding-class be
user@switch# set term accept-traffic then loss-priority high
```

3. Apply the filter **ingress-filter** to a port, VLAN, or Layer 3 interface. For information about applying the filter, see [“Configuring Firewall Filters” on page 4531](#). (Assigning forwarding classes and PLP is supported only on ingress filters.)

## Configuring Color-Blind Egress Policers for Medium-Low PLP

If you use color-blind mode and want to configure an egress policer that marks packets to have medium-low PLP, you must configure a single-rate two-color policer at the **[edit firewall policer *policer-name*]** hierarchy level, because color-blind mode does not support medium-low priority. For example:

1. Specify the name of the policer, the bandwidth limit in bits per second (bps) to control the traffic rate on an interface, and the maximum allowed burst size to control the amount of traffic bursting:

```
[edit]
user@switch# set firewall policer policer-name if-exceeding bandwidth-limit bytes
burst-size-limit bytes
```

2. Specify medium-low loss priority for matching packets:

```
[edit]
user@switch# set firewall policer policer-name then loss-priority medium-low;
```

3. Apply the filter to a port, VLAN, or Layer 3 interface.

## Configuring Two-Color and Three-Color Policers to Control Traffic Rates

You can rate-limit traffic by configuring a policer and specifying it as an action modifier for a term in a firewall filter. By default, if you specify the same policer in multiple terms, Junos OS creates a separate policer instance for each term and applies rate limiting separately for each instance. For example, if you configure a policer to discard traffic that exceeds 1 Gbps and reference that policer in three different terms, each policer instance enforces a 1-Gbps limit. In this case, the total bandwidth allowed by the filter is 3 Gbps.

You can also configure a policer to be filter-specific, which means that Junos OS creates only one policer instance regardless of how many times the policer is referenced. When you do this, rate limiting is applied in aggregate, so if you configure a policer to discard traffic that exceeds 1 Gbps and reference that policer in three different terms, the total bandwidth allowed by the filter is 1 Gbps.

**NOTE:** You can include two-color policer actions on ingress firewall filters only. You can include three-color policer actions on ingress and egress filters.

1. [Configuring Two-Color Policers on page 4538](#)
2. [Configuring Three-Color Policers on page 4539](#)
3. [Specifying Policers in a Firewall Filter Configuration on page 4539](#)
4. [Applying a Firewall Filter That Includes a Policer on page 4540](#)

### Configuring Two-Color Policers

---

To configure a two-color policer:

1. Specify the name of the policer, the bandwidth limit to control the traffic rate on an interface, and the maximum allowed burst size to control the amount of traffic bursting:

```
[edit firewall]
user@switch# set policer policer-name <filter-specific> if-exceeding bandwidth-limit bps
burst-size-limit bytes
```

The policer name can contain letters, numbers, and hyphens (-) and can have as many as 64 characters.

The range for the bandwidth limit is 32000 (32k) through 102,300,000,000 (102300m) bps.

To determine the value for the burst-size limit, multiply the bandwidth of the interface on which the filter is applied by the amount of time to allow a burst of traffic at that bandwidth to occur and divide the result by 8:

**maximum burst size = (interface bandwidth) X (allowable time for burst) / (8 bits/byte)**

The range for the burst-size limit is 1 through 2,147,450,880 bytes.

- Specify the policer action to discard or assign a loss priority to packets that exceed the rate limits:

```
[edit firewall policer policer-name]
user@switch# set then (discard | loss-priority low | loss-priority high)
```

### Configuring Three-Color Policers

To configure a three-color policer:

- Specify the name of the policer and (optionally) whether to automatically discard packets with high loss priority (PLP):

```
[edit firewall]
user@switch# set three-color-policer policer-name
user@switch# set three-color-policer policer-name action loss-priority high then discard
```

- Specify whether the three-color policer should be single-rate or two-rate and whether it should be color-aware or color-blind:

```
[edit firewall three-color-policer policer-name]
user@switch# set (single-rate | two-rate) (color-aware | color-blind)
```

- For single-rate three-color policers, configure the CIR, CBS, and EBS:

```
[edit firewall three-color-policer policer-name single-rate]
user@switch# set committed-information-rate bps
user@switch# set committed-burst-size bytes
user@switch# set excess-burst-size bytes
```

- For two-rate three-color policers, configure the CIR, CBS, PIR, and PBS:

```
[edit firewall three-color-policer policer-name single-rate]
user@switch# set committed-information-rate bps
user@switch# set committed-burst-size bytes
user@switch# set peak-information-rate bps
user@switch# set peak-burst-size bytes
```

### Specifying Policers in a Firewall Filter Configuration

To use a two-color policer, configure a filter term that includes the action **policer**:

```
[edit firewall family family-name]
user@switch# set filter filter-name term name then name
```

For example, the following commands apply a two-color policer to all packets sent from 192.0.2.0/24.

```
[edit firewall family family-name]
user@switch# set filter limit—hosts term term1 from source-address 192.0.2.0/24
user@switch# set filter limit—hosts term term1 then policer policer1
```

To use a three-color policer, configure a filter term that includes the action **three-color-policer**:

```
[edit firewall family name]
user@switch# set filter name term name from match-condition
```

```
user@switch# set filter name term name then three-color-policer (single-rate | two-rate) name
```

For example, the following commands apply a single-rate three-color policer to all packets received or sent by interface **ge-0/0/6** (depending on whether the filter is an ingress or egress filter).

```
[edit firewall family name]
```

```
user@switch# set filter srTCM term term-one from interface ge-0/0/6
```

```
user@switch# set filter srTCM term term-one then three-color-policer single-rate srTCM1-ca
```

You must specify whether the three-color policer is single-rate or two-rate, and this must match the policer itself. Otherwise, the configuration listing includes an error message indicating that the three-color policer you referenced in the filter does not exist.

---

### Applying a Firewall Filter That Includes a Policer

A firewall filter that includes one or more policer action modifiers must be applied to a port, VLAN, or Layer 3 interface like any other filter. For information about applying firewall filters, see “Configuring Firewall Filters” on page 4531.

**NOTE:** You can include two-color policer actions on ingress firewall filters only. You can include three-color policer actions on ingress and egress filters.

## Configuring MPLS Firewall Filters and Policers

You can configure an MPLS firewall filter to count packets based on the EXP bits for the top-level MPLS label in a packet. You can also configure policers for MPLS LSPs.

The following sections discuss MPLS firewall filters and policers:

- [Configuring MPLS Firewall Filters on page 4540](#)
- [Examples: Configuring MPLS Firewall Filters on page 4541](#)
- [Configuring Policers for LSPs on page 4542](#)

---

### Configuring MPLS Firewall Filters

You can configure an MPLS firewall filter to count packets based on the EXP bits for the top-level MPLS label in a packet. You can then apply this filter to a specific interface on input or output. You can also configure a policer for the MPLS filter to police (that is, rate-limit) the traffic on the interface to which the filter is attached. You cannot apply MPLS firewall filters to loopback interfaces.

You can configure the following match conditions for MPLS filters at the **[edit firewall family mpls filter filter-name term term-name from]** hierarchy level:

- **exp**
- **label**

These **exp** match condition can accept EXP bits in the range 0 through 7. You can configure the following choices:

- A single EXP bit—for example, **exp 3**;
- Several EXP bits—for example, **exp 0, 4**;
- A range of EXP bits—for example, **exp [0-5]**;

The **label** match condition can accept a range of values from 0 to 1048575.

If you do not specify a match criterion (that is, you do not configure the **from** statement and use only the **then** statement with the **count** action keyword), all the MPLS packets passing through the interface on which the filter is applied will be counted.

You also can configure any of the following action keywords at the **[edit firewall family mpls filter *filter-name* term *term-name* then]** hierarchy level:

- **accept**
- **count**
- **discard**
- **policer**
- **three-color-policer**

### Examples: Configuring MPLS Firewall Filters

The following examples illustrate how you might configure an MPLS firewall filter and then apply the filter to an interface. This filter is configured to count MPLS packets with EXP bits set to either 0 or 4.

The following shows a configuration for an MPLS firewall filter:

```
[edit firewall]
family mpls {
 filter expf {
 term expt0 {
 from {
 exp 0,4;
 }
 then {
 count counter0;
 accept;
 }
 }
 }
}
```

## Configuring Policers for LSPs

---

MPLS LSP policing allows you to control the amount of traffic forwarded through a particular LSP. Policing helps to ensure that the amount of traffic forwarded through an LSP never exceeds the requested bandwidth allocation. LSP policing is supported on regular LSPs, LSPs configured with DiffServ-aware traffic engineering, and multiclass LSPs. You can configure multiple policers for each multiclass LSP. For regular LSPs, each LSP policer is applied to all of the traffic traversing the LSP. The policer's bandwidth limitations become effective as soon as the total sum of traffic traversing the LSP exceeds the configured limit.

You configure the multiclass LSP and DiffServ-aware traffic engineering LSP policers in a filter. The filter can be configured to distinguish between the different class types and apply the relevant policer to each class type. The policers distinguish between class types based on the EXP bits.

You configure LSP policers under the **family any** filter. The **family any** filter is used because the policer is applied to traffic entering the LSP. This traffic might be from different families: IPv6, MPLS, and so on. You do not need to know what sort of traffic is entering the LSP, as long as the match conditions apply to all types of traffic.

### *LSP Policer Limitations*

When configuring MPLS LSP policers, be aware of the following limitations:

- LSP policers are supported for packet LSPs only.
- LSP policers are supported for unicast next hops only. Multicast next hops are not supported.
- LSP policers are not supported on aggregated interfaces.
- The LSP policer runs before any output filters.
- Traffic sourced from the Routing Engine (for example, ping traffic) does not take the same forwarding path as transit traffic. This type of traffic cannot be policed.

## Configuring Port Security (CLI Procedure)

Ethernet LANs are vulnerable to attacks such as address spoofing and Layer 2 denial of service (DoS) on network devices. Port security features such as DHCP snooping, DAI (dynamic ARP inspection), MAC limiting, MAC move limiting, and persistent MAC learning, as well as trusted DHCP server, help protect the access ports on the switch against the losses of information and productivity that can result from such attacks.

Depending on the particular feature, you can configure the port security feature either on:

- VLANs—A specific VLAN or all VLANs
- Interfaces—A specific interface or all interfaces

**NOTE:** If you configure one of the port security features on all VLANs or all interfaces, the switch software enables that port security feature on all VLANs and all interfaces that are not explicitly configured with other port security features.

However, if you do explicitly configure one of the port security features on a specific VLAN or on a specific interface, you must explicitly configure any additional port security features that you want to apply to that VLAN or interface. Otherwise, the switch software automatically applies the default values for the feature.

For example, if you disable DHCP snooping on all VLANs and decide to explicitly enable IP source guard only on a specific VLAN, you must also explicitly enable DHCP snooping on that specific VLAN. Otherwise, the default value of no DHCP snooping applies to that VLAN.

To configure port security features using the CLI:

- [Enabling DHCP Snooping on page 4544](#)
- [Enabling Dynamic ARP Inspection \(DAI\) on page 4544](#)
- [Limiting Dynamic MAC Addresses on an Interface on page 4544](#)

- [Enabling Persistent MAC Learning on an Interface on page 4545](#)
- [Limiting MAC Address Movement on page 4545](#)
- [Configuring Trusted DHCP Servers on an Interface on page 4545](#)

---

### Enabling DHCP Snooping

You can configure DHCP snooping to allow the device to monitor DHCP messages received, ensure that hosts only use the IP addresses assigned to them, and allow access only to authorized DHCP servers.

To enable DHCP snooping:

- On a specific VLAN:

```
[edit vlans forwarding-options dhcp-security]
user@switch# set vlan default examine-dhcp
```

- On all VLANs:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan all examine-dhcp
```

---

### Enabling Dynamic ARP Inspection (DAI)

You can enable DAI to protect against ARP snooping. To enable DAI:

- On a single VLAN (here, the VLAN is **employee-vlan**):

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee-vlan arp-inspection
```

- On all VLANs:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan all arp-inspection
```

---

### Limiting Dynamic MAC Addresses on an Interface

Limit the number of dynamic MAC addresses allowed on an interface and specify the action to take if the limit is exceeded—for example, set a MAC limit of **5** with an action of **drop**:

- On a single interface:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface ge-0/0/1 mac-limit 5 action drop
```

- On all interfaces:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface all mac-limit 5 action drop
```

You can also specify the actions **log** (do not drop the packet but generate an alarm, an SNMP trap, or a system log entry), **none** (no action), or **shutdown** (disable the interface and generate an alarm) to occur if the number of dynamic MAC addresses is exceeded.

### Enabling Persistent MAC Learning on an Interface

You can configure learned MAC addresses to persist on an interface across restarts of the switch:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface ge-0/0/1 persistent-learning
```

### Limiting MAC Address Movement

You can limit the number of times a MAC address can move from its original interface in 1 second—for example, set a MAC move limit of **5** with an action of **drop** if the limit is exceeded:

- On a single VLAN (here, the VLAN is **employee-vlan**):

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee-vlan mac-move-limit 5 action drop
```

- On all VLANs:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan all mac-move-limit 5 action drop
```

You can also specify the actions **log** (do not drop the packet but generate an alarm, an SNMP trap, or a system log entry), **none** (no action), or **shutdown** (disable the interface or VLAN and generate an alarm) to occur if the MAC address moves more than the specified number of times in 1 second.

### Configuring Trusted DHCP Servers on an Interface

Configure a trusted DHCP server on an interface:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface ge-0/0/1 dhcp-trusted
```

## Configuring MAC Limiting

To configure MAC limiting on a specific interface or on all interfaces:

1. To limit the number of dynamic MAC addresses, set a MAC limit of 5.

The action is not specified, so the switch performs the default action **drop** if the limit is exceeded:

- On a single interface (here, the interface is **xe-0/0/1**):

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface xe-0/0/1 mac-limit (Access Port Security) 5
```

- On all interfaces:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface all mac-limit 5
```

**CAUTION:** Do not set the MAC limit to 1. The first learned MAC address is often inserted into the forwarding database automatically. (For instance, the first MAC address inserted into the forwarding database for routed VLAN interfaces is the MAC address of the RVI. For Aggregated Ethernet bundles using LACP, the first MAC address inserted into the forwarding database in the forwarding table is the source address of the protocol packet.) The switch therefore fails to learn MAC addresses other than the automatic addresses when the MAC limit is set to 1, and this causes problems with MAC learning and forwarding.

2. To specify allowed MAC addresses:

- On a single interface (here, the interface is **xe-0/0/2**):

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface xe-0/0/2 allowed-mac 00:05:85:3A:82:80
user@switch# set interface xe-0/0/2 allowed-mac 00:05:85:3A:82:81
user@switch# set interface xe-0/0/2 allowed-mac 00:05:85:3A:82:83
```

- On all interfaces:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface all allowed-mac 00:05:85:3A:82:80
user@switch# set interface all allowed-mac 00:05:85:3A:82:81
user@switch# set interface all allowed-mac 00:05:85:3A:82:83
```

## Configuring MAC Move Limiting (CLI Procedure)

When MAC move limiting is configured, MAC address movements are tracked by the switch and, if a MAC address changes more than the configured number of times within 1 second, the changes to MAC addresses are dropped, logged, ignored, or the interface is shut down.

**NOTE:** Although you enable this feature on VLANs, the MAC move limitation pertains to the number of movements for each individual MAC address rather than the total number of MAC address moves in the VLAN. For example, if the MAC move limit is set to 1, the switch allows an unlimited number of MAC address movements within the VLAN as long as the same MAC address does not change more than once.

You configure MAC move limiting per VLAN, not per interface (port). In the default configuration, the number of MAC moves permitted is unlimited.

You can choose to have one of the following actions performed when the MAC move limit is exceeded:

- **drop**—Drop the packet and generate a system log entry. This is the default.
- **log**—Do not drop the packet but generate a system log entry.
- **none**—Take no action.
- **shutdown**—Disable the interfaces in the VLAN and generate a system log entry. If you have configured the switch with the **port-error-disable** statement, the disabled interfaces recover automatically upon expiration of the specified disable timeout. If you have not configured the switch for autorecovery from port error disabled conditions, you can bring up the disabled interfaces by running the **clear ethernet-switching port-error** command.

To configure a MAC move limit for MAC addresses within a specific VLAN or for MAC addresses within all VLANs, using the CLI:

- On a single VLAN: To limit the number of MAC address movements that can be made by an individual MAC address within the VLAN **employee-vlan**, set a MAC move limit of 5:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee-vlan mac-move-limit 5
```

The action is not specified, so the switch performs the default action **drop** if it tracks that an individual MAC address within the **employee-vlan** has moved more than 5 times within one second.

- On all VLANs: To limit the number of MAC movements that can be made by individual MAC addresses within all VLANs, set a MAC move limit of 5:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan all mac-move-limit 5
```

The action is not specified, so the switch performs the default action **drop** if it tracks that an individual MAC address within any of the VLANs has moved more than 5 times within 1 second.

## Configuring Autorecovery for MAC Limited or Storm Control Interfaces (CLI Procedure)

An Ethernet access interface might shut down or be disabled as a result of one of the following configurations:

- MAC limiting—**mac-limit** statement is configured with action **shutdown**.
- MAC move limiting—**mac-move-limit** statement is configured with action **shutdown**.
- Storm control—**storm-control** statement is configured with the action **shutdown**.

You can configure a device to automatically restore the disabled interfaces to service after a specified period of time. Autorecovery applies to all the interfaces that have been disabled due to MAC limiting, MAC move limiting, or storm control errors.

To configure autorecovery from the disabled state due to MAC limiting, MAC move limiting, or storm control shutdown actions:

```
[edit ethernet-switching-options]
user@switch# set port-error-disable disable-timeout seconds
```

**NOTE:** You must specify the disable timeout value—there is no default disable timeout period. If you do not specify a timeout value, you must use the [clear ethernet-switching port-error](#) command to clear the errors and restore the interfaces to service.

## Configuring the none Action to Override a MAC Limit Applied to All Interfaces (CLI Procedure)

If you set a MAC limit in your port security settings to apply to all interfaces, you can override that setting for a particular interface by specifying the action **none**.

To use the **none** action to override a MAC limit setting:

1. Set the MAC limit for all interfaces—for example, a limit of **5** with action **drop**:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface all mac-limit (Access Port Security) 5 action drop
```

2. Change the action for one interface with this command.

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface xe-0/0/2 mac-limit action none
```

## Configuring Static ARP Entries

You can create static ARP table entries, which are explicit mappings between IP addresses and MAC addresses.

- To configure a static ARP entry:

```
[edit interfaces interface-name unit logical-unit-number family inet address address]
user@switch# set arp ip-address (mac | multicast-mac) mac-address
```

The IP address that you specify must be part of the subnet defined in the enclosing **address** statement.

To associate a multicast MAC address with a unicast IP address, use the **multicast-mac** statement.

Specify the MAC address as 6 hexadecimal bytes in one of the following formats: *nnnn.nnnn.nnnn* or *nn:nn:nn:nn:nn:nn*; for example, 0011.2233.4455 or 00:11:22:33:44:55.

### Related Documentation

- [Understanding Static ARP Entries on page 4470](#)
- *arp*

## Configuring Static IP Addresses for DHCP Bindings on Access Ports (CLI Procedure)

You can add static (fixed) IP addresses and bind them to fixed MAC addresses in the DHCP snooping database. These bindings are labeled as “static” in the database, while those bindings that have been added through the process of DHCP snooping are labeled “dynamic.”

To configure a static IP address/MAC address binding in the DHCP snooping database (replace **ge-0/0/2**, **10.0.10.12**, **data-vlan**, and **00:05:85:3A:82:80** with values for your configuration):

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface ge-0/0/2 static-ip 10.0.10.12 vlan data-vlan mac 00:05:85:3A:82:80
```

To view results of the configuration steps before committing the configuration, type the **show** command at the user prompt.

To commit these changes to the active configuration, type the **commit** command at the user prompt.

### Related Documentation

- [Understanding DHCP Snooping for Port Security on page 4456](#)
- *secure-access-port*

- [secure-access-port on page 4622](#)

## Enabling DHCP Snooping (CLI Procedure)

DHCP snooping allows the switch to monitor and control DHCP messages received from untrusted devices connected to the switch. It builds and maintains a database of valid IP-address/MAC-address (IP-MAC) bindings called the DHCP snooping database.

**NOTE:** If you configure DHCP snooping for all VLANs and you enable a different port security feature on a specific VLAN, you must also explicitly enable DHCP snooping on that VLAN. Otherwise, the default value of no DHCP snooping applies to that VLAN.

This topic describes:

- [Enabling DHCP Snooping on page 4552](#)
- [Applying CoS Forwarding Classes to Prioritize Snooped Packets on page 4552](#)

## Enabling DHCP Snooping

---

You configure DHCP snooping per VLAN, not per interface (port). By default, DHCP snooping is disabled for all VLANs. You can enable DHCP snooping on all VLANs or on specific VLANs.

To enable DHCP snooping on a VLAN or all VLANs:

- On a specific VLAN:

```
[edit ethernet-switching-options secure-access port]
user@switch# set vlan vlan-name examine-dhcp
```

- On all VLANs:

```
[edit ethernet-switching-options secure-access port]
user@switch# set vlan all examine-dhcp
```

**TIP:** By default, the IP-MAC bindings are lost when the switch is rebooted and DHCP clients (the network devices, or hosts) must reacquire bindings. However, you can configure the bindings to persist by setting the `dhcp-snooping-file` statement to store the database file either locally or remotely.

**TIP:** For private VLANs (PVLANS), enable DHCP snooping on the primary VLAN. If you enable DHCP snooping only on a community VLAN, DHCP messages coming from PVLAN trunk ports are not snooped.

## Applying CoS Forwarding Classes to Prioritize Snooped Packets

---

On EX Series switches you might need to use class of service (CoS) to protect packets from critical applications from being dropped during periods of network congestion and delay and you might also need the port security features of DHCP snooping on the same ports through which those critical packets are entering and leaving.

**NOTE:** This is not supported on the QFX Series switch.

To apply CoS forwarding classes and queues to snooped packets:

1. Create a user-defined forwarding class to be used for prioritizing snooped packets:

```
[edit class-of-service]
user@switch# set forwarding-classes class class-name queue queue-number
```

2. Enable DHCP snooping on a specific VLAN or on all VLANs and apply the desired forwarding class on the snooped packets:

- On a specific VLAN:

```
[edit ethernet-switching-options secure-access port]
user@switch# set vlan vlan-name examine-dhcp forwarding-class class-name
```

- On all VLANs:

```
[edit ethernet-switching-options secure-access port]
user@switch# set vlan all examine-dhcp forwarding-class class-name
```

#### Related Documentation

### Enabling Dynamic ARP Inspection (CLI Procedure)

Dynamic ARP inspection (DAI) protects switches against ARP spoofing. DAI inspects ARP packets on the LAN and uses the information in the DHCP snooping database on the switch to validate ARP packets and to protect against ARP cache poisoning.

This topic describes:

- [Enabling DAI on page 4554](#)
- [Applying CoS Forwarding Classes to Prioritize Inspected Packets on page 4554](#)

## Enabling DAI

---

You configure DAI for each VLAN, not for each interface (port). By default, DAI is disabled for all VLANs.

To enable DAI on a VLAN or all VLANs:

- On a single VLAN:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan vlan-name arp-inspection
```

- On all VLANs:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan all arp-inspection
```

## Applying CoS Forwarding Classes to Prioritize Inspected Packets

---

You might need to use class of service (CoS) to protect packets from critical applications from being dropped during periods of network congestion and delay and you might also need the port security features of DHCP snooping on the same ports through which those critical packets are entering and leaving.

To apply CoS forwarding classes and queues to DAI packets:

1. Create a user-defined forwarding class to be used for prioritizing DAI packets:

```
[edit class-of-service]
user@switch# set forwarding-classes class class-name queue queue-number
```

2. Enable DAI on a specific VLAN or on all VLANs and apply the desired forwarding class on the DAI packets:

- On a specific VLAN:

```
[edit ethernet-switching-options secure-access port]
user@switch# set vlan vlan-name arp-inspection forwarding-class class-name
```

- On all VLANs:

```
[edit ethernet-switching-options secure-access port]
user@switch# set vlan all arp-inspection forwarding-class class-name
```

## Enabling a Trusted DHCP Server (CLI Procedure)

You can configure any interface on a switch that connects to a DHCP server as a trusted interface (port). Configuring a DHCP server on a trusted interface protects against rogue DHCP servers sending leases.

You configure a trusted DHCP server on an interface, not on a VLAN. By default, all access interfaces are untrusted, and all trunk interfaces are trusted.

To configure a trusted interface for a DHCP server by using the CLI (here, the interface is **ge-0/0/8**):

```
[edit ethernet-switching-options secure-access port]
user@switch# set interface ge-0/0/8 dhcp-trusted
```

### Related Documentation

- [secure-access-port on page 4622](#)

## Enabling a Trusted Port for DHCP

By default, all access ports are untrusted and all trunk ports are trusted with regard to DHCP. Trusted ports allow DHCP servers to provide IP addresses and other information to requesting devices. Untrusted ports drop traffic from DHCP servers to prevent unauthorized servers from providing any configuration information to clients.

If you attach a DHCP server to an access port, you must configure it as trusted. You configure a trusted DHCP server on an interface, not on a VLAN.

**NOTE:** Before you attach a DHCP server to a trusted access port, ensure that the server is physically secure—that is, that access to the server is monitored and controlled.

- To configure a trusted interface for a DHCP server by using the CLI (here, the interface is **xe-0/0/8**):

```
[edit ethernet-switching-options secure-access port]
user@switch# set interface xe-0/0/8 dhcp-trusted
```

## Setting Up DHCP Option 82 on the Switch with No Relay Agent Between Clients and DHCP Server (CLI Procedure)

You can use DHCP option 82, also known as the DHCP relay agent information option, to help protect the switch against attacks such as spoofing (forging) of IP addresses and MAC addresses, and DHCP IP address starvation. Option 82 provides information about the network location of a DHCP client, and the DHCP server uses this information to implement IP addresses or other parameters for the client.

You can configure the DHCP option 82 feature in two topologies:

- The switch, DHCP clients, and DHCP server are all on the same VLAN. The switch forwards the clients' requests to the server and forwards the server's replies to the clients. This topic describes this configuration.
- The switch functions as a relay agent when the DHCP clients or the DHCP server is connected to the switch through a Layer 3 interface. On the switch, these interfaces are configured as routed VLAN interfaces, or RVIs. The switch relays the clients' requests to the server and then forwards the server's replies to the clients. This configuration is described in [“Setting Up DHCP Option 82 with the Switch as a Relay Agent Between Clients and DHCP Server \(CLI Procedure\)”](#) on page 4560.

Before you configure DHCP option 82 on the switch, perform these tasks:

- Connect and configure the DHCP server.

**NOTE:** Your DHCP server must be configured to accept DHCP option 82. If the server is not configured for DHCP option 82, the server does not use the DHCP option 82 information in the requests sent to it when it formulates its reply messages.

- Configure a VLAN on the switch and associate the interfaces on which the clients and the server connect to the switch with that VLAN.

To configure DHCP option 82:

**NOTE:** Replace values displayed in *italics* with values for your configuration.

1. Specify DHCP option 82 for all VLANs associated with the switch or for a specified VLAN. (You can also configure the feature for a VLAN range.)
  - On a specific VLAN:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee dhcp-option82
```
  - On all VLANs:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan all dhcp-option82
```

The remaining steps are optional.
2. To configure a prefix for the circuit ID suboption (the prefix is always the hostname of the switch):

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee dhcp-option82 circuit-id prefix hostname
```
3. To specify that the circuit ID suboption value should contain the interface description rather than the interface name (the default):

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee dhcp-option82 circuit-id use-interface-description
```
4. To specify that the circuit ID suboption value should contain the VLAN ID rather than the VLAN name (the default):

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee dhcp-option82 circuit-id use-vlan-id
```
5. To specify that the remote ID suboption be included in the DHCP option 82 information:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee dhcp-option82 remote-id
```
6. To configure a prefix for the remote ID suboption (here, the prefix is the MAC address of the switch):

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee dhcp-option82 remote-id prefix mac
```
7. To specify that the prefix for the remote ID suboption be the hostname of the switch rather than the MAC address of the switch (the default):

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee dhcp-option82 remote-id prefix hostname
```
8. To specify that the remote ID suboption value should contain the interface description:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee dhcp-option82 remote-id use-interface-description
```
9. To specify that the remote ID suboption value should contain a character string:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee dhcp-option82 remote-id use-string mystring
```
10. To configure a vendor ID suboption and use the default value (the default value is **Juniper**), do not type a character string after the **vendor-id** option keyword:

```
[edit ethernet-switching-options secure-access-port]
```

```
user@switch# set vlan employee dhcp-option82 vendor-id
```

11. To specify that the vendor ID suboption value should contain a character string value that you specify rather than **Juniper** (the default):

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan employee dhcp-option82 vendor-id mystring
```

To view results of the configuration steps before committing the configuration, type the **show** command at the user prompt.

To commit these changes to the active configuration, type the **commit** command at the user prompt.

- RFC 3046, *DHCP Relay Agent Information Option*, at <http://tools.ietf.org/html/rfc3046>.

## Setting Up DHCP Option 82 with the Switch as a Relay Agent Between Clients and DHCP Server (CLI Procedure)

You can use DHCP option 82, also known as the DHCP relay agent information option, to help switches against attacks such as spoofing (forging) of IP addresses and MAC addresses, and DHCP IP address starvation. Option 82 provides information about the network location of a DHCP client, and the DHCP server uses this information to implement IP addresses or other parameters for the client.

You can configure the DHCP option 82 feature in two topologies:

- The switch functions as a relay agent when the DHCP clients or the DHCP server is connected to the switch through a Layer 3 interface. On the switch, these interfaces are configured as routed VLAN interfaces, or RVIs. The switch relays the clients' requests to the server and then forwards the server's replies to the clients. This topic describes this configuration. The configuration for this topology is the same regardless of whether your switch is running Junos OS for EX Series switches with support for the Enhanced Layer 2 Software (ELS) configuration style or not.
- The switch, DHCP clients, and DHCP server are all on the same VLAN. The switch forwards the clients' requests to the server and forwards the server's replies to the clients. This configuration for this topology differs if your switch is running Junos OS for EX Series switches with support for the Enhanced Layer 2 Software (ELS) configuration style.
  - If your switch is running Junos OS for EX Series switches with support for the Enhanced Layer 2 Software (ELS) configuration style. see *Setting Up DHCP Option 82 on the Switch with No Relay Agent Between Clients and DHCP Server (CLI Procedure)*.
  - If your switch is running Junos OS for EX Series switches without support for ELS, see *"Setting Up DHCP Option 82 on the Switch with No Relay Agent Between Clients and DHCP Server (CLI Procedure)" on page 4557*.

Before you configure DHCP option 82 on the switch, perform these tasks:

- Connect and configure the DHCP server.

**NOTE:** Your DHCP server must be configured to accept DHCP option 82. If the server is not configured for DHCP option 82, the server does not use the DHCP option 82 information in the requests sent to it when it formulates its reply messages.

- Configure the VLAN on the switch and associate the interfaces on which the clients connect to the switch with that VLAN.
- Configure the routed VLAN interface (RVI) to allow the switch to relay packets to the server and receive packets from the server. See *Configuring Routed VLAN Interfaces (CLI Procedure)* or *"Configuring Routed VLAN Interfaces" on page 1532* for the QFX Series.
- Configure the switch as a BOOTP relay agent. See *DHCP/BOOTP Relay for Switches Overview*.

To configure DHCP option 82:

**NOTE:** Replace values displayed in *italics* with values for your configuration.

1. Specify DHCP option 82 for the BOOTP server:

- On all interfaces that connect to the server:

```
[edit forwarding-options helpers bootp]
user@switch# set dhcp-option82
```

- On a specific interface that connects to the server:

```
[edit forwarding-options helpers bootp]
user@switch# set interface ge-0/0/10 dhcp-option82
```

The remaining steps are optional. They show configurations for all interfaces; include the specific interface designation to configure any of the following options on a specific interface:

2. To configure a prefix for the circuit ID suboption (the prefix is always the hostname of the switch):

```
[edit forwarding-options helpers bootp]
user@switch# set dhcp-option82 circuit-id prefix hostname
```

3. To specify that the circuit ID suboption value should contain the interface description rather than the interface name (the default):

```
[edit forwarding-options helpers bootp]
user@switch# set dhcp-option82 circuit-id use-interface-description
```

4. To specify that the circuit ID suboption value should contain the VLAN ID rather than the VLAN name (the default):

```
[edit forwarding-options helpers bootp]
user@switch# set dhcp-option82 circuit-id use-vlan-id
```

5. To specify that the remote ID suboption be included in the DHCP option 82 information:

```
[edit forwarding-options helpers bootp]
user@switch# set dhcp-option82 remote-id
```

6. To configure a prefix for the remote ID suboption (here, the prefix is the MAC address of the switch):

```
[edit forwarding-options helpers bootp]
user@switch# set dhcp-option82 remote-id prefix mac
```

7. To specify that the prefix for the remote ID suboption be the hostname of the switch rather than the MAC address of the switch (the default):

```
[edit forwarding-options helpers bootp]
user@switch# set dhcp-option82 remote-id prefix hostname
```

8. To specify that the remote ID suboption value should contain the interface description:

```
[edit forwarding-options helpers bootp]
user@switch# set dhcp-option82 remote-id use-interface-description
```

9. To specify that the remote ID suboption value should contain a character string:

```
[edit forwarding-options helpers bootp]
user@switch# set dhcp-option82 remote-id use-string mystring
```

10. To configure a vendor ID suboption and use the default value (the default value is **Juniper**), do not type a character string after the **vendor-id** option keyword:

```
[edit forwarding-options helpers bootp]
user@switch# set dhcp-option82 vendor-id
```

11. To specify that the vendor ID suboption value contains a character string value that you specify rather than **Juniper** (the default):

```
[edit forwarding-options helpers bootp]
user@switch# set dhcp-option82 vendor-id mystring
```

To view results of the configuration steps before committing the configuration, type the **show** command at the user prompt.

To commit these changes to the active configuration, type the **commit** command at the user prompt.

## Device Security Configuration Tasks

- [Configuring Unicast RPF \(CLI Procedure\) on page 4562](#)
- [Disabling Unicast RPF \(CLI Procedure\) on page 4564](#)
- [Configuring Unknown Unicast Forwarding \(CLI Procedure\) on page 4565](#)

### Configuring Unicast RPF (CLI Procedure)

Unicast reverse-path forwarding (RPF) can help protect your LAN from denial-of-service (DoS) and distributed denial-of-service (DDoS) attacks on untrusted interfaces. Enabling unicast RPF on the switch interfaces filters traffic with source addresses that do not use the incoming interface as the best return path back to the source. When a packet comes into an interface, if that interface is not the best return path to the source, the switch discards the packet. If the incoming interface is the best return path to the source, the switch forwards the packet.

**NOTE:** On EX3200, EX4200, and EX4300 switches, you can enable unicast RPF only globally—that is, on all switch interfaces. You cannot enable unicast RPF on a per-interface basis.

Before you begin:

- On an EX8200, EX6200, or QFX Series switch, ensure that the selected switch interface is symmetrically routed before you enable unicast RPF. A symmetrically routed interface is an interface that uses the same route in both directions between the source and the destination. Do not enable unicast RPF on asymmetrically routed interfaces. An

asymmetrically routed interface uses different paths to send and receive packets between the source and the destination.

- On an EX3200, EX4200, or EX4300 switch, ensure that *all* switch interfaces are symmetrically routed before you enable unicast RPF on an interface. When you enable unicast RPF on any interface, it is enabled globally on all switch interfaces. Do not enable unicast RPF on asymmetrically routed interfaces. An asymmetrically routed interface uses different paths to send and receive packets between the source and the destination.

To enable unicast RPF, configure it explicitly on a selected customer-edge interface:

[edit interfaces]

user@switch# **set ge-1/0/10 unit 0 family inet rpf-check**

**BEST PRACTICE:** On EX3200, EX4200, and EX4300 switches, unicast RPF is enabled globally on *all* switch interfaces, regardless of whether you configure it explicitly on only one interface or only on some interfaces.

On EX3200, EX4200, and EX4300 switches, we recommend that you enable unicast RPF explicitly on either all interfaces or only one interface. To avoid possible confusion, do not enable it on only some interfaces:

- Enabling unicast RPF explicitly on only one interface makes it easier if you choose to disable it in the future because you must explicitly disable unicast RPF on every interface on which you explicitly enabled it. If you explicitly enable unicast RPF on two interfaces and you disable it on only one interface, unicast RPF is still implicitly enabled globally on the switch. The drawback of this approach is that the switch displays the flag that indicates that unicast RPF is enabled only on interfaces on which unicast RPF is explicitly enabled, so even though unicast RPF is enabled on all interfaces, this status is not displayed.
- Enabling unicast RPF explicitly on all interfaces makes it easier to know whether unicast RPF is enabled on the switch because every interface shows the correct status. (Only interfaces on which you explicitly enable unicast RPF display the flag that indicates that unicast RPF is enabled.) The drawback of this approach is that if you want to disable unicast RPF, you must explicitly disable it on every interface. If unicast RPF is enabled on any interface, it is implicitly enabled on all interfaces.

#### Related Documentation

- [Example: Configuring Unicast RPF on an EX Series Switch](#)
- [Verifying Unicast RPF Status on page 4679](#)
- [Disabling Unicast RPF \(CLI Procedure\) on page 4564](#)
- [Troubleshooting Unicast RPF](#)
- [Understanding Unicast RPF on page 4473](#)

## Disabling Unicast RPF (CLI Procedure)

Unicast reverse-path forwarding (RPF) can help protect your LAN from denial-of-service (DoS) and distributed denial-of-service (DDoS) attacks on untrusted interfaces. Unicast RPF filters traffic with source addresses that do not use the incoming interface as the best return path back to the source. If the network configuration changes so that an interface that has unicast RPF enabled becomes a trusted interface or becomes asymmetrically routed (the interface that receives a packet is not the best return path to the packet's source), disable unicast RPF.

To disable unicast RPF on an EX3200, EX4200, or EX4300 switch, you must delete it from every interface on which you explicitly configured it. If you do not disable unicast RPF on every interface on which you explicitly enabled it, it remains implicitly enabled on all interfaces. If you attempt to delete unicast RPF from an interface on which it was not explicitly enabled, the **warning: statement not found** message appears. If you do not disable unicast RPF on every interface on which you explicitly enabled it, unicast RPF remains implicitly enabled on all interfaces of the EX3200, EX4200, or EX4300 switch.

On EX8200, EX6200, and QFX Series switches, the switch does not apply unicast RPF to an interface unless you explicitly enable that interface for unicast RPF.

To disable unicast RPF, delete its configuration from the interface:

[edit interfaces]

user@switch# **delete** ge-1/0/10 unit 0 family inet **rpf-check**

**NOTE:** On EX3200, EX4200, and EX4300 switches, if you do not disable unicast RPF on every interface on which you explicitly enabled it, unicast RPF remains implicitly enabled on all interfaces.

## Configuring Unknown Unicast Forwarding (CLI Procedure)

**NOTE:** This task uses Junos OS for EX Series switches or QFX Series with support for the Enhanced Layer 2 Software (ELS) configuration style. If your EX Series switch runs software that does not support ELS, see *Configuring Unknown Unicast Forwarding (CLI Procedure)*. For ELS details, see “[Getting Started with Enhanced Layer 2 Software](#)” on page 58

Unknown unicast traffic consists of packets with unknown destination MAC addresses. By default, the switch floods these packets to all interfaces associated with a VLAN. Forwarding such traffic to interfaces on the switch can create a security issue.

To prevent flooding unknown unicast traffic across the switch, configure unknown unicast forwarding to direct all unknown unicast packets within a VLAN out to a specific interface. You can configure each VLAN to divert unknown unicast traffic to different interfaces or use one interface for multiple VLANs.

To configure unknown unicast forwarding options:

- Configure unknown unicast forwarding for a specific VLAN (here, the VLAN name is employee), and specify the interface to which all unknown unicast traffic will be forwarded:

```
[edit switch-options]
user@switch# set unknown-unicast-forwarding vlan vlan-name interface ge-x/y/z.0
```

## filter

<b>Syntax</b>	<pre> filter <i>filter-name</i> {   <i>interface-specific</i>;   term <i>term-name</i> {     from {       <i>match-conditions</i>;     }     then {       <i>action</i>;       <i>action-modifiers</i>;     }   } } </pre>
<b>Hierarchy Level</b>	[edit <b>firewall family</b> <i>family-name</i> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Configure firewall filters.
<b>Options</b>	<p><b><i>filter-name</i></b>—Name that identifies the filter. The name can contain letters, numbers, and hyphens (-), and can be up to 64 characters long. To include spaces in the name, enclose it in quotation marks.</p> <p>The remaining statements are explained separately.</p>
<b>Required Privilege Level</b>	<p>firewall—To view this statement in the configuration.</p> <p>firewall-control—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Firewall Filter Match Conditions and Actions on page 4419</a></li> <li>• <a href="#">Configuring Firewall Filters on page 4531</a></li> <li>• <a href="#">Overview of Firewall Filters on page 4409</a></li> </ul>

## filter (Layer 2 and Layer 3 Interfaces)

---

<b>Syntax</b>	<code>filter (input   output) <i>filter-name</i>;</code>
<b>Hierarchy Level</b>	[ <a href="#">edit</a> <a href="#">interfaces</a> <i>interface-name</i> <a href="#">unit</a> <i>logical-unit-number</i> <a href="#">family</a> <i>family-name</i> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Apply a firewall filter to traffic transiting a port or Layer 3 interface.
<b>Default</b>	All incoming traffic is accepted unmodified on the port or Layer 3 interface, and all outgoing traffic is sent unmodified from the port or Layer 3 interface.
<b>Options</b>	<p><b><i>filter-name</i></b>—Name of a firewall filter defined at the [<a href="#">edit</a> <a href="#">firewall</a> <a href="#">family</a> <i>family-name</i> <a href="#">filter</a>] hierarchy level.</p> <p><b>input</b>—Apply a firewall filter to traffic entering the port or Layer 3 interface.</p> <p><b>output</b>—Apply a firewall filter to traffic exiting the port or Layer 3 interface.</p>
<b>Required Privilege Level</b>	<p>interface—To view this statement in the configuration.</p> <p>interface-control—To add this statement to the configuration.</p>

```

Hierarchy Level    [\[edit\]](#)

**Release Information**    Statement introduced in Junos OS Release 11.1 for the QFX Series.

**Description**    Configure firewall filters and policers.

The remaining statements are explained separately.

<b>Required Privilege Level</b>	firewall—To view this statement in the configuration. firewall-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Firewall Filter Match Conditions and Actions on page 4419</a></li> <li>• <a href="#">Configuring Firewall Filters on page 4531</a></li> <li>• <a href="#">Configuring Two-Color and Three-Color Policers to Control Traffic Rates on page 4538</a></li> <li>• <a href="#">Overview of Firewall Filters on page 4409</a></li> </ul>

## from

---

<b>Syntax</b>	<pre>from {     match-conditions; }</pre>
<b>Hierarchy Level</b>	[edit <b>firewall</b> <b>family</b> <i>family-name</i> <b>filter</b> <i>filter-name</i> <b>term</b> <i>term-name</i> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Match packet fields to values specified in a match condition. If the <b>from</b> statement is not included in a firewall filter configuration, all packets are considered to match and the actions and action modifiers in the <b>then</b> statement are implemented.
<b>Options</b>	<b>match-conditions</b> —Conditions that define the values or fields that the incoming or outgoing packets must contain for a match. You can specify one or more match conditions. If you specify more than one, they all must match for a match to occur and for the action in the <b>then</b> statement to be implemented.
<b>Required Privilege Level</b>	firewall—To view this statement in the configuration. firewall-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Firewall Filter Match Conditions and Actions on page 4419</a></li> <li>• <a href="#">Configuring Firewall Filters on page 4531</a></li> <li>• <a href="#">Understanding Firewall Filter Match Conditions on page 4415</a></li> </ul>

## interface-specific

---

<b>Syntax</b>	interface-specific;
<b>Hierarchy Level</b>	[edit <b>firewall</b> <b>family</b> <i>family-name</i> <b>filter</b> <i>filter-name</i> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Configure separate counters for each interface to which a filter is applied.
<b>Required Privilege Level</b>	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Firewall Filter Match Conditions and Actions on page 4419</a></li><li>• <a href="#">Configuring Firewall Filters on page 4531</a></li><li>• <a href="#">Overview of Firewall Filters on page 4409</a></li></ul>

## term

---

<b>Syntax</b>	<pre>term <i>term-name</i> {     from {         <i>match-conditions</i>;     }     then {         <i>action</i>;         <i>action-modifiers</i>;     } }</pre>
<b>Hierarchy Level</b>	[edit <b>firewall</b> <b>family</b> <i>family-name</i> <b>filter</b> <i>filter-name</i> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Define a firewall filter term.
<b>Options</b>	<p><b><i>term-name</i></b>—Name that identifies the term. The name can contain letters, numbers, and hyphens (-), and can be up to 64 characters long. To include spaces in the name, enclose it in quotation marks.</p> <p>The remaining statements are explained separately.</p>
<b>Required Privilege Level</b>	firewall—To view this statement in the configuration. firewall-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Firewall Filter Match Conditions and Actions on page 4419</a></li><li>• <a href="#">Configuring Firewall Filters on page 4531</a></li><li>• <a href="#">Overview of Firewall Filters on page 4409</a></li></ul>

## then (Filters)

---

<b>Syntax</b>	<pre>then {     action;     action-modifiers; }</pre>
<b>Hierarchy Level</b>	[edit <b>firewall family</b> <i>family-name</i> <b>filter</b> <i>filter-name</i> <b>term</b> <i>term-name</i> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Configure a firewall filter action.
<b>Options</b>	<p><b>action</b>—Actions to accept, discard, or forward packets that match all conditions specified in a filter term.</p> <p><b>action-modifiers</b>—Additional actions to analyze, classify, count, or police packets that match all conditions specified in a filter term.</p>
<b>Required Privilege Level</b>	<p>firewall—To view this statement in the configuration.</p> <p>firewall-control—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Firewall Filter Match Conditions and Actions on page 4419</a></li> <li>• <a href="#">Configuring Firewall Filters on page 4531</a></li> <li>• <a href="#">Understanding Firewall Filter Match Conditions on page 4415</a></li> </ul>

## action

<b>Syntax</b>	<code>action {     <a href="#">loss-priority high then discard</a>; }</code>
<b>Hierarchy Level</b>	[edit <a href="#">firewall three-color-policer name</a> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Discard traffic on a logical interface using tricolor marking policing.
<b>Options</b>	The statements are explained separately.
<b>Required Privilege Level</b>	<code>firewall</code> —To view this statement in the configuration. <code>firewall-control</code> —To add this statement to the configuration.

---

## bandwidth-limit

<b>Syntax</b>	<code>bandwidth-limit <i>bps</i>;</code>
<b>Hierarchy Level</b>	[edit <a href="#">firewall policer policer-name if-exceeding</a> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Specify the traffic rate in bits per second.
<b>Options</b>	<code><i>bps</i></code> —Traffic rate in bits per second. Specify <i>bps</i> as a decimal value or as a decimal number followed by one of the abbreviation <code>k</code> (1000), <code>m</code> (1,000,000), or <code>g</code> (1,000,000,000). <b>Range:</b> 32000 bps (32 Kbps) through 10,000,000,000 bps (10 Gbps)
<b>Required Privilege Level</b>	<code>firewall</code> —To view this statement in the configuration. <code>firewall-control</code> —To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Configuring Two-Color and Three-Color Policers to Control Traffic Rates on page 4538</a></li><li>• <a href="#">Overview of Policers on page 4441</a></li></ul>

---

## burst-size-limit

---

<b>Syntax</b>	<code>burst-size-limit bytes;</code>
<b>Hierarchy Level</b>	[edit <code>firewall policer policer-name if-exceeding</code> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Specify the maximum allowed burst size to control the amount of traffic bursting.
<b>Options</b>	<b>bytes</b> —Decimal value or a decimal number followed by k (thousand), m (million), or g (giga). <b>Range:</b> 1 through 2,147,450,880 bytes (2147 MB)
<b>Required Privilege Level</b>	firewall—To view this statement in the configuration. firewall-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Configuring Two-Color and Three-Color Policers to Control Traffic Rates on page 4538</a></li><li>• <a href="#">Overview of Policers on page 4441</a></li></ul>

## color-aware

---

<b>Syntax</b>	color-aware;
<b>Hierarchy Level</b>	[edit <a href="#">firewall three-color-policer</a> <i>policer-name</i> single-rate], [edit <a href="#">firewall three-color-policer</a> <i>policer-name</i> two-rate]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Configure the way preclassified packets are metered. In color-aware mode, the switch can assign a higher packet-loss priority, but cannot assign a lower packet loss priority (PLP). For example, suppose an upstream device assigns medium-high PLP to a packet because the packet exceeded its committed information rate (CIR). The switch cannot change the PLP to low even if the packet conforms to the configured CIR of the appropriate interface. On the other hand, if an upstream device assigns low PLP to a packet but the packet exceeds the CIR and committed burst size (CBS) of the switch interface, the switch can increase the PLP to medium-high.
<b>Default</b>	If you omit the <b>color-aware</b> statement, the default behavior is color-aware mode.
<b>Required Privilege Level</b>	firewall—To view this statement in the configuration. firewall-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Overview of Policers on page 4441</a></li><li>• <a href="#">Understanding Color-Aware Mode for Single-Rate Tricolor Marking on page 4447</a></li><li>• <a href="#">Understanding Color-Aware Mode for Two-Rate Tricolor Marking on page 4449</a></li><li>• <a href="#">color-blind on page 4577</a></li></ul>

## color-blind

---

<b>Syntax</b>	color-blind;
<b>Hierarchy Level</b>	[edit <a href="#">firewall three-color-policer</a> <i>policer-name</i> single-rate], [edit <a href="#">firewall three-color-policer</a> <i>policer-name</i> two-rate]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Configure the way preclassified packets are metered. In color-blind mode, the switch ignores any preclassification of packets and can assign a higher or lower packet loss priority (PLP). For example, suppose an upstream device assigns medium-high PLP to a packet because the packet exceeded the CIR on the upstream device. The switch can change the PLP to low if the packet conforms to the CIR of the appropriate interface.
<b>Default</b>	If you omit the <b>color-blind</b> statement, the default behavior is color-aware mode.
<b>Required Privilege Level</b>	firewall—To view this statement in the configuration. firewall-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Overview of Policers on page 4441</a></li> <li>• <a href="#">Understanding Color-Blind Mode for Single-Rate Tricolor Marking on page 4447</a></li> <li>• <a href="#">Understanding Color-Blind Mode for Two-Rate Tricolor Marking on page 4449</a></li> <li>• <a href="#">Configuring Color-Blind Egress Policers for Medium-Low PLP on page 4537</a></li> <li>• <a href="#">color-aware on page 4576</a></li> </ul>

## committed-burst-size

---

<b>Syntax</b>	<code>committed-burst-size bytes;</code>
<b>Hierarchy Level</b>	[edit <a href="#">firewall three-color-policer</a> <i>policer-name</i> single-rate], [edit <a href="#">firewall three-color-policer</a> <i>policer-name</i> two-rate]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Configure the maximum number of bytes allowed for incoming traffic to burst above the committed information rate and still be marked with low packet loss priority (green).
<div> <b>NOTE:</b> When you include the <code>committed-burst-size</code> statement in the configuration, you must also include the <code>committed-information-rate</code> statement at the same hierarchy level.</div>	
<b>Options</b>	<b>bytes</b> —Number of bytes. You can specify a value in bytes either as a complete decimal number or as a decimal number followed by the abbreviation <b>k</b> (1000), <b>m</b> (1,000,000), or <b>g</b> (1,000,000,000). <b>Range:</b> 512 bytes through 268435456 bytes (268 MB)
<b>Required Privilege Level</b>	<b>firewall</b> —To view this statement in the configuration. <b>firewall-control</b> —To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Configuring Two-Color and Three-Color Policers to Control Traffic Rates on page 4538</a></li><li>• <a href="#">Overview of Policers on page 4441</a></li></ul>

## committed-information-rate

<b>Syntax</b>	<code>committed-information-rate <i>bits-per-second</i>;</code>
<b>Hierarchy Level</b>	[edit <code>firewall three-color-policer <i>policer-name</i> single-rate</code> ], [edit <code>firewall three-color-policer <i>policer-name</i> two-rate</code> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Configure the guaranteed bandwidth under normal line conditions and the average rate up to which packets are marked with low packet loss priority (green).
<div>  <p><b>NOTE:</b> When you include the <code>committed-information-rate</code> statement in the configuration, you must also include the <code>committed-burst-size</code> statement at the same hierarchy level.</p> </div>	
<b>Options</b>	<p><b><i>bits-per-second</i></b>—Number of bits per second. You can specify a value in bits per second either as a complete decimal number or as a decimal number followed by the abbreviation <b>k</b> (1000), <b>m</b> (1,000,000), or <b>g</b> (1,000,000,000).</p> <p><b>Range:</b> 32,000 bps through 10,000,000,000 bps (10 gbps)</p>
<b>Required Privilege Level</b>	<p><code>firewall</code>—To view this statement in the configuration.</p> <p><code>firewall-control</code>—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Configuring Two-Color and Three-Color Policers to Control Traffic Rates on page 4538</a></li> <li>• <a href="#">Overview of Policers on page 4441</a></li> </ul>

## excess-burst-size

---

<b>Syntax</b>	<code>excess-burst-size bytes;</code>
<b>Hierarchy Level</b>	[edit <a href="#">firewall three-color-policer</a> <i>policer-name</i> single-rate]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Configure the maximum number of bytes allowed for incoming traffic to burst above the committed information rate and still be marked with medium-high packet loss priority (yellow). Packets that exceed the excess burst size (EBS) are marked with high packet loss priority (red).
<div> <b>NOTE:</b> When you include the <code>excess-burst-size</code> statement in the configuration, you must also include the <code>committed-burst-size</code> and <code>committed-information-rate</code> statements at the same hierarchy level.</div>	
<b>Options</b>	<b>bytes</b> —Number of bytes. You can specify a value in bytes either as a complete decimal number or as a decimal number followed by the abbreviation <b>k</b> (1000), <b>m</b> (1,000,000), or <b>g</b> (1,000,000,000). <b>Range:</b> 512 bytes through 268435456 bytes (268 MB)
<b>Required Privilege Level</b>	<b>firewall</b> —To view this statement in the configuration. <b>firewall-control</b> —To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Configuring Two-Color and Three-Color Policers to Control Traffic Rates on page 4538</a></li><li>• <a href="#">Overview of Policers on page 4441</a></li></ul>

---

## filter-specific

---

<b>Syntax</b>	filter-specific;
<b>Hierarchy Level</b>	[edit <b>firewall policer</b> <i>policer-name</i> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	<p>Configure a policer to be filter-specific, which means that Junos OS creates only one policer instance regardless of how many times the policer is referenced. If you use a filter-specific policer in multiple terms, both of the following are true:</p> <ul style="list-style-type: none"><li>• Traffic is policed at the aggregate rate. For example, if you create a policer that has a bandwidth limit of 100 Mbps and use the policer in two terms, the total allowed bandwidth for both terms is 100 Mbps—not 100 Mbps for each term.</li><li>• The implicit counter counts all the packets are that matched by any of the terms. For example, if you reference the same filter-specific policer in term1 and term2, and term1 matches 1000 packets and term2 matches 500 packets, the implicit counter shows 1500 matches for the policer.</li></ul>
<b>Required Privilege Level</b>	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Configuring Two-Color and Three-Color Policers to Control Traffic Rates on page 4538</a></li><li>• <a href="#">Overview of Policers on page 4441</a></li></ul>

<b>Hierarchy Level</b>	[edit <a href="#">firewall policer</a> <i>policer-name</i> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	<p>Configure policer rate limits.</p> <p>The remaining statements are explained separately.</p>
<b>Required Privilege Level</b>	firewall—To view this statement in the configuration. firewall-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Configuring Two-Color and Three-Color Policers to Control Traffic Rates on page 4538</a></li> <li>• <a href="#">Overview of Policers on page 4441</a></li> </ul>

## loss-priority high then discard (Three-Color Policer)

---

<b>Syntax</b>	loss-priority high then discard;
<b>Hierarchy Level</b>	[edit firewall <b>three-color-policer</b> <i>policer-name</i> <b>action</b> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	<p>For packets with high loss priority, discard the packets. The loss priority setting is not configurable. Include this statement if you do not want the switch to forward packets that have high packet-loss priority.</p> <p>For single-rate three-color policers, Junos OS assigns high loss priority to packets that exceed the committed information rate and the excess burst size.</p> <p>For two-rate three-color policers, Junos OS assigns high loss priority to packets that exceed the peak information rate and the peak burst size.</p>
<b>Required Privilege Level</b>	firewall—To view this statement in the configuration. firewall-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Configuring Two-Color and Three-Color Policers to Control Traffic Rates on page 4538</a></li><li>• <a href="#">Overview of Policers on page 4441</a></li></ul>

## peak-burst-size

<b>Syntax</b>	<code>peak-burst-size bytes;</code>
<b>Hierarchy Level</b>	[edit <code>firewall three-color-policer policer-name two-rate</code> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Configure the maximum number of bytes allowed for incoming packets to burst above the peak information rate (PIR) and still be marked with medium-high packet loss priority (yellow). Packets that exceed the peak burst size (PBS) are marked with high packet loss priority (red).
<div>  <p><b>NOTE:</b> When you include the <code>peak-burst-size</code> statement in the configuration, you must also include the <code>committed-burst-size</code> and <code>peak-information-rate</code> statements at the same hierarchy level.</p> </div>	
<b>Options</b>	<p><b>bytes</b>—Number of bytes. You can specify a value in bytes either as a complete decimal number or as a decimal number followed by the abbreviation <b>k</b> (1000), <b>m</b> (1,000,000), or <b>g</b> (1,000,000,000).</p> <p><b>Range:</b> 1500 bytes through 100,000,000,000 bytes (100 GB)</p>
<b>Required Privilege Level</b>	<p><code>firewall</code>—To view this statement in the configuration.</p> <p><code>firewall-control</code>—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Configuring Two-Color and Three-Color Policers to Control Traffic Rates on page 4538</a></li> <li>• <a href="#">Overview of Policers on page 4441</a></li> </ul>

## peak-information-rate

---

<b>Syntax</b>	<code>peak-information-rate <i>bits-per-second</i>;</code>
<b>Hierarchy Level</b>	[edit <code>firewall three-color-policer <i>policer-name</i> two-rate</code> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Configure the maximum achievable rate. Packets that exceed the committed information rate (CIR) but are below the peak information rate (PIR) are marked with medium-high packet loss priority (yellow). Packets that exceed the PIR are marked with high packet loss priority (red). You can configure a discard action for packets that exceed the PIR.
<div> <b>NOTE:</b> When you include the <code>peak-information-rate</code> statement in the configuration, you must also include the <code>committed-information-rate</code> and <code>peak-burst-size</code> statements at the same hierarchy level.</div>	
<b>Options</b>	<b><i>bits-per-second</i></b> —Number of bits per second. You can specify a value in bits per second either as a complete decimal number or as a decimal number followed by the abbreviation <b>k</b> (1000), <b>m</b> (1,000,000), or <b>g</b> (1,000,000,000). <b>Range:</b> 32,000 bps through 10,000,000,000 bps (10 gbps)
<b>Required Privilege Level</b>	<code>firewall</code> —To view this statement in the configuration. <code>firewall-control</code> —To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Configuring Two-Color and Three-Color Policers to Control Traffic Rates on page 4538</a></li><li>• <a href="#">Overview of Policers on page 4441</a></li></ul>

## policer

<b>Syntax</b>	<pre> policer <i>policer-name</i> {   filter-specific;   if-exceeding {     bandwidth-limit <i>bps</i>;     burst-size-limit <i>bytes</i>;   }   then {     <i>policer-action</i>;   } } </pre>
<b>Hierarchy Level</b>	[edit <a href="#">firewall</a> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	<p>Configure policer rate limits and actions. To activate a policer, you must include the <b>policer</b> action modifier in the <b>then</b> statement in a firewall filter term.</p> <p>Each policer that you configure includes an implicit counter that counts the number of packets that exceed the rate limits that are specified for the policer. If you use the same policer in multiple terms—either within the same filter or across filters—the policer's implicit counter is used to count packets that are policed in all of these terms. If you want to obtain separate packet counts for each term, use these approaches:</p> <ul style="list-style-type: none"> <li>• Configure a unique policer for each term.</li> <li>• Configure only one policer, but use a unique, explicit counter in each term.</li> </ul>
<b>Options</b>	<p><b><i>policer-name</i></b>—Name that identifies the policer. The name can contain letters, numbers, hyphens (-), and can be up to 64 characters long.</p> <p>The remaining statements are explained separately.</p>
<b>Required Privilege Level</b>	<p>firewall—To view this statement in the configuration.</p> <p>firewall-control—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Configuring Two-Color and Three-Color Policers to Control Traffic Rates on page 4538</a></li> <li>• <a href="#">Configuring Firewall Filters on page 4531</a></li> <li>• <a href="#">Overview of Policers on page 4441</a></li> </ul>

## single-rate

---

<b>Syntax</b>	<pre>single-rate {   (color-aware   color-blind);   committed-information-rate <i>bps</i>;   committed-burst-size <i>bytes</i>;   excess-burst-size <i>bytes</i>; }</pre>
<b>Hierarchy Level</b>	[edit <a href="#">firewall three-color-policer</a> <i>policer-name</i> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	<p>Configure a single-rate three-color policer in which marking is based on the committed information rate (CIR), committed burst size (CBS), and excess burst size (EBS).</p> <p>Packets that conform to the CIR or the CBS are assigned low loss priority (green). Packets that exceed the CIR and the CBS but are within the EBS are assigned medium-high loss priority (yellow). Packets that exceed the EBS are assigned high loss priority (red).</p> <p>Green and yellow packets are always forwarded; this action is not configurable. You can configure red packets to be discarded. By default, red packets are forwarded.</p> <p>The remaining statements are explained separately.</p>
<b>Options</b>	<b><i>policer-name</i></b> —Name of the three-color policer. Use this name when you apply the policer to an interface.
<b>Required Privilege Level</b>	<b>firewall</b> —To view this statement in the configuration. <b>firewall-control</b> —To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Configuring Two-Color and Three-Color Policers to Control Traffic Rates on page 4538</a></li><li>• <a href="#">Overview of Policers on page 4441</a></li></ul>

## then (Policers)

---

<b>Syntax</b>	then { <i>policer-action</i> ; }
<b>Hierarchy Level</b>	[edit <b>firewall</b> <b>policer</b> <i>policer-name</i> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Configure a policer action.
<b>Options</b>	<i>policer-action</i> —Allowed policer actions are <b>discard</b> , <b>loss-priority high</b> , and <b>loss-priority low</b> . <b>discard</b> causes the system to drop traffic that exceeds the rate limits defined by the policer. Use <b>loss-priority high</b> to allow the system to forward matching traffic in some cases.
<div>  <b>NOTE:</b> If you specify a policer in an egress firewall filter, the only supported action is <b>discard</b>.         </div>	
<b>Required Privilege Level</b>	firewall—To view this statement in the configuration. firewall-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Configuring Two-Color and Three-Color Policers to Control Traffic Rates on page 4538</a></li> <li>• <a href="#">Configuring Firewall Filters on page 4531</a></li> <li>• <a href="#">Overview of Policers on page 4441</a></li> </ul>

## three-color-policer

---

Syntax	<pre>three-color-policer <i>policer-name</i> {   action {     loss-priority high then discard;   }   single-rate {     (color-aware   color-blind);     committed-information-rate <i>bps</i>;     committed-burst-size <i>bytes</i>;     excess-burst-size <i>bytes</i>;   }   two-rate {     (color-aware   color-blind);     committed-information-rate <i>bps</i>;     committed-burst-size <i>bytes</i>;     peak-information-rate <i>bps</i>;     peak-burst-size <i>bytes</i>;   } }</pre>
Hierarchy Level	[edit <a href="#">firewall</a> ], [edit logical-systems <i>logical-system-name</i> firewall]
Release Information	Statement introduced in Junos OS Release 11.1 for the QFX Series.
Description	Configure a three-color policer.
Options	<p><b><i>policer-name</i></b>—Name of the three-color policer. Use this name when you apply the policer to an interface.</p> <p>The remaining statements are explained separately.</p>
Required Privilege Level	firewall—To view this statement in the configuration. firewall-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"><li>• <a href="#">Configuring Two-Color and Three-Color Policers to Control Traffic Rates on page 4538</a></li><li>• <a href="#">Overview of Policers on page 4441</a></li></ul>

## two-rate

<b>Syntax</b>	<pre>two-rate {   (color-aware   color-blind);   committed-information-rate <i>bps</i>;   committed-burst-size <i>bytes</i>;   peak-information-rate <i>bps</i>;   peak-burst-size <i>bytes</i>; }</pre>
<b>Hierarchy Level</b>	[edit <a href="#">firewall three-color-policer</a> <i>policer-name</i> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	<p>Configure a two-rate three-color policer in which marking is based on the committed information rate (CIR), committed burst size (CBS), peak information rate (PIR), and peak burst size (PBS).</p> <p>Packets that conform to the CIR or the CBS are assigned low loss priority (green). Packets that exceed the CIR and the CBS but are within the PIR or the PBS are assigned medium-high loss priority (yellow). Packets that exceed the PIR and the PBS are assigned high loss priority (red).</p> <p>Green and yellow packets are always forwarded; this action is not configurable. You can configure red packets to be discarded. By default, red packets are forwarded.</p> <p>The remaining statements are explained separately.</p>
<b>Required Privilege Level</b>	<p><b>firewall</b>—To view this statement in the configuration.</p> <p><b>firewall-control</b>—To add this statement to the configuration.</p>

## dhcp-snooping-file

---

<b>Syntax</b>	<pre>dhcp-snooping-file {   location <i>local_pathname</i>   <i>remote_URL</i>;   timeout <i>seconds</i>;   write-interval <i>seconds</i>; }</pre>
<b>Hierarchy Level</b>	<p>For platforms without ELS:</p> <p>[edit <a href="#">ethernet-switching-options secure-access-port</a>]</p> <p>For platforms with ELS:</p> <p>[edit system processes] <a href="#">dhcp-service</a> ]</p>
<b>Release Information</b>	Statement introduced in Junos OS Release 12.1 for the QFX Series.
<b>Description</b>	<p>Specify a local pathname or remote URL for the DHCP snooping database file to maintain persistence of IP-MAC bindings.</p> <p>The remaining statements are explained separately.</p>
<b>Default</b>	The IP-MAC bindings in the DHCP snooping database file are not persistent. If the switch is rebooted, the bindings are lost.
<b>Required Privilege Level</b>	<p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Understanding DHCP Snooping for Port Security on page 4456</a></li> </ul>

## fc-map

**Syntax** `fc-map fc-map-value;`

**Hierarchy Level** Original CLI

[edit ethernet-switching options secure-access-port vlan (all | *vlan-name*) [examine-fip](#)]

ELS CLI for Platforms that Support FCoE

[edit [vlans](#) *vlan-name* [forwarding-options fip-security](#)]

**NOTE:** The `fc-map` configuration statement is in a different hierarchy on the original CLI than on the Enhanced Layer 2 Software (ELS) CLI.

QFX Series that Support FCoE-FC Gateway Configuration

[edit [fc-fabrics](#) *fc-fabric-name* [protocols fip](#)]

**Release Information** Statement introduced in Junos OS Release 10.4 for EX Series switches.  
Statement introduced in Junos OS Release 11.1 for the QFX Series.  
Statement introduced for the ELS CLI in Junos OS Release 13.2 for the QFX Series.

**Description** Set the FCoE mapped address prefix (FC-MAP) value for the FCoE VLAN to match the FC switch (or FCoE forwarder) FC-MAP value for the FC fabric. The FC-MAP value is a unique MAC address prefix an FC switch uses to identify FCoE traffic for a given FC fabric (traffic on a particular FCoE VLAN).

You can configure the FC-MAP value or use the default value. The default FC-MAP value is different for VN\_Port to VF\_Port (VN2VF\_Port) FIP snooping (0x0EFC00) than for VN\_Port to VN\_Port (VN2VN\_Port) FIP snooping.

The FC switch provides the FC-MAP value to FCoE nodes (ENodes) in the FIP discovery advertisement message. If the EX Series switch or the QFX Series FCoE VLAN FC-MAP value does not match the FC switch FC-MAP value, neither device discovers the FC switch on that VLAN, and the ENodes on that VLAN cannot access the FC switch. The FC switch accepts only FCoE traffic that uses the correct FC-MAP value as part of the VN\_Port MAC address.

When the QFX Series acts as an FCoE-FC gateway, the FC-MAP value for the gateway and the FCoE devices must match the FC switch FC-MAP value in order to communicate with the FC switch.

**NOTE:** Changing the FC-MAP value causes all logins to drop and forces the ENodes to log in again.

**Options** `fc-map value`—FC-MAP value, hexadecimal value preceded by “0x”.

**Range:** 0x0EFC00 through 0x0EFCFF

**Default:** 0x0EFC00 for VN2VF\_Port FIP snooping 0x0EFD00 for VN2VN\_Port FIP snooping

**Required Privilege** routing—To view this statement in the configuration.  
**Level** routing-control—To add this statement to the configuration.

**Related Documentation**

- [examine-fip on page 4613](#)
- [show fip snooping on page 5254](#)

## fcoe-trusted

**Syntax** `fcoe-trusted;`

**Hierarchy Level** Original CLI

[edit ethernet-switching-options secure-access-port interface *interface-name*]

ELS CLI for Platforms that Support FCoE

[edit **v**lans *vlan-name* **f**orwarding-**o**ptions **f**ip-security interface *interface-name*]

**NOTE:** The `fcoe-trusted` configuration statement is in a different hierarchy on the original CLI than on the Enhanced Layer 2 Software (ELS) CLI.

QFX Series that Support FCoE-FC Gateway Configuration

[edit fc-fabrics *fc-fabric-name* protocols fip]

**Release Information** Statement introduced in Junos OS Release 10.4 for EX Series switches.  
Statement introduced in Junos OS Release 11.1 for the QFX Series.  
Statement introduced for the FC fabric in Junos OS Release 11.3 for the QFX Series.  
Statement introduced for the ELS CLI in Junos OS Release 13.2 for the QFX Series.

**Description** Configure the specified 10-Gigabit Ethernet interface to trust Fibre Channel over Ethernet (FCoE) traffic. If an interface is connected to another switch such as an FCoE forwarder (FCF) or a transit switch, you can configure the interface as trusted so that the interface forwards FCoE traffic from the switch to the FCoE devices without installing FIP snooping filters.

(QFX Series FCoE-FC gateway) Configure the specified local Fibre Channel fabric to trust FCoE traffic on all ports in the fabric. Changing the fabric ports from untrusted to trusted removes any existing FIP snooping filters from the ports. Changing the fabric ports from trusted to untrusted by removing the **fcoe-trusted** configuration from the fabric forces all of the FCoE sessions on those ports to log out so that when the ENodes and VN\_Ports log in again, the switch can build the appropriate FIP snooping filters.

**Required Privilege Level** routing—To view this statement in the configuration.  
routing-control—To add this statement to the configuration.

**Related Documentation**

## mac-move-limit

<b>Syntax</b>	<code>mac-move-limit <i>limit</i> &lt;fabric-limit <i>limit</i>&gt; action <i>action</i>;</code>
<b>Hierarchy Level</b>	<p>For platforms without ELS:</p> <p>[edit <a href="#">ethernet-switching-options secure-access-port</a> (all   <i>vlan-name</i>)]</p> <p>For platforms with ELS:</p> <p>[edit vlans <i>vlan-name</i> <a href="#">switch-options</a>],</p>
<b>Release Information</b>	Statement introduced in Junos OS Release 12.1 for the QFX Series.
<b>Description</b>	Specify the number of times a MAC address can move to a new interface (port) in 1 second and the action to be taken by the switch if the MAC address move limit is exceeded.
<b>Default</b>	The default move limit is unlimited. The default action is <b>drop</b> .
<b>Options</b>	<p><b>fabric-limit</b>—Specify the maximum number of moves in a QFabric system. If you do not specify a fabric limit, the value for <b>mac-move-limit</b> applies to the QFabric system.</p> <p><b>limit</b>—Maximum number of moves to a new interface per second.</p> <p><b>action <i>action</i></b>—(Optional) Action to take when the MAC address move limit is reached:</p> <ul style="list-style-type: none"> <li>• <b>drop</b>—Drop the packet and generate an alarm, an SNMP trap, or a system log entry. This is the default.</li> <li>• <b>log</b>—Do not drop the packet but generate an alarm, an SNMP trap, or a system log entry.</li> <li>• <b>none</b>—No action.</li> <li>• <b>shutdown</b>—Disable the interface and generate an alarm. If you have configured the switch with the <b>port-error-disable</b> statement, the disabled interfaces recover automatically upon expiration of the specified disable timeout. If you have not configured the switch for autorecovery from port error disabled conditions, you can bring up the disabled interfaces by running the <b>clear-ethernet-switch-port</b> command.</li> </ul>
<b>Required Privilege Level</b>	<p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">mac-limit on page 4617</a></li> <li>• <a href="#">Example: Configuring Basic Port Security Features on page 4488</a></li> <li>• <a href="#">Configuring MAC Move Limiting (CLI Procedure) on page 4547</a></li> <li>• <a href="#">Configuring Autorecovery From the Disabled State on Secure or Storm Control Interfaces (CLI Procedure)</a></li> </ul>

## no-allowed-mac-log

---

<b>Syntax</b>	no-allowed-mac-log;
<b>Hierarchy Level</b>	<ul style="list-style-type: none"><li>For platforms without ELS: [edit <a href="#">ethernet-switching-options secure-access-port interface</a> (all   <i>interface-name</i>)]</li><li>For platforms with ELS: [edit switch-options interface <i>interface-name</i>]</li></ul>
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Specify that the switch should not log messages when it receives packets from invalid MAC addresses on an interface that has been configured for allowed MAC addresses.
<b>Default</b>	The switch logs messages when it receives packets from invalid MAC addresses on an interface that has been configured for particular allowed (specific) MAC addresses.
<b>Required Privilege Level</b>	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li><a href="#">Understanding MAC Limiting and MAC Move Limiting for Port Security on page 4465</a></li><li><a href="#">Configuring MAC Limiting on page 4545</a></li><li><a href="#">allowed-mac on page 4605</a></li><li><a href="#">mac-limit on page 4617</a></li></ul>

## no-gratuitous-arp-request

---

<b>Syntax</b>	no-gratuitous-arp-request;
<b>Hierarchy Level</b>	[edit <a href="#">interfaces interface-name</a> ], [edit <a href="#">interfaces interface-range interface-name</a> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Configure the switch not to respond to gratuitous ARP requests. You can disable responses to gratuitous ARP requests on both Layer 2 Ethernet switching interfaces and routed VLAN interfaces (RVIs).
<b>Default</b>	Gratuitous ARP responses are enabled on all Ethernet switching interfaces and RVIs.
<b>Required Privilege Level</b>	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li><a href="#">Configuring Routed VLAN Interfaces on page 1532</a></li></ul>

## persistent-learning

---

<b>Syntax</b>	<code>persistent-learning;</code>
<b>Hierarchy Level</b>	<ul style="list-style-type: none"> <li>For platforms without ELS: [edit ethernet-switching-options secure-access-port interface (all   <i>interface-name</i>)]</li> <li>For platforms with ELS: [edit switch-options interface <i>interface-name</i>]</li> </ul>
<b>Release Information</b>	<p>Statement introduced in Junos OS Release 11.4 for EX Series switches.</p> <p>Statement introduced in Junos OS Release 12.1 for the QFX Series.</p> <p>Hierarchy level [edit switch-options interface <i>interface-name</i>] introduced in Junos OS Release 13.2X50-D10</p>
<b>Description</b>	Specify that learned MAC addresses persist on the specified interfaces across restarts of the switch and link-down conditions. This feature is also known as sticky MAC.
<b>Required Privilege Level</b>	<p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li><a href="#">Example: Configuring Basic Port Security Features on page 4488</a></li> <li><i>Configuring Persistent MAC Learning (CLI Procedure)</i></li> <li><i>Configuring Persistent MAC Learning (CLI Procedure)</i></li> </ul>

## port-error-disable

---

<b>Syntax</b>	<pre>port-error-disable {     (disable-timeout seconds   recovery-timeout seconds); }</pre>
<b>Hierarchy Level</b>	<ul style="list-style-type: none"><li>For platforms without ELS: [edit <a href="#">ethernet-switching-options</a>]</li><li>For platforms with ELS: [edit switch-options ]</li></ul>
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 on the QFX Series.
<b>Description</b>	Disable rather than block an interface when enforcing MAC limiting, MAC move limiting, and storm control, and allow the interface to recover automatically from the error condition after a specified period of time:
	<div> <b>NOTE:</b> The <code>port-error-disable</code> configuration does not apply to preexisting error conditions. It affects only error conditions that are detected after you enable and commit the <code>port-error-disable</code> statement. To clear a preexisting error condition and restore the interface to service, use the <a href="#">clear ethernet-switching port-error</a> command.</div>
	<ul style="list-style-type: none"><li>If you enable the <a href="#">mac-limit</a> statement with the <code>shutdown</code> option and also enable the <code>port-error-disable</code> statement, the switch disables (rather than shuts down) the interface when the MAC address limit is reached.</li><li>If you have enabled the <a href="#">mac-move-limit</a> statement with the <code>shutdown</code> option and you enable the <code>port-error-disable</code> statement, the switch disables (rather than shuts down) the interface when the maximum number of moves to a new interface is reached.</li><li>If you enable the <a href="#">storm-control</a> statement with the <code>action-shutdown</code> option and you also enable <code>port-error-disable</code>, the switch disables (rather than shuts down) the interface when broadcast traffic and unknown unicast traffic exceed the specified levels.</li></ul>
<b>Default</b>	Not enabled.
<b>Required Privilege Level</b>	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li><a href="#">Understanding MAC Limiting and MAC Move Limiting for Port Security on page 4465</a></li><li><a href="#">Understanding Storm Control on page 4471</a></li><li><a href="#">Example: Configuring Storm Control to Prevent Network Outages on page 4527</a></li></ul>

## vendor-id

---

<b>Syntax</b>	<code>vendor-id &lt;string&gt;;</code>
<b>Hierarchy Level</b>	<ul style="list-style-type: none"><li>For platforms with ELS: [edit vlans <i>vlan-name</i> forwarding-options <a href="#">dhcp-security option-82</a>]</li><li>For platforms without ELS: [edit ethernet-switching-options secure-access-port vlan (all   <i>vlan-name</i>) <a href="#">dhcp-option82</a>], [edit forwarding-options helpers bootp <a href="#">dhcp-option82</a>], [edit forwarding-options helpers bootp interface <i>interface-name</i> <a href="#">dhcp-option82</a>]</li></ul>
<b>Release Information</b>	<p>Statement introduced in Junos OS Release 9.3 for EX Series switches. Statement introduced in Junos OS Release 11.3 for the QFX Series. Hierarchy level [edit vlans <i>vlan-name</i> forwarding-options <a href="#">dhcp-security</a>] introduced in Junos OS Release 13.2X50-D10. (See <a href="#">“Getting Started with Enhanced Layer 2 Software” on page 58</a> for information about ELS.)</p>
<b>Description</b>	Insert a vendor ID in the DHCP option 82 information in a DHCP request packet header before forwarding or relaying the request to a DHCP server.
<b>Default</b>	If <b>vendor-id</b> is not explicitly configured for DHCP option 82, then no vendor ID is set.
<b>Options</b>	<p><b>string</b>—(Optional) A single string that designates the vendor ID.</p> <p><b>Range:</b> 1–255 characters</p> <p><b>Default:</b> If you specify <b>vendor-id</b> with no <b>string</b> value, then the default vendor ID <b>Juniper Networks</b> is configured.</p>
<b>Required Privilege Level</b>	<p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"><li><a href="#">Example: Setting Up DHCP Option 82 with a Switch with No Relay Agent Between Clients and a DHCP Server on page 4521</a></li><li><a href="#">Example: Setting Up DHCP Option 82 with a Switch as a Relay Agent Between Clients and a DHCP Server on page 4525</a></li><li><a href="#">Setting Up DHCP Option 82 on the Switch with No Relay Agent Between Clients and DHCP Server (CLI Procedure) on page 4557</a></li><li><a href="#">Setting Up DHCP Option 82 on the Switch with No Relay Agent Between Clients and DHCP Server (CLI Procedure)</a></li><li><a href="#">Setting Up DHCP Option 82 with the Switch as a Relay Agent Between Clients and DHCP Server (CLI Procedure) on page 4560</a></li></ul>

## write-interval

<b>Syntax</b>	<code>write-interval <i>seconds</i>;</code>
<b>Hierarchy Level</b>	For platforms without ELS:  [edit <a href="#">ethernet-switching-options secure-access-port dhcp-snooping-file</a> ]  For platforms with ELS:  [edit <a href="#">system processes</a> ] <a href="#">dhcp-service</a> <a href="#">dhcp-snooping-file</a> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 12.1 for the QFX Series.
<b>Description</b>	Specify how frequently the switch writes the database entries from memory into the specified DHCP snooping database file.
<b>Default</b>	None
<b>Options</b>	<b><i>seconds</i></b> —Value in seconds. <b>Range:</b> 60 through 86400
<b>Required Privilege Level</b>	<b>routing</b> —To view this statement in the configuration. <b>routing-control</b> —To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Understanding DHCP Snooping for Port Security on page 4456</a></li> </ul>

## allowed-mac

<b>Syntax</b>	<code>allowed-mac mac-address-list</code>
<b>Hierarchy Level</b>	[edit <a href="#">ethernet-switching-options secure-access-port interface</a> (all   <i>interface-name</i> )]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Specify particular MAC addresses to be added to the MAC address cache.

**NOTE:** Although this configuration restricts the addresses that can be added to the MAC address cache, it does not block the switch from receiving Layer 2 control packets—such as Link Layer Discovery Protocol (LLDP) packets—transmitted from MAC addresses that are not specified in the list of allowed MAC addresses. Control packets do not undergo the MAC address check, and they are therefore included in the statistics of packets received, though, they are not forwarded to another destination.

<b>Default</b>	Allowed MAC addresses take precedence over dynamic MAC values. For example, if the <b>mac-limit</b> statement is set to four and three allowed MACs are configured, only one dynamic MAC can be learned on that interface.
<b>Options</b>	<b>mac-address-list</b> —One or more MAC addresses configured as allowed MAC addresses for a specified interface or all interfaces.
<b>Required Privilege Level</b>	routing—To view this statement in the configuration. routing—control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Understanding MAC Limiting and MAC Move Limiting for Port Security on page 4465</a></li> <li>• <a href="#">Configuring MAC Limiting on page 4545</a></li> <li>• <a href="#">Configuring MAC Move Limiting (CLI Procedure) on page 4547</a></li> <li>• <a href="#">mac-limit on page 4617</a></li> <li>• <a href="#">no-allowed-mac-log on page 4598</a></li> </ul>

## arp-inspection

---

<b>Syntax</b>	(arp-inspection   no-arp-inspection) { forwarding-class (for DHCP Snooping or DAI Packets) <i>class-name</i> ; }
<b>Hierarchy Level</b>	[edit] <b>ethernet-switching-options secure-access-port vlan</b> (all   <i>vlan-name</i> )
<b>Release Information</b>	Statement introduced in Junos OS Release 12.1 for the QFX Series.
<b>Description</b>	Perform dynamic ARP inspection on all VLANs or on the specified VLAN. <ul style="list-style-type: none"><li>• <b>arp-inspection</b>—Enable ARP inspection.</li></ul> <div> <b>NOTE:</b> When ARP inspection is enabled, the switch logs ARP request packets that it rejects.</div> <ul style="list-style-type: none"><li>• <b>no-arp-inspection</b>—Disable ARP inspection.</li></ul>
<b>Default</b>	Disabled.
<b>Required Privilege Level</b>	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Enabling Dynamic ARP Inspection (CLI Procedure) on page 4553</a></li><li>• <a href="#">Example: Configuring Basic Port Security Features on page 4488</a><a href="#">Example: Configuring DHCP Snooping, DAI, and MAC Limiting on a Switch with Access to a DHCP Server Through a Second Switch on page 4506</a></li><li>• <a href="#">Example: Configuring DHCP Snooping and DAI to Protect the Switch from ARP Spoofing Attacks on page 4513</a></li></ul>

---

## dhcp-trusted

---

<b>Syntax</b>	(dhcp-trusted   no-dhcp-trusted);
<b>Hierarchy Level</b>	[edit ethernet-switching-options secure-access-port interface (Access Port Security) (all   <i>interface-name</i> )]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Allow or deny DHCP responses from the specified interfaces (ports) or all interfaces. <ul style="list-style-type: none"><li>• <b>dhcp-trusted</b>—Allow DHCP responses.</li><li>• <b>no-dhcp-trusted</b>—Deny DHCP responses.</li></ul>
<b>Default</b>	Trusted for trunk ports, untrusted for access ports.
<b>Required Privilege Level</b>	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Overview of Access Port Protection on page 4451</a></li><li>• <a href="#">Enabling a Trusted Port for DHCP on page 4556</a></li></ul>

## dhcp-option82

---

<b>Syntax</b>	<pre>dhcp-option82 {   circuit-id {     prefix hostname;     use-interface-description;     use-vlan-id;   }   remote-id {     prefix hostname   mac   none;     use-interface-description;     use-string string;   }   vendor-id &lt;string&gt;; }</pre>
<b>Hierarchy Level</b>	<p>[edit ethernet-switching-options secure-access-port vlan (all   <i>vlan-name</i>)]</p> <p>[edit forwarding-options helpers bootp]</p> <p>[edit forwarding-options helpers bootp interface <i>interface-name</i>]</p>
<b>Release Information</b>	<p>Statement introduced in Junos OS Release 9.3 for EX Series switches.</p> <p>Statement introduced in Junos OS Release 11.3 for the QFX Series.</p>
<b>Description</b>	<p>When the switch receives a DHCP request from a DHCP client connected on one of the switch's interfaces, have the switch insert DHCP option 82 (also known as the DHCP relay agent information option) information in the DHCP request packet header before it forwards or relays the request to a DHCP server. The server uses the option 82 information, which provides details about the circuit and host the request came from, in formulating the reply; the server does not, however, make any changes to the option 82 information in the packet header. The switch receives the reply and then removes the DHCP option 82 information before forwarding the reply to the client.</p> <p>The remaining statements are explained separately.</p>
<b>Default</b>	Insertion of DHCP option 82 information is not enabled.
<b>Required Privilege Level</b>	<p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Example: Setting Up DHCP Option 82 with a Switch with No Relay Agent Between Clients and a DHCP Server on page 4521</a></li><li>• <a href="#">Example: Setting Up DHCP Option 82 with a Switch as a Relay Agent Between Clients and a DHCP Server on page 4525</a></li><li>• <a href="#">Setting Up DHCP Option 82 on the Switch with No Relay Agent Between Clients and DHCP Server (CLI Procedure) on page 4557</a></li><li>• <a href="#">Setting Up DHCP Option 82 with the Switch as a Relay Agent Between Clients and DHCP Server (CLI Procedure) on page 4560</a></li><li>• <a href="#">[edit forwarding-options] Configuration Statement Hierarchy on EX Series Switches</a></li></ul>

- RFC 3046, *DHCP Relay Agent Information Option*, at <http://tools.ietf.org/html/rfc3046>.

## disable-timeout (Port Error Disable)

<b>Syntax</b>	<code>disable-timeout <i>timeout</i>;</code>
<b>Hierarchy Level</b>	[edit <a href="#">ethernet-switching-options port-error-disable</a> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Specify how long Ethernet switching interfaces remain in a disabled state due to MAC limiting, MAC move limiting, or storm control errors.
<div>  <p><b>NOTE:</b> If you modify an existing timeout value, the new timeout value does not affect currently disabled interfaces are configured for automatic recovery. The new timeout value applies only to subsequent port errors. Run the <a href="#">clear ethernet-switching port-error</a> command to restore currently disabled interfaces.</p> </div>	
<b>Default</b>	The disable timeout statement is not enabled.
<b>Options</b>	<p><b><i>timeout</i></b>—Time, in seconds, that an interface remains disabled. The disabled interface automatically returns to service when the specified time expires.</p> <p><b>Range:</b> 10 through 3600 seconds</p>
<b>Required Privilege Level</b>	<p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Understanding MAC Limiting and MAC Move Limiting for Port Security on page 4465</a></li> <li>• <a href="#">Understanding Storm Control on page 4471</a></li> <li>• <a href="#">Example: Configuring Storm Control to Prevent Network Outages on page 4527</a></li> <li>• <a href="#">Configuring Autorecovery for MAC Limited or Storm Control Interfaces (CLI Procedure) on page 4549</a></li> <li>• <a href="#">action-shutdown on page 4650</a></li> </ul>

## forwarding-class (for DHCP Snooping or DAI Packets)

---

<b>Syntax</b>	forwarding-class class <i>class-name</i> ;
<b>Hierarchy Level</b>	[edit ethernet-switching-options secure-access-port vlan (all   <i>vlan-name</i> ) (examine-dhcp   <a href="#">arp-inspection</a> )]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.2 for EX Series switches. Statement introduced in Junos OS Release 12.1 for the QFX Series.
<b>Description</b>	Assign a user-defined or a predefined forwarding class to the packets that have been checked for DHCP snooping or dynamic ARP inspection (DAI).
<div> <b>NOTE:</b> To assign a user-defined class, you must first configure the user-defined class by using the <i>forwarding-classes</i> configuration statement at the [edit <i>class-of-service</i>] hierarchy level.</div>	
<b>Default</b>	Disabled.
<b>Options</b>	<i>class-name</i> —Name of the forwarding class. The forwarding class can be one of the predefined forwarding classes (best-effort, assured-forwarding, expedited-forwarding, network-control) or it can be a user-defined forwarding class.
<b>Required Privilege Level</b>	system—To view this statement in the configuration. system-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <i>Example: Using CoS Forwarding Classes to Prioritize Snooped Packets in Heavy Network Traffic</i></li><li>• <i>Understanding Junos OS CoS Components for EX Series Switches</i></li><li>• <a href="#">Understanding DHCP Snooping for Port Security on page 4456</a></li><li>• <a href="#">Understanding DAI for Port Security on page 4463</a></li></ul>

## interface (Secure Access Port)

<b>Syntax</b>	<pre> interface (all   <i>interface-name</i>) {   allowed-mac <i>mac-address-list</i>;   (dhcp-trusted   no-dhcp-trusted);   mac-limit <i>limit</i> action <i>action</i>;   no-allowed-mac-log;   static-ip <i>ip-address</i> {     vlan <i>vlan-name</i>;     mac <i>mac-address</i>;   } } </pre>
<b>Hierarchy Level</b>	[edit <a href="#">ethernet-switching-options secure-access-port</a> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	<p>Apply port security features to all interfaces or to the specified interface.</p> <p>The remaining statements are explained separately.</p>
<b>Options</b>	<p><b>all</b>—Apply port security features to all interfaces. Does not apply to QFabric systems.</p> <p><b><i>interface-name</i></b>—Apply port security features to the specified interface.</p>
<b>Required Privilege Level</b>	<p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Overview of Access Port Protection on page 4451</a></li> <li>• <a href="#">Understanding MAC Limiting and MAC Move Limiting for Port Security on page 4465</a></li> <li>• <a href="#">Understanding Trusted and Untrusted Ports on page 4467</a></li> <li>• <a href="#">Configuring MAC Limiting on page 4545</a></li> <li>• <a href="#">Enabling a Trusted Port for DHCP on page 4556</a></li> </ul>

## location

---

<b>Syntax</b>	<code>location <i>local_pathname</i>   <i>remote_URL</i>;</code>
<b>Hierarchy Level</b>	[edit <a href="#">ethernet-switching-options secure-access-port dhcp-snooping-file</a> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 12.1 for the QFX Series.
<b>Description</b>	Specify either a local pathname or a remote URL as the location in which to store the DHCP snooping database.
<b>Options</b>	<p><i>local_pathname</i>   <i>remote_URL</i> —Location for storing the DHCP snooping database.</p> <ul style="list-style-type: none"><li>• <i>local_pathname</i> —Use <i>/path</i> to store the database on a local switch.</li><li>• <i>remote_URL</i> —Use <code>ftp://ip-address</code> or <code>ftp://hostname/path</code> to store the database at a remote location.</li></ul>
<b>Required Privilege Level</b>	<p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>

## mac

---

<b>Syntax</b>	<code>mac <i>mac-address</i>;</code>
<b>Hierarchy Level</b>	[edit <a href="#">ethernet-switching-options secure-access-port</a> interface (Access Port Security) (all   <i>interface-name</i> ) <a href="#">static-ip ip-address</a> vlan (DHCP Bindings on Access Ports) <i>vlan-name</i> ] [edit vlans <i>vlan-name</i> forwarding-options <a href="#">dhcp-security group group-name</a> <a href="#">interface interface-name static-ip ip-address</a> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 on the QFX Series switches.
<b>Description</b>	Specify a media access control (MAC) address (hardware address) for the specified static IP address.
<b>Options</b>	<i>mac-address</i> —Value in hexadecimal format.
<b>Required Privilege Level</b>	<p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>

## mac-limit

<b>Syntax</b>	<code>mac-limit <i>limit</i> {     &lt;action <i>action</i>&gt;; }</code>
<b>Hierarchy Level</b>	[edit <a href="#">ethernet-switching-options secure-access-port interface</a> (all   <i>interface-name</i> )]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Specify the number of MAC addresses that can be dynamically added to the MAC address cache for this access interface (port) and the action to be taken if the limit is exceeded.
<b>Default</b>	The default action is <b>drop</b> .
<b>Options</b>	<p><i>limit</i>—Maximum number of MAC addresses.</p> <p><i>action action</i>—(Optional) Action to take when the MAC address limit is exceeded:</p> <ul style="list-style-type: none"> <li>• <b>drop</b>—Drop the packet and generate a system log entry. This is the default.</li> <li>• <b>log</b>—Do not drop the packet but generate a system log entry.</li> <li>• <b>none</b>—No action.</li> <li>• <b>shutdown</b>—Disable the interface and generate an alarm. If you configure the switch with the <a href="#">port-error-disable</a> statement, the disabled interface recovers automatically upon expiration of the specified timeout. If this statement is not configured, you can bring up the disabled interfaces by running the <a href="#">clear ethernet-switching port-error</a> command.</li> </ul>
<b>Required Privilege Level</b>	<p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Understanding MAC Limiting and MAC Move Limiting for Port Security on page 4465</a></li> <li>• <a href="#">Configuring MAC Limiting on page 4545</a></li> <li>• <a href="#">allowed-mac on page 4605</a></li> </ul>

## no-dhcp-trusted

---

<b>Syntax</b>	(dhcp-trusted   no-dhcp-trusted);
<b>Hierarchy Level</b>	[edit <a href="#">ethernet-switching-options secure-access-port</a> interface (Access Port Security) (all   <i>interface-name</i> )]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	<p>Port security features, such as DHCP snooping and dynamic ARP inspection inspect packets only on untrusted interfaces.</p> <p>Allow or deny DHCP responses from the specified interfaces (ports) or all interfaces.</p> <ul style="list-style-type: none"><li>• <b>dhcp-trusted</b>—Allow DHCP responses.</li><li>• <b>no-dhcp-trusted</b>—Deny DHCP responses.</li></ul>
<b>Default</b>	Trusted for trunk ports, untrusted for access ports.
<b>Required Privilege Level</b>	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Overview of Access Port Protection on page 4451</a></li><li>• <a href="#">Enabling a Trusted Port for DHCP on page 4556</a></li></ul>

## prefix (Remote ID for Option 82)

<b>Syntax</b>	prefix hostname   mac   none;
<b>Hierarchy Level</b>	<p>[edit ethernet-switching-options secure-access-port vlan (all   <i>vlan-name</i>) <b>dhcp-option82 remote-id</b>]</p> <p>[edit forwarding-options helpers bootp <b>dhcp-option82 remote-id</b>]</p> <p>[edit forwarding-options helpers bootp interface <i>interface-name</i> <b>dhcp-option82 remote-id</b>]</p>
<b>Release Information</b>	<p>Statement introduced in Junos OS Release 9.3 for EX Series switches.</p> <p>Statement introduced in Junos OS Release 12.1 for the QFX Series.</p>
<b>Description</b>	Configure an optional prefix for the remote ID suboption in the DHCP option 82 information that is inserted by the switch into the packet header of a DHCP request before it forwards or relays the request to a DHCP server.
<b>Default</b>	If <b>prefix</b> is not explicitly specified, no prefix is appended to the remote ID.
<b>Options</b>	<p><b>hostname</b>—Name of the host system (the switch) that is forwarding or relaying the DHCP request from the DHCP client to the DHCP server.</p> <p><b>mac</b>—MAC address of the host system (the switch) that is forwarding or relaying the DHCP request from the DHCP client to the DHCP server.</p> <p><b>none</b>—No prefix is applied to the remote ID.</p>
<b>Required Privilege Level</b>	<p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Example: Setting Up DHCP Option 82 with a Switch with No Relay Agent Between Clients and a DHCP Server on page 4521</a></li> <li>• <a href="#">Example: Setting Up DHCP Option 82 with a Switch as a Relay Agent Between Clients and a DHCP Server on page 4525</a></li> <li>• <a href="#">Setting Up DHCP Option 82 on the Switch with No Relay Agent Between Clients and DHCP Server (CLI Procedure) on page 4557</a></li> <li>• <a href="#">Setting Up DHCP Option 82 with the Switch as a Relay Agent Between Clients and DHCP Server (CLI Procedure) on page 4560</a></li> <li>• <a href="#">[edit forwarding-options] Configuration Statement Hierarchy on EX Series Switches</a></li> <li>• RFC 3046, <i>DHCP Relay Agent Information Option</i>, at <a href="http://tools.ietf.org/html/rfc3046">http://tools.ietf.org/html/rfc3046</a>.</li> </ul>

## remote-id

---

<b>Syntax</b>	<pre>remote-id {     host-name <i>host-name</i>;     prefix hostname   mac   none;   host     use-interface-description;     use-string <i>string</i>; }</pre>
<b>Hierarchy Level</b>	<ul style="list-style-type: none"><li>For platforms with ELS: [edit vlans <i>vlan-name</i> forwarding-options <b>dhcp-security option-82</b> ]</li><li>For platforms without ELS: [edit ethernet-switching-options secure-access-port vlan (all   <i>vlan-name</i>) <b>dhcp-option82</b>], [edit forwarding-options helpers bootp <b>dhcp-option82</b>], [edit forwarding-options helpers bootp interface <i>interface-name</i> <b>dhcp-option82</b>]</li></ul>
<b>Release Information</b>	<p>Statement introduced in Junos OS Release 9.3 for EX Series switches. Statement introduced in Junos OS Release 11.3 for the QFX Series. Hierarchy level [edit vlans <i>vlan-name</i> forwarding-options <b>dhcp-security option-82</b>] introduced in Junos OS Release 13.2X50-D10. (See <a href="#">“Getting Started with Enhanced Layer 2 Software” on page 58</a> for information about ELS.)</p>
<b>Description</b>	<p>Insert the <b>remote-id</b> suboption of DHCP option 82 (also known as the DHCP relay agent information option) in DHCP request packet headers before forwarding or relaying requests to a DHCP server. This suboption provides a trusted identifier for the host system that has forwarded or relayed requests to the server.</p> <p>The remaining statements are explained separately, and their availability depends on the hierarchy level at which <b>remote-id</b> is specified, as follows:</p> <ul style="list-style-type: none"><li>The statement <b>prefix</b> is <i>not</i> supported at the [edit vlans <i>vlan-name</i> forwarding-options <b>dhcp-security option-82</b>] hierarchy level.</li><li>The statement <b>host-name</b> is supported <i>only</i> at the [edit vlans <i>vlan-name</i> forwarding-options <b>dhcp-security option-82</b>] hierarchy level.</li></ul>
<b>Default</b>	<p>If <b>remote-id</b> is not explicitly set, no remote ID value is inserted in the DHCP request packet header.</p> <p>If <b>remote-id</b> is explicitly set, but is not qualified by a keyword:</p> <ul style="list-style-type: none"><li>At the [edit vlans <i>vlan-name</i> forwarding-options <b>dhcp-security</b>] hierarchy level, the default keyword value is <i>interface-name</i>.</li><li>At all other hierarchy levels, the <b>remote-id</b> default keyword value of is the MAC address of the switch.</li></ul>
<b>Required Privilege Level</b>	<p>system—To view this statement in the configuration. system-control—To add this statement to the configuration.</p>

## timeout (DHCP Snooping)

---

<b>Syntax</b>	timeout <i>seconds</i> ;
<b>Hierarchy Level</b>	[edit <a href="#">ethernet-switching-options secure-access-port dhcp-snooping-file</a> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Specify a timeout value for remote read and write operations. This value determines the amount of time that the switch waits for a remote system to respond when the DHCP snooping database is stored on a remote FTP site.
<b>Default</b>	None
<b>Options</b>	<i>seconds</i> —Value in seconds. <b>Range:</b> 10 through 3600
<b>Required Privilege Level</b>	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Understanding DHCP Snooping for Port Security on page 4456</a></li></ul>

## use-interface-description

<b>Syntax</b>	<code>use-interface-description;</code>
<b>Hierarchy Level</b>	<ul style="list-style-type: none"> <li>For platforms with ELS:  <code>[edit vlans <i>vlan-name</i> forwarding-options <b>dhcp-security option-82 circuit-id</b>]</code></li> <li>For platforms without ELS:  <code>[edit ethernet-switching-options secure-access-port vlan (all   <i>vlan-name</i>) <b>dhcp-option82 circuit-id</b>],</code>  <code>[edit forwarding-options helpers bootp <b>dhcp-option82 circuit-id</b>],</code>  <code>[edit forwarding-options helpers bootp interface <i>interface-name</i> <b>dhcp-option82 circuit-id</b>],</code>  <code>[edit ethernet-switching-options secure-access-port vlan (all   <i>vlan-name</i>) <b>dhcp-option82 remote-id</b>],</code>  <code>[edit forwarding-options helpers bootp <b>dhcp-option82 remote-id</b>],</code>  <code>[edit forwarding-options helpers bootp interface <i>interface-name</i> <b>dhcp-option82 remote-id</b>]</code></li> </ul>
<b>Release Information</b>	<p>Statement introduced in Junos OS Release 9.3 for EX Series switches.</p> <p>Statement introduced in Junos OS Release 11.3 for the QFX Series.</p> <p>Hierarchy level <code>[edit vlans <i>vlan-name</i> forwarding-options <b>dhcp-security</b>]</code> introduced in Junos OS Release 13.2X50-D10. (See “<a href="#">Getting Started with Enhanced Layer 2 Software</a>” on page 58 for information about ELS.)</p>
<b>Description</b>	Use the interface description rather than the interface name (which is the default value) in the circuit ID or remote ID value in the DHCP option 82 information.
<b>Required Privilege Level</b>	<p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li><a href="#">Example: Setting Up DHCP Option 82 with a Switch with No Relay Agent Between Clients and a DHCP Server on page 4521</a></li> <li><a href="#">Example: Setting Up DHCP Option 82 with a Switch as a Relay Agent Between Clients and a DHCP Server on page 4525</a></li> <li><a href="#">Setting Up DHCP Option 82 on the Switch with No Relay Agent Between Clients and DHCP Server (CLI Procedure) on page 4557</a></li> <li><a href="#">Setting Up DHCP Option 82 with the Switch as a Relay Agent Between Clients and DHCP Server (CLI Procedure) on page 4560</a></li> <li><a href="#">Setting Up DHCP Option 82 on the Switch with No Relay Agent Between Clients and DHCP Server (CLI Procedure)</a></li> <li>RFC 3046, <i>DHCP Relay Agent Information Option</i>, at <a href="http://tools.ietf.org/html/rfc3046">http://tools.ietf.org/html/rfc3046</a>.</li> </ul>

## use-string

---

<b>Syntax</b>	<code>use-string <i>string</i>;</code>
<b>Hierarchy Level</b>	<ul style="list-style-type: none"><li>For platforms with ELS: <code>[edit vlans <i>vlan-name</i> forwarding-options <b>dhcp-security option-82 remote-id</b>]</code></li><li>For platforms without ELS: <code>[edit ethernet-switching-options secure-access-port vlan (all   <i>vlan-name</i>) <b>dhcp-option82 remote-id</b>],</code> <code>[edit forwarding-options helpers bootp <b>dhcp-option82 remote-id</b>],</code> <code>[edit forwarding-options helpers bootp interface <i>interface-name</i> <b>dhcp-option82 remote-id</b>]</code></li></ul>
<b>Release Information</b>	<p>Statement introduced in Junos OS Release 9.3 for EX Series switches.</p> <p>Statement introduced in Junos OS Release 11.3 for the QFX Series.</p> <p>Hierarchy level <code>[edit vlans <i>vlan-name</i> forwarding-options <b>dhcp-security</b>]</code> introduced in Junos OS Release 13.2X50-D10. (See <a href="#">“Getting Started with Enhanced Layer 2 Software” on page 58</a> for information about ELS.)</p>
<b>Description</b>	Use a string rather than the MAC address of the host system (the default) in the remote ID value in the DHCP option 82 information.
<b>Options</b>	<p><b>string</b>—Character string used as the remote ID value.</p> <p><b>Range:</b> 1–255 characters</p>
<b>Required Privilege Level</b>	<p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>

 vendor-id {
 use-string string;
 }
 }
 }
```

**Hierarchy Level** [edit vlans *vlan-name* forwarding-options]

**Release Information** Statement introduced in Junos OS Release 13.2X50-D10 for EX Series switches.  
Statement introduced in Junos OS Release 13.2 for the QFX series.

**Description** Configure port security features on the switch. DHCP snooping is enabled automatically if you configure any of the following port security features within this hierarchy:

- Dynamic ARP inspection (DAI)
- IP source guard
- DHCP option 82

- Static IP

For switches that support DHCPv6, both DHCP snooping and DHCPv6 snooping are enabled automatically if you configure any of the features listed above or any of the following IPv6 features:

- IPv6 Neighbor Discovery inspection
- IPv6 source guard
- Static IPv6

**NOTE:** On EX9200 switches, DHCP snooping, DAI, and IP source guard are not supported in an MC-LAG scenario.

---

The remaining statements are explained separately.

**Required Privilege  
Level**

interface—To view this statement in the configuration.  
interface-control—To add this statement to the configuration.

## dhcp-service

---

<b>Syntax</b>	<pre>dhcp-service {   dhcp-snooping-file (<i>local_pathname</i>   <i>remote_URL</i>);   write-interval <i>interval</i>; }</pre>
<b>Hierarchy Level</b>	[edit system processes]
<b>Release Information</b>	Statement introduced in Junos OS Release 13.2X50-D10 for EX Series switches. Statement introduced in Junos OS Release 13.2 for the QFX Series.
<b>Description</b>	<p>Enable DHCP services on the switch. DHCP services automate network-parameter assignment to network devices. The DHCP service process is enabled by default on your switch. However, by default, IP-MAC bindings in the DHCP snooping database do not persist. You can configure the IP-MAC bindings in the DHCP database to persist through switch reboots by configuring a storage location for the DHCP database file. When specifying the location for the DHCP database, you must also specify how frequently the switch writes the database entries into the DHCP snooping database file.</p> <p>The remaining statements are explained separately.</p>
<b>Required Privilege Level</b>	<p>admin—To view this statement in the configuration.</p> <p>admin-control—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li><i>Configuring Persistent Bindings in the DHCP or DHCPv6 Snooping Database (CLI Procedure)</i></li> </ul>

## group (DHCP Security)

---

**Syntax**    `group group-name {  
              interface interface-name {  
                  static-ip ip-address {  
                      mac mac-address;  
                  }  
              static-ipv6 ip-address {  
                  mac mac-address;  
              }  
              }  
              overrides {  
                  no-option37;  
                  no-option-82;  
                  trusted;  
                  untrusted;  
              }  
          }`

**Hierarchy Level**    [edit vlans *vlan-name* forwarding-options [dhcp-security](#)]

**Release Information**    Statement introduced in Junos OS Release 13.2X50-D10 for EX Series switches.  
Statement introduced in Junos OS Release 13.2 for the QFX series.  
Support for the **static-ipv6** and **no-option37** statements introduced in Junos OS Release 13.2X51-D20 for EX Series switches.

**Description**    Specify the name of a group of access interfaces that you want to configure for DHCP security attributes that are different from the attributes set for other interfaces in the VLAN. A group must contain at least one interface. The remaining statements are explained separately.

**Required Privilege Level**    interface—To view this statement in the configuration.  
                                  interface-control—To add this statement to the configuration.

                          [edit switch-options interface *interface-name*],  
                          [edit vlans *vlan-name* switch-options],  
                          [edit vlans *vlan-name* switch-options interface *interface-name*]

**Release Information**    Statement introduced in Junos OS Release 8.4.  
                              Support for the **switch-options** statement added in Junos OS Release 9.2.  
                              Support for top-level configuration for the **virtual-switch** type of routing instance added  
                              in Junos OS Release 9.2. In Junos OS Release 9.1 and earlier, the routing instances hierarchy  
                              supported this statement only for a VPLS instance or a bridge domain configured within  
                              a virtual switch.  
                              Support for logical systems added in Junos OS Release 9.6.  
                              Support at [edit switch-options], [edit switch-options interface *interface-name*], [edit  
                              vlans *vlan-name* switch-options], and [edit vlans *vlan-name* switch-options interface  
                              *interface-name*] hierarchy levels introduced in Junos OS Release 12.3R2 for EX Series  
                              switches.  
                              Support at hierarchy levels under [edit vlans *vlan-name*] introduced in Junos OS Release  
                              13.2X50-D10 for EX Series switches.  
                              Statement introduced in Junos OS Release 13.2 for the QFX Series.

<b>Description</b>	(MX Series routers, EX Series switches, and the QFX Series) Configure a limit to the number of MAC addresses that can be learned from a bridge domain or VLAN, virtual switch, or set of bridge domains or VLANs.
<b>Default</b>	All devices except the EX Series switches: 1024 MAC addresses for each logical interface; EX Series switches: 65,536 MAC addresses for each interface and VLAN.
<b>Options</b>	<p><b>limit</b>—Maximum number of MAC addresses learned from an interface.</p> <p><b>Range:</b> 1 through 131,071 MAC addresses per interface, or 1 through 65,535 MAC addresses per interface</p> <p>The remaining statement is explained separately.</p>
<b>Required Privilege Level</b>	<p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <i>Layer 2 Learning and Forwarding for Bridge Domains Overview</i></li><li>• <a href="#">Layer 2 Learning and Forwarding for VLANs Overview on page 1401</a></li><li>• <i>Layer 2 Learning and Forwarding for Bridge Domains Functioning as Switches with Layer 2 Trunk Ports</i></li><li>• <a href="#">Configuring MAC Limiting (CLI Procedure) on page 1539</a></li></ul>

## no-dhcp-snooping

---

<b>Syntax</b>	no-dhcp-snooping;
<b>Hierarchy Level</b>	[edit vlans <i>vlan-name</i> forwarding-options <a href="#">dhcp-security</a> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 13.2X50-D10 for EX Series switches. Statement introduced in Junos OS Release 13.2 for the QFX series.
<b>Description</b>	Disable DHCP snooping for the specified VLAN.

**NOTE:** Explicitly disabling DHCP snooping also disables any other port security features that you have enabled under [edit vlans *vlan-name* forwarding-options [dhcp-security](#)], including dynamic ARP inspection (DAI) and IP source guard for the specified VLAN.

There is no configuration statement that explicitly enables DHCP snooping.

---

<b>Default</b>	DHCP snooping is not enabled.
----------------	-------------------------------

**NOTE:** Junos OS for EX Series switches with support for the Enhanced Layer 2 Software (ELS) configuration style does not have a configuration statement that explicitly enables DHCP snooping.

DHCP snooping is enabled automatically by Junos OS if any of the following is configured at the [edit vlans *vlan-name* forwarding-options [dhcp-security](#)] hierarchy level:

- DAI
- IP source guard
- Static IP
- DHCP option 82

---

<b>Required Privilege Level</b>	system—To view this statement in the configuration. system-control—To add this statement to the configuration.
---------------------------------	-------------------------------------------------------------------------------------------------------------------

<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Understanding DHCP Snooping for Port Security on page 4456</a></li></ul>
------------------------------	------------------------------------------------------------------------------------------------------------------------------

---

## no-option-82

---

<b>Syntax</b>	no-option-82;
<b>Hierarchy Level</b>	[edit vlans <i>vlan-name</i> forwarding-options <b>dhcp-security group</b> <i>group-name</i> <b>overrides</b> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 13.2X50-D10 for EX Series switches. Statement introduced in Junos OS Release 13.2 for the QFX series.
<b>Description</b>	Configure a specific group of one or more access interfaces within the VLAN <i>not</i> to transmit DHCP option 82 information, even if the VLAN is configured to use option 82.
<b>Required Privilege Level</b>	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">option-82 on page 4644</a></li><li>• <i>Setting Up DHCP Option 82 on the Switch with No Relay Agent Between Clients and DHCP Server (CLI Procedure)</i></li><li>• <i>Understanding DHCP Option 82 for Port Security on EX Series Switches</i></li><li>• <a href="#">Understanding DHCP Snooping for Port Security on page 4456</a></li></ul>

## option-82

---

**Syntax**

```
option-82 {
 circuit-id {
 prefix (host-name | routing-instance-name);
 use-interface-description;
 use-vlan-id;
 }
 remote-id {
 host-name;
 use-interface-description;
 use-string string;
 }
 vendor-id;
 use-string string;
}
```

**Hierarchy Level** [edit vlans *vlan-name* forwarding-options **dhcp-security**]

**Release Information** Statement introduced in Junos OS Release 13.2X50-D10 for EX Series switches.  
Statement introduced in Junos OS Release 13.2 for the QFX series.

**Description** When the switch receives a DHCP request from a DHCP client connected on one of the switch's interfaces, have the switch insert DHCP option 82 (also known as the DHCP relay agent information option) information in the DHCP request packet header before it forwards or relays the request to a DHCP server. The server uses the option 82 information, which provides details about the circuit and host the request came from, in formulating the reply; the server does not, however, make any changes to the option 82 information in the packet header. The switch receives the reply and then removes the DHCP option 82 information before forwarding the reply to the client.

The remaining statements are explained separately.

**Default** Insertion of DHCP option 82 information is not enabled.

**Required Privilege Level** system—To view this statement in the configuration.  
system-control—To add this statement to the configuration.

## overrides (DHCP Security)

<b>Syntax</b>	<code>overrides (trusted   untrusted [no-option37   no-option-82]);</code>
<b>Hierarchy Level</b>	<code>[edit vlans <i>vlan-name</i> forwarding-options <b>dhcp-security group</b> <i>group-name</i>]</code>
<b>Release Information</b>	Statement introduced in Junos OS Release 13.2X50-D10 for EX Series switches. Statement introduced in Junos OS Release 13.2 for the QFX series. Support for the <b>no-option37</b> option introduced in Junos OS Release 13.2X51-D20 for EX Series switches.
<b>Description</b>	Modify selected attributes of a specific interface within a group of interfaces that is configured within a specified VLAN.
<b>Options</b>	<p><b>no-option37</b>—The interface specified in this group does not support DHCPv6 option 37.</p> <p><b>no-option82</b>—The interface specified in this group does not support DHCP option 82.</p> <p><b>trusted</b>—The interface specified in this group is trusted. DHCP snooping does not apply to the trusted interface. Likewise, DAI and IP source guard—even if they are enabled for the VLAN—do not apply to the interface that is configured with the <b>overrides</b> and the <b>trusted</b> options. Access interfaces are untrusted by default.</p> <p><b>untrusted</b>—(Only for EX9200) The interface specified in this group is untrusted. Trunk interface are trusted by default. Access interfaces are untrusted by default.</p>
<b>Required Privilege Level</b>	<p><b>interface</b>—To view this statement in the configuration.</p> <p><b>interface-control</b>—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <i>Enabling a Trusted DHCP Server (CLI Procedure)</i></li> <li>• <a href="#">Understanding DHCP Snooping for Port Security on page 4456</a></li> <li>• <i>Understanding DHCP Option 82 for Port Security on EX Series Switches</i></li> </ul>

## recovery-timeout

---

<b>Syntax</b>	<code>recovery-timeout seconds;</code>
<b>Hierarchy Level</b>	[edit interfaces <i>interface-name</i> family ethernet-switching]
<b>Release Information</b>	Statement introduced in Junos OS Release 13.2X50-D10 for EX Series switches. Statement introduced in Junos OS Release 13.2 for the QFX Series.
<b>Description</b>	<p>Disable rather than block an interface when enforcing MAC limiting, MAC move limiting, or rate-limiting configuration options for shutting down the interface, and allow the interface to recover automatically from the error condition after the specified period of time:</p> <ul style="list-style-type: none"><li>• If you have enabled MAC limiting with the <b>shutdown</b> option and you enable <b>recovery-timeout</b>, the switch disables (rather than shuts down) the interface when the MAC address limit is reached.</li><li>• If you have enabled MAC move limiting (Not supported on EX9200) with the <b>shutdown</b> option and you enable <b>recovery-timeout</b>, the switch disables (rather than shuts down) the interface when the maximum number of moves to a new interface is reached.</li><li>• If you have enabled storm control with the <b>action-shutdown</b> option and you enable <b>recovery-timeout</b> the switch disables (rather than shuts down) the interface when applicable traffic exceeds the specified levels. Depending upon the configuration, applicable traffic could include broadcast, unknown unicast, and multicast traffic.</li></ul>
	<div> <b>NOTE:</b> The <b>recovery-timeout</b> configuration does not apply to pre-existing error conditions. It impacts only error conditions that are detected after <b>recovery-timeout</b> has been enabled and committed. To clear a pre-existing error condition and restore the interface to service, use the operational mode command <code>clear ethernet-switching recovery-timeout</code>.</div>
<b>Default</b>	Not enabled.
<b>Options</b>	<b>seconds</b> — Number of seconds that the interface remains in a disabled state due to a port error prior to automatic recovery. <b>Range:</b> 10 through 3600
<b>Required Privilege Level</b>	system—To view this statement in the configuration. system-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <i>action-shutdown</i></li><li>• <a href="#">Configuring MAC Limiting (CLI Procedure) on page 1539</a></li><li>• <i>Configuring MAC Move Limiting (CLI Procedure)</i></li></ul>

- *Configuring or Disabling Storm Control (CLI Procedure)*

## static-ip

<b>Syntax</b>	<pre>static-ip <i>ip-address</i> {     vlan <i>vlan-name</i>;     mac <i>mac-address</i>; }</pre>
<b>Hierarchy Level</b>	<ul style="list-style-type: none"> <li>• For platforms with ELS:            [edit vlans <i>vlan-name</i> forwarding-options <b>dhcp-security group</b> <i>group-name</i> <b>interface</b> <i>interface-name</i>]         </li> <li>• For platforms without ELS:            [edit ethernet-switching-options secure-access-port interface (all   <i>interface-name</i>)]         </li> </ul>
<b>Release Information</b>	<p>Statement introduced in Junos OS Release 9.2 for EX Series switches.</p> <p>Hierarchy level [edit vlans <i>vlan-name</i> forwarding-options <b>dhcp-security</b>] introduced in Junos OS Release 13.2X50-D10. (See <a href="#">“Getting Started with Enhanced Layer 2 Software” on page 58</a> for information about ELS.)</p>
<b>Description</b>	Configure a static IP address to MAC address (IP-MAC) binding to be added to the DHCP snooping database.
<div style="display: flex; align-items: center;">  <div> <p><b>NOTE:</b> The VLAN is specified at the higher hierarchy level when <b>static-ip</b> is configured at [edit vlans <i>vlan-name</i> forwarding-options <b>dhcp-security group</b> <i>group-name</i> <b>interface</b> <i>interface-name</i>].</p> </div> </div>	
<b>Options</b>	<p><b><i>ip-address</i></b>—Static IP address assigned to a device connected on the specified interface.</p> <p><b><i>macmac-address</i></b>—Static MAC address assigned to a device connected on the specified interface.</p> <p>The remaining statements are explained separately.</p>
<b>Required Privilege Level</b>	<p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Configuring Static IP Addresses for DHCP Bindings on Access Ports (CLI Procedure) on page 4550</a></li> <li>• <i>Configuring Static IP Addresses for DHCP Bindings on Access Ports (CLI Procedure)</i></li> </ul>

## switch-options

---

<b>Syntax</b>	<pre>switch-options {   interface <i>interface-name</i> {     interface-mac-limit <i>limit</i> {       packet-action drop;     }     no-mac-learning;     static-mac <i>static-mac-address</i> {       vlan-id <i>number</i>;     }   }   interface-mac-limit <i>limit</i> {     packet-action drop;   }   mac-statistics;   mac-table-size <i>limit</i> {     packet-action drop;   }   no-mac-learning;   service-id <i>number</i>; }</pre>
<b>Hierarchy Level</b>	<pre>[edit <i>number</i>], [edit vlans <i>vlan--name</i>], [edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> vlans   <i>vlan-name</i>], [edit routing-instances <i>routing-instance-name</i> vlans <i>vlan-name</i>]</pre>
<b>Release Information</b>	<p>Statement introduced in Junos OS Release 12.3R2 for EX Series switches and MX Series routers.</p> <p>Statement introduced in Junos OS Release 13.2 for the QFX Series.</p>
<b>Description</b>	<p>Configure Layer 2 learning and forwarding properties for a VLAN or a virtual switch.</p> <p>The remaining statements are explained separately.</p>
<b>Required Privilege Level</b>	<p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>

## trusted

---

<b>Syntax</b>	trusted;
<b>Hierarchy Level</b>	[edit vlans <i>vlan-name</i> forwarding-options <b>dhcp-security group</b> <i>group-name</i> <b>overrides</b> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 13.2X50-D10 for EX Series switches. Statement introduced in Junos OS Release 13.2 for the QFX series.
<b>Description</b>	Allow DHCP responses from the specified interface. The interface is not subject to DHCP snooping, even if the VLAN is enabled for DHCP snooping.
<b>Required Privilege Level</b>	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Enabling a Trusted DHCP Server (CLI Procedure)</a></li> <li>• <a href="#">Understanding Trusted DHCP Servers for Port Security on page 4467</a></li> <li>• <a href="#">Understanding DHCP Snooping for Port Security on page 4456</a></li> </ul>

## untrusted

---

<b>Syntax</b>	untrusted;
<b>Hierarchy Level</b>	[edit vlans <i>vlan-name</i> forwarding-options <b>dhcp-security group</b> <i>group-name</i> <b>overrides</b> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 13.2 for EX Series switches. Statement introduced in Junos OS Release 13.2 for the QFX series.
<b>Description</b>	Override the default behavior of a trunk interface from trusted to untrusted.
<b>Required Privilege Level</b>	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Enabling a Trusted DHCP Server (CLI Procedure)</a></li> <li>• <a href="#">Understanding Trusted DHCP Servers for Port Security on page 4467</a></li> <li>• <a href="#">Understanding DHCP Snooping for Port Security on page 4456</a></li> </ul>

## Configuration Statements for Device Security

---

- [action-shutdown on page 4650](#)

---

## action-shutdown

---

<b>Syntax</b>	action-shutdown;
<b>Hierarchy Level</b>	For platforms without ELS:  [edit <a href="#">ethernet-switching-options storm-control</a> ]  For platforms with ELS:  [edit <a href="#">forwarding-options storm-control-profiles</a> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	<p>Shut down or disable interfaces when the storm control level is exceeded, as follows:</p> <ul style="list-style-type: none"><li>• If you set both the <b>action-shutdown</b> and the <b>port-error-disable</b> statements, the affected interfaces are disabled temporarily and recover automatically when the disable timeout expires.</li><li>• If you set the <b>action-shutdown</b> statement and do not set the <b>port-error-disable</b> statement, the affected interfaces are shut down when the storm control level is exceeded, and they do not recover automatically. You must issue the <b>clear ethernet-switching port-error</b> command to clear the port error and restore the interfaces to service.</li></ul>
<b>Default</b>	The <b>action-shutdown</b> feature is disabled. If the storm control level is exceeded, the switch drops broadcast and unknown unicast messages on the specified interfaces.
<b>Required Privilege Level</b>	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Understanding Storm Control on page 4471</a></li><li>• <a href="#">Example: Configuring Storm Control to Prevent Network Outages on page 4527</a></li><li>• <a href="#">port-error-disable on page 4600</a></li><li>• <a href="#">disable-timeout on page 4609</a></li><li>• <a href="#">clear ethernet-switching port-error on page 4686</a></li></ul>

## interface (Unknown Unicast Forwarding)

<b>Syntax</b>	<code>interface <i>interface-name</i>;</code>
<b>Hierarchy Level</b>	<ul style="list-style-type: none"> <li>For platforms with ELS: [edit switch-options <b>unknown-unicast-forwarding</b> vlan <i>vlan-name</i>]</li> <li>For platforms without ELS: [edit ethernet-switching-options <b>unknown-unicast-forwarding</b> vlan <i>vlan-name</i>]</li> </ul>
<b>Release Information</b>	<p>Statement introduced in Junos OS Release 9.3 for EX Series switches.</p> <p>Statement introduced in Junos OS Release 13.2 for the QFX Series.</p> <p>Hierarchy level <b>[edit switch-options]</b> introduced in Junos OS Release 13.2X50-D10. (See <a href="#">“Getting Started with Enhanced Layer 2 Software”</a> on page 58 for information about ELS.)</p>
<b>Description</b>	Specify the interface to which unknown unicast packets will be forwarded.
<b>Required Privilege Level</b>	<p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li><i>show vlans</i></li> <li><i>show ethernet-switching table</i></li> <li><i>Configuring Unknown Unicast Forwarding (CLI Procedure)</i></li> <li><a href="#">Understanding Unknown Unicast Forwarding on page 4477</a></li> </ul>

## no-broadcast

---

<b>Syntax</b>	no-broadcast;
<b>Hierarchy Level</b>	For platforms without ELS:  [edit <a href="#">ethernet-switching-options storm-control interface</a> (all   <i>interface-name</i> )]  For platforms with ELS:  [edit <a href="#">forwarding-options storm-control-profiles</a> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	For interfaces configured for storm control, disable broadcast traffic storm control on the interface.
<b>Default</b>	When storm control is enabled on an interface, it is enabled for both unknown unicast traffic and broadcast traffic.
<b>Required Privilege Level</b>	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Understanding Storm Control on page 4471</a></li><li>• <a href="#">Example: Configuring Storm Control to Prevent Network Outages on page 4527</a></li></ul>

## no-multicast

---

<b>Syntax</b>	no-multicast;
<b>Hierarchy Level</b>	<p>For platforms without ELS:</p> <p>[edit <a href="#">ethernet-switching-options storm-control interface</a> (all   <i>interface-name</i>)]</p> <p>For platforms with ELS:</p> <p>[edit <a href="#">forwarding-options storm-control-profiles</a>]</p>
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Disable storm control for all multicast traffic (both registered multicast and unregistered multicast) for the specified interface or for all interfaces.
<b>Default</b>	Storm control is enabled for unknown unicast traffic, multicast traffic, and broadcast traffic.
<b>Required Privilege Level</b>	<p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Understanding Storm Control on page 4471</a></li> <li>• <a href="#">Example: Configuring Storm Control to Prevent Network Outages on page 4527</a></li> </ul>

## no-unknown-unicast

---

<b>Syntax</b>	no-unknown-unicast;
<b>Hierarchy Level</b>	For platforms without ELS:  [edit <a href="#">ethernet-switching-options storm-control interface</a> (all   <i>interface-name</i> )]  For platforms with ELS:  [edit <a href="#">forwarding-options storm-control-profiles</a> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	For interfaces configured for storm control, disable unknown unicast traffic storm control on the interface.
<b>Default</b>	When storm control is enabled on an interface, it is enabled for both unknown unicast traffic and broadcast traffic.
<b>Required Privilege Level</b>	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Understanding Storm Control on page 4471</a></li><li>• <a href="#">Example: Configuring Storm Control to Prevent Network Outages on page 4527</a></li></ul>

## rpf-check

---

<b>Syntax</b>	<code>rpf-check;</code>
<b>Hierarchy Level</b>	[edit interfaces <i>interface-name</i> unit <i>logical-unit-number</i> family inet], [edit interfaces <i>interface-name</i> unit <i>logical-unit-number</i> family inet6]
<b>Release Information</b>	Statement introduced in Junos OS Release 9.3 for EX Series switches. Statement introduced in Junos OS Release 13.2 for the QFX Series.
<b>Description</b>	<p>On EX3200 and EX4200 switches, enable a reverse-path forwarding (RPF) check on unicast traffic (except ECMP packets) on all ingress interfaces.</p> <p>On EX4300 switches, enable a reverse-path forwarding (RPF) check on unicast traffic, including ECMP packets, on all ingress interfaces.</p> <p>On EX8200 and EX6200 switches, enable an RPF check on unicast traffic, including ECMP packets, on the selected ingress interfaces.</p> <p>On QFX Series switches, enable an RPF check on unicast traffic (except ECMP packets) on the selected ingress interfaces.</p>
<b>Default</b>	Unicast RPF is disabled on all interfaces.
<b>Required Privilege Level</b>	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <i>Example: Configuring Unicast RPF on an EX Series Switch</i></li> <li>• <a href="#">Configuring Unicast RPF (CLI Procedure) on page 4562</a></li> <li>• <a href="#">Disabling Unicast RPF (CLI Procedure) on page 4564</a></li> <li>• <a href="#">Understanding Unicast RPF on page 4473</a></li> </ul>

## unknown-unicast-forwarding

---

<b>Syntax</b>	<pre>unknown-unicast-forwarding {   vlan <i>vlan-name</i> {     interface <i>interface-name</i>;   } }</pre>
<b>Hierarchy Level</b>	<ul style="list-style-type: none"><li>• For platforms with ELS: [edit switch-options]</li><li>• For platforms without ELS: [edit ethernet-switching-options]</li></ul>
<b>Release Information</b>	<p>Statement introduced in Junos OS Release 9.3 for EX Series switches. Statement introduced in Junos OS Release 13.2 for the QFX Series. Hierarchy level [edit switch-options] introduced in Junos OS Release 13.2X50-D10. (See <a href="#">“Getting Started with Enhanced Layer 2 Software”</a> on page 58 for information about ELS.)</p>
<b>Description</b>	<p>Configure the switch to forward all unknown unicast packets in a VLAN or on all VLANs to a particular interface.</p> <p>The remaining statements are explained separately.</p>
<b>Default</b>	Unknown unicast packets are flooded to all interfaces that belong to the same VLAN.
<b>Required Privilege Level</b>	<p>system—To view this statement in the configuration. system-control—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <i>show vlans</i></li><li>• <i>show ethernet-switching table</i></li><li>• <i>Configuring Unknown Unicast Forwarding (CLI Procedure)</i></li><li>• <i>Configuring Unknown Unicast Forwarding (CLI Procedure)</i> on page 4565</li><li>• <i>Understanding Unknown Unicast Forwarding</i> on page 4477</li></ul>

## Configuration Statements for Device Security (ELS CLI Only)

---

- *bandwidth-level* on page 4657
- *bandwidth-percentage* on page 4658
- *no-registered-multicast* on page 4659
- *no-unregistered-multicast* on page 4660
- *storm-control* on page 4661
- *storm-control-profiles* on page 4661

## bandwidth-level

<b>Syntax</b>	<code>bandwidth-level <i>kbps</i>;</code>
<b>Hierarchy Level</b>	[edit forwarding-options <a href="#">storm-control-profiles</a> <i>profile-name</i> all]
<b>Release Information</b>	Statement introduced in Junos OS Release 13.2X50-D10 for EX Series switches. Statement introduced in Junos OS Release 13.2 for the QFX series.
<b>Description</b>	Configure the storm control level as the bandwidth in kilobits per second of the available bandwidth used by the combined broadcast, multicast, and unknown unicast traffic streams.
<div>  <p><b>NOTE:</b> When you configure storm control level on an aggregated Ethernet interface, the storm control level for each member of the aggregated Ethernet interface is set to that bandwidth. For example, if you configure a storm control level of 15,000 Kbps on ae1, and ae1 has two members, ge-0/0/0 and ge-0/0/1, each member has a storm control level of 15,000 Kbps. Thus, the storm control level on ae1 allows a traffic rate of up to 30,000 Kbps of combined broadcast, multicast, and unknown unicast traffic.</p> </div>	
<b>Default</b>	<p>On EX4300 switches—If you do not specify the storm control level using either the <b>bandwidth-level</b> or the <b>bandwidth-percentage</b> statements, the storm control level defaults to 80 percent of the available bandwidth used by the combined broadcast, unknown unicast, and multicast traffic streams.</p> <p>On EX9200 switches—Storm control is not enabled by default.</p>
<b>Options</b>	<p><b>bandwidth-level <i>kbps</i></b>—Traffic rate in kilobits per second of the combined broadcast, multicast, and unknown unicast traffic streams.</p> <p><b>Range:</b> 100 through 10,000,000</p> <p><b>Default:</b> None</p>
<b>Required Privilege Level</b>	<p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">bandwidth-percentage on page 4658</a></li> <li>• <i>Example: Configuring Storm Control to Prevent Network Outages on EX Series Switches</i></li> <li>• <i>Configuring or Disabling Storm Control (CLI Procedure)</i></li> </ul>

## bandwidth-percentage

---

<b>Syntax</b>	<code>bandwidth-percentage <i>percentage</i>;</code>
<b>Hierarchy Level</b>	[edit forwarding-options <a href="#">storm-control-profiles</a> <i>profile-name</i> all]
<b>Release Information</b>	Statement introduced in Junos OS Release 13.2X50-D10 for EX Series switches. Statement introduced in Junos OS Release 13.2 for the QFX series.
<b>Description</b>	Configure the storm control level as the percentage of available bandwidth used by the combined broadcast, multicast, and unknown unicast traffic streams on an interface. The storm control level is configured as part of the storm control profile.  <div> <b>NOTE:</b> When you configure storm control level on an aggregated Ethernet interface, the storm control level for each member of the aggregated Ethernet interface is set to that bandwidth. For example, if you configure a storm control level of 15,000 Kbps on ae1, and ae1 has two members, ge-0/0/0 and ge-0/0/1, each member has a storm control level of 15,000 Kbps. Thus, the storm control level on ae1 allows a traffic rate of up to 30,000 Kbps of combined broadcast, multicast, and unknown unicast traffic.</div>
<b>Default</b>	On EX4300 switches—The storm control level is 80 percent of the available bandwidth used by the combined broadcast, unknown unicast, and multicast traffic streams.  On EX9200 switches—Storm control is not enabled by default.
<b>Required Privilege Level</b>	system—To view this statement in the configuration. system-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">bandwidth-level on page 4657</a></li><li>• <i>Example: Configuring Storm Control to Prevent Network Outages on EX Series Switches</i></li><li>• <i>Configuring or Disabling Storm Control (CLI Procedure)</i></li></ul>

## no-registered-multicast

<b>Syntax</b>	no-registered-multicast;
<b>Hierarchy Level</b>	<ul style="list-style-type: none"> <li>For platforms with ELS: [edit forwarding-options <b>storm-control-profiles</b> <i>profile-name</i> all]</li> <li>For platforms without ELS: [edit ethernet-switching-options storm-control interface (all   <i>interface-name</i>)],</li> </ul>
<b>Release Information</b>	<p>Statement introduced in Junos OS Release 10.3 for EX Series switches.</p> <p>Hierarchy level [edit forwarding-options] introduced in Junos OS Release 13.2X50-D10. (See “<a href="#">Getting Started with Enhanced Layer 2 Software</a>” on page 58 for information about ELS.)</p> <p>Statement introduced in Junos OS Release 13.2 for the QFX series.</p>
<b>Description</b>	<p>(EX8200 switches only) Disable storm control for registered multicast traffic for the specified interface or for all interfaces.</p> <p>(EX4300 and EX9200 switches only) Exclude storm control for registered multicast traffic from a storm control profile.</p>
<b>Default</b>	<p>EX4300 and EX8200 switches—Storm control is enabled for unknown unicast traffic, multicast traffic, and broadcast traffic. The default storm control level is 80 percent of the available bandwidth used by the combined applicable traffic streams.</p> <p>EX9200 switches—Storm control is not enabled by default.</p>
<b>Required Privilege Level</b>	<p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li><i>no-multicast</i></li> <li><a href="#">no-unregistered-multicast on page 4660</a></li> <li><i>Understanding Storm Control on EX Series Switches</i></li> <li><i>Understanding Storm Control on EX Series Switches</i></li> </ul>

## no-unregistered-multicast

---

<b>Syntax</b>	no-unregistered-multicast;
<b>Hierarchy Level</b>	<ul style="list-style-type: none"><li>For platforms with ELS: [edit forwarding-options <b>storm-control-profiles</b> <i>profile-name</i> all]</li><li>For platforms without ELS: [edit ethernet-switching-options storm-control interface (all   <i>interface-name</i>)],</li></ul>
<b>Release Information</b>	<p>Statement introduced in Junos OS Release 10.3 for EX Series switches.</p> <p>Hierarchy level [edit forwarding-options] introduced in Junos OS Release 13.2X50-D10. (See “<a href="#">Getting Started with Enhanced Layer 2 Software</a>” on page 58 for information about ELS.)</p> <p>Statement introduced in Junos OS Release 13.2 for the QFX series.</p>
<b>Description</b>	<p>(EX8200 switches only) Disable storm control for unregistered multicast traffic for the specified interface or for all interfaces.</p> <p>(EX4300 and EX9200 switches only) Exclude storm control for unregistered multicast traffic from a storm control profile.</p>
<b>Default</b>	<p>EX4300 and EX8200 switches—Storm control is enabled for unknown unicast traffic, multicast traffic, and broadcast traffic. The default storm control level is 80 percent of the available bandwidth used by the combined applicable traffic streams.</p> <p>EX9200 switches—Storm control is not enabled by default.</p>
<b>Required Privilege Level</b>	<p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"><li><i>no-multicast</i></li><li><a href="#">no-registered-multicast on page 4659</a></li><li><i>Understanding Storm Control on EX Series Switches</i></li><li><i>Understanding Storm Control on EX Series Switches</i></li></ul>

## storm-control

<b>Syntax</b>	<code>storm-control storm-control-profile;</code>
<b>Hierarchy Level</b>	[edit interfaces <i>interface-name</i> unit <i>number</i> family ethernet-switching]
<b>Release Information</b>	Statement introduced in Junos OS Release 13.2X50-D10 for EX Series switches. Statement introduced in Junos OS Release 13.2 for the QFX series.
<b>Description</b>	Bind a storm control profile to a logical interface.
<b>Required Privilege Level</b>	system—To view this statement in the configuration. system-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <i>Example: Configuring Storm Control to Prevent Network Outages on EX Series Switches</i></li> <li>• <i>Understanding Storm Control on EX Series Switches</i></li> </ul>

<b>Syntax</b>	<pre>storm-control-profiles profile-name {   action-shutdown;   all {     bandwidth-level;     bandwidth-percentage;     no-broadcast;     no-multicast;     no-registered-multicast;     no-unknown-unicast;     no-unregistered-multicast;   } }</pre>
<b>Hierarchy Level</b>	[edit forwarding-options]
<b>Release Information</b>	Statement introduced in Junos OS Release 13.2X50-D10 for EX Series switches. Statement introduced in Junos OS Release 13.2 for the QFX Series.
<b>Description</b>	Configure a storm control profile on the switch.  The remaining statements are explained separately.
<b>Required Privilege Level</b>	system—To view this statement in the configuration. system-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <i>Example: Configuring Storm Control to Prevent Network Outages on EX Series Switches</i></li> <li>• <i>Understanding Storm Control on EX Series Switches</i></li> </ul>

## Configuration Statements for Device Security (Original CLI Only)

---

- [bandwidth](#) on page 4663
- [ethernet-switching-options](#) on page 4664
- [interface \(Storm Control\)](#) on page 4666
- [storm-control](#) on page 4667

## bandwidth

<b>Syntax</b>	<code>bandwidth <i>bandwidth</i>;</code>
<b>Hierarchy Level</b>	[edit <code>ethernet-switching-options storm-control interface</code> (all   <i>interface-name</i> )]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	For interfaces configured for storm control, configure the storm control level as the bandwidth in kilobits per second (Kbps). If the combination of broadcast and unknown unicast traffic exceeds this level, the switch performs the appropriate action.
<b>Default</b>	None.
<b>Options</b>	<b>bandwidth</b> —Broadcast and unknown unicast traffic rate in Kbps. <b>Range:</b> 100 through 10000000 Kbps <b>Default:</b> None

**NOTE:** When you configure storm control bandwidth, the value you configure is rounded off internally to the closest multiple of 64 Kbps, and the rounded-off value represents the bandwidth that is actually enforced. For example, if you configure a bandwidth limit of 150 Kbps, storm control enforces a bandwidth limit of 128 Kbps.

**CAUTION:** Junos OS allows you to configure a storm control value that exceeds the bandwidth of the interface. If you configure an interface with such a value, storm control does not drop broadcast or unknown unicast packets even if they consume all the available bandwidth.

<b>Required Privilege Level</b>	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Understanding Storm Control on page 4471</a></li> <li>• <a href="#">Example: Configuring Storm Control to Prevent Network Outages on page 4527</a></li> <li>• <a href="#">action-shutdown on page 4650</a></li> <li>• <a href="#">port-error-disable on page 4600</a></li> <li>• <a href="#">disable-timeout on page 4609</a></li> <li>• <a href="#">clear ethernet-switching port-error on page 4686</a></li> </ul>

---

## interface (Storm Control)

---

<b>Syntax</b>	<pre>interface (all   <i>interface-name</i>) {     <i>bandwidth bandwidth</i>;     no-broadcast;     no-multicast;     no-unknown-unicast; }</pre>
<b>Hierarchy Level</b>	[edit <a href="#">ethernet-switching-options storm-control</a> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Apply storm control to all interfaces or to the specified interface.  The remaining statement is explained separately.
<b>Default</b>	Storm control is disabled.
<b>Options</b>	<b>all</b> —Apply storm control to all interfaces.  <b><i>interface-name</i></b> —Apply storm control to the specified interface.
<b>Required Privilege Level</b>	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Understanding Storm Control on page 4471</a></li><li>• <a href="#">Example: Configuring Storm Control to Prevent Network Outages on page 4527</a></li></ul>

## storm-control

**Syntax**

```
storm-control {
 action-shutdown;
 interface (all | interface-name) {
 bandwidth bandwidth;
 no-broadcast;
 no-multicast;
 no-unknown-unicast;
 }
}
```

**Hierarchy Level** [edit [ethernet-switching-options](#)]

**Release Information** Statement introduced in Junos OS Release 11.1 for the QFX Series.

**Description** Apply storm control to all interfaces or to the specified interfaces.

The statements are explained separately.

**NOTE:** The `no-multicast` option is not supported on QFabric systems.

**Default** By default, storm control is enabled on all switch interfaces at a level of 80 percent of the combined broadcast, multicast, and unknown unicast streams. You can change the storm control level by configuring it as a specific bandwidth value.

When you configure storm control bandwidth on an aggregated Ethernet interface, each member of the aggregated interface is assigned that bandwidth. For example, if you configure 7000000 Kbps on aggregated interface `ae1`, and `ae1` has two members, `xe-2:0/0/0` and `xe-2:0/0/1`, each member is allowed a bandwidth level of 7000000 Kbps. Thus, the storm control bandwidth on `ae1` could be as much as 14000000 Kbps of combined broadcast and unknown unicast traffic.

**Required Privilege Level**

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

## CHAPTER 52

# Administration

- [Routine Monitoring on page 4669](#)
- [Monitoring Commands on page 4683](#)

### Routine Monitoring

---

- [Monitoring Firewall Filter Traffic on page 4669](#)
- [Monitoring Port Security on page 4671](#)
- [Verifying That Firewall Filters Are Operational on page 4672](#)
- [Verifying That DAI Is Working Correctly on page 4673](#)
- [Verifying That DHCP Snooping Is Working Correctly on page 4673](#)
- [Verifying That MAC Limiting Is Working Correctly on page 4674](#)
- [Verifying That MAC Move Limiting Is Working Correctly on page 4677](#)
- [Verifying That the Port Error Disable Setting Is Working Correctly on page 4678](#)
- [Verifying Unicast RPF Status on page 4679](#)
- [Verifying That a Trusted DHCP Server Is Working Correctly on page 4681](#)
- [Verifying That Three-Color Policers Are Operational on page 4682](#)
- [Verifying That Two-Color Policers Are Operational on page 4683](#)

### Monitoring Firewall Filter Traffic

You can use operational mode commands to monitor firewall filter traffic.

- [Monitoring Traffic for All Firewall Filters and Policers That Are Configured on page 4669](#)
- [Monitoring Traffic for a Specific Firewall Filter on page 4670](#)
- [Monitoring Traffic for a Specific Policer on page 4670](#)

#### Monitoring Traffic for All Firewall Filters and Policers That Are Configured

**Purpose** Monitor the number of packets and bytes that matched the firewall filters and monitor the number of packets that exceeded policer rate limits:

**Action** Use the **show firewall** operational mode command:

```
user@switch> show firewall
```

```
Filter: egress-vlan-watch-employee
Counters:
Name Bytes Packets
counter-employee-web 3348 27
Filter: ingress-port-limit-tcp-icmp
Counters:
Name Bytes Packets
icmp-counter 560 10
Policers:
Name Packets
icmp-connection-policer 10
tcp-connection-policer 0
Filter: ingress-vlan-rogue-block
Filter: ingress-vlan-limit-guest
```

**Meaning** The **show firewall** command displays the names of all firewall filters, counters, and policers that are configured. For each counter that is specified in a filter configuration, the output field shows the byte count and packet count for the term in which the counter is specified. For each policer that is specified in a filter configuration, the output field shows the packet count for packets that exceed the specified rate limits.

---

#### Monitoring Traffic for a Specific Firewall Filter

**Purpose** Monitor the number of packets and bytes that matched a firewall filter and monitor the number of packets that exceeded policer rate limits.

**Action** Use the **show firewall filter *filter-name*** operational mode command:

```
user@switch> show firewall filter ingress-port-limit-tcp-icmp
Filter: ingress-port-limit-tcp-icmp
Counters:
Name Bytes Packets
icmp-counter 560 10
```

**Meaning** The **show firewall filter *filter-name*** command limits the display information to the counters and policers that are defined for the specified filter.

---

#### Monitoring Traffic for a Specific Policer

**Purpose** Monitor the number of packets that exceeded the rate limits of a policer:

**Action** Use the **show firewall policer *policer-name*** operational mode command:

```
user@switch> show firewall policer icmp-connection-policer
Filter: ingress-port-limit-tcp-icmp
Policers:
Name Packets
icmp-connection-policer 10
```

**Meaning** The **show firewall policer *policer-name*** command displays the number of packets that exceeded the rate limits for the specified policer.

- Related Documentation**

  - [Configuring Two-Color and Three-Color Policers to Control Traffic Rates on page 4538](#)
  - [Verifying That Firewall Filters Are Operational on page 4672](#)

## Monitoring Port Security

**Purpose** Use the monitoring functionality to view these port security details:

- DHCP snooping database for a VLAN or all VLANs
- ARP inspection details for all interfaces

**Action** To monitor port security in the J-Web interface, select **Monitor > Security > Port Security**.

To monitor and manipulate the DHCP snooping database and ARP inspection statistics in the CLI, enter the following commands:

- **show dhcp snooping binding**
- **clear dhcp snooping binding**—In addition to clearing the whole database, you can clear database entries for specified VLANs or MAC addresses.
- **show arp inspection statistics**
- **clear arp inspection statistics**

**NOTE:** On EX4300 switches, to monitor and manipulate the DHCP snooping database and ARP inspection statistics in the CLI, enter the following commands:

- **show dhcp-security binding**
- **clear dhcp-security binding**—In addition to clearing the whole database, you can clear database entries for specified VLANs or IP Address.
- **show dhcp-security arp inspection statistics**
- **clear arp inspection statistics**

**Meaning** The J-Web Port Security Monitoring page comprises two sections:

- **DHCP Snooping Details**—Displays the DHCP snooping database for all the VLANs for which DHCP snooping is enabled. To view the DHCP snooping database for a specific VLAN, select the specific VLAN from the list.
- **ARP Inspection Details**—Displays the ARP inspection details for all interfaces. The information includes details of the number of packets that passed ARP inspection and the number of packets that failed the inspection. The pie chart graphically represents these statistics when you select an interface. To view ARP inspection statistics for a specific interface, select the interface from the list.

You can use the following options on the page to clear DHCP snooping and ARP inspection details:

- **Clear All**—Clears the DHCP snooping database, either for all VLANs if the option **ALL** has been selected in the Select VLANs list or for the specific VLAN that has been selected in that list.
- **Clear**—Deletes a specific IP address from the DHCP snooping database.

To clear ARP inspection details on the page, click **Clear All** in the ARP inspection details section.

**NOTE:** Clear All button in the ARP inspection details section is not supported on EX4300 switches.

Use the CLI commands to show and clear DHCP snooping database and ARP inspection statistics details.

## Verifying That Firewall Filters Are Operational

**Purpose** Verify that firewall filters are working properly after you apply them to ports, VLANs, or Layer 3 interfaces.

**Action** Use the **show firewall** operational mode command to verify that the firewall filters are working properly:

```
user@switch> show firewall
Filter: egress-vlan-watch-employee
Counters:
Name Bytes Packets
counter-employee-web 0 0
Filter: ingress-port-limit-tcp-icmp
Counters:
Name Bytes Packets
icmp-counter 560 10
Policers:
Name Packets
icmp-connection-policer 10
tcp-connection-policer 0
Filter: ingress-vlan-rogue-block
Filter: ingress-vlan-limit-guest
```

**Meaning** The **show firewall** command displays the names of all firewall filters, counters, and policers that are configured. For each counter that is specified in a filter configuration, the output field shows the byte count and packet count for the term in which the counter

is specified. In the above example, the **icmp-counter** in the filter **ingress-port-limit-tcp-icmp** shows that the filter matched 10 packets. For each policer that is specified in a filter configuration, the output field shows the packet count for packets that exceed the specified rate limits. The policer **icmp-connection-policer** shows that 10 ICMP packets were policed.

- Related Documentation**
- [Configuring Firewall Filters on page 4531](#)
  - [Configuring Two-Color and Three-Color Policers to Control Traffic Rates on page 4538](#)
  - [Monitoring Firewall Filter Traffic on page 4669](#)

## Verifying That DAI Is Working Correctly

**Purpose** Verify that dynamic ARP inspection (DAI) is working on the switch.

**Action** Send some ARP requests from network devices connected to the switch.

Display the DAI information:

```
user@switch> show arp inspection statistics
```

ARP inspection statistics:

Interface	Packets received	ARP inspection pass	ARP inspection failed
ge-0/0/1.0	7	5	2
ge-0/0/2.0	10	10	0
ge-0/0/3.0	12	12	0

**Meaning** The sample output shows the number of ARP packets received and inspected per interface, with a listing of how many packets passed and how many failed the inspection on each interface. The switch compares the ARP requests and replies against the entries in the DHCP snooping database. If a MAC address or IP address in the ARP packet does not match a valid entry in the database, the packet is dropped.

- Related Documentation**
- [Enabling Dynamic ARP Inspection \(CLI Procedure\) on page 4553](#)
  - [Enabling Dynamic ARP Inspection \(J-Web Procedure\)](#)
  - [Example: Configuring Basic Port Security Features on page 4488](#)

  - [Monitoring Port Security on page 4671](#)

## Verifying That DHCP Snooping Is Working Correctly

**Purpose** Verify that DHCP snooping is working on the switch and that the DHCP snooping database is correctly populated with both dynamic and static bindings.

**Action** Send some DHCP requests from network devices (here they are DHCP clients) connected to the switch.

Display the DHCP snooping information when the interface on which the DHCP server connects to the switch is trusted. The following output results when requests are sent from the MAC addresses and the server has provided the IP addresses and leases:

```
user@switch> show dhcp snooping binding
```

DHCP Snooping Information:

MAC address	IP address	Lease (seconds)	Type	VLAN	Interface
00:05:85:3A:82:77	192.0.2.17	600	dynamic	employee	ge-0/0/1.0
00:05:85:3A:82:79	192.0.2.18	653	dynamic	employee	ge-0/0/1.0
00:05:85:3A:82:80	192.0.2.19	720	dynamic	employee	ge-0/0/2.0
00:05:85:3A:82:81	192.0.2.20	932	dynamic	employee	ge-0/0/2.0
00:05:85:3A:82:83	192.0.2.21	1230	dynamic	employee	ge-0/0/2.0
00:05:85:27:32:88	192.0.2.22	–	static	data	ge-0/0/4.0

**Meaning** When the interface on which the DHCP server connects to the switch has been set to trusted, the output (see preceding sample) shows, for each MAC address, the assigned IP address and lease time—that is, the time, in seconds, remaining before the lease expires. Static IP addresses have no assigned lease time. The statically configured entry never expires.

If the DHCP server had been configured as untrusted, no entries would be added to the DHCP snooping database and nothing would be shown in the output of the **show dhcp snooping binding** command.

## Verifying That MAC Limiting Is Working Correctly

MAC limiting protects against flooding of the Ethernet switching table by setting a limit on the number of MAC addresses that can be learned on a single Layer 2 access interface (port).

Junos OS provides two MAC limiting methods:

- **Maximum number of MAC addresses**—You configure the maximum number of dynamic MAC addresses allowed per interface. When the limit is exceeded, incoming packets with new MAC addresses can be ignored, dropped, or logged. You can also specify that the interface be shut down or temporarily disabled.
- **Allowed MAC addresses**—You configure specific “allowed” MAC addresses for the access interface. Any MAC address that is not in the list of configured addresses is not learned, and the switch logs an appropriate message. The allowed MAC method binds MAC addresses to a VLAN so that the address is not registered outside the VLAN. If an allowed MAC setting conflicts with a dynamic MAC setting, the allowed MAC setting takes precedence.

This topic includes the following tasks:

1. [Verifying That MAC Limiting for Dynamic MAC Addresses Is Working Correctly on page 4675](#)
2. [Verifying That Allowed MAC Addresses Are Working Correctly on page 4676](#)
3. [Verifying That Interfaces Are Shut Down on page 4676](#)
4. [Customizing the Ethernet Switching Table Display to View Information for a Specific Interface on page 4677](#)

### Verifying That MAC Limiting for Dynamic MAC Addresses Is Working Correctly

**Purpose** Verify that MAC limiting for dynamic MAC addresses is working.

**Action** Display the MAC addresses that have been learned. The following sample output shows the results of sending two packets from hosts connected to **xe-1:0/0/1** and five packets from hosts connected to **xe-1:0/0/2**, with both interfaces configured with a MAC limit of 4 and the action **drop**:

```
user@switch> show ethernet-switching table
Ethernet-switching table: 7 entries, 6 learned
```

VLAN	MAC address	Type	Age	Interfaces
employee-vlan	*	Flood	–	xe-1:0/0/2.0
employee-vlan	00:05:85:3A:82:77	Learn	0	xe-1:0/0/1.0
employee-vlan	00:05:85:3A:82:79	Learn	0	xe-1:0/0/1.0
employee-vlan	00:05:85:3A:82:80	Learn	0	xe-1:0/0/2.0
employee-vlan	00:05:85:3A:82:81	Learn	0	xe-1:0/0/2.0
employee-vlan	00:05:85:3A:82:83	Learn	0	xe-1:0/0/2.0
employee-vlan	00:05:85:3A:82:85	Learn	0	xe-1:0/0/2.0

**Meaning** The output shows that the fifth packet received on the **xe-1:0/0/2** interface was dropped because it exceeded the MAC limit for that interface. The address was not learned, and thus an asterisk (\*) rather than an address appears in the MAC address column in the first line of the sample output.

### Verifying That Allowed MAC Addresses Are Working Correctly

---

**Purpose** Verify that allowed MAC addresses are working.

**Action** Display the MAC cache information after allowed MAC addresses have been configured on an interface. The following sample shows the MAC cache after four allowed MAC addresses had been configured on interface **xe-1:0/0/2** and a fifth MAC address appeared on the interface.

```
user@switch> show ethernet-switching table
Ethernet-switching table: 5 entries, 4 learned
 VLAN MAC address Type Age Interfaces
 ---- -
employee-vlan 00:05:85:3A:82:80 Learn 0 xe-1:0/0/2.0
employee-vlan 00:05:85:3A:82:81 Learn 0 xe-1:0/0/2.0
employee-vlan 00:05:85:3A:82:83 Learn 0 xe-1:0/0/2.0
employee-vlan 00:05:85:3A:82:85 Learn 0 xe-1:0/0/2.0
employee-vlan * Flood - xe-1:0/0/2.0
```

**Meaning** Because the fifth address was not allowed it was not learned, and an asterisk (\*) rather than an address appears in the MAC address column in the last line of the sample output.

### Verifying That Interfaces Are Shut Down

---

**Purpose** Verify that an interface is shut down when the MAC limit is exceeded.

**Action** For more information about interfaces that have been shut down because the MAC limit was exceeded, use the **show ethernet-switching interfaces** command.

```
user@switch> show ethernet-switching interfaces
Interface State VLAN members Tag Tagging Blocking

bme0.32770 down mgmt untagged unblocked
xe-0/0/0.0 down v1 untagged MAC limit exceeded
xe- 0/0/1.0 up v1 untagged unblocked
xe-0/0/2.0 up v1 untagged unblocked
me0.0 up mgmt untagged unblocked
```

**NOTE:** You can configure interfaces to recover automatically when the MAC limit has been exceeded by specifying the `port-error-disable` statement with a `disable timeout` value. The switch automatically restores the disabled interface to service when the disable timeout expires. The `port-error-disable` configuration does not apply to preexisting error conditions—it affects only error conditions that are detected after the `port-error-disable` statement has been enabled and the configuration has been committed. To clear a preexisting error condition and restore the interface to service, use the `clear ethernet-switching port-error` command.

### Customizing the Ethernet Switching Table Display to View Information for a Specific Interface

**Purpose** You can use the `show ethernet-switching table` command to view information for a specific interface.

**Action** For example, to display the MAC addresses that have been learned on the `xe-0/0/2` interface, enter:

```
user@switch> show ethernet-switching table interface xe-0/0/2.0
Ethernet-switching table: 1 unicast entries
```

VLAN	MAC address	Type	Age	Interfaces
v1	*	Flood	-	All-members
v1	00:00:06:00:00:00	Learn	0	xe-0/0/2.0

**Meaning** The MAC limit value for the `xe-0/0/2` interface had been set to 1, and the output shows that only one MAC address was learned and added to the MAC cache.

- Related Documentation**
- [Configuring MAC Limiting on page 4545](#)
  - [Monitoring Port Security on page 4671](#)
  - [Configuring Autorecovery From the Disabled State on Secure or Storm Control Interfaces \(CLI Procedure\)](#)
  - [Example: Configuring Allowed MAC Addresses to Protect the Switch from DHCP Snooping Database Alteration Attacks on page 4518](#)
  - [Example: Configuring MAC Limiting to Protect the Switch from DHCP Starvation Attacks on page 4495](#)

### Verifying That MAC Move Limiting Is Working Correctly

**Purpose** Verify that MAC move limiting is working on the switch.

**Action** Display the MAC addresses in the Ethernet switching table when MAC move limiting has been configured for a VLAN. The following sample shows the results after two of the hosts on **ge-0/0/2** sent packets after the MAC addresses for those hosts had moved to other interfaces more than five times in 1 second. The VLAN, **employee-vlan**, was set to a MAC move limit of 5 with the action **drop**:

```
user@switch> show ethernet-switching table
```

```
Ethernet-switching table: 7 entries, 4 learned
```

VLAN	MAC address	Type	Age	Interfaces
employee-vlan	00:05:85:3A:82:77	Learn	0	ge-0/0/1.0
employee-vlan	00:05:85:3A:82:79	Learn	0	ge-0/0/1.0
employee-vlan	00:05:85:3A:82:80	Learn	0	ge-0/0/2.0
employee-vlan	00:05:85:3A:82:81	Learn	0	ge-0/0/2.0
employee-vlan	*	Flood	-	ge-0/0/2.0
employee-vlan	*	Flood	-	ge-0/0/2.0

**Meaning** The last two lines of the sample output show that MAC addresses for two hosts on **ge-0/0/2** were not learned, because the hosts had been moved back and forth from the original interfaces more than five times in 1 second.

#### Related Documentation

- [Configuring MAC Move Limiting \(CLI Procedure\) on page 4547](#)
- [Configuring MAC Move Limiting \(J-Web Procedure\)](#)
- [Configuring Autorecovery From the Disabled State on Secure or Storm Control Interfaces \(CLI Procedure\)](#)
- [Example: Configuring Basic Port Security Features on page 4488](#)
- [Monitoring Port Security on page 4671](#)

## Verifying That the Port Error Disable Setting Is Working Correctly

**Purpose** Verify that the port error disable setting is working as expected for MAC limited and storm control interfaces.

**Action** Display information about interfaces:

```
user@switch> show ethernet-switching interfaces
```

Interface	State	VLAN members	Blocking
xe-2:0/0/0.0	up	T1122	unblocked
xe-2:0/0/1.0	down	default	MAC limit exceeded
xe-2:0/0/2.0	down	default	Storm control in effect
xe-2:0/0/3.0	down	default	unblocked
xe-2:0/0/4.0	down	default	unblocked
xe-2:0/0/5.0	down	default	unblocked
xe-2:0/0/6.0	down	default	unblocked

**Meaning** For interfaces disabled by port security features, the sample output from the **show ethernet-switching interfaces** command specifies the reasons that the interfaces are disabled:

- **MAC limit exceeded**—The interface is temporarily disabled because of a [mac-limit](#) error. The disabled interface is automatically restored to service when the [disable-timeout \(Port Error Disable\)](#) expires.
- **MAC move limit exceeded**—The interface is temporarily disabled because of a *mac-move-limit* error. The disabled interface is automatically restored to service when the *disable-timeout* expires.
- **Storm control in effect**—The interface is temporarily disabled because of a [storm-control](#) error. The disabled interface is automatically restored to service when the [disable-timeout \(Port Error Disable\)](#) expires.

- Related Documentation**

## Verifying Unicast RPF Status

- Purpose** Verify that unicast reverse-path forwarding (RPF) is enabled and is working on the interface.
- Action** Use one of the **show interfaces *interface-name*** commands with either the **extensive** or **detail** options to verify that unicast RPF is enabled and working on the switch. The following example displays output from the **show interfaces ge- extensive** command.

```
user@switch> show interfaces ge-1/0/10 extensive
Physical interface: ge-1/0/10, Enabled, Physical link is Down
Interface index: 139, SNMP ifIndex: 58, Generation: 140
Link-level type: Ethernet, MTU: 1514, Speed: Auto, MAC-REWRITE Error: None,
Loopback: Disabled, Source filtering: Disabled, Flow control: Enabled,
Auto-negotiation: Enabled, Remote fault: Online
Device flags : Present Running
Interface flags: Hardware-Down SNMP-Traps Internal: 0x0
Link flags : None
CoS queues : 8 supported, 8 maximum usable queues
Hold-times : Up 0 ms, Down 0 ms
Current address: 00:19:e2:50:95:ab, Hardware address: 00:19:e2:50:95:ab
Last flapped : Never
Statistics last cleared: Never
Traffic statistics:
Input bytes : 0 0 bps
Output bytes : 0 0 bps
Input packets : 0 0 pps
Output packets: 0 0 pps

Output bytes : 0
Input packets: 0
Output packets: 0
 Protocol inet, Generation: 144, Route table: 0
Flags: uRPF
Addresses, Flags: Is-Preferred Is-Primary

```

**Meaning** The `show interfaces ge-1/0/10 extensive` command (and the `show interfaces ge-1/0/10 detail` command) displays in-depth information about the interface. The **Flags:** output field near the bottom of the display reports the unicast RPF status. If unicast RPF has not been enabled, the **uRPF** flag is not displayed.

On EX3200, EX4200, and EX4300 switches, unicast RPF is implicitly enabled on *all* switch interfaces, including aggregated Ethernet interfaces (also referred to as link aggregation groups or LAGs), integrated routing and bridging (IRB) interfaces, and routed VLAN interfaces (RVIs) when you enable unicast RPF on a single interface. However, the unicast RPF status is shown as enabled only on interfaces for which you have explicitly configured unicast RPF. Thus, the **uRPF** flag is not displayed on interfaces for which you have not explicitly configured unicast RPF even though unicast RPF is implicitly enabled on all interfaces on EX3200 and EX4200 switches.

## Verifying That a Trusted DHCP Server Is Working Correctly

**Purpose** Verify that a DHCP trusted server is working on the switch. See what happens when the DHCP server is trusted and then untrusted.

**Action** Send some DHCP requests from network devices (here they are DHCP clients) connected to the switch.

Display the DHCP snooping information when the interface on which the DHCP server connects to the switch is trusted. The following output results when requests are sent from the MAC addresses and the server has provided the IP addresses and leases:

```
user@switch> show dhcp snooping binding
```

DHCP Snooping Information:

MAC Address	IP Address	Lease	Type	VLAN	Interface
-----	-----	-----	----	----	-----
00:05:85:3A:82:77	192.0.2.17	600	dynamic	employee-vlan	ge-0/0/1.0
00:05:85:3A:82:79	192.0.2.18	653	dynamic	employee-vlan	ge-0/0/1.0
00:05:85:3A:82:80	192.0.2.19	720	dynamic	employee-vlan	ge-0/0/2.0
00:05:85:3A:82:81	192.0.2.20	932	dynamic	employee-vlan	ge-0/0/2.0
00:05:85:3A:82:83	192.0.2.21	1230	dynamic	employee-vlan	ge-0/0/2.0
00:05:85:27:32:88	192.0.2.22	3200	dynamic	employee-vlan	ge-0/0/2.0

**Meaning** When the interface on which the DHCP server connects to the switch has been set to trusted, the output (see preceding sample) shows, for each MAC address, the assigned IP address and lease time—that is, the time, in seconds, remaining before the lease expires.

If the DHCP server had been configured as untrusted, no entries would be added to the DHCP snooping database and nothing would be shown in the output of the **show dhcp snooping binding** command.

## Verifying That Three-Color Policers Are Operational

**Purpose** Verify that three-color policers in firewall filter configurations are working properly.

**Action** Use the following operational mode commands to verify that a three-color policer is working properly:

- **show class-of-service forwarding-table classifiers**
- **show interfaces *interface-name* extensive**

- `show interfaces queue interface-name`

- Related Documentation**
- [Overview of Policers on page 4441](#)
  - [Configuring Two-Color and Three-Color Policers to Control Traffic Rates on page 4538](#)

## Verifying That Two-Color Policers Are Operational

**Purpose** Verify that two-color policers in firewall filter configurations are working properly.

**Action** Use the `show firewall policer` operational mode command to verify that the policers are working properly:

```
user@switch> show firewall policer
Filter: egress-vlan-watch-employee
Filter: ingress-port-filter
Filter: ingress-port-limit-tcp-icmp
Policies:
Name Packets
icmp-connection-policer 10
tcp-connection-policer 539
Filter: ingress-vlan-rogue-block
Filter: ingress-vlan-limit-guest
```

**Meaning** The `show firewall policer` command displays the names of all firewall filters and policers that are configured. For each policer that is specified in a filter configuration, the output field shows the current packet count for all packets that exceed the specified rate limits.

- Related Documentation**
- [Configuring Two-Color and Three-Color Policers to Control Traffic Rates on page 4538](#)
  - [Configuring Firewall Filters on page 4531](#)
  - [Monitoring Firewall Filter Traffic on page 4669](#)

## Monitoring Commands

- `clear arp inspection statistics`
- `clear dhcp snooping binding`
- `clear ethernet-switching port-error`
- `clear firewall`
- `show arp inspection statistics`
- `show dhcp snooping binding`
- `show firewall`
- `show firewall policer`
- `show interfaces filters`

## clear arp inspection statistics

---

<b>Syntax</b>	clear arp inspection statistics <interface <i>interface</i> >
<b>Release Information</b>	Command introduced in Junos OS Release 9.0 for EX Series switches. Command introduced in Junos OS Release 12.1 for the QFX Series.
<b>Description</b>	Clear ARP inspection statistics.
<b>Options</b>	<b>none</b> —Clears ARP statistics on all interfaces.  <b>interface <i>interface-names</i></b> —(Optional) Clear ARP statistics on one or more interfaces.
<b>Required Privilege Level</b>	clear
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">show arp inspection statistics on page 4688</a></li><li>• <a href="#">Example: Configuring Basic Port Security Features on page 4488</a></li><li>• <a href="#">Verifying That DAI Is Working Correctly on page 4673</a></li></ul>
<b>List of Sample Output</b>	<a href="#">clear arp inspection statistics on page 4684</a>
<b>Output Fields</b>	This command produces no output.

## Sample Output

### clear arp inspection statistics

```
user@switch> clear arp inspection statistics
```

## clear dhcp snooping binding

---

<b>Syntax</b>	clear dhcp snooping binding <mac (all   <i>mac-address</i> )> <vlan (all   <i>vlan-name</i> )> <vlan (all   <i>vlan-name</i> ) mac (all   <i>mac-address</i> )>
<b>Release Information</b>	Command introduced in Junos OS Release 12.1 for the QFX Series.
<b>Description</b>	Clear the DHCP snooping database information.
<b>Options</b>	<p><b>mac (all   <i>mac-address</i>)</b>—(Optional) Clear DHCP snooping information for the specified MAC address or all MAC addresses.</p> <p><b>vlan (all   <i>vlan-name</i>)</b>—(Optional) Clear DHCP snooping information for the specified VLAN or all VLANs.</p>
<b>Required Privilege Level</b>	clear
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Example: Configuring Basic Port Security Features on page 4488</a></li> <li>• <a href="#">show dhcp snooping binding on page 4689</a></li> </ul>
<b>List of Sample Output</b>	<a href="#">clear dhcp snooping binding on page 4685</a>
<b>Output Fields</b>	This command produces no output.

### Sample Output

#### clear dhcp snooping binding

```
user@switch> clear dhcp snooping binding
```

## clear ethernet-switching port-error

---

<b>Syntax</b>	clear ethernet-switching port-error <interface <i>interface-name</i> >
<b>Release Information</b>	Command introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Clear all MAC limiting, MAC move limiting, and storm control errors from all the Ethernet switching interfaces on the switch or from the specified interface, and restore the interfaces or the specified interface to service.
<b>Options</b>	<b>none</b> —Clear all MAC limiting, MAC move limiting, and storm control errors from all the Ethernet switching interfaces on the switch and restore the interfaces to service.  <b>interface <i>interface-name</i></b> —(Optional) Clear all MAC limiting, MAC move limiting, and storm control errors from the specified interface and restore the interface to service.
<b>Required Privilege Level</b>	clear
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Configuring MAC Limiting on page 4545</a></li><li>• <a href="#">Example: Configuring Storm Control to Prevent Network Outages on page 4527</a></li><li>• <a href="#">Configuring Port Security (CLI Procedure) on page 4543</a></li><li>• <a href="#">port-error-disable on page 4600</a></li><li>• <a href="#">Configuring Autorecovery for MAC Limited or Storm Control Interfaces (CLI Procedure) on page 4549</a></li></ul>
<b>Output Fields</b>	This command produces no output.

## clear firewall

<b>Syntax</b>	<code>clear firewall (all   counter <i>counter-name</i>   filter <i>filter-name</i>)</code>
<b>Release Information</b>	Command introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	<p>Clear statistics provided by firewall filters.</p> <p>When you clear the counters of a filter, this not only impacts the counters shown by the CLI, but also the ones tracked by SNMP 2.</p>
<b>Options</b>	<p><b>all</b>—Clear the packet and byte counts for all firewall filter counters and clear the packet counts for all policer counters.</p> <p><b>counter <i>counter-name</i></b>—Clear the packet and byte counts for the specified firewall filter counter.</p> <p><b>filter <i>filter-name</i></b>—Clear the packet and byte counts for the specified firewall filter.</p>
<b>Required Privilege Level</b>	clear
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Verifying That Firewall Filters Are Operational on page 4672</a></li> <li>• <a href="#">Verifying That Two-Color Policers Are Operational on page 4683</a></li> <li>• <a href="#">Overview of Firewall Filters on page 4409</a></li> <li>• <a href="#">Overview of Policers on page 4441</a></li> </ul>

## Sample Output

**clear firewall all**

```
user@switch> clear firewall all
```

**clear firewall counter**

```
user@switch> clear firewall counter port-filter-counter
```

**clear firewall filter**

```
user@switch> clear firewall filter ingress-port-filter
```

## show arp inspection statistics

<b>Syntax</b>	show arp inspection statistics
<b>Release Information</b>	Command introduced in Junos OS Release 9.0 for EX Series switches. Command introduced in Junos OS Release 12.1 for the QFX Series.
<b>Description</b>	Display ARP inspection statistics.
<b>Required Privilege Level</b>	view
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">clear arp inspection statistics on page 4684</a></li> <li>• <a href="#">Example: Configuring Basic Port Security Features on page 4488</a></li> <li>• <a href="#">Verifying That DAI Is Working Correctly on page 4673</a></li> </ul>
<b>List of Sample Output</b>	<a href="#">show arp inspection statistics on page 4688</a>
<b>Output Fields</b>	<a href="#">Table 360 on page 4688</a> lists the output fields for the <b>show arp inspection statistics</b> command. Output fields are listed in the approximate order in which they appear.

**Table 360: show arp inspection statistics Output Fields**

Field Name	Field Description	Level of Output
Interface	Interface on which ARP inspection has been applied.	All levels
Packets received	Total number of packets total that underwent ARP inspection.	All levels
ARP inspection pass	Total number of packets that passed ARP inspection.	All levels
ARP inspection failed	Total number of packets that failed ARP inspection.	All levels

## Sample Output

### show arp inspection statistics

```
user@switch> show arp inspection statistics
```

Interface	Packets received	ARP inspection pass	ARP inspection failed
-----	-----	-----	-----
ge-0/0/0	0	0	0
ge-0/0/1	0	0	0
ge-0/0/2	0	0	0
ge-0/0/3	0	0	0
ge-0/0/4	0	0	0
ge-0/0/5	0	0	0
ge-0/0/6	0	0	0
ge-0/0/7	703	701	2

## show dhcp snooping binding

<b>Syntax</b>	<b>show dhcp snooping binding</b> <b>&lt;interface <i>interface-name</i>&gt;</b> <b>&lt;vlan <i>vlan-name</i>&gt;</b>
<b>Release Information</b>	Command introduced in Junos OS Release 9.0 for EX Series switches. Command introduced in Junos OS Release 12.1 for the QFX Series.
<b>Description</b>	Display the DHCP snooping database information.
<b>Options</b>	<b>interface <i>interface-name</i></b> —(Optional) Display the DHCP snooping database information for an interface.  <b>vlan <i>vlan-name</i></b> —(Optional) Display the DHCP snooping database information for a VLAN.
<b>Required Privilege Level</b>	view
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">clear dhcp snooping binding</a></li> <li>• <a href="#">Example: Configuring Basic Port Security Features on page 4488</a></li> <li>• <a href="#">Verifying That DHCP Snooping Is Working Correctly on page 4673</a></li> </ul>
<b>List of Sample Output</b>	<a href="#">show dhcp snooping binding on page 4689</a>
<b>Output Fields</b>	<a href="#">Table 361 on page 4689</a> lists the output fields for the <b>show dhcp snooping binding</b> command. Output fields are listed in the approximate order in which they appear.

**Table 361: show dhcp snooping binding Output Fields**

Field Name	Field Description	Level of Output
MAC Address	MAC address of the network device; bound to the IP address.	All levels
IP Address	IP address of the network device; bound to the MAC address.	All levels
Lease	Lease granted to the IP address.	All levels
Type	How the MAC address was acquired.	All levels
VLAN	VLAN name of the network device whose MAC address is shown.	All levels
Interface	Interface address (port).	All levels

## Sample Output

### show dhcp snooping binding

```
user@switch> show dhcp snooping binding
```

## DHCP Snooping Information:

MAC Address	IP Address	Lease	Type	VLAN	Interface
00:00:01:00:00:03	192.0.2.0	640	dynamic	guest	ge-0/0/12.0
00:00:01:00:00:04	192.0.2.1	720	dynamic	guest	ge-0/0/12.0
00:00:01:00:00:05	192.0.2.5	800	dynamic	guest	ge-0/0/13.0

## show firewall

<b>Syntax</b>	show firewall <counter <i>counter-name</i> > <filter <i>filter-name</i> > <log <detail   interface <i>interface-name</i> >> <terse>
<b>Release Information</b>	Command introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Display statistics about configured firewall filters.
<b>Options</b>	<p><b>counter <i>counter-name</i></b>—(Optional) Display statistics about a particular firewall filter counter.</p> <p><b>filter <i>filter-name</i></b>—(Optional) Display statistics about a particular firewall filter.</p> <p><b>log</b>—(Optional) Display log entries for all firewall filter activity.</p> <p><b>terse</b>—(Optional) Display firewall filter names only.</p>
<b>Required Privilege Level</b>	view
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Verifying That Firewall Filters Are Operational on page 4672</a></li> <li>• <a href="#">Verifying That Two-Color Policers Are Operational on page 4683</a></li> <li>• <a href="#">Overview of Firewall Filters on page 4409</a></li> <li>• <a href="#">Overview of Policers on page 4441</a></li> </ul>
<b>List of Sample Output</b>	<a href="#">show firewall on page 4692</a> <a href="#">show firewall filter <i>filter-name</i> on page 4693</a> <a href="#">show firewall counter <i>counter-name</i> on page 4693</a> <a href="#">show firewall log on page 4693</a> <a href="#">show firewall log detail on page 4693</a>
<b>Output Fields</b>	<a href="#">Table 362 on page 4691</a> lists the output fields for the <b>show firewall</b> command. Output fields are listed in the approximate order in which they appear.

**Table 362: show firewall Output Fields**

Field Name	Field Description	Level of Output
Filter	Name of the filter that is configured at the <b>[edit firewall family <i>family-name</i> filter]</b> hierarchy level.	All levels

Table 362: show firewall Output Fields (*continued*)

Field Name	Field Description	Level of Output
<b>Counters</b>	Display filter counter information: <ul style="list-style-type: none"> <li>Name—Name of a filter counter that has been configured with the <b>count</b> firewall filter action modifier.</li> <li>Bytes—Number of bytes that match the filter term where the <b>count</b> action modifier was specified.</li> <li>Packets—Number of packets that matched the filter term where the <b>count</b> action modifier was specified.</li> </ul>	All levels
<b>Policers</b>	Display policer information: <ul style="list-style-type: none"> <li>Name—Name of the policer that is configured at the <b>[edit firewall policer]</b> hierarchy level.</li> <li>Packets—Number of packets that matched the filter term where the <b>policer</b> action modifier was specified. This is the number of packets that exceeded the rate limits that the policer specifies.</li> </ul>	All levels
<b>Action</b>	Filter action: <ul style="list-style-type: none"> <li>A—Accept</li> <li>D—Discard</li> </ul>	All levels
<b>Interface</b>	Interface on which the firewall filter is applied.	All levels
<b>Protocol</b>	Name of the packet protocol.	All levels
<b>Packet Length</b>	Length of the packet.	All levels
<b>Src Addr</b>	Source address of the packet.	All levels
<b>Dest Addr</b>	Destination address of the packet.	All levels

## Sample Output

## show firewall policer

<b>Syntax</b>	<code>show firewall policer</code> <code>&lt;policer-name&gt;</code>
<b>Release Information</b>	Command introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Display statistics about configured policers.
<b>Options</b>	<p><b>none</b>—Display the count of policed packets for all configured policers.</p> <p><b>policer-name</b>—(Optional) Display the count of policed packets for the specified policer.</p>
<b>Required Privilege Level</b>	view
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Verifying That Firewall Filters Are Operational on page 4672</a></li> <li>• <a href="#">Verifying That Two-Color Policers Are Operational on page 4683</a></li> <li>• <a href="#">Overview of Firewall Filters on page 4409</a></li> <li>• <a href="#">Overview of Policers on page 4441</a></li> </ul>
<b>List of Sample Output</b>	<p><a href="#">show firewall policer on page 4695</a></p> <p><a href="#">show firewall policer policer-name on page 4696</a></p>
<b>Output Fields</b>	Table 363 on page 4695 lists the output fields for the <b>show firewall policer</b> command. Output fields are listed in the approximate order in which they appear.

**Table 363: show firewall policer Output Fields**

Field Name	Field Description	Level of Output
<b>Filter</b>	Name of the filter that is configured at the <code>[edit firewall family <i>family-name</i> filter]</code> hierarchy level.	All levels
<b>Policers</b>	Display policer information: <ul style="list-style-type: none"> <li>• <b>Filter</b>—Name of filter that specifies the <b>policer</b> action modifier.</li> <li>• <b>Name</b>—Name of policer.</li> <li>• <b>Packets</b>—Number of packets that matched the filter term in which the <b>policer</b> action modifier is specified. This is the number of packets that exceed the rate limits that the policer specifies.</li> </ul>	All levels

## Sample Output

### show firewall policer

```

user@switch> show firewall policer
Filter: egress-vlan-filter
Filter: ingress-port-filter
Policers:
Name Packets

```

icmp-connection-policer	0
tcp-connection-policer	0
Filter: ingress-vlan-rogue-block	

**show firewall policer policer-name**

```
user@switch> show firewall policer tcp-connection-policer
Filter: ingress-port-filter
Policers:
Name Packets
tcp-connection-policer 0
```

## show interfaces filters

<b>Syntax</b>	show interfaces filters <interface-name>
<b>Release Information</b>	Command introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	Display firewall filters that are configured on each interface in a switch.
<b>Options</b>	<b>none</b> —Display firewall filter information about all interfaces.  <b>interface-name</b> —(Optional) Display firewall filter information about a particular interface.
<b>Required Privilege Level</b>	view
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">show firewall on page 4691</a></li> </ul>
<b>List of Sample Output</b>	<a href="#">show interfaces filters on page 4697</a> <a href="#">show interfaces filters interface-name on page 4698</a>
<b>Output Fields</b>	Table 364 on page 4697 lists the output fields for the <b>show interfaces filters</b> command. Output fields are listed in the approximate order in which they appear.

Table 364: show interfaces filters Output Fields

Field Name	Field Description	Level of Output
Interface	Name of the physical interface.	All levels
Admin	Interface state: <b>up</b> or <b>down</b> .	All levels
Link	Link state: <b>up</b> or <b>down</b> .	All levels
Proto	Protocol that is configured on the interface.	All levels
Input Filter	Name of the firewall filter to be evaluated when packets are received on the interface.	All levels
Output Filter	Name of the firewall filter to be evaluated when packets are transmitted on the interface.	All levels

## Sample Output

### show interfaces filters

```

user@switch> show interfaces filters
Interface Admin Link Proto Input Filter Output Filter
ge-0/0/6 up up eth-switch ingress-port-limit-tcp-icmp

## Troubleshooting Procedures

---

- [Troubleshooting Firewall Filter Configuration on page 4699](#)
- [Troubleshooting Policer Configuration on page 4705](#)

## Troubleshooting Firewall Filter Configuration

Use the following information to troubleshoot your firewall filter configuration.

- [Firewall Filter Configuration Returns a No Space Available in TCAM Message on page 4699](#)
- [Filter Counts Previously Dropped Packet on page 4701](#)
- [Matching Packets Not Counted on page 4701](#)
- [Counter Reset When Editing Filter on page 4702](#)
- [Cannot Include loss-priority and policer Actions in Same Term on page 4702](#)
- [Cannot Egress Filter Certain Traffic Originating on QFX Switch on page 4702](#)
- [Firewall Filter Match Condition Not Working with Q-in-Q Tunneling on page 4703](#)
- [Egress Firewall Filters with Private VLANs on page 4703](#)
- [Egress Filtering of L2PT Traffic Not Supported on page 4704](#)
- [Cannot Drop BGP Packets in Certain Circumstances on page 4704](#)
- [Invalid Statistics for Policer on page 4704](#)
- [Policers can Limit Egress Filters on page 4704](#)

### Firewall Filter Configuration Returns a No Space Available in TCAM Message

**Problem** When a firewall filter configuration exceeds the amount of available Ternary Content Addressable Memory (TCAM) space, the system returns the following **syslogd** message:

```
No space available in tcam.
Rules for filter filter-name will not be installed.
```

A switch returns this message during the commit operation if the firewall filter that has been applied to a port, VLAN, or Layer 3 interface exceeds the amount of space available in the TCAM table. The filter is not applied, but the commit operation for the firewall filter configuration is completed in the CLI module.

**Solution** When a firewall filter configuration exceeds the amount of available TCAM table space, you must configure a new firewall filter with fewer filter terms so that the space requirements for the filter do not exceed the available space in the TCAM table.

You can perform either of the following procedures to correct the problem:

To delete the filter and its binding and apply the new smaller firewall filter to the same binding:

1. Delete the filter and its binding to ports, VLANs, or Layer 3 interfaces. For example:

```
[edit]
user@switch# delete firewall family ethernet-switching filter ingress-vlan-rogue-block
user@switch# delete vlans employee-vlan description "filter to block rogue devices on
employee-vlan"
user@switch# delete vlans employee-vlan filter input ingress-vlan-rogue-block
```

2. Commit the changes:

```
[edit]
user@switch# commit
```

3. Configure a smaller filter with fewer terms that does not exceed the amount of available TCAM space. For example:

```
[edit]
user@switch# set firewall family ethernet-switching filter new-ingress-vlan-rogue-block ...
```

4. Apply (bind) the new firewall filter to a port, VLAN, or Layer 3 interface. For example:

```
[edit]
user@switch# set vlans employee-vlan description "filter to block rogue devices on
employee-vlan"
user@switch# set vlans employee-vlan filter input new-ingress-vlan-rogue-block
```

5. Commit the changes:

```
[edit]
user@switch# commit
```

To apply a new firewall filter and overwrite the existing binding but not delete the original filter:

1. Configure a firewall filter with fewer terms than the original filter:

```
[edit]
user@switch# set firewall family ethernet-switching filter new-ingress-vlan-rogue-block...
```

2. Apply the firewall filter to the port, VLAN, or Layer 3 interfaces to overwrite the binding of the original filter—for example:

```
[edit]
user@switch# set vlans employee-vlan description "smaller filter to block rogue devices on
employee-vlan"
user@switch# set vlans employee-vlan filter input new-ingress-vlan-rogue-block
```

Because you can apply no more than one firewall filter per VLAN per direction, the binding of the original firewall filter to the VLAN is overwritten with the new firewall filter **new-ingress-vlan-rogue-block**.

3. Commit the changes:

```
[edit]
user@switch# commit
```

**NOTE:** The original filter is not deleted and is still available in the configuration.

### Filter Counts Previously Dropped Packet

**Problem** If you configure two or more filters in the same direction for a physical interface and one of the filters includes a counter, the counter will be incorrect if the following circumstances apply:

- You configure the filter that is applied to packets first to discard certain packets. For example, imagine that you have a VLAN filter that accepts packets sent to 10.10.1.0/24 addresses and implicitly discards packets sent to any other addresses. You apply the filter to the **admin** VLAN in the output direction, and interface xe-0/0/1 is a member of that VLAN.
- You configure a subsequent filter to accept and count packets that are dropped by the first filter. In this example, you have a port filter that accepts and counts packets sent to 192.168.1.0/24 addresses that is also applied to xe-0/0/1 in the output direction.

The egress VLAN filter is applied first and correctly discards packets sent to 192.168.1.0/24 addresses. The egress port filter is applied next and counts the discarded packets as matched packets. The packets are not forwarded, but the counter displayed by the egress port filter is incorrect.

Remember that the order in which filters are applied depends on the direction in which they are applied, as indicated here:

Ingress filters:

1. Port (Layer 2) filter
2. VLAN filter
3. Router (Layer 3) filter

Egress filters:

1. Router (Layer 3) filter
2. VLAN filter
3. Port (Layer 2) filter

**Solution** This is expected behavior.

### Matching Packets Not Counted

**Problem** If you configure two egress filters with counters for a physical interface and a packet matches both of the filters, only one of the counters includes that packet.

For example:

- You configure an egress port filter with a counter for interface xe-0/0/1.
- You configure an egress VLAN filter with a counter for the **adminVLAN**, and interface xe-0/0/1 is a member of that VLAN.
- A packet matches both filters.

In this case, the packet is counted by only one of the counters even though it matched both filters.

**Solution** This is expected behavior.

---

#### Counter Reset When Editing Filter

**Problem** If you edit a firewall filter term, the value of any counter associated with any term in the same filter is set to 0, including the implicit counter for any policer referenced by the filter. Consider the following examples:

- Assume that your filter has **term1**, **term2**, and **term3**, and each term has a counter that has already counted matching packets. If you edit any of the terms in any way, the counters for all the terms are reset to 0.
- Assume that your filter has **term1** and **term2**. Also assume that **term2** has a **policer** action modifier and the implicit counter of the policer has already counted 1000 matching packets. If you edit **term1** or **term2** in any way, the counter for the policer referenced by **term2** is reset to 0.

**Solution** This is expected behavior.

---

#### Cannot Include loss-priority and policer Actions in Same Term

**Problem** You cannot include both of the following actions in the same firewall filter term in a QFX Series switch:

- **loss-priority**
- **policer**

If you do so, you see the following error message when you attempt to commit the configuration: "cannot support policer action if loss-priority is configured."

**Solution** This is expected behavior.

---

#### Cannot Egress Filter Certain Traffic Originating on QFX Switch

**Problem** On a QFX Series switch, you cannot filter certain traffic with a firewall filter applied in the output direction if the traffic originates on the QFX switch. This limitation applies to control traffic for protocols such as ICMP (ping), STP, LACP, and so on.

**Solution** This is expected behavior.

### Firewall Filter Match Condition Not Working with Q-in-Q Tunneling

**Problem** If you create a firewall filter that includes a match condition of **dot1q-tag** or **dot1q-user-priority** and apply the filter on input to a trunk port that participates in a service VLAN, the match condition does not work if the Q-in-Q EtherType is not 0x8100. (When Q-in-Q tunneling is enabled, trunk interfaces are assumed to be part of the service provider or data center network and therefore participate in service VLANs.)

**Solution** This is expected behavior. To set the Q-in-Q EtherType to 0x8100, enter the **set dot1q-tunneling ethertype 0x8100** statement at the **[edit ethernet-switching-options]** hierarchy level. You must also configure the other end of the link to use the same EtherType.

### Egress Firewall Filters with Private VLANs

**Problem** If you apply a firewall filter in the output direction to a primary VLAN, the filter also applies to the secondary VLANs that are members of the primary VLAN when the traffic egresses with the primary VLAN tag or isolated VLAN tag, as listed below:

- Traffic forwarded from a secondary VLAN trunk port to a promiscuous port (trunk or access)
- Traffic forwarded from a secondary VLAN trunk port that carries an isolated VLAN to a PVLAN trunk port.
- Traffic forwarded from a promiscuous port (trunk or access) to a secondary VLAN trunk port
- Traffic forwarded from a PVLAN trunk port. to a secondary VLAN trunk port
- Traffic forwarded from a community port to a promiscuous port (trunk or access)

If you apply a firewall filter in the output direction to a primary VLAN, the filter does *not* apply to traffic that egresses with a community VLAN tag, as listed below:

- Traffic forwarded from a community trunk port to a PVLAN trunk port
- Traffic forwarded from a secondary VLAN trunk port that carries a community VLAN to a PVLAN trunk port
- Traffic forwarded from a promiscuous port (trunk or access) to a community trunk port
- Traffic forwarded from a PVLAN trunk port. to a community trunk port

If you apply a firewall filter in the output direction to a community VLAN, the following behaviors apply:

- The filter is applied to traffic forwarded from a promiscuous port (trunk or access) to a community trunk port (because the traffic egresses with the community VLAN tag).
- The filter is applied to traffic forwarded from a community port to a PVLAN trunk port (because the traffic egresses with the community VLAN tag).

- The filter is *not* applied to traffic forwarded from a community port to a promiscuous port (because the traffic egresses with the primary VLAN tag or untagged).

**Solution** These are expected behaviors. They occur only if you apply a firewall filter to a private VLAN in the output direction and do not occur if you apply a firewall filter to a private VLAN in the input direction.

---

### Egress Filtering of L2PT Traffic Not Supported

---

**Problem** Egress filtering of L2PT traffic is not supported on the QFX3500 switch. That is, if you configure L2PT to tunnel a protocol on an interface, you cannot also use a firewall filter to filter traffic for that protocol on that interface in the output direction. If you commit a configuration for this purpose, the firewall filter is not applied to the L2PT-tunneled traffic.

**Solution** This is expected behavior.

---

### Cannot Drop BGP Packets in Certain Circumstances

---

**Problem** BGP packets with a time-to-live (TTL) value greater than 1 cannot be discarded using a firewall filter applied to a loopback interface or applied on input to a Layer 3 interface. BGP packets with TTL value of 1 or 0 can be discarded using a firewall filter applied to a loopback interface or applied on input to a Layer 3 interface.

**Solution** This is expected behavior.

---

### Invalid Statistics for Policer

---

**Problem** If you apply a single-rate two-color policer in more than 128 terms in a firewall filter, the output of the **show firewall** command displays incorrect data for the policer.

**Solution** This is expected behavior.

---

### Policers can Limit Egress Filters

---

**Problem** The number of egress policers that you configure can affect the total number of allowed egress firewall filters. Every policer has two implicit counters that consume two entries in a 1024-entry TCAM that is used for counters, including counters that are configured as action modifiers in firewall filter terms. (Policers consume two entries because one is used for green packets and one is used for nongreen packets regardless of policer type.) If the TCAM becomes full, you cannot commit any more egress firewall filters that have terms with counters. For example, if you configure and commit 512 egress policers (two-color, three-color, or a combination of both policer types), all of the memory entries for counters are used up. If later in your configuration file you insert additional egress firewall filters with terms that also include counters, *none* of the terms in those filters are committed because there is no available memory space for the counters.

Here are some additional examples:

- Assume that you configure egress filters that include a total of 512 policers and no counters. Later in your configuration file you include another egress filter with 10 terms, 1 of which has a counter action modifier. None of the terms in this filter are committed because there is not enough TCAM space for the counter.
- Assume that you configure egress filters that include a total of 500 policers, so 1000 TCAM entries are occupied. Later in your configuration file you include the following two egress filters:
  - Filter A with 20 terms and 20 counters. All the terms in this filter are committed because there is enough TCAM space for all the counters.
  - Filter B comes after Filter A and has five terms and five counters. *None* of the terms in this filter are committed because there is not enough memory space for *all* the counters. (Five TCAM entries are required but only four are available.)

**Solution** You can prevent this problem by ensuring that egress firewall filter terms with counter actions are placed earlier in your configuration file than terms that include policers. In this circumstance, Junos OS commits policers even if there is not enough TCAM space for the implicit counters. For example, assume the following:

- You have 1024 egress firewall filter terms with counter actions.
- Later in your configuration file you have an egress filter with 10 terms. None of the terms have counters but one has a policer action modifier.

You can successfully commit the filter with 10 terms even though there is not enough TCAM space for the implicit counters of the policer. The policer is committed without the counters.

- [Policers Can Limit Egress Filters on page 4708](#)

### Incomplete Count of Packet Drops

---

**Problem** Under certain circumstances, Junos OS might display a misleading number of packets dropped by an ingress policer.

If packets are dropped because of ingress admission control, policer statistics might not show the number of packet drops you would expect by calculating the difference between ingress and egress packet counts. This might happen if you apply an ingress policer to multiple interfaces, and the aggregate ingress rate of those interfaces exceeds the line rate of a common egress interface. In this case, packets might be dropped from the ingress buffer. These drops are not included in the count of packets dropped by the policer, which causes policer statistics to underreport the total number of drops.

**Solution** This is expected behavior.

### Counter Reset When Editing Filter

---

**Problem** If you edit a firewall filter term, the value of any counter associated with any term in the same filter is set to 0, including the implicit counter for any policer referenced by the filter. Consider the following examples:

- Assume that your filter has **term1**, **term2**, and **term3**, and each term has a counter that has already counted matching packets. If you edit any of the terms in any way, the counters for all the terms are reset to 0.
- Assume that your filter has **term1** and **term2**. Also assume that **term2** has a **policer** action modifier and the implicit counter of the policer has already counted 1000 matching packets. If you edit **term1** or **term2** in any way, the counter for the policer referenced by **term2** is reset to 0.

**Solution** This is expected behavior.

### Invalid Statistics for Policer

---

**Problem** If you apply a single-rate two-color policer in more than 128 terms in a firewall filter, the output of the **show firewall** command displays incorrect data for the policer.

**Solution** This is expected behavior.

### Egress Policers on QFX3500 Devices Might Allow More Throughput Than Is Configured

---

**Problem** If you configure a policer to rate-limit throughput and apply it on egress to multiple interfaces on a QFX3500 switch or Node, the measured aggregate policed rate might be twice the configured rate, depending on which interfaces you apply the policer to. The doubling of the policed rate occurs if you apply a policer to multiple interfaces and *both* of the following are true:

- There is at least one policed interface in the range xe-0/0/0 to xe-0/0/23 or the range xe-0/1/1 to xe-0/1/7.
- There is at least one policed interface in the range xe-0/0/24 to xe-0/0/47 or the range xe-0/1/8 to xe-0/1/15.

For example, if you configure a policer to rate-limit traffic at 1 Gbps and apply the policer (by using a firewall filter) to xe-0/0/0 and xe-0/0/24 in the output direction, each interface is rate-limited at 1 Gbps, for a total allowed throughput of 2 Gbps. The same behavior occurs if you apply the policer to xe-0/1/1 and xe-0/0/24—each interface is rate-limited at 1 Gbps.

If you apply the same policer on egress to multiple interfaces in these groups, each *group* is rate-limited at 1 Gbps. For example, if you apply the policer to xe-0/0/0 through xe-0/0/4 (five interfaces) and xe-0/0/24 through xe-0/0/33 (ten interfaces), each group is rate-limited at 1 Gbps, for a total allowed throughput of 2 Gbps.

Here is another example: If you apply the policer to xe-0/0/0 through xe-0/0/4 and xe-0/1/1 through xe-0/1/5 (a total of ten interfaces), that group is rate-limited at 1 Gbps in aggregate. If you also apply the policer to xe-0/0/24, that one interface is rate-limited at 1 Gbps while the other ten are still rate-limited at 1 Gbps in aggregate.

Interfaces xe-0/1/1 through xe-0/1/15 are physically located on the QSFP+ uplink ports, according to the following scheme:

- xe-0/1/1 through xe-0/1/3 are on Q0.
- xe-0/1/4 through xe-0/1/7 are on Q1.
- xe-0/1/8 through xe-0/1/11 are on Q2.
- xe-0/1/12 through xe-0/1/15 are on Q3.

The doubling of the policed rate occurs only if the policer is applied in the output direction. If you configure a policer as described above but apply it in the input direction, the total allowed throughput for all interfaces is 1 Gbps.

**Solution** This is expected behavior.

### Filter-Specific Egress Policers on QFX3500 Devices Might Allow More Throughput Than Is Configured

**Problem** You can configure policers to be filter-specific, which means that Junos OS creates only one policer instance regardless of how many times the policer is referenced. When you do this, rate limiting is applied in aggregate, so if you configure a policer to discard traffic that exceeds 1 Gbps and reference that policer in three different terms, the total bandwidth allowed by the filter is 1 Gbps. However, the behavior of a filter-specific policer is affected by how the firewall filter terms that reference the policer are stored in ternary content addressable memory (TCAM). If you create a filter-specific policer and reference it in multiple firewall filter terms, the policer allows more traffic than expected if the terms are stored in different TCAM slices. For example, if you configure a policer to discard traffic that exceeds 1 Gbps and reference that policer in three different terms that are

stored in three separate memory slices, the total bandwidth allowed by the filter is 3 Gbps, not 1 Gbps.

**Solution** To prevent this unexpected behavior, use the information about TCAM slices presented in [“Planning the Number of Firewall Filters to Create” on page 4435](#) to organize your configuration file so that all the firewall filter terms that reference a given filter-specific policer are stored in the same TCAM slice.

### Policers Can Limit Egress Filters

**Problem** The number of egress policers that you configure can affect the total number of allowed egress firewall filters. Every policer has two implicit counters that consume two entries in a 1024-entry TCAM that is used for counters, including counters that are configured as action modifiers in firewall filter terms. (Policers consume two entries because one is used for green packets and one is used for nongreen packets regardless of policer type.) If the TCAM becomes full, you cannot commit any more egress firewall filters that have terms with counters. For example, if you configure and commit 512 egress policers (two-color, three-color, or a combination of both policer types), all of the memory entries for counters are used up. If later in your configuration file you insert additional egress firewall filters with terms that also include counters, *none* of the terms in those filters are committed because there is no available memory space for the counters.

Here are some additional examples:

- Assume that you configure egress filters that include a total of 512 policers and no counters. Later in your configuration file you include another egress filter with 10 terms, 1 of which has a counter action modifier. None of the terms in this filter are committed because there is not enough TCAM space for the counter.
- Assume that you configure egress filters that include a total of 500 policers, so 1000 TCAM entries are occupied. Later in your configuration file you include the following two egress filters:
  - Filter A with 20 terms and 20 counters. All the terms in this filter are committed because there is enough TCAM space for all the counters.
  - Filter B comes after Filter A and has five terms and five counters. *None* of the terms in this filter are committed because there is not enough memory space for *all* the counters. (Five TCAM entries are required but only four are available.)

**Solution** You can prevent this problem by ensuring that egress firewall filter terms with counter actions are placed earlier in your configuration file than terms that include policers. In this circumstance, Junos OS commits policers even if there is not enough TCAM space for the implicit counters. For example, assume the following:

- You have 1024 egress firewall filter terms with counter actions.
- Later in your configuration file you have an egress filter with 10 terms. None of the terms have counters but one has a policer action modifier.

You can successfully commit the filter with 10 terms even though there is not enough TCAM space for the implicit counters of the policer. The policer is committed without the counters.

### Port Mirroring Overview

---

Port mirroring copies packets entering or exiting a port or entering a VLAN and sends the copies to a local interface for local monitoring or to a VLAN for remote monitoring. Use port mirroring to send traffic to applications that analyze traffic for purposes such as monitoring compliance, enforcing policies, detecting intrusions, monitoring and predicting traffic patterns, correlating events, and so on.

Port mirroring is needed for traffic analysis on a switch because a switch normally sends packets only to the port to which the destination device is connected. You configure port mirroring on the switch to send copies of unicast traffic to a local interface or a VLAN and run an analyzer application on a device connected to the interface or VLAN. You configure port mirroring by using the **analyzer** statement.

Keep performance in mind when configuring port mirroring. For example, If you mirror traffic from multiple ports, the mirrored traffic may exceed the capacity of the output interface. We recommend that you limit the amount of copied traffic by selecting specific interfaces instead of using the **all** keyword. You can also limit the amount of mirrored traffic by using a firewall filter. Mirroring only the necessary packets reduces the possibility of a performance impact.

You can use port mirroring to copy any of the following:

- All packets entering or exiting an interface (in any combination)—For example, you can send copies of the packets entering some interfaces and the packets exiting other interfaces to the same local interface or VLAN. If you configure port mirroring to copy packets exiting an interface, traffic that originates on that switch or Node device (in a QFabric system) is not copied when it egresses. Only switched traffic is copied on egress. (See the limitation on egress mirroring below.)
- All packets entering a VLAN—You cannot use port mirroring to copy packets exiting a VLAN.
- Firewall-filtered sample—Sample of packets entering a port or VLAN. Configure a firewall filter to select certain packets for mirroring.

**NOTE:** Firewall filters are not supported on egress ports; therefore, you cannot specify policy-based sampling of packets exiting an interface.

### Port-Mirroring Terminology

Table 365 on page 4714 lists the terms used in the documentation about port mirroring and provides definitions.

**Table 365: Port Mirroring Terms and Definitions**

Term	Description
Analyzer	Port-mirroring configuration. The analyzer includes a name, source interfaces or source VLAN, and a destination for mirrored packets (either a local access interface or a VLAN).
Output interface (also known as monitor interface)	<p>Access interface to which packet copies are sent and to which a device running an analyzer application is connected.</p> <p>The following limitations apply to an output interface:</p> <ul style="list-style-type: none"> <li>• Cannot also be a source port.</li> <li>• Cannot be used for switching.</li> <li>• Cannot be an aggregated Ethernet interface (LAG).</li> <li>• Does not participate in Layer 2 protocols, such as Spanning Tree Protocol (STP).</li> <li>• Loses any existing VLAN associations when you configure it as an analyzer output interface.</li> </ul> <p>If the capacity of the output interface is insufficient to handle the traffic from the source ports, overflow packets are dropped.</p>

Table 365: Port Mirroring Terms and Definitions (*continued*)

Output IP address	<p>IP address of the device running an analyzer application. The device can be on a remote network. When you use this feature, the mirrored packets are GRE-encapsulated. The analyzer device must be able to de-encapsulate GRE-encapsulated packets, or the GRE-encapsulated packets must be de-encapsulated before reaching the analyzer device. (You can use a network sniffer to de-encapsulate the packets.)</p> <ul style="list-style-type: none"> <li>• An output IP address cannot be in the same subnet as any of the switch's management interfaces.</li> <li>• If you create virtual routing instances and also create an analyzer configuration that includes an output IP address, the output address belongs to the default virtual routing instance (inet.0 routing table).</li> </ul>
Output VLAN (also known as monitor or analyzer VLAN)	<p>VLAN to which copies are sent and to which a device running an analyzer application is connected. The analyzer VLAN can span multiple switches.</p> <p>The following limitations apply to an output VLAN:</p> <ul style="list-style-type: none"> <li>• Cannot be a private VLAN or VLAN range.</li> <li>• Cannot be shared by multiple <b>analyzer</b> statements.</li> <li>• An output VLAN interface cannot be a member of any other VLAN.</li> <li>• An output VLAN interface cannot be an aggregated Ethernet interface (LAG).</li> <li>• On the source (monitored) switch, only one interface can be a member of the analyzer VLAN.</li> </ul>
Input interface (also known as mirrored or monitored interface)	Interface that provides traffic to be mirrored. This traffic can be entering or exiting the interface. (Ingress or egress traffic can be mirrored.) An input interface cannot also be an output interface for an analyzer.
Monitoring station	Computer running an analyzer application.
Local port mirroring	Port-mirroring configuration in which the mirrored packets are sent to an interface on the same switch.
Remote port mirroring	Flooding mirrored packets to an analyzer VLAN that you create to receive mirror traffic or sending the mirrored packets to a remote IP address. (You cannot send mirrored packets to a remote IP address on a QFabric system.)
Policy-based mirroring	Mirroring of packets that match the match a firewall filter term. The action <b>analyzer analyzer-name</b> is used in the firewall filter to send the packets to the analyzer.

### Port Mirroring Constraints and Limitations

- [Local and Remote Port Mirroring on page 4715](#)
- [Remote Port Mirroring Only on page 4717](#)

#### Local and Remote Port Mirroring

The following constraints and limitations apply to local and remote port mirroring with the QFX Series:

- You can create a total of four port-mirroring configurations on a QFX Series standalone switch.

- You can create a total of four port-mirroring configurations on each Node group in a QFabric system, subject to the following constraints:
  - As many as four of the configurations can be for local port mirroring.
  - As many as three of the configurations can be for remote port mirroring.
- Regardless of whether you are configuring a standalone switch or a Node group, the following limits apply:
  - There can be no more than two configurations that mirror ingress traffic. (If you configure a firewall filter to send traffic to a port mirror—that is, you use the **analyzer** action modifier in a filter term—this counts as an ingress mirroring configuration for switch or Node group on which the filter is applied.)
  - There can be no more than two configurations that mirror egress traffic.

**NOTE:** On QFabric systems, there is no system-wide limit on the total number of mirror sessions.

---

- You can configure no more than one type of output in one port-mirroring configuration. That is, you can use no more than one of the following to complete a **set analyzer name output** statement:
  - **interface**
  - **ip-address**
  - **vlan**
- If you configure Junos OS to mirror egress packets, do not configure more than 2000 VLANs on a QFX3500 device or QFabric system. If you do so, some VLAN packets might contain incorrect VLAN IDs. This applies to any VLAN packets—not only the mirrored copies.
- The **ratio** and **loss-priority** options are not supported.
- Packets with physical layer errors are filtered out and are not sent to the output port or VLAN.
- If you use sFlow monitoring to sample traffic, it does not sample the mirror copies when they exit from the output interface.
- You cannot mirror packets exiting or entering the following ports:
  - Dedicated Virtual Chassis interfaces
  - Management interfaces (me0 or vme0)
  - Fibre Channel interfaces
  - Routed VLAN interfaces
- An aggregated Ethernet interface cannot be an output interface.

- Do not include an 802.1Q subinterface that has a unit number other than 0 in a port mirroring configuration. Port mirroring does not work with subinterfaces if their unit number is not 0. (You configure 802.1Q subinterfaces using the **vlan-tagging** statement.)
- When packet copies are sent out the output interface, they are not modified for any changes that are normally applied on egress, such as CoS rewriting.
- An interface can be the input interface for only one mirroring configuration. Do not use the same interface as the input interface for multiple mirroring configurations.
- CPU-generated packets (such as ARP, ICMP, BPDU, and LACP packets) cannot be mirrored on egress.
- VLAN-based mirroring is not supported for STP traffic.
- (QFabric systems only) If you configure a QFabric analyzer to mirror egress traffic and the input and output interfaces are on different Node devices, the mirrored copies have incorrect VLAN IDs. This limitation does not apply if you configure a QFabric analyzer to mirror egress traffic and the input and output interfaces are on the *same* Node device. In this case the mirrored copies have the correct VLAN IDs (as long as you do not configure more than 2000 VLANs on the QFabric system).

#### ***Remote Port Mirroring Only***

The following constraints and limitations apply to remote port mirroring with the QFX Series:

- If you configure an output IP address, the address cannot be in the same subnetwork as any of the switch's management interfaces.
- If you create virtual routing instances and also create an analyzer configuration that includes an output IP address, the output address belongs to the default virtual routing instance (inet.0 routing table).
- An output VLAN cannot be a private VLAN or VLAN range.
- An output VLAN cannot be shared by multiple **analyzer** statements.
- An output VLAN interface cannot be a member of any other VLAN.
- An output VLAN interface cannot be an aggregated Ethernet interface.
- On the source (monitored) switch, only one interface can be a member of the analyzer VLAN.

## Understanding Layer 3 Logical Interfaces

A Layer 3 logical interface is a logical division of a physical interface that operates at the network level and therefore can receive and forward 802.1Q VLAN tags. You can use Layer 3 logical interfaces to route traffic among multiple VLANs along a single trunk line that connects a Juniper Networks QFX3500 Switch to a Layer 2 switch. Only one physical connection is required between the switches. You can also use Layer 3 logical interfaces to provide alternative gateway addresses for smart DHCP relay.

To create Layer 3 logical interfaces on a switch, enable VLAN tagging, partition the physical interface into logical partitions, and bind the VLAN ID to the logical interface.

We recommend that you use the VLAN ID as the logical interface number when you configure the logical interface. QFX Series systems support a maximum of 4089 VLANs, which includes the default VLAN. You can, however, assign a VLAN ID in the range of 1 to 4094, but five of these VLAN IDs are reserved for internal use.

VLAN tagging places the VLAN ID in the frame header, allowing each physical interface to handle multiple VLANs. Double-tagging, which is assigning more than one VLAN ID in the frame header, is not supported. When you configure multiple VLANs on an interface, you must also enable tagging on that interface. Junos OS on switches supports a subset of the 802.1Q standard for receiving and forwarding routed or bridged Ethernet frames with single VLAN tags and running Virtual Router Redundancy Protocol (VRRP) over 802.1Q-tagged interfaces.

---

## DHCP Relay

- [DHCP and BOOTP Relay Overview on page 4718](#)

### DHCP and BOOTP Relay Overview

You can configure a Juniper Networks switch to act as a Dynamic Host Configuration Protocol (DHCP) or Bootstrap Protocol (BOOTP) relay agent. This means that if the switch receives a broadcast DHCP or BOOTP request from a locally attached host (client), it relays the message to a specified DHCP or BOOTP server. You should configure the switch to be a DHCP/BOOTP relay agent if you have locally attached hosts and a distant DHCP or BOOTP server.

If you configure a switch to be a DHCP relay agent, you can also enable smart DHCP relay, which enables you to configure alternative gateway addresses for a DHCP server so that if the server fails to reply to the requests sent to the primary gateway address, the switch can resend the requests to the alternative gateway addresses. To use this

feature, you must configure a routed VLAN interface or Layer 3 subinterface with multiple IP addresses and configure that interface to be a relay agent.

**NOTE:** Because DHCP and BOOTP messages are broadcast and are not directed to a specific server, switch, or router, Juniper switches cannot function as both a DHCP server and a DHCP/BOOTP relay agent at the same time. The Junos operating system (Junos OS) generates a commit error if both options are configured at the same time, and the commit operation does not succeed until one of the options is removed.

#### Requirements

---

This example uses the following hardware and software components:

- Junos OS Release 11.1
- A switch

## Overview and Topology

This topic includes two related examples that describe how to mirror traffic entering interfaces on the switch to an access interface on the same switch. The first example shows how to mirror all traffic sent by employee computers to the switch. The second example includes a filter to mirror only the employee traffic going to the Web.

In this example, **xe-0/0/0** and **xe-0/0/6** serve as connections for employee computers. Interface **xe-0/0/47** is connected to a device running an analyzer application.

**NOTE:** Multiple ports mirrored to one interface can cause buffer overflow and dropped packets.

Figure 169 on page 4722 shows the network topology for this example.

**Figure 169: Network Topology for Local Port Mirroring Example**

## Mirroring All Employee Traffic for Local Analysis

To configure port mirroring for all traffic sent by employee computers for local analysis, perform the tasks explained in this section.

### CLI Quick Configuration

To quickly configure local port mirroring for ingress traffic to the two ports connected to employee computers, copy the following commands and paste them into a switch terminal window:

```
[edit]
set interfaces xe-0/0/0 unit 0 family ethernet-switching
set interfaces xe-0/0/6 unit 0 family ethernet-switching
set interfaces xe-0/0/47 unit 0 family ethernet-switching
set ethernet-switching options analyzer employee-monitor input ingress interface xe-0/0/0.0
set ethernet-switching options analyzer employee-monitor input ingress interface xe-0/0/6.0
set ethernet-switching options analyzer employee-monitor output interface xe-0/0/47.0
```

### Step-by-Step Procedure

To configure an analyzer called **employee-monitor** and specify the input (source) interfaces and the output interface:

1. Configure the interfaces connected to employee computers as input interfaces for the port-mirror analyzer **employee-monitor**:

```
[edit ethernet-switching-options]
user@switch# set analyzer employee-monitor input ingress interface xe-0/0/0.0
user@switch# set analyzer employee-monitor input ingress interface xe-0/0/6.0
2. Configure the output analyzer interface for the employee-monitor analyzer. This will
be the destination interface for the mirrored packets:

[edit ethernet-switching-options]
user@switch# set analyzer employee-monitor output interface xe-0/0/47.0
```

**Results** Check the results of the configuration:

```
[edit]
user@switch# show ethernet-switching-options
analyzer employee-monitor {
 input {
 ingress {
 interface xe-0/0/0.0;
 interface xe-0/0/6.0;
 }
 }
 output {
 interface {
 xe-0/0/47.0;
 }
 }
}
```

### Mirroring Employee-to-Web Traffic for Local Analysis

To mirror only traffic sent by employees to the Web for local analysis, perform the tasks explained in this section.

#### CLI Quick Configuration

To quickly configure local port mirroring of traffic from employee computers that is destined for the Web, copy the following commands and paste them into a switch terminal window:

```
[edit]
set ethernet-switching-options analyzer employee-web-monitor output interface xe-0/0/47.0
set firewall family ethernet-switching filter watch-employee term employee-to-corp from
destination-address 192.0.2.16/28
set firewall family ethernet-switching filter watch-employee term employee-to-corp from
source-address 192.0.2.16/28
set firewall family ethernet-switching filter watch-employee term employee-to-corp then accept
set firewall family ethernet-switching filter watch-employee term employee-to-web from
destination-port 80
set firewall family ethernet-switching filter watch-employee term employee-to-web then analyzer
employee-web-monitor
set interfaces xe-0/0/0 unit 0 family ethernet-switching filter input watch-employee
set interfaces xe-0/0/6 unit 0 family ethernet-switching filter input watch-employee
```

**Step-by-Step Procedure** To configure local port mirroring of employee-to-web traffic from the two ports connected to employee computers:

1. Configure the output interface:

```
[edit interfaces]
user@switch# set xe-0/0/47 unit 0 family ethernet-switching
```

2. Configure the **employee-web-monitor** analyzer output. (Configure only the output—the input comes from the filter.)

```
[edit ethernet-switching-options]
user@switch# set analyzer employee-web-monitor output interface xe-0/0/47.0
```

3. Configure a firewall filter called **watch-employee** that includes a term to match traffic sent to the Web and send it to the analyzer **employee-web-monitor**. Traffic to and from the corporate subnet (destination or source address of **192.0.2.16/28**) does not need to be copied, so create another term to accept that traffic before it reaches the term that sends Web traffic to the analyzer:

```
[edit firewall family ethernet-switching]
user@switch# set filter watch-employee term employee-to-corp from destination-address 192.0.2.16/28
user@switch# set filter watch-employee term employee-to-corp from source-address 192.0.2.16/28
user@switch# set filter watch-employee term employee-to-corp then accept
user@switch# set filter watch-employee term employee-to-web from destination-port 80
user@switch# set filter watch-employee term employee-to-web then analyzer employee-web-monitor
```

4. Apply the firewall filter to the appropriate interfaces as an ingress filter (egress filters do not allow analyzers):

```
[edit interfaces]
user@switch# set xe-0/0/0 unit 0 family ethernet-switching filter input watch-employee
user@switch# set xe-0/0/6 unit 0 family ethernet-switching filter input watch-employee
```

**Results** Check the results of the configuration:

```
[edit]
user@switch# show ethernet-switching-options
 analyzer employee-web-monitor {
 output {
 interface xe-0/0/47.0;
 }
 }
...
firewall family ethernet-switching {
 filter watch-employee {
 term employee-to-web {
 from {
 destination-port 80;
 }
 then analyzer employee-web-monitor;
 }
 }
}
...
interfaces {
```

```

xe-0/0/0 {
 unit 0 {
 family ethernet-switching {
 filter {
 input watch-employee;
 }
 }
 }
}
xe-0/0/6 {
 family ethernet-switching {
 filter {
 input watch-employee;
 }
 }
}

```

### Verification

#### *Verifying That the Analyzer Has Been Correctly Created*

**Purpose** Verify that the analyzer named **employee-monitor** or **employee-web-monitor** has been created on the switch with the appropriate input interfaces and appropriate output interface.

**Action** You can verify that the port mirror analyzer has been configured as expected using the **show analyzer** command.

```

user@switch> show analyzer
Analyzer name : employee-monitor
Output interface : xe-0/0/47.0
Mirror ratio : 1
Loss priority : Low
Ingress monitored interfaces : xe-0/0/0.0
Ingress monitored interfaces : xe-0/0/6.0
Egress monitored interfaces : None

```

**Meaning** This output shows that the **employee-monitor** analyzer:

- Has a ratio of 1 (mirroring every packet, the default setting)
- Has a loss priority of low (set this option to high only when the analyzer output is to a VLAN)
- Is mirroring the traffic entering the **xe-0/0/0** and **xe-0/0/6** interfaces
- Is sending the mirrored traffic to the **xe-0/0/47** interface

## Example: Configuring Port Mirroring for Remote Analysis

Use port mirroring to send traffic to applications that analyze traffic for purposes such as monitoring compliance, enforcing policies, detecting intrusions, monitoring and predicting traffic patterns, correlating events, and so on. Port mirroring copies packets entering or exiting an interface or entering a VLAN and sends the copies either to a local interface for local monitoring or to a VLAN for remote monitoring. This example describes how to configure port mirroring for remote analysis.

- [Requirements on page 4726](#)
- [Overview and Topology on page 4726](#)
- [Mirroring All Employee Traffic for Remote Analysis on page 4727](#)
- [Mirroring Employee-to-Web Traffic for Remote Analysis on page 4728](#)
- [Verification on page 4730](#)

---

### Requirements

This example uses the following hardware and software components:

- Junos OS Release 12.1 for the QFX Series
- A switch

---

### Overview and Topology

This topic includes two related examples that describe how to mirror traffic entering ports on the switch to an analyzer VLAN so that you can perform analysis using a remote device. The first example shows how to mirror all traffic sent by employee computers to the switch. The second example includes a filter to mirror only the employee traffic going to the Web.

In this example:

- Interfaces **ge-0/0/0** and **ge-0/0/1** are Layer 2 interfaces that connect to employee computers.
- Interface **ge-0/0/10** is a Layer 2 interface that connects to another switch.
- VLAN **remote-analyzer** is configured on all switches in the topology to carry the mirrored traffic.

**NOTE:** In addition to performing the configuration steps described here, you must also configure the analyzer VLAN (**remote-analyzer** in this example) on the other switches that are used to connect the source switch (the one in this configuration) to the one that the monitoring station is connected to.

---

### Mirroring All Employee Traffic for Remote Analysis

**CLI Quick Configuration** To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **edit** hierarchy level:

```
[edit]
set vlans remote-analyzer vlan-id 999
set interfaces ge-0/0/10 unit 0 family ethernet-switching port-mode trunk
set interfaces ge-0/0/10 unit 0 family ethernet-switching vlan members 999
set ethernet-switching-options analyzer employee-monitor input ingress interface ge-0/0/0.0
set ethernet-switching-options analyzer employee-monitor input ingress interface ge-0/0/1.0
set ethernet-switching-options analyzer employee-monitor output vlan remote-analyzer
```

**Step-by-Step Procedure** To configure basic remote port mirroring:

1. Configure the analyzer VLAN (called **remote-analyzer** in this example):  

```
[edit vlans]
user@switch# set vlans remote-analyzer vlan-id 999
```
2. Configure the interface connected to another switch for trunk mode and associate it with the **remote-analyzer** VLAN:  

```
[edit interfaces]
user@switch# set ge-0/0/10 unit 0 family ethernet-switching port-mode trunk
user@switch# set ge-0/0/10 unit 0 family ethernet-switching vlan members 999
```
3. Configure the **employee-monitor** analyzer:  

```
[edit ethernet-switching-options]
user@switch# set analyzer employee-monitor
user@switch# set analyzer employee-monitor input ingress interface ge-0/0/0.0
user@switch# set analyzer employee-monitor input ingress interface ge-0/0/1.0
user@switch# set analyzer employee-monitor output vlan remote-analyzer
```
4. Configure the **remote-analyzer** VLAN on the switches that connect this switch to the monitoring workstation.

**Results** Check the results of the configuration:

```
[edit]
user@switch# show
ethernet-switching-options {
 analyzer employee-monitor {
 input {
 ingress {
 interface ge-0/0/0.0;
 interface ge-0/0/1.0;
 }
 }
 output {
 vlan {
 remote-analyzer;
 }
 }
 }
}
```

## Mirroring Employee-to-Web Traffic for Remote Analysis

**CLI Quick Configuration** To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **edit** hierarchy level:

```
[edit]
set vlans remote-analyzer vlan-id 999
set interfaces ge-0/0/10 unit 0 family ethernet-switching port mode trunk
set interfaces ge-0/0/10 unit 0 family ethernet-switching vlan members 999
set ethernet-switching-options analyzer employee-web-monitor loss-priority high output vlan 999
set firewall family ethernet-switching filter watch-employee term employee-to-web from destination-port 80
set firewall family ethernet-switching filter watch-employee term employee-to-web then analyzer employee-web-monitor
set ge-0/0/0 unit 0 family ethernet-switching filter input watch-employee
set interfaces ge-0/0/1 unit 0 family ethernet-switching filter input watch-employee
```

**Step-by-Step Procedure**

1. Configure the analyzer VLAN (called **remote-analyzer** in this example):  

```
[edit vlans]
user@switch# set remote-analyzer vlan-id 999
```
2. Configure an interface to associate it with the **remote-analyzer** VLAN:  

```
[edit interfaces]
user@switch# set interfaces ge-0/0/10 unit 0 family ethernet-switching port mode trunk
user@switch# set ge-0/0/10 unit 0 family ethernet-switching vlan members 999
```
3. Configure the **employee-web-monitor** analyzer. (Configure only the output—the input comes from the filter.)  

```
[edit ethernet-switching-options]
user@switch# set ethernet-switching-options analyzer employee-web-monitor output vlan 999
```
4. Configure a firewall filter called **watch-employee** to match traffic sent to the Web and send it to the analyzer **employee-web-monitor**:  

```
[edit firewall family ethernet-switching]
user@switch# set filter watch-employee term employee-to-web from destination-port 80
user@switch# set filter watch-employee term employee-to-web then analyzer employee-web-monitor
```
5. Apply the firewall filter to the appropriate interfaces as an ingress filter:  

```
[edit interfaces]
user@switch# set ge-0/0/0 unit 0 family ethernet-switching filter input watch-employee
user@switch# set ge-0/0/1 unit 0 family ethernet-switching filter input watch-employee
```
6. Configure the **remote-analyzer** VLAN on the switches that connect this switch to the monitoring workstation.

**Results** Check the results of the configuration:

```
[edit]
user@switch# show
interfaces {
 ...
 ge-0/0/10 {
 unit 0 {
 family ethernet-switching {
```

```

 port-mode trunk;
 vlan {
 members remote-analyzer;
 }
 }
}
ge-0/0/0 {
 unit 0 {
 family ethernet-switching {
 filter {
 input watch-employee;
 }
 }
 }
}
ge-0/0/1 {
 unit 0 {
 family ethernet-switching {
 filter {
 input watch-employee;
 }
 }
 }
}
...
firewall {
 family ethernet-switching {
 ...
 filter watch-employee {
 term employee-to-web {
 from {
 destination-port 80;
 }
 then analyzer employee-web-monitor;
 }
 }
 }
}
ethernet-switching-options {
 analyzer employee-web-monitor {
 output {
 vlan {
 999;
 }
 }
 }
}
vlands {
 remote-analyzer {
 vlan-id 999;
 }
}

```

## Verification

---

### *Verifying That the Analyzer Has Been Correctly Created*

- Purpose** Verify that the analyzer named **employee-monitor** or **employee-web-monitor** has been created on the switch with the appropriate input interfaces and appropriate output interface.
- Action** You can verify the port mirror analyzer is configured as expected using the **show analyzer** command.
- ```
user@switch> show analyzer
Analyzer name           : employee-monitor
Output VLAN            : remote-analyzer
Ingress monitored interfaces : ge-0/0/0.0
Ingress monitored interfaces : ge-0/0/1.0
```
- Meaning** This output shows that the **employee-monitor** analyzer is mirroring the traffic entering **ge-0/0/0** and **ge-0/0/1** and is sending the mirror traffic to the analyzer **remote-analyzer**.
- Related Documentation**
- [Understanding Port Mirroring on page 4713](#)
 - [Configuring Port Mirroring on page 4730](#)
 - [Example: Configuring Port Mirroring for Local Analysis on page 4721](#)
 - [Overview of Firewall Filters on page 4409](#)

Configuration Tasks

- [Configuring Port Mirroring on page 4730](#)
- [Configuring DHCP and BOOTP Relay on page 4733](#)

Configuring Port Mirroring

You use port mirroring to copy packets and send the copies to a device running an application such as a network analyzer or intrusion detection application so that you can analyze traffic without delaying it. You can mirror traffic entering or exiting a port or entering a VLAN, and you can send the copies to a local access interface or to a VLAN through a trunk interface.

We recommend that you disable port mirroring when you are not using it. To avoid creating a performance issue. If you do enable port mirroring, we recommend that you select specific input interfaces instead of using the **all** keyword. You can also limit the amount of mirrored traffic by using a firewall filter.

NOTE: If you want to create additional analyzers without deleting an existing analyzer, first disable the existing analyzer using the **disable analyzer analyzer-name** command.

NOTE: You must configure port mirroring output interfaces as family `ethernet-switching`.

- [Configuring Port Mirroring for Local Analysis on page 4731](#)
- [Configuring Port Mirroring for Remote Analysis on page 4731](#)
- [Filtering the Traffic Entering an Analyzer on page 4732](#)

Configuring Port Mirroring for Local Analysis

To mirror interface traffic to a local interface on the switch:

1. If you want to mirror traffic that is ingressing or egressing specific interfaces, choose a name for the port-mirroring configuration and configure what traffic should be mirrored by specifying the interfaces and direction of traffic:

```
[edit ethernet-switching-options]
user@switch# set analyzer analyzer-name input (ingress | egress) interface interface-name
```

NOTE: If you configure Junos OS to mirror egress packets, do not configure more than 2000 VLANs. If you do so, some VLAN packets might contain incorrect VLAN IDs.

NOTE: If you configure mirroring for packets that egress an access interface, the original packets lose any VLAN tags when they exit the access interface, but the mirrored (copied) packets retain the VLAN tags when they are sent to the analyzer system.

2. If you want to specify that all traffic entering a VLAN should be mirrored, choose a name for the port-mirroring configuration and specify the VLAN:

```
[edit ethernet-switching-options]
user@switch# set analyzer analyzer-name input ingress vlan vlan-name
```

NOTE: You cannot configure port mirroring to copy traffic that egresses a VLAN.

3. Configure the destination interface for the mirrored packets:

```
[edit ethernet-switching-options]
user@switch# set analyzer analyzer-name output interface interface-name
```

Configuring Port Mirroring for Remote Analysis

To mirror traffic to a VLAN for analysis at a remote location:

1. Configure a VLAN to carry the mirrored traffic:

```
[edit]
```

```
user@switch# set vlans vlan-name vlan-id number
```

2. Configure the interface that connects to another switch (the uplink interface) to trunk mode and associate it with the appropriate VLAN:

```
[edit]
```

```
user@switch# set interfaces interface-name unit 0 family ethernet-switching port-mode  
trunk vlan members (vlan-name | vlan-id)
```

3. Configure the analyzer:

- a. Choose a name for the analyzer:

```
[edit ethernet-switching-options]
```

```
user@switch# set analyzer analyzer-name
```

- b. Specify the interface to be mirrored and whether the traffic should be mirrored on ingress or egress:

```
[edit ethernet-switching-options]
```

```
user@switch# set analyzer analyzer-name input (ingress | egress) interface interface-name
```

- c. Specify the appropriate IP address or VLAN as the output (a VLAN is specified in this example:

```
[edit ethernet-switching-options]
```

```
user@switch# set analyzer analyzer-name output vlan (vlan-name | vlan-id)
```

If you specify an IP address as the output, note the following constraints:

- The address cannot be in the same subnet as any of the switch's management interfaces.
- If you create virtual routing instances and also create an analyzer configuration that includes an output IP address, the output address belongs to the default virtual routing instance (*inet.0* routing table).
- The analyzer device must be able to de-encapsulate GRE-encapsulated packets, or the GRE-encapsulated packets must be de-encapsulated before reaching the analyzer device. (You can use a network sniffer to de-encapsulate the packets.)

Filtering the Traffic Entering an Analyzer

In addition to specifying which traffic to mirror by configuring an analyzer, you can also use a firewall filter to exercise more control over which packets are copied. For example, you might use a filter to specify that only traffic from certain applications be mirrored. The filter can use any of the available match conditions and must have an action of **analyzer *analyzer-name***. If you use the same analyzer in multiple filters or terms, the output packets are copied only once.

NOTE: You can include the action **analyzer** in ingress firewall filters only. You can apply ingress filters with this action to ports (Layer 2 interfaces), Layer 3 interfaces, and VLANs.

When you use a firewall filter as the input to an analyzer, you output the copied traffic to a local interface or a VLAN just as you do when a firewall is not involved.

To configure port mirroring with filters:

1. Configure an analyzer for local or remote analysis. Configure only the output. For example, for local analysis enter:

```
[edit ethernet-switching-options]
user@switch# set analyzer analyzer-name output interface interface-name
```

NOTE: Do not configure input to this analyzer.

2. Create a firewall filter using any of the available match conditions and specify the action as **analyzer *analyzer-name***.
3. Apply the firewall filter to the interfaces or VLAN that should provide the input to the analyzer:

```
[edit]
user@switch# set interfaces interface-name unit 0 family ethernet-switching filter input
filter-name
[edit]
user@switch# set vlan (vlan-name | vlan-id) filter input filter-name
```

Related Documentation

- [Example: Configuring Port Mirroring for Local Analysis on page 4721](#)
- [Example: Configuring Port Mirroring for Remote Analysis on page 4726](#)
- [Overview of Firewall Filters on page 4409](#)

Configuring DHCP and BOOTP Relay

You can configure the QFX Series to act as a Dynamic Host Configuration Protocol (DHCP) and Bootstrap Protocol (BOOTP) relay agent. This means that if a locally attached host can issue a DHCP or BOOTP request as a broadcast message and the switch relays the message to a specified DHCP or BOOTP server. You should configure a switch to be a DHCP and BOOTP relay agent if you have locally attached hosts and a remote DHCP or BOOTP server.

If you configure a switch to be a DHCP relay agent, you can also enable smart DHCP relay, which allows you to configure alternative gateway addresses for a DHCP server so that if the server fails to reply to the requests sent using the primary gateway address, the switch can resend the requests via the alternative gateway addresses. To use this feature, you must configure a routed VLAN interface or Layer 3 logical interface with multiple IP addresses and configure that interface to be a relay agent.

- [Configuring a DHCP and BOOTP Relay Agent on page 4733](#)
- [Configuring DHCP Smart Relay on page 4735](#)

Configuring a DHCP and BOOTP Relay Agent

To configure a switch to act as a DHCP and BOOTP relay agent, include the **bootp** statement at the **[edit forwarding-options helpers]** hierarchy level:

```
[edit forwarding-options helpers]
bootp {
  apply-secondary-as-giaddr text-description;
  client-response-ttl number;
  description text-description;
  interface (interface-name | interface-group) {
    client-response-ttl number;
    description text-description;
    maximum-hop-count number;
    minimum-wait-time seconds;
    no-listen;
    server address
    apply-secondary-as-giaddr
  }
  maximum-hop-count number;
  minimum-wait-time seconds;
  relay-agent-option;
  server server-identifier
}
```

To include a description of the BOOTP service, DHCP service, or interface, use the **description** statement.

To configure a logical interface or a group of logical interfaces with a specific DHCP relay or BOOTP configuration, include the **interface** statement.

To stop packets from being forwarded, include the **no-listen** statement.

To set the maximum allowed number in the hops field of the BOOTP message, include the **maximum-hop-count** statement. BOOTP messages that have a larger number in the hops field than the maximum allowed are not forwarded. If you omit the **maximum-hop-count** statement, the default maximum number of hops is four.

To set the minimum allowed number of seconds in the **secs** field of the BOOTP message, include the **minimum-wait-time** statement. This setting configures a minimum number of seconds since the client sent its first BOOTP request. BOOTP messages that have a smaller number in the **secs** field than the allowed minimum are not forwarded. The default value for the minimum wait time is zero (0).

To set the IP address that specify the DHCP or BOOTP server for the router, switch, or interface, include the **server** statement. You can include multiple **server** statements.

To set an IP time-to-live (TTL) value for DHCP response packets sent to a DHCP client, include the **client-response-ttl** statement.

The following example demonstrates a BOOTP relay agent configuration.

```
user@host# show forwarding-options
helpers {
  bootp {
    description "dhcp relay agent global parameters";
    server 192.168.55.44;
    server 172.16.0.3 routing-instance c3;
    maximum-hop-count 10;
    minimum-wait-time 8;
```

```

interface {
  xe-0/0/1 {
    description "use this info for this interface";
    server 10.10.10.10;
    server 192.168.14.14;
    maximum-hop-count 11;
    minimum-wait-time 3;
  }
  xe-0/0/2 {
    no-listen; ###ignore DHCPDISCOVER messages on this interface
  }
  all {
    description "globals apply to all other interfaces";
  }
}
}

```

Configuring DHCP Smart Relay

You can use DHCP smart relay to provide redundancy and resiliency to your DHCP relay configuration. Smart relay provides additional relay functionality and requires all of the configuration settings required by DHCP relay. To use DHCP smart relay, you also need an interface with multiple IP addresses assigned to it. You can achieve this by doing either of the following tasks:

- Create a routed VLAN interface and assign at least two IP addresses to it. See [“Configuring Routed VLAN Interfaces” on page 1532](#) and [“Example: Configuring Routing Between VLANs on One Switch” on page 1428](#) for information about this approach.
- Create a Layer 3 logical interface (by using VLAN tagging) and assign at least two IP addresses to it. See [“Understanding Layer 3 Logical Interfaces” on page 1851](#) and [“Configuring a Layer 3 Logical Interface” on page 2019](#) for information about this approach.

Once you have created an interface with multiple IP addresses, complete the smart relay configuration by entering one of the following statements:

- **set forwarding-options helpers bootp smart-relay-global:** Use this statement to enable smart relay on all the interfaces that are configured as relay agents.
- **set forwarding-options helpers bootp interface *interface-name* smart-relay-agent:** Use this statement to enable smart relay on a specific interface.

When smart relay is configured for an interface, the switch initially sends DHCP request (discover) messages out of that interface using the primary address of the interface as the gateway IP address (in the giaddr field) for the DHCP message. If no DHCP offer message is received from a server in reply, the switch allows the client to send as many as three more discover messages using the same gateway IP address. If no DHCP offer message is received after three retries, the switch resends the discover message using the alternate IP address as the gateway IP address. If you configure more than two IP addresses on the relay agent interface, the switch repeats this process until a DHCP offer message is received or all of the IP addresses have been used without success.

Configuration Statements for Port Mirroring

[edit [ethernet-switching-options](#)]

For platforms with ELS:

[edit [forwarding-options](#)]

Release Information Statement introduced in Junos OS Release 11.1 for the QFX Series.
Option **output** **vlan** added in Junos OS Release 12.1 for the QFX Series.
Option **output** **ip-address** added in Junos OS Release 12.3 for the QFX Series.

Description Configure port mirroring. You can create a total of four port-mirroring configurations on the QFX Series, subject to the following limits:

- There can be no more than two configurations that mirror ingress traffic.
- There can be no more than two configurations that mirror egress traffic.

Default Port mirroring is disabled, and Junos OS creates no default analyzers.

Options **all**—Mirror all the access interfaces. Using this option does not cause the QSFP+ or management interfaces to be mirrored.

CAUTION: Configuring the **all** option in a QFabric system causes all the access interfaces on all the nodes to be mirrored. Be cautious about using this option on a QFabric system.

name—Name of the analyzer. The name can include as many as 125 characters; must begin with a letter; and can include uppercase letters, lowercase letters, numbers, dashes, and underscores. No other special characters are allowed.

The remaining statements are explained separately.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

egress

Syntax egress {
 interface (all | *interface-name*);
}

Hierarchy Level For platforms without ELS:

[edit **ethernet-switching-options analyzer name input**]

For platforms with ELS:

[edit **forwarding-options analyzer name input**]

Release Information Statement introduced in Junos OS Release 11.2 for the QFX Series.

Description Specify interfaces for which egressing traffic is mirrored.

The statement is explained separately.

NOTE: If you configure Junos OS to mirror egress packets, do not configure more than 2000 VLANs. If you do so, some of the mirrored packets might contain incorrect VLAN IDs.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

interface (Port Mirroring)

| | |
|----------------------------|---|
| Syntax | interface (all <i>interface-name</i>); |
| Hierarchy Level | <p>For platforms without ELS:</p> <pre>[edit ethernet-switching-options analyzer <i>name</i> input (egress ingress)], [edit ethernet-switching-options analyzer <i>name</i> output]</pre> <p>For platforms with ELS:</p> <pre>[edit forwarding-options analyzer <i>name</i> input (egress ingress)] [edit forwarding-options analyzer <i>name</i> output]</pre> |
| Release Information | Statement introduced in Junos OS Release 11.1 for the QFX Series. |
| Description | Specify the interfaces for which ingressing traffic is mirrored. Specify the interface that mirrored traffic should be copied to (the output interface). |
| Options | <p>all—Apply port mirroring to all interfaces on the switch (except the output interface). Mirroring a high volume of traffic can cause performance issues, so you should generally select specific input interfaces.</p> |

CAUTION: Configuring all in a QFabric system causes all the access interfaces on all the nodes to be mirrored. Be cautious about using this option on a QFabric system.

interface-name—Apply port mirroring to the specified interface only.

| | |
|---------------------------------|---|
| Required Privilege Level | <p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p> |

ldap-url

| | |
|---------------------------------|--|
| Syntax | <ldap-url <i>url-name</i> >; |
| Hierarchy Level | [edit security certificates certification-authority <i>ca-profile-name</i>] |
| Release Information | Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.1 for the QFX Series. |
| Description | (Encryption interface on M Series and T Series routers and EX Series switches only)
(Optional) Specify the Lightweight Directory Access Protocol (LDAP) URL for digital certificates. |
| Options | <i>url-name</i> —Name of the LDAP URL. |
| Required Privilege Level | system—To view this statement in the configuration.
system-control—To add this statement to the configuration. |
| Related Documentation | <ul style="list-style-type: none">• <i>Configuring Digital Certificates for an ES PIC</i> |

local

| | |
|---------------------------------|--|
| Syntax | <pre>local <i>certificate-name</i> {
 <i>certificate-key-string</i>;
 load-key-file <i>URL filename</i>;
}</pre> |
| Hierarchy Level | [edit security certificates] |
| Release Information | Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.1 for the QFX Series. |
| Description | Import a paired X.509 private key and authentication certificate, to enable Junos XML protocol client applications to establish Secure Sockets Layer (SSL) connections to the router or switch. |
| Options | <p><i>certificate-namecertificate-key-string</i>—String of alphanumeric characters that constitute the private key and certificate.</p> <p><i>certificate-name</i>—Name that uniquely identifies the certificate.</p> <p><i>load-key-file URL filename</i>—File that contains the private key and certificate. It can be one of two types of values:</p> <ul style="list-style-type: none">• Pathname of a file on the local disk (assuming you have already used another method to copy the certificate file to the router's or switch's local disk)• URL to the certificate file location (for instance, on the computer where the Junos XML protocol client application runs) |
| Required Privilege Level | system—To view this statement in the configuration.
system-control—To add this statement to the configuration. |
| Related Documentation | <ul style="list-style-type: none">• <i>Importing SSL Certificates for Junos XML Protocol Support</i> |

maximum-certificates

| | |
|---------------------------------|--|
| Syntax | maximum-certificates <i>number</i> ; |
| Hierarchy Level | [edit security certificates] |
| Release Information | Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.1 for the QFX Series. |
| Description | (Encryption interface on M Series and T Series routers and EX Series switches only)
Configure the maximum number of peer digital certificates to be cached. |
| Options | <i>number</i> —Maximum number of peer digital certificates to be cached.
Range: 64 through 4,294,967,295 peer certificates
Default: 1024 peer certificates |
| Required Privilege Level | system—To view this statement in the configuration.
system-control—To add this statement to the configuration. |
| Related Documentation | <ul style="list-style-type: none"> • <i>Configuring Digital Certificates for an ES PIC</i> |

path-length

| | |
|---------------------------------|--|
| Syntax | path-length <i>certificate-path-length</i> ; |
| Hierarchy Level | [edit security certificates] |
| Release Information | Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.1 for the QFX Series. |
| Description | (Encryption interface on M Series and T Series routers and EX Series switches only)
Configure the digital certificate path length. |
| Options | <i>certificate-path-length</i> —Digital certificate path length.
Range: 2 through 15 certificates
Default: 15 certificates |
| Required Privilege Level | admin—To view this statement in the configuration.
admin-control—To add this statement to the configuration. |
| Related Documentation | <ul style="list-style-type: none"> • <i>Configuring Digital Certificates for an ES PIC</i> |

secret

| | |
|---------------------------------|---|
| Syntax | <code>secret <i>secret-data</i>;</code> |

ssh-known-hosts

| | |
|--------------------------|---|
| Syntax | <pre>ssh-known-hosts {
 host <i>host-name</i> {
 fetch-from-server <i>host-name</i>;
 load-key-file <i>file-name</i>;
 }
}</pre> |
| Hierarchy Level | [edit security ssh-known-hosts] |
| Release Information | Statement introduced in Junos OS Release 11.1 for the QFX Series. |
| Description | Configure SSH support for known hosts and for administering SSH host key updates. |
| Options | <p>host <i>host-name</i>—Hostname of the SSH known host entry. This option has the following suboptions:</p> <ul style="list-style-type: none">• fetch-from-server <i>host-name</i>—Retrieve SSH public host key information from a specified server.• load-key-file <i>filename</i>—Import SSH host key information from the <code>/var/tmp/ssh-known-hosts</code> file. |
| Required Privilege Level | <p>admin—To view this statement in the configuration.</p> <p>admin-control—To add this statement to the configuration.</p> |

start-time (Authentication Key Transmission)

| | |
|---------------------------------|--|
| Syntax | <code>start-time (now yyyy-mm-dd.hh:mm:ss);</code> |
| Hierarchy Level | [edit security authentication-key-chains key-chain <i>key-chain-name</i> key <i>key</i>] |
| Release Information | <p>Statement introduced in Junos OS Release 7.6.</p> <p>Statement introduced in Junos OS Release 9.0 for EX Series switches.</p> <p>Support for the BFD protocol introduced in Junos OS Release 9.6.</p> <p>Support for the BFD protocol introduced in Junos OS Release 9.6 for EX Series switches.</p> <p>Support for IS-IS introduced in JUNOS OS Release 11.2.</p> <p>Statement introduced in Junos OS Release 11.3 for QFX Series switches.</p> |
| Description | <p>Specify a start time for key transmission. You do not need to specify an end time for the key. If a new key is present with a new start time, the keychain rolls over to the new one. The start time must be unique within the keychain.</p> |
| Options | <p>now—Start time as the current year, month, day, hour, minute, and second.</p> <p>daydays—Start time as the specified number of days after the current day. For example, if the current day is the 12th and you configure start-time 2day, the start time will be on the 14th, exactly two days after the configuration is entered.</p> <p>hourhours—Start time as the specified number of hours after the current hour. For example, if the current hour is 9:00 and you configure start-time 3hour, the start time will be in 12:00, exactly three hours after the configuration is entered.</p> <p>minuteminutes—Start time as the specified number of minutes after the current minute. For example, if the current minute is 27 minutes after the hour and you configure start-time 5min, the start time will be in 32 minutes after the hour, exactly five minutes after the configuration is entered.</p> <p>monthmonths—Start time as the specified number of months after the current month. For example, if the current month is March and you configure start-time 4month, the start time will be in July, exactly four months after the configuration is entered.</p> <p>secondseconds—Start time as the specified number of seconds after the current second. For example, if the current second is 10:20:40 and you configure start-time 10seconds, the start time will be 10:20:50, exactly 10 seconds after the configuration is entered.</p> <p>yearyears—Start time as the specified number of years after the current year. For example, if the current year is 2011 and you configure start-time 1year, the start time will be in 2012, exactly one year after the configuration is entered.</p> <p>yyyy-mm-dd.hh:mm:ss—Start time in UTC (Coordinated Universal Time). The start time must be unique within the keychain.</p> |
| Required Privilege Level | <p>admin—To view this statement in the configuration.</p> <p>admin-control—To add this statement to the configuration.</p> |

traceoptions

| | |
|---|--|
| Syntax | <pre> traceoptions { file <i>filename</i> <files <i>number</i>> <size <i>size</i>>; flag all; flag certificates; flag database; flag general; flag ike; flag parse; flag policy-manager; flag routing-socket; flag timer; level no-remote-trace } </pre> |
| Hierarchy Level | <p>[edit security],
[edit services ipsec-vpn]</p> <p>Trace options can be configured at either the [edit security] or the [edit services ipsec-vpn] hierarchy level, but not at both levels.</p> |
| Release Information | <p>Statement introduced before Junos OS Release 7.4.</p> <p>Statement introduced in Junos OS Release 9.0 for EX Series switches.</p> <p>Statement introduced in Junos OS Release 11.1 for the QFX Series.</p> |
| Description | <p>Configure security trace options.</p> <p>To specify more than one trace option, include multiple flag statements. Trace option output is recorded in the <code>/var/log/kmd</code> file.</p> |
| <div style="display: flex; align-items: center;">  <p>NOTE: The <code>traceoptions</code> statement is not supported on QFabric systems.</p> </div> | |
| Options | <p>files <i>number</i>—(Optional) Maximum number of trace files. When a trace file (for example, kmd) reaches its maximum size, it is renamed kmd.0, then kmd.1, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.</p> <p>If you specify a maximum number of files, you must also specify a maximum file size with the size option.</p> <p>Range: 2 through 1000 files</p> <p>Default: 0 files</p> <p>size <i>size</i>—(Optional) Maximum size of each trace file, in kilobytes (KB). When a trace file (for example, kmd) reaches this size, it is renamed, kmd.0, then kmd.1 and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.</p> <p>Default: 1024 KB</p> |

flag *flag*—Trace operation to perform. To specify more than one trace operation, include multiple **flag** statements.

- **all**—Trace all security events.
- **certificates**—Trace certificate events.
- **database**—Trace database events.
- **general**—Trace general events.
- **ike**—Trace IKE module processing.
- **parse**—Trace configuration processing.
- **policy-manager**—Trace policy manager processing.
- **routing-socket**—Trace routing socket messages.
- **timer**—Trace internal timer events.

level *level*—(Optional) Set traceoptions level.

- **all**—match all levels.
- **error**—Match error conditions.
- **info**—Match informational messages.
- **notice**—Match conditions that should be handled specially.
- **verbose**—Match verbose messages.
- **warning**—Match warning messages.

no-remote-trace—(Optional) Disable remote tracing

| | |

List of Sample Output [show analyzer on page 4776](#)

Output Fields [Table 366 on page 4776](#) describes the output fields for the **show analyzer** command. Output fields are listed in the approximate order in which they appear.

Table 366: show analyzer Output Fields

| Field Name | Field Description |
|------------------------------|---|
| Analyzer name | Name of the analyzer. |
| Output interface | Local interface to which mirror packets are sent. If you configure an output interface, you cannot also configure an output VLAN. |
| Output VLAN | VLAN to which mirror packets are sent. If you configure an output VLAN, you cannot also configure an output interface. |
| Egress monitored interfaces | Interfaces for which egress traffic is mirrored. |
| Ingress monitored interfaces | Interfaces for which ingress traffic is mirrored. |
| Ingress monitored VLANs | VLANs for which ingress traffic is mirrored. |

Sample Output

show analyzer

```

user@switch> show analyzer
Analyzer name      : employee-monitor
Output interface   : ge-0/0/10.0
Output VLAN        : remote-analyzer

```

```
Egress monitored interfaces : ge-0/0/7.0  
Ingress monitored interfaces : ge-0/0/8.0  
Ingress monitored interfaces : ge-0/0/9.0
```

Port Mirroring Constraints and Limitations

- [Local and Remote Port Mirroring on page 4779](#)
- [Remote Port Mirroring Only on page 4781](#)

Local and Remote Port Mirroring

The following constraints and limitations apply to local and remote port mirroring with the QFX Series:

- You can create a total of four port-mirroring configurations on a QFX Series standalone switch.
- You can create a total of four port-mirroring configurations on each Node group in a QFabric system, subject to the following constraints:
 - As many as four of the configurations can be for local port mirroring.
 - As many as three of the configurations can be for remote port mirroring.
- Regardless of whether you are configuring a standalone switch or a Node group, the following limits apply:
 - There can be no more than two configurations that mirror ingress traffic. (If you configure a firewall filter to send traffic to a port mirror—that is, you use the **analyzer** action modifier in a filter term—this counts as an ingress mirroring configuration for switch or Node group on which the filter is applied.)
 - There can be no more than two configurations that mirror egress traffic.

NOTE: On QFabric systems, there is no system-wide limit on the total number of mirror sessions.

- You can configure no more than one type of output in one port-mirroring configuration. That is, you can use no more than one of the following to complete a **set analyzer name output** statement:
 - **interface**
 - **ip-address**
 - **vlan**
- If you configure Junos OS to mirror egress packets, do not configure more than 2000 VLANs on a QFX3500 device or QFabric system. If you do so, some VLAN packets might contain incorrect VLAN IDs. This applies to any VLAN packets—not only the mirrored copies.
- The **ratio** and **loss-priority** options are not supported.
- Packets with physical layer errors are filtered out and are not sent to the output port or VLAN.
- If you use sFlow monitoring to sample traffic, it does not sample the mirror copies when they exit from the output interface.
- You cannot mirror packets exiting or entering the following ports:
 - Dedicated Virtual Chassis interfaces
 - Management interfaces (me0 or vme0)
 - Fibre Channel interfaces
 - Routed VLAN interfaces
- An aggregated Ethernet interface cannot be an output interface.
- Do not include an 802.1Q subinterface that has a unit number other than 0 in a port mirroring configuration. Port mirroring does not work with subinterfaces if their unit number is not 0. (You configure 802.1Q subinterfaces using the **vlan-tagging** statement.)
- When packet copies are sent out the output interface, they are not modified for any changes that are normally applied on egress, such as CoS rewriting.
- An interface can be the input interface for only one mirroring configuration. Do not use the same interface as the input interface for multiple mirroring configurations.
- CPU-generated packets (such as ARP, ICMP, BPDUs, and LACP packets) cannot be mirrored on egress.
- VLAN-based mirroring is not supported for STP traffic.
- (QFabric systems only) If you configure a QFabric analyzer to mirror egress traffic and the input and output interfaces are on different Node devices, the mirrored copies have incorrect VLAN IDs. This limitation does not apply if you configure a QFabric analyzer

to mirror egress traffic and the input and output interfaces are on the *same* Node device. In this case the mirrored copies have the correct VLAN IDs (as long as you do not configure more than 2000 VLANs on the QFabric system).

Remote Port Mirroring Only

The following constraints and limitations apply to remote port mirroring with the QFX Series:

- If you configure an output IP address, the address cannot be in the same subnetwork as any of the switch's management interfaces.
- If you create virtual routing instances and also create an analyzer configuration that includes an output IP address, the output address belongs to the default virtual routing instance (inet.0 routing table).
- An output VLAN cannot be a private VLAN or VLAN range.
- An output VLAN cannot be shared by multiple **analyzer** statements.
- An output VLAN interface cannot be a member of any other VLAN.
- An output VLAN interface cannot be an aggregated Ethernet interface.
- On the source (monitored) switch, only one interface can be a member of the analyzer VLAN.

Egress Port Mirroring with VLAN Translation

Problem If you create a port-mirroring configuration that mirrors customer VLAN (CVLAN) traffic on egress and the traffic undergoes VLAN translation before being mirrored, the VLAN translation does not apply to the mirrored packets. That is, the mirrored packets retain the service VLAN (SVLAN) tag that should be replaced by the CVLAN tag on egress. The original packets are unaffected—on these packets VLAN translation works properly, and the SVLAN tag is replaced with the CVLAN tag on egress.

Solution This is expected behavior.

Egress Port Mirroring with Private VLANs

Problem If you create a port-mirroring configuration that mirrors private VLAN (PVLAN) traffic on egress, the mirrored traffic (the traffic that is sent to the analyzer system) has the VLAN tag of the ingress VLAN instead of the egress VLAN. For example, assume the following PVLAN configuration:

- Promiscuous trunk port that carries primary VLANs pvlan100 and pvlan400.
- Isolated access port that carries secondary VLAN isolated200. This VLAN is a member of primary VLAN pvlan100.
- Community port that carries secondary VLAN comm300. This VLAN is also a member of primary VLAN pvlan100.
- Output interface (monitor interface) that connects to the analyzer system. This interface forwards the mirrored traffic to the analyzer.

If a packet for pvlan100 enters on the promiscuous trunk port and exits on the isolated access port, the original packet is untagged on egress because it is exiting on an access port. However, the mirror copy retains the tag for pvlan100 when it is sent to the analyzer.

Here is another example: If a packet for comm300 ingresses on the community port and egresses on the promiscuous trunk port, the original packet carries the tag for pvlan100 on egress, as expected. However, the mirrored copy retains the tag for comm300 when it is sent to the analyzer.

Solution This is expected behavior.

Overview of Fibre Channel on the QFX Series

Fibre Channel (FC) is a high-speed network technology that interconnects network elements and allows them to communicate with one another. The International Committee for Information Technology Standards (INCITS) T11 Technical Committee sets FC standards.

FC networks provide high-performance characteristics such as lossless transport combined with flexible network topology. FC is primarily used in storage area networks (SANs) because it provides reliable, lossless, in-order frame transport between initiators and targets. FC components include initiators, targets, and FC-capable switches that interconnect FC devices and may also interconnect FC devices with Fibre Channel over Ethernet (FCoE) devices. Initiators originate I/O commands. Targets receive I/O commands. For example, a server can initiate an I/O request to a storage device target.

Juniper Networks QFX Series can function as an FCoE-FC gateway or as an FCoE transit switch.

FCoE transports native FC frames over an Ethernet network by encapsulating the unmodified frames in Ethernet. It also provides protocol extensions to discover FCoE devices through the Ethernet network. FCoE requires that the Ethernet network support data center bridging (DCB) extensions that ensure lossless transport and allow the Layer 2 Ethernet domain to meet the requirements of FC transport.

The FCoE-FC gateway functionality is a licensed feature on the QFX Series. As an FCoE-FC gateway, the switch connects FCoE devices on an Ethernet network to a SAN FC switch.

You do not need a license to use the switch as an FCoE transit switch. As an FCoE transit switch, the switch:

- Is a Layer 2 data center bridging (DCB) switch that can transport FCoE frames.
- Implements FCoE Initialization Protocol (FIP) snooping.
- Connects multiple FCoE endpoints to the FC network.

NOTE: The QFX3600 switch does not support FC because it does not support native FC port configuration. The QFX3600 switch supports FCoE.

QFX3500 and QFX3600 Virtual Chassis switches do not support FC or FCoE.

This topic describes:

Fibre Channel Transport Protocol

The Fibre Channel Protocol is a transport protocol that consists of five layers as shown in [Table 367 on page 4787](#):

Table 367: Fibre Channel Protocol Layers

| FC Protocol Layer | Description |
|-------------------|--|
| FC-0 | Physical (cabling, connectors, and so on) |
| FC-1 | Data link layer |
| FC-2 | Network layer (defines the main protocols) |
| FC-3 | Common services |
| FC-4 | Protocol mapping |

The FC protocol layers are generally split into three groups:

- FC-0 and FC-1 are the physical layers.
- FC-2 is the protocol layer, similar to OSI Layer 3.
- FC-3 and FC-4 are the services layers.

The FCoE-FC gateway operates the physical layers and the protocol layer, and provides FIP and service redirection at the services layer.

How FC Works on the QFX Series

The switch connects devices that support FC and Ethernet (such as FCoE servers on an Ethernet network) to an FC SAN, thus converging the Ethernet and FC networks on a single physical network infrastructure. The switch provides the class-of-service (CoS) features needed to handle the different types of traffic appropriately.

To converge FC and Ethernet networks, you can configure the switch as an:

- [FCoE-FC Gateway on page 4787](#)
- [FCoE Transit Switch on page 4788](#)
- [FCoE VLANs on page 4788](#)

FCoE-FC Gateway

When the switch functions as an FCoE-FC gateway, the switch aggregates FCoE traffic and performs the encapsulation and de-encapsulation of native FC frames in Ethernet as it transports the frames between FCoE devices in the Ethernet network and the FC switch. In effect, the switch translates Ethernet to FC and FC to Ethernet.

The gateway receives FC frames encapsulated in Ethernet from FCoE devices through an FCoE VLAN interface composed of one or more 10-Gigabit Ethernet interfaces. The

gateway removes the Ethernet encapsulation from the FC frames, and then sends the native FC frames to the FC switch through a native FC interface.

The gateway receives native FC frames from the FC switch on the gateway's native FC interfaces. The gateway encapsulates the native FC frames in Ethernet, and then sends the encapsulated frames to the appropriate FCoE device through the FCoE VLAN interface.

To FCoE devices, the gateway behaves like an FC switch and can present multiple virtual F_Ports (VF_Ports) on a single interface. To an FC switch, the gateway behaves like an FC node that is doing N_Port ID virtualization (NPIV).

FCoE Transit Switch

When the switch functions as an FCoE transit switch, it forwards traffic (including FCoE traffic) based on Layer 2 media access control (MAC) forwarding and is a normal DCB-enabled Layer 2 switch that also performs FIP snooping. The switch aggregates FCoE traffic and passes it through to an FCF. The switch does not remove the Ethernet encapsulation from the FC frames, but it does preserve the class of service (CoS) required to transport FC frames.

The switch inspects (snoops) FIP information in order to create filters that permit only valid FCoE traffic to flow through the switch between FCoE devices and the FCF. The switch does not use native FC ports because the FC frames are encapsulated in Ethernet when they flow between the FCoE devices and the FCF. Virtual point-to-point links between each FCoE device and the FCF pass transparently through the switch, so the switch is not seen as a terminating point or an intermediate point by FCoE devices or by the FCF.

FCoE VLANs

On the QFX Series, all FCoE traffic must travel in a VLAN dedicated to transporting only FCoE traffic. Only FCoE interfaces should be members of an FCoE VLAN. Ethernet traffic that is not FCoE or FIP traffic must travel in a different VLAN.

NOTE: On a QFX3500 or QFabric system Node device, the same VLAN cannot be used in both transit switch mode and FCoE-FC gateway mode.

NOTE: FCoE VLANs (any VLAN that carries FCoE traffic) support only Spanning Tree Protocol (STP) and link aggregation group (LAG) Layer 2 features. IGMP snooping is enabled by default on all VLANs; be sure to disable IGMP snooping on FCoE VLANs.

You can configure more than one FCoE VLAN, but any given virtual link must be in only one FCoE VLAN.

NOTE: All 10-Gigabit Ethernet interfaces that connect to FCoE devices must have a native VLAN configured in order to transport FIP traffic, because FIP VLAN discovery and notification frames are exchanged as untagged packets.

BEST PRACTICE: Only FCoE traffic is permitted on the FCoE VLAN. A native VLAN might need to carry untagged traffic of different types and protocols. Therefore, it is a good practice to keep the native VLAN separate from FCoE VLANs.

Supported FC Features and Functions

QFX Series supports the following features and functionality:

- As an FCoE-FC gateway:
 - DCB, including Data Center Bridging Capability Exchange protocol (DCBX), priority-based flow control (PFC), enhanced transmission service (ETS), and 10-Gigabit Ethernet interfaces
 - FCoE Initialization Protocol (FIP)
 - Proxy for FCoE devices when communicating with FC switches and acts as a proxy for FC switches when communicating with FCoE devices
 - Up to 12 native FC interfaces per QFX3500 switch (each interface can be configured as a 2-Gigabit, 4-Gigabit, or 8-Gigabit Ethernet interface)
- As an FCoE transit switch:
 - DCB functions
 - FIP snooping
 - Transparent Layer 2 MAC forwarding of FCoE frames

Lossless Transport Support

The QFX Series supports up to six lossless forwarding classes. For lossless transport, you must enable PFC on the IEEE 802.1p code point of lossless forwarding classes. The following limitations apply to support lossless transport:

- The external cable length from the QFX3500 or QFabric system Node device to other devices cannot exceed 300 meters.
- The internal cable length from the QFabric system Node device to the QFabric system Interconnect device cannot exceed 150 meters.
- For FCoE traffic, the interface maximum transmission unit (MTU) must be at least 2180 bytes to accommodate the packet payload, headers, and checks.

Overview of FIP

Fibre Channel over Ethernet (FCoE) Initialization Protocol (FIP) is a Layer 2 protocol that establishes and maintains Fibre Channel (FC) virtual links between pairs of FCoE devices such as server FCoE Nodes (ENodes) and FC switches. FIP can also establish and maintain virtual links between FCoE devices and an FCoE-FC gateway such as the QFX Series, where the gateway acts on behalf of the FC switch.

FIP enables FCoE devices to discover one another and to initialize and maintain virtual links over a physical Ethernet network. This allows FCoE devices in the Ethernet network to access storage devices in the FC storage area network (SAN).

FIP solves the problem presented by the FC requirement for point-to-point connections (FC does not permit point-to-multipoint connections) by creating a unique virtual link for each connection between an ENode VN_Port and an FC switch VF_Port. Multiple virtual links can use a single physical link and virtual links can traverse Ethernet transit (passthrough) switches while appearing to be direct point-to-point connections to the FC switch.

FIP has its own EtherType (0x8914) to distinguish its traffic from payload-carrying FCoE traffic and other Ethernet traffic. FIP operations occur on a per-VLAN basis.

For more details about FIP, see the Technical Committee T11 organization document *Fibre Channel Backbone - 5 (FC-BB-5) Rev 2.00* available at <http://www.t11.org/ftp/t11/pub/fc/bb-5/09-056v5.pdf>.

Understanding Fibre Channel

Fibre Channel (FC) is a serial I/O interconnect network technology capable of supporting multiple protocols. It is used primarily for storage area networks (SANs). The committee standardizing FC is the International Committee for Information Technology Standards (INCITS).

When configured as a Fibre Channel over Ethernet (FCoE)-FC gateway, the QFX Series supports the transport of native FC traffic between FC switches and the gateway's native FC interfaces.

NOTE: The QFX3600 switch does not support FC because it does not support native FC port configuration. In addition, QFX3500 and QFX3600 Virtual Chassis switches do not support FC.

FC concepts include:

- [FC Fabrics on page 4792](#)
- [FC Port Types on page 4792](#)
- [FC Switches on page 4793](#)
- [Adapters on page 4793](#)
- [N_Port ID Virtualization \(NPIV\) on page 4793](#)
- [FC Services on page 4794](#)

FC Fabrics

An FC fabric is a switched network topology that interconnects FC devices using FC switches, usually to create a SAN. An FC switch is a Layer 3 network switch that is compatible with the FC protocol, forwards FC traffic, and provides FC services to the components of the FC fabric. FC devices are usually servers or storage devices such as disk arrays.

Switches called FCoE forwarders (FCFs) perform a subset of FC switch functions. An FCF is a Layer 3 network switch that is compatible with the FC protocol and forwards FC traffic, but does not provide network services.

When configured as an FCoE-FC gateway, the QFX Series acts a proxy for the FCF functionality of an FC switch. The gateway provides FCoE devices on the Ethernet network access to the FC network without requiring the FC switches in the SAN to support Ethernet interfaces. The gateway is not an FCF and does not provide FC services.

FC network design often uses two fabrics (dual-rail topology) for redundancy. The two fabrics connect to edge devices but are otherwise unconnected, so that if one fabric goes down, the other fabric can continue to provide connectivity.

FC Port Types

The QFX Series supports the following FC port types:

- **N_Port**—An N_Port is a port on the node of an FC device such as a server or a storage device and is also known as a node port.
- **F_Port**—An F_Port is a port on an FC switch that connects to an FC device N_Port in a point-to-point connection. F_Ports are also known as fabric ports.

These port types are a subset of the existing FC port types that can be supported in an FC fabric.

FC Switches

FC switches provide FC services to the FC network. FC switches forward Layer 3 traffic. They may transport a combination of native FC traffic and other traffic, such as Internet Small Computer Systems Interface (iSCSI) or FCoE, or they may transport only native FC traffic. When an FC switch supports FCoE, it combines FCoE termination functions with the FC stack on an FC switching element. This is also known as a dual-stack switch.

When FC switches support FCoE, they present virtual FC interfaces in the form of virtual F_Ports (VF_Ports) to the FCoE nodes (ENodes) on FCoE devices. A VF_Port is an endpoint in a virtual point-to-point connection with an ENode virtual N_Port (VN_Port). A VF_Port emulates a native FC F_Port and performs similar functions. A VF_Port is an intermediate port in a connection between an FCoE device such as a server in the Ethernet network and a storage device in the FC SAN.

FC switches that support FCoE contain at least one lossless Ethernet media access controller (MAC) paired with an FCoE controller. The lossless Ethernet MAC implements Ethernet extensions to avoid frame loss due to congestion. The FCoE controller instantiates and terminates virtual port instances as they are needed. Each VF_Port instance has one unique virtual link to an ENode VN_Port.

FCoE support also requires one FCoE Link End Point (LEP) for each VF_Port connection. An FCoE LEP is a virtual FC interface mapped onto the physical Ethernet interface. It transmits and receives FCoE frames on the virtual link, and handles FC frame encapsulation for traffic going from the FC switch to the FCoE device and frame de-encapsulation of traffic received from the FCoE device.

When you configure the QFX Series as an FCoE-FC gateway, the gateway performs these FC-to-Ethernet and Ethernet-to-FC conversion functions so that the FC switch does not need Ethernet (FCoE) ports.

Adapters

FC host bus adapters (HBAs) in FC switches and devices perform functions similar to those of Ethernet adapters in Ethernet switches and devices. Switches that perform FCoE functions and FCoE devices have converged network adapters (CNAs) that support both native FC and Ethernet functionality.

N_Port ID Virtualization (NPIV)

FC requires a unique point-to-point link between the FC switch (F_Port) and each host N_Port. In order to avoid using one physical link for each F_Port to N_Port connection, the port connections must be virtualized so that they can share a physical link while maintaining logical separation.

FC accomplishes this by enabling you to create an independent virtual link for each FC session by mapping each session to a virtualized N_Port. This process is called N_Port ID virtualization (NPIV).

NPIV makes each virtual link look like a dedicated point-to-point link. In this way, multiple FC devices and multiple applications or virtual machines (VMs) on a single FC device can connect to an FC switch using one physical port instead of using a physical port for each connection. The virtual link creates a secure boundary between traffic from different sources on a single physical connection.

NPIV works by creating a unique virtual port identifier for each logical connection on a physical port. Conceptually, this is similar to splitting a single physical interface into multiple logical interfaces or subinterfaces. A virtual port identifier consists of the port's unique worldwide name (WWN) combined with a Fibre Channel ID (FCID) that the FC switch assigns to the virtual connection. This creates a virtual host bus adapter (HBA) for each virtual link that uniquely identifies the link to the FC switch.

FC Services

When you configure the QFX Series as an FCoE-FC gateway, the gateway connects FCoE devices in the Ethernet network to the FC fabric. The gateway does not provide FC services directly. The gateway logs in to the FC fabric and obtains FC services from the FC fabric, including:

- Management servers
 - Zone server—Defines which devices can connect to each other in the FC fabric.
 - Fabric configuration server—Discovers FC fabric topology and attributes.
 - Policy server—Distributes the rules for administering, managing, and controlling access to FC fabric resources.
 - HBA management server—Registers HBA information with the FC fabric.
- Domain manager—Allocates domain IDs to virtual switches.
- Fabric login server—Provides login services to the gateway so that the native FC ports on the gateway can perform initial fabric login (FLOGI) to the FC fabric and subsequent fabric discovery (FDISC) logins for the physical and virtual ports on the FCoE devices in the Ethernet network. This includes allocating Fibre Channel IDs (FCIDs) to ports.
- Name server—Discovers, registers, and unregisters N_Port attributes, including the attributes of the native FC ports on the gateway that connect to the FC fabric.
- Event server—Validates incoming events to ensure transaction integrity.
- Time server—Maintains a common time for devices in the FC fabric.
- Fabric controller
 - Fabric Shortest Path First (FSPF)—The FC fabric provides link-state path selection to the gateway.

- State change notification (SCN) / registered state change notification server (RSCN)—Notifies the appropriate nodes when new devices come online, when other nodes fail, or when changes on an online node affect system operation.

Understanding DCB Features and Requirements

Data center bridging (DCB) is a set of enhancements to the IEEE 802.1 bridge specifications. DCB modifies and extends Ethernet behavior to support I/O convergence in the data center. I/O convergence includes but is not limited to the transport of Ethernet LAN traffic and Fibre Channel (FC) storage area network (SAN) traffic on the same physical Ethernet network infrastructure.

A converged architecture saves cost by reducing the number of networks and switches required to support both types of traffic, reducing the number of interfaces required, reducing cable complexity, and reducing administration activities.

The Juniper Networks QFX Series supports the DCB features required to transport converged Ethernet and FC traffic while providing the class-of-service (CoS) and other characteristics FC requires for transmitting storage traffic. To accommodate FC traffic, DCB specifications provide:

- A flow control mechanism called priority-based flow control (PFC, described in IEEE 802.1Qbb) to help provide lossless transport.
- A discovery and exchange protocol for conveying configuration and capabilities among neighbors to ensure consistent configuration across the network, called Data Center Bridging Capability Exchange protocol (DCBX), which is an extension of Link Layer Data Protocol (LLDP, described in IEEE 802.1AB).
- A bandwidth management mechanism called enhanced transmission selection (ETS, described in IEEE 802.1Qaz).
- A congestion management mechanism called quantized congestion notification (QCN, described in IEEE 802.1Qau).

The switch supports the PFC, DCBX, and ETS standards but does not support QCN. The switch also provides the high-bandwidth interfaces (10-Gbps minimum) required to support DCB and converged traffic.

This topic describes the DCB standards and requirements the switch supports:

- [Lossless Transport on page 4796](#)
- [ETS on page 4797](#)
- [DCBX on page 4797](#)

Lossless Transport

FC traffic requires lossless transport (defined as no frames dropped because of congestion). Standard Ethernet does not support lossless transport, but the DCB extensions to Ethernet along with proper buffer management enable an Ethernet network to provide the level of class of service (CoS) necessary to transport FC frames encapsulated in Ethernet over an Ethernet network.

This section describes these factors in creating lossless transport over Ethernet:

- [PFC on page 4796](#)
- [Buffer Management on page 4796](#)
- [Physical Interfaces on page 4796](#)

PFC

PFC is a link-level flow control mechanism similar to Ethernet PAUSE (described in IEEE 802.3x). Ethernet PAUSE stops all traffic on a link for a period of time. PFC enables you to divide traffic on a link into eight priorities and stop the traffic of a selected priority without stopping the traffic assigned to other priorities on the link.

Pausing the traffic of a selected priority enables you to provide lossless transport for traffic assigned that priority and at the same time use standard lossy Ethernet transport for the rest of the link traffic.

Buffer Management

Buffer management is critical to the proper functioning of PFC, because if buffers are allowed to overflow, frames are dropped and transport is not lossless.

For each lossless flow priority, the switch requires sufficient buffer space to:

- Store frames sent during the time it takes to send the PFC pause frame across the cable between devices.
- Store the frames that are already on the wire when the sender receives the PFC pause frame.

The propagation delay due to cable length and speed, as well as processing speed, determines the amount of buffer space needed to prevent frame loss due to congestion.

The switch automatically sets the threshold for sending PFC pause frames to accommodate delay from cables as long as 150 meters (492 feet) and to accommodate large frames that might be on the wire when the switch sends the pause frame. This ensures that the switch sends pause frames early enough to allow the sender to stop transmitting before the receive buffers on the switch overflow.

Physical Interfaces

The switch supports 10-Gbps, full-duplex interfaces. The switch enables DCB capability only on 10-Gbps (or faster) Ethernet interfaces.

ETS

PFC divides traffic into up to eight separate streams (priorities, configured on the switch as forwarding classes) on a physical link. ETS enables you to manage the link bandwidth by:

- Grouping the priorities into priority groups (configured on the switch as forwarding class sets).
- Specifying the bandwidth available to each of the priority groups as a percentage of the total available link bandwidth.
- Allocating the bandwidth to the individual priorities in the priority group.

The available link bandwidth is the bandwidth remaining after servicing strict priority flows.

Managing link bandwidth with ETS provides several advantages:

- There is uniform management of all types of traffic on the link, both congestion-managed traffic and standard Ethernet traffic.
- When a priority group does not use all of its allocated bandwidth, other priority groups on the link can use that bandwidth as needed.

When a priority in a priority group does not use all of its allocated bandwidth, other priorities in the group can use that bandwidth.

The result is better bandwidth utilization, because priorities that consist of bursty traffic can share bandwidth during periods of low traffic transmission instead of consuming their entire bandwidth allocation when traffic loads are light.

- You can assign traffic types with different service needs to different priorities so that each traffic type receives appropriate treatment.
- Strict priority traffic retains its allocated bandwidth.

DCBX

DCB devices use DCBX to exchange configuration information with directly connected peers (switches and endpoints such as servers). DCBX is an extension of LLDP. If you disable LLDP on an interface, that interface cannot run DCBX. If you attempt to enable DCBX on an interface on which LLDP is disabled, the configuration commit fails.

DCBX can:

- Discover the DCB capabilities of peers.
- Detect DCB feature misconfiguration or mismatches between peers.
- Configure DCB features on peers.

You can configure DCBX operation for PFC, ETS, and for Layer 2 and Layer 4 applications such as FCoE and iSCSI. DCBX is enabled or disabled on a per-interface basis.

Understanding FCoE

Fibre Channel over Ethernet (FCoE) is a method of supporting converged Fibre Channel (FC) and Ethernet traffic on a data center bridging (DCB) network. FCoE encapsulates unmodified FC frames in Ethernet to transport the FC frames over a physical Ethernet network. The T11 Technical Committee, which is the International Committee for Information Technology Standards (INCITS) committee responsible for FC interfaces, developed the FCoE standard to provide a method for transporting FC frames over a DCB network. The T11 document *Fibre Channel Backbone - 5 (FC-BB-5) Rev 2.00* at <http://www.t11.org/ftp/t11/pub/fc/bb-5/09-056v5.pdf> provides details about the FCoE version 1 standard.

NOTE: The switch does not support T11 Annex F *FCoE Pre-FIP Virtual Link Instantiation Protocol*.

To the Ethernet network, an FCoE frame is the same as any other Ethernet frame because the Ethernet encapsulation provides the header information needed to forward the frames. However, to achieve the lossless behavior that FC transport requires, the Ethernet network must conform to DCB standards.

DCB standards create an environment over which FCoE can transport native FC traffic encapsulated in Ethernet while preserving the mandatory class of service (CoS) and other characteristics that FC traffic requires.

Supporting FCoE in a DCB network requires that the FCoE devices in the Ethernet network and the FC switches at the edge of the SAN network handle both Ethernet and native FC traffic. To handle Ethernet traffic, an FC switch does one of two things:

- Incorporates FCoE interfaces.
- Uses an FCoE-FC gateway such as a QFX Series to de-encapsulate FCoE traffic from FCoE devices into native FC and to encapsulate native FC traffic from the FC switch into FCoE and forward it to FCoE devices through the Ethernet network.

NOTE: QFX3500 and QFX3600 Virtual Chassis switches do not support FCoE.

FCoE concepts include:

- [FCoE Devices on page 4800](#)
- [FCoE Frames on page 4801](#)
- [Virtual Links on page 4802](#)
- [FCoE VLANs on page 4802](#)

FCoE Devices

Each FCoE device has a converged network adapter (CNA) that combines the functions of an FC host bus adapter (HBA) and a lossless Ethernet network interface card (NIC) with 10-Gbps Ethernet ports. The portion of the CNA that handles FCoE traffic is called an FCoE Node (ENode). An ENode combines FCoE termination functions and the client part of the FC stack on the CNA.

ENodes present virtual FC interfaces to FC switches in the form of virtual N_Ports (VN_Ports). A VN_Port is an endpoint in a virtual point-to-point connection called a virtual link. The other endpoint of the virtual link is an FC switch (or FCF) port. A VN_Port emulates a native FC N_Port and performs similar functions: handling the creation, detection, and flow of messages to and from the FC switch. A single ENode can host multiple VN_Ports. Each VN_Port has a separate, unique virtual link with a FC switch.

ENodes contain at least one lossless Ethernet media access controller (MAC). Each Ethernet MAC is paired with an FCoE controller. The lossless Ethernet MAC is a full-duplex Ethernet MAC that implements Ethernet extensions to avoid frame loss due to congestion and supports frames of at least 2500 bytes. The FCoE controller instantiates and terminates VN_Port instances dynamically as they are needed for FCoE sessions. Each VN_Port instance has a unique virtual link to an FC switch.

NOTE: A *session* is a fabric login (FLOGI) or fabric discovery (FDISC) login to the FC SAN fabric. Session does not refer to end-to-end server-to-storage sessions.

ENodes also contain one FCoE link end point (LEP) for each VN_Port connection. An FCoE LEP is a virtual FC interface mapped onto the physical Ethernet interface.

An FCoE LEP:

- Transmits and receives FCoE frames on the virtual link.
- Handles FC frame encapsulation for traffic going from the server to the FC switch.
- Performs frame de-encapsulation of traffic received from the FC switch.

Figure 170 on page 4801 shows a block diagram of the major ENode components.

Figure 170: ENode Components

FCoE Frames

The FCoE protocol specification replaces the FC0 and FC1 layers of the FC stack with Ethernet, but retains the FC frame header. Retaining the FC frame header enables the FC frame to pass directly to a native FC SAN after de-encapsulation. The FCoE header carries the FC start of file (SOF) bits and end of file (EOF) bits in an encoded format. FCoE supports two frame types, control frames and data frames. FCoE Initialization Protocol (FIP) carries all of the discovery and fabric login frames.

FIP control frames handle FCoE device discovery, initializing communication, and maintaining communication. They do not carry a data payload. FIP has its own EtherType (0x8914) to distinguish FIP traffic from FCoE traffic and other Ethernet traffic. To establish communication, the ENode uses the globally unique MAC address assigned to it by the CNA manufacturer.

After FIP establishes a connection between FCoE devices, the FCoE data frames handle the transport of the FC frames encapsulated in Ethernet. FCoE also has its own EtherType (0x8906) to distinguish FCoE frames from other Ethernet traffic and ensure the in-order frame handling that FC requires. FCoE frames include:

- 2112 bytes FC payload
- 24 bytes FC header
- 14 bytes standard Ethernet header
- 14 bytes FCoE header
- 8 bytes cyclic redundancy check (CRC) plus EOF
- 4 bytes VLAN header
- 4 bytes frame check sequence (FCS)

The payload, headers, and checks add up to 2180 bytes. Therefore, interfaces that carry FCoE traffic should have a configured maximum transmission unit (MTU) of 2180 or larger. An MTU size of 2180 bytes is the minimum size; some network administrators prefer an MTU of 2240 or 2500 bytes.

Virtual Links

Native FC uses point-to-point physical links between FC devices. In FCoE, virtual links replace the physical links. A virtual link emulates a point-to-point link between two FCoE device endpoints, such as a server VN_Port and an FC switch (or FCF) VF_Port.

Each FCoE interface can support multiple virtual links. The MAC addresses of the FCoE endpoints (the VN_Port and the VF_Port) uniquely identify each virtual link and allow traffic for multiple virtual links to share the same physical link while maintaining data separation and security.

A virtual link exists in one FCoE VLAN and cannot belong to more than one VLAN. Although the FC switch and the FCoE device detect a virtual link as a point-to-point connection, virtual links do not need to be direct connections between a VF_Port and a VN_Port. A virtual link can traverse one or more transit switches, also known as passthrough switches. A transit switch can transparently aggregate virtual links while still appearing and functioning as a point-to-point connection to the FCoE devices. However, a virtual link must remain within a single Layer 2 domain.

FCoE VLANs

On the QFX Series, all FCoE traffic must travel in a VLAN dedicated to transporting only FCoE traffic. Only FCoE interfaces should be members of an FCoE VLAN. Ethernet traffic that is not FCoE or FIP traffic must travel in a different VLAN.

NOTE: On a QFX3500 or QFabric system Node device, the same VLAN cannot be used in both transit switch mode and FCoE-FC gateway mode.

NOTE: FCoE VLANs (any VLAN that carries FCoE traffic) support only Spanning Tree Protocol (STP) and link aggregation group (LAG) Layer 2 features. IGMP snooping is enabled by default on all VLANs; be sure to disable IGMP snooping on FCoE VLANs.

You can configure more than one FCoE VLAN, but any given virtual link must be in only one FCoE VLAN.

NOTE: All 10-Gigabit Ethernet interfaces that connect to FCoE devices must have a native VLAN configured in order to transport FIP traffic, because FIP VLAN discovery and notification frames are exchanged as untagged packets.

On QFX5100 switches that use the Enhanced Layer 2 Software (ELS) CLI, it is not sufficient only to configure the native VLAN on the interface, the interface must also be configured as a member of the native VLAN. (This is because the ELS CLI does not support tagged-access interface mode, so interfaces that are members of FCoE VLANs must use trunk mode, and trunk port interfaces must be explicitly included as members of a native VLAN.)

In addition, the VLAN ID must match the native VLAN ID that you configure on the physical interface. For example, to configure a native VLAN with an ID of 20 on interface xe-0/0/15 that is a member of an FCoE VLAN, you must include both of the following statements in the configuration:

1. Configure the native VLAN on the interface:

```
user@switch# set interfaces xe-0/0/15 native-vlan-id 20
```

(The equivalent configuration statement on a non-ELS device such as a QFX3500 or QFX3600 switch would be `set interfaces xe-0/0/15 unit 0 family ethernet-switching native-vlan-id 20`.)

2. Configure the port as a member of the native VLAN (this step is not required on QFX3500 and QFX3600 switches):

```
user@switch# set interfaces xe-0/0/15 unit 0 family ethernet-switching vlan members 20
```

BEST PRACTICE: Only FCoE traffic is permitted on the FCoE VLAN. A native VLAN might need to carry untagged traffic of different types and protocols. Therefore, it is a good practice to keep the native VLAN separate from FCoE VLANs.

Understanding FCoE Transit Switch Functionality

You can use the QFX Series as a Fibre Channel over Ethernet (FCoE) transit switch. An FCoE transit switch is a Layer 2 data center bridging (DCB) switch that can transport FCoE frames and implements FCoE Initialization Protocol (FIP) snooping. A DCB switch transports both FCoE and Ethernet LAN traffic over the same network infrastructure while preserving the class of service (CoS) that Fibre Channel (FC) traffic requires.

An FCoE transit switch does not encapsulate or de-encapsulate FC frames in Ethernet. It is an access switch that transports FC frames that have already been encapsulated in Ethernet between FCoE initiators such as servers and a storage area network (SAN) FC switch that supports both Ethernet and native FC traffic on its interfaces. The transit switch acts as a passthrough switch and is transparent to the FC switch, which detects each connection to an FCoE device as a direct point-to-point link.

When a QFX Series acts as a transit switch, the VLANs you configure for FCoE traffic can use any of the switch ports on the QFX Series or QFabric system Node device because the traffic in both directions is standard Ethernet traffic, not native FC traffic.

NOTE: The Ethernet interfaces that connect to FCoE devices must include a native VLAN to transport FIP traffic, because FIP VLAN discovery and notification frames are exchanged as untagged packets. It is a good practice to keep the native VLAN separate from the VLANs that carry FCoE traffic. FCoE VLANs should carry only FCoE traffic, but other types of untagged traffic might use the native VLAN.

QFX3500 and QFX3600 switches and QFabric system Node devices only require that you configure the native VLAN on the FCoE interfaces that belong to the FCoE VLAN by including the `[set interfaces interface-name unit unit family ethernet-switching native-vlan-id native-vlan-id]` statement in the configuration.

QFX5100 switches require that you include two statements in the configuration to configure a native VLAN on FCoE interfaces. Include the `[set interfaces interface-name native-vlan-id vlan-id]` statement in the configuration to configure the native VLAN on the interface, and also include the `[set interfaces interface-name unit unit family ethernet-switching native-vlan-id vlan-id]` statement in the configuration to configure the port as a member of the native VLAN.

FCoE traffic should use a VLAN dedicated only to FCoE traffic. Do not mix FCoE traffic with standard Ethernet traffic on a VLAN on the switch.

NOTE: FCoE VLANs (any VLAN that carries FCoE traffic) support only Spanning Tree Protocol (STP) and link aggregation group (LAG) Layer 2 features. IGMP snooping is enabled by default on all VLANs; be sure to disable IGMP snooping on FCoE VLANs.

NOTE: On a QFX3500 switch or on a QFabric system Node device, the same VLAN cannot be used in both transit switch mode and FCoE-FC gateway mode. If you configure both a transit switch and an FCoE-FC gateway on the same QFX3500 switch or QFabric system Node device, configure different FCoE VLANs for the transit switch and the FCoE-FC gateway.

Transit switch architecture differs from FCoE-FC gateway architecture. As an FCoE-FC gateway, the system transports traffic to the FC SAN as native FC frames, and the VLAN must use an FCoE VLAN interface and native FC interfaces to transport that traffic. As a transit switch, the system forwards Ethernet traffic, and requires DCB configuration for lossless transport of that traffic and FIP snooping at FCoE device access ports, but not the FCoE-FC gateway features necessary for transporting FC traffic.

The QFX Series complies with DCB standards for ensuring lossless transport and low latency, and provides 10-Gbps ports for FCoE traffic. For lossless transport to function correctly, you must use priority-based flow control (PFC, described in IEEE 802.1Qbb) to create bandwidth reservations and ensure proper CoS for FCoE traffic.

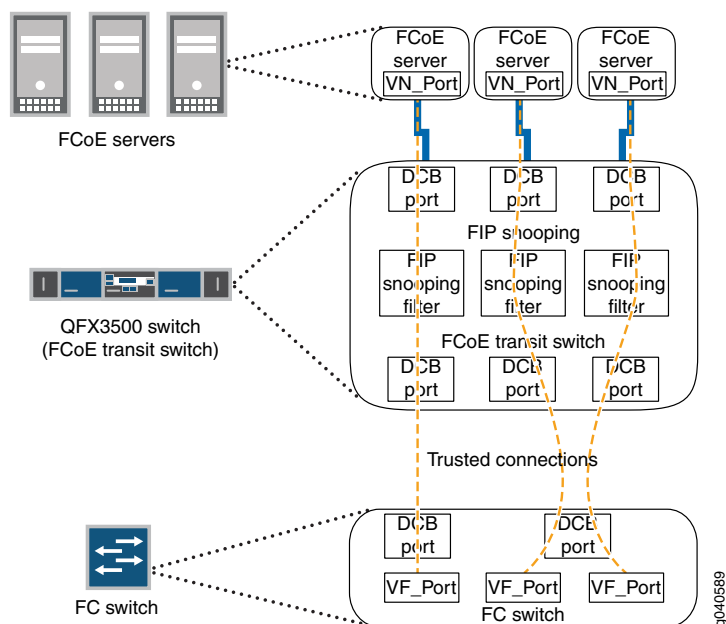

FIP snooping adds security by filtering access so that only traffic from servers that have successfully logged in to the FC network passes through the transit switch and reaches the FC network. The Technical Committee T11 organization specifications describe two types of FIP snooping:

- The FC-BB-5 specification describes VN_Port to VF_Port (VN2VF_Port) FIP snooping, which provides security for communication between FCoE device VN_Ports on the Ethernet network and FCF or FC switch VF_Ports.
- The FC-BB-6 specification describes VN_Port to VN_Port (VN2VN_Port) FIP snooping, which provides security for communication between FCoE device VN_Ports on the Ethernet network.

To accommodate the larger size of Ethernet-encapsulated frames, FCoE interfaces should be configured with a maximum transmission unit (MTU) size of at least 2180 bytes.

The transit switch transparently connects FCoE-capable devices such as servers in an Ethernet LAN to an FC switch or to a gateway switch (hereafter referred to as the FC switch), as shown in [Figure 171 on page 4806](#). The transit switch acts as a transparent DCB access layer between FCoE servers and the FC switch.

Figure 171: FCoE Transit Switch Connecting FCoE Devices to an FC Switch

The transit switch performs FIP snooping at the ports connected to the FCoE devices. For VN2VF_Port FIP snooping, at the SAN edge, the FC switch must be able to convert the FCoE traffic to native FC traffic. (VN2VN_Port FIP snooping switches traffic between VN_Ports directly through the transit switch, without going through the FC switch, so no conversion of FCoE traffic to native FC traffic is needed.)

Encapsulated FCoE traffic flows through the transit switch to the FCoE ports on the FC switch. The FC switch removes the Ethernet encapsulation from the FCoE frames to restore the native FC frames. Native FC traffic travels out native FC ports to storage devices in the FC SAN.

Native FC traffic from storage devices flows to the FC switch FC ports, and the FC switch encapsulates that traffic in Ethernet as FCoE traffic. The FCoE traffic flows through the transit switch to the appropriate FCoE device.

NOTE: The FC switch and FC fabric apply appropriate zoning checks on traffic to and from each ENode and provide FC services (for example, name server, fabric login server, or event server).

NOTE: The QFX3500 switch supports VN_Port to VN_Port FIP snooping to allow FCoE initiators and targets to communicate directly through the switch without going through an FCoE forwarder (FCF) or an FC switch. An FCoE VLAN can support either VN2VF_Port FIP snooping (FC-BB-5) or VN2VN_Port FIP snooping (FC-BB-6), but not both. The same QFX3500 switch can have multiple FCoE VLANs configured, some FCoE VLANs for VN2VF FIP snooping traffic and others for VN2VN FIP snooping traffic.

For load balancing, increasing available bandwidth, and port failover protection, you can configure the 10-Gigabit Ethernet interfaces that belong to an FCoE VLAN as a link aggregation group (LAG). In addition, creating a LAG prevents spanning tree algorithms from blocking physical links and wasting bandwidth.

Understanding an FCoE-FC Gateway

A Fibre Channel over Ethernet (FCoE)-Fibre Channel (FC) gateway connects FCoE devices on an Ethernet network to an FC switch in an FC storage area network (SAN) as shown in [Figure 172 on page 4808](#). To FCoE devices such as servers, the FCoE-FC gateway presents virtual fabric ports (VF_Ports) and appears to be an FCoE forwarder (FCF). To the FC switch, the FCoE-FC gateway presents a proxy node port (NP_Port) and appears to be an FC device.

Figure 172: FCoE-FC Gateway Topology

The FCoE-FC gateway handles FCoE Initialization Protocol (FIP) and FCoE traffic on the interfaces connected to FCoE devices. The gateway forwards native FC traffic on the interfaces to the FC switch. The gateway does not provide FC services (such as fabric login server or name server). It is a proxy for an FCF, not an FCF or an FC switch. The gateway transparently substitutes for the FC switch when communicating with FCoE devices and transparently substitutes for FCoE devices when communicating with the FC switch.

The gateway does not use an FC domain ID, so it extends the SAN fabric while saving domain resources. Using the gateway also means that the FC switch does not have to handle FCoE traffic (and therefore requires no FCoE blades or ports). The gateway converges Ethernet and FC backbones to leverage existing resources.

- [Gateway FC Fabric on page 4809](#)
- [Fabric Services on page 4810](#)
- [FCoE-FC Gateway Traffic Switching on page 4810](#)

Gateway FC Fabric

A gateway FC fabric is a QFX Series configuration construct. It is not the same thing as an FC fabric in the SAN; the gateway FC fabric is local to the switch. It creates associations that connect FCoE devices with converged network adapters (CNAs) on the Ethernet network to an FC switch on the Fibre Channel network. A gateway FC fabric consists of:

- A unique fabric name.
- A unique fabric ID.
- At least one dedicated VLAN for FCoE traffic. VLANs that carry FCoE traffic should not carry any other type of traffic.

NOTE: On a QFX3500 or QFabric system Node device, the same VLAN cannot be used in both transit switch mode and FCoE-FC gateway mode.

- At least one FCoE VLAN interface (Layer 3 VLAN interface) that includes one or more 10-Gigabit Ethernet interfaces connected to FCoE devices. The FCoE VLANs transport traffic between the FCoE servers and the FCoE-FC gateway. Each FCoE VLAN must carry only FCoE traffic. You cannot mix FCoE traffic and standard Ethernet traffic on the same VLAN.

The 10-Gigabit Ethernet interfaces that connect to FCoE devices must include a native VLAN to transport FIP traffic because FIP VLAN discovery and notification frames are exchanged as untagged packets.

Each FCoE VLAN interface can present multiple VF_Port interfaces to the FCoE network.

NOTE: Storm control must be disabled on all Ethernet interfaces that belong to the FCoE VLAN to prevent FCoE traffic from being dropped.

- One or more native FC interfaces. The native FC interfaces transport traffic between the gateway and the FC switch.

TIP: If the network does not use a dual-rail architecture for redundancy, configure more than one native FC interface for each FC fabric to create redundant connections between the FCoE devices and the FC switch. If one physical link goes down, any sessions it carried can log in again and connect to the FC switch on a different interface. Even in dual-rail architecture networks, creating redundant connections between the QFabric system and the FC switch is the best practice.

You can also configure FIP parameters for the fabric or accept the default FIP parameters. VN_Port to VF_Port (VN2VF_Port) FIP snooping is automatically enabled on all server-facing ports because all ports are untrusted by default. You can disable VN2VF_Port FIP snooping on a port-by-port basis by marking a port as an FCoE trusted interface. You

can disable VN2VF_Port FIP snooping on all Ethernet ports in an FC fabric by configuring the fabric as FCoE trusted.

Because the switch has 12 native FC ports and each FC fabric requires a minimum of one native FC port, the switch supports a maximum of 12 FC fabrics. However, as a best practice for redundancy, we recommend that you assign at least two native FC interfaces to each FC fabric.

On a QFabric system, all of the FC and FCoE traffic that belongs to a particular gateway FC fabric must ingress and egress the same gateway Node device. Gateway FC fabrics do not span across Node devices. All of the native FC interfaces and the Ethernet interfaces that belong to the FCoE VLAN must reside on the same gateway Node device to be included in an FC fabric on that Node device.

Traffic from FC and FCoE devices that are not in the same FC fabric remain separate and cannot communicate with each other through the gateway.

Fabric Services

The FC switch provides all FC services (domain manager, name server, fabric login server, and so on) except FIP to the FCoE devices. The FC switch assigns all FCIDs (through N_Port ID virtualization) and fabric attributes to FCoE device VN_Ports.

The FCoE-FC gateway does not provide FC services (except FIP). The gateway relays communication between the FC switch and the FCoE devices, encapsulates and de-encapsulates native FC frames, converges Ethernet and FC backbones, and aggregates FCoE device VN_Port sessions.

FCoE-FC Gateway Traffic Switching

All traffic that flows through the gateway FC fabric is switched through the FC switch. Even if two hosts on the Ethernet FCoE network connect directly to the gateway, FCoE communication between them goes through the FC switch, as shown in [Figure 173 on page 4811](#).

Figure 173: Traffic Switching Between FCoE Hosts Connected to the FC Network by an FCoE-FC Gateway

For example, FCoE host server *Host1* sends frames destined for FCoE host server *Host2*. Both *Host1* and *Host2* are directly connected to the gateway. The communication path looks like this:

1. *Host1* sends FCoE frames destined for *Host2* to the gateway .
2. The gateway de-encapsulates the FCoE frames from *Host1* into native FC frames and switches them to the FC switch.
3. The FC switch processes the native FC frames and sends them back to the gateway destined for *Host2*.
4. The gateway encapsulates the FC frames in Ethernet and sends the resulting FCoE frames to *Host2*.
5. When *Host2* replies, the FCoE reply goes to the gateway. The gateway de-encapsulates the reply and switches it to the FC switch for processing. The FC switch then sends it back to the gateway, which encapsulates the FC frames and sends them to *Host1*.

Understanding FCoE-FC Gateway Functions

When it functions as a Fibre Channel over Ethernet (FCoE)-Fibre Channel (FC) gateway, the QFX Series provides the following functions:

- [Login and Logout on page 4812](#)
- [FCoE and FC Frame Handling on page 4812](#)
- [Data Center Bridging on page 4812](#)
- [Disabling the Fabric WWN Verification Check on page 4813](#)
- [Load Balancing on page 4814](#)

Login and Logout

Each of the native FC interfaces on the gateway performs a fabric login (FLOGI) to the FC switch when each interface initializes. This establishes the link between each gateway FC interface and the FC switch.

When FCoE devices on the Ethernet network send an FCoE Initialization Protocol (FIP) login (FIP FLOGI) or FIP discovery (FIP FDISC) request to the gateway, the gateway acts on behalf of those devices and converts their FIP FLOGI and FIP FDISC requests to FC FDISC requests. The gateway then sends the FC FDISC requests to the FC switch. When the FC switch responds to an FDISC request, the gateway converts the FC response into a FIP response and sends it to the appropriate FCoE device.

The gateway also converts FIP logout (LOGO) requests from FCoE devices into FC LOGO requests to the FC switch, and converts the FC switch response into a FIP response for the FCoE device.

FCoE and FC Frame Handling

When it receives FCoE frames from FCoE devices, the gateway strips away the Ethernet encapsulation from the FC frame before sending the native FC frame to the FC switch.

When it receives native FC frames from the FC switch, the gateway encapsulates the native FC frames in Ethernet before sending the resulting FCoE frames to the appropriate VN_Port.

Data Center Bridging

The Ethernet ports connected to the FCoE devices are 10-Gbps Ethernet ports and support data center bridging (DCB) specifications:

- Priority-based flow control (PFC, described in IEEE 802.1Qbb)
- Data Center Bridging Capability Exchange protocol (DCBX), which is an extension of Link Layer Data Protocol (LLDP, described in IEEE 802.1AB)
- Enhanced transmission selection (ETS, described in IEEE 802.1Qaz)
- 10-Gigabit Ethernet ports

Disabling the Fabric WWN Verification Check

The gateway connects to a SAN fabric using the gateway NP_Ports (native FC ports). When the NP_Ports initialize, each port sends a FLOGI to the FC switch to which it is connected in the SAN fabric. The FC switch sends a FLOGI accept (FLOGI-ACC) message back to each NP_Port. The FLOGI-ACC message includes the SAN fabric worldwide name (WWN). The gateway uses the SAN fabric WWN in the multicast discovery advertisement (MDA) that the gateway sends to the ENodes in the FCoE network.

Some FC switches substitute their own WWN (often the FC switch's virtual WWN) for the SAN fabric WWN in the FLOGI-ACC message. When the FC switch substitutes its own WWN for the fabric WWN, gateway NP_Ports that log in to the same SAN fabric might receive different fabric WWNs in the FLOGI-ACC messages if the NP_Ports are connected to different FC switches in that SAN fabric. This creates a problem, because different fabric WWNs indicate different SAN fabrics. But in this scenario, the different fabric WWNs come from different FC switches in the same SAN fabric.

If the gateway receives different fabric WWNs on NP_Ports that are connected to the same SAN fabric, the gateway uses the first fabric WWN it receives in the MDA it sends to the ENodes. The gateway isolates the NP_Ports connected to that fabric that receive a different fabric WWN in the FLOGI-ACC message. No ENode sessions are assigned to the isolated NP_Ports. FC traffic is assigned only to NP_Ports that receive a fabric WWN that matches the fabric WWN received by the first NP_Port to log in to the FC fabric. (If an NP_Port receives a fabric WWN that does not match the fabric WWN received by the first NP_Port to log in to the FC fabric, it does not carry traffic to the SAN fabric.)

In summary, the scenario is:

1. The gateway has multiple NP_Ports connected to more than one FC switch in a SAN fabric.
2. When the NP_Ports initialize, each NP_Port sends a FLOGI to the FC switch to which it is connected.
3. The FC switches substitute their own WWNs for the fabric WWN in the FLOGI-ACC message, so different NP_Ports receive different fabric WWNs.
4. In the MDA the gateway sends to FCoE devices, the gateway uses the fabric WWN that the first NP_Port to log in to the fabric receives in the FLOGI-ACC message. If other NP_Ports receive a different fabric WWN from other FC switches in the SAN fabric, that fabric WWN is not advertised.
5. NP_Ports that receive a fabric WWN that does not match the first received fabric WWN are isolated, and the ENode sessions cannot use those ports.

To prevent this from happening, you can disable the gateway fabric WWN verification check so that all NP_Ports connected to a SAN fabric are used to carry traffic between the gateway and the FC switch, regardless of the fabric WWN the NP_Port receives in the FLOGI-ACC message.

NOTE: Disabling or enabling the fabric WWN verification check logs out all FCoE sessions.

Load Balancing

The switch performs automatic link load balancing for the connections between the gateway and the FC SAN and can also perform load balancing for the connections between the gateway and the FCoE devices in the Ethernet network. On the native FC links (NP_Ports) between the gateway and the FC SAN, the gateway can use one of the following three load-balancing algorithms:

- Simple load balancing—The switch assigns each ENode FLOGI session and VN_Port FDISC session to the least-loaded link. The switch can place FDISC sessions on a different link than the parent FLOGI session (an ENode FLOGI session and its subsequent FDISC sessions can be placed on different links). Simple load balancing is the default load-balancing algorithm. Rebalancing the link load disrupts only selected sessions to minimize the impact (the switch uses an algorithm to log out only the sessions that need to be moved to other links to balance the load when those sessions log in again).
- ENode-based load balancing—When an ENode logs in to the fabric, the switch places all subsequent VN_Port FDISC sessions associated with that ENode on the same link as the ENode FLOGI session, regardless of the link load. New ENode FLOGIs are placed on the least-loaded link. The switch calculates the link load based on the combined total of FLOGIs and FDISCs on each NP_Port link. Rebalancing the link load disrupts all sessions (all sessions log out and then log in again).
- FLOGI-based load balancing—Similar to ENode-based load balancing; when an ENode logs in to the fabric, the switch places all subsequent VN_Port FDISC sessions associated with that ENode on the same link as the ENode FLOGI session, regardless of the link load. New ENode FLOGIs are placed on the least-loaded link.

NOTE: Changing the load-balancing algorithm when FCoE sessions are running forces the FCoE sessions to log out, then log in again.

You can balance the load on the Ethernet ports facing the FCoE devices by configuring those ports as a link aggregation group (LAG).

Understanding FCoE and FIP Session High Availability

The QFX Series provides high availability features to maintain storage network sessions when a system process is terminated and during certain types of upgrades:

- [High Availability for Fibre Channel Process Termination \(FCoE-FC Gateway Mode\)](#) on page 4815
- [High Availability for FIP Snooping](#) on page 4815
- [Nonstop Software Upgrade \(QFabric Systems\)](#) on page 4816

High Availability for Fibre Channel Process Termination (FCoE-FC Gateway Mode)

In FCoE-FC gateway mode, the QFX3500 switch provides high availability to restore the FCoE sessions running on the switch in case the Fibre Channel (FC) process is terminated. A session is a fabric login (FLOGI) or fabric discovery (FDISC) login to the FC SAN fabric, not an end-to-end server-to-storage session.

The switch stores FCoE session data in a persistent storage module. If the FC process terminates, the switch restores the existing FCoE sessions on the same interfaces that they were on before the FC process terminated. Data traffic for existing sessions is not affected during session restoration.

For a brief time, the system does not process control traffic because of the FC process restart and session restoration. During this brief time, no new FCoE sessions can be established, and no existing sessions can log out.

NOTE: During the restoration process, if the FC process does not receive an *interface up* notification from a particular interface within a certain time, the switch times out the restore operation and discards the data on that interface. The previously existing FCoE sessions on that interface are not restored, and the ENodes must log in again.

NOTE: An FC process restart and session restoration resets the Fibre Channel statistics.

If the FC process terminates repeatedly, the operating system disables the process until you manually restart it. To restart the FC process manually, issue the **restart fibre-channel** command.

High Availability for FIP Snooping

You can configure the system to perform FIP snooping on Ethernet interfaces that are connected to FCoE devices that have ENodes. The QFX Series provides high availability to restore running FIP snooping sessions in case the Ethernet switching process is terminated.

The Ethernet switching process stores the FIP snooping state in a persistent storage module. If the Ethernet switching process terminates, the QFX Series restores the existing FIP snooping sessions on the same interfaces that they were on before the Ethernet switching process terminated. The high availability features preserve:

- Logged in ENodes
- Discovered FCFs
- Existing sessions
- Existing FIP snooping filters

The complete restoration process, including reconciling all valid states, takes a maximum of 8 seconds. During the restoration process, the switch can learn a new FCF or a new FC switch, and new ENodes can log in to the FC network. However, FDISC messages from an ENode that is already logged in to the network might be dropped if the ENode has not yet been restored.

When the Ethernet switching process terminates ungracefully, the FIP keepalive timer is reset to the normal initial value, not the value at the time of the Ethernet switching process termination.

In the event of an Ethernet switching process termination, ENodes remain logged in, and existing sessions are not interrupted.

NOTE: An Ethernet switching process restart and session restoration resets the FIP snooping statistics.

Nonstop Software Upgrade (QFabric Systems)

On QFabric system Node groups that have more than one Node device, nonstop software upgrade (NSSU) enables you to upgrade the Node devices with minimal packet loss and maximum uptime. NSSU automates software upgrades on the QFabric system components in an orderly and consistent manner to maximize system uptime.

The system upgrades components with redundant architectures, such as redundant server Node groups and network Node groups that have two or more members, in stages. While the system upgrades one component, the redundant component continues to function.

For example, while one member of a redundant server Node group is upgraded, the other member continues to forward traffic. When the first Node group member completes the upgrade, it comes online while the system upgrades the second member.

NSSU provides high availability for the lossless traffic forwarding required to support storage networks. If your system design includes redundancy (redundant Node devices in Node groups, LAGs, and so on) so that an alternate traffic path is available, when you upgrade a Node device, traffic is not impacted.

In fully redundant topologies, NSSU preserves FIP session, FIP snooping filter, VN2VF_Port session, and VN2VN_Port session information and prevents traffic loss in most cases. An exception is that Node devices that are directly connected to ENodes experience momentary traffic loss when the Node device reboots.

Understanding FIP Functions

Fibre Channel over Ethernet (FCoE) Initialization Protocol (FIP) performs four major functions:

- FIP VLAN discovery: FCoE device FCoE nodes (ENodes) discover the FCoE VLANs on which to transmit and receive FIP and FCoE traffic.
- FIP discovery: FCoE devices discover Fibre Channel (FC) switches to which they can connect.
- Initialization: FCoE devices perform fabric login (FLOGI) and fabric discovery (FDISC) to create a virtual link with an FC switch.
- Maintenance: The QFX Series ensures that the virtual link between the FCoE device and the FC switch remains valid, and also that the link termination logout (LOGO) functions properly.

When you configure the switch as an FCoE-FC gateway, it converts FIP requests and information from FCoE devices into FC requests and information and relays them to the FC switch. To FCoE devices, the gateway appears to be an FCoE forwarder (FCF) and presents virtual fabric port (VF_Port) interfaces to the server ENode. To FC switches, the gateway appears to be an FC device that supports N_Port ID virtualization (NPIV) and presents an N_Port interface to the FC switch F_Port interface. When you configure the QFX Series as an FCoE transit switch, you do not configure FIP parameters on the switch.

FIP FLOGI, FDISC, and LOGO are similar to the same processes in the native FC protocol.

This topic describes:

- [FIP VLAN Discovery on page 4818](#)
- [FIP Discovery on page 4818](#)
- [FIP FLOGI on page 4819](#)
- [FIP FDISC on page 4820](#)
- [FIP Maintenance \(Keepalive Messages\) on page 4820](#)
- [FIP LOGO on page 4821](#)

FIP VLAN Discovery

The gateway supports FIP VLAN discovery. Host ENodes use FIP VLAN discovery to discover the FCoE VLANs on which they will send and receive FIP and FCoE traffic and on which they will establish a virtual link with the FC switch. This means FCoE devices do not need manually configured FCoE VLANs.

FIP VLAN discovery and notification takes place on the native VLAN that the FCoE device uses for Ethernet traffic:

1. The ENode sends a FIP VLAN discovery request to a multicast address called *ALL-FCF-MACs* to which all FC switches and FCFs on the VLAN listen.
2. The FC switches and FCFs respond on the native VLAN with a list of the FCoE VLANs that are available for login.
3. The ENode selects an FCoE VLAN and continues the FIP process on that VLAN.

Except for FIP VLAN discovery, all other FIP and FCoE traffic runs on an FCoE VLAN.

BEST PRACTICE: Only FCoE traffic is permitted on the FCoE VLAN. A native VLAN might need to carry untagged traffic of different types and protocols. Therefore, it is a good practice to keep the native VLAN separate from FCoE VLANs.

FIP Discovery

The FIP discovery process allows an FCoE device ENode MAC to locate (discover) the FC switches in the FCoE VLAN to which it belongs. The ENode selects an FC switch to log in to from the available FC switches. Either the ENode MAC or the FC switch can initiate the FIP discovery process.

Server ENode MACs initiate FIP discovery:

1. When an ENode MAC comes online, it sends a multicast discovery solicitation message on its FCoE VLAN to a multicast address called *ALL-FCF-MACs* to which all FCFs (including the FCF functionality of FC switches) on the VLAN listen. The discovery solicitation message includes the ENode's addressing mode and the maximum protocol data unit (PDU) size the ENode MAC uses for FCoE traffic.

The ENode uses the globally unique ENode MAC address assigned to it by the converged network adapter (CNA) manufacturer as an identifier in the FIP frame header.

2. The FCFs on the VLAN that have a similar supported addressing mode, match the maximum FCoE size, and can accept a login from the ENode reply to the discovery solicitation message by sending a solicited unicast discovery advertisement message to the soliciting ENode MAC.
3. The ENode MAC compiles a list of FCFs that are available for login, selects an FCF (the FCF with the highest priority setting), and is then ready to log in to the FCF.

The FIP discovery process is similar when the FC switch or FCF initiates discovery:

1. FCF MACs periodically send unsolicited multicast discovery advertisements on the FCoE VLAN to the *ALL-ENode-MACs* multicast address, to which all ENode MACs on the VLAN listen. The FIP keepalive advertisement period timer (FKA_ADV_PERIOD) controls the interval between multicast discovery advertisements. The multicast discovery advertisements inform ENodes on the VLAN that FCF VF_Ports are available for establishing virtual links with ENode VN_Ports.
2. ENodes on the FCoE VLAN create an entry for the FCF-MAC in their FCF-MAC lists.
3. An ENode can respond to the unsolicited multicast discovery advertisement with a unicast discovery solicitation message to the FCF.
4. Upon receiving the ENode's unicast discovery solicitation, the FCF replies with a unicast discovery advertisement sent to the ENode MAC.

After the ENode MAC selects an FCF to log in to, FIP initialization begins. To proceed from discovery to initialization, the server ENode addressing mode must match the FCF addressing mode and maximum FCoE size. In addition, the FCF must be configured to allow FIP FLOGI from that ENode.

FIP FLOGI

FIP initialization is the server ENode login process to the FCF after the ENode discovers the FCFs (including FC switches) on the FCoE VLAN:

1. The ENode sends a fabric login (FLOGI) request message to the FCF.
2. The FCF replies to confirm the ENode login and provides the ENode a locally unique MAC address to use for FCoE frame transactions. The locally unique MAC address identifies the VN_Port interface of the ENode for the session the login establishes. (The ENode continues to use the globally unique ENode MAC address for FIP frame transactions.)

The locally unique ENode MAC address for FCoE operations depends on whether the ENode address mode is configured as a fabric-provided MAC address (FPMA) or as a server-provided MAC address (SPMA; the gateway does not support ENodes in SPMA mode and rejects login attempts from ENodes in SPMA mode):

- For FPMA mode, the FCF provides a MAC address to the ENode during the FIP FLOGI exchange. The FPMA MAC address is a 48-bit value that is unique to the local fabric and consists of a 24-bit FCoE mapped address prefix (FC-MAP) and a 24-bit FC identifier (FCID). You can configure the FC-MAP value on the FCF or use the default value of 0EFC00h. The FCoE device must use the same FC-MAP value as the FCF, or else discovery and login fail.
- For SPMA mode, the server provides its MAC address to the FCF. The FCF compares the server MAC address to a list of addresses approved for FCoE access. The gateway does not support ENodes in SPMA mode.

Successful login instantiates a secure virtual link between the ENode and the FCF and terminates the FIP virtual link instantiation phase. The initiating server behind the ENode

can exchange FC payloads with storage devices in the FC SAN by sending FCoE frames over the virtual link.

FIP FDISC

After an ENode successfully logs in to an FCF and establishes a virtual link, the ENode can request more virtual links (sessions) over the same physical link by sending a FIP fabric discovery (FDISC) request. FDISC allows the creation of multiple separate secure VN_Port virtual links on one physical link. Each virtual link receives a locally unique identifier from the FCF to enable security and separation between the VN_Port virtual links sharing a physical ENode port. This is called N_Port ID virtualization (NPIV).

FDISC is similar to FLOGI in that it requests a login and a unique ID from the FCF. The difference is that FLOGI obtains the initial login and ID for the physical link, whereas FDISC obtains additional logins and IDs so that multiple virtual links can share one physical link securely.

After a VN_Port FDISC is complete, the application using that VN_Port can send FCoE frames over the virtual link.

FIP Maintenance (Keepalive Messages)

Although FCoE protocol handles the payload communication between the initiating ENode and the target FC device, FIP continues to run in the background. FIP constantly updates ENode FCF lists by listening to the periodic FCF multicast discovery advertisements, and it verifies the ability to reach the FCF by transmitting periodic FIP keepalive advertisements.

The ENode sends periodic ENode FIP keepalive advertisements to the FCF with the ENode MAC address as the identifier. The ENode also sends periodic VN_Port FIP keepalive advertisements on behalf of each VN_Port on the ENode, using the VN_Port MAC address as the source MAC. The VN_Port FIP keepalive advertisements occur every 90 seconds. The keepalive advertisements reset the session timer for the virtual link connection to the FCF. If the FCF does not receive a keepalive advertisement for a logged-in ENode or VN_Port before the session timer expires, the virtual link is terminated.

The periodic unsolicited multicast discovery advertisements the FCF sends to the *ALL-ENode-MACs* address continuously verify that the FCF is still reachable. The ENode and the FCF periodic unsolicited multicast discovery advertisements occur at the configured FIP keepalive advertisement period interval (FKA_ADV_PERIOD) plus or minus a random offset to prevent a flood of simultaneous keepalive advertisements.

If the FCF does not receive the ENode keepalive advertisements before the FCF's FIP keepalive timer expires, the FCF considers the virtual link to the ENode as "down" and terminates the virtual link to the ENode. The keepalive timer expires in 2.5 times the configured timer value. This also terminates any VN_Port virtual links instantiated by that ENode.

If the FCF does not receive a VN_Port keepalive advertisement before the FCF's FIP keepalive timer expires, the FCF considers the virtual link to the VN_Port as "down" and terminates the virtual link to that VN_Port. The VN_Port keepalive timer expires in 2.5 times the configured timer value.

If the ENode does not receive the FCF unsolicited multicast discovery advertisement before the ENode's FIP keepalive timer expires, the ENode considers the virtual link to the FCF as "down" and all of the VN_Port virtual links to that FCF on the ENode are terminated.

FIP LOGO

FIP handles ENode and VN_Port logout when a session is finished.

Understanding FIP Implementation

In a network that converges Fibre Channel (FC) and Ethernet traffic, when you configure the QFX Series as a Fibre Channel over Ethernet (FCoE)-FC gateway, it translates FCoE Initialization Protocol (FIP) frames from FCoE nodes (ENodes) into native FC frames for FC switches and translates native FC frames from FC switches into FIP frames for ENodes. To an FCoE device, the gateway appears to be an FCoE forwarder (FCF) and presents a fabric port (F_Port) interface to the FCoE device ENode. To an FC switch, the gateway appears to be an FC host capable of N_Port ID virtualization (NPIV) and presents a node port (N_Port) interface to the FC switch F_Port interface.

NOTE: The N_Ports that the gateway presents to the FC switch are called proxy N_Ports (NP_Ports). To the FC switch, the gateway NP_Ports appear to be native FC N_Ports that are capable of performing NPIV. The NP_Ports are proxies for the FCoE devices in the Ethernet network. The NP_Ports convert FCoE traffic from the FCoE devices into native FC traffic for the FC switch. The NP_Ports also convert native FC traffic from the FC switch into FCoE traffic for the FCoE devices on the Ethernet network.

- [Proxy FIP Logout on page 4825](#)

FIP Basics

FIP is enabled by default on all VLAN interfaces that belong to each FC fabric configured on the gateway. You can configure FIP parameters at a global level or on an individual

interface. When you configure a parameter on an interface, it overrides the global configuration only for that interface. If you do not explicitly configure a FIP parameter, the gateway uses the default value.

In order for the gateway to connect FCoE devices with FCFs, the FIP parameters you configure on the gateway must be compatible with the parameters configured on the FC switch (for example, the FC-MAP values of the FC switch and of the FC fabric FIP configuration on the gateway must match, or the FC switch drops the frames).

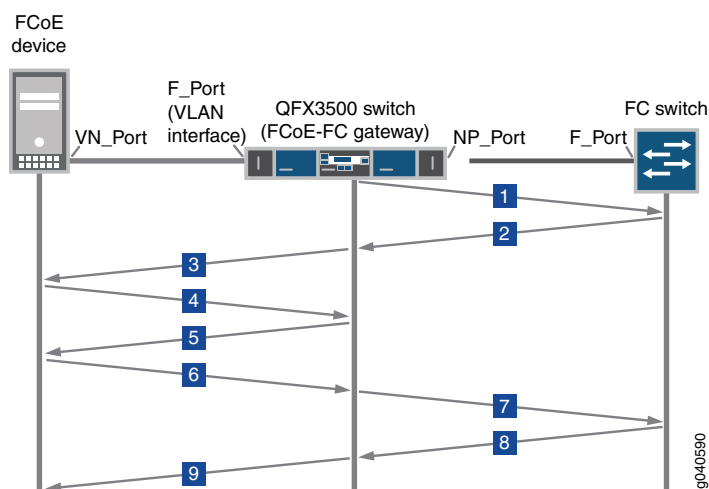

When the NP_Ports on the gateway come up, they perform an FC FLOGI to the connected FC switch. Successful login establishes communication between the gateway and the FC switch, and gateway NP_Ports are marked for sending FDISC messages. Successful login also creates a next-hop entry in the gateway for the FC switch. If the FC switch rejects the FLOGI request, no link is established. The gateway maintains a list of valid FCF-MACs with which ENodes can connect.

After establishing communication with an FC switch, the gateway can connect FCoE devices in the Ethernet network to the FC switch. All of the subsequent connections the gateway makes with FC switches as a proxy for ENodes (on behalf of ENodes) are virtualized (NPIV) connections.

Fabric Login and FIP Login Overview

Figure 174 on page 4822 provides a brief overview of the FCoE-FC gateway fabric login to the FC switch and the FCoE device FIP login to the gateway.

Figure 174: FCoE-FC Gateway Fabric Login and FIP Login

The numbers in the following list correspond to the numbers in Figure 174 on page 4822 and briefly describe each step of the login process:

1. The FCoE-FC gateway NP_Port sends an FC fabric login (FLOGI) request to the FC switch F_Port.
2. The FC switch accepts the gateway FLOGI.
3. The gateway sends FIP multicast discovery advertisements on the FCoE VLAN (the gateway F_Port interface) to all connected FCoE device ENodes.

4. The FCoE device ENode sends a discovery solicitation message to the gateway.
5. The gateway responds with a unicast discovery advertisement to the ENode.

NOTE: The gateway limits the number of discovery solicitations it accepts from FCoE devices to a maximum of 100 outstanding requests at any given time. If the gateway has 100 discovery solicitations outstanding, the gateway does not respond to new discovery solicitations. Instead, the gateway drops new discovery solicitations and reports the number of dropped discovery solicitations in the **Dropped** field of the **show fibre-channel fip statistics** command output. When there are fewer than 100 outstanding discovery solicitations, the system responds to new requests as usual with a discovery advertisement.

6. The FCoE device sends a FIP FLOGI or FIP FDISC message to the gateway.
7. The gateway converts the FIP FLOGI or FIP FDISC to an FC FDISC and forwards it to the FC switch to obtain a login for the FCoE device.
8. The FC switch responds to the FC FDISC by sending a new ID for the NPIV session to the gateway.
9. The gateway converts the FC FDISC response from the FC switch to a FIP FDISC response and forwards it to the FCoE device.

The following sections describe some of these steps in greater detail.

Proxy FIP Discovery

After the gateway establishes a connection with an FC switch:

1. The gateway sends periodic FIP multicast discovery advertisements on the FCoE VLAN so that ENodes can add the gateway to their FCF lists.
2. The ENode initializes and sends a multicast discovery solicitation message on the FCoE VLAN. If the ENode has already initialized and has a list of FCFs, it can send a unicast discovery solicitation message to a particular FCF such as the gateway.

NOTE: The gateway limits the number of discovery solicitations it accepts from FCoE devices to a maximum of 100 outstanding requests at any given time. If the gateway has 100 discovery solicitations outstanding, the gateway does not accept new discovery solicitations until there are fewer than 100 discovery solicitations outstanding.

3. When the gateway receives a multicast discovery solicitation from an ENode, it responds by sending a unicast discovery advertisement to that ENode.

When the gateway receives a unicast discovery solicitation from an ENode, it also responds with a unicast discovery advertisement to the ENode.

To the ENode, the gateway appears to be an FCF.

The FIP discovery process adds the ENode to the gateway ENode database.

Proxy FIP Initialization

1. If the ENode chooses to log in to the gateway, it responds to the gateway's unicast discovery advertisement by sending a login request in the form of a FIP FLOGI if it is the initial connection to the gateway. If the ENode already has an established session with the gateway and another application or virtual machine wants to connect to the gateway, the ENode sends a FIP FDISC to the gateway.
2. The gateway receives the FIP FLOGI or FIP FDISC from the ENode, converts it into an FC FDISC, and sends it through the least-loaded NP_Port to the FC switch on behalf of the ENode. The FC FDISC message requests an FCID for the new virtual link.

NOTE: The gateway converts both ENode FIP FLOGI and FIP FDISC messages into FC FDISC messages, because the gateway has already performed FC FLOGI with the FC switch, so all subsequent connection requests on the gateway NP_Port are FDISC requests for virtual (NPIV) connections. FDISC messages request a virtual N_Port connection over an existing physical N_Port connection.

3. The FC switch processes the request, accepts it, assigns a unique FCID for the connection, and then sends the response to the gateway. If the FC switch rejects the FDISC request, no virtual link is established.
4. The gateway maps the FC switch response to the ENode VN_Port, converts the FC acceptance message to a FIP FLOGI or FIP FDISC response, and sends it to the ENode VN_Port.
5. The ENode VN_Port accepts the FCID, and the virtual link is established.

If an ENode sends an FDISC, the proxy gateway switch checks whether the ENode has already performed a FLOGI to create the initial connection. If the ENode has not performed a FLOGI, the FDISC request is dropped.

The FC protocol does not recognize multipoint-to-point connections. Although the gateway can aggregate traffic from multiple FCoE servers on one NP_Port, each virtual link appears to be an individual point-to-point link between an FCoE ENode VN_Port and the FC switch, not as an aggregated multipoint-to-point link. The gateway is essentially invisible to the FC protocol, so the virtual link looks and acts like a point-to-point link from the FCoE device to the FC switch.

Proxy FIP Maintenance

The gateway sends and receives periodic FIP keepalive messages to and from ENode VN_Ports to maintain the connection between the gateway and the ENodes.

Proxy FIP Logout

As with FIP discovery and FIP FLOGI, the gateway represents the FCoE device in transactions with the FC switch and represents the FC switch in transactions with the FCoE device:

1. An ENode VN_Port sends a FIP LOGO message to log off and terminate the virtual link connection.
2. The gateway converts the FIP LOGO to an FC LOGO and relays it to the FC switch.
3. The FC switch responds to the LOGO request.
4. The gateway converts the FC LOGO response to a FIP LOGO response and relays it to the VN_Port, completing the logout and terminating the virtual link.

Understanding FIP Parameters on an FCoE-FC Gateway

By default, FIP is enabled, and the default FIP settings are valid on all FCoE interfaces that are part of the gateway FC fabric. You can configure some FIP parameters at a global level or on a specific interface. Some FIP parameters can be configured only at the global level or only at the individual interface level. When you configure a parameter at the interface level, the configuration overrides the global setting for that interface only.

- [FIP Keepalive Advertisement Period on page 4825](#)
- [Addressing Mode on page 4826](#)
- [FC-MAP on page 4827](#)
- [FCoE Trusted Fabric on page 4827](#)
- [Maximum Number of FCoE Sessions Per ENode on page 4827](#)
- [Priority on page 4828](#)

FIP Keepalive Advertisement Period

The FIP keepalive advertisement period (fka-adv-period) is the time interval between messages that verify the connection is still valid and the device at the other end of the virtual link is still reachable. The ENode sends an ENode FIP keepalive advertisement to the gateway with the ENode MAC address as the source address to verify its reachability. The ENode also sends VN_Port FIP keepalive messages for every VN_Port on the ENode that is logged in to the gateway, with the VN_Port MAC address as the source address.

The FIP keepalive advertisement period also determines the time interval between unsolicited multicast discovery advertisements from the gateway to the *ALL-ENode-MACs* multicast address. Unsolicited multicast discovery advertisements serve as keepalive messages from the gateway to the ENodes and also advertise the gateway's presence on the network.

The gateway sends the periodic unsolicited multicast discovery advertisements to the ENodes. On the gateway, you can configure a global FIP keepalive advertisement period for an FC fabric and you can configure a FIP keepalive advertisement period for individual interfaces to override the global setting.

Addressing Mode

For FIP transactions, the ENode identifies itself using the globally unique MAC address assigned to the CNA by the manufacturer. After FIP has established a virtual link between an ENode VN_Port and the gateway, for FCoE transactions, the VN_Port identifies itself using a locally unique MAC address. The format of the locally unique MAC address depends on the addressing mode the fabric supports and the addressing mode the ENode is programmed to use.

The addressing mode is not a configurable parameter on the gateway. FC fabrics on the gateway support only the fabric provided MAC address (FPMA) addressing mode for FCoE transactions. The gateway does not support the server provided MAC address (SPMA) addressing mode. ENodes that use SPMA cannot log in to the gateway.

The FC switch assigns a locally unique FPMA to an ENode MAC through the FLOGI or FDISC process:

1. During the FIP discovery process, the ENode compiles a list of compatible FCFs (including the gateway) in the fabric. A compatible addressing mode is one of the criteria an FCF must meet to be added to an ENode's compatible FCFs list.
2. The ENode MAC transmits a FLOGI or FDISC to the FCF that includes the addressing modes the ENode supports.
3. If the FCF supports an addressing mode the ENode uses, the FCF accepts the FLOGI or FDISC and assigns the FPMA in the accept message (FIP FLOGI LS_ACC or FIP NPIV FDISC LS_ACC). If the ENode uses an addressing mode that is incompatible with the FCF, the FLOGI or FDISC is rejected.

The FPMA uniquely identifies a single VN_Port at that ENode MAC in FCoE transactions with the FCF. Each VN_Port connection receives its own unique FPMA to identify its virtual link connection. When an ENode uses NPIV to create multiple VN_Ports, each VN_Port virtual link receives its own unique FPMA to identify its traffic.

An FPMA consists of two concatenated 24-bit values:

1. The upper 24 bits are the FCF's FC-MAP value, which is a MAC address prefix that is unique to the fabric.
2. The lower 24 bits are the locally unique FCID that the FCF (FC switch) assigns to the VN_Port.

The combination of these values guarantees that each FPMA is unique within a fabric.

FC-MAP

The FCoE mapped address prefix (FC-MAP) value is a MAC address prefix used by the FCF that is unique within a given fabric. The FCF uses the FC-MAP for FCoE traffic within that fabric. The FCF rejects FCoE traffic that uses an FC-MAP value that does not match the FCF's FC-MAP value. In most cases, the FCF uses the default FC-MAP value (0EFC00), but a pool of 256 values is available (0EFC00 through 0EFCFF).

The gateway learns FC switches in the fabric that match the gateway fabric's FC-MAP value. To learn and communicate with an FC switch, the FC-MAP value for a fabric (or for the fabric's FCoE VLAN) on the gateway must match the FC switch's FC-MAP value. If the FC-MAP values do not match, no connection is established.

NOTE: Changing the FC-MAP value causes all logins to drop and forces the ENodes to log in again.

FCoE Trusted Fabric

By default, all interfaces are untrusted interfaces. You can globally configure all of the ports in a specified gateway FC fabric to be FCoE trusted. This reduces system overhead by eliminating the need for filters. The total number of FCoE sessions (ENode to FCF sessions) the system can support is 2500 sessions. Sessions are defined as the combined number of VN_Port to VF_Port sessions and VN_Port to VN_Port sessions. (Although VN2VF and VN2VN sessions run in different FCoE VLANs, the session limit is a system limit, not a per-VLAN limit.)

NOTE: A session is a FLOGI or FDISC login to the FC SAN fabric. Session does not refer to end-to-end server-to-storage sessions. There is no limit to the number of end-to-end server-to-storage sessions.

NOTE: Changing the fabric ports from untrusted to trusted removes any existing FIP snooping filters from the ports and terminates the existing sessions. Changing the fabric ports from trusted to untrusted forces all of the FCoE sessions on those ports to log out so that when the ENodes and VN_Ports log in again, the switch can build the appropriate FIP snooping filters.

Maximum Number of FCoE Sessions Per ENode

You can configure the maximum number of FCoE session logins from each ENode that are permitted on the gateway FC fabric. The number of sessions is the ENode FLOGI session plus the VN_Port FDISC sessions on that ENode. Regardless of whether the fabric is trusted or untrusted, the maximum number of FCoE sessions per ENode is

2500 sessions. The total number of sessions cannot exceed the gateway fabric's maximum limit of 2500 sessions.

The maximum number of FCoE sessions per ENode is a global configuration for all members of the gateway FC fabric and cannot be configured on a per-interface basis.

NOTE: Session does not refer to end-to-end server-to-storage sessions. There is no limit to the number of end-to-end server-to-storage sessions.

Priority

When the FIP discovery process offers an ENode the choice of more than one FCF-MAC on a given FCF to use for login, the ENode chooses the FCF-MAC to which to send a login request based on the FCF-MAC priority. The lower the priority number, the higher the FCF-MAC's priority. The ENode selects the highest-priority (lowest priority number) FCF-MAC for the login request.

An ENode can receive multiple FCF-MAC advertisements from the same FCF in two ways:

- During the FIP discovery process, an FCF can receive an ENode MAC's multicast discovery solicitation on multiple FCF-MACs. Each FCF-MAC replies with a unicast discovery advertisement to the ENode. The ENode determines that the advertisements are from the same FCF, because the value in the Name_Identifier descriptor is the same in each advertisement.
- During the FIP discovery process, an ENode MAC can receive unsolicited multicast discovery advertisements from multiple FCF-MACs on the same FCF. The ENode determines that the advertisements are from the same FCF, because the value in the Name_Identifier descriptor is the same in each advertisement.

On the gateway, you can configure the priority value for an entire fabric or for an individual interface. The default value for both the fabric and the individual interfaces is 128 (the highest priority is 0; the lowest priority is 255).

Understanding Fibre Channel Virtual Links

A virtual link emulates a secure point-to-point connection between the virtual node port (VN_Port) of a Fibre Channel over Ethernet (FCoE) node (ENode) and the virtual fabric port (VF_Port) of an FCoE forwarder (FCF). The combination of the FCF media access control (MAC) address and the VN_Port MAC address uniquely identifies each virtual

link. Uniquely identifying each virtual link enables the logical separation of traffic that belongs to each virtual link. A single physical link between an ENode and an FCF can carry multiple virtual links and maintain secure, separate transport of traffic on the different virtual links.

Virtual links are necessary because Fibre Channel protocol does not recognize multipoint-to-point connections. Even when multiple connections are aggregated on one physical port, FCoE Initialization Protocol (FIP) presents each virtual link as an individual point-to-point link between an ENode VN_Port and an FCF VF_Port.

Understanding Interfaces on an FCoE-FC Gateway

When the QFX Series functions as an FCoE-FC gateway to connect FCoE devices on an Ethernet network to a Fibre Channel (FC) switch in a storage area network (SAN), it handles FCoE traffic from hosts and native FC traffic from the FC switch. To support this architecture, each local FC fabric configured on the gateway (in the **fc-fabrics** configuration hierarchy) must have:

- An Ethernet-network-facing F_Port interface for the FCoE VLAN to connect to FCoE device VN_Ports in the form of an FCoE VLAN interface. Multiple VF_Ports are initiated on the F_Port interface, one VF_Port for each ENode that logs in to the FC network.
- One or two blocks of six proxy N_Port (NP_Port) interfaces to connect to FC switch fabric ports (F_Ports).

Each FC fabric is local to the gateway on which you configure it. This means that both the FC switch and the FCoE devices must be connected to the same gateway (QFX3500 switch or QFabric system Node device), and that all of the interfaces configured for the local fabric also must be on that gateway. FC fabric traffic does not flow between different Node devices in a QFabric system.

This topic describes:

- [Deleting a Fibre Channel Interface on page 4840](#)

Native FC Interfaces to the FC Switch

You must configure either 6 or 12 of the physical interfaces on the gateway as native FC NP_Port interfaces to connect to FC switch F_Port interfaces. By default, all of the gateway interfaces are Ethernet interfaces, so you must explicitly configure the interfaces that you want to use as FC interfaces.

You can configure the FC-capable ports xe-0/0/0 through xe-0/0/5 as fc-0/0/0 through fc-0/0/5, and ports xe-0/0/42 through xe-0/0/47 as fc-0/0/42 through fc-0/0/47 to create blocks of native FC interfaces. You cannot individually configure a single port as a native FC interface. Within these port blocks, you cannot mix FC interfaces with Ethernet interfaces. All of the ports in a block must be either native FC interfaces or Ethernet interfaces.

You cannot configure ports xe-0/0/6 through xe-0/0/41 and ports xe-0/1/1 through xe-0/1/15 as native FC ports; they can only be Ethernet ports. Native FC ports do not handle Ethernet traffic (including FCoE traffic); they handle only native FC traffic and must connect to native FC ports.

You can configure:

- Six native FC interfaces by configuring either ports xe-0/0/0 through xe-0/0/5 as fc-0/0/0 through fc-0/0/5 or ports xe-0/0/42 through xe-0/0/47 as fc-0/0/42 through fc-0/0/47.
- Twelve native FC interfaces by configuring ports xe-0/0/0 through xe-0/0/5 as fc-0/0/0 through fc-0/0/5 and ports xe-0/0/42 through xe-0/0/47 as fc-0/0/42 through fc-0/0/47.
- No native FC interfaces by leaving ports xe-0/0/0 through xe-0/0/5 and ports xe-0/0/42 through xe-0/0/47 in their default state as Ethernet interfaces.

Each native FC interface can belong to only one local FC fabric configured on the gateway. You can configure up to 12 FC fabrics on a gateway, but each FC fabric must use different native FC interfaces to connect to an FCF. (Although the native FC ports are configured in blocks, each individual port can belong to a different FC fabric.) Native FC interfaces can be configured as loopback interfaces.

- [Port Mode on page 4830](#)
- [NPIV on page 4831](#)
- [Port Speed on page 4831](#)

Port Mode

The gateway presents a proxy N_Port (NP_Port) interface to the FC switch. An NP_Port connects to a single FC switch F_Port using a point-to-point link (in other architectures an N_Port can also connect in a point-to-point link to another N_Port, but that is not a valid configuration on the gateway).

You must explicitly configure each native FC interface connected to an FC switch as an NP_Port. The gateway NP_Ports act as a proxy for the FCoE device virtual N_Ports (VN_Ports) when the VN_Ports attempt to connect to the FC switch.

When the FC switch is a trusted switch, configure the fabric as **fcoe-trusted** to reduce overhead caused by the VN_Port to VF_Port (VN2VF_Port) FIP snooping filters that are automatically installed on untrusted ports.

NPIV

FC requires a unique point-to-point link between the FC switch and each host N_Port. The gateway creates an independent virtual link for each FCoE device session by mapping each FCoE device to a virtualized N_Port through the gateway's proxy function. This process is called N_Port ID virtualization (NPIV).

NPIV makes each virtual link look like a dedicated point-to-point link to the FC switch. In this way, multiple FCoE devices, multiple applications, and multiple virtual machines on an FCoE device can connect to an FC switch using one physical port instead of using a physical port for each host connection. The virtual link creates a secure boundary between traffic from different sources that are on a single physical port.

FCoE-FC gateway mode implements NPIV as follows:

1. An NP_Port on the gateway comes up and logs in to the attached F_Port on the FC switch. The FC switch sees the gateway port as a physical FC device N_Port and assigns it a unique FCID. This establishes the physical point-to-point link between the gateway and the FC switch.
2. The gateway receives a FIP discovery message from an FCoE device that seeks to log in to the FC network. To the FCoE device, the gateway presents a virtual F_Port (VF_Port) interface and appears to be an FCF.
3. The gateway converts the FCoE device's message into an FC fabric discovery (FDISC) message and sends it through the least-loaded physical NP_Port to the FC switch. The FDISC message requests an FCID for the new virtual link.
4. The FC switch processes the request, accepts it, assigns a unique FCID for the connection, and sends the response.
5. The gateway maps the FC switch response to the host FCoE device's VN_Port and sends a FIP acceptance advertisement to the FCoE device.
6. The FCoE device accepts the FCID.

If the FC switch rejects the FDISC, the gateway relays the rejection to the FCoE device VN_Port.

Port Speed

The gateway supports configuring FC port speeds of 2 Gbps, 4 Gbps, or 8 Gbps. FC ports can also autonegotiate the port speed to 2, 4, or 8 Gbps.

FIP Login Session Limits

A FIP login session is a fabric login (FLOGI) or fabric discovery (FDISC) login to the FC SAN fabric. (A session here does not refer to an end-to-end server-to-storage session; there is no limit to the number of end-to-end server-to-storage sessions.) You can limit the maximum number of FIP login sessions on each gateway Node device (QFX3500

switch or QFabric system Node device configured in FCoE-FC gateway mode), on each local gateway FC fabric, and on each individual NP_Port interface in a local FC fabric:

- **Gateway Node devices and Node groups**—The total number of FIP login sessions on the gateway Node or Node group (the sum of the sessions on all of the NP_Port interfaces in all of the local FC fabrics on the gateway Node or Nodes) cannot exceed the limit. When a gateway reaches the maximum session limit, the gateway sends subsequent multicast discovery advertisements (MDAs) with the availability bit set to 0 (zero) to prevent additional ENode login attempts. If the maximum number of sessions is running on the gateway, ENodes cannot use the gateway to log in new sessions to the FC switch. When the number of sessions falls below the maximum, the gateway sets the availability bit in MDAs to 1 so that ENodes can again log in new sessions. When a session slot becomes available, the system accepts the first session request to fill the slot.
- **FC fabric**—The total number of FIP login sessions on an FC fabric (the sum of the sessions on all of the NP_Port interfaces that belong to the fabric) cannot exceed the limit. When a fabric reaches the maximum session limit, the gateway sends MDAs associated with that fabric with the availability bit set to 0 to prevent additional ENode login attempts.

NOTE: Other FC fabrics on the same gateway can still accept ENode logins as long as the maximum session limit for those fabrics and the maximum session limit for the gateway (the Node device) have not been met.

- **NP_Port interfaces**—The total number of FIP login sessions cannot exceed the interface's limit. When an interface reaches the maximum session limit, the gateway removes it from the load-balancing list for that FC fabric to prevent the gateway from attempting to assign new sessions to the interface. Other interfaces in the FC fabric can still accept logins until the FC fabric or gateway reaches its maximum session limit. However, the interface that reached the maximum session limit cannot be assigned new sessions until the number of sessions on the interface falls below the limit.

BEST PRACTICE: Configure a maximum session limit for each NP_Port interface that is less than or equal to the number of FIP sessions the directly connected FC switch port is configured to support. This prevents the gateway from attempting to assign new login sessions to an interface when the connected FC switch port reaches its maximum number of sessions.

- [Decreasing Session Limits on page 4834](#)
- [Increasing Session Limits on page 4834](#)
- [Effect of Deactivating and Then Reactivating the Configuration on Session Limits on page 4834](#)

FCoE Trusted and Untrusted Interface Session Limits

The maximum number of VN2VF_Port FCoE login sessions that each gateway can support is 2500 sessions, regardless of whether interfaces are trusted or untrusted. (In software releases earlier than Junos OS Release 12.3, the session limit on untrusted interfaces and untrusted fabrics was 376 sessions.)

Configuring Consistent Session Limits

The system does not perform commit checks to enforce consistent session limit configuration. For example, the system does not prevent you from configuring a higher limit for ENode sessions than the total session limit for the gateway Node device, or from configuring a higher limit on an interface than on the fabric to which the interface belongs.

To prevent unexpected FIP login rejections, you should configure consistent Node device, fabric, and interface session limits. For example:

- The session limit of an interface should not exceed the session limit of the fabric to which it belongs.
- For interfaces that belong to the same fabric, the sum of the interface session limits should not exceed the fabric session limit.
- The fabric session limit should not exceed the session limit of the gateway Node device.
- For fabrics that belong to the same gateway Node device, the sum of the fabric session limits should not exceed the Node device session limit.

Session limit configuration considerations include:

- The fabric session limit restricts how many sessions can run on the NP_Port interfaces that belong to that fabric. If the combined session limits of the interfaces exceed the fabric session limit, the total number of sessions on the interfaces is the fabric limit.

For example, if a fabric has three NP_Port interfaces, and each NP_Port interface has a limit of 500 sessions (total of 1500 sessions for the three interfaces), but the fabric has a limit of 1000 sessions, the combined number of sessions on the three interfaces is limited to 1000 sessions.

- The gateway Node device session limit restricts how many sessions can run on the fabrics that belong to that gateway. If the combined session limits of the fabrics exceed the gateway Node device session limit, the total number of sessions on the fabrics is the gateway Node device limit.

For example, if a gateway has two fabrics, and each fabric has a limit of 1000 sessions (total of 2000 sessions for the two fabrics), but the gateway has a limit of 1500 sessions, the combined number of sessions on the two fabrics is limited to 1500 sessions.

Hierarchically, the gateway Node device session limit is the maximum limit for all sessions on the gateway, regardless of fabric and interface session limits. In the same way, the fabric session limit supersedes the interface session limit.

When session limits are exceeded, no new logins are accepted until a session slot becomes free.

Decreasing Session Limits

If you decrease the session limit, the currently logged in sessions are terminated as follows:

- Gateway Node devices and Node groups—Decreasing the session limit terminates all of the sessions on the Node device (all sessions on all interfaces on all fabrics). If the gateway Node device is part of a Node group, all sessions on all members of the Node group are terminated.
- Fabric—Decreasing the session limit terminates all of the sessions on all of the interfaces that belong to the fabric.
- NP_Port interfaces—Decreasing the session limit terminates all of the sessions on the interface and also terminates all of the sessions on any other interfaces that belong to the same fabric.

After you decrease a session limit, the sessions are terminated even if the new session limit is greater than the number of currently active sessions. For example:

- An interface has 300 active sessions.
- The current session limit is 1000 sessions.
- You decrease the session limit to 500 sessions and commit the new configuration.
- All 300 sessions are logged out, even though the new session limit is greater than the number of sessions running.

After the session limit change takes effect, the ENodes log in again and establish new sessions, up to the new session limits.

Increasing Session Limits

Increasing the session limits does not disrupt logged in sessions.

Effect of Deactivating and Then Reactivating the Configuration on Session Limits

If you decrease session limits, all ENodes are logged out. Deactivating and then reactivating the configuration can have the same effect as decreasing the session limit, which results in the ENodes being logged out.

The ENode logouts occur because when you deactivate the configuration, the system reverts to the default session limit of 2500 sessions (the maximum number of sessions). When you reactivate the configuration, the system uses the configured session limit. Unless the configured session limit is equal to the maximum session limit, reactivating the configuration decreases the session limit, which causes the ENodes to be logged out.

For example, if you:

1. Configure and commit a limit of 400 sessions.
2. Allow ENodes to log in and start sessions.
3. Deactivate the configuration.

4. Reactivate the configuration.
5. The ENode sessions are logged out because deactivating the session increased the session limit from 400 to 2500.

Because an increase in the session limit does not affect existing sessions, the running ENode sessions are not affected. However, reactivating the configuration decreased the session limit from 2500 back to 400. The session limit decrease causes the ENode sessions to be logged out.

Trusted and Untrusted Interfaces

By default, gateway fabric interfaces are untrusted interfaces. If you do not configure a gateway fabric as an FCoE trusted fabric to set all of the gateway fabric interfaces as trusted interfaces, the gateway installs VN2VF_Port FIP snooping filters on the fabric ports.

If you configure a gateway fabric as an FCoE trusted fabric, the gateway does not install VN2VF_Port FIP snooping filters on the fabric interfaces. This is usually done when the gateway is connected to an FCoE transit switch that has VN2VF_Port FIP snooping enabled.

Regardless of whether an interface is trusted or untrusted, the maximum session limit is 2500 sessions.

NOTE: The session limit for a Node group is the same as the session limit for an individual Node device, 2500 sessions. Even if more than one Node device in a Node group is acting as an FCoE-FC gateway, the total maximum number of sessions on all Node devices in the Node group is 2500 sessions.

The default maximum login session value for Node devices (on QFabric systems, the maximum applies to each Node device), trusted fabrics, and interfaces in trusted fabrics is 2500 sessions.

Buffer-to-Buffer Credit Recovery

Buffer-to-buffer credits represent the number of receive buffers an interface can use to store FC frames. Buffer-to-buffer credit determines buffer-to-buffer flow control. When an interface transmits a frame, it decrements its buffer-to-buffer credit count by one. When the destination interface forwards the frame and frees a buffer, it sends a receiver ready (R_RDY) primitive to the transmitting interface. Each R_RDY primitive the transmitting interface receives increments its buffer-to-buffer credit count by one.

Both interfaces on an FC link track buffer-to-buffer credits. As long as buffer-to-buffer credits are available, the transmitter continues to send frames. If the number of buffer-to-buffer credits reaches zero (0), transmission stops until buffer-to-buffer credits are available, as indicated by the reception of an R_RDY primitive. Buffer-to-buffer credits can compensate for long cable distances to limit throughput and prevent buffer overflow.

However, if frame corruption or errors transmitting R_RDY primitives occur, the buffer-to-buffer credit counters on the sending and receiving interfaces do not have the

same values. This causes the permanent loss of buffer-to-buffer credits. When credits are lost, the buffer credit count can decrement to zero and indicate that there is no available buffer space even if buffer space is actually available. This can result in unnecessary link idle time.

To recover lost buffer-to-buffer credits, you can configure a buffer-to-buffer credit state change number (BB_SC_N). BB_SC_N must be configured on both ends of the connection. If only one end of the connection is configured for BB_SC_N, the feature is disabled. The two directly connected FC interfaces communicate the BB_SC_N value during fabric login (FLOGI).

When you enable BB_SC_N on the interfaces on both ends of an FC link, the interfaces exchange buffer-to-buffer state change send (BB_SCs) and buffer-to-buffer state change receive (BB_SCr) primitives to track the number of frames sent and the number of R_RDY primitives received. The state change number determines the number of frames and R_RDY primitives the interfaces exchange between consecutive BB_SCn primitives and between consecutive BB_SCr primitives. The state change primitives inform each interface of the other interface's frame count and R_RDY count states.

The state counters should match so that each interface knows and agrees with the other interface's state. If the interface at either end of the link detects a discrepancy, it knows that a frame or an R_RDY primitive was corrupted or dropped.

For example, if a receiving interface has sent two R_RDY primitives but the BB_SCr that the interface receives from the sending interface only counts one R_RDY primitive received, it reveals that one R_RDY primitive was not delivered successfully and that one buffer-to-buffer credit was lost. When one of the interfaces on the link detects a discrepancy, the interfaces can take corrective action and recover the lost buffer-to-buffer credits.

Enabling the buffer-to-buffer credit recovery feature does not impact buffer resources and has an insignificant impact on processing resources.

If buffer-to-buffer credit recovery is not used, then when there is no buffer credit on a port, a timeout and recovery mechanism prevents buffer overflow.

FCoE VLAN Interface to FCoE Devices

Each FC fabric configured on the gateway includes at least one FCoE VLAN interface to connect the FCoE devices on the FCoE VLAN to the FC switch. (Including the FCoE VLAN interface and the native FC interfaces in the FC fabric configuration connects them.) FCoE VLANs can include any Ethernet interface on the switch that is in tagged-access or trunk mode. The best practice is to configure Ethernet interfaces that belong to FCoE VLANs in **tagged-access** port mode.

NOTE: The Ethernet interfaces that connect to FCoE devices must include a native VLAN to transport FIP traffic, because FIP VLAN discovery and notification frames are exchanged as untagged packets.

FCoE VLANs should carry only FCoE traffic. You should not mix FCoE traffic and standard Ethernet traffic on the same VLAN.

NOTE: FCoE VLANs (any VLAN that carries FCoE traffic) support only Spanning Tree Protocol (STP) and link aggregation group (LAG) Layer 2 features.

Each FCoE VLAN interface can belong to only one FC fabric configured on the gateway. A gateway FC fabric can have more than one FCoE VLAN, but each FCoE VLAN in the FC fabric must belong only to that FC fabric. You can configure more than one FC fabric on a gateway; each FC fabric must use different FCoE VLAN interfaces to connect to FCoE devices.

NOTE: Storm control must be disabled on all Ethernet interfaces that belong to the FCoE VLAN to prevent FCoE traffic from being dropped.

- [Port Mode on page 4837](#)
- [Disabling Storm Control on FCoE Interfaces on page 4838](#)
- [NPIV Support on page 4839](#)
- [VN2VF_Port FIP Snooping on page 4839](#)

Port Mode

You must explicitly configure the FCoE VLAN interface in F_Port mode. All members of the FCoE VLAN use the FCoE VLAN interface as the connection to the gateway NP_Port interfaces and ultimately to the FC switch.

All of the 10-Gigabit Ethernet interfaces that are members of an FCoE VLAN should be configured as **tagged-access** port mode interfaces. However, the system also supports configuring these interfaces in **trunk** port mode.

BEST PRACTICE: Use **tagged-access** port mode for Ethernet interfaces that are connected to converged network adapters (CNAs) in FCoE access devices.

Use **trunk** port mode when an Ethernet interface is an interswitch link (ISL)—that is, when the port is connected to another switch. For example, if a port is connected to a transit switch that is performing VN2VF_Port FIP snooping, configure the port in **trunk** mode and as an FCoE trusted port.

The **tagged-access** port mode was not available in Junos OS Release 11.3 and earlier releases. In Release 11.3 and earlier, only **trunk** port mode was used for Ethernet interfaces that belong to an FCoE VLAN. Because **tagged-access** mode is now available, using **trunk** mode for interfaces connected to FCoE CNAs is not recommended.

If an existing configuration uses trunk mode for ports connected to FCoE CNAs, you can change the port mode to **tagged-access** without disrupting traffic. Although we recommend changing the port mode of these ports from trunk mode to **tagged-access** mode as a best practice, it is not mandatory. New configurations should use **tagged-access** mode for interfaces that connect to FCoE devices.

There are several advantages of configuring Ethernet ports connected to FCoE devices in **tagged-access** mode instead of in **trunk** mode:

- It is standard practice to configure ISL ports as trunk ports.
- It is standard practice not to configure ports that connect to servers as trunk ports.
- When an interface goes down, if that interface is in **trunk** mode, then the FCoE sessions on that interface are terminated only after the gateway stops receiving FIP keepalive messages from the ENode and exceeds 2.5 times the FIP keepalive advertisement value. If the interface is in **tagged-access** mode and the interface goes down, the gateway sends a FIP message to terminate the sessions on the interface.
- Similarly, if an ENode session moves from one interface to another interface, if the original interface is in **trunk** mode, the session is not removed from the interface until the gateway stops receiving FIP keepalive messages and exceeds 2.5 times the FIP keepalive advertisement timeout value. But if the interface is in **tagged-access** mode, the gateway detects that the session is no longer on the interface, does not refresh the FIP keepalive timer, and thus ages out the session.

NOTE: FIP is enabled on the FCoE VLAN, which is a Layer 3 interface. As with other Layer 3 interfaces under Junos OS, when the last member (10-Gigabit Ethernet interface) of the FCoE VLAN is deleted, the FCoE VLAN interface is internally marked as “down.” When the Layer 3 FCoE VLAN interface is marked as “down”, FIP stops running on it. When the last member interface is deleted from an FCoE VLAN and FIP stops running, the result could be an immediate timeout for the VN_Ports that were connected on that interface, regardless of whether the port mode is **tagged-access** or **trunk**.

Disabling Storm Control on FCoE Interfaces

Storm control is not supported on the FCoE interfaces of an FCoE-FC gateway VLAN. Enabling storm control on an FCoE-FC gateway VLAN interface may cause FCoE packet loss. Storm control is disabled by default on all interfaces. However, if you enabled storm control globally on all switch interfaces or on any interfaces that are part of the FCoE VLAN interface, you must disable storm control on the Ethernet interfaces of the FCoE VLAN.

If storm control is enabled on only a few interfaces of the FCoE VLAN, you can disable storm control on individual interfaces by including the **delete ethernet-switching-options**

storm-control interface *interface-name* statement in the configuration, where *interface-name* is the name of the interface on which you want to disable storm control.

If storm control is enabled globally on the switch when the switch is acting as an FCoE-FC gateway, it is often easiest to disable storm control on all interfaces, then enable storm control only on Ethernet interfaces that are not part of the FCoE VLAN interface.

If storm control is enabled globally, you can disable storm control in either of two ways:

- Disable storm control on all interfaces, then enable storm control on the interfaces you want to use storm control. (From the default configuration, you cannot disable storm control on individual interfaces because the default configuration enables storm control on **all** interfaces, not on individual interfaces.)

For example, if you want interfaces xe-0/0/20, xe-0/0/21, and xe-0/0/22 to use storm control, disable storm control on all interfaces, then enable storm control on those three interfaces:

1. Disable storm control on all interfaces:

```
user@switch# delete ethernet-switching-options storm-control interface all
```

2. Enable storm control on interfaces xe-0/0/20, xe-0/0/21, and xe-0/0/22:

```
user@switch# set ethernet-switching-options storm-control interface xe-0/0/20
```

```
user@switch# set ethernet-switching-options storm-control interface xe-0/0/21
```

```
user@switch# set ethernet-switching-options storm-control interface xe-0/0/22
```

- Disable storm control for all unknown unicast traffic on all interfaces by including the following statement in your configuration:

```
user@switch# set ethernet-switching-options storm-control interface all no-unknown-unicast
```

NPIV Support

The gateway supports FCoE device NPIV. For example, a single physical FCoE device can have multiple virtual machines running on it. Each virtual machine can instantiate a separate virtual connection to the gateway, which results in its own virtual link to the FC switch. In this way, an FCoE device can have multiple separate connections to the FC SAN on a single physical port.

This is similar to the NPIV function the gateway performs with the FC switch to support multiple virtual FCoE device connections on one physical NP_Port.

The gateway presents multiple VF_Port interfaces on each FCoE VLAN interface to support the requirement for unique, secure virtual links.

VN2VF_Port FIP Snooping

The FCoE-facing ports that belong to an FCoE VLAN on a gateway are enabled for VN2VF_Port FIP snooping automatically. You can disable VN2VF_Port FIP snooping on any individual interface by configuring it as a trusted interface.

Assigning Interfaces to a Fibre Channel Fabric

You assign at least one FCoE VLAN interface and at least one native FC interface to each FC fabric you configure on the gateway. All of the interfaces that belong to an FC fabric

must reside on the same gateway device. Interfaces on different gateways cannot belong to the same FC fabric, because an FC fabric is local to a single gateway device.

Deleting a Fibre Channel Interface

To delete an FC interface or an FCoE VLAN interface, you must delete the interface from the fabric first and then delete the interface from the switch.

Understanding Load Balancing in an FCoE-FC Gateway Proxy Fabric

You can balance or rebalance the load on the ports in an FCoE-FC gateway proxy fabric in order to avoid overutilizing or underutilizing the links. Load balancing is distributing sessions across the available native Fibre Channel (FC) interfaces (NP_Ports) that belong to a local gateway FC fabric to create a relatively equal load on all the fabric links. Load rebalancing is redistributing the existing sessions across the available NP_Port links on a local gateway FC fabric.

NOTE: A session is a fabric login (FLOGI) or fabric discovery (FDISC) login to the FC SAN fabric. Session does not refer to end-to-end server-to-storage sessions.

The fabric-facing NP_Port links of an FCoE-FC gateway use different load-balancing methods than the FCoE-network-facing Ethernet links. You can balance the load on the FCoE-network facing Ethernet port members of the FCoE-FC gateway by configuring the ports in a link aggregation group (LAG). This topic focuses on NP_Port load balancing.

Balancing the load on FCoE-FC gateway NP_Port links consists of two steps:

1. Choosing the algorithm used to balance and rebalance the link load
2. Choosing whether to rebalance link loads automatically or only when you explicitly request a rebalance (load-rebalancing method)

You can configure a different load-balancing algorithm and use a different rebalancing method for each local FC fabric on the FCoE-FC gateway. The load-balancing algorithm and automated rebalancing, if configured, apply to all NP_Port interfaces in the local FC fabric.

Load-Balancing Algorithms

You can choose one of three load-balancing algorithms to configure the way the switch balances the link loads. The switch uses the configured algorithm to balance the link loads when NP_Ports are initialized and whenever link loads are rebalanced. Regardless of whether you configure automated load rebalancing or use on-demand load rebalancing, the switch uses the configured algorithm to balance the link load:

- Simple load balancing—The switch assigns each ENode FLOGI session and VN_Port FDISC session to the least-loaded link. The switch can place FDISC sessions on a different link than the parent FLOGI session (an ENode FLOGI session and its subsequent FDISC sessions can be placed on different links). Simple load balancing is the default load-balancing algorithm. Rebalancing the link load disrupts only selected sessions to minimize the impact (the switch uses an algorithm to log out only the sessions that need to be moved to other links to balance the load when those sessions log in again).
- ENode-based load balancing—When an ENode logs in to the fabric, the switch places all subsequent VN_Port FDISC sessions associated with that ENode on the same link as the ENode FLOGI session, regardless of the link load. New ENode FLOGIs are placed on the least-loaded link. The switch calculates the link load based on the combined total of FLOGIs and FDISCs on each NP_Port link. Rebalancing the link load disrupts all sessions (all sessions log out and then log in again).
- FLOGI-based load balancing—Similar to ENode-based load balancing; when an ENode logs in to the fabric, the switch places all subsequent VN_Port FDISC sessions associated with that ENode on the same link as the ENode FLOGI session, regardless of the link load. New ENode FLOGIs are placed on the least-loaded link.

One difference between ENode-based load balancing and FLOGI-based load balancing is that the switch calculates the link load based only on the number of FLOGIs on each NP_Port link. The algorithm does not count FDISCs. Another difference is that instead of disrupting all sessions on a link load rebalance, the system disrupts only selected sessions to minimize the impact (the switch uses an algorithm to log out only the sessions that need to be moved to other links to balance the load when those sessions log in again).

NOTE: Changing the load-balancing algorithm when FCoE sessions are running forces the FCoE sessions to log out and then log in again.

If you do not explicitly configure the load-balancing algorithm, the switch uses simple load balancing by default on the all NP_Port interfaces that belong to a given local FC fabric.

The following sections describe how each algorithm works, its advantages and disadvantages, and what happens when NP_Port links come up for the first time, when an NP_Port link is added to existing links, and when you rebalance the link load:

- [Simple Load Balancing on page 4843](#)
- [ENode-Based Load Balancing on page 4844](#)
- [FLOGI-Based Load Balancing on page 4844](#)
- [Load-Balancing Algorithm Comparison on page 4845](#)

Simple Load Balancing

Simple load balancing provides the most equal load balancing across links because each VN_Port FDISC session can be assigned to the least-loaded link, regardless of whether the parent ENode FLOGI session is on that link. (The parent ENode is the ENode that originates the logins to the fabric. After the parent ENode logs in, the VN_Ports on that ENode can log in to the fabric using FDISC.)

The FCoE-FC gateway performs simple load balancing by default on the NP_Ports that connect the gateway to the FC SAN. When an ENode sends a FLOGI request to the gateway, the gateway checks the NP_Ports that connect it to the FC SAN and assigns the new session to the least-loaded link.

Every time an ENode sends a FLOGI or an FDISC request, the gateway assigns the new session to the least-loaded NP_Port link. After the gateway assigns an ENode FLOGI session to an NP_Port, subsequent FDISC requests by the same ENode can result in sessions being assigned to different NP_Ports, because the gateway always assigns the new session to the least-loaded interface.

NOTE: Because VN_Port sessions might be placed on a different link than their parent ENode, if the link that contains the ENode goes down, only the ENode session and any of its VN_Port sessions that are on that link go down. VN_Port sessions on other links remain active as long as the link is up and the VN_Port is not logged out.

When a new link comes up, the switch logs out enough sessions so that when the sessions log in again, they are placed on the new link and the link loads are balanced. The switch uses an algorithm to log out sessions in the least disruptive manner by first logging out FDISCs whose FLOGI is not on the same link, then the least-loaded FLOGIs (loaded in terms of related FDISC logins).

Similarly, when you rebalance an existing link load, the switch logs out only enough sessions so that when the sessions log in again, they balance the load on the existing links. In this case (rebalance without a new link up), the switch takes into account the dependencies between FLOGIs and FDISCs when selecting sessions to log out.

The simple load-balancing algorithm uses the sum of the FLOGI and FDISC sessions to determine the session load on each link for both initial load balancing and load rebalancing.

ENode-Based Load Balancing

ENode-based load balancing can result in a less balanced load across the NP_Port links because the VN_Port FDISC sessions are assigned to the same link as the parent ENode FLOGI session, regardless of how many FDISC sessions are associated with the ENode. However, ENode-based load balancing has the advantage of keeping all of the sessions associated with a particular ENode on one link, which provides better control and predictability.

When you use the ENode-based load-balancing algorithm, the gateway assigns the ENode to an NP_Port link when the ENode sends its FLOGI message to the gateway. The gateway places the ENode session on the least-loaded link at that time. The VN_Port FDISC sessions associated with an ENode are placed on the same link as the ENode FLOGI session, regardless of the link load. Essentially, the ENode sessions are load-balanced, but the VN_Port sessions are not.

ENode-based load balancing ensures that each ENode and its associated VN_Port sessions are assigned to the same NP_Port link. ENode-based load balancing provides more control and predictability and ensures that if the link carrying an ENode goes down, all of the ENodes associated VN_Port sessions also go down.

The disadvantage of ENode-based load balancing is that if one ENode has a large number of sessions and the other ENodes do not, the link that carries the ENode with the large number of sessions might have a much larger load than the other NP_Port links in the gateway proxy fabric.

For example, if a gateway fabric has two NP_Ports connected to the FC fabric, and two ENodes log in to the fabric, one ENode session is placed on each link. If two VN_Port sessions are initiated on one of the ENodes, those sessions are placed on the same link as the parent ENode. If 1000 VN_Port sessions are initiated on the other ENode, all of the 1000 VN_Port sessions are placed on the same link as that ENode. In this case, one link has 3 sessions (1 ENode FLOGI session and 2 VN_Port FDISC sessions) and the other link has 1001 sessions (1 ENode FLOGI session and 1000 VN_Port FDISC sessions).

When a new link comes up or when you rebalance an existing load, the switch logs out all sessions (FLOGIs and FDISCs) in the fabric. As the sessions log in again, the switch assigns them to NP_Ports in a balanced manner, with all FDISCs assigned to the same link as the parent FLOGI. A new link coming up or a rebalance disrupts all of the existing sessions.

The ENode-based load-balancing algorithm uses the sum of the FLOGI and FDISC sessions to determine the session load on each link for both initial load balancing and load rebalancing.

FLOGI-Based Load Balancing

FLOGI-based load balancing is similar to ENode-based load balancing in most ways:

- It can result in a less balanced load across the NP_Port links because the VN_Port FDISC sessions are assigned to the same link as the parent ENode FLOGI session, regardless of how many FDISC sessions are associated with the ENode.
- When an ENode logs in with a FLOGI, the gateway places the session on the least-loaded link, and the FDISC logins associated with the FLOGI are placed on the same link, regardless of link load.
- Provides control and predictability because each ENode and its associated VN_Port (FDISC) sessions are assigned to the same link, so if the link an ENode is on goes down, all of its associated sessions also go down.
- If one ENode has a large number of sessions and the other ENodes do not, the link that carries the ENode with the large number of sessions might have a much larger load than the other NP_Port links in the gateway proxy fabric.

FLOGI-based load balancing differs from ENode-based load balancing in two important ways:

1. The switch uses the sum of the FLOGI sessions on a link to determine the link load. The switch does not use FDISC sessions when calculating the number of sessions on a link. (ENode-based load balancing uses the sum of the FLOGI and FDISC sessions to calculate the number of sessions on a link.)
2. When a new link comes up or when you rebalance an existing load, the switch logs out enough FLOGI (and FDISC) sessions so that when the FLOGI sessions log in again, the load is balanced. The switch balances the load based only on the number of FLOGI sessions, not the sum of FLOGI and FDISC sessions. However, the FDISC sessions associated with a FLOGI follow the FLOGI to the new link if the FLOGI session is part of the rebalancing.

The FLOGI-based load-balancing algorithm uses only the FLOGI sessions to determine the session load on each link for both initial load balancing and load rebalancing.

Load-Balancing Algorithm Comparison

[Table 368 on page 4845](#) compares the three load-balancing algorithms and summarizes their differences, advantages, and disadvantages.

Table 368: Load-Balancing Algorithm Comparison

| Load-Balancing Algorithm | Session Assignment | Session Disruption on Rebalance | Session Count Method | Advantages | Disadvantages |
|----------------------------|---|---|---------------------------------|--|---|
| Simple (default algorithm) | FDISC sessions can be placed on different links than the parent FLOGI session | Minimum number of selected sessions logged out (FDISC sessions can be logged out independent of the parent FLOGI session) | Sum of FLOGI and FDISC sessions | <ul style="list-style-type: none"> • Most equal session distribution across links • Minimum number of sessions logged out when rebalancing • Least disruptive algorithm | <ul style="list-style-type: none"> • Less session control and predictability |

Table 368: Load-Balancing Algorithm Comparison (*continued*)

| Load-Balancing Algorithm | Session Assignment | Session Disruption on Rebalance | Session Count Method | Advantages | Disadvantages |
|--------------------------|---|--|--|---|---|
| ENode-based | FDISC sessions are always placed on the same link as the parent FLOGI session | All sessions are logged out | Sum of FLOGI and FDISC sessions | <ul style="list-style-type: none"> Better session control and predictability (on link down, all sessions associated with an ENode go down) | <ul style="list-style-type: none"> Most disruptive algorithm; all sessions logged out on rebalance Might result in less balanced link load because FDISCs are placed on the same link as parent FLOGI |
| FLOGI-based | FDISC sessions are always placed on the same link as the parent FLOGI session | Minimum number of selected sessions logged out (but FDISC sessions logged out when parent FLOGI session is logged out) | FLOGI sessions only (FDISC sessions not included in the session count) | <ul style="list-style-type: none"> Better session control and predictability (on link down, all sessions associated with an ENode go down) Minimum number of sessions logged out when rebalancing | <ul style="list-style-type: none"> Might result in less balanced link load because FDISCs are placed on the same link as parent FLOGI |

Load-Rebalancing Methods

The load-rebalancing method determines the way the system redistributes sessions to balance the load on the NP_Ports that belong to a local FC fabric on an FCoE-FC gateway.

You can rebalance the existing load on existing NP_Port links using either of two methods:

- Automated load rebalancing—When a load rebalancing trigger occurs, the switch automatically rebalances the link loads by redistributing the sessions across the active NP_Port links. There are three possible load rebalancing triggers:

- When you enable automated load rebalancing, the switch checks the load balance on the existing NP_Port links. If the links are already balanced, the switch does not rebalance the link load. If the links are not balanced, the switch rebalances the link loads using the configured load-balancing algorithm.

Enabling automated load rebalancing causes sessions to be logged out in accordance with the configured load-balancing algorithm if the link load is unbalanced. If the link load is already balanced when you enable automated load rebalancing, the links are not rebalanced. (Disabling automated load rebalancing is not disruptive because the link load is already balanced.)

- When a new NP_Port link comes up on a local FCoE-FC gateway fabric, the switch rebalances the link load using the configured load-balancing algorithm if automated load balancing is enabled.
- When the port speed is changed (unless the port speed change does not change the actual port speed, for example, changing the port speed from auto to 8 Gbps).

Use automated load rebalancing if you want link loads to be rebalanced automatically when a load-balancing trigger occurs, instead of at times of your choosing. Keep in mind that load rebalancing is a disruptive event (sessions are logged out).

- On-demand load rebalancing—You choose when to rebalance the NP_Port links by explicitly requesting a load rebalance using an operational command. The system rebalances the link load only when you issue the rebalancing command.

Use on-demand load rebalancing if you only want to rebalance the link load once or if you want to rebalance the link loads at controlled times instead of automatically.

You can also request a load rebalancing *dry run*. A dry run simulates rebalancing and lists the sessions that might be affected if you choose to perform an actual load-rebalancing operation. The link loads are not rebalanced when you request a dry run.

NP_Port Interface FIP Session Limit Effect on Load Balancing

The maximum number of FIP login sessions configured for each NP_Port interface affects load balancing. When an interface reaches its maximum number of FIP login sessions, that interface is removed from the list of interfaces used for load balancing. The other interfaces in the gateway fabric continue to accept ENode login sessions until they reach their configured maximum session limit. Only interfaces that have not reached their maximum session limit are included in the load-balancing calculations.

NOTE: If all NP_Port interfaces in a gateway fabric reach their FIP login session limits, the fabric sends subsequent multicast discovery advertisements (MDAs) with the availability bit set to 0 (zero) to prevent additional ENode login attempts. While the maximum number of sessions is running on the gateway fabric, ENodes cannot use that fabric to log in to the FC switch. When the number of sessions falls below the maximum, the gateway sets the availability bit in MDAs to 1 so that ENodes can log in to the fabric again.

Load-Balancing Triggers and Timing

Several events trigger load balancing. Some of the events trigger load balancing only when automated load balancing is enabled. Other events trigger load rebalancing whether or not automated rebalancing is enabled.

This section describes the load-balancing triggers, what happens when the trigger action occurs, and how the switch determines if and when to balance the link load:

- [Load-Balancing Triggers on page 4847](#)
- [Load-Balancing Timer on page 4848](#)

Load-Balancing Triggers

[Table 369 on page 4848](#) describes the four different events can trigger load balancing or load rebalancing. In every case, link load rebalancing uses the configured load-balancing algorithm to determine the placement of sessions on links.

Table 369: Load-Balancing Triggers and Actions

| Trigger Event | Action |
|--|---|
| New link comes up | <p>Triggers a load-rebalancing operation regardless of whether or not automated load rebalancing is enabled. (The new link has no sessions, so the sessions on other links must be redistributed to balance the load.)</p> <p>The link load is not rebalanced if there are no sessions on the existing links or if there are so few sessions on the existing links that they cannot be redistributed.</p> |
| On-demand load rebalancing request issued from CLI | <p>The switch checks the NP_Port link load. If the load is not balanced across the links, the switch rebalances the link load. If the load is already balanced, nothing happens.</p> <p>NOTE: Requesting a dry run displays sessions that might be disrupted if you rebalance the link load, but does not rebalance the link load.</p> |
| Automated load balancing configured for the first time | <p>The switch checks the NP_Port link load. If the load is not balanced across the links, the switch rebalances the link load. If the load is already balanced, nothing happens.</p> |
| NP_Port speed change | <p>If automated rebalancing is enabled, changing the port speed brings the port up and down (flaps the port) and causes the switch to rebalance the link loads. If the port speed change does not change the actual port speed (for example, changing the port speed from <i>auto</i> to 8 Gbps), the link loads are not rebalanced.</p> <p>If automated rebalancing is not enabled, port speed changes do not cause link load rebalancing.</p> |

NOTE: When an NP_Port link goes down, it does not trigger load rebalancing. The loads on the remaining active links are already balanced, and as the sessions logged out from the down link log in again, they are they assigned to links in a balanced manner determined by the configured load-balancing algorithm.

Load-Balancing Timer

When you trigger load balancing from the CLI, the load-balancing action occurs immediately after you execute the command. However, when a load-balancing trigger occurs that is not a CLI command, the switch does not balance the link loads immediately. Instead, the switch follows an intelligent timer process:

1. The switch checks the current load balance on the NP_Port links in the local gateway FC fabric. If the load is already balanced, the switch does nothing, and there is no session disruption.
2. If the check shows that the link load is not balanced, the switch starts a 10-second timer. If no other load-balancing triggers occur during the 10-second interval, the switch rebalances the load.

If another load-balancing trigger occurs during the 10-second interval, the timer resets to 10 seconds. The 10-second timer prevents the switch from performing multiple disruptive load-rebalancing actions in a short period of time.

NOTE: The switch processes new sessions that log in after the timer starts in the normal manner. The new sessions are considered in the load-balancing evaluation and operation.

3. At a maximum of 30 seconds after the first load-balancing trigger occurs, the switch checks the link load balance again. If the links are already balanced, the switch cancels the load-rebalancing operation. If the links are not balanced, the switch rebalances the link loads.

NOTE: If the trigger event that started the load-rebalancing timer is no longer valid when the timer elapses, the switch cancels the rebalancing operation. For example, if a new NP_Port link comes up and triggers the timer, then goes down before the timer expires, the original link up event is no longer valid, and the switch cancels the rebalancing operation (unless another valid rebalancing trigger occurs in that time frame).

When a link load rebalancing operation is in progress, the switch defers any load-rebalancing triggers that occur until the load-rebalancing operation is complete. The new rebalancing operation begins after the current rebalancing operation finishes if a check shows that rebalancing is required.

If you explicitly request load rebalancing from the CLI using the **request fibre-channel proxy load-rebalance** operational command, the switch rejects the command and displays an error message stating that rebalancing is already in progress.

Load Rebalancing Behavior When a Link Goes Down

If an NP_Port link goes down, the ENode and VN_Port sessions on that link are logged out. The ENodes and VN_Port sessions log in again and are assigned to NP_Port links based on the link load and the load-balancing algorithm. If a link goes down, the switch does not rebalance the remaining load on the remaining links to avoid disrupting the existing ENode and VN_Port sessions. (Also, it is not necessary to rebalance the links in that manner because after a link goes down, the sessions on the remaining links are already balanced. As the logged out sessions log back in, the switch places them on the remaining active links in a balanced manner, according to the configured load-balancing algorithm.)

NOTE: When you use the simple load-balancing algorithm, an ENode and its associated VN_Port sessions might be on different links. In that case, if the NP_Port with the ENode goes down, only the VN_Ports on the same link are logged out. VN_Ports on other links remain up and running.

Interface Load Calculation Algorithm

A weighted round-robin (WRR) algorithm determines the interface load based on:

- The current number of sessions on the interface

NOTE: The configured load-balancing algorithm determines how the switch counts the number of sessions. For simple and ENode-based load balancing, the number of sessions is the sum of the FLOGI and FDISC sessions on each link. For FLOGI-based load balancing, the number of sessions is the sum of the FLOGI sessions on each link.

- The interface weight, which is the speed of the Fibre Channel link (2 Gbps, 4 Gbps, or 8 Gbps)

The interface load algorithm is:

$$(\text{number-of-sessions} * \text{max-weight}) / \text{weight}$$

where *max-weight* is an internal constant.

If the load on the FC interfaces is equal, the session is assigned to the interface with the highest link speed (the greatest weight).

For example, if the three FC interfaces have the characteristics shown in [Table 370 on page 4850](#), the loads of the interfaces are not equal:

Table 370: FC Interface Session-Based Load-Balancing Characteristics for Unequal Loads

| Interface | Number of Sessions | Weight (Speed) |
|-----------|--------------------|----------------|
| fc-0/0/0 | 4 | 4 Gbps |
| fc-0/0/1 | 1 | 2 Gbps |
| fc-0/0/2 | 8 | 8 Gbps |

In this example, interfaces fc-0/0/0 and fc-0/0/2 have a greater load than fc-0/0/1. For simple load balancing, the gateway assigns the next new FLOGI or FDISC to fc-0/0/1 because it is the least-loaded interface. For both ENode-based and FLOGI-based load balancing, the gateway assigns the next new FLOGI to fc-0/0/1 because it is the least-loaded interface. Then all VN_Port FDISCs from that ENode follow the ENode FLOGI and are also assigned to fc-0/0/1 regardless of the link load.

For another example, if the three FC interfaces have the characteristics shown in [Table 371 on page 4851](#), the loads of the interfaces are equal:

Table 371: FC Interface Session-Based Load-Balancing Characteristics for Equal Loads

| Interface | Number of Sessions | Weight (Speed) |
|-----------|--------------------|----------------|
| fc-0/0/0 | 4 | 4 Gbps |
| fc-0/0/1 | 2 | 2 Gbps |
| fc-0/0/2 | 8 | 8 Gbps |

In this case, all interfaces have the same relative load. For simple load balancing, the gateway assigns the next new FLOGI or FDISC to fc-0/0/2 because although the loads of the three interfaces are equal, fc-0/0/2 has the greatest weight. For both ENode-based and FLOGI-based load balancing, the gateway assigns the next new FLOGI to fc-0/0/2, and all VN_Port FDISCs from that ENode follow the ENode FLOGI and are also assigned to fc-0/0/2 regardless of the link load.

After the gateway establishes a session between an ENode or a VN_Port and an FC switch on an NP_Port, the session remains on that NP_Port until the ENode or VN_Port performs a LOGO.

If the physical FC interface link goes down, the FLOGI and FDISC sessions on the down link are logged out. The ENodes and VN_Ports log in again to start new sessions on other NP_Ports in the local gateway FC fabric in accordance with the configured load-balancing algorithm (assuming there is more than one NP_Port connected to the FC fabric).

Load-Balancing Scenarios

The configured load-balancing algorithm, the sequence in which ENodes log in to the FC network, the current session count (number of sessions per interface) and the interface speed determine the way the session load is balanced across the native FC interfaces (NP_Ports) in a gateway FC fabric. Whether you are balancing the link load for the first time or rebalancing an existing link load, the way the load is distributed across the active links is the same.

NOTE: The way the switch counts the number of sessions on a port depends on the load-balancing algorithm. For simple and ENode-based load balancing, the sum of the FLOGI and FDISC sessions equals the session count. For FLOGI-based load balancing, only the FLOGI sessions are counted in the total session count.

The following scenarios demonstrate how sessions are assigned to links for each load-balancing algorithm:

- [Simple Load-Balancing Algorithm Scenario on page 4852](#)
- [ENode-Based Load-Balancing Algorithm Scenarios on page 4853](#)
- [FLOGI-Based Load-Balancing Algorithm Scenarios on page 4854](#)

All of the scenarios use the topology shown in [Figure 175 on page 4852](#).

Figure 175: Sample Load-Balancing Topology

Simple Load-Balancing Algorithm Scenario

Simple load balancing results in the most equal load distribution among the NP_Ports connected to an FC SAN fabric because VN_Port FDISC sessions do not need to “follow” the parent ENode FLOGI session on the same link between the gateway and the FC fabric. When a new FLOGI or FDISC session is initiated, it is assigned to the least-loaded link.

The simple load-balancing algorithm example uses the topology shown in [Figure 175 on page 4852](#) and has the following characteristics:

- QFX Series configured as an FCoE-FC gateway
- Two gateway NP_Ports, **fc-0/0/0** and **fc-0/0/1**, connected to an FC SAN fabric switch at a speed of 8 Gbps
- Three ENodes, ENode_A, ENode_B, and ENode_C connected to the gateway
- NP_Ports **fc-0/0/0** and **fc-0/0/1**, and ENode_A, ENode_B, and ENode_C, belong to the same local FC fabric on the gateway

When the NP_Ports initialize, they send FLOGI messages to the FC switch and log in to the FC SAN fabric. The gateway then advertises the fabric to the ENodes on the Ethernet side of the network. At this point, the load on both of the NP_Ports is equal. Now the ENodes and VN_Ports start to log in to the fabric:

1. ENode_A sends a FLOGI to log in to the fabric. Because the loads on the two NP_Ports are equal, the session for ENode_A is randomly placed on one of the links. In this example, the ENode_A FLOGI session is placed on port **fc-0/0/0**.
2. ENode_B logs in. Because the load is less on port **fc-0/0/1**, the ENode_B FLOGI session is placed on port **fc-0/0/1**.

3. ENode_C logs in. Because the link loads are equal, the ENode_C login session is randomly placed on one of the links. In this example, the ENode_C login session is placed on port **fc-0/0/0**.
4. A VN_Port on ENode_A sends an FDISC to log in to the fabric. Because port **fc-0/0/1** currently is the least-loaded link, the VN_Port session is placed on port **fc-0/0/1**, even though its parent ENode session is on port **fc-0/0/0**.
5. As each new VN_Port session comes up, it is placed on the least-loaded link, regardless of the link on which its parent ENode session is placed.

ENode-Based Load-Balancing Algorithm Scenarios

ENode-based load balancing ensures that VN_Port FDISC sessions are placed on the same link as their parent ENode FLOGI sessions, regardless of the link load. ENode-based load balancing can result in a less-balanced load among the NP_Port links, but it provides the control and predictability of keeping ENodes and their VN_Port sessions on the same link.

The examples in this section use the topology shown in [Figure 175 on page 4852](#).

- QFX Series configured as an FCoE-FC gateway
- Two gateway NP_Ports, **fc-0/0/0** and **fc-0/0/1**, connected to an FC SAN fabric switch at a speed of 8 Gbps
- Three ENodes connected to the gateway:
 - ENode_A, which has 2 VN_Port FDISC sessions
 - ENode_B, which has 20 VN_Port FDISC sessions
 - ENode_C, which has 100 VN_Port FDISC sessions
- NP_Ports **fc-0/0/0** and **fc-0/0/1**, and ENode_A, ENode_B, and ENode_C, belong to the same local FC fabric on the gateway

When the NP_Ports initialize, they send FLOGI messages to the FC switch and log in to the FC SAN fabric. The gateway then advertises the fabric to the ENodes on the Ethernet side of the network. At this point, the load on both of the NP_Ports is equal. Now the ENodes and VN_Ports start to log in to the fabric. As the following two scenarios show, how these sessions are placed on the links depends on the sequence in which they log in to the fabric.

Scenario 1:

1. ENode_A sends a FLOGI to log in to the fabric. Because the loads on the two NP_Ports are equal, the session for ENode_A is randomly placed on one of the links. In this example, the ENode_A FLOGI session is placed on port **fc-0/0/0**.
2. ENode_B logs in. Because the load is less on port **fc-0/0/1**, the ENode_B FLOGI session is placed on port **fc-0/0/1**.
3. The two VN_Ports on ENode_A log in to the fabric. Their sessions are placed on port **fc-0/0/0**, following ENode_A on the link. Now port **fc-0/0/0** has a greater load (one FLOGI session plus two FDISC sessions) than port **fc-0/0/1** (one FLOGI session).

4. The 20 VN_Ports on ENode_B log in to the fabric. Their sessions are placed on port **fc-0/0/1**, following ENode_B on the link. Now port **fc-0/0/0** has a lesser load (one FLOGI, two FDISC) than port **fc-0/0/1**.
5. ENode_C logs in. Because the load is less on port **fc-0/0/0**, the ENode_C FLOGI session is placed on port **fc-0/0/0**.
6. The 100 VN_Ports on ENode_C log in to the fabric. Their sessions follow the ENode_C session onto port **fc-0/0/0**.
7. If more VN_Ports come up, their FDISC sessions are placed on the same link as the corresponding parent ENode session.

Scenario 2:

1. ENode_A sends a FLOGI to log in to the fabric. Because the loads on the two NP_Ports are equal, the session for ENode_A is randomly placed on one of the links. In this example, the ENode_A FLOGI session is placed on port **fc-0/0/0**.
2. ENode_B logs in. Because the load is less on port **fc-0/0/1**, the ENode_B FLOGI session is placed on port **fc-0/0/1**.
3. The two VN_Ports on ENode_A log in to the fabric. Their sessions are placed on port **fc-0/0/0**, following ENode_A on the link. Now port **fc-0/0/0** has a greater load (one FLOGI session plus two FDISC sessions) than port **fc-0/0/1** (one FLOGI session).
4. In this step, the login sequence in Scenario 2 differs from the login sequence in Scenario 1, resulting in a different placement of sessions on the links, and therefore a different load on the links. ENode_C logs in before the ENode_B VN_Ports log in, which changes the session count on the links compared to the first scenario. Because the load in this scenario is less on port **fc-0/0/1**, the ENode_C FLOGI session is placed on port **fc-0/0/1** (instead of port **fc-0/0/0** as in the first scenario).
5. The 20 VN_Ports on ENode_B log in to the fabric. Their sessions are placed on port **fc-0/0/1**, following ENode_B on the link. Now port **fc-0/0/0** carries one FLOGI and two FDISC sessions, and port **fc-0/0/1** carries two FLOGI and 20 FDISC sessions.
6. The 100 VN_Ports on ENode_C log in to the fabric. Their sessions follow the ENode_C session onto port **fc-0/0/1**. Now port **fc-0/0/1** carries 2 FLOGI and 120 FDISC sessions, whereas port **fc-0/0/0** carries one FLOGI and two FDISC sessions.
7. If more VN_Ports come up, their FDISC sessions are placed on the same link as the corresponding parent ENode session.

Because of the sequence of ENode logins in Scenario 2, port **fc-0/0/1** carries a greater load than port **fc-0/0/0**. If the simple load-balancing algorithm had been used, the FLOGI and FDISC sessions would be allocated to the two links evenly. However, because the FDISC sessions are placed on the same link as their parent FLOGI sessions, this example demonstrates how using the ENode-based load-balancing algorithm can lead to scenarios in which the link loads are not equal.

FLOGI-Based Load-Balancing Algorithm Scenarios

FLOGI-based load balancing is similar in many ways to ENode-based load balancing. An important difference that affects how the switch places sessions on links is that for

FLOGI-based load balancing, only the FLOGI sessions are counted when the link load is calculated. FDISC sessions are not counted to determine the link load. Because ENode-based load balancing uses the sum of the FLOGI and FDISC sessions to determine the link load, an interface with exactly the same combination of FLOGI and FDISC sessions can have a different session count depending on the algorithm used. A different session count can change the interface to which the switch assigns the next session.

As with ENode-based load balancing, FLOGI-based load balancing ensures that VN_Port FDISC sessions are placed on the same link as their parent ENode FLOGI sessions, regardless of the link load. FLOGI-based load balancing can result in a less-balanced load among the NP_Port links, but it provides the control and predictability of keeping ENodes and their VN_Port sessions on the same link.

The examples in this section use the topology shown in [Figure 175 on page 4852](#).

- QFX Series configured as an FCoE-FC gateway
- Two gateway NP_Ports, **fc-0/0/0** and **fc-0/0/1**, connected to an FC SAN fabric switch at a speed of 8 Gbps
- Three ENodes connected to the gateway:
 - ENode_A, which has 2 VN_Port FDISC sessions
 - ENode_B, which has 20 VN_Port FDISC sessions
 - ENode_C, which has 100 VN_Port FDISC sessions
- NP_Ports **fc-0/0/0** and **fc-0/0/1**, and ENode_A, ENode_B, and ENode_C, belong to the same local FC fabric on the gateway

When the NP_Ports initialize, they send FLOGI messages to the FC switch and log in to the FC SAN fabric. The gateway then advertises the fabric to the ENodes on the Ethernet side of the network. At this point, the load on both of the NP_Ports is equal. Now the ENodes and VN_Ports start to log in to the fabric.

Because FLOGI-based load balancing does not count FDISC sessions when calculating the link load, how the sessions are placed on the link depends only on the number of FLOGI sessions per interface, not on the number of FLOGI sessions plus FDISC sessions. This means that an ENode with a FLOGI session and many FDISC sessions is counted as having the same load as an ENode with a FLOGI session and no FDISC sessions.

Scenario 1:

1. ENode_A sends a FLOGI to log in to the fabric. Because the loads on the two NP_Ports are equal, the session for ENode_A is randomly placed on one of the links. In this example, the ENode_A FLOGI session is placed on port **fc-0/0/0**.
2. ENode_B logs in. Because the load is less on port **fc-0/0/1**, the ENode_B FLOGI session is placed on port **fc-0/0/1**.
3. The two VN_Ports on ENode_A log in to the fabric. Their sessions are placed on port **fc-0/0/0**, following ENode_A on the link. However, unlike simple load balancing or ENode-based load balancing, the session count of the two ports is still equal (one session each) because the FDISC sessions are not used in the session count.

4. The 20 VN_Ports on ENode_B log in to the fabric. Their sessions are placed on port **fc-0/0/1**, following ENode_B on the link. Again, unlike simple load balancing or ENode-based load balancing, the session count of the two ports is still equal (one session each) because the FDISC sessions are not used in the session count.
5. ENode_C logs in. Because the link loads are counted as equal, the ENode_C login session is randomly placed on one of the links. In this example, the ENode_C login session is placed on port **fc-0/0/0**.
6. The 100 VN_Ports on ENode_C log in to the fabric. Their sessions follow the ENode_C session onto port **fc-0/0/0**.
7. If more VN_Ports come up, their FDISC sessions are placed on the same link as the corresponding parent ENode session.

If a fourth ENode, ENode_D, sends a FLOGI to log in to the fabric, it is placed on port **fc-0/0/1** because port **fc-0/0/0** has a session count of two (two FLOGIs from ENode_A and ENode_C, FDISCs not counted) and port **fc-0/0/1** has a session count of one (one FLOGI from ENode_B, FDISCs not counted), so port **fc-0/0/1** is the least-loaded port.

With FLOGI-based load balancing, it is possible for ENodes with many FDISC sessions to be placed on the same link, whereas ENodes with few FDISC sessions are placed on different links because only FLOGIs are used in the session count.

Load Balancing on the FCoE Interfaces (Ethernet Links)

You can achieve load balancing on the 10-Gigabit Ethernet interfaces that belong to an FCoE VLAN by configuring them in one or more link aggregation groups (LAGs). In addition to load balancing, LAGs offer the advantages of protecting against port failover, increasing available link bandwidth, and preventing spanning-tree algorithms from blocking physical links and wasting bandwidth.

Understanding OxID Hash Control for FCoE Traffic Load Balancing

The originator exchange identifier (OxID) field is one of several fields that the switch can use in its hash function computation for FCoE traffic load balancing over multiple outgoing links in an Ethernet link aggregation group (LAG). The originator of an exchange between a pair of Fibre Channel (FC) endpoints (such as an FCoE host and an FC storage device) uses the OxID field as an identifier for that exchange. The originator also uses the OxID field to track the progress of the series of sequences that comprise the exchange.

When FCoE traffic traverses a LAG, it can take multiple different links between the source and destination endpoints. The idea is to distribute the FCoE traffic across the LAG links, thus balancing the link load. The switch creates a hash value from some of the packet header fields, and uses the hash value to assign each packet to one of the LAG links. The switch always uses five packet header fields to compute the hash value:

- Source ID (SID)
- Destination ID (DID)
- Fabric ID (FID)
- Source Port ID (SPID)
- Source Module ID (SMID)

In addition, the OxID field is included by default in the FCoE load-balancing hash computation. However, if you do not want to use the OxID field in the FCoE load-balancing hash computation, you can remove it from the computation by using the **set forwarding-options hash-key family fcoe oxid disable** command.

Including the OxID field in the load-balancing hash computation allows different exchanges between a pair of Fibre Channel (FC) endpoints (such as an FCoE host and an FC storage device) to take different paths across the network, thus improving the aggregate network throughput.

However, if the paths between different sets of FC endpoints have common links, congestion on one set of FC endpoints can affect the other set of endpoints. Such congestion can happen if the FCoE traffic on the two sets of endpoints uses the same priority (IEEE 802.1p code point). It is common for networks to use priority 3 (IEEE 802.1p code point 011) for FCoE traffic. However, on the QFX3500 switch, you can assign different IEEE priorities to different lossless FCoE flows as described in [“Understanding CoS IEEE 802.1p Priorities for Lossless Traffic Flows” on page 5427](#) to further separate the traffic flows.

Understanding VN_Port to VF_Port FIP Snooping on an FCoE Transit Switch

Fibre Channel over Ethernet (FCoE) Initialization Protocol (FIP) snooping is a security mechanism that is designed to prevent unauthorized access and data transmission to a Fibre Channel (FC) network. It works by filtering traffic to permit only servers that have logged in to an FC network to access that network.

You explicitly enable VN_Port to VF_Port (VN2VF_Port) FIP snooping (FC-BB-5) on FCoE VLANs when the QFX Series is an FCoE transit switch at the access edge that connects FCoE devices on the Ethernet network to FC switches or gateways at the FC storage area network (SAN) edge. The transit switch applies FIP snooping filters at the ports associated with the FCoE VLANs on which you enable VN2VF_Port FIP snooping. An FCoE transit switch is a data center bridging (DCB) switch with FIP snooping capability.

An FCoE device that has a converged network adapter (CNA) uses the FIP process to log in to the FC network as an FCoE Node (ENode). The login process establishes a dedicated virtual link between a virtual N_Port (VN_Port) on the ENode and a virtual F_Port (VF_Port) on the FC switch. This dedicated virtual link emulates a point-to-point connection. The emulated connection is called a virtual link.

Virtual links pass transparently through the switch. The ENode VN_Port and the FC switch VF_Port do not detect the transit switch, and virtual links appear to be direct point-to-point links.

The QFX Series applies VN2VF_Port FIP snooping firewall filters at the directly attached edge ports associated with the FCoE VLANs on which you enable VN2VF_Port FIP snooping. FIP snooping provides security for virtual links by creating firewall filters based on information gathered (snooped) about FC devices during FIP transactions.

The QFX Series also supports VN_Port to VN_Port (VN2VN_Port) FIP snooping (FC-BB-6) to allow FCoE initiators and targets to communicate directly through the switch without going through an FCoE forwarder (FCF) or an FC switch, as described in [“Understanding VN_Port to VN_Port FIP Snooping on an FCoE Transit Switch” on page 4865](#).

NOTE: An FCoE VLAN can support either VN2VF_Port FIP snooping (FC-BB-5) or VN2VN_Port FIP snooping (FC-BB-6), but not both. The same QFX Series switch can have multiple FCoE VLANs configured, some for VN2VF_Port FIP snooping traffic and others for VN2VN_Port FIP snooping traffic. On FCoE VLANs that are configured as VN2VN_Port snooping VLANs, VN2VF_Port FIP snooping traffic is dropped.

When you enable VN2VF_Port FIP snooping, the system snoops VN_Port to VF_Port packets and enforces security only on VN2VF_Port virtual links. When you enable VN2VN_Port FIP snooping, the system snoops VN_Port to VN_Port packets and enforces security only on VN2VN_Port virtual links.

FC Network Security

In traditional FC networks, the FC switch is usually a trusted entity, and server ENodes connect directly to its VF_Ports. After an ENode gains access to the network through the fabric login (FLOGI) process, the FC switch enforces zoning configurations, ensures that the ENode uses valid addresses, monitors the connection, and performs other security functions to prevent unauthorized access.

However, FCoE exposes FC frames to Ethernet networks, which do not have the same level of security as native FC networks. VN2VF_Port FIP snooping firewall filters emulate the native FC network security functions by preventing unauthorized access to the FC switch through the transit switch and by ensuring the security of the virtual link between each ENode and the FC switch, as shown in [Figure 176 on page 4859](#). VN2VF_Port FIP snooping also prevents man-in-the-middle attacks.

Figure 176: FCoE Transit Switch Performs VN2VF_Port FIP Snooping

The transit switch performs VN2VF_Port FIP snooping at the ports connected to the FCoE devices. At the SAN edge, the FC switch must be able to convert the FCoE traffic to native FC traffic.

VN2VF_Port FIP Snooping Functions

When VN2VF_Port FIP snooping is enabled, the QFX3500 transit switch sets and applies filters to block all FCoE traffic by default. The transit switch monitors FIP logins, solicitations, and advertisements that pass through it and gathers information about the ENode address and the address of the port on the FC switch. The transit switch uses the information to construct firewall filters that permit access only to logged-in ENodes. All other traffic on the VLAN is denied.

For example, when an ENode on an FCoE VLAN performs a successful login to an FC switch port, the transit switch snoops the FIP information and constructs a firewall filter that provides access for the ENode to that port on the FC switch.

The firewall filters enable FCoE frames to pass through the transit switch only on a virtual link established between an FCoE device ENode VN_Port and the FC switch VF_Port to which it has logged in. The firewall filters ensure that ENodes can only connect to the FC switches they have successfully logged in to and that only valid FCoE traffic along valid paths is transmitted. VN2VF_Port FIP snooping maintains the filters by tracking FCoE sessions (ENode to FCF sessions).

FIP Snooping Firewall Filters

The effect of the firewall filters is to protect the FCoE ports. VN2VF_Port FIP snooping performs the following actions and checks to ensure that FCoE traffic is valid:

- Denies ENodes that use the FC switch media access control (MAC) address as the source address.
- Enables ENodes to transmit FIP and FCoE frames to the FC switch address.
- Ensures that the FCoE source address the FC switch assigns or accepts is only used for FCoE traffic.
- Ensures that FCoE frames are only addressed to the accepting FC switch.

Session Scalability

The system supports up to 2500 total FIP snooping sessions on an interface, a gateway FC fabric, a QFX Series switch, a QFabric Node device, or a QFabric Node group. For example, you can:

- Place all 2500 sessions on one FCoE interface.
- Split the 2500 sessions among multiple FCoE interfaces on one FCoE VLAN.
- Split the 2500 sessions among multiple FCoE interfaces on multiple FCoE VLANs.
- Split the 2500 sessions among the FCoE interfaces on multiple gateway FC fabrics on a switch.
- Split the 2500 sessions among the FCoE interfaces on multiple gateway FC fabrics on multiple Node devices in a QFabric Node group.

Regardless of how you allocate the sessions among interfaces and local FC fabrics on a QFX Series switch or on a QFabric system Node device or Node group, the combined FIP session limit is a maximum of 2500 sessions.

NOTE: The total number of sessions the system can support is the combined number of VN2VF_Port sessions and VN2VN_Port sessions. If VN2VN_Port sessions are active, the total number of available VN2VF_Port sessions is reduced.

VN2VF_Port FIP Snooping Implementation

You enable VN2VF_Port FIP snooping on a per-VLAN basis on VLANs that carry FCoE traffic. The switch snoops FIP frames at the ports associated with FCoE VLANs enabled for VN2VF_Port FIP snooping. The switch then installs the resulting firewall filters on the ports to ensure that all VN2VF_Port FIP snooping occurs on the switch network edge.

VN2VF_Port FIP snooping FCoE VLANs must meet the following criteria:

- An FCoE VLAN should be dedicated to FCoE traffic only.
- An FCoE VLAN cannot support both VN2VF_Port FIP snooping and VN2VN_Port FIP snooping simultaneously. You must configure separate FCoE VLANs for VN2VF_Port FIP snooping traffic and for VN2VN_Port FIP snooping traffic.

NOTE: Changing an FCoE VLAN from VN2VF_Port FIP snooping mode to VN2VN_Port snooping mode terminates the existing virtual links on the VLAN. The transit switch removes the existing FIP snooping filters, creates the new FIP snooping filters, and applies them to the FIP snooping ports. If you downgrade the software to Junos OS Release 12.1 or earlier, VLANs configured for VN2VN_Port FIP snooping revert to VN2VF_Port FIP snooping VLANs.

- For QFX3500 switches, QFX3600 switches, and QFabric system Node devices, configure all access ports that belong to an FCoE VLAN (ports connected to a converged network adapter [CNA] in an FCoE device) in **tagged-access** port mode. Access ports associated with an FCoE VLAN should not be configured as access ports or trunk ports on these platforms, although trunk port configuration is supported.

However, on QFX5100 switches that run the Enhanced Layer 2 Software (ELS) CLI, configure access ports that belong to an FCoE VLAN in **trunk** interface mode.

- All ports connected to an FC switch (or FCoE forwarder) must be configured in **trunk** port mode. Ports connected to an FC switch must be configured as trusted ports.
- FIP traffic uses the native VLAN (FIP VLAN discovery and notification frames are exchanged as untagged packets).
- All FCoE VLAN traffic must be tagged and cannot belong to the native VLAN.
- FCoE VLAN traffic cannot be untagged or priority-tagged.

When you enable VN2VF_Port FIP snooping, the switch inspects FIP frames.

The VN2VF_Port FIP snooping implementation includes these considerations:

- [ENode-Facing Interfaces on page 4862](#)
- [Network-Facing Interfaces on page 4863](#)
- [FC-MAP on page 4863](#)

ENode-Facing Interfaces

When the interfaces that belong to an FCoE VLAN connect directly to FCoE devices (there is no other transit switch between the FCoE devices and the QFX Series switch), we recommend that you enable VN2VF_Port FIP snooping on all FCoE VLANs that connect VN_Ports to VF_Ports. Enabling FIP snooping ensures secure connections between server ENodes and FC switches. (Enabling VN2VN_Port FIP snooping ensures secure connections on FCoE VLANs that connect VN_Ports to other VN_Ports). FIP snooping should always be enabled at the access edge.

Systems that run Enhanced Layer 2 Software (ELS) such as the QFX5100 switch support a slightly different configuration on ENode-facing interfaces than systems that do not run ELS. This section describes:

- [Non-ELS Port Mode for FCoE Interfaces on page 4862](#)
- [ELS Interface Mode for FCoE Interfaces on page 4862](#)
- [Trusted and Untrusted FCoE Interfaces on page 4863](#)

Non-ELS Port Mode for FCoE Interfaces

The interfaces that belong to FCoE VLANs (interfaces that connect to CNAs in FCoE devices) on systems that do not support ELS should be configured in **tagged-access** port mode. After you enable VN2VF_Port FIP snooping on an FCoE VLAN, the transit switch denies FCoE traffic from any ENode on that VLAN until the ENode performs a valid fabric login with an FC switch.

The **tagged-access** port mode was not available in Junos OS Release 11.3 and prior releases. In Release 11.3 and earlier, **trunk** port mode was used for Ethernet interfaces that connected to FCoE access devices. Because **tagged-access** mode is now available, using **trunk** mode for interfaces connected to FCoE CNAs is not recommended.

If an existing configuration uses **trunk** mode for ports connected to FCoE CNAs, you can change the port mode to **tagged-access** without disrupting traffic. Although we recommend changing the port mode of these ports from **trunk** to **tagged-access** as a best practice, it is not mandatory. New configurations should use **tagged-access** mode for interfaces that connect to FCoE devices.

ELS Interface Mode for FCoE Interfaces

The interfaces that belong to FCoE VLANs (interfaces that connect to CNAs in FCoE devices) on systems that support ELS should be configured in **trunk** interface mode. After you enable VN2VF_Port FIP snooping on an FCoE VLAN, the transit switch denies FCoE traffic from any ENode on that VLAN until the ENode performs a valid fabric login with an FC switch.

Trusted and Untrusted FCoE Interfaces

Do not configure ENode-facing interfaces as FCoE trusted interfaces when VN2VF_Port FIP snooping is enabled on those interfaces. If you enable VN2VF_Port FIP snooping on an FCoE VLAN and you configure ENode-facing interfaces that are members of the FIP snooping VLAN as **fcoe-trusted**, then FCoE devices might not be able to log in to the FC network.

Changing ports from untrusted to trusted removes any existing VN2VF_Port FIP snooping filters from the ports and terminates the existing sessions. Changing the fabric ports from trusted to untrusted forces all of the FCoE sessions on those ports to log out so that when the ENodes and VN_Ports log in again, the switch can build the appropriate VN2VF_Port FIP snooping filters.

Network-Facing Interfaces

When the switch acts as an FCoE transit switch, you must configure any interface that is connected to a switch as an FCoE trusted interface in **trunk** port mode and as a 10-Gigabit Ethernet interface.

Switch-facing Ethernet interfaces have the following requirements and behaviors:

- You must explicitly configure switch-facing trunk ports on an FCoE transit switch as FCoE trusted interfaces.
- After you configure an FC switch-facing trunk port as a trusted interface, the FCoE transit switch always processes FC switch frames because they come from a source on a trusted interface.
- All ports in an FCoE VLAN must be configured as tagged access or trunk ports.

FC-MAP

When the switch acts as an FCoE transit switch and you enable VN2VF_Port FIP snooping on an FCoE VLAN, you can optionally specify a 24-bit FCoE mapped address prefix (FC-MAP) value. On a given VLAN, the transit switch learns only those FC switches that have a matching FC-MAP value. If the transit switch FCoE VLAN FC-MAP value does not match the FC switch FC-MAP value, the transit switch does not discover the FC switch on that VLAN, and the ENodes on that VLAN cannot access the FC switch. An FCoE VLAN can have one and only one FC-MAP value.

The FC-MAP value is a MAC address prefix unique to an FC switch in the FC SAN fabric that the FC switch uses to identify FCoE traffic for a given FC fabric (traffic on a particular FCoE VLAN). The FC switch combines the FC-MAP value with a unique 24-bit FCID value for the ENode VN_Port during the login process. This creates a 48-bit identifier that is unique to the fabric. The FC switch assigns this 48-bit value to the ENode VN_Port as its MAC address and unique identifier for the session. Each VN_Port session the ENode establishes with the FC switch receives a unique FCID from the FC switch, so an FCoE device can host multiple virtual links (one for each VN_Port) to an FC switch, each with a 48-bit MAC address that is unique to the fabric.

The VN2VF_Port FIP snooping filter compares the configured FC-MAP value with the FC-MAP value in the header of frames coming from the ENode VN_Port. If the values do not match, the transit switch denies access.

NOTE: Changing the FC-MAP value causes all logins to be dropped and forces ENodes to log in again.

NOTE: Do not configure static MAC addresses with the FC-MAP value as a prefix (the first 24 bits of the MAC address). If you configure a static MAC address that uses the FC-MAP value as a prefix, the system deletes the static MAC address automatically after you enable FIP snooping. The static MAC address configuration is not restored even if you disable FIP snooping later. (The system considers a static MAC address with the FC-MAP value as the prefix to be a misconfiguration.) Do not use a MAC address with the FC-MAP value as the prefix for any traffic other than the FIP snooping traffic when the QFX Series is acting as a transit switch.

T11 VN2VF_Port FIP Snooping Specification

For more details about VN2VF_Port FIP snooping, see <http://www.t11.org/ftp/t11/pub/fc/bb-5/08-264v3.pdf> for the Technical Committee T11 organization document *Increasing FCoE Robustness using FIP Snooping*.

Understanding VN_Port to VN_Port FIP Snooping on an FCoE Transit Switch

VN_Port to VN_Port (VN2VN_Port) Fibre Channel over Ethernet (FCoE) Initialization Protocol (FIP) snooping (FC-BB-6) on an FCoE transit switch is conceptually similar to VN_Port to VF_Port (VN2VF_Port) FIP snooping (FC-BB-5) on an FCoE transit switch. An FCoE transit switch is a data center bridging (DCB) switch with FIP snooping capability. VN2VN_Port FIP snooping provides security in the form of filters. The filters help prevent unauthorized access and data transmission on a bridge that connects ENodes on the Ethernet network.

The main difference between VN2VN_Port FIP snooping and VN2VF_Port FIP snooping is that you use VN2VN_Port FIP snooping when the FCoE devices reside on the Ethernet network, so there is no need to forward traffic between FCoE devices to the Fibre Channel (FC) network, and you use VN2VF_Port FIP snooping when FCoE devices on the Ethernet network need to access targets on the FC network, so FCoE traffic must be forwarded to the FC network. See “[Understanding VN_Port to VF_Port FIP Snooping on an FCoE Transit Switch](#)” on page 4858 for information about VN2VF_Port FIP snooping.

You enable VN2VN_Port FIP snooping on the FCoE VLAN that transports the VN2VN traffic. The transit switch applies VN2VN_Port FIP snooping filters at the ports associated with the FCoE VLANs on which you enable VN2VN FIP snooping.

A key benefit of VN2VN_Port FIP snooping is that it enables FCoE initiators and targets to communicate directly through the switch without going through an FCoE forwarder (FCF) or an FC switch. The transit switch does not differentiate between initiators and targets because the transit switch sees both VN_Ports as FIP virtual link end points. Direct VN2VN_Port communication requires secure access (FIP snooping filters) because ENodes are not trusted entities.

VN2VN_Port FIP Snooping and FIP Snooping Virtual Links

FIP snooping under the T11 FC-BB-5 specification requires that an FC switch or an FCF be in the path between two VN_Ports when they communicate. Introduced in the T11 FC-BB-6 specification (see <http://www.t11.org/ftp/t11/pub/fc/bb-6/10-019v3.pdf>), VN2VN_Port FIP snooping allows the FCoE transit switch to connect two VN_Ports to

each other directly, without going through an FC switch or an FCF, provided that the ENodes have logged in to the FC network.

In VN2VF_Port FIP snooping, when an ENode logs in to the FC network, the FCoE transit switch snoops the FIP communication between the ENode and the FC switch. In VN2VN_Port FIP snooping mode, the transit switch creates filters on the switch access ports to control VN_Port access to other VN_Ports on the Ethernet network. The VN2VN_Port FIP snooping filters allow the switch to establish a dedicated virtual link that emulates a point-to-point connection between two VN_Ports, through the switch.

Virtual links pass transparently through the transit switch. The VN_Ports do not detect the transit switch, and virtual links appear to be direct point-to-point links.

You explicitly enable VN2VN_Port FIP snooping on FCoE VLANs when the QFX Series switch or QFabric system is an FCoE transit switch connecting FCoE devices on the Ethernet network to each other and to FC switches or gateways at the FC storage area network (SAN) edge.

NOTE: An FCoE VLAN can support either VN2VF_Port FIP snooping or VN2VN_Port FIP snooping, but not both. Configure separate FCoE VLANs for VN2VF_Port FIP snooping traffic and for VN2VN_Port FIP snooping traffic. On FCoE VLANs that are configured as VN2VN_Port FIP snooping VLANs, VN_Port to VF_Port traffic is dropped.

When you enable FIP snooping, the system snoops VN2VF_Port packets and enforces security only on VN_Port to VF_Port virtual links. When you enable VN2VN_Port FIP snooping, the system snoops VN_Port to VN_Port FIP packets and enforces security only on VN_Port to VN_Port virtual links.

The transit switch applies VN2VN_Port FIP snooping filters at the ports associated with the FCoE VLANs on which you enable VN2VN_Port FIP snooping. VN2VN_Port FIP snooping provides security for virtual links by creating filters based on information gathered (snooped) about FCoE devices during FIP transactions.

VN2VN_Port Communication Modes

The transit switch supports two VN2VN_Port communication modes:

- Point-to-point mode
- Multipoint mode

In point-to-point mode, two ENodes are connected to the network and form a single VN_Port to VN_Port virtual link. This is analogous to the point-to-point FC link between an FC initiator and an FC target.

In multipoint mode, multiple ENodes are connected to the network and form multiple virtual links. Each virtual link is created between one pair of VN_Ports. This is analogous to loop mode in traditional FC networks.

The VN2VN_Port communication mode is not configured; it is determined by the number of ENodes connected to the network.

Network Security

In traditional FC networks, the FC switch is usually a trusted entity and the server ENodes are untrusted entities. The ENodes connect directly to the FC switch VF_Ports. After an ENode gains access to the network through the fabric login (FLOGI) process, the FC switch enforces zoning configurations, ensures that the ENode uses valid addresses, monitors the connection, and performs other security functions to prevent unauthorized access.

However, FCoE exposes FC frames to Ethernet networks, which do not have the same level of security as native FC networks. VN2VN_Port FIP snooping filters emulate the native FC network security functions by preventing unauthorized access and by ensuring the security of the virtual link between ENode VN_Ports. The transit switch performs VN2VN_Port FIP snooping at the ports connected to the FCoE VN_Port devices.

VN2VN_Port FIP Snooping Functions

When you enable VN2VN_Port FIP snooping, the transit switch sets and applies filters to block all FCoE traffic on the VLAN by default. The transit switch monitors FIP logins, solicitations, and advertisements that pass through it and gathers information about the ENode address. The transit switch uses the information to construct filters that permit access only to logged-in ENodes. All other traffic on the VLAN is denied.

The filters enable FCoE frames to pass through the transit switch only on a virtual link established between two VN_Ports. The filters ensure that ENodes can only connect to other ENodes if they have successfully logged in to each other, and that only valid FCoE traffic along valid paths is transmitted. VN2VN_Port FIP snooping maintains the filters by tracking VN_Port to VN_Port sessions.

Scalability

Because ENodes are untrusted and the system needs to apply filters to untrusted FIP snooping interfaces, the total number of combined VN2VN_Port FIP snooping sessions per switch is 376 sessions (ENode to ENode sessions) on untrusted interfaces. On interfaces that are configured as trusted interfaces, no FIP snooping filters are applied.

NOTE: The total number of sessions the system can support is the combined number of VN2VF_Port sessions and VN2VN_Port sessions. If VN2VF_Port sessions are active, the total number of available VN2VN_Port sessions is reduced.

VN2VN_Port FIP Snooping Implementation

You enable VN2VN_Port FIP snooping on a per-VLAN basis on VLANs that carry FCoE traffic. The switch snoops FIP frames at the ports associated with FCoE VLANs enabled for VN2VN_Port FIP snooping. The switch then installs the resulting filters on the ENode-facing ports to ensure that all FIP snooping occurs on the switch network edge.

VN2VN_Port FIP snooping FCoE VLANs must meet the following criteria:

- An FCoE VLAN should be dedicated to FCoE traffic only.
- An FCoE VLAN cannot support both VN2VF_Port FIP snooping (FC-BB-5) and VN2VN_Port FIP snooping (FC-BB-6) simultaneously. You must configure separate FCoE VLANs for FIP snooping traffic and for VN2VN_Port FIP snooping traffic.

NOTE: Changing an FCoE VLAN from VN2VF_Port FIP snooping mode to VN2VN_Port FIP snooping mode terminates the existing virtual links on the VLAN. The transit switch removes the existing FIP snooping filters, creates the new FIP snooping filters, and applies them to the FIP snooping ports. If you downgrade the software to Junos OS Release 12.1 or earlier, VLANs configured for VN2VN_Port FIP snooping revert to VN2VF_Port FIP snooping VLANs.

- For QFX3500 switches, QFX3600 switches, and QFabric system Node devices, as a best practice, you should configure all access ports that belong to an FCoE VLAN (ports connected to a converged network adapter [CNA] in an FCoE device) in **tagged-access** port mode. However, access and trunk port modes are also supported. For QFX5100 switches, configure access ports that belong to an FCoE VLAN in **trunk** interface mode.
- Access ports should be configured as untrusted ports.
- All ports connected to another transit switch must be configured in **trunk** port mode.
- FIP traffic uses the native VLAN.
- You can enable VN2VN_Port FIP snooping on a native VLAN.

ENode-Facing Interfaces

When the interfaces that belong to an FCoE VLAN connect directly to FCoE devices (there is no other transit switch between the FCoE devices and the QFX Series switch), we recommend that you either enable VN2VN_Port FIP snooping on all FCoE VLANs to ensure secure connections between VN_Ports, or enable VN2VF_Port FIP snooping on FCoE VLANs that connect ENodes to an FC switch. FIP snooping should always be enabled at the access edge.

Systems that run Enhanced Layer 2 Software (ELS) such as the QFX5100 switch support a slightly different configuration on ENode-facing interfaces than systems that do not run ELS. This section describes:

- [Non-ELS Port Mode for FCoE Interfaces on page 4868](#)
- [ELS Interface Mode for FCoE Interfaces on page 4869](#)
- [Trusted and Untrusted FCoE Interfaces on page 4869](#)

Non-ELS Port Mode for FCoE Interfaces

The interfaces that belong to FCoE VLANs (interfaces that connect to CNAs in FCoE devices) should be configured in **tagged-access** port mode, unless your CNA does not support tagged VN2VN traffic. After you enable VN2VN_Port FIP snooping on an FCoE

VLAN, the transit switch denies FCoE traffic from any ENode on that VLAN until the ENode performs a valid fabric login (FIP FLOGI) with another ENode.

The **tagged-access** port mode was not available in Junos OS Release 11.3 and prior releases. In Release 11.3 and earlier, **trunk** port mode was used for Ethernet interfaces that connected to FCoE access devices. Because **tagged-access** mode is now available, using **trunk** mode for interfaces connected to FCoE CNAs is not recommended.

If an existing configuration uses **trunk** mode for ports connected to FCoE CNAs, you can change the port mode to **tagged-access** without disrupting traffic. Although we recommend changing the port mode of these ports from **trunk** to **tagged-access** as a best practice, it is not mandatory. New configurations should use **tagged-access** mode for interfaces that connect to FCoE devices.

ELS Interface Mode for FCoE Interfaces

The interfaces that belong to FCoE VLANs (interfaces that connect to CNAs in FCoE devices) on systems that support ELS should be configured in **trunk** interface mode. After you enable VN2VF_Port FIP snooping on an FCoE VLAN, the transit switch denies FCoE traffic from any ENode on that VLAN until the ENode performs a valid fabric login with an FC switch.

Trusted and Untrusted FCoE Interfaces

Do not configure ENode-facing interfaces as FCoE trusted interfaces when VN2VF_Port FIP snooping is enabled on those interfaces. If you enable VN2VF_Port FIP snooping on an FCoE VLAN and you configure ENode-facing interfaces that are members of the FIP snooping VLAN as **fcoe-trusted**, then FCoE devices might not be able to log in to the FC network.

Changing ports from untrusted to trusted removes any existing VN2VF_Port FIP snooping filters from the ports and terminates the existing sessions. Changing the fabric ports from trusted to untrusted forces all of the FCoE sessions on those ports to log out so that when the ENodes and VN_Ports log in again, the switch can build the appropriate VN2VF_Port FIP snooping filters.

Network-Facing Interfaces (Connecting to Another Transit Switch)

Configure any interface that is connected to another transit switch (not to an ENode) as an FCoE trusted interface, in **trunk** port mode, and as a 10-Gigabit Ethernet interface.

Network-facing Ethernet interfaces have the following requirements and behaviors:

- You must explicitly configure network-facing trunk ports on an FCoE transit switch as FCoE trusted interfaces.
- After you configure a network-facing trunk port as a trusted interface, the FCoE transit switch always processes frames from the connected switch because they come from a source on a trusted interface.
- As a best practice, configure ports in an FCoE VLAN as tagged access ports, but access and trunk port modes are also supported to accommodate whatever types of VN2VN traffic your CNA supports.

Beacon Period (VN2VN_Port FIP Snooping Link Maintenance)

The transit switch needs to maintain the virtual links between VN_Ports, and needs to know when sessions begin and end, and when to install and remove the FIP snooping filters. FIP snooping uses a FIP keepalive advertisement to accomplish this task. VN2VN_Port FIP snooping does not exchange FIP keepalive timer information. Instead, you configure a *beacon period*, which performs the same function as a keepalive timer.

The beacon period is the time interval between messages which verify that the connection is still valid and that the device at the other end of the virtual link is still reachable. You set the beacon period value for each FCoE VLAN that you configure to do VN2VN_Port FIP snooping.

NOTE: Explicitly set the beacon period when you configure VN2VN_Port FIP snooping. VN_Ports do not automatically send beacons.

ENodes transmit periodic multicast N_Port_ID beacons to the ALL-VN2VN-ENode-MACs address. The transmission period varies by a random delay of between 0 ms and 100 ms to avoid synchronized bursts of multicast traffic on the network.

If the transit switch does not receive a beacon message from an ENode within 2.5 times the configured beacon period, the transit switch considers the virtual link to be down and terminates the virtual link to that ENode.

QFabric System Differences in VN2VN_Port FIP Snooping Traffic Handling

Configuring VN2VN_Port FIP snooping on a QFabric system is the same as configuring VN2VN_Port FIP snooping on the QFX Series. However, there are internal differences in the way a QFabric system handles VN2VN_Port FIP snooping traffic compared to the way a QFX Series switch handles VN2VN_Port FIP snooping traffic. The internal differences are transparent. Whether you configure VN2VN_Port FIP snooping on a QFabric system or on the QFX Series, the proper FIP snooping filters and forwarding information are installed on each device.

On the QFX Series, the VN2VN_Port FIP snooping traffic does not cross a fabric (Interconnect device). VN2VN_Port traffic enters and exits ports on a single switch, so the ingress port and the egress port have access to the same *local* forwarding and FIP snooping databases.

However, on a QFabric system, VN2VN_Port FIP snooping traffic might enter on the ingress port of one Node device, traverse the Interconnect device fabric, and exit on the egress port of a different Node device. In this case, the QFabric system must ensure that the FIP snooping database and forwarding information for the VN2VN_Port traffic is installed correctly on both of the Node devices so that traffic is correctly filtered and forwarded.

For example, [Figure 177 on page 4871](#) shows that VN2VN_Port traffic from FCoE host ENode E1 enters the QFabric system at Node device ND1, traverses the Interconnect device fabric, and then exits from Node device ND2 before arriving at FCoE host ENode E2. Similarly,

VN2VN_Port traffic from FCoE host ENode E2 enters the QFabric system at Node device ND2, traverses the Interconnect device fabric, and then exits from Node device ND1 before arriving at FCoE host ENode E1.

Figure 177: VN2VN_Port Traffic Across a QFabric Interconnect Device

When the QFabric system receives a FLOGI ACC from either ENode E1 or ENode E2, the QFabric system creates and installs the correct VN2VN_Port FIP snooping filters on both Node devices, and updates the forwarding tables accordingly.

In addition, the QFabric system must also ensure that the VN2VN_Port FIP snooping session statistics are correctly counted. Even though a session is running on each of the two Node devices, the QFabric system counts the complete VN2VN_Port connection as one session because the two Node devices belong to the same session. This ensures that VN2VN_Port sessions that traverse the Interconnect device fabric are counted as one unique session, not as two separate sessions.

Understanding FIP Snooping, FBF, and MVR Filter Scalability

The VLAN filter processor (VFP) ternary content addressable memory (TCAM) stores the VLAN filter configuration for three filter types:

- Fibre Channel over Ethernet (FCoE) Initialization Protocol (FIP) snooping—FIP snooping filters prevent an FCoE device from gaining unauthorized access to a Fibre Channel (FC) storage device or to another FCoE device. VN2VF_Port FIP snooping filters prevent an FCoE device from gaining unauthorized access to devices on an FC network. VN2VN_Port FIP snooping filters prevent an FCoE device from gaining unauthorized access to another FCoE device directly through the QFX Series or QFabric system, without traversing the FC network.

The VFP TCAM stores the VN2VF_Port and VN2VN_Port FIP snooping filters that the switch automatically creates when you enable FIP snooping on a VLAN that carries FCoE traffic. See [“Understanding VN_Port to VF_Port FIP Snooping on an FCoE Transit Switch” on page 4858](#) and [“Understanding VN_Port to VN_Port FIP Snooping on an FCoE Transit Switch” on page 4865](#) for more information.

- Filter-based forwarding (FBF)—FBF enables you to use firewall filters to direct packets to virtual routing instances. The switch then forwards the matching packets based on the configuration of the routing instances. The VFP TCAM stores the terms you configure for FBF filters. See [“Understanding Filter-Based Forwarding” on page 4412](#) for more information.
- Multicast VLAN registration (MVR)—MVR enables you to configure a multicast source VLAN (MVLAN) that is shared across a Layer 2 network. An MVLAN distributes IPTV multicast streams across different VLANs without having to create a separate multicast stream for each VLAN, and without compromising the security and separation of traffic in the different VLANs. The VFP TCAM stores the MVR rules you configure for MVLANS. See [“Understanding Multicast VLAN Registration” on page 3974](#) for more information.

FIP snooping filters, FBF filters, and MVR rules share the VFP TCAM memory space. In most use cases, the VFP TCAM memory is sufficient to store filter terms and information for all three applications.

- [VFP TCAM Architecture and Allocation on page 4872](#)
- [VFP TCAM Entry Consumption on page 4873](#)
- [Rejected Filter Configurations \(No Available VFP TCAM Space\) on page 4876](#)
- [VFP TCAM Allocation and Consumption \(Scaling\) Examples on page 4877](#)
- [Filter Configuration Recommendations on page 4879](#)

VFP TCAM Architecture and Allocation

When packets arrive at an ingress interface, the VFP TCAM is the first TCAM in the packet pipeline. The VFP TCAM stores a total of 1024 entries. The 1024 entries are partitioned into four equal *slices* of 256 entries.

The VFP TCAM allocates entries to three filter types (FIP snooping filters, FBF filter terms, and MVR rules) in 256-entry slices. The VFP TCAM dynamically allocates the minimum number of memory slices required to store the filters for a particular filter type, as needed.

The TCAM does not allocate partial slices to a filter type, and slices cannot be shared among filter types. At any given time, each slice contains entries for one and only one filter type.

For example, if you configure one MVR rule, the system allocates a whole slice to MVR rules, even if the MVR rule consumes only one TCAM entry. The remaining 256 entries in the slice allocated to MVR rules can store subsequently configured MVR rules, but not FIP snooping or FBF filters. Similarly, if FIP snooping filters consume 50 entries of a 256-entry slice, the remaining 206 entries in the FIP snooping slice are available only to store more FIP snooping filters, not to store FBF filter terms or MVR rules.

The VFP TCAM allocates slices to a filter type only if there is at least one configured filter or rule for that filter type. If no filters exist for a filter type, then the VFP TCAM does not allocate a slice to that filter type.

NOTE: The VFP TCAM rejects partial filters. For example, if an FBF filter contains six terms, but there is only space in the TCAM for four of those terms, the whole filter is not committed.

Each filter type can use from zero slices to all four slices of VFP TCAM space. However, if one filter type uses three slices, then only one slice remains, so only one other filter type can use the remaining slice. In that situation, if you configure filters for all three filter types, the last filter type that you configure receives no TCAM space for its filter entries. Filters that receive no TCAM entry space are not implemented.

VFP TCAM Entry Consumption

FIP snooping filters, FBF filters, and MVR rules consume VFP TCAM entry space in different ways:

- [FIP Snooping Filter VFP TCAM Consumption on page 4873](#)
- [FBF Filter VFP TCAM Consumption on page 4874](#)
- [MVR Filter VFP TCAM Consumption on page 4875](#)
- [VFP TCAM Consumption Summary Table on page 4875](#)

FIP Snooping Filter VFP TCAM Consumption

VN2VF_Port FIP snooping filters consume VFP TCAM entry space differently than VN2VN_Port FIP snooping filters:

- [VN2VF_Port FIP Snooping Filter VFP TCAM Consumption on page 4874](#)
- [VN2VN_Port FIP Snooping Filter VFP TCAM Consumption on page 4874](#)

NOTE: One FCoE VLAN cannot support both VN2VF_Port traffic and VN2VN_Port traffic. Configure separate FCoE VLANs for VN2VF_Port traffic and for VN2VN_Port traffic.

VN2VF_Port FIP Snooping Filter VFP TCAM Consumption

The switch uses an algorithm that allows one 256-entry slice of the VFP TCAM to store the maximum possible number of VN2VF_Port FIP snooping filters (2500 filters). VN2VF_Port FIP snooping filters never consume more than one slice of the VFP TCAM.

Regardless of whether there is one VN2VF_Port FIP snooping session or there are 2500 VN2VF_Port FIP snooping sessions, VN2VF_Port FIP snooping filters consume one slice of the VFP TCAM. (If there are no VN2VF_Port or VN2VN_Port FIP snooping sessions, the TCAM does not allocate a slice for FIP snooping filters.)

VN2VN_Port FIP Snooping Filter VFP TCAM Consumption

VN2VN_Port FIP snooping filters consume one VFP TCAM entry for each VN2VN_Port session. The maximum number of VN2VN_Port FIP snooping sessions is 376 sessions per switch. (If you configure an interface that carries VN2VN_Port FIP snooping traffic as a trusted interface, the switch does not apply filters on the trusted interface.)

Because the switch can have up to 376 VN2VN_Port sessions running simultaneously, with each session consuming one entry, VN2VN_Port FIP snooping filters consume VFP TCAM space as follows:

- 1–256 filters consume one slice
- 257–376 filters consume two slices

FBF Filter VFP TCAM Consumption

Each FBF filter term is double-wide, so each FBF filter term consumes two entries in the VFP TCAM. One 256-entry slice can contain up to 128 FBF filter terms. FBF filters consume VFP TCAM space as follows:

- 1–128 entries consume one slice
- 129–256 entries consume two slices
- 257–384 entries consume three slices
- 385–512 entries consume four slices

NOTE: In practice, FBF filters can consume only three slices of the VFP TCAM because FBF filters are also stored simultaneously in the ingress filter processor (IFP) TCAM, and the IFP TCAM can store only 384 FBF filter terms (768 entries, or 3 TCAM slices).

For example, if you configure FBF filters that contain 200 terms, then the FBF filters require 400 VFP TCAM entries and consume 2 slices.

FBF filter entries are simultaneously stored in the VFP TCAM and the IFP TCAM. The IFP TCAM can only contain up to 768 entries—256 fewer entries (1 slice) than the VFP TCAM. As with the VFP TCAM, FBF filters consume two IFP TCAM entries per filter term. In addition to FBF filter terms, the IFP TCAM stores filter entries for firewall filters.

CAUTION: There must be enough space in the VFP TCAM *and* the IFP TCAM for the FBF filter entries. If both TCAMs do not have enough space for the FBF filters, the switch rejects the portion of the configuration that it cannot store and sends a syslog message to notify you.

For example, if you configure FBF filters that have 400 terms, even though the VFP TCAM has enough space to store the resulting 800 entries, the switch rejects a portion of the configuration because the IFP TCAM can store a maximum of only 768 entries. If the IFP TCAM stores no other filter entries, the switch rejects 32 FBF filter entries.

In another example, if you configure firewall filters that have a total of 200 terms, which consume 200 entries in the IFP TCAM, and you then configure FBF filters that have a total of 300 terms, the switch rejects a portion of the configuration because the FBF filters require 600 entries. Combined with the 200 entries required for the firewall filters, the total number of 800 entries exceeds the maximum of 768 entries that the IFP TCAM can store. In this case, the switch accepts the first 768 entries and rejects the rest of the filter entries. The switch installs the filter entries in the order that they are committed; the rejected entries are the last entries the switch attempts to commit after the TCAM space is exhausted.

The IFP TCAM limit of 768 entries means that the true maximum number of FBF filter terms is 384 terms, even though the VFP TCAM can store up to 512 FBF terms.

MVR Filter VFP TCAM Consumption

Each MVR rule consumes one entry in the VFP TCAM, so MVR rules consume VFP TCAM space as follows:

- 1–256 rules consume one slice
- 257–512 rules consume two slices
- 513–758 rules consume three slices
- 759–1024 rules consume four slices

VFP TCAM Consumption Summary Table

Table 372 on page 4876 summarizes VFP TCAM consumption.

NOTE: FBF filters are simultaneously stored in the VFP TCAM and in the IFP TCAM. Due to the IFP TCAM limit of 768 entries (384 FBF filters), which is 256 entries fewer than the VFP TCAM, the effective VFP TCAM consumption limit for FBF filters is lower than the total amount of VFP TCAM entry space, even when no other filters consume VFP TCAM space.

Table 372: VFP TCAM Entry Consumption Summary

| Filter Type | VFP TCAM Entry Consumption | Maximum VFP TCAM Slices Consumed | Other Limitations |
|---------------------------------|------------------------------------|--|--|
| VN2VF_Port FIP snooping filters | Never consumes more than one slice | One slice (regardless of number of sessions) | 2500 session maximum |
| VN2VN_Port FIP snooping filters | One entry per session | Two | 376 session maximum |
| FBF filters | Two entries per filter | Three (due to IFP TCAM limitation) | 384 filters (due to IFP TCAM limitation) |
| MVR rules | One entry per rule | Four | 1024 rule maximum |

Rejected Filter Configurations (No Available VFP TCAM Space)

If there is not enough space available in the VFP TCAM to store the FIP snooping filters, the configured FBF filters, and the MVR rules, the switch rejects only the portion of the configuration that it cannot store. Any portion of the filter configuration that the TCAM can store, is stored. In most cases, even if the switch rejects part of the configuration, part of the configuration is also stored.

If the switch rejects any portion of a configuration, the switch sends a syslog message to notify you of the failure. The switch does not generate a commit error, and the rejected portion of the configuration remains on the switch, even though the rejected configuration does not function. (The accepted portions of the configuration function as expected.) The syslog message shows you the filter configuration that the switch rejected.

We strongly recommend that you always delete rejected filter configurations from the switch. It is important to delete rejected filter configurations because:

- Even though the rejected configuration remains on the switch, it does not function.
- After a reboot, there is no guarantee that the same filters will be rejected. The previously rejected filters might be accepted, and other filters that had previously been accepted might be rejected. Therefore, the functioning filter configuration could be changed inadvertently and unexpectedly.
- Even if a VFP TCAM slice becomes available, the switch does not automatically allocate the available slice to the rejected configuration. To use the available slice, you must delete and reconfigure the rejected configuration.

For example, you configure FBF filters and MVR rules on a switch, and that switch also transports FCoE traffic with VN2VF_Port FIP snooping (never consumes more than one slice) enabled on FCoE access interfaces. After you commit the configuration, you check the syslog. You find that the VN2VF_Port FIP snooping and FBF filters consume all four slices of the VFP TCAM, and the MVR configuration was rejected. Instead of deleting the MVR configuration, you leave it on the switch. Subsequently, all VN2VF_Port FIP snooping sessions end, the FIP snooping filters time out and are removed from the VFP TCAM, so the slice that was allocated to VN2VF_Port FIP snooping filters becomes free. However, the MVR rules do *not* automatically receive the free slice.

To force the switch to allocate the free slice to the MVR rules, you should delete the MVR rules from the configuration and then reconfigure the MVR rules. When you commit the new configuration, check the syslog messages to ensure that the MVR rule configuration was accepted.

In this example, you could also choose to free a VFP TCAM slice for MVR rule storage by deleting some of the FBF filters. To do this, you delete both the unneeded FBF filters and the MVR rule configuration. Then you reconfigure the MVR rules, and check the syslog to ensure that the configuration was successful.

VFP TCAM Allocation and Consumption (Scaling) Examples

The following examples illustrate how FIP snooping entries, FBF filter entries, and MVR rule entries consume VFP TCAM slices:

- [Example 1: Three Filter Types Consume Three Slices on page 4877](#)
- [Example 2: Three Filter Types Consume Four Slices on page 4877](#)
- [Example 3: Two Filter Types Consume Four Slices on page 4878](#)
- [Example 4: Three Filter Types Oversubscribe the VFP TCAM on page 4878](#)

Example 1: Three Filter Types Consume Three Slices

Filters and rules are configured in the following sequence:

- 100 VN2VN_Port FIP snooping filters (1 slice)
- 2 MVR rules (1 slice, 2 entries)
- 60 FBF filter terms (1 slice, 120 entries)

One slice remains free. The slice allocated to VN2VN_Port FIP snooping filters can store 156 more filters before another slice is required. The slice allocated to MVR rules can store 254 more rules before another slice is required. The slice allocated to FBF filters can store 68 more filter terms (136 entries) before another slice is required. Providing that the IFP TCAM has space for the FBF filter terms, the switch accepts this configuration and rejects no filters.

Example 2: Three Filter Types Consume Four Slices

Filters and rules are configured in the following sequence:

- 2000 VN2VF_Port FIP snooping filters (always 1 slice)
- 18 MVR rules (1 slice, 18 entries)
- 150 FBF filter terms (2 slices, 300 entries)

All four slices are allocated to filter types. The slice allocated to MVR rules can store 238 more rules before it is full. The slice allocated to FBF filters can store 106 more filter terms (212 entries) before it is full. Providing that the IFP TCAM has space for the FBF filter terms, the switch accepts this configuration and rejects no filters.

NOTE: If you configure more MVR rules or FBF filters than entry space remaining in the slices, the switch rejects those rules and filters because no slice is available. The switch installs filters in the order that they were configured, so if filters are rejected, the filters configured last are rejected.

Example 3: Two Filter Types Consume Four Slices

Filters and rules are configured in the following sequence:

- 50 VN2VF_Port FIP snooping filters (always 1 slice)
- 300 FBF filter terms (3 slices, 600 entries)

All four slices are allocated to filter types. No slices are available for MVR rules. The third slice allocated to FBF filters can store 84 more filter terms (168 entries) before it consumes all of its entry space. Providing that the IFP TCAM has space for the FBF filter terms, the switch accepts this configuration and rejects no filters.

NOTE: If you configure MVR rules or if you configure more than 84 more FBF filters, the switch rejects those rules and filters because no slice is available for the MVR rules, and the FBF filter slice has entry space for only 84 more filter terms.

Example 4: Three Filter Types Oversubscribe the VFP TCAM

Filters and rules are configured in the following sequence:

- 1750 VN2VF_Port FIP snooping filters (always 1 slice)
- 10 MVR rules (1 slice, 10 entries)
- 275 FBF filter terms (2 slices, 512 accepted entries, 38 rejected entries)

All four slices are allocated to filter types. The slice allocated to MVR rules can store 246 more rules before it is full, but the number of FBF filter terms exceeds the amount of available VFP TCAM storage space. (The 275 FBF filter terms consume 550 VFP TCAM entries. However, there are only two available slices, for a total of 512 available entry spaces, so only 256 FBF filter terms can be stored, leaving 19 rejected FBF filter terms.)

The switch accepts the VN2VF_Port FIP snooping filters, the MVR rules, and 256 FBF filter terms. The switch retains the excess FBF filters in the configuration, but does not install those filters in the VFP TCAM. In this case, you delete the rejected FBF filter terms from the configuration. Alternatively, you could delete the MVR rules from the configuration to free a slice of the TCAM, and then delete and reconfigure the rejected FBF filters so that the system allocates the freed slice to the FBF filters.

NOTE: The sequence of configuration makes a difference; if there is not enough VFP TCAM space for a given filter type, the switch installs the filters that fit in the order they are configured. For example, if you configure the FBF filters before you configure the MVR rules, the VFP TCAM allocates one slice to FIP snooping filters, three slices to FBF filters (assuming the IFP TCAM has available space), and no slices to MVR rules, because all four slices are allocated before the switch attempts to install the MVR rules in the VFP TCAM.

Filter Configuration Recommendations

To utilize the VFP TCAM space most efficiently:

- [Configure and Maintain the Fewest Number of Filters Needed on page 4879](#)
- [Always Delete Rejected Filter Configurations on page 4880](#)

Configure and Maintain the Fewest Number of Filters Needed

To conserve VFP TCAM entry space, and because FBF filter storage also depends on the availability of IFP TCAM space, we recommend that you configure as few FBF filters and MVR rules as is practical to serve your network needs. The more filters you configure, the greater the possibility of exceeding TCAM storage capacity.

Several factors determine VFP TCAM consumption:

- **Type of filters configured**—Different filter types consume different amounts of VFP TCAM space. VN2VF_Port FIP snooping filters never consume more than one slice. MVR rules and VN2VN_Port FIP snooping filters consume entries in a slice at a rate of one entry per MVR rule or VN2VN_Port session. FBF filter terms consume entries in a slice at a rate of two entries per FBF filter term.
- **Number of filters configured**—Although the number of filters does not affect the number of slices allocated to the VN2VF_Port FIP snooping filter type (it is always one slice for one or more VN2VF_Port FIP snooping filters and no slice for no FIP snooping filters), the number of VN2VN_Port FIP snooping filters, MVR rules, and FBF filter terms that you configure determine how many VFP TCAM slices are required for each filter type.

For example, if you configure 257 MVR rules, the MVR rule entries consume 2 slices. One slice stores 256 MVR rules (entries), and one slice stores 1 MVR rule (entry). In this case, if you can eliminate one MVR rule, you can free a slice to allocate to other filter types.

- **Sequence of filter configuration**—If you configure too many filters for the VFP TCAM to store, the last filters you configure are not stored in the TCAM.

Always check the syslog after you configure FBF filters or MVR rules to ensure that the configuration was not rejected. If you enable FIP snooping on access ports, check the syslog to ensure that the configuration was not rejected due to lack of VFP TCAM space.

If you check the syslog and a filter configuration has been rejected, delete the filters that were rejected from the configuration.

TIP: If you no longer need an FBF filter or an MVR rule, delete it from the configuration to conserve VFP TCAM space. Enable VN2VF_Port or VN2VN_Port FIP snooping on access ports only if the switch port is directly connected to FCoE devices. (FIP snooping should be performed at the access edge. FIP snooping should not be performed on traffic that has already been snooped and filtered at the access edge. If another switch between the QFX Series or QFabric system and the FCoE devices already performs FIP snooping, do not enable FIP snooping on the QFX Series or QFabric system.)

Always Delete Rejected Filter Configurations

The switch does not return a commit error if it rejects any portion of a configuration. Instead, the switch sends a syslog message to report the rejected portion of the configuration. The rejected portion of the configuration remains on the switch, but does not function.

After you configure FBF filters or MVR rules, or enable FIP snooping, check the syslog messages to ensure that the switch accepted the configuration. If the switch rejected any portion of the configuration, delete that portion of the configuration. (You do not need to delete the portion of the configuration that was accepted, unless you want to reconfigure those filters or rules.)

CAUTION: If you do not delete rejected filter configurations, and if you reboot the system, you cannot predict which filters the system installs after the reboot. For example, a switch with the following configuration has more configured filters than the VFP TCAM can support:

- VN2VF_Port FIP snooping sessions (always consumes one slice)
- 20 MVR rules (consume one slice)
- 300 FBF filters (attempt to consume three slices, but because only two slices are available, 256 filters consume two slices, and the remaining 44 filters are rejected)

If you do not delete the 44 rejected FBF filters, then if the switch reboots, the 44 FBF filters that were rejected might be accepted, and 44 different FBF filters might be rejected. This unpredictable behavior is the reason that you should check the syslog messages after you configure filters, and if any filters were rejected, you should always delete the rejected filters from the configuration.

Understanding MC-LAGs on an FCoE Transit Switch

Multichassis link aggregation groups (MC-LAGs) provide redundancy and load balancing between two QFX Series switches, multihoming support for client devices such as servers, and a loop-free Layer 2 network without running Spanning Tree Protocol (STP).

You can use an MC-LAG to provide a redundant aggregation layer for Fibre Channel over Ethernet (FCoE) traffic. To support lossless transport of FCoE traffic across an MC-LAG, you must configure the appropriate class of service (CoS) on both of the QFX Series switches with MC-LAG port members. The CoS configuration must be the same on both of the MC-LAG switches because MC-LAGs do not carry forwarding class and IEEE 802.1p priority information.

Ports that are part of an FCoE-FC gateway configuration (a virtual FCoE-FC gateway fabric) do not support MC-LAGs. Ports that are members of an MC-LAG act as passthrough transit switch ports.

QFX Series switches support MC-LAGs. QFabric system Node devices do not support MC-LAGs, and QFX3500 and QFX3600 Virtual Chassis switches do not support FCoE.

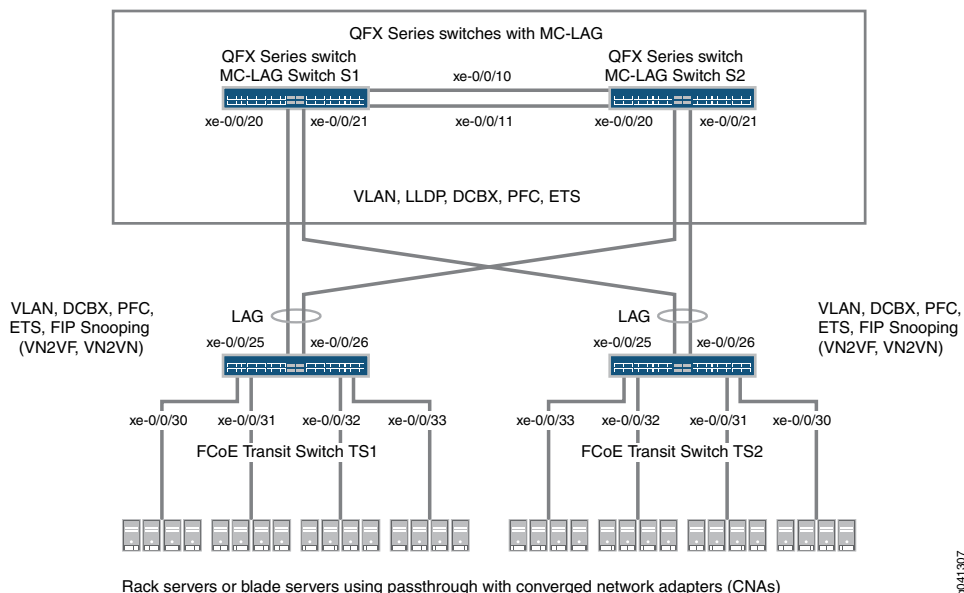

This topic describes:

- [Supported Topology on page 4881](#)
- [FIP Snooping and FCoE Trusted Ports on page 4883](#)
- [CoS and Data Center Bridging \(DCB\) on page 4884](#)

Supported Topology

QFX Series switches that are not directly connected to FCoE hosts and that act as passthrough transit switches support MC-LAGs for FCoE traffic in an *inverted-U* network topology. [Figure 178 on page 4882](#) shows an inverted-U topology using QFX3500 switches.

Figure 178: Supported Topology for an MC-LAG on an FCoE Transit Switch

The following rules and guidelines apply to MC-LAGs when used for FCoE traffic. The rules and guidelines help ensure the proper handling and lossless transport characteristics required for FCoE traffic:

- The two QFX Series switches that form the MC-LAG (Switches S1 and S2) cannot use ports that are part of an FCoE-FC gateway fabric. The MC-LAG switch ports must be passthrough transit switch ports (used as part of an intermediate transit switch that is not directly connected to FCoE hosts).
- MC-LAG Switches S1 and S2 cannot be not directly connected to the FCoE hosts.
- The two QFX Series switches that serve as access devices for FCoE hosts (FCoE Transit Switches TS1 and TS2) use standard LAGs to connect to MC-LAG Switches S1 and S2. FCoE Transit Switches TS1 and TS2 can be standalone QFX Series switches or they can be Node devices in a QFabric system.
- Transit Switches TS1 and TS2 must use transit switch ports for the FCoE hosts and for the standard LAGs to MC-LAG Switches S1 and S2.
- Enable FIP snooping on the FCoE VLAN on Transit Switches TS1 and TS2. You can configure either VN_Port to VF_Port (VN2VF_Port) FIP snooping or VN_Port to VN_Port (VN2VN_Port) FIP snooping, depending on whether the FCoE hosts need to access targets in the FC SAN (VN2VF_Port FIP snooping) or targets in the Ethernet network (VN2VN_Port FIP snooping).

FIP snooping should be performed at the access edge and is not supported on MC-LAG switches. Do not enable FIP snooping on MC-LAG Switches S1 and S2. (Do not enable FIP snooping on the MC-LAG ports that connect Switches S1 and S2 to Switches TS1 and TS2 or on the LAG ports that connect Switch S1 to S2.)

- The CoS configuration must be consistent on the MC-LAG switches. Because MC-LAGs carry no forwarding class or priority information, each MC-LAG switch needs to have

the same CoS configuration to support lossless transport. (On each MC-LAG switch, the name, egress queue, and CoS provisioning of each forwarding class must be the same, and the priority-based flow control (PFC) configuration must be the same.)

Transit Switches (Server Access)

The role of FCoE Transit Switches TS1 and TS2 is to connect FCoE hosts in a multihomed fashion to the MC-LAG switches. In essence, Transit Switches TS1 and TS2 act as access switches for the FCoE hosts. (FCoE hosts are directly connected to Transit Switches TS1 and TS2.)

The transit switch configuration depends on whether you want to do VN2VF_Port FIP snooping or VN2VN_Port FIP snooping, and whether the QFX Series transit switches also have ports configured as part of an FCoE-FC gateway virtual fabric. Ports that the QFX Series switch uses in an FCoE-FC gateway virtual fabric cannot be included in the transit switch LAG connection to the MC-LAG switches. (Ports cannot belong to both a transit switch and an FCoE-FC gateway; you must use different ports for each mode of operation.)

MC-LAG Switches (FCoE Aggregation)

The role of MC-LAG Switches S1 and S2 is to provide redundant, load-balanced connections between FCoE transit switches. In essence, MC-LAG Switches S1 and S2 act as aggregation switches. FCoE hosts are not directly connected to the MC-LAG switches.

The MC-LAG switch configuration is the same regardless of which type of FIP snooping that FCoE Transit Switches TS1 and TS2 perform.

FIP Snooping and FCoE Trusted Ports

To maintain secure access, enable VN2VF_Port FIP snooping or VN2VN_Port FIP snooping at the transit switch access ports connected directly to the FCoE hosts. FIP snooping should be performed at the access edge of the network to prevent unauthorized access. For example, in [Figure 178 on page 4882](#), you enable FIP snooping on the FCoE VLANs on Transit Switches TS1 and TS2 that include the access ports connected to the FCoE hosts.

Do not enable FIP snooping on the switches used to create the MC-LAG. For example, in [Figure 178 on page 4882](#), you would not enable FIP snooping on the FCoE VLANs on Switches S1 and S2.

Configure links between switches as FCoE trusted ports to reduce FIP snooping overhead and ensure that the system performs FIP snooping only at the access edge. In the sample topology, configure the Transit Switch TS1 and TS2 LAG ports connected to the MC-LAG switches as FCoE trusted ports, configure the Switch S1 and S2 MC-LAG ports connected to Switches TS1 and TS2 as FCoE trusted ports, and configure the ports in the LAG that connects Switches S1 to S2 as FCoE trusted ports.

CoS and Data Center Bridging (DCB)

The MC-LAG links do not carry forwarding class or priority information. The following CoS properties must have the same configuration on each MC-LAG switch or on each MC-LAG interface to support lossless transport:

- FCoE forwarding class name—For example, the forwarding class for FCoE traffic could use the default **fcoe** forwarding class on both MC-LAG switches.
- FCoE output queue—For example, the **fcoe** forwarding class could be mapped to queue 3 on both MC-LAG switches (queue 3 is the default mapping for the **fcoe** forwarding class).
- Classifier—The forwarding class for FCoE traffic must be mapped to the same IEEE 802.1p code point on each member interface of the MC-LAG on both MC-LAG switches. For example, the FCoE forwarding class **fcoe** could be mapped to IEEE 802.1p code point **011** (code point **011** is the default mapping for the **fcoe** forwarding class).
- Priority-based flow control (PFC)—PFC must be enabled on the FCoE code point on each MC-LAG switch and applied to each MC-LAG interface using a congestion notification profile.

You must also configure enhanced transmission selection (ETS) on the MC-LAG interfaces to provide sufficient scheduling resources (bandwidth, priority) for lossless transport. The ETS configuration can be different on each MC-LAG switch, as long as enough resources are scheduled to support lossless transport for the expected FCoE traffic.

LLDP and DCBX must be enabled on each MC-LAG member interface (LLDP and DCBX are enabled by default on all interfaces).

NOTE: As with all other FCoE configurations, FCoE traffic requires a dedicated VLAN that carries only FCoE traffic, and IGMP snooping must be disabled on the FCoE VLAN.

Understanding CoS Flow Control (Ethernet PAUSE and PFC)

Flow control supports lossless transmission by regulating traffic flows to avoid dropping frames during periods of congestion. Flow control stops and resumes the transmission of network traffic between two connected peer nodes on a full-duplex Ethernet physical link. Controlling the flow by pausing and restarting it prevents buffers on the nodes from overflowing and dropping frames. You configure flow control on a per-interface basis.

The QFX Series supports two methods of flow control:

- IEEE 802.3X Ethernet PAUSE
- IEEE 802.1Qbb priority-based flow control (PFC)

Ethernet PAUSE and PFC are link-level flow control mechanisms.

Ethernet PAUSE pauses transmission of all traffic on a physical Ethernet link.

PFC decouples the pause function from the physical Ethernet link and enables you to divide traffic on one link into eight priorities. You can think of the eight priorities as eight “lanes” of traffic that are mapped to forwarding classes and output queues. Each priority is mapped to a 3-bit IEEE 802.1p CoS code point flag in the VLAN header. You can enable PFC on one or more priorities (IEEE 802.1p code points) on a link. When PFC-enabled traffic is paused on a link, traffic that is not PFC-enabled continues to flow (or is dropped if congestion is severe enough).

Use Ethernet PAUSE when you want to prevent packet loss on all of the traffic on a link. Use PFC to prevent traffic loss only on specified types of traffic (for example, Fibre Channel over Ethernet traffic).

NOTE: Depending on the amount of traffic on a link or assigned to a priority, pausing traffic can cause ingress port congestion and spread congestion through the network.

Attempting to configure both Ethernet PAUSE and PFC on a link causes a commit error. Ethernet PAUSE and PFC are mutually exclusive configurations on an interface.

By default, all forms of flow control are disabled. You must explicitly enable flow control on interfaces to pause traffic.

- [Ethernet PAUSE on page 4885](#)
- [PFC on page 4889](#)
- [Lossless Transport Support Summary on page 4893](#)

Ethernet PAUSE

Ethernet PAUSE is a congestion relief feature that works by providing link-level flow control for all traffic on a full-duplex Ethernet link. Ethernet PAUSE works in both directions on the link. In one direction, an interface generates and sends Ethernet PAUSE messages to stop the connected peer from sending more traffic. In the other direction, the interface

responds to Ethernet PAUSE messages it receives from the connected peer to stop sending traffic. Ethernet PAUSE also works on aggregated Ethernet interfaces. For example, if the connected peer interfaces are called Node A and Node B:

- When the receive buffers on interface Node A reach a certain level of fullness, the interface generates and sends an Ethernet PAUSE message to the connected peer (interface Node B) to tell the peer to stop sending frames. The Node B buffers store frames until the time period specified in the Ethernet PAUSE frame elapses; then Node B resumes sending frames to Node A.
- When interface Node A receives an Ethernet PAUSE message from interface Node B, interface Node A stops transmitting frames until the time period specified in the Ethernet PAUSE frame elapses; then Node A resumes transmission. (The Node A transmit buffers store frames until Node A resumes sending frames to Node B.)

In this scenario, if Node B sends an Ethernet PAUSE frame with a time value of 0 to Node A, the 0 time value indicates to Node A that it can resume transmission. This happens when the Node B buffer empties to below a certain threshold and the buffer can once again accept traffic.

Symmetric flow control means an interface has the same Ethernet PAUSE configuration in both directions. The Ethernet PAUSE generation and Ethernet PAUSE response functions are both configured as enabled, or they are both disabled. You configure symmetric flow control by including the **flow-control** statement at the **[edit interfaces interface-name ether-options]** hierarchy level.

Asymmetric flow control allows you to configure the Ethernet PAUSE functionality in each direction independently on an interface. The configuration for generating Ethernet PAUSE messages and for responding to Ethernet PAUSE messages does not have to be the same. It can be enabled in both directions, disabled in both directions, or enabled in one direction and disabled in the other direction. You configure asymmetric flow control by including the **configured-flow-control** statement at the **[edit interfaces interface-name ether-options]** hierarchy level.

On any particular interface, symmetric and asymmetric flow control are mutually exclusive. Asymmetric flow control overrides and disables symmetric flow control. (If PFC is configured on an interface, the PFC configuration overrides Ethernet PAUSE flow control.) The QFX Series supports both symmetric and asymmetric flow control.

- [Symmetric Flow Control on page 4886](#)
- [Asymmetric Flow Control on page 4887](#)

Symmetric Flow Control

Symmetric flow control configures both the receive and transmit buffers in the same state. The interface can both send Ethernet PAUSE messages and respond to them (flow control is enabled), or the interface cannot send Ethernet PAUSE messages or respond to them (flow control is disabled).

When you enable symmetric flow control on an interface, the Ethernet PAUSE behavior depends on the configuration of the connected peer. With symmetric flow control enabled, the interface can perform any Ethernet PAUSE functions that the connected peer can

perform. (When symmetric flow control is disabled, the interface does not send or respond to Ethernet PAUSE messages.)

Asymmetric Flow Control

Asymmetric flow control enables you to specify independently whether or not the interface receive buffer generates and sends Ethernet PAUSE messages to stop the connected peer from transmitting traffic, and whether or not the interface transmit buffer responds to Ethernet PAUSE messages it receives from the connected peer and stops transmitting traffic. The receive buffer configuration determines if the interface transmits Ethernet PAUSE messages, and the transmit buffer configuration determines if the interface receives and responds to Ethernet PAUSE messages:

- Receive buffers on—Enable Ethernet PAUSE transmission (generate and send Ethernet PAUSE frames)
- Transmit buffers on—Enable Ethernet PAUSE reception (respond to received Ethernet PAUSE frames)

You must explicitly set the flow control for both the receive buffer and the transmit buffer (**on** or **off**) to configure asymmetric Ethernet PAUSE. [Table 373 on page 4887](#) describes the configured flow control state when you set the receive (Rx) and transmit (Tx) buffers on an interface:

Table 373: Asymmetric Ethernet PAUSE Flow Control Configuration

| Receive (Rx) Buffer | Transmit (Tx) Buffer | Configured Flow Control State |
|---------------------|----------------------|---|
| On | Off | Interface generates and sends Ethernet PAUSE messages. Interface does not respond to Ethernet PAUSE messages (interface continues to transmit even if peer requests that the interface stop sending traffic). |
| Off | On | Interface responds to Ethernet PAUSE messages received from the connected peer, but does not generate or send Ethernet PAUSE messages. (The interface does not request that the connected peer stop sending traffic.) |
| On | On | Same functionality as symmetric Ethernet PAUSE. Interface generates and sends Ethernet PAUSE messages and responds to received Ethernet PAUSE messages. |
| Off | Off | Ethernet PAUSE flow control is disabled. |

The configured flow control is the Ethernet PAUSE state configured on the interface.

On 1-Gigabit Ethernet interfaces, the QFX Series supports autonegotiation of Ethernet PAUSE with the connected peer. (The QFX Series does not support autonegotiation on 10-Gigabit Ethernet interfaces.) Autonegotiation enables the interface to exchange state advertisements with the connected peer so that the two devices can agree on the Ethernet PAUSE configuration. Each interface advertises its flow control state to the connected peer using a combination of the Ethernet PAUSE and ASM_DIR bits, as described in [Table 374 on page 4888](#):

Table 374: Flow Control State Advertised to the Connected Peer (Autonegotiation)

| Rx Buffer State | Tx Buffer State | PAUSE Bit | ASM_DIR Bit | Description |
|-----------------|-----------------|-----------|-------------|--|
| Off | Off | 0 | 0 | The interface advertises no Ethernet PAUSE capability. This is equivalent to disabling flow control on an interface. |
| On | On | 1 | 0 | The interface advertises symmetric flow control (both the transmission of Ethernet PAUSE messages and the ability to receive and respond to Ethernet PAUSE messages). |
| On | Off | 0 | 1 | The interface advertises asymmetric flow control (the transmission of Ethernet PAUSE messages, but not the ability to receive and respond to Ethernet PAUSE messages). |
| Off | On | 1 | 1 | The interface advertises both symmetric and asymmetric flow control. Although the interface does not generate and send Ethernet PAUSE requests to the peer, the interface supports both symmetric and asymmetric Ethernet PAUSE configuration on the peer because the peer is not affected if the peer does not receive Ethernet PAUSE requests. (If the interface responds to the peer's Ethernet PAUSE requests, that is sufficient to support either symmetric or asymmetric flow control on the peer.) |

The flow control configuration on each switch interface interacts with the flow control configuration of the connected peer. Each peer advertises its state to the other peer. The interaction of the flow control configuration of the peers determines the flow control behavior (resolution) between them, as shown in [Table 375 on page 4889](#). The first four columns show the Ethernet PAUSE configuration on the local QFX Series and on the connected peer (also known as the link partner). The last two columns show the Ethernet PAUSE resolution that results from the local and peer configurations on each interface. This illustrates how the Ethernet PAUSE configuration of each interface affects the Ethernet PAUSE behavior on the other interface.

NOTE: In the Resolution columns of the table, disabling Ethernet PAUSE transmit means that the interface receive buffers do not generate and send Ethernet PAUSE messages to the peer. Disabling Ethernet PAUSE receive means that the interface transmit buffers do not respond to Ethernet PAUSE messages received from the peer.

Table 375: Asymmetric Ethernet PAUSE Behavior on Local and Peer Interfaces

| Local Interface (QFX Series) | | Peer Interface | | Local Resolution | Peer Resolution |
|------------------------------|-------------|----------------|-------------|---|---|
| PAUSE Bit | ASM_DIR Bit | PAUSE Bit | ASM_DIR Bit | | |
| 0 | 0 | Don't care | Don't care | Disable Ethernet PAUSE transmit and receive | Disable Ethernet PAUSE transmit and receive |
| 0 | 1 | 0 | Don't care | Disable Ethernet PAUSE transmit and receive | Disable Ethernet PAUSE transmit and receive |
| 0 | 1 | 1 | 0 | Disable Ethernet PAUSE transmit and receive | Disable Ethernet PAUSE transmit and receive |
| 0 | 1 | 1 | 1 | Enable Ethernet PAUSE transmit and disable Ethernet PAUSE receive | Disable Ethernet PAUSE transmit and enable Ethernet PAUSE receive |
| 1 | 0 | 0 | Don't care | Disable Ethernet PAUSE transmit and receive | Disable Ethernet PAUSE transmit and receive |
| 1 | 0 | 1 | Don't care | Enable Ethernet PAUSE transmit and receive | Enable Ethernet PAUSE transmit and receive |
| 1 | 1 | 0 | 0 | Disable Ethernet PAUSE transmit and receive | Disable Ethernet PAUSE transmit and receive |
| 1 | 1 | 0 | 1 | Enable Ethernet PAUSE receive and disable Ethernet PAUSE transmit | Enable Ethernet PAUSE transmit and disable Ethernet PAUSE receive |
| 1 | 1 | Don't care | Don't care | Enable Ethernet PAUSE transmit and receive | Enable Ethernet PAUSE transmit and receive |

NOTE: For your convenience, [Table 375 on page 4889](#) replicates Table 28B-3 of Section 2 of the IEEE 802.X specification.

PFC

PFC is a lossless transport and congestion relief feature that works by providing granular link-level flow control for each IEEE 802.1p code point (priority) on a full-duplex Ethernet link. When the receive buffer on a switch interface fills to a threshold, the switch transmits

a pause frame to the sender (the connected peer) to temporarily stop the sender from transmitting more frames. The buffer threshold must be low enough so that the sender has time to stop transmitting frames and the receiver can accept the frames already on the wire before the buffer overflows. The switch automatically sets queue buffer thresholds to prevent frame loss.

When congestion forces one priority on a link to pause, all of the other priorities on the link continue to send frames. Only frames of the paused priority are not transmitted. When the receive buffer empties below another threshold, the switch sends a message that starts the flow again.

You configure PFC using a congestion notification profile (CNP). A CNP has two parts:

- Input—Specify the code point (or code points) on which to enable PFC, and optionally specify the maximum receive unit (MRU) and the cable length between the interface and the connected peer interface.
- Output—Specify the output queue or output queues that respond to pause messages from the connected peer.

You apply a PFC configuration by configuring a CNP on one or more interfaces. Each interface that uses a particular CNP is enabled to pause traffic with the priorities (code points) specified in that CNP. You can configure one CNP on an interface, and you can configure different CNPs on different interfaces. When you configure a CNP on an interface, ingress traffic that is mapped to a priority that the CNP enables for PFC is paused whenever the queue buffer fills to the pause threshold. (The pause threshold is not user-configurable.)

Configure PFC for a priority end to end along the entire data path to create a lossless lane of traffic on the network. You can selectively pause the traffic in any queue without pausing the traffic for other queues on the same link. You can create lossless lanes for traffic such as Fibre Channel over Ethernet (FCoE), LAN backup, or management, while using standard frame-drop congestion management for IP traffic on the same link.

Potential consequences of link-level flow control are:

- Ingress port congestion (configuring too many lossless flows can cause ingress port congestion)
- A paused priority that causes upstream devices to pause the same priority, thus spreading congestion back through the network

By definition, PFC supports symmetric pause only (as opposed to Ethernet PAUSE, which supports symmetric and asymmetric pause). With symmetric pause, a device can:

- Transmit pause frames to pause incoming traffic. (You configure this using the input stanza of a congestion notification profile.)
- Receive pause frames and stop sending traffic to a device whose buffer is too full to accept more frames. (You configure this using the output stanza of a congestion notification profile.)

Receiving a PFC frame from a connected peer pauses traffic on egress queues based on the IEEE 802.1p priorities that the PFC pause frame identifies. The priorities are 0 through 7. By default, the priorities map to queue numbers 0 through 7, respectively, and to specific forwarding classes, as shown in [Table 376 on page 4891](#):

Table 376: Default PFC Priority to Queue and Forwarding Class Mapping

| IEEE 802.1p Priority (Code Point) | Queue | Forwarding Class |
|-----------------------------------|-------|------------------|
| 0 (000) | 0 | best-effort |
| 1 (001) | 1 | best-effort |
| 2 (010) | 2 | best-effort |
| 3 (011) | 3 | fcoe |
| 4 (100) | 4 | no-loss |
| 5 (101) | 5 | best-effort |
| 6 (110) | 6 | network-control |
| 7 (111) | 7 | network-control |

For example, a received PFC pause frame that pauses priority 3 pauses output queue 3. If you do not want to use the default configuration, you can configure customized mapping of priorities to queues and forwarding classes.

NOTE: By convention, deployments with converged server access typically use IEEE 802.1p priority 3 for FCoE traffic. The default forwarding class configuration sets the fcoe forwarding class as a lossless forwarding class that is mapped to queue 3. The default classifier maps incoming priority 3 traffic to the fcoe forwarding class. *However, you must apply PFC to the entire FCoE data path to configure the end-to-end lossless behavior that FCoE traffic requires.*

If your network uses priority 3 for FCoE traffic, we recommend that you use the default configuration. If your network uses a priority other than 3 for FCoE traffic, you can configure lossless FCoE transport on any IEEE 802.1p priority as described in [“Understanding CoS IEEE 802.1p Priorities for Lossless Traffic Flows” on page 5427](#) and [“Understanding CoS IEEE 802.1p Priority Remapping on an FCoE-FC Gateway” on page 5446](#).

You enable PFC on a priority by:

1. Specifying the IEEE 802.1p code point to pause in the input stanza of a CNP
2. Applying the CNP to the ingress interfaces on which you want to pause the traffic

CAUTION: Any change to the PFC configuration on a port temporarily blocks the entire port (not just the priorities affected by the PFC change) so that the port can implement the change, then unblocks the port. Blocking the port stops ingress and egress traffic, and causes packet loss on all queues on the port until the port is unblocked.

A change to the PFC configuration means any change to a CNP, including changing the input portion of the CNP (enabling or disabling PFC on a priority, or changing the MRU or cable-length values) or changing the output portion the CNP that enables or disables output flow control on a queue. A PFC configuration change only affects ports that use the changed CNP.

The following actions change the PFC configuration:

- Deleting or disabling a PFC configuration (input or output) in a CNP that is in use on one or more interfaces. For example:
 1. An existing CNP with an input stanza that enables PFC on priorities 3, 5, and 6 is configured on interfaces xe-0/0/20 and xe-0/0/21.
 2. We disable the PFC configuration for priority 6 in the input CNP, and then commit the configuration.
 3. The PFC configuration change causes all traffic on interfaces xe-0/0/20 and xe-0/0/21 to stop until the PFC change has been implemented. When the PFC change has been implemented, traffic resumes.
- Configuring a CNP on an interface. (This changes the PFC state by enabling PFC on one or more priorities.)
- Deleting a CNP from an interface. (This changes the PFC state by disabling PFC on one or more priorities.)

When you associate the CNP with an interface, the interface uses PFC to send pause requests when the output queue buffer for the lossless traffic fills to the pause threshold.

Although unicast traffic and multideestination (multicast, broadcast, and destination lookup fail) traffic must use different classifiers, you can map a unicast queue (queue 0 through 7) and a multideestination queue (queue 8, 9, 10, or 11) to the same PFC priority so that both unicast and multicast traffic use that priority. Do not map multideestination traffic to lossless priorities. Starting with Junos OS Release 12.3, you can map one priority to multiple output queues.

NOTE: You can attach a maximum of one CNP to an interface, but you can create an unlimited number of CNPs that explicitly configure only the input stanza and use the default output stanza.

The output stanza of the CNP maps to a profile that interfaces use to respond to pause messages received from the connected peer. On standalone QFX3500 switches and QFX3600 switches, you can create two CNPs with an explicitly configured output stanza.

When a QFX3500 switch or a QFX3600 switch is a Node device in a QFabric system, you can create one CNP with an explicitly configured output stanza. (One fewer profile is available on QFabric systems because the system needs a default profile for fabric interfaces, which are not used as fabric interfaces when the switches are not part of a QFabric system. “[Understanding CoS IEEE 802.1p Priorities for Lossless Traffic Flows](#)” on page 5427 describes configuring output flow control.

Lossless Transport Support Summary

The QFX Series supports up to six lossless forwarding classes. For lossless transport, you must enable PFC on the IEEE 802.1p priorities (code points) mapped to lossless forwarding classes.

CAUTION: Any change to the PFC configuration on a port temporarily blocks the entire port (not just the priorities affected by the PFC change) so that the port can implement the change, then unblocks the port. Blocking the port stops ingress and egress traffic, and causes packet loss on all queues on the port until the port is unblocked.

The following limitation applies to support lossless transport on QFabric systems only:

- The internal fiber cable length from the QFabric system Node device to the QFabric system Interconnect device cannot exceed 150 meters.

The default CoS configuration provides two lossless forwarding classes, *fcoe* and *no-loss*. If you explicitly configure lossless forwarding classes, you must include the **no-loss** packet drop attribute to enable lossless behavior, or the traffic is not lossless. For both default and explicit lossless forwarding class configuration, you must configure CNP input stanzas to enable PFC on the priority of the lossless traffic and apply the CNPs to ingress interfaces.

NOTE: Junos OS Release 12.2 introduced changes to the way the QFX Series handles lossless forwarding classes (including the default fcoe and no-loss forwarding classes).

In Junos OS Release 12.1, either explicitly configuring the fcoe and no-loss forwarding classes or using the default configuration for these forwarding classes resulted in the same lossless behavior for traffic mapped to those forwarding classes.

However, in Junos OS Release 12.2, if you explicitly configure the fcoe or the no-loss forwarding class, that forwarding class is no longer treated as a lossless forwarding class. Traffic mapped to these forwarding classes is treated as lossy (best-effort) traffic. This is true even if the explicit configuration is exactly the same as the default configuration.

If your CoS configuration from Junos OS Release 12.1 or earlier includes the explicit configuration of the fcoe or the no-loss forwarding class, then when you upgrade to Junos OS Release 12.2, those forwarding classes are not lossless. To preserve the lossless treatment of these forwarding classes, delete the the explicit fcoe and no-loss forwarding class configuration before you upgrade to Junos OS Release 12.2.

See [“Overview of CoS Changes Introduced in Junos OS Release 12.2” on page 5304](#) for detailed information about this change and how to delete an existing lossless configuration.

In Junos OS Release 12.3, the default behavior of the fcoe and no-loss forwarding classes is the same as in Junos OS Release 12.2. However, in Junos OS Release 12.3, you can configure up to six lossless forwarding classes. All explicitly configured lossless forwarding classes must include the new no-loss packet drop attribute or the forwarding class is lossy.

[“Understanding CoS IEEE 802.1p Priorities for Lossless Traffic Flows” on page 5427](#) provides detailed information about the explicit configuration of lossless priorities and about the default configuration of lossless priorities, including the input and output stanzas of the CNP.

NOTE: PFC and Ethernet PAUSE are used only on Ethernet interfaces. Fabric (fte) ports on QFabric systems (Node device fabric ports and Interconnect device fabric ports) use link-layer flow control (LLFC) to ensure the appropriate treatment of lossless traffic.

Understanding Fibre Channel Terminology

To understand the Fibre Channel (FC) and Fibre Channel over Ethernet (FCoE) capabilities of the QFX Series, you should become familiar with the terms defined in [Table 377 on page 4895](#).

Table 377: Fibre Channel Terms

| Term | Definition |
|---------------------------------|--|
| addressing mode | <p>Format for the locally unique MAC address the FC switch assigns to FCoE devices for FCoE transactions after FIP establishes a connection between an FCoE device and the FC switch. The two addressing modes are <i>fabric-provided MAC address (FPMA)</i> and <i>server-provided MAC address (SPMA)</i>. The QFX Series supports only FPMA.</p> <p>During FLOGI or FDISC, the ENode advertises the addressing modes it supports. If the FC switch supports an addressing mode that the ENode uses, the virtual link can be established, and the devices can communicate.</p> <p>See also <i>fabric-provided MAC address (FPMA)</i> and <i>server-provided MAC address (SPMA)</i>.</p> |
| ALL-ENode-MACs | <p>Well-known multicast MAC address to which all FCoE ENodes listen. FCFs send multicast <i>FIP discovery advertisement</i> messages and <i>FIP keepalive</i> messages to the ALL-ENode-MACs address so that ENodes can discover and maintain connections to FCFs. The hexadecimal format of the address is 01:10:18:01:00:01.</p> <p>See also <i>well-known address (WKA)</i>.</p> |
| ALL-FCF-MACs | <p>Well-known multicast MAC address to which all FCFs listen. ENodes send multicast <i>FIP discovery solicitation</i> messages to the ALL-FCF-MACs address to find out which FCFs can accept a login. The hexadecimal format of the address is 01:10:18:01:00:02.</p> <p>See also <i>well-known address (WKA)</i>.</p> |
| congestion notification | See <i>quantized congestion notification (QCN)</i> . |
| converged network adapter (CNA) | <p>Physical adapter that combines the functions of a Fibre Channel <i>host bus adapter (HBA)</i> to process FCoE frames and a <i>lossless Ethernet network interface card (NIC)</i> to process non-FCoE Ethernet frames. CNAs have one or more Ethernet ports. CNAs encapsulate Fibre Channel frames in Ethernet for FCoE transport and de-encapsulate Fibre Channel frames from FCoE to native Fibre Channel.</p> <p>See also <i>host bus adapter (HBA)</i>.</p> |

Table 377: Fibre Channel Terms (*continued*)

| Term | Definition |
|--|--|
| data center bridging (DCB) | <p>Set of IEEE specifications that enhance Ethernet to allow it to support converged Ethernet (LAN) and Fibre Channel (SAN) traffic on one Ethernet network. DCB features include <i>priority-based flow control (PFC)</i>, <i>enhanced transmission selection (ETS)</i>, <i>Data Center Bridging Capability Exchange protocol (DCBX)</i>, <i>quantized congestion notification (QCN)</i>, and full-duplex 10-Gigabit Ethernet ports.</p> <p>See also <i>priority-based flow control (PFC)</i>, <i>Ethernet PAUSE</i>, <i>enhanced transmission selection (ETS)</i>, <i>Data Center Bridging Capability Exchange protocol (DCBX)</i>, and <i>quantized congestion notification (QCN)</i>.</p> |
| expansion port (E_Port) | An expansion port in an FC switch/FCF that connects the FC switch/FCF to the E_Port of another FC switch/FCF to form an <i>Interswitch Link (ISL)</i> in a common FC fabric. |
| Data Center Bridging Capability Exchange protocol (DCBX) | <p>Discovery and exchange protocol for conveying configuration and capabilities among neighbors to ensure consistent configuration across the network. It is an extension of the Link Layer Data Protocol (LLDP, described in IEEE 802.1AB)</p> <p>See also <i>data center bridging (DCB)</i>.</p> |
| enhanced transmission selection (ETS) | <p>Mechanism that provides finer granularity of bandwidth management within a link.</p> <p>See also <i>data center bridging (DCB)</i>.</p> |
| ENode | See <i>FCoE Node (ENode)</i> |
| ENode MAC | <p><i>Lossless Ethernet MAC</i> paired with an <i>FCoE controller</i> in an ENode.</p> <p>See also <i>FCoE node (ENode)</i>.</p> |
| ENode MAC address | Globally unique address assigned to the CNA by the manufacturer and used to identify the node for FIP transactions. |
| Ethernet PAUSE | <p>As defined in IEEE 802.3X, a flow control mechanism that temporarily stops the transmission of Ethernet frames on a link for a specified period. A receiving element sends an Ethernet PAUSE frame when a sender transmits data faster than the receiver can accept it. Ethernet PAUSE affects the entire link, not just an individual flow. An Ethernet PAUSE frame temporarily stops all traffic transmission on the link and allows the receiver's input buffer to empty sufficiently to restart traffic on the link. Ethernet PAUSE messages are sent to the previous hop and do not automatically propagate to the source of the congestion.</p> <p>See also <i>priority-based flow control (PFC)</i>.</p> |
| fabric | Interconnection of network nodes using one or more network switches that function as a network single logical entity. |

Table 377: Fibre Channel Terms (*continued*)

| Term | Definition |
|------------------------------------|--|
| fabric discovery (FDISC) | <p>Subsequent logins from the same ENode for different users, applications, or virtual machines after an ENode performs an initial FLOGI to log in to a switch.</p> <p>FC and FIP FDISC messages serve the same function in FC and FCoE networks, respectively. N_Ports send FC FDISC messages to the FC switch and VN_Ports send FIP FDISC messages to the FCF.</p> <p>After an N_Port acquires its initial N_Port ID through the FC FLOGI process, it can acquire additional N_Port IDs by sending an FC FDISC with a new worldwide port name and a source ID of 0x000000. The new port name and blank source ID tell the FC switch to assign a new N_Port ID to the N_Port. The different N_Port IDs allow multiple virtual machines or users on the N_Port to have separate, secure virtual links on the same physical N_Port. These additional ports are also referred to as VN_Ports.</p> <p>FIP FDISC works the same way, except the VN_Port logs in using a FIP FLOGI message.</p> <p>See also <i>fabric login (FLOGI)</i> and <i>N_Port ID</i>.</p> |
| fabric login (FLOGI) | <p>Creation of a logical connection to the FC switch and establishment of a node's operating environment.</p> <p>For FC devices, an N_Port logs in to the FC network by sending an FC FLOGI message to the F_Port of an FC switch.</p> <p>For FCoE devices, a VN_Port logs in to the FC network by sending a FIP FLOGI message to the VF_Port of an FC switch.</p> |
| fabric port (F_Port) | <p>FC port on an FC switch or an FCF that connects point-to-point to an FC node port (N_Port) on an FC host (server or storage device). An F_Port provides access to fabric services for FC devices.</p> <p>F_Ports are intermediate ports in a connection between FC device end-point N_Ports. For example, a connection between an FC host server and an FC storage device through an FC switch looks like this: FC server N_Port to FC switch ingress F_Port to FC switch egress F_Port to FC storage device N_Port.</p> <p>See also <i>node port (N_Port)</i>.</p> |
| fabric-provided MAC address (FPMA) | <p>MAC address that an FCF assigns to a single ENode MAC through the FLOGI or FDISC process that is unique to the local fabric. The FPMA uniquely identifies a single VN_Port at that ENode MAC in FCoE transactions with the FCF.</p> <p>Because an ENode can have more than one ENode MAC, an FCF can assign multiple FPMAs to an ENode, one FPMA per ENode MAC.</p> <p>An FPMA is a 48-bit value that consists of two 24-bit values, the N_Port ID and the FC-MAP value. The N_Port ID uniquely identifies the VN_Port and the FC-MAP value identifies the FCF.</p> <p>See also <i>FCoE node (ENode)</i>, <i>N_Port ID</i>, and <i>FCoE mapped address prefix (FC-MAP)</i>.</p> |
| FCF-MAC | Lossless Ethernet MAC paired with an FCoE controller in an FCF. The FCF-MAC enables the FCF to handle FCoE traffic. |

Table 377: Fibre Channel Terms (*continued*)

| Term | Definition |
|-------------------------------------|---|
| FCoE controller | <p>Instantiates and terminates VN_Port and VF_Port instances on an ENode. An ENode can have more than one FCoE controller. Each FCoE controller is paired with a lossless Ethernet MAC on the ENode.</p> <p>See also <i>lossless Ethernet MAC</i>.</p> |
| FC forwarder (FCF) | Alternative term and acronym to refer to an FC switch that has all physical Fibre Channel ports and the necessary set of services as defined in the T11 Organization <i>Fibre Channel Switched Fabric</i> (FC-SW) standards. |
| FCoE forwarder (FCF) | Defined by the <i>Fibre Channel Backbone - 5 (FC-BB-5) Rev 2.00</i> specification available at http://www.t11.org/ftp/t11/pub/fc/bb-5/09-056v5.pdf as a device that has the necessary set of services as defined in FC-SW and the FCoE capabilities to act as an FCoE-based FC switch. |
| FCoE Initialization Protocol (FIP) | <p>Layer 2 protocol for endpoint discovery, fabric login, and fabric association. FIP enables FCoE devices and FC switches to discover one another. Through FIP, FCoE nodes can log in to an FC switch, access the SAN FC fabric, and communicate with target FC devices. FIP messages also maintain the connection between the FCoE initiator and the FCF.</p> <p>FIP has its own EtherType (0x8914) to distinguish its traffic from payload-carrying FCoE traffic and other Ethernet traffic.</p> |
| FCoE link endpoint (LEP) | Virtual FC interface mapped onto a physical Ethernet interface to handle FC frame encapsulation and de-encapsulation and transmission and reception of FC frames encapsulated in Ethernet through a single virtual link. |
| FCoE mapped address prefix (FC-MAP) | <p>24-bit value that identifies the FC switch and is half of the 48-bit FPMA MAC address. The FC-MAP value can be configured on the FC switch and has a default value of 0EFC00h. The FC-MAP value was originally called the Fibre Channel Organizationally Unique Identifier (FC-OUI).</p> <p>See also <i>fabric-provided MAC address (FPMA)</i>.</p> |
| FCoE node (ENode) | <p>Fibre Channel node that has one or more lossless Ethernet MACs, each paired with an <i>FCoE Controller</i> in order to transmit FCoE frames. An ENode combines FCoE termination functions and the FC stack on a CNA. ENodes present virtual FC interfaces to FC switches or FCFs in the form of VN_Ports, which can establish FCoE virtual links with FC switch/FCF VF_Ports. ENodes perform FCoE related functions in a <i>converged network adapter (CNA)</i>.</p> <p>See also <i>converged network adapter (CNA)</i>.</p> |
| FCoE-FC gateway | A form of N_Port virtualizer in which the node-facing ports are FCoE ports and the FC switch-facing ports are FC ports. |
| FCoE-FCoE gateway | A form of N_Port virtualizer in which the node-facing ports are FCoE ports and the FC switch-facing ports are FCoE ports. |
| FC-FC gateway | A form of N_Port virtualizer in which the node-facing ports are FC ports and the FC switch-facing ports are FC ports. |

Table 377: Fibre Channel Terms (*continued*)

| Term | Definition |
|---|---|
| FCoE transit switch (also known as a FIP snooping bridge) | <p>Switch with a minimum set of features designed to support FCoE Layer 2 forwarding and FCoE security. The switch can also have optional additional features.</p> <p>Minimum feature support is:</p> <ul style="list-style-type: none"> • Priority-based flow control (PFC) • Enhanced transmission selection (ETS) • Data Center Bridging Capability Exchange Protocol (DCBX), including the FCoE application TLV • FIP snooping (minimum support is FIP automated filter programming at the ENode edge) <p>Additional FIP snooping capabilities can include learning the virtual FC connection paths (VN2VF, VN2VN, or VE2VE) and monitoring the FIP keepalive mechanisms. Other optional capabilities can also enhance FCoE within the standards. FIP snooping is typically configurable on a per-VLAN basis.</p> <p>A transit switch has an FC stack even though it is not an FC switch or an FCF.</p> |
| FCoE VLAN | VLAN dedicated to carrying only FCoE traffic. FCoE traffic must travel in a VLAN. Only FCoE interfaces should be members of an FCoE VLAN. Ethernet traffic that is not FCoE traffic must travel in a different VLAN. |
| Fibre Channel | High-speed network technology used for storage area networks (SANs). |
| Fibre Channel fabric | <p>Network of Fibre Channel devices that allows communication among devices, device name lookup, security, and redundancy.</p> <p>Also a local fabric on a QFX3500 switch with FCoE interfaces connected to FCoE devices on the Ethernet network and native FC interfaces connected to an FC switch in a SAN.</p> |
| Fibre Channel ID (FCID) | <p>24-bit value the FC switch assigns to the N_Port or VN_Port as a unique identifier within the local FC network. The FCID consists of an 8-bit domain value, an 8-bit area value, and an 8-bit port value. The FCID is sometimes called an N_Port ID.</p> <p>See also <i>N_Port ID</i>.</p> |
| Fibre Channel over Ethernet (FCoE) | <p>Standard for transporting FC frames over Ethernet networks. FCoE encapsulates Fibre Channel frames in Ethernet so that the same high-speed Ethernet physical infrastructure can transport both data and storage traffic while preserving the lossless CoS that FC requires. FCoE has its own EtherType (0x8906) to differentiate it from other Ethernet traffic.</p> <p>FCoE runs on a DCB network. FCoE servers connect to a switch that supports both FCoE and native FC protocols. This allows FCoE servers on the Ethernet network to access FC storage devices in the SAN fabric on one converged network.</p> <p>See also <i>data center bridging (DCB)</i>.</p> |

Table 377: Fibre Channel Terms (*continued*)

| Term | Definition |
|-----------------------------|--|
| Fibre Channel services | Functions required for establishing FC network connectivity among devices and for managing devices on the FC network, such as login servers, domain managers, name servers, and zone servers. |
| FC stack | <p>FC or FCoE protocol capability implemented on a device to support the FC or FCoE functionality. Having an FC stack does not imply consuming a domain ID.</p> <p>Each FC or FCoE enabled server or storage device has an FC stack. Similarly, an FC or FCoE switch, an FCF, an FCoE-FC gateway, and an FCoE transit switch have FC stacks.</p> |
| Fibre Channel switch | Network switch that implements the Fibre Channel protocol. |
| FIP discovery advertisement | <p>Multicast or unicast message that the FC switch (or FCF) transmits to ENodes to advertise the switch's presence on the network so that ENodes can discover the switch and request to log in to the FC fabric.</p> <p>The FC switch periodically sends multicast FIP discovery advertisements to the ALL-ENode-MACs address, a well-known address to which all ENodes listen. The multicast messages advertise the FC switch to all ENodes on the VLAN and serve as keepalive messages to maintain connectivity between the FC switch and ENodes.</p> <p>When an ENode sends a FIP discovery solicitation message to the FC switch, the FC switch responds with a unicast FIP discovery advertisement to that ENode.</p> |
| FIP discovery solicitation | <p>Multicast or unicast message that an ENode transmits to FC switches (or FCFs) to find compatible switches in the network.</p> <p>When an ENode initializes, it sends a multicast FIP discovery solicitation to the ALL-FCF-MACs address, a well-known address to which all FC switches and FCFs listen. Compatible switches reply with a unicast FIP discovery advertisement.</p> <p>The ENode compiles a list of compatible switches, selects a switch, and logs in to that switch.</p> |
| FIP keepalive | Periodic multicast FIP discovery advertisement sent from the FC switch or FCF to all ENodes to maintain connectivity. |

Table 377: Fibre Channel Terms (*continued*)

| Term | Definition |
|------------------------|---|
| FIP snooping | <p>For VN_Port to VF_Port (VN2VF) paths (Technical Committee T11 BB-FC-5 specification), FIP snooping is a security feature enabled for FCoE VLANs on an Ethernet switch that connects ENodes to FC switches or FCFs. FIP snooping inspects data in FIP frames and uses that data to create firewall filters. The filters permit only traffic from sources that perform a successful FLOGI to the FC switch. All other traffic on the VLAN is denied. FIP snooping filters are installed on the ports in the FCoE VLAN.</p> <p>For VN_Port to VN_Port (VN2VN) paths (Technical Committee T11 BB-FC-6 specification), the FIP snooping security feature filters access between VN_Ports in a similar manner to VN2VF_Port FIP snooping.</p> <p>FIP snooping can also apply similarly to VE_Port to VE_Port (VE2VE) paths.</p> <p>FIP snooping can also snoop to provide additional visibility of FCoE Layer 2 operation.</p> <p>See also <i>FCoE node (ENode)</i>.</p> |
| FIP snooping bridge | See <i>FCoE transit switch</i> and <i>FIP snooping</i> . |
| host bus adapter (HBA) | Physical mechanism that connects a host system to other FC network and storage devices. HBAs have a unique worldwide node name (WWNN) for the HBA node, which all of the ports on the HBA share, and each port on an HBA has a unique worldwide port name (WWPN). |
| initiator | System component that originates an I/O command over an I/O bus or network. An FCoE server sending a request to an FC storage device is an example of an initiator. |
| iSCSI transit switch | <p>Layer 2 Ethernet switch with a minimum set of best-practice Ethernet features to support iSCSI, along with optional enhancements. Minimum feature support is:</p> <ul style="list-style-type: none"> • IEEE 802.3X asymmetric and symmetric flow control on ports not running in DCB mode • Priority-based flow control (PFC) • Enhanced transmission selection (ETS) • Data Center Bridging Capability Exchange Protocol (DCBX), including the iSCSI application TLV <p>Other capabilities such as Internet storage name service (iSNS) are optional.</p> |
| interswitch link (ISL) | Link between the <i>E_Ports</i> of two FC switches in a common FC fabric. When two FCoE-based FC switches are connected together, there is a virtual ISL through Layer 2. |
| logout (LOGO) | <p>For FC devices, an N_Port logs out from the FC network by sending an FC LOGO message to the F_Port of an FC switch. The switch can also send a LOGO message to an N_Port to terminate its connection.</p> <p>For FCoE devices, a VN_Port logs out from the FC network by sending a FIP LOGO message to the VF_Port of an FC switch. The switch can also send a LOGO message to a VN_Port to terminate its connection.</p> |

Table 377: Fibre Channel Terms (*continued*)

| Term | Definition |
|---------------------------------|--|
| lossless Ethernet MAC | <p>Full-duplex Ethernet MAC that implements Ethernet extensions to avoid Ethernet frame loss due to congestion and supports at least 2.5-KB jumbo frames. Each lossless Ethernet MAC combines with an FCoE Controller to perform FCoE termination functions on an ENode.</p> <p>See also <i>priority-based flow control (PFC)</i>, <i>quantized congestion notification (QCN)</i>, <i>FCoE controller</i>, and <i>FCoE node (ENode)</i>.</p> |
| lossless Ethernet network | Ethernet network composed of only full-duplex links and lossless Ethernet MACs and with CoS and flow control to prevent dropping of frames. |
| lossless transport | In DCB networks, the ability to switch FCoE frames over an Ethernet network without dropping any frames. Lossless transport uses mechanisms such as priority-based flow control and quantized congestion notification to control traffic flows and avoid congestion. |
| N_Port ID | See <i>Fibre Channel ID (FCID)</i> . |
| N_Port ID virtualizer | <p>Presents itself as an FC or FCoE switch to external devices, but connects to an actual FC or FCoE switch in the other direction to provide the FC-SW services.</p> <p>An N_Port ID virtualizer logs in to the actual FC or FCoE switch in the same way as a normal node device and uses the NPIV mechanism to proxy incoming FLOGIs to FDISCs on the actual FC or FCoE switch.</p> <p>An N_Port ID virtualizer has an FC stack even though it is not an FC switch or an FCF.</p> <p>The acronym <i>NPV</i> is commonly used for N_Port ID virtualizer even though the acronym is not defined in the standards.</p> |
| N_Port ID Virtualization (NPIV) | <p>NPIV enables a physical N_Port to acquire multiple N_Port IDs. Each N_Port ID maps to a different application (such as a virtual machine) or to a different user. This allows you to associate one F_Port with many N_Port IDs and create multiple discrete, secure virtual links over one physical point-to-point connection.</p> <p>NPIV increases resource and bandwidth utilization and allows the implementation of access control, zoning, and port security on a per-application or per-user basis.</p> <p>After an N_Port performs a FLOGI and receives its first N_Port ID, it can request more N_Port IDs by sending FDISC messages.</p> <p>See also <i>fabric login (FLOGI)</i>, <i>fabric discovery (FDISC)</i>, and <i>virtual link</i>.</p> |

Table 377: Fibre Channel Terms (*continued*)

| Term | Definition |
|-----------------------------------|---|
| node port (N_Port) | <p>N_Ports can be in two modes:</p> <ul style="list-style-type: none"> Fabric N_Port—Node port that is an FC host or storage device end port in a point-to-point link between the device and the F_Port of an FC switch. The point-to-point link can be virtual or physical. Point-to-point N_Port—Node port that connects to another N_Port. The QFX3500 switch does not support this configuration. <p>N_Ports handle creation, detection, and flow of messages to and from the connected devices.</p> |
| node worldwide name (NWWN) | WWN that is unique worldwide and is assigned to an FC node. An NWWN is valid for multiple ports that are on that node (this identifies the ports as network interfaces of a particular node). |
| port mode | <p>Role that the port plays in the FC fabric (endpoint device, FC switch connection to endpoint devices, interswitch link).</p> <p>See also <i>node port (N_Port)</i>, <i>virtual node port (VN_Port)</i>, <i>proxy node port (NP_Port)</i>, <i>fabric port (F_Port)</i>, and <i>virtual fabric port (VF_Port)</i>.</p> |
| port worldwide name (PWWN) | WWN that is unique worldwide and is assigned to an FC port. |
| priority-based flow control (PFC) | <p>Link-level flow control mechanism defined by IEEE 802.1Qbb that allows independent flow control for each class of service (as defined in the 3-bit CoS field of the Ethernet header by IEEE 802.1Q tags) to ensure that no frame loss from congestion occurs in DCB networks.</p> <p>PFC is an enhancement of the Ethernet PAUSE mechanism, but PFC controls classes of flows, whereas Ethernet PAUSE indiscriminately pauses all of the traffic on a link. With PFC, a receiving device can signal a transmitting device to pause transmission based on traffic class.</p> <p>PFC provides application-specific bandwidth reservations so you can ensure that time-critical protocols and applications such as FCoE receive the priority necessary to prevent frame loss. PFC allows the same physical link to carry FCoE traffic and provide lossless service while also carrying loss-tolerant Ethernet traffic.</p> <p>See also <i>Ethernet PAUSE</i>.</p> |
| proxy gateway mode | Connects FCoE initiators to FC switches in a converged Ethernet and Fibre Channel network and acts as an intermediary for these devices. The FCoE-FC gateway represents and acts for the FCoE initiators in transactions from the FCoE initiators destined for an FC switch, including converting FIP and FCoE frames to FC frames. The gateway represents and acts for an FC switch in transactions from the FC switch destined for an FCoE initiator, including converting FC frames to FIP frames and encapsulating FC frames in Ethernet. |
| proxy node port (NP_Port) | N_Port on the QFX Series that performs proxy functions when it is configured as an FCoE-FC gateway. The NP_Port acts as a proxy for the FCoE device VN_Ports in transactions with the FC switch. |

Table 377: Fibre Channel Terms (*continued*)

| Term | Definition |
|---|--|
| quantized congestion notification (QCN) | Mechanism defined by IEEE 802.1Qau that manages network congestion within a Layer 2 domain. When a queue reaches a configured threshold, QCN throttles traffic at the source of the congestion by transmitting messages that propagate back to the source and temporarily stop the source from transmitting. When the queue crosses the threshold that indicates the congestion has dissipated, QCN sends a message to allow the source to resume transmitting frames. |
| session | Fabric login (FLOGI) or fabric discovery (FDISC) login to the FC SAN fabric. Session does not refer to end-to-end server-to-storage sessions. |
| server-provided MAC address (SPMA) | <p>MAC address that an ENode assigns to one of its ENode MACs and is not assigned to any other ENode MAC in the same FCoE VLAN. An SPMA can be associated with more than one VN_Port at that ENode MAC.</p> <p>The QFX Series does not support SPMA.</p> <p>See also <i>ENode MAC</i> and <i>fabric-provided MAC address (FPMA)</i>.</p> |
| storage area network (SAN) | Network whose primary purpose is the transfer of data between computer systems and storage devices. This term is most commonly used in the context of any network that supports block storage, usually iSCSI, FC, and FCoE networks. |
| target | System component that receives an I/O command. An FC storage device that receives a request from a server is an example of a target. |
| VE_Port | Virtual ports created to form a connection (an <i>interswitch link</i>) between two FCoE-based FC switches as part of a common FC fabric. |
| VE2VE (VE_Port to VE_Port) | The <i>Fibre Channel Backbone - 5 (FC-BB-5) Rev 2.00</i> specification capability of FCFs to connect to each other as a single FCoE FC SAN. |
| VN2VF (VN_Port to VF_Port) | The <i>Fibre Channel Backbone - 5 (FC-BB-5) Rev 2.00</i> specification capability of an ENode to connect to an FCF or to an FCoE-enabled FC SAN. |
| VN2VN (VN_Port to VN_Port) | The <i>Fibre Channel Backbone - 6 (FC-BB-6)</i> specification capability of an ENode to connect directly over Layer 2 to another ENode without the need of any FC-related services. This capability is most often used in small-scale FCoE SANs. |
| virtual fabric port (VF_Port) | <p>Data-forwarding component that emulates an F_Port. A VF_Port is dynamically instantiated on successful completion of a FIP FLOGI exchange and connects to one or more VN_Ports. The term <i>virtual</i> indicates the use of a non-FC link such as an FCoE link.</p> <p>See also <i>fabric port (F_Port)</i>.</p> |
| virtual link | <p>Logical link connecting two FCoE Link End Points (LEPs) over a lossless Ethernet network, for example, the link between a VF_Port and a VN_Port. The MAC addresses of the two LEPs identifies a virtual link.</p> <p>See also <i>FCoE link end point (LEP)</i> and <i>lossless Ethernet network</i>.</p> |

Table 377: Fibre Channel Terms (*continued*)

| Term | Definition |
|-----------------------------|--|
| virtual node port (VN_Port) | <p>Data-forwarding component that emulates an N_Port. With FCoE, a VN_Port is dynamically instantiated on successful completion of a FIP FLOGI exchange and connects to one or more VF_Ports. The term <i>virtual</i> indicates the use of a non-FC link such as an FCoE link.</p> <p>VN_Port is also used for the virtual N_Ports created in both FC and FCoE when additional NPIV-based logins occur over a previously created N_Port-to-VN_Port or N_Port-to-VF_Port connection.</p> <p>See also <i>node port (N_Port)</i>.</p> |
| well-known address (WKA) | Address identifier used to access a service provided by an FC fabric. The service can be distributed in many elements throughout a fabric, or it can be centralized in one element. A WKA is always accessible, regardless of zoning. An example of a WKA is the <i>ALL-FCF-MACs</i> address to which all FCFs listen. |
| worldwide name (WWN) | 64-bit identifier that is similar to a MAC address except that it is not used for forwarding. It uniquely identifies an FC device. The WWN is derived from the IEEE organizationally unique identifier (OUI) and vendor-supplied information. A WWN is unique worldwide. |
| worldwide node name (WWNN) | See <i>node worldwide name (NWWN)</i> . |
| worldwide port name (WWPN) | See <i>port worldwide name (PWWN)</i> . |

Understanding DCBX

Data Center Bridging Capability Exchange protocol (DCBX) is an extension of Link Layer Data Protocol (LLDP). If you disable LLDP on an interface, that interface cannot run DCBX. If you attempt to enable DCBX on an interface on which LLDP is disabled, the configuration commit operation fails. Data center bridging (DCB) devices use DCBX to exchange configuration information with directly connected peers.

This topic describes:

- [DCBX Basics on page 4906](#)
- [DCBX Modes and Support on page 4907](#)
- [DCBX Attribute Types on page 4909](#)
- [DCBX Application Protocol TLV Exchange on page 4911](#)

- [DCBX and PFC on page 4912](#)
- [DCBX and ETS on page 4912](#)

DCBX Basics

DCBX can:

- Discover the DCB capabilities of peers.
- Detect DCB feature misconfiguration or mismatches between peers.
- Configure DCB features on peers.

You can configure DCBX operation for priority-based flow control (PFC), Layer 2 and Layer 4 applications such as FCoE and iSCSI, and ETS. DCBX is enabled or disabled on a per-interface basis.

By default, for PFC and ETS, DCBX automatically negotiates administrative state and configuration with each interface's connected peer. To enable DCBX negotiation for applications, you must configure the applications, map them to IEEE 802.1p code points in an application map, and apply the application map to interfaces.

The FCoE application only needs to be included in an application map when you want an interface to exchange type, length, and values (TLVs) for other applications in addition to FCoE. If FCoE is the only application you want an interface to advertise, then you do not need to use an application map. For ETS, DCBX pushes the switch configuration to peers if they are set to learn the configuration from the switch (unless you disable sending the ETS recommendation TLV on interfaces in IEEE DCBX mode).

You can override the default behavior for PFC, for ETS, or for all applications mapped to an interface by turning off autonegotiation to force an interface to enable or disable that feature. You can also disable DCBX autonegotiation for applications on an interface by excluding those applications from the application map you apply to that interface or by deleting the application map from the interface.

The default autonegotiation behavior for applications that are mapped to an interface is:

- DCBX is enabled on the interface if the connected peer device also supports DCBX.
- DCBX is disabled on the interface if the connected peer device does not support DCBX.

During negotiation of capabilities, the switch can push the PFC configuration to an attached peer if the peer is configured as “willing” to learn the PFC configuration from other peers. The Juniper Networks switch does not support self autoprovisioning and does not change its configuration during autonegotiation to match the peer configuration. (The Juniper switch is not “willing” to learn the PFC configuration from peers.)

NOTE: When a port with DCBX enabled begins to exchange type, length, and value (TLV) entries, optional LLDP TLVs on that port are not advertised to neighbors, so that the switch can interoperate with a wider variety of converged network adapters (CNAs) and Layer 2 switches that support DCBX.

DCBX Modes and Support

This section describes DCBX support on the QFX Series:

- [DCBX Modes \(Versions\) on page 4907](#)
- [Autonegotiation on page 4909](#)
- [CNA Support for DCBX Modes on page 4909](#)
- [Interface Support for DCBX on page 4909](#)

DCBX Modes (Versions)

The QFX Series supports the two most common DCBX modes:

- IEEE DCBX—The newest DCBX version. Different TLVs have different subtypes (for example, the subtype for the ETS configuration TLV is 9); the IEEE DCBX Organizationally Unique Identifier (OUI) is 0x0080c2.
- DCBX version 1.01—The Converged Enhanced Ethernet (CEE) version of DCBX. It has a subtype of 2 and an OUI of 0x001b21.

IEEE DCBX and DCBX version 1.01 differ mainly in frame format. DCBX version 1.01 uses one TLV that includes all DCBX attribute information, which is sent as sub-TLVs. IEEE DCBX uses a unique TLV for each DCB attribute.

NOTE: The QFX Series does not support pre-CEE (pre-DCB) DCBX versions. Unsupported older versions of DCBX have a subtype of 1 and an OUI of 0x001b21. The QFX Series drops LLDP frames that contain pre-CEE DCBX TLVs.

[Table 378 on page 4907](#) summarizes the differences between IEEE DCBX and DCBX version 1.01, including show command output:

Table 378: Summary of Differences Between IEEE DCBX and DCBX Version 1.01

| Characteristic | IEEE DCBX | DCBX Version 1.01 |
|--|--|--|
| OUI | 0x0080c2 | 0x001b21 |
| Frame Format | Sends a separate, unique TLV for each DCBX attribute. For example, IEEE DCBX uses separate TLVs for ETS, PFC, and each application. Configuration and Recommendation information is sent in different TLVs | Sends one TLV that includes all DCBX attribute information organized in sub-TLVs. The “willing” bit determines whether or not an interface can change its configuration to match the connected peer. |
| Symmetric/asymmetric configuration with peer | Asymmetric or symmetric | Symmetric only |

Table 378: Summary of Differences Between IEEE DCBX and DCBX Version 1.01 (continued)

| Characteristic | IEEE DCBX | DCBX Version 1.01 |
|--|--|--|
| Differences in the show dcbx interface interface-name operational command | <ul style="list-style-type: none"> Synchronization information is not shown because symmetric configuration is not required. Operational state information is not shown because the operational states do not have to be symmetric. TLV type is shown because unique TLVs are sent for each DCBX attribute. ETS peer Configuration TLV and Recommendation TLV information is shown separately because they are different TLVs. | <ul style="list-style-type: none"> Synchronization information is shown because symmetric configuration is required. Operational state information is shown because the operational states do have to be symmetric. TLV type is not shown because one TLV is used for all attribute information. Recommendation TLV is not sent (DCBX Version 1.01 uses the "willing" bit to determine whether or not an interface uses the peer interface configuration). |

For more information about how each DCBX mode exchanges TLVs, see the following specifications:

- For DCBX version 1.01—<http://www.ieee802.org/1/files/public/docs2008/az-wedlar-dcb-capability-exchange-discovery-protocol-108-v101.pdf>
- For IEEE DCBX—<http://www.ieee802.org/1/files/private/az-drafts/d2/802-1az-d2-4.pdf>

NOTE: As of Junos OS Release 12.2, this document is located in a private area of the IEEE website, and access requires a password from the IEEE organization. If you are not an IEEE member, you might not be able to access this document until it moves to the public area of the IEEE website.

You can configure interfaces to use the following DCBX modes:

- IEEE DCBX—The interface uses IEEE DCBX regardless of the configuration on the connected peer.
- DCBX version 1.01—The interface uses DCBX version 1.01 regardless of the configuration on the connected peer.
- Autonegotiation—The interface automatically negotiates with the connected peer to determine the DCBX version the peers use. Autonegotiation is the default DCBX mode.

If you configure a DCBX mode on an interface, the interface ignores DCBX protocol data units (PDUs) it receives from the connected peer if the PDUs do not match the DCBX version configured on the interface. For example, if you configure an interface to use IEEE DCBX and the connected peer sends DCBX version 1.01 LLDP PDUs, the interface ignores the version 1.01 PDUs. If you configure an interface to use DCBX version 1.01 and the peer sends IEEE DCBX LLDP PDUs, the interface ignores the IEEE DCBX PDUs.

NOTE: On interfaces that use the IEEE DCBX mode, the `show dcbx neighbors interface interface-name` operational command does not include application, PFC, or ETS operational state in the output.

Autonegotiation

Autonegotiation is the default DCBX mode. Each interface automatically negotiates with its connected peer to determine the DCBX version that both interfaces use to exchange DCBX information.

When an interface connects to its peer interface, the interface advertises IEEE DCBX TLVs to the peer. If the interface receives one IEEE DCBX PDU from the peer, the interface sets the DCBX mode as IEEE DCBX. If the interface receives three DCBX version 1.01 TLVs from the peer, the interface sets DCBX version 1.01 as the DCBX mode.

Autonegotiation works slightly differently on QFX3500 switches and QFabric systems:

- QFX3500 switch—When an interface connects to its peer interface, the interface advertises IEEE DCBX TLVs to the peer. If the interface receives an IEEE DCBX TLV from the peer, the interface sets IEEE DCBX as the DCBX mode. If the interface receives three consecutive DCBX version 1.01 TLVs from the peer, the interface sets DCBX version 1.01 as the DCBX mode.
- QFabric system—When an interface connects to its peer interface, the interface advertises DCBX version 1.01 TLVs to the peer. If the interface receives an IEEE DCBX TLVs from the peer, the interface sets IEEE DCBX as the DCBX mode. If the interface receives three consecutive DCBX version 1.01 TLVs from the peer, the interface retains DCBX version 1.01 as the DCBX mode.

NOTE: If the link flaps or the LLDP process restarts, the interface starts the autonegotiation process again. The interface does not use the last received DCBX communication mode.

CNA Support for DCBX Modes

Different CNA vendors support different versions and capabilities of DCBX. The DCBX configuration you use on QFX Series interfaces depends on the DCBX features that the CNAs in your network support.

Interface Support for DCBX

You can configure DCBX on 10-Gigabit Ethernet interfaces and on link aggregation group (LAG) interfaces whose member interfaces are all 10-Gigabit Ethernet interfaces.

DCBX Attribute Types

DCBX has three attribute types:

- **Informational**—These attributes are exchanged using LLDP, but do not affect DCBX state or operation; they only communicate information to the peer. For example, application priority TLVs are informational TLVs.
- **Asymmetric**—The values for these types of attributes do not have to be the same on the connected peer interfaces. Peers exchange asymmetric attributes when the attribute values can differ on each peer interface. The peer interface configurations might match or they might differ. For example, ETS Configuration and Recommendation TLVs are asymmetric TLVs.
- **Symmetric**—The intention is that the values for these types of attributes should be the same on both of the connected peer interfaces. Peer interfaces exchange symmetric attributes to ensure symmetric DCBX configuration for those attributes. For example, PFC Configuration TLVs are symmetric TLVs.

The following sections describe asymmetric and symmetric DCBX attributes:

- [Asymmetric Attributes on page 4910](#)
- [Symmetric Attributes on page 4910](#)

Asymmetric Attributes

DCBX passes asymmetric attributes between connected peer interfaces to communicate parameter information about those attributes (features). The resulting configuration for an attribute might be different on each peer, so the parameters configured on one interface might not match the parameters on the connected peer interface.

There are two types of asymmetric attribute TLVs:

- **Configuration TLV**—Configuration TLVs communicate the current operational state and the state of the “willing” bit. The “willing” bit communicates whether or not the interface is willing to accept and use the configuration from the peer interface. If an interface is “willing,” the interface uses the configuration it receives from the peer interface. (The peer interface configuration can override the configuration on the “willing” interface.) If an interface is “not willing,” the configuration on the interface cannot be overridden by the peer interface configuration.
- **Recommendation TLV**—Recommendation TLVs communicate the parameters the interface recommends that the connected peer interface should use. When an interface sends a Recommendation TLV, if the connected peer is “willing,” the connected peer changes its configuration to match the parameters in the Recommendation TLV.

Symmetric Attributes

DCBX passes symmetric attributes between connected peer interfaces to communicate parameter information about those attributes (features), with the objective that both interfaces should use the same configuration. The intent is that the parameters configured on one interface should match the parameters on the connected peer interface.

There is one type of symmetric attribute TLV, the Configuration TLV. As with asymmetric attributes, symmetric attribute Configuration TLVs communicate the current operational state and the state of the “willing” bit. “Willing” interfaces use the peer interface parameter

values for the attribute. (The attribute configuration of the peer overrides the configuration on the “willing” interface.)

DCBX Application Protocol TLV Exchange

DCBX advertises the switch's capabilities for Layer 2 applications such as FCoE and Layer 4 applications such as iSCSI:

- [Application Protocol TLV Exchange on page 4911](#)
- [FCoE Application Protocol TLV Exchange on page 4911](#)
- [Disabling Application Protocol TLV Exchange on page 4912](#)

Application Protocol TLV Exchange

For all applications, DCBX advertises the application's state and IEEE 802.1p code points on the interfaces to which the application is mapped. If an application is not mapped to an interface, that interface does not advertise the application's TLVs. There is an exception for FCoE application protocol TLV exchange when FCoE is the only application you want DCBX to advertise on an interface.

FCoE Application Protocol TLV Exchange

Protocol TLV exchange for the FCoE application depends on whether FCoE is the only application you want the interface to advertise or whether you want the interface to exchange other application TLVs in addition to FCoE TLVs.

If FCoE is the only application you want DCBX to advertise on an interface, DCBX exchanges FCoE application protocol TLVs by default if the interface:

- Carries FCoE traffic (traffic mapped by CoS configuration to the FCoE forwarding class)
- Has a congestion notification profile with PFC enabled on the FCoE priority (IEEE 802.1p code point)
- Does *not* have an application map

NOTE: If no CoS configuration for FCoE is mapped to an interface, that interface does not exchange FCoE application protocol TLVs.

If you want DCBX to advertise FCoE and other applications on an interface, you must specify all of the applications, including FCoE, in an application map, and apply the application map to the desired interfaces.

NOTE: If an application map is applied to an interface, the FCoE application must be explicitly configured in the application map, or the interface does not exchange FCoE TLVs.

When DCBX advertises the FCoE application, it advertises the FCoE state and IEEE 802.1p code points. If a peer device connected to a switch interface does not support FCoE,

DCBX uses autonegotiation to mark the interface as “FCoE down,” and FCoE is disabled on that interface.

Disabling Application Protocol TLV Exchange

To disable DCBX application protocol exchange for all applications on an interface, issue the **set protocols dcbx interface *interface-name* applications no-auto-negotiation** command.

You can also disable DCBX application protocol exchange for applications on an interface by deleting the application map from the interface, or by deleting a particular application from the application map. However, when you delete an application from an application map, the application protocol is no longer exchanged on any interface which uses that application map.

DCBX and PFC

After you enable PFC on a switch interface, DCBX uses autonegotiation to control the operational state of the PFC functionality.

If the peer device connected to the interface supports PFC and is provisioned compatibly with the switch, DCBX sets the PFC operational state to enabled. If the peer device connected to the interface does not support PFC or is not provisioned compatibly with the switch, DCBX sets the operational state to disabled. (PFC must be symmetrical.)

If the peer advertises that it is “willing” to learn its PFC configuration from the switch, DCBX pushes the switch’s PFC configuration to the peer and does not check the peer’s administrative state.

You can manually override DCBX control of the PFC operational state on a per-interface basis by disabling autonegotiation. If you disable autonegotiation on an interface on which you have configured PFC, then PFC is enabled on that interface regardless of the peer configuration. To disable PFC on an interface, do not configure PFC on that interface.

DCBX and ETS

This section describes:

- [Default DCBX ETS Advertisement on page 4912](#)
- [ETS Advertisement and Peer Configuration on page 4913](#)
- [ETS Recommendation TLV on page 4913](#)

Default DCBX ETS Advertisement

If you do not configure ETS on an interface, the switch automatically creates a default priority group that contains all of the priorities (forwarding classes, which represent output queues) and assigns 100 percent of the port output bandwidth to that priority group. The default priority group is transparent. It does not appear in the configuration and is used for DCBX advertisement. DCBX advertises the default priority group, its priorities, and the assigned bandwidth.

If you configure ETS on an interface, DCBX advertises:

- Each priority group on the interface

- The priorities in each priority group
- The bandwidth properties of each priority group and priority

Any priority on that interface that is not part of an explicitly configured priority group (forwarding class set) is assigned to the automatically generated default priority group and receives no bandwidth. If you configure ETS on an interface, every forwarding class (priority) on that interface for which you want to forward traffic must belong to a forwarding class set (priority group).

ETS Advertisement and Peer Configuration

DCBX does not control the switch's ETS (hierarchical scheduling) operational state. If the connected peer is configured as "willing," DCBX pushes the switch's ETS configuration to the switch's peers if the ETS Recommendation TLV is enabled (it is enabled by default). If the peer does not support ETS or is not consistently provisioned with the switch, DCBX does not change the ETS operational state on the switch. The ETS operational state remains enabled or disabled based only on the switch hierarchical scheduling configuration and is enabled by default.

When ETS is configured, DCBX advertises the priority groups, the priorities in the priority groups, and the bandwidth configuration for the priority groups and priorities. Any priority (essentially a forwarding class or queue) that is not part of a priority group has no scheduling properties and receives no bandwidth.

You can manually override whether DCBX advertises the ETS state to the peer on a per-interface basis by disabling autonegotiation. This does not affect the ETS state on the switch or on the peer, but it does prevent the switch from sending the Recommendation TLV or the Configuration TLV to the connected peer. To disable ETS on an interface, do not configure priority groups (forwarding class sets) on the interface.

ETS Recommendation TLV

The ETS Recommendation TLV communicates the ETS settings that the switch wants the connected peer interface to use. If the peer interface is "willing," it changes its configuration to match the configuration in the ETS Recommendation TLV. By default, the switch interfaces send the ETS Recommendation TLV to the peer. The settings communicated are the egress ETS settings defined by configuring hierarchical scheduling on the interface.

We recommend that you use the same ETS settings on the connected peer that you use on the switch interface and that you leave the ETS Recommendation TLV enabled. However, on interfaces that use IEEE DCBX as the DCBX mode, if you want an asymmetric configuration between the switch interface and the connected peer, you can disable the ETS Recommendation TLV by including the **no-recommendation-tlv** statement at the **[edit protocols dcbx interface *interface-name* enhanced-transmission-selection]** hierarchy level.

NOTE: You can disable the ETS Recommendation TLV only when the DCBX mode on the interface is IEEE DCBX. Disabling the ETS Recommendation TLV has no effect if the DCBX mode on the interface is DCBX version 1.01. (IEEE DCBX uses separate application attribute TLVs, but DCBX version 1.01 sends all application attributes in the same TLV and uses sub-TLVs to separate the information.)

If you disable the ETS Recommendation TLV, the switch still sends the ETS Configuration TLV to the connected peer. The result is that the connected peer is informed about the switch DCBX ETS configuration, but even if the peer is “willing,” the peer does not change its configuration to match the switch configuration. This is asymmetric configuration—the two interfaces can have different parameter values for the ETS attribute.

For example, if you want a CNA connected to a switch interface to have different bandwidth allocations than the switch ETS configuration, you can disable the ETS Recommendation TLV and configure the CNA for the desired bandwidth. The switch interface and the CNA exchange configuration parameters, but the CNA does not change its configuration to match the switch interface configuration.

Understanding DCBX Application Protocol TLV Exchange

Data Center Bridging Capability Exchange protocol (DCBX) discovers the data center bridging (DCB) capabilities of connected peers. DCBX also advertises the capabilities of applications on interfaces by exchanging application protocol information through application type, length, and value (TLV) elements. DCBX is an extension of Link Layer Discovery Protocol (LLDP). LLDP must remain enabled on every interface on which you want to use DCBX.

NOTE: LLDP and DCBX are enabled by default on all interfaces.

Setting up application protocol exchange consists of:

- Defining applications
- Mapping the applications to IEEE 802.1p code points in an *application map*
- Configuring classifiers to prioritize incoming traffic and map the incoming traffic to the application by the traffic code points
- Applying the application maps and classifiers to interfaces

You need to explicitly define the applications that you want an interface to advertise. The FCoE application is a special case (see [“Applications” on page 4915](#)) and only needs to be defined on an interface if you want DCBX to exchange application protocol TLVs for other applications in addition to FCoE on that interface.

You also need to explicitly map all defined applications that you want an interface to advertise to IEEE 802.1p code points in an application map. The FCoE application is a special case (see [“Application Maps” on page 4916](#)) and only requires inclusion in an application map when you want an interface to use DCBX for other applications in addition to FCoE, as described later in this topic.

This topic describes:

- [Applications on page 4915](#)
- [Application Maps on page 4916](#)
- [Classifying and Prioritizing Application Traffic on page 4917](#)
- [Enabling Interfaces to Exchange Application Protocol Information on page 4918](#)
- [Disabling DCBX Application Protocol Exchange on page 4918](#)

Applications

Before an interface can exchange application protocol information, you need to define the applications that you want to advertise, except FCoE if FCoE is the only application that you want the interface to advertise.

NOTE: If FCoE is the only application that you want DCBX to advertise on an interface, DCBX exchanges FCoE application protocol TLVs by default if the interface:

- Carries FCoE traffic (traffic mapped by CoS configuration to the FCoE forwarding class and applied to the interface)
- Has a congestion notification profile with PFC enabled on the FCoE priority (IEEE 802.1p code point)
- Does *not* have an application map

If you apply an application map to an interface, then all applications that you want DCBX to advertise must be defined and configured in the application map, including the FCoE application.

If no CoS configuration for FCoE is mapped to an interface, that interface does not exchange FCoE application protocol TLVs.

You can define:

- Layer 2 applications by EtherType
- Layer 4 applications by a combination of protocol (TCP or UDP) and destination port number

The EtherType is a two-octet field in the Ethernet frame that denotes the protocol encapsulated in the frame. For a list of common EtherTypes, see <http://standards.ieee.org/develop/regauth/ethertype/eth.txt> on the IEEE standards organization website. For a list of port numbers and protocols, see the *Service Name and Transport Protocol Port Number Registry* at <http://www.iana.org/assignments/service-names-port-numbers/service-names-port-numbers.xml> on the Internet Assigned Numbers Authority (IANA) website.

You must explicitly define each application that you want to advertise, except FCoE. The FCoE application is defined by default (EtherType 0x8906).

Application Maps

An application map maps defined applications to one or more IEEE 802.1p code points. Each application map contains one or more applications. DCBX includes the configured application code points in the protocol TLVs exchanged with the connected peer.

To exchange protocol TLVs for an application, you must include the application in an application map. The FCoE application is a special case:

- If you want DCBX to exchange application protocol TLVs for more than one application on a particular interface, you must configure the applications, define an application map to map the applications to code points, and apply the application map to the interface. In this case, you must also define the FCoE application and add it to the application map.

This is the same process and treatment required for all other applications. In addition, for DCBX to exchange FCoE application TLVs, you must enable priority-based flow control (PFC) on the FCoE priority (the FCoE IEEE 802.1p code point) on the interface.

- If FCoE is the only application that you want DCBX to advertise on an interface, then you do not need to configure an application map and apply it to the interface. By default, when an interface has no application map, and the interface carries traffic mapped to the FCoE forwarding class, and PFC is enabled on the FCoE priority, the interface advertises FCoE TLVs (autonegotiation mode). DCBX exchanges FCoE application protocol TLVs by default until you apply an application map to the interface, remove the FCoE traffic from the interface (you can do this by removing the or editing the classifier for FCoE traffic), or disable PFC on the FCoE priority.

If you apply an application map to an interface that did not have an application map and was exchanging FCoE application TLVs, and you do not include the FCoE application in the application map, the interface stops exchanging FCoE TLVs. Every interface that has an application map must have FCoE included in the application map (and PFC enabled on the FCoE priority) in order for DCBX to exchange FCoE TLVs.

Mapping an application to code points does two things:

- Maps incoming traffic with the same code points to that application
- Allows you to configure classifiers that map incoming application traffic, by code point, to a forwarding class and a loss priority, in order to apply class of service (CoS) to application traffic and prioritize application traffic

You apply an application map to an interface to enable DCBX application protocol exchange on that interface for each application specified in the application map. All of the applications that you want an interface to advertise must be configured in the application map that you apply to the interface, with the previously noted exception for the FCoE application when FCoE is the only application for which you want DCBX to exchange protocol TLVs on an interface.

Classifying and Prioritizing Application Traffic

When traffic arrives at an interface, the interface classifies the incoming traffic based on its code points. Classifiers map code points to loss priorities and forwarding classes. The loss priority prioritizes the traffic. The forwarding class determines the traffic output queue and CoS service level.

When you map an application to an IEEE 802.1p code point in an application map and apply the application map to an interface, incoming traffic on the interface that matches the application code points is mapped to the appropriate application. The application receives the loss priority and the CoS associated with the forwarding class for those code points, and is placed in the output queue associated with the forwarding class.

You can use the default classifier or you can configure a classifier to map the application code points defined in the application map to forwarding classes and loss priorities.

Enabling Interfaces to Exchange Application Protocol Information

Each interface with the **fcoe** forwarding class and PFC enabled on the FCoE code point is enabled for FCoE application protocol exchange by default until you apply an application map to the interface. If you apply an application map to an interface and you want that interface to exchange FCoE application protocol TLVs, you must include the FCoE application in the application map. (In all cases, to achieve lossless transport, you must also enable PFC on the FCoE code point or code points.)

Except when FCoE is the only protocol you want DCBX to advertise on an interface, interfaces on which you want to exchange application protocol TLVs must include the following two items:

- The application map that contains the application(s)
- A classifier

NOTE: You must also enable PFC on the code point of any traffic for which you want to achieve lossless transport.

Disabling DCBX Application Protocol Exchange

To disable DCBX application protocol exchange for all applications on an interface, issue the **set protocols dcbx interface *interface-name* applications no-auto-negotiation** command.

You can also disable DCBX application protocol exchange for applications on an interface by deleting the application map from the interface, or by deleting a particular application from the application map. However, when you delete an application from an application map, the application protocol is no longer exchanged on any interface which uses that application map.

On interfaces that use IEEE DCBX mode to exchange DCBX parameters, you can disable sending the enhanced transmission selection (ETS) Recommendation TLV to the peer if you want an asymmetric ETS configuration between the peers.

Example: Configuring CoS PFC for FCoE Traffic

Priority-based flow control (PFC, described in IEEE 802.1Qbb) is a link-level flow control mechanism that you apply at ingress interfaces. PFC enables you to divide traffic on one physical link into eight priorities. You can think of the eight priorities as eight “lanes” of traffic that correspond to queues (forwarding classes). Each priority is mapped to a 3-bit IEEE 802.1p CoS flag in the VLAN header.

You can selectively apply PFC to the traffic in any queue without pausing the traffic in other queues on the same link. You must apply PFC to FCoE traffic to ensure lossless transport.

To configure PFC on FCoE traffic, use the default FCoE forwarding-class-to-queue mapping and:

- Configure a classifier that associates the FCoE forwarding class with FCoE traffic.
- Configure a congestion notification profile to apply PFC to the FCoE traffic.
- Apply the classifier and the PFC configuration to ingress interfaces.
- Configure the bandwidth scheduling for the FCoE forwarding class output queue.

- Create a forwarding class set (priority group) that includes the FCoE forwarding class; this is required to configure enhanced transmission selection (ETS) and support data center bridging (DCB).
- Configure the bandwidth scheduling for the FCoE priority group.
- Apply the scheduling to the egress interfaces.

NOTE: If you are using Junos OS Release 12.2 or later, use the default forwarding classes for the lossless fcoe forwarding class. If you explicitly configure default lossless forwarding classes, the traffic mapped to those forwarding classes is treated as lossy (best-effort) traffic and does *not* receive lossless treatment.

In Junos OS Release 12.3 and later, you can include the *no-loss* packet drop attribute in explicit forwarding class configurations to configure a lossless forwarding class.

This example describes how to configure PFC for FCoE traffic:

- [Requirements on page 4922](#)
- [Overview on page 4922](#)
- [Configuration on page 4924](#)
- [Verification on page 4927](#)

Requirements

This example uses the following hardware and software components:

- A Juniper Networks QFX3500 Switch
- Junos OS Release 11.1 or later for the QFX Series

Overview

FCoE traffic requires PFC to ensure lossless packet transport. This example shows you how to:

- Assign FCoE traffic to the FCoE priority at the ingress.
- Create and apply CoS for the FCoE traffic using ETS (hierarchical port scheduling).
- Apply PFC to the FCoE traffic.
- Apply the configuration to ingress and egress interfaces.

NOTE: Configuring or changing PFC on an interface blocks the entire port until the PFC change is completed. After a PFC change is completed, the port is unblocked and traffic resumes. Blocking the port stops ingress and egress traffic, and causes packet loss on all queues on the port until the port is unblocked.

Each interface in this example is configured as both an ingress interface and an egress interface, so the classifier, congestion notification profile, and port scheduling are applied to all of the interfaces.

Topology

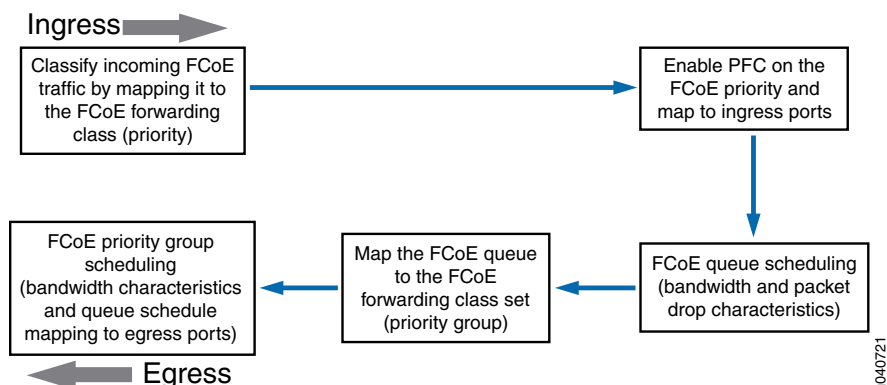

[Table 379 on page 4923](#) shows the configuration components for this example.

Table 379: Components of the PFC for FCoE Traffic Configuration Topology

| Component | Settings |
|---|---|
| Hardware | QFX3500 switch |
| Behavior aggregate classifier (maps the FCoE forwarding class to incoming packets by IEEE 802.1 code point) | Code point 011 to forwarding class fcoe and loss priority low
Ingress interfaces: xe-0/0/31, xe-0/0/32, xe-0/0/33, xe-0/0/34 |
| PFC congestion notification profile | fcoe-cnp:
Code point 011
Ingress interfaces: xe-0/0/31, xe-0/0/32, xe-0/0/33, xe-0/0/34 |

Figure 179: PFC for FCoE Traffic Configuration Components Block Diagram

Configuration

CLI Quick Configuration

To quickly configure PFC for FCoE traffic, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level:

```
[edit class-of-service]
set classifiers ieee-802.1 fcoe-classifier forwarding-class fcoe loss-priority low code-points 011
set congestion-notification-profile fcoe-cnp input ieee-802.1 code-point 011 pfc
set interfaces xe-0/0/31 unit 0 classifiers ieee-802.1 fcoe-classifier
set interfaces xe-0/0/32 unit 0 classifiers ieee-802.1 fcoe-classifier
set interfaces xe-0/0/33 unit 0 classifiers ieee-802.1 fcoe-classifier
set interfaces xe-0/0/34 unit 0 classifiers ieee-802.1 fcoe-classifier
set interfaces xe-0/0/31 congestion-notification-profile fcoe-cnp
set interfaces xe-0/0/32 congestion-notification-profile fcoe-cnp
set interfaces xe-0/0/33 congestion-notification-profile fcoe-cnp
set interfaces xe-0/0/34 congestion-notification-profile fcoe-cnp
set schedulers fcoe-sched priority low transmit-rate 3g
set schedulers fcoe-sched shaping-rate percent 100
set scheduler-maps fcoe-map forwarding-class fcoe scheduler fcoe-sched
set forwarding-class-sets fcoe-pg class fcoe
set traffic-control-profiles fcoe-tcp scheduler-map fcoe-map guaranteed-rate 3g
set traffic-control-profiles fcoe-tcp shaping-rate percent 100
set interfaces xe-0/0/31 forwarding-class-set fcoe-pg output-traffic-control-profile fcoe-tcp
set interfaces xe-0/0/32 forwarding-class-set fcoe-pg output-traffic-control-profile fcoe-tcp
set interfaces xe-0/0/33 forwarding-class-set fcoe-pg output-traffic-control-profile fcoe-tcp
set interfaces xe-0/0/34 forwarding-class-set fcoe-pg output-traffic-control-profile fcoe-tcp
```

Step-by-Step Procedure

To configure the FCoE forwarding class (priority), ingress classifier, output queue scheduling, forwarding class set (priority group) and its output port scheduling, PFC application, and interfaces to set up PFC for FCoE traffic:

1. Configure a classifier to set the loss priority and IEEE 802.1 code point assigned to the FCoE forwarding class at the ingress:

```
[edit class-of-service]
user@switch# set classifiers ieee-802.1 fcoe-classifier forwarding-class fcoe loss-priority low code-points 011
```
2. Configure PFC on the FCoE queue by applying FCoE to the IEEE 802.1 code point 011:

```
[edit class-of-service]
user@switch# set congestion-notification-profile fcoe-cnp input ieee-802.1 code-point
011 pfc
```

3. Apply the PFC configuration to the ingress interfaces:

```
[edit class-of-service]
user@switch# set interfaces xe-0/0/31 congestion-notification-profile fcoe-cnp
user@switch# set interfaces xe-0/0/32 congestion-notification-profile fcoe-cnp
user@switch# set interfaces xe-0/0/33 congestion-notification-profile fcoe-cnp
user@switch# set interfaces xe-0/0/34 congestion-notification-profile fcoe-cnp
```

4. Assign the classifier to the ingress interfaces:

```
[edit class-of-service]
user@switch# set interfaces xe-0/0/31 unit 0 classifiers ieee-802.1 fcoe-classifier
user@switch# set interfaces xe-0/0/32 unit 0 classifiers ieee-802.1 fcoe-classifier
user@switch# set interfaces xe-0/0/33 unit 0 classifiers ieee-802.1 fcoe-classifier
user@switch# set interfaces xe-0/0/34 unit 0 classifiers ieee-802.1 fcoe-classifier
```

5. Configure output scheduling for the FCoE queue:

```
[edit class-of-service]
user@switch# set schedulers fcoe-sched priority low transmit-rate 3g
user@switch# set schedulers fcoe-sched shaping-rate percent 100
```

6. Map the FCoE forwarding class to the FCoE scheduler:

```
[edit class-of-service]
user@switch# set scheduler-maps fcoe-map forwarding-class fcoe scheduler fcoe-sched
```

7. Configure the forwarding class set for the FCoE traffic:

```
[edit class-of-service]
user@switch# set forwarding-class-sets fcoe-pg class fcoe
```

8. Define the traffic control profile for the FCoE forwarding class set:

```
[edit class-of-service]
user@switch# set traffic-control-profiles fcoe-tcp scheduler-map fcoe-map
guaranteed-rate 3g
user@switch# set traffic-control-profiles fcoe-tcp shaping-rate percent 100
```

9. Apply the FCoE forwarding class set and traffic control profile to the egress ports:

```
[edit class-of-service]
user@switch# set interfaces xe-0/0/31 forwarding-class-set fcoe-pg
output-traffic-control-profile fcoe-tcp
user@switch# set interfaces xe-0/0/32 forwarding-class-set fcoe-pg
output-traffic-control-profile fcoe-tcp
user@switch# set interfaces xe-0/0/33 forwarding-class-set fcoe-pg
output-traffic-control-profile fcoe-tcp
user@switch# set interfaces xe-0/0/34 forwarding-class-set fcoe-pg
output-traffic-control-profile fcoe-tcp
```

Results

Display the results of the configuration (the system shows only the explicitly configured parameters; it does not show default parameters such as the **fcoe** lossless forwarding class):

```
user@switch> show configuration class-of-service
classifiers {
```

```
ieee-802.1 fcoe-classifier {
  forwarding-class fcoe {
    loss-priority low code-points 011;
  }
}
traffic-control-profiles {
  fcoe-tcp {
    scheduler-map fcoe-map;
    shaping-rate percent 100;
    guaranteed-rate 3000000000;
  }
}
forwarding-class-sets {
  fcoe-pg {
    class fcoe;
  }
}
congestion-notification-profile {
  fcoe-cnp {
    input {
      ieee-802.1 {
        code-point 011 {
          pfc;
        }
      }
    }
  }
}
}
interfaces {
  xe-0/0/31 {
    congestion-notification-profile fcoe-cnp;
    forwarding-class-set {
      fcoe-pg {
        output-traffic-control-profile fcoe-tcp;
      }
    }
    unit 0 {
      classifiers {
        ieee-802.1 fcoe-classifier;
      }
    }
  }
  xe-0/0/32 {
    congestion-notification-profile fcoe-cnp;
    forwarding-class-set {
      fcoe-pg {
        output-traffic-control-profile fcoe-tcp;
      }
    }
    unit 0 {
      classifiers {
        ieee-802.1 fcoe-classifier;
      }
    }
  }
  xe-0/0/33 {
```

```

congestion-notification-profile fcoe-cnp;
forwarding-class-set {
    fcoe-pg {
        output-traffic-control-profile fcoe-tcp;
    }
}
unit 0 {
    classifiers {
        ieee-802.1 fcoe-classifier;
    }
}
}
xe-0/0/34 {
    congestion-notification-profile fcoe-cnp;
    forwarding-class-set {
        fcoe-pg {
            output-traffic-control-profile fcoe-tcp;
        }
    }
    unit 0 {
        classifiers {
            ieee-802.1 fcoe-classifier;
        }
    }
}
}
scheduler-maps {
    fcoe-map {
        forwarding-class fcoe scheduler fcoe-sched;
    }
}
schedulers {
    fcoe-sched {
        transmit-rate 3000000000;
        shaping-rate percent 100;
        priority low;
    }
}
}

```

TIP: To quickly configure the interfaces, issue the `load merge terminal` command and then copy the hierarchy and paste it into the switch terminal window.

Verification

To verify that the PFC configuration for FCoE traffic components has been created and is operating properly, perform these tasks:

- [Verifying That Priority-Based Flow Control Has Been Enabled on page 4928](#)
- [Verifying the Ingress Interface PFC Configuration on page 4928](#)

Verifying That Priority-Based Flow Control Has Been Enabled

Purpose Verify that PFC is enabled on the FCoE queue to enable lossless transport.

Action List the congestion notification profiles using the operational mode command **show class-of-service congestion-notification**:

```
user@switch> show class-of-service congestion-notification
```

```
Type: Input, Name: fcoe-cnp, Index: 51697
```

```
Cable Length: 100 m
```

| Priority | PFC | MRU |
|----------|----------|------|
| 000 | Disabled | |
| 001 | Disabled | |
| 010 | Disabled | |
| 011 | Enabled | 2500 |
| 100 | Disabled | |
| 101 | Disabled | |
| 110 | Disabled | |
| 111 | Disabled | |

```
Type: Output
```

| Priority | Flow-Control-Queues |
|----------|---------------------|
| 000 | |
| | 0 |
| 001 | |
| | 1 |
| 010 | |
| | 2 |
| 011 | |
| | 3 |
| 100 | |
| | 4 |
| 101 | |
| | 5 |
| 110 | |
| | 6 |
| 111 | |
| | 7 |

Meaning The **show class-of-service congestion-notification** operational command lists all of the congestion notification profiles and which IEEE 802.1p code points have PFC enabled. The command output shows that PFC is enabled on code point **011** for the **fcoe-cnp** congestion notification profile.

The command also shows the default cable length (100 meters), the default maximum receive unit (2500 bytes), and the default mapping of priorities to output queues because this example does not include configuring these options.

Verifying the Ingress Interface PFC Configuration

Purpose Verify that the classifier **fcoe-classifier** and the congestion notification profile **fcoe-cnp** are configured on ingress interfaces **xe-0/0/31**, **xe-0/0/32**, **xe-0/0/33**, and **xe-0/0/34**.

Action List the ingress interfaces using the operational mode command **show configuration class-of-service interfaces**:

```
user@switch> show configuration class-of-service interfaces xe-0/0/31
```

```

congestion-notification-profile fcoe-cnp;
unit 0 {
    classifiers {
        ieee-802.1 fcoe-classifier;
    }
}

user@switch> show configuration class-of-service interfaces xe-0/0/32
congestion-notification-profile fcoe-cnp;
unit 0 {
    classifiers {
        ieee-802.1 fcoe-classifier;
    }
}

user@switch> show configuration class-of-service interfaces xe-0/0/33
congestion-notification-profile fcoe-cnp;
unit 0 {
    classifiers {
        ieee-802.1 fcoe-classifier;
    }
}

user@switch> show configuration class-of-service interfaces xe-0/0/34
congestion-notification-profile fcoe-cnp;
unit 0 {
    classifiers {
        ieee-802.1 fcoe-classifier;
    }
}

```

Meaning The **show configuration class-of-service interfaces** commands list the congestion notification profile that is mapped to the interface (**fcoe-cnp**) and the IEEE 802.1p classifier associated with the interface (**fcoe-classifier**).

- Related Documentation**
- [Example: Configuring CoS Hierarchical Port Scheduling \(ETS\) on page 5474](#)
 - [Configuring CoS PFC \(Congestion Notification Profiles\) on page 5685](#)

 - [Understanding CoS Flow Control \(Ethernet PAUSE and PFC\) on page 4885](#)

Example: Configuring DCBX Application Protocol TLV Exchange

Data Center Bridging Capability Exchange protocol (DCBX) discovers the data center bridging (DCB) capabilities of connected peers by exchanging application configuration information. DCBX detects feature misconfiguration and mismatches and can configure DCB on peers. DCBX is an extension of the Link Layer Discovery Protocol (LLDP). LLDP must remain enabled on every interface on which you want to use DCBX.

NOTE: LLDP and DCBX are enabled by default on all interfaces.

The switch supports DCBX application protocol exchange for Layer 2 and Layer 4 applications such as the Internet Small Computer System Interface (iSCSI). You specify applications by EtherType (for Layer 2 applications) or by the destination port and protocol (for Layer 4 applications; the protocol can be either TCP or UDP).

The QFX Series handles Fibre Channel over Ethernet (FCoE) application protocol exchange differently than other protocols in some cases:

- If FCoE is the only application for which you want to enable DCBX application protocol TLV exchange on an interface, you do not have to explicitly configure the FCoE application or an application map. By default, the QFX Series exchanges FCoE application protocol TLVs on all interfaces that carry FCoE traffic (traffic mapped to the **fcoe** forwarding class) and have priority-based flow control (PFC) enabled on the FCoE priority (the FCoE IEEE 802.1p code point). The default priority mapping for the FCoE application is IEEE 802.1p code point 011 (the default **fcoe** forwarding class code point).
- If you want an interface to use DCBX to exchange application protocol TLVs for any other applications in addition to FCoE, you must configure the applications (including FCoE), define an application map (including FCoE), and apply the application map to the interface. If you apply an application map to an interface, you must explicitly configure the FCoE application, or the interface does not exchange FCoE application protocol TLVs.

This example shows how to configure interfaces to exchange both Layer 2 and Layer 4 applications by configuring one interface to exchange iSCSI and FCoE application protocol information and configuring another interface to exchange iSCSI and Precision Time Protocol (PTP) application protocol information.

- [Requirements on page 4930](#)
- [Overview on page 4930](#)
- [Configuration on page 4934](#)
- [Verification on page 4936](#)

Requirements

This example uses the following hardware and software components:

- Juniper Networks QFX Series device
- Junos OS Release 12.1 or later for the QFX Series

Overview

The switch supports DCBX application protocol exchange for:

- Layer 2 applications, defined by EtherType
- Layer 4 applications, defined by destination port and protocol

NOTE: DCBX also advertises PFC and enhanced transmission selection (ETS) information. See [“Configuring DCBX Autonegotiation” on page 5076](#) for how DCBX negotiates and advertises configuration information for these features and for the applications.

DCBX is configured on a per-interface basis for each supported feature or application. For applications that you want to enable for DCBX application protocol exchange, you must:

- Define the application name and configure the EtherType or the destination port and protocol (TCP or UDP) of the application. Use the EtherType for Layer 2 applications, and use the destination port and protocol for Layer 4 protocols.
- Map the application to an IEEE 802.1p code point in an application map.
- Add the application map to DCBX interface.

In addition, for all applications (including FCoE, even when you do not use an application map), you either must create an IEEE 802.1p classifier and apply it to the appropriate ingress interfaces or use the default classifier. A classifier maps the code points of incoming traffic to a forwarding class and a loss priority so that ingress traffic is assigned to the correct class of service (CoS). The forwarding class determines the output queue on the egress interface.

If you do not create classifiers, trunk and tagged-access ports use the unicast IEEE 802.1 default trusted classifier. [Table 380 on page 4931](#) shows the default mapping of IEEE 802.1 code-point values to unicast forwarding classes and loss priorities for ports in trunk mode or tagged-access mode. [Table 381 on page 4932](#) shows the default untrusted classifier IEEE 802.1 code-point values to unicast forwarding class mapping for ports in access mode.

Table 380: Default IEEE 802.1 Classifiers for Trunk Ports and Tagged-Access Ports (Default Trusted Classifier)

| Code Point | Forwarding Class | Loss Priority |
|------------|------------------|---------------|
| be (000) | best-effort | low |
| be1 (001) | best-effort | low |
| ef (010) | best-effort | low |
| ef1 (011) | fcoe | low |
| af11 (100) | no-loss | low |
| af12 (101) | best-effort | low |
| nc1 (110) | network-control | low |

Table 380: Default IEEE 802.1 Classifiers for Trunk Ports and Tagged-Access Ports (Default Trusted Classifier) (continued)

| Code Point | Forwarding Class | Loss Priority |
|------------|------------------|---------------|
| nc2 (111) | network-control | low |

Table 381: Default IEEE 802.1 Unicast Classifiers for Access Ports (Default Untrusted Classifier)

| Code Point | Forwarding Class | Loss Priority |
|------------|------------------|---------------|
| 000 | best-effort | low |
| 001 | best-effort | low |
| 010 | best-effort | low |
| 011 | best-effort | low |
| 100 | best-effort | low |
| 101 | best-effort | low |
| 110 | best-effort | low |
| 111 | best-effort | low |

Topology

This example shows how to configure DCBX application protocol exchange for three protocols (iSCSI, PTP, and FCoE) on two interfaces. One interface exchanges iSCSI and FCoE application protocol information, and the other interface exchanges iSCSI and PTP application protocol information.

NOTE: You must map FCoE traffic to the interfaces on which you want to forward FCoE traffic. You must also enable PFC on the FCoE interfaces and create an ingress classifier for FCoE traffic, or else use the default classifier.

Table 382 on page 4932 shows the configuration components for this example.

Table 382: Components of DCBX Application Protocol Exchange Configuration Topology

| Component | Settings |
|-----------|---|
| Hardware | QFX Series device |
| LLDP | Enabled by default on Ethernet interfaces |

Table 382: Components of DCBX Application Protocol Exchange Configuration Topology (*continued*)

| Component | Settings |
|---|--|
| DCBX | Enabled by default on Ethernet interfaces |
| iSCSI application (Layer 4) | Application name— iscsi
protocol— TCP
destination-port— 3260
code-points— 111 |
| PTP application (Layer 2) | Application name— ptp
ether-type— 0x88F7
code-points— 001, 101 |
| FCoE application (Layer 2) | Application name— fcoe
ether-type— 0x8906
code-points— 011

NOTE: You explicitly configure the FCoE application because you are applying an application map to the interface. When you apply an application map to an interface, all applications must be explicitly configured and included in the application map. |
| Application maps | dcbx-iscsi-fcoe-app-map —Maps the iSCSI and FCoE applications to IEEE 802.1p code points

dcbx-iscsi-ptp-app-map —Maps iSCSI and PTP applications to IEEE 802.1p code points |
| Interfaces | xe-0/0/10 —Configured to exchange FCoE and iSCSI application TLVs (uses application map dcbx-iscsi-fcoe-app-map , carries FCoE traffic, and has PFC enabled on the FCoE priority)

xe-0/0/11 —Configured to exchange iSCSI and PTP application TLVs (uses application map dcbx-iscsi-ptp-app-map) |
| PFC congestion notification profile for FCoE application exchange | fcoe-cnp: <ul style="list-style-type: none"> Code point—011 Interface—xe-0/0/10 |

Table 382: Components of DCBX Application Protocol Exchange Configuration Topology (*continued*)

| Component | Settings |
|---|---|
| Behavior aggregate classifiers (map forwarding classes to incoming packets by the packet's IEEE 802.1 code point) | <p>fcoe-iscsi-cl1:</p> <ul style="list-style-type: none"> Maps the fcoe forwarding class to the IEEE 802.1p code point used for the FCoE application (011) and a loss priority of high Maps the network-control forwarding class to the IEEE 802.1p code point used for the iSCSI application (111) and a loss priority of high Applied to interface xe-0/0/10 <p>iscsi-ntp-cl2:</p> <ul style="list-style-type: none"> Maps the network-control forwarding class to the IEEE 802.1p code point used for the iSCSI application (111) and a loss priority of low Maps the best-effort forwarding class to the IEEE 802.1p code points used for the PTP application (001 and 101) and a loss priority of low Applied to interface xe-0/0/11 |

NOTE: This example does not include scheduling (bandwidth allocation) configuration or lossless configuration for the iSCSI forwarding class.

Configuration

CLI Quick Configuration

To quickly configure DCBX application protocol exchange, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```

set applications application iSCSI protocol tcp destination-port 3260
set applications application FCoE ether-type 0x8906
set applications application PTP ether-type 0x88F7
set policy-options application-maps dcbx-iscsi-fcoe-app-map application iSCSI code-points 111
set policy-options application-maps dcbx-iscsi-fcoe-app-map application FCoE code-points 011
set policy-options application-maps dcbx-iscsi-ntp-app-map application iSCSI code-points 111
set policy-options application-maps dcbx-iscsi-ntp-app-map application PTP code-points [001 101]
set protocols dcbx interface xe-0/0/10 application-map dcbx-iscsi-fcoe-app-map
set protocols dcbx interface xe-0/0/11 application-map dcbx-iscsi-ntp-app-map
set class-of-service congestion-notification-profile fcoe-cnp input ieee-802.1 code-point 011 pfc
set class-of-service interfaces xe-0/0/10 congestion-notification-profile fcoe-cnp
set class-of-service classifiers ieee-802.1 fcoe-iscsi-cl1 import default forwarding-class fcoe
loss-priority high code-points 011
set class-of-service classifiers ieee-802.1 fcoe-iscsi-cl1 import default forwarding-class
network-control loss-priority high code-points 111
set class-of-service classifiers ieee-802.1 iscsi-ntp-cl2 import default forwarding-class

set class-of-service classifiers ieee-802.1 iscsi-ntp-cl2 import default forwarding-class best-effort
loss-priority low code-points [001 101]
set class-of-service interfaces xe-0/0/10 unit 0 classifiers ieee-802.1 fcoe-iscsi-cl1

```

```
set class-of-service interfaces xe-0/0/11 unit 0 classifiers ieee-802.1 iscsi-ptp-cl2
```

Configuring DCBX Application Protocol TLV Exchange

Step-by-Step Procedure To define the applications, map the applications to IEEE 802.1p code points, apply the applications to interfaces, and create classifiers for DCBX application protocol exchange:

1. Define the iSCSI application by specifying its protocol and destination port, and define the FCoE and PTP applications by specifying their EtherTypes.

```
[edit applications]
user@switch# set application iSCSI protocol tcp destination-port 3260
user@switch# set application FCoE ether-type 0x8906
user@switch# set application PTP ether-type 0x88F7
```
2. Define an application map that maps the iSCSI and FCoE applications to IEEE 802.1p code points.

```
[edit policy-options]
user@switch# set application-maps dcbx-iscsi-fcoe-app-map application iSCSI code-points 111
user@switch# set application-maps dcbx-iscsi-fcoe-app-map application FCoE code-points 011
```
3. Define the application map that maps the iSCSI and PTP applications to IEEE 802.1p code points.

```
[edit policy-options]
user@switch# set application-maps dcbx-iscsi-ptp-app-map application iSCSI code-points 111
user@switch# set application-maps dcbx-iscsi-ptp-app-map application PTP code-points [001 101]
```
4. Apply the iSCSI and FCoE application map to interface xe-0/0/10, and apply the iSCSI and PTP application map to interface xe-0/0/11.

```
[edit protocols dcbx]
user@switch# set interface xe-0/0/10 application-map dcbx-iscsi-fcoe-app-map
user@switch# set interface xe-0/0/11 application-map dcbx-iscsi-ptp-app-map
```
5. Create the congestion notification profile to enable PFC on the FCoE code point (011), and apply the congestion notification profile to interface xe-0/0/10.

```
[edit class-of-service]
user@switch# set congestion-notification-profile fcoe-cnp input ieee-802.1 code-point 011 pfc
user@switch# set interfaces xe-0/0/10 congestion-notification-profile fcoe-cnp
```
6. Configure the classifier to apply to the interface that exchanges iSCSI and FCoE application information.

```
[edit class-of-service classifiers]
user@switch# set ieee-802.1 fcoe-iscsi-cl1 import default forwarding-class fcoe loss-priority high code-points 011
user@switch# set ieee-802.1 fcoe-iscsi-cl1 import default forwarding-class network-control loss-priority high code-points 111
```
7. Configure the classifier to apply to the interface that exchanges iSCSI and PTP application information.

```
[edit class-of-service classifiers]
```

```
user@switch# set ieee-802.1 iscsi-ptp-cl2 import default forwarding-class network-control
loss-priority low code-points 111
user@switch# set ieee-802.1 iscsi-ptp-cl2 import default forwarding-class best-effort
loss-priority low code-points [001 101]
```

8. Apply the classifiers to the appropriate interfaces.

```
[edit class-of-service]
user@switch# set interfaces xe-0/0/10 unit 0 classifiers ieee-802.1 fcoe-iscsi-cl1
user@switch# set interfaces xe-0/0/11 unit 0 classifiers ieee-802.1 iscsi-ptp-cl2
```

Verification

To verify that DCBX application protocol exchange configuration has been created and is operating properly, perform these tasks:

- [Verifying the Application Configuration on page 4936](#)
- [Verifying the Application Map Configuration on page 4936](#)
- [Verifying DCBX Application Protocol Exchange Interface Configuration on page 4937](#)
- [Verifying the PFC Configuration on page 4937](#)
- [Verifying the Classifier Configuration on page 4938](#)

Verifying the Application Configuration

Purpose Verify that DCBX applications have been configured.

Action List the applications by using the configuration mode command **show applications**:

```
user@switch# show applications
application iSCSI {
    protocol tcp;
    destination-port 3260;
}

application fcoe {
    ether-type 0x8906;
}

application ptp {
    ether-type 0x88F7;
}
```

Meaning The **show applications** configuration mode command lists all of the configured applications and either their protocol and destination port (Layer 4 applications) or their EtherType (Layer 2 applications). The command output shows that the iSCSI application is configured with the **tcp** protocol and destination port **3260**, the FCoE application is configured with the EtherType **0x8906**, and that the PTP application is configured with the EtherType **0x88F7**.

Verifying the Application Map Configuration

Purpose Verify that the application maps have been configured.

Action List the application maps by using the configuration mode command **show policy-options application-maps**:

```
user@switch# show policy-options application-maps
dcbx-iscsi-fcoe-app-map {
    application iSCSI code-points 111;
    application FCoE code-points 011;
}

dcbx-iscsi-ptp-app-map {
    application iSCSI code-points 111;
    application PTP code-points [001 101];
}
```

Meaning The **show policy-options application-maps** configuration mode command lists all of the configured application maps and the applications that belong to each application map. The command output shows that there are two application maps, **dcbx-iscsi-fcoe-app-map** and **dcbx-iscsi-ptp-app-map**.

The application map **dcbx-iscsi-fcoe-app-map** consists of the iSCSI application, which is mapped to IEEE 802.1p code point 111, and the FCoE application, which is mapped to IEEE 802.1p code point 011.

The application map **dcbx-iscsi-ptp-app-map** consists of the iSCSI application, which is mapped to IEEE 802.1p code point 111, and the PTP application, which is mapped to IEEE 802.1p code points 001 and 101.

Verifying DCBX Application Protocol Exchange Interface Configuration

Purpose Verify that the application maps have been applied to the correct interfaces.

Action List the application maps by using the configuration mode command **show protocols dcbx**:

```
user@switch# show protocols dcbx
interface xe-0/0/10.0 {
    application-map dcbx-iscsi-fcoe-app-map;
}

interface xe-0/0/11.0 {
    application-map dcbx-iscsi-ptp-app-map;
}
```

Meaning The **show protocols dcbx** configuration mode command lists whether the interfaces are enabled for DCBX and lists the application map applied to each interface. The command output shows that interfaces **xe-0/0/10.0** and **xe-0/0/11.0** are enabled for DCBX, and that interface **xe-0/0/10.0** uses application map **dcbx-iscsi-fcoe-app-map**, and interface **xe-0/0/11.0** uses application map **dcbx-iscsi-ptp-app-map**.

Verifying the PFC Configuration

Purpose Verify that PFC has been enabled on the FCoE code point and applied to the correct interface.

Action Display the PFC configuration to verify that PFC is enabled on the FCoE code point (011) in the congestion notification profile **fcoe-cnp** by using the configuration mode command **show class-of-service congestion-notification-profile**:

```
user@switch# show class-of-service congestion-notification-profile
fcoe-cnp {
  input {
    ieee-802.1 {
      code-point 011 {
        pfc;
      }
    }
  }
}
```

Display the class-of-service (CoS) interface information to verify that the correct interface has PFC enabled for the FCoE application by using the configuration mode command **show class-of-service interfaces**:

```
user@switch# show class-of-service interfaces
xe-0/0/10 {
  congestion-notification-profile fcoe-cnp;
}
```

NOTE: The sample output does not include all of the information this command can show. The output is abbreviated to focus on verifying the PFC configuration.

Meaning The **show class-of-service congestion-notification-profile** configuration mode command lists the configured congestion notification profiles. The command output shows that the congestion notification profile **fcoe-cnp** has been configured and has enabled PFC on the IEEE 802.1p code point **011** (the default FCoE code point).

The **show class-of-service interfaces** configuration mode command shows the interface CoS configuration. The command output shows that the congestion notification profile **fcoe-cnp**, which enables PFC on the FCoE code point, is applied to interface **xe-0/0/10**.

Verifying the Classifier Configuration

Purpose Verify that the classifiers have been configured and applied to the correct interfaces.

Action Display the classifier configuration by using the configuration mode command **show class-of-service**:

```
user@switch# show class-of-service
classifiers {
  ieee-802.1 fcoe-iscsi-cl1 {
    import default;
    forwarding-class network-control {
      loss-priority high code-points 111;
    }
  }
  forwarding-class fcoe {
    loss-priority high code-points 011;
  }
}
```

```

    }
  }
  ieee-802.1 iscsi-ptp-cl2 {
    import default;
    forwarding-class network-control {
      loss-priority low code-points 111;
    }
    forwarding-class best-effort {
      loss-priority low code-points [ 001 101 ];
    }
  }
}
interfaces {
  xe-0/0/10 {
    congestion-notification-profile fcoe-cnp;
    unit 0 {
      classifiers {
        ieee-802.1 fcoe-iscsi-cl1;
      }
    }
  }
  xe-0/0/11 {
    unit 0 {
      classifiers {
        ieee-802.1 iscsi-ptp-cl2;
      }
    }
  }
}
}

```

NOTE: The sample output does not include all of the information this command can show. The output is abbreviated to focus on verifying the classifier configuration.

Meaning The **show class-of-service** configuration mode command lists the classifier and CoS interface configuration, as well as other information not shown in this example. The command output shows that there are two classifiers configured, **fcoe-iscsi-cl1** and **iscsi-ptp-cl2**.

Classifier **fcoe-iscsi-cl1** uses the **default** classifier as a template and edits the template as follows:

- The forwarding class **network-control** is set to a loss priority of **high** and is mapped to code point **111** (the code point mapped to the iSCSI application).
- The forwarding class **fcoe** is set to a loss priority of **high** and is mapped to code point **011** (the code point mapped by default to the FCoE application).

Classifier **iscsi-ptp-cl2** uses the **default** classifier as a template and edits the template as follows:

- The forwarding class **network-control** is set to a loss priority of **low** and is mapped to IEEE 802.1p code point **111** (the code point mapped to the iSCSI application).

- The forwarding class **best-effort** is set to a loss priority of **low** and is mapped to IEEE 802.1p code points **001** and **101** (the code points mapped by default to the PTP application).

The command output also shows that classifier **fcoe-iscsi-cl1** is mapped to interface **xe-0/0/10.0** and that classifier **iscsi-ptp-cl2** is mapped to interface **xe-0/0/11.0**.

Example: Configuring CoS for FCoE Transit Switch Traffic Across an MC-LAG

Multichassis link aggregation groups (MC-LAGs) provide redundancy and load balancing between two QFX Series switches, multihoming support for client devices such as servers, and a loop-free Layer 2 network without running Spanning Tree Protocol (STP).

NOTE: This example uses Junos OS without support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that supports ELS, see [“Example: Configuring CoS for FCoE Transit Switch Traffic Across an MC-LAG” on page 5002](#).

You can use an MC-LAG to provide a redundant aggregation layer for Fiber Channel over Ethernet (FCoE) traffic in an *inverted-U* topology. To support lossless transport of FCoE traffic across an MC-LAG, you must configure the appropriate class of service (CoS) on both of the QFX Series switches with MC-LAG port members. The CoS configuration must be the same on both of the MC-LAG switches because an MC-LAG does not carry forwarding class and IEEE 802.1p priority information.

NOTE: This example describes how to configure CoS to provide lossless transport for FCoE traffic across an MC-LAG that connects two QFX Series switches. It also describes how to configure CoS on the FCoE transit switches that connect FCoE hosts to the QFX Series switches that form the MC-LAG.

This example does *not* describe how to configure the MC-LAG itself. For a detailed example of MC-LAG configuration, see [“Example: Configuring Multichassis Link Aggregation” on page 1904](#). However, this example includes a subset of MC-LAG configuration that only shows how to configure interface membership in the MC-LAG.

Ports that are part of an FCoE-FC gateway configuration (a virtual FCoE-FC gateway fabric) do not support MC-LAGs. Ports that are members of an MC-LAG act as FCoE passthrough transit switch ports.

QFX Series switches support MC-LAGs. QFabric system Node devices do not support MC-LAGs, and QFX3500 and QFX3600 Virtual Chassis switches do not support FCoE.

This topic describes:

- [Requirements on page 4941](#)
- [Overview on page 4942](#)
- [Configuration on page 4946](#)
- [Verification on page 4954](#)

Requirements

This example uses the following hardware and software components:

- Two Juniper Networks QFX3500 Switches that form an MC-LAG for FCoE traffic.
- Two Juniper Networks QFX3500 Switches that provide FCoE server access in transit switch mode and that connect to the MC-LAG switches. These switches can be standalone QFX3500 switches or they can be Node devices in a QFabric system.
- FCoE servers (or other FCoE hosts) connected to the transit switches.
- Junos OS Release 12.2 or later for the QFX Series.

Overview

FCoE traffic requires lossless transport. This example shows you how to:

- Configure CoS for FCoE traffic on the two QFX3500 switches that form the MC-LAG, including priority-based flow control (PFC) and enhanced transmission selection (ETS; hierarchical scheduling of resources for the FCoE forwarding class priority and for the forwarding class set priority group).

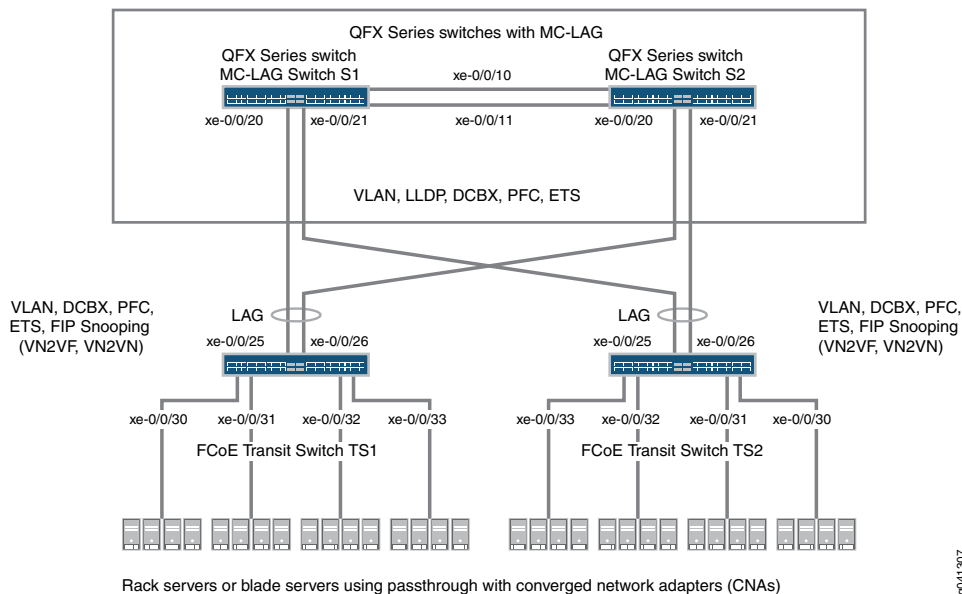

NOTE: Configuring or changing PFC on an interface blocks the entire port until the PFC change is completed. After a PFC change is completed, the port is unblocked and traffic resumes. Blocking the port stops ingress and egress traffic, and causes packet loss on all queues on the port until the port is unblocked.

- Configure CoS for FCoE on the two FCoE transit switches that connect FCoE hosts to the MC-LAG switches and enable FIP snooping on the FCoE VLAN at the FCoE transit switch access ports.
- Disable IGMP snooping on the FCoE VLAN.
- Configure the appropriate port mode, MTU, and FCoE trusted or untrusted state for each interface to support lossless FCoE transport.

Topology

QFX3500 switches that act as transit switches support MC-LAGs for FCoE traffic in an inverted-U network topology, as shown in [Figure 180 on page 4942](#).

Figure 180: Supported Topology for an MC-LAG on an FCoE Transit Switch

[Table 383 on page 4943](#) shows the configuration components for this example.

Table 383: Components of the CoS for FCoE Traffic Across an MC-LAG Configuration Topology

| Component | Settings |
|--|--|
| Hardware | Four QFX3500 switches (two to form the MC-LAG as passthrough transit switches and two transit switches for FCoE access). |
| Forwarding class (all switches) | Default fcoe forwarding class. |
| Classifier (forwarding class mapping of incoming traffic to IEEE priority) | Default IEEE 802.1p trusted classifier on all FCoE interfaces. |
| LAGs and MC-LAG | <p>S1—Ports xe-0/0/10 and x-0/0/11 are members of LAG ae0, which connects Switch S1 to Switch S2.

ID— 100

Include the FCoE VLAN on the interfaces that carry FCoE traffic on all four switches.

Disable IGMP snooping on the interfaces that belong to the FCoE VLAN on all four switches. |
| FIP snooping | Enable FIP snooping on Transit Switches TS1 and TS2 on the FCoE VLAN. Configure the LAG interfaces that connect to the MC-LAG switches as FCoE trusted interfaces so that they do not perform FIP snooping.

This example enables VN2VN_Port FIP snooping on the FCoE transit switch interfaces connected to the FCoE servers. The example is equally valid with VN2VF_Port FIP snooping enabled on the transit switch access ports. The method of FIP snooping you enable depends on your network configuration. |

NOTE: This example uses the default IEEE 802.1p trusted BA classifier, which is automatically applied to trunk mode and tagged access mode ports if you do not apply an explicitly configured classifier.

To configure CoS for FCoE traffic across an MC-LAG:

- Use the default FCoE forwarding class and forwarding-class-to-queue mapping (do not explicitly configure the FCoE forwarding class or output queue). The default FCoE forwarding class is `fcoe`, and the default output queue is `queue 3`.

NOTE: In Junos OS Release 12.2, traffic mapped to explicitly configured forwarding classes, even lossless forwarding classes such as `fcoe`, is treated as lossy (best-effort) traffic and does *not* receive lossless treatment. To receive lossless treatment in Release 12.2, traffic must use one of the default lossless forwarding classes (`fcoe` or `no-loss`).

In Junos OS Release 12.3 and later, you can include the *no-loss* packet drop attribute in the explicit forwarding class configuration to configure a lossless forwarding class.

- Use the default trusted BA classifier, which maps incoming packets to forwarding classes by the IEEE 802.1p code point (CoS priority) of the packet. The trusted classifier is the default classifier for interfaces in trunk and tagged-access port modes. The default trusted classifier maps incoming packets with the IEEE 802.1p code point 3 (011) to the FCoE forwarding class. If you choose to configure the BA classifier instead of using the default classifier, you must ensure that FCoE traffic is classified into forwarding classes in exactly the same way on both MC-LAG switches. Using the default classifier ensures consistent classifier configuration on the MC-LAG ports.
- Configure a congestion notification profile that enables PFC on the FCoE code point (code point 011 in this example). The congestion notification profile configuration must be the same on both MC-LAG switches.
- Apply the congestion notification profile to the interfaces.
- Configure enhanced transmission selection (ETS, also known as hierarchical scheduling) on the interfaces to provide the bandwidth required for lossless FCoE transport. Configuring ETS includes configuring bandwidth scheduling for the FCoE forwarding class, a forwarding class set (priority group) that includes the FCoE forwarding class, and a traffic control profile to assign bandwidth to the forwarding class set that includes FCoE traffic.
- Apply the ETS scheduling to the interfaces.
- Configure the port mode, MTU, and FCoE trusted or untrusted state for each interface to support lossless FCoE transport.

In addition, this example describes how to enable FIP snooping on the Transit Switch TS1 and TS2 ports that are connected to the FCoE servers and how to disable IGMP

snooping on the FCoE VLAN. To provide secure access, FIP snooping must be enabled on the FCoE access ports.

This example focuses on the CoS configuration to support lossless FCoE transport across an MC-LAG. This example does not describe how to configure the properties of MC-LAGs and LAGs, although it does show you how to configure the port characteristics required to support lossless transport and how to assign interfaces to the MC-LAG and to the LAGs.

Before you configure CoS, configure:

- The MC-LAGs that connect Switches S1 and S2 to Switches TS1 and TS2. ([“Example: Configuring Multichassis Link Aggregation” on page 1904](#) describes how to configure MC-LAGs.)
- The LAGs that connect the Transit Switches TS1 and TS2 to MC-LAG Switches S1 and S2. ([“Configuring Link Aggregation” on page 2019](#) describes how to configure LAGs.)
- The LAG that connects Switch S1 to Switch S2.

Configuration

To configure CoS for lossless FCoE transport across an MC-LAG, perform these tasks:

- [Configuring MC-LAG Switches S1 and S2 on page 4948](#)
- [Configuring FCoE Transit Switches TS1 and TS2 on page 4949](#)
- [Results on page 4952](#)

CLI Quick Configuration

To quickly configure CoS for lossless FCoE transport across an MC-LAG, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI for MC-LAG Switch S1 and MC-LAG Switch S2 at the **[edit]** hierarchy level. The configurations on Switches S1 and S2 are identical because the CoS configuration must be identical, and because this example uses the same ports on both switches.

Switch S1 and Switch S2

```
set class-of-service schedulers fcoe-sched priority low transmit-rate 3g
set class-of-service schedulers fcoe-sched shaping-rate percent 100
set class-of-service scheduler-maps fcoe-map forwarding-class fcoe scheduler fcoe-sched
set class-of-service forwarding-class-sets fcoe-pg class fcoe
set class-of-service traffic-control-profiles fcoe-tcp scheduler-map fcoe-map guaranteed-rate
3g
set class-of-service traffic-control-profiles fcoe-tcp shaping-rate percent 100
set class-of-service interfaces ae0 forwarding-class-set fcoe-pg output-traffic-control-profile
fcoe-tcp
set class-of-service interfaces ae1 forwarding-class-set fcoe-pg output-traffic-control-profile
fcoe-tcp
set class-of-service congestion-notification-profile fcoe-cnp input ieee-802.1 code-point 011 pfc
set class-of-service interfaces ae0 congestion-notification-profile fcoe-cnp
set class-of-service interfaces ae1 congestion-notification-profile fcoe-cnp
set vlans fcoe_vlan vlan-id 100
set protocols igmp-snooping vlan fcoe_vlan disable

beacon-period 90000
```

Configuring MC-LAG Switches S1 and S2

Step-by-Step Procedure

To configure CoS resource scheduling (ETS), PFC, the FCoE VLAN, and the LAG and MC-LAG interface membership and characteristics to support lossless FCoE transport across an MC-LAG (this example uses the default **fcoe** forwarding class and the default classifier to map incoming FCoE traffic to the FCoE IEEE 802.1p code point **011**, so you do not configure them):

1. Configure output scheduling for the FCoE queue:

```
[edit class-of-service]
user@switch# set schedulers fcoe-sched priority low transmit-rate 3g
user@switch# set schedulers fcoe-sched shaping-rate percent 100
```
2. Map the FCoE forwarding class to the FCoE scheduler (**fcoe-sched**):

```
[edit class-of-service]
user@switch# set scheduler-maps fcoe-map forwarding-class fcoe scheduler fcoe-sched
```
3. Configure the forwarding class set (**fcoe-pg**) for the FCoE traffic:

```
[edit class-of-service]
user@switch# set forwarding-class-sets fcoe-pg class fcoe
```
4. Define the traffic control profile (**fcoe-tcp**) to use on the FCoE forwarding class set:

```
[edit class-of-service]
user@switch# set traffic-control-profiles fcoe-tcp scheduler-map fcoe-map
guaranteed-rate 3g
user@switch# set traffic-control-profiles fcoe-tcp shaping-rate percent 100
```
5. Apply the FCoE forwarding class set and traffic control profile to the LAG and MC-LAG interfaces:

```
[edit class-of-service]
user@switch# set interfaces ae0 forwarding-class-set fcoe-pg output-traffic-control-profile
fcoe-tcp
user@switch# set interfaces ae1 forwarding-class-set fcoe-pg output-traffic-control-profile
fcoe-tcp
```
6. Enable PFC on the FCoE priority by creating a congestion notification profile (**fcoe-cnp**) that applies FCoE to the IEEE 802.1 code point **011**:

```
[edit class-of-service]
user@switch# set congestion-notification-profile fcoe-cnp input ieee-802.1 code-point
011 pfc
```
7. Apply the PFC configuration to the LAG and MC-LAG interfaces:

```
[edit class-of-service]
user@switch# set interfaces ae0 congestion-notification-profile fcoe-cnp
user@switch# set interfaces ae1 congestion-notification-profile fcoe-cnp
```
8. Configure the VLAN for FCoE traffic (**fcoe_vlan**):

```
[edit vlans]
user@switch# set fcoe_vlan vlan-id 100
```

9. Disable IGMP snooping on the FCoE VLAN:

```
[edit protocols]
user@switch# set igmp-snooping vlan fcoe_vlan disable
```
10. Add the member interfaces to the LAG between the two MC-LAG switches:

```
[edit interfaces]
user@switch# set xe-0/0/10 ether-options 802.3ad ae0
user@switch# set xe-0/0/11 ether-options 802.3ad ae0
```
11. Add the member interfaces to the MC-LAG:

```
[edit interfaces]
user@switch# set xe-0/0/20 ether-options 802.3ad ae1
user@switch# set xe-0/0/21 ether-options 802.3ad ae1
```
12. Configure the port mode as **trunk** and membership in the FCoE VLAN (**fcoe_vlan**) for the LAG (**ae0**) and for the MC-LAG (**ae1**):

```
[edit interfaces]
user@switch# set interfaces ae0 unit 0 family ethernet-switching port-mode trunk vlan
members fcoe_vlan
user@switch# set interfaces ae1 unit 0 family ethernet-switching port-mode trunk vlan
members fcoe_vlan
```
13. Set the MTU to **2180** for the LAG and MC-LAG interfaces. 2180 bytes is the minimum size required to handle FCoE packets because of the payload and header sizes; you can configure the MTU to a higher number of bytes if desired, but not less than 2180 bytes:

```
[edit interfaces]
user@switch# set ae0 mtu 2180
user@switch# set ae1 mtu 2180
```
14. Set the LAG and MC-LAG interfaces as FCoE trusted ports. Ports that connect to other switches should be trusted and should not perform FIP snooping:

```
[edit]
user@switch# set ethernet-switching-options secure-access-port interface ae0 fcoe-trusted
user@switch# set ethernet-switching-options secure-access-port interface ae1 fcoe-trusted
```

Configuring FCoE Transit Switches TS1 and TS2

Step-by-Step Procedure The CoS configuration on FCoE Transit Switches TS1 and TS2 is similar to the CoS configuration on MC-LAG Switches S1 and S2. However, the port configurations differ, and you must enable FIP snooping on the Switch TS1 and Switch TS2 FCoE access ports.

To configure resource scheduling (ETS), PFC, the FCoE VLAN, and the LAG interface membership and characteristics to support lossless FCoE transport across the MC-LAG (this example uses the default **fcoe** forwarding class and the default classifier to map incoming FCoE traffic to the FCoE IEEE 802.1p code point **011**, so you do not configure them):

1. Configure output scheduling for the FCoE queue:

```
[edit class-of-service]
user@switch# set schedulers fcoe-sched priority low transmit-rate 3g
user@switch# set schedulers fcoe-sched shaping-rate percent 100
```
2. Map the FCoE forwarding class to the FCoE scheduler (**fcoe-sched**):

- ```
[edit class-of-service]
user@switch# set scheduler-maps fcoe-map forwarding-class fcoe scheduler fcoe-sched
```
3. Configure the forwarding class set (**fcoe-pg**) for the FCoE traffic:
- ```
[edit class-of-service]
user@switch# set forwarding-class-sets fcoe-pg class fcoe
```
4. Define the traffic control profile (**fcoe-tcp**) to use on the FCoE forwarding class set:
- ```
[edit class-of-service]
user@switch# set traffic-control-profiles fcoe-tcp scheduler-map fcoe-map
guaranteed-rate 3g
user@switch# set traffic-control-profiles fcoe-tcp shaping-rate percent 100
```
5. Apply the FCoE forwarding class set and traffic control profile to the LAG interface and to the FCoE access interfaces:
- ```
[edit class-of-service]
user@switch# set interfaces ae1 forwarding-class-set fcoe-pg output-traffic-control-profile
fcoe-tcp
user@switch# set class-of-service interfaces xe-0/0/30 forwarding-class-set fcoe-pg
output-traffic-control-profile fcoe-tcp
user@switch# set class-of-service interfaces xe-0/0/31 forwarding-class-set fcoe-pg
output-traffic-control-profile fcoe-tcp
user@switch# set class-of-service interfaces xe-0/0/32 forwarding-class-set fcoe-pg
output-traffic-control-profile fcoe-tcp
user@switch# set class-of-service interfaces xe-0/0/33 forwarding-class-set fcoe-pg
output-traffic-control-profile fcoe-tcp
```
6. Enable PFC on the FCoE priority by creating a congestion notification profile (**fcoe-cnp**) that applies FCoE to the IEEE 802.1 code point 011:
- ```
[edit class-of-service]
user@switch# set congestion-notification-profile fcoe-cnp input ieee-802.1 code-point
011 pfc
```
7. Apply the PFC configuration to the LAG interface and to the FCoE access interfaces:
- ```
[edit class-of-service]
user@switch# set interfaces ae1 congestion-notification-profile fcoe-cnp
user@switch# set class-of-service interfaces xe-0/0/30 congestion-notification-profile
fcoe-cnp
user@switch# set class-of-service interfaces xe-0/0/31 congestion-notification-profile
fcoe-cnp
user@switch# set class-of-service interfaces xe-0/0/32 congestion-notification-profile
fcoe-cnp
user@switch# set class-of-service interfaces xe-0/0/33 congestion-notification-profile
fcoe-cnp
```
8. Configure the VLAN for FCoE traffic (**fcoe_vlan**):
- ```
[edit vlans]
user@switch# set fcoe_vlan vlan-id 100
```
9. Disable IGMP snooping on the FCoE VLAN:
- ```
[edit protocols]
user@switch# set igmp-snooping vlan fcoe_vlan disable
```
10. Add the member interfaces to the LAG:
- ```
[edit interfaces]
user@switch# set xe-0/0/25 ether-options 802.3ad ae1
```

```
user@switch# set xe-0/0/26 ether-options 802.3ad ae1
```

11. On the LAG (**ae1**), configure the port mode as **trunk** and membership in the FCoE VLAN (**fcoe\_vlan**):

```
[edit interfaces]
user@switch# set interfaces ae1 unit 0 family ethernet-switching port-mode trunk vlan
members fcoe_vlan
```

12. On the FCoE access interfaces (**xe-0/0/30**, **xe-0/0/31**, **xe-0/0/32**, **xe-0/0/33**), configure the port mode as **tagged-access** and membership in the FCoE VLAN (**fcoe\_vlan**):

```
[edit interfaces]
user@switch# set interfaces xe-0/0/30 unit 0 family ethernet-switching port-mode
tagged-access vlan members fcoe_vlan
user@switch# set interfaces xe-0/0/31 unit 0 family ethernet-switching port-mode
tagged-access vlan members fcoe_vlan
user@switch# set interfaces xe-0/0/32 unit 0 family ethernet-switching port-mode
tagged-access vlan members fcoe_vlan
user@switch# set interfaces xe-0/0/33 unit 0 family ethernet-switching port-mode
tagged-access vlan members fcoe_vlan
```

13. Set the MTU to **2180** for the LAG and FCoE access interfaces. 2180 bytes is the minimum size required to handle FCoE packets because of the payload and header sizes; you can configure the MTU to a higher number of bytes if desired, but not less than 2180 bytes:

```
[edit interfaces]
user@switch# set ae1 mtu 2180
user@switch# set xe-0/0/30 mtu 2180
user@switch# set xe-0/0/31 mtu 2180
user@switch# set xe-0/0/32 mtu 2180
user@switch# set xe-0/0/33 mtu 2180
```

14. Set the LAG interface as an FCoE trusted port. Ports that connect to other switches should be trusted and should not perform FIP snooping:

```
[edit]
user@switch# set ethernet-switching-options secure-access-port interface ae1 fcoe-trusted
```

**NOTE:** Access ports **xe-0/0/30**, **xe-0/0/31**, **xe-0/0/32**, and **xe-0/0/33** are not configured as FCoE trusted ports. The access ports remain in the default state as untrusted ports because they connect directly to FCoE devices and must perform FIP snooping to ensure network security.

15. Enable FIP snooping on the FCoE VLAN to prevent unauthorized FCoE network access (this example uses VN2VN\_Port FIP snooping; the example is equally valid if you use VN2VF\_Port FIP snooping):

```
[edit]
user@switch# set ethernet-switching-options secure-access-port vlan fcoe_vlan
examine-fip examine-vn2vn beacon-period 90000
```

### Results

Display the results of the CoS configuration on MC-LAG Switch S1 and on MC-LAG Switch S2 (the results on both switches are the same):

```
user@switch> show configuration class-of-service
traffic-control-profiles {
 fcoe-tcp {
 scheduler-map fcoe-map;
 shaping-rate percent 100;
 guaranteed-rate 3000000000;
 }
}

 }
}
```

**NOTE:** The forwarding class and classifier configurations are not shown because the show command does not display default portions of the configuration.

---

## Verification

---

To verify that the CoS components and FIP snooping have been configured and are operating properly, perform these tasks. Because this example uses the default **fcoe**

forwarding class and the default IEEE 802.1p trusted classifier, the verification of those configurations is not shown:

- [Verifying That the Output Queue Schedulers Have Been Created on page 4955](#)
- [Verifying That the Priority Group Output Scheduler \(Traffic Control Profile\) Has Been Created on page 4956](#)
- [Verifying That the Forwarding Class Set \(Priority Group\) Has Been Created on page 4956](#)
- [Verifying That Priority-Based Flow Control Has Been Enabled on page 4957](#)
- [Verifying That the Interface Class of Service Configuration Has Been Created on page 4957](#)
- [Verifying That the Interfaces Are Correctly Configured on page 4959](#)
- [Verifying That FIP Snooping Is Enabled on the FCoE VLAN on FCoE Transit Switches TS1 and TS2 Access Interfaces on page 4962](#)
- [Verifying That the FIP Snooping Mode Is Correct on FCoE Transit Switches TS1 and TS2 on page 4962](#)
- [Verifying That IGMP Snooping Is Disabled on the FCoE VLAN on page 4963](#)

#### ***Verifying That the Output Queue Schedulers Have Been Created***

**Purpose** Verify that the output queue scheduler for FCoE traffic has the correct bandwidth parameters and priorities, and is mapped to the correct forwarding class (output queue). Queue scheduler verification is the same on each of the four switches.

**Action** List the scheduler map using the operational mode command **show class-of-service scheduler-map fcoe-map**:

```
user@switch> show class-of-service scheduler-map fcoe-map
Scheduler map: fcoe-map, Index: 9023
```

```
Scheduler: fcoe-sched, Forwarding class: fcoe, Index: 37289
Transmit rate: 3000000000 bps, Rate Limit: none, Buffer size: remainder,
Buffer Limit: none, Priority: low
Excess Priority: unspecified
Shaping rate: 100 percent,
drop-profile-map-set-type: mark
Drop profiles:
 Loss priority Protocol Index Name
 Low any 1 <default-drop-profile>
 Medium high any 1 <default-drop-profile>
 High any 1 <default-drop-profile>
```

**Meaning** The **show class-of-service scheduler-map fcoe-map** command lists the properties of the scheduler map **fcoe-map**. The command output includes:

- The name of the scheduler map (**fcoe-map**)
- The name of the scheduler (**fcoe-sched**)
- The forwarding classes mapped to the scheduler (**fcoe**)
- The minimum guaranteed queue bandwidth (transmit rate **3000000000 bps**)
- The scheduling priority (**low**)

- The maximum bandwidth in the priority group the queue can consume (shaping rate **100 percent**)
- The drop profile loss priority for each drop profile name. This example does not include drop profiles because you do not apply drop profiles to FCoE traffic.

#### ***Verifying That the Priority Group Output Scheduler (Traffic Control Profile) Has Been Created***

**Purpose** Verify that the traffic control profile **fcoe-tcp** has been created with the correct bandwidth parameters and scheduler mapping. Priority group scheduler verification is the same on each of the four switches.

**Action** List the FCoE traffic control profile properties using the operational mode command **show class-of-service traffic-control-profile fcoe-tcp**:

```
user@switch> show class-of-service traffic-control-profile fcoe-tcp
Traffic control profile: fcoe-tcp, Index: 18303
 Shaping rate: 100 percent
 Scheduler map: fcoe-map
 Guaranteed rate: 3000000000
```

**Meaning** The **show class-of-service traffic-control-profile fcoe-tcp** command lists all of the configured traffic control profiles. For each traffic control profile, the command output includes:

- The name of the traffic control profile (**fcoe-tcp**)
- The maximum port bandwidth the priority group can consume (shaping rate **100 percent**)
- The scheduler map associated with the traffic control profile (**fcoe-map**)
- The minimum guaranteed priority group port bandwidth (guaranteed rate **3000000000** in bps)

#### ***Verifying That the Forwarding Class Set (Priority Group) Has Been Created***

**Purpose** Verify that the FCoE priority group has been created and that the **fcoe** priority (forwarding class) belongs to the FCoE priority group. Forwarding class set verification is the same on each of the four switches.

**Action** List the forwarding class sets using the operational mode command **show class-of-service forwarding-class-set fcoe-pg**:

```
user@switch> show class-of-service forwarding-class-set fcoe-pg
Forwarding class set: fcoe-pg, Type: normal-type, Forwarding class set index:
31420
 Forwarding class Index
 fcoe 1
```

**Meaning** The **show class-of-service forwarding-class-set fcoe-pg** command lists all of the forwarding classes (priorities) that belong to the **fcoe-pg** priority group, and the internal index number

of the priority group. The command output shows that the forwarding class set **fcoe-pg** includes the forwarding class **fcoe**.

### *Verifying That Priority-Based Flow Control Has Been Enabled*

**Purpose** Verify that PFC is enabled on the FCoE code point. PFC verification is the same on each of the four switches.

**Action** List the FCoE congestion notification profile using the operational mode command **show class-of-service congestion-notification fcoe-cnp**:

```
user@switch> show class-of-service congestion-notification fcoe-cnp
Type: Input, Name: fcoe-cnp, Index: 6879
Cable Length: 100 m
 Priority PFC MRU
 000 Disabled
 001 Disabled
 010 Disabled
 011 Enabled 2500
 100 Disabled
 101 Disabled
 110 Disabled
 111 Disabled
Type: Output
 Priority Flow-Control-Queues
 000
 001 0
 010 1
 011 2
 100 3
 101 4
 110 5
 111 6
 111 7
```

**Meaning** The **show class-of-service congestion-notification fcoe-cnp** command lists all of the IEEE 802.1p code points in the congestion notification profile that have PFC enabled. The command output shows that PFC is enabled on code point **011** (**fcoe** queue) for the **fcoe-cnp** congestion notification profile.

The command also shows the default cable length (100 meters), the default maximum receive unit (2500 bytes), and the default mapping of priorities to output queues because this example does not include configuring these options.

### *Verifying That the Interface Class of Service Configuration Has Been Created*

**Purpose** Verify that the CoS properties of the interfaces are correct. The verification output on MC-LAG Switches S1 and S2 differs from the output on FCoE Transit Switches TS1 and TS2.

**Action** List the interface CoS configuration on MC-LAG Switches S1 and S2 using the operational mode command **show configuration class-of-service interfaces**:

```
user@switch> show configuration class-of-service interfaces
ae0 {
 forwarding-class-set {
 fcoe-pg {
 output-traffic-control-profile fcoe-tcp;
 }
 }
 congestion-notification-profile fcoe-cnp;
}

ae1 {
 forwarding-class-set {
 fcoe-pg {
 output-traffic-control-profile fcoe-tcp;
 }
 }
 congestion-notification-profile fcoe-cnp;
}
```

List the interface CoS configuration on FCoE Transit Switches TS1 and TS2 using the operational mode command **show configuration class-of-service interfaces**:

```
user@switch> show configuration class-of-service interfaces
xe-0/0/30 {
 forwarding-class-set {
 fcoe-pg {
 output-traffic-control-profile fcoe-tcp;
 }
 }
 congestion-notification-profile fcoe-cnp;
}
xe-0/0/31 {
 forwarding-class-set {
 fcoe-pg {
 output-traffic-control-profile fcoe-tcp;
 }
 }
 congestion-notification-profile fcoe-cnp;
}
xe-0/0/32 {
 forwarding-class-set {
 fcoe-pg {
 output-traffic-control-profile fcoe-tcp;
 }
 }
 congestion-notification-profile fcoe-cnp;
}
xe-0/0/33 {
 forwarding-class-set {
 fcoe-pg {
 output-traffic-control-profile fcoe-tcp;
 }
 }
 congestion-notification-profile fcoe-cnp;
}
ae1 {
 forwarding-class-set {
```

```

 fcoe-pg {
 output-traffic-control-profile fcoe-tcp;
 }
 }
 congestion-notification-profile fcoe-cnp;
}

```

**Meaning** The **show configuration class-of-service interfaces** command lists the class of service configuration for all interfaces. For each interface, the command output includes:

- The name of the interface (for example, **ae0** or **xe-0/0/30**)
- The name of the forwarding class set associated with the interface (**fcoe-pg**)
- The name of the traffic control profile associated with the interface (output traffic control profile, **fcoe-tcp**)
- The name of the congestion notification profile associated with the interface (**fcoe-cnp**)

**NOTE:** Interfaces that are members of a LAG are not shown individually. The LAG or MC-LAG CoS configuration is applied to all interfaces that are members of the LAG or MC-LAG. For example, the interface CoS configuration output on MC-LAG Switches S1 and S2 shows the LAG CoS configuration but does not show the CoS configuration of the member interfaces separately. The interface CoS configuration output on FCoE Transit Switches TS1 and TS2 shows the LAG CoS configuration but also shows the configuration for interfaces xe-0/0/30, xe-0/0/31, xe-0/0/32, and xe-0/0/33, which are not members of a LAG.

### *Verifying That the Interfaces Are Correctly Configured*

**Purpose** Verify that the LAG membership, MTU, VLAN membership, and port mode of the interfaces are correct. The verification output on MC-LAG Switches S1 and S2 differs from the output on FCoE Transit Switches T1 and T2.

**Action** List the interface configuration on MC-LAG Switches S1 and S2 using the operational mode command **show configuration interfaces**:

```

user@switch> show configuration interfaces
xe-0/0/10 {
 ether-options {
 802.3ad ae0;
 }
}
xe-0/0/11 {
 ether-options {
 802.3ad ae0;
 }
}
xe-0/0/20 {
 ether-options {
 802.3ad ae1;
 }
}

```

```
 }
 }
 xe-0/0/21 {
 ether-options {
 802.3ad ae1;
 }
 }
 ae0 {
 mtu 2180;
 unit 0 {
 family ethernet-switching {
 port-mode trunk;
 vlan {
 members fcoe_vlan;
 }
 }
 }
 }
 ae1 {
 mtu 2180;
 unit 0 {
 family ethernet-switching {
 port-mode trunk;
 vlan {
 members fcoe_vlan;
 }
 }
 }
 }
}
```

List the interface configuration on FCoE Transit Switches TS1 and TS2 using the operational mode command **show configuration interfaces**:

```
user@switch> show configuration interfaces
```

```
xe-0/0/25 {
 ether-options {
 802.3ad ae1;
 }
}
xe-0/0/26 {
 ether-options {
 802.3ad ae1;
 }
}
xe-0/0/30 {
 mtu 2180;
 unit 0 {
 family ethernet-switching {
 port-mode tagged-access;
 vlan {
 members fcoe_vlan;
 }
 }
 }
}
xe-0/0/31 {
 mtu 2180;
 unit 0 {
 family ethernet-switching {
 port-mode tagged-access;
 }
 }
}
```

```

 vlan {
 members fcoe_vlan;
 }
 }
}
xe-0/0/32 {
 mtu 2180;
 unit 0 {
 family ethernet-switching {
 port-mode tagged-access;
 vlan {
 members fcoe_vlan;
 }
 }
 }
}
xe-0/0/33 {
 mtu 2180;
 unit 0 {
 family ethernet-switching {
 port-mode tagged-access;
 vlan {
 members fcoe_vlan;
 }
 }
 }
}

ae1 {
 mtu 2180;
 unit 0 {
 family ethernet-switching {
 port-mode trunk;
 vlan {
 members fcoe_vlan;
 }
 }
 }
}

```

**Meaning** The **show configuration interfaces** command lists the configuration of each interface by interface name.

For each interface that is a member of a LAG, the command lists only the name of the LAG to which the interface belongs.

For each LAG interface and for each interface that is not a member of a LAG, the command output includes:

- The MTU (**2180**)
- The unit number of the interface (**0**)
- The port mode (**trunk** mode for interfaces that connect two switches, **tagged-access** mode for interfaces that connect to FCoE hosts)
- The name of the VLAN in which the interface is a member (**fcoe\_vlan**)

***Verifying That FIP Snooping Is Enabled on the FCoE VLAN on FCoE Transit Switches TS1 and TS2 Access Interfaces***

**Purpose** Verify that FIP snooping is enabled on the FCoE VLAN access interfaces. FIP snooping is enabled only on the FCoE access interfaces, so it is enabled only on FCoE Transit Switches TS1 and TS2. FIP snooping is not enabled on MC-LAG Switches S1 and S2 because FIP snooping is done at the Transit Switch TS1 and TS2 FCoE access ports.

**Action** List the port security configuration on FCoE Transit Switches TS1 and TS2 using the operational mode command **show configuration ethernet-switching-options secure-access-port**:

```
user@switch> show configuration ethernet-switching-options secure-access-port
interface ae1.0 {
 fcoe-trusted;
}
vlan fcoe_vlan {
 examine-fip {
 examine-vn2vn {
 beacon-period 90000;
 }
 }
}
```

**Meaning** The **show configuration ethernet-switching-options secure-access-port** command lists port security information, including whether a port is trusted. The command output shows that:

- LAG port **ae1.0**, which connects the FCoE transit switch to the MC-LAG switches, is configured as an FCoE trusted interface. FIP snooping is not performed on the member interfaces of the LAG (**xe-0/0/25** and **xe-0/0/26**).
- FIP snooping is enabled (**examine-fip**) on the FCoE VLAN (**fcoe\_vlan**), the type of FIP snooping is VN2VN\_Port FIP snooping (**examine-vn2vn**) and the beacon period is set to 90000 milliseconds. On Transit Switches TS1 and TS2, all interface members of the FCoE VLAN perform FIP snooping unless the interface is configured as FCoE trusted. On Transit Switches TS1 and TS2, interfaces **xe-0/0/30**, **xe-0/0/31**, **xe-0/0/32**, and **xe-0/0/33** perform FIP snooping because they are not configured as FCoE trusted. The interface members of LAG **ae1** (**xe-0/0/25** and **xe-0/0/26**) do not perform FIP snooping because the LAG is configured as FCoE trusted.

***Verifying That the FIP Snooping Mode Is Correct on FCoE Transit Switches TS1 and TS2***

**Purpose** Verify that the FIP snooping mode is correct on the FCoE VLAN. FIP snooping is enabled only on the FCoE access interfaces, so it is enabled only on FCoE Transit Switches TS1 and TS2. FIP snooping is not enabled on MC-LAG Switches S1 and S2 because FIP snooping is done at the Transit Switch TS1 and TS2 FCoE access ports.

**Action** List the FIP snooping configuration on FCoE Transit Switches TS1 and TS2 using the operational mode command **show fip snooping brief**:

```
user@switch> show fip snooping brief
```

```
VLAN: fcoe_vlan, Mode: VN2VN Snooping
FC-MAP: 0e:fd:00
...
```

**NOTE:** The output has been truncated to show only the relevant information.

**Meaning** The **show fip snooping brief** command lists FIP snooping information, including the FIP snooping VLAN and the FIP snooping mode. The command output shows that:

- The VLAN on which FIP snooping is enabled is **fcoe\_vlan**
- The FIP snooping mode is VN2VN\_Port FIP snooping (**VN2VN Snooping**)

#### *Verifying That IGMP Snooping Is Disabled on the FCoE VLAN*

**Purpose** Verify that IGMP snooping is disabled on the FCoE VLAN on all four switches.

**Action** List the IGMP snooping protocol information on each of the four switches using the **show configuration protocols igmp-snooping** command:

```
user@switch> show configuration protocols igmp-snooping
vlan fcoe_vlan {
 disable;
}
```

**Meaning** The **show configuration protocols igmp-snooping** command lists the IGMP snooping configuration for the VLANs configured on the switch. The command output shows that IGMP snooping is disabled on the FCoE VLAN (**fcoe\_vlan**).

### **Example: Setting Up Fibre Channel and FCoE VLAN Interfaces in an FCoE-FC Gateway Fabric**

To transmit Fibre Channel (FC) traffic between FCoE devices and a storage area network (SAN) FC switch, you configure a local FC fabric on the gateway. The gateway FC fabric includes FCoE and native FC interfaces, and a VLAN to carry FCoE traffic from FCoE-capable devices. The gateway FC fabric creates the path between the FCoE devices and the SAN.

This example describes how to configure the interfaces, VLAN, and FC fabric to connect FCoE devices to the FC switch and route traffic between the VLAN and FC interfaces:

- [Requirements on page 4964](#)
- [Overview on page 4964](#)
- [Configuration on page 4967](#)
- [Verification on page 4974](#)

---

## Requirements

This example uses the following hardware and software components:

- A configured and provisioned Juniper Networks QFX3500 Switch to act as an FCoE-FC gateway
- FCoE-capable devices in an Ethernet network equipped with converged network adapters (CNAs)
- An FC switch to transmit and receive native FC traffic
- FC storage devices in the SAN
- Junos OS Release 11.1 or later for the QFX Series

---

## Overview

No interfaces are configured for FC network connectivity by default. You need to configure the FC fabric and its interfaces explicitly. Each FC fabric consists of a combination of at least one FCoE VLAN interface between the FCoE-FC gateway and the FCoE devices, and one or more native FC interfaces between the FCoE-FC gateway and the FC switch.

An FCoE VLAN interface connects the FCoE-FC gateway to FCoE devices. FCoE traffic between the devices and the FCoE-FC gateway requires a dedicated VLAN used only for FCoE traffic. You cannot mix standard Ethernet traffic and FCoE traffic on the FCoE VLAN.

**NOTE:** IGMP snooping is not supported on FCoE VLANs. Disable IGMP snooping on FCoE VLANs.

Storm control is not supported on Ethernet interfaces that belong to the FCoE VLAN. Ensure that storm control is disabled on all Ethernet interfaces that belong to the FCoE VLAN to prevent FCoE traffic from being dropped.

---

When FCoE frames enter the FCoE-FC gateway, the gateway:

1. Strips the Ethernet encapsulation from the FCoE frames.
2. Sends the resulting native FC frames to the FC switch through the gateway's native FC interfaces.

Each FC interface and FCoE VLAN interface can belong to only one FC fabric. Different FC fabrics must use different native FC interfaces and different FCoE VLAN interfaces.

Multiple FC fabrics on the FCoE-FC gateway can connect to the same FC switch, but they must use different FC interfaces and different FCoE VLAN interfaces.

The Ethernet interfaces that belong to the FCoE VLAN should be configured in tagged-access port mode and must include the native VLAN because FIP VLAN discovery and notification frames are exchanged as untagged packets. These Ethernet interfaces require a maximum transmission unit (MTU) size of at least 2180 bytes to accommodate the FC payload and FCoE encapsulation. (Sometimes the MTU is rounded up to 2500 bytes. If larger frames are expected on the interface, set the MTU size accordingly.)

This example shows a simple configuration to illustrate the basic steps for creating:

- The FCoE-device-facing VLAN and its 10-Gigabit Ethernet interfaces
- The VLAN interface
- The FC-switch-facing native FC interfaces
- One FC fabric on the FCoE-FC gateway

Configuring these elements results in traffic being routed between the VLAN and FC interfaces, thus connecting the FCoE devices to the FC switch through the FCoE-FC gateway.

A VLAN called **blue** transports FCoE traffic between FCoE devices and the FCoE-FC gateway using an FCoE VLAN interface called **vlan.100**. The FCoE-FC gateway's **vlan.100** interface presents an F\_Port interface to the FCoE devices on the VLAN. For each FCoE device ENode that logs in to the FCoE-FC gateway, the gateway instantiates a virtual F\_Port (VF\_Port) interface. This creates a virtual link between the ENode VN\_Port and the FCoE-FC gateway. The FCoE-FC gateway's native FC interfaces transport FC traffic between the gateway and the FC switch.

Configuring both the FCoE VLAN interface and the native FC interfaces as part of a gateway fabric associates them in the switch and makes the connection between the FCoE servers and the FC switch.

### Topology

The topology for this example consists of one QFX3500 switch with FC-capable ports to connect to the FC switch and with Ethernet ports in tagged-access mode to connect to the FCoE devices. [Table 384 on page 4965](#) and [Figure 181 on page 4966](#) show the configuration components of this example.

**Table 384: Components of the Fibre Channel Interface Configuration Topology**

Property	Settings
Switch hardware	QFX3500 switch in gateway mode
FCoE VLAN name and tag ID	<b>blue</b> , tag <b>100</b>  IGMP snooping disabled on the FCoE VLAN.

Table 384: Components of the Fibre Channel Interface Configuration Topology (*continued*)

Property	Settings
Interfaces in VLAN blue	<p>Interfaces: <b>xe-0/0/6</b>, <b>xe-0/0/7</b>, <b>xe-0/0/8</b>, <b>xe-0/0/9</b>, <b>xe-0/0/10</b>, <b>xe-0/0/11</b></p> <p>Port mode: <b>tagged-access</b></p> <p>MTU: <b>2180</b></p> <p>Native VLAN: <b>1</b></p> <p><b>NOTE:</b> You can bundle two or more of the VLAN interfaces in a link aggregation group (LAG) if you wish.</p> <p><b>NOTE:</b> FCoE VLANs (any VLAN that carries FCoE traffic) support only Spanning Tree Protocol (STP) and link aggregation group (LAG) Layer 2 features.</p>
FCoE VLAN interface	<p><b>vlan.100</b></p> <p>Port mode: <b>f-port</b></p>
Native Fibre Channel interfaces	<p>Interfaces: <b>fc-0/0/0</b>, <b>fc-0/0/1</b>, <b>fc-0/0/2</b>, <b>fc-0/0/3</b>, <b>fc-0/0/4</b>, <b>fc-0/0/5</b></p> <p>Port mode: <b>np-port</b></p> <p>Speed: <b>4 Gbps</b></p>
Fibre Channel fabric <b>fcproxy1</b>	<p>Fabric type: <b>proxy</b></p> <p>Fabric ID: <b>1</b></p> <p>FC interfaces: <b>fc-0/0/0</b>, <b>fc-0/0/1</b>, <b>fc-0/0/2</b>, <b>fc-0/0/3</b>, <b>fc-0/0/4</b>, <b>fc-0/0/5</b></p>

Figure 181: Fibre Channel Interface Configuration Topology

This configuration example creates a VLAN for FCoE traffic and routes its traffic to an FCoE VLAN interface that is part of the FC fabric. It also creates the FC interfaces needed to connect to the FC switch.

To set up FC interfaces and FCoE VLAN interfaces:

- Configure a VLAN to use as a dedicated FCoE VLAN:
  - Configure the interfaces the FCoE VLAN uses as Ethernet switching interfaces in tagged-access port mode.
  - If storm control is enabled, disable it on the interfaces.
  - Configure the interfaces the FCoE VLAN uses with the native VLAN.
  - Configure the FCoE VLAN to use the desired Ethernet interfaces.
  - Disable IGMP snooping on the FCoE VLAN. (IGMP snooping is enabled by default on all VLANs, but is not supported on FCoE VLANs).
- Configure the FCoE VLAN interface.
- Define the interface for the FCoE VLAN (associate the VLAN with the FCoE VLAN interface).
- Configure the physical FC interfaces (either one or two 6-port blocks) that connect to the FC switch.
- Configure the logical FC interfaces that connect to the FC switch.
- Configure the FCoE-FC gateway fabric:
  - Configure the fabric ID.
  - Configure the fabric as a proxy fabric.
  - Add the FCoE VLAN interface and the native FC interfaces to the fabric.

To keep the example simple, the configuration steps show six Ethernet interfaces in the FCoE VLAN and six native FC interfaces in the FC fabric. Use the same configuration procedure to add more interfaces to the FCoE VLAN or to the FC fabric.

### Configuration

#### CLI Quick Configuration

To quickly configure FCoE and native FC interfaces on an FCoE-FC gateway and route traffic between the FCoE VLAN and FC interfaces, copy the following commands and paste them into the switch terminal window:

```
[edit]
set vlans blue vlan-id 100
set vlans native vlan-id 1
set interfaces xe-0/0/6 unit 0 family ethernet-switching port-mode tagged-access vlan members blue
set interfaces xe-0/0/7 unit 0 family ethernet-switching port-mode tagged-access vlan members blue
set interfaces xe-0/0/8 unit 0 family ethernet-switching port-mode tagged-access vlan members blue
set interfaces xe-0/0/9 unit 0 family ethernet-switching port-mode tagged-access vlan members blue
set interfaces xe-0/0/10 unit 0 family ethernet-switching port-mode tagged-access vlan members blue
set interfaces xe-0/0/11 unit 0 family ethernet-switching port-mode tagged-access vlan members blue
set interfaces xe-0/0/6 unit 0 family ethernet-switching native-vlan-id 1
set interfaces xe-0/0/7 unit 0 family ethernet-switching native-vlan-id 1
set interfaces xe-0/0/8 unit 0 family ethernet-switching native-vlan-id 1
```

```

set interfaces xe-0/0/9 unit 0 family ethernet-switching native-vlan-id 1
set interfaces xe-0/0/10 unit 0 family ethernet-switching native-vlan-id 1
set interfaces xe-0/0/11 unit 0 family ethernet-switching native-vlan-id 1
set interfaces xe-0/0/6 mtu 2180
set interfaces xe-0/0/7 mtu 2180
set interfaces xe-0/0/8 mtu 2180
set interfaces xe-0/0/9 mtu 2180
set interfaces xe-0/0/10 mtu 2180
set interfaces xe-0/0/11 mtu 2180
set vlans blue interface xe-0/0/6.0
set vlans blue interface xe-0/0/7.0
set vlans blue interface xe-0/0/8.0
set vlans blue interface xe-0/0/9.0
set vlans blue interface xe-0/0/10.0
set vlans blue interface xe-0/0/11.0
set protocols igmp-snooping vlan blue disable
set interfaces vlan unit 100 family fibre-channel port-mode f-port
set vlans blue l3-interface vlan.100
set chassis fpc 0 pic 0 fibre-channel port-range 0 5
set interfaces fc-0/0/0 unit 0 family fibre-channel port-mode np-port
set interfaces fc-0/0/1 unit 0 family fibre-channel port-mode np-port
set interfaces fc-0/0/2 unit 0 family fibre-channel port-mode np-port
set interfaces fc-0/0/3 unit 0 family fibre-channel port-mode np-port
set interfaces fc-0/0/4 unit 0 family fibre-channel port-mode np-port
set interfaces fc-0/0/5 unit 0 family fibre-channel port-mode np-port
set interfaces fc-0/0/0 fibrechannel-options speed 4g
set interfaces fc-0/0/1 fibrechannel-options speed 4g
set interfaces fc-0/0/2 fibrechannel-options speed 4g
set interfaces fc-0/0/3 fibrechannel-options speed 4g
set interfaces fc-0/0/4 fibrechannel-options speed 4g
set interfaces fc-0/0/5 fibrechannel-options speed 4g
set fc-fabrics fcproxy1 fabric-id 1
set fc-fabrics fcproxy1 fabric-type proxy
set fc-fabrics fcproxy1 interface vlan.100
set fc-fabrics fcproxy1 interface fc-0/0/0.0
set fc-fabrics fcproxy1 interface fc-0/0/1.0
set fc-fabrics fcproxy1 interface fc-0/0/2.0
set fc-fabrics fcproxy1 interface fc-0/0/3.0
set fc-fabrics fcproxy1 interface fc-0/0/4.0
set fc-fabrics fcproxy1 interface fc-0/0/5.0

```

#### Step-by-Step Procedure

Configure FCoE and FC interfaces in an FCoE-FC gateway FC fabric and set up traffic routing between the FCoE VLAN and FC interfaces:

1. Configure the VLAN for FCoE traffic:
 

```
[edit vlans]
user@switch# set blue vlan-id 100
```
2. Configure the native VLAN:
 

```
[edit vlans]
user@switch# set native vlan-id 1
```
3. Configure the Ethernet interfaces for the FCoE VLAN in tagged-access mode and as members of the FCoE VLAN (VLAN blue):
 

```
[edit interfaces]
user@switch# set xe-0/0/6 unit 0 family ethernet-switching port-mode tagged-access
vlan members blue
```

```

user@switch# set xe-0/0/7 unit 0 family ethernet-switching port-mode tagged-access
vlan members blue
user@switch# set xe-0/0/8 unit 0 family ethernet-switching port-mode tagged-access
vlan members blue
user@switch# set xe-0/0/9 unit 0 family ethernet-switching port-mode tagged-access
vlan members blue
user@switch# set xe-0/0/10 unit 0 family ethernet-switching port-mode tagged-access
vlan members blue
user@switch# set xe-0/0/11 unit 0 family ethernet-switching port-mode tagged-access
vlan members blue

```

4. Configure the native VLAN on the Ethernet interfaces in the FCoE VLAN:

```

[edit interfaces]
user@switch# set xe-0/0/6 unit 0 family ethernet-switching native-vlan-id 1
user@switch# set xe-0/0/7 unit 0 family ethernet-switching native-vlan-id 1
user@switch# set xe-0/0/8 unit 0 family ethernet-switching native-vlan-id 1
user@switch# set xe-0/0/9 unit 0 family ethernet-switching native-vlan-id 1
user@switch# set xe-0/0/10 unit 0 family ethernet-switching native-vlan-id 1
user@switch# set xe-0/0/11 unit 0 family ethernet-switching native-vlan-id 1

```

5. Set the MTU to 2180 for each Ethernet interface:

```

[edit interfaces]
user@switch# set xe-0/0/6 mtu 2180
user@switch# set xe-0/0/7 mtu 2180
user@switch# set xe-0/0/8 mtu 2180
user@switch# set xe-0/0/9 mtu 2180
user@switch# set xe-0/0/10 mtu 2180
user@switch# set xe-0/0/11 mtu 2180

```

6. Assign the Ethernet interfaces to the FCoE VLAN:

```

[edit vlans blue interface]
user@switch# set xe-0/0/6.0
user@switch# set xe-0/0/7.0
user@switch# set xe-0/0/8.0
user@switch# set xe-0/0/9.0
user@switch# set xe-0/0/10.0
user@switch# set xe-0/0/11.0

```

7. Disable IGMP snooping on the FCoE VLAN:

```

[edit protocols]
user@switch# set igmp-snooping vlan blue disable

```

8. Configure the FCoE VLAN interface and port mode for the FCoE traffic:

```

[edit interfaces]
user@switch# set vlan unit 100 family fibre-channel port-mode f-port

```

9. Define the FCoE VLAN interface as the interface for the FCoE VLAN:

```

[edit vlans]
user@switch# set blue l3-interface vlan.100

```

10. Configure the physical FC interfaces the fabric uses to connect to the FC switch:

```

[edit chassis fpc 0 pic 0]
user@switch# set fibre-channel port-range 0 5

```

**NOTE:** When you configure ports as FC ports, the port designation changes from xe-n/n/n.n format to fc-n/n/n.n format to indicate that the interface is an FC interface. FC interfaces do not support 10-Gbps interface speed but instead conform to FC interface speeds of 2 Gbps, 4 Gbps, or 8 Gbps.

11. Configure the native FC interfaces and port mode:

```
[edit interfaces]
user@switch# set fc-0/0/0 unit 0 family fibre-channel port-mode np-port
user@switch# set fc-0/0/1 unit 0 family fibre-channel port-mode np-port
user@switch# set fc-0/0/2 unit 0 family fibre-channel port-mode np-port
user@switch# set fc-0/0/3 unit 0 family fibre-channel port-mode np-port
user@switch# set fc-0/0/4 unit 0 family fibre-channel port-mode np-port
user@switch# set fc-0/0/5 unit 0 family fibre-channel port-mode np-port
```

12. Configure the native FC interface port speed:

```
[edit interfaces]
user@switch# set fc-0/0/0 fibrechannel-options speed 4g
user@switch# set fc-0/0/1 fibrechannel-options speed 4g
user@switch# set fc-0/0/2 fibrechannel-options speed 4g
user@switch# set fc-0/0/3 fibrechannel-options speed 4g
user@switch# set fc-0/0/4 fibrechannel-options speed 4g
user@switch# set fc-0/0/5 fibrechannel-options speed 4g
```

13. Configure the FC fabric name and unique ID:

```
[edit fc-fabrics]
user@switch# set fcproxy1 fabric-id 1
```

14. Define the FC fabric as an FCoE-FC gateway:

```
[edit fc-fabrics]
user@switch# set fcproxy1 fabric-type proxy
```

15. Assign the FCoE VLAN interface to the fabric:

```
[edit fc-fabrics]
user@switch# set fcproxy1 interface vlan.100
```

16. Assign the native FC interfaces to the fabric:

```
[edit fc-fabrics]
user@switch# set fcproxy1 interface fc-0/0/0.0
user@switch# set fcproxy1 interface fc-0/0/1.0
user@switch# set fcproxy1 interface fc-0/0/2.0
user@switch# set fcproxy1 interface fc-0/0/3.0
user@switch# set fcproxy1 interface fc-0/0/4.0
user@switch# set fcproxy1 interface fc-0/0/5.0
```

**Results** Display the results of the configuration:

```
user@switch> show configuration
fc-0/0/0 {
 fibrechannel-options {
 speed 4g;
 }
}
```

```

## Verification

To verify that the native FC interfaces and FCoE VLAN interface have been created, added to the FC fabric, and are operating properly, perform these tasks:

- [Verifying That the Native FC Interfaces and the FCoE VLAN Interface Have Been Created on page 4974](#)
- [Verifying That the FCoE VLAN Includes the Correct Ethernet Interfaces on page 4975](#)
- [Verifying That the FC Fabric Includes the Correct Interfaces on page 4975](#)
- [Verifying Native FC Interface Operation on page 4976](#)
- [Verifying That IGMP Snooping Has Been Disabled on the FCoE VLAN on page 4976](#)

### *Verifying That the Native FC Interfaces and the FCoE VLAN Interface Have Been Created*

- Purpose** Verify that the six native FC interfaces and the FCoE VLAN interface have been created on the switch and are configured in the correct mode.
- Action** List all of the FC interfaces configured on the switch using the `show fibre-channel interfaces` command:

```
user@switch> show fibre-channel interfaces
```

Interface	Idx	Type	Native Fabric-id	NPIV	Config Mode	Oper Mode	State
fc-0/0/0.0	70	FC	1	YES	NP	NP	up
fc-0/0/1.0	71	FC	1	YES	NP	NP	up
fc-0/0/2.0	72	FC	1	YES	NP	NP	up
fc-0/0/3.0	73	FC	1	YES	NP	NP	up
fc-0/0/4.0	74	FC	1	YES	NP	NP	up
fc-0/0/5.0	75	FC	1	YES	NP	NP	up
vlan.100	67	FCoE	1	YES	F	F	up

- Meaning** The `show fibre-channel interfaces` command lists all native FC interfaces and FCoE VLAN interfaces configured on the switch. The command output shows that the FC interfaces `fc-0/0/0.0`, `fc-0/0/1.0`, `fc-0/0/2.0`, `fc-0/0/3.0`, `fc-0/0/4.0`, and `fc-0/0/5.0` have been created and that those six interfaces:

- Are native Fibre Channel interfaces (type `FC`).
- Belong to the FC fabric with a configured fabric ID of 1.

- Are capable of N\_Port ID virtualization (NPIV).
- Have a configured mode and an operational mode of proxy N\_Port (**NP**), which means that they should be connected to an FCF or an FC switch, not to an FCoE device, and that they carry native FC traffic.
- Show an operational state of **up**.

The command output also shows that the FCoE VLAN interface **vlan.100** has been created and that interface:

- Is an FCoE VLAN interface (type **FCOE**).
- Belongs to the FC fabric with a configured fabric ID of 1.
- Is capable of N\_Port ID virtualization (NPIV).
- Has a configured mode and an operational mode of F\_Port (**F**), which means that its interfaces connect to FCoE devices and carry FCoE traffic.
- Shows an operational state of **up**.

#### *Verifying That the FCoE VLAN Includes the Correct Ethernet Interfaces*

**Purpose** Verify that the FCoE VLAN **blue** has been created with the correct VLAN tag (**100**) and with the correct Ethernet interfaces.

**Action** List all of the interfaces configured on the switch in VLAN **blue** using the **show vlans** command:

```
user@switch> show vlans blue
Name Tag Interfaces
blue 100 xe-0/0/6.0, xe-0/0/7.0, xe-0/0/8.0, xe-0/0/9.0, xe-0/0/10.0
 xe-0/0/11.0
```

**Meaning** The **show vlans blue** command lists the interfaces that are members of the FCoE VLAN **blue**. The command output shows that the **blue** VLAN has a tag ID of 100 and includes the interfaces **xe-0/0/6.0**, **xe-0/0/7.0**, **xe-0/0/8.0**, **xe-0/0/9.0**, **xe-0/0/10.0**, and **xe-0/0/11.0**.

#### *Verifying That the FC Fabric Includes the Correct Interfaces*

**Purpose** Verify that the FC fabric configuration is configured on the switch with the correct native FC and FCoE VLAN interfaces.

**Action** List all of the interfaces configured on FC fabrics on the switch using the **show fibre-channel fabric** command:

```
user@switch> show fibre-channel fabric
Name Fabric-id Type Interfaces
fcproxy1 1 PROXY fc-0/0/0.0
 fc-0/0/1.0
 fc-0/0/2.0
```

```
fc-0/0/3.0
fc-0/0/4.0
fc-0/0/5.0
vlan.100
```

**Meaning** The **show fibre-channel fabric** command lists the interfaces that are members of each FC fabric. The command output shows that the only fabric configured on the switch is named **fcproxy1**, has a fabric-id of 1, and is a **proxy** fabric in an FCoE-FC gateway. The command output also shows that the native FC interfaces **fc-0/0/0.0**, **fc-0/0/1.0**, **fc-0/0/2.0**, **fc-0/0/3.0**, **fc-0/0/4.0**, and **fc-0/0/5.0**, and the FCoE VLAN interface **vlan.100** belong to **fcproxy1**.

#### *Verifying Native FC Interface Operation*

**Purpose** Verify that the native FC interfaces are online and display the number of FC sessions on each interface.

**Action** List all of the native FC NP\_Port interface states and sessions by FC fabric using the **show fibre-channel proxy np-port** command:

```
user@switch> show fibre-channel proxy np-port
Fabric: fcproxy1, Fabric-id: 1

```

NP-Port	State	Sessions	LB state	LB weight
fc-0/0/0.0	online	3	ON	4
fc-0/0/1.0	online	3	ON	4
fc-0/0/2.0	online	2	ON	4
fc-0/0/3.0	online	2	ON	4
fc-0/0/4.0	online	2	ON	4
fc-0/0/5.0	online	2	ON	4

**Meaning** The **show fibre-channel proxy np-port** command lists the interfaces that are configured as native FC proxy N\_Port interfaces. The command output shows:

- The fabric name is **fcproxy1** and its fabric ID is 1.
- The interfaces are **online**.
- The number of FC sessions (virtual links) running on each interface.
- The load-balancing (LB) state is **ON** for all of the interfaces.
- The LB weight reflects the port speed of each interface, which is 4 Gbps.

#### *Verifying That IGMP Snooping Has Been Disabled on the FCoE VLAN*

**Purpose** Verify that IGMP snooping is disabled on the FCoE VLAN.

**Action** List the IGMP snooping protocol information for the FCoE VLAN using the **show configuration protocols igmp-snooping vlan blue** command:

```
user@switch> show configuration protocols igmp-snooping vlan blue
disable;
```

**Meaning** The `show configuration protocols igmp-snooping vlan blue` command lists the IGMP snooping configuration for the FCoE VLAN. The command output shows that IGMP snooping is disabled on the FCoE VLAN.

### Example: Configuring VN2VN\_Port FIP Snooping (FCoE Hosts Directly Connected to the Same FCoE Transit Switch)

This example shows how to configure VN\_Port to VN\_Port (VN2VN\_Port) FIP snooping when the hosts are directly connected to the same FCoE transit switch.

**NOTE:** This example uses Junos OS without support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that supports ELS, see “[Example: Configuring VN2VN\\_Port FIP Snooping \(FCoE Hosts Directly Connected to the Same FCoE Transit Switch\)](#)” on page 5025.

VN2VN\_Port FIP snooping on an FCoE transit switch provides security to help prevent unauthorized access and data transmission on a bridge that connects ENodes in the Ethernet network. VN2VN\_Port FIP snooping provides security for virtual links by creating filters based on information gathered (snooped) about FCoE devices during FIP transactions.

VN2VN\_Port FIP snooping is conceptually similar to VN2VN\_Port FIP snooping between VN\_Ports and VF\_Ports, but VN2VN\_Port FIP snooping does not require traffic between VN\_Ports to traverse the Fibre Channel (FC) switch or FCoE forwarder (FCF). Instead, a VN\_Port communicates transparently through the transit switch on a virtual link that emulates a direct connection to the VN\_Port at the other end of the virtual link.

To configure VN2VN\_Port FIP snooping when the hosts are directly connected to the same FCoE transit switch, you must follow these configuration rules:

- VN2VN\_Port traffic must use a dedicated FCoE VLAN, and all ENodes that communicate using VN2VN\_Port FIP snooping must use that FCoE VLAN. You cannot mix VN2VN\_Port FIP snooping traffic with VN2VF\_Port FIP snooping traffic in the same FCoE VLAN.

**NOTE:** An FCoE VLAN can support either VN2VF\_Port FIP snooping or VN2VN\_Port FIP snooping, but not both. Configure separate FCoE VLANs for VN2VF\_Port FIP snooping traffic and for VN2VN\_Port FIP snooping traffic. On FCoE VLANs that are configured as VN2VN\_Port FIP snooping VLANs, VN\_Port to VF\_Port (FIP snooping) traffic is dropped.

- ENode-facing ports must be set in **tagged-access** port mode.
- ENode-facing ports must be untrusted ports.
- Network-facing (switch-facing) ports must be set in **trunk** port mode.
- Network-facing ports must be FCoE trusted ports.
- Explicitly configure the beacon period. The beacon period is essentially a keepalive timer for virtual link maintenance.

When you enable VN2VF\_Port FIP snooping, the system snoops VN\_Port to VF\_Port packets and enforces security only on VN\_Port to VF\_Port virtual links. When you enable VN2VN\_Port FIP snooping, the system snoops VN\_Port to VN\_Port packets and enforces security only on VN\_Port to VN\_Port virtual links.

The transit switch applies VN2VN\_Port FIP snooping filters at the ports associated with the FCoE VLANs on which you enable VN2VN FIP snooping.

This example describes how to configure VN2VN\_Port FIP snooping when the FCoE hosts are directly connected to the same transit switch:

- [Requirements on page 4978](#)
- [Overview on page 4979](#)
- [Configuration on page 4979](#)
- [Verification on page 4980](#)

---

### Requirements

This example uses the following hardware and software components:

- One Juniper Networks QFX3500 Switch used as a transit switch
- Junos OS Release 12.2 or later for the QFX Series
- Two FCoE hosts that have ENodes

## Overview

This example shows you how to:

- Set the correct interface port modes on the transit switch.
- Configure the interfaces to use the dedicated FCoE VLAN for VN2VN\_Port FIP snooping.
- Configure the dedicated FCoE VLAN for VN2VN\_Port FIP snooping traffic.
- Enable VN2VN\_Port FIP snooping on the FCoE VLAN and configure the beacon period.

## Topology

Table 385 on page 4979 shows the configuration components for this example.

**Table 385: Components of the VN2VN\_Port FIP Snooping Configuration Topology (FCoE Hosts Directly Connected to the Same FCoE Transit Switch)**

Component	Settings
Hardware	QFX3500 switch (FCoE transit switch TS1)  Two FCoE hosts that have ENodes (ENode1 and ENode2, respectively)
Interfaces and port modes	<ul style="list-style-type: none"> <li>• Interface <b>xe-0/0/20</b>, port mode <b>tagged-access</b>, connects directly to the FCoE host with ENode1.</li> <li>• Interface <b>xe-0/0/21</b>, port mode <b>tagged-access</b>, connects directly to the FCoE host with ENode2.</li> </ul>
Interface VLAN membership	Both interfaces use VLAN <b>vlan200</b> .
VN2VN_Port FIP snooping VLAN	VLAN name— <b>vlan200</b> VLAN ID—200
FIP snooping mode and beacon period	Set <b>examine-vn2vn</b> (VN2VN_Port FIP snooping) Beacon period—90000 ms

Figure 182 on page 4979 shows the network topology for this example.

**Figure 182: VN2VN\_Port FIP Snooping (FCoE Hosts Connected to Same Transit Switch) Topology**

## Configuration

### CLI Quick Configuration

To quickly configure VN2VN\_Port FIP snooping for FCoE hosts connected directly to the same transit switch, copy the following commands, paste them in a text file, remove line

breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level:

```
set interfaces xe-0/0/20 unit 0 family ethernet-switching port-mode tagged-access
set interfaces xe-0/0/21 unit 0 family ethernet-switching port-mode tagged-access
set interfaces xe-0/0/20 unit 0 family ethernet-switching vlan members vlan200
set interfaces xe-0/0/21 unit 0 family ethernet-switching vlan members vlan200
set vlans vlan200 vlan-id 200
set ethernet-switching-options secure-access-port vlan vlan200 examine-fip examine-vn2v2
beacon-period 90000
```

### ***Configuring VN2VN\_Port FIP Snooping (FCoE Hosts Directly Connected to the Same FCoE Transit Switch)***

#### **Step-by-Step Procedure**

To configure interface port modes, configure interface VLAN membership in the FCoE VLAN dedicated to VN2VN\_Port traffic, configure the VLAN, set the beacon period, and enable VN2VN\_Port FIP snooping:

1. Configure the port modes of the interfaces that connect directly to the FCoE host ENodes:  

```
user@switch# set interfaces xe-0/0/20 unit 0 family ethernet-switching port-mode tagged-access
set interfaces xe-0/0/21 unit 0 family ethernet-switching port-mode tagged-access
```
2. Configure the interface VLAN membership so that the interfaces connected to the ENodes are members of the dedicated VN2VN\_Port VLAN (**vlan200**):  

```
user@switch# set interfaces xe-0/0/20 unit 0 family ethernet-switching vlan members vlan200
set interfaces xe-0/0/21 unit 0 family ethernet-switching vlan members vlan200
```
3. Configure the FCoE VLAN dedicated to VN2VN\_Port FIP snooping:  

```
user@switch# set vlans vlan200 vlan-id 200
```
4. Enable VN2VN\_Port FIP snooping on the VLAN and configure the beacon period:  

```
user@switch# set ethernet-switching-options secure-access-port vlan vlan200 examine-fip examine-vn2v2 beacon-period 90000
```

---

### **Verification**

To verify that the VN2VN\_Port FIP snooping configuration has been created and is operating properly, perform these tasks:

- [Verifying That VN2VN\\_Port FIP Snooping is Enabled on the FCoE VLAN on page 4980](#)
- [Verifying the Interface Port Mode on page 4981](#)

### ***Verifying That VN2VN\_Port FIP Snooping is Enabled on the FCoE VLAN***

**Purpose** Verify that VN2VN\_Port FIP snooping is enabled on the correct VLAN (**vlan200**), the beacon period is set to 90000 milliseconds, and the correct interfaces (**xe-0/0/20** and **xe-0/0/21**) are members of the VLAN.

**Action** List the FIP snooping information using the operational mode command **show fip snooping detail**.

```
user@switch> show fip snooping detail
VLAN: vlan200, Mode: VN2VN Snooping
FC-MAP: 0e:fd:00
Beacon_Period: 90000
VN2VN Mode: Point-to-Point
 Enode Information
 Enode-MAC: 10:10:94:01:00:02, Interface: xe-0/0/20
 Active VN_Ports : 1
 VN_Port Information
 VN-Port MAC: 0e:fd:00:00:0a:01
 Active Sessions : 1
 Session Information
 Vlink far-end VN-Port-MAC: 0e:fd:00:00:0b:01
 Enode-MAC: 10:10:94:01:00:02, Interface: xe-0/0/21
 Active VN_Ports : 1
 VN_Port Information
 VN-Port MAC: 0e:fd:00:00:0b:01
 Active Sessions : 1
 Session Information
 Vlink far-end VN-Port-MAC: 0e:fd:00:00:0a:01
```

**Meaning** The **show fip snooping detail** command lists all of the transit switch information about VN2VN\_Port FIP snooping and VN2VF\_Port FIP snooping. The command shows that:

- The VLAN is **vlan200**.
- The mode is FIP snooping mode **VN2VN**, for VN2VN\_Port FIP snooping. (If the Mode field shows **VN2VF**, then the FIP snooping mode is VN2VF\_Port FIP snooping.)
- The beacon period is **90000**.
- The interfaces for the ENodes are **xe-0/0/20** and **xe-0/0/21**.

In addition, this useful command shows information about the ENodes and the VN2VN\_Port sessions.

### *Verifying the Interface Port Mode*

**Purpose** Verify that the interface port modes are **tagged-access**.

**Action** List the Ethernet switching interfaces to confirm the port mode using the **show ethernet-switching interfaces detail** operational command.

Use the operational mode commands **show ethernet-switching interfaces xe-0/0/20.0 detail** and **show ethernet-switching interfaces xe-0/0/21.0 detail** to list the Ethernet switching interface information. The output is truncated to show only the relevant portions:

```
user@switch> show ethernet-switching interfaces xe-0/0/20.0 detail
Interface: xe-0/0/20.0, Index: 75, State: up, Port mode: Tagged-Access
.
.
.
```

```
user@switch> show ethernet-switching interfaces xe-0/0/21.0 detail
Interface: xe-0/0/21.0, Index: 83, State: up, Port mode: Tagged-Access
.
.
.
```

**Meaning** The `show ethernet-switching interfaces detail` command lists the port mode as `tagged-access` for both interfaces.

### Example: Configuring VN2VN\_Port FIP Snooping (FCoE Hosts Directly Connected to Different FCoE Transit Switches)

This example shows how to configure VN\_Port to VN\_Port (VN2VN\_Port) FIP snooping when the hosts are directly connected to different FCoE transit switches, and the transit switches are directly connected to each other.

**NOTE:** This example uses Junos OS without support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that supports ELS, see [“Example: Configuring VN2VN\\_Port FIP Snooping \(FCoE Hosts Directly Connected to Different FCoE Transit Switches\)” on page 5030](#).

VN2VN\_Port FIP snooping on an FCoE transit switch provides security to help prevent unauthorized access and data transmission on a bridge that connects ENodes in the Ethernet network. VN2VN\_Port FIP snooping provides security for virtual links by creating filters based on information gathered (snooped) about FCoE devices during FIP transactions.

VN2VN\_Port FIP snooping is conceptually similar to VN2VF\_Port FIP snooping between VN\_Ports and VF\_Ports, but VN2VN\_Port FIP snooping does not require traffic between VN\_Ports to traverse the Fibre Channel (FC) switch or FCoE forwarder (FCF). Instead, a VN\_Port communicates transparently through one or more transit switches on a virtual link that emulates a direct connection to the VN\_Port at the other end of the virtual link.

To configure VN2VN\_Port FIP snooping when the hosts are directly connected to different FCoE transit switches, and the transit switches are directly connected to each other, you must follow these configuration rules:

- VN2VN\_Port traffic must use a dedicated FCoE VLAN, and all ENodes that communicate using VN2VN\_Port FIP snooping must use that FCoE VLAN. The FCoE VLAN must be configured on each transit switch. You cannot mix VN2VN\_Port FIP snooping traffic with VN2VF\_Port FIP snooping traffic in the same FCoE VLAN.

**NOTE:** An FCoE VLAN can support either VN2VF\_Port FIP snooping or VN2VN\_Port FIP snooping, but not both. Configure separate FCoE VLANs for VN2VF\_Port FIP snooping traffic and for VN2VN\_Port FIP snooping traffic. On FCoE VLANs that are configured as VN2VN\_Port FIP snooping VLANs, VN2VF\_Port traffic is dropped.

- ENode-facing ports must be set in **tagged-access** port mode.
- ENode-facing ports must be untrusted ports.
- Network-facing (switch-facing) ports must be set in **trunk** port mode.
- Network-facing ports must be FCoE trusted ports.
- Explicitly configure the beacon period. The beacon period is essentially a keepalive timer for virtual link maintenance.

When you enable VN2VF\_Port FIP snooping, the system snoops VN\_Port to VF\_Port packets and enforces security only on VN\_Port to VF\_Port virtual links. When you enable VN2VN\_Port FIP snooping, the system snoops VN\_Port to VN\_Port packets and enforces security only on VN\_Port to VN\_Port virtual links.

The transit switch applies VN2VN\_Port FIP snooping filters at the ports associated with the FCoE VLANs on which you enable VN2VN FIP snooping.

This example describes how to configure VN2VN\_Port FIP snooping when the FCoE hosts are directly connected to different transit switches, and the transit switches are directly connected to each other:

- [Requirements on page 4983](#)
- [Overview on page 4984](#)
- [Configuration on page 4985](#)
- [Verification on page 4986](#)

## Requirements

This example uses the following hardware and software components:

- Two Juniper Networks QFX3500 Switches used as transit switches
- Junos OS Release 12.2 or later for the QFX Series
- Two FCoE hosts that have ENodes

## Overview

This example shows you how to:

- Set the correct interface port modes on the transit switch.
- Configure the interfaces to use the dedicated FCoE VLAN for VN2VN\_Port FIP snooping.
- Configure the network-facing interfaces as FCoE trusted interfaces.
- Configure the dedicated FCoE VLAN for VN2VN\_Port FIP snooping traffic.
- Enable VN2VN\_Port FIP snooping on the FCoE VLAN and configure the beacon period.

## Topology

Table 386 on page 4984 shows the configuration components for this example.

**Table 386: Components of the VN2VN\_Port FIP Snooping Configuration Topology (FCoE Hosts Directly Connected to Different FCoE Transit Switches)**

Component	Settings
Hardware	Two QFX3500 switches (FCoE transit switch TS1 and FCoE transit switch TS2)  Two FCoE hosts that have ENodes (ENode1 and ENode2, respectively)
Interfaces and port modes	<ul style="list-style-type: none"> <li>• Interface <b>xe-0/0/20</b>, port mode <b>tagged-access</b>, connects directly from transit switch TS1 to the FCoE host with ENode1.</li> <li>• Interface <b>xe-0/0/21</b>, port mode <b>trunk</b>, connects directly from transit switch TS1 to transit switch TS2.</li> <li>• Interface <b>xe-0/0/31</b>, port mode <b>trunk</b>, connects directly from transit switch TS2 to transit switch TS1.</li> <li>• Interface <b>xe-0/0/30</b>, port mode <b>tagged-access</b>, connects directly from transit switch TS2 to the FCoE host with ENode2.</li> </ul>
Interface VLAN membership	The interfaces on both transit switches use VLAN <b>vlan200</b> .
VN2VN_Port FIP snooping VLAN	VLAN name (both transit switches)— <b>vlan200</b> VLAN ID—200
FIP snooping mode and beacon period	Set <b>examine-vn2vn</b> (VN2VN_Port FIP snooping) Beacon period—90000 ms

Figure 183 on page 4984 shows the network topology for this example.

**Figure 183: VN2VN\_Port FIP Snooping (FCoE Hosts Connected to Different Transit Switches) Topology**

## Configuration

To configure VN2VN\_Port FIP snooping for VN\_Ports that are directly connected to different transit switches (and the transit switches are directly connected to each other), perform these tasks:

- [Configuring VN2VN\\_Port FIP Snooping on FCoE Transit Switch TS1 on page 4985](#)
- [Configuring VN2VN\\_Port FIP Snooping on FCoE Transit Switch TS2 on page 4986](#)

### CLI Quick Configuration

The configuration for each FCoE transit switch is shown separately.

To quickly configure VN2VN\_Port FIP snooping for FCoE hosts connected directly to different transit switches, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level. To configure FCoE transit switch TS1:

```
set interfaces xe-0/0/20 unit 0 family ethernet-switching port-mode tagged-access
set interfaces xe-0/0/21 unit 0 family ethernet-switching port-mode trunk
set interfaces xe-0/0/20 unit 0 family ethernet-switching vlan members vlan200
set interfaces xe-0/0/21 unit 0 family ethernet-switching vlan members vlan200
set ethernet-switching-options secure-access-port interface xe-0/0/21 fcoe-trusted
set vlans vlan200 vlan-id 200
set ethernet-switching-options secure-access-port vlan vlan200 examine-fip examine-vn2v2
beacon-period 90000
```

To quickly configure VN2VN\_Port FIP snooping for FCoE hosts connected directly to different transit switches, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level. To configure FCoE transit switch TS2:

```
set interfaces xe-0/0/30 unit 0 family ethernet-switching port-mode tagged-access
set interfaces xe-0/0/31 unit 0 family ethernet-switching port-mode trunk
set interfaces xe-0/0/30 unit 0 family ethernet-switching vlan members vlan200
set interfaces xe-0/0/31 unit 0 family ethernet-switching vlan members vlan200
set vlans vlan200 vlan-id 200
set ethernet-switching-options secure-access-port interface xe-0/0/31 fcoe-trusted
set ethernet-switching-options secure-access-port vlan vlan200 examine-fip examine-vn2v2
beacon-period 90000
```

### *Configuring VN2VN\_Port FIP Snooping on FCoE Transit Switch TS1*

### Step-by-Step Procedure

To configure interface port modes, configure interface VLAN membership in the FCoE VLAN dedicated to VN2VN\_Port traffic, set the network-facing port as FCoE trusted, configure the VLAN, set the beacon period, and enable VN2VN\_Port FIP snooping:

1. Configure the port modes of the interfaces that connect directly to the FCoE host with ENode1 (**xe-0/0/20**) and to FCoE transit switch TS2 (**xe-0/0/21**):  
  

```
user@switch# set interfaces xe-0/0/20 unit 0 family ethernet-switching port-mode tagged-access
set interfaces xe-0/0/21 unit 0 family ethernet-switching port-mode trunk
```
2. Configure the interface VLAN membership so that the interfaces are members of the dedicated VN2VN\_Port VLAN (**vlan200**):

```
user@switch# set interfaces xe-0/0/20 unit 0 family ethernet-switching vlan members
vlan200
```

```
set interfaces xe-0/0/21 unit 0 family ethernet-switching vlan members vlan200
```

3. Configure the network-facing port (**xe-0/0/21**) as an FCoE trusted port:

```
user@switch# set ethernet-switching-options secure-access-port interface xe-0/0/21
fcoe-trusted
```

4. Configure the FCoE VLAN dedicated to VN2VN\_Port FIP snooping:

```
user@switch# set vlans vlan200 vlan-id 200
```

5. Enable VN2VN\_Port FIP snooping on the VLAN and configure the beacon period:

```
user@switch# set ethernet-switching-options secure-access-port vlan vlan200 examine-fip
examine-vn2v2 beacon-period 90000
```

### *Configuring VN2VN\_Port FIP Snooping on FCoE Transit Switch TS2*

#### **Step-by-Step Procedure**

To configure interface port modes, configure interface VLAN membership in the FCoE VLAN dedicated to VN2VN\_Port traffic, set the network-facing port as FCoE trusted, configure the VLAN, set the beacon period, and enable VN2VN\_Port FIP snooping:

1. Configure the port modes of the interfaces that connect directly to the FCoE host with ENode2 (**xe-0/0/30**) and to FCoE transit switch TS1 (**xe-0/0/31**):

```
user@switch# set interfaces xe-0/0/30 unit 0 family ethernet-switching port-mode
tagged-access
set interfaces xe-0/0/31 unit 0 family ethernet-switching port-mode trunk
```

2. Configure the interface VLAN membership so that the interfaces are members of the dedicated VN2VN\_Port VLAN (**vlan200**):

```
user@switch# set interfaces xe-0/0/30 unit 0 family ethernet-switching vlan members
vlan200
set interfaces xe-0/0/31 unit 0 family ethernet-switching vlan members vlan200
```

3. Configure the network-facing port (**xe-0/0/31**) as an FCoE trusted port:

```
user@switch# set ethernet-switching-options secure-access-port interface xe-0/0/31
fcoe-trusted
```

4. Configure the FCoE VLAN dedicated to VN2VN\_Port FIP snooping:

```
user@switch# set vlans vlan200 vlan-id 200
```

5. Enable VN2VN\_Port FIP snooping on the VLAN and configure the beacon period:

```
user@switch# set ethernet-switching-options secure-access-port vlan vlan200 examine-fip
examine-vn2v2 beacon-period 90000
```

### **Verification**

---

To verify that the VN2VN\_Port FIP snooping configuration has been created and is operating properly on both switches, perform these tasks:

- [Verifying That VN2VN\\_Port FIP Snooping is Enabled on the FCoE VLAN \(Transit Switches TS1 and TS2\) on page 4987](#)
- [Verifying the Interface Port Mode on page 4989](#)

*Verifying That VN2VN\_Port FIP Snooping is Enabled on the FCoE VLAN (Transit Switches TS1 and TS2)*

**Purpose** Verify that VN2VN\_Port FIP snooping is enabled on the correct VLAN (**vlan200**), the beacon period is set to **90000** milliseconds, and that the correct interfaces (**xe-0/0/20** and **xe-0/0/21** on TS1, and **xe-0/0/30** and **xe-0/0/31** on TS2) are members of the VLAN.

**Action** List the FIP snooping information on transit switch TS1 using the operational mode command **show fip snooping detail**

```
user@switch> show fip snooping detail
VLAN: vlan200, Mode: VN2VN Snooping
FC-MAP: 0e:fd:00
Beacon_Period: 90000
VN2VN Mode: Point-to-Point
 Enode Information
 Enode-MAC: 10:10:94:01:00:02, Interface: xe-0/0/20
 Active VN_Ports : 1
 VN_Port Information
 VN-Port MAC: 0e:fd:00:00:0a:01
 Active Sessions : 1
 Session Information
 Vlink far-end VN-Port-MAC: 0e:fd:00:00:0b:01
 Enode-MAC: 10:10:94:01:00:02, Interface: xe-0/0/21
 Active VN_Ports : 1
 VN_Port Information
 VN-Port MAC: 0e:fd:00:00:0b:01
 Active Sessions : 1
 Session Information
 Vlink far-end VN-Port-MAC: 0e:fd:00:00:0a:01
```

List the FIP snooping information on transit switch TS2 using the operational mode command **show fip snooping detail**

```
user@switch> show fip snooping detail
VLAN: vlan200, Mode: VN2VN Snooping
FC-MAP: 0e:fd:00
Beacon_Period: 90000
VN2VN Mode: Point-to-Point
 Enode Information
 Enode-MAC: 10:10:94:01:00:02, Interface: xe-0/0/30
 Active VN_Ports : 1
 VN_Port Information
 VN-Port MAC: 0e:fd:00:00:0b:01
 Active Sessions : 1
 Session Information
 Vlink far-end VN-Port-MAC: 0e:fd:00:00:0a:01
 Enode-MAC: 10:10:94:01:00:02, Interface: xe-0/0/31
 Active VN_Ports : 1
 VN_Port Information
 VN-Port MAC: 0e:fd:00:00:0a:01
 Active Sessions : 1
 Session Information
 Vlink far-end VN-Port-MAC: 0e:fd:00:00:0b:01
```

**Meaning** The **show fip snooping detail** command lists all of the transit switch information about VN2VN\_Port FIP snooping and VN2VF\_Port FIP snooping on each transit switch. The command shows that:

- The VLAN is **vlan200**.
- The mode is FIP snooping mode **VN2VN**, for VN2VN\_Port FIP snooping. (If the Mode field shows **VN2VF**, then the FIP snooping mode is VN2VF\_Port FIP snooping.)

- The beacon period is **90000**.
- The interfaces connected to the ENodes are **xe-0/0/20** and **xe-0/0/21** on transit switch TS1, and **xe-0/0/30** and **xe-0/0/31** on transit switch TS2. Because the transit switches are transparent passthrough switches, the network-facing trunk ports “see” the FCoE host ENodes at the far end of the VN2VN\_Port virtual link.

In addition, this useful command shows information about the ENodes and the VN2VN\_Port sessions.

### *Verifying the Interface Port Mode*

**Purpose** Verify that the interface port modes are **tagged-access** for ENode-facing ports and **trunk** for network-facing ports on each transit switch.

**Action** List the Ethernet switching interfaces to confirm the port mode using the **show ethernet-switching interfaces detail** operational command.

Use the operational mode commands **show ethernet-switching interfaces xe-0/0/20.0 detail** and **show ethernet-switching interfaces xe-0/0/21.0 detail** to list the Ethernet switching interface information on FCoE transit switch TS1. The output is truncated to show only the relevant portions:

```
user@switch> show ethernet-switching interfaces xe-0/0/20.0 detail
Interface: xe-0/0/20.0, Index: 75, State: up, Port mode: Tagged-Access
.
.
.
```

```
user@switch> show ethernet-switching interfaces xe-0/0/21.0 detail
Interface: xe-0/0/21.0, Index: 83, State: up, Port mode: Trunk
.
.
.
```

List the Ethernet switching interface information on FCoE transit switch TS2 using the operational mode commands **show ethernet-switching interfaces xe-0/0/30.0 detail** and **show ethernet-switching interfaces xe-0/0/31.0 detail**:

```
user@switch> show ethernet-switching interfaces xe-0/0/30.0 detail
Interface: xe-0/0/30.0, Index: 56, State: up, Port mode: Tagged-Access
.
.
.
```

```
user@switch> show ethernet-switching interfaces xe-0/0/31.0 detail
Interface: xe-0/0/31.0, Index: 59, State: up, Port mode: Trunk
.
.
.
```

### Example: Configuring VN2VN\_Port FIP Snooping (FCoE Hosts Indirectly Connected Through an Aggregation Layer FCoE Transit Switch)

This example shows how to configure VN\_Port to VN\_Port (VN2VN\_Port) FIP snooping when the hosts are indirectly connected through an aggregation layer FCoE transit switch. Each FCoE host ENode is directly connected to an FCoE transit switch, but the FCoE transit switches are not directly connected to each other. The FCoE transit switches are both connected to a third FCoE transit switch that acts as an aggregation layer switch.

**NOTE:** This example uses Junos OS without support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that supports ELS, see [“Example: Configuring VN2VN\\_Port FIP Snooping \(FCoE Hosts Indirectly Connected Through an Aggregation Layer FCoE Transit Switch\)” on page 5036](#).

VN2VN\_Port FIP snooping on an FCoE transit switch provides security to help prevent unauthorized access and data transmission on a bridge that connects ENodes in the Ethernet network. VN2VN\_Port FIP snooping provides security for virtual links by creating filters based on information gathered (snooped) about FCoE devices during FIP transactions.

VN2VN\_Port FIP snooping is conceptually similar to VN2VN\_Port FIP snooping between VN\_Ports and VF\_Ports, but VN2VN\_Port FIP snooping does not require traffic between VN\_Ports to traverse the Fibre Channel (FC) switch or FCoE forwarder (FCF). Instead, a VN\_Port communicates transparently through one or more transit switches on a virtual link that emulates a direct connection to the VN\_Port at the other end of the virtual link.

To configure VN2VN\_Port FIP snooping when the hosts are indirectly connected, you must follow these configuration rules:

- VN2VN\_Port traffic must use a dedicated FCoE VLAN, and all ENodes that communicate using VN2VN\_Port FIP snooping must use that FCoE VLAN. The FCoE VLAN must be configured on each transit switch. You cannot mix VN2VN\_Port FIP snooping traffic with VN2VF\_Port FIP snooping traffic in the same FCoE VLAN.

**NOTE:** An FCoE VLAN can support either VN2VF\_Port FIP snooping or VN2VN\_Port FIP snooping, but not both. Configure separate FCoE VLANs for VN2VF\_Port FIP snooping traffic and for VN2VN\_Port FIP snooping traffic. On FCoE VLANs that are configured as VN2VN\_Port FIP snooping VLANs, VN\_Port to VF\_Port traffic is dropped.

- ENode-facing ports must be set in **tagged-access** port mode.

- ENode-facing ports must be untrusted ports.
- Network-facing (switch-facing) ports must be set in **trunk** port mode.
- Network-facing ports must be FCoE trusted ports.
- Explicitly configure the beacon period. The beacon period is essentially a keepalive timer for virtual link maintenance.

When you enable FIP snooping, the system snoops VN\_Port to VF\_Port packets and enforces security only on VN\_Port to VF\_Port virtual links. When you enable VN2VN\_Port FIP snooping, the system snoops VN\_Port to VN\_Port packets and enforces security only on VN\_Port to VN\_Port virtual links.

The transit switch applies VN2VN\_Port FIP snooping filters at the ports associated with the FCoE VLANs on which you enable VN2VN FIP snooping.

This example describes how to configure VN2VN\_Port FIP snooping when the FCoE hosts are indirectly connected across an aggregation layer FCoE transit switch:

- [Requirements on page 4991](#)
- [Overview on page 4991](#)
- [Configuration on page 4993](#)
- [Verification on page 4995](#)

---

### Requirements

This example uses the following hardware and software components:

- Three Juniper Networks QFX3500 Switches used as transit switches
- Junos OS Release 12.2 or later for the QFX Series
- Two FCoE hosts that have ENodes

---

### Overview

This example shows you how to:

- Set the correct interface port modes on the transit switch.
- Configure the interfaces to use the dedicated FCoE VLAN for VN2VN\_Port FIP snooping.
- Configure the network-facing interfaces as FCoE trusted interfaces.
- Configure the dedicated FCoE VLAN for VN2VN\_Port FIP snooping traffic.
- Enable VN2VN\_Port FIP snooping on the FCoE VLAN and configure the beacon period.

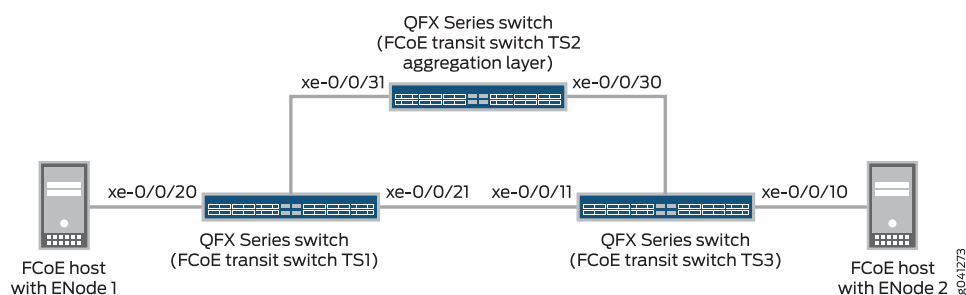

### Topology

[Table 387 on page 4992](#) shows the configuration components for this example.

**Table 387: Components of the VN2VN\_Port FIP Snooping Configuration Topology (FCoE Hosts Indirectly Connected Across an Aggregation Layer FCoE Transit Switch)**

Component	Settings
Hardware	<p>Three QFX3500 switches, two of which are FCoE transit switches that are directly attached to the FCoE hosts (transit switches TS1 and TS2) and one of which is an aggregation layer FCoE transit switch (TS3)</p> <p>Two FCoE hosts that have ENodes (ENode1 and ENode2, respectively)</p>

Figure 184 on page 4992 shows the network topology for this example.

**Figure 184: VN2VN\_Port FIP Snooping (FCoE Hosts Indirectly Connected) Topology**

## Configuration

To configure VN2VN\_Port FIP snooping for VN\_Ports that are indirectly connected across an aggregation layer FCoE transit switch, perform these tasks:

- [Configuring VN2VN\\_Port FIP Snooping on FCoE Transit Switch TS1 on page 4994](#)
- [Configuring VN2VN\\_Port FIP Snooping on Aggregation Layer FCoE Transit Switch TS2 on page 4994](#)
- [Configuring VN2VN\\_Port FIP Snooping on FCoE Transit Switch TS3 on page 4995](#)

### CLI Quick Configuration

The configuration for each FCoE transit switch is shown separately.

To quickly configure VN2VN\_Port FIP snooping for FCoE hosts that are indirectly connected across an aggregation layer FCoE transit switch, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level. To configure FCoE transit switch TS1:

```
set interfaces xe-0/0/20 unit 0 family ethernet-switching port-mode tagged-access
set interfaces xe-0/0/21 unit 0 family ethernet-switching port-mode trunk
set interfaces xe-0/0/20 unit 0 family ethernet-switching vlan members vlan200
set interfaces xe-0/0/21 unit 0 family ethernet-switching vlan members vlan200
set ethernet-switching-options secure-access-port interface xe-0/0/21 fcoe-trusted
set vlans vlan200 vlan-id 200
set ethernet-switching-options secure-access-port vlan vlan200 examine-fip examine-vn2v2
beacon-period 90000
```

To quickly configure VN2VN\_Port FIP snooping for FCoE hosts that are indirectly connected across an aggregation layer FCoE transit switch, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level. To configure FCoE transit switch TS2:

```
set interfaces xe-0/0/30 unit 0 family ethernet-switching port-mode trunk
set interfaces xe-0/0/31 unit 0 family ethernet-switching port-mode trunk
set interfaces xe-0/0/30 unit 0 family ethernet-switching vlan members vlan200
set interfaces xe-0/0/31 unit 0 family ethernet-switching vlan members vlan200
set vlans vlan200 vlan-id 200
set ethernet-switching-options secure-access-port interface xe-0/0/30 fcoe-trusted
set ethernet-switching-options secure-access-port interface xe-0/0/31 fcoe-trusted
set ethernet-switching-options secure-access-port vlan vlan200 examine-fip examine-vn2v2
beacon-period 90000
```

To quickly configure VN2VN\_Port FIP snooping for FCoE hosts that are indirectly connected across an aggregation layer FCoE transit switch, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level. To configure FCoE transit switch TS3:

```
set interfaces xe-0/0/10 unit 0 family ethernet-switching port-mode tagged-access
set interfaces xe-0/0/11 unit 0 family ethernet-switching port-mode trunk
set interfaces xe-0/0/10 unit 0 family ethernet-switching vlan members vlan200
set interfaces xe-0/0/11 unit 0 family ethernet-switching vlan members vlan200
set vlans vlan200 vlan-id 200
set ethernet-switching-options secure-access-port interface xe-0/0/11 fcoe-trusted
set ethernet-switching-options secure-access-port vlan vlan200 examine-fip examine-vn2v2
beacon-period 90000
```

### *Configuring VN2VN\_Port FIP Snooping on FCoE Transit Switch TS1*

- Step-by-Step Procedure** To configure interface port modes, configure interface VLAN membership in the FCoE VLAN dedicated to VN2VN\_Port traffic, set the network-facing port as FCoE trusted, configure the VLAN, set the beacon period, and enable VN2VN\_Port FIP snooping:
1. Configure the port modes of the interfaces that connect directly to the FCoE host with ENode1 (xe-0/0/20) and to aggregation layer FCoE transit switch TS2 (xe-0/0/21):  

```
user@switch# set interfaces xe-0/0/20 unit 0 family ethernet-switching port-mode tagged-access
set interfaces xe-0/0/21 unit 0 family ethernet-switching port-mode trunk
```
  2. Configure the interface VLAN membership so that the interfaces are members of the dedicated VN2VN\_Port VLAN (vlan200):  

```
user@switch# set interfaces xe-0/0/20 unit 0 family ethernet-switching vlan members vlan200
set interfaces xe-0/0/21 unit 0 family ethernet-switching vlan members vlan200
```
  3. Configure the network-facing port (xe-0/0/21) as an FCoE trusted port:  

```
user@switch# set ethernet-switching-options secure-access-port interface xe-0/0/21 fcoe-trusted
```
  4. Configure the FCoE VLAN dedicated to VN2VN\_Port FIP snooping:  

```
user@switch# set vlans vlan200 vlan-id 200
```
  5. Enable VN2VN\_Port FIP snooping on the VLAN and configure the beacon period:  

```
user@switch# set ethernet-switching-options secure-access-port vlan vlan200 examine-fip examine-vn2v2 beacon-period 90000
```

### *Configuring VN2VN\_Port FIP Snooping on Aggregation Layer FCoE Transit Switch TS2*

- Step-by-Step Procedure** To configure interface port modes, configure interface VLAN membership in the FCoE VLAN dedicated to VN2VN\_Port traffic, set the network-facing ports as FCoE trusted, configure the VLAN, set the beacon period, and enable VN2VN\_Port FIP snooping:
1. Configure the port modes of the interfaces that connect directly to FCoE transit switches TS1 (xe-0/0/31) and TS3 (xe-0/0/30). Both interfaces are network-facing and must be configured as trunk interfaces:  

```
user@switch# set interfaces xe-0/0/30 unit 0 family ethernet-switching port-mode trunk
set interfaces xe-0/0/31 unit 0 family ethernet-switching port-mode trunk
```
  2. Configure the interface VLAN membership so that the interfaces are members of the dedicated VN2VN\_Port VLAN (vlan200):  

```
user@switch# set interfaces xe-0/0/30 unit 0 family ethernet-switching vlan members vlan200
set interfaces xe-0/0/31 unit 0 family ethernet-switching vlan members vlan200
```
  3. Configure the network-facing ports (xe-0/0/30 and xe-0/0/31) as FCoE trusted ports:  

```
user@switch# set ethernet-switching-options secure-access-port interface xe-0/0/30 fcoe-trusted
```

```
user@switch# set ethernet-switching-options secure-access-port interface xe-0/0/31
fcoe-trusted
```

4. Configure the FCoE VLAN dedicated to VN2VN\_Port FIP snooping:

```
user@switch# set vlans vlan200 vlan-id 200
```

5. Enable VN2VN\_Port FIP snooping on the VLAN and configure the beacon period:

```
user@switch# set ethernet-switching-options secure-access-port vlan vlan200 examine-fip
examine-vn2v2 beacon-period 90000
```

### *Configuring VN2VN\_Port FIP Snooping on FCoE Transit Switch TS3*

#### **Step-by-Step Procedure**

To configure interface port modes, configure interface VLAN membership in the FCoE VLAN dedicated to VN2VN\_Port traffic, set the network-facing port as FCoE trusted, configure the VLAN, set the beacon period, and enable VN2VN\_Port FIP snooping:

1. Configure the port modes of the interfaces that connect directly to the FCoE host with ENode2 (xe-0/0/10) and to aggregation layer FCoE transit switch TS2 (xe-0/0/11):

```
user@switch# set interfaces xe-0/0/10 unit 0 family ethernet-switching port-mode
tagged-access
set interfaces xe-0/0/11 unit 0 family ethernet-switching port-mode trunk
```

2. Configure the interface VLAN membership so that the interfaces are members of the dedicated VN2VN\_Port VLAN (vlan200):

```
user@switch# set interfaces xe-0/0/10 unit 0 family ethernet-switching vlan members
vlan200
set interfaces xe-0/0/11 unit 0 family ethernet-switching vlan members vlan200
```

3. Configure the network-facing port (xe-0/0/11) as an FCoE trusted port:

```
user@switch# set ethernet-switching-options secure-access-port interface xe-0/0/11
fcoe-trusted
```

4. Configure the FCoE VLAN dedicated to VN2VN\_Port FIP snooping:

```
user@switch# set vlans vlan200 vlan-id 200
```

5. Enable VN2VN\_Port FIP snooping on the VLAN and configure the beacon period:

```
user@switch# set ethernet-switching-options secure-access-port vlan vlan200 examine-fip
examine-vn2v2 beacon-period 90000
```

### **Verification**

To verify that the VN2VN\_Port FIP snooping configuration has been created and is operating properly on all three switches, perform these tasks:

- [Verifying That VN2VN\\_Port FIP Snooping Is Enabled on the FCoE VLAN \(All Three Transit Switches\)](#) on page 4995
- [Verifying the Interface Port Mode](#) on page 4998

#### ***Verifying That VN2VN\_Port FIP Snooping Is Enabled on the FCoE VLAN (All Three Transit Switches)***

**Purpose** Verify that VN2VN\_Port FIP snooping is enabled on the correct VLAN (vlan200), the beacon period is set to 90000 milliseconds, and that the correct interfaces (xe-0/0/20

and **xe-0/0/21** on TS1, **xe-0/0/30** and **xe-0/0/31** aggregation layer TS2, and **xe-0/0/10** and **xe-0/0/11** on TS3) are members of the VLAN.

**Action** List the FIP snooping information on transit switch TS1 using the operational mode command **show fip snooping detail**

```
user@switch> show fip snooping detail
VLAN: vlan200, Mode: VN2VN Snooping
FC-MAP: 0e:fd:00
Beacon_Period: 90000
VN2VN Mode: Point-to-Point
 Enode Information
 Enode-MAC: 10:10:94:01:00:02, Interface: xe-0/0/20
 Active VN_Ports : 1
 VN_Port Information

Active VN_Ports : 1
VN_Port Information
VN-Port MAC: 0e:fd:00:00:0a:01
Active Sessions : 1
Session Information
Vlink far-end VN-Port-MAC: 0e:fd:00:00:0b:01
```

**Meaning** The **show fip snooping detail** command lists all of the transit switch information about VN2VN\_Port FIP snooping and VN2VF\_Port FIP snooping on each transit switch. The command shows that:

- The VLAN is **vlan200**.
- The mode is FIP snooping mode **VN2VN**, for VN2VN\_Port FIP snooping. (If the Mode field shows **VN2VF**, then the FIP snooping mode is VN2VF\_Port FIP snooping.)
- The beacon period is **90000**.
- The interfaces connected to the ENodes are **xe-0/0/20** and **xe-0/0/21** on transit switch TS1, **xe-0/0/30** and **xe-0/0/31** on aggregation layer transit switch TS2, and **xe-0/0/10** and **xe-0/0/11** on transit switch TS3. Because the transit switches are transparent passthrough switches, the network-facing trunk ports “see” the FCoE host ENodes at the far end of the VN2VN\_Port virtual link.

In addition, this useful command shows information about the ENodes and the VN2VN\_Port sessions.

#### *Verifying the Interface Port Mode*

**Purpose** Verify that the interface port modes are **tagged-access** for ENode-facing ports and **trunk** for network-facing ports on each transit switch.

**Action** List the Ethernet switching interfaces to confirm the port mode using the **show ethernet-switching interfaces detail** operational command for each interface. The output is truncated to show only the relevant portions.

List the Ethernet switching interface information on FCoE transit switch TS1 using the operational mode commands **show ethernet-switching interfaces xe-0/0/20.0 detail** and **show ethernet-switching interfaces xe-0/0/21.0 detail**:

```
user@switch> show ethernet-switching interfaces xe-0/0/20.0 detail
Interface: xe-0/0/20.0, Index: 75, State: up, Port mode: Tagged-Access
.
.
.
user@switch> show ethernet-switching interfaces xe-0/0/21.0 detail
```

```
Interface: xe-0/0/21.0, Index: 83, State: up, Port mode: Trunk
.
.
.
```

List the Ethernet switching interface information on aggregation layer FCoE transit switch TS2 using the operational mode commands **show ethernet-switching interfaces xe-0/0/30.0 detail** and **show ethernet-switching interfaces xe-0/0/31.0 detail**:

```
user@switch> show ethernet-switching interfaces xe-0/0/30.0 detail
Interface: xe-0/0/30.0, Index: 71, State: up, Port mode: Trunk
.
.
.
```

```
user@switch> show ethernet-switching interfaces xe-0/0/31.0 detail
Interface: xe-0/0/31.0, Index: 73, State: up, Port mode: Trunk
.
.
.
```

List the Ethernet switching interface information on FCoE transit switch TS3 using the operational mode commands **show ethernet-switching interfaces xe-0/0/10.0 detail** and **show ethernet-switching interfaces xe-0/0/11.0 detail**:

```
user@switch> show ethernet-switching interfaces xe-0/0/10.0 detail
Interface: xe-0/0/10.0, Index: 56, State: up, Port mode: Tagged-Access
.
.
.
```

```
user@switch> show ethernet-switching interfaces xe-0/0/11.0 detail
Interface: xe-0/0/11.0, Index: 59, State: up, Port mode: Trunk
.
.
.
```

## Example: Configuring Automated Fibre Channel Interface Load Rebalancing

Automated Fibre Channel (FC) interface (NP\_Port) load rebalancing configures the switch to rebalance the session loads on the native FC interfaces automatically on a load-rebalancing trigger event. (Alternatively, you can rebalance the link load on the FC interfaces on demand so that you control when the link load is rebalanced.) Rebalancing the FC link load is a disruptive action that causes some or all of the current sessions to log out, then log in again to be placed on the active FC links in a balanced manner.

This example shows you how to configure and verify automated FC link load rebalancing on an FCoE-FC gateway local FC fabric.

- [Requirements on page 5000](#)
- [Overview on page 5000](#)
- [Configuration on page 5001](#)
- [Verification on page 5002](#)

---

## Requirements

This example uses the following hardware and software components:

- Juniper Networks QFX3500 Switch
- Junos OS Release 12.3 or later for the QFX Series

---

## Overview

When a load rebalancing trigger occurs, the switch automatically rebalances the link loads by redistributing the sessions across the active NP\_Port links.

There are three possible load-rebalancing triggers:

1. When you enable automated load rebalancing, the switch checks the load balance on the existing NP\_Port links. If the links are already balanced, the switch does not rebalance the link load. If the links are not balanced, the switch rebalances the link loads using the configured load-balancing algorithm.
2. When a new NP\_Port link comes up on a local FCoE-FC gateway fabric, the switch rebalances the link load using the configured load-balancing algorithm if automated load balancing is enabled.
3. When the port speed is changed (unless the port speed change does not change the actual port speed, for example, changing the port speed from auto to 8 Gbps).

Automated load rebalancing logs out sessions in accordance with the configured load-balancing algorithm. Disabling automated load rebalancing is not disruptive because the link load is already balanced.

Use automated load rebalancing if you want link loads to be rebalanced automatically instead of at times of your choosing. Keep in mind that load rebalancing is a disruptive event (sessions are logged out).

## Topology

This example configures automated load rebalancing on a local FC fabric on an FCoE-FC gateway. This example does not show you how to configure the load-balancing algorithm or any other load-balancing characteristics. The load-balancing configuration for this example is:

- FC fabric name—`fc_fabric_100`
- FC fabric ID—100

- FC fabric type—Proxy
- FC fabric interfaces—fc-0/0/0, fc-0/0/1, fc-0/0/42, fc-0/0/43, vlan.100, vlan.20
- Load-balancing algorithm—Simple
- No fabric WWN verify—Configured
- Traceoptions—Configured to log in file fc\_fabric\_100\_proxy.log

## Configuration

To configure automated load balancing on a local FC fabric, perform this task:

- [\[xref target has no title\]](#)
- [Results on page 5001](#)

### CLI Quick Configuration

To quickly configure automated load balancing, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level:

```
[edit]
set fc-fabrics fc_fabric_100 proxy auto-load-rebalance
```

### Step-by-Step Procedure

- Configure automated load balancing on FC fabric fc\_fabric\_100:  
user@switch# set fc-fabrics fc\_fabric\_100 proxy auto-load-rebalance

## Results

Display the results of the configuration:

```
user@switch> show configuration fc-fabrics
fc_fabric_100 {
 fabric-id 100;
 fabric-type proxy;
 interface {
 fc-0/0/0.0;
 fc-0/0/1.0;
 vlan.100;
 vlan.20;
 fc-0/0/42.0;
 fc-0/0/43.0;
 }
 proxy {
 traceoptions {
 file fc_fabric_100_proxy.log size 20m;
 flag all;
 }
 load-balance-algorithm simple;
 auto-load-rebalance;
 no-fabric-wwn-verify;
 }
}
```

## Verification

---

### *Verifying That Automated Load Rebalancing Is Enabled*

**Purpose** Verify that automated load rebalancing is configured on local FC fabric **fc\_fabric\_100**.

**Action** Verify the results of the automated load-rebalancing configuration using the operational mode command **show fibre-channel proxy fabric-state fabric fc\_fabric\_100**:

```
user@switch> show fibre-channel proxy fabric-state fabric fc_fabric_100
Fabric: fc_fabric_100, Fabric-id: 100
Proxy load balance algorithm: Simple, Fabric WWN verification: No
Auto load rebalance enabled : Yes
Last rebalance start-time : Never
Last rebalance end-time : Never
Last rebalance trigger : None
Last rebalance trigger-time : Mon Sep 10 21:42:30 2012 usec: 814602
Last rebalance trigger-result: None
```

**Meaning** The **show fibre-channel proxy fabric-state fabric fc\_fabric\_100** operational command displays information about the specified local FC fabric. The output shows that the **Auto load rebalance enabled** field value is **Yes**, which indicates that automated load rebalancing is enabled on fabric **fc\_fabric\_100**.

- [Example: Configuring VN2VN\\_Port FIP Snooping \(FCoE Hosts Indirectly Connected Through an Aggregation Layer FCoE Transit Switch\) on page 5036](#)

### Example: Configuring CoS for FCoE Transit Switch Traffic Across an MC-LAG

Multichassis link aggregation groups (MC-LAGs) provide redundancy and load balancing between two QFX Series switches, multihoming support for client devices such as servers, and a loop-free Layer 2 network without running Spanning Tree Protocol (STP).

**NOTE:** This example uses the Junos OS Enhanced Layer 2 Software (ELS) configuration style for QFX Series switches. If your switch runs software that does not support ELS, see [“Example: Configuring CoS for FCoE Transit Switch Traffic Across an MC-LAG” on page 4940](#). For ELS details, see [“Getting Started with Enhanced Layer 2 Software” on page 58](#).

You can use an MC-LAG to provide a redundant aggregation layer for Fiber Channel over Ethernet (FCoE) traffic in an *inverted-U* topology. To support lossless transport of FCoE traffic across an MC-LAG, you must configure the appropriate class of service (CoS) on both of the QFX Series switches with MC-LAG port members. The CoS configuration must be the same on both of the MC-LAG switches because an MC-LAG does not carry forwarding class and IEEE 802.1p priority information.

Ports that are members of an MC-LAG act as FCoE passthrough transit switch ports.

**NOTE:** This example describes how to configure CoS to provide lossless transport for FCoE traffic across an MC-LAG that connects two QFX Series switches. It also describes how to configure CoS on the FCoE transit switches that connect FCoE hosts to the QFX Series switches that form the MC-LAG.

This example does *not* describe how to configure the MC-LAG itself. For a detailed example of MC-LAG configuration, see [“Example: Configuring Multichassis Link Aggregation” on page 1904](#). However, this example includes a subset of MC-LAG configuration that only shows how to configure interface membership in the MC-LAG.

QFX3500 and QFX3600 Virtual Chassis switches do not support FCoE.

This topic describes:

- [Requirements on page 5003](#)
- [Overview on page 5004](#)
- [Configuration on page 5008](#)
- [Verification on page 5017](#)

## Requirements

This example uses the following hardware and software components:

- Two Juniper Networks QFX5100 Switches running the ELS CLI that form an MC-LAG for FCoE traffic.
- Two Juniper Networks QFX5100 Switches running the ELS CLI that provide FCoE server access in transit switch mode and that connect to the MC-LAG switches.
- FCoE servers (or other FCoE hosts) connected to the transit switches.
- Junos OS Release 13.2 or later for the QFX Series.

## Overview

---

FCoE traffic requires lossless transport. This example shows you how to:

- Configure CoS for FCoE traffic on the two QFX5100 switches that form the MC-LAG, including priority-based flow control (PFC) and enhanced transmission selection (ETS; hierarchical scheduling of resources for the FCoE forwarding class priority and for the forwarding class set priority group).

**NOTE:** Configuring or changing PFC on an interface blocks the entire port until the PFC change is completed. After a PFC change is completed, the port is unblocked and traffic resumes. Blocking the port stops ingress and egress traffic, and causes packet loss on all queues on the port until the port is unblocked.

- Configure CoS for FCoE on the two FCoE transit switches that connect FCoE hosts to the MC-LAG switches and enable FIP snooping on the FCoE VLAN at the FCoE transit switch access ports.
- Configure the appropriate port mode, MTU, and FCoE trusted or untrusted state for each interface to support lossless FCoE transport.

**NOTE:** Do not enable IGMP snooping on the FCoE VLAN. (IGMP snooping is enabled on the default VLAN by default, but is disabled by default on all other VLANs.)

## Topology

QFX5100 switches that act as transit switches support MC-LAGs for FCoE traffic in an inverted-U network topology, as shown in [Figure 180 on page 4942](#).

Figure 185: Supported Topology for an MC-LAG on an FCoE Transit Switch

g041307

Table 383 on page 4943 shows the configuration components for this example.

Table 388: Components of the CoS for FCoE Traffic Across an MC-LAG Configuration Topology

Component	Settings
Hardware	Four QFX5100 switches running the ELS CLI (two to form the MC-LAG as passthrough transit switches and two transit switches for FCoE access).
Forwarding class (all switches)	Default <b>fcoe</b> forwarding class.
Classifier (forwarding class mapping of incoming traffic to IEEE priority)	Default IEEE 802.1p trusted classifier on all FCoE interfaces.

FCoE VLAN name and tag ID	<p>Name—<b>fcoe_vlan</b> ID—<b>100</b></p> <p>Include the FCoE VLAN on the interfaces that carry FCoE traffic on all four switches.</p>
FIP snooping	<p>Enable FIP snooping on Transit Switches TS1 and TS2 on the FCoE VLAN. Configure the LAG interfaces that connect to the MC-LAG switches as FCoE trusted interfaces so that they do not perform FIP snooping.</p> <p>This example enables VN2VN_Port FIP snooping on the FCoE transit switch interfaces connected to the FCoE servers. The example is equally valid with VN2VF_Port FIP snooping enabled on the transit switch access ports. The method of FIP snooping you enable depends on your network configuration.</p>

**NOTE:** This example uses the default IEEE 802.1p trusted BA classifier, which is automatically applied to trunk mode interfaces if you do not apply an explicitly configured classifier.

To configure CoS for FCoE traffic across an MC-LAG:

- Use the default FCoE forwarding class and forwarding-class-to-queue mapping (do not explicitly configure the FCoE forwarding class or output queue). The default FCoE forwarding class is **fcoe**, and the default output queue is queue **3**.
- Use the default trusted BA classifier, which maps incoming packets to forwarding classes by the IEEE 802.1p code point (CoS priority) of the packet. The trusted classifier is the default classifier for interfaces in trunk interface mode. The default trusted classifier maps incoming packets with the IEEE 802.1p code point 3 (**011**) to the FCoE forwarding class. If you choose to configure the BA classifier instead of using the default classifier, you must ensure that FCoE traffic is classified into forwarding classes in exactly the same way on both MC-LAG switches. Using the default classifier ensures consistent classifier configuration on the MC-LAG ports.

- Configure a congestion notification profile that enables PFC on the FCoE code point (code point 011 in this example). The congestion notification profile configuration must be the same on both MC-LAG switches.
- Apply the congestion notification profile to the interfaces.
- Configure enhanced transmission selection (ETS, also known as hierarchical scheduling) on the interfaces to provide the bandwidth required for lossless FCoE transport. Configuring ETS includes configuring bandwidth scheduling for the FCoE forwarding class, a forwarding class set (priority group) that includes the FCoE forwarding class, and a traffic control profile to assign bandwidth to the forwarding class set that includes FCoE traffic.
- Apply the ETS scheduling to the interfaces.
- Configure the interface mode, MTU, and FCoE trusted or untrusted state for each interface to support lossless FCoE transport.

In addition, this example describes how to enable FIP snooping on the Transit Switch TS1 and TS2 ports that are connected to the FCoE servers. To provide secure access, FIP snooping must be enabled on the FCoE access ports.

This example focuses on the CoS configuration to support lossless FCoE transport across an MC-LAG. This example does not describe how to configure the properties of MC-LAGs and LAGs, although it does show you how to configure the port characteristics required to support lossless transport and how to assign interfaces to the MC-LAG and to the LAGs.

Before you configure CoS, configure:

- The MC-LAGs that connect Switches S1 and S2 to Switches TS1 and TS2. ([“Example: Configuring Multichassis Link Aggregation” on page 1904](#) describes how to configure MC-LAGs.)
- The LAGs that connect the Transit Switches TS1 and TS2 to MC-LAG Switches S1 and S2. ([“Configuring Link Aggregation” on page 2019](#) describes how to configure LAGs.)
- The LAG that connects Switch S1 to Switch S2.

---

## Configuration

To configure CoS for lossless FCoE transport across an MC-LAG, perform these tasks:

- [Configuring MC-LAG Switches S1 and S2 on page 5010](#)
- [Configuring FCoE Transit Switches TS1 and TS2 on page 5012](#)
- [Results on page 5014](#)

### CLI Quick Configuration

To quickly configure CoS for lossless FCoE transport across an MC-LAG, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI for MC-LAG Switch S1 and MC-LAG Switch S2 at the **[edit]** hierarchy level. The configurations on Switches S1 and S2 are identical because the CoS configuration must be identical, and because this example uses the same ports on both switches.

## Switch S1 and Switch S2

```

set class-of-service schedulers fcoe-sched priority low transmit-rate 3g
set class-of-service schedulers fcoe-sched shaping-rate percent 100
set class-of-service scheduler-maps fcoe-map forwarding-class fcoe scheduler fcoe-sched
set class-of-service forwarding-class-sets fcoe-pg class fcoe
set class-of-service traffic-control-profiles fcoe-tcp scheduler-map fcoe-map guaranteed-rate
3g
set class-of-service traffic-control-profiles fcoe-tcp shaping-rate percent 100
set class-of-service interfaces ae0 forwarding-class-set fcoe-pg output-traffic-control-profile
fcoe-tcp
set class-of-service interfaces ae1 forwarding-class-set fcoe-pg output-traffic-control-profile
fcoe-tcp
set class-of-service congestion-notification-profile fcoe-cnp input ieee-802.1 code-point 011 pfc
set class-of-service interfaces ae0 congestion-notification-profile fcoe-cnp
set class-of-service interfaces ae1 congestion-notification-profile fcoe-cnp
set vlans fcoe_vlan vlan-id 100
set interfaces xe-0/0/10 ether-options 802.3ad ae0
set interfaces xe-0/0/11 ether-options 802.3ad ae0
set interfaces xe-0/0/20 ether-options 802.3ad ae1
set interfaces xe-0/0/21 ether-options 802.3ad ae1
set interfaces ae0 unit 0 family ethernet-switching interface-mode trunk vlan members fcoe_vlan
set interfaces ae1 unit 0 family ethernet-switching interface-mode trunk vlan members fcoe_vlan
set interfaces ae0 mtu 2180
set interfaces ae1 mtu 2180
set vlans fcoe_vlan forwarding-options fip-security interface ae0 fcoe-trusted
set vlans fcoe_vlan forwarding-options fip-security interface ae1 fcoe-trusted

```

To quickly configure CoS for lossless FCoE transport across an MC-LAG, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI for Transit Switch TS1 and Transit Switch TS2 at the **[edit]** hierarchy level. The configurations on Switches TS1 and TS2 are identical because the CoS configuration must be identical, and because this example uses the same ports on both switches.

## Switch TS1 and Switch TS2

```

set class-of-service schedulers fcoe-sched priority low transmit-rate 3g
set class-of-service schedulers fcoe-sched shaping-rate percent 100

set vlans fcoe_vlan forwarding-options fip-security examine-vn2v2 beacon-period 90000

```

### Configuring MC-LAG Switches S1 and S2

#### Step-by-Step Procedure

To configure CoS resource scheduling (ETS), PFC, the FCoE VLAN, and the LAG and MC-LAG interface membership and characteristics to support lossless FCoE transport across an MC-LAG (this example uses the default **fcoe** forwarding class and the default classifier to map incoming FCoE traffic to the FCoE IEEE 802.1p code point 011, so you do not configure them):

1. Configure output scheduling for the FCoE queue:

```

[edit class-of-service]
user@switch# set schedulers fcoe-sched priority low transmit-rate 3g
user@switch# set schedulers fcoe-sched shaping-rate percent 100

```

2. Map the FCoE forwarding class to the FCoE scheduler (**fcoe-sched**):

```

[edit class-of-service]
user@switch# set scheduler-maps fcoe-map forwarding-class fcoe scheduler fcoe-sched

```

3. Configure the forwarding class set (**fcoe-pg**) for the FCoE traffic:

```

[edit class-of-service]
user@switch# set forwarding-class-sets fcoe-pg class fcoe

```

4. Define the traffic control profile (**fcoe-tcp**) to use on the FCoE forwarding class set:

```

[edit class-of-service]
user@switch# set traffic-control-profiles fcoe-tcp scheduler-map fcoe-map
guaranteed-rate 3g
user@switch# set traffic-control-profiles fcoe-tcp shaping-rate percent 100

```

5. Apply the FCoE forwarding class set and traffic control profile to the LAG and MC-LAG interfaces:

```

[edit class-of-service]
user@switch# set interfaces ae0 forwarding-class-set fcoe-pg output-traffic-control-profile fcoe-tcp
user@switch# set interfaces ae1 forwarding-class-set fcoe-pg output-traffic-control-profile fcoe-tcp

```

6. Enable PFC on the FCoE priority by creating a congestion notification profile (**fcoe-cnp**) that applies FCoE to the IEEE 802.1 code point **011**:

```
[edit class-of-service]
user@switch# set congestion-notification-profile fcoe-cnp input ieee-802.1 code-point
011 pfc
```

7. Apply the PFC configuration to the LAG and MC-LAG interfaces:

```
[edit class-of-service]
user@switch# set interfaces ae0 congestion-notification-profile fcoe-cnp
user@switch# set interfaces ae1 congestion-notification-profile fcoe-cnp
```

8. Configure the VLAN for FCoE traffic (**fcoe\_vlan**):

```
[edit vlans]
user@switch# set fcoe_vlan vlan-id 100
```

9. Add the member interfaces to the LAG between the two MC-LAG switches:

```
[edit interfaces]
user@switch# set xe-0/0/10 ether-options 802.3ad ae0
user@switch# set xe-0/0/11 ether-options 802.3ad ae0
```

10. Add the member interfaces to the MC-LAG:

```
[edit interfaces]
user@switch# set xe-0/0/20 ether-options 802.3ad ae1
user@switch# set xe-0/0/21 ether-options 802.3ad ae1
```

11. Configure the interface mode as **trunk** and membership in the FCoE VLAN (**fcoe\_vlan**) for the LAG (**ae0**) and for the MC-LAG (**ae1**):

```
[edit interfaces]
user@switch# set interfaces ae0 unit 0 family ethernet-switching interface-mode trunk
vlan members fcoe_vlan
user@switch# set interfaces ae1 unit 0 family ethernet-switching interface-mode trunk
vlan members fcoe_vlan
```

12. Set the MTU to **2180** for the LAG and MC-LAG interfaces. 2180 bytes is the minimum size required to handle FCoE packets because of the payload and header sizes; you can configure the MTU to a higher number of bytes if desired, but not less than 2180 bytes:

```
[edit interfaces]
user@switch# set ae0 mtu 2180
user@switch# set ae1 mtu 2180
```

13. Set the LAG and MC-LAG interfaces as FCoE trusted ports. Ports that connect to other switches should be trusted and should not perform FIP snooping:

```
[edit]
user@switch# set vlans fcoe_vlan forwarding-options fip-security interface ae0 fcoe-trusted
user@switch# set vlans fcoe_vlan forwarding-options fip-security interface ae1 fcoe-trusted
```

### *Configuring FCoE Transit Switches TS1 and TS2*

#### **Step-by-Step Procedure**

The CoS configuration on FCoE Transit Switches TS1 and TS2 is similar to the CoS configuration on MC-LAG Switches S1 and S2. However, the port configurations differ, and you must enable FIP snooping on the Switch TS1 and Switch TS2 FCoE access ports.

To configure resource scheduling (ETS), PFC, the FCoE VLAN, and the LAG interface membership and characteristics to support lossless FCoE transport across the MC-LAG (this example uses the default **fcoe** forwarding class and the default classifier to map incoming FCoE traffic to the FCoE IEEE 802.1p code point **011**, so you do not configure them):

1. Configure output scheduling for the FCoE queue:

```
[edit class-of-service]
user@switch# set schedulers fcoe-sched priority low transmit-rate 3g
user@switch# set schedulers fcoe-sched shaping-rate percent 100
```

2. Map the FCoE forwarding class to the FCoE scheduler (**fcoe-sched**):

```
[edit class-of-service]
user@switch# set scheduler-maps fcoe-map forwarding-class fcoe scheduler fcoe-sched
```

3. Configure the forwarding class set (**fcoe-pg**) for the FCoE traffic:

```
[edit class-of-service]
user@switch# set forwarding-class-sets fcoe-pg class fcoe
```

4. Define the traffic control profile (**fcoe-tcp**) to use on the FCoE forwarding class set:

```
[edit class-of-service]
user@switch# set traffic-control-profiles fcoe-tcp scheduler-map fcoe-map
guaranteed-rate 3g
user@switch# set traffic-control-profiles fcoe-tcp shaping-rate percent 100
```

5. Apply the FCoE forwarding class set and traffic control profile to the LAG interface and to the FCoE access interfaces:

```
[edit class-of-service]
user@switch# set interfaces ae1 forwarding-class-set fcoe-pg output-traffic-control-profile
fcoe-tcp
user@switch# set class-of-service interfaces xe-0/0/30 forwarding-class-set fcoe-pg
output-traffic-control-profile fcoe-tcp
user@switch# set class-of-service interfaces xe-0/0/31 forwarding-class-set fcoe-pg
output-traffic-control-profile fcoe-tcp
user@switch# set class-of-service interfaces xe-0/0/32 forwarding-class-set fcoe-pg
output-traffic-control-profile fcoe-tcp
user@switch# set class-of-service interfaces xe-0/0/33 forwarding-class-set fcoe-pg
output-traffic-control-profile fcoe-tcp
```

6. Enable PFC on the FCoE priority by creating a congestion notification profile (**fcoe-cnp**) that applies FCoE to the IEEE 802.1 code point **011**:

```
[edit class-of-service]
user@switch# set congestion-notification-profile fcoe-cnp input ieee-802.1 code-point
011 pfc
```

7. Apply the PFC configuration to the LAG interface and to the FCoE access interfaces:

```
[edit class-of-service]
user@switch# set interfaces ae1 congestion-notification-profile fcoe-cnp
```

```

user@switch# set class-of-service interfaces xe-0/0/30 congestion-notification-profile
fcoe-cnp
user@switch# set class-of-service interfaces xe-0/0/31 congestion-notification-profile
fcoe-cnp
user@switch# set class-of-service interfaces xe-0/0/32 congestion-notification-profile
fcoe-cnp
user@switch# set class-of-service interfaces xe-0/0/33 congestion-notification-profile
fcoe-cnp

```

8. Configure the VLAN for FCoE traffic (**fcoe\_vlan**):

```

[edit vlans]
user@switch# set fcoe_vlan vlan-id 100

```

9. Add the member interfaces to the LAG:

```

[edit interfaces]
user@switch# set xe-0/0/25 ether-options 802.3ad ae1
user@switch# set xe-0/0/26 ether-options 802.3ad ae1

```

10. On the LAG (**ae1**), configure the interface mode as **trunk** and membership in the FCoE VLAN (**fcoe\_vlan**):

```

[edit interfaces]
user@switch# set interfaces ae1 unit 0 family ethernet-switching interface-mode trunk
vlan members fcoe_vlan

```

11. On the FCoE access interfaces (**xe-0/0/30**, **xe-0/0/31**, **xe-0/0/32**, **xe-0/0/33**), configure the interface mode as **trunk** and membership in the FCoE VLAN (**fcoe\_vlan**):

```

[edit interfaces]
user@switch# set interfaces xe-0/0/30 unit 0 family ethernet-switching interface-mode
trunk vlan members fcoe_vlan
user@switch# set interfaces xe-0/0/31 unit 0 family ethernet-switching interface-mode
trunk vlan members fcoe_vlan
user@switch# set interfaces xe-0/0/32 unit 0 family ethernet-switching interface-mode
trunk vlan members fcoe_vlan
user@switch# set interfaces xe-0/0/33 unit 0 family ethernet-switching interface-mode
trunk vlan members fcoe_vlan

```

12. Set the MTU to **2180** for the LAG and FCoE access interfaces. 2180 bytes is the minimum size required to handle FCoE packets because of the payload and header sizes; you can configure the MTU to a higher number of bytes if desired, but not less than 2180 bytes:

```

[edit interfaces]
user@switch# set ae1 mtu 2180
user@switch# set xe-0/0/30 mtu 2180
user@switch# set xe-0/0/31 mtu 2180
user@switch# set xe-0/0/32 mtu 2180
user@switch# set xe-0/0/33 mtu 2180

```

13. Set the LAG interface as an FCoE trusted port. Ports that connect to other switches should be trusted and should not perform FIP snooping:

```

[edit]
user@switch# set vlans fcoe_vlan forwarding-options fip-security interface ae1 fcoe-trusted

```

**NOTE:** Access ports xe-0/0/30, xe-0/0/31, xe-0/0/32, and xe-0/0/33 are not configured as FCoE trusted ports. The access ports remain in the default state as untrusted ports because they connect directly to FCoE devices and must perform FIP snooping to ensure network security.

14. Enable FIP snooping on the FCoE VLAN to prevent unauthorized FCoE network access (this example uses VN2VN\_Port FIP snooping; the example is equally valid if you use VN2VF\_Port FIP snooping):

```
[edit]
user@switch# set vlans fcoe_vlan forwarding-options fip-security examine-vn2vn
beacon-period 90000
```

### Results

Display the results of the CoS configuration on MC-LAG Switch S1 and on MC-LAG Switch S2 (the results on both switches are the same):

```
user@switch> show configuration class-of-service
traffic-control-profiles {
 fcoe-tcp {
 scheduler-map fcoe-map;
 shaping-rate percent 100;
 guaranteed-rate 30000000000;
 }
}
forwarding-class-sets {
 fcoe-pg {
 class fcoe;
 }
}
congestion-notification-profile {
 fcoe-cnp {
 input {
 ieee-802.1 {
 code-point 011 {
 pfc;
 }
 }
 }
 }
}
}
interfaces {
 ae0 {
 forwarding-class-set {
 fcoe-pg {
 output-traffic-control-profile fcoe-tcp;
 }
 }
 congestion-notification-profile fcoe-cnp;
 }
 ae1 {
```

```

forwarding-class-set {
 fcoe-pg {
 output-traffic-control-profile fcoe-tcp;
 }
 congestion-notification-profile fcoe-cnp;
}
scheduler-maps {
 fcoe-map {
 forwarding-class fcoe scheduler fcoe-sched;
 }
}
schedulers {
 fcoe-sched {
 transmit-rate 3000000000;
 shaping-rate percent 100;
 priority low;
 }
}

```

**NOTE:** The forwarding class and classifier configurations are not shown because the show command does not display default portions of the configuration.

For MC-LAG verification commands, see [“Example: Configuring Multichassis Link Aggregation” on page 1904](#).

Display the results of the CoS configuration on FCoE Transit Switch TS1 and on FCoE Transit Switch TS2 (the results on both transit switches are the same):

```

user@switch> show configuration class-of-service
traffic-control-profiles {
 fcoe-tcp {
 scheduler-map fcoe-map;
 shaping-rate percent 100;
 guaranteed-rate 3000000000;
 }
}
forwarding-class-sets {
 fcoe-pg {
 class fcoe;
 }
}
congestion-notification-profile {
 fcoe-cnp {
 input {
 ieee-802.1 {
 code-point 011 {
 pfc;
 }
 }
 }
 }
}

```

```
 }
 }
 interfaces {
 xe-0/0/30 {
 forwarding-class-set {
 fcoe-pg {
 output-traffic-control-profile fcoe-tcp;
 }
 }
 congestion-notification-profile fcoe-cnp;
 }
 xe-0/0/31 {
 forwarding-class-set {
 fcoe-pg {
 output-traffic-control-profile fcoe-tcp;
 }
 }
 congestion-notification-profile fcoe-cnp;
 }
 xe-0/0/32 {
 forwarding-class-set {
 fcoe-pg {
 output-traffic-control-profile fcoe-tcp;
 }
 }
 congestion-notification-profile fcoe-cnp;
 }
 xe-0/0/33 {
 forwarding-class-set {
 fcoe-pg {

 }
 }
 congestion-notification-profile fcoe-cnp;
 }
 ae1 {
 forwarding-class-set {
 fcoe-pg {
 output-traffic-control-profile fcoe-tcp;
 }
 }
 congestion-notification-profile fcoe-cnp;
 }
 }
 scheduler-maps {
 fcoe-map {
 forwarding-class fcoe scheduler fcoe-sched;
 }
 }
 schedulers {
 fcoe-sched {
 transmit-rate 3000000000;
 shaping-rate percent 100;
 priority low;
 }
 }
}
```

**NOTE:** The forwarding class and classifier configurations are not shown because the `show` command does not display default portions of the configuration.

## Verification

To verify that the CoS components and FIP snooping have been configured and are operating properly, perform these tasks. Because this example uses the default **fcoe** forwarding class and the default IEEE 802.1p trusted classifier, the verification of those configurations is not shown:

- [Verifying That the Output Queue Schedulers Have Been Created on page 5017](#)
- [Verifying That the Priority Group Output Scheduler \(Traffic Control Profile\) Has Been Created on page 5018](#)
- [Verifying That the Forwarding Class Set \(Priority Group\) Has Been Created on page 5018](#)
- [Verifying That Priority-Based Flow Control Has Been Enabled on page 5019](#)
- [Verifying That the Interface Class of Service Configuration Has Been Created on page 5020](#)
- [Verifying That the Interfaces Are Correctly Configured on page 5021](#)
- [Verifying That FIP Snooping Is Enabled on the FCoE VLAN on FCoE Transit Switches TS1 and TS2 Access Interfaces on page 5024](#)
- [Verifying That the FIP Snooping Mode Is Correct on FCoE Transit Switches TS1 and TS2 on page 5024](#)

### *Verifying That the Output Queue Schedulers Have Been Created*

**Purpose** Verify that the output queue scheduler for FCoE traffic has the correct bandwidth parameters and priorities, and is mapped to the correct forwarding class (output queue). Queue scheduler verification is the same on each of the four switches.

**Action** List the scheduler map using the operational mode command `show class-of-service scheduler-map fcoe-map`:

```
user@switch> show class-of-service scheduler-map fcoe-map
Scheduler map: fcoe-map, Index: 9023
```

```
Scheduler: fcoe-sched, Forwarding class: fcoe, Index: 37289
 Transmit rate: 3000000000 bps, Rate Limit: none, Buffer size: remainder,
 Buffer Limit: none, Priority: low
 Excess Priority: unspecified
 Shaping rate: 100 percent,
 drop-profile-map-set-type: mark
 Drop profiles:
 Loss priority Protocol Index Name
 Low any 1 <default-drop-profile>
 Medium high any 1 <default-drop-profile>
 High any 1 <default-drop-profile>
```

**Meaning** The **show class-of-service scheduler-map fcoe-map** command lists the properties of the scheduler map **fcoe-map**. The command output includes:

- The name of the scheduler map (**fcoe-map**)
- The name of the scheduler (**fcoe-sched**)
- The forwarding classes mapped to the scheduler (**fcoe**)
- The minimum guaranteed queue bandwidth (transmit rate **3000000000 bps**)
- The scheduling priority (**low**)
- The maximum bandwidth in the priority group the queue can consume (shaping rate **100 percent**)
- The drop profile loss priority for each drop profile name. This example does not include drop profiles because you do not apply drop profiles to FCoE traffic.

***Verifying That the Priority Group Output Scheduler (Traffic Control Profile) Has Been Created***

**Purpose** Verify that the traffic control profile **fcoe-tcp** has been created with the correct bandwidth parameters and scheduler mapping. Priority group scheduler verification is the same on each of the four switches.

**Action** List the FCoE traffic control profile properties using the operational mode command **show class-of-service traffic-control-profile fcoe-tcp**:

```
user@switch> show class-of-service traffic-control-profile fcoe-tcp
Traffic control profile: fcoe-tcp, Index: 18303
 Shaping rate: 100 percent
 Scheduler map: fcoe-map
 Guaranteed rate: 3000000000
```

**Meaning** The **show class-of-service traffic-control-profile fcoe-tcp** command lists all of the configured traffic control profiles. For each traffic control profile, the command output includes:

- The name of the traffic control profile (**fcoe-tcp**)
- The maximum port bandwidth the priority group can consume (shaping rate **100 percent**)
- The scheduler map associated with the traffic control profile (**fcoe-map**)
- The minimum guaranteed priority group port bandwidth (guaranteed rate **3000000000** in bps)

***Verifying That the Forwarding Class Set (Priority Group) Has Been Created***

**Purpose** Verify that the FCoE priority group has been created and that the **fcoe** priority (forwarding class) belongs to the FCoE priority group. Forwarding class set verification is the same on each of the four switches.

**Action** List the forwarding class sets using the operational mode command **show class-of-service forwarding-class-set fcoe-pg**:

```
user@switch> show class-of-service forwarding-class-set fcoe-pg
Forwarding class set: fcoe-pg, Type: normal-type, Forwarding class set index:
31420
 Forwarding class Index
 fcoe 1
```

**Meaning** The **show class-of-service forwarding-class-set fcoe-pg** command lists all of the forwarding classes (priorities) that belong to the **fcoe-pg** priority group, and the internal index number of the priority group. The command output shows that the forwarding class set **fcoe-pg** includes the forwarding class **fcoe**.

### *Verifying That Priority-Based Flow Control Has Been Enabled*

**Purpose** Verify that PFC is enabled on the FCoE code point. PFC verification is the same on each of the four switches.

**Action** List the FCoE congestion notification profile using the operational mode command **show class-of-service congestion-notification fcoe-cnp**:

```
user@switch> show class-of-service congestion-notification fcoe-cnp
Type: Input, Name: fcoe-cnp, Index: 6879
Cable Length: 100 m
 Priority PFC MRU
 000 Disabled
 001 Disabled
 010 Disabled
 011 Enabled 2500
 100 Disabled
 101 Disabled
 110 Disabled
 111 Disabled
Type: Output
 Priority Flow-Control-Queues
 000
 001 0
 010 1
 011 2
 100 3
 101 4
 110 5
 111 6
 111 7
```

**Meaning** The **show class-of-service congestion-notification fcoe-cnp** command lists all of the IEEE 802.1p code points in the congestion notification profile that have PFC enabled. The command output shows that PFC is enabled on code point 011 (**fcoe** queue) for the **fcoe-cnp** congestion notification profile.

The command also shows the default cable length (100 meters), the default maximum receive unit (2500 bytes), and the default mapping of priorities to output queues because this example does not include configuring these options.

### ***Verifying That the Interface Class of Service Configuration Has Been Created***

**Purpose** Verify that the CoS properties of the interfaces are correct. The verification output on MC-LAG Switches S1 and S2 differs from the output on FCoE Transit Switches TS1 and TS2.

**Action** List the interface CoS configuration on MC-LAG Switches S1 and S2 using the operational mode command **show configuration class-of-service interfaces**:

```
user@switch> show configuration class-of-service interfaces
ae0 {
 forwarding-class-set {
 fcoe-pg {
 output-traffic-control-profile fcoe-tcp;
 }
 }
 congestion-notification-profile fcoe-cnp;
}

ae1 {
 forwarding-class-set {
 fcoe-pg {
 output-traffic-control-profile fcoe-tcp;
 }
 }
 congestion-notification-profile fcoe-cnp;
}
```

List the interface CoS configuration on FCoE Transit Switches TS1 and TS2 using the operational mode command **show configuration class-of-service interfaces**:

```
user@switch> show configuration class-of-service interfaces
xe-0/0/30 {
 forwarding-class-set {
 fcoe-pg {
 output-traffic-control-profile fcoe-tcp;
 }
 }
 congestion-notification-profile fcoe-cnp;
}
xe-0/0/31 {
 forwarding-class-set {
 fcoe-pg {
 output-traffic-control-profile fcoe-tcp;
 }
 }
 congestion-notification-profile fcoe-cnp;
}
xe-0/0/32 {
 forwarding-class-set {
 fcoe-pg {
 output-traffic-control-profile fcoe-tcp;
 }
 }
}
```

```

 congestion-notification-profile fcoe-cnp;
 }
 xe-0/0/33 {
 forwarding-class-set {
 fcoe-pg {
 output-traffic-control-profile fcoe-tcp;
 }
 }
 congestion-notification-profile fcoe-cnp;
 }
 ae1 {
 forwarding-class-set {
 fcoe-pg {
 output-traffic-control-profile fcoe-tcp;
 }
 }
 congestion-notification-profile fcoe-cnp;
 }
}

```

**Meaning** The **show configuration class-of-service interfaces** command lists the class of service configuration for all interfaces. For each interface, the command output includes:

- The name of the interface (for example, **ae0** or **xe-0/0/30**)
- The name of the forwarding class set associated with the interface (**fcoe-pg**)
- The name of the traffic control profile associated with the interface (output traffic control profile, **fcoe-tcp**)
- The name of the congestion notification profile associated with the interface (**fcoe-cnp**)

**NOTE:** Interfaces that are members of a LAG are not shown individually. The LAG or MC-LAG CoS configuration is applied to all interfaces that are members of the LAG or MC-LAG. For example, the interface CoS configuration output on MC-LAG Switches S1 and S2 shows the LAG CoS configuration but does not show the CoS configuration of the member interfaces separately. The interface CoS configuration output on FCoE Transit Switches TS1 and TS2 shows the LAG CoS configuration but also shows the configuration for interfaces xe-0/0/30, xe-0/0/31, xe-0/0/32, and xe-0/0/33, which are not members of a LAG.

### *Verifying That the Interfaces Are Correctly Configured*

**Purpose** Verify that the LAG membership, MTU, VLAN membership, and port mode of the interfaces are correct. The verification output on MC-LAG Switches S1 and S2 differs from the output on FCoE Transit Switches T1 and T2.

**Action** List the interface configuration on MC-LAG Switches S1 and S2 using the operational mode command **show configuration interfaces**:

```
user@switch> show configuration interfaces
```

```
xe-0/0/10 {
 ether-options {
 802.3ad ae0;
 }
}
xe-0/0/11 {
 ether-options {
 802.3ad ae0;
 }
}
xe-0/0/20 {
 ether-options {
 802.3ad ae1;
 }
}
xe-0/0/21 {
 ether-options {
 802.3ad ae1;
 }
}
ae0 {
 mtu 2180;
 unit 0 {
 family ethernet-switching {
 interface-mode trunk;
 vlan {
 members fcoe_vlan;
 }
 }
 }
}
ae1 {
 mtu 2180;
 unit 0 {
 family ethernet-switching {
 interface-mode trunk;
 vlan {
 members fcoe_vlan;
 }
 }
 }
}
```

List the interface configuration on FCoE Transit Switches TS1 and TS2 using the operational mode command **show configuration interfaces**:

```
user@switch> show configuration interfaces
xe-0/0/25 {
 ether-options {
 802.3ad ae1;
 }
}
xe-0/0/26 {
 ether-options {
 802.3ad ae1;
 }
}
xe-0/0/30 {
 mtu 2180;
 unit 0 {
```

```

 family ethernet-switching {
 interface-mode trunk;
 vlan {
 members fcoe_vlan;
 }
 }
 }
}
xe-0/0/31 {
 mtu 2180;
 unit 0 {
 family ethernet-switching {
 interface-mode trunk;
 vlan {
 members fcoe_vlan;
 }
 }
 }
}
xe-0/0/32 {
 mtu 2180;
 unit 0 {
 family ethernet-switching {
 interface-mode trunk;
 vlan {
 members fcoe_vlan;
 }
 }
 }
}
xe-0/0/33 {
 mtu 2180;
 unit 0 {
 family ethernet-switching {
 interface-mode trunk;
 vlan {
 members fcoe_vlan;
 }
 }
 }
}
ae1 {
 mtu 2180;
 unit 0 {
 family ethernet-switching {
 interface-mode trunk;
 vlan {
 members fcoe_vlan;
 }
 }
 }
}

```

**Meaning** The `show configuration interfaces` command lists the configuration of each interface by interface name.

For each interface that is a member of a LAG, the command lists only the name of the LAG to which the interface belongs.

For each LAG interface and for each interface that is not a member of a LAG, the command output includes:

- The MTU (**2180**)
- The unit number of the interface (**0**)
- The interface mode (**trunk** mode both for interfaces that connect two switches and for interfaces that connect to FCoE hosts)
- The name of the VLAN in which the interface is a member (**fcoe\_vlan**)

***Verifying That FIP Snooping Is Enabled on the FCoE VLAN on FCoE Transit Switches TS1 and TS2 Access Interfaces***

**Purpose** Verify that FIP snooping is enabled on the FCoE VLAN access interfaces. FIP snooping is enabled only on the FCoE access interfaces, so it is enabled only on FCoE Transit Switches TS1 and TS2. FIP snooping is not enabled on MC-LAG Switches S1 and S2 because FIP snooping is done at the Transit Switch TS1 and TS2 FCoE access ports.

**Action** List the port security configuration on FCoE Transit Switches TS1 and TS2 using the operational mode command **show configuration vlans fcoe\_vlan forwarding-options fip-security**:

```
user@switch> show configuration vlans fcoe_vlan forwarding-options fip-security
interface ae1.0 {
 fcoe-trusted;
}
examine-vn2vn {
 beacon-period 90000;
}
```

**Meaning** The **show configuration vlans fcoe\_vlan forwarding-options fip-security** command lists VLAN FIP security information, including whether a port member of the VLAN is trusted. The command output shows that:

- LAG port **ae1.0**, which connects the FCoE transit switch to the MC-LAG switches, is configured as an FCoE trusted interface. FIP snooping is not performed on the member interfaces of the LAG (**xe-0/0/25** and **xe-0/0/26**).
- VN2VN\_Port FIP snooping is enabled (**examine-vn2vn**) on the FCoE VLAN and the beacon period is set to 90000 milliseconds. On Transit Switches TS1 and TS2, all interface members of the FCoE VLAN perform FIP snooping unless the interface is configured as FCoE trusted. On Transit Switches TS1 and TS2, interfaces **xe-0/0/30**, **xe-0/0/31**, **xe-0/0/32**, and **xe-0/0/33** perform FIP snooping because they are not configured as FCoE trusted. The interface members of LAG **ae1** (**xe-0/0/25** and **xe-0/0/26**) do not perform FIP snooping because the LAG is configured as FCoE trusted.

***Verifying That the FIP Snooping Mode Is Correct on FCoE Transit Switches TS1 and TS2***

**Purpose** Verify that the FIP snooping mode is correct on the FCoE VLAN. FIP snooping is enabled only on the FCoE access interfaces, so it is enabled only on FCoE Transit Switches TS1 and TS2. FIP snooping is not enabled on MC-LAG Switches S1 and S2 because FIP snooping is done at the Transit Switch TS1 and TS2 FCoE access ports.

**Action** List the FIP snooping configuration on FCoE Transit Switches TS1 and TS2 using the operational mode command **show fip snooping brief**:

```
user@switch> show fip snooping brief
VLAN: fcoe_vlan, Mode: VN2VN Snooping
FC-MAP: 0e:fc:00
...
```

**NOTE:** The output has been truncated to show only the relevant information.

**Meaning** The **show fip snooping brief** command lists FIP snooping information, including the FIP snooping VLAN and the FIP snooping mode. The command output shows that:

- The VLAN on which FIP snooping is enabled is **fcoe\_vlan**
- The FIP snooping mode is VN2VN\_Port FIP snooping (**VN2VN Snooping**)

## Example: Configuring VN2VN\_Port FIP Snooping (FCoE Hosts Directly Connected to the Same FCoE Transit Switch)

This example shows how to configure VN\_Port to VN\_Port (VN2VN\_Port) FIP snooping when the hosts are directly connected to the same FCoE transit switch.

**NOTE:** This example uses the Junos OS Enhanced Layer 2 Software (ELS) configuration style for QFX Series switches. If your switch runs software that does not support ELS, see [“Example: Configuring VN2VN\\_Port FIP Snooping \(FCoE Hosts Directly Connected to the Same FCoE Transit Switch\)” on page 4977](#). For ELS details, see [“Getting Started with Enhanced Layer 2 Software” on page 58](#).

VN2VN\_Port FIP snooping on an FCoE transit switch provides security to help prevent unauthorized access and data transmission on a bridge that connects ENodes in the Ethernet network. VN2VN\_Port FIP snooping provides security for virtual links by creating filters based on information gathered (snooped) about FCoE devices during FIP transactions.

VN2VN\_Port FIP snooping is conceptually similar to VN2VN\_Port FIP snooping between VN\_Ports and VF\_Ports, but VN2VN\_Port FIP snooping does not require traffic between VN\_Ports to traverse the Fibre Channel (FC) switch or FCoE forwarder (FCF). Instead, a VN\_Port communicates transparently through the transit switch on a virtual link that emulates a direct connection to the VN\_Port at the other end of the virtual link.

To configure VN2VN\_Port FIP snooping when the hosts are directly connected to the same FCoE transit switch, you must follow these configuration rules:

- VN2VN\_Port traffic must use a dedicated FCoE VLAN, and all ENodes that communicate using VN2VN\_Port FIP snooping must use that FCoE VLAN. You cannot mix VN2VN\_Port FIP snooping traffic with VN2VF\_Port FIP snooping traffic in the same FCoE VLAN.

**NOTE:** An FCoE VLAN can support either VN2VF\_Port FIP snooping or VN2VN\_Port FIP snooping, but not both. Configure separate FCoE VLANs for VN2VF\_Port FIP snooping traffic and for VN2VN\_Port FIP snooping traffic. On FCoE VLANs that are configured as VN2VN\_Port FIP snooping VLANs, VN\_Port to VF\_Port (FIP snooping) traffic is dropped.

- ENode-facing ports must be set in **trunk** interface mode.
- ENode-facing ports must be untrusted ports.
- Network-facing (switch-facing) ports must be set in **trunk** interface mode.
- Network-facing ports must be FCoE trusted ports.
- Explicitly configure the beacon period. The beacon period is essentially a keepalive timer for virtual link maintenance.

When you enable VN2VF\_Port FIP snooping, the system snoops VN\_Port to VF\_Port packets and enforces security only on VN\_Port to VF\_Port virtual links. When you enable VN2VN\_Port FIP snooping, the system snoops VN\_Port to VN\_Port packets and enforces security only on VN\_Port to VN\_Port virtual links.

The transit switch applies VN2VN\_Port FIP snooping filters at the ports associated with the FCoE VLANs on which you enable VN2VN FIP snooping.

This example describes how to configure VN2VN\_Port FIP snooping when the FCoE hosts are directly connected to the same transit switch:

- [Requirements on page 5026](#)
- [Overview on page 5027](#)
- [Configuration on page 5028](#)
- [Verification on page 5028](#)

---

### Requirements

This example uses the following hardware and software components:

- One Juniper Networks QFX5100 Switch running the ELS CLI and used as a transit switch

- Junos OS Release 13.2 or later for the QFX Series
- Two FCoE hosts that have ENodes

Overview

This example shows you how to:

- Set the correct interface mode on the transit switch.
- Configure the interfaces to use the dedicated FCoE VLAN for VN2VN\_Port FIP snooping.
- Configure the dedicated FCoE VLAN for VN2VN\_Port FIP snooping traffic.
- Enable VN2VN\_Port FIP snooping on the FCoE VLAN and configure the beacon period.

Topology

Table 385 on page 4979 shows the configuration components for this example.

Table 389: Components of the VN2VN\_Port FIP Snooping Configuration Topology (FCoE Hosts Directly Connected to the Same FCoE Transit Switch)

Component	Settings
Hardware	QFX5100 switch running the ELS CLI (FCoE transit switch TS1)  Two FCoE hosts that have ENodes (ENode1 and ENode2, respectively)
Interfaces and interface mode	<ul style="list-style-type: none"><li>• Interface <b>xe-0/0/20</b>, interface mode <b>trunk</b>, connects directly to the FCoE host with ENode1.</li><li>• Interface <b>xe-0/0/21</b>, interface mode <b>trunk</b>, connects directly to the FCoE host with ENode2.</li></ul>
Interface VLAN membership	Both interfaces use VLAN <b>vlan200</b> .
VN2VN_Port FIP snooping VLAN	VLAN name— <b>vlan200</b> VLAN ID—200
FIP snooping mode and beacon period	Set <b>examine-vn2vn</b> (VN2VN_Port FIP snooping) Beacon period—90000 ms

Figure 182 on page 4979 shows the network topology for this example.

Figure 186: VN2VN\_Port FIP Snooping (FCoE Hosts Connected to Same Transit Switch) Topology

## Configuration

---

**CLI Quick Configuration** To quickly configure VN2VN\_Port FIP snooping for FCoE hosts connected directly to the same transit switch, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level:

```
set interfaces xe-0/0/20 unit 0 family ethernet-switching interface-mode trunk
set interfaces xe-0/0/21 unit 0 family ethernet-switching interface-mode trunk
set interfaces xe-0/0/20 unit 0 family ethernet-switching vlan members vlan200
set interfaces xe-0/0/21 unit 0 family ethernet-switching vlan members vlan200
set vlans vlan200 vlan-id 200
set vlans vlan200 forwarding-options fip-security examine-vn2vn beacon-period 90000
```

### *Configuring VN2VN\_Port FIP Snooping (FCoE Hosts Directly Connected to the Same FCoE Transit Switch)*

**Step-by-Step Procedure** To configure interface mode, configure interface VLAN membership in the FCoE VLAN dedicated to VN2VN\_Port traffic, configure the VLAN, set the beacon period, and enable VN2VN\_Port FIP snooping:

1. Configure the modes of the interfaces that connect directly to the FCoE host ENodes:

```
user@switch# set interfaces xe-0/0/20 unit 0 family ethernet-switching interface-mode trunk
set interfaces xe-0/0/21 unit 0 family ethernet-switching interface-mode trunk
```

2. Configure the interface VLAN membership so that the interfaces connected to the ENodes are members of the dedicated VN2VN\_Port VLAN (**vlan200**):

```
user@switch# set interfaces xe-0/0/20 unit 0 family ethernet-switching vlan members vlan200
set interfaces xe-0/0/21 unit 0 family ethernet-switching vlan members vlan200
```

3. Configure the FCoE VLAN dedicated to VN2VN\_Port FIP snooping:

```
user@switch# set vlans vlan200 vlan-id 200
```

4. Enable VN2VN\_Port FIP snooping on the VLAN and configure the beacon period:

```
user@switch# set vlans vlan200 forwarding-options fip-security examine-vn2vn beacon-period 90000
```

## Verification

---

To verify that the VN2VN\_Port FIP snooping configuration has been created and is operating properly, perform these tasks:

- [Verifying That VN2VN\\_Port FIP Snooping is Enabled on the FCoE VLAN on page 5028](#)

### *Verifying That VN2VN\_Port FIP Snooping is Enabled on the FCoE VLAN*

**Purpose** Verify that VN2VN\_Port FIP snooping is enabled on the correct VLAN (**vlan200**), the beacon period is set to **90000** milliseconds, and the correct interfaces (**xe-0/0/20** and **xe-0/0/21**) are members of the VLAN.

**Action** List the FIP snooping information using the operational mode command **show fip snooping detail**.

```
user@switch> show fip snooping detail
VLAN: vlan200, Mode: VN2VN Snooping
FC-MAP: 0e:fd:00
Beacon_Period: 90000
VN2VN Mode: Point-to-Point
 Enode Information
 Enode-MAC: 10:10:94:01:00:02, Interface: xe-0/0/20
 Active VN_Ports : 1
 VN_Port Information
 VN-Port MAC: 0e:fd:00:00:0a:01
 Active Sessions : 1
 Session Information
 Vlink far-end VN-Port-MAC: 0e:fd:00:00:0b:01
 Enode-MAC: 10:10:94:01:00:02, Interface: xe-0/0/21
 Active VN_Ports : 1
 VN_Port Information
 VN-Port MAC: 0e:fd:00:00:0b:01
 Active Sessions : 1
 Session Information
 Vlink far-end VN-Port-MAC: 0e:fd:00:00:0a:01
```

**Meaning** The **show fip snooping detail** command lists all of the transit switch information about VN2VN\_Port FIP snooping and VN2VF\_Port FIP snooping. The command shows that:

- The VLAN is **vlan200**.
- The mode is FIP snooping mode **VN2VN**, for VN2VN\_Port FIP snooping. (If the Mode field shows **VN2VF**, then the FIP snooping mode is VN2VF\_Port FIP snooping.)
- The beacon period is **90000**.
- The interfaces for the ENodes are **xe-0/0/20** and **xe-0/0/21**.

In addition, this useful command shows information about the ENodes and the VN2VN\_Port sessions.

## Example: Configuring VN2VN\_Port FIP Snooping (FCoE Hosts Directly Connected to Different FCoE Transit Switches)

This example shows how to configure VN\_Port to VN\_Port (VN2VN\_Port) FIP snooping when the hosts are directly connected to different FCoE transit switches, and the transit switches are directly connected to each other.

**NOTE:** This example uses the Junos OS Enhanced Layer 2 Software (ELS) configuration style for QFX Series switches. If your switch runs software that does not support ELS, see [“Example: Configuring VN2VN\\_Port FIP Snooping \(FCoE Hosts Directly Connected to Different FCoE Transit Switches\)”](#) on page 4982. For ELS details, see [“Getting Started with Enhanced Layer 2 Software”](#) on page 58.

VN2VN\_Port FIP snooping on an FCoE transit switch provides security to help prevent unauthorized access and data transmission on a bridge that connects ENodes in the Ethernet network. VN2VN\_Port FIP snooping provides security for virtual links by creating filters based on information gathered (snooped) about FCoE devices during FIP transactions.

VN2VN\_Port FIP snooping is conceptually similar to VN2VF\_Port FIP snooping between VN\_Ports and VF\_Ports, but VN2VN\_Port FIP snooping does not require traffic between VN\_Ports to traverse the Fibre Channel (FC) switch or FCoE forwarder (FCF). Instead, a VN\_Port communicates transparently through one or more transit switches on a virtual link that emulates a direct connection to the VN\_Port at the other end of the virtual link.

To configure VN2VN\_Port FIP snooping when the hosts are directly connected to different FCoE transit switches, and the transit switches are directly connected to each other, you must follow these configuration rules:

- VN2VN\_Port traffic must use a dedicated FCoE VLAN, and all ENodes that communicate using VN2VN\_Port FIP snooping must use that FCoE VLAN. The FCoE VLAN must be configured on each transit switch. You cannot mix VN2VN\_Port FIP snooping traffic with VN2VF\_Port FIP snooping traffic in the same FCoE VLAN.

**NOTE:** An FCoE VLAN can support either VN2VF\_Port FIP snooping or VN2VN\_Port FIP snooping, but not both. Configure separate FCoE VLANs for VN2VF\_Port FIP snooping traffic and for VN2VN\_Port FIP snooping traffic. On FCoE VLANs that are configured as VN2VN\_Port FIP snooping VLANs, VN2VF\_Port traffic is dropped.

- ENode-facing ports must be set in **trunk** interface mode.
- ENode-facing ports must be untrusted ports.
- Network-facing (switch-facing) ports must be set in **trunk** interface mode.

- Network-facing ports must be FCoE trusted ports.
- Explicitly configure the beacon period. The beacon period is essentially a keepalive timer for virtual link maintenance.

When you enable VN2VF\_Port FIP snooping, the system snoops VN\_Port to VF\_Port packets and enforces security only on VN\_Port to VF\_Port virtual links. When you enable VN2VN\_Port FIP snooping, the system snoops VN\_Port to VN\_Port packets and enforces security only on VN\_Port to VN\_Port virtual links.

The transit switch applies VN2VN\_Port FIP snooping filters at the ports associated with the FCoE VLANs on which you enable VN2VN FIP snooping.

This example describes how to configure VN2VN\_Port FIP snooping when the FCoE hosts are directly connected to different transit switches, and the transit switches are directly connected to each other:

- [Requirements on page 5031](#)
- [Overview on page 5031](#)
- [Configuration on page 5032](#)
- [Verification on page 5034](#)

---

### Requirements

This example uses the following hardware and software components:

- Two Juniper Networks QFX5100 Switches running the ELS CLI and used as transit switches
- Junos OS Release 13.2 or later for the QFX Series
- Two FCoE hosts that have ENodes

---

### Overview

This example shows you how to:

- Set the correct interface mode on the transit switch.
- Configure the interfaces to use the dedicated FCoE VLAN for VN2VN\_Port FIP snooping.
- Configure the network-facing interfaces as FCoE trusted interfaces.
- Configure the dedicated FCoE VLAN for VN2VN\_Port FIP snooping traffic.
- Enable VN2VN\_Port FIP snooping on the FCoE VLAN and configure the beacon period.

### Topology

[Table 386 on page 4984](#) shows the configuration components for this example.

**Table 390: Components of the VN2VN\_Port FIP Snooping Configuration Topology (FCoE Hosts Directly Connected to Different FCoE Transit Switches)**

Component	Settings
Hardware	Two QFX5100 switches running the ELS CLI (FCoE transit switch TS1 and FCoE transit switch TS2)  Two FCoE hosts that have ENodes (ENode1 and ENode2, respectively)
Interfaces and interface mode	<ul style="list-style-type: none"> <li>Interface <b>xe-0/0/20</b>, interface mode <b>trunk</b>, connects directly from transit switch TS1 to the FCoE host with ENode1.</li> <li>Interface <b>xe-0/0/21</b>, interface mode <b>trunk</b>, connects directly from transit switch TS1 to transit switch TS2.</li> <li>Interface <b>xe-0/0/31</b>, interface mode <b>trunk</b>, connects directly from transit switch TS2 to transit switch TS1.</li> <li>Interface <b>xe-0/0/30</b>, interface mode <b>trunk</b>, connects directly from transit switch TS2 to the FCoE host with ENode2.</li> </ul>
Interface VLAN membership	The interfaces on both transit switches use VLAN <b>vlan200</b> .
VN2VN_Port FIP snooping VLAN	VLAN name (both transit switches)— <b>vlan200</b> VLAN ID—200
FIP snooping mode and beacon period	Set <b>examine-vn2vn</b> (VN2VN_Port FIP snooping) Beacon period—90000 ms

Figure 183 on page 4984 shows the network topology for this example.

**Figure 187: VN2VN\_Port FIP Snooping (FCoE Hosts Connected to Different Transit Switches) Topology**

### Configuration

To configure VN2VN\_Port FIP snooping for VN\_Ports that are directly connected to different transit switches (and the transit switches are directly connected to each other), perform these tasks:

- [Configuring VN2VN\\_Port FIP Snooping on FCoE Transit Switch TS1 on page 5033](#)
- [Configuring VN2VN\\_Port FIP Snooping on FCoE Transit Switch TS2 on page 5034](#)

### CLI Quick Configuration

The configuration for each FCoE transit switch is shown separately.

To quickly configure VN2VN\_Port FIP snooping for FCoE hosts connected directly to different transit switches, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level. To configure FCoE transit switch TS1:

## FCoE Transit Switch TS1

```
set interfaces xe-0/0/20 unit 0 family ethernet-switching interface-mode trunk
set interfaces xe-0/0/21 unit 0 family ethernet-switching interface-mode trunk
set interfaces xe-0/0/20 unit 0 family ethernet-switching vlan members vlan200
set interfaces xe-0/0/21 unit 0 family ethernet-switching vlan members vlan200
set vlans vlan200 vlan-id 200
set vlans vlan200 forwarding-options fip-security interface xe-0/0/21 fcoe-trusted
set vlans vlan200 forwarding-options fip-security examine-vn2vn beacon-period 90000
```

To quickly configure VN2VN\_Port FIP snooping for FCoE hosts connected directly to different transit switches, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level. To configure FCoE transit switch TS2:

## FCoE Transit Switch TS2

```
set interfaces xe-0/0/30 unit 0 family ethernet-switching interface-mode trunk
set interfaces xe-0/0/31 unit 0 family ethernet-switching interface-mode trunk
set interfaces xe-0/0/30 unit 0 family ethernet-switching vlan members vlan200
set interfaces xe-0/0/31 unit 0 family ethernet-switching vlan members vlan200
set vlans vlan200 vlan-id 200
set vlans vlan200 forwarding-options fip-security interface xe-0/0/31 fcoe-trusted
set vlans vlan200 forwarding-options fip-security examine-vn2vn beacon-period 90000
```

### *Configuring VN2VN\_Port FIP Snooping on FCoE Transit Switch TS1*

#### Step-by-Step Procedure

To configure interface mode, configure interface VLAN membership in the FCoE VLAN dedicated to VN2VN\_Port traffic, set the network-facing port as FCoE trusted, configure the VLAN, set the beacon period, and enable VN2VN\_Port FIP snooping:

1. Configure the modes of the interfaces that connect directly to the FCoE host with ENode1 (**xe-0/0/20**) and to FCoE transit switch TS2 (**xe-0/0/21**):  
  

```
user@switch# set interfaces xe-0/0/20 unit 0 family ethernet-switching interface-mode trunk
set interfaces xe-0/0/21 unit 0 family ethernet-switching interface-mode trunk
```
2. Configure the interface VLAN membership so that the interfaces are members of the dedicated VN2VN\_Port VLAN (**vlan200**):  
  

```
user@switch# set interfaces xe-0/0/20 unit 0 family ethernet-switching vlan members vlan200
set interfaces xe-0/0/21 unit 0 family ethernet-switching vlan members vlan200
```
3. Configure the FCoE VLAN dedicated to VN2VN\_Port FIP snooping:  
  

```
user@switch# set vlans vlan200 vlan-id 200
```
4. Configure the network-facing port (**xe-0/0/21**) as an FCoE trusted port:  
  

```
user@switch# set vlans vlan200 forwarding-options fip-security interface xe-0/0/21 fcoe-trusted
```
5. Enable VN2VN\_Port FIP snooping on the VLAN and configure the beacon period:  
  

```
user@switch# set vlans vlan200 forwarding-options fip-security examine-vn2vn beacon-period 90000
```

### ***Configuring VN2VN\_Port FIP Snooping on FCoE Transit Switch TS2***

**Step-by-Step Procedure** To configure interface mode, configure interface VLAN membership in the FCoE VLAN dedicated to VN2VN\_Port traffic, set the network-facing port as FCoE trusted, configure the VLAN, set the beacon period, and enable VN2VN\_Port FIP snooping:

1. Configure the modes of the interfaces that connect directly to the FCoE host with ENode2 (**xe-0/0/30**) and to FCoE transit switch TS1 (**xe-0/0/31**):

```
user@switch# set interfaces xe-0/0/30 unit 0 family ethernet-switching interface-mode trunk
set interfaces xe-0/0/31 unit 0 family ethernet-switching interface-mode trunk
```

2. Configure the interface VLAN membership so that the interfaces are members of the dedicated VN2VN\_Port VLAN (**vlan200**):

```
user@switch# set interfaces xe-0/0/30 unit 0 family ethernet-switching vlan members vlan200
set interfaces xe-0/0/31 unit 0 family ethernet-switching vlan members vlan200
```

3. Configure the FCoE VLAN dedicated to VN2VN\_Port FIP snooping:

```
user@switch# set vlans vlan200 vlan-id 200
```

4. Configure the network-facing port (**xe-0/0/31**) as an FCoE trusted port:

```
user@switch# set vlans vlan200 forwarding-options fip-security interface xe-0/0/31 fcoe-trusted
```

5. Enable VN2VN\_Port FIP snooping on the VLAN and configure the beacon period:

```
user@switch# set vlans vlan200 forwarding-options fip-security examine-vn2vn beacon-period 90000
```

---

### **Verification**

To verify that the VN2VN\_Port FIP snooping configuration has been created and is operating properly on both switches, perform these tasks:

- [Verifying That VN2VN\\_Port FIP Snooping is Enabled on the FCoE VLAN \(Transit Switches TS1 and TS2\) on page 5034](#)

#### ***Verifying That VN2VN\_Port FIP Snooping is Enabled on the FCoE VLAN (Transit Switches TS1 and TS2)***

**Purpose** Verify that VN2VN\_Port FIP snooping is enabled on the correct VLAN (**vlan200**), the beacon period is set to **90000** milliseconds, and that the correct interfaces (**xe-0/0/20** and **xe-0/0/21** on TS1, and **xe-0/0/30** and **xe-0/0/31** on TS2) are members of the VLAN.

**Action** List the FIP snooping information on transit switch TS1 using the operational mode command **show fip snooping detail**

```
user@switch> show fip snooping detail
VLAN: vlan200, Mode: VN2VN Snooping
FC-MAP: 0e:fc:00
Beacon_Period: 90000
VN2VN Mode: Point-to-Point

```

List the FIP snooping information on transit switch TS2 using the operational mode command **show fip snooping detail**

```
user@switch> show fip snooping detail
VLAN: vlan200, Mode: VN2VN Snooping
FC-MAP: 0e:fd:00
Beacon_Period: 90000
VN2VN Mode: Point-to-Point
 Enode Information
 Enode-MAC: 10:10:94:01:00:02, Interface: xe-0/0/30
 Active VN_Ports : 1
 VN_Port Information
 VN-Port MAC: 0e:fd:00:00:0b:01
 Active Sessions : 1
 Session Information
 Vlink far-end VN-Port-MAC: 0e:fd:00:00:0a:01
 Enode-MAC: 10:10:94:01:00:02, Interface: xe-0/0/31
 Active VN_Ports : 1
 VN_Port Information
 VN-Port MAC: 0e:fd:00:00:0a:01
 Active Sessions : 1
 Session Information
 Vlink far-end VN-Port-MAC: 0e:fd:00:00:0b:01
```

**Meaning** The **show fip snooping detail** command lists all of the transit switch information about VN2VN\_Port FIP snooping and VN2VF\_Port FIP snooping on each transit switch. The command shows that:

- The VLAN is **vlan200**.
- The mode is FIP snooping mode **VN2VN**, for VN2VN\_Port FIP snooping. (If the Mode field shows **VN2VF**, then the FIP snooping mode is VN2VF\_Port FIP snooping.)

- The beacon period is **90000**.
- The interfaces connected to the ENodes are **xe-0/0/20** and **xe-0/0/21** on transit switch TS1, and **xe-0/0/30** and **xe-0/0/31** on transit switch TS2. Because the transit switches are transparent passthrough switches, the network-facing trunk ports “see” the FCoE host ENodes at the far end of the VN2VN\_Port virtual link.

In addition, this useful command shows information about the ENodes and the VN2VN\_Port sessions.

### Example: Configuring VN2VN\_Port FIP Snooping (FCoE Hosts Indirectly Connected Through an Aggregation Layer FCoE Transit Switch)

This example shows how to configure VN\_Port to VN\_Port (VN2VN\_Port) FIP snooping when the hosts are indirectly connected through an aggregation layer FCoE transit switch. Each FCoE host ENode is directly connected to an FCoE transit switch, but the FCoE transit switches are not directly connected to each other. The FCoE transit switches are both connected to a third FCoE transit switch that acts as an aggregation layer switch.

**NOTE:** This example uses the Junos OS Enhanced Layer 2 Software (ELS) configuration style for QFX Series switches. If your switch runs software that does not support ELS, see [“Example: Configuring VN2VN\\_Port FIP Snooping \(FCoE Hosts Indirectly Connected Through an Aggregation Layer FCoE Transit Switch\)”](#) on page 4990. For ELS details, see [“Getting Started with Enhanced Layer 2 Software”](#) on page 58.

VN2VN\_Port FIP snooping on an FCoE transit switch provides security to help prevent unauthorized access and data transmission on a bridge that connects ENodes in the Ethernet network. VN2VN\_Port FIP snooping provides security for virtual links by creating filters based on information gathered (snooped) about FCoE devices during FIP transactions.

VN2VN\_Port FIP snooping is conceptually similar to VN2VN\_Port FIP snooping between VN\_Ports and VF\_Ports, but VN2VN\_Port FIP snooping does not require traffic between VN\_Ports to traverse the Fibre Channel (FC) switch or FCoE forwarder (FCF). Instead, a VN\_Port communicates transparently through one or more transit switches on a virtual link that emulates a direct connection to the VN\_Port at the other end of the virtual link.

To configure VN2VN\_Port FIP snooping when the hosts are indirectly connected, you must follow these configuration rules:

- VN2VN\_Port traffic must use a dedicated FCoE VLAN, and all ENodes that communicate using VN2VN\_Port FIP snooping must use that FCoE VLAN. The FCoE VLAN must be configured on each transit switch. You cannot mix VN2VN\_Port FIP snooping traffic with VN2VF\_Port FIP snooping traffic in the same FCoE VLAN.

**NOTE:** An FCoE VLAN can support either VN2VF\_Port FIP snooping or VN2VN\_Port FIP snooping, but not both. Configure separate FCoE VLANs for VN2VF\_Port FIP snooping traffic and for VN2VN\_Port FIP snooping traffic. On FCoE VLANs that are configured as VN2VN\_Port FIP snooping VLANs, VN\_Port to VF\_Port traffic is dropped.

- ENode-facing ports must be set in **trunk** interface mode.
- ENode-facing ports must be untrusted ports.
- Network-facing (switch-facing) ports must be set in **trunk** interface mode.
- Network-facing ports must be FCoE trusted ports.
- Explicitly configure the beacon period. The beacon period is essentially a keepalive timer for virtual link maintenance.

When you enable FIP snooping, the system snoops VN\_Port to VF\_Port packets and enforces security only on VN\_Port to VF\_Port virtual links. When you enable VN2VN\_Port FIP snooping, the system snoops VN\_Port to VN\_Port packets and enforces security only on VN\_Port to VN\_Port virtual links.

The transit switch applies VN2VN\_Port FIP snooping filters at the ports associated with the FCoE VLANs on which you enable VN2VN FIP snooping.

This example describes how to configure VN2VN\_Port FIP snooping when the FCoE hosts are indirectly connected across an aggregation layer FCoE transit switch:

- [Requirements on page 5037](#)
- [Overview on page 5038](#)
- [Configuration on page 5039](#)
- [Verification on page 5042](#)

### Requirements

This example uses the following hardware and software components:

- Three Juniper Networks QFX5100 Switches running the ELS CLI and used as transit switches
- Junos OS Release 13.2 or later for the QFX Series
- Two FCoE hosts that have ENodes

## Overview

This example shows you how to:

- Set the correct interface mode on the transit switch.
- Configure the interfaces to use the dedicated FCoE VLAN for VN2VN\_Port FIP snooping.
- Configure the network-facing interfaces as FCoE trusted interfaces.
- Configure the dedicated FCoE VLAN for VN2VN\_Port FIP snooping traffic.
- Enable VN2VN\_Port FIP snooping on the FCoE VLAN and configure the beacon period.

## Topology

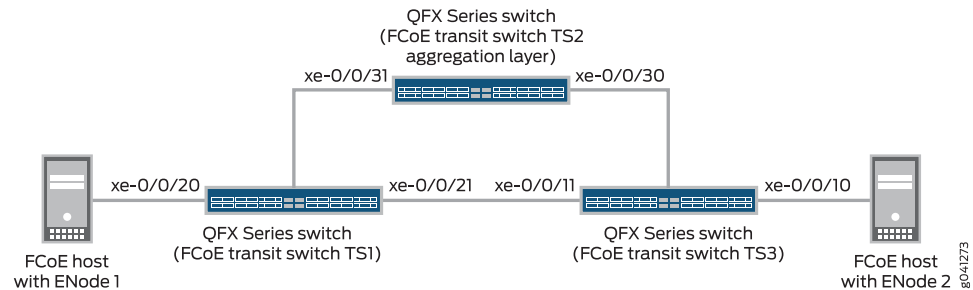

Table 387 on page 4992 shows the configuration components for this example.

**Table 391: Components of the VN2VN\_Port FIP Snooping Configuration Topology (FCoE Hosts Indirectly Connected Across an Aggregation Layer FCoE Transit Switch)**

Component	Settings
Hardware	<p>Three QFX5100 switches running the ELS CLI, two of which are FCoE transit switches that are directly attached to the FCoE hosts (transit switches TS1 and TS2) and one of which is an aggregation layer FCoE transit switch (TS3)</p> <p>Two FCoE hosts that have ENodes (ENode1 and ENode2, respectively)</p>

### Configuration

To configure VN2VN\_Port FIP snooping for VN\_Ports that are indirectly connected across an aggregation layer FCoE transit switch, perform these tasks:

- [Configuring VN2VN\\_Port FIP Snooping on FCoE Transit Switch TS1 on page 5040](#)
- [Configuring VN2VN\\_Port FIP Snooping on Aggregation Layer FCoE Transit Switch TS2 on page 5041](#)
- [Configuring VN2VN\\_Port FIP Snooping on FCoE Transit Switch TS3 on page 5041](#)

#### CLI Quick Configuration

The configuration for each FCoE transit switch is shown separately.

To quickly configure VN2VN\_Port FIP snooping for FCoE hosts that are indirectly connected across an aggregation layer FCoE transit switch, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level. To configure FCoE transit switch TS1:

#### FCoE Transit Switch TS1

```
set interfaces xe-0/0/20 unit 0 family ethernet-switching interface-mode trunk
set interfaces xe-0/0/21 unit 0 family ethernet-switching interface-mode trunk
set interfaces xe-0/0/20 unit 0 family ethernet-switching vlan members vlan200
set interfaces xe-0/0/21 unit 0 family ethernet-switching vlan members vlan200
set vlans vlan200 vlan-id 200
set vlans vlan200 forwarding-options fip-security interface xe-0/0/21 fcoe-trusted
set vlans vlan200 forwarding-options fip-security examine-vn2vn beacon-period 90000
```

To quickly configure VN2VN\_Port FIP snooping for FCoE hosts that are indirectly connected across an aggregation layer FCoE transit switch, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level. To configure FCoE transit switch TS2:

#### FCoE Transit Switch TS2

```
set interfaces xe-0/0/30 unit 0 family ethernet-switching interface-mode trunk
set interfaces xe-0/0/31 unit 0 family ethernet-switching interface-mode trunk
set interfaces xe-0/0/30 unit 0 family ethernet-switching vlan members vlan200
set interfaces xe-0/0/31 unit 0 family ethernet-switching vlan members vlan200
set vlans vlan200 vlan-id 200
```

```
set vlans vlan200 forwarding-options fip-security interface xe-0/0/30 fcoe-trusted
set vlans vlan200 forwarding-options fip-security interface xe-0/0/31 fcoe-trusted
set vlans vlan200 forwarding-options fip-security examine-vn2vn beacon-period 90000
```

To quickly configure VN2VN\_Port FIP snooping for FCoE hosts that are indirectly connected across an aggregation layer FCoE transit switch, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level. To configure FCoE transit switch TS3:

### FCoE Transit Switch TS3

```
set interfaces xe-0/0/10 unit 0 family ethernet-switching interface-mode trunk
set interfaces xe-0/0/11 unit 0 family ethernet-switching interface-mode trunk
set interfaces xe-0/0/10 unit 0 family ethernet-switching vlan members vlan200
set interfaces xe-0/0/11 unit 0 family ethernet-switching vlan members vlan200
set vlans vlan200 vlan-id 200
set vlans vlan200 forwarding-options fip-security interface xe-0/0/11 fcoe-trusted
set vlans vlan200 forwarding-options fip-security examine-vn2vn beacon-period 90000
```

#### *Configuring VN2VN\_Port FIP Snooping on FCoE Transit Switch TS1*

#### Step-by-Step Procedure

To configure interface mode, configure interface VLAN membership in the FCoE VLAN dedicated to VN2VN\_Port traffic, set the network-facing port as FCoE trusted, configure the VLAN, set the beacon period, and enable VN2VN\_Port FIP snooping:

1. Configure the modes of the interfaces that connect directly to the FCoE host with ENode1 (**xe-0/0/20**) and to aggregation layer FCoE transit switch TS2 (**xe-0/0/21**):

```
user@switch# set interfaces xe-0/0/20 unit 0 family ethernet-switching interface-mode trunk
set interfaces xe-0/0/21 unit 0 family ethernet-switching interface-mode trunk
```

2. Configure the interface VLAN membership so that the interfaces are members of the dedicated VN2VN\_Port VLAN (**vlan200**):

```
user@switch# set interfaces xe-0/0/20 unit 0 family ethernet-switching vlan members vlan200
set interfaces xe-0/0/21 unit 0 family ethernet-switching vlan members vlan200
```

3. Configure the FCoE VLAN dedicated to VN2VN\_Port FIP snooping:

```
user@switch# set vlans vlan200 vlan-id 200
```

4. Configure the network-facing port (**xe-0/0/21**) as an FCoE trusted port:

```
user@switch# set vlans vlan200 forwarding-options fip-security interface xe-0/0/21 fcoe-trusted
```

5. Enable VN2VN\_Port FIP snooping on the VLAN and configure the beacon period:

```
user@switch# set vlans vlan200 forwarding-options fip-security examine-vn2vn beacon-period 90000
```

**Configuring VN2VN\_Port FIP Snooping on Aggregation Layer FCoE Transit Switch TS2**

**Step-by-Step Procedure** To configure interface mode, configure interface VLAN membership in the FCoE VLAN dedicated to VN2VN\_Port traffic, set the network-facing ports as FCoE trusted, configure the VLAN, set the beacon period, and enable VN2VN\_Port FIP snooping:

1. Configure the mode of the interfaces that connect directly to FCoE transit switches TS1 (xe-0/0/31) and TS3 (xe-0/0/30). Both interfaces are network-facing and must be configured as trunk interfaces:

```
user@switch# set interfaces xe-0/0/30 unit 0 family ethernet-switching interface-mode trunk
set interfaces xe-0/0/31 unit 0 family ethernet-switching interface-mode trunk
```

2. Configure the interface VLAN membership so that the interfaces are members of the dedicated VN2VN\_Port VLAN (vlan200):

```
user@switch# set interfaces xe-0/0/30 unit 0 family ethernet-switching vlan members vlan200
set interfaces xe-0/0/31 unit 0 family ethernet-switching vlan members vlan200
```

3. Configure the FCoE VLAN dedicated to VN2VN\_Port FIP snooping:

```
user@switch# set vlans vlan200 vlan-id 200
```

4. Configure the network-facing ports (xe-0/0/30 and xe-0/0/31) as FCoE trusted ports:

```
user@switch# set vlans vlan200 forwarding-options fip-security interface xe-0/0/30 fcoe-trusted
user@switch# set vlans vlan200 forwarding-options fip-security interface xe-0/0/31 fcoe-trusted
```

5. Enable VN2VN\_Port FIP snooping on the VLAN and configure the beacon period:

```
user@switch# set vlans vlan200 forwarding-options fip-security examine-vn2vn beacon-period 90000
```

**Configuring VN2VN\_Port FIP Snooping on FCoE Transit Switch TS3**

**Step-by-Step Procedure** To configure interface mode, configure interface VLAN membership in the FCoE VLAN dedicated to VN2VN\_Port traffic, set the network-facing port as FCoE trusted, configure the VLAN, set the beacon period, and enable VN2VN\_Port FIP snooping:

1. Configure the mode of the interfaces that connect directly to the FCoE host with ENode2 (xe-0/0/10) and to aggregation layer FCoE transit switch TS2 (xe-0/0/11):

```
user@switch# set interfaces xe-0/0/10 unit 0 family ethernet-switching interface-mode trunk
set interfaces xe-0/0/11 unit 0 family ethernet-switching interface-mode trunk
```

2. Configure the interface VLAN membership so that the interfaces are members of the dedicated VN2VN\_Port VLAN (vlan200):

```
user@switch# set interfaces xe-0/0/10 unit 0 family ethernet-switching vlan members vlan200
set interfaces xe-0/0/11 unit 0 family ethernet-switching vlan members vlan200
```

3. Configure the FCoE VLAN dedicated to VN2VN\_Port FIP snooping:

```
user@switch# set vlans vlan200 vlan-id 200
```

4. Configure the network-facing port (**xe-0/0/11**) as an FCoE trusted port:  

```
user@switch# set vlans vlan200 forwarding-options fip-security interface xe-0/0/11 fcoe-trusted
```
5. Enable VN2VN\_Port FIP snooping on the VLAN and configure the beacon period:  

```
user@switch# set vlans vlan200 forwarding-options fip-security examine-vn2vn beacon-period 90000
```

---

### Verification

To verify that the VN2VN\_Port FIP snooping configuration has been created and is operating properly on all three switches, perform these tasks:

- [Verifying That VN2VN\\_Port FIP Snooping Is Enabled on the FCoE VLAN \(All Three Transit Switches\)](#) on page 5042

#### ***Verifying That VN2VN\_Port FIP Snooping Is Enabled on the FCoE VLAN (All Three Transit Switches)***

**Purpose** Verify that VN2VN\_Port FIP snooping is enabled on the correct VLAN (**vlan200**), the beacon period is set to **90000** milliseconds, and that the correct interfaces (**xe-0/0/20** and **xe-0/0/21** on TS1, **xe-0/0/30** and **xe-0/0/31** aggregation layer TS2, and **xe-0/0/10** and **xe-0/0/11** on TS3) are members of the VLAN.

**Action** List the FIP snooping information on transit switch TS1 using the operational mode command **show fip snooping detail**

```
user@switch> show fip snooping detail

Vlink far-end VN-Port-MAC: 0e:fd:00:00:0b:01
```

**Meaning** The **show fip snooping detail** command lists all of the transit switch information about VN2VN\_Port FIP snooping and VN2VF\_Port FIP snooping on each transit switch. The command shows that:

- The VLAN is **vlan200**.
- The mode is FIP snooping mode **VN2VN**, for VN2VN\_Port FIP snooping. (If the Mode field shows **VN2VF**, then the FIP snooping mode is VN2VF\_Port FIP snooping.)
- The beacon period is **90000**.
- The interfaces connected to the ENodes are **xe-0/0/20** and **xe-0/0/21** on transit switch TS1, **xe-0/0/30** and **xe-0/0/31** on aggregation layer transit switch TS2, and **xe-0/0/10** and **xe-0/0/11** on transit switch TS3. Because the transit switches are transparent passthrough switches, the network-facing trunk ports “see” the FCoE host ENodes at the far end of the VN2VN\_Port virtual link.

In addition, this useful command shows information about the ENodes and the VN2VN\_Port sessions.

## Configuring an FCoE-FC Gateway Fibre Channel Fabric

Fibre Channel (FC) fabric configuration consists of creating a unique name and identifier for each FC fabric you want to create and configuring it as an FCoE-FC gateway.

You can create a maximum of 12 FC fabrics on a QFX3500 switch. After you create a fabric, you can create and assign interfaces to the fabric, configure FIP parameters for the fabric, and set proxy traceoptions.

To configure an FC fabric using the CLI, specify a unique name and identification number for the fabric:

1. Configure the fabric name and fabric ID:

```
[edit]
user@switch# set fc-fabrics fabric-name fabric-id fabric-id
```

**NOTE:** Changing the fabric name or the fabric ID causes all logins to drop and forces the ENodes to log in again.

For example, to configure an FC fabric with the name **fab\_ulous** and the fabric ID 10 (the range of **fabric-id** values is 1 through 4095):

```
[edit]
user@switch# set fc-fabrics fab_ulous fabric-id 10
```

2. Configure the fabric as a gateway fabric:

```
[edit fc-fabrics fabric-name]
user@switch# set fabric-type proxy
```

For example, to configure the FC fabric with the name **fab\_ulous** as a gateway fabric:

```
[edit fc-fabrics fab_ulous]
user@switch# set fabric-type proxy
```

## Disabling the Fabric WWN Verification Check

When a QFX Series NP\_Port sends a fabric login (FLOGI) request to a Fibre Channel (FC) switch, the FLOGI accept (FLOGI-ACC) reply from the FC switch contains the SAN fabric worldwide name (WWN). The QFX Series uses the SAN fabric WWN in the multicast discovery advertisement (MDA) that the QFX Series sends to the ENodes in the FCoE network.

However, some FC switches substitute their own WWN (often the FC switch's virtual WWN) for the SAN fabric WWN in the FLOGI-ACC message. In this case, different NP\_Ports that log in to the same FC fabric might receive different fabric WWNs in the FLOGI-ACC messages if the NP\_Ports are connected to different FC switches in the SAN fabric.

If the QFX Series receives different fabric WWNs on NP\_Ports that are connected to the same SAN fabric, the QFX Series uses the first fabric WWN it receives in the MDA it sends to the ENodes. The QFX Series isolates the NP\_Ports that receive a different fabric WWN from other FC switches in that SAN fabric. No ENode sessions are assigned to the isolated NP\_Ports. FC traffic is assigned only to NP\_Ports that receive a fabric WWN in the FLOGI-ACC message that matches the fabric WWN received by the first NP\_Port to log in to the FC fabric. (If an NP\_Port receives a fabric WWN that does not match the fabric WWN received by the first NP\_Port to log in to the FC fabric, it does not carry traffic to the SAN fabric.)

To prevent ENodes from being isolated due to a mismatched fabric WWN, you can disable the gateway fabric WWN verification check. Disabling the fabric WWN verification check enables all NP\_Ports connected to a SAN fabric are used to carry traffic between the gateway and the FC switch, regardless of the fabric WWN the NP\_Port receives in the FLOGI-ACC message.

**NOTE:** Disabling or enabling the fabric WWN verification check logs out all FCoE sessions.

To disable the fabric WWN verification check:

- [edit fc-fabrics *fabric-name* proxy]  
user@switch# **set no-fabric-wwn-verify**

## Configuring a Physical Fibre Channel Interface

When you configure the switch as an FCoE-FC gateway, you must configure either 6 or 12 of the physical interfaces as native FC interfaces. Native FC interfaces connect to the storage area network (SAN) FC switch.

You can configure ports xe-0/0/0 through xe-0/0/5 as fc-0/0/0 through fc-0/0/5, and ports xe-0/0/42 through xe-0/0/47 as fc-0/0/42 through fc-0/0/47 to create blocks of native FC interfaces. You cannot individually configure a single port as a native FC interface. Within these port blocks, you cannot mix FC interfaces with Ethernet interfaces. All of the ports in a block must be either native FC interfaces or Ethernet interfaces.

You can configure:

- Six native FC interfaces by configuring either ports xe-0/0/0 through xe-0/0/5 as fc-0/0/0 through fc-0/0/5, or ports xe-0/0/42 through xe-0/0/47 as fc-0/0/42 through fc-0/0/47.
- Twelve native FC interfaces by configuring ports xe-0/0/0 through xe-0/0/5 as fc-0/0/0 through fc-0/0/5 and ports xe-0/0/42 through xe-0/0/47 as fc-0/0/42 through fc-0/0/47.
- No native FC interfaces by leaving ports xe-0/0/0 through xe-0/0/5 and ports xe-0/0/42 through xe-0/0/47 in their default state as Ethernet interfaces.
- To configure physical FC interfaces using the CLI, specify the physical port block you want to configure on the switch as native FC interfaces:

```
[edit chassis]
user@switch# set fpc fpc pic pic fibre-channel port-range port-range-low port-range-high
```

For example, to configure six native FC interfaces, you can configure ports 0 through 5 as physical FC interfaces:

```
[edit chassis]
user@switch# set fpc 0 pic 0 fibre-channel port-range 0 5
```

To configure 12 native FC interfaces requires two separate statements:

```
[edit chassis]
user@switch# set fpc 0 pic 0 fibre-channel port-range 0 5
user@switch# set fpc 0 pic 0 fibre-channel port-range 42 47
```

- [Understanding Interfaces on an FCoE-FC Gateway on page 4829](#)

## Configuring a Fibre Channel Interface

When a QFX3500 acts as an FCoE-FC gateway, native Fibre Channel (FC) traffic flows between the switch and the storage area network (SAN) FC switch. When you configure a port as an FC interface, it transports only FC traffic. It does not transport Ethernet traffic.

You can configure ports xe-0/0/0 through xe-0/0/5 as fc-0/0/0 through fc-0/0/5 and ports xe-0/0/42 through xe-0/0/47 as fc-0/0/42 through fc-0/0/47 to create blocks of native FC interfaces.

Each of these blocks of ports must be configured either as all Ethernet ports or as all native FC ports. Within each block of ports, you cannot mix FC and Ethernet interfaces. This means that you can configure 0, 6, or 12 ports as native FC ports. “[Configuring a Physical Fibre Channel Interface](#)” on page 5048 describes how to configure the port blocks as physical FC interfaces.

**NOTE:** Do not configure ports that you want to use for native FC traffic as part of an Ethernet VLAN or as Ethernet ports.

Configure a port as an FC interface when the port connects to the F\_Port of an FC switch.

FC interface configuration includes:

- Explicitly specifying one or more ports as an FC family interface in NP\_Port mode (mandatory).
- Configuring the FC interface options port speed and buffer-to-buffer credit state change number (BB\_SC\_N) (optional).
- Configuring the interface as a loopback interface (optional).

The buffer-to-buffer state change number feature prevents the loss of buffer-to-buffer credits between the two interfaces on either end of an FC link. The state change number determines the number of frames and receiver ready (R\_RDY) primitives the interfaces exchange between the state change send (BB\_SCs) and the state change receive (BB\_SCr) primitives used to track these transactions.

Enabling BB\_SC\_N by configuring BB\_SC\_N on both of the FC link interfaces:

- Requests that  $2^{BB\_SC\_N}$  number of frames be sent between two consecutive BB\_SCs primitives, and
- Requests that  $2^{BB\_SC\_N}$  number of R\_RDY primitives be sent between two consecutive BB\_SCr primitives.

When the number of R\_RDY primitives received equals  $2^{BB\_SC\_N}$ , the R\_RDY counter resets to zero. When the number of frames received equals  $2^{BB\_SC\_N}$ , the frame counter resets to zero. The interfaces calculate the number of buffer-to-buffer credits lost based on counter discrepancies and take corrective action to recover the lost credits.

If you enable BB\_SC\_N, the recommended BB\_SC\_N setting is eight. Setting the BB\_SC\_N number to zero (0) disables the feature. If either of the two connected FC interfaces is configured with zero as the BB\_SC\_N value, then both interfaces disable the feature. If the two connected FC interfaces have different nonzero BB\_SC\_N numbers configured, both interfaces use the higher number.

For the port to transport FC traffic, you must also set the physical port as an FC port using the **port-range** command.

To configure an FC interface using the CLI:

1. Specify the interface as family FC and set the port mode to NP\_Port (setting the port mode to NP\_Port is a mandatory configuration):

```
[edit]
user@switch# set interfaces interface-name unit unit family fibre-channel port-mode np-port
```

For example, to configure the interface **fc-0/0/3** as an FC interface and set the port mode to **np-port**:

```
[edit]
user@switch# set interfaces fc-0/0/3 unit 0 family fibre-channel port-mode np-port
```

2. Configure the FC interface speed option:

```
[edit]
user@switch: set interfaces interface-name fibrechannel-options speed (auto-negotiation
| 2g | 4g | 8g)
```

For example, to set the FC interface speed option to **8g** for the interface **fc-0/0/3**:

```
[edit]
user@switch: set interfaces fc-0/0/3 fibrechannel-options speed 8g
```

The default port mode is **auto-negotiation**, which sets the port speed to match the speed of the attached FC F\_Port interface (2 Gbps, 4 Gbps, or 8 Gbps).

3. Configure the optional buffer-to-buffer credit state change number:

```
[edit]
user@switch: set interfaces interface-name fibrechannel-options bb-sc-n 0..15
```

For example, to set the FC interface buffer-to-buffer credit state change number to **8** for the interface **fc-0/0/3**:

```
[edit]
user@switch: set interfaces fc-0/0/3 fibrechannel-options bb-sc-n 8
```

After you configure one or more FC interfaces, assign them and an FCoE VLAN to an FC fabric.

## Configuring an FCoE VLAN Interface on an FCoE-FC Gateway

When you configure the switch as an FCoE-FC gateway, a Layer 3 FCoE VLAN interface transmits and receives Fibre Channel over Ethernet (FCoE) traffic between the gateway and FCoE-capable servers on the Ethernet network. Configuring a Layer 3 FCoE VLAN interface on the switch creates virtual fabric port (VF\_Port) interfaces facing the FCoE server virtual node ports (VN\_Ports).

The FCoE VLAN interface is the interface for the dedicated VLAN the FCoE servers use for FCoE traffic. Each FC fabric requires at least one dedicated FCoE VLAN and at least one Layer 3 FCoE VLAN interface to transport FCoE traffic. On QFabric systems, the FCoE VLAN interface, the FCoE VLAN, and the interfaces that are members of the FCoE VLAN must be on the same Node device.

**NOTE:** FCoE VLANs (any VLANs that carries FCoE traffic) support only Spanning Tree Protocol (STP) and link aggregation group (LAG) Layer 2 features.

**NOTE:** To configure an FCoE VLAN on a device that you are using as transit switch, you do not an FCoE VLAN interface. Instead, use the procedure described in [“Configuring VLAN Interfaces for FCoE Traffic on an FCoE Transit Switch” on page 5066](#).

Before you configure an FCoE VLAN interface, create the FCoE VLAN and assign 10-Gigabit Ethernet interfaces configured in tagged-access port mode to the VLAN. These 10-Gigabit Ethernet interfaces are the physical interfaces that transport the FCoE traffic to and from the FCoE devices in the Ethernet network.

Each Ethernet interface that connects to FCoE devices must also include the native VLAN to transport FIP traffic, because FIP VLAN discovery and notification frames are exchanged as untagged packets. The FCoE VLAN must carry only FCoE traffic. A VLAN cannot transport a mix of FCoE and standard Ethernet traffic.

FCoE VLAN interface configuration includes:

- Configuring a VLAN to use as a dedicated FCoE VLAN.
- Configuring a native VLAN for FIP traffic.
- Configuring member interfaces for the FCoE VLAN.
- Configuring the FCoE VLAN as a Fibre Channel (family) VLAN and setting the port mode value to **f-port**. Explicitly configuring the FCoE VLAN interface in F\_Port mode is

mandatory. The switch interface with which the FCoE server VN\_Ports communicate must present a VF\_Port to the servers.

- Configuring the FCoE VLAN interface as the Layer 3 interface for FCoE traffic.

To configure an FCoE VLAN interface:

1. Configure a dedicated FCoE VLAN:

```
[edit vlans]
user@switch# set vlan-name vlan-id vlan-id
```

For example, to configure a VLAN named **fcoe\_vlan** with a VLAN ID of **100** as the FCoE VLAN:

```
[edit vlans]
user@switch# set fcoe_vlan vlan-id 100
```

2. Configure a native VLAN for FIP traffic:

```
[edit vlans]
user@switch# set native vlan-id vlan-id
```

For example, to configure the native VLAN with a VLAN ID of 1:

```
[edit vlans]
user@switch# set native vlan-id 1
```

3. Configure member interfaces for the FCoE VLAN (use **ethernet-switching** as the family and **tagged-access** as the port mode):

```
[edit interfaces]
user@switch# set interface-name unit unit family family port-mode mode vlan members
vlan-name
```

For example, to configure the interface **xe-0/0/10** as a member of the FCoE VLAN **fcoe\_vlan**:

```
[edit interfaces]
user@switch# set xe-0/0/10 unit 0 family ethernet-switching port-mode tagged-access vlan
members fcoe_vlan
```

4. Configure the native VLAN on the FCoE VLAN member interfaces:

```
[edit interfaces]
user@switch# set interface-name unit unit family family native-vlan-id vlan-id
```

For example, to configure the interface **xe-0/0/10** as a member of the native VLAN with the native VLAN ID 1:

```
[edit interfaces]
user@switch# set xe-0/0/10 unit 0 family ethernet-switching native-vlan-id 1
```

5. Assign the Ethernet interfaces to the FCoE VLAN:

```
[edit vlans]
user@switch# set vlan-name interface interface-name
```

For example, to assign the interface **xe-0/0/10.0** to the FCoE VLAN named **fcoe\_vlan**:

```
[edit vlans]
user@switch# set fcoe_vlan interface xe-0/0/10.0
```

6. Define an interface as an FCoE VLAN interface in F\_Port mode (to present a VF\_Port to the FCoE servers):

```
[edit interfaces]
user@switch# set vlan unit unit family fibre-channel port-mode f-port
```

For example, to configure VLAN unit **100** as an FCoE VLAN interface and set the port mode to **f-port**:

```
[edit interfaces]
user@switch# set vlan unit 100 family fibre-channel port-mode f-port
```

7. Define the Layer 3 FCoE VLAN interface:

```
[edit vlans]
user@switch# set vlan-name l3-interface vlan-interface-name
```

For example, to configure VLAN interface unit **100** (the FCoE VLAN interface defined earlier in this example) as the Layer 3 FCoE VLAN interface for FCoE VLAN **fcoe\_vlan**:

```
[edit vlans]
user@switch# set fcoe_vlan l3-interface vlan.100
```

## Assigning Interfaces to a Fibre Channel Fabric

When you configure the switch as an FCoE-FC gateway, you assign one or more (up to 12) native Fibre Channel (FC) interfaces and at least one FCoE VLAN interface to each FC fabric. FC interfaces transport native FC traffic between the proxy gateway and the storage area network (SAN) FC switch. FCoE VLAN interfaces transport FCoE traffic between FCoE-capable servers and the gateway.

Each FC fabric needs both types of interfaces to transport traffic between FCoE servers on the Ethernet network and FC storage devices in the core FC network behind the FC switch. FCoE traffic between the FCoE servers and the gateway must travel in a dedicated FCoE VLAN. Native FC traffic passes between the gateway and the FC switch on the native FC interfaces.

You must configure the FC interfaces and the FCoE VLAN interfaces that you assign to a particular fabric on the same Juniper Networks QFX3500 Switch. Traffic between an FCoE device and the FC switch must ingress and egress the same gateway.

To assign core-facing native FC interfaces and a server-facing FCoE VLAN interface to an FC fabric, configure a fabric and then specify the interfaces:

1. Assign the native FC interfaces to the FC fabric:

```
[edit fc-fabrics fabric-name]
user@switch: set interface interface-name
user@switch: set interface interface-name
user@switch: set interface interface-name
...
```

2. Assign an FCoE VLAN interface to the FC fabric:

```
[edit fc-fabrics fabric-name]
user@switch: set interface vlan-name
```

For example, to assign the native FC interfaces **fc-0/0/0.0**, **fc-0/0/1.0**, and **fc-0/0/2.0** and the FCoE VLAN interface **vlan.100** to an FC fabric named **san\_tana**:

```
user@switch: set fc-fabrics san_tana interface fc-0/0/0.0
user@switch: set fc-fabrics san_tana interface fc-0/0/1.0
user@switch: set fc-fabrics san_tana interface fc-0/0/2.0
user@switch: set fc-fabrics san_tana interface vlan.100
```

- [Understanding an FCoE-FC Gateway on page 4808](#)

## Deleting a Fibre Channel Interface

Before you delete a Fibre Channel (FC) interface, you must first delete the interface from the FC fabric configuration. This prevents configuration errors that would result if you deleted an FC interface from the **[edit interfaces]** hierarchy level but did not delete the interface from the FC fabric.

When you configure the switch as an FCoE-FC gateway, FC interfaces transmit and receive native FC traffic between the gateway and the FC switch. You can configure ports xe-0/0/0 through xe-0/0/5 as fc-0/0/0 through fc-0/0/5 and ports xe-0/0/42 through xe-0/0/47 as fc-0/0/42 through fc-0/0/47 to create one or two blocks of six native FC interfaces.

To delete an FC interface using the CLI:

1. Delete the FC interface from the FC fabric to which it belongs:

```
[edit]
user@switch# delete fc-fabrics fabric-name interface interface-name
```

For example, to delete the FC interface **fc-0/0/3.0** from an FC fabric named **sanfab1**:

```
[edit]
user@switch# delete fc-fabrics sanfab1 interface fc-0/0/3.0
```

2. Delete the FC interface from the switch **[edit interfaces]** hierarchy:

```
[edit]
user@switch: delete interfaces interface-name
```

For example, to delete the interface **fc-0/0/3.0** from the switch:

```
[edit]
user@switch: delete interfaces fc-0/0/3.0
```

The FC interface has been deleted from the FC fabric and from the switch.

## Disabling Storm Control on FCoE Interfaces on an FCoE-FC Gateway

Storm control is not supported on the FCoE interfaces of an FCoE-FC gateway VLAN. Enabling storm control on an FCoE-FC gateway VLAN interface may cause FCoE packet loss. Storm control is disabled by default on all interfaces. However, if you enabled storm control globally on all switch interfaces or on any interfaces that are part of the FCoE VLAN interface, you must disable storm control on the Ethernet interfaces of the FCoE VLAN.

If storm control is enabled on only a few interfaces of the FCoE VLAN, you can disable storm control on individual interfaces by including the **delete ethernet-switching-options storm-control interface *interface-name*** statement in the configuration, where *interface-name* is the name of the interface on which you want to disable storm control.

If storm control is enabled globally on the switch when the switch is acting as an FCoE-FC gateway, it is often easiest to disable storm control on all interfaces, then enable storm control only on Ethernet interfaces that are not part of the FCoE VLAN interface.

If storm control is enabled globally, you can disable storm control in either of two ways:

- Disable storm control on all interfaces, then enable storm control on the interfaces you want to use storm control. (From the default configuration, you cannot disable storm control on individual interfaces because the default configuration enables storm control on **all** interfaces, not on individual interfaces.)

For example, if you want interfaces xe-0/0/20, xe-0/0/21, and xe-0/0/22 to use storm control, disable storm control on all interfaces, then enable storm control on those three interfaces:

1. Disable storm control on all interfaces:

```
user@switch# delete ethernet-switching-options storm-control interface all
```

2. Enable storm control on interfaces xe-0/0/20, xe-0/0/21, and xe-0/0/22:

```
user@switch# set ethernet-switching-options storm-control interface xe-0/0/20
user@switch# set ethernet-switching-options storm-control interface xe-0/0/21
user@switch# set ethernet-switching-options storm-control interface xe-0/0/22
```

- Disable storm control for all unknown unicast traffic on all interfaces by including the following statement in your configuration:

```
user@switch# set ethernet-switching-options storm-control interface all no-unknown-unicast
```

## Defining the Proxy Load-Balancing Algorithm

When the QFX Series is configured as an FCoE-FC gateway, it balances the FCoE session load assigned to each NP\_Port link between the gateway and the FC switch in the FC

SAN to avoid overloading or underutilizing each link. The QFX Series supports three types of load-balancing mechanisms:

- **Simple load balancing**—Load balancing is based on the weighted utilization (session load) of the NP\_Ports connected to an FC fabric. The session load is the sum of the FLOGI and FDISC sessions on each link. Each new ENode fabric login (FLOGI) or VN\_Port fabric discovery (FDISC) session is assigned to the least-loaded link, so an FDISC session initiated by the VN\_Port on an ENode might not be assigned to the same link as the parent ENode's FLOGI session. Simple load balancing is the default algorithm. Simple load balancing is the default load-balancing algorithm. Rebalancing the link load disrupts only selected sessions to minimize the impact (the switch uses an algorithm to log out only the sessions that need to be moved to other links to balance the load when those sessions log in again).
- **ENode-based load balancing**—Load balancing is based on the weighted utilization (session load) of the NP\_Ports connected to an FC fabric. The session load is the sum of the FLOGI and FDISC sessions on each link. However, when an ENode logs in to the fabric, the switch places all subsequent VN\_Port FDISC sessions associated with that ENode on the same link as the ENode FLOGI session, regardless of the link load. New ENode FLOGIs are placed on the least-loaded link. The switch calculates the link load based on the combined total of FLOGIs and FDISCs on each NP\_Port link. Rebalancing the link load disrupts all sessions (all sessions log out and then log in again).
- **FLOGI-based load balancing**—Load balancing is based on the weighted utilization (session load) of the NP\_Ports connected to an FC fabric. The session load is the sum of the FLOGI sessions on each link. FDISC sessions are not counted. When an ENode logs in to the fabric, the switch places all subsequent VN\_Port FDISC sessions associated with that ENode on the same link as the ENode FLOGI session, regardless of the link load. New ENode FLOGIs are placed on the least-loaded link. Rebalancing the link load disrupts only selected sessions to minimize the impact (the switch uses an algorithm to log out only the sessions that need to be moved to other links to balance the load when those sessions log in again).

To define the proxy load-balancing algorithm for a proxy fabric on the FCoE-FC gateway, set the algorithm as **enode-based**, **simple**, or **flogi-based**:

- `[edit fc-fabrics fabric-name proxy]`  
`user@switch# set load-balance-algorithm (enode-based | simple | flogi-based)`

For example, to configure a gateway fabric named **san\_fab1** to use **enode-based** load balancing:

```
user@switch# set fc-fabrics san_fab1 proxy load-balance-algorithm enode-based
```

#### Related Documentation

- [Understanding Load Balancing in an FCoE-FC Gateway Proxy Fabric on page 4841](#)
- [Monitoring Fibre Channel Interface Load Balancing on page 5147](#)

## Simulating On-Demand Fibre Channel Link Load Rebalancing (Dry Run Test)

On-demand Fibre Channel (FC) link load rebalancing is a disruptive action that causes sessions to log out of the network, then log back in to be placed on FC links (NP\_Ports) in a balanced manner. The number of sessions logged out to rebalance the links depends on the load-balancing algorithm used (simple, ENode-based, or FLOGI-based) and whether or not the load is already balanced. (If the link load is already balanced, the switch does not rebalance the loads when you request on-demand load rebalancing.)

You can use the **dry-run** option to list the sessions that might be affected (logged out to be redistributed among the active FC interface links) by on-demand load rebalancing *before* you actually rebalance the link load. (Because new sessions might log in between the time you perform a dry run and the time you request on-demand load rebalancing, the affected sessions may change. Therefore, the sooner that you perform an on-demand load rebalance after you perform a dry run, the more accurate the dry run results are likely to be.)

To request a link load rebalancing dry run:

```
user@switch> request fibre-channel proxy load-rebalance dry-run fabric fabric-name
```

For example, to request a dry run on an FC fabric named *fc\_fabric\_100* to display a list of sessions that might be disrupted if you request an actual link load rebalance:

```
user@switch> request fibre-channel proxy load-rebalance dry-run fabric fc_fabric_100
Fabric: fc_fabric_100, Fabric-id: 100
F-Port FCID Port-WWN NP-Port
vlan.100 0x8a013a 02:01:00:64:00:00:2a fc-0/0/1.0
vlan.100 0x8a013c 02:01:00:64:00:00:2b fc-0/0/1.0
vlan.100 0x8a0146 02:01:00:64:00:00:2e fc-0/0/1.0
vlan.100 0x8a014c 02:01:00:64:00:00:2f fc-0/0/1.0
```

## Enabling and Disabling CoS OxID Hash Control

The originator exchange identifier (OxID) field is one of several fields that the switch can use in its hash function computation for FCoE traffic load balancing over multiple outgoing links. You can configure whether or not the switch uses the OxID in the hash computation.

Including the OxID field in the load-balancing hash computation allows different exchanges between a pair of Fibre Channel (FC) endpoints (such as an FCoE host and an FC storage device) to take different paths across the network, thus improving the aggregate network throughput.

However, if the paths between different sets of FC endpoints have common links, congestion on one set of FC endpoints can affect the other set of endpoints. Such congestion can happen if the FCoE traffic on the two sets of endpoints uses the same priority (IEEE 802.1p code point). It is common for networks to use priority 3 (IEEE 802.1p code point 011) for FCoE traffic. However, on the QFX3500, you can assign different IEEE priorities to different lossless FCoE flows as described in [“Understanding CoS IEEE 802.1p Priorities for Lossless Traffic Flows” on page 5427](#) to further separate the traffic flows.

OxID hash control is enabled by default.

- To enable OxID hash control field for FCoE traffic load balancing:

```
[edit forwarding-options hash-key]
user@switch# set family fcoe oxid enable
```

- To disable OxID hash control field for FCoE traffic load balancing:

```
[edit forwarding-options hash-key]
user@switch# set family fcoe oxid disable
```

## Configuring FIP on an FCoE-FC Gateway

Fibre Channel over Ethernet (FCoE) Initialization Protocol (FIP) establishes and maintains Fibre Channel (FC) virtual links between pairs of FCoE devices. A virtual link emulates the physical point-to-point link that FC requires between two FC devices.

FIP is enabled by default and uses the default FIP settings on all FCoE interfaces that are part of the gateway FC fabric. You can use the default FIP parameter values, or you can configure FIP parameters globally or on a per-interface basis. Configuring FIP on an individual interface overrides the global FIP configuration.

You can configure the following parameters globally for the fabric and per interface:

- FIP keepalive message transmission interval—This interval is the time period between sending FIP keepalive messages.

- **Priority**—If an FCoE node (ENode) connects to more than one switch, the priority value determines the switch to which the ENode connects. The switch with the lowest priority number has the highest priority.

You can only configure the following parameters globally on an FC fabric:

- **FC-MAP**—The 24-bit FCoE mapped address prefix that identifies the attached FC switch in the SAN fabric. The FC-MAP value is used in the fabric provided MAC address (FPMA) created for each ENode that logs in. This value must be the same for the FC switch and the QFX Series.

**NOTE:** Changing the FC-MAP value causes all logins to drop and forces the ENodes to log in again.

- **FCoE trusted**—You can globally configure all of the Ethernet ports in a specified FC fabric to be FCoE trusted. You might want to configure interfaces as FCoE trusted if the interfaces are connected to a transit switch that is performing FIP snooping. For interfaces that are directly connected to FCoE hosts, FIP snooping should be enabled, and you should not configure the fabric as FCoE trusted.

**NOTE:** Do not configure interfaces with FIP snooping enabled as FCoE trusted.

Configuring interfaces as FCoE trusted reduces system overhead by eliminating the need for filters. The total number of sessions the system can support is 2500 sessions. Sessions are defined as the combined number of VN\_Port to VF\_Port sessions and VN\_Port to VN\_Port sessions. (Although VN2VF and VN2VN sessions run in different FCoE VLANs, the session limit is a system limit, not a per-VLAN limit.)

**NOTE:** A session is a FLOGI or FDISC login to the FC SAN fabric. Session does not refer to end-to-end storage sessions. There is no limit to the number of end-to-end storage sessions.

**NOTE:** Changing the fabric ports from untrusted to trusted removes any existing FIP snooping filters from the ports. Changing the fabric ports from trusted to untrusted forces all of the FCoE sessions on those ports to log out so that when the ENodes and VN\_Ports log in again, the switch can build the appropriate FIP snooping filters.

- **Maximum number of FCoE sessions per ENode**—You can globally configure the maximum number of FCoE sessions (FLOGI plus FDISC) permitted from an ENode. The maximum number of sessions per ENode is 2000 sessions. The total number of sessions (VN2VF\_Port sessions and VN2VN\_Port sessions combined) cannot exceed the gateway fabric's maximum limit of 2500 sessions.

To configure FIP options globally using the CLI:

1. Specify the fabric on which you want to configure FIP:

```
[edit]
user@switch# set fc-fabrics fabric-name protocols fip
```

2. Configure the FIP keepalive message transmission interval in milliseconds to specify the amount of time between periodic FIP discovery advertisements for the fabric interfaces (the default is 8000 ms; the range is 250 through 90000 ms):

```
[edit fc-fabrics fabric-name protocols fip]
user@switch# set fka-adv-period milliseconds
```

3. Configure the priority value the switch advertises to ENodes in the range from 0 through 255; the default value is 128:

```
[edit fc-fabrics fabric-name protocols fip]
user@switch# set priority priority
```

4. Configure the FC-MAP value to match the FC-MAP value of the attached FC switch in the FC SAN fabric; the range of possible values is 0EFC00 through 0EFCFF, and the default value is 0EFC00:

```
[edit fc-fabrics fabric-name protocols fip]
user@switch# set fc-map fc-map
```

5. Configure the interfaces in the FC fabric as FCoE trusted (in this example, we assume that the interfaces have not been enabled for FIP snooping):

```
[edit fc-fabrics fabric-name protocols fip]
user@switch# set fcoe-trusted
```

6. Configure the maximum number of FCoE sessions for each ENode in the fabric:

```
[edit fc-fabrics fabric-name protocols fip]
user@switch# set max-sessions-per-enode
```

For example, to configure all FCoE interfaces associated with an FC fabric called **movieco\_san** with a FIP keepalive interval value of **25000** milliseconds, a priority of **70**, an FC-MAP value of **0EFC01**, as FCoE trusted, and with a maximum number of FCoE sessions per ENode of 200 sessions:

```
[edit fc-fabrics movieco_san protocols fip]
user@switch# set fka-adv-period 25000
user@switch# set priority 70
user@switch# set fc-map 0EFC01
user@switch# set fcoe-trusted
user@switch# set max-sessions-per-enode 200
```

To override the global FC fabric FIP configuration for a specific FCoE interface using the CLI:

1. Specify the fabric and interface on which you want to configure FIP:

```
[edit fc-fabrics fabric-name protocols fip interface interface-name]
```

2. Configure the FIP keepalive message transmission interval and priority:

```
[edit fc-fabrics fabric-name protocols fip interface interface-name]
user@switch# set fka-adv-period milliseconds
user@switch# set priority priority
```

## Setting the Maximum Number of FIP Login Sessions per ENode

When the switch acts as an FCoE-FC gateway, FCoE node (ENode) devices in the Ethernet network use the gateway to connect to the Fibre Channel (FC) storage area network (SAN). You can limit the maximum number of FIP login sessions permitted on each ENode. Limiting the number of login sessions can prevent login session rejections caused when the connected FC switch port configuration limits the number of FIP login sessions.

The maximum number of FIP sessions per ENode is 2000 sessions (FLOGI plus FDISC sessions). The limit you set applies to every ENode in the specified gateway fabric. Each ENode in the fabric can have up to the maximum number of sessions, but the total number of active sessions cannot exceed the session limits you apply to the fabric or the Node device.

There are also configurable FIP login session limits that you can apply to the gateway FC fabric, to the QFX3500 switch or QFabric system Node device, and to the interfaces in each FC fabric.

- To set a maximum number of FIP login sessions per ENode using the CLI:

```
[edit fc-fabrics fc-fabric-name protocols fip]
user@switch# set max-sessions-per-enode max-login-sessions
```

For example, to configure the ENodes on an FC fabric named **sanfab1** with a maximum FIP login session limit of **250** sessions:

```
[edit fc-fabrics sanfab1]
user@switch# set protocols fip max-sessions-per-enode 250
```

## Setting the Maximum Number of FIP Login Sessions per FC Interface

When the switch acts as an FCoE-FC gateway, NP\_Ports are the native FC interfaces the gateway uses to connect to the FC switch. You can limit the maximum number of FIP login sessions permitted on an NP\_Port interface. Limiting the number of login sessions on an interface can prevent login session rejections caused when the connected FC switch port configuration limits the number of FIP login sessions.

**TIP:** A good practice is to configure a maximum number of login sessions on each NP\_Port that is less than or equal to the maximum number of login sessions permitted on the connected FC switch port.

The maximum number of FIP sessions is 2500 sessions. (This is the combined total of all VN2VF\_Port and VN2VN\_Port sessions on the system.)

There are also configurable FIP login session limits that you can apply to the gateway FC fabric, to the QFX3500 switch or QFabric system Node device, and to the ENodes in each FC fabric. To prevent unexpected FIP login rejections, the sum of the maximum FIP login sessions on all of the NP\_Port interfaces that belong to an FC fabric should not exceed the maximum number of sessions the FC fabric supports or the device supports.

- To set a maximum number of FIP login sessions on an NP\_Port using the CLI:

```
[edit fc-fabrics fc-fabric-name interface interface-name]
user@switch# set max-login-sessions max-login-sessions
```

For example, to configure NP\_Port interface **fc-0/0/5** with a maximum FIP login session limit of **500** sessions on an FC fabric named **sanfab1**:

```
[edit fc-fabrics sanfab1]
user@switch# set interface fc-0/0/5 max-login-sessions 500
```

### Related Documentation

## Setting the Maximum Number of FIP Login Sessions per FC Fabric

When the QFX Series acts as an FCoE-FC gateway, you configure at least one local FC fabric on the gateway. A gateway FC fabric creates associations that connect FCoE devices on an Ethernet network to an FC switch on a Fibre Channel network. Each FC fabric on a gateway includes native FC interfaces (NP\_Ports) that connect the gateway to the FC switch. When FCoE devices want to log in to the FC switch, the gateway sends the FIP login requests to the FC switch on the NP\_Port links.

You can limit the maximum number of FIP login sessions permitted on a gateway FC fabric. If a QFX3500 switch or QFabric system Node device has more than one FC fabric, limiting the number of login sessions on an FC fabric can prevent one FC fabric from using all of the login sessions available on the device.

The maximum number of FIP sessions is 2500 sessions. (This is the combined total of all VN2VF\_Port and VN2VN\_Port sessions on the system.)

There are also configurable FIP login session limits that you can apply to the FC fabric NP\_Port interfaces, to the QFX3500 switch or QFabric system Node device, and to the ENodes in each FC fabric. To prevent unexpected FIP login rejections:

- The sum of the maximum FIP login sessions on all of the NP\_Port interfaces that belong to an FC fabric should not exceed the maximum number of sessions the FC fabric supports or the device supports.
- The sum of the maximum FIP login sessions on all of the FC fabrics on a device should not exceed the maximum number of sessions per device.
- To set a maximum number of FIP login sessions on an FC fabric using the CLI:

```
[edit fc-fabrics fc-fabric-name]
user@switch# set max-login-sessions max-login-sessions
```

For example, to configure an FC fabric named **sanfab1** with a maximum FIP login session limit of **2000** sessions:

```
[edit fc-fabrics sanfab1]
user@switch# set fc-fabrics sanfab1 max-login-sessions 2000
```

## Setting the Maximum Number of FIP Login Sessions per Node Device

When a QFX3500 switch or QFabric system Node device acts as an FCoE-FC gateway, it connects FCoE devices on an Ethernet network to an FC switch in a Fibre Channel network. You can limit the maximum number of FIP login sessions for the FCoE devices on each Node device.

For QFX3500 switches, the maximum limit means that the sum of the FIP login sessions on all of the local FC fabrics on that QFX3500 switch cannot exceed the device maximum.

For the QFabric system, the limit applies to each Node device in the QFabric system. For example, if you configure a maximum FIP login session value of 2000 sessions, each Node device in the QFabric system can have a total of up to 2000 FIP login sessions running on its FC fabrics.

The maximum number of FIP sessions a device can support is 2500 sessions. (This is the combined total of all VN2VF\_Port and VN2VN\_Port sessions on the system.)

There are also configurable FIP login session limits that you can apply to the FC fabrics on the devices, to the NP\_Port interfaces in each FC fabric, and to the ENodes in each FC fabric. To prevent unexpected FIP login rejections:

- The sum of the maximum FIP login sessions for all of the FC fabrics on a device should not exceed the maximum number of sessions per device.
- The sum of the maximum FIP login sessions on all of the NP\_Port interfaces that belong to an FC fabric should not exceed the maximum number of sessions the FC fabric supports or the device supports.
- To set a maximum number of FIP login sessions for Node devices using the CLI:

[edit **fc-options**]

```
user@switch# set max-login-sessions-per-node max-login-sessions-per-node
```

For example, to configure a maximum FIP login limit of **2000** sessions on a QFX3500 switch or on all Node devices in a QFabric system:

[edit **fc-options**]

```
user@switch# set max-login-sessions-per-node 2000
```

## Configuring VLAN Interfaces for FCoE Traffic on an FCoE Transit Switch

When you configure a QFX Series as a Fibre Channel over Ethernet (FCoE) transit switch, you must configure a VLAN that transports only FCoE traffic. FCoE traffic requires a dedicated VLAN and cannot share a VLAN with any other type of traffic. Because FCoE traffic is tagged traffic, the port (or interface) mode cannot be access mode, it must be either tagged-access port-mode (for switches that run the original CLI, such as QFX3500 and QFX3600 standalone switches and QFabric system Node devices) or trunk interface-mode (for switches that run the Enhanced Layer 2 Software (ELS) CLI, such as the QFX5100 switch).

However, each interface that belongs to an FCoE VLAN must not only transport the tagged FCoE traffic, it must also transport the untagged FCoE Initialization Protocol (FIP) traffic. FIP communicates with the storage area network (SAN) Fibre Channel (FC) switch to set up the FCoE session for the FCoE client.

To transport untagged traffic on a tagged-access or trunk mode interface, the interface must have a native VLAN configured on it. Therefore, each interface that belongs to an FCoE VLAN must also have a native VLAN on it.

There are slight differences in the way you configure a native VLAN on an interface, depending on whether the switch uses the ELS CLI or the original CLI. This topic describes both methods.

**NOTE:** FCoE VLANs (any VLANs that carries FCoE traffic) support only Spanning Tree Protocol (STP) and link aggregation group (LAG) Layer 2 features.

**NOTE:** To configure an FCoE VLAN on a QFX3500 switch or a QFabric system Node device that you are using as an FCoE-FC gateway, you must also configure an FCoE VLAN interface as described in [“Configuring an FCoE VLAN Interface on an FCoE-FC Gateway” on page 5051](#). (QFX3600, QFX5100, and Virtual Chassis switches do not support FCoE-FC gateway configuration.)

FCoE VLAN configuration includes:

- Configuring a VLAN to use as a dedicated FCoE VLAN
- Configuring the interface members of the FCoE VLAN.
- Configuring a native VLAN for FIP traffic.

This topic includes two configuration procedures, one for switches that run the original CLI, and one for switches that run the ELS CLI.

## Original CLI Configuration

To configure an FCoE VLAN on a non-ELS switch (QFX3500, QFX3600, QFabric system Node devices):

1. Configure a dedicated FCoE VLAN:

```
[edit vlans]
user@switch# set vlan-name vlan-id vlan-id
```

For example, to configure a VLAN named **fcoe\_vlan** with a VLAN ID of **100** as the FCoE VLAN:

```
[edit vlans]
user@switch# set fcoe_vlan vlan-id 100
```

2. Configure the FCoE VLAN on the interface (use **ethernet-switching** as the family and **tagged-access** as the port mode):

```
[edit interfaces]
user@switch# set interface-name unit unit family family port-mode mode vlan members
vlan-name
```

For example, to configure the interface **xe-0/0/10** as a member of the FCoE VLAN **fcoe\_vlan**:

```
[edit interfaces]
user@switch# set xe-0/0/10 unit 0 family ethernet-switching port-mode tagged-access vlan
members fcoe_vlan
```

3. Configure the Ethernet interface membership in the FCoE VLAN:

```
[edit vlans]
user@switch# set vlan-name interface interface-name
```

For example, to assign the interface **xe-0/0/10.0** to the FCoE VLAN named **fcoe\_vlan**:

```
[edit vlans]
user@switch# set fcoe_vlan interface xe-0/0/10.0
```

4. Configure a native VLAN for the untagged FIP traffic:

```
[edit vlans]
user@switch# set native vlan-id vlan-id
```

For example, to configure the native VLAN with a VLAN ID of 1:

```
[edit vlans]
user@switch# set native vlan-id 1
```

5. Assign member interfaces to the native VLAN:

```
[edit interfaces]
user@switch# set interface-name unit unit family family native-vlan-id vlan-id
```

For example, to configure the interface **xe-0/0/10** as a member of the native VLAN with the native VLAN ID 1:

```
[edit interfaces]
user@switch# set xe-0/0/10 unit 0 family ethernet-switching native-vlan-id 1
```

## ELS CLI Configuration

To configure an FCoE VLAN on a QFX5100 switch running ELS:

1. Configure a dedicated FCoE VLAN:

```
[edit vlans]
user@switch# set vlan-name vlan-id vlan-id
```

For example, to configure a VLAN named **fcoe\_vlan** with a VLAN ID of **100** as the FCoE VLAN:

```
[edit vlans]
user@switch# set fcoe_vlan vlan-id 100
```

2. Configure the FCoE VLAN on the interface (use **ethernet-switching** as the family and **trunk** as the interface mode):

```
[edit interfaces]
user@switch# set interface-name unit unit family family interface-mode mode vlan members
vlan-name
```

For example, to configure the interface **xe-0/0/10** as a member of the FCoE VLAN **fcoe\_vlan**:

```
[edit interfaces]
user@switch# set xe-0/0/10 unit 0 family ethernet-switching interface-mode trunk vlan
members fcoe_vlan
```

3. Configure the Ethernet interface membership in the FCoE VLAN:

```
[edit vlans]
user@switch# set vlan-name interface interface-name
```

For example, to assign the interface **xe-0/0/10.0** to the FCoE VLAN named **fcoe\_vlan**:

```
[edit vlans]
user@switch# set fcoe_vlan interface xe-0/0/10.0
```

4. Configure a native VLAN on the physical Ethernet interface for the untagged FIP traffic:

```
[edit interfaces]
user@switch# set interface-name native-vlan-id vlan-id
```

For example, to configure the native VLAN on interface **xe-0/0/10** with a VLAN ID of **1**:

```
[edit interfaces]
user@switch# set xe-0/0/10 native-vlan-id 1
```

5. Configure the Ethernet interface as a member of the native VLAN:

```
[edit interfaces]
user@switch# set interface-name unit unit family family vlan members native-vlan-id
```

**NOTE:** The *native-vlan-id* number must be the same as the native VLAN ID number that you configured on the physical Ethernet interface (see step 4).

---

For example, to configure the interface **xe-0/0/10** as a member of the native VLAN with the native VLAN ID **1**:

```
[edit interfaces]
```

```
user@switch# set xe-0/0/10 unit 0 family ethernet-switching vlan members 1
```

## Configuring VN2VF\_Port FIP Snooping and FCoE Trusted Interfaces on an FCoE Transit Switch

VN\_Port to VF\_Port (VN2VF\_Port) Fibre Channel over Ethernet (FCoE) Initialization Protocol (FIP) snooping uses information gathered during FIP discovery and login to create firewall filters that provide security against unauthorized access to the FC switch or FCoE forwarder (FCF) through the EX4500 or QFX Series when the switch is acting as an FCoE transit switch. The firewall filters allow only FCoE devices that succeed at logging in to the FC fabric to access the FCF through the transit switch. VN2VF\_Port FIP snooping provides security for the point-to-point virtual links that connect host FCoE Nodes (ENodes) and FCFs in the FCoE VLAN by denying access to any device that does not successfully log in to the FCF.

VN2VF\_Port FIP snooping is disabled by default. You enable VN2VF\_Port FIP snooping on a per-VLAN basis for VLANs that carry FCoE traffic. Ensure that a VLAN that carries FCoE traffic carries only FCoE traffic, because enabling VN2VF\_Port FIP snooping denies access for all other Ethernet traffic.

**NOTE:** All of the transit switch ports are untrusted by default. If an ENode on an FCoE device logs in to an FCF before you enable VN2VF\_Port FIP snooping on the VLAN and you then enable VN2VF\_Port FIP snooping, the transit switch denies traffic from the ENode because the transit switch has not snooped (learned) the ENode state. The following process automatically logs the ENode back in to the FCF to reestablish the connection:

1. VN2VF\_Port FIP snooping is enabled on an FCoE VLAN on the switch.
2. The switch denies existing connections between servers and the FCF on the FCoE VLAN by filtering the FCoE traffic and FIP traffic, so no keepalive messages from the ENodes reach the FCF.
3. The FCF port timer for each ENode and for each VN\_Port on each ENode expires.
4. The FCF sends each ENode whose port timer has expired a Clear Virtual Links (CVL) message.
5. The CVL message causes the ENode to log in again.

Because the FCF is a trusted source, you configure interfaces that connect to the FCF as FCoE trusted interfaces. FCoE trusted interfaces do not filter traffic (FIP snooping filtering should occur only at the FCoE access edge), but VN2VF\_Port FIP snooping continues to run on trusted interfaces so that the switch learns the FCF state.

**NOTE:** Do not configure ENode-facing interfaces both with FIP snooping enabled and as trusted interfaces. FCoE VLANs with interfaces that are directly connected to FCoE hosts should be configured with FIP snooping enabled and the interfaces should *not* be trusted interfaces. Ethernet interfaces that are connected to an FCF should be configured as trusted interfaces and should not have FIP snooping enabled. Interfaces that are connected to a transit switch that is performing FIP snooping can be configured as trusted interfaces if the FCoE VLAN is not enabled for FIP snooping.

Optionally, you can specify an FC-MAP value for each FCoE VLAN. On a given FCoE VLAN, the switch learns only FCFs that have a matching FC-MAP value. The default FC-MAP value is 0EFC00h for all FC devices. (Enter hexadecimal values for FC-MAP preceded by the hexadecimal indicator “0x”—for example, 0x0EFC00.) If you change the FC-MAP value of an FCF, change the FC-MAP value for the FCoE VLAN it belongs to on the switch and on the servers you want to communicate with the FCF. An FCoE VLAN can have one and only one FC-MAP value.

There are differences in the way you configure FIP snooping and FCoE trusted interfaces on a switch that depend on whether the switch uses the original QFX/QFabric CLI (for example, a standalone QFX3500 or QFX3600 switch or a QFabric system Node device) or the Enhanced Layer 2 Software (ELS) CLI (for example, a standalone QFX5100 switch). This topic includes two configuration procedures, one for switches that run the original CLI, and one for switches that run the ELS CLI.

#### Original CLI Configuration

To enable VN2VF\_Port FIP snooping:

- To enable VN2VF\_Port FIP snooping on a single VLAN and specify the optional FC-MAP value:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan vlan-name examine-fip fc-map fc-map-value
```

For example, to enable VN2VF\_Port FIP snooping on a VLAN named **san1\_vlan** and change the FC-MAP value to **0x0EFC03**:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan san1_vlan examine-fip fc-map 0x0EFC03
```

**NOTE:** Changing the FC-MAP value causes all logins to drop and forces ENodes to log in again.

- To enable VN2VF\_Port FIP snooping on all VLANs and use the default FC-MAP value:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan all examine-fip
```

- To configure an interface as an FCoE trusted interface:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface interface-name fcoe-trusted
```

For example, to configure interface **xe-0/0/30** as an FCoE trusted interface:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface xe-0/0/30 fcoe-trusted
```

## ELS CLI Configuration

To enable VN2VF\_Port FIP snooping:

- To enable VN2VF\_Port FIP snooping on a VLAN and specify the optional FC-MAP value:

```
[edit]
user@switch# set vlans vlan-name forwarding-options fip-security fc-map fc-map-value
examine-vn2vf
```

For example, to enable VN2VF\_Port FIP snooping on a VLAN named **san1\_vlan** and change the FC-MAP value to **0x0EFC03**:

```
[edit]
user@switch# set vlans san1_vlan forwarding-options fip-security fc-map 0x0EFC03
examine-vn2vf
```

**NOTE:** Changing the FC-MAP value causes all logins to drop and forces ENodes to log in again.

- To configure an interface as an FCoE trusted interface:

```
[edit]
user@switch# set vlans vlan-name forwarding-options fip-security interface interface-name
fcoe-trusted
```

For example, to configure interface **xe-0/0/30** on VLAN named **san1\_vlan** as an FCoE trusted interface:

```
[edit]
user@switch# set vlans san1_vlan forwarding-options fip-security interface xe-0/0/30
fcoe-trusted
```

## Disabling VN2VF\_Port FIP Snooping on an FCoE-FC Gateway Switch Interface

When the switch acts as an FCoE-FC gateway, the FCoE-network-facing Ethernet interfaces in the FCoE VLAN are automatically enabled for VN\_Port to VF\_Port (VN2VF\_Port) FIP snooping. You can disable VN2VF\_Port FIP snooping on an individual Ethernet interface or you can disable VN2VF\_Port FIP snooping globally for all Ethernet interfaces in a gateway Fibre Channel (FC) fabric.

Disable VN2VF\_Port FIP snooping on an Ethernet interface by configuring it as an FCoE trusted interface. Disable VN2VF\_Port FIP snooping on all Ethernet interfaces in an FC fabric by configuring the FC fabric as FCoE trusted.

Do not disable VN2VF\_Port FIP snooping on an interface unless you are certain that the interface is connected to a trusted device. Do not disable VN2VF\_Port FIP snooping on an FC fabric unless all of the FCoE-network-facing interfaces in the fabric are either connected to a transit switch that is performing VN2VF\_Port FIP snooping on the FCoE devices as they log in to the FC network or all of the interfaces are connected to trusted devices.

VN2VF\_Port FIP snooping installs firewall filters that block FIP and FCoE frames from sources that have not logged in to the switch and prevents unauthorized access to the network. Disabling VN2VF\_Port FIP snooping disables these firewall filters and permits access to all FIP and FCoE frames transported on that interface.

- To disable VN2VF\_Port FIP snooping on an FCoE-device-facing Ethernet interface in an FCoE VLAN, configure that interface as a trusted interface:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface interface-name fcoe-trusted
```

For example, to configure interface **xe-0/0/7** as a trusted FC interface:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface xe-0/0/7 fcoe-trusted
```

- To disable VN2VF\_Port FIP snooping on all FCoE-device-facing interfaces in a gateway FC fabric, configure that fabric as a trusted fabric:

```
[edit]
user@switch# set fc-fabrics fabric-name protocols fip fcoe-trusted
```

For example, to configure an FC fabric named *santastic* as an FCoE trusted fabric:

```
[edit]
user@switch# set fc-fabrics santastic protocols fip fcoe-trusted
```

## Enabling VN2VN\_Port FIP Snooping and Configuring the Beacon Period on an FCoE Transit Switch

VN\_Port to VN\_Port (VN2VN\_Port) FIP snooping on an FCoE transit switch provides security to help prevent unauthorized access and data transmission on a bridge that connects ENodes in the Ethernet network. VN2VN\_Port FIP snooping provides security for virtual links by creating filters based on information gathered (snooped) about FCoE devices during FIP transactions.

VN2VN\_Port FIP snooping is conceptually similar to VN2VF\_Port FIP snooping between VN\_Ports and VF\_Ports, but VN2VN\_Port FIP snooping does not require traffic between VN\_Ports to traverse the Fibre Channel (FC) switch or FCoE forwarder (FCF). Instead, a VN\_Port communicates transparently through the transit switch on a virtual link that emulates a direct connection to the VN\_Port at the other end of the virtual link.

VN2VN\_Port FIP snooping is disabled by default. You enable VN2VN\_Port FIP snooping on a per-VLAN basis on VLANs that carry VN2VN\_Port FCoE traffic. Ensure that the VLAN carries only FCoE traffic between VN\_Ports, because enabling VN2VN\_Port FIP snooping denies access for all other traffic, including VN2VF\_Port FIP snooping traffic.

All ENodes that you want to communicate using VN2VN\_Port FIP snooping must use an FCoE VLAN dedicated to VN2VN\_Port traffic. You cannot mix VN2VN\_Port FIP snooping traffic with VN2VF\_Port FIP snooping traffic in the same FCoE VLAN.

**NOTE:** An FCoE VLAN can support either VN2VF\_Port FIP snooping or VN2VN\_Port FIP snooping, but not both. Configure separate FCoE VLANs for VN2VF\_Port FIP snooping traffic and for VN2VN\_Port FIP snooping traffic. On FCoE VLANs that are configured as VN2VN\_Port FIP snooping VLANs, VN2VF\_Port traffic is dropped.

The *beacon period* is conceptually similar to the FIP keepalive period (timer) for VN2VF\_Port FIP snooping virtual link maintenance. The beacon period performs virtual link maintenance for VN2VN\_Port FIP snooping. It is the time interval between messages that verify the connection is still valid and the device at the other end of the virtual link is still reachable. You set the beacon period value for each FCoE VLAN that you configure to do VN2VN\_Port FIP snooping.

**NOTE:** In addition to enabling VN2VN\_Port FIP snooping and configuring the beacon period, you must also configure a dedicated FCoE VLAN for the VN2VN\_Port traffic, and set the FCoE transit switch ports in the proper port mode and trusted or untrusted state (interfaces are untrusted by default). See the VN2VN\_Port FIP snooping configuration example topics for complete configurations of several common network topologies.

There are differences in the way you configure a native VLAN on an interface that depend on whether the switch uses the original QFX/QFabric CLI (for example, a standalone QFX3500 or QFX3600 switch or a QFabric system Node device) or the Enhanced Layer

2 Software (ELS) CLI (for example, a standalone QFX5100 switch). This topic includes two configuration procedures, one for switches that run the original CLI, and one for switches that run the ELS CLI.

### Original CLI Configuration

To enable VN2VN\_Port FIP snooping and set the beacon period on an FCoE VLAN that is dedicated to VN2VN\_Port traffic:

- [edit ethernet-switching-options secure-access-port]  
user@switch# **set vlan *vlan-name* examine-fip examine-vn2vn beacon-period *milliseconds***

For example, to enable VN2VN\_Port FIP snooping on a VLAN named **vlan200** and set the beacon period to **90000** milliseconds:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan vlan200 examine-fip examine-vn2vn beacon-period 90000
```

### ELS CLI Configuration

To enable VN2VN\_Port FIP snooping and set the beacon period on an FCoE VLAN that is dedicated to VN2VN\_Port traffic:

- [edit]  
user@switch# **set vlans *vlan-name* forwarding-options fip-security examine-vn2vn beacon-period *milliseconds***

For example, to enable VN2VN\_Port FIP snooping on a VLAN named **vlan200** and set the beacon period to **90000** milliseconds:

```
[edit]
user@switch# set vlans vlan200 forwarding-options fip-security examine-vn2vn beacon-period 90000
```

## Configuring the DCBX Mode

You can configure the DCBX mode that an interface uses to communicate with the connected peer. QFX Systems support three DCBX modes:

- **Autonegotiation**—The interface negotiates with the connected peer to determine the DCBX mode. This is the default DCBX mode.
- **IEEE DCBX**—The interface uses IEEE DCBX type, length, and value (TLV) to exchange DCBX information with the connected peer. QFX3500 Node devices come up with IEEE DCBX enabled by default and then autonegotiate with the connected peer to determine the final DCBX mode.
- **DCBX Version 1.01**—The interface uses Converged Enhanced Ethernet (CEE) DCBX version 1.01 TLVs to exchange DCBX information with the connected peer. QFabric Node devices come up with DCBX version 1.01 enabled by default and then autonegotiate with the connected peer to determine the final DCBX mode.

**NOTE:** QFX Systems do not support pre-CEE (pre-DCB) versions of DCBX such as DCBX version 1.00. If a QFX Series interface receives an LLDP frame with pre-CEE DCBX TLVs, the system drops the frame.

Configure the DCBX mode by specifying the mode for one interface or for all interfaces.

- To configure the DCBX mode, specify the interface and the mode:

```
[edit protocols dcbx]
user@switch# set interface interface-name mode (auto-negotiate | ieee-dcbx |
dcbx-version-1.01)
```

For example, to configure DCBX version 1.01 on interface **xe-0/0/21**:

```
user@switch# set protocols dcbx interface xe-0/0/21 mode dcbx-version-1.01
```

To configure IEEE DCBX on all interfaces:

```
user@switch# set protocols dcbx interface all mode ieee-dcbx
```

## Configuring DCBX Autonegotiation

Data Center Bridging Capability Exchange protocol (DCBX) discovers the data center bridging (DCB) capabilities of peers by exchanging feature configuration information. DCBX also detects feature misconfiguration and mismatches, and can configure DCB on peers. DCBX is an extension of the Link Layer Discovery Protocol (LLDP), and LLDP must remain enabled on every interface for which you want to use DCBX. If you attempt to enable DCBX on an interface on which LLDP is disabled, the configuration commit operation fails.

**NOTE:** LLDP and DCBX are enabled by default on all interfaces.

The switch supports DCBX autonegotiation for:

- Priority-based flow control (PFC) configuration
- Layer 2 and Layer 4 applications such as Fibre Channel over Ethernet (FCoE) and Internet Small Computer System Interface (iSCSI)
- Enhanced transmission selection (ETS) advertisement

DCBX autonegotiation is configured on a per-interface basis for each supported feature or application. The PFC and application DCBX exchanges use autonegotiation by default. The default autonegotiation behavior is:

- DCBX is enabled on the interface if the connected peer device also supports DCBX.
- DCBX is disabled on the interface if the connected peer device does not support DCBX.

You can override the default behavior for each feature by turning off autonegotiation to force an interface to enable or disable the feature.

Autonegotiation of ETS means that when ETS is enabled on an interface (priority groups are configured), the interface advertises its ETS configuration to the peer device. In this case, priorities (forwarding classes) that are not part of a priority group (forwarding class set) receive no bandwidth and are advertised in an automatically generated default forwarding class. If ETS is not enabled on an interface (no priority groups are configured), all of the priorities are advertised in one automatically generated default priority group that receives 100 percent of the port bandwidth.

Disabling ETS autonegotiation prevents the interface from sending the Recommendation TLV or the Configuration TLV to the connected peer.

On interfaces that use IEEE DCBX mode to exchange DCBX parameters, you can disable autonegotiation of the enhanced transmission selection (ETS) Recommendation TLV to the peer if you want an asymmetric ETS configuration between the peers. DCBX still exchanges the ETS Configuration TLV if you disable the ETS Recommendation TLV.

Autonegotiation of PFC means that when PFC is enabled on an interface, if the peer device connected to the interface supports PFC and is provisioned compatibly with the switch, DCBX sets the PFC operational state to enabled. If the peer device connected to

the interface does not support PFC or is not provisioned compatibly with the switch, DCBX sets the operational state to disabled.

In addition, if the peer advertises that it is “willing” to learn its PFC configuration from the switch, DCBX pushes the switch’s PFC configuration to the peer and does not check the peer’s administrative state. The switch does not learn PFC configuration from peers (the switch does not advertise its state as “willing”).

Disabling PFC autonegotiation prevents the interface from exchanging PFC configuration information with the peer. It forces the interface to enable PFC if PFC is configured on the interface or to disable PFC if PFC is not configured on the interface. If you disable PFC autonegotiation, the assumption is that the peer is also configured manually.

Autonegotiation of applications depends on whether or not you apply an application map to an interface. If you apply an application map to an interface, the interface autonegotiates DCBX for each application in the application map. PFC must be enabled on the FCoE priority (the FCoE IEEE 802.1p code point) for the interface to advertise the FCoE application. The interface only advertises applications that are included in the application map.

For example, if you apply an application map to an interface and the application map does not include the FCoE application, then that interface does not perform DCBX advertisement of FCoE.

If you do not apply an application map to an interface, DCBX does not advertise applications on that interface, with the exception of FCoE, which is handled differently than other applications.

**NOTE:** If you do not apply an application map to an interface, the interface performs autonegotiation of FCoE if the interface carries traffic in the FCoE forwarding class and also has PFC enabled on the FCoE priority. On such interfaces, if DCBX detects that the peer device connected to the interface supports FCoE, the switch advertises its FCoE capability and IEEE 802.1p code point on that interface. If DCBX detects that the peer device connected to the interface does not support FCoE, DCBX marks that interface as “FCoE down” and disables FCoE on the interface.

When DCBX marks an interface as “FCoE down,” the behavior of the switch depends on how you use it in the network:

- When the switch acts as an FCoE-FC gateway, it does not send or receive FCoE Initialization Protocol (FIP) packets.
- When the switch acts as an FCoE transit switch, the interface drops all of the FIP packets it receives. In addition, FIP packets received from an FCoE forwarder (FCF) are not forwarded to interfaces marked as “FCoE down.”

Disabling autonegotiation prevents the interface from exchanging application information with the peer. In this case, the assumption is that the peer is also configured manually.

To disable DCBX autonegotiation of PFC, applications (including FCoE), and ETS using the CLI:

1. Turn off autonegotiation for PFC.

```
[edit]
user@switch# set protocols dcbx interface interface-name priority-flow-control
no-auto-negotiation
```

2. Turn off autonegotiation for applications.

```
[edit]
user@switch# set protocols dcbx interface interface-name applications no-auto-negotiation
```

3. Turn off autonegotiation for ETS.

```
[edit]
user@switch# set protocols dcbx interface interface-name enhanced-transmission-selection
no-auto-negotiation
```

To disable autonegotiation of the ETS Recommendation TLV so that DCBX exchanges only the ETS Configuration TLV:

- [edit protocols dcbx interface *interface-name*]  
user@switch# set enhanced-transmission-selection no-recommendation-tlv

- [Disabling the ETS Recommendation TLV on page 5079](#)
- [Understanding DCBX Application Protocol TLV Exchange on page 4915](#)

## Disabling the ETS Recommendation TLV

The enhanced transmission selection (ETS) Recommendation TLV communicates the ETS settings that the switch wants the connected peer interface to use. If the peer interface is “willing,” the peer interface changes its configuration to match the configuration in the ETS Recommendation TLV. By default, the switch interfaces send the ETS Recommendation TLV to the peer. The settings communicated are the egress ETS settings defined by configuring hierarchical scheduling on the interface.

We recommend that you use the same ETS settings on the connected peer that you use on the switch interface and that you leave the ETS Recommendation TLV enabled. However, on interfaces that use IEEE DCBX as the DCBX mode, if you want an asymmetric configuration between the switch interface and the connected peer, you can disable the ETS Recommendation TLV.

**NOTE:** Disabling the ETS Recommendation TLV on interfaces that use DCBX version 1.01 as the DCBX mode has no effect and does not change DCBX behavior.

If you disable the ETS Recommendation TLV, the switch still sends the ETS Configuration TLV to the connected peer. The result is that the connected peer is informed about the switch DCBX ETS configuration, but even if the peer is “willing,” the peer does not change its configuration to match the switch configuration. This is asymmetric configuration—the two interfaces can have different parameter values for the ETS attribute.

To disable the ETS Recommendation TLV:

- [edit protocols dcbx interface *interface-name*]  
user@switch# **set enhanced-transmission-selection no-recommendation-tlv**

## Defining an Application for DCBX Application Protocol TLV Exchange

Define each application for which you want DCBX to exchange application protocol information. You can define Layer 2 and Layer 4 applications. After you define applications, you map them to IEEE 802.1p code points, and then apply the application map to the interfaces on which you want DCBX to exchange application protocol information with connected peers. (See *Related Documentation* for how to configure application maps and apply them to interfaces, and for an example of the entire procedure that also includes classifier configuration.)

**NOTE:** In Junos OS Release 12.1, the FCoE application was configured by default, so you did not need to configure it in an application map. In Junos OS Release 12.2, if you want DCBX to advertise the FCoE application on an interface and you apply an application map to that interface, you must explicitly configure FCoE in the application map. You also must enable priority-based flow control (PFC) on the FCoE code point on all interfaces that you want to advertise FCoE. If you apply an application map to an interface, the interface sends DCBX TLVs only for the applications configured in the application map.

Define Layer 2 applications by mapping an application name to an EtherType. Define Layer 4 applications by mapping an application name to a protocol (TCP or UDP) and a destination port.

- To define a Layer 2 application, specify the name of the application and its EtherType:

```
[edit applications]
user@switch# set application application-name ether-type ether-type
```

For example, to configure an application named **PTP** (for Precision Time Protocol) that uses the EtherType **0x88F7**:

```
user@switch# set applications application ptp ether-type 0x88F7
```

- To define a Layer 4 application, specify the name of the application, its protocol (TCP or UDP), and its destination port:

```
[edit]
user@switch# set applications application application-name protocol (tcp | udp)
destination-port port-value
```

For example, to configure an application named **iscsi** (for Internet Small Computer System Interface) that uses the protocol **TCP** and the destination port **3260**:

```
user@switch# set applications application iscsi protocol tcp destination-port 3260
```
